Abstract

Background: Telehealth interventions, that is, health care provided over a distance using information and communication technology, are suggested as a solution to rising health care costs by reducing hospital service use. However, the extent to which this is possible is unclear.

Objective: The aim of this study is to evaluate the effect of telehealth on the use of hospital services, that is, (duration of) hospitalizations, and to compare the effects between telehealth types and health conditions.

Methods: We searched PubMed, Scopus, and the Cochrane Library from inception until April 2019. Peer-reviewed randomized controlled trials (RCTs) reporting the effect of telehealth interventions on hospital service use compared with usual care were included. Risk of bias was assessed using the Cochrane Risk of Bias 2 tool and quality of evidence according to the Grading of Recommendations Assessment, Development and Evaluation guidelines.

Results: We included 127 RCTs in the meta-analysis. Of these RCTs, 82.7% (105/127) had a low risk of bias or some concerns overall. High-quality evidence shows that telehealth reduces the risk of all-cause or condition-related hospitalization by 18 (95% CI 0-30) and 37 (95% CI 20-60) per 1000 patients, respectively. We found high-quality evidence that telehealth leads to reductions in the mean all-cause and condition-related hospitalizations, with 50 and 110 fewer hospitalizations per 1000 patients, respectively. Overall, the all-cause hospital days decreased by 1.07 (95% CI −1.76 to −0.39) days per patient. For hospitalized patients, the mean hospital stay for condition-related hospitalizations decreased by 0.89 (95% CI −1.42 to −0.36) days. The effects were similar between telehealth types and health conditions. A trend was observed for studies with longer follow-up periods yielding larger effects.

Conclusions: Small to moderate reductions in hospital service use can be achieved using telehealth. It should be noted that, despite the large number of included studies, uncertainties around the magnitude of effects remain, and not all effects are statistically significant.

Introduction

Many see the COVID-19 crisis as an opportunity to stimulate digital transformation. We can expect digital care and eHealth to receive a boost during this era. Creativity and flexibility are stimulated to formulate an answer to challenges in patients fearing infection in a hospital and to social distancing being necessary within hospital premises. Telehealth, defined as health care provided over a distance using information and communication technology (ICT) to enable interaction between patients and health professionals [1], may offer a solution. However, the efficacy of telehealth is unclear. When the dust has settled, there is a need to properly evaluate experiences and the evidence base underlying various forms of telehealth.

In addition, digital transformation is considered in response to the need to improve patient centeredness and concerns about growing health care expenditures [2,3]. Limiting the need for inpatient care, which is the main driver of hospital costs, may reduce health care expenditures [4,5]. Manufacturers' claims and commercial pilot reports seem to dominate the debate, and policy makers frequently embrace those claims. In the Netherlands, the government presumes that hospital care can return to a very low percentage of annual volume growth in view of the anticipated effects of digital transformation. However, the extent to which telehealth can reduce hospital service use remains unclear. Some reviews have reported on the effect of telehealth on this outcome, finding both reductions and increases in hospital service use [6-8]. A recent systematic overview of telehealth interventions found that the effect on all-cause hospitalizations ranged from a reduction of 13.8% to an increase of 4.7% [6]. No prior review has compared the effects between health conditions, and most have focused on a single telehealth type, limiting generalizability [6-8]. Firm evidence for economic benefits is also limited, as cost-effectiveness studies are sparse and show contradictory results [9,10]. Moreover, telehealth can be implemented in various ways. Telehealth interventions include (1) video consultation, (2) automated device-based monitoring, (3) web-based monitoring, (4) interactive voice response (IVR) systems, (5) mobile telemonitoring, and (6) structured telephone support (STS) [6].

We conducted a systematic literature review of randomized controlled trials (RCTs) aiming to provide an overview of the evidence for the effect of telehealth on hospital services use, that is, all-cause and condition-related hospitalizations, and their duration (per patient and per hospitalization). Furthermore, we evaluated the risk of bias in all studies, as well as the quality of evidence for all outcomes. Finally, we explored which types of telehealth are most effective and which patient groups are the optimal target for reducing hospital service use.

Methods

Overview

This review followed the guidelines of the Cochrane Handbook, with some modifications [11]. Notably, we used reporting of the outcomes of interest as an inclusion criterion, selected studies and extracted data partially in duplicate (20%), and deviated somewhat from the suggested algorithm to judge the risk of bias arising from the randomization process (Multimedia Appendix 1).

Data Sources and Searches

We searched MEDLINE, Scopus (Elsevier), and the Cochrane Central Register of Controlled Trials (Wiley) from inception up to April 2019. The search strategy (Multimedia Appendix 2) was developed by GMP using MeSH (Medical Subject Headings) terms and reference lists of relevant reviews until it encompassed all important keywords, and the search found all pertinent articles included in earlier reviews. WHVH and CJMD critically evaluated the search strategy before implementation.

Eligibility Criteria

RCTs and cluster RCTs reporting the use of telehealth interventions compared with usual care were included. Telehealth was defined as health care interventions provided over a distance using ICT to enable interactions between patients and health professionals or among health professionals. Patients of any age and with any health conditions were considered. Reported outcomes included at least one of the following: all-cause hospitalization, condition-related hospitalization, or length of hospital stay. We considered only published, English, full-text, and peer reviewed articles. We did not apply any restrictions to the setting or date of publication.

This review follows the taxonomy of telehealth interventions developed in another systematic review [8], which differentiates between video consultations, (automated) device-based monitoring, web-based telemonitoring, IVR, mobile telemonitoring, and STS.

Video consultations are defined as any intervention using synchronous, two-way, audio-visual communication between patients and health care providers to perform triage or provide health advice. If measurement devices were provided, measurements were communicated solely during the video consultations.

In device-based monitoring, patients are provided with devices to measure vital signs or to report symptoms essential for detecting changes in health status. Automated alerts triggering actions from health care providers, such as phone calls, are frequently included.

Web-based telemonitoring includes interventions using a web portal to enable patients to report vital signs and symptoms, and to enable health professionals to provide educational material and feedback.

In IVR systems, patients are required to enter vital signs and symptoms through their home or mobile telephone in response to automated questions. These systems are typically combined with automated alerts that trigger actions from health care providers.

With mobile telemonitoring, patients actively submit vital signs and symptoms through their personal mobile devices. Vital signs are measured using external measurement devices.

STS provides patients with a specified number of telephone contacts for a given period of time, during which patients report

their health status and receive health advice, medication adjustments, or referrals to health professionals.

We defined condition-related hospitalizations as hospitalizations due to the targeted health conditions. Studies that explicitly reported only condition-related outcomes are not aggregated with all-cause outcomes, as outcomes resulting from causes other than the condition of interest are unknown in that case, which could bias the results.

For the mean length of hospital stay, the total number of hospital days was divided by the total number of hospital stays. This is in contrast to the number of hospital days, where the total number of hospital days was divided by the total number of patients.

Data Collection and Extraction

GMP screened all titles and abstracts. This screening was independently verified on a sample basis (10%) by LK and AL. Screening of full text articles was performed identically. Disagreements were resolved through discussion, or adjudication by CJMD. Screening was performed using the Covidence systematic review software [12].

Using a standardized data extraction form, GMP extracted the following data from all included studies: study characteristics (eg, country and setting), population characteristics (eg, health condition, age, and gender), intervention details (eg, ICT components used and frequency of use), and outcomes (hospitalizations, length of hospital stay, and hospital days; Multimedia Appendix 3). Data extraction was verified by LK on a sample basis.

Assessment of Risk of Bias

We used the Cochrane Risk of Bias 2 (RoB 2) tool to assess the risk of bias for each study [13]. A number of rules were derived from the manual to ensure consistent judgments between reviewers (Multimedia Appendix 1). GMP assessed the risk of bias of all studies. Risk of bias assessment was performed independently and in duplicate for all studies by LK, AL, or CJMD. Disagreements were resolved through discussion or arbitration by a third reviewer, if necessary. The authors of the studies were not contacted for additional information in case of missing data or methodological unclarities.

Data Synthesis and Analysis

Risk differences between telehealth and usual care were calculated for data reported as cumulative incidences. Cumulative incidences reported as percentages were converted to the number of participants with events. For data reported as means, such as the mean number of hospitalizations per patient, the mean differences (MDs) between telehealth and usual care were calculated. Missing SDs were calculated, where possible. All calculations were performed according to Chapter 6 of the Cochrane Handbook [14]. Meta-analyses were conducted with the meta package in R, Version 3.6.3, (R Foundation for Statistical Computing) [15], using Mantel-Haenszel random-effects models. Hartung-Knapp adjustment is used to better reflect the uncertainty in the estimation of between-study heterogeneity in CIs [16,17].

The overall quality of evidence was rated according to the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach (Multimedia Appendix 4) [18]. GMP rated the quality of evidence for each outcome (Multimedia Appendix 5). This rating was verified by all other authors, and disagreements were resolved by discussion.

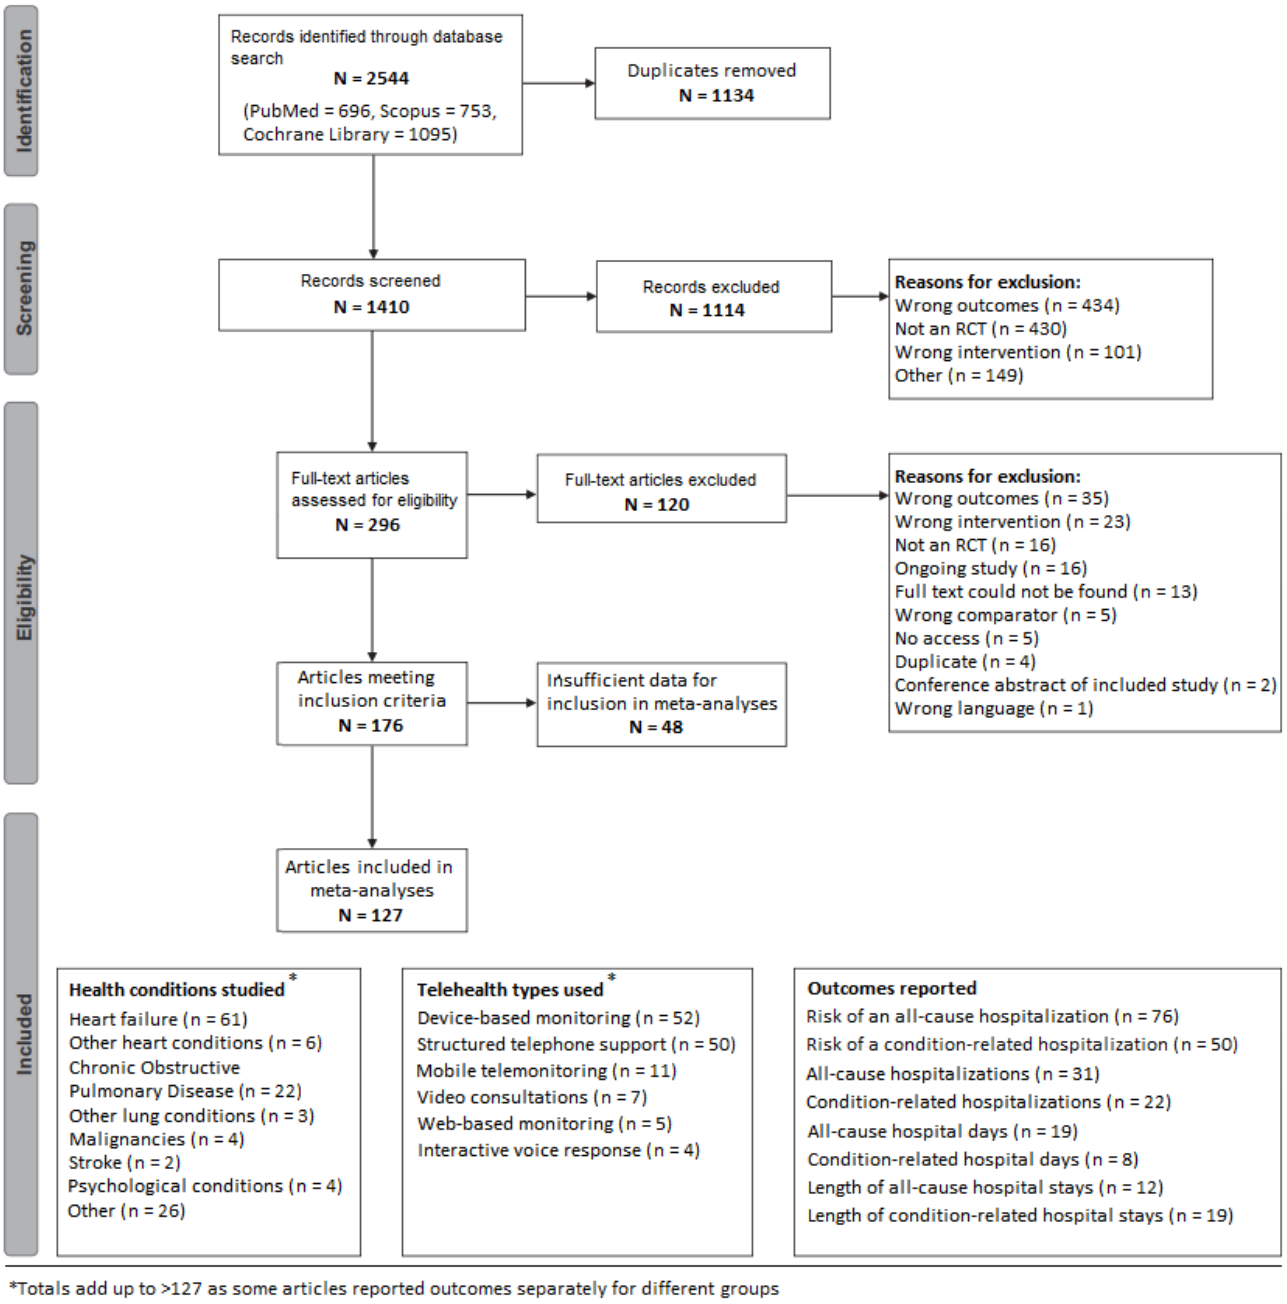
We conducted subgroup analyses for health conditions that were studied in at least two articles, as well as for each type of telehealth, length of follow-up, and risk of bias. These analyses were planned a priori. The risk of bias was analyzed using the robvis package in R [19]. To assess publication bias, we visually inspected funnel plots (using the meta package in R).

Results

Study Selection

The search identified 2544 records. After removing duplicates, 1410 records remained for the screening of titles and abstracts, through which 1114 (79.0%) records were excluded. We assessed 296 full-text articles for eligibility and excluded 120 articles. Of the remaining 176 articles, 127 (72.2%) provided sufficient data for inclusion in the meta-analysis (Multimedia Appendix 6). Figure 1 provides an overview of the study selection process.

Figure 1. Study selection flowchart and study characteristics. RCT: randomized controlled trial.



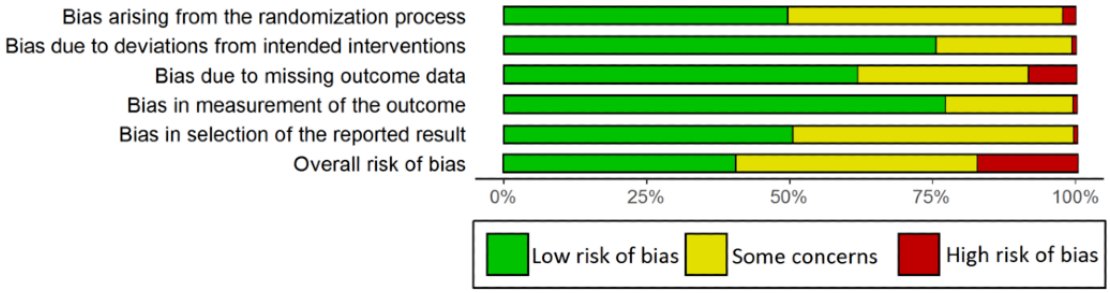
Study Characteristics

An overview of telehealth types, health conditions, and outcomes is provided in Figure 1 (details are provided in Multimedia Appendix 3). Most studies were conducted in Europe (n=55) and North America (n=41).

Risk of Bias

We judged 50 articles to be at low overall risk of bias, 55 to have some concerns, and 22 to be at high risk of bias. Most articles were assessed at low risk of bias for all five domains (64/127, 50.4% to 98/127, 77.2%), except for selection of the reported result (63/127, 49.6%; Figure 2). High risk was found for bias arising from the randomization process in only 3 articles, bias due to deviations from intended interventions in one, due to missing outcome data in 11, bias in measurement of the outcome in one, and in selection of the reported result in 1 out of 127 articles. Weighted risk of bias summaries are provided for each analysis in Multimedia Appendix 5. In the analyses of condition-related hospitalizations and the length of hospital stay due to any cause, studies at high risk of bias in at least one domain cumulatively accounted for approximately 20% of the weight. In all other analyses, this figure was below 10%.

Figure 2. Unweighted risk of bias summary.



Outcomes

The summary of findings table (Table 1) provides a comprehensive overview of the main results for all outcomes.

For each analysis, most RCTs used device-based monitoring or STS and included mainly patients with heart failure or chronic obstructive pulmonary disease (COPD; details Multimedia Appendix 3). Complete analyses are available in Multimedia Appendix 5.

The outcomes are reported as rates in 14 articles. Although these could not be incorporated in the meta-analyses, an overview of these results is provided in Multimedia Appendix 7.

Table 1. Summary of findings table for the effect of telehealth interventions on various outcome measures compared with usual care.

Outcome	Studies (RCTs[a]), n	Participants, n	Follow-up (months)	Usual care estimate	Intervention effect estimate	Effect estimate (95% CI)	GRADE[b] Strength of evidence[c]	Plain language summary
Patients with an all-cause hospitalization (patients hospitalized per 1000 patients)	76	34,423	1-60	373	355	Risk difference: −18 (−30 to −0)	High	The number of patients hospitalized for any cause is reduced by 4.8%[d]
Patients with a condition-related hospitalization (hospitalizations per 1000 patients)	50	20,867	1-60	237	200	Risk difference: −37 (−60 to −20)	High	The number of patients hospitalized for the condition targeted is reduced by 15.6%[d]
Mean all-cause hospitalizations per patient (hospitalizations per 1000 patients)	31	11,191	3-12	880	830	Mean difference: −50 (−140 to +30)	High	All-cause hospitalizations are reduced by 5.7%[d]
Mean condition-related hospitalizations per patient (hospitalizations per 1000 patients)	22	3461	1-60	470	360	Mean difference: −110 (−200 to −10)	High	Condition-related hospitalizations are reduced by 23.4%[d]
All-cause hospital days[e] (hospital days per patient)	19	9735	0-60	6.06	4.99	Mean difference: −1.07 (−1.76 to −0.39)	High	The mean number of days spent in the hospital for any cause per patient is reduced by 17.7%[d]
Condition-related hospital days[e] (hospital days per patient)	8	1216	3-60	2.84	1.71	Mean difference: −1.13 (−1.64 to −0.61)	Moderate[f]	The mean number of days spent in the hospital for the condition targeted is reduced by 39.8%[d]
Length of all-cause hospital stay[g] (days per hospitalization)	12	1964	0-60	8.37	7.89	Mean difference: −0.48 (−1.50 to 0.53)	Low[h]	Hospitalizations for any cause are 5.7%[d] shorter with telehealth
Condition-related hospital length of stay[g] (days per hospital stay)	15	2047	0-24	2.92	2.03	Mean difference: −0.89 (−1.42 to −0.36)	High	Hospitalizations for the condition targeted are 30.5%[d] shorter with telehealth

[a]RCT: randomized controlled trial.

[b]GRADE: Grading of Recommendations Assessment, Development and Evaluation.

[c]High: we are very confident that the true effect lies close to that of the estimate of the effect; moderate: we are moderately confident in the effect estimate: the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different; low: our confidence in the effect estimate is limited: the true effect may be substantially different from the estimate of the effect.

[d]Percentages were calculated by dividing the effect estimate by the usual care estimate.

[e]Participants are the unit of analysis.

[f]Downgraded by one level for risk of publication bias.

[g]Hospitalizations are the unit of analysis.

[h]Downgraded by one level for risk of bias and another for imprecision.

Risk of All-Cause Hospitalization

The risk of all-cause hospitalization was reported by 76 RCTs, including 34,423 participants. The analysis provides high-quality evidence for a risk difference of −18 (95% CI −30 to 0) hospitalized patients per 1000 patients (−4.8% of usual care).

Risk of Condition-Related Hospitalization

We found 50 RCTs reporting the risk of condition-related hospitalization, including 20,867 participants. The absolute risk was reduced by 37 per 1000 patients (95% CI 20-60), with high-quality evidence (−5.7% of usual care). When stratified by health condition, only the heart failure group showed a statistically significant effect (risk difference = −0.03), although the subgroup difference was not significant (P=.40).

Mean All-Cause Hospitalizations

We found 31 RCTs reporting the mean number of all-cause hospitalizations per patient, including 11,191 participants. Follow-up varied between 3 and 12 months. The analysis showed high-quality evidence for an MD of −50 (95% CI −140 to +30) hospitalizations per 1000 patients, a 5.7% reduction with regards to the number of hospitalizations in the usual care group. Only the COPD subgroup showed a statistically significant MD between telehealth and usual care of −200 (95% CI −390 to −10) hospitalizations per 1000 patients. No effects

were found for heart failure and other diseases. In addition, an RCT studying malignancies reported an MD of +0.09 hospitalizations per patient compared with usual care but did not report a SD and was therefore excluded from the meta-analysis.

Mean Condition-Related Hospitalizations

The mean number of condition-related hospitalizations per patient was reported in 22 RCTs, including 3461 participants. Follow-up varied between 1 and 60 months. The analysis showed high-quality evidence for an MD of −110 (−200 to −10; −23.4% of usual care) hospitalizations per 1000 patients with telehealth compared with usual care. Differences between outcomes appeared to depend on the length of follow-up (P<.01). The difference increased gradually with a longer follow-up from an MD of −90 between 3 and 6 months up to a reduction of 1190 hospitalizations per 1000 patients for outcomes reported after more than 12 months. When stratified by health condition, only heart failure showed a statistically significant effect (MD −120; −200 to −40 hospitalizations per 1000 patients).

All-Cause Hospital Days

The mean number of days patients were hospitalized for any cause was reported in 19 RCTs including 9735 participants. Overall, the analysis showed high quality evidence for an MD of −1.07 (95% CI −1.76 to −0.39) hospital days per patient. In addition, 9 RCTs reported the total number of days for which patients were hospitalized, and 2 reported the rate of hospital days. Furthermore, 1 RCT reported an MD of +0.60 hospital days with telehealth compared with usual care but did not report an SD nor the necessary information to calculate one. These 12 RCTs, which included 3144 participants, could not be incorporated in the meta-analysis.

Condition-Related Hospital Days

The mean number of days patients were hospitalized for the condition of interest was reported by 8 RCTs, including a total of 1216 participants. The analysis showed moderate quality evidence of an MD of −1.13 (95% CI −1.64 to −0.61) hospital days per patient. The quality of evidence was downgraded because of risk of publication bias. A statistically significant difference was found for the length of follow-up (P<.01), with longer follow-up resulting in larger reductions in hospital days. It is notable that when stratified by health condition, a statistically significant result was only achieved in heart failure (MD −1.06 hospital days, 95% CI −1.71 to −0.40). For COPD, an MD of −1.75 (95% CI −4.62 to 1.11) was found. In addition, 7 studies reported the total number of days patients were hospitalized, and one reported the rate of hospital days. These studies, including 2492 participants, could not be included in the meta-analysis.

Length of All-Cause Hospital Stay for Hospitalized Patients

A total of 12 RCTs reported length of all-cause hospital stay, including 1964 hospitalized patients. Low-quality evidence was found for an MD of −0.48 (95% CI −1.44 to +0.47 days) hospital days per stay. The quality of evidence was downgraded by one level for risk of bias and by another for imprecision. Subgroup differences were found between different lengths of follow-up (P<.01) and different levels of risk of bias (P≤.01), but no clear trends were found. Three studies reported the length of hospital stay as medians and IQRs, and they could therefore not be included in the meta-analysis.

Length of Condition-Related Hospital Stay for Hospitalized Patients

Fifteen RCTs reported length of condition-related hospital stay, including 2047 hospitalized patients. The analysis showed high-quality evidence for an MD of −0.89 hospital days per stay (95% CI −1.42 to −0.36 days).

Subgroup differences were found in reporting outcomes at different lengths of follow-up (P<.01). An MD of −3.95 hospital days per stay (95% CI −6.06 to −1.84 days) was found for reporting between 7 and 12 months, whereas other MDs ranged from −1.00 to −0.42 days. An additional 3 RCTs reported the length of hospital stay as medians and IQRs and 4 did not report SDs nor any information that could be used to calculate them. These 7 RCTs, including 922 participants, were therefore excluded from the meta-analysis.

Discussion

Principal Findings

Our review indicates that the risk of all-cause hospitalization decreased significantly by 18 hospitalizations per 1000 patients (−4.8%) and 37 (−15.6%) for condition-related hospitalizations. We found high-quality evidence that, compared with usual care, telehealth leads to reductions in mean all-cause (MD −0.05, 95% CI −0.14 to 0.03 hospitalizations per patient; −5.7% of usual care) and condition-related hospitalizations (MD −0.11, 95% −0.20 to −0.01; −23.4%), that is, 50 to 110 fewer mean hospitalizations, respectively, per 1000 patients. Overall, it is evident that all-cause hospital days decreased significantly with a mean of −1.07 (−17.7%) hospital days per patient and condition-related hospital days with −1.13 (−39.8%) days, although evidence for the latter was only moderate. For hospitalized patients, the mean stay for any cause could potentially be reduced (MD −0.48 days, 95% CI −1.50 to 0.53; 5.7%, low-quality evidence), and mean stay for condition-related hospitalizations even more (MD −0.89 days, 95% CI −1.42 to −0.36; 30.5%, high-quality evidence). The effects were similar for various health conditions and types of telehealth. A trend was observed for studies with longer follow-up periods, yielding larger effects. It should, however, be noted that, although this is a systematic review including a large number of studies, uncertainties around the magnitude of effects remain, and not all differences were statistically significant.

The quality of evidence was high for most of the analyses. Downgrading was only necessary for two analyses because of the risk of bias, risk of publication bias, and imprecision because of a small cumulative sample size. Overall, there were approximately as many articles with some concerns as there were articles at low risk of bias. The main culprits were insufficient reporting of the randomization method, lack of available trial registrations or study protocols, and incomplete outcome data (mostly due to deaths). None of these aspects

necessarily indicate issues with the study itself, but rather with the reporting of a study. It is desirable that more information is made available, such as by providing web-based supplementary material.

Comparison With Prior Work

In our review, the most commonly used telehealth types were device-based monitoring and STS. In general, only small differences in effects were found between telehealth types, which did not appear to be relevant. This finding is in line with a Cochrane review including RCTs investigating the effect of either STS or device-based monitoring in the management of heart failure, which also found no difference [20]. It should be explored whether design aspects, such as monitoring frequency or duration, or patient engagement, could explain the differences in effect. Furthermore, patient compliance is often important for the success of telehealth interventions. For example, the patients must consistently take and send measurements, be available for telephone contacts or video consultations, or report symptoms. If these actions are not taken by the patient, telehealth interventions cannot function. Therefore, it is important to consider patient preferences during the design process [21,22].

Studies including patients with heart failure or COPD accounted for the majority of the weight in the meta-analyses of this review, although the effects found for other health conditions seemed similar. No other review has combined the results for multiple health conditions. However, reviews of heart failure and COPD specifically are available for comparison. A systematic review including reviews on telehealth for chronic heart failure patients published between 1996 and 2014 found low-quality evidence for absolute risk reductions in patients with an all-cause hospitalization of 4.7% to 13.8% and of 3.7% to 8.2% for patients with a condition-related hospitalization [6]. Our estimate for patients with all-cause hospitalization was considerably lower (2%) and more precise. This is caused by the larger number of studies (75 in our study vs 8 in the other meta-analysis) and thus participants in our analysis (N=30,937 vs N=2343). Our estimate for patients with condition-related hospitalization was similar (3.8%). A recent review on telehealth for heart failure patients also found a trend toward reduced hospitalizations [23]. Another recent review, on coronary heart disease patients, found a relative risk of 0.56 (95% CI 0.39-0.81), although absolute differences were also small [24].

A systematic overview of reviews including COPD patients found 3 reviews investigating the effect of telehealth on hospitalizations, all of which found a reduction in hospitalizations [7]. Another systematic review reported reduced hospitalizations in 8 out of 11 studies, ranging from −10% to −63%. The findings were similar for all-cause hospitalization and condition-related hospitalizations [25]. Our review confirms the reduction in hospitalizations also found in previous reviews and provides a more realistic estimate of the effect through meta-analyses, which was rarely performed in previous reviews.

In a systematic overview of the use of telehealth for various chronic health conditions, reviews on health conditions other than heart failure or COPD also found only a few articles, except for diabetes [8]. This result is consistent with the findings of our review. As COPD and heart failure only make up a small part of the care provided by hospitals [26], more research is necessary on the effect of telehealth on hospital services use in health conditions other than COPD and heart failure, which are also highly prevalent.

The length of follow-up seems to be an important factor influencing the effect of telehealth in our review. We found subgroup differences in length of hospital stay (both all-cause and condition-related), condition-related hospitalizations, and condition-related hospital days, with larger effect sizes for studies with longer follow-up. A similar trend was observed for all-cause hospital days. One review reported a reduction in mortality at 6 months, with no differences at 1 year [21]. No other reviews assessed differences in effects between the lengths of follow-up.

When telehealth replaces face-to-face contact, it is clear that this can aid in reducing outpatient contacts and supporting social distancing in outpatient departments. In view of the small effects on hospitalizations and moderate effects on hospital inpatient days, it is important to determine whether telehealth actually contributes to cost reduction. Telehealth comes at a cost, for example, because health professionals make phone calls, conduct video consultations, or interpret data. To reduce the costs of interventions, automation of some of these aspects, for example, by developing algorithms to recognize deterioration of patients' health status, should be studied. Although we investigated whether the mechanism by which telehealth is often claimed to reduce costs is indeed present, we did not directly investigate whether costs were reduced. Thorough budget impact and cost-effectiveness studies are needed to reach firm conclusions in this domain.

Limitations

This review has several strengths and limitations. First, the wide scope enabled us to find a large number of articles meeting our inclusion criteria. Furthermore, we quantitatively compared the effects achieved in different health conditions using different types of telehealth and length of follow-up. Another important strength is that we assessed all included articles for risk of bias and graded the strength of evidence for each analysis, providing a comprehensive overview of the evidence on the effect of telehealth on hospital service use.

The wide scope also acts as a double-edged sword in that it makes the participants in the various studies less comparable than in a typical review. This concern is alleviated by the fact that we did not find significant differences between health conditions or types of telehealth, although for some comparisons only a few studies were available. Telehealth interventions often entail many more changes to the health care process, besides the application of technology [27]. The effect of the telehealth type thus becomes entangled with the effects of changes to processes and infrastructure, which requires a more detailed analysis to unravel. Study selection was performed partially in duplicate, which may have caused some articles to have been missed. As we only included peer reviewed articles published in English, it is unknown what evidence exists in other languages. This review is further limited by our scope, which focuses on types of telehealth requiring interaction between

patients and health professionals. Passive forms of digital health care, such as self-management applications or health information provision, were not included. These types of services could reduce hospital service use [28], while potentially being more efficient in terms of resource use because of their passive nature. Furthermore, we did not contact the study authors for details in the case of missing data or methodological unclarities.

Conclusions

Thus, the effects of telehealth are small to moderate and appear to be stronger for condition-related outcomes than for all-cause outcomes. Further research is needed to obtain more insight into the effects of telehealth on other diseases, apart from COPD and heart failure, and into which aspects of telehealth interventions result in positive effects.

Finally, in the context of the COVID-19 crisis, it is important to acknowledge that a great deal of health care can be provided from a distance, eliminating the need for vulnerable individuals to come to a potentially hazardous environment to receive health care and enabling hospitals to continue providing care to all who need it.

Acknowledgments

This study was funded by a nonrestricted grant from Menzis, a Dutch insurance company. The funding source was not involved in the design of the study, data analysis, writing of the manuscript, or the decision to submit for publication.

GMP was involved in the study concept and design, data acquisition (abstract and full-text screening, risk of bias assessment, data extraction), analyses and interpretation of the results, and drafting and revising of the manuscript. CJMD was involved in the study concept and design, interpretation of the results, and critically revised the manuscript for important intellectual content. LK and AL were involved in data acquisition and critically revised the manuscript. WHVH was involved in the study concept, obtained funding, and critically revised the manuscript. CJMD and WHVH both supervised the study equally. All authors approved the final version of the manuscript.

The authors thank Martin Hemels (Rijnstate Hospital) for providing input from a clinical perspective.

Conflicts of Interest

GMP, LK, AL, and CJMD have nothing to declare. WHVH received nonrestricted research grants from Novartis and Agendia BV.

Abstract

Background: Consumer health informatics (CHI) originated in the 1990s. With the rapid development of computer and information technology for health decision making, an increasing number of consumers have obtained health-related information through the internet, and CHI has also attracted the attention of an increasing number of scholars.

Objective: The aim of this study was to analyze the research themes and evolution characteristics of different study periods and to discuss the dynamic evolution path and research theme rules in a time-series framework from the perspective of a strategy map and a data flow in CHI.

Methods: The Web of Science core collection database of the Institute for Scientific Information was used as the data source to retrieve relevant articles in the field of CHI. SciMAT was used to preprocess the literature data and construct the overlapping map, evolution map, strategic diagram, and cluster network characterized by keywords. Besides, a bibliometric analysis of the general characteristics, the evolutionary characteristics of the theme, and the evolutionary path of the theme was conducted.

Results: A total of 986 articles were obtained after the retrieval, and 931 articles met the document-type requirement. In the past 21 years, the number of articles increased every year, with a remarkable growth after 2015. The research content in 4 different study periods formed the following 38 themes: *patient education*, *medicine*, *needs*, and *bibliographic database* in the 1999-2003 study period; *world wide web*, *patient education*, *eHealth*, *patients*, *medication*, *terminology*, *behavior*, *technology*, and *disease* in the 2004-2008 study period; *websites*, *information seeking*, *physicians*, *attitudes*, *technology*, *risk*, *food labeling*, *patient*, *strategies*, *patient education*, and *eHealth* in the 2009-2014 study period; and *electronic medical records*, *health information seeking*, *attitudes*, *health communication*, *breast cancer*, *health literacy*, *technology*, *natural language processing*, *user-centered design*, *pharmacy*, *academic libraries*, *costs*, *internet utilization*, and *online health information* in the 2015-2019 study period. Besides, these themes formed 10 evolution paths in 3 research directions: patient education and intervention, consumer demand attitude and behavior, and internet information technology application.

Conclusions: Averaging 93 publications every year since 2015, CHI research is in a rapid growth period. The research themes mainly focus on patient education, health information needs, health information search behavior, health behavior intervention, health literacy, health information technology, eHealth, and other aspects. Patient education and intervention research, consumer demand, attitude, and behavior research comprise the main theme evolution path, whose evolution process has been relatively stable. This evolution path will continue to become the research hotspot in this field. Research on the internet and information technology application is a secondary theme evolution path with development potential.

KEYWORDS

consumer health informatics; consumer health information; thematic evaluation; co-word analysis; informatics; SciMAT

Introduction

The concept prototype of consumer health informatics (CHI) was first proposed by Kenneth R. Thornton of the School of Health Information Science (University of Victoria) in 1994. Kenneth R. Thornton also elaborated 4 important research directions: network evolution, automation of the patient record, outcome and other quality-related databases, and consumer health education [1]. In 1995, Ferguson [2] of the Harvard University School of Medicine put forward the concept of consumer health informatics (CHI) for the first time in his paper. He pointed out that CHI is a branch of science that studies the application of computer and wireless communication technology in consumer health care [2]. Eysenbach [3] proposed that CHI is the branch of medical information that does the following: analyses the consumers' needs for information; studies and implements methods of making information accessible to consumers; and models and integrates the consumers' preferences into medical information systems. This definition has been cited by the academic community more than 300 times. The American Medical Informatics Association defines CHI as the field devoted to informatics from multiple consumer or patient views and which includes patient-focused informatics, health literacy, and consumer education [4]. CHI is an interdisciplinary subject that includes nursing information, public health, health promotion, health education, library science, and communication science [4].

With the rapid development of computer and information technology, the continuous popularization of the internet, and the continuous strengthening of people's health awareness, consumption awareness, and information literacy for making health decisions, increasingly more people obtain health-related information through the internet. Because of the interdisciplinary nature of CHI, there is no consensus on the definition of CHI. However, the core content of various definitions can be summarized as follows: CHI emphasizes consumers or users as the center and takes consumers or users and computer and information technology as the research object to explore how to use computer and information technology to meet consumers' health or medical information needs. It is a discipline that helps consumers access relevant health or medical information and make decisions about health care and health promotion.

Previous studies have analyzed and summarized the research progress of CHI. For example, Eysenbach [3] collected literature, internet information, and reports related to CHI before 2000 and summarized the research progress of CHI in the context of health care in the information age, medical knowledge delivery to consumers, the accessibility of electronic health records to patients, decision aids to support the consumers' choices, the quality control of health information on the internet, and other aspects. Kokol et al [5] carried out a bibliometric analysis on the literature related to health informatics and electronic health for the period 1984-2015 and discussed the current research status in this field, including trends in literary production, the geographic and journal distribution, and theoretical analyses. However, their research only clusters all research topics and does not reflect the dynamic changes in research themes at different times. Zhao and Zhang [6] reviewed the literature about consumer health information seeking in social media before 2016 and discussed the characteristics of existing research from the following perspectives: the prevalence of health information seeking in social media, discussion topics emerging from health information in social media, seeking health information from online peers, social and emotional support from social media, concerns of accessing consumer health information in social media, and other aspects. However, they did not discuss the dynamic evolution path and the evolution rules of the research themes of CHI. Further, many of these studies are qualitative research. There is also considerable subjectivity in the selection of literature, identification of important topics, and prediction of research frontiers. The combination of qualitative and quantitative analysis methods can increase the objectivity, accuracy, and comprehensiveness of the research results [7]. Bibliometrics is a measurable informatic method [8], and is often used to discover top journals and authors in a field, identify research progress [9], and predict research trends [10].

Many bibliometrics visualization tools are available, such as SciMAT, CiteSpace, UCINET, HistCite, VOSviewer. The full name of SciMAT is the Science Mapping Analysis tool. In 2012, it was developed by Cobo, López-Herrera, Herrera-Viedma, and Herrera at the Department of Computer and Artificial Intelligence in Granada University, Spain. It can be used for data preprocessing, data network analysis documentation, and result visualization. It can also be used to produce 4 kinds of maps: an overlapping map, an evolution map, a strategic diagram, and a cluster network [11]. Compared with other bibliometric visualization tools, SciMAT is unique in expressing the evolution of the theme and performs excellently in longitudinal timing analysis [7].

Overall, there have been few achievements in the field of CHI research based on bibliometrics, and the dynamic evolution of the research theme of CHI has not been explored. Therefore, this article conducted a bibliometric analysis to present the evolutionary overview of CHI by using SciMAT. The main research questions of this paper are as follows:

- What was the development trend of CHI research in 1999-2019?
- What is the main research direction of CHI research?
- How does the theme of CHI research evolve?
- What are the research trends of CHI?

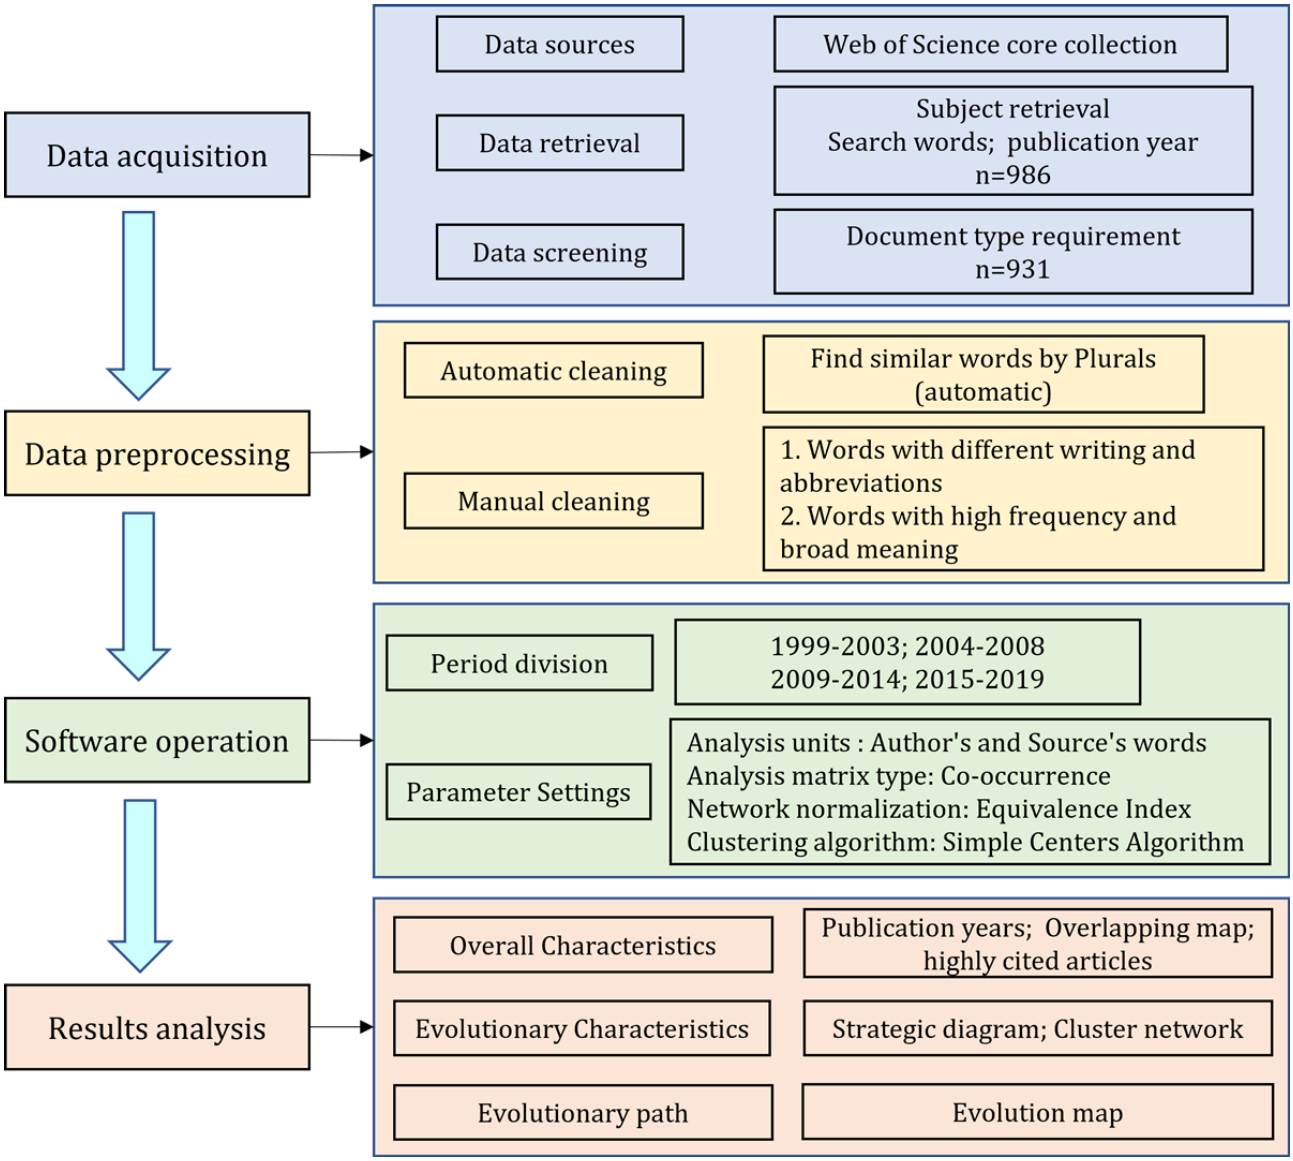
Methods

Overview

In bibliometrics, to obtain the research topic of a certain research field in a specific period, it is common to carry out keyword co-occurrence analysis and cluster analysis on the literature collected and to obtain the development path and state of the research topic through a comparative analysis of the split and fusion of research themes in different periods. This paper uses SciMAT tool to draw the research themes' knowledge map, analyzes the research themes and evolution status of CHI in different study periods using a strategic diagram and data flow, and discusses the dynamic evolution path and evolution law of the research themes of CHI.

The analysis framework of this paper is shown in Figure 1, which is mainly divided into 4 parts: data acquisition, data preprocessing, software operation, and results analysis.

Figure 1. Analysis framework of consumer health informatics evolutionary.



Data Sources and Retrieve Strategies

The Web of Science core collection database of the Institute for Scientific Information is an important database for obtaining global academic information [7]. It consists of the Science Citation Index Expanded, Social Sciences Citation Index, Arts & Humanities Citation Index, and so on. Users can access core academic literature from the fields of natural sciences, social sciences, biomedicine, engineering, arts, and humanities from the database. Therefore, we selected Web of Science as the data source. In this database, subject retrieval was used, and the search terms were "consumer health informatics", "consumer health information", "consumer medic * informatics", "consumer medic * information". The publication years were limited to 2019 and before. All languages were selected. Selecting all languages provides a more comprehensive coverage of the literature on this topic. Non-English articles generally have English titles, abstracts, and keywords, from which one can understand their main research content. For these articles, we also used translation software to read the full text and obtained the main research content. The literature types were limited to articles, proceeding papers, and reviews. All papers

were retrieved on May 2, 2020. A total of 986 documents were obtained, of which 931 met the document-type requirement. The downloaded data were saved in a text format that SciMAT could read directly.

Data Preprocessing

To accurately obtain the research themes in this field, it was necessary to perform data cleaning. SciMAT was used to clean keyword information. First, SciMAT's cleaning function "find similar words by Plurals (automatic)" automatically merges the singular and plural expressions of keywords, such as "attitude" and "attitudes" into "attitudes". Then, similar words with different forms and abbreviations were merged by hand. For example, "consumer health information technology," "consumer health IT," "consumer health information technologies," and "consumer health information technology (CHIT)" were merged into " consumer health information technology." synonyms, such as "physician patient relations," "physician–patient relationship," "patient–physician relationship," "doctor–patient relationship," "doctor–patient relations," and "doctor–patient relationships" were merged into "doctor–patient relationship." Some words, such as "consumer health information," "consumer health informatics," "association," and "campaign," which had high frequency and broad meaning and that might cover the association between other micro words, were deleted.

Parameter Settings

Words (the author's words and the source's words) were selected as the units of analysis. The data reduction thresholds of the 4 study periods are 1, 1, 1, and 2, and the type of analysis matrix is co-occurrence. The network reduction thresholds are 1, 1, 1, and 1, and the network normalization method is the equivalence index. The clustering algorithm used was the simple centers algorithm. The maximum network value was 15 and the minimum network value was 3, and the scale of the cluster network was limited to a reasonable range. The H-index and sum citations were selected as the measurement indexes of clustering quality. Jaccard's index and the Salton index were selected as similarity measurement methods for the evolution map and the overlapping map, respectively.

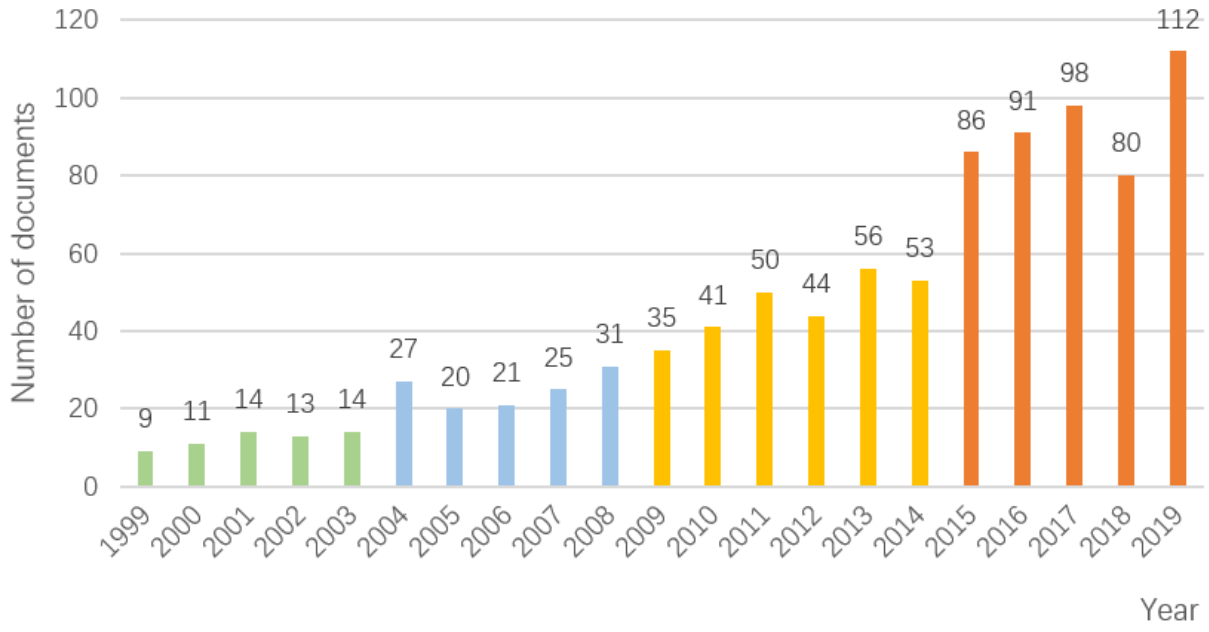
Results

Overall Characteristics Analysis

Trends in the Number of Articles

The number and trend of the articles published each year in a certain field can reflect the scholars' attention to this field. As shown in Figure 2, the amount of literature can be divided into 3 stages: slow growth, stable growth, and rapid growth. The 1999-2003 period was the first stage, with an average of 12.2 papers published each year. The period from 2004 to 2014 was the second stage, with an average of 36.6 papers published each year. The period from 2015 to 2019 was the third stage. After 2015, the number of articles increased substantially, with an average of 93.4 papers published each year. The volume of published articles peaked in 2019 at 112, with an annual total accounting for 12.0% (112/931) of all literature.

Figure 2. Consumer health informatic research documents published from 1999 to 2019.



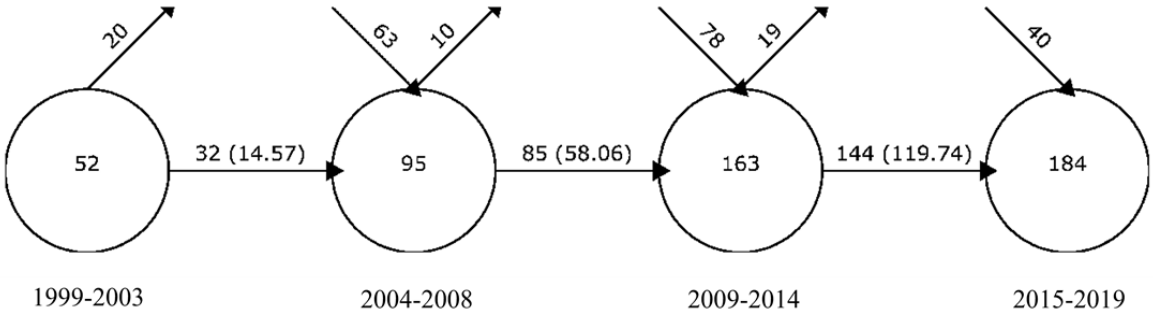
Based on the trend of literature growth, this paper divides the research on CHI into 4 study periods: 1999-2003, the first study period; 2004-2008, the second study period; 2009-2014, the third study period; and 2015-2019, the fourth study period. The number of articles in the 4 study periods is 61, 124, 279, and 467.

Overlapping Map Analysis

An overlapping map uses the number of keywords to represent the number of themes at each period and shows the stability of a research theme in a certain field in the form of a data flow. Figure 3 is an overlapping map of CHI research for the period from 1999 to 2019 and clearly shows the emerging and declining themes in this field. The 4 circles in the figure represent the 4

study periods. Displayed from left to right, they are as follows: the 1999-2003 study period, the 2004-2008 study period, the 2009-2014 study period, and the 2015-2019 study period. The number of themes in the first, second, third, and fourth study periods is 52, 95, 163, and 184, respectively. As can be seen, the number of themes increases rapidly.

Figure 3. Overlapping map of the consumer health informatics research from 1999 to 2019.



From 1999 to 2003, a total of 32 themes were passed to the next study period, and the stability index with the next study period was 14.57. In this study period, the research on CHI remains in a slow-growth stage, which is part of the basic research stage. The number of new themes in the 2004-2008 study period was 63. In the 2009-2014 period, 85 themes were continued from the previous study period, and the stability index between the 2 study periods was 58.06. Reflecting the steady growth of CHI research and the steady increase of research articles in these 2 study periods, many emerging themes and a small number of declining themes were included. There were 40 new themes in the 2015-2019 study period, and the stability index between this and the previous study period was 119.74. At this point, the number of themes is increasing steadily, which reflects that the research area of CHI is gradually expanding, and the research content is becoming increasingly richer.

Analysis of Highly Cited Articles

Six of the top 10 highly cited articles in this field came from the 1999-2003 study period (Table 1), and the cited frequency of the articles is ranked as the first, second, third, fifth, sixth, and tenth. This reflects that the papers published in this period form the basis of the research on CHI and play a fundamental role in the research in this field. The most frequently cited paper (940 times) is an empirical study of the quality evaluation of online consumer health information. The evaluation of health-related websites is quite different due to the differences in research methods, preciseness, quality standards, research population, and subjects. Therefore, the operability of quality standards needs to be defined [12]. The second most frequently cited (804 times) paper is the one by Cline in 2001 [13]. This paper summarizes, from the perspective of communication, the potential benefits and comprehensive quality of online consumer health information searching and identifies and discusses the criteria of online health information evaluation. In 1999, Charnock et al [14] developed a tool named DISCERN, which can be used by health information providers and consumers to judge the quality of written consumer health information about treatment options. This paper was cited 521 times. At present, DISCERN has become a highly useful tool for the quality evaluation of network health information. Many scholars use this tool to evaluate the quality of online health information about different diseases and published in different languages. For example, Cerminara et al [15] used the DISCERN tool to evaluate the reliability, accuracy, and relevance of the top 50 links for childhood epilepsy (online information) displayed by the Google search engine. Alnaim [16] used the DISCERN tool to assess the quality of information published on websites that share breast cancer information online in Arabic.

Four of the top 10 highly cited articles in the field of CHI research came from the 2004-2008 and 2009-2014 study period (Table 1). The paper “eHealth literacy: Essential Skills for Consumer Health in a Networked World” was published in the *Journal of Medical Internet Research* in 2006. In this article, the concept of eHealth literacy was defined for the first time. The ability to find, discover, understand, and evaluate health information from electronic resources, and the ability to apply the acquired knowledge to solve health problems were also explained in this paper [17]. Ranking fourth in the number of citations, the paper was cited 514 times. eHealth literacy has become a mature research topic, and increasingly more scholars are paying attention to it. For example, Kim et al [18] examined the association among eHealth literacy, perceived benefits, self-efficacy, and health-promoting behaviors in patients with type 2 diabetes. Cherid et al [19] investigated the level of mobile technology acceptance, health literacy, and electronic health literacy of 401 patients aged over 50 years with recent fractures.

Table 1. Top 10 cited articles in the consumer health informatics research field.

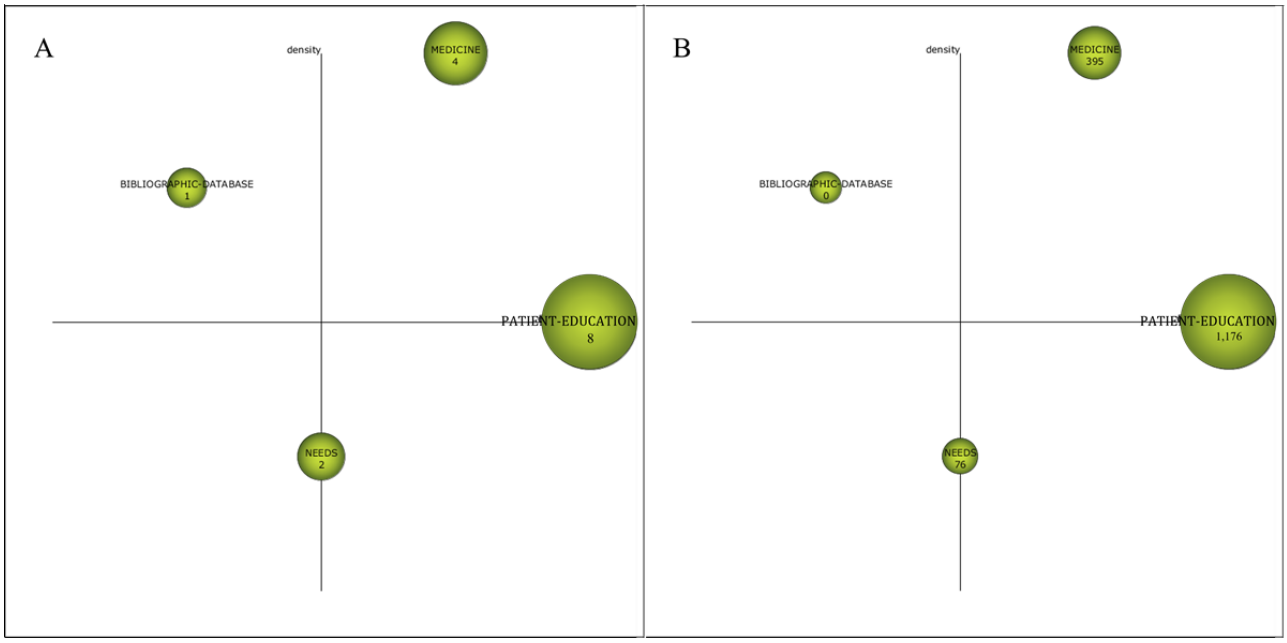
Evolutionary Characteristics Analysis

Design and Overview

The strategic map is mainly used to describe the relationship between themes and the relationship strength within the theme to reflect the importance of the theme in the development of the whole field and the development of the theme. The node in Figure 4 is a cluster, and the sizes of the nodes indicate the sizes of the theme clusters. The horizontal axis is the centrality, which measures the relevance of the theme to other themes. With higher centrality, the theme is more important in the whole field. The vertical axis is the density, which measures the relational strength of the cluster keywords within a theme. The higher the density of the theme, the more mature the theme. The strategic map is divided into 4 quadrants. Quadrant 1 (Q1) contains motor themes, quadrant 2 (Q2) contains highly developed and isolated themes, quadrant 3 (Q3) contains emerging or declining themes, and quadrant 4 (Q4) contains basic and transversal themes. The strategic map of the 4 study periods, the relevant bibliometrics indicators, and the evolutionary status of the research themes are as follows.

Figure 4. Strategic diagram of themes for the subperiod of 1999-2003 (A: based on the publications, B: based on the citation frequency).



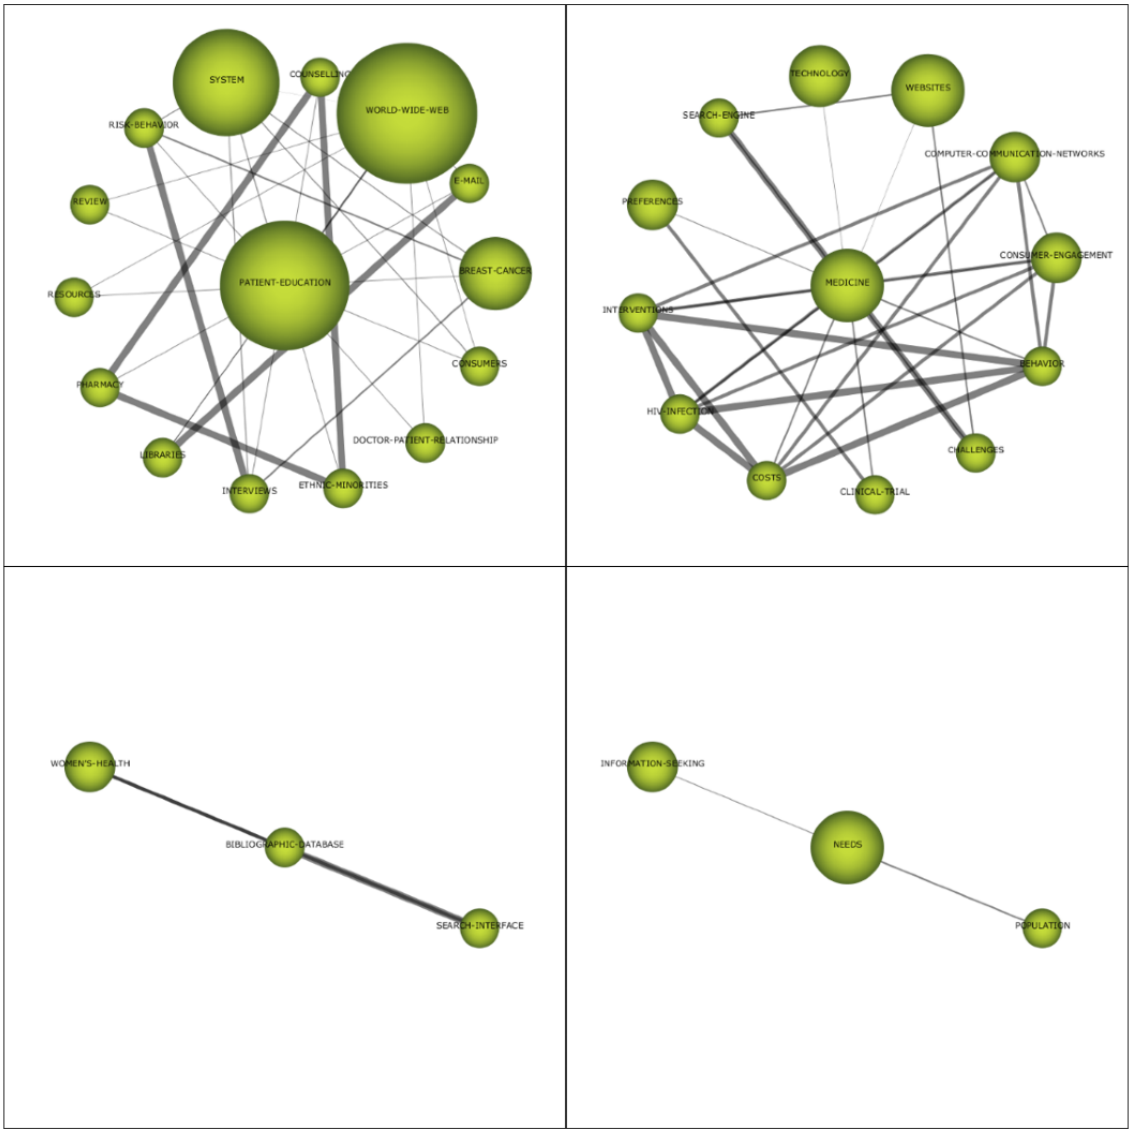
Themes (n=4) in 1999-2003: Patient Education, Medicine, Needs, and Bibliographic Database

The theme of Q1 is *medicine*, which has the highest density value and a higher centrality (Table 2 and Figure 4). The keywords closely connected to *medicine* are *search engine*, *interventions*, and *challenges* (Figure 5). The websites and pages displayed by search engines have become the main source from which people obtain medical and health information [25]. Health information/support systems for health promotion are also emerging, such as the CHESS comprehensive health promotion support system [20].

Table 2. Performance measures for the themes of the subperiod 1999-2003.

Theme	Centrality	Density	Number of documents	H-index	Number of citations
Patient education	45.99	56.26	8	7	1176
Medicine	36.24	111.7	4	3	395
Needs	1.85	12.5	2	2	76
Bibliographic database	1.25	66.67	1	0	0

Figure 5. Cluster network of the themes (1999-2003).



The theme of Q2 is *bibliographic database*, which has centrality and density values of 1.25 and 66.67, respectively. The theme is closely related internally and has low relevance with other themes. The amount of relevant literature is the least, as the theme has not attracted the attention of the academic circle. The keywords closely connected to *bibliographic database* are *search interface* and *women's health*. For the prototype network interface of the women's health bibliography database, Marton et al [26] performed a comparative analysis from 3 aspects: web interface design, overall visual effect, and hypertext navigation and information organization.

Patient education is located on the centrality axis and has the highest centrality. *Patient education* has the largest amount of research literature and has been cited the most times, indicating that it is an area of high concern and has had a great impact on later research. *Patient education* is interconnected with many different keywords, such as world wide web and system, but the connection is not strong. The result of the cluster network shows that the internet and information systems are important tools and approaches in patient education [13] and that individualized customized education can be carried out for patients through computers [27]

Needs is located on the density axis and has centrality and density values of 1.85 and 12.5, respectively. The cluster network shows that *needs* is connected with *population* and *information seeking*. The internal demand for health information drives millions of consumers to search for health information on the internet. If the search terms used by consumers do not match the terms set at the information source, the search results will not meet the needs of consumers. Therefore, consumer health information retrieval needs a full range of terminology support [28].

Themes (n=9) in 2004-2008: World Wide Web, Patient Education, eHealth, Patients, Medication, Terminology, Behavior, Technology, and Disease

The themes of Q1 have higher centrality and density (Table 3 and Figure 6) and are *world wide web*, *patient education*, *eHealth*, and *medication*. *World wide web* has the largest amount of research literature and has been cited 635 times. The cluster network shows that the relationship between the *world wide web* and internal keywords is weak. The keywords that are strongly connected to *patient education* are *internet health information*, *record*, and *challenges* (Figure 7). Patient education is an important part of providing health care services and helps to improve the effect of medical care. Doupi and van der Lei [29] discussed the possibility of integrating electronic medical record data and online health information resources to provide personalized patient education for patients. *eHealth* has the highest density and a relatively high centrality; the cluster network reveals that it is closely related to *health communication*, *tailored intervention*, *cell phone*, and *teleconsultation*, which is an important research topic in this field. Tufano and Karras [30] used teleconsultation for an obesity intervention that was expected to achieve mass customization function, interactive function, and national customized electronic health information. The location of *medication* is far from the centrality axis and close to the density axis. The cluster network shows that it has a strong relationship with *health literacy* and *pharmacist*. In the research on drug treatment in the field of CHI, scholars are concerned about the health literacy of consumers and whether they can understand the accompanying instructions of drugs [31]. Webb et al [32] have proposed that the design of patient-centered consumer medication information can improve the comprehensibility of warning labels.

Table 3. Performance measures for the themes of the subperiod of 2004-2008

Theme	Centrality	Density	Number of documents	H-index	Number of citations
World wide web	77.3	28.66	14	11	635
Patient education	64.37	26.23	10	8	786
eHealth	41.52	87.63	3	3	129
Patients	33.26	16.05	6	5	439
Medication	31.25	32.5	4	4	80
Terminology	3.85	16.67	2	2	45
Behavior	2.38	17.59	3	3	77
Technology	18.49	41.2	2	2	238
Disease	16.39	8.33	2	2	48

Figure 6. Strategic diagram of themes for the subperiod of 2004-2008 (A: based on the publications, B: based on the citation frequency).

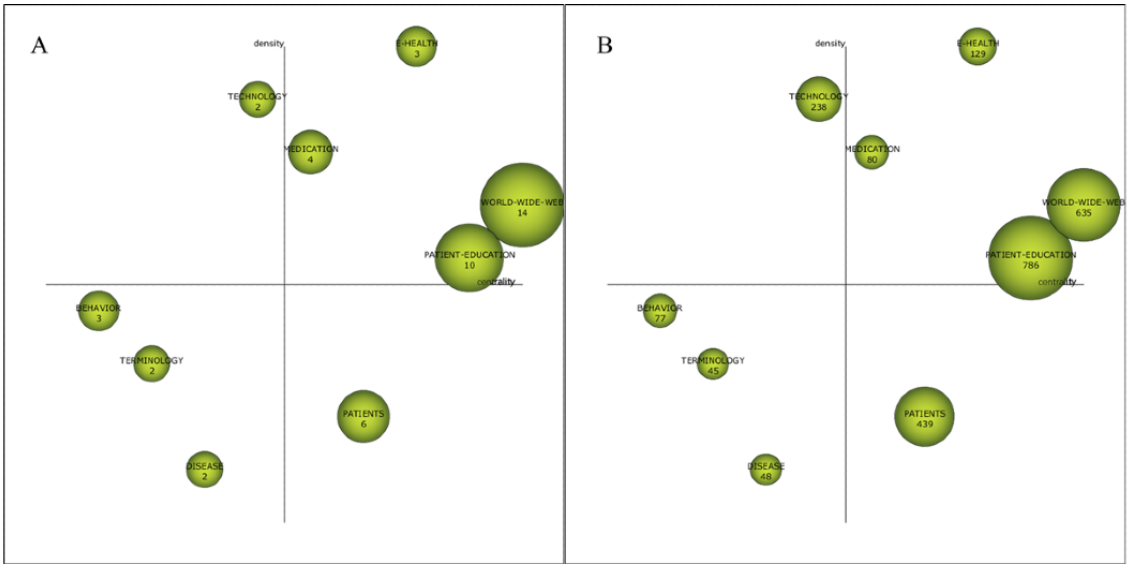


Figure 7. Cluster network of the themes (2004-2008).

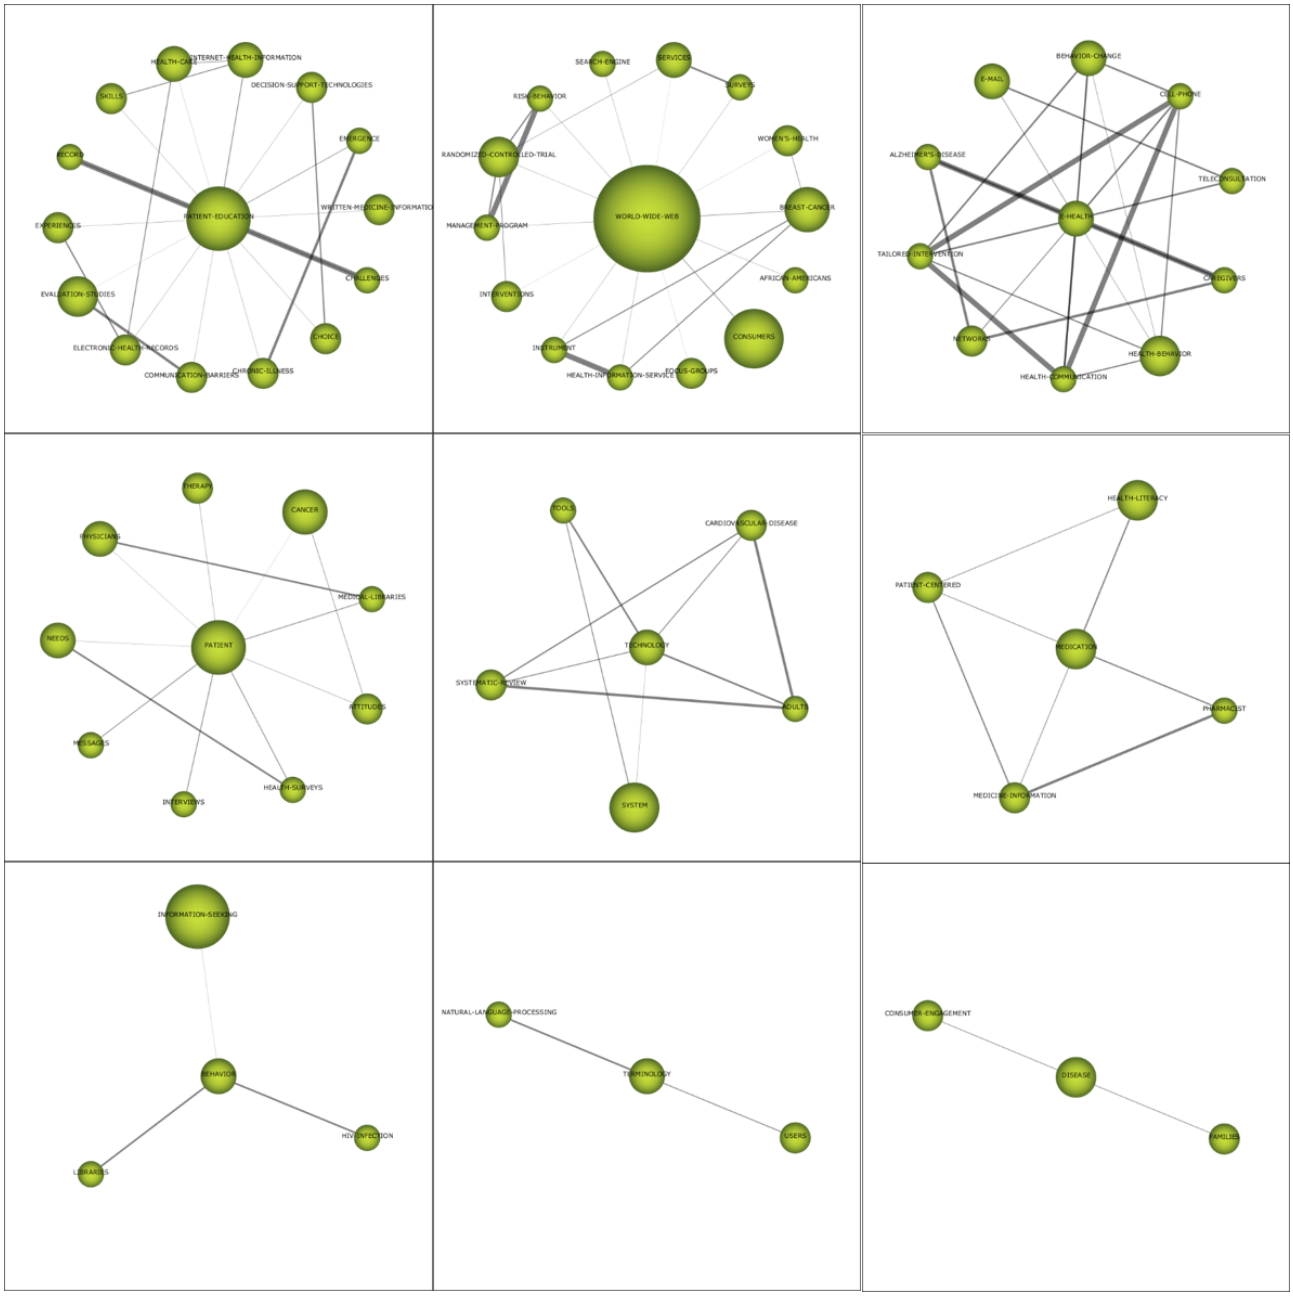


The theme of Q2 is *technology*, with centrality and density values of 18.49 and 41.2, respectively. The important nodes that are connected internally are *tools* and *adults*. The literature corresponding to cluster nodes reveals that scholars began using internet technology to intervene in people's health activities [22].

The themes of Q3 are *terminology*, *behavior*, and *disease*, which have centralities of 3.85, 2.38 and 16.39, respectively, and density values of 16.67, 17.59, and 8.33, respectively. *Terminology* is only associated with *natural language processing* and *users*. The literature corresponding to *terminology* reveals that the rapid development of consumer health education websites and other applications has promoted research on consumer health vocabulary and that term *recognition* [33] is one of the important research directions. *Disease* has weak internal relations. *Behavior* is associated with *libraries*, *HIV infection*, and *information seeking*. By studying the literature corresponding to *behavior*, we found that researchers had analyzed health information searching behavior according to different populations. For example, Hesse et al [34] analyzed the 2005 Administration of the Health Information National Trends Survey data to explore the information searching behavior of survivors of cancer and found that their information searching behavior was very common and would not decrease with time.

The theme of Q4 is *patients*, with centrality and density values of 33.26 and 16.05, respectively. The internal correlation of the *patients* theme cluster was not strong. An examination of the literature corresponding to cluster nodes revealed that scholars paid more attention to the research of the patients' attitude, cognition, and intention regarding health information [35].

Themes (n=11) in 2009-2014: Websites, Information Seeking, Physicians, Attitudes, Technology, Risk, Food

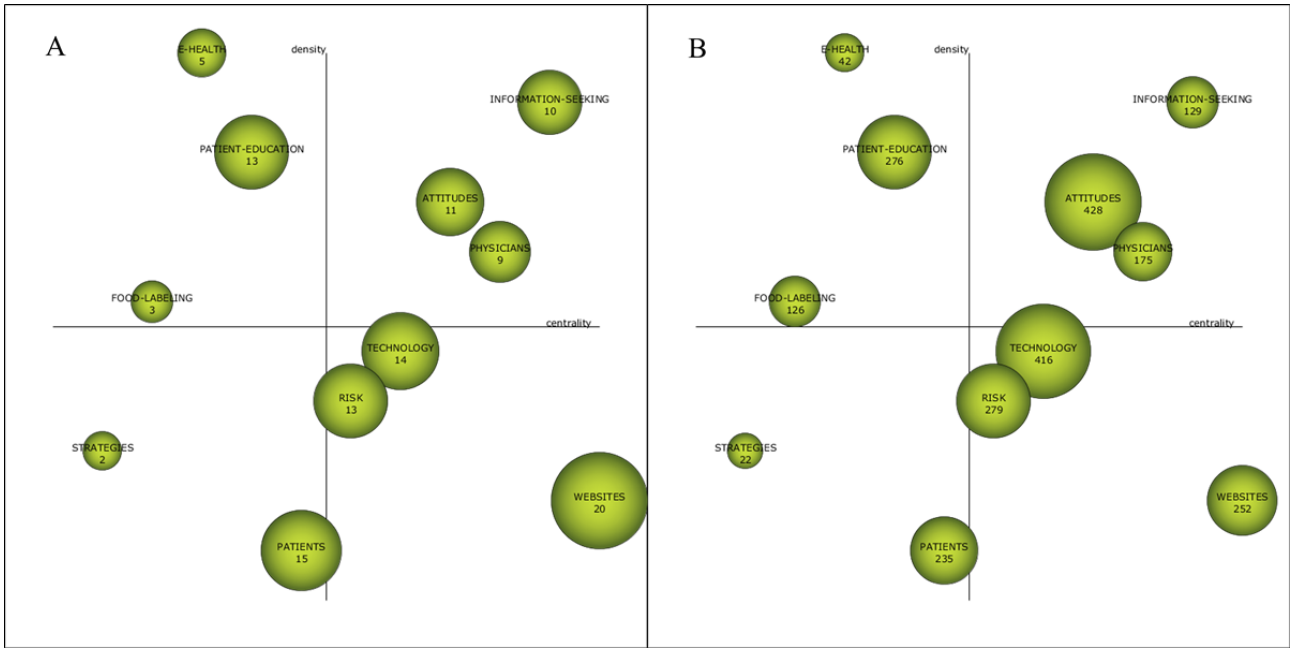
Labeling, Patient, Strategies, Patient Education, and eHealth

The themes of Q1 are *information seeking*, *physicians*, and *attitudes*, which have centralities of 69.64, 67.77, and 64.83, respectively, and density values of 37.42, 19.27, and 28.02, respectively (Table 4 and Figure 8). The cluster network (Multimedia Appendix 1) shows that there are 15 nodes and 25 links in *information seeking* and that the keywords closely related to *information seeking* are *search interface*, *management program*, and *community*. The literature corresponding to *information seeking* revealed that scholars analyzed, from the perspective of consumers, the content of online questions, explored the influencing factors of health information searching, and designed a new connected exploratory navigation interface to improve the effectiveness of health information searching [36]. *Attitudes* had the highest citation frequency, indicating that it had a great influence on the subsequent research. The cluster network shows that *attitudes* is associated with a large number of different keywords, but the relationship is not strong; among these different keywords, the closely related nodes are *community pharmacies*, *information and communication techniques*, and *electronic medical records*. The cluster network reveals that the nodes that are close to *physicians* are *interviews*, *patient centered care*, *patient–provider relationship*, and *teleconsultation*. The literature corresponding to *attitudes* and *physicians* reveals that the consumers' attitude toward, access to, and use of online information related to diseases [37], medicines, diet, and other health issues are the research hotspots in this period. For example, Amicizia et al [38] believes that information and communications technology provide an opportunity for health care workers to use mobile internet to disseminate vaccine-related knowledge interactively and entertainingly and to monitor adolescent attitudes toward vaccination through social media.

Table 4. Performance measures for the themes of the subperiod of 2009-2014.

Theme	Centrality	Density	Number of documents	H-index	Number of citations
Websites	77.12	8.45	20	9	252
Information seeking	69.64	37.42	10	7	129
Physicians	67.77	19.27	9	6	175
Attitudes	64.83	28.02	11	10	428
Technology	61.65	15.53	14	10	416
Risk	60.43	12.61	13	10	279
Food labeling	6.56	15.62	3	3	126
Patient	59.71	6.02	15	10	235
Strategies	5.5	11.11	2	2	22
Patient education	40.51	31.32	13	9	276
eHealth	30.79	37.44	5	3	42

Figure 8. Strategic diagram of themes for the subperiod of 2009-2014 (A: based on the publications, B: based on the citation frequency).



The themes of Q2 are *patient education*, *eHealth*, and *food labeling*, which have centralities of 40.51, 30.79, and 6.56, respectively, and density values of 31.32, 37.44, and 15.62, respectively. The cluster network shows that *patient education* is closely related to *smartphone*, *pamphlet*, *resources*, and *Alzheimer's disease*. Scholars mainly conducted research from 3 aspects: patients' health education needs [39], the effect of health education materials, and health information technology. For example, Kraschnewski et al [40] studied how pregnant women use the internet and mobile phone technology to acquire health care knowledge. They found that women thought that the educational materials they received during prenatal care were not helpful, and therefore, they turned to the internet and smartphone apps to fill the knowledge gap [40]. There are 9 nodes and 12 connections in the *eHealth* theme. Compared with the previous study period, in this study period, there are fewer nodes and connections. The research content of the theme is more concentrated. The keywords closely related to *eHealth* are *tailored intervention*, and *online health information*. Scholars are concerned about how to use information and communication technology to help patients improve their health status and strengthen their self-health management skills [41]. For example, as a health literacy intervention for Hispanic patients with AIDS, Jacobs et al [42] developed a Spanish-language computer application, which can provide information about HIV infection, treatment, and drugs. *Food labeling* is a new theme, for which the cluster network shows the related keywords are *consumer opinions*, *recommendations*, and *ratings*. King et al [43] investigated the consumers' understanding of common terms used to guide food consumption frequency and quantity and found that some terms are highly subjective and that more simple and clear terms need to be developed.

The themes of Q3 are *patients* and *strategies*, which have lower centralities and density values. The cluster network reveals that the keywords strongly related to *patients* were *health information service*, *information behavior*, and *conflict of interest*. *Strategies* is an emerging theme. The cluster network shows that the keywords associated with it are only *evidence-based practice* and *task* and that the weight of the connection is 0.17.

Having higher centralities and lower density values, the themes of Q4 are *websites*, *technology*, and *risk*. The cluster network shows that the keywords closely related to *websites* are *world wide web*, *evaluation studies*, *tools*, *email*. By studying the literature corresponding to *websites*, it is found that the research on the content evaluation of websites and health information intervention through websites are the research hotspots in this period [44]. Thakor et al [45] investigated the information quality of ecommerce websites selling *Hypericum perforatum* and found that most sites received poor reviews and lacked information on drug interactions, contraindications, and adverse reactions. The keywords closely related to *technology* are *hometelehealth* and *aging*. With the aggravation of the aging of the population, the research on home telehealth for the aged group has attracted much attention. Cimperman et al [46] studied the important factors affecting the elderly's adoption of home telehealth services and found that the following factors play an important role in the perception of home telehealth: perceived usefulness, expectation, social influence, perceived security, computer anxiety, convenience, and the doctor's opinion [46,47]. *Risk* is split from *medication*. The cluster network shows that the relationship between internal keywords is weak and that the relatively strong ones are *costs*, *patient decision aid*, and *cardiovascular disease*. For veterans with and without multiple sclerosis, Cameron et al [48] studied the relative risk of falling and requiring medical care and found that the adjusted odds ratio of falling was 3 times higher for female veterans with multiple sclerosis than for female veterans without multiple sclerosis.

Themes (n=14) in 2015-2019: Electronic Medical Records, Health Information Seeking, Attitudes, Health Communication, Breast Cancer, Health Literacy, Technology, Natural Language Processing, User-Centered Design, Pharmacy, Academic Libraries, Costs, Internet Utilization, and Online Health Information

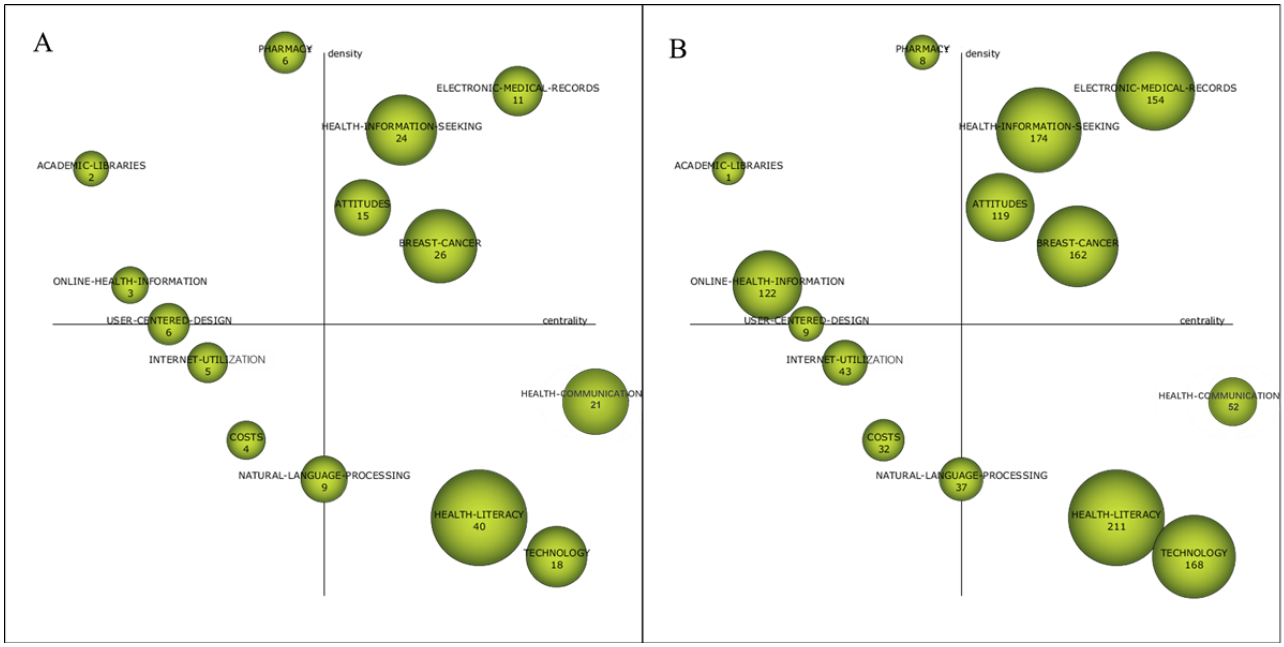
The themes of Q1 are *electronic medical records*, *health information seeking*, *attitudes*, and *breast cancer*, with centralities of 53.52, 47.78, 45.18, and 48.08, respectively, and density values of 19.71, 18.14, 8.89, and 7.11, respectively (Table 5 and Figure 9). The cluster network (Multimedia Appendix 2) shows that *electronic medical records* has a strong relationship with internal keywords, which include *personal health information management* and *care partner*. Scholars mainly focus on the patients' health information management, including the sharing of access to the patients' health records, personal health data visualization, and other contents. For example, Wolff et al [49] sent the doctor's medical records to patients and authorized nurses through OpenNotes. The scholars verified the acceptability and effect of this approach, and the results showed that it was acceptable for patients and their nursing staff to view the doctors' medical records; the results also reflected that this method improved the communication with patients and enhanced the patients' confidence in cooperating with nurses. Keywords closely related to *healthinformation seeking* are *users*, *behavior*, *health information needs*, and *consumer health information behavior*. An examination of the literature corresponding to important nodes revealed that the users of library, online health consultation platform, social media, and other media were often considered research objects and that a discussion of these users' health information needs and behaviors was a research hotspot in this period [50,51]. For example, taking the online health consultation case on "Taiwan eDoctor," an online health consultation platform, as the research object, Chiu et al [52] studied the length, time, communication mode, purpose, and identity disclosure of online consultation questions and described the communication mode of patients in the process of health information searching. *Attitudes* was closely related to internal keywords, such as *HPV vaccines*, *risk*, *evaluation studies*, and *physicians*. Systematically studying the rankings, quality, and contents of the web pages related to HPV vaccines, Fu et al [53] classified the included web pages into critical and noncritical ones and found that the quality of the critical web pages was poor but that the critical web pages often obtained higher rankings. Keywords closely related to *breast cancer* are *online*

healthcommunities, *support groups*, and *preferences*. The scholars mainly focused on the content analysis of the online health community [54] and its supporting role for patients with cancer. For example, through interviews and questionnaires, Huh et al [55] developed online health community roles to reflect the users' needs and requirements when using an online health community. These roles can help provide users with customized social support and patient support. The study found that the roles of online health communities can be divided into 4 categories: managers, opportunists, scientists, and adventurers. These roles reveal user interaction behavior and attitude patterns when using online health communities.

Table 5. Performance measures for the themes of the subperiod 2015-2019.

Theme	Centrality	Density	Number of documents	H-index	Number of citations
Electronic medical records	53.52	19.71	11	7	154
Health information seeking	47.78	18.14	24	5	174
Attitudes	45.18	8.89	15	7	119
Health communication	57.98	4.7	21	4	52
Breast cancer	48.08	7.11	26	7	162
Health literacy	50.29	3.55	40	8	211
Technology	54.79	3.46	18	7	168
Natural language processing	24.1	4.18	9	4	37
User-centered design	11.9	6.3	6	2	9
Pharmacy	16.52	28.49	6	2	8
Academic libraries	4.52	9.03	2	1	1
Costs	14.08	4.34	4	4	32
Internet utilization	12.67	4.72	5	3	43
Online health information	7.82	6.49	3	2	122

Figure 9. Strategic diagram of themes for the subperiod of 2015-2019 (A: based on the publications, B: based on the citation frequency).



The themes of Q2 are *pharmacy*, *online health information*, and *academic libraries*, with centralities of 16.52, 4.52, and 7.82, respectively, and density values of 28.49, 9.03, and 6.49, respectively. A mature professional theme (*pharmacy*) has the highest density and is close to the density axis. The keyword most closely related to *pharmacy* is *patient medication information*. Monkman and Kushniruk [56] studied consumer medication information in pharmacies and found that the organization and presentation of online consumer medication information need to be improved. The content of consumer medication information needs to be improved in order to promote the safety and effective use of drugs [57]. The keywords in the *online health information* cluster network include *video*, *web* 2.0, and *world wide web*. Scholars mainly pay close attention to the use and quality evaluation of online health information [58]. As an emerging theme, *academic libraries*

has the lowest centrality, the lowest amount of relevant literature, and the lowest citation frequency.

User-centered design, with centrality and density values of 11.9 and 6.3, respectively, is located on the centrality axis. One of the keywords clustering with *user-centered design* is *smartphone apps*. An examination of the key literature corresponding to cluster networks reveals that scholars focus on designing user-centered, smartphone-based mobile health apps, such as nutrition education apps that, for example, provide technical support for adolescents with overweight and obesity [59].

Having lower centralities and density values, the themes of Q3 are *internet utilization* and *costs*. The internal relationship between *internet utilization* and *costs* is weak; both are in an immature development stage and have little impact. The cluster network shows that the keywords in *costs* include *search engine* and *health records*; the keywords in *internet utilization* include *health behavior*, *systematic review*, and *patient education as topic*. The literature corresponding to *internet utilization* reveals that the content of relevant literature involved patients using the internet to search for health information for self-care. For example, Jamal et al [60] studied the online health information searching behavior of patients with type 2 diabetes in the Middle East and its influence on their self-care behavior. The results showed that most internet health information searchers had positive changes in their behaviors after searching and had a stronger awareness of diabetes self-care [60].

Natural language processing is located on the density axis, with centrality and density values of 24.1 and 4.18, respectively. The cluster network shows that *natural language processing* is connected with *consumer health vocabulary*, *state*, *online support groups*, and *text*. An examination of the core literature corresponding to the cluster shows that most scholars mined and dealt with the health-related contents of consumers through social media, health websites, health forums, and other ways to obtain the users' health needs, explore the users' health behaviors, and investigate the application of health information technology [61,62].

The themes of Q4 are *health communication*, *health literacy*, and *technology*, with centralities of 57.98, 50.29, and 54.79, respectively, and density values of 4.7, 3.55, and 3.46, respectively. The *technology* cluster network formed 15 nodes and 21 wires, but the internal relationship was very weak. *Health communication* has the highest centrality and has many connections with external themes. It is a key theme with development potential. The cluster network shows that *health communication* is strongly related to keywords such as *medicine*, *telehealth*, and *perspectives*. Benis et al [63] studied the use of communication channels between patients and health care organizations. By matching the communication channels with the patients' personal information, the communication between medical institutions and patients can be transformed into a more active mode, and the patient's participation can be improved. *Health literacy* is an emerging theme; it has the largest number of related literature and the largest citation frequency sum. The keywords closely related to *health literacy* include *skills*, *patient education*, and *public libraries*. Health literacy is the ability of individuals to access and understand health information and to use it to maintain and promote their health. An examination of the literature of important nodes reveals that scholars pay more attention to the assessment and intervention of health literacy [64] and the assessment of internet health information quality [65,66].

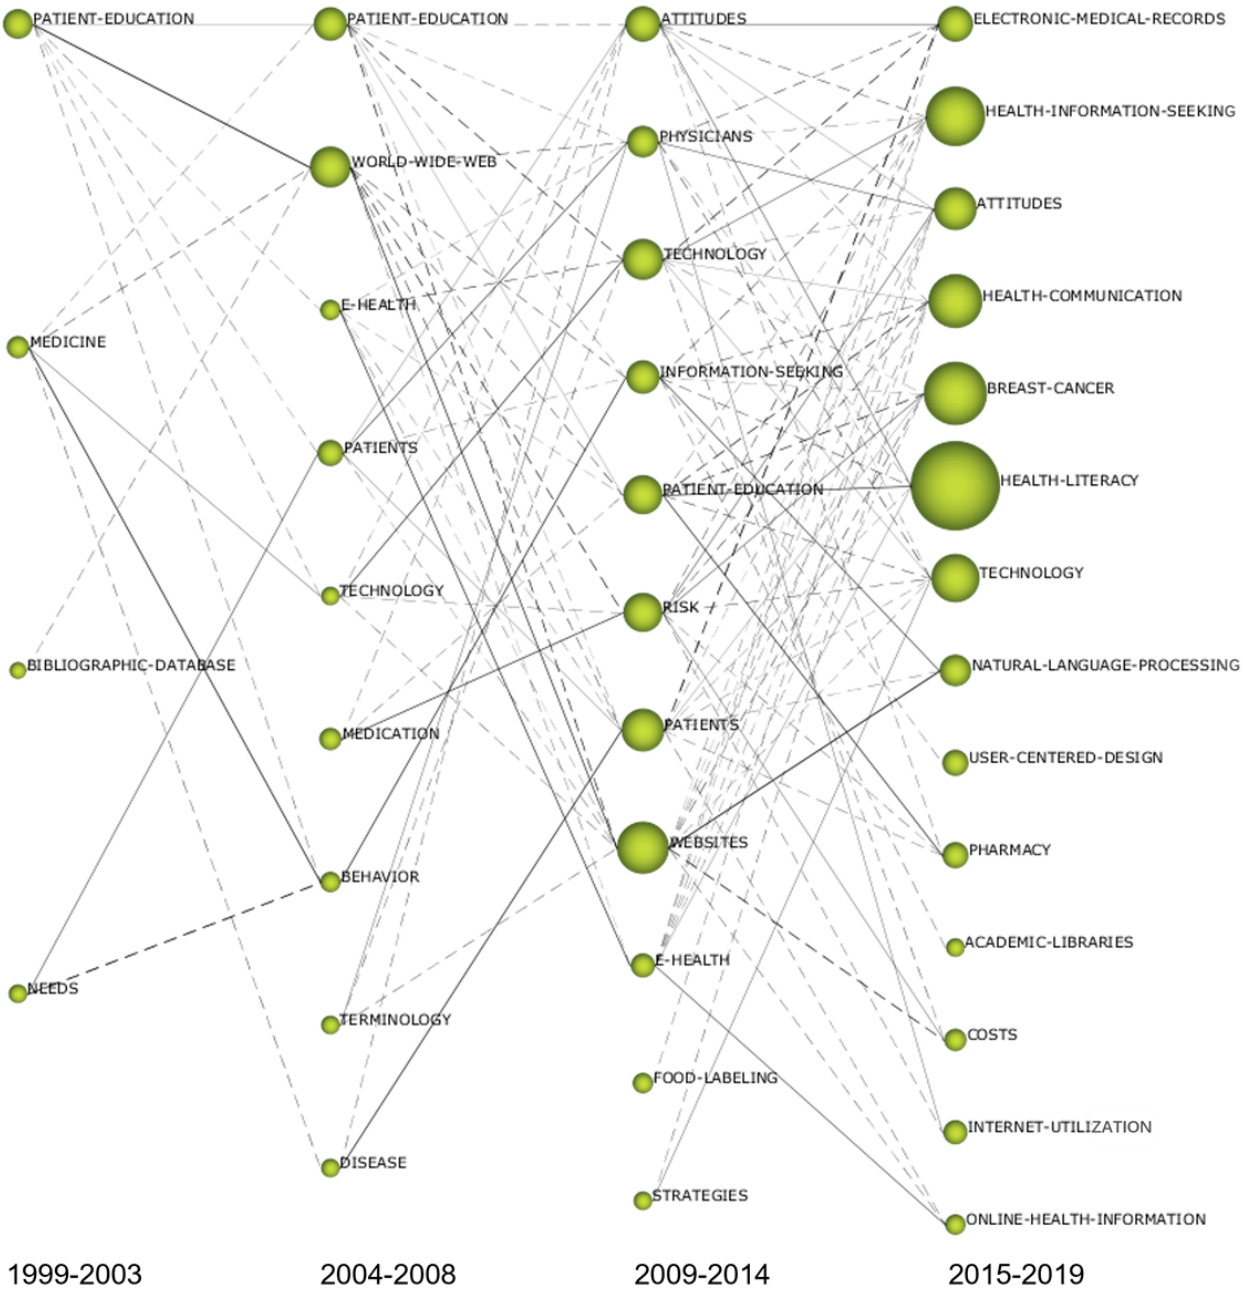
Evolutionary Path Analysis

Design and Overview

The theme evolution map shows, through a data flow, the evolution of the 4 study period themes of CHI research. It can analyze and track the dynamic evolution of the themes in the field of CHI research over a period. Figure 10 shows the CHI research field's theme evolution map. Each column in the figure represents a study period. In the figure, the nodes represent the research themes, and the size of the nodes is proportional to the number of related articles of the research themes. The connection between the nodes represents the theme data flow, the solid line represents the main keywords shared by 2 themes, and the dotted line represents the shared keywords are not the main keywords. The width of the connection is proportional to the Inclusion index [11].

From Figure 10, it can be seen intuitively that *patient education* and *technology* appear in 3 study periods, and that *eHealth*, *attitudes*, and *patients* appear in 2 study periods. With time, the circle in the theme evolution map becomes larger, the number of the research themes increases, and the data flow between the research themes becomes increasingly complex. This reflects the emergence of new research themes and contents from 1999 to 2019. According to the theme evolution map, the size of the research theme circle, and the data flow between themes, 10 theme evolution paths of 3 research directions in the field of CHI were determined.

Figure 10. Thematic evaluation map of the consumer health informatics research field (1999-2019).



Supply-Side Research of Consumer Health Informatics: Patient Education and Intervention Research

Consumer health education is the process of assisting one to acquire the correct information and understanding so that one will be able to make wise decisions about a certain health item [67]. *Patient education → patient education → patient education → health literacy*, *pharmacy* (subpath 1). *Patient education → world wide web → websites → health communication* (subpath 2). *Patient education → eHealth → eHealth → health literacy*, *breast cancer*, *health communication* (subpath 3).

The 3 subpaths above evolved from the main and branch directions of the *patient education* theme in the first study period. Over time, the nodes on the evolutionary path become larger, the number of research articles increases, and the data flow from node splitting is greater. The data flow of patient education and intervention research evolution is relatively clear and represents the main path of the evolution theme of CHI. The theme on the path mainly moves between the first quadrant and the fourth quadrant, and the split and fusion of themes are obvious. In the second study period, subpaths 1 and 3 became the focus of research. In the third study period, the theme density increased and the centrality decreased, demonstrating a professional and mature research direction in the field. In the fourth study period, the themes split into several themes with great influence and development potential (*health communication* and *health literacy*). In the third study period, the subpath 2 integrated multiple themes, and the density of themes decreased. In the fourth study period, the theme split

into several low-density but high centrality themes (*natural language processing*).

Consumer-Side Research of Consumer Health Informatics: Consumer Demand, Attitude, and Behavior

The evolutionary path of consumer demand, attitude, and behavior research consists of 3 subparts. *Needs → patients → attitudes*, *physicians → attitudes*, *health literacy*, *healthinformation seeking*, *internet utilization* (subpath 1); *medicine*, *needs → behavior → information seeking → healthinformation seeking*, *health literacy* (subpath 2); and *medicine → diseases → patients → electronic medical records* (subpath 3).

These 3 subpaths evolved from the main and branch directions of *medicine* and *needs* in the first study period. With time, the number of nodes on the evolutionary path increases, the number of research articles increases year by year, and the data flow of node splitting also increases. The themes in the evolutionary path of consumer demand, attitude, and behavior research mainly move between the first, third, and fourth quadrants, and the themes are divided and integrated. The theme of subpath 1 has gone through a stage in which centrality and density rise, and in this field, it finally forms many core themes, such as *healthinformation seeking*, *health literacy*, and *attitudes*. In the second study period, subpath 2 splits to form a new theme (*behavior*). Later, this theme attracted the attention of many scholars in the field; its density and centrality increased rapidly, and it became the core theme in the field. In the second and third study periods, subpath 3 is an edge theme that is not of high concern. In the fourth study period, some themes (*attitudes*, *physicians*, *technology*, *patients*, *websites*) split and merge into a high centrality and density key theme (*electronic medical records*).

The Technology Research of Consumer Health Informatics: The Application Research of Internet and Information Technology

Currently, big data, internet plus, artificial intelligence, and other emerging information technologies have been tightly integrated with traditional medical and health industries. The application of internet and information technology in the field of CHI has attracted more attention from computer science and communication science scholars. The evolution path of internet and information technology application research consists of 4 subpaths. *Medicine → technology → technology → technology*, *health communication* (subpath 1); *patient education → eHealth → eHealth → online health information* (subpath 2); *needs*, *bibliographic database → patients*, *world wide web → information seeking → natural language processing*, *user-centered design*, *academic libraries* (subpath 3); and *medicine → world wide web*, *terminology → websites → online health information*, *natural language processing*, *breast cancer* (subpath 4).

These 4 subpaths evolved from the main directions of *bibliographic database* in the first study period as well as the branch directions of *patient education* and *medicine*. The number of research articles is gradually increasing, and the phenomenon of node splitting and fusion is also obvious. The theme of the evolution path of the internet and information technology application research mainly moves between the first, second, and fourth quadrants. The evolution path is relatively complex, which may be related to the application of information technology in different research directions. Subpath 1 emerged from the theme of the first study period, and the density decreased in the second study period. In the third and fourth study periods, the centrality increased. The density decreased after the split of multiple themes, and some important themes with strong influence and development potential developed. Subpath 2 divides from the theme of *patient education* in the first study period. In the second study period, a key theme with high centrality and density was formed. In the third and fourth study periods, the centrality decreased, and the density increased; it became a professional theme in the field. The data flow of subpaths 3 and 4 is relatively complex and is formed by the convergence of 2 routes in the first and second study period.

Discussion

Overall Development Status of Consumer Health Informatics

In the past 21 years, CHI research has been on the rise and has gone through 3 stages: slow growth, stable growth, and rapid growth. In the early stage, the development was slow, the themes were few, and the intensity was low. In the later stages, the development became diversified. After 2015, the number of research papers on CHI increased substantially, and it became a hotspot of academic research. In 2019, it reached a peak of 112 papers, a research volume accounting for 12.03% of the total literature.

The period 1999-2003 comprises the basic research stage of consumer health information. Six of the top 10 highly cited literature in this field come from this study period. This literature constitutes the cornerstone of CHI research. Consumer health information evaluation tools, such as DISCERN, that were developed in this study period have become recognized mature tools in the field. The period 2004-2014 was one of steady growth in the research on CHI. During this period, fewer keywords disappeared, and more new ones were absorbed. In 2015-2019, the number of keywords was the largest, and the research content involved was increasingly more abundant. A similarity index for the fourth study period reached a higher level, reflecting that the research field of CHI had become more mature, the inheritance of research had become stronger, and researchers were continuing to focus on more research topics.

Evolutionary Characteristics Analysis

By analyzing the rise, decline, and the change in the density and centrality of the themes in different study periods, the evolution characteristics and status of the research themes can be reflected.

The motor themes include the following: *medicine* and *patient education* in 1999-2003; *world wide web*, *patient education*, *eHealth*, and *medication* in 2004-2008; *information seeking*, *physicians*, and *attitudes* in 2009-2014; and *electronic medical records*, *healthinformation seeking*, *attitudes*, and *breast cancer*

in 2015-2019. These themes have high centralities and density values. Besides, the research studies are popular and influential, and the internal relations within these themes are closely relevant. These themes are the core of the research field and their development is mature.

The highly developed and isolated themes include the following: *bibliographic database* in 1999-2003; *technology* in 2004-2008; *eHealth*, *patient education*, and *food labeling* in 2009-2014; and *pharmacy*, *academic libraries*, *online health information*, and *user-centered design* in 2015-2019. Having high-density values and low centralities, these themes do not represent the research center. They are mature and peripheral themes in this field.

The emerging or declining themes include the following: *behavior*, *terminology*, and *disease* in 2004-2008; *patient* and *strategies* in 2009-2014; and *costs* and *internet utilization* in 2015-2019. Because of their low centralities and density values, these themes have been weakly developed and are marginalized themes in this field.

The basic and transversal themes include the following: *needs* in 1999-2003; *patients* in 2004-2008; *websites*, *technology*, and *risk* in 2009-2014; and *health communication*, *breast cancer*, *health literacy*, *technology*, and *natural language processing* in 2015-2019. These themes have high centralities and low-density values, indicating that these have a high influence on the field of CHI but are not well developed.

By analyzing the evolutionary status of the themes in the 2015-2019 study period, the paper expects to predict the future development trend of the field. The centrality and density value of *electronic medical records* are extremely high. Although there are not many related documents, each document has been cited 14 times on average, indicating that it has received extremely high attention and may appear in the next research period. *Healthinformation seeking* is relatively stable because of its high centrality and density value. After an internal keyword splitting and recombination, the *attitudes* theme is still high in centrality and density value, and the research enthusiasm has not decreased. It will continue to become a hot topic in the field of CHI research. *Breast cancer* split from *risk* in the previous study period, with increased centrality and density value (transferred from Q4 to Q1). With the expansion of research influence, it became more mature and eventually became the research core in the field. Although the number of studies related to *online health information* is not large, the average citation frequency of each study is the highest, indicating that it has a great influence on future research. Online health information is one of the foundations of the CHI research field, has great development potential, and may continue to appear in the next study period. *Natural language processing* has been a hot topic in recent years, and it is likely to continue to appear in the next study period. *Health literacy* is an emerging topic, with the largest number of relevant studies and total cited frequency. This indicates that it has a high level of attention and has a strong evolution and development ability. It will continue to be a hot topic in this field. *Technology* has been transferred from Q2 to Q4. Its research influence and development potential have improved, reflecting that it will continue to be the basic theme in this field.

Evolutionary Path Analysis

By analyzing the evolution characteristics of patient education and intervention research themes, it can be found that the research in the slow growth period mainly focuses on the application and exploration of the internet and information systems and explores the health education for patients through computers and websites [13]. The research in the stable growth period mainly focuses on the use of network health information [41], the design of personalized or customized patient education [29], and the application of intelligent and mobile devices [30]. The research in the rapid growth period mainly focuses on the role and mechanism of the online health community in patient support [54], doctor–patient communication [63], and the quality evaluation of online health information [66].

By analyzing the evolution characteristics of consumer demand, attitude, and behavior research themes, it can be found that the research in the slow growth period mainly focuses on the users' demand for online health information search, as well as demand-driven behavioral research, such as an analysis of the characteristics of health information–retrieval terms [28]. Studies in the stable growth period mainly focus on the patients' attitude and cognition toward health information [23], health information searching behavior, and its influencing factors [68]. The research in the rapid growth period mainly focuses on personal health information management [69], health literacy assessment, and health literacy intervention [70]. The internet health information search behavior of patients with different diseases is still the research hotspot in this period.

By analyzing the evolution characteristics of the research themes regarding the internet and information technology application, it can be found that the research in the slow growth period mainly focuses on the technology applied to patient education [71] and the development of a bibliographic database network interface [26]. The studies in the stable growth period mainly focus on the use of the internet and information technology to intervene in people's health activities [72], help improve the patients' health status, and strengthen the patients' self-care skills [73]. They also examined the use of information technology in the patients' health information search behavior [74], identifying text difficulty of health information and classifying health care webpages using machine learning and natural language processing methods [75,76]. The research in the rapid growth period mainly focuses on the application of natural language processing [77] and the development and evaluation of user-centered mobile medical apps [78]. Wongchaisuwat et al [79] developed an algorithm to automatically answer health-related question by implementing a semisupervised learning algorithm. Park et al [80] analyzed the online discussion content of 3 online health communities employing text mining and k-means machine learning algorithm to compare the discussion topics.

Limitations

In this paper, we used the SciMAT tool to analyze the keywords of the literature data and constructed the overlapping map,

evolution map, strategic diagram, and a cluster network. Owing to the limitation of the scope of our school's database, we only obtained the literature from 1999 to 2019, failed to trace the earliest research literature on CHI, and failed to build a complete evolution path of the CHI research theme.

Conclusions

In this research, a bibliometric analysis was carried out to explore the dynamic evolution path and evolution laws of CHI research themes on a time dimension and from the perspective of strategic diagrams and data flows. CHI research focuses on themes, such as the patients' education, health information needs, information search behavior, health behavior intervention, health literacy, health information technology, and eHealth. The research content in 4 different study periods formed the 38 themes. These themes formed 10 evolution paths in 3 research directions: patient education and intervention, consumer demand attitude and behavior, and internet information technology application. Patient education and intervention research, consumer demand, attitude, and behavior research comprise the main theme evolution path. The path's evolution process has been relatively stable, and it will continue to represent the research hotspot in this field. Research on the internet and information technology application is a secondary theme evolution path, where obvious absorption, fragmentation, and extinction of themes have occurred. Its complex evolution process has also attracted the attention of many scholars. The research status and influence of this evolution path have gradually increased, making it a research direction with development potential.

According to the existing literature, themes that will continue to appear in the next study period include the following: *electronic medical records*, *online health information*, *health information seeking*, *attitudes*, *health literacy*, *technology*, and *natural language processing*. The first 2 themes are information resource elements *in* the consumer health information ecosystem. Because of the continuous advancement of medical informatization and the rapid development of social media, electronic health records, online health information, and online health question answering data have formed massive health information repositories. These health information big data are like gold mines waiting to be explored by researchers. The middle 3 themes are information subject elements, and the last 2 themes are the information technical elements in the environment. To maintain the sustainable development of the consumer health information ecosystem, it is necessary to start from the supply side and the demand side of health information and to solve the mismatch between service and demand by using computer and information technology.

Acknowledgments

We thank the State Key Program of National Social Science of China (grant no. 17AZD037) for assistance in this study. We also appreciate the support of all participants.

Authors' Contributions

AL and WX co-designed this research. WO, ZX, and HH conducted the data retrieval/construction, data collection, and analysis. YY, FL, and YC helped preprocess and analyze the data. WO interpreted the results and drafted the manuscript. TW, XP, and PD made major revisions. All authors reviewed and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Traditional psychological theories are inadequate to fully leverage the potential of smartphones and improve the effectiveness of physical activity (PA) and sedentary behavior (SB) change interventions. Future interventions need to consider dynamic models taken from other disciplines, such as engineering (eg, control systems). The extent to which such dynamic models have been incorporated in the development of interventions for PA and SB remains unclear.

Objective: This review aims to quantify the number of studies that have used dynamic models to develop smartphone-based interventions to promote PA and reduce SB, describe their features, and evaluate their effectiveness where possible.

Methods: Databases including PubMed, PsycINFO, IEEE Xplore, Cochrane, and Scopus were searched from inception to May 15, 2019, using terms related to mobile health, dynamic models, SB, and PA. The included studies involved the following: PA or SB interventions involving human adults; either developed or evaluated integrated psychological theory with dynamic theories; used smartphones for the intervention delivery; the interventions were adaptive or just-in-time adaptive; included randomized controlled trials (RCTs), pilot RCTs, quasi-experimental, and pre-post study designs; and were published from 2000 onward. Outcomes included general characteristics, dynamic models, theory or construct integration, and measured SB and PA behaviors. Data were synthesized narratively. There was limited scope for meta-analysis because of the variability in the study results.

Results: A total of 1087 publications were screened, with 11 publications describing 8 studies included in the review. All studies targeted PA; 4 also included SB. Social cognitive theory was the major psychological theory upon which the studies were based. Behavioral intervention technology, control systems, computational agent model, exploit-explore strategy, behavioral analytic algorithm, and dynamic decision network were the dynamic models used in the included studies. The effectiveness of quasi-experimental studies involved reduced SB (1 study; P=.08), increased light PA (1 study; P=.002), walking steps (2 studies; P=.06 and P<.001), walking time (1 study; P=.02), moderate-to-vigorous PA (2 studies; P=.08 and P=.81), and nonwalking exercise time (1 study; P=.31). RCT studies showed increased walking steps (1 study; P=.003) and walking time (1 study; P=.06). To measure activity, 5 studies used built-in smartphone sensors (ie, accelerometers), 3 of which used the phone's GPS, and 3 studies used wearable activity trackers.

Conclusions: To our knowledge, this is the first systematic review to report on smartphone-based studies to reduce SB and promote PA with a focus on integrated dynamic models. These findings highlight the scarcity of dynamic model–based smartphone studies to reduce SB or promote PA. The limited number of studies that incorporate these models shows promising findings. Future research is required to assess the effectiveness of dynamic models in promoting PA and reducing SB.

smartphone; mobile phone; physical activity; sedentary behavior; computational models; control systems; systematic review

Introduction

In the past decade, there has been a widespread proliferation in the use of digital technologies to deliver behavior change interventions for health [1]. Given their ubiquity, smartphones, in particular, have been used to improve a wide range of health-related behaviors, including physical activity (PA) and sedentary behavior (SB) [2,3]. Smartphones offer a host of relevant functions, including computational capabilities, built-in sensors (eg, accelerometers and GPS), and internet connectivity, enabling users to run software apps and connect with third-party sensors. Collectively, these features offer the potential for delivering real-time, context-aware, and interactive health care interventions [4].

Theory-based lifestyle interventions have been shown to be more effective than nontheoretical approaches [5]. Thus, to better leverage the potential of mobile technologies for health behavior interventions (mobile health [mHealth]), appropriate behavior change theories and models are needed. Such theories and models need to guide the design and development of complex smartphone interventions that can adapt rapidly in response to various inputs [4]. To date, many smartphone-based interventions to promote PA and reduce SB have relied predominantly on psychological theory, including social cognitive theory (SCT) and self-efficacy theory [2,6]. In a seminal paper, Riley et al [4] argued that current behavioral theories do not meet the need for a more dynamic and interactive nature of digital behavior change interventions, such as just-in-time adaptive interventions. These just-in-time adaptive interventions are complex interventions that adapt throughout time to an individual's time-varying context (where) and status (when) to meet an individual's changing needs for support [7-9]. Riley et al [4] argued that existing psychological theories are relatively static and linear and lack sufficient within-subject dynamic regulatory processes. Furthermore, current psychological theories have been used to tailor interventions based on preintervention data rather than deliver adaptive interventions.

To transform current theories into dynamic frameworks and fully maximize the potential of smartphone technologies, Riley et al [4] highlighted the need to incorporate theories from other disciplines (eg, computer science and engineering) for the future development of adaptive and dynamic digital behavior change interventions. One such theory is the control systems theory—derived from the *control theory* or *cybernetics*—which is a general concept for the understanding of regulatory processes [10] and has various applications in engineering, mathematics, medicine, and economics, among others. Control systems engineering explores how to influence and regulate a dynamic system (eg, time-varying adaptive PA intervention) [11,12]. Applying these dynamic models to health behaviors offers the potential to better predict behavior and provide greater insight into real-time changes, which, in turn, enable the optimization and maintenance of behaviors [9].

Since the study by Riley et al [4] was published, it is unclear how many smartphone-based interventions targeting PA and SB have integrated nonpsycholgical theories to create more dynamic models for digital behavior change interventions, what adaptive factors have been considered, and whether these dynamic interventions improve behaviors. Therefore, this review aims to (1) quantify the number of studies that have used integrated dynamic models to develop smartphone-based interventions to promote PA and reduce SB, (2) describe their features, and (3) evaluate their effectiveness, where possible.

Methods

Design

The systematic review was performed according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement [13] and was registered with PROSPERO (International Prospective Register of Systematic Reviews; CRD42020139350) [14].

Study Criteria

This review included studies that developed or evaluated digital behavior change interventions targeting PA, SB, or both and integrated psychological theories with dynamic theories and computational models (eg, control systems engineering); were either adaptive or just-in-time adaptive interventions that included smartphones for delivery; involved human adult participants; included randomized controlled trials (RCTs), pilot RCTs, quasi-experimental, pre-post study designs; and were published from 2000 onward.

Exclusion Criteria

Studies that used conventional theories of behavior change alone without integration with dynamic theories or computational models, case studies, protocols, conference abstracts, dissertations, and reviews were excluded.

Definition

For this review, *dynamic theories* refer to dynamic models taken from other disciplines, including engineering (eg, control systems engineering) and computer science (eg, agent-based modeling). The defining features of dynamic approaches are that they are not static, nonlinear in nature, and capable of capturing complex and rapid changes in behaviors (ie, time-variant) and their influential factors (ie, multivariate). Furthermore, they are quantifiable, empirical, and testable models.

Search Strategy

Databases (IEEE, PubMed, PsycINFO, Cochrane, and Scopus) were searched from January 2000 to May 15, 2019, without language restriction. Keywords (including Medical Subject Headings terms) and phrases comprised 3 components (mHealth, dynamic models, and activity), where "OR" and "AND" Boolean operators were used for within and between component searching (Multimedia Appendix 1). The wild-card term "*" was used where necessary to potentiate sensitivity. Snowball searching was performed using the included studies to identify additional relevant research. The search results were exported to a reference manager software (EndNote X9; Clarivate Analytics) for review and extraction.

Screening Process and Data Extraction

Two researchers (JMV and RDK) independently screened and reviewed the titles and abstracts to identify eligible studies. The full text of the included papers was assessed based on the study criteria. The following information was collected: author and year, country, study design, duration of the study, recruitment and setting, the population of the study, sample size, inclusion criteria, participant characteristics, dynamic model, theory or constructs integrated, and outcomes measured (SB and PA behaviors).

Quality Assessment

Two researchers (JMV and RDK) assessed the risk of bias. The Cochrane Handbook for Systematic Reviews of Interventions [15] was used to evaluate randomized studies for selection bias, detection bias, attrition bias, performance bias, and reporting bias as the main sources of bias. Other sources of bias were also considered. In addition, the Joanna Briggs Institute Critical Appraisal Checklist for Quasi-Experimental Studies [16] was used to assess nonrandomized studies. Where available, protocols and trial registry data were found for risk of bias assessment. Where multiple reports existed for the same study, data were extracted from all reports and expressed together. The authors were contacted for further information, as needed.

Data Analysis

The data were synthesized narratively to address the aims of this review. Given the heterogeneity of the included studies in terms of methodology, outcome measures, and statistical approaches, a meta-analysis of effectiveness data was not conducted. Instead, a synthesis without a meta-analysis method—vote counting based on the direction of effects—was used to synthesize data [17]. The effect direction is a standardized binary metric based on the observed benefit (positive) or harm (negative). Vote counting is based on effect direction and compares the number of positive effects with the number of negative effects on an outcome. An effect direction plot is used for the visual representation of data and linking narrative synthesis to the overall conclusion [18,19]. In this review, the updated method of the effect direction plot is used as outlined elsewhere [20]. Changes within the intervention arm of controlled studies and changes from baseline in uncontrolled studies were considered for judgment. PA outcomes including light activity, walking (time and steps), moderate-to-vigorous PA (MVPA), nonwalking exercise, and total PA time from 6 studies were grouped as PA health domains. For studies with multiple PA outcomes, the effect direction was where 70% or more of the outcomes reported a similar direction (positive or negative). If less than 70% of outcomes showed a similar direction, they were reported as conflicting findings or no clear effect. A sign test was applied to test any evidence of an effect across studies. A 2-tailed *P* value was then calculated to show the probability of observing positive and negative findings for the PA health domain.

Results

Overview

A total of 1087 study reports were identified after removing duplicates. In addition, 9 studies were identified through a manual search. A total of 76 research articles underwent a full review, and 11 reports describing 8 studies were eligible and included in this systematic review. The characteristics of the included studies are summarized in Table 1. The inclusion process and reasons for exclusion are shown in the PRISMA flow diagram (Figure 1). The reasons for excluding 65 studies (in full-text review) are provided in Multimedia Appendix 2 [21-85].

Table 1. General characteristics of the included studies.

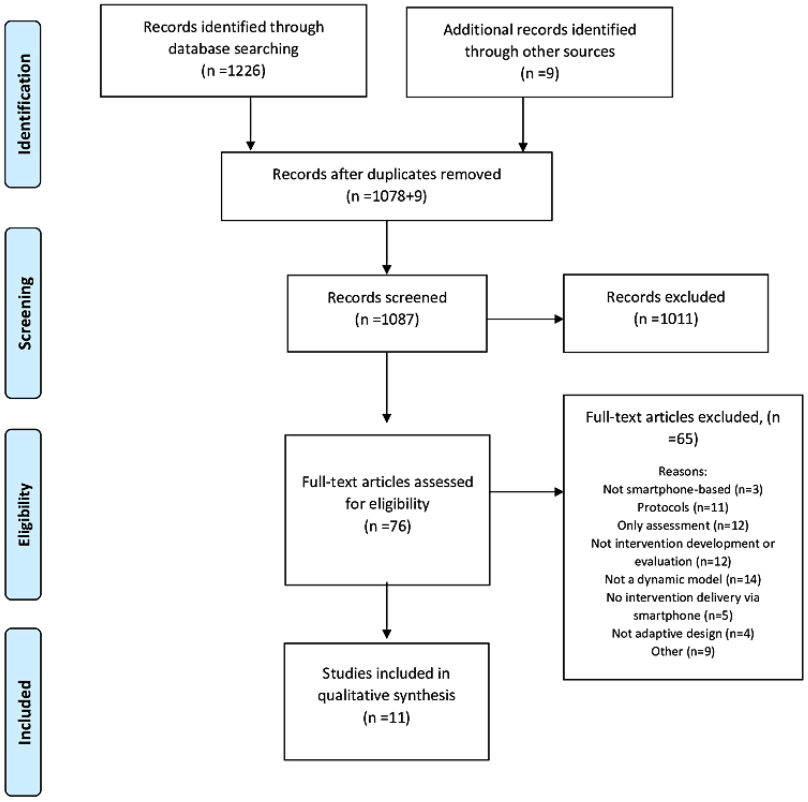
Author (year)	Country	Study design and duration	Recruitment setting	Sample, n	Inclusion criteria	Participants' characteristics
Baretta et al (2019) [86]	Italy	Intervention development; 8 weeks	Indoor activity settings (eg, gyms)	60	Not described	• People who did not meet PAa guidelines • Age (35-60 years) • Female (35/60, 58%)
Direito et al (2019) [87] (other related reference: Direito et al [88])	New Zealand	Pre-post single-arm intervention; 8 weeks	Community	69	• 17-69 years • Owning an Android phone	• Insufficiently active healthy adults (either those who did not meet PA recommendations or who intended to decrease sedentary behavior) • Mean age 34.5 (SD 11.8) years • Female (54/69, 78%) • Mean BMI 25.6 (SD 4.95) kg/m2 • Ethnicity: New Zealand European (38/69, 55%)
Conroy et al (2018) [12]	United States	Single-group microintervention; 16 weeks	Community (via advertisement)	10	Adults not meeting federally recommended levels of aerobic PA but had no contraindications to PA	• Mean age 34.4 (SD 9.0) years • Female (9/10, 90%) • Employed full time (8/10, 80%) • Parents (6/10, 60%) • Single (5/10, 50%), married (4/10, 40%), or divorced (1/10, 10%) • Education (6/10, 60% with at least a bachelor's degree) • White (9/10, 90%), Asian American (1/10, 10%), and none were Hispanic or Latino
Middelweerd et al (2020) [89] (Other related references: Klein et al [90] and Middelweerd et al [91])	The Netherlands	3-arm quasi-experimental; 12 weeks	Community (flyers, posters, social media, personal contacts, and snowball strategies)	104	Adults aged 18-30 years at the time of registration, in possession of a suitable smartphone running on Android or iOS, apparently healthy, Dutch-speaking, and signed the informed consent form	• Healthy young adults • Mean age 23.4 (SD 3.0) years • Female (83/104, 79.8%) • Students (72/104, 69.2%) • Mean BMI 22.8 (SD 3.4) kg/m2 • Previous experience with PA apps (33/104, 31.7%)
Korinek et al (2018) [92] (other related references: Freigoun et al [93] and Martin et al [22])	United States	Pre-post single-arm intervention; 14 weeks	Nationally via community advertising methods (eg, email to student listservs, word-of-mouth, and social media ads)	20	Generally healthy, insufficiently active, 40 to 65 years, BMI 25 to 45 kg/m^2, owned and regularly used an Android phone capable of connecting to a Fitbit Zip via Bluetooth 4.0	• Overweight and sedentary adults • Age (47 years) • Mean BMI 33.8 (SD 6.82) kg/m2 • Female (18/20, 90%) • Walked on average 4863 steps per day

Author (year)	Country	Study design and duration	Recruitment setting	Sample, n	Inclusion criteria	Participants' characteristics
Rabbi et al (2015) [94]	United States	Pilot RCT[b]; 3 weeks	Advertisement placed throughout the university campus	17 (intervention=9; control=8)	Owned an Android mobile phone, interested in fitness	• Adult students and staff • Mean age 28.3 (SD 6.96) years • Student (13/17, 76%) • Female (8/17, 47%) • All participants (low-to-moderate PA)
Rabbi et al (2018) [95]	United States	Pilot Pre-post single-arm intervention; 5 weeks	Via the Wellness Center and retiree mailing lists from Cornell University	10	People with a history of chronic back pain (≥6 months in duration); willing to use MyBehavior-CBP; having some reasonable level of outdoor movement (eg, traveling to and from work); not being significantly housebound; with a basic level of mobile phone proficiency; aged between 18 years and 65 years; and fluent in English	• Adults with chronic low back pain • Mean age 41.1 (SD 11.3; range 31-60) years • Female (7/10, 70%)
Zhou et al (2018) [96]	United States	RCT; 10 weeks	Email announcement; university campus	64 (intervention=34; control=30)	Staff member, intended to be physically active in the next 10 weeks; own an iPhone 5s or newer; willing to keep the phone in the pocket during the day; willing to install and use the study App; able to read and speak English	• Adult staff employees • Small fraction had the following conditions: high blood pressure (5/64, 8%), type 2 diabetes (5/64, 8%), hypercholesterolemia (7/64, 11%) • Married or cohabitating (34/64, 56%) • White or non-Hispanic (29/64, 45%) • Full-time job (45/64, 70%) • Mean age 41.1 (SD 11.3) years • Female (53/64, 83%)

[a]PA: physical activity.

[b]RCT: randomized controlled trial.

Figure 1. Flow of studies. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses [13].



General Description of the Studies

A total of 5 studies were conducted in the United States [12,92,94-96], 1 in Italy [86], 1 in New Zealand [87,88], and 1 in the Netherlands [89-91]. Of these, 3 studies used pre-post intervention designs [87,92,95], 2 were RCTs [94,96], 1 was a 3-arm quasi-experimental study [89], 1 was a single-group microrandomized trial [12], and 1 was development study [86]. The duration of the studies ranged from 3 weeks to 6 months. A total of 5 studies recruited participants from community settings [12,86,87,89], 1 from the university campus and community [92], 2 from the university only [94,96], and 1 from a university wellness center and retiree mailing list [95]. Populations included insufficiently active and sedentary healthy adults, healthy and highly educated young adults, overweight and sedentary adults, adults with chronic low back pain, and students and staff from a university setting. Sample sizes ranged from 10 to 104 participants in the intervention evaluation studies and 60 in the development study. Participants were predominantly women in all studies except one [94]. The general characteristics of the included studies are summarized in Table 1.

Theoretical Premise

SCT was the predominant psychological theory used [12,89,92,94,95]. A study incorporated self-efficacy theory [86], with a dynamic decision network—a sequence of simple Bayesian networks used to describe probabilistic computational models [97]. A study used an integrated behavior change model incorporating 33 behavior change techniques (eg, self-monitoring, goal setting, and review of goals) combined with the behavioral intervention technology model [87]. Two studies incorporated control systems engineering models integrated with SCT [12,92]. In a study, SCT, self-regulation theory, and health action process approaches were integrated with a computational agent model—an intelligent reasoning system [89]. Learning theory, the Fogg behavior model, and SCT were combined with the exploit-explore strategy in 2 studies [94,95]. Rather than using a theoretical framework, a study integrated a single behavior change technique (goal setting) with a behavioral analytic algorithm [96].

Featured Description of Interventions

All studies promoted PA, whereas 4 studies also involved interventions for reducing SB [12,87,94,95]. Few studies explicitly stated the inclusion of behavior change techniques [87,89,92] as part of their intervention, 2 of which included a range of behavior change techniques [87,89]. Conroy et al [12] did not describe specific behavior change techniques but stated using intervention messages, which targeted key SCT constructs (eg, outcome expectancies, risk awareness and planning, efficacy-building affirmations, social support, and evoking anticipated reward or regret). The most common behavior change technique used across all studies was goal setting [86,87,89,92,96]. In terms of PA, 3 studies [87,92,96] included daily goal setting to achieve PA targets, whereas 1 study promoted weekly goal setting [89]. In a study, weekly step goals were initially established and then broken down into daily short-term goals [86]. Only 1 study set goals for SB [87]. To help participants set PA and SB goals, 5 studies used past activity performance [86,87,89,92,96], whereas 2 also took into account individuals' perceptions of self-efficacy [86,92]. Instead of setting goals, 2 studies focused on habit formation by providing suggestions from an individual's past frequent and infrequent activities after manual and automatic logging and

clustering of past activities [94,95]. Habit formation was also accounted for in another study [87]. For SB, Direito et al [87] encouraged participants to replace periods of extended sedentary time with light-intensity walking and standing, whereas Conroy et al [12] included *sit less* and *move more* messages. Two other studies by Rabbi et al [94,95] targeted both SB and standing by promoting short walks. None of the studies measured standing as an outcome.

Monitoring and feedback on behavior was another widely used behavior change technique [86,87,89,92,94,96]. All 6 studies used visual and numerical feedback on behavior, whereas 2 used biofeedback to help monitor behavior [86,94]. Four studies included a reward in the form of social rewards [19,20,94] and material incentives [17]. In terms of the type of intervention, 2 studies used push notification messages [87,89], 3 used push notifications to present step goals or minutes of activity goals (eg, walking) [86,92,96], 2 had in-app suggestions selected from frequent and infrequent past activities [94,95], and 1 used text messages [12].

In total, 7 studies used mobile apps, 6 of which ran on Android [86,87,89,92,94,95] and 1 on iPhone operating systems (iOS) [96]; 1 study did not mention the operating system used [12]. Four studies including TODAY, MyBehavior, MyBehaviorCBP, and CalFit [87,94-96] used built-in smartphone sensors (ie, accelerometers) to measure activity, and 3 studies used wearable activity trackers (Fitbit One, Fitbit Zip, and ActivPAL3) [12,89,92]. A heart rate sensor was used to measure activity in the study by Baretta et al [86]. Furthermore, 3 studies used the phone GPS to identify geo-locations [89,94,95]. Some studies used built-in phone GPS and apps to capture and account for environmental contexts such as location (eg, workplace) [87,89,94,95], weather [89,92], and weekend or weekday [12,92]. The JustWalk intervention incorporated psychological states (eg, stress) and measures of busyness and sleep quality. Further details have been provided in Table 2.

Table 2. Features of smartphone-based physical activity intervention development or evaluation.

Author (year)	Intervention	Control	Theoretical premise	Primary outcome	Other outcomes	Technology feature	Results
Baretta et al (2019) [86]	Weekly tailored PA[a] goals • Starting goal (first week): 120 METb • Long-term goal: 600 METs per week of PA • Weekly goals broken down into daily goals • Factors not considered in the intervention development but proposed for the next study: working hours, time of the day, day of the week, health and illness, weather, etc	N/A[c]	Self-efficacy theory and dynamic decision network	PA measured by HR[d] sensor, self-efficacy beliefs	N/A	• Android app: Muoviti (visualizing the heart-beat rate graph of the last training session, the curves of weight and waistline variations week by week, the burned calories graph, session by session, and the percentage of vigorous activity with respect to moderate activity) • Other: HR wristbands (MioAlpha and PulseON)	• N/A
Direito et al (2018 and 2019) [87,88]	Daily individualized and adaptive PA and SB[e] goals: • Daily activities (eg, transport to or from work, PA at work) • Light-intensity activity to replace SB (eg, walking to a colleague's desk rather than call or email, stand up while on the phone) • Leisure-time moderate-to-vigorous PA (eg, cycling) • Daily goals, visual and numerical feedback on past day and historical data, tips or suggestions, infographics, videos, and links, frequently asked questions, reminders, and push notifications • Context: workplace (location)	N/A	Intervention mapping taxonomy to identify behavior change techniques (eg, self-monitoring, goal setting, or review of goals) from literature. Integrated behavior change model constructs and behavioral intervention technology; 33 behavior change techniques were included	Test the acceptability and feasibility of just-in-time adaptive intervention on PA and SB	Pilot-testing the TODAY[f] app	• Android apps: Art of Living app and TODAY app. Other: built-in phone sensors for SB and activity (ie, accelerometer)	• TODAY app: low-effort and pleasant (54.3%), provides guidance on changing activity profile (52.6%), positively framed messages (64.4%), the app sustained interest over the 8 weeks (28.8%) • Most favorable behavior change techniques for the users (goal setting, discrepancy between current behavior and goal, feedback on behavior, instruction on how to perform the behavior, and behavior substitution) • Only significant improvement was occurred on light PA (see the results for statistics)

[j]Grounded in artificial intelligence and a subcategory of a broader decision-making framework called multiarmed bandit, which stems from probability theory.

[k]Behavioral analytics algorithm uses machine learning to build a predictive model–based on historical and goal steps for a particular person and then uses this estimation to generate challenging yet realistic and adaptive step goals based on a predictive model that would maximize the physical activity in the future.

[l]IPAQ: International Physical Activity Questionnaire.

Effectiveness of Interventions

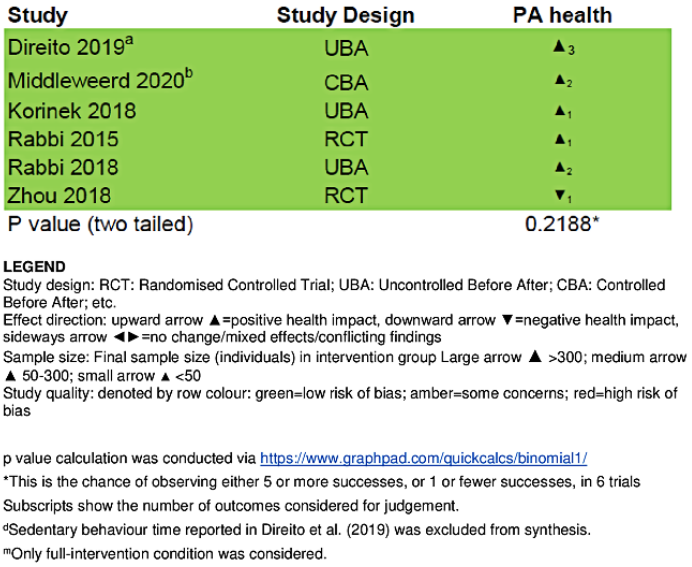
Narrative Synthesis of Individual Studies

A total of 6 studies reported on the effectiveness of the intervention [87,89,92,94-96]; the details are presented in Table 1. The intervention by Direito et al [87] increased the time spent in light and moderate-to-vigorous intensity PA and total PA time; however, only light-intensity PA achieved statistical significance from pre- to postintervention assessments (adjusted mean difference 2.2 minutes, SE of difference 1.0; 95% CI 0.78-3.56; *P*=.002). A small, but statistically nonsignificant, decrease in SB was observed (adjusted mean difference −9.5 minutes, SE of difference 7.5; 95% CI 19.98-1.05; *P*=.08). The Active2Gether intervention involved 3 arms of Active2Gether-full (tailored coaching messages, self-monitoring, and social comparison), Active2Gether-light (self-monitoring and social comparison), and Fitbit app control condition (self-monitoring). The Active2Gether did not show an effect on PA levels (average daily minutes of MVPA and step counts) compared with the Fitbit app (β=1.2, 95% CI −8.7 to 11.1, *P*=.81, for minutes of MVPA; β=−389, 95% CI −1750 to 972, *P*=.57, for steps and β=3.1, 95% CI −6.66 to 12.78, *P*=.53, for minutes of MVPA; β=5.2, 95% CI −1334 to 1345, *P*=.99, for steps, for the full and light app, respectively). The JustWalk intervention increased the average daily steps by 2650 steps in 16 days (t_{98}=6.54; *P*<.001). This effect decreased from day 16 to day 96 (average daily change −109.1 steps; t_{98}=−1.42; *P*=.15), suggesting acceptable maintenance. Users of the MyBehavior app walked an average of 10 minutes per day more from the first to the third week. There was no change in the control group (between-group differences were statistically significant (t_{15}=2.1; *P*=.06; 95% CI −0.23 to 19.05; *d*=0.9). In the second study by Rabbi et al [95], MyBehaviorCBP was associated with an increased daily walking time of 4.9 minutes (β=4.9; *P*=.02; 95% CI 0.8-0.89; *d*=0.31) among adults with chronic back pain. Nonwalking exercise time also increased by 9.5 minutes, but it was not statistically significant (β=9.5; *P*=.31; 95% CI −6.3 to 21.8; *d*=0.03). The Cal Fitness trial showed that the mean daily step count decreased in the 10-week intervention for both the intervention (mean −390, SD 490) and control group (mean −1350, SD 420; net mean difference 960; 95% CI 90-1830; *P*=.03). The Conroy et al [12] study was conducted to determine proof-of-concept and did not report effectiveness data (for descriptive results, see Table 2).

Effect Direction Plot

This study included 6 interventional studies. Figure 2 shows the effect direction plot for the PA health outcome domain; 5 of 6 interventions reported a positive effect direction, with 1 study showing a negative effect on PA health. The *P* value for the sign test for PA health was *P*=.21.

Figure 2. Effect direction plot summarizing the direction of impact from smartphone-based physical activity interventions.



Risk of Bias Assessment of the Included Interventions

Judgments on the risk of bias for the 2 RCTs and 4 quasi-experimental studies are presented in Multimedia Appendix 3 [12,87,89,92,94-96]. Overall, the included studies were of relatively high quality. The 2 RCTs [94,96] were judged to be low risk in all domains except one (ie, blinding of participants and personnel). All included quasi-experimental studies lacked a control group because of a pre-post [87,92,95] or single-group intervention [12] design. These interventions did not introduce additional risks to the remaining eight domains.

Discussion

Principal Findings

This review aims to quantify the number of studies that have integrated traditional psychological theories with dynamic computational models in the development or evaluation of smartphone interventions to reduce SB and promote PA. Although we showed that a few studies—mainly pilot, feasibility, and proof-of-concept—have taken an integrated dynamic approach, there was no consensus on what dynamic model–based approach should be used and how. Overall, it was difficult to draw a conclusion on the effectiveness of the included smartphone interventions; however, preliminary findings on PA are promising, less so for SB. Moreover, an effect direction plot was used to illustrate the direction of the intervention effect on PA outcomes, regardless of their statistical significance.

This review was driven in part by a paper by Riley et al [4] who argued that to truly capture the benefits of smartphones to deliver real-time and adaptive interventions, they need to adopt principles from other disciplines, such as control systems engineering, and integrate them with traditional health behavior theories. In total, we found only 8 studies that had adopted this notion, most of which used SCT for integration, with considerable complexity in the approaches used, ranging from a basic use of behavioral analytic algorithms to a more sophisticated approach using control systems.

Advancements in smartphone technology have enabled the collection of intensive contextual and longitudinal (time-variant) data, which facilitate the delivery of automated, real-time, and adaptive behavior change interventions such as just-in-time adaptive interventions. These features permit the testing of specific intervention components (eg, behavioral messaging comprising behavior change techniques). Control systems appear to offer an excellent fit for the development of adaptive smartphone interventions. It explores ways to influence a dynamic system (eg, time-varying adaptive PA intervention) and how to regulate it [11,12]. In other words, control systems engineering provides a dynamic approach to designing tailored interventions that adapt over time and are based on real-time data (ie, intensive longitudinal data) [98]. Despite the variability in the application of dynamic models outlined in this review, existing evidence suggests that their integration with traditional behavior change and psychological theories offer exciting opportunities to better understand human behavior (eg, SB and PA), identify patterns of behavior, and optimize individually adapted behavior change interventions.

Few of the included studies evaluated the effectiveness of the interventions, and small effects were observed on PA and SB. Possible reasons for the small effect sizes may have included inappropriate design (nonrandom allocation) [89], lack of exposure to automated intervention because of technical problems [89], use of nonpersonalized behavioral interventions [94], lack of participant engagement with the intervention [87], and insufficient inclusion of behavior change techniques [96]. Moreover, a binary sign test conducted in this review attempts to provide additional information and contribute to transparency in interpreting the effect direction. However, this should be interpreted carefully, as the small number of studies may have underpowered the test.

Most of the studies included in the review focused on PA, whereas only a few targeted SB; none assessed standing as a distinct outcome. Moreover, most smartphone-based SB and

PA interventions used built-in smartphone accelerometers and sensors as a tool to capture individual behaviors to inform behavioral interventions (ie, step counts were used to help participants set goals and monitor progress or provide activity suggestions) [87,94-96].

The benefits of smartphone interventions include the ability to collect and measure contextual factors (eg, location, weather, and emotional or psychological states), which could be used to personalize behavior interventions [99]. Existing research evidence has shown that contextually aware reminders increase the effectiveness of mHealth PA interventions [21,100]. Furthermore, leveraging contextual information in PA interventions enables the triggering of more frequent reminders without annoying the individual receiving the reminder, and these types of interventions are considered more acceptable [100]. Despite these proposed benefits, most of the included studies lacked an assessment of contextual factors. A likely reason for the lack of contextual factors in the reviewed studies is the technical challenges, such as system requirements. For example, high battery consumption and low localization speed by a built-in smartphone GPS compromise mobile app performance [101]. Another important reason might be the privacy implications for smartphone users [102]. Privacy breaches are most probable when context-sensitive information such as location is monitored [103]. Moreover, people generally refuse to be monitored for where they go or what they do [104]. A limitation of using native smartphone sensors is that they do not provide research-grade precision for measuring PA and SB. Commonly used accelerometers (eg, built-in smartphone accelerometers and Actigraph GT3X) measure SB by focusing on periods where the device records activity counts below a certain cutoff point, such as less than 100 counts per minute [105]. This leads to the miscategorization of SB [106]. Although postural devices (inclinometers) such as activPAL have excellent accuracy in measuring SB [107], they require proprietary software (activPAL Professional Research Edition, PAL Technologies) to process and collect the data and thus have low utility for real-time interventions. Finally, as highlighted above, none of the included studies assessed standing as an outcome, despite 3 studies promoting standing in their intervention messages [87,94,95]. This might be explained by the inability to measure standing in real time for a dynamic intervention purpose and limited evidence advocating standing as a distinct activity that brings health benefits. However, short-term and small-scale studies that support standing are emerging. In a lab-based study, breaking up every 30 minutes of sitting by 5 minutes of standing was shown to reduce postprandial blood glucose (34% reduction) compared with prolonged sitting in postmenopausal women [108]. Moreover, an office-based study has shown that an afternoon of standing reduced postprandial glucose (43% reduction) compared with sitting while performing computer work [109].

The included interventions comprised pre-post, RCT, and 3-arm quasi-experimental designs. These commonly used experimental designs are unable to assess rich context and time-intensive data. For example, RCTs do not provide information on the particular time when the intervention had an effect and the moderators that affected the behavior change [110]. In fact, RCTs typically consider the overall impact of an intervention package on behavior or health outcomes, not specific components of that intervention. Other study designs, such as factorial designs, are capable of investigating the effects of each intervention component and the interactions between components and the dosing of the intervention. However, they are not sufficient to delineate when the intervention was most effective and what moderators influenced the intervention [110]. A microrandomized trial may address these design limitations. The microrandomized trial is a novel experimental design to determine the optimal delivery of just-in-time adaptive interventions [110]. A key advantage is that microrandomized trials not only assess the effect of specific intervention components but also changes in effects over time and moderators, including contextual and psychological factors [110]. Microrandomization can help elucidate potential causal relationships between each randomized intervention feature and proximal effects (what happens in a limited time window, for example within 1 hour, following a randomized intervention) and allow assessment of time-varying contextual and psychological factors moderating those proximal effects [110].

Most of the included studies lacked comprehensive incorporation and testing of behavior change techniques, although they were theory-based. The precise specification of behavior change techniques—which are active ingredients of behavior change interventions and specification of intervention features of PA (eg, mode of delivery and frequency)—help provide accumulative evidence for effective and replicable interventions [111]. Smartphone-based interventions undertaking dynamic approaches with a proper experimental design (ie, microrandomized), while testing various behavior change techniques, are expected to provide more robust evidence than traditional theory approaches.

Limitations and Strengths

A limitation of this review is the heterogeneity in the reported effectiveness data that prevented a pooled meta-analysis. Other limitations include the small sample size and short duration of the included interventions and nonrandomized study designs. Moreover, women exceeded men in most studies, and all studies involved adult populations, which might limit the generalizability of the findings. A key strength of this review is that it focuses on the integration of dynamic models in smartphone-based PA and SB studies, as such dynamic models fit best with mobile technologies. Another strength is the use of the effect direction plot to present the direction of the effectiveness results. This methodology is superior to narrative synthesis, as it helps with the overall interpretation of the findings. Future studies, in the context of SB and PA behaviors, are suggested to incorporate and assess the effect of relevant environmental and internal contextual moderators, use computational models, and investigate SB, in particular, as there is a significant evidence gap.

Conclusions

In conclusion, despite the recommendation for integrating dynamic models such as control systems to better harness the potential of mobile technologies, this review showed that few studies have actually adopted this approach to promote PA and

reduce SB. To some extent, this research gap may be because of the complex and multifaceted nature of dynamic models, such as control systems, in integrating adaptive contexts and real-time measurement of outcomes.

Acknowledgments

The authors would like to thank Rachel West (Liaison Librarian at Deakin University) and Dr Gavin Abbott (Senior Research Fellow and Biostatistician at Deakin University) for their guidance. RDK received a Deakin University Postgraduate Research Scholarship for his PhD.

Authors' Contributions

RDK, RM, and SMSI designed the study. RDK conducted the search and removed duplicates; RDK and JM screened the titles, abstracts, and full text of the studies and extracted data; and RDK drafted the systematic review manuscript. RM, SMSI, DWD, and MA contributed to verifying screening; all coauthors—SMSI, DWD, JM, MA, and RM—contributed to the critical revision of the manuscript and approved the final manuscript.

Abstract

Background: Regular physical activity (PA) is crucial for well-being; however, healthy habits are difficult to create and maintain. Interventions delivered via conversational agents (eg, chatbots or virtual agents) are a novel and potentially accessible way to promote PA. Thus, it is important to understand the evolving landscape of research that uses conversational agents.

Objective: This mixed methods systematic review aims to summarize the usability and effectiveness of conversational agents in promoting PA, describe common theories and intervention components used, and identify areas for further development.

Methods: We conducted a mixed methods systematic review. We searched seven electronic databases (PsycINFO, PubMed, Embase, CINAHL, ACM Digital Library, Scopus, and Web of Science) for quantitative, qualitative, and mixed methods studies that conveyed primary research on automated conversational agents designed to increase PA. The studies were independently screened, and their methodological quality was assessed using the Mixed Methods Appraisal Tool by 2 reviewers. Data on intervention impact and effectiveness, treatment characteristics, and challenges were extracted and analyzed using parallel-results convergent synthesis and narrative summary.

Results: In total, 255 studies were identified, 7.8% (20) of which met our inclusion criteria. The methodological quality of the studies was varied. Overall, conversational agents had moderate usability and feasibility. Those that were evaluated through randomized controlled trials were found to be effective in promoting PA. Common challenges facing interventions were repetitive program content, high attrition, technical issues, and safety and privacy concerns.

Conclusions: Conversational agents hold promise for PA interventions. However, there is a lack of rigorous research on long-term intervention effectiveness and patient safety. Future interventions should be based on evidence-informed theories and treatment approaches and should address users' desires for program variety, natural language processing, delivery via mobile devices, and safety and privacy concerns.

KEYWORDS

physical activity; health behavior; behavior change; conversational agent; virtual agent; chatbot; digital health; eHealth; mHealth; mobile health; mobile phone

Introduction

Background

Physical activity (PA) is crucial to health and well-being, and regular exercise can reduce the risk of disease, improve mental health, and boost quality of life [1]. In 2016, 28% of adults globally did not meet the World Health Organization's PA guidelines for 150 minutes of aerobic activity per week [2]. Global PA levels have not improved since 2001, and the prevalence of inactivity has steadily risen in high-income countries [2]. Therefore, innovative interventions are required to increase PA.

Recently, there has been an increase in digital health interventions that promote healthy lifestyle changes through technologies such as smartphone apps, web-based programs, and text messages [3]. Some of these interventions are as effective as in-person interventions at modifying behavior [4]. Programs may include virtual health coaching, workout or diet plans, progress monitoring, and positive reinforcement for healthy eating and PA. Tailored feedback based on individual goals, habits, and circumstances can create a more personalized experience for users. Furthermore, some digital platforms offer users the option of pairing activity trackers such as pedometers, accelerometers, and heart rate monitors to improve the accuracy of data tracking and performance feedback.

In addition to their customizability, digital interventions allow health programs to have a wide reach. In 2018, mobile phone ownership rates ranged from 83% in emerging economies to >90% in advanced economies worldwide [5]. Smartphone ownership and internet use are nearly universal in most advanced economies and continue to grow rapidly in emerging economies [5]. With the advent of technology, demographic groups that previously did not have access to health coaching because of prohibitive costs can now access that support. Low-income Hispanic adults and Black adults in the United States, in particular, may benefit, as they have a significantly higher prevalence of physical inactivity than non-Hispanic White adults [6]. Smartphone ownership and use are more common in Hispanic and Black households than in non-Hispanic White households [7], making mobile platforms suitable for disseminating health-related interventions to underserved communities.

Digital interventions can take the form of a conversational agent, also known as a chatbot or virtual agent. Conversational agents are software programs that mimic written or spoken human conversations. They come in many forms, from chatbots engaging in written conversations to avatars simulating face-to-face discussions through synthetic speech [8]. Depending on their form, conversational agents may be deployed through standalone computer software, messaging apps, web-based platforms, mobile apps, and SMS text messaging or multimedia messaging services (MMSs). Interacting with conversational agents typically does not require much digital literacy beyond chatting or typing.

Simple conversational agents operate according to expert systems or rule-based systems, meaning they generate conversations based on questions and responses written by program developers [9]. In such cases, users are often restricted to selecting predefined answers. Conversational agents with more advanced capabilities are programmed to conduct natural language processing and integrate machine learning. Users are free to enter any command, and conversational agents formulate appropriate responses based on artificial intelligence algorithms.

Conversational agents have been increasingly used in the health care sector to help patients achieve their health goals, owing to their ability to provide interactive and personalized content [8]. Many of these conversational agents provide daily feedback, encouragement, and adaptive goals based on objective data received from fitness trackers. In contrast to in-person health coaching, conversational agents can be accessed around the clock for the duration of the intervention.

An example of a conversational agent that supports individuals in reaching their health goals is Ally, a smartphone-based chatbot that incorporates self-monitoring prompts, exercise planning, and financial incentives (cash and donations to a charity organization) to motivate users to walk more [10]. Another example, FitChat, uses goal setting, discussions of barriers, and motivational messages to encourage older adults to engage in aerobic activity and muscle-strengthening exercises [11]. A third example, Laura, falls into the subset of conversational agents termed *relational agents* [12-14]. Relational agents are computational artifacts, often with humanlike appearance and speech, designed to establish social-emotional relationships with users [12]. Relational agents such as Laura use social dialog, empathy, humor, and self-disclosure to keep users engaged over time and motivate them to create and maintain exercise habits [12].

Rationale

Systematic and scoping reviews have been conducted on the use of digital interventions to increase PA [15-18] and the use of conversational agents in health care [8,19-21]. Previous reviews have found that many digital interventions are not theoretically based or evidence informed [4]. These interventions may be limited in their impact, as they do not include established constructs for behavior change. Although there is emerging evidence that most behavior change interventions are suitable for adaptation to a digital platform [22], few studies have addressed how digital content is linked to empirically tested frameworks and how program content and dialog flows are translated from face-to-face to virtual delivery.

It is unknown whether previous findings extend to PA conversational agents. To our knowledge, no systematic reviews have focused exclusively on PA conversational agents and analyzed their use of theories, treatment approaches, and intervention components. Research in this domain may help elucidate the successes and shortcomings of current interventions, thus guiding the development of program content and dialog flows that will have maximum impact on users.

Objectives

Our objective is to conduct a systematic review to (1) summarize the usability and effectiveness of PA conversational agents; (2) describe common theoretical frameworks, treatment approaches,

and intervention techniques; and (3) identify areas for further development.

Methods

Overview

We conducted a mixed methods systematic review following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines [23] (Multimedia Appendix 1 [23]). The protocol for this systematic review was registered on the Open Science Framework registries [24].

We chose a mixed methods systematic review as conversational agents are still relatively new. As such, there is a shortage of randomized controlled trials (RCTs) investigating their efficacy and effectiveness in the health care sector [8]. Many studies of conversational agents include both quantitative data (eg, step counts and participant ratings on Likert scales) and qualitative data (eg, quotes from individual interviews or focus group sessions); a mixed methods design produces a more comprehensive overview of conversational agents than synthesizing quantitative or qualitative data only.

Eligibility Criteria

The formulation of the eligibility criteria was based on the PICOS (patient problem, intervention, comparison, outcomes, and studies) framework (Textbox 1) [25].

Textbox 1. Inclusion and exclusion criteria using the PICOS (patient problem, intervention, comparison, outcomes, and studies) framework.

Inclusion criteria

- Patient problem: studies that targeted physical activity in users
- Intervention: interventions that involved an automated conversational agent
- Comparison: another intervention type or delivery method (eg, face-to-face and app), treatment as usual, no treatment, or one group pre-post comparison
- Outcomes: reporting of intervention impact on participants or participants' experiences with the conversational agent; some description of theoretical basis, dialog flow development, or intervention components of the program
- Study type: quantitative, qualitative, and mixed methods studies

Exclusion criteria

- Patient problem: studies that did not target physical activity in users
- Intervention: interventions that did not involve an automated conversational agent
- Comparison: studies without a comparison condition were not excluded, provided they still included sufficient outcome data
- Outcomes: no mention of intervention impact or participant experiences; no description of the applied intervention
- Study type: literature reviews, conference abstracts, dissertations, protocol papers, and tutorials

The inclusion criteria for this review included primary literature that involved an automated conversational agent. We focused on studies describing existing conversational agents, as opposed to studies exploring hypothetical uses of conversational agents, in an attempt to present concrete findings with external validity. We did not place any limitations on the conversational agent type, delivery platform, dialog technique, or input and output modalities. PA had to be one of the targets of the intervention. No restrictions were imposed on the target population or setting.

Studies were excluded if there was no primary research conducted or if the intervention did not use an automated conversational agent to target PA. Studies were not excluded for the lack of a comparison condition, provided they still offered outcome data on intervention impact or participant experiences and described the intervention in sufficient detail. Protocol papers and tutorials on building conversational interfaces were excluded as they did not provide any outcome data.

Information Sources

We searched seven relevant electronic databases (PsycINFO, PubMed, Embase, CINAHL, ACM Digital Library, Scopus, and Web of Science) from their inception through July 22, 2020. We also reviewed the reference lists of relevant papers.

Search Strategy

We based our search strategy on a preliminary scan of the literature on digital health interventions. We also consulted a librarian at the University of California, Berkeley, to generate search strings for selected databases, using Boolean operators and thesaurus terms where applicable. We combined search terms for two major topic areas: conversational agents and PA (complete search strategy available in Multimedia Appendix 2).

Study Selection

One author conducted the initial search in each database and imported all references into Covidence (Veritas Health Innovation), a web-based software program that facilitates collaboration among reviewers. Duplicate records were identified and removed.

The titles and abstracts of all the citations were independently screened by 2 authors for eligibility. Potentially relevant articles were retrieved in full for review. Full-text studies that did not meet the predefined eligibility criteria were excluded. Any

discrepancies regarding the inclusion of an article were resolved through discussion between the 2 reviewers. Cohen κ was calculated to measure intercoder agreement.

Data Management and Collection

Data from the selected studies were charted in a spreadsheet developed by the authors for this review (Multimedia Appendix 3). Data extraction was performed by one reviewer, with a second reviewer cross-checking the data extraction table for accuracy.

Data Items

Descriptive Data

The following descriptive data were extracted from each study: authors, publication year, title, study design, targeted behaviors (in addition to PA), population (eg, clinical vs nonclinical samples), geographic focus, initial and final sample size, conversational agent name, conversational agent type, delivery method, delivery platform, conversational agent output modality, user input modality, comparison conditions, control type, and outcome measures. Data were also analyzed for the variables given in the following sections.

Intervention Effectiveness and Impact

Evaluation measures for assessing changes in users' activity levels or motivation to exercise as a result of the intervention included data derived from subjective measures (eg, questionnaires and self-reports) and objective measures (eg, pedometers).

Theory

Theories attempt to explain how and why a behavior occurs. Theoretical frameworks may guide the design and selection of the program content. In addition, the integration of theoretical content may boost the effectiveness of behavior change interventions [4]. Examples of established theories of PA promotion that have guided some of the interventions discussed in this review include behavior change theory, the habit formation model, and the health action process approach.

Dialog Flow Development

Dialog flows for conversational agents are often adapted from counseling techniques for a specific treatment approach, such as motivational interviewing or cognitive behavioral therapy. These approaches can help enhance motivation for behavior change and identify barriers to PA.

Intervention Components

Conversational agents implement specific program elements to help users overcome exercise barriers and increase their activity levels. Examples include health education, self-monitoring, goal setting, and exercise reminders.

Challenges and Areas for Improvement

Study limitations, ethical considerations, barriers to program development or implementation, and key areas for improving the conversational agent were noted.

Outcomes and Prioritization

The primary outcomes for which we collected data were (1) usability and effectiveness of PA conversational agents; (2) theories, intervention components, and cognitive and behavioral constructs used to motivate individuals to engage in PA; and (3) challenges and areas for improvement. Quantitative and qualitative data were collected to assess the outcomes.

Appraisal of Studies

The methodological quality of the included studies was assessed using the Mixed Methods Appraisal Tool (MMAT) [26]. The MMAT is a valid, reliable, and efficient tool that allows the simultaneous appraisal of qualitative, quantitative, and mixed methods studies [27]. The methods section of each included study was read by 2 reviewers independently, and each study was categorized as qualitative research, RCT, nonrandomized study, quantitative descriptive study, or mixed methods study. Then, studies were rated based on their fulfillment of the MMAT criteria in each of their respective categories. Examples of methodological quality indicators include the appropriateness of study design, choice of sampling strategy, adherence to data collection methods, intervention integrity, and integration of results. Any disagreements on ratings were resolved through discussion between the 2 reviewers.

Assigning studies an overall numerical score based on the ratings of each criterion is discouraged because a single number cannot provide insight into which aspects of the study methodology are problematic [26]. Instead, we classified studies as having lower methodological quality when they met ≤60% of the MMAT criteria and higher quality when they met >60% of the criteria. In addition, we included a detailed overview of our ratings of each criterion. All eligible studies were discussed in this review regardless of their MMAT ratings, as it is discouraged to exclude studies on the basis of low methodological quality [28].

Data Synthesis

A meta-analysis was not conducted because of the heterogeneity of study types and outcome data. Instead, data were analyzed using parallel-results convergent synthesis, which allows qualitative and quantitative evidence to be synthesized concurrently, without data transformation [29]. Parallel-results convergent synthesis is suitable for systematic reviews that pose two or more complementary review questions [29]. Following evidence synthesis, we presented a narrative summary of our findings and made recommendations for future work.

Results

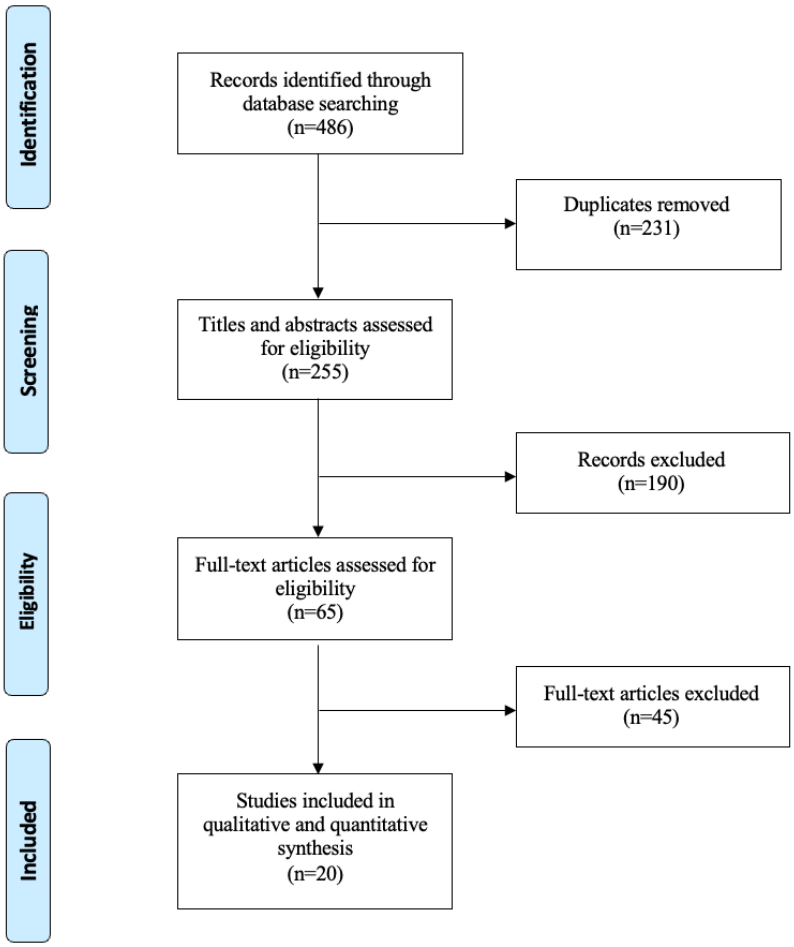
Search Results

Our literature search retrieved 486 citations. After the removal of duplicates, 255 studies remained. An additional 74.5% (190/255) of studies were excluded after the title and abstract screening. Of the 65 remaining studies, 20 (31%) were selected for inclusion after full-text screening. Our review of the reference lists of relevant papers did not yield any additional records. The study selection process is illustrated in Figure 1.

Excluded studies with reasons for exclusion are listed in Multimedia Appendix 4.

Interrater reliability was assessed at both screening stages. The κ coefficients were 0.71 (moderate agreement) for the title and abstract screening and 0.65 (moderate agreement) for the full-text screening.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.



Overview of Included Studies

We included 20 studies evaluating 17 unique conversational agents in this review (Table 1) [12-14,30-46]. Out of the 20 studies, 10 (50%) were RCTs, 8 (40%) were quasi-experimental studies, and 2 (10%) were qualitative studies. PA was the sole target of intervention in half of the studies [12,13,32,35,37,38,41,43,45,46]. In the other half of the studies, PA was a primary target, but there were additional targets such as diet [33,34,36,39,44], fruit and vegetable consumption [30,31,40], medication adherence [14], mental well-being [33,36], stress management [33,34,36,44], and sun protection [42]. A total of 60% (12/20) studies used subjective measures to gauge intervention effectiveness and user satisfaction, and the other 40% (8/20) studies relied on objective data from pedometers or accelerometers.

The studies were conducted in 8 different countries. Studies were primarily conducted in nonclinical populations (eg, healthy adults and college students), with only 5 studies recruiting from clinical settings (eg, clinics and hospitals) [12,14,32,36,45]. The sample size ranged from 4-958 participants (median 55; mean 117, SD 206.3). Half of the studies were published in the last 3 years (2017-2020 [33,34,36-42,46]), and the other half were published between 2005 and 2014 [12-14,30-32,35,43-45].

Results of Appraisal

Of the 20 included studies, 10 (50%) were categorized as quantitative research (RCT or nonrandomized study), 8 (40%) as mixed methods studies, and 2 (10%) as qualitative research. Overall, the methodological quality of the 20 studies varied: 55% (11/20) of the studies met ≤60% of the criteria outlined by the MMAT (lower methodological quality), and 45% (9/20) of the studies met >60% of the criteria (higher methodological quality). Reviewers' ratings for each methodological quality criterion are presented in Multimedia Appendix 5 [12-14,30-46].

Overview of Conversational Agents

The 20 included studies evaluated 17 unique conversational agents (Table 2). A conversational agent, Laura, was used in 15% (3/20) of the studies [12-14], and another agent, Karen, was used in 10% (2/20) of the studies [30,31]. Conversational agents Steps to Health [32], Gabby [36], Emily [40], and Elsie/Meimei [46] were designed with similar architectural systems; however, they used distinct dialog flows tailored to different populations (eg, older adults, racially diverse city-dwelling women, and Chinese adults living in the United

States), so they were categorized as unique agents. For example, the conversational agent developed for racially diverse city-dwelling women delivered culturally aware patient strategies and health information and mentioned prayers and spiritual traditions [36]. Similarly, the conversational agent developed for Chinese adults emphasized values common to the Chinese culture, including collectivism [46].

Table 2. Conversational agent characteristics.

Conversational agent or program name	Delivery method (computer or phone)	Delivery platform	Conversational agent output (speech or text)	User input (constrained or unconstrained)

[a]ECA: embodied conversational agent.

[b]MMS: multimedia messaging service.

Of the 17 conversational agents, 10 (59%) were computer-based [12-14,30-32,35,36,40,42,43,45,46], 4 (24%) could be used on computers or phones [33,34,39,41], and 3 (18%) were designed for mobile devices only [37,38,44]. Conversational agents were implemented using standalone computer software [12-14,30-32,40,42,43,45,46], messaging apps [33,34,39,41], web-based platforms [35,36], mobile apps [38,44], and SMS text messaging or MMS [37].

In total, of the 17 agents, 8 (47%) were embodied conversational agents (ECAs) with synthesized speech [12-14,30-32,36,40,42,45,46], 6 (35%) were text-only chatbots [33,34,37-39,41], and 3 (18%) had both an ECA and chatbot option [35,43,44]. With all 17 conversational agents, participants gave input by typing on a keyboard or selecting answer options with a mouse, touchpad, or touchscreen; 59% (10/17) of the conversational agents limited users to constrained input, whereby users selected answers from a multiple-choice list of options, and conversational agents responded according to predefined templates [12-14,30-32,36,38,40,43-46]. Only 29% (5/17) of the conversational agents accepted free-text responses and used machine learning and natural language processing to understand users' input and generate replies [33,34,37,39,41], and 6% (1/17) of the conversational agents accepted free-text responses and multiple-choice answers [35]. The remaining 6% (1/17) conversational agents did not specify what user inputs were accepted [42].

Intervention Effectiveness and Impact

RCTs

Of the 10 RCTs, 6 (60%) found that participants in the conversational agent group outperformed participants in the control group on various PA measures. Intervention groups increased daily walking more quickly [31], achieved >30 minutes of exercise or 10,000 steps per day more times per week [13], significantly increased step count during the study period [12,32], significantly increased self-reported PA at 1 month [35], and maintained step counts throughout time [45]. Only

10% (1/10) RCTs did not find significant differences in activity levels between the intervention and control groups [36].

The remaining 30% (3/10) of RCTs used conversational agents in both experimental and control groups but varied the conversational agent conditions (eg, cash incentives vs charity incentives vs no incentives [38], rewards vs no rewards [41], and ECA vs text-only chatbot [44]). In 67% (2/3) of these studies, interacting with a conversational agent significantly increased step counts and self-reported activity across all conditions; however, including financial incentives and rewards further boosted activity levels [38,41]. The last RCT determined that conversational agents were useful but limited by low adherence [44].

Quasi-Experimental Studies

Of the 8 quasi-experimental studies, 6 (75%) used within-subjects pre-post designs [14,30,33,34,37,39] and 2 (25%) included comparator groups [40,46] (Multimedia Appendix 6 [12-14,30-46]). Of the 8 quasi-experimental studies, 3 (38%) measured changes in activity level as a result of interacting with a conversational agent [14,34,39]; 2 found positive impacts in the form of increased enjoyment during walking [14], higher frequency of step-goal achievement [14], and increased weekly exercise time [39], and 1 did not find any differences in activity levels [34].

An additional 38% (3/8) of the quasi-experimental studies measured participants' attitudes toward exercise before and after the intervention [37,40,46]. Conversational agents successfully triggered reflection on new exercise routines [37], increased participants' self-efficacy and motivation to exercise for at least 30 minutes every day [40] and persuaded participants to start regular exercise [46].

The remaining 25% (2/8) of the quasi-experimental studies discussed users' preliminary experiences with conversational agents [30,33]. Overall, these conversational agents had moderately high usability and feasibility. Participants perceived them to be satisfactory [30,33], trustworthy [30], empathetic [30], useful [33], and easy to use [33].

Qualitative Studies

Of the 20 included studies, only 2 (10%) were qualitative studies [42,43]. In one study, most participants had positive, satisfying interactions with the relational agent and found the agent humanlike, caring, and supportive [42]. About half of the participants viewed the relational agent as informative and felt motivated to maintain regular exercise. Another qualitative study compared two different PA conversational agents: a text-based chatbot and an ECA [43]. Participants had positive experiences with both systems and felt that conversational agents could provide motivation and serve as information channels.

ECAs Versus Chatbots

ECAs and text-only chatbots performed similarly, with 88% (7/8) of the ECAs and 83% (5/6) of the chatbots positively affecting participants' PA levels, motivation to exercise, or perceptions of conversational agents. Of all 20 studies, 3 (15%) directly compared ECAs with chatbots; one study found that both were equally effective at building social relationships and increasing PA [35], one study suggested that ECAs could provide a slightly more engaging user experience than chatbots [42], and the remaining study described the benefits and drawbacks of each conversational agent [43].

Intervention Characteristics

Theory

Of the 20 studies, 11 (55%) cited a theory that guided their intervention development (Table 3). Of these 11 studies, 6 (55%) designed the intervention and selected program elements according to the referenced theories [37,38,40,41,44,46], and 5 (45%) mentioned a theory as their overarching framework but did not explicitly link intervention components with corresponding theoretical constructs [13,30,31,34,42].

The used theories could be broadly categorized into learning theories, which describe how people receive and process knowledge, and behavior change theories, which explain how behaviors develop and shift throughout time. Four interventions were based on a combination of theories [30,31,40,44], and 1 intervention used the Hofstede cultural dimensions theory to develop culturally appropriate dialog for an American and a Chinese conversational agent [46].

Table 3. Distribution of theories.

Dialog Flow Development

Of the 20 studies, 9 (45%) discussed the use of one or more treatment approaches to guide the development of dialog flows for conversational agents. The most commonly used approach was motivational interviewing [30,31,35-37,40], followed by cognitive behavioral therapy [13,33,34,45] and behavioral therapy [13,45].

Of the 9 studies, 4 (44%) described how dialog flows were adapted from face-to-face counseling and prepared for virtual delivery. Techniques included using transcripts from videotaped counseling sessions as a basis for the conversational structure [30,40], using a dialog interpreter to convert statements from counseling sessions into interactive virtual conversations [31], and developing scripts through literature reviews and consultations with physicians, computer scientists, and exercise trainers [45]. The remaining 56% (5/9) studies did not explain how dialog flows for conversational agents were written.

Intervention Components

The most common program components were health education, motivational messages, problem-solving barriers to exercise, goal setting, self-monitoring, and exercise tips (Table 4). Additional components included reminders, homework, workout planning, incentives, and reflection.

Participants found health education helpful [36,42], as it allowed them to learn new ways of increasing PA [40]. They also enjoyed receiving tips for new exercise routines [40] and periodic exercise reminders [31,42]. Positive feedback motivated participants [37], built rapport [42], and increased agent likeability [31]. Participants appreciated progress tracking features [34] and visual step charts [31,32]. Conversational agents helped participants formulate concrete goals, action plans, and overcome obstacles [37]. However, participants mentioned that they would have liked to talk more about how their health problems affected their ability to exercise [12]. Change talk and reflection helped participants increase their commitment to positive health behaviors [37,40]. Finally, rewards were implemented with moderate success, with one study finding that daily cash incentives increased step-goal achievement by 8.1% [38] and another study finding that intrinsic rewards improved habit formation and enhanced intervention sustainability [41].

Table 4. Distribution of intervention components.

[a]Intervention component present.

Challenges and Areas for Improvement

Conversational Agent Constraints

The most common challenges were related to the capabilities of conversational agents. In 59% (10/17) of the conversational agents, users were required to respond via multiple-choice answers. This format limited user freedom [12,13] and lacked the personalization necessary to address more complex issues [14]. Although researchers acknowledged the need for more sophisticated dialog systems, they were concerned about the difficulty of implementing machine learning and the increased chance of misunderstanding users' intents [13].

Another area for improvement was communication modality. None of the conversational agents were built to accept spoken input. Participants were required to type out their answers or select answers using a mouse, touchpad, or touchscreen. In one study, participants universally stated that they would have preferred speaking to the conversational agent [12].

Studies have presented mixed findings on the value of ECAs with synthesized speech. According to qualitative data, talking ECAs seemed more versatile than text-only chatbots [43] and provided a closer approximation of face-to-face conversations with health care providers [32]. However, 45% (5/11) ECAs were criticized by participants for their robotic voices, slow pace, unnatural movements, and limited relational skills [35,36,40,42,46].

Program Delivery

Participants encountered more issues with computer-based than with phone-based conversational agents. Some participants had limited access to computers, limited time to sit in front of computers [36], or difficulties installing software and entering information [12]. Internet access was also an issue, with network breaks preventing participants from starting apps, synchronizing devices and databases, and connecting fitness trackers [43]. Many participants across studies felt that having the conversational agent on their phone would be more convenient and accessible, allowing them to complete the program "on the go" [32,36,42].

Mobile interventions were well-liked, particularly those that used familiar messaging apps, as they did not require participants to download and learn to use additional applications [41]. However, some participants had minimal smartphone skills

and did not know how to send text messages, thus limiting their engagement with the intervention [39]. In addition, one mobile app suffered from poor usability because of slow performance on older smartphones [44].

Program Content

Of the 20 studies, 7 (35%) studies mentioned the repetitiveness of program content as a key area for improvement [12,13,30,31,37,42,43]. This included dialog flows that were often repeated, leading to lower satisfaction [30] and increased boredom [37,43]. Participants desired more personalized responses and suggestions based on their health information, preferences, and PA history [37,40]. Owing to repetitiveness, participants felt that continued use would not lead to any additional impact [42].

User engagement waned throughout time [45], and high attrition rates limited the efficacy of the interventions. In one study, participants responded to 50% of the self-monitoring prompts and completed only a few exercise and coping plans, explaining that weekly planning was too difficult and time-consuming [38]. In another study, participants found the conversational agent engaging, but without external support, almost half of them discontinued the use of the service [44]. Participants who lapsed for a short period were more likely to quit the program [41].

Ethical Issues

Many relational agents relied on social dialog, humor, empathic statements, and personal stories to build rapport with users [14,31,32,42,46]. The use of these techniques may have increased the potential for misperceptions and false illusions, as virtual agents do not have emotions or personal histories. Humans tend to anthropomorphize advanced technology [13], and conversational agents may have deceived some users into thinking they were interacting with a human. One study pointed out that patients with schizophrenia who are experiencing a psychotic episode could be more likely to confuse relational agents with real people, develop parasocial relationships with relational agents, or become paranoid that relational agents or their programmers are monitoring their behavior [14]. Researchers attempted to address this matter by having the relational agent periodically remind users that it was “just a computer character with limited capabilities” [14].

Standards of Care

Of the 20 studies, only 1 (5%) compared the quality of care between a human and a conversational agent. This study found that a human agent was often more motivating, engaging, and supportive than a virtual agent [34].

Most studies did not address privacy features or data storage and access procedures despite participants expressing concerns that conversational agents could collect and share their personal information [12,14]. One study discussed security measures, such as requiring usernames and passwords and automatically logging users out after a period of inactivity [36]. Another study described weekly backup procedures to mitigate the possibility of data loss due to system crashes or computer theft [12].

Finally, 10% (2/20) of studies discussed user safety issues. One conversational agent provided videos demonstrating exercises that a participant with arthritis could not safely perform without the help of an elastic band [43]. Another study discussed the necessity of improving automated dialog flows because of conversational agents’ inadequate responses to safety concerns mentioned in users’ free-text answers [40].

Discussion

Principal Findings

This literature review charted data from 20 studies that evaluated 17 PA conversational agents. Overall, conversational agent interventions were feasible and promising for increasing PA. Of the 10 RCTs, 6 (60%) found that participants assigned to the conversational agent group outperformed participants in the control group on PA measures, such as step counts and exercise frequency and duration. Conversational agents had moderate usability and acceptability, as measured by subjective data in the form of questionnaires, interviews, activity logs, and diaries. The interventions were generally found to be useful, easy to use, and satisfactory to participants; however, they faced some implementation challenges, including high attrition, technical issues, limited options for user input, and privacy and security risks. Methodological quality varied across studies, and few studies adequately addressed issues of user engagement, safety, and ethics.

Comparison With Prior Work

To the best of our knowledge, this is the first systematic review to evaluate PA conversational agents. Previous reviews have reported on the effectiveness of digital interventions for increasing PA [15-18]. Our results are consistent with their findings that digital interventions have a modest effect on activity levels, particularly in the short term; however, user engagement tends to decline over time [16-18]. Our findings are also in line with other reviews’ evaluations of health care conversational agents, which show that natural language processing and machine learning are underused, high-quality evidence and attention to patient safety are lacking, and study methods and evaluation measures are often inconsistently reported [8,20,21].

Recommendations

On the basis of the findings of this review, we propose several recommendations for the future design and implementation of PA conversational agents.

Program Content

Participant feedback indicated that many intervention programs lost their novelty over time, resulting in decreased user engagement. More diverse program content is required to maintain long-term user satisfaction. A way to reduce repetitiveness is through just-in-time adaptive interventions (JITAIs), which provide dynamically tailored support when users need it while minimizing user burden [10]. JITAIs can inform participants when they have been sedentary for long periods or when they are behind on their step goals. In addition, JITAIs can offer exercise suggestions based on weather conditions, time of day, and users’ physical surroundings. JITAIs

for conversational agents are currently being explored and developed through microrandomized trials [10].

Another way to improve the sustainability of interventions is to base their programming on relevant behavior change theories and evidence-based treatment approaches. Behavior change theories may help identify intervention techniques that tap into users' motivations and result in increased engagement. Similarly, dialog flows based on treatment approaches, such as motivational interviewing and cognitive behavioral therapy, can help users explore and resolve barriers to PA. Owing to the heterogeneity of the studies, we were unable to determine if the inclusion of a theoretical framework or treatment approach increased intervention effectiveness in this review. Future work should assess this as the number of studies increases.

Programming conversational agents to send periodic tips and exercise reminders may help decrease the high attrition rates reported in a few studies [38,41,44,45]. In addition, as many PA interventions are self-guided, encouraging users to share goals and progress with their social circles may increase accountability.

Conversational Agent Delivery

Computer-based ECAs were the most common agents used; however, qualitative interviews revealed that participants desired mobile delivery platforms. Phone ownership rates are higher than computer ownership rates [7]; thus, conversational agents operating via SMS or MMS text messaging may increase scalability. They are also appropriate for those with low digital literacy. For computer-based agents, web-based platforms and familiar messaging apps that do not need to be installed or regularly updated may be more accessible than standalone software.

ECAs have the potential to improve human-computer interactions; however, they are commonly criticized as robotic and unnatural. ECAs can be improved by replacing synthesized speech with human voice, giving users control over pacing of messages, and designing higher-quality animation. Automatic speech recognition is highly desirable, particularly among populations with low vision or difficulty typing. In addition, although artificially intelligent conversational agents may take more time to develop, they afford users more freedom and personalized content to sustain engagement and maximize treatment efficacy.

Safety and Ethics

Most conversational agent programs were designed for healthy and able-bodied adults; however, programs should also be equipped with education and exercise tips for users of different age groups and users with physical limitations. Conversational agents should offer suggestions for exercise-related injuries or pain, such as performing pre- and postworkout stretches, modifying activities, and consulting with health care providers. Users may mention mental health conditions such as depression or anxiety that prevent them from exercising. Thus, researchers should consider incorporating dialog flows that refer users to mental health resources and crisis hotlines. If interventions are designed specifically for clinical populations, additional safety features may be necessary, such as periodic check-ins with a human advisor. Furthermore, for individuals with severe mental illnesses, such as psychosis, additional consideration may be warranted, including ensuring agents are not too anthropomorphic.

Users often share sensitive health information with conversational agents. However, only a few studies have discussed privacy and security issues. User privacy should be protected through measures such as requiring logins and passwords for apps and software, deidentifying user data, and archiving past conversations.

Finally, efforts must be made to uphold the quality of digital interventions. There are currently no regulations regarding the standards of care for conversational agents. Similar to health interventions provided by human coaches, conversational agent programs should be based on a relevant theory and treatment approach to ensure that they are grounded in evidence-based practice.

Limitations

The findings of this review must be considered in the context of a few limitations. First, we may have missed relevant studies in additional databases despite our search strategy being fairly broad. In particular, we lacked quantitative descriptive studies and qualitative studies without comparison conditions, which could suggest that our PICOS criteria were better suited for effectiveness studies that included comparison conditions. Although we aimed to include usability studies without comparison conditions, we had to exclude many such studies because of insufficient data on study participants' experiences, the intervention's impact on activity levels, or the intervention's theoretical mechanisms of change.

Second, because of the heterogeneity of study designs and outcome data, we could not conduct a meta-analysis or directly compare different interventions. We synthesized the main findings from the existing literature; however, without effect sizes, it was difficult to draw definitive conclusions about intervention effectiveness. This field of research would benefit from more longitudinal RCTs that evaluate the long-term sustainability of conversational agents.

Third, we appraised the methodological quality of the included studies following the appropriate method-related standards using the MMAT, one of the few tools designed specifically for mixed methods reviews. However, the MMAT is not designed to grade the level of evidence or the risk of bias in effectiveness studies. We chose not to apply an ad hoc tool to appraise the risk of bias of effectiveness studies because only half of the included studies were RCTs that reported on treatment effectiveness. To date, there is no single, unified approach for assessing confidence in findings generated from combined quantitative and qualitative evidence [56]. More research is needed on best practices for critically appraising included studies in mixed methods reviews.

Fourth, we refrained from analyzing the more technical aspects of conversational agents (eg, programming and interfaces), choosing instead to focus on intervention components and guiding frameworks. Additional questions regarding technical design should be studied in systematic reviews to maximize the user-friendliness of conversational agents.

Fifth, intervention techniques were difficult to identify, as some studies embedded them within figures rather than discussing them descriptively, and there was no uniform language across studies regarding techniques.

Finally, more than half of the included studies focused exclusively on healthy adults, thus limiting the generalizability of their results. As conversational agents are often designed for a broad audience, future studies should also consider sampling from youth and clinical populations (eg, individuals with mental illness or pre-existing health conditions).

Conclusions

On the basis of current evidence, conversational agents appear to be a feasible and effective modality for delivering PA interventions. However, more research comparing conversational agents with other forms of interventions, including human-delivered interventions, is required. Most conversational agents reviewed were computer-based and constrained users to written, predefined inputs. Future conversational agents should consider accessibility and inclusive design and consider supporting automatic speech recognition, natural language processing, and mobile phone platforms. In addition, program content should be further personalized and diversified by using relevant evidence-based frameworks and their accompanying behavior change methods. Researchers should provide a clear overview of how they select intervention components and how these components affect health behavior. This can lead to a deeper understanding of the mechanisms of change in interventions, and consequently, increase the effectiveness of these interventions. Personalization of program content may also lead to higher user satisfaction and engagement while supporting user choice and agency. Finally, in addition to user experiences, safety, privacy, and ethical concerns should be prioritized in the design of PA conversational agents.

Acknowledgments

The authors would like to thank Margaret Phillips from the University of California, Berkeley, for her help in building search strings for the review. The authors received no specific funding for this study.

Authors' Contributions

This study was designed by TCL and CAF, with input from AA and CRL. Screening and appraisal of articles were completed by TCL and CAF. Data extraction and analysis were performed by TCL. The first draft of the manuscript was written by TCL. Revisions and subsequent drafts were completed by TCL, AA, CRL, and CAF.

Abstract

Background: Digital clinical measures collected via various digital sensing technologies such as smartphones, smartwatches, wearables, ingestibles, and implantables are increasingly used by individuals and clinicians to capture health outcomes or behavioral and physiological characteristics of individuals. Although academia is taking an active role in evaluating digital sensing products, academic contributions to advancing the safe, effective, ethical, and equitable use of digital clinical measures are poorly characterized.

Objective: We performed a systematic review to characterize the nature of academic research on digital clinical measures and to compare and contrast the types of sensors used and the sources of funding support for specific subareas of this research.

Methods: We conducted a PubMed search using a range of search terms to retrieve peer-reviewed articles reporting US-led academic research on digital clinical measures between January 2019 and February 2021. We screened each publication against specific inclusion and exclusion criteria. We then identified and categorized research studies based on the types of academic research, sensors used, and funding sources. Finally, we compared and contrasted the funding support for these specific subareas of research and sensor types.

Results: The search retrieved 4240 articles of interest. Following the screening, 295 articles remained for data extraction and categorization. The top five research subareas included operations research (research analysis; n=225, 76%), analytical validation (n=173, 59%), usability and utility (data visualization; n=123, 42%), verification (n=93, 32%), and clinical validation (n=83, 28%). The three most underrepresented areas of research into digital clinical measures were ethics (n=0, 0%), security (n=1, 0.5%), and data rights and governance (n=1, 0.5%). Movement and activity trackers were the most commonly studied sensor type, and physiological (mechanical) sensors were the least frequently studied. We found that government agencies are providing the most funding for research on digital clinical measures (n=192, 65%), followed by independent foundations (n=109, 37%) and industries (n=56, 19%), with the remaining 12% (n=36) of these studies completely unfunded.

Conclusions: Specific subareas of academic research related to digital clinical measures are not keeping pace with the rapid expansion and adoption of digital sensing products. An integrated and coordinated effort is required across academia, academic partners, and academic funders to establish the field of digital clinical measures as an evidence-based field worthy of our trust.

KEYWORDS

digital clinical measures; academic research; funding; biosensor; digital measures; digital health; health outcomes

Introduction

Digital clinical measures are health outcomes or physiological characteristics of an individual's health, wellness, or condition that are collected digitally with a sensor [1]. Digital sensing products enable rapid assessment of health outcomes and support remote and longitudinal monitoring of patients with chronic diseases under daily living conditions [2-5]. During the COVID-19 pandemic, the utility of digital sensor technologies in clinical research [6], clinical care [7], and public health [8,9] have become even more apparent.

In recent years, digital clinical measures have drawn substantial interest from industry, government agencies, academia, and nonprofit institutions, as digital sensing tools, including consumer products and medical devices, are becoming increasingly popular. Consumer products such as smartwatches and smartphones have become part of daily life for many Americans. These have emerged as popular and multipurpose real-time physiological monitoring products capable of measuring sleep and stress in addition to the more traditional actigraphy and heart rate monitoring. In 2020, 26% of Americans owned a smartwatch [10] and 72% of Americans owned a smartphone [11], with annual sales of over US $70 billion [12]. Apart from consumer products, digital sensing products have demonstrated their efficacy as medical devices, both in clinical and remote home monitoring settings to continuously assess vital signs [13], pulmonary congestion in patients with heart failure [14,15], blood and interstitial glucose in patients with diabetes [3], and more.

To support the development and assessment of digital consumer products and medical devices, the volume of academic research has increased across the total product life cycle of digital clinical measures [16]. However, academic contributions to advancing the safe, effective, ethical, and equitable use of digital clinical measures are poorly characterized and, we hypothesize, underfunded. Trust in digital clinical measures is limited, and engaging the academic community is essential to ensure that the field evolves to be worthy of public trust.

For these reasons, a multi-stakeholder group of experts collaborating on The Playbook [1], a precompetitive collaborative of experts in digital health convened by the Digital Medicine Society (DiMe), set out to investigate the nature of academic research related to digital clinical measures. DiMe is a nonprofit professional society dedicated to advancing digital medicine to optimize health [17]. In this systematic review, we explore the representation of subtypes of academic research on digital clinical measures and compare and contrast the funding support for these subareas of research. This systematic review aims to describe the nature of academic research into digital clinical measures, identify areas of focus and gaps, and explore how and whether funding plays a role. With these findings, we hope to establish an integrated and coordinated effort across academia, academic partners, and academic funders to ensure that the expertise within the field is harnessed to ensure that the rapidly expanding domain of digital clinical measures is established as an evidence-based field worthy of our trust.

Methods

Screening

We conducted a systematic search of peer-reviewed literature indexed in PubMed and published between January 1, 2019, and February 24, 2021. For the purposes of this review, we did not restrict the scope of our search to any single digital clinical measure or area of academic research. A multi-stakeholder team of clinical, academic, technical, and operational experts developed the search terms (Multimedia Appendix 1), inclusion criteria (Textbox 1), and selection of data to be extracted from the final publications (Table 1). A biomedical librarian supported the development of the search terms.

Textbox 1. Inclusion criteria adopted to enable the identification of clearly defined academic research related to digital clinical measures.

Research lead

US-led research (ie, ≥50% US-based authors)

Academic research

Academic research with at least one US-based academic researcher (industry-only research articles were excluded)

Article types

Peer-reviewed journals and full-length conference articles (systematic reviews, meta-analyses, editorials, opinion pieces, case reports, and case studies were excluded)

Sensing modality

All portable biometric monitoring technologies (BioMeTs) that rely upon a biometric sensor, such as microphones and accelerometers [16]. BioMeTs are connected digital medicine products that process data captured by mobile sensors using algorithms to generate measures of behavioral or physiological function. (Note: smartphone apps are excluded if they do not rely upon a biometric sensor.)

Publication date

Papers published between January 1, 2019, and February 24, 2021

Table 1. Data fields extracted from identified academic research.

Field	Definition	Allowed values
Title	N/A[a]	Free text
Authors	Last name, first name	Free text
Author affiliation	N/A	Free text
Journal	Name	Free text
Year	N/A	2019, 2020, 2021
DOI	Digital object identifier: a unique alphanumeric string used to identify content and provide a persistent link to the manuscript's online location.	Free text
Nature of academic research	Academic research measured here by the publication of peer-reviewed journals and full-length conference articles by study teams that include researchers from either a university or academic institute and society or nonprofit foundation.	Verification, analytical validation, measure identification, clinical validation, security, ethics, data rights and governance, usability and utility (human factors/behavioral economics), standards, usability and utility (data visualization), economic feasibility, operations (care), operations (research design), operations (research analysis), and operations (data)
Digital clinical measure	Health outcomes or physiological characteristics of an individual's health, wellness, or condition that are collected digitally with a sensor [1]	Biochemical, movement and activity, physiological (electrical, mechanical, optics and imaging)
Funding sources	Funding information	Government, industry, independent foundation, and unfunded

[a]N/A: not applicable.

Following the PubMed search, we conducted a multistep review process to screen articles for inclusion following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [18]. First, we used natural language processing (ie, a custom built Python script; provided in Multimedia Appendix 2 and available on the digital biomarker discovery pipeline [19]) to select papers based on the "Research Lead" and "Academic Research" criteria (Textbox 1). We also excluded articles with "Review" in the title in this step. Second, two of our three trained analysts (authors MMHS, KR, and AB) independently reviewed each publication title against the inclusion criteria. Third, each remaining abstract was reviewed by two of the three analysts (MMHS, KR, and AB) to determine whether the article met our inclusion criteria (Textbox 1). When there was disagreement between two reviewers during either the title or abstract review phase, the decision whether to advance a publication was resolved by the third analyst. Finally, two of three analysts (MMHS, KR, and AB) reviewed the full text of each of the publications that passed the abstract screening stage, with the involvement of a third analyst to settle interrater disagreements (approximately 15% of papers reviewed), to establish the final list of publications for inclusion. The list of articles excluded from the full-text screening process is given in Multimedia Appendix 3.

Data Extraction and Categorization

Following the screening phase, seven analysts (authors MMHS, KR, AB, AVK, AF, YJ, and WKW) extracted data from the articles included in the data extraction phase and categorized each publication as described in Table 1. The articles were categorized according to the following three criteria: nature of academic research, category of digital clinical measures, and source of funding.

The categories to subgroup the "nature of academic research" included verification, analytical validation, measure identification, clinical validation, security, ethics, data rights and governance, usability and utility (human factors and behavioral economics), standards, usability and utility (data visualization), economic feasibility, operations (care), operations (research design), operations (research analysis), and operations (data).

The categories to subgroup "digital clinical measures" included biochemical, movement and activity, and physiological (electrical, mechanical, and optics and imaging).

"Funding sources" were subgrouped by government, industry, independent foundation, and unfunded. Articles with missing funding information were categorized as unfunded. The details of these categories are given in Table 2.

Table 2. Categories for data extraction.

Category	Definitions	Reference
Nature of academic research		
Verification	Evaluates and demonstrates the performance of a sensor technology within a BioMeT[a], and the sample-level data it generates, against a prespecified set of criteria	[16]
Analytical validation	Evaluates the performance of the algorithm, and the ability of this component of the BioMeT to measure, detect, or predict physiological or behavioral metrics	[16]
Clinical validation	Evaluates whether a BioMeT acceptably identifies, measures, or predicts a meaningful clinical, biological, physical, functional state, or experience in the stated context of use (which includes a specified population)	[16]
Measure identification	Research studies to identify key variables from the information extracted from digital sensors, to support decision-making	[20]
Security	Research studies to assess the risks associated with digital clinical measures and taking necessary measures for information security	[21]
Data rights and governance	Research studies to assess the data access, privacy, and sharing (following the FAIR[b] guiding principle)	[22]
Ethics	Research studies to ensure equity and justice during every step of the development and deployment of digital clinical measures (eg, reduce health disparities or racial injustice)	[23]
Usability and utility (human factors/behavioral economics)	Research studies to investigate human factors associated with digital clinical measures (eg, how usable, useful, or unobtrusive a digital clinical measure can be for an end user). It involves surveys from the participants on user experience.	[24]
Standards	Involves standardization of the data extracted from digital clinical measures for interoperability	[25]
Usability and utility (data visualization)	Involves data visualization/result presentation for all end uses	[24]
Economic feasibility	Research studies to investigate economic feasibility of a digital clinical measure	[26]
Operations (care)	Involves clinicians and economists to design clinical workflow and corresponding evaluation that is typically done for a clinical trial	[27]
Operations (research design)	Involves clinicians and biostatisticians to design a research study and execution plan, which is typically done for a clinical trial via power analysis and statistical analysis plan	[28]
Operations (research analysis)	Involves analyzing data from digital clinical measures (eg, data analyst or data scientists)	[29]
Operations (data)	Involves monitoring data and metadata from digital clinical measures (eg, bioinformatics)	[30]
Digital clinical measures		
Biochemical	Senses biochemicals (eg, sweat sensor or continuous glucose monitors)	[31]
Movement and activity	Tracks movement and activity (eg, step count or actigraph)	[31]
Physiological (electrical)	Senses electrical signals related to physiological phenomena (eg, electrocardiography, electroencephalography, electromyography, bioimpedance, electrodermal activity, or electrooooculography)	[32-34]
Physiological (mechanical)	Senses mechanical signals related to physiological phenomena (eg, phonocardiography, speech, lung sounds, joint acoustic emission, seismocardiography, or ballistocardiography)	[35,36]
Physiological (optics and imaging)	Senses optical signals related to physiological phenomena (eg, photoplethysmography, camera for blood volume pulse, or bioradar)	[37]
Funding sources		
Government	US Government funding agencies	[38]
Industry	Pharma, tech, and medical device industry	[38]
Independent foundation	Universities, private nonprofits, societies, and independent associations	[38]
Unfunded	Investigator initiated with no funding sources explicitly stated	

[a]BioMeT: biometric monitoring technology.

[b]FAIR: Findable, Accessible, Interoperable, and Reusable.

For the data extraction process, each publication was reviewed by at least three of the seven analysts (MMHS, KR, AB, AVK, AF, WKW, and YJ). Each publication was assigned to one or more categories of a particular criterion as a result of two or more votes for a particular category for each publication. This method of subgrouping was used to reduce the impact of

individual analyst subjectivity at this stage. Following the initial categorization, articles falling into the government funding subgroup were further categorized by US government agency (ie, National Institutes of Health [NIH], National Science Foundation [NSF], Department of Defense [DOD], Veteran Affairs [VA], National Aeronautics and Space Administration [NASA], Department of Energy [DOE], and "Other"). The "Other" category constitutes government funding sources that were listed for just one article in our pool. Articles with NIH funding were further subgrouped by NIH institutes and centers [39]. Data was standardized after extraction by the five analysts (MMHS, KR, AVK, AF, and AB), and the details of this process are presented in Multimedia Appendix 4.

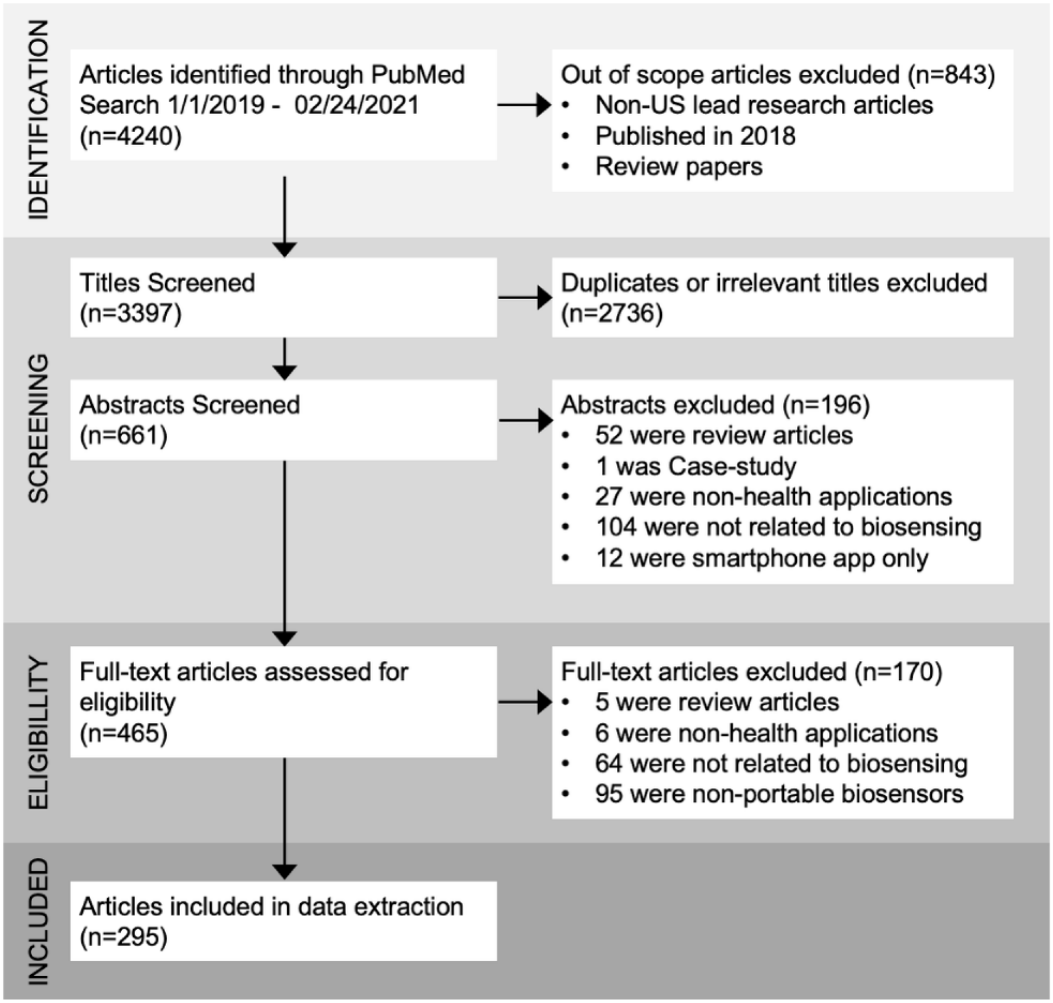
Following the data extraction process, we performed Pearson chi-square tests with one categorical variable to determine whether the representation of academic research studies varies significantly within the following categories: academic research, digital sensors, and funding sources. We assumed equal representation for all categories as the null hypothesis. In this work, we considered *P* values less than .05 to be statistically significant. The statistical tests and data visualization were performed using Python 3.8.5 (Python Software Foundation) on the Spyder-integrated development environment 4.1.5.

Results

Screening

Our initial search on PubMed retrieved 4240 articles (Figure 1). With our custom built Python script, we excluded 843 articles from this initial list based on research lead, publication year, and publication type. Of the 3397 identified articles for subsequent screening, we excluded over 75% (n=2736) after title screening and a further 30% (n=196) after abstract screening, based on our inclusion criteria. The majority of the excluded articles were not related to biosensing, were review articles, or explored nonhealth applications. Following the abstract screening, a total of 465 articles were included in the full-text review, during which we further excluded 170 (37%) articles on the basis of our inclusion criteria. At this stage, articles were mainly excluded because the sensors being studied were nonportable biosensors or because they covered topics unrelated to biosensing; Multimedia Appendix 3 lists the articles excluded in this phase. Data for further analysis was extracted from the remaining 295 articles.

Figure 1. Article screening process and diagram following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) review methodology.

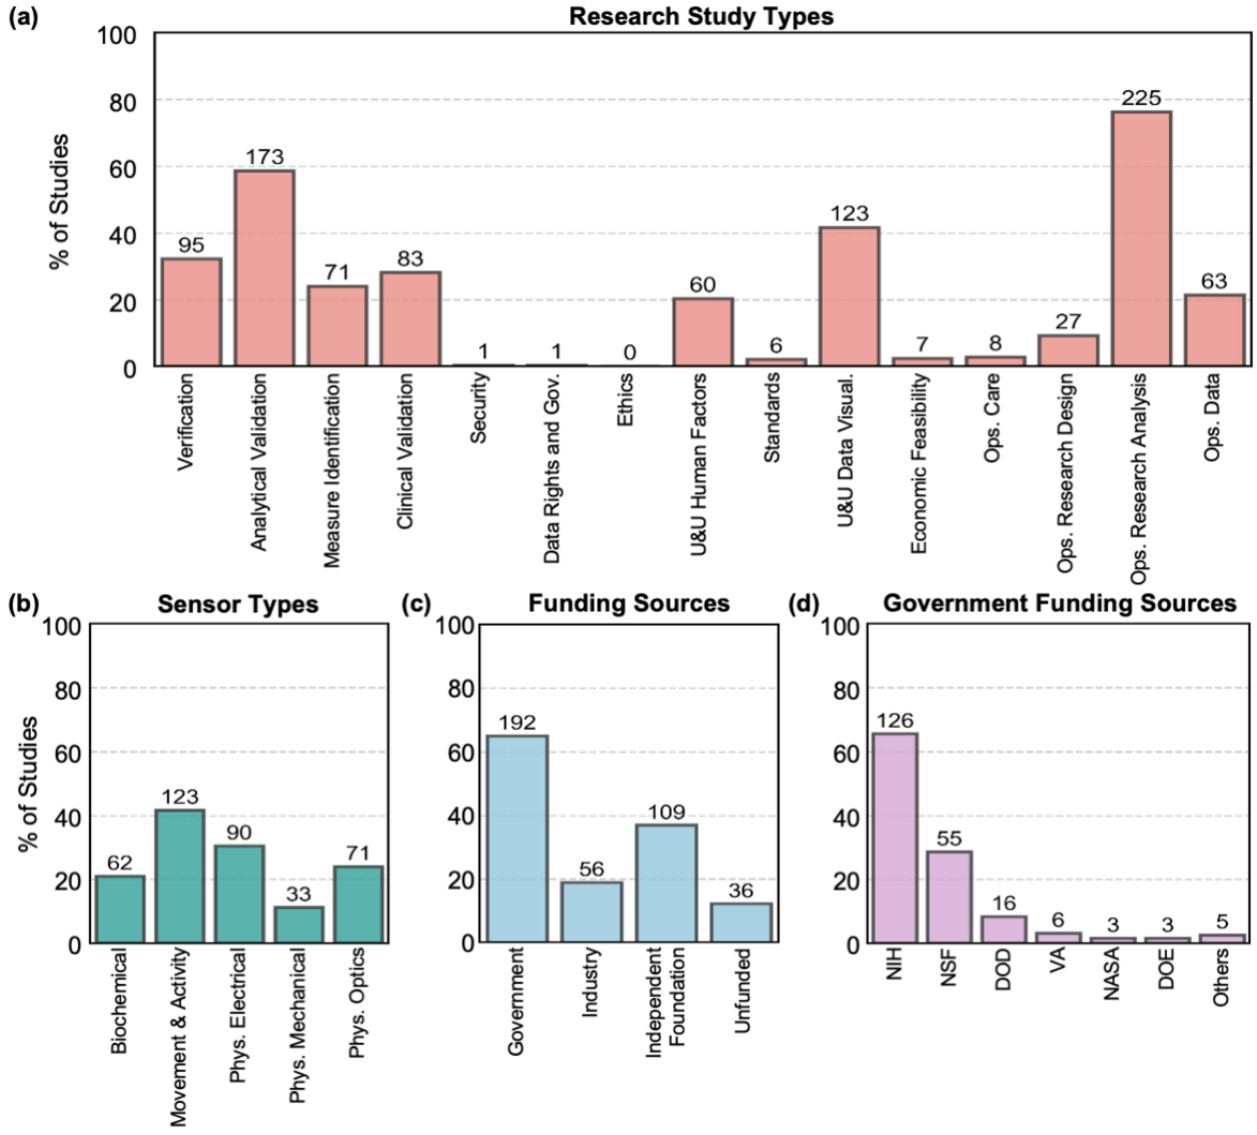


Data Categorization

The 295 articles used for analysis were categorized by research study type, sensor type, and funding source, including broad US government funding sources and specific NIH funding sources (Figure 2). The list of the 295 articles included in the data extraction process with their corresponding categories is located in Multimedia Appendix 4. We observed statistically significant differences (Pearson one-sample chi-square test $P<.001$), indicating unequal distribution of research studies across subcategories for all three overarching categories: academic research, digital sensors, and funding sources. Nearly 76% (n=225) of the studies evaluated were conducted in operations research analysis (Figure 2a). Analytical validation (n=173, 59%), usability and utilities (data visualization; n=123, 42%), verification (n=93, 32%), and clinical validation (n=83, 28%) were other commonly represented study types. On the contrary, ethics (n=0), security (n=1), and data rights and governance (n=1) were uncommon study types. Research on standards (n=6), economic feasibility (n=7), and operations care (n=8) were also uncommon in this pool of articles.

Categorization by sensor types (Figure 2b) revealed that movement and activity were the most commonly studied sensors in the article pool (n=123, 42%), followed by physiological (electrical) sensors (n=90, 31%), physiological (optics and imaging) sensors (n=71, 24%), biochemical sensors (n=62, 21%), and physiological (mechanical) sensors (n=33, 11%). For those studies evaluating movement and activity sensors, actigraphy and activity monitors with wearable accelerometers were the most commonly studied sensors.

Figure 2. Distribution of articles across (a) research study types, (b) different sensing modalities, (c) different funding sources, and (d) different government funding agencies. The bars are showing the percentage of studies, with 100% equivalent to 295 papers included in the data extraction process for (a-c) and 100% equivalent to 192 papers with government funding for (d). The text on top of the bars in all the plots showing the actual number of articles per category. Others in (d): state governments, National Institute of Justice, US Department of Agriculture, National Institute of Food and Agriculture. One article can be grouped into multiple categories for (a-d). DOD: Department of Defense; DOE: Department of Energy; Gov: governance; NASA: National Aeronautics and Space Administration; NIH: National Institutes of Health; NSF: National Science Foundation; Ops: operations; Phys: physiological; U&U: usability and utility; Visual: visualization; VA: Veteran Affairs.



Studies categorized by funding source (Figure 2c) indicated that government agencies are funding the majority (n=192, 65%) of academic research on digital clinical measures, followed by independent foundations (n=109, 37%) and industry (n=56, 19%). Interestingly, more than 1 in 10 digital clinical measures studies (n=36, 12%) was unfunded. Of these unfunded studies, 22 articles explicitly stated that the research team did not receive any external funding, and 14 did not include a statement on funding.

For studies receiving government funding, the NIH was the most frequent contributor in terms of the number of articles funded—66% (n=126) of the studies with government funding were funded by the NIH (Figure 2d). The NSF was the second most frequent government funder of research on digital clinical measures (n=55, 29%), followed by DOD (n=16, 8%), VA (n=6, 3%), NASA (n=3, 2%), DOE (n=3, 2%), and others (the 5 remaining studies were funded by state governments, National Institute of Justice, US Department of Agriculture, or National Institute of Food and Agriculture). Of the 27 institutes and centers at the NIH [39], 24 institutes funded studies on digital clinical measures (Figure 3), indicating widespread interest and applications in this field. The majority of studies were funded by the National Institute of Neurological Disorders and Stroke (n=18, 14% of the studies with NIH funding); the National Institute of Biomedical Imaging and Bioengineering (n=18, 14%); the National Heart, Lung, and Blood Institute (n=17, 13%); and the National Center for Advancing Translational Sciences (n=14, 11%).

Of the articles that reported receiving funding from independent foundations (n=109), 75 (69%) studies received funding from institutional funds at universities, 46 (42%) studies received funding from private nonprofits (eg, Bill and Melinda Gates Foundation or Chan Zuckerberg Initiative), and 6 (6%) received funding from societies and associations (eg, American Heart Association).

To understand whether specific funding types may be driving specific sectors of digital clinical measures research, and where a lack of funding may be contributing to low research output, we explored the distribution of funding across different research study types (Figure 4). Subdividing the research topics by funding type, we found that the proportion of research support from each of the four funding categories was fairly consistent across research areas. The most frequent research and funding combination out of the 295 articles was operations research analysis supported by government funding (n=148, 50%). The second most common combination was analytical validation studies supported by government funding (n=105, 36% of overall studies). Operations research analysis and analytical validation also represent the first- and second-largest sectors of overall digital clinical measures research, respectively (Figure 2a). Interestingly, the third most frequent research and funding combination was not another research category but rather an operations research analysis funded by foundations (n=80, 27% of overall studies), indicating the large overall footprint that operations research analysis occupies in the academic digital clinical measures research space. By contrast, even given the large proportion of government funding, research categorized as analytical validation was also the most likely to be unfunded, with 30 out of the 173 (17%) studies reported as unfunded.

Figure 3. Distribution of articles across different NIH institutes and centers. The bars are showing the percentage of studies, with 100% equivalent to 126 papers with NIH funding. The text on top of the bars showing the actual number of articles per category. One article can be grouped into multiple categories. FIC: Fogarty International Center; NBIB: National Institute of Biomedical Imaging and Bioengineering; NCATS: National Center for Advancing Translational Sciences; NCCIH: National Center for Complementary and Integrative Health; NEI: National Eye Institute; NHLBI: National Heart, Lung, and Blood Institute; NIA: National Institute on Aging; NIAAA: National Institute on Alcohol Abuse and Alcoholism; NICHD: National Institute of Child Health and Human Development; NIDA: National Institute on Drug Abuse; NIDCD: National Institute on Deafness and Other Communication Disorders; NIDCR: National Institute of Dental and Craniofacial Research; NIDDK: National Institute of Diabetes and Digestive and Kidney Diseases; NIEHS: National Institute of Environmental Health Sciences; NIGMS: National Institute of General Medical Sciences; NIH: National Institutes of Health; NIMH: National Institute of Mental Health; NIMHD: National Institute on Minority Health and Health Disparities; NINDS: National Institute of Neurological Disorders and Stroke; NLM: National Library of Medicine; OAR: Office of AIDS Research; OD: Office of Dietary Supplements.

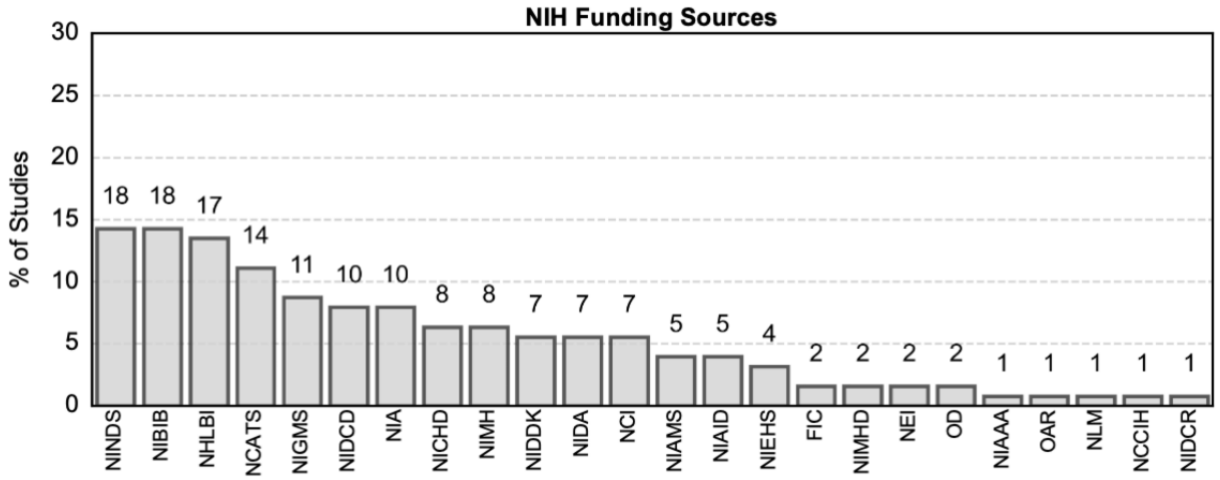


Figure 4. Distribution of funding sources across different research study types, with the heat map color showing the percentage of studies (100% equivalent to 295 papers included in the data extraction process) and the text in each cell showing the actual number of articles per category. One article can be grouped into multiple categories. Gov: governance; Ops: operations; U&U: usability and utility; Visual: visualization.

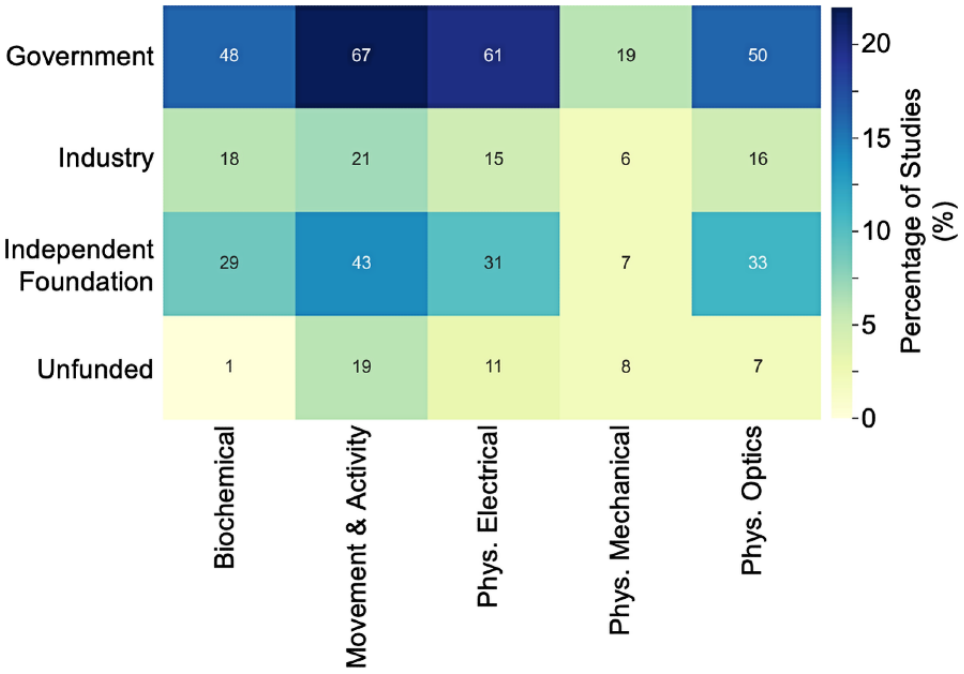
Similar to the previous analysis subdividing research topics by funding type, we sought to understand whether the volume of literature surrounding particular types of digital sensors is related to funding. Therefore, we subdivided the articles in the different digital sensor categories from Figure 2b by funding type. We found that the most frequent digital sensor and funding combination was movement and activity sensors funded by government agencies (n=67, 23% of overall studies; Figure 5). Government funding also supported the majority of research into physiological (electrical) sensors (n=61, 21%), physiological (optics and imaging) sensors (n=50, 17%), and biochemical sensors (n=48, 16%). By contrast, even given the large proportion of government funding, digital sensors categorized as movement and activity were the second most likely to be unfunded, with 15% (n=19) of the 123 studies on movement and activity sensors being unfunded. Biochemical sensors were the least likely to be studied without funding (n=1, 1% of studies that used biochemical sensors), whereas studies into physiological (mechanical) sensors were most the commonly unfunded, with 8 of 33 (24%) studies reported as unfunded.

Figure 5. Distribution of funding sources across different digital sensor types, with the heat map color showing the percentage of studies (100% equivalent to 295 papers included in the data extraction process) and the text in each cell showing the actual number of articles per category. One article can be grouped into multiple categories. Phys: physiological.



Discussion

Principal Findings

In this systematic review, we describe the nature of academic research related to digital clinical measures and the distribution of funding across different types of academic research and sensing modalities.

Verification, analytical validation, and clinical validation studies [16] are, together, the most frequently published study types in this review. As verification, analytical validation, and clinical validation is foundational to establishing whether a digital clinical measure is fit-for-purpose [16], these findings indicate that academic research supporting the development and evaluation of digital clinical measures is appropriate for a nascent field. However, the paucity of published studies examining the security, data rights and governance, ethics, standards, and economic feasibility of digital sensing products are alarming given the rapid growth and adoption of digital clinical measures [40]. The risks of harm to individuals from unauthorized access to data arising from inadequate security, misuse of data due to poor data rights and governance, and inequities arising from the development and deployment of digital clinical measures without sufficient consideration of the ethical implications are substantial [21,23,41,42]. It is imperative that academic investigators skilled in these areas are motivated and funded to pursue a systematic evaluation of the current state of affairs and to propose best practices to ensure that digital clinical measures fulfill their promise without causing harm to individuals or populations.

Research studies examining the usability and utility of digital sensing products are relatively common compared to publications reporting research into security, data rights and governance, and economic feasibility, which ought to trend together [24]. This is not to say that usability and utility of digital clinical measures is overstudied, but rather suggests that research into these other characteristics of digital sensing products is lagging. Similarly, the number of publications reporting measure identification is relatively low compared to research into the development and deployment of these same measures. This may be cause for concern if we cannot be certain that digital clinical measures being developed have already been determined to be clinically relevant and grounded in aspects of health that patients and clinicians care most about [20]. As we strive to increase the patient focus and efficiency of health care, it is critical that we are separating signals from noise and not advancing digital clinical measures that offer little value to individual patients and the health care system.

Research into the operational aspects of deploying digital clinical measures is the largest single study type identified by our review. Although digital clinical measures cannot add value unless they are successfully operationalized during routine clinical care and in clinical trials, focusing academic research on deployment without first ensuring that the digital clinical measures are fit-for-purpose and trustworthy leaves the entire field of digital health at risk of collecting vast swaths of data that, at best, are of no value and, at worst, could cause harm. During the rapid acceleration of digital clinical measurements, research into the selection and development of high-quality measures and tools must be a primary focus of academic research in this new field.

Research related to movement and activity sensors are most common when we parse the article pool by sensor type. This finding is consistent with other literature where digital measures of activity have been found to be most commonly used to answer clinical questions [43]. Movement and activity sensors also inform the majority of digital end points used by the industry in medical product development [40]. Physiological (electrical),

physiological (optical and imaging), and biochemical sensors are well represented in this review, which is consistent with the recent growth in the use of portable electrocardiograms, photoplethysmography, and continuous glucose monitoring, respectively.

Our review indicates that government agencies and independent foundations are funding most of the academic research studies related to digital clinical measures. Industry funding was relatively low, and this is likely due to our definition of academic studies that excludes studies that only have industry-affiliated authors without academic research partnerships. Of the government agencies, the NIH is funding most of the academic research studies, which is consistent with previous research examining funding of US biomedical research [38]. The distribution of funding across different NIH institutes and centers demonstrates that certain therapeutic areas might be getting more funds compared to others. However, we have not extracted information on funding distribution across different therapeutic areas, as it was out of scope for this systematic review. Future work should explore which therapeutic areas are more likely to receive funding and which areas are least funded. Of the independent foundation–funded research studies, institutional funds at universities are funding the majority on digital clinical measures as compared with private nonprofits and public charities, which is also consistent with the literature [38].

After operational research, analytical validation is the most common government-funded study type in digital clinical measurement. This is critically important as analytical validation includes examination of algorithmic bias [16], which must be an area of focus given research findings that digital sensing products may not perform equally well across different skin tones, among other factors [44,45]. However, although the total number of government-funded analytical validation publications is high, analytical validation studies are also the most likely to be unfunded (n=30, 17%), suggesting that academic researchers are pursuing analytical validation studies even when funding may not exist. This work is to be applauded but is not sustainable. Additional funding for analytical validation must be made available to ensure that digital clinical measures are developed equitably.

Although movement and activity sensors are the most used sensors in academic research, these sensors are still the second most likely to be unfunded (n=19, 15%), suggesting that academic researchers are pursuing research into movement and activity sensors even when funding may not exist. This is again praiseworthy but not sustainable, considering the rapid adoption of these sensors in our daily life [10,11] and clinical studies [43]. Sufficient funding is required to ensure the development and deployment of these movement and activity sensors reliably and equitably.

Our review has several limitations. First, we have focused only on academic research led by US-based academic researchers. Future research should expand beyond the United States to examine trends in academic research into digital clinical measures globally. Second, we searched only one database (PubMed) to retrieve articles for this review. PubMed only indexes research related to life sciences and biomedicine [46]. As digital medicine is a highly interdisciplinary field, many relevant studies may not have been captured in our review. For example, sensor verification studies may be published in traditional engineering journals that are not indexed by PubMed. Future studies will be enhanced by the use of multiple databases across disciplines. In addition, as an emerging interdisciplinary field, we must strive to reference the complete corpus of relevant literature, not only those publications familiar to us in our individual disciplines. Finally, the subjective nature of the review and data extraction process may hinder repeatability, and we attempted to mitigate this risk using innovative methods such as using a majority voting system and using natural language processing to automate the initial screening phase.

This review reports the current state of academic research on the rapidly expanding and highly promising field of digital clinical measures. Substantial work is being done in areas such as validation and operations, with a paucity of research in other areas like security and ethics. Future studies should investigate why critical research into the safe, effective, ethical, and equitable advancement of digital clinical measures is largely absent from the published literature. Both academic researchers and funding agencies should focus on the subareas of academic research on digital clinical measures that are underrepresented and relatively underfunded to ensure that funding priorities adequately reflect the evidentiary needs of the field.

Conclusion

Academic research related to digital clinical measures is not keeping pace with the rapid expansion and adoption of digital sensing products. Although substantial foundational research validating the performance of digital clinical measures is being conducted, academic studies of security, data rights and governance, economic feasibility, ethics, and standards necessary to advance the field are lagging. These areas must be bolstered to minimize the growing chasm between the promised benefits of digital clinical measures and their potential risks. As expected, research funding appears to be associated with increased research publications. An integrated and coordinated effort is required across academia, academic partners, and academic funders to establish the field of digital clinical measures as an evidence-based field worthy of our trust.

Acknowledgments

The authors would like to thank Sarah Park, librarian for engineering and computer science at Duke University, for her support in the development of the search terms. This study was funded, in part, by the Digital Medicine Society. This project has been made possible, in part, by grant 2020-218599 from the Chan Zuckerberg Initiative Doner-Advised Fund, an advised fund of Silicon Valley Community Foundation.

Authors' Contributions

JCG and JD conceived the study. MMHS, JCG, TH, JP, SC, JC, and JD participated in the study's design and coordination, and drafted the search terms and inclusion criteria. MMHS ran the search on PubMed. MMHS, KR, and AB participated in the screening phase. MMHS, KR, AB, AVK, AF, YJ, and WKW participated in the data extraction phase. MMHS, KR, AB, AVK, and AF standardized the extracted data. MMHS carried out the data analysis and created visual representations. MMHS, JCG, and JD drafted the manuscript. All authors read and approved the final manuscript.

Conflicts of Interest

TH is employed by Activinsights Ltd. The other authors declare no conflicts of interest.

Abstract

Background: With the increasing health care burden of cancer, public health organizations are increasingly emphasizing the importance of calling people to engage in long-term prevention and periodical detection. How to best deliver behavioral recommendations and health outcomes in messaging is an important issue.

Objective: This study aims to disaggregate the effects of gain-framed and loss-framed messages on cancer prevention and detection behaviors and intentions and attitudes, which has the potential to inform cancer control programs.

Methods: A search of three electronic databases (Web of Science, Scopus, and PubMed) was conducted for studies published between January 2000 and December 2020. After a good agreement achieved on a sample by two authors, the article selection (κ=0.8356), quality assessment (κ=0.8137), and data extraction (κ=0.9804) were mainly performed by one author. The standardized mean difference (attitude and intention) and the odds ratio (behaviors) were calculated to evaluate the effectiveness of message framing (gain-framed message and loss-framed message). Calculations were conducted, and figures were produced by Review Manager 5.3.

Results: The title and abstract of 168 unique citations were scanned, of which 53 were included for a full-text review. A total of 24 randomized controlled trials were included, predominantly examining message framing on cancer prevention and detection behavior change interventions. There were 9 studies that used attitude to predict message framing effect and 16 studies that used intention, whereas 6 studies used behavior to examine the message framing effect directly. The use of loss-framed messages improved cancer detection behavior (OR 0.76, 95% CI 0.64-0.90; *P*=.001), and the results from subgroup analysis indicated that the effect would be weak with time. No effect of framing was found when effectiveness was assessed by attitudes (prevention: SMD=0.02, 95% CI –0.13 to 0.17; *P*=.79; detection: SMD=–0.05, 95% CI –0.15 to 0.05; *P*=.32) or intentions (prevention: SMD=–0.05, 95% CI –0.19 to 0.09; *P*=.48; detection: SMD=0.02, 95% CI –0.26 to 0.29; *P*=.92) among studies encouraging cancer prevention and cancer detection.

Conclusions: Research has shown that it is almost impossible to change people's attitudes or intentions about cancer prevention and detection with a gain-framed or loss-framed message. However, loss-framed messages have achieved preliminary success in persuading people to adopt cancer detection behaviors. Future studies could improve the intervention design to achieve better intervention effectiveness.

gain framing; loss framing; attitude; intention; behaviors; cancer prevention; cancer detection

Introduction

Background

Cancer accounts for 1 in 6 deaths globally. The number of cancer cases worldwide may increase by 60%, especially in low-income and middle-income countries where the increase may be as high as 81%, as estimated by the latest World Cancer Report [1]. This trend will undoubtedly lead to socioeconomic pressure and a shortage of medical resources. The current clinical research on cancer medicine mainly focuses on finding the cause of cancer and preventing the spread of cancer cells in the early stage [2,3]. However, these findings can be helpful only if people are sufficiently aware of adopting healthy behavior (ie, prevention and detection). This is a unique form of a health crisis that requires intensive communicative efforts. Therefore, messages need to be carefully designed in cancer communication to achieve positive health outcomes.

Message framing is an effective technique to change health behavior [4-10]. Health messaging attempts to change people's attitudes, intentions, or behaviors toward a specific health topic by emphasizing the expected benefits of undergoing specific health behaviors (ie, gain-framed messaging) or the possible loss if specific health behaviors are not done (ie, loss-framed messaging), to persuade people to follow healthy guidelines. According to the theory of reasoned action, attitude (or intention) is an essential direct predictor of behavior [11-13]. Moreover, attitudes, intentions, and behaviors are the standard measures of the effectiveness of health messages [4,14].

Health behaviors include disease prevention and detection behavior [4,6]. The former aims to avoid illness or deterioration, while the latter aims to reflect the presence or absence of risk. Gain-framed messaging fulfills the promise of a safer and more certain disease prevention measure in terms of disease prevention, so it is more effective than loss-framed messaging [4,15]. O'Keefe and Jensen [16] also showed the advantage of the gain-framed messaging in disease prevention, but they indicate that it does not apply to skin cancer [17,18]. On the other hand, in terms of disease detection, it was thought that the loss-framed messaging showed a higher persuasive effect [4,15]. However, the meta-analysis results show no significant difference between gain and loss framing [6,16]. Thus, apart from demonstrating the contribution of loss-framed messaging to breast cancer detection [17], there has been no definitive conclusion regarding cancer and message framing.

Objectives

The concept of message framing is an essential strategy in health promotion, but research on how to optimally frame cancer prevention and detection messaging is scarce. Furthermore, while the effectiveness of message framing in cancer prevention and detection remains unclear, there is still an increasing number of related studies that combine message framing with other variables (ie, color) to verify the strengthening or weakening of the framing effect. Therefore, a thorough examination of the effectiveness of the message framing in the context of cancer is needed.

This review mainly aims to systematically summarize the characteristics of the relevant intervention studies and then pool the effect sizes from the relevant studies to quantify the effects of those interventions on attitude, intention, and behavior change. The findings of this review can provide recommendations for researchers and clinicians to design effective messages in cancer communication.

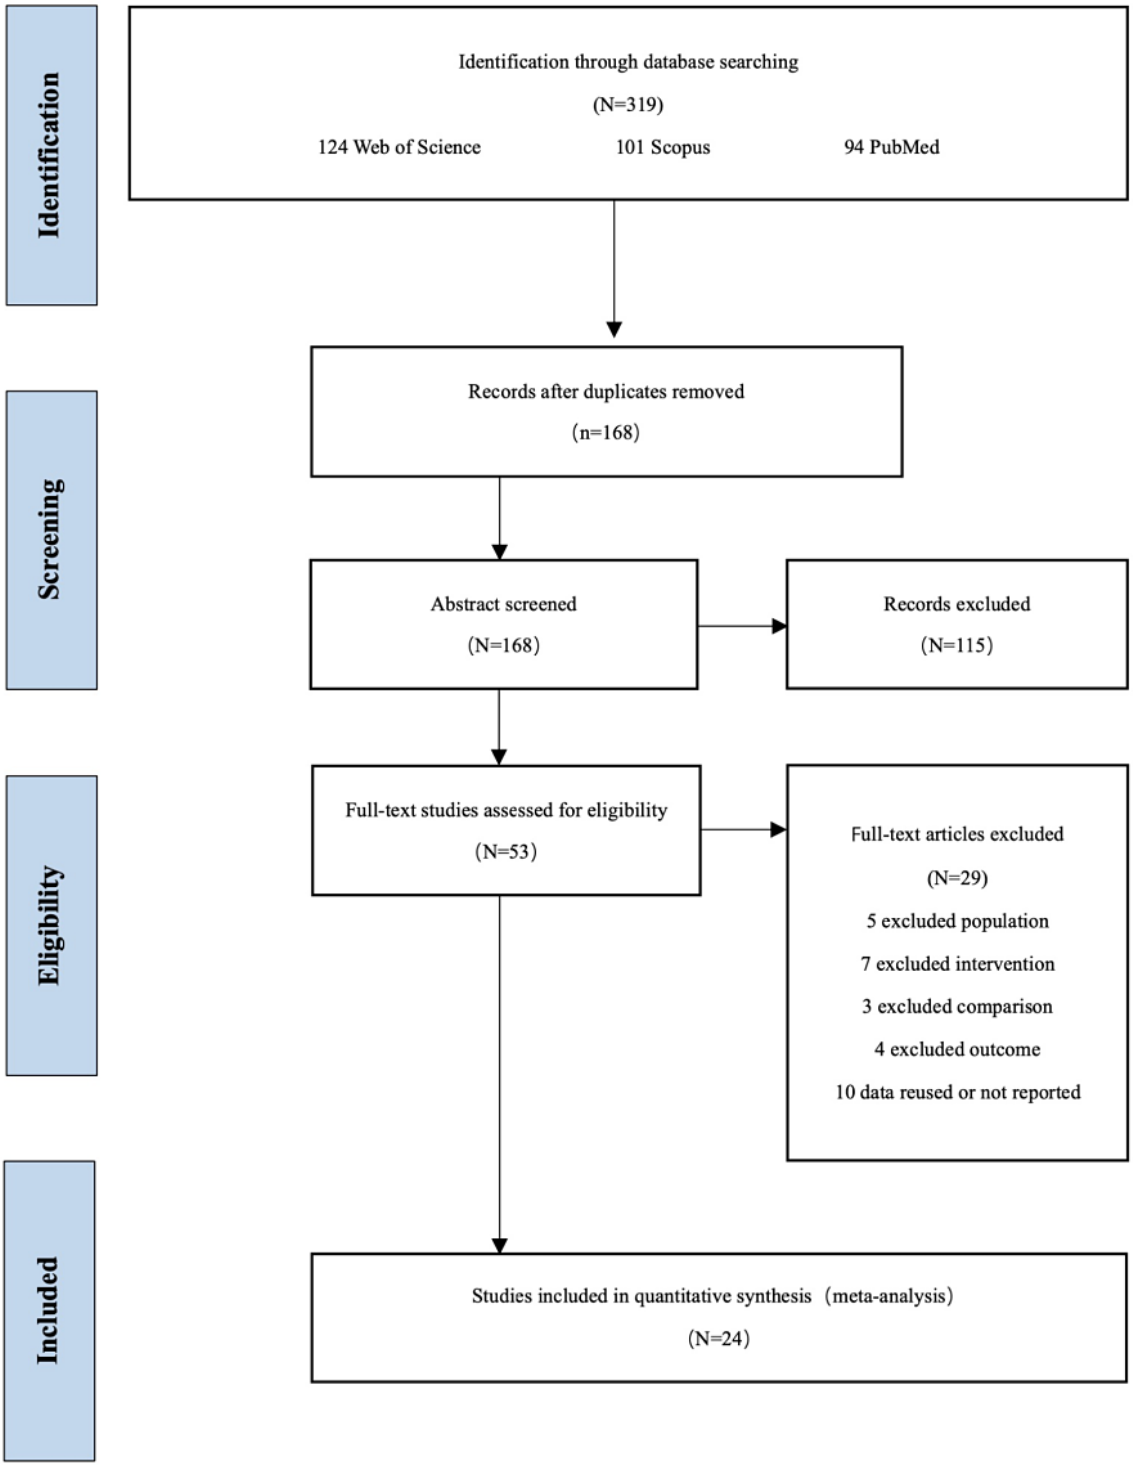
Methods

Search Strategies

This review was conducted and is reported according to the PRISMA (preferred reporting items for systematic reviews and meta-analyses) guidelines. As mentioned in the initial registration (registration ID CRD42021252658), a series of structured electronic searches were performed in three English databases, including Web of Science, Scopus, and PubMed, focusing on the effectiveness of message framing related to a cancer topic and dated from January 1, 2000, to December 31, 2020. The procedures guiding article inclusion are presented in the flow chart in Figure 1. Example search terms are as follows: goal fram*, loss fram*, message fram*, goal fram*, health message, health infor*AND attitude, intention, behavio*, behavio*intention, behavio* chang* AND cancer, screen*, prevention, detection, AND specific validated database filters for randomized controlled trials

All articles identified in the search strategy were exported into reference management software (version 2.48.0; Mendeley) for duplicate checking and further screening. The reference lists of eligible articles were further reviewed to identify other relevant studies. Relevant reviews that emerged from the search strategy were checked for any additional studies. Grey literature (ie, working papers, unpublished studies, conference proceedings or abstracts, and dissertations) was not considered eligible. The preliminary retrieval process was taken as the total literature volume combining the reviews independently completed by two authors. The authors selected a sample of eligible studies after achieving good agreement (κ=0.8356), with the remainder being selected by one author.

Figure 1. Preferred reporting items for systematic reviews and meta-analysis flowchart.



Study Inclusion and Exclusion Criteria

Studies were included if they met the following criteria: (1) participants (not cancer patient or survivors) of both genders and any age range exposed to either the loss-framed or the gain-framed cancer prevention or detection (not treatment) message in experimental research; (2) interventions that have been delivered via either emphasizing the expected benefits of taking specific health behaviors (gain-framed message) or the possible loss of not taking specific health behaviors (loss-framed message); (3) the gain-framed and loss-framed message must come in pairs as a comparison and related to a specific cancer topic, not cancer in general; (4) the effectiveness of cancer-related messages was measured in terms of change in attitude (by scale), intention (by scale), and behavior (by yes or no), and the analysis of primary data was reported, and sufficient quantitative data was provided for estimating the total effect size. In addition, only randomized controlled trials (RCTs) were

included. Finally, published studies that repeatedly used the same data were excluded, leaving only one study that reported the most complete results.

Data Extraction

Data from a sample of eligible studies was extracted by two authors, and after they achieved good agreement (κ=0.9804), the remainder was extracted by one author. The main framework of the extraction criteria was drawn by the authors altogether. The following information was extracted: (1) basic study characteristics including the first author, publication date, country, and funding of the study; (2) participant characteristics including sample size, age, ethnic, and gender ratio (female); (3) intervention characteristics including cancer type, research setting (lab or not), message contents, message resources, message delivery channel, intervention duration, and underpinning theories; (4) outcome measures including measurement of the outcomes; and (5) main results including intervention completion ratio and converted effect size (standardized mean difference [SMD] and odds ratio [OR]).

Bias Assessments

The risk of bias for RCTs was independently assessed by two authors (κ=0.8137) using the Cochrane Collaboration tool for assessing bias [19]. Differences of opinion were discussed and agreed upon by the two authors.

Strategy for Data Synthesis and Meta-Analysis

All meta-analyses were performed with Review Manager 5.3 (version 5.3; The Cochrane Collaboration) [20]. This study performed meta-analyses on the three message effectiveness indicators (attitude, intention, and behavior). Among them, for the two continuous variables (attitude and intention), the SMD of the gain-frame (as the intervention group) and the loss-frame (as the control group) are calculated to represent an effect size. Moreover, two subgroups of cancer prevention and cancer detection were designed separately and analyzed under each indicator. For the two-category variable (behavior), the OR of the gain-frame (as the intervention group) and the loss-frame (as the control group) are calculated to represent an effect size. In addition, two subgroups of cancer detection within 6 months (<6 months) or more than 6 months (>6 months) after the experiment were designed for comparison and analysis of the impact of the timing of the framing effect on cancer detection behavior. All meta-analyses used random-effects models. I^2 statistics are used to determine heterogeneity and measure the degree of inconsistency. I^2 values are 25%, 50%, and 75%, corresponding to low, medium, and high levels of heterogeneity, respectively. For high heterogeneity, the source of heterogeneity was investigated by conducting a subgroup analysis to explore potential moderators and demonstrate why heterogeneity existed. We used the funnel plot to observe whether there is publication bias and used the Egger regression line to confirm possible publication bias further.

Results

Study Characteristics

The literature search identified a total of 319 studies extracted by two authors. After deduplication, a total of 168 studies' titles and abstracts were screened, with 53 remaining for full-text screening. Among those, 24 articles met the inclusion criteria, and 4 studies met the inclusion criteria but did not meet the exclusion criteria. The authors attempted to obtain the research data of 8 studies that met the first two inclusion criteria but failed to provide usable data by contacting their corresponding authors via email and received 2 replies [21,22]. Due to the oversize issue, the main content of each study is summarized in Multimedia Appendix 1. Of the 24 studies used in the final analysis, 13 were conducted by the United States [21,23-34], 2 by the United Kingdom [35,36], South Korea [22,37], and China [38,39], and 1 by Australia [40], Ireland [41], Italy [42], Singapore [43], and South Africa [44]. Among the studies used, 5 were funded by the government or institute grant [22,23,25,26,38], 2 by the institute and the center [24,29], 2 by the institute and universities [30,34], 2 by universities [28,37], and 1 by the health charity and behavioral insights project [35]. The remaining 12 studies did not report receiving any funding [21,27,31-33,36,39-44].

The total sample size was 11,637, ranging from n=85 (intervention group) to n=752 (control group). The participants' average age ranged from 12 to 91 years. Because some cancers are associated with a particular sex, 2 studies notably recruited all-male participants [32,42], while another 10 studies recruited all-female participants [21,23,24,26,30,34,35,37,39,44]. Also, there was a range of different cancer topics targeted during the study interventions, including 9 studies for skin cancer [22,25,27,31,33,36,40,41,45], 2 for colorectal cancer [28,38], and 1 for lung cancer [29].

Most of the experiments were conducted online, through email [27-29,40,43,44], a phone call [23] or text message [35], and other methods like webpage URLs [31,37]. There are also a small number of experiments that were done in a laboratory setting using traditional printed materials [21,22,25,32,33,41,42,45]. Messages were delivered in a variety of ways, including text only [27,28,36,44], text plus images or graphics [26,29,38,40], and video [24,30,34,39,43]. The majority of studies were based on prospect theory [21,22,24,27,29,32,34,37,41,43-45], and some of them used theory of planned (or reasoned) behavior [28,31,38,39], self-affirmation theory [36], and the health belief model [30,42]. There are also some studies that did not use theories or models [23,25,35]. The majority of studies focused on attitude [28,31,32,37-40,42,43] and intention [21,22,25-29,33,36,37,39-43,45], whereas 6 studies used behavior to examine the message framing effect directly [23,24,30,34,35,44].

Bias and Heterogeneity Assessments

As shown in Figures 2 and 3, the risk of bias assessment indicated that the included articles were relatively high in quality. For the publication bias examination, the funnel plot

was used for preliminary identification and the Egger regression line to confirm the possible publication bias further.

Figure 2. Risk of bias summary of the individual studies (k=24).

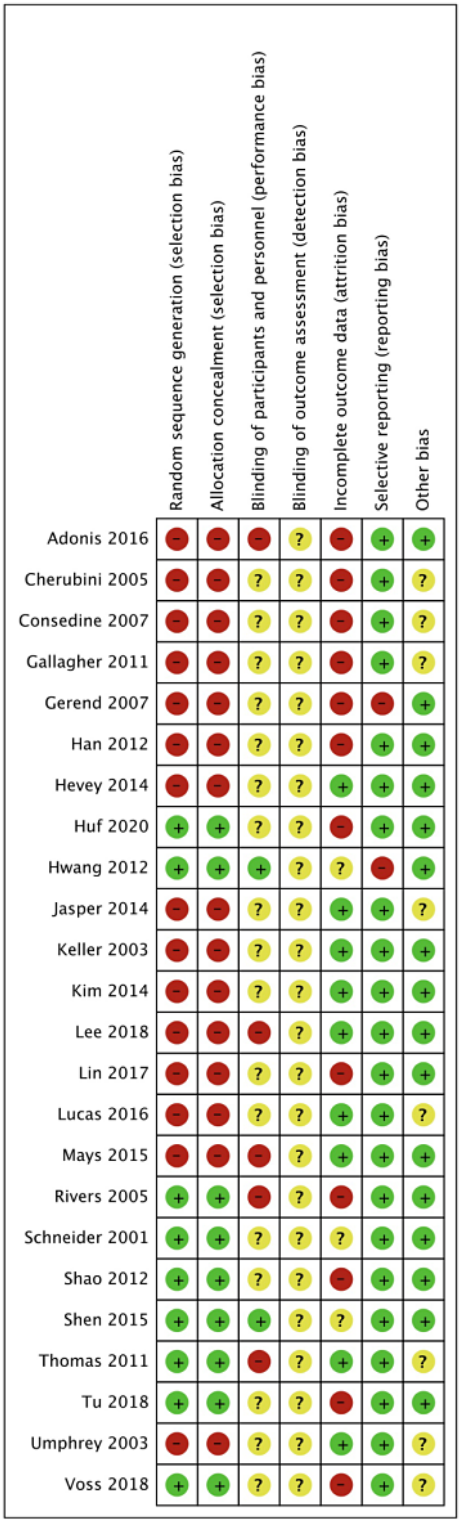


Figure 3. Risk of bias graph.

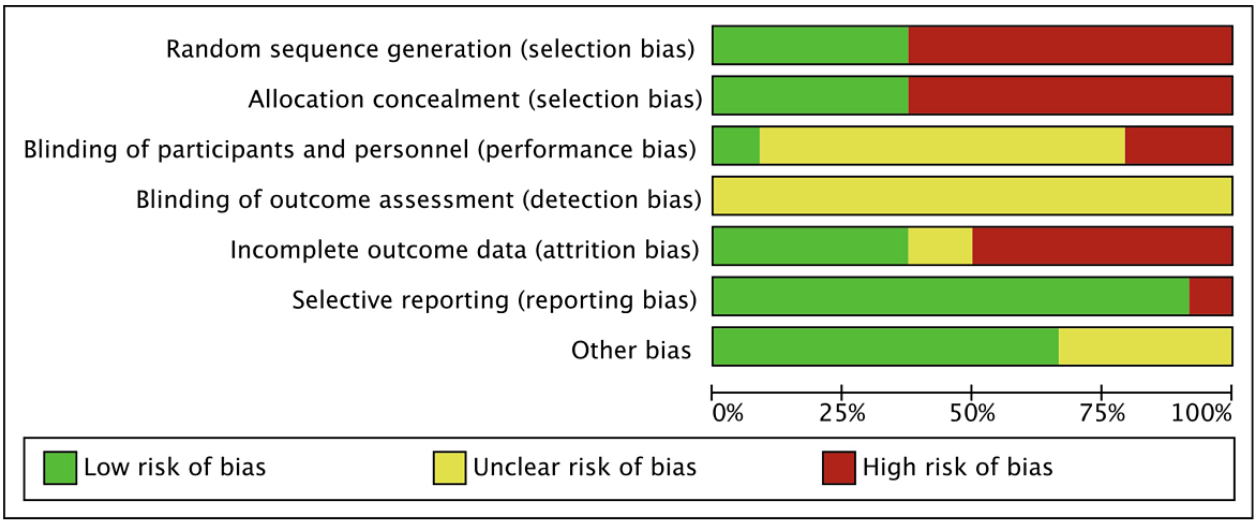


Intervention Effectiveness

In the following sections, the synthesized results regarding attitude-related, intention-related, and behavior-related outcomes are introduced individually. The main results are visualized in the forest plot.

Attitude-Related Outcomes

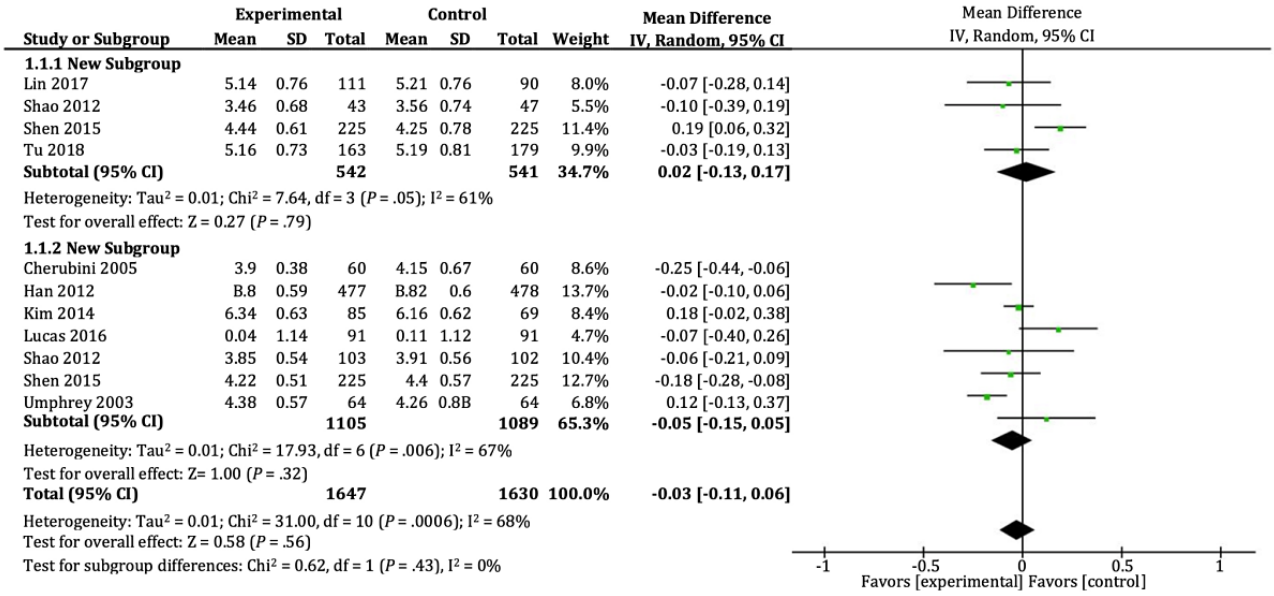
Attitudes are commonly defined as "a psychological tendency that is expressed by evaluating a particular entity with some degree of favor or disfavor." In this study, an attitude refers to the tendency towards engaging in a particular behavior or object targeted by a study's intervention.

The attitude was used to indicate the persuasiveness of cancer-related messages in 9 studies. The relevant data involved a total of 3277 participants, including 1647 in the gain group and 1630 in the loss group. As seen in Figure 4, no significant difference was found between the two groups in either cancer prevention attitude (SMD=0.02, 95% CI –0.13 to 0.17; *P*=.79) or cancer detection attitude (SMD=–0.05, 95% CI –0.15 to 0.05; *P*=.32). There was medium heterogeneity (I^2=68%; *P*<.001) across the trials.

The medium heterogeneity can be attributed to the study by Kim [43] and Shen [31]. Participants of both genders were involved in Kim [43], which focused on breast cancer, while the other studies all invited gender-specific participants who were more likely to be affected by the cancer of interest. In addition, Shen [31] invited students to participate in the experiment, and women accounted for 69% of participants. As undergraduates may be more sensitive to information about skin cancer because they are more focused on appearance rather than because they perceive health risks, excluding these 2 studies did decrease the heterogeneity (I^2=0%, *P*=.11), but no significant difference still existed between the gain and loss groups in either cancer prevention intention (SMD=–0.05, 95% CI –0.17 to 0.06; *P*=.37) or cancer detection intention (SMD=–0.05, 95% CI –0.15 to 0.04; *P*=.26).

The funnel plot (Multimedia Appendix 2) demonstrates relative symmetry for the studies of cancer detection or prevention attitude, which suggests no publication bias existed and the above analysis was reliable.

Figure 4. Forest plots of cancer detection attitude and cancer prevention attitude.



Intention-Related Outcomes

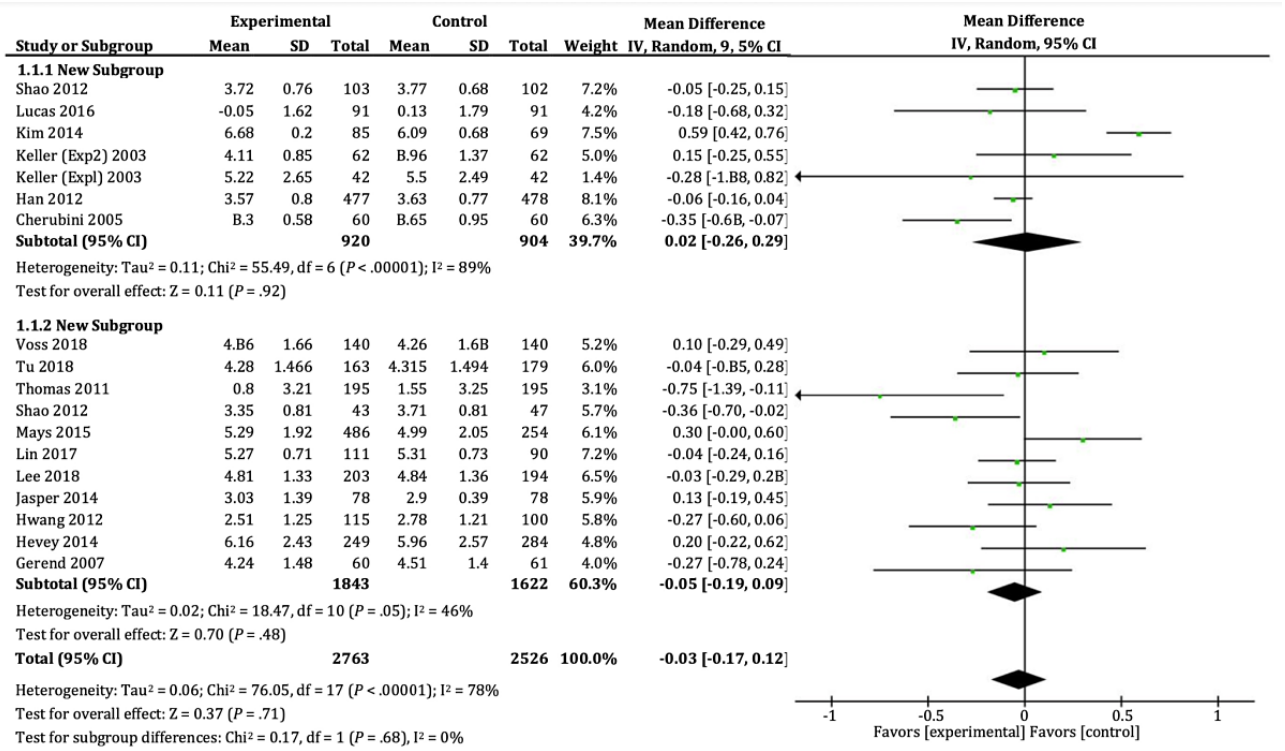
Intention refers to a state of wanting, planning, or expecting to act in a given way. It can be general (ie, intending to mammogram) or specific (i.e., intending to mammogram in 3 months). In this study, the difference between intentions and other related cognitions such as expectations or willingness was not distinguished.

The intention was used to indicate the persuasiveness of cancer-related messages in 16 studies. The relevant data involved a total of 5289 participants, including 2763 in the gain group and 2526 in the loss group. As shown in Figure 5, no significant difference was found between the 2 groups in either cancer prevention intention (SMD=–0.05, 95% CI –0.19 to 0.09; *P*=.48) or cancer detection intention (SMD=0.02, 95% CI –0.26 to 0.29; *P*=.92). There was large heterogeneity (I^2=78%; *P*<.001) across the trials.

Because the large heterogeneity can also be attributed to the study by Kim [43], excluding this study did decrease the heterogeneity (I^2=34%, *P*=.09). In addition, the heterogeneity is due to the gender characteristics of the participants, as mentioned above. However, there is still no significant difference between the gain and loss groups in either cancer prevention intention (SMD=–0.05, 95% CI –0.19 to 0.09; *P*=.48) or cancer detection intention (SMD=–0.08, 95% CI –0.17 to 0.01; *P*=.08).

The funnel plot (Multimedia Appendix 3) demonstrates relative symmetry for the studies of cancer detection or prevention intention except for Kim [43], which suggests that there existed no publication bias after excluding this study.

Figure 5. Forest plots of cancer detection intention and cancer prevention intention.



Behavior-Related Outcomes

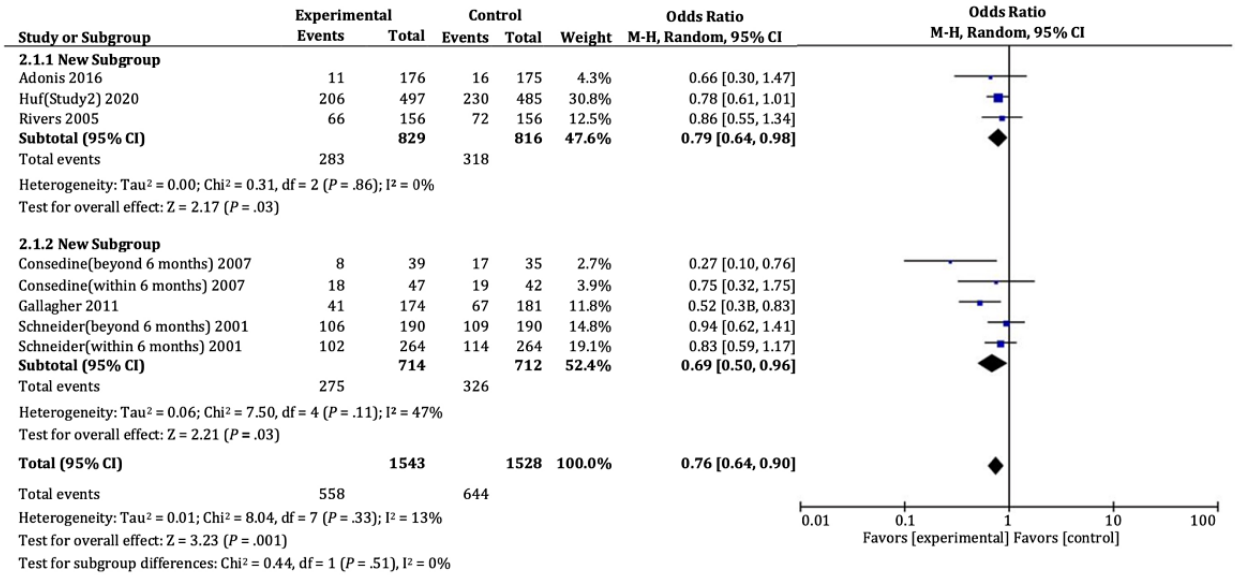
In most cases, behavioral measures are obtained by researchers using self-reported data from participants through follow-up surveys. However, it does not rule out the existence of special access to behavioral data (eg, a health insurance database record).

Behavior was used to indicate the persuasiveness of messages about cancer detection in 6 studies. The relevant data involved a total of 3071 participants, including 1543 in the gain group and 1528 in the loss group. It should be mentioned that cancer detection behavior was measured twice in Schneider et al [30] and Consedine et al [23]. According to Figure 6, loss-framed messages were significantly more likely than gain-framed ones to persuade people into engaging in both cervical cancer detection behavior (OR 0.79, 95% CI 0.64-0.98; *P*=.03) and breast cancer detection behavior (OR 0.69, 95% CI 0.50-0.96; *P*=.03), with no heterogeneity (I^2=13%; *P*=.33).

There was often a time interval between cancer detection behavior and the experiment in which the participants read the framed messages. For the five measurements of cancer detection behavior that were performed within 6 months after the experiments, loss-framed messages were still significantly more persuasive than gain-framed ones (OR 0.76, 95% CI 0.61-0.95; *P*=.01), with no heterogeneity (I^2=0%; *P*=.82). However, the intervention of loss framing became ineffective beyond 6 months (OR 0.73, 95% CI 0.49-1.11; *P*=.14), with medium heterogeneity (I^2=59%; *P*=.09).

The funnel plot (Multimedia Appendix 4) demonstrates asymmetry for the studies of cancer detection behavior, from which one cannot tell whether publication bias existed. However, the Egger linear regression analysis suggests there was no publication bias (*P*=.09).

Figure 6. Forest plots of cervical cancer detection behavior and breast cancer detection behavior.



Relationships Between Behavior and Attitude or Intention

Given that significant results were obtained for cervical or breast cancer detection behavior, 4 studies of detection attitude or intention focusing on either of these two cancers were extracted to examine the relationships between behavior and attitude or intention. Excluding Kim [43] as a source of heterogeneity, the relevant data involved a total of 1284 participants, including 641 in the gain group and 643 in the loss group. No significant difference was found between the two groups in cancer detection attitude or intention (SMD=–0.05, 95% CI –0.14 to 0.03; *P*=.20), with no heterogeneity (I^2=0.0%; *P*=.76). That is, as far as cervical and breast cancers are concerned, cancer detection behavior was not necessarily preceded by cancer detection attitude or intention. The funnel plot demonstrates relative symmetry for the studies of cancer detection attitude or intention, which suggests no publication bias existed, and the above analysis was reliable.

Discussion

Principal Findings

This study meta-analyzed 24 empirical studies on the persuasive effect of message framing in cancer prevention and detection. By subdividing the convincing effect into three dimensions, attitude, intention, and behavior, the results show that gain-framed and loss-framed messages have no significant differences in people's attitudes and intentions to change their cancer prevention or detection behavior. However, for cancer detection behavior, especially breast and cervical cancer detection, loss-framed messaging is more persuasive than gain-framed messaging, and this effect gradually weakens over time.

This meta-analysis did not identify any advantages of gain-framed messaging. Previous studies have proposed that gain-framed messaging is more persuasive than loss-framed in disease prevention, especially preventative behavior [6,16]. Since no relevant data on prevention behavior in the cancer-related literature are included in this meta-analysis, it cannot further verify whether the predecessors' benefits in disease prevention behavior can be equally applicable to the cancer topic. The results also negated the comparative advantage of loss framing in disease detection. There are several possible reasons for this contradictory conclusion. First, the previous meta-analysis did not distinguish between the three measurement indicators, so the results were affected by a large number of measurement indicators [16]. Second, the amount of cancer-related literature included in the previous meta-analysis is small, so the conclusions drawn do not apply to all cancer topics [6]. Therefore, it is necessary to verify whether these existing conclusions can be applied to all health topics based on previous studies. Moreover, because of different health topics, the focus also varies. Some emphasize daily prevention (such as using sunscreen), while some require regular detection (such as a colonoscopy).

This meta-analysis also supports some of the results of previous studies. Neither gain-framed nor loss-framed messaging can exert the framing effect of changing people's attitudes or intentions [6]. Our meta-analysis includes multiple cancer themes, and it also expands the positive impact of the loss framing found in breast cancer detection [46].

One interesting finding of this meta-analysis is that the message framing effect is time-limited. Others have questioned the duration of the framing effect in explaining the declining return rate [34]. On the other hand, this meta-analysis evaluates a larger scale of data and finds that the framing effect diminishes over time. Therefore, future research could further investigate how often health information stimulation can exert the framing effect and determine the effect of repeating the same framing.

Another notable result of this study is the disconnect between people's attitudes, intentions, and behavior. When reorganizing data related to attitudes and intention for breast and cervical cancer prevention and detection, these results also show that attitudes and intentions cannot effectively predict behavior,

indicating that there may indeed be a disconnect between people's attitudes, intentions, and behavior. This conclusion has also been confirmed by previous studies [6,47]. The ultimate purpose of any framed message, but especially a health message, is to promote a specific behavior. In the research process, paying too much attention to the influence of other variables besides behavior may outweigh the gains. Further verification is worthwhile to measure whether subjective attitudes and intentions to target behaviors can replace or predict the subsequent behavior after reading the framed message. The exploration in this area cannot stop at testing latent variables such as attitude and intention, and it should return its focus to "behavior" itself [48].

Limitations

As with all meta-analyses, this study was limited by the included literature measurement indicators and provided data. For example, the measurement data of attitude and intention included in the literature far exceed behavior-related data. Cancer detection behavior data were obtained only due to the lack of actual behavioral data related to cancer prevention. Also, the data are limited to two types of cancer (breast cancer and cervical cancer). Its generalizability also needs to be further verified based on more relevant research. Due to the low email response rate (2 out of 8), this meta-analysis excluded some studies meeting the inclusion criteria.

Conclusions

This meta-analysis shows that gain framing and loss framing have no significant difference in attitudes and intentions about cancer prevention and detection. On the other hand, loss framing can promote breast cancer and cervical cancer detection better than gain framing. However, the effect of the loss framing gradually weakens over time. Therefore, when constructing a message to promote cancer detection, more considerations can be given to loss framing's promised short-term effects. People can be screened for related cancers quickly by emphasizing the possible risk of not performing cancer detection.

Abstract

Background: The increasing use of smartphones by providers and patients alike demonstrates that digital health utilizing mobile applications has the potential to transform perioperative care and education in anesthesia.

Objective: This literature review describes the current scope of the use of mobile applications in anesthesiology.

Methods: Literature was searched using PubMed, Scopus, and clinicaltrials.gov for articles published from January 1, 2010, through April 1, 2020. Only English language studies were included. Articles were included if they examined the use of a mobile health application in the setting of anesthesia or the perioperative (immediate preoperative, intraoperative, and postoperative) period. Studies were excluded if they explored video interventions or did not examine the feasibility or efficacy of the mobile app.

Results: We included 29 articles, and three areas of clinical functionality were identified: patient-centered care (preoperative, intraoperative, and postoperative), systems-based improvement, and medical education. Several studies demonstrate the feasibility and reliability of mobile apps in these areas, but many are only tested for efficacy in simulated environments or with small patient samples

Conclusions: Mobile health applications show promise in improving communication between anesthesiologists, improving workflow efficiency, enhancing medical education, and reducing hospital costs. However, there is a need for validation and improvement before full implementation by the provider, patients, and hospital systems. Future studies are needed to demonstrate meaningful health outcomes to create guidelines and recommendations specific to the application of mobile technology to health care.

KEYWORDS

mobile applications; mHealth; perioperative medicine; anesthesia

Introduction

Mobile health (mHealth)—digital health technologies using mobile phones, tablets, and wearables to improve health outcomes—have the potential to rapidly change the face of medicine, health care, and medical education. By 2019, 81% of Americans owned a smartphone, a significant increase from 35% in 2011 [1]. Additionally, there has been an increased level of interest in using mobile apps to monitor health in the US population, with 45,028 mHealth related applications available for download in Apple's App Store in 2019, up from 28,343 in 2015 [2]. New advances in mobile apps provide opportunities for innovative patient care, real-time data delivery, and patient-provider engagement in anesthesiology.

Previous reviews in anesthesia have discussed commercially available digital health apps provided in the Apple App Store or Google Play market [3]. This review, however, describes recent clinically tested digital health apps found in scientific

literature and how these tools may be integrated into anesthesiologists' clinical practice.

This review aimed to describe the current scope of mobile application use within anesthesiology. We classified apps found in recent scientific literature into areas of clinical functionality that were deduced from the analysis of the included studies. We also described the limitations of mobile application studies and suggested future directions.

Methods

Overview

A review was conducted to answer the following research question: What mHealth applications in anesthesiology have been described in the published literature, and what are their utility and future potential in clinical practice?

Database Search

A complete literature search was conducted with the librarian's assistance using PubMed, Scopus, and clinicaltrials.gov for articles published from January 1, 2010, through April 1, 2020. The search terms were "mobile applications" OR "mobile health" OR "digital health" OR "mobile app" OR "iOS app" OR "mHealth" OR "smartphone" AND "anesthesiology" OR "anesthesia" OR "anesthetic" OR "anesthesiology" OR "anesthesia" OR "anesthetic. The search included titles, abstracts, and keywords for all databases.

Article Selection

Title, abstract, and full text of studies were reviewed by the first author (SP), and the senior author (LR) resolved any ambiguities. Only English language studies were included. Articles were included if they examined the use of an mHealth application in the setting of anesthesia or perioperative evaluation. Studies were excluded if they explored video interventions or did not examine the feasibility or utility of the mobile app.

Data Collection and Summary

Each article was assessed by design, population characteristics, methods, area of clinical functionality, and outcomes. A qualitative analysis was then conducted to summarize the depth and breadth of mHealth apps that have been utilized within anesthesiology. Major clinical functionalities were deduced from this qualitative analysis, and each study was then classified into one of these categories. We then described the limitations of the data from these studies and provided a basis for the future direction of mHealth in the field.

Results

Our search returned 80 studies on PubMed, 141 on Scopus, and 5 studies on clinicaltrials.gov, yielding a total of 226 studies, of which 49 were duplicate studies. The titles and abstracts of the remaining 177 articles were screened. We identified 66 that meet the criteria, and their full text was reviewed, after which 29 articles were selected for a qualitative review.

Within the literature, we identified three areas of clinical functionality: patient-centered care, systems-based improvement, and medical education. Patient-centered care was further subdivided into preoperative, intraoperative, and postoperative monitoring. Certain mobile applications within systems-based improvement were also subcategorized into medication safety or adverse event reporting or guideline compliance. An overview of each study's characteristics, methods, and outcomes can be found in Table 1.

Table 1. Characteristics and outcomes of included studies.

Study	Design	Sample, N	Sample characteristics	Category	Methods	Results
Cumino et al 2017 [4]	RCT[a]	84	Pediatric (4-8 years) undergoing elective surgeries	Patient-centered care: Preoperative	Four groups: control (verbal anesthesia), informed (parent given an information leaflet about the anesthetic procedure), smartphone (with a child in holding area), and combined (smartphone or informed). Primary endpoint: m-YPAS[b] in holding area and OR[c]	The OR anxiety in the control group was higher (76.2%; *P*=.001) than in the other groups: informed group (38.1%), smartphone group (23.3%), and combined (19.0%).
Lee et al 2013 [5]	RCT	120	Pediatric (1-10 years) surgical patients	Patient-centered care: Preoperative	Midazolam (M group), smartphone app (S), or midazolam & smartphone (SM). Primary outcome: m-YPAS before and after the intervention.	Group S score was significantly lower than group M (*P*=.01, group SM was significantly lower than group M (*P*<.01), and group SM was significantly lower than group S (*P*<.01).
Rubin et al 2019 [6]	Prospective	86	Adult surgical patients	Patient-centered care: Preoperative	An app was designed to administer the Duke Activity Status Index and the 6-minute walk test. Linear regression was performed to estimate the distance walked during the 6MWT from the number of steps measured by the app.	Steps measured by app and research-grade pedometer demonstrated intraclass correlation of 0.87 (0.79-0.92; *P*<.001). Overall model fit was r^2=.72 for the distance estimation algorithm.
Barrachina et al 2017 [7]	Cross-sectional	20	Intensive care unit patients	Patient-centered care: Intraoperative	Analysis of snapshots from patient monitor and photos using Capstesia app were assessed for concordance of PPV[d], CO[e], and dP/dt[f]	Intraclass correlation coefficient or PPV, CO and max dP/dt were 0.991 (95% CI 0.98-0.99), 0.966 (0.96-0.97) and 0.96 (0.95-0.97), respectively.
Carvalho et al 2019 [8]	Prospective	22	Patients with surgery requiring NMB[g]	Patient-centered care: Intraoperative	NMB grade assessed intraoperative care with TOF[h] ratios obtained by a Stimpod accelerometer versus the new app	For 142 time points, there was no significant difference between the two methods (*P*=.78). However, insufficient data that the app can diagnose a TOF higher than 0.
Desebbe et al 2016 [9]	Prospective	2100	N/A[i]	Patient-centered care: Intraoperative	The simulator is used to display arterial waveforms on a computer screen. Data was obtained with different sweep speeds (6 and 12 mm/s) and randomly generated PPV values, pulse pressures, and vitals. Each metric was recorded 5 times at an arterial height scale X1 and 5 times at an arterial height scale X3. Primary outcome: Reproducibility of PPV_{app}[j] and PPV_{man}[k].	The precision error of PPV_{app} and PPV_{man} was 10% (7%-14%) and 6% (3%-10%), respectively. PPV_{app} shows acceptable accuracy with PPV_{man} when at least three pictures are taken to average PPV_{app} at scale X1 (upper limit of the 95% CI of the measurement error<12%).

Joosten et al 2019 [10]	Cross-sectional	40	Abdominal surgery patients	Patient-centered care: Intraoperative	PPV_{CAP}[l] compared with SVV_{PC}[m] at postinduction, preincision, postincision, the end of surgery, and during every hypotensive episode. PPV and SVV are classified into no fluids, gray zone, and fluid administration. Primary outcome: the overall agreement between PPV and SVV and agreement in the fluid administration category	549 pairs of PPV-SVV data were obtained. The overall agreement of PPV_{CAP} with SVV_{PC} was 79% (κ=0.55), demonstrating moderate agreement with only 1% of all measurements resulting in opposite clinical decisions regarding fluid administration.
Joosten et al 2019 [11]	Prospective	57	Elective coronary artery bypass graft patients	Patient-centered care: Intraoperative	The ability of PPV_{CAP} or PPV_{PC}[n] to predict fluid responsiveness after infusion of 5 ml/kg of colloid. Primary outcome: overall agreement of PPV_{CAP} and PPV_{PC} as well as CO_{CAP}[o] and CO from CO_{TD}[p]	No difference in the ability of PPV_{CAP} and PPV_{PC} to predict fluid responsiveness (AUROC[q] 0.74, 95% CI 0.60-0.84 vs AUROC 0.68, 95% CI 0.54-0.80; *P* =.30). CO_{CAP} did not correlate well with CO_{TD}.
Chiu et al 2019 [12]	RCT	156	Procedural patients, age 19-75 years,	Patient-centered care: Preoperative	Completed VAS-100[r] and NRS-11[s] for pain using paper versus smartphone VAS-100 and NRS-11. Primary outcome: correlation at various time points	Panda VAS-100 and original tool correlated strongly at emergence (r =.93) and upon discharge (r =.94); Panda NRS-11 correlated strongly with the original at emergence (r =.93) and upon discharge (r =.96)
Dahlberg et al 2017 [13]	RCT	1027	>17 y/o undergoing day surgery	Patient-centered care: Postoperative	Patients answered SwQoR[t] daily for 14 days: smartphone app versus standard care (control). Primary outcome: cost-effectiveness.	Net savings of €4.77 (approximately US $5.65) per patient w/ intervention. No difference in SwQoR between the two groups.
Dahlberg et al 2019 [14]	RCT	494	>17 years undergoing day surgery	Patient-centered care: Postoperative	Patients randomized to RAPP[u] daily for 14 days via app versus standard care (no follow-up).	62% of contacts made by patients were on postoperative days 1 to 7 and 38% on postoperative days 8 to 14. Demonstrated follow-up should be more long-term.
Highland et al 2019 [15]	RCT	50	Military surgery patients	Patient-centered care: Postoperative	Mobile app (mCare) group vs control telephone group to complete Defense and Veterans Pain Rating Scale, nerve block questions, satisfaction surveys, and system usability survey after surgery.	No difference in initial response rates between app and control. On day 8, 64% of mCare group completed follow-up versus 48% of the control group (*P*=.29).

Study	Design	Sample, N	Sample characteristics	Category	Methods	Results
Jaensson et al 2017 [16]	RCT	997	Adult day surgery patients	Patient-centered care: Postoperative	SwQoR daily for 14 days via app intervention (RAPP) or standard care (control). Primary outcome: SwQoR on postoperative days 7 and 14	Global SwQoR score was significantly lower (better recovery) in the RAPP group compared to the control group on day 7 (28.23 vs 34.87; $P<.001$) and day 14 (20.12 vs 21.90; $P=.002$).
Ke et al 2019 [17]	Qualitative study	15	Obstetric anesthesiologists (9) and cesarean section patients (15)	Patient-centered care: Postoperative	Structured phone or in-person interviews with patients and anesthesiologists to assess care after a cesarean section and to solicit feedback on a prototype mobile app for postoperative cesarean section care	App focusing on patient education and self-monitoring. 80% of patients interacted with the app >2x. Most accessed resources were controlling pain, an overview about days after surgery, and key contacts.
Soh et al 2019 [18]	RCT	42	Gastric cancer surgical patients	Patient-centered care: Postoperative	Alarm on the app every 60 min for 2 days with nurse dashboard versus app without alarms or dashboard. Primary outcome: ISI[v] to assess the frequency of ISI use.	ISI was higher in the test group versus control but not significant (113.5 vs 93.2; $P=.22$). Active coughing showed significantly higher performance in the test group (107.8) compared with the control (94.8).
Sun et al 2014 [19]	Prospective	62	Pediatric patients (4-18 years)	Patient-centered care: Postoperative	Assessed pain with both paper FPS-R[w] and CAS[x] assessments as well as app-based (Panda) versions post-surgery. Primary outcome: correlation between scores.	Panda FPS-R scores correlated strongly with the original tool ($r > .93$). Panda CAS scores correlated strongly with the original CAS scores at both time points ($r>0.87$); mean pain scores were higher (up to plus 0.47) with Panda than with the original.
Warren-Stomburg et al 2016 [20]	Mixed	83	Adult surgical patients	Patient-centered care: Postoperative	Part I: paper-based questionnaire to identify patients' attitudes towards follow-up techniques. Part II: feasibility test of a mobile app for follow-up.	42.2% prefer to respond by the mobile app in part I, but in part II, adherence to answering questions in the app was only 27.2%. Patients > 60 yrs prefer paper follow-up while patients <40 prefer telemedicine ($P=.001$).
Baumann et al 2019 [21]	Randomized crossover	74	Resident and attending anesthesiologists	Systems-based: Medication safety	Compared simulations with and without the app. Primary outcome: the probability of administering the accurate dosage.	The probability of "accurate" rated dosage was 77.7 (70.9-84.5%) in control versus 94 (90-97.8%) with the app.
Gorges et al 2019 [22]	Feasibility study	N/A	N/A	Systems-based	telePORT app designed with input from anesthesiology assistants for design features and work-domain analysis. Primary outcome: Usage patterns quantified.	telePORT is used more for help requests (approximately 4.5 per day) than team messaging (approximately 1 per day). OR monitoring was frequently utilized (34%). Loss of wireless connectivity was a barrier.

Study	Design	Sample, N	Sample characteristics	Category	Methods	Results
Haffey et al 2013 [23]	Retrospective	23	Opioid conversion apps	Systems-based: Medication safety	Apps with opioid dose conversion abilities identified. Dose calculations of seven commonly used opioid switches were compared between apps.	Of 23 apps, 52% had no stated medical professional involvement. There is a significant difference in mean conversion output for hydromorphone between apps with and without medical professional involvement (0.2256 vs 0.2536; *P*=.038).
Jabaley et al 2018 [24]	Cross-sectional	13,846	Anesthesiologists	Systems-based: Medication safety	A free mobile app (Anesthesiologist) deployed a 10-question survey about sugammadex use and related adverse events.	About 50% of anesthesia providers had access to sugammadex and were given a survey. Anaphylaxis rates are estimated to be between 0.005%-0.098%. 22.7% reported adverse drug reactions.
Lane et al 2012 [25]	Feasibility	40	Anesthesiologists	Systems-based	Development of VigiVU, a mobile app for OR awareness and communication, at Vanderbilt University Medical Center followed by beta testing done with a group of 40.	VigiVU push notifications to iPhone were faster than pager (mean 18 sec, SD 8.2). All beta users continued to use the app for the benefits of situational awareness in up to 4 ORs.
Lelaidier et al 2017 [26]	RCT	52	Anesthesia residents	Systems-based: Guideline compliance	Two simulated crises, with and without MAX app. Primary outcome: technical performance during crisis defined by the ESC[y]. Secondary outcome: nontechnical performance	Mean technical performance was higher in the MAX group vs. control group: 81.6%, SD 11.9) versus 58.6%, SD 10.8; *P*<.001 and nontechnical 33.7%, SD 4.4 versus 30.9%, SD 4.9 points; *P*<.001.
McEvoy et al 2016 [27]	RCT	259	Anesthesiologists	Systems-based: Guideline compliance	A 20-question test regarding clinical scenarios related to ASRA[z] guidelines using ASRA Coag app versus any resource except the app (control). Primary outcome: test score	App group (92.4%, SD 6.6) scored higher than control (68.0%, SD 15.8; *P*<.001). App use increased the odds of selecting correct answers (7.8, 95% CI 5.7-10.7).
Rothman et al 2013 [28]	Cross-sectional	N/A	N/A	Systems-based	Message sent with VigiVu versus paging system. Primary outcome: transmission and receipt times calculated as their differences.	Mean latencies <1 sec for iPad and iPod devices and <4 sec for iPhone. Service performed better than third party paging systems (Aquis paging system had 0.6% incidence of prolonged message delivery, >100 sec)
Rubin et al 2017 [29]	Retrospective	N/A	Clinical anesthesia personnel	Systems-based: Medication Safety	Two years before intervention used as the baseline rates of adverse event reporting. Primary outcome: monthly reporting and same-day adverse event reporting compared before and after app implementation.	Median reported 12 events for the first year, 14 for the second year, and 20 after the introduction of the mobile app (*P*=.01). The rate of same-day reporting increased by 10% after the introduction of the app (*P*=.048).
Burstein et al 2018 [30]	Feasibility	N/A	N/A	Medical education	An app that to teaches Bier block.	It was implemented in 2015 with data collection until 2021.

Study	Design	Sample, N	Sample characteristics	Category	Methods	Results
De Oliveira et al 2013 [31]	RCT	20	Medical students	Medical education	Students were randomized to intervention (iLarynx app for 30 min) versus control (no iLarynx access). Primary outcome: the time required to advance fiberscope from the mouth up to the carina on a mannequin. Failed if carina not seen in <120 sec.	80% of the control group failed versus 20% in the intervention group (P=.01). 24 failed attempts in the control group and 4 in the iLarynx group (P<.005).
Linganna et al 2020 [32]	RCT	18	Anesthesiology residents	Medical education	Traditional intraoperative teaching of transesophageal echocardiography (control) vs access to EchoEducator app. Primary outcome: score increase from preintervention to postintervention assessment.	Intervention group demonstrated a greater increase in score; (plus 19.19%, 95% CI 4.14%-34.24%; P=.02) compared to control.

Discussion

Patient-Centered Care

Within anesthesia, the perioperative surgical home has arisen as a model that encompasses the goals of patient-centered care [33]. Mobile apps will play a large role in this area as they can directly engage patients before they arrive at the hospital and after their procedures. By providing on-the-go education, monitoring, and behavioral interventions, the anesthesia team can reduce patient anxiety preoperatively, increase communication through real-time mobile interactions perioperatively, and improve compliance with perioperative instructions.

Preoperative Interventions

Mobile apps provide an opportunity to decrease anxiety without additional sedatives in the pediatric population. Preoperative anxiety in pediatric populations is estimated to be as high as 50% [34]. Lee et al randomized 120 children between ages 1 and 10 (ASA I, II) who were undergoing elective surgery to receive intravenous midazolam (M), behavioral intervention through smartphone applications (eg, Soundtouch interactive, Pororo Sticker Book, Angry Bird) tailored to the child's developmental status and preferences (S), or both (SM). While they found that anxiety using the modified Yale Preoperative Anxiety Scale (m-YPAS) was lower post-intervention for all three groups (M group: mean 52.8, SD 11.8 vs mean 41.0, SD 7.0; S group: mean 59.2, SD 17.6 vs mean 36.4, SD 7.3; SM group: mean 58.3, SD 17.5 vs mean 26.0, SD 3.4), the S group had lower anxiety levels relative to the M group ($P<.01$), and the SM group had the lowest level of anxiety ($P<.01$) [5].

In another randomized controlled trial (RCT) of 84 pediatric patients ages 4 to 8, the children's median anxiety levels were lower for patients in the smartphone group (parents verbally informed of the anesthetic procedure and child received smartphone app) versus the control group (parent verbally informed about the anesthetic procedure only). The smartphone group had significantly lower m-YPAS scores compared to the control group, measured in the operating room (OR) before anesthesia induction (55.0 vs 23.4; $P<.001$) [4]. The ability to tailor mobile app choices to a child's developmental stage demonstrates how mobile technology can be customizable for individual patients.

Another novel use for smartphone apps in the preoperative area is to improve dynamic communications using a centralized platform such as Listeo+. The Listeo+ app provides personalized information to patients, reminders for preoperative recommendations, and a channel for various provider communications. Listeo+ is currently being tested in a multicenter RCT to evaluate the percentage of compliance to preoperative recommendations, thereby decreasing the rate of surgery cancellations [35].

Mobile apps, such as a preoperative functional capacity app, can assist with preoperative risk assessment, even before the patient enters the health care facility. At the University of Chicago, the Step Test app integrates the Duke Activity Status Index (DASI) with the 6-minute walk test (6MWT) [6]. Step Test uses voice prompts and Apple's CMPedometer to derive calculated step counts for the 6MWT. Rubin et al demonstrated that Step Test's estimated steps exhibited good agreement with a research-grade pedometer in a cohort of 78 patients (intraclass correlation coefficient of 0.87; $P<.001$). The app facilitates efficient administration of DASI and 6MWT and provides immediate data to providers without occupying clinic staff. Future applications may include improving functional capacity through patient optimization before procedures. In summary, emerging mHealth apps demonstrate their potential to transform preoperative care by decreasing anxiety and providing coordinated, efficient care. Hopefully, in the future, providing an interface to optimize patient health status before surgery to improve outcomes.

Intraoperative Monitoring

Digital mHealth apps have also been tested as tools to enhance intraoperative monitoring. An ideal mobile app for intraoperative monitoring should be easy-to-use, accurate, noninvasive, cost-effective, and reliable. Capstesia (version 1.1.6; Galenic App SL) is an inexpensive and attractive smartphone app used to calculate pulse pressure variations (PPV) and cardiac output (CO) from a picture taken of the arterial waveform on a monitor screen. In a simulated environment comparing 408 pairs of PPV readings, Capstesia's PPV demonstrated acceptable accuracy compared with the manual PPV if at least 3 photos of the waveform were taken (measurement error <12%). Accuracy was improved if it was averaged across 5 photos [9] but is less practical in the OR setting. Additional validation studies showed that Capstesia had a percentage of error of 20% for PPV and 13.8% for CO among 20 patients in the intensive care unit [7]. However, when the app was studied in 57 patients undergoing elective cardiac surgeries, its calculated PPV only weakly predicted fluid responsiveness (sensitivity of 73%, 95% CI 0.54-0.92, and a specificity of 74%, 95% CI 0.48-0.90) [11]. When comparing Capstesia's PPV to stroke volume variation from an uncalibrated pulse wave analysis monitor, Joosten et al found that there was 79% overall agreement between the two, with a kappa coefficient of 0.55 [10]. These results demonstrate the promise and difficulties of creating a mobile app for real-world clinical intraoperative settings.

Digital mHealth apps have also shown promise in intraoperative neuromuscular blockade (NMB) assessment. Often, recovery of NMB is done subjectively due to the lack of accelerators [36,37] and can result in residual weakness and respiratory complications [38]. In a sample of 22 patients, Carvalho et al demonstrated a strong correlation between train-of-four ratios obtained by a standard accelerometer against an Android app used with the phone attached to the patient's hand (R=0.98). The app also had a small mean difference (0.0004, 95% limits of agreement +/ 0.12) against standard accelerometry [8]. Thus, the digital app is a feasible way to assess NMB. However, further studies are needed to demonstrate efficacy before the widespread application of mobile apps as monitoring devices in the OR.

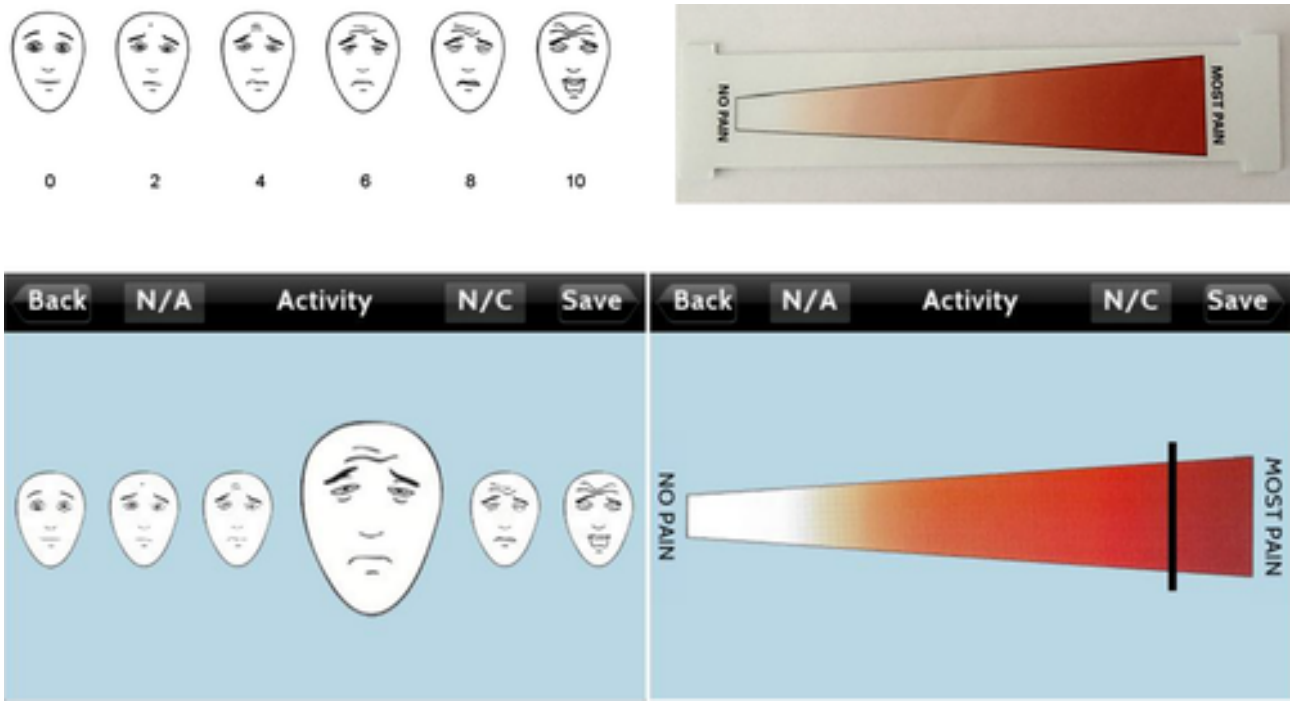
Postoperative Monitoring

There is an increasing focus on patient-reported outcome measures (PROM), alongside traditional biomarkers, in evaluating clinical care [39]. Mobile apps have emerged as an exciting new tool to track PROMs such as symptoms, pain, and satisfaction with health care delivery beyond the inpatient stay. Apps have been tested in clinical trials demonstrating initial feasibility and cost-effectiveness compared to the standard of care [13,15,16].

One important measure that mobile apps help track is poorly managed acute postoperative pain, which can be related to increased risk of psychological morbidity, decreased quality of life (QoL), and chronic postsurgical pain [40]. The application Pain Assessment using a Novel Digital Application (Panda) contains electronic versions of the faces pain scale revised (FPS-R) and color analog scale (CAS). Figure 1 demonstrates both the original FPS-R and the electronic version seen on the

app. In a prospective study of 62 patients, the app version correlated strongly with original scores at various postoperative time points (FPS-R: r>0.93; CAS: r>0.87) [19] and was preferable to the paper version (81% of FPS-R and 76% of CAS participants). Therefore, digital apps may improve adherence to self-reported pain. Additionally, in a study of 156 adult patients undergoing procedures commonly associated with postsurgical pain, Chiu et al found that the app version of the numeric rating scale 11 pain scores were equivalent to that of the paper version when used in adult patients following emergence from anesthesia and at discharge from the postanesthesia care unit [12]. The use of Panda in both adults and pediatric patients demonstrates the app's potential to be used in a variety of patient populations.

Figure 1. Original faces pain scale-revised (top) and adapted electronic faces pain scale-revised for Panda app (bottom) (reproduced with permission from John Wiley and Sons) [19].



Another postoperative mobile app was built for patient-initiated inquiry to identify complications earlier and improve patients' QoL after surgery. An RCT of 1027 day-surgery patients examined postoperative follow-up with a smartphone app known as recovery assessment by phone points (RAPP). The authors found that there were lower health care costs associated with smartphone app follow-up compared to standard of care follow-up (€60.69 vs €37.29; P=.008 with a mean difference of €23.66). However, after the intervention costs were included, net savings were only €4.77 per patient [13]. Patients using the RAPP also reported better global Swedish Quality of Recovery compared to patients using paper assessments on postoperative day 7 (28.23, SD 29.97 vs 34.87, SD 30.68; P<.001) and postoperative day 14 (20.12, SD 26.19 vs 21.90, SD 22.40; P=.002) [16]. The study also helped determine that most patient inquiries (62%) occurred 1 to 7 days postsurgery, most commonly related to the surgical wound (43/119, 36%) and pain (33/119, 28%) [14].

mHealth apps can also incentivize patients to improve respiratory mechanics postoperatively. The Go-breath app was tested in 42 patients who received general anesthesia undergoing a robotic or laparoscopic surgery or laparotomy to encourage the improved use of incentive spirometry (IS). Although it is a nice concept, patients who used the Go-breath app did not score statistically higher on the incentive spirometer index (frequency of IS use over two days) compared to patients who did not (113.5 vs 93.2; P=.22) [18].

Mobile apps can also provide a platform for multidisciplinary care in the postcesarean section period. For example, in a feasibility study including 15 patients of an app designed with obstetric anesthesiologists, 80% of patients used the app at least twice to self-monitor for complications and access pain control resources, thus increasing the amount of patient monitoring for common postcesarean complications and pain [17].

Systems-Based Improvement

For anesthesiologists, smartphone apps are a convenient and accessible way to improve patient safety and quality of care [41,42] through medication safety, adverse event rates, guideline adherence, and responsiveness to emergencies.

For example, immediate response to OR emergencies is of utmost importance, with patient safety and outcomes on the line. Anesthesiologists at Vanderbilt have built an extensive iOS platform known as VigiVu to improve responsiveness through real-time OR videos, vital signs, anesthetic interventions, voice and text communication, and electronic medical record access [25]. Rothman et al demonstrated the superior reliability of the app's push notifications compared to traditional paging systems—only 0.03% of iPhone notification latencies were over 100 seconds compared to 0.6% for third-party paging latencies [28]. Similarly, anesthesiologists

at the University of British Columbia developed an iPhone app, telePORT, to support team-based communication and real-time OR monitoring. Initial results showed that telePORT was successfully integrated for OR help requests (4.5 requests per day) and OR monitoring, representing 34% of app visits [22]. The use of smartphone apps in these situations increases patient safety by prioritizing emergency situations and proper resource allocation. Additionally, data collection from patient monitoring and outcomes in mobile apps can also be utilized for both quality improvement and clinical research in the future.

Medication Safety and Adverse Event Reporting

Mobile apps have also been used to increase adverse event reporting through transparent and convenient processes that help further a culture of safety and quality. An iOS and Android adverse event–reporting app was developed at the University of Chicago (see figure 1 in Rubin et al [29] for an example of the iOS interface used to report events). After implementation, median monthly reporting rates for all providers increased from 12 to 20 (P<.001), with same-day reporting increasing by 10% during the intervention period (P=.048) [29]. Similarly, apps have shown efficacy in monitoring global adverse events regarding the administration of newer drugs. Jabaley et al repurposed a calculator app (Anesthesiologist) to distribute a survey regarding adverse drug reactions associated with sugammadex administration. Using the mobile app, the investigators gathered data from 2770 anesthesia providers that had experience administering the drug across 119 countries [24], demonstrating that an app may be used for crowdsourcing and surveilling new drugs. The app survey found that anaphylaxis rates were estimated to be between 0.005%-0.098%, and 22.7% of survey responders reported witnessing any sugammadex-related adverse drug reactions such as bradycardia and incomplete reversal of NMB [24].

Finally, anesthesiologists have historically used smartphones to calculate drug dosages. Baumann et al compared the probability of administering accurate medication dosages in emergency simulations with a dosage calculator app versus without it [21]. The probability of an accurate dose administration was higher in the app group compared to the control group (94%, SD 90-97.8 vs 77.7%, SD 70.9-84.5) [21]. Apps are often used for medication conversion in the outpatient pain management setting as well. For example, there are many opioid conversion applications designed to reduce medication errors. However, these apps should be used cautiously. In a study examining 23 opioid apps, only 50% provided direct references to sources for their conversion ratios, and over 50% had no documented medical professional involvement [23]. The conversion from 1 mg of oral morphine to oral hydromorphone was statistically different between apps with medical professional involvement versus those without (0.24 vs. 0.25; P=.04), demonstrating that there may be varying degrees of reliability for these mobile apps.

Guideline Compliance

Built-in smartphone-based decision support tools can similarly improve adherence to anesthesia guidelines to reduce technical errors. Numerous reports have found that poor application of guideline standards results in worse patient safety outcomes [43-45]. However, guidelines are numerous, lengthy, and cumbersome to follow. In an RCT across eight institutions, 259 anesthesiologists completed a test requiring the application of the American Society of Regional Anesthesia and Pain Medicine (ASRA) guidelines to clinical situations. The intervention group used an electronic decision support tool, ASRA Coags, which was programmed with the latest guidelines and decision logic, and the control group used any other resource. The authors found that the intervention group had a significantly higher score on a clinical scenario knowledge test (92.4 vs 68.0; P<.001) compared to the control group [27], irrespective of training. Together, these studies show the potential for mobile apps to act as a platform for the rapid application of complex guidelines in clinical situations, potentially reducing adverse events, preventing errors, and improving the quality of care.

Mobile apps have also been developed to improve performance in high-stress situations in lieu of posters, flow charts, and checklists. For example, MAX, a handheld cognitive aid app, was used as an intervention in a RCT of 52 anesthesia residents. Results demonstrated that residents performed better technically, as rated by independent observers when using MAX in simulated crises compared to without MAX use (81.6%, SD 11.9 vs 58.6%, 10.8; P<.001). The app also improved leadership (P=.003), problem-solving (P<.001), and resource-using (P=.006) as assessed by the Ottawa Global Rating scale [26].

Medical Education

The landscape of medical education is changing from the traditional model of classroom teaching to models such as the flipped classroom and asynchronous learning. Mobile technology enables asynchronous learning—a time and location-independent learning model—with greater access to online modules, podcasts, and videos. For example, smartphone apps have now been developed for point-of-care learning of regional anesthetic procedures such as the Bier Block [30]. These apps may provide an all-in-one learning center with videos, cognitive aids, dose calculators, self-timers, and evidence-based references readily available at the learner's convenience [30]. Additionally, education apps use gamification or game-design elements to increase user motivation. Linganna et al developed EchoEducator, a mobile app with transesophageal echocardiography image-based content, and tested it against traditional intraoperative teaching amongst 18 anesthesiology residents over two weeks (please see figure 2 in Linganna et al [32] for examples of questions testing pathology and structures as well as the feedback the resident receives). The app group had a greater knowledge increase than the control group (+19.19%, 95% CI 4.14-34.24; P=.02) in an assessment based on the perioperative transesophageal echocardiography exam [32]. Residents also reported that they would recommend the app to others because of its content customizability and convenience.

Another application of mobile apps in medical education is through simulation. For example, iLarynx utilizes the iPhone's built-in accelerometer to mimic hand movements for fiberoptic intubation. When tested in 20 novice medical students, 80% of students in the standard training group had at least one failed attempt (>120 seconds) of visualizing the carina compared to

20% of students in the iLarynx group (P=.01). There was also continued group improvement in the iLarynx group but not in the standard training group [31].

Current Obstacles and Future Directions

Despite the many functions that mobile technology could fulfill in anesthesia, various obstacles, including low patient participation, privacy and security, provider responsibility, and shifting workplace norms, ultimately impede their comprehensive integration into the clinical environment. For example, preoperative and postoperative monitoring interventions depend on patient interaction and motivation. While there are some reports of high adherence to mobile app interventions [15], other studies show a poorer response rate, especially among the elderly—a large hurdle in app development [20]. Intraoperative apps need to be assessed for ease of use, reliability, and accuracy in the OR and not distract anesthesiologists. Monitoring apps, although promising, need more clinical validation across a range of populations.

More evidence is needed to demonstrate mobile apps can meaningfully improve clinical outcomes moving forward. Large-scale, prospective studies with outcomes data are necessary to provide sufficient evidence for widespread implementation. Investigators should also consider using the mHealth evidence reporting and assessment guidelines, which address the complex nature of mobile technology research [46].

Limitations

Similar to all narrative reviews, this review is limited by the lack of appraisal criteria for included studies. Additionally, only mobile apps derived from the scientific literature have been included. Thus, there are likely mobile applications apps not studied in the literature that were omitted. We have performed a qualitative review of the search and included only studies that fit into the categories we created, thus excluding other studies.

There are additional limitations to the mHealth apps described. Many are often inadequately tested clinically, lack efficacy data, and do not adhere to standard guidelines. Similarly, there are limited guidelines and protocols on how to use the data collected by these apps, despite their potential for engaging a wide population. Future research should explore if patient engagement through smartphone apps may increase efficiency, patient satisfaction, and outcomes during the perioperative period.

Conclusion

With the rapid uptake of smartphones amongst patients and clinicians alike, mobile applications will likely play a larger role within anesthesiology in the future. mHealth apps have novel roles in improving patient care, efficiency, and intraoperative monitoring during surgery. Mobile apps have also been shown to facilitate systems-wide change by creating a culture of improving patient quality and safety. However, as the field of anesthesiology moves forward into the digital health space, demonstrating feasibility is not sufficient; clinicians must critically evaluate mobile app study protocols and rigor. Despite studies with smaller populations and simulated environments, this review still finds emerging evidence that mHealth applications have the potential to significantly improve communication between anesthesiologists, improve workflow efficiency, enhance medical education, and reduce hospitals' costs in the perioperative arena.

Abstract

Background: Self-tracking technologies are widely used in people's daily lives and health care. Academic research on self-tracking and the quantified self has also accumulated rapidly in recent years. Surprisingly, there is a paucity of research that reviews, classifies, and synthesizes the state of the art with respect to self-tracking and the quantified self.

Objective: Our objective was to identify the state of the art of self-tracking and the quantified self in terms of health and well-being.

Methods: We have undertaken a systematic literature review on self-tracking and the quantified self in promoting health and well-being. After a rigorous literature search, followed by inclusions, exclusions, and the application of article quality assessment protocols, 67 empirical studies qualified for the review.

Results: Our results demonstrate that prior research has focused on 3 stakeholders with respect to self-tracking and the quantified self, namely end users, patients and people with illnesses, and health care professionals and caregivers. We used these stakeholder groups to cluster the research themes of the reviewed studies. We identified 11 research themes. There are 6 themes under the end-user cluster: user motivation and goal setting, usage and effects of self-tracking, continuance intention and long-term usage, management of personal data, rejection and discontinuance, and user characteristics. The patient and people with illnesses cluster contains three themes: usage experience of patients and people with illnesses, management of patient-generated data, and advantages and disadvantages in the clinical context. The health care professional and caregiver cluster contains two themes: collaboration among patients, health care professionals, and caregivers, and changes in the roles of patients and professionals. Moreover, we classified the future research suggestions given in the literature into 5 directions in terms of research designs and research topics. Finally, based on our reflections on the observations from the review, we suggest four future research directions: (1) users' cognitions and emotions related to processing and interpreting the information produced by tracking devices and apps; (2) the dark side of self-tracking (eg, its adverse psychosocial consequences); (3) self-tracking as a societal phenomenon; and (4) systemic impacts of self-tracking on health care and the actors involved.

Conclusions: This systematic literature review contributes to research and practice by assisting future research activities and providing practitioners with a concise overview of the state of the art of self-tracking and the quantified self.

KEYWORDS

self-tracking; quantified self; health; well-being; systematic literature review; literature review

Introduction

Self-tracking—also referred to as the quantified self, self-monitoring, lifelogging, personal analytics, and personal informatics [1]—has become pervasive in people's daily lives and increasingly common in health care. For example, health and fitness ranked ninth out of 34 categories on the App Store, accounting for 3.41% of all the available apps [2,3]. In Google Play, health and fitness apps ranked 13th out of 33, accounting for 3.53% of all the available apps [4]. Moreover, the App Store hosted 48,608 apps for health care purposes, and Google Play 47,140 in the third quarter during 2020 [5,6]. Although global smartwatch shipments have been estimated to exceed 100 million units in 2020 and continue to grow in 2021 [7], self-tracking tools have become available for increasing numbers of people across the globe.

Research on self-tracking and the quantified self has proliferated rapidly in recent years [8-14]. This growth calls for review studies that help enrich the knowledge base by classifying and synthesizing prior research and providing directions for future research activities [15,16]. However, dedicated review studies are scant in the most recent literature on self-tracking and the quantified self. Altogether, the extant literature features 8 review studies [17-24], of which 5 have been published in journals [17-19,22,24] and 3 in conference proceedings [20,21,23].

Moreover, some of the prior review studies have not focused exclusively on self-tracking or the quantified self. For example, Paton et al [18] focused on wearable self-tracking devices, social media platforms used by the self-tracking community, and personal health records. West et al [19] conducted a review of self-tracking in the context of patient-generated data, whereas Lentferink et al [24] identified the key components of self-tracking and persuasive eCoaching in automated healthy lifestyle interventions to improve the design of these interventions. Therefore, a review focusing only on the quantified self and self-tracking is needed.

Third, with respect to the scope, prior review studies have typically focused on a certain subset of the literature. For example, Moya et al [20] focused on the adoption and utilization of self-tracking technologies. Almalki et al [17] limited their scope to studies that applied activity theory for health self-quantification. Jiang and Cameron [22] only focused on self-monitoring in the context of chronic disease. Furthermore, most of the extant reviews covered a relatively small number of studies. The number of studies covered by the prior reviews are 43 [21], 32 [24], 28 [23], 26 [17], and 23 [19] respectively, and one of the prior reviews did not clearly mention the number of reviewed studies. Considering these limitations in terms of the scope of prior reviews and the increasing research volume on self-tracking and the quantified self, there is a need for an up-to-date and comprehensive literature review.

To address this gap in the literature, we undertook a systematic literature review (SLR) of the research on self-tracking and the quantified self in terms of health and well-being. The purpose of this study can be summarized as follows: (1) to identify high-quality contributions in the area, (2) to classify the literature based on publication channels, research methods, theoretical backgrounds, and variables used, (3) to synthesize the main research areas and research themes, and (4) to identify future research directions. The final pool of the reviewed articles comprised 67 empirical studies.

We mapped the research subjects of the reviewed articles and identified three main stakeholder groups: end users, patients and people with illnesses, and health care professionals and caregivers. For the end users, the primary usage of self-tracking is for tracking exercise, daily activity levels, and sleep. For the two other stakeholder groups (ie, patients and people with illnesses as well as health care professionals and caregivers), the primary usage of self-tracking is to support the treatment of an illness or other medical conditions. We further used these stakeholder groups for clustering the research themes of the reviewed studies. By mapping the research themes, examining the focal constructs of the prior studies, synthesizing the future research directions, and finally reflecting on the findings and suggesting new research areas, this study aids in building future research efforts [15,16].

The remainder of the paper is structured as follows. The background and related works are discussed next followed by the research methodology and details of the article selection procedure. Then, we report the results of the analysis. Finally, the implications, limitations, and some directions for future research are discussed. Multimedia Appendix 1 presents the article search strategy. Multimedia Appendix 2 contains the quality assessment criteria used for selecting the articles to be included in the review. Multimedia Appendices 3, 4, and 5 contain detailed information about the reviewed articles. Multimedia Appendix 6 presents a summary of the reviewed studies based on their foci and research theme matrices.

Background and Related Works

Self-tracking and the Quantified Self

Self-tracking and the quantified self are not new labels. As early as the 1970s, wearable computers for self-tracking were used as forms of personal surveillance [25]. In 2001, a small number of media practitioners began to use newly available digital technology to track their daily life for designing web 1.0 interfaces [26]. According to Lupton [1], self-tracking "involves practices in which people knowingly and purposively collect information about themselves, which they then review and consider applying in their lives."

As further pointed out by Lupton [1], in addition to self-tracking, there are several other terms—such as lifelogging, personal informatics, and the quantified self—used to describe the practices by which people may seek to monitor their everyday life. Lifelogging can be viewed as the practice of recording information about one's life using digital tools. Personal informatics is a term used mostly in the academic human-computer interaction community [1]. The concept of the "quantified self," originally coined by Wolf and Kelly in 2007, refers to "self-knowledge through numbers" [1]. They used quantitative data as a means or an embodiment of monitoring the elements of everyday life. The term can be further viewed as a collaboration between users and toolmakers [27], a cultural phenomenon involving technology [8], and an

outcome of self-tracking [28]. In fact, the original intention of Wolf and Kelly was to use the term "the quantified self" to describe this digital self-tracking phenomenon [1].

Health and Well-being

According to the World Health Organization, health is explicitly linked with well-being, which is "a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity" [29]. With the development and diffusion of wearable, wireless communication, and cloud computing technologies, self-tracking devices can not only provide data, but also refine them into key performance indicators and produce visualizations of these data. People use self-tracking technologies to self-collect personal data including biological, physical, behavioral, or environmental information [30,31]. Moreover, according to Lupton (2016), the domain of self-tracking today also includes relationships and work productivity. In the scope of self-tracking or the quantified self, health and well-being are the main tracking domains. People who knowingly and purposively track their health and well-being information (such as heart rate, sleep, physical activity, calories, clinical symptoms, stress, and recovery) to review and modify their lives widely use self-tracking devices.

Related Works

Self-tracking and the quantified self have been examined in various disciplines and from various theoretical and methodological premises. For example, the computer science research field has examined wearable augmented reality systems based on walking locomotion analysis [32] and developed algorithms for monitoring sleep [33]. The relevant literature also indicates certain design considerations, such as presenting negative data in a way that does not demotivate users [34]. Communication research has discussed topics such as self-tracking as a communicative phenomenon with social media, the self, and social networks of peers [35]. Furthermore, sociological studies have discussed ways of attributing meaning to data-gathering practices in terms of the quantified self [36]. Prior literature also includes research focusing on the societal and ethical concerns regarding self-tracking [37], including the value of personalized health care. In medicine, prior studies have explored the clinical experience of self-tracking technologies in the context of chronic diseases [38,39] and use of self-tracking devices in rehabilitation [40,41]. Finally, research on information systems has examined themes such as user acceptance of self-tracking, user motivation, and goal attainment related to self-tracking and the quantified self [42-44].

To keep the scope of the study manageable, we deliberately focused on self-tracking and the quantified self, executed via devices, apps, and platforms, and excluded digital diaries and video recordings to focus solely on the role of self-tracking in health and well-being. Moreover, we focused on empirical research where the primary research subjects are humans. Thus, purely technical papers and articles focusing on products, services, and markets were excluded.

Methods

Research Questions

The purpose of the SLR is to determine the current state of research on self-tracking and the quantified self in the domain of health and well-being. To this end, we address 6 specific research questions (RQs) that are presented in Table 1.

Table 1. Research questions.

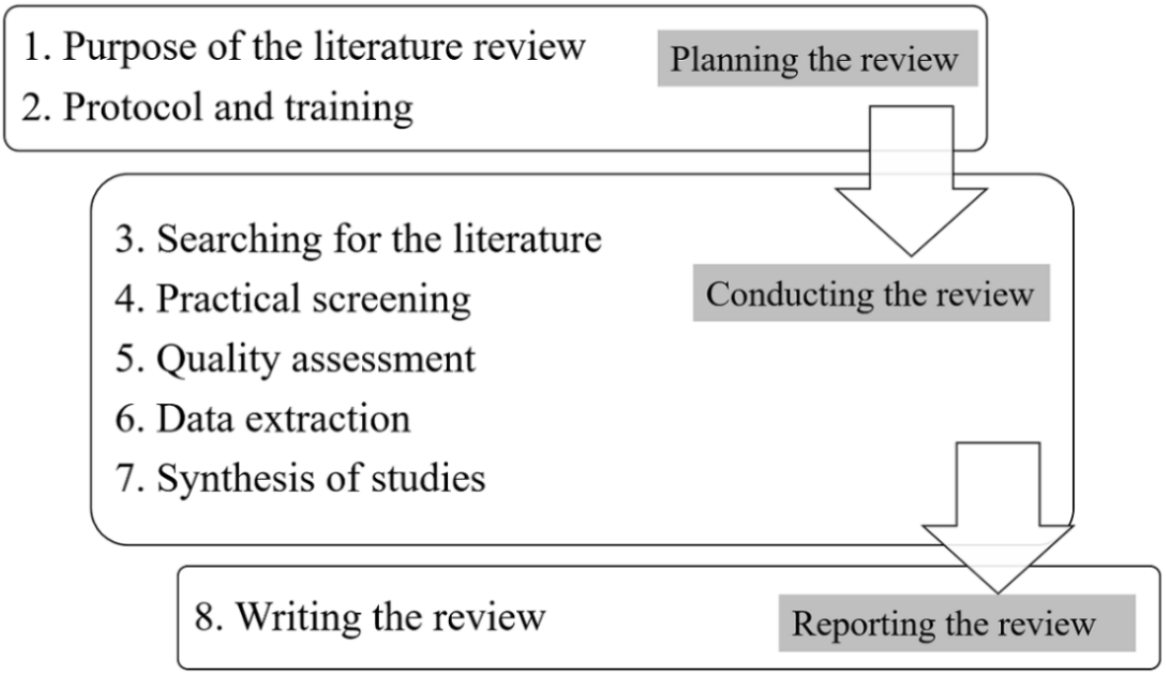
Number	Research question
RQ1[a]	How has the volume of publications on self-tracking and the quantified self in the domain of health and well-being evolved?
RQ2	What are the most important publication channels?
RQ3	What research methods have been used?
RQ4	What theoretical backgrounds and variables have been employed?
RQ5	What recurring research themes can be identified from the literature?
RQ6	What future research directions can be synthesized from the literature?

[a]RQ: research question.

Research Design

SLRs have been developed as a specific method for identifying and synthesizing research findings [45]. They are considered particularly useful to disseminate the key findings of large and complex bodies of research. SLRs employ a transparent and rigorous approach (review protocol) to identify and synthesize all available research findings of sufficient quality concerning a specific research question or subject [46]. According to Victor [47], an SLR differs from a traditional literature review owing to its specific emphasis on the following features: (1) comprehensive coverage of the literature as far as possible; (2) paying careful attention to the quality of the included evidence; (3) taking a clear, systematic approach to data synthesis, and (4) generally following transparent and rigorous processes. In this research, we followed a well-established 8-step review protocol [48]. Figure 1 summarizes the review process.

Figure 1. Review process.



Database and Search Syntax

Articles were obtained from five academic databases: Scopus, Web of Science, PubMed, Taylor & Francis, and the Association for Information Systems eLibrary. The search strategy included keywords such as "self-track*," "self track*," "quantified self," "quantified-self," "self quantif*," and "self-quantif*." We limited the search to journal and conference papers published in English. After conducting the literature search in the 5 databases, we eliminated duplicates. The details of the search strategy are shown in Multimedia Appendix 1.

Inclusion and Exclusion Criteria

Two authors (SF and MM) conducted the inclusion/exclusion procedure, prepared notes, and exchanged information throughout the process. Citation chaining was conducted to further reinforce the comprehensiveness of the article search. Textbox 1 presents the inclusion and exclusion criteria.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria (IC)
IC1: Studies with the main topic (title/abstract/keywords) containing self-tracking or the quantified self
IC2: Studies published in a peer-reviewed journal or scientific conference
IC3: Studies published in English
IC4: Studies with title/keywords/abstract-based screening
IC5: Studies with full-text–based screening
IC6: Studies with humans as primary empirical research subjects
IC7: Studies based on citation chaining
Exclusion criteria (EC)
EC1: Studies with matching title and digital object identifiers
EC2: Studies whose main topic is not self-tracking or the quantified self (digitized self-tracking and self-quantification via mobile devices, apps, and platforms; ignore diary and video recordings)
EC3: Studies where the purpose of the paper is not improving health and well-being
EC4: Studies that are not empirical studies (literature reviews, conceptual papers, technical papers, or editorials)
EC5: Studies in which the primary empirical subjects are not human, such as products, services, or markets
EC6: Studies based on quality assessment

Quality Assessment

Quality assessment is a step in the SLR process conducted to ensure that the results of the review are suitable and impartial by identifying the articles that are not of sufficient quality to be included in the sample pool in an objective and replicable manner [48]. The quality assessment protocol incorporates the research method, structuring, implications (contributions or implications), and limitations, and ranking of the publication channel. The maximum total score from the assessment was 8.5. The criteria for quality assessment are presented in Table 2. To further ensure the high quality of the articles included in the review, we followed the approach proposed by Idri et al [49] and Behera et al [50] and set 50% of the maximum quality score as the threshold for a paper to be included in the in-depth review. Hence, 17 articles that received a total score of less than half of the maximum score (ie, 4.25) were omitted from the review. The quality score of each article can be found in Multimedia Appendix 2.

Table 2. Quality assessment criteria.

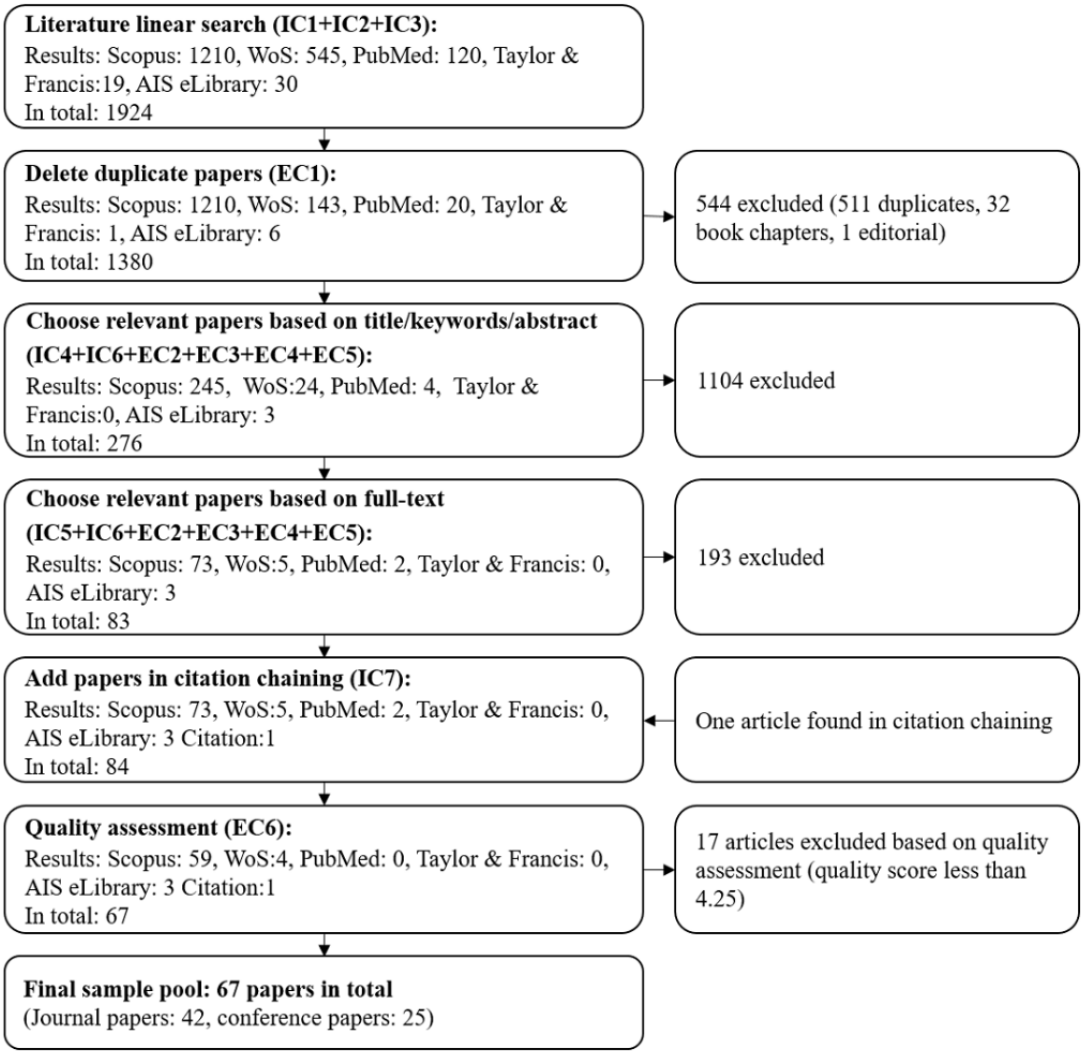
Criterion	Description	References
QA1[a]	The empirical study adopts a qualitative, quantitative, or mixed method approach. The possible answers are mixed method (+2), and quantitative or qualitative research (+1).	[50]
QA2	The study is a fully structured article divided into four basic sections: introduction, methods, results, and discussion. The answers are Yes (+1) and No (+0).	[51]
QA3	The study unequivocally describes the research process in sufficient detail. A quantitative study shows the questionnaire items, a qualitative one the coding and categorization process, and an experimental one the details of the experiment. The answers are Yes (+2), Partially (+1), and No (+0).	[17]
QA4	The study clearly documents the research implications (contributions or implications) and limitations. The answers are Yes (+2), Partially (+1), and No (+0).	[50]
QA5	The study was published in a reliable and recognized publication journal.	[49,52]
	Based on Journal Citation Reports (JCR: an annual publication that provides information about academic journals with impact factor data): journal in the top 25% (Q1 +1.5), in the 25%–50% group (Q2 +1), in the 50%–100% group (Q3 or Q4 +0.5), and no JCR ranking (+0).	
	Conference ranking based on CORE (conference ranking portal): CORE A* or A (+1.5), CORE B (+1), CORE C (+0.5), and no CORE ranking (+0).	

[a]QA: quality assessment.

Pool of Articles Included in the Review

Finally, 67 articles were selected as the final sample, of which 42 were journal articles and 25 articles were published in conference proceedings. Figure 2 presents the pool of articles in each stage of the inclusion and exclusion procedure.

Figure 2. Inclusion and exclusion procedure. AIS: Association for Information Systems; IC: inclusion criterion; EC: exclusion criterion; WoS: Web of Science.



Results

RQs 1 and 2: Publications by Year and Channel

In the pool of articles included in the review, the first was published in 2013. As shown in Figure 3, the number of papers published per year increased from 2013 until 2019. Table 3 presents the most popular publication channels. A considerable proportion of the conference papers appeared in information systems conferences, whereas the journal articles were published mostly in outlets focusing on health.

Figure 3. Articles included in the review by year.

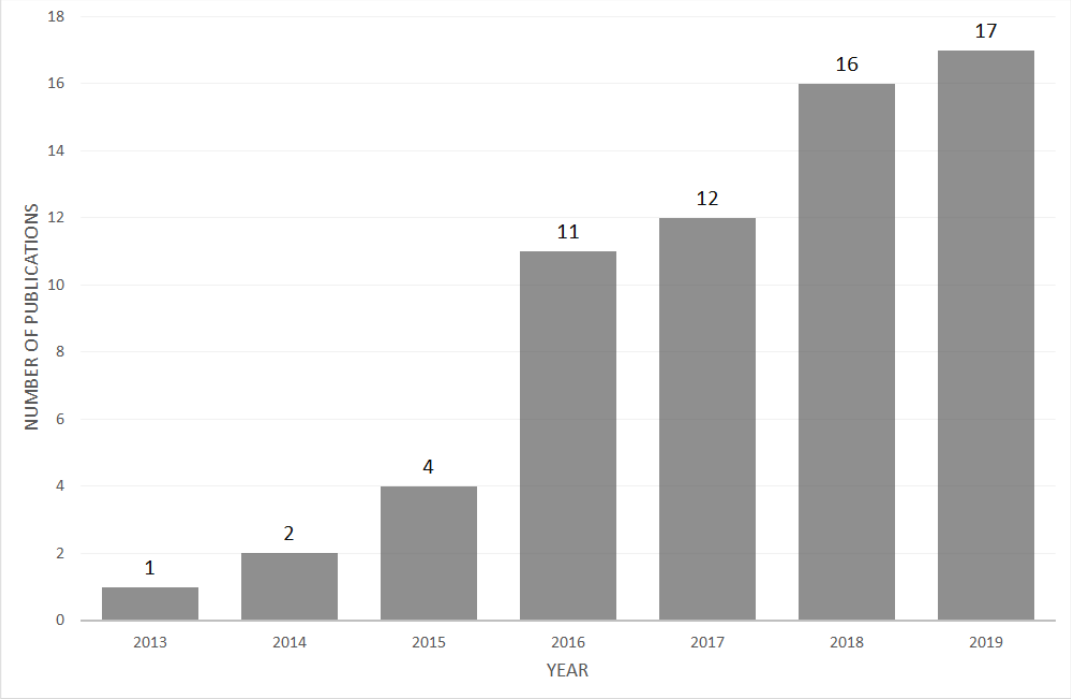


Table 3. Most common publication channels (number of publications greater than 1).

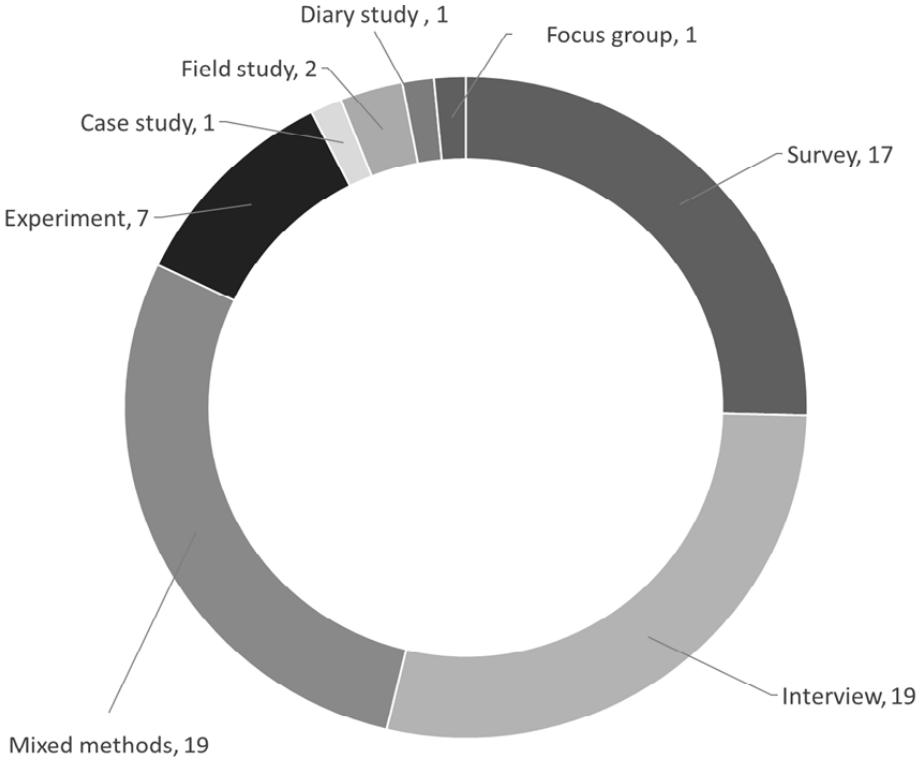
Conference/journal	Number of papers, n (%) (N=67)
Conference	
Conference on Human Factors in Computing Systems	6 (8.96)
Americas Conference on Information Systems	3 (4.48)
Pacific Asia Conference on Information Systems	2 (2.99)
International Conference on Information Systems	2 (2.99)
Other conferences	12 (17.91)
Total	25 (37.31)
Journal	
Computers in Human Behavior	5 (7.46)
JMIR mHealth and uHealth	5 (7.46)
Journal of Medical Internet Research	4 (5.97)
Digital Health	2 (2.99)
Health Sociology Review	2 (2.99)
International Journal of Human-Computer Studies	2 (2.99)
Sociology of Health and Illness	2 (2.99)
Telemedicine and e-Health	2 (2.99)
Other journals	18 (26.87)
Total	42 (62.69)

RQ 3: Distribution of Articles by Study Method

We categorized the pool of studies based on the research methods (see Figure 4). For this purpose, we examined how the empirical data were collected. The 2 most commonly used methodologies were mixed-methods research and interviews. In the mixed-methods research category, combining surveys with interviews was the most frequently used investigative approach. Most of the experimental research was conducted in a longitudinal fashion. Multimedia Appendices 3, 4, and 5 provide more information about the reviewed studies, including theories, methods, and focal constructs.

Figure 4. Pool of articles reviewed by research methods (total number of articles=67).



RQ 4: Theoretical Backgrounds and Variables on Self-tracking and the Quantified Self

In our pool of 67 studies, 39 articles explicitly stated the theoretical foundation on which their studies were based. The remaining articles typically discussed prior literature but did not explicitly build on any theoretical foundation. This includes articles using the grounded theory methodology to build or contribute to theory [38,53-55]. In the aforementioned 39 articles, 18 studies used theories to develop hypotheses and research models to be tested with quantitative methods, whereas in 21 studies, the primary role of the theory was to support qualitative research.

Among the 18 quantitative studies with explicitly stated theoretical backgrounds, the most widely used theoretical lenses were the technology acceptance model (TAM) and self-determination theory. Understandably, these theoretical backgrounds were common among studies focusing on self-tracking behaviors, motivations, goals, and use continuance. Table 4 provides information about the theoretical backgrounds and dependent variables of the studies where the theoretical foundation was explicitly stated. Multimedia Appendices 3, 4, and 5 provide more details about the reviewed articles [56-68].

Table 4. Theoretical backgrounds and dependent variables.

Dependent variable categories	Theory/theories	References
Self-tracking behavior/technology usage		
Habitual web-based fitness community use	Self-determination theory, technology acceptance model	[68]
Number of activities	Social cognitive theory	[56]
Behavior (activity index + sleep index + food index)	Health information technology acceptance model	[57]
Behavior (compliance of self-tracking behavior)	Health information technology acceptance model	[58]
Behavioral intention to use (wearable devices in the workplace)	Self-determination theory, technology acceptance model	[59]
Motivation/goal to use self-tracking technologies		
Classes of motivational designs (gamification, social networking, and self-quantification)	Self-determination theory, social comparison theory, goal-setting theory	[60]
Self-tracking motivation fulfillment	Gimpel five-factor framework of self-tracking motivations	[11]
Continuance intention of self-tracking		
Continuance intention (of using smartwatches)	Net valence framework	[61]
Continuance intention (of using quantified-self technology)	Motivational affordance theory, technology continuance theory	[62]
Continuance intention (of the quantified self)	Trans-theoretical model, expectation-confirmation theory	[63]
Cognitive dissonance when using self-tracking technologies		
Awareness of two inconsistent cognitions, self-tracking usage, and cognitive dissonance	Cognitive dissonance theory	[64-66]
Self-disclosure of personal information		
Self-disclosure (personal information in self-tracking apps)	Stage-based model, five-factor model	[28]
Dependency effect on wearing activity trackers		
Dependency effect (on wearing activity trackers)	Self-determination theory	[10]
Health consciousness, physical and psychological well-being		
Health consciousness, physical health, and psychological well-being	PERMA (positive emotion, engagement, relationships, meaning, accomplishment) model	[67]
Sharing health-tracking records		
Sharing health-tracking records	Health belief model	[27]

In addition to the dependent variables presented in Table 4, we also investigated the independent, mediating, and moderating variables employed in the reviewed studies. Multimedia Appendices 3, 4, and 5 provide more details about the reviewed studies. As depicted in Table 4, the most common dependent variables were self-tracking behavior and device usage, followed by motivation and goal for using self-tracking technologies, and continuance intention of self-tracking. Independent variables in the reviewed studies were normally extracted from theories; for example, perceived ease of use and usefulness were extracted from TAM [57,59,68], 3 strategies for reducing cognitive dissonance from the cognitive dissonance theory [64-66], 5 personality traits from the big-five personality domains [28], and 5-factor motivation (self-entertainment, self-association, self-design, self-discipline, and self-healing) from the Gimpel five-factor framework of self-tracking motivations [11]. Some studies combined theory with self-tracking practices and classified independent variables into more specific categories; for example, Chuah [61] divided perceived benefits into four perspectives, including utilitarian, hedonic, social, and symbolic, and divided perceived risks into privacy-related risks and physical risks. Suh [62] specifically subdivided motivation into hedonic, utilitarian, and eudaemonic (refers to self-fulfillment and self-improvement) motivations. In addition, Hamari [60] specifically described three independent variables: goal focus (outcome and process), goal orientation (proving, avoidance, and mastery), and goal attributes (difficulty and specificity).

In addition to the aforementioned dependent variables, the reviewed literature has covered various other variables. For example, perceived empowerment and personalization had mediating effects between self-tracking technology and advice compliance [69]. Intrinsic motivation was identified a mediator between need for cognitive closure and the dependency effect on self-tracking technologies [10]. When using smartwatches, inspiration and well-being played a mediating role between the perceived benefits and risks, and continuance intention [61]. Perceived threat, perceived usefulness, perceived ease of use mediated consumers' health statuses, beliefs and concerns, subjective norms, and self-efficacy to attitude [57]. Finally, prior research has also explored the moderating effects of demographics such as gender, education, income [70], and BMI [69].

RQ 5: Themes in the Existing Literature

To structure the literature analysis, we developed a classification scheme. To this end, we applied the concept matrix approach presented by Webster and Watson [71]. A concept matrix represents a logical method of defining a set of "concepts" according to which the reviewed articles can be classified.

We first identified the focus of each reviewed article based on its title, abstract, research question/objective, and results. Thereafter, we classified the articles based on the subjects of the empirical research. This led to the formation of three stakeholder groups, namely end users, patients and people with illnesses, and health care professionals and caregivers. The studies adopting the end-user perspective focused on self-tracking related to personal health, well-being, fitness, or sleep. The second, (ie, the patients' perspectives) focused on self-tracking use usage cases related to treatment of illnesses. The third, (ie, the health care professional and caregiver perspectives) focused on treatment of illnesses and medical conditions, but the primary users are the patients' doctors, nurses, or family members. Consequently, we used the perspectives of these stakeholder groups to establish a concept matrix. Finally, we classified the studies into 11 themes that will be discussed in the following section. Multimedia Appendix 6 presents a summary of the reviewed studies based on their foci and research theme matrices.

Stakeholder Group 1: End Users

(1) User Motivation and Goal Setting

With respect to the studies that adopted the end users' perspectives, user motivation constitutes an important stream of research. Most of the research examined the motivation for self-tracking usage [10-12,62,72]. In their research, Attig and Franke [10] divided the motivation for tracking physical activity into intrinsic and extrinsic motivations. The results revealed that people with strong extrinsic motivation may be highly dependent on the use of the tracking devices. Suh [62] classified motivation into hedonic, utilitarian, and eudaemonic. The results illustrated that unlike hedonic motivation, utilitarian and eudaemonic motivations positively impact continuance intention use of self-tracking technologies. Further, Pingo and Narayan [12] suggested that users may experience gratification when they can use tracking devices to control their health status. To clarify the reason for the usage of tracking devices, Gimpel et al [44] employed a survey to develop a five-factor framework of self-tracking motivations. The factors were self-entertainment, self-association, self-design, self-discipline, and self-healing. Gimpel et al [11] also illustrated that only the motivation for self-entertainment increases the wearable self-tracking device usage, which in turn influences the fulfillment of the self-entertainment motivation. Baudier et al [59] also emphasized that self-entertainment and self-design have a positive effect on the behavioral intention to use the health care Internet of Things in the workplace.

In prior research, goal setting and motivation always appeared at the same time. Gordon et al [13] found that users of weight loss–tracking apps preferred to choose achieving goals as their motivation. Self-monitoring motivation and attitude toward weight loss goals are vital for predicting goal achievement. For fitness tracking apps and exercise encouragement apps, Rockmann and Gewald [14], and Hamari et al [60] noted individual differences and found that different motivational affordances, such as self-quantification, gamification, and social networking capabilities, help users achieve their goals.

(2) Usage and Effects of Self-tracking

The second cluster under the end users' perspective focused on the different uses of self-tracking and the outcomes of usage. With respect to the different uses and use cases, prior research has explored the use of self-tracking for physical activities [8,9,35,57,58,73-77], sleep [57,58,74,78], diet [57,58], fertility [55], caloric intake [79], and alcohol-harm reduction [80].

Prior literature also provides classifications of users and self-tracking tools. Makkonen et al [81] identified 4 distinct consumer segments of self-tracking based on their technology adoption patterns: pro-trackers, semitrackers, interested trackers, and nontrackers. In the context of app usage for alcohol consumption reduction, Milward et al [80] identified three types of users: the trackers, cut-downers, and non-committers. Spotswood et al [9] explored the role of self-tracking in supporting healthy behavior and found three mechanisms for teleoaffective shaping: labeling, rewarding, and materializing effort. Lyall and Robards [82] identified three roles of self-tracking devices for the user, namely as a tool, toy, and tutor.

Moreover, previous research has explored the outcomes of self-tracking. Shin and Biocca [63] noted that health consciousness is the most significant factor for staying healthy. Stiglbauer, Weber, and Batinic [67] proved that wearing a fitness tracking device can make users more conscious regarding their physical health but did not have a significant effect on their mental health. Furthermore, according to Ravichandran [78], sleep-tracking devices can help users better understand and improve their overall sleep habits. Rönkkö [74] proposed that certain design features such as graphical feedback, information sharing, and social communities in self-tracking devices may be particularly important in contributing toward positive lifestyle changes, with the most important factor being the presence of personal long-term goals.

(3) Continuance Intention and Long-term Usage

The third cluster of studies from the end users' perspectives focused on sustained usage of self-tracking and the quantified self. For example, Chuah [61] found that the perceived benefits (utilitarian, hedonic, social, and symbolic) indirectly affect users' continuance intentions regarding smartwatch use through inspiration and well-being. Shin and Biocca [63] investigated the relative effects of hedonic and utilitarian motives as determinants of confirmation, satisfaction, and continuance intention regarding wearable devices. In contrast, Suh [62] observed that hedonic motivation has a negative influence on the continuance intention when using self-tracking devices, but utilitarian and eudaemonic motivations have a positive effect. As for web-based fitness community usage, Stragier et al [68] proposed that self-regulatory and social motives directly predict sustained web-based fitness community usage. Rockmann et al

[83] also theorized an emotional "carry-over effect" in activity continuance decisions on activity tracking.

With respect to the long-term use of self-tracking and the quantified self, Hardey [84] employed a mixed-methods approach and found that visualization and a long-term healthy state motivate and support long-term tracking. In addition, Meyer et al [85] built 5 use cases for personal health devices that can be used as a long- and short-term comparison list. The five use cases are supporting health behavior, improved self-understanding, identification of trends and relations, decision-making, and data collection for future use.

(4) Management of Personal Data

The fourth cluster of studies from the end users' perspectives emphasized managing personal data. This comprises two subtopics: coping with personal data and privacy concerns. Feng et al [86] showed that people preferred to use health or fitness apps as their personal health information management tools, and the most popular app was Fitbit. When reflecting on the personal data stored on self-tracking devices, Maltseva and Lutz [28] proposed that individuals who habitually use self-tracking apps and devices are more likely to self-disclose their personal data. When self-tracking devices are to social networks, the proportion of lower-performing friends may positively influence users' physical activities [56]. Moreover, Yli-Kauhaluoma and Pantzar [87] examined the gap between individual experiences and self-tracking data. They found that individuals always feel upset and confused when comparing invisible or inaccurate personal health data with their daily experiences and may eventually refuse to use self-tracking devices. In another words, individuals may experience an emotional reaction, which can then stop changing their behavior [43].

Literature has also documented problems related to tracking, managing, visualizing, and using personal data [88]. Privacy issues are obviously a central concern related to sharing self-tracking data. Chen et al [89] examined the sharing of health data among college students. Their results implied that users are generally willing to share personal health data for research purposes, and the reasons for not sharing are related to privacy concerns. Gui et al [53] pointed out that when fitness devices are connected to social networks, users are encouraged to share fitness data. However, the challenges of balancing awareness and privacy issues were still prevalent. To solve this problem, Zimmer [90] employed the communication privacy management theory to better understand the privacy boundaries related to personal fitness information and found that the advantages outweigh the disadvantages.

(5) Rejection and Discontinuance

The fifth cluster of studies from the end users' perspectives relates to rejection and discontinuance. In their study of experiences during the implementation of self-tracking technology, Kari et al [42] found that the experience during the initial phase of implementation will influence the decision on adoption or rejection. Moreover, previous studies have found that the abandonment of wearable fitness tracking devices can be owing to a loss of motivation, low acceptance levels for such devices, or inaccuracy and uselessness [91]. Harrison et al [92] cited tracking accuracy and device aesthetics as barriers to activity tracking. Esmonde [93] identified the following 4 strategies of resistance used by people to datafication in fitness tracking practices: excessive labeling of some forms of data rather than tracking everything, choosing not to track every day, acknowledging that they cannot be perfect and track without interruption like a machine, and accepting that people's feelings are more important than data.

(6) User Characteristics

The sixth subset of studies under the end users' perspectives focused on user characteristics. McKinney et al [94] showed that in self-tracking of food and activity levels, high health literacy supports health goals, which comprises proper understanding of a record and how to use data to support a health goal and the awareness of privacy and ownership. The digital divide may also influence the adoption of self-tracking and the quantified self [95]. According to Régnier and Chauvel, better-off individuals use self-tracking more than the socially disadvantaged [95]. In addition, Baumgart conducted a series of studies to investigate the interaction of self-tracking with users' cognitions, behaviors, and emotions [64-66].

Stakeholder Group 2: Patients and People With Illnesses

(1) Usage Experience of Patients and People With Illnesses

In the clinical context, patients, and doctors need to track health records for symptoms or contemporary sensor data. The feasibility and acceptability of using tracking technology may differ from that of healthy individuals. Beukenhorst et al [96] focused on the feasibility and acceptability of smartwatches in patients with knee osteoarthritis; people expressed enthusiasm for self-tracking of health data, but there were barriers to full engagement, such as limited battery lives, technical issues, and unfulfilled expectations. Kim et al [54] conducted a food logger applicability test on patients, and their results demonstrated a high adherence rate. However, wrong and unreasonable usage of weight loss apps may contribute to and exacerbate eating disorders [97]. Self-tracking also demonstrated potential in managing chronic diseases and rehabilitation. Goal-directed self-tracking can help people be well prepared in all stages and support chronic condition management [98]. Mishra et al [99] researched how tracking apps and technologies helped patients cope with Parkinson disease. Furthermore, Vogel et al [40] provided evidence for the positive effects of self-tracking technology on a patient's cardiovascular system.

(2) Management of Patient-Generated Data

Patient-generated data for clinical purposes have also attracted research attention. Ancker et al [39] examined personal data tracking for people with multiple chronic conditions, revealing that health-tracking data may come at an emotional cost, such as depression and anxiety, which could ultimately lead to low adoption levels for consumer health information technology. Ivanov et al [27] provided insights into the influencing factors for sharing health-tracking data. They found that health motivation, the severity of the health problem or condition, and age positively influenced patients to share data with professors.

People who had a certain perceived health status preferred to share data with an acquaintance.

(3) Advantages and Disadvantages of Self-tracking in the Clinical Context

Literature contains specialized research on the advantages and disadvantages of self-tracking in the clinical context. With the development of tracking technology, the clinical context now provides more agency, control, and information for patients, which can help them establish a relationship with professionals [100]. Piras and Miele [38] supported this idea, stating that self-tracking mediates the patient–doctor relationship.

As for the disadvantages of self-tracking, collaborations between patients and professionals involving personal data can easily cause misunderstandings regarding the patient-generated data usage, duration, and type of tracked data. There are also patient privacy issues to address [101]. In terms of special disorders, such as Parkinson disease, Riggare et al [102] indicated that self-tracking gives people a deeper understanding of their motor or nonmotor symptoms and contributes to decision-making regarding their self-care. However, the tracking workload is heavy. It is difficult to know what and how to track, and it is also difficult to ignore the risks of obsessive tracking. Therefore, it is necessary to find a proper balance between burdens and benefits [102].

Stakeholder Group 3: Health Care Professionals and Caregivers

(1) Collaboration Among Patients, Health Care Professionals, and Caregivers

Self-tracking technology provides an easier way to collect patients' health information. Health care professionals are also willing to accept self-tracking data to assess the health status of patients [39]. Therefore, patient-provider collaborations with respect to patient-generated data became one of the research topics for self-tracking usage in clinical setting. In a previous study, Chung et al [101] used a stage-based model of personal informatics and the theory of boundary negotiating artifacts to explain misunderstandings and privacy concerns in the collaboration stage. Prior research has also demonstrated that tracking apps and technologies helped patients cope with Parkinson disease. Based on the tracking data, health care partners who are friends and family members can significantly help Parkinson patients adopt positive strategies [99].

(2) Changes in the Roles of Patients and Professionals

Tracking technology has also shifted the roles of patients and doctors. Owing to these technological changes, patients become health managers, and doctors are health organizers [103]. Schroeder et al [98] showed that goal-directed self-tracking can help people in setting goals, preparing knowledge, and contributing to the patient-doctor collaboration. Piras and Miele [38] supported this idea, stating that patients can negotiate a satisfactory relationship with their health care providers when using self-tracking. However, there is still a gap between users, experts, and self-tracking technologies [78]. To gain a professional view of self-tracking in clinical usage, prior research has collected data from doctors, such as in the study by Gabriels and Moerenhout [103]. They conducted an interview study to explore how medical doctors evaluate self-tracking methods and the changes after using those methods. Gabriels and Moerenhout found that regarding self-care, it is important to emphasize the contextual facets of self-tracking and the involvement of the health care professionals [103].

RQ 6: Directions for Future Research Identified From the Literature

Following our analysis of the themes in the extant literature on self-tracking and the quantified self, we move on to describing future research directions presented in the reviewed literature. Based on the analyses and conclusions, we propose 2 perspectives with 5 main future research directions from the reviewed literature: 2 from the perspective of research design, and 3 from the perspective of research topics (see Table 5).

Table 5. Directions for future research.

Perspective	Future research direction	Description
Research design	Employment of longitudinal research designs	Investigate the influence variables corresponding to different usage stages; changes in the evolution of an individual's acceptance level and self-disclosure over time [28,59,91,99].
Research design	User modalities: regular users, intermittent users, nonusers, and former users	Nonuser group: nonusers and their goal orientations and perceptions about the affordances [14,102]
		Former users: comparative studies with short-term and long-term users to identify barriers; people who effectively quit using web-based fitness communities and wearables [53,68]
		Intermittent users, nonusers, and former users [95]
Research topics	Issues related to data sharing and privacy	Data sharing: active sharing and comparing of digital activity data; employees' attitudes about sharing data; browsing others' tracking data and sharing one's own tracking data; means of sharing health-tracking records [8,27,56,104]
		Privacy and security: personal data privacy and security challenges; privacy awareness; perceived risks around data privacy for employees [27,59,105]
Research topics	Psychological and behavioral aspects of self-tracking	Dependent variables: willingness to make in-app purchases; personal health information management; underlying motivations; decisions of consumers to adopt a self‐tracking technology [61,81,86]
		Independent variables: intrinsic and extrinsic motivation, health literacy, duration of self-tracking, number of devices, level of analysis, and demographic characteristics [10,43,55]
		Moderator variables: individual characteristics and personality types [60]
Research topics	Self-tracking in clinical use	Health-tracking data and patient–doctor relationship: whether and how the data are integrated into the patient–doctor relationship; patient–provider interactions with self-tracking data [101,103]
		Patients' and doctors' attitudes toward self-tracking: exploring doctors' communication needs and perspectives and patients' experiences [99,103]

Research Designs Suggested in the Literature

(1) Employment of Longitudinal Research Designs

Changing habits typically takes time, and changes in people's health often occur over time. Moreover, in different stages of usage, people may have different feelings or intentions, and engagement with their health data may change over time [106]. Prior research has extensively underscored the importance of this evolution over time and that of longitudinal research [28,59,91,99]. A longitudinal research design may also provide a better understanding of the causalities by observing and explaining changes over time [28,91]. Therefore, future studies should pay close attention to the evolution of the aforementioned aspects over time. A series of interesting topics were mentioned in prior research. First, the evolution of consumers' acceptance level could be used to discover users' attitudes and identify the barriers for continued usage [59]. Second, in clinical settings, changes in the roles of caregivers (friends and family members who manage the patients' diseases) in helping patients' self-tracking should be identified via longitudinal research [99].

(2) User Modalities: Regular Users, Intermittent Users, Nonusers, and Former Users

As a second research direction, prior research has identified the need to shift focus from the mainstream users of self-tracking toward an increased emphasis on the modalities of use, namely intermittent users, nonusers, or prior users of self-tracking [14,53,68,95,102]. In extant literature, intermittent users comprise those who use self-tracking and self-quantification but not on a regular basis [95,99]. On the other hand, nonusers are those who are reluctant to adopt self-tracking technologies in all social milieus [95]. Former users are those who have used self-tracking or self-quantification in the past but have quit [68,95]. Focusing on the non-mainstream groups to identify and reduce the burden of self-tracking [102] as well as discovering ways to attract new users [14] are topics worthy of future research.

Research Topics Suggested in the Literature

(1) Issues Related to Data Sharing and Privacy

Issues related to sharing data generated by self-tracking, data privacy, and security have frequently been proposed as areas for future research [8,27,56,59,104,105]. Different experiences and concerns may promote different attitudes toward sharing personal data [104]. For example, Zhou et al [56] indicated that sharing self-tracking data may enable social comparisons. Furthermore, multiplatform and cross-platform data sharing has become a common phenomenon, which has consequently created challenges in terms of data privacy and security [27,105]. The tracking process of data collection, analysis, and storage also raises ethical issues [59].

(2) Psychological and Behavioral Aspects of Self-tracking

Psychological and behavioral research encompasses themes such as users' behaviors, attitudes, intentions, acceptance of technologies, and their respective motivations. The literature on motivation for personal health information management can provide new ideas to improve research design [86]. Existing research shows that future research will benefit from exploring the antecedents of the adoption decisions from a microlevel perspective [81]. Moreover, as the freemium business model is extremely popular among various web-based services and software firms [107,108], existing research highlights that future research could examine consumers' willingness to make in-app purchases in the context of self-tracking and the quantified self [61].

In terms of independent variables, the subdivisions of intrinsic and extrinsic motivations should be considered in the research on usage [10]. In addition, the demographic characteristics, such as the educational level, socioeconomic status, and cultural background, could be examined as predictors of self-tracking usage [55]. Hamari et al [60] recommend that individual characteristics and personality types can be regarded as moderating variables of goal setting and the perception of motivational design.

(3) Self-tracking in Clinical Use

With respect to the clinical apps of self-tracking, prior research has highlighted 2 specific areas for future research. The first direction involves health-tracking data and the patient-doctor relationship [38,100,101]. For example, future studies could explore the patient-doctor interaction with self-tracking in different clinical settings [101] and integrate the health-tracking data in the patient-doctor relationship [103]. Second, patients' and doctors' attitudes toward self-tracking also play important roles in clinical research. Patient usage experiments and the feasibility and acceptability of self-tracking should be investigated in the future [103]. As pointed out by Mishra et al [99], self-tracking can help patients communicate with clinicians. Thus, understanding clinicians' communication needs and attitudes toward self-tracking represents another viable future research area.

Discussion

Key Findings

The purpose of this study was to identify the state of the art in self-tracking and the quantified self in health and well-being. To this end, we conducted an SLR of 67 articles, comprising 42 journal articles and 25 conference papers. We have presented the development of the number of publications over time. We also identified the key academic outlets that published research on self-tracking and the quantified self, and the most prevalent research methods and theoretical foundations.

Our results demonstrate that the outputs provided by self-tracking can be used by various stakeholders. By classifying the stakeholders into end users, patients and people with illnesses, and health care professionals and caregivers, and investigating the focal themes of prior research across these 3 groups, our review provides a structured view of the extant body of knowledge. Moreover, we have classified the future research directions provided in the reviewed studies into two categories: suggestions focusing on research designs and suggestions focusing on research topics. Against this backdrop, we highlight three main findings related to the research subjects, research designs, and the role of theory stemming from the reviewed literature.

First, with respect to the stakeholders being considered as the research subjects, our results demonstrate that of the 67 studies that qualified for the review, the majority (54) focused on end users who use self-tracking to obtain feedback on their sport and fitness activities, daily activity levels, and sleep. Although self-tracking technologies are increasingly invading various clinical settings, we claim that adopting a multi-stakeholder perspective to a greater extent could be a beneficial avenue to advance research in this area.

Second, with respect to research design, considering that in many use cases reaping the potential benefits of the self-tracking requires sustained engagement in the process and use of these technologies, it is not surprising that self-tracking continuance is a key focal area of the reviewed literature. The temporal perspective has also been incorporated in the research design as 21 of the 67 reviewed studies feature longitudinal research. This observation also echoes the notion that employment of longitudinal research methods is one of the key future research directions suggested in the reviewed literature.

Third, with respect to the role of theory, 28 out of the 67 reviewed studies did not explicate or build on any theoretical foundation. In light of this observation, there is still scope for more theory-oriented research to reinforce the theoretical and conceptual foundations and enrich the knowledge base on self-tracking and the quantified self.

Limitations

The results and implications of this review should be evaluated in the light of its limitations. There are 2 main limitations to this review that must be acknowledged. First, the scope of the review is limited by the keywords used in the article search. We specifically employed only "self-tracking" and "quantified self" as the search terms. Consequently, superordinate and subordinate words were not included in the literature search. Second, to keep the scope of the review manageable, we focused solely on empirical articles. Therefore, future research could cover nonempirical research and the superordinate and subordinate keywords of self-tracking and the quantified self.

Future Research Directions

By presenting and summarizing the key studies in the existing body of literature in a systematic fashion, this review will assist future research activities and thus accelerate the development of the relevant research areas. To this end, our review has outlined the theories and methods used in the extant literature. Moreover, we constructed a research theme matrix from three stakeholders' perspectives and identified 5 main future research directions provided in the reviewed literature. Beyond these contributions to research and practice, we delineate 4 primary future research directions based on our observations and

reflections of the current review and provide our views on the shortcomings and limitations of the extant literature that future studies could address.

First, surprisingly few studies in our review have focused on investigating how people perceive and interpret the information produced by tracking devices [9,13,56,83]. Although studies have examined the behavioral outcomes of self-tracking, the human information processing aspects seem to have received less attention. There are two groups of factors that largely determine how users perceive information from self-tracking, namely their cognitive processes and the information along with the way the information is being provided to the users. Thus, we suggest that future research should determine how people make sense of the information produced by self-tracking to ensure that this information fits the cognitive style and knowledge structure of the users.

Second, our review revealed a significant paucity of empirical research examining the potentially adverse psychological consequences of self-tracking. This is notable considering that there is a well-established body of literature discussing self-tracking and the quantified self from a critical standpoint [109] and a stream of literature scrutinizing the so-called dark side of information technology (IT) [110,111]. Prior research in this area has classified the dark side of IT into five categories: IT-usage-related stress, work overload, interruptions, addiction, and misuse [112]. It is plausible to assume that these phenomena may also occur in relation to self-tracking and self-quantification devices. Thus, future research could, for example, examine whether the use of self-tracking and quantified-self technologies may induce health-related obsessive-compulsive thoughts and behaviors, particularly over time. Moreover, future research could examine the role of technology addiction in the continued use of self-tracking technologies.

Third, pertaining to the level of analysis, most of the reviewed studies have examined self-tracking and the quantified self essentially as individual-level phenomena. However, as argued by Lupton [113] and Sharon [37], the rise of self-tracking and the emergence of a market for health-related products and services can be related to a societal shift toward neoliberal thinking. Neoliberalism is generally associated with policies of economic liberalization. Lupton claims that individuals who use self-tracking technology "have readily adopted the subject of the responsible, entrepreneurial citizen as it is privileged in neoliberal governmentality in seeking to take action to achieve healthy and fit embodiments and engaging in self-governance" [113]. Therefore, the individual is increasingly emphasized in the societal discourse. Against this backdrop, future studies could investigate the group- and community-level implications of self-tracking and quantified self.

Fourth, related to the stakeholder perspective adopted in this study, self-tracking has the potential to reinforce people's sense of agency in terms of understanding their health. This in turn can alter the roles of various actors and the power balance among these actors in the health care system. Hence, future studies could focus on the systemic effects of self-tracking from a societal perspective.

Acknowledgments

SF was financially supported by Chinese Scholarship Council (grant 201806770140). We extend our thanks to the participants of the Information Systems Research Seminar in Scandinavia held on the internet in August 2020 and the anonymous reviewers for their comments and suggestions.

Authors' Contributions

SF synthesized the literature according to the described methodology and wrote the first draft of the manuscript. SF and MM reviewed the literature and prepared the manuscript. HS and AD commented on the manuscript.

Abstract

Background: Glaucoma leads to irreversible blindness. Globally, it is the second most common retinal disease that leads to blindness, slightly less common than cataracts. Therefore, there is a great need to avoid the silent growth of this disease using recently developed generative adversarial networks (GANs).

Objective: This paper aims to introduce a GAN technology for the diagnosis of eye disorders, particularly glaucoma. This paper illustrates deep adversarial learning as a potential diagnostic tool and the challenges involved in its implementation. This study describes and analyzes many of the pitfalls and problems that researchers will need to overcome to implement this kind of technology.

Methods: To organize this review comprehensively, articles and reviews were collected using the following keywords: ("Glaucoma," "optic disc," "blood vessels") and ("receptive field," "loss function," "GAN," "Generative Adversarial Network," "Deep learning," "CNN," "convolutional neural network" OR encoder). The records were identified from 5 highly reputed databases: IEEE Xplore, Web of Science, Scopus, ScienceDirect, and PubMed. These libraries broadly cover the technical and medical literature. Publications within the last 5 years, specifically 2015-2020, were included because the target GAN technique was invented only in 2014 and the publishing date of the collected papers was not earlier than 2016. Duplicate records were removed, and irrelevant titles and abstracts were excluded. In addition, we excluded papers that used optical coherence tomography and visual field images, except for those with 2D images. A large-scale systematic analysis was performed, and then a summarized taxonomy was generated. Furthermore, the results of the collected articles were summarized and a visual representation of the results was presented on a T-shaped matrix diagram. This study was conducted between March 2020 and November 2020.

Results: We found 59 articles after conducting a comprehensive survey of the literature. Among the 59 articles, 30 present actual attempts to synthesize images and provide accurate segmentation/classification using single/multiple landmarks or share certain experiences. The other 29 articles discuss the recent advances in GANs, do practical experiments, and contain analytical studies of retinal disease.

Conclusions: Recent deep learning techniques, namely GANs, have shown encouraging performance in retinal disease detection. Although this methodology involves an extensive computing budget and optimization process, it saturates the greedy nature of deep learning techniques by synthesizing images and solves major medical issues. This paper contributes to this research field by offering a thorough analysis of existing works, highlighting current limitations, and suggesting alternatives to support other researchers and participants in further improving and strengthening future work. Finally, new directions for this research have been identified.

Introduction

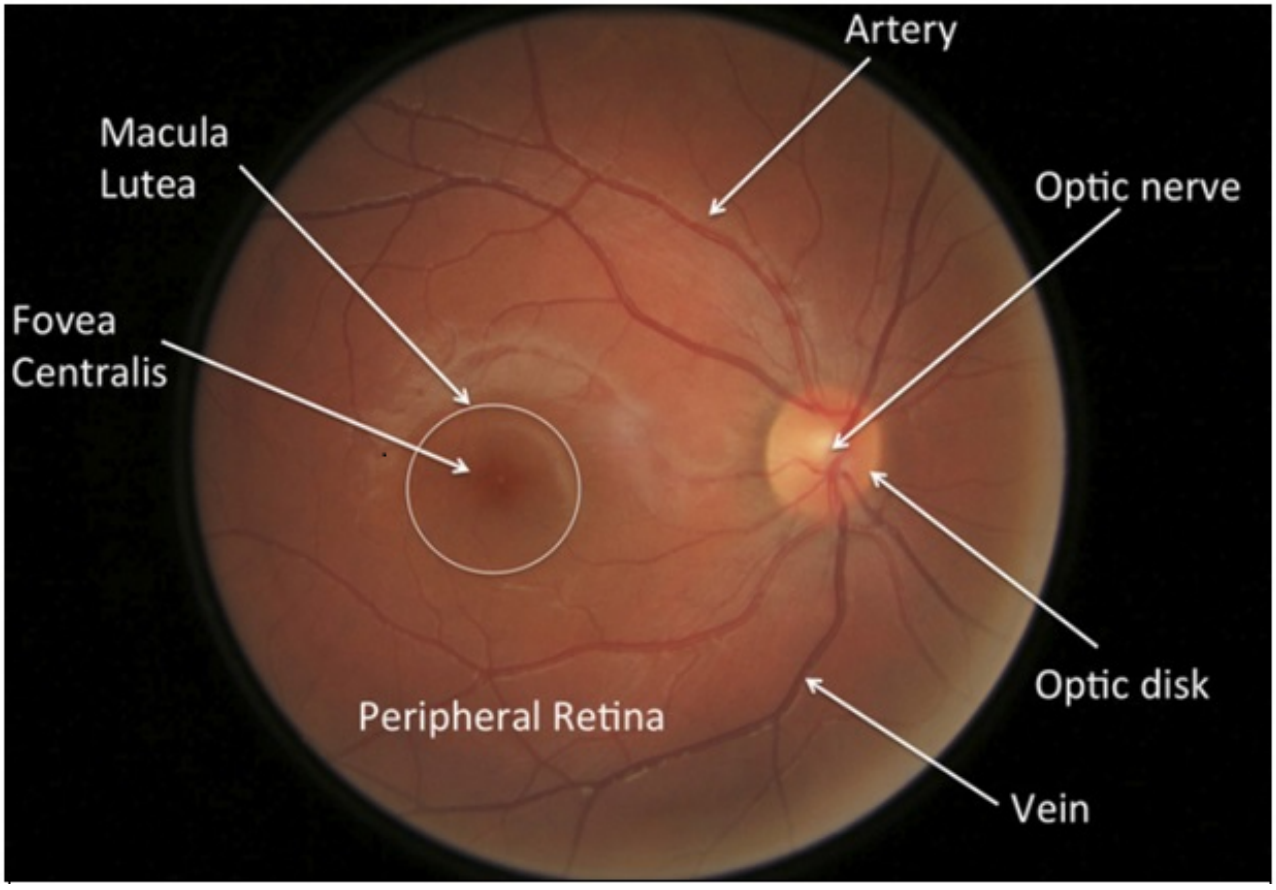
Medical and Statistical Overview

Blindness and visual impairments often result from cataracts, age-related macular degeneration, and glaucoma [1,2]. Glaucoma is a neurodegenerative disease that damages the optic nerve and causes visual field loss [3]. As it is an asymptomatic disease, it is known as the silent thief of sight [4], and patients are unaware of the infection until their vision is irreversibly impaired. Among affected individuals, 50% are ignorant of the disorder [5-7]. Early phases of glaucoma have no symptoms or visual field changes [8]. As the disease progresses, a slow narrowing of the visual field can occur. If left untreated, glaucoma may contribute to total blindness [9]. Loss of vision usually begins on the eye's side and then approaches the middle.

Statistically, glaucoma affects millions of people globally, with more than 64 million cases recorded in 2013, and other studies have estimated that 76 million people will be affected by 2020 and 111.5 million by 2040 [9,10]. Glaucoma is the second leading cause of blindness worldwide, preceded by cataracts [11], and it impacts 4.5 million individuals [9,12], more than 10% of the gross population [10]. Owing to the asymptotic function of glaucoma, approximately 70% of individuals with glaucoma are unaware of the illness's existence [13,14] in the early stage. Thus, we need to provide an early detection and evaluation method [15]. Once glaucoma is detected, a more effective follow-up takes place as a cure can slow down the transmission of the disease [8].

Cataracts may be reversed by surgery, while glaucoma causes lifelong blindness. Elevated intraocular pressure (IOP) is the most common cause of glaucoma. The tonometer measures IOP. However, IOP is not always an accurate and adequate indicator of glaucoma, because glaucoma does not always cause a rise in IOP [16] but rather a deterioration of the optic nerve head (ONH). Visual information flows through the ONH to the brain. The ONH consists of a bright spherical area called the optic disc (OD) and a wider circle-like area called the optic cup (OC). Figure 1 shows these structures in ocular images.

Figure 1. Fundus image structure.



ONH assessment is a widely used glaucoma screening tool that utilizes differential division to distinguish between glaucomatous and normal images [17]. Manual calculations of ONH geometric structures, such as the cup-to-disc ratio (CDR); inferior, superior, nasal, and temporal (ISNT) rule; disc diameter; and rim area, are recommended as diagnostic features for glaucoma screening [18-20]. Among them, the CDR is a reliable therapeutic feature for early glaucoma screening and diagnosis [21,22]. Each of

the derived CDR parameters (diameter or area) is the ratio between the OC and the OD. CDR values rise when the illness progresses and become higher than approximately 0.6-0.7 when the patient has a stronger chance of developing glaucoma [23]. Based on an earlier study [24], a CDR of at least 0.65 is deemed glaucomatous in clinical practice. The CDR score tracks the development of glaucoma over time, effectively screening the condition early [25]. Currently, to check for retinal diseases, specialists tend to manually extract the blood vessel (BV), OD, or OC from retinal images. Accurate segmentation of the retinal structure is very important during the diagnostic process. However, doing this process manually is very labor intensive, time consuming, and risky in terms of human mistakes. Furthermore, the analysis results may lack objectivity, as different experts may produce different results. Therefore, it is important to automate retinal image segmentation/classification while minimizing expert interference.

Research Background

The development of medical imaging technology has helped to accelerate the detection of diseases. Additionally, several studies have been conducted using image processing techniques to automatically process medical images without the intervention of experts [26]. Several studies [22,27,28] have examined vascular tracking and OD and OC segmentation using fundoscopic images. The main segmentation techniques depend on visual features such as color and contrast thresholding, region segmentation, and boundary recognition. Such methods use a learned classifier to classify pixels as foreground pixels (eg, OD, OC, or BV) or as background pixels (regions out of the area of interest) [29,30]. However, most of these methods are based on hand-crafted features (eg, texture, red green blue [RGB] color, gradient and Gabor filter), which are susceptible to low image contrast, pathological regions, and have a lack of deep feature extraction.

In recent years, automatic learning has been significantly improved with the assistance of machine learning (ML) techniques [31]. According to several studies [32,33], ML and deep learning (DL) algorithms have evolved to the point that they can compete with and sometimes even outperform humans on certain tasks, such as object detection [34] and image classification on ImageNet [35]. Currently, deep learning methods (DLMs) are an active research field because they can automatically generate and learn extremely complex features from input data. In particular, DLMs with deeper and complicated perceptron layers [eg, convolutional neural networks (CNNs)] have shown better performance in object detection than other methods [33]. Researchers have attempted to use various types of architectures, such as GoogLeNet [36], AlexNet [33], and DenseNet [37], for glaucoma diagnosis with the introduction of deep neural networks. Such research mainly focuses on 2 aspects: using DL for complex and deep feature extraction and utilizing medical features and spatial domain knowledge in the detection process. However, the use of deep fully connected networks is susceptible to imbalanced learning problems such as high false-negative or false-positive rates, leading to more fake or skinny branches than those of the ground truth [38,39]. In other words, retinal BV segmentation still has issues such as false pathological information segmentation and low microvascular segmentation [40].

For addressing complex learning issues, deep architectures often have advantages over shallow architectures; for example, deep CNNs have demonstrated significant efficiency improvements over conventional vision-based models [41]. A fully connected convolutional network has been used to address insufficient public data. Such methods, however, create very fuzzy vessels with false positives along with tiny and weak roots. This error primarily occurs because the CNNs used in current methods depend solely on pixel-level objective feature to equate the standard image to the image created by the model and are incapable of adapting actively to the fundus image of the natural vascular structure [42]. Empirical studies have proven that deep CNNs can learn invariant representations and attain human-level success if sufficient training data are provided. However, one of the leading shortfalls of DLMs is the lack of available data. Medical data annotation often requires specific domain experts. This shortage leads to the need for CNN training approaches with a limited number of annotated data. However, this can easily lead to underfitting, and as a result, high error rates on both training and testing data are recorded. Lahiri et al [43] demonstrated the effectiveness of using generative adversarial networks (GANs) [44] to perform some discriminative task with only 0.8%-1.6% of the amount of annotation data used by other methods.

GANs belong to the family of unsupervised learning algorithms that have proven their merits in generating synthetic images close to real images and solving image-to-image translation problems in the natural domain [45,46]. GANs have gradually shown their extraordinary ability and have started to shine brilliantly in various application fields [45,47,48]. Inspired by the prevailing learning capability of GANs, Wu et al [49] proposed the generative adversarial network with U-net, referred as (U-GAN), which includes an attention gate model in the generator and a densely connected convolutional network to segment the BVs automatically. Lahiri et al [50] proposed deep convolutional GANs (DCGANs) for retinal segmentation to segment the region of interest (ROI) from a given image. In addition to segmentation tasks, the synthesis of retinal images is a large part of the literature. Haoqi and Ogawara [51] trained a GAN model to learn the mappings of vessels from retinal images to segmented images for training a model to generate a synthesized image close to a given real image.

To date, several review articles summarizing the technology of DL in ophthalmology have been published [20,52-55]. Nevertheless, none of them have particularly focused on the emerging breakthrough GAN techniques using fundus photographs. Moreover, despite the rapid development of telecommunication technology, only a few study groups have examined the possibility of integrating artificial intelligence (AI) technologies with teleophthalmology [56]. To the best of our knowledge, no researchers have adopted telescreening for glaucoma using DL techniques, particularly the GAN.

Shedding light on the importance of telecommunication technology in DL techniques is a current and very urgent need. Alongside the emergence of newer low-cost handheld devices,

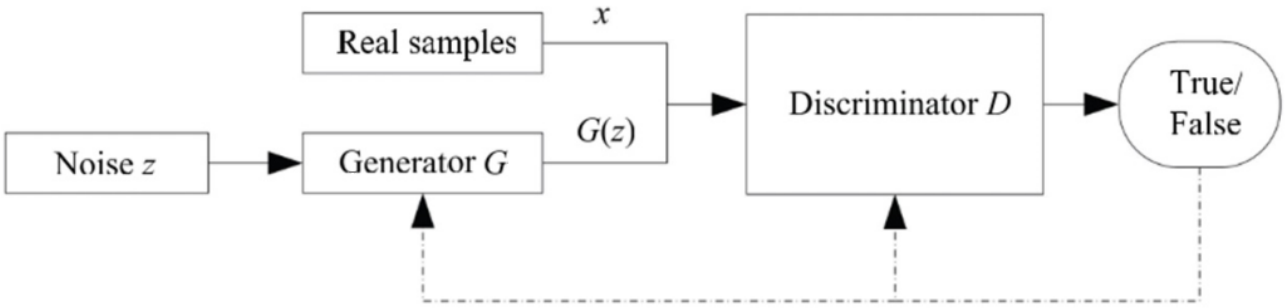
glaucoma screening will become more available, even to distant and poor communities. In addition, maintaining social distance is very important for mitigating the spread of the coronavirus pandemic. This paper summarizes the work in the literature on glaucoma diagnosis and highlights the challenges and gaps of current studies to uncover the possibilities of filling these gaps with the recommended suggestions. We aim to elucidate all research efforts, such as the GAN architectures mentioned earlier, that have been developed in response to the new and disruptive technology, mapping the research landscape from the literature onto a coherent taxonomy of the key features that characterize such an emerging line of research. Finally, the future work of this research will be proposed and described in detail.

Methods

Basic Theory of GANs

We start by reviewing the concept of GANs [44]. GANs consist of 2 separate neural networks, a generation network (G) and a discriminator network (D), plus a noise vector (z) sampled from a known distribution (eg, a Gaussian distribution), which is used to generate data points (fake samples; see Figure 2). A 2-player min-max game inspires the basic idea of this technique. The goal is to train the generator G to learn to capture the potential distribution in the real data sample and generate a new sample close to the real data to deceive the discriminator. The discriminator D is a binary classifier that attempts to discriminate whether the input data are real or fake [44]. To win the game, both G and D need to continuously improve their generation and discrimination capabilities, respectively. The training process lasts until both G and D reach a convergence point (Nash equilibrium), where G generates an output distribution very close to the real data distribution [42,57,58].

Figure 2. GAN architecture. GAN: generative adversarial network.



Mathematically, let G be parameterized by θ, which takes random noise z as input and produces synthetic images G(z) as output. The generated G(z) is mapped from a distribution G(z; θ) ~ p_g. Additionally, the training data set x is sampled from the real data distribution p_{data}, and the objective function of the generator network is used to train G to approximate p_{data} using p_g. By contrast, the discriminator (D) takes either the original image x or G(z) as input and indicates whether the input is from a true data distribution (x) or a synthetic data distribution G(z) by outputting a probability of D(x) or D(G[z]). This can be seen in the followig equation, where p_{data}(x) is the true data distribution and p_z(z) is the noise distribution.

However, the training mechanism of such a model is critical. Unbalanced training between the G and D networks leads to model collapse. This happens when D is trained much better than G. In this case, D is able to easily discriminate between the real and synthetic images generated by G and reject all its outputs; thus, the loss log{1 − D(G[z])} saturates, and G learns nothing from the zero gradient. To avoid the model collapse issue, the loss function of G should be trained to maximize logD(G[z]) instead of minimizing log{1 − D(G[z])}. This can avoid the saturation of the gradient and provides the same gradient direction as that yielded by the old loss function.

Extension Models of GANs

The first GAN [44] was composed of fully connected layers. Later, the DCGAN [59] introduced the use of fully CNNs to increase training stability and improve efficiency. Since then, many GAN models have followed this set up as the main components of GAN architecture. Unlike the DCGAN, the Wasserstein GAN (WGAN) [60] increases the permutation in the fully connected layer. In this model, the Wasserstein distance metric is used instead of the Jensen–Shannon divergence to measure the distance between the generated data distribution and the real data distribution. Therefore, the problems of model collapse and training instability were partially solved in this model. Subsequently, an improved version of the WGAN called the WGAN-GP (gradient penalty) [61] was proposed. The WGAN-GP depends on gradient penalty replacement so that it can solve slow training problems encountered by the WGAN. Moreover, inspired by the WGAN, Mao et al [62] proposed the least-squares GAN (LSGAN) to improve the quality of the generated images. The main idea of the LSGAN is to use a new loss function in the D network for smooth and unsaturated gradients.

The original GAN randomly generated a date distribution that is beyond our control, as the output depends on random noise. Therefore, a conditional GAN (cGAN) was invented to add a vector c as a conditional input to the noise vector z so that the

generator could generate the required data. Hence, the generator output of the cGAN was defined by G(c,z).

Since the cGAN was proposed, many articles have used the cGAN applications, for example, Pix2Pix [45], a cGAN-based technique proposed by PatchGAN to map a set of images to another image using N × N pixels. It classifies each N × N path of the image and averages all the scores of patches to obtain the final score for the image. The main limitation of Pix2Pix is that it requires images x1 and y1 that are paired with each other in the training stage. By contrast, CycleGAN [47], which is also a cGAN-based technique, utilizes an image translation method that does not need paired data, even though Pix2Pix still outperforms CycleGAN's remarkable margin.

Another variation of the GAN combines a variational autoencoder (VAE) and a GAN in a single model named VAE-GAN [63]. The idea behind this technique is to exploit the strength of both the GAN and VAE, as the GAN can generate sharp images but misses some modes while the VAE produces blurry images but with a large variety. Studies have demonstrated that VAE-GAN images are better than those produced by the VAE or GAN alone.

Information Sources

Guided by [64], we conducted a comprehensive search to find all GANs-based articles related to glaucoma by searching the best and most reliable libraries: (1) Scopus, (2) ScienceDirect, (3) IEEE Xplore, (4) Web of Science, and (5) PubMed Central. This collection includes technical and medical literature, perfectly reflecting all research activities in this discipline.

Study Selection Procedure

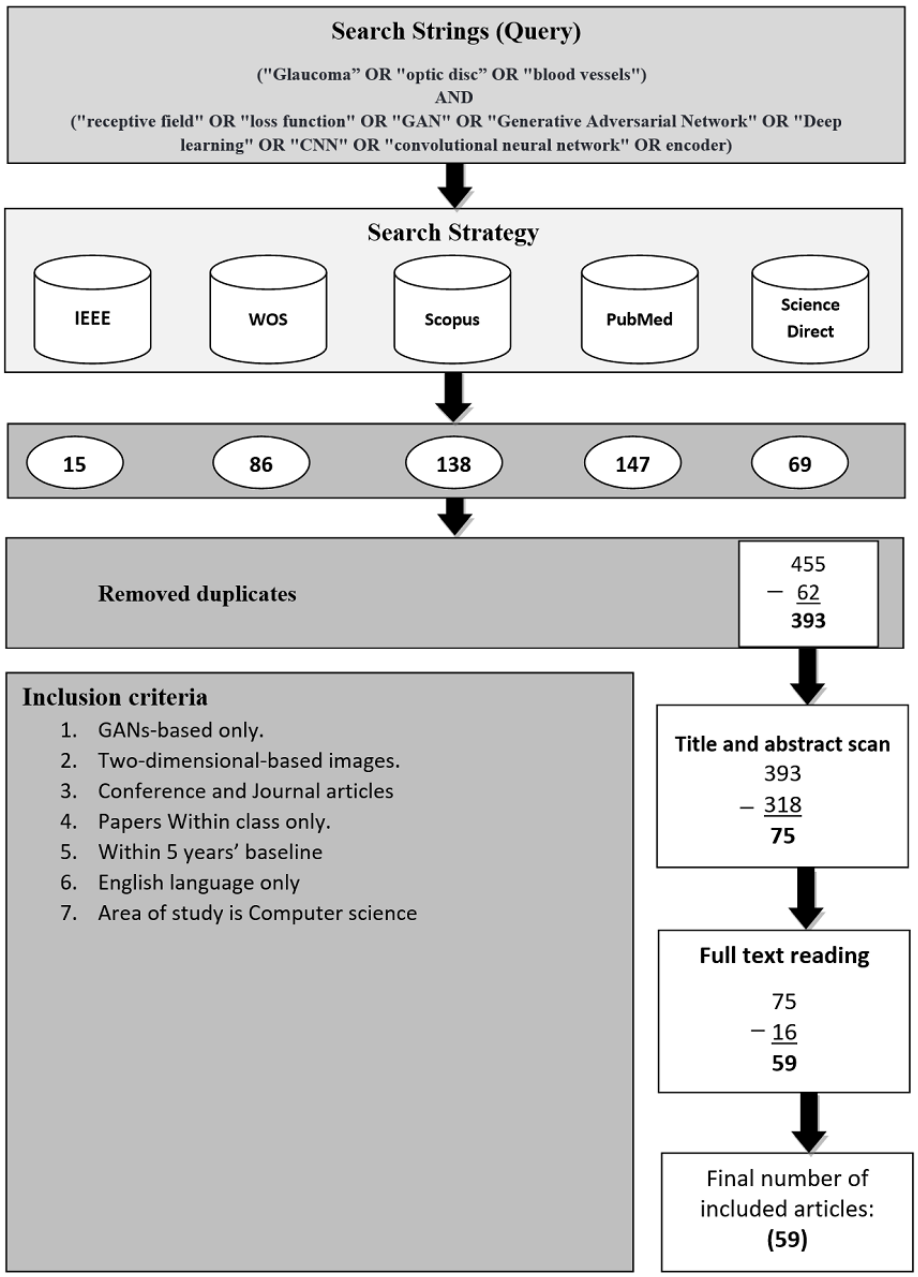
The method for choosing appropriate studies was on the basis of 2 stages: screening and filtering. Successively, both stages met the same criterion for inclusion and exclusion. Both duplicates and unrelated studies by title and abstract skimming were omitted during the first stage. Then, the result in a set of papers was entirely read, analyzed, and summarized in the filtration stage.

Search

This work was carried out between March 2020 and November 2020. Various keyword combinations were used in the search of highly reputable libraries (IEEE Xplore, Science Direct, PubMed, Scopus, and Web of Science). Our search query consist of 2 parts that are connected with each other using the operator "and." The following set of keywords ("glaucoma," "optic disk," "blood vessels") and ("receptive field," "loss function," "GAN," "generative adversarial network," "deep learning," "convolutional neural network," "CNN," Encoder) belong to the first and second parts, respectively. The operator "or" is used to connect keywords within the same part. Based on this, our study scope is formulated.

The quest focused on different journals and conferences and omitted books and all other forms of literature. Therefore, we mainly concentrated on up-to-date and applicable scientific studies related to the use of GANs in retinal disease, especially glaucoma. Figure 3 shows the research query and inclusion criteria used in this work.

Figure 3. Flowchart of the study selection with the research query and inclusion criteria. GAN: generative adversarial network; WOS: Web of Science.



Validity of the Collected Papers (Scope Validation)

The total number of keywords in the collected papers was 115. To validate our research scope, we analyzed these keywords and categorized them according to their co-occurrences. Then, we set a threshold indicating the co-occurrences of each keyword across all papers. Let k≥3, where k is a threshold. As a result, we obtained 15 keywords out of 115 that met the threshold. That is, each of these 15 keywords occurred at least three times in all the collected papers.

Figure 4 illustrates the connections of these 15 keywords to each other. The size of each circle indicates how frequently a single corresponding keyword occurred. The more frequently a keyword occurred, the larger circle size it gets, for example, the keyword "deep learning" has the biggest circle size in the diagram, which means it is the most frequently appeared keyword in the collected papers. The second factor is the color, which indicates how often a single keyword occurred per year. The last factor is the total link strength, which indicates the total connection of a keyword to other keywords. The more frequently 2 keywords appeared in the same article, the thicker is the line drawn between them. For example, the keywords "deep learning" and "glaucoma" were linked by a thicker line than the line between the keywords "generative adversarial network" and "glaucoma," which means that both "deep learning" and "glaucoma" appeared together in the collected articles more than the keywords "generative adversarial network" and "glaucoma" did. This indication reveals that GANs have been used less than other DL techniques in glaucoma detection.

Figure 4. Scope validation diagram.

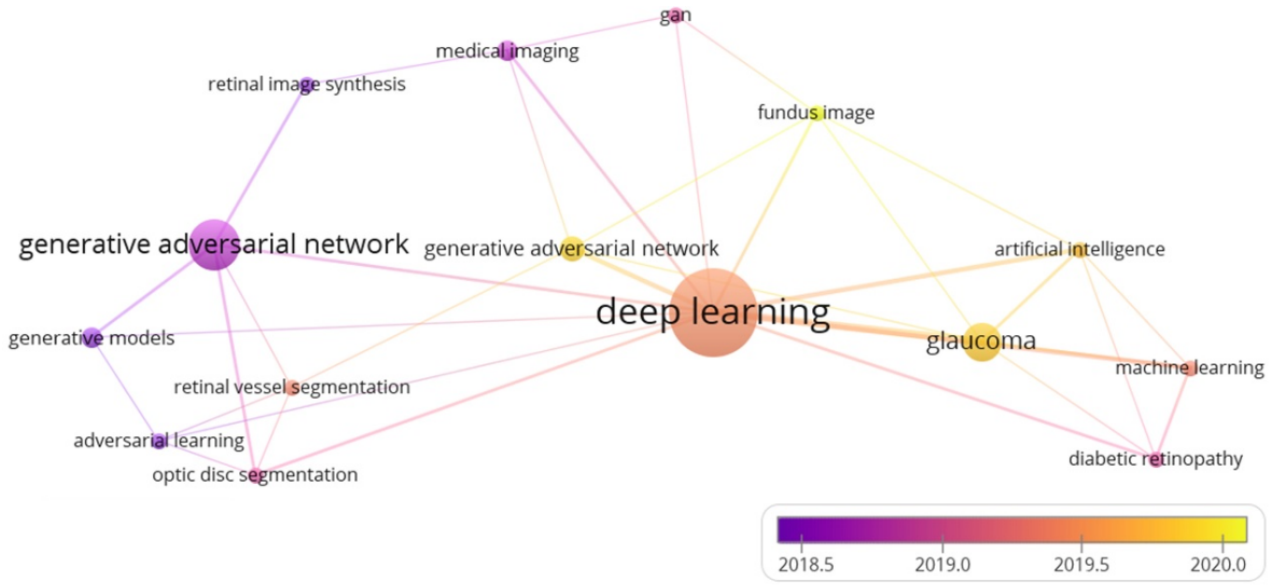


Table 1 shows the occurrences and the total link strength of the 15 keywords that met our threshold (k≥3). Deep learning is the most frequently occurring keyword, which has uniquely appeared 20 times in the collected articles and 27 times with other different keywords. GANs occurred 17 times, with 18 connections to other keywords, while the keyword glaucoma occurred 8 times, with 12 connections to other keywords. In conclusion, these highest scores for the aforementioned keywords empirically demonstrated the validity of our search query that is used to collect literature publications. Furthermore, it proves that our research scope revolves around 3 main keywords, namely, deep learning, generative adversarial network, and glaucoma, as they have the biggest circle sizes with the thickest connection among them.

Table 1. Keywords occurrence.

Keywords	Occurrences	Total link strength
Techniques		
Deep learning	20	27
Generative adversarial network(s)/GAN	17	18
Artificial intelligence	3	8
Machine learning	3	8
Diseases		
Glaucoma	8	12
Diabetic retinopathy	3	6
Imaging		
Fundus image	3	6
Medical imaging	4	5
Papers' contribution		
Adversarial learning	3	4
Optic disc segmentation	3	6
Retinal vessel segmentation	3	4
Generative models	3	3
Retinal image synthesis	3	3

Inclusion and Exclusion Criteria

In this section, papers that met the criteria in Figure 3 were included. We taxonomized the included papers on a general and in-depth diagram consisting of 2 paper groups, namely, the development studies group and the reviews and surveys group. The papers in the first group were classified according to 8 consecutive layers. In the literature, researchers classified GANs into 2-4 categories; these categories were separately used by different researchers, as referenced accordingly in the points

below. However, in our taxonomy, we combined them all. Furthermore, we added 4 more classification criteria as follows: (1) method architecture (direct, hierarchical, iterative) [32]; (2) model structure (2 players, multiple players) [65]; (3) GAN category (optimization function, structure, and conditional) [66-68]; and (4) generator backbone (U-Net based or CNN based) [69].

Further, we added 4 additional categories as follows: (1) type of GAN used in a paper (eg, variational autoencoder with GAN [VAEGAN], DCGAN, cGAN, CycleGAN); (2) discriminator's receptive field (PixelGAN, PatchGAN, ImageGAN); (3) landmarks used during the segmentation/classification process (single, multiple); (4) paper contributions (segmentation, classification, image synthesis, mixed).

The exclusion criteria followed in this paper were as follows: (1) ML approaches, (2) 3D-based imaging methods (optical coherence tomography), (3) between-class papers, and (4) out-of-scope papers.

Data Collection Process

All papers from different sources were summarized and saved in a single spreadsheet file for simplicity and a quick review. Significant remarks and comments were illustrated by full-text reading in our analysis scope and classification stage, which further refined our taxonomy. Finally, our results were summarized on an Excel sheet (Microsoft) and listed in a tabular format. The additional data set includes a list of articles, publishing source, articles' abstracts and contributions, the tools used in papers, audiences, objectives, architecture-based categorization table, and a list of relevant figures.

Results

Overview

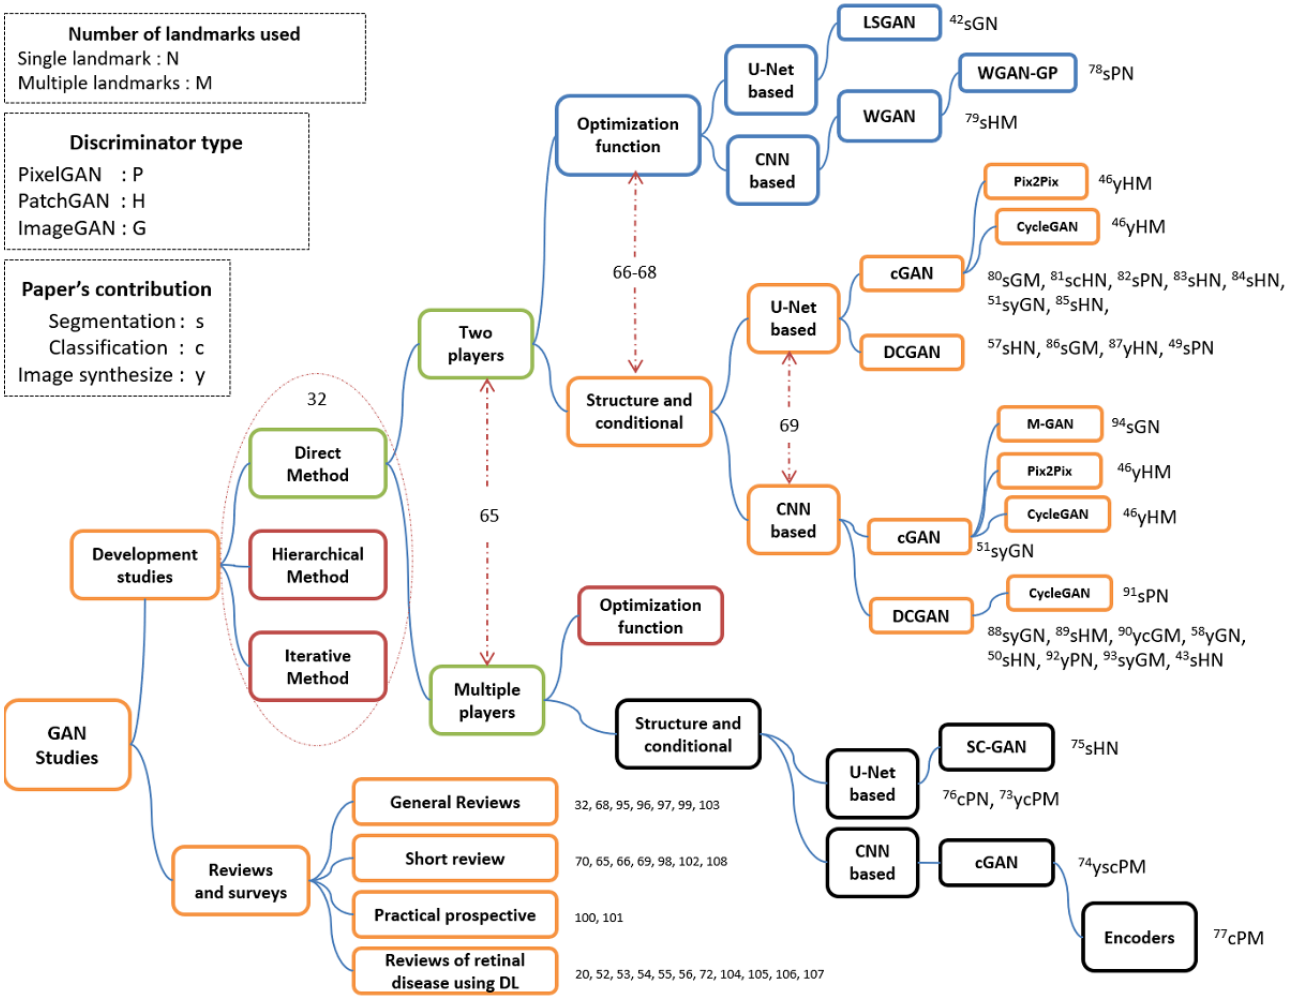
The cumulative number of articles in the original search process was 455. Eighty percent (364/455) of the findings released in 2018-2021 and 20% (91/455) in 2015-2017 were distributed as follows: 15 papers from IEEE Xplore, 86 from Web of Science, 138 from Scopus, 147 from PubMed, and 69 from ScienceDirect. Approximately 62 papers were duplicates across the 5 databases.

Later, 318 papers (not GAN based) were omitted after skimming through the articles' titles and abstracts, leaving only 75 papers. Further screening via full-text reading was carried out on these 75 papers, which resulted in excluding 16 nonrelevant papers. A comprehensive reading was performed on the final 59 papers to create a general map to study this newly emerging methodology.

Of these 59 papers, 51% (n=30) focused on the development and training of various GAN models and real attempts to improve the efficiency of the network architecture to improve segmentation/classification precision, especially at an early stage of the disease with fewer false positives/negatives. Nearly 49% (29/59) of publications included general reviews and surveys relating to GAN technique and its variants; recent GAN applications, limitations, and potential future prospects; reviews of retinal diseases; various DL detection methods; general analytical knowledge such as the most frequently used data sets; and the countries contributing to the current research area. From all these observations, we got a thorough view on the literature, determined the general categories of the study scope, and boosted the taxonomic classification of the literature. Figure 5 presents the groupings of the GAN-based approaches used in the literature according to their structures or optimization functions.

Kumar and Dhawan [70] classified GANs based on their architectures or the loss functions used to train their generators. It is worth noting that the first 4 layers of our taxonomy have been separately used in other papers; therefore, inspired by those studies, we used these categories together as a baseline for our taxonomy. We added other categories to classify brief literature works in depth according to (1) their level of feature discrimination (PixelGAN, PatchGAN, or ImageGAN), (2) the numbers of landmarks used in the segmentation or classification process (a single landmark or multiple landmarks), (3) the backbones of the GANs used in the articles (eg, DCGAN [59], Info-GAN [71], WGAN [60], CGAN [45], Pix2Pix [45], and Cycle-GAN [47]), and (4) the contribution of each paper (eg, segmentation [s], classification [c], or synthesis [y]). In the following sections, we describe each category and provide some accompanying statistics.

Figure 5. Taxonomy of the literature on glaucoma screening based GANs technique. cGAN: conditional GAN; CNN: convolutional neural network; DCGAN: deep convolutional generative adversarial network; DL: deep learning; GAN: generative adversarial network; LSGAN: least-square GAN; WGAN-GP: Wasserstein GAN-gradient penalty.



Development Studies Category

GANs were first developed by Goodfellow et al [44] in 2014. Although researchers have continuously attempted to improve the performance of GANs in various ways, such as weight regularization, new loss functions, weight pruning, and Nash equilibrium, it is still a new research field among deep learning techniques [70,72]. Only recently did this technique start to be adopted by researchers in the field of retinal disease, particularly glaucoma (roughly at the beginning of 2018). Therefore, the total set of papers that described various experiments and tools used for the detection or segmentation of retinal images included 30/59 (51%) articles.

Among these categories, it is notable in Figure 5 that the first 4 layers classified articles based on the method used (direct, hierarchical, or iterative) [32], the model structure [65], the architecture category (optimization function or structure and conditional based) [66-68], and the generator's backbone (CNN based or U-Net based) [69] consecutively.

In the first layer, all the literature work followed the direct methods. This means that all these methods follow the philosophy of using 1 generator and 1 discriminator, and the structures of the G and D are straightforward without any branches. None of the articles used hierarchal or iterative methods; this reveals a new opportunity to apply GANs in the field of retinal disease.

The second layer classified articles based on the number of players. Nearly 25/30 (83%) articles used 2 players, and only 5/30 (17%) articles utilized multiple players. In the latter case, some studies used 3 player-based methods [73-75], with the frameworks of [74] and [75] comprising segmentation, generator, and discriminator networks. In the study by Liu et al [74], the segmentation network and generator enlarged the training data set to improve the segmentation performance, while the discriminator solely focused on identifying fake image–label pairs to ensure compatible utilities. However, in Yu et al [75], the same architecture was used to synthesize images after performing traditional annotation-free methods to obtain coarse segmentations.

A slight difference was observed in Wang et al [73], where a pathology-aware visualization network was used instead of the segmentation network, with both pathology-aware visualization and the generator used to enhance the synthesized glaucoma images in specific pathological areas. The synthesized image was re-enforced to provide a heatmap close to that of the input reference image. The Patho-GAN can thus generate images of glaucoma fundus with clearer pathologies. In Yang et al [76],

the VGG19 network was incorporated with the 3 players to find the topology structure loss, which was combined with the other 3 losses (adversarial loss, weighted cross-entropy loss, and total variation loss) to be used by the generator. However, in [77], the authors used 2 encoders, namely, E_s and E_t, where (s) is the source domain and (t) is the target domain; these encoders were trained to impede the classification performance of the discriminators (D+, D–). In turn, D+ and D– were trained to distinguish between positive/negative source images and positive/negative target images, and finally, a classifier (C) tried to classify source/target images.

Following [66-68], we added a third layer to our taxonomy to classify papers as either structure-based or optimization-based methods. The majority of studies (27/30, 90%) at this level were structure- and conditional-based methods, while only 3/30 (10%) of the studies, namely, those in [42,78,79], were optimization-based methods with 2-player structures; none of these methods have been recorded as multiplayer-based structures.

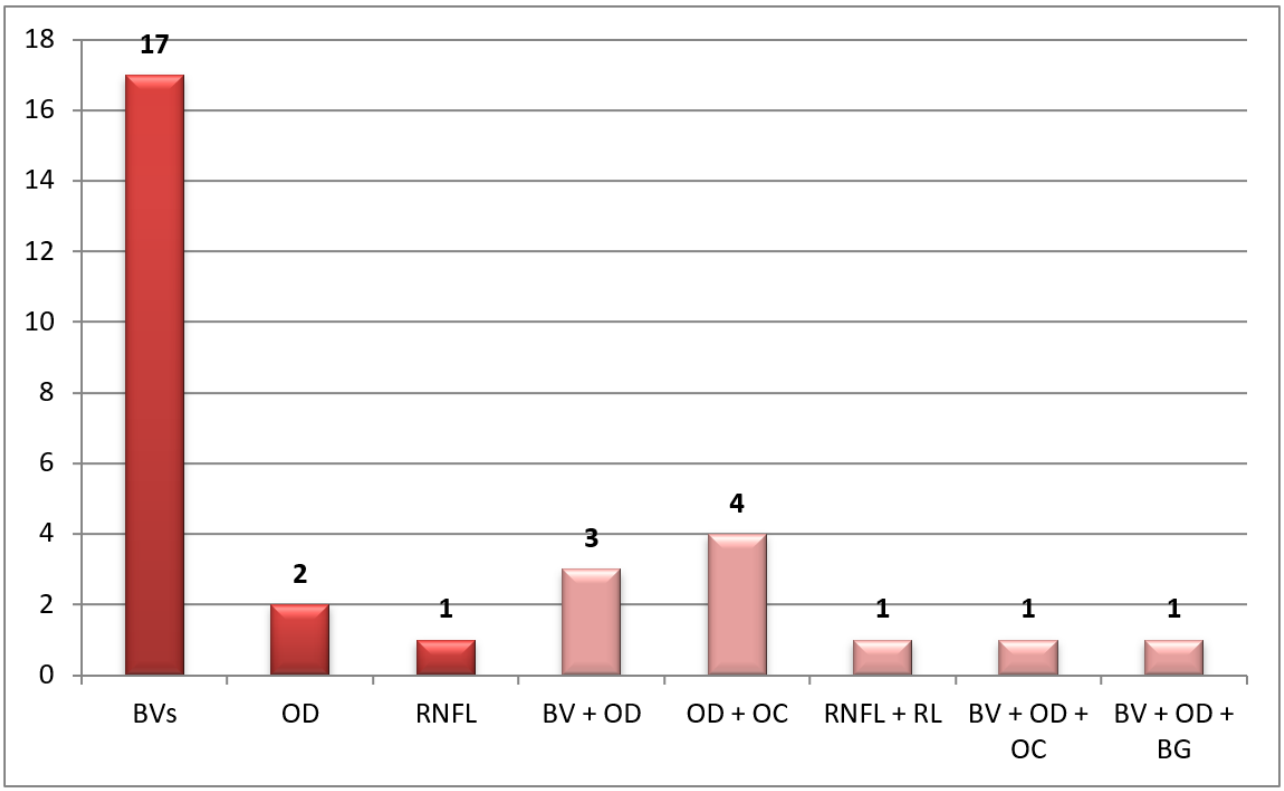
Some researchers tend to use objective function–based methods by updating specific loss functions or using a combination of losses to overcome the model collapse of GANs. This occurs when the generator continuously generates images with the same distribution or generates images with the same texture themes or color as the original image but with marginal differences in human understanding [65]; for example, Ma et al [42] used a least-squares loss function instead of sigmoid cross-entropy. Therefore, their experiment greatly improved the segmentation accuracy of the utilized model on both the digital retinal image for vessels extraction (DRIVE) and structured analysis of the retina (STARE) data sets by forcing the generator to generate images with distributions close to those of the real images. In Tu et al [78], the authors used the WGAN-GP method to overcome the training instability of the traditional GAN and generate accurate probability maps of BVs. The WGAN-GP is an extension of the WGAN; it uses a gradient penalty instead of weight clipping to enforce the Lipschitz constraint. This type of GAN can be trained faster and generates higher-quality samples than those produced by WGANs [61,68,70,78]. Last, Kadambi et al [79] proposed a framework for domain adaptation guided by the Wasserstein distance metric instead of typical adversarial methods for more stable training and better convergence.

The subsequent layer in our taxonomy was to classify methods according to the generator's backbone (eg, U-Net based or CNN based) [69]. Papers [42,46,49,51,57,73,75,76,80-87] represented about 50% of the studies (n=16) and were U-Net-based architectures. However, the other 50% of the papers [43,46,50,51,58,74,77-79,88-94] were CNN-based generators (n=16).

The study by Yu et al [46] was very intensive; the authors proposed multiple-channels-multiple-landmarks as a new preprocessing framework. They used a combination of landmarks (vessel trees, ODs, and OC images) to synthesize colored images with 2 types of GANs (Pix2Pix and CycleGAN). Additionally, they used a Pix2Pix architecture with 2 different generator structures (eg, U-Net-based and CNN-based). They empirically demonstrated that the Pix2Pix network with a ResU-Net generator using high-resolution paired images and multiple-channels-multiple-landmarks outperforms every single landmark-based GAN method regardless of their architectures. Furthermore, they were able to generate significant and realistic images.

The next distinguishing level in our taxonomy addressed the landmarks used in the papers. As Figure 5 shows, references containing "N" letters refer to a single landmark (eg, the BV, OD, OC, retinal nerve fiber layer [RNFL], or rim loss [RL]). These references contributed to 20/30 (67%) of the total papers. Seventeen of them were BV-based methods [42,43,49-51,58,75,76,78,81-85,88,91,92,94]. Only 2 studies [57,81] were OD-based detection approaches, and 1 [82] utilized RNFL-based detection (Figure 6).

Figure 6. Distribution of papers per landmark(s). BG: background; BV, blood vessel; OC: optic cup; OD: optic disc; RL: rim loss; RNFL: retinal nerve fiber layer.



Another set of articles used multiple landmarks and was represented with an "M" letter in Figure 5. These articles contributed to 33% (10/30) of total papers. Some studies [80,90,93] used the BV and OD, while [74,77,79,86,89] used the OD and OC to classify the disease. In addition, Wang et al [73] used RL and RNFL, and Yu et al [46] used BV, OD, and OC.

The rest of the researchers used multiple landmarks, such as [74,77,79,86,89], which involved OD and OC segmentation. Studies [80,93] worked on BV and OD segmentation, and only Wang et al [73] used RNFL and RL. The rest of the papers used triple landmarks in their work, such as [58] and [90], which involved work on BV, OD, and background, and Yu et al [46] used BV, OD, and OC.

In the next layer of our taxonomy, articles were classified according to the discriminator's receptive field. As illustrated in Figure 5, references with P, H, or G letters represent refer to PixelGAN, PatchGAN, or ImageGAN, respectively. ImageGAN papers were [42,51,58,80,86,88,90,93,94], while PixelGAN papers were [49,73,74,76-78,82,91,92]. In addition, PatchGAN papers were [43,46,50,57,75,79,81,83-85,87,89].

Isola et al [45] proposed a Pix2Pix-based conditional adversarial network (cGAN) as a general-purpose solution to image-to-image translation problems, and demonstrated that a 70 × 70 PatchGAN alleviates artifacts and achieves the best scores. Scaling beyond 70 × 70 to a full 286 × 286 ImageGAN did not appear to improve the quality of the results and, in fact, the latter model obtained a considerably lower fully connected network (FCN) score. This scaling mechanism may have been effective because there are more parameters in ImageGAN than PatchGAN and greater depth, which made it harder to train. By contrast, 3 studies [57,81,89] proved that the 64 × 64 Patch-SAN is the best, while one [84] concluded that a 120 × 120 patch is better than a 64 × 64 patch size. Studies [80,88] concluded that ImageGAN is better than PatchGAN. Last, pixel-level annotation [50] is much more tedious than image-level annotation.

Each reference in Figure 5 is denoted with a letter indicating the contribution of the relevant paper. Nearly 57% (17/30) of papers worked on the segmentation task and were denoted by (s), 17% (5/30) worked on image synthesis and were denoted by (y), and only 2 papers worked on the classification task and were denoted by (c). The remaining 6/30 (20%) papers worked on multiple tasks (eg, sc, sy, ysc). Multimedia Appendices 1-7 summarize the literature results reported in the papers.

Reviews and Surveys Category

In this category, 2 sets of reviews were identified. In the first set, detailed discussion is presented about recent breakthrough techniques of GANs, their development, variations, and medical field applications. The second set shows the impact of deep learning on ophthalmology. In total, this category includes 29/59 (49%) papers.

For the first set, studies [32,65,66,68-70,95-98] provided detailed reviews about GANs including their basic background, theory, and implementations. Also, they present current research hotspots and proposed GANs in different applications. They provided the reader with a clear insight into GANs' advantages and disadvantages, its different evaluation metrics, and proposed a bright prospect of this technique. Studies [32,95] focused on the importance of GANs, especially in medical field

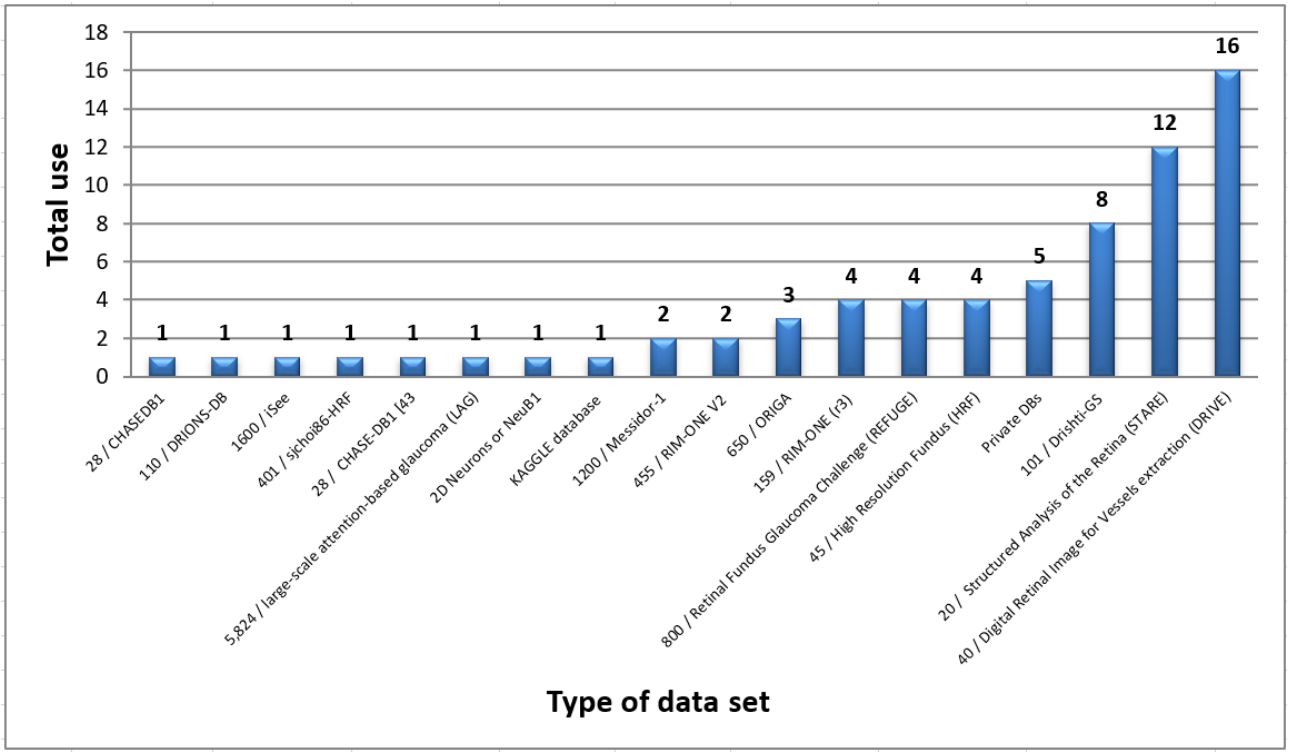
applications, and their capability to generate data through image synthesis technique without explicitly modeling the probability of density function. Wang et al [96] provided a further investigation of GAN in parallel intelligence. Another study, [99], discussed incorporating GANs in the signal processing community, showing different training methods, constructing GANs, and highlighting current challenges to their theories and applications. References [100,101] are practical prospective studies, and in [100], the authors tried to assess GAN algorithms and find the best architecture among all. However, they concluded that most of the models could achieve similar scores with enough hyperparameter optimization and random restarts. Additionally, they tried to overcome the limitation of evaluation metrics by computing precision and recall on several proposed data sets. Also, in [101], the authors reproduced the current state-of-the-art GANs, aiming to explore their landscape, discussing their pitfalls, and reproducibility issues. Turhan and Bilge [102] presented a comprehensive study about generative models such as GANs and autoencoders (AEs) and identified the relationship among them for better understanding and emphasizing on the importance of generative models. Oussidi and Elhassouny [103] proposed a starting point survey for those who have interests in deep generative models such as deep belief networks (DBNs), deep Boltzmann machine (DBM), restricted Boltzmann machines (RBMs), VAE, and GAN. They explained their building blocks, learning procedures, and limitations.

In the second set of articles, [52,54,72,104] presented an overview of DL applications in ophthalmic disorder using digital fundus images. They summarized the publicly available data sets used for different retinal diseases such as cataracts, retinopathy, glaucoma, and age-related macular degeneration. They also provided a detailed summary of the pros and cons of this emerging technique for both computer scientists and ophthalmologists and specified the clinical and technical aspects to address deep learning challenges and future directions. Some studies [56,105,106] discussed the importance of clinical considerations and potential challenges for clinical adoption and telemedicine integration to reduce cost, increase accuracy, and facilitate health care accessibility. Ting et al [53] described the importance of deploying deep learning algorithms within clinical settings. Hogarty et al [55] clarified the misunderstanding between ML and deep learning terms and presented an overview of AI and its development in the ophthalmology field. Mayro et al [107] also provided an overview of AI and deep learning DL applications in glaucoma detection using fundus images, optical coherence tomography, and visual field interpretation.

Other studies, [20,108], followed the systematic framework in their reviews: [20] discussed the main algorithms used for glaucoma detection using ML, indicating the importance of this technology from a medical aspect, especially retinal image processing, whereas [108] performed a systematic review on investigating and evaluating DL methods' performance for automatically detecting glaucoma using fundus images.

Figure 7 illustrates the publicly available data sets, their sizes, and how often researchers used them. Each data set is collected using a particular camera with different standards and used for a specific disease type. Thus, generalization is the key problem of DL approaches as described in the "Challenges" section.

Figure 7. Total use of various datasets in glaucoma screening.

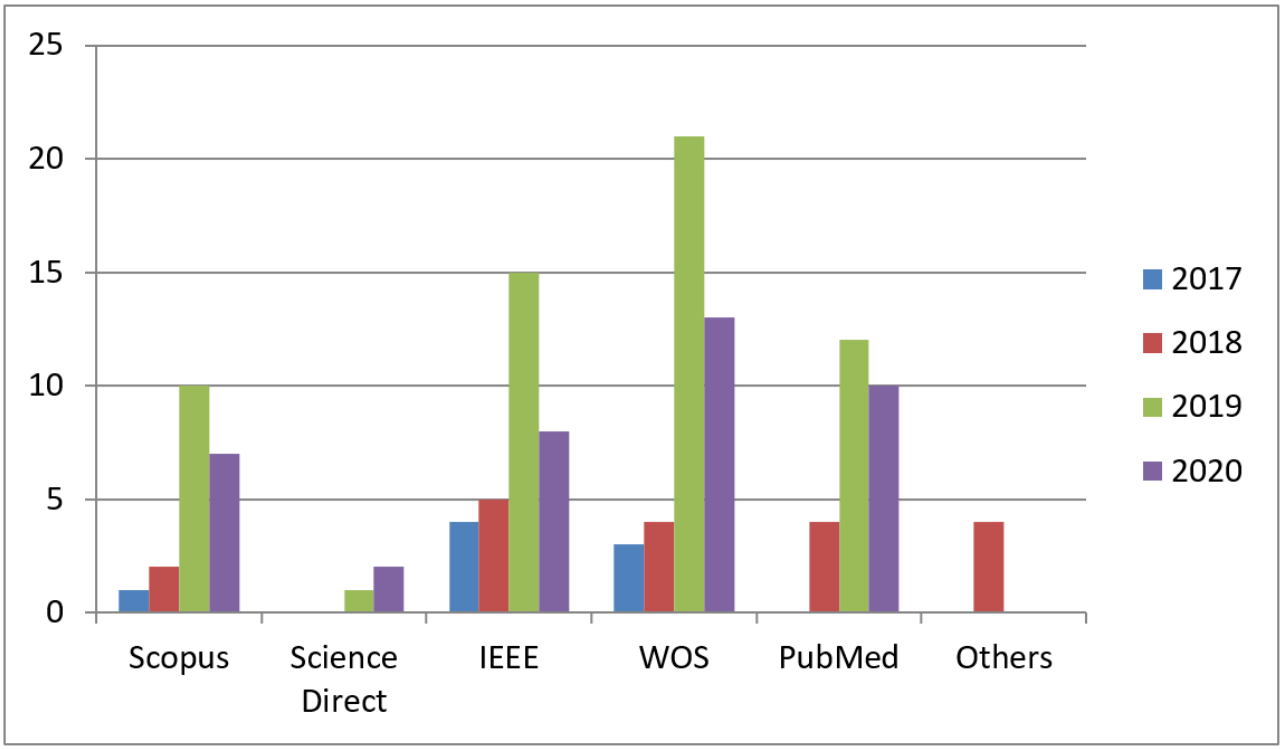


As Figure 7 illustrates, DRIVE and STARE are the most frequently used data sets. In other words, researchers often rely on BV segmentation in the diagnosing process [72]. However, few researchers have used Messidor-1, high-resolution fundus, 2D Neurons(NeuB1), and CHASEDB. For OD and OC landmarks segmentation, DRIONS-DB, retinal fundus glaucoma

challenge (REFUGE), ORIGA, RIM-ONE (r3/v2), and Drishti-GS were the most used, while seldom used is the large-scale attention-based glaucoma (LAG) data set, which is for RNFL and RL landmarks segmentation.

Figure 8 shows the distribution of the collected papers per year regardless of their duplications. The statistics in Figure 8 indicates the recent interest of researchers to adopt GANs techniques. Furthermore, it reveals the need to explore this newly emerging technique in ophthalmology. Therefore, extensive further work is needed to cover this area of research.

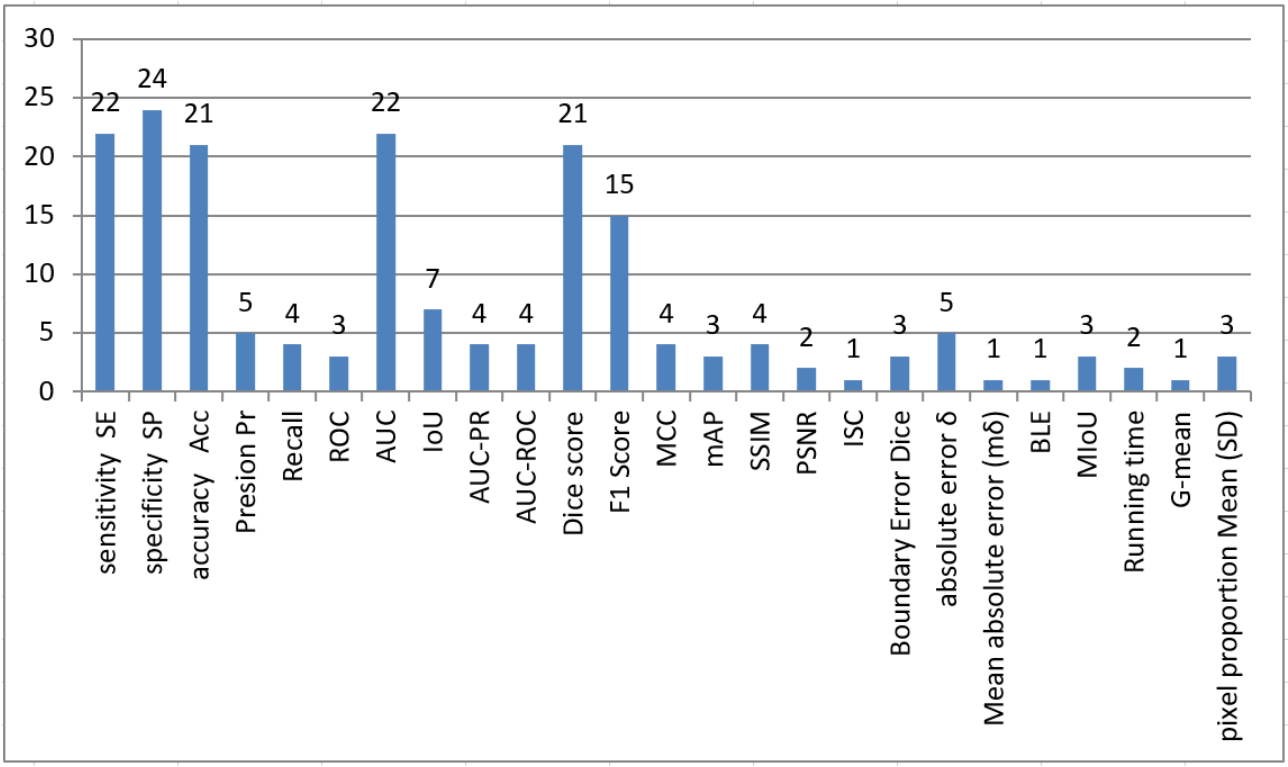
Figure 8. Distribution of papers per libraries. WOS: Web of Science.



This work has targeted 5 search engines: Scopus, ScienceDirect, Web of Science, IEEE, and PubMed, which are highly reputed and reliable resources for research. They include studies on implementation of deep learning techniques for different retinal disorder fields to help ophthalmologists and patients. Journal articles comprised 36 papers and only 23 were published in conferences.

According to Multimedia Appendices 1-7, each paper has used a different set of evaluation metrics; thus, we concur with Yu et al [46] in concluding that there are no uniform evaluation indexes in the literature to evaluate synthetic and real images. To further clarify this issue, Figure 9 shows the distribution of evaluation metrics used in the collected papers. To present Multimedia Appendices 1-7 visually, a T-shaped matrix diagram in Multimedia Appendix 8 illustrates in the upper part, named "Metrics used," the total use of each metric in all articles according to the used data set. Similarly, in the lower part, named "Task," the diagram shows the total use of each data set in all articles according to a specific task (classification, segmentation, or synthesizing).

Figure 9. Distribution of frequently used evaluation metrics in glaucoma screening. AUC: area under the curve; BLE: Boundary Distance Localization Error; IoU: Intersection over Union; ISC: Image Structure Clustering; MCC: Matthews correlation coefficient; mAP: Mean Average Precision; MIoU: Mean Intersection over Union; PSNR: peak signal-to-noise ratio; ROC: receiver operating characteristic curve; SSIM: structural index similarity.



Based on the observations of the upper part of the diagram, the top 5 metrics (sensitivity, specificity, accuracy, area under the curve [AUC], F1 score, and Dice Co.) were used the most with various data sets. Furthermore, 87% (13/15) of metrics were mainly performed on STARE and DRIVE data sets, unlike other data sets, such as Rim-ONEv3 and Drishti-GS, that use another set of metrics (eg, F1 score, Dice Co, peak signal-to-noise ratio, structural index similarity, and δ) to evaluate the performance. This indicates the need to consider standard effect metrics in future research irrespective of the type of data set used.

By contrast, in the lower part, the segmentation task was reported as the most applied task in the collected articles, followed by images synthesizing, with the classification task being the seldom applied. Nevertheless, the best results reported were in a classification study by Bisneto et al [81], which utilized a combination of Dristh-GS and RIM-ONE data sets. They achieved 100% in sensitivity, specificity, accuracy, and AUC in OD/OC classification. Their method was based on cGANs with taxonomic diversity and distinction indexes. Although most of the studies are on segmentation tasks and professionally segmented BVs and ODs [42,78,80,91], they still lack segmenting fine and small vessels and suffer from false positives. By contrast, images synthesizing attracted increased interest of researchers, as it assists in overcoming the shortage of medical images. Some researchers, such as [58,87], have used GAN with adversarial AE to enhance the generated image and some others tend to rely on using different loss functions to better train G and D networks. However, generated images are blurry, noisy, and of low quality with lack of details. Other studies, such as [76,88,89,94], adopted preprocessing (eg, data augmentation, localization of ROI, automatic color equalization) and postprocessing (eg, Lanczos resampling method, morphological operation, contrast enhancement) to enhance the performance of their methods, and they experienced a further improvement in their segmentation result.

Discussion

Principal Findings

This study aimed to provide a detailed summary of the literature on retinal disease detection or segmentation, particularly glaucoma, using GANs and highlight the recent trends exhibited by researchers on this topic. We mainly focused on articles that worked on enhancing the segmentation or detection of the disease rather than improving GAN techniques. Furthermore, we provide a taxonomy of papers related to this area to further assist future research.

Several benefits may arise from our taxonomy. First, organizing tens of papers in a single diagram provides better understanding of literature work, as people with less experience may be confused if many papers remain unorganized. Second, the taxonomy helps sort literature works and activities into meaningful, easy to manage, and coherent frameworks. Third, it provides researchers with better insights into a given theme, thus finding current literature gaps and discovering new research directions. Last and most importantly, it helps highlighting articles' strengths and weaknesses of a particular research scope.

From the developed taxonomy, we can quickly see that all the published papers followed the direct method of the GAN architecture; hence, there is an urgent need to discover the impact of the hierarchical or iterative method on glaucoma screening. Moreover, almost all of the researchers worked on

BV segmentation, and very few used OD and OC segmentation, which are the most reliable indications of glaucoma according to ophthalmologists. Future GAN research should focus on disease classification rather than on the segmentation of retinal anatomy. Most of the literature studies faced difficulties in terms of the early detection of glaucoma and low segmentation of fine vessels; therefore, alternatives should be developed, for example, using the RNFL to indicate the early presence of the disease or exploiting the prior knowledge of vascular connectivity to improve upon the segmentation performance of the current methods. Although the RNFL is a good sign for early glaucoma screening and has been incorporated as one of the gold standards of glaucoma evaluation [109], very few studies utilized the RNFL with GANs. OD/OC segmentation may lead to interference with pathological aspects such as large genetic OD sizes. Based on the reviewed papers, we noticed that only one article [1] has used RNFL for glaucoma screening. Although that study achieved impressive results, the authors used a private data set.

Most of the previous studies concentrated on the segmentation task. As much as 17/30 papers worked on retinal landmark segmentation [1-17], while only 2 papers worked on disease classification [18,19], and 5 papers worked on image synthesis to address the lack of medical images [20-24]. However, the rest of the papers (6/30) performed multiple tasks (eg, segmentation and classification, synthesis and segmentation) [25-30]. In conclusion, more than 50% (17/30) of the literature worked on segmentation task and few researchers have worked on classification and synthesizing retinal images. Therefore, future studies should take these statistics into considerations.

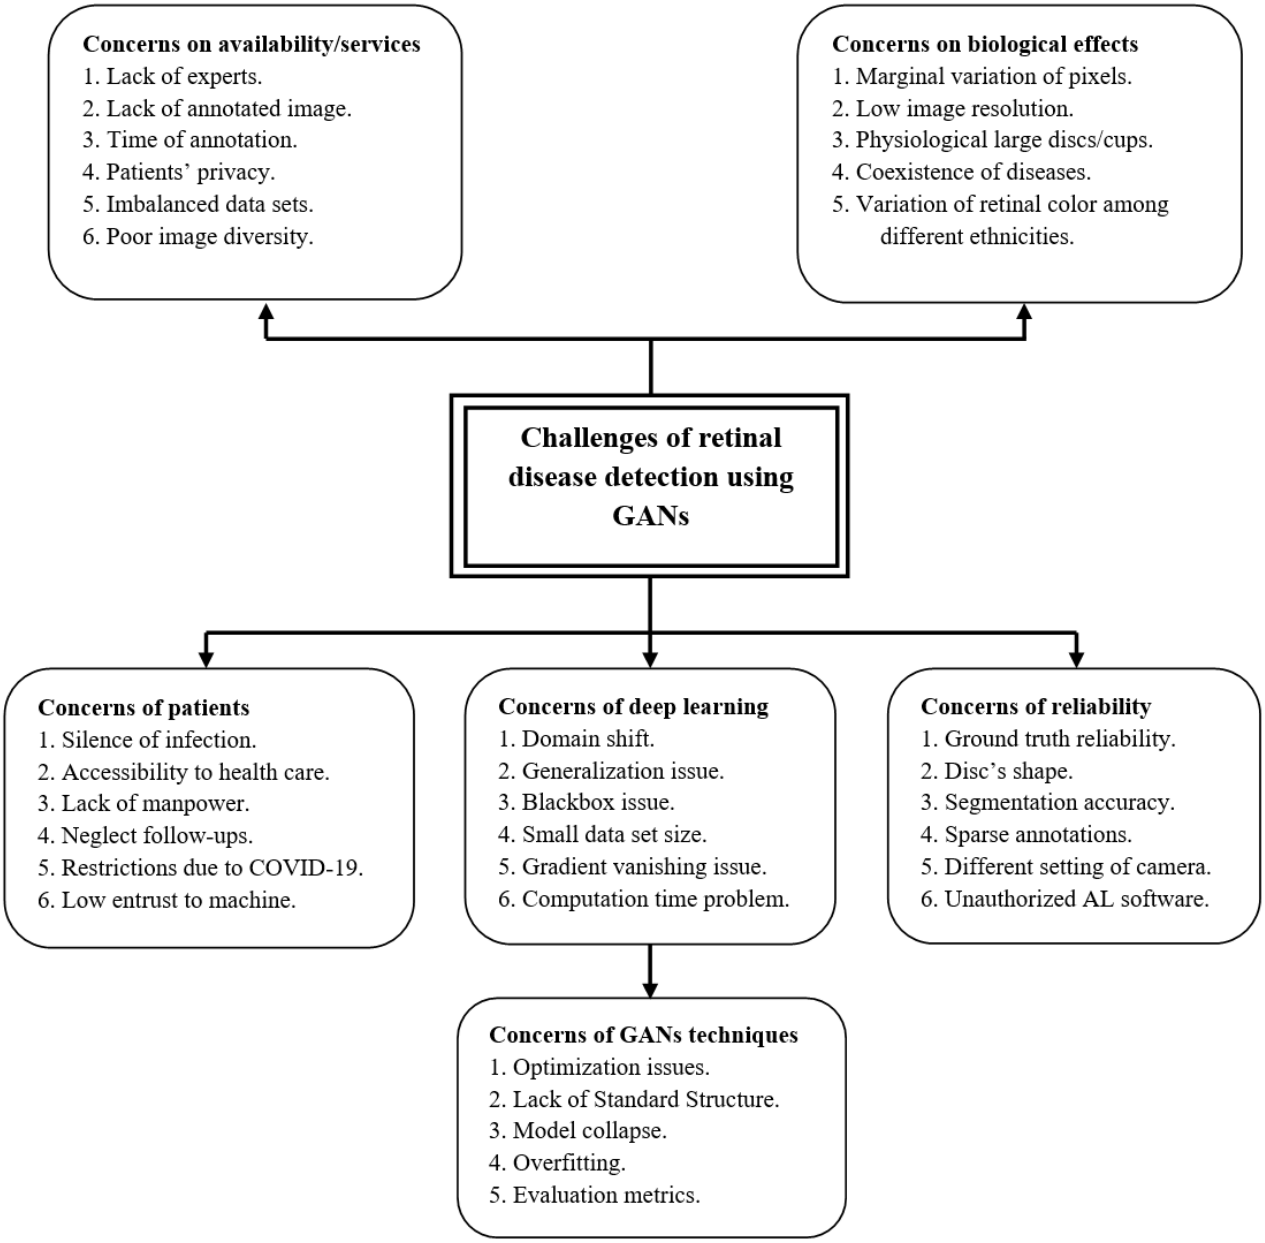
In the following sections, the included papers will be discussed in detail. We present comprehensive diagrams showing the factors that motivate researchers to carry out their work in this area, highlighting their encountered challenges, and summarizing significant recommendations for addressing their faults in future work.

Challenges

Overview

Glaucoma is a serious disease. Therefore, researchers and developers attempt to exploit the magic of DL technique to help doctors and patients diagnose the disease at its early stage. However, various challenges hinder their expectations; some of those challenges implicitly exist in the nature of DLMs, or are somehow incorporated within DLMs (eg, data richness, diversity of data, and powerful hardware), besides the challenges of GANs architectures (eg, model collapse, optimization, Nash equilibrium, and evaluation metrics). All these challenges have been summarized and discussed in this section along with their relevant references to provide the readers with direct access to the original papers for further discussion. Figure 10 categorizes literature challenges into 6 groups to further assist discussion. Each group is indicated with a separate shape.

Figure 10. Challenges of glaucoma screening using GANs technique. AL: artificial learning; GAN: generative adversarial network.



Challenges Related to Patients

The silent progress of glaucoma disease constitutes a crucial challenge worldwide. Half of the infected people do not experience any symptoms at early stages [5-7]. According to various studies, more than 60 million cases were diagnosed globally in 2013, and it is expected to exceed 75 million and 111 million cases by 2020 and 2040, respectively [9,10]. Especially among rural populations, China and India are considered to be the home to approximately 40% of glaucoma cases globally [110]. These populations, mostly in developing countries, suffer from difficulties in accessing medical centers, unavailability of experts, high costs of health care, and sustainability of health care services [111], in contrast to Western countries, where health care is cost-effective and different socioeconomic situations of patients are supported, and thus treatment for glaucoma remains affordable [106].

In addition, the recent pandemic, COVID-19, has enforced social distancing during communication. Therefore, there is a great need to promote ocular screening in conjunction with telemedicine as a remote monitoring tool [112], alongside the presence of handy cheap smartphones, whereby patients can collect their own IOP data themselves with accurate tonometers and free anesthesia [113]. Although DLMs positively affect both doctors and patients' style in terms of decision making, cost affordability, and health care accessibility, there remain some serious challenges, such as technical and clinical challenges, interpretation of the results, and patient trust in machines [112]. Zapata et al [114] predict that very soon AI will start assisting specialists in achieving high levels of consistency and accuracy beyond human abilities.

Challenges Related to Reliability

Reliability is a key to adopting computer technology in the medical field. Deep learning techniques may misclassify

segmenting some pixels due to low image contrast or heavy overlap between foreground and background pixels, leading to false-positive/false-negative result [57,81]. In some cases, doctors are dissatisfied with deep learning segmentation performance, as it is not as real as their expectations. Taking RNFL segmentation as an example, the segmentation results do not have specific geometrical shape of RNFLD as the gold standards and large segmentation errors of fundus images [83]. Furthermore, the variability of shape and extremely inhomogeneous OD structure appearance result in inaccurate CDR measurement compared with ideal ones [115-117]. In some cases, deep learning approaches neglect domain knowledge that doctors care about, such as CDR [118].

Existing methods often suffer from poor segmentation of the fine vessels [78,80] due to weak ability of antinoise interference or insufficient segmentation of vessels [49]; therefore, prior knowledge of BVs connectivity may improve the segmentation performance. Meanwhile, the low reliability of manual detection and the small size of public data sets increase the complexity of morphological assessment of nonglaucomatous optic neuropathy [119,120]. Robust ground truth labeling must be generated after a comprehensive evaluation, including structural imaging, clinical examination, and perimetry [121]. Doctors mostly decide the disease status. Although all clinical symptoms occur, it can lead to differences within annotators, and thus exaggerated annotations [52,106,122,123]. The reliability of glaucoma algorithms is restricted due to the lack of reference ground reality for glaucoma [115,124]. DLMs have a remarkable ability to address glaucoma. However, it is critical to have gold-standard algorithms for assessing and detecting glaucoma [54], as well as for editing or synthesizing images using the GAN techniques [97].

Sometimes, researchers tend to exclude low-quality or sparsely annotated images during the training phase; this kind of regime weakens the algorithm and leads to less reliability in real-life cases [111]. Furthermore, incorporating nonspecialists for image grading limits the reliability of identification [125]. Finally, although most of the reviewed papers have shown outstanding diagnostic performance, at times researchers do not mention some hyperparameter values used in the training stage, particularly when they use their own private dataset [112]. Excessive screening can result in overdiagnosis. DLMs could also be harmful if the diagnostic software is issued directly to patients, as future opportunities and risk of AI could be magnified [55].

Challenges Related to Biological Effects

Pathological change and image quality play a major role in the accuracy of glaucoma diagnosis [57,73,123]. Early and moderate glaucoma stages are considered one of the biggest challenges faced by ophthalmological practice due to the marginal variation size of CDR compared with normal eye [126]. Serener and Serte [127] have used ResNet-50 and GoogLeNet with transfer learning for early and advanced glaucoma detection, and found that GoogLeNet outperforms ResNet-50 with a trade-off performance between sensitivity and specificity. Besides, Bisneto et al [81] proposed GAN-based OD segmentation allied with an index of taxonomic diversity for extracting texture attributes aiming to detect early stages of glaucoma. They achieved outstanding results reaching up to 100% for accuracy and 1 for the receiver-operating characteristic curve. The misclassification of glaucoma and nonglaucoma is usually due to heavy overlap and extremely bad contrast between ocular structure and the background, leading to unsatisfied segmentation performance due to OC's undistinguishable boundaries [116]. Low-quality images (blurring and contrast) can result in unreliable model predictions. Furthermore, the lack of a clear OC border increases the misclassification rate [128].

There is a trade-off between image's quality and computational parameters of the network [129]. Therefore, the need for DLMs to downsample images into lower resolution (ie, 224 × 224) to reduce the computation time leads to reducing image contrast, and hence deteriorating key diagnostic parts of ocular images and weakening the capability to recover contextual information [86]. By contrast, performance of DLMs varied among ethnicities, for example, the Saudi population's performance is not the same as on Western populations. The differences among populations is due to the richness of melanocytes in the retinal pigmented epithelium of darkly skinned people compared with Whites [52]. Therefore, data sets used in glaucoma detection must follow specific standards to ensure heterogeneity and diversity of images.

Multiple eye disorders such as high myopia or pathologic are another major challenge leading to false-negative and false-positive results [54]. The main reason for the incorrect segmentation of glaucoma in myopia cases is the alteration of the macula and optic nerve appearance. In addition, the use of RNFL imaging for glaucoma diagnosis in patients with diabetes should be made carefully [130]. Myopia affects macular and RNFL thickness measurements due to the thinning and stretching of these layers caused by the increased axial length and optical projection artifact of the scanning region [131]. Myopia mostly causes misclassification of glaucoma due to its irregular ONH appearance [132]. In severe myopic cases, the color contrast between the foreground (OC) and the neuroretinal rim decreases due to an increased pallor in the rim. Furthermore, the increased pixels' values brighten the underlying peripapillary tissue and lead to difficult evaluation of the RNFL in the peripapillary area. In addition, torsion or tilting of the OD can occur, and the OD's rotation can result in an oblique view of the ONH [128].

In other cases, it is hard to distinguish between physiologic large cups and glaucomatous cases because both cases share a common feature (eg, large CDR) [117]. Diseases such as OD edema, OD hemorrhage, and glaucoma frequently make segmentation of OD rather difficult [133]. By contrast, retinal BV segmentation also has inherent challenges such as incorrect segmentation of pathological details and low microvascular segmentation [40].

Challenges Related to Availability/Services

Time, efforts, and lack of experts are the main challenges of medical care centers [88,134]. Therefore, computers have been increasingly used for automatic retinal segmentation to serve as a second opinion to the doctors, improve the diagnostic accuracy, and reduce the tedious work of annotating images

[43,46,135]. Particularly, GANs showed impressive performance in medical image synthesis and it is usually employed to tackle the shortage of annotated data or lack of experts [74,79,95]. Generally, medical images are usually rare, expensive, and full of patient privacy issues [51,88] and the publicly available data sets are often imbalanced in size and annotation [46,57,84]. In general, segmentation tasks suffer from an immense problem of class imbalance. Thus, the accuracy metric is not sufficient alone until concluding a system's efficiency on both sensitivity and specificity. They should, however, be considered as an essential evaluation metric [72].

Diaz-Pinto et al [90] proposed a GAN method with semisupervised learning to develop a good image synthesizer to tackle the shortage of retinal image availability and support generalization ability. Additionally, Liu et al [136] created a large-scale glaucoma diagnostic fundus images (FIGD) database. They proposed the glaucoma diagnosis with a complicated neural networks method for automatic detection of glaucomatous optic neuropathy. Importantly, the method has the potential to be generalized throughout populations.

Various GAN-based methods have been proposed to mitigate image labeling [43,50,51,75,87,92]. However, this challenge remained open as the current literature results are still inaccurate (eg, fail to generate very thin vessels). Lahiri et al [43] concluded that the diversity of annotated images is more important than the actual number of annotations. Finally, rural areas experience difficulties in locating ophthalmologists. This also necessitates more future work to use telemedicine in ophthalmology [55].

Challenges Related to the Nature of Deep Learning

With the recent advancements in DLM methodologies, promising results in the field of ophthalmology have been obtained. Many GANs and CNNs models are proposed in computer vision. However, DL approaches face several difficulties, such as domain shift.

Domain shift is the disparity in appearance distribution between various data sets due to different camera settings, illumination variation, different screening angles, or out-of-focus ROI. As a result, domain shift hinders the generalization capability of deep networks [89]. In most literature, training and test data sets come from the same image distribution. However, this is not always the case in real life. Therefore, it may significantly damage the real-life applications if not handled beforehand [72]. Kadambi et al [79] proposed an unsupervised domain adaptation framework by allowing the model to learn domain-invariant features to enhance segmentation performance and generalization capability. Wang et al [77] tried to align the distributions of the source and target domains so that the labeled source images can be used to enhance the classification efficiency of the target domain.

Deep learning addressed many issues in the traditional methods of ML. However, it also brought new difficulties. The most crucial issue is the ambiguity of the diagnosing result; in other words, the blackbox problem [53,56]. DLMs are blackbox in nature and do not have diagnostic explanations to confirm their effectiveness in a real clinical setting. Wang et al [73] proposed a pathology-aware visualization approach for feature visualization using DNNs to explain better how decisions are taken by computer, and therefore find pathological evidence through computer-aided diagnosis. Furthermore, for this purpose, Zhao et al [115] proposed a weakly supervised model due to its ability to simultaneously learn the clinical evidence identification and perform the segmentation task from large-scale weak-label data that further improves glaucoma diagnosis.

The lack of publicly available data sets for training the model is another significant challenge concerning deep learning approaches. Therefore, Orlando et al [132] proposed a data set named REFUGE, which contains 1200 fundus photographs with standard gold segmentations and clinical glaucoma marks. Moreover, Li et al [137] created the LAG database containing 11,760 fundus photographs classified as either positive glaucoma (4,878) or negative glaucoma (6,882), which is the largest among the currently existing databases. According to Asiri et al [52], the key problem of constructing a robust deep CNN method is not the availability of broad data sets but instead the diversity of annotation of those images [43]. A major difficulty of each algorithm is its validity in multiple patient cohorts with diverse conditions. Therefore, for a DLM to be sturdy, it must be effective across various data sets [105].

Recent studies demonstrated that more complicated and informative image features might be discovered when growing the depth of the network [138,139]. However, as the network depth rises, deeper CNN has poor diagnostic efficiency due to the gradient disappearance issue or the gradient explosion problem [88,140,141]. Researchers mostly use shortcut links (skip connections) that skip one or more layers while training deep networks, as was the case with [88,126,128,129]. Alternatively, in GANs techniques, using WGAN or LSGAN gives a smoother gradient that contributes to stable training [42,79]. Another concern that should be considered before building up deep models is the *computation time*. As there is a trade-off between model's depth and the efficiency, the deeper the architecture the greater the number of parameters it gets, which eventually increases computation time [140].

Challenges Related to GAN Technique

Despite all the ongoing developments and studies, GANs suffer from several challenges and weaknesses besides the challenges related to deep learning nature (eg, blackbox, generalization capability, computation time, and annotation cost). The most critical concern with GANs is the instability of the training process (Nash equilibrium point) [98,142]. Zhao et al [82] used the residual module that allowed easy optimization of competitive networks, while Tu et al [78] used WGAN-GP to alleviate training instability of the traditional GAN. Biswas et al [92] carefully adjusted hyperparameters to balance between the 2 networks (G and D). Park et al [94] improved learning performance and mitigated imbalanced learning by introducing new loss functions for the generator and re-designing the discriminator's network. However, it remains challenging to determine which algorithm works better than others or what modifications are critical to enhancing the results. Lucic et al [100] found that most models could achieve comparable scores

with appropriate hyperparameter optimization and random restarts. According to Kurach et al [101], the nonsaturating loss over data sets, architectures, and hyperparameters is sufficiently stable.

Besides, in GANs, the possibility of mode failure/collapse persists while training the model. Model collapse occurs when data generated from GANs mostly concentrate on very narrower modes (partial collapse) or 1 single mode (complete collapse) [68,99]. By contrast, if the discriminator becomes very strong during training, the generator gradient gradually decreases and eventually disappears. As a result, the generator learns nothing. The imbalance between generator and discriminator networks contributes to overfitting. Many approaches have been proposed to tackle these challenges; for example, Radford et al [59] aimed to address instability training issues, and Kadambi et al [79] created a new adversarial domain adaptation architecture, led by Wasserstein for better stability and convergence.

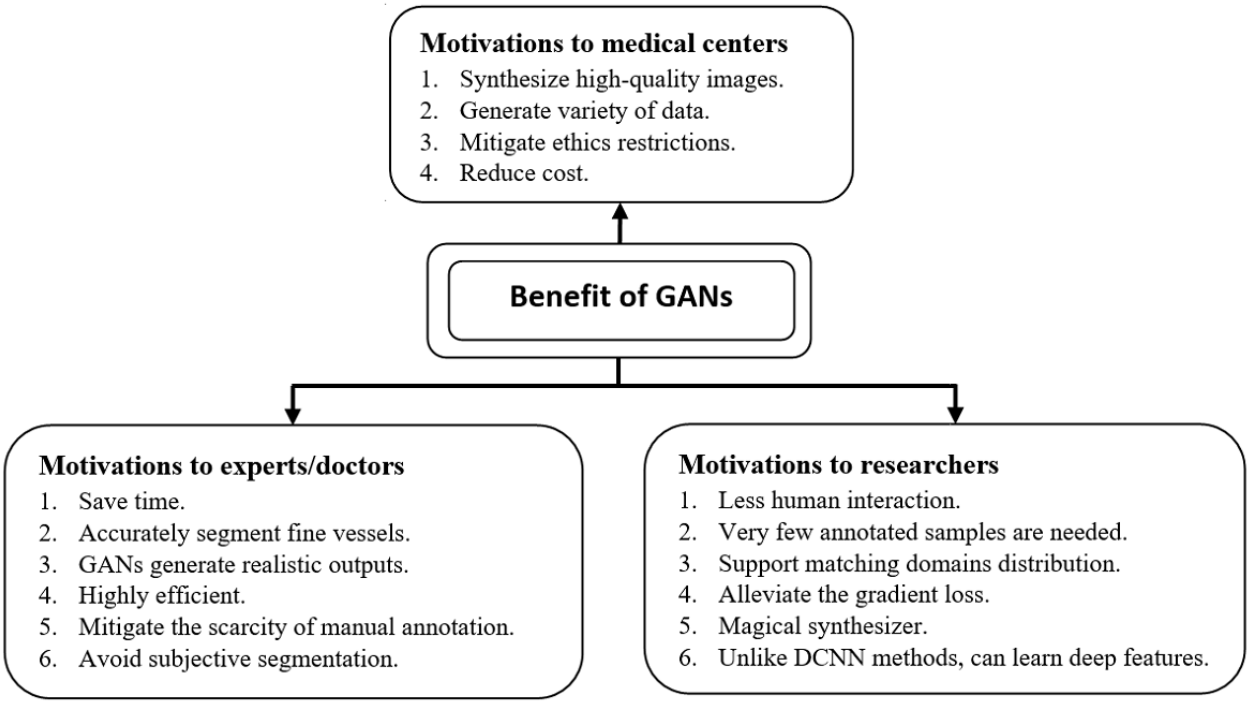
The lack of standard evaluation metrics is another big issue in GANs compared with other generative models. Inception score (IS), average log likelihood, Fréchet inception distance (FID), Wasserstein metric, etc. are quantitative measurements of GANs. There is no majority vote on which assessing measurement is the best. Different scores rely on various aspects of image generation. However, some measurements seem more plausible than others (eg, FID is more durable to noise). FID can compare the similarity between real and generated images [143], which is considered more effective than IS [70].

In conclusion, the main causes of GAN problems can be summarized as follows: (1) The distance calculation of the corresponding optimization (such as Kullback–Leibler divergence and Jensen–Shannon divergence) is unreasonable. (2) It is difficult to overlap the generated distribution with real distribution. Although the GAN technique is a new, interesting, and attractive field of study in many applications, further studies are needed to resolve the uniqueness of generated samples, poor convergence, and complete model collapse challenges.

Motivations

Adopting deep GAN in ophthalmology is a promising and significant field of study. This section reports some of the literature's characteristics, which we classified on the basis of references to support further discussion (Figure 11).

Figure 11. Benefits of GANs-based methods for glaucoma screening. DCNN: deep convolutional neural network; GAN: generative adversarial network.



Motivations Related to Experts/Doctors

Detection of any retinal defects must be through analysis of ocular images. Analysis of retinal images, however, must involve trained physicians to analyze and assess digital color fundus images. Such a process requires a great deal of time and human work; therefore, GANs support doctors in mitigating this extensive bottleneck [50,51,91]. Furthermore, deep GANs techniques are unlike CNNs, where the same GAN approach could be applied to a wide variety of cases and still produce reasonable results [45]. GANs can detect the OD in fundus photos with pathological changes or irregular highlights [57,86]. In the case of vessel segmentation with CNN-based methods, outputs are usually blurry around small and weak branches or suffer from a problem of nonconnectivity of segmented vessels; however, GANs better segment capillary/thin vessels of fundus images [76,80,84], and thus serve as a second opinion to ophthalmologists [72]. GANs are the framework that allows to create and use practical outputs as a gold standard [44]. Therefore, these frameworks were adopted by Lu et al [83] due to their ability to generate the required specific geometry of RNFLD, which is close to ground truth with high precisions, accuracy, and fewer segmentation errors, despite the existence of multiple pieces of RNFL or low-contrast images. Thus, its

segmentation results are much more trusted by doctors than CNN's.

Adversarial learning avoids scarcity of manual annotation and subjective segmentation made by non-expert clinicians as this methodology is mainly data driven [72,85]. In glaucoma classification, enforcing GANs to synthesize images with similar visualization results as the reference image will help mitigate the drawbacks of binary labels (negative or positive) that limit the visualization methods to recognize pathological facts underlying diagnosis by DNNs [73].

Motivations Related to Researchers

Deep learning in retina images is very effective and useful [72]. However, they are often affected by domain shifts across data sets. As a result, a generalization of DLMs was severely hindered. Therefore, researchers tend to exploit generative adversarial learning for domain adaptation by encouraging the target domain predictions to be close to the source ones [79,89]. Domain adaptation is often used to overcome the lack of large pixel annotation using off-the-shelf annotated images from other relevant domains. Alternatively, researchers exploit the existence of a large amount of unlabeled data to train a classifier using the power of DCGAN in a semisupervised learning scenario [90]. Semisupervised learning is in the middle way between unsupervised and supervised learning; therefore, less human intervention is required when combined with GANs for better semantic segmentation [74]. Using GANs techniques, Lahiri et al [43] performed image segmentation with very few annotated samples (0.8%-1.6%), nearly 500-1000 annotations. Further, Zhao et al [93] proposed an image synthesizer using GANs with style transfer and then integrated the outputs into the training stage to boost segmentation efficiency using just 10 samples.

With deep adversarial learning, researchers aim to reduce domain discrepancy [144,145] by improving the quality of the generated outputs to be as close as possible as the inputs. Wang et al [77] exploited label information for matching domain distribution. Ma et al [42] applied the least-squares loss function instead of sigmoid cross-entropy to generate images with distribution close to the real ones and also alleviate gradient vanishing problems. Furthermore, Liu et al [57] added a patch-level adversarial network to enhance image consistency between ground truth and the generated samples, which further boosts segmentation performance.

GANs are capable of learning the mapping from the input image to the output image as well as learning a loss function to train this mapping [45], unlike existing DLMs, which use a unified loss function for retinal vessels segmentation, thereby producing blurry outputs with false positives around faint and tiny vessels [84], which is in contrast to GAN variations (eg, WGAN-GP and M-GAN) that provide accurate segmentation results around small and weak branches [78], reduce low microvascular segmentation [94], and preserve the connectivity of arteriovenous vessels [76]. Moreover, AEs and GANs in a single system facilitate generating vessel maps without the previous existence of retinal vessel tree [87]. Besides, unconditional GANs can synthesize retinal images without using prior vessel images [92].

Although researchers recommend using DCNN for efficient segmentation tasks [146], the existing limitations of DCNNs are insufficiency of feature extraction, weak generalization capability, and poor capability to recover low-context information, unlike GANs, which are used to alleviate these problems as in Jiang et al [86], who proposed GAN with transfer learning, data augmentation, and skip connection concepts to overcome these challenges. Bisneto et al [81] impressively improved glaucoma segmentation and classification results using GANs allied with texture attributes identified by taxonomic diversity indexes. They achieved promising results (sensitivity, specificity, and accuracy of up to 100%).

For optimizing network complexity, Wu et al [49] applied the attention Gates technique in a standard GAN to encourage the propagation of features, promote reuse of features, and greatly reduce network parameters when paired with DenseNet instead of conversion layer. Alternatively, using dilated convolutions in the generative networks effectively expands the generator's receptive field without the number of calculations [82]. Adversarial training has been shown to improve the long-range spatial label interaction without expanding the segmentation network's complexity [147].

Motivations Related to Medical Centers

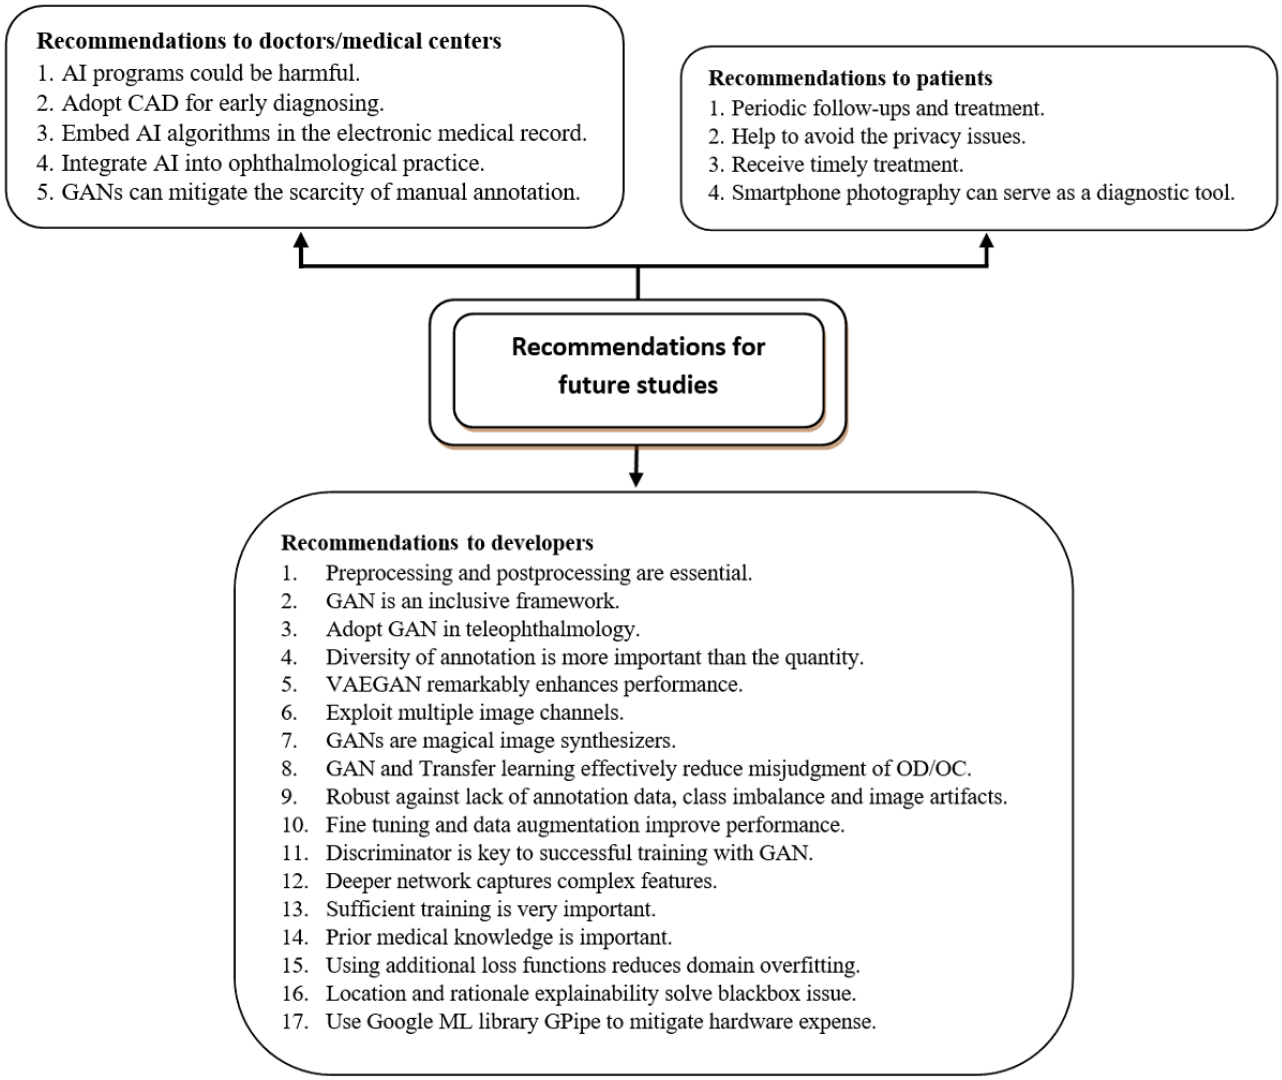
We think the best medical treatment is achieved when the doctor–patient relationship is built on honesty and concern. DL cannot substitute real relationships, but can complement them [104]. GAN architectures are versatile. For various training samples, the objective feature can be re-designed and more free model designs can be used [98]. The extraordinary feature of GANs in the medical field is synthesizing high-quality images with global consistency(eg, color consistency and both BV and OD occupy the same proportional area as the real images) [58,92]. Bisneto et al [81] proposed a method that learns the mapping function between retinal landmarks (BV, OD, and OC) and synthesizes images using the 3 channels (RGB). Furthermore, the method exploits the merit of a large receptive field of GANs to generate good segmentation results [82].

Incorporating GAN techniques in the medical field helps enrich health care centers with various data and effectively solves data imbalance problem [87,134]. As a result, this feature facilitates solving ethical issues surrounding patients' privacy [72], saves memory and time needed to collecting images [79], reduces costs [88], and saturates the nature of data-hungry DLMs [51].

Recommendation

In this section, we briefly include guidelines from the literature to alleviate existing challenges faced by researchers, doctors, medical centers, and patients, as well as present ways to achieve a correct diagnosis of retinal defects (Figure 12).

Figure 12. Recommendations of using GANs-based methods in glaucoma screening. AI: artificial intelligence; CAD: computed-aided design; GAN: generative adversarial network; OC: optic cup; OD: optic disc; VAEGAN: variational autoencoder with GAN.



Recommendations to Doctors and Medical Centers

Higher-image resolutions significantly improve performance of GANs [87,148]. The key factor in obtaining GAN's high-quality synthetic outputs is the high-resolution paired images and the architecture of the generator [46]. Moreover, annotation variety is more important than the actual number of annotations [43]. Therefore, doctors must develop a public data set with high-resolution images that meet the quality assessment system [105]. Furthermore, it must be accessible and include multiethnicities to ensure generalization capability [108]. Besides, experts must validate deep learning models on the sizable heterogeneous population under different conditions [52], as direct release of DL application without prior checking could be harmful [55].

To improve public health, reduce health care costs, and enhance patients' perception, doctors shall adopt DL techniques in the medical field to tackle these challenges [53]. Adopting deep learning applications in magnetic resonance imaging and X-ray image processing is an interesting area of research [93]. All glaucoma studies emphasized the importance of CAD programs for early disease detection and for improvement of screening reliability [20].

In the future, GANs may be utilized to speed up AI development and application, allowing AI to comprehend and explore the environment [66]. Innovative and radical solutions for the health care system must be improved alongside glaucoma screening [106]. Significant improvements in instrumentation and interpretation can lower the cost of glaucoma screening in the future. Embedding glaucoma AI algorithms in the electronic medical record will improve outpatient management [107]. However, it is up to the physicians to lead the way in deciding how to incorporate AI in a new era of glaucoma management.

Automated retinal imaging technologies can reduce barriers to access and monitoring of the health system. Thus, AI integration into ophthalmology can improve patient care [56], help clinicians focus on patient relationships, and enhance health services [104], all of which can decrease irreversible blindness [54]. GANs can reduce the scarcity of manual data annotation and also be used as a clinical support tool [72].

Recommendations to Developers

A CNN in a generative learner is used for image segmentation tasks and obtaining successful outcomes [149]. GAN is an inclusive system that can be combined with various deep learning models to address problems that conventional ML algorithms cannot solve, such as poor quality of outputs, insufficient training samples, and deep feature extraction [68]. Furthermore, it outperforms conventional methods in editing and synthesizing image [69]. GAN allied with transfer learning can effectively reduce misjudgment of OD/OC in glaucoma cases and improve accuracy and generalization capability; however, better backbone network and different upsampling methods are required to improve performance [86] and exploring other downstream tasks may enhance the model's performance [93]. Although there is a vast increase of GAN applications, further studies are required to improve its efficiency and performance [70]. Incorporating spatial information, attention-based information, feature-maps information, and image channels (RGB) to improve network performance is a current research trend [140].

GANs can generate samples with distribution close to real data. Thus, they can be used in a systematic study of parallel systems [96]. GANs or its variants remain the future trends for mitigating imbalanced learning through generating samples close to real data, or enhancing model performance when combined with VAEs [58,65,72]. Thus, it is used as a sophisticated data augmentation technique to generate heterogeneous samples and ensure prognostic characteristics of images [52].

To date, only a few studies have experienced AI technologies in teleophthalmology [56]; photography using smartphones can be used as a diagnostic tool for ocular diseases [105]. Nowadays, there is a great need for remote disease monitoring and screening [107], especially during the COVID-19 pandemic and the vast infection transmission [150]. Thus, future study should emphasize on deep learning and telemedicine/teleretinal as potential gamechangers in the eye-care field [106].

Wang et al [89] proposed a very lightweight network architecture for joint OD and OC segmentation based on the MobileNetV2 backbone, which has few parameters and half testing time compared with the XCeption backbone, which promotes the network as a mobile app for glaucoma detection. Bisneto et al [81] presented GAN and texture features for automatic detection of glaucoma, and achieved impressive results that reached up to 100% for sensitivity, specificity, and accuracy. The authors indicated a proposal to transfer their method into a mobile app in a future study.

Future research should emphasize GANs and semisupervised learning for image synthesizing, aiming to improve the classification accuracy and the quality of the generated images simultaneously [43,75,90]. Adopting GANs in the medical field remains in its infancy, with no breakthrough application yet clinically implemented for GAN-based approaches [95]. For better feature extraction, researchers must exploit full feature information on RBG channels, spatial structure, and geometry of landmarks [83]. Semantic segmentation may reduce manual labeling effort [50,74] and enhance model performance when incorporated with WGAN domain adaptation [79]. In ophthalmology diagnosis, adversarial domain adaptation can be an important and effective direction for future research [72,88,151]. In addition, exploring the relationship between the quality of the generated image and the performance of the CAD system is needed [46].

With the envision to improve deep learning performance, preprocessing and postprocessing are essential for accurate segmentation [52,80,94]. Barros et al [20] concluded that data set size has a huge impact on the results. However, Lahiri et al [43] amazingly demonstrated that annotation diversity is more important than annotation count. GAN can make use of large amounts of unlabeled data [66,87].

Regarding GAN evaluation metrics, future studies should focus on more objective and systematic evaluation methods. However, further FID examination is required [100]. Developing quantitative assessment metrics thus remains a crucial research direction [152,153]. Researchers should evaluate their segmentation performance on public data sets [74] with heterogeneous and multimodal designs using less data-hungry algorithms [105]. In addition, the performance other classifiers (eg, XGBoost) and other cGAN architectures should be examined for faster and more accurate learning [81].

For glaucoma diagnosis, CDR and ISNT metrics present substantial information to be assessed [20]. More studies are needed to assess the validity of ophthalmology applications to detect AMD, diabetic retinopathy, and glaucoma in terms of accuracy, sensitivity, and specificity [54]. AUC, sensitivity, and specificity should be included in AI studies as the bare minimum [53].

Moreover, future research may utilize fine-tuning and data augmentation techniques to effectively improve model performance [52,81,86] and increase data set size for better training, and thus, synthesizing better classifiers [77]. GANs strength lies in its discriminator [32,80]. Duplicating the generator's structure improves robustness [94]. Adding more network layers help capture more in-depth features [82]. Training and optimizing the model remain critical [84,87], with regard to careful balancing between G and D [92]. Patch-based images should be used as input for both G and D [51,84]. U-GAN instead of U-Net should be used to improve the model's performance [49]. Additionally, exploiting previous knowledge of vessel structure [78,80,92] is critical for accurate segmentation [91]. Objective function supported with various loss functions may enhance model performance [84]; for example, WGAN-GP can avoid gradient disappearing and enhance training [92], Dice coefficient loss function for segmenting hard images [57], and least-squares loss function with dilated convolution can enhance small vessel segmentation [42]. On top of that, topological structure loss can enhance the connectivity of A/V classification [76], whereas binary cross-entropy loss function with false-negative loss function can improve training efficiency and increase segmentation robustness [94]. Furthermore, an adversarial loss can reduce the domain overfitting [154], and Wasserstein distance is preferable for domain adaptation, as it decreases the probability of mode collapse and avoids the gradient vanishing [79]. Weight normalization along with average pooling is the best design

setting when structured prediction is used with U-Net [43]. Exploring a combination of different styles instead of training dedicated models for a particular style is necessary [93]. MISH is a modern activation function that presented better results than ReLU on most current benchmark data sets [155].

To date, explainable DLMs for glaucoma screening utilizing retinal fundus images have not been proposed [156]. Researchers should focus on relational and locational explanation using saliency maps, heatmaps, or other invented methods to provide plausible explanations of DL decisions.

Lastly, future research should incorporate the distributed ML library GPipe proposed by Google [157] to mitigate hardware limitations. This may help train large-sized models and enhance performance without tuning hyperparameters [140].

Recommendations to Patients

Increasing the amount of data using a successful GANs synthesizer significantly saves the privacy of patients [72]. Good DLM offers timely treatment by providing wealthy information regarding patients' eye conditions [49]. In the near future, AI can support telemedicine platforms by facilitating the self-monitoring by patients through home-based diagnosis [56]. The availability of cheap, handy smartphones may also assist as a remote diagnostic tool [105]. This eventually could improve patient's perception and satisfactions [53], as well as encourage continuous follow-up and treatment [106].

New Direction of DL

Recently, DLMs have achieved positive retinal disease identification and segmentation outcomes. These technologies can revolutionize our way of life, and, probably in the next few decades, the field of medicine will change rapidly [53]. However, these techniques involve expensive hardware (eg, GPU requirements) and are greedy for images by nature. Thus, more advanced data augmentation techniques must be introduced to create heterogeneous samples while preserving the prognostic features of fundus images. A possible approach in this regard is to explore GANs [52,158]. Building systematic deep learning models trained on heterogeneous and multimodal data with fewer data-hungry algorithms can boost the effectiveness of AI in clinical settings [105]. Additionally, AI algorithms should be incorporated into electronic medical records to promote outpatient management, which is another fascinating subject [107].

From the viewpoints of accessibility, cost-effectiveness, and health care protection, there is a tremendous need to promote remote glaucoma monitoring in developed countries and rural communities, allow patients with glaucoma to obtain their own IOP data with anesthesia-free and reliable tonometers [113], and enable home-based evaluation and disease control (eg, rendering home tonometry accessible at a lower cost). Most importantly, within the current situation of the COVID-19 pandemic, new directions for DLMs can be implemented via teleretinal screening apps in ophthalmic settings to maintain maximum protection for both physicians and patients at a lower cost.

Improving the quality of diagnosis in terms of class imbalance, refining the training phases of GANs, and enhancing the computation time to better diagnose glaucoma variants remain obstacles [20,52,100]. Furthermore, it is necessary to note that GANs have not been used to diagnose difficult retinal disease to date, and GAN evaluation metrics are yet another challenging path of study [68].

Finally, combining GANs with other approaches is another prospective research approach; for example, the fusion of GANs with reinforcement learning, function learning, or conventional learning to create new AI applications and facilitate the advancement of these methods is also worth investigating [66,98].

Limitations of the Study

This most important limitation of our analysis is the number and identification of the source databases; however, the selected works form a reasonable and broadly representative selection of the chosen sources. Furthermore, the exclusion of other retinal diseases besides glaucoma, due to its severity worldwide, is considered another limitation. In addition, a quick view of the research activities on this critical retinal disease and GANs does not necessarily reflect the research community's response.

Conclusion

Providing adequate health services to people with retinal disorders has been a global issue. Studies are still ongoing to diagnose retinal disorders using deep learning; however, papers adopting GANs for glaucoma detection are not as abundant as those utilizing DL or ML methods. Consequently, insights into this emerging area are needed. Six papers [18,19,26-29] have worked on glaucoma classification–based GANs, and the majority tended to use GANs for segmentation or synthesizing retinal images.

The contribution of this study lies in analyzing and taxonomizing literature works in the field of glaucoma detection using GAN-based methods. To the best of our knowledge, all the previous studies generally discussed AL or DL effects on retinal diseases, and none particularly surveyed GANs for glaucoma detection. This makes our work first to address this emerging technique.

According to our taxonomy, the majority of the collected papers paid more attention to single landmark segmentation (eg, BVs) than to the segmentation of multiple landmarks. Some techniques were of tremendous or little interest (eg, the DCGAN and cGANs). Researchers worked in this field, identified their difficulties, and suggested recommendations to overcome the current and expected challenges. Other studies focused on improving GAN architectures rather than adopting them for diagnosis. To date, there has been no specific work adopting a GAN as a smartphone app or in telemedicine. Therefore, filling this gap is important for both patients and physicians to ensure fewer physical meetings during the global COVID-19 pandemic. Furthermore, new directions in this field have been explained.

Abstract

Background: Web-based content is rapidly becoming the primary source of health care information. There is a pressing need for web-based health care content to not only be accurate but also be engaging. Improved engagement of people with web-based health care content has the potential to inform as well as influence behavioral change to enable people to make better health care choices. The factors associated with better engagement with web-based health care content have previously not been considered.

Objective: The aims of this study are to identify the factors that affect engagement with web-based health care content and develop a framework to be considered when creating such content.

Methods: A comprehensive search of the PubMed and MEDLINE database was performed from January 1, 1946, to January 5, 2020. The reference lists of all included studies were also searched. The Medical Subject Headings database was used to derive the following keywords: “patient information,” “online,” “internet,” “web,” and “content.” All studies in English pertaining to the factors affecting engagement in web-based health care patient information were included. No restrictions were set on the study type. Analysis of the themes arising from the results was performed using inductive content analysis.

Results: The search yielded 814 articles, of which 56 (6.9%) met our inclusion criteria. The studies ranged from observational and noncontrolled studies to quasi-experimental studies. Overall, there was significant heterogeneity in the types of interventions and outcome assessments, which made quantitative assessment difficult. Consensus among all authors of this study resulted in six categories that formed the basis of a framework to assess the factors affecting engagement in web-based health care content: easy to understand, support, adaptability, accessibility, visuals and content, and credibility and completeness.

Conclusions: There is a paucity of high-quality data relating to the factors that improve the quality of engagement with web-based health care content. Our framework summarizes the reported studies, which may be useful to health care content creators. An evaluation of the utility of web-based content to engage users is of significant importance and may be accessible through tools such as the Net Promoter score. Web 3.0 technology and development of the field of psychographics for health care offer further potential for development. Future work may also involve improvement of the framework through a co-design process.

(J Med Internet Res 2021;23(9):e19896) doi:10.2196/19896

KEYWORDS

patient education; web-based health information; internet; patient engagement; mobile phone

Introduction

Background

In the United Kingdom, up to two-third use the internet to obtain health-related information at some point in their journey [1,2]. The internet has become an important source of education for patients, who are increasingly expected to, and are motivated to, play an active role in making decisions related to their health [3]. Patient education is defined as "the process by which health professionals and others impart information to patients that will alter their health behaviours or improve their health status" [4]. This may include information that is factual or related to patient experience, depending on the issue being addressed [5,6]. Reports suggest that 70% of the patients would like their physicians to recommend a source of web-based information relating to their medical condition, but only 4% of the patients receive such a recommendation [7].

Web-based patient health care information has several potential benefits, including convenient 24-hour access potentially wherever you are, ability to enhance knowledge acquisition [8,9], reduce anxiety [9], and improve the quality of conversations during health-related encounters. However, the effect of web-based content on patient empowerment, self-efficacy, and health attitudes has been found to be variable [9]. This may be due to the absence of an evidence-based framework outlining the factors that should be considered for improving engagement with web-based health care information.

Objectives

In this narrative review, we aim to identify and evaluate the factors that should be considered when producing engaging and high-quality web-based health care patient information. We also aim to incorporate these findings into a framework that may be useful as a guide to developing web-based health care information.

Methods

Overview

A comprehensive search of the PubMed and MEDLINE database was performed from January 1, 1946, to January 5, 2020. The Medical Subject Headings database was used to derive keywords and search term combinations, which included "patient information," "online," "internet," "web," and "content." All studies pertaining to the factors affecting engagement in web-based health care patient information were included. No restrictions were set on the study type. Only studies in English were included. Analysis of themes arising from the results was performed using inductive content analysis. All retrieved abstracts and titles were reviewed by 2 independent investigators (EA and LAO) for relevance pertaining to engagement with web-based health care content. Disagreements between the reviewers were solved by consensus. Manual cross-checking of the reference lists of the identified papers was carried out to identify any other potentially relevant studies.

Analysis of themes arising from the results was performed using inductive content analysis [10]. This involved the reviewing of titles and abstracts by an author (UJ), with free generation of the categories relating to *factors associated with high-quality and engaging web-based content*. The categories were named using content characteristic words, and these were expanded into subcategories. The number of times a category was reported in the articles was totaled, and a list of categories was created in order of the frequency of mentions. All authors reviewed this list to decide which categories would be included in the final list.

Eligibility Criteria

As this is the first narrative review of its kind, no limitation was placed on study type or on surrogate measures of the outcome described.

Outcomes

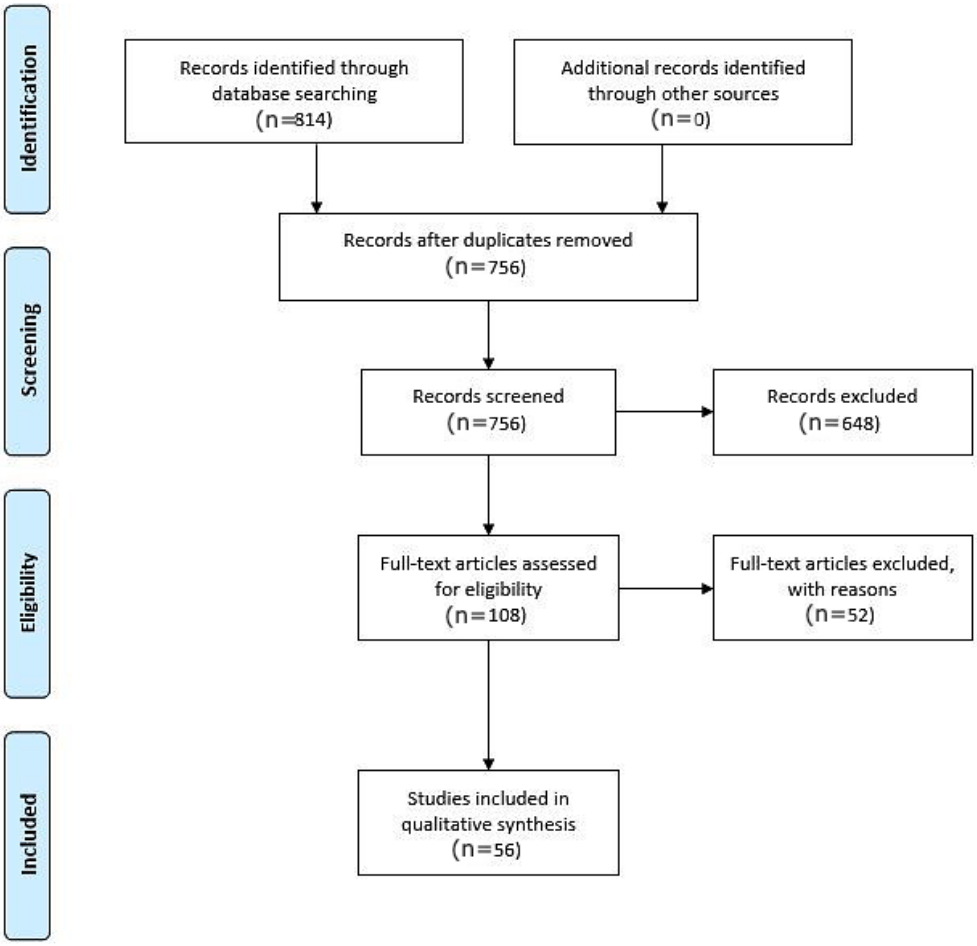
All studies relevant to quality of engagement in web-based health care content were included.

Results

Overview

A total of 814 articles were identified, and of these, 108 (13.3%) were selected for full-text review based on their title and abstract. Full-text screening of the 108 articles resulted in the final selection of 56 (51.9%) articles, from which seven categories were derived. Figure 1 shows the Preferred Reporting Items for Systematic Reviews and Meta-Analyses flowchart which depicts the stages of article selection.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart showing article selection.



Description of Studies

Development of Categories

The studies were mostly observational and qualitative. A total of 3 randomized controlled trials and 5 systematic reviews were also identified. Categories relating to *factors associated with high-quality and engaging web-based content* were developed according to themes that were found to arise in the studies identified. The categories settled upon were as follows (with the number of papers reporting included in parentheses): (1) textual information (16 papers); (2) discussion boards or web-based groups (3 papers); (3) video content (11 papers); (4) visuals or pictographs (1 paper); (5) device accessibility (12 papers); (6) stage of patient journey (8 papers); and (7) credibility and completeness of information (4 papers; Table 1).

Table 1. Studies pertaining to engagement with web-based content. Studies are according to mode of engagement (N=56).

Study	Study type	Content	Outcomes pertaining to quality of web-based health care patient content	Main results
Textual information				
Chedid et al (2018) [11]	Observational study	Government-hosted website, textual, and visual aids for prenatal health promotion	• Comprehensiveness, evidence-based information, accessibility, and inclusivity. • Minimum of three referenced prenatal health topics necessary to be classed as evidence-based.	• Assessment of prenatal health promotion material revealed that 66.4% of the federal, 84.6% of the provincial or territorial, and 80% of the public health regional unit–hosted websites, and 87.5% of the e-classes were evidence based. Only 25% of the municipal websites met this standard. • No *P* values stated.
Ernst et al (2019) [12]	Observational study	Disorders of sex development, affiliated health care system's web-based information	• The SMOGa Readability Formula determined reading level, the PEMATb evaluated content for understandability and actionability, and the DISCERN Tool assessed treatment decision-making information.	• Reading level of webpages as determined with the SMOG Readability Formula met or exceeded high school grade level. The mean PEMAT understandability score for team pages and team links was 68% (SD 6%). On average, the pages met less than 70% of the understandability criteria. The mean PEMAT actionability score was 23% (SD 20%). The DISCERN Tool found that the quality of information relating to hormone treatment and to surgery was poor. • No *P* values stated.
Hjelmager et al (2019) [13]	Qualitative study	Web-based information material for patients with low back pain in general practice discussed in the context of app development	• Barriers to and facilitators for future use of the health information technology app for patients with low back pain.	• Eight 1-hour interviews with general practitioners revealed the following: content for lower back pain should be validated by general practitioners; from a trustworthy source; support ongoing treatment plan. • No *P* values stated.
Rofaiel et al (2018) [14]	Observational study	Websites that describe the biologic agents used as treatment options for inflammatory bowel disease	• The DISCERN model was used to evaluate the quality of the information content.	• The mean DISCERN score across all websites was 3.21 out of a 5-point scale. No significant difference was found between patient-searched and physician-recommended websites, with a mean score of 3.21 versus 3.63, respectively (*P*=.16).
Alfonso et al (2019) [15]	Observational study	American Cleft Palate–Craniofacial Association–approved teams' websites	• Content and readability of team websites.	• The mean reading level 10.7 (SD 1.9) exceeded the American Medical Association-recommended sixth grade reading level. • Children's Hospital–affiliated teams (n=86) yielded significantly higher content scores (14.8 vs 13.5; *P*=.03). • Children's Hospital teams also had better readability as indicated by lower reading grade level (10.5 vs 11.4; *P*=.04).
Ayyaswami et al (2019) [16]	Observational study	Web-based cardiovascular disease–related health education articles accessed through Google	• Readability according to 10 readability measures (Flesch Reading Ease, Coleman-Liau Index, Flesch-Kincaid Grade Level, Gunning Fog Index, FORCAST Readability Formula, New Dale-Chall formula, New Fog Count, SMOG Index, Fry Readability Formula, and Raygor Readability Estimate).	• All measures that assessed mean reading grade level found that 196 articles were written at a mean 10.9 (SD 1.8) grade reading level. • 99.5% of the articles were written beyond the fifth to sixth grade reading level. • No *P* values stated.

Study	Study type	Content	Outcomes pertaining to quality of web-based health care patient content	Main results
Fajardo et al (2019) [17]	Systematic review	Web-based deprescribing patient education materials	• PEMAT and International Patient Decision Aids Standards Inventory. • Readability using Gunning Fog Index and Flesch-Kincaid Grade Level.	• Patient education materials addressing deprescribing of medications for symptom control (81%) were most common. • 37% of deprescribing patient education materials present potential benefits and harms of deprescribing. • Most patient education materials are pitched above average reading levels (average minimum reading level of grade 12). • No *P* values stated.
Vivekanantham et al (2017) [18]	Observational study	Web-based health information for patients with polymyalgia rheumatica	• Readability using the Flesch Reading Ease and SMOG Readability Formula tools. • 8-item Credibility Indicator (incorporating authorship, affiliation, editorial team, date of creation, date of update, backing, accreditation, and financing).	• Of the websites identified (n=52), the mean Flesch Reading Ease and SMOG Readability Formula scores were 48 (SD 15) and 10 (SD 2), respectively. • The mean Credibility Indicator was 2 (SD 1). • Of 52 websites, 50 (96%) of the websites were accurate. • No *P* values stated.
Harris et al (2018) [19]	Cross-sectional descriptive	Evaluation of leading web-based content on tympanostomy tube placement	• PEMAT understandability and actionability scores	• The PEMAT scores found that all sites (n=10) were understandable (mean 81.9%). • Seven of the sites had a low actionability score (mean 44.6%). • No *P* values stated.
Maciolek et al (2017) [20]	Observational study	Prostate biopsy web-based patient education materials	• Readability was assessed using Flesch-Kincaid Grade Level. Understandability and actionability were measured using the PEMAT.	• Of the 148 sites, 31 (20.9%) met the recommended below eighth grade reading level. • The PEMAT understandability score for academic institution–sourced patient education materials was higher than that for patient education materials sourced from the private sector (*P*=.02) and from institutions unaffiliated with urologists (*P*=.01).
Siddhanamatha et al (2017) [21]	Observational study	Websites providing educational content for patients with rheumatoid arthritis	• Accuracy, completeness, technical elements, design and aesthetics, readability, usability, and accessibility of the websites	• Of 46 websites in total, 45 (98%) provided accurate information. The mean reading level was grade 12.1 (SD 2.3). • In total, 78% (36/46) were easy to navigate, but only 33% (15/46) were user friendly for people with visual and or hearing impairments. • No *P* values stated.
Nielsen-Bohlman et al (2004) [22]	Observational study	An evaluation of health literacy in the United States; formulate solution to overcome associated obstacles	• Current level of readability of web-based content	• More than 300 studies indicate that health-related materials exceed the average reading grade level of US adults. • No *P* values stated.
Chin et al (2018) [23]	Observational study	Improve patient understanding of web-based content pertaining to adults with hypertension.	• Information retention and comprehension	• The revised passages yielded improved retention and comprehension, with less reading time required per unit uptake of information also noted. The methods included simplifying language and signaling clear organization. • On average, the participants were found to significantly better remember the revised passages (mean 0.74, SD 0.14) compared with the typical passages (mean 0.70, SD 0.11; *P*<.01).

Study	Study type	Content	Outcomes pertaining to quality of web-based health care patient content	Main results
Boudewyns et al (2015) [24]	Randomized controlled trial	Web-based information handouts	• Information comprehension and application	• Individuals who received the revised and improved web-based formats had higher comprehension scores than those who received the MedGuide (P<.001).
Morrow et al (2005) [25]	Observational study	Patient-centered medication instructions to empower patients to plan a medication-taking regimen	• Information comprehension and retention, health-related literacy, and verbal working memory	• Patient-centered instructions were more accurately understood for unfamiliar medications (P<.05). • The standard instructions were more accurate for familiar medications (P<.05).
Pander Maat et al (2010) [26]	Observational study	Revision of patient information leaflets	• Usability, speed of information retrieval, and comprehension.	• Once located, comprehension of the information was approximately 90%. • Revisions led to better performance. Information was found more quickly. Comprehension scores were also improved. • No P values stated.
Discussion boards or web-based groups				
Cedars et al (2019) [27]	Qualitative and thematic analysis	Web-based discussion boards for urethral stricture disease and urethroplasty	• To describe the patient experience and chief concerns with urethroplasty to improve physician understanding and patient education • To understand how men use web-based discussion boards and what information is available about urethroplasty	• Problems in navigating the health care system with urethral stricture disease (n=141) and weak urine stream (n=70) were the most frequent preurethroplasty complaints. • The patients participated in web-based discussions to share experiences with urethral stricture disease and urethroplasty, share emotional support, and search for answers. • No P values stated.
Teaford et al (2019) [28]	Descriptive statistics and qualitative content analysis	New mothers' experiences with web-based postpartum forums	• To explore women's experiences with a web-based forum during the postpartum period	• Five themes were produced through data analysis: (1) social support, (2) anonymity, (3) in-groups, (4) drama, and (5) entertainment or pastime. • The participants found that the discussion board could facilitate sharing of information, act as an entertainment source, and provide community. • No P values stated.
Castaneda et al (2019) [29]	Qualitative study	eHealth peripheral artery disease community forums	Original posts and related responses were analyzed for thematic content.	• The themes identified included medical advice (41%), personal experiences with peripheral artery disease (33%), and social support (13%). Negative attitudes were discussed in 10 of the 18 (56%) posts related to poor experiences with health care providers; 15.1% of the medical advice was inconsistent with clinical treatment guidelines. • No P values stated.
Video				

Study	Study type	Content	Outcomes pertaining to quality of web-based health care patient content	Main results
Bae et al (2018) [30]	Observational study	YouTube videos in English as a patient education resource for cataract surgery	• 14 criteria important for educating patients about the procedure.	• The mean number of usefulness criteria satisfied was only 2.28 (SD 1.80) out of 14. • There was no significant difference in view counts between the most useful videos and other videos (P=.94). • Videos from medical bodies such as the National Health Service were found more useful in terms of patient education (P<.001).
Pedersen et al (2019) [31]	Feasibility study	Development of a preventive educational video for patients exposed to whiplash trauma	• The development followed a systematic approach and was theory driven, supplemented with available empirical knowledge.	• The participants (n=4) felt that the content was "relevant, helpful, and reassuring to watch." • All four preferred video content instead of written material. • No P values stated.
Finnegan et al (2018) [32]	Case study	A web-based vaccine communication project (textual, videos, and infographics)	• Case study of a provaccine information hub launched in 2011. Vaccines Today provides high-quality information about vaccines and diseases, expert interviews, answers to frequently asked questions, parent or patient stories, and videos or infographics.	• Two categories of informing patients were found to work well: (1) the storytelling approach and (2) answering questions posed by patients. • No P values stated.
Button et al (2018) [33]	Mixed methods study (qualitative and feasibility study)	A web-based intervention (TRAK[c]) that provides knee patients with health information	• Testing the TRAK intervention in patients undergoing physiotherapy to gain their subjective insights into its use	• The participants reported that TRAK was easy to use overall. Basic internet skills were all that were required. • Using TRAK as an adjunct to physiotherapist management increased the patients' understanding and confidence. • No P values stated.
Vogel et al (2018) [34]	User survey	VaPE[d] in anesthesia	• The content of the videos, the technique of video presentation, usefulness of VaPE • Interviews carried out with patients and physicians	• In total, 98% (78/80) of the anesthetists found VaPE useful for patient education. • In total, 93% (74/80) observed time saved for the following interview. • In total, 96% (77/80) stated that watching the video left patients better informed. • Increased anxiety caused by VaPE was noted by 46% (37/80); 54% (43/80) found no such effect. • No P values stated.
Pithadia et al (2019) [35]	Cross-sectional study	YouTube videos as a source of patient information about phototherapy and excimer laser for psoriasis	• Assess the educational quality of YouTube videos about phototherapy and excimer laser for psoriasis	• In total, 11.2% (15/135) of the videos contained high-quality patient educational information, 2.5% (3/135) were fair quality, and 66.1% (89/135) were low quality. • A total of 28.2% (35/135) of videos provided background information regarding psoriasis. Of these 35 videos, 28 (80%) contained evidence-based content about the epidemiology, systemic involvement, genetics, and immune nature of psoriasis. • Of the 35 videos, 7 (20%) presented nonevidence-based claims and high mortality rates associated with psoriasis. • No P values stated.
Ferhatoglu et al (2019) [36]	Observational study			

Study	Study type	Content	Outcomes pertaining to quality of web-based health care patient content	Main results
		Sleeve gastrectomy videos shared on YouTube	• The popularity of the videos was evaluated with the Video Power Index. • The educational quality of the videos was measured using the DISCERN score, JAMAe benchmark criteria, and GQSf. The technical quality was measured by the SGSSg.	• The DISCERN, JAMA benchmark criteria, GQS, and SGSS evaluations of academic-sourced videos yielded significantly higher scores than patient-sourced videos (*P*<.001, *P*<.001, *P*=.001, and *P*<.001, respectively). • However, the Video Power Index evaluation of patient-sourced videos yielded significantly higher scores than academic- and physician-sourced videos (*P*<.001 and *P*=.003, respectively). • Negative correlations between the Video Power Index and the JAMA, GQS, and SGSS scores were found.
Erdem et al (2018) [37]	Observational study	Bariatric surgery videos (n=175) on YouTube	• Usefulness of bariatric surgery videos on YouTube: A usefulness score (very useful, useful, or not useful)	• Of the 175 videos, 94 (53.7%) were useful, and 43 (24.6%) were very useful. No videos were found containing misleading information. • A Spearman rank correlation found no significant correlation between the usefulness score and the number of views (ρ=−0.118; *P*=.12), number of likes (ρ=−0.038; *P*=.61), number of dislikes (ρ=−0.003; *P*=.97) or video length (ρ=−0.106; *P*=.16).
Biggs et al (2013) [38]	Observational study	YouTube as a source of information on rhinosinusitis	• Videos (n=100) were graded on their ability to inform the layperson about rhinosinusitis.	• 45% of the videos were deemed to provide some useful information. 55% of the videos contained little or no useful facts, 27% of which contained potentially misleading or even dangerous information. Videos uploaded by medical professionals or those from health information websites contained more useful information than those uploaded by independent users. • No *P* values stated.
Kwok et al (2017) [39]	Observational study	Videos available on YouTube pertaining to interventional treatment for varicose veins	• Informational and scientific quality (good, fair, and poor) and stance (for, neutral, against, and unclear) toward the treatment option discussed, treatment type, and video source.	• The largest group of videos (47.3%) received a quality rating of fair, meaning that they discussed one or two aspects of a treatment option, such as procedural technique and indications. Among those videos rated poor (25%), nearly all (98.2%) failed to mention a specific treatment. • No *P* values stated.
Bademci et al (2017) [40]	Observational study	YouTube videos on deep venous thrombosis	• Scientific content, accuracy, and currency	• Although most of the videos uploaded (25/111, 22.9%) were created by physicians, the number of views for website-based videos was significantly higher (*P*=.002). When the uploaded videos were assessed in terms of their usefulness, the videos from physicians and hospitals were statistically more useful than the other videos (*P*<.001).
Visuals or pictographs				

Study	Study type	Content	Outcomes pertaining to quality of web-based health care patient content	Main results
Christensen et al (2017) [41]	Pilot study	Doodle Health: A crowdsourcing web-based game for the co-design and testing of pictographs to reduce disparities in health care communication	• To test the usability of the game and its appeal to health care consumers in the co-design and evaluation of pictographs.	• Initial testing indicates that crowdsourcing is a promising approach to pictograph development and testing for relevancy and comprehension. More than 596 drawings were collected, and 1758 guesses were performed to date with 70%-90% accuracy. • No *P* values stated.
Device on which content is accessed				

Study	Study type	Content	Outcomes pertaining to quality of web-based health care patient content	Main results
Gogovor et al (2017) [42]	Literature review and qualitative focus group study	Development of an internet-based chronic pain self-management program	• Information needs and gaps in chronic pain management as well as technology features to inform the development of an internet-based self-management program	• The gaps identified in terms of chronic pain management included lack of knowledge, limited access to health care, substandard care, and scarce self-management support. • The focus group themes included patient education on chronic pain care, attitude-belief-culture, financial and legal issues, and motivational content. • No *P* values stated.
Lüchtenberg et al (2008) [43]	Observational study	Websites containing medical information addressing laymen or patients (n=139)	• Accessibility using a quantitative checklist based upon the Web Content Accessibility Guidelines of the World Wide Web Consortium	• Of the 139 sites, 25 (17.9%) of the sites were categorized as WAIh guidelines level A or AA. • WAI guidelines level AA was reached by 0.7% (1/139) of website. • None of the websites reached level AAA. • Of the 139 sites, 82% (114) of the assessed consumer websites were not completely accessible to persons who are visually impaired. • No *P* values stated.
Bashi et al (2018) [44]	Systematic review	Patient educational interventions using mobile apps	• The reporting quality of the studies was assessed according to the mHealthi evidence and predefined reporting assessment criteria.	• Of the 15 studies, none reported on the data security, privacy, and confidentiality measures. • No *P* values stated.
Noel et al (2017) [45]	Prospective cohort study	A mobile medical app was developed to improve postoperative care of patients who had undergone plastic surgery	• The content, design, and efficacy of the app were assessed with a questionnaire (n=60).	• The participants reported that the questions regarding postoperative management were addressed effectively, with a mean score of 4.1/5. • Most of the participants recommended the app to patients who had undergone plastic surgery, with a mean score of 4.6/5. • The app's information prevented 12 patients from calling the plastic surgeon or the emergency department unnecessarily. • No *P* values stated.
Nicholas et al (2015) [46]	Systematic review	Mobile apps for bipolar disorder	• The comprehensiveness and quality of information was assessed against core psychoeducation principles and current bipolar disorder treatment guidelines. • The management tools were evaluated with reference to the best practice resources for the specific area. • General app features and privacy and security.	• Informative apps covered more than a third (4/11, 36%) of core psychoeducation principles and 15% (2/13) of best practice guidelines. • A third (10/32, 31%) cited their sources. • "Neither comprehensiveness of psychoeducation information (ρ=−0.11; *P*=.80) nor adherence to best practice guidelines (ρ=−0.02; *P*=.96) were significantly correlated with average user ratings."
Jamison et al (2017) [47]	Randomized controlled trial	To test an app that enables patients with chronic pain to assess, monitor, and communicate their status to their health care provider.	• Frequency of app use and app satisfaction scores	• In total, 78.1% (82/105) of the participants reported daily using the app. • Patient satisfaction survey results: • Ease of use: 1.8/10 (0=very easy to use, 10=unusable) • Willingness to use after the study: 2.4/10 (0=very willing; 10=unwilling. • Participants with more daily assessments reported higher app satisfaction (*P*<.05) than those who used the app less.

Study	Study type	Content	Outcomes pertaining to quality of web-based health care patient content	Main results
Schulz et al (2007) [48]	Randomized controlled trial	Website designed to enhance self-management in chronic lower back pain	• Change in pain levels, change in knowledge, behavioral changes, and medication use	• Users accessed the website an average of 11.5 times during the 5-month study. • Mean pain levels fell in the control group from 5 to 3.9 (10=most severe pain imaginable, 1=no pain), whereas the mean pain levels in the control group remained largely the same (6.1 to 6.3). • No *P* values stated.
Caiata Zufferey et al (2009) [49]	Observational study	Website *Oneself* designed to promote self-management and inform patients on lower back pain management	• Self-comprehension • Improvement of vocabulary, knowledge of exercises, self-confidence, and motivation	• Of the 129 survey participants, 32 (24.8%) reported that Oneself increased their knowledge about back pain. • Successful testimonials indicated that self-management was encouraged. • No *P* values stated.
Hagerman et al (2017) [50]	Observational study	DAs[j] for patients with low-risk PCa[k]	• What are the informational needs of patients with low-risk PCa, and what are the essential aspects of treatment DAs that increase the likelihood of physicians recommending them to the patient?	• Semistructured interviews found that "Physicians highlighted the importance of patient education and described the characteristics of a low-risk PCa DA that would increase the likelihood of its use in clinical practice." • Encourage patients to take their time in decision-making. • Frankly inform on posttreatment side effects. • Incorporate physician recommendations on content and mode of delivery. • No *P* values stated.
Kim et al (2002) [51]	Observational study	Website comprising a situational approach to the organization of disease-specific patient information	• Interface usability, personal relevance of retrieved information, comprehension of retrieved information.	• Responses (n=37) yielded high ratings for the following: interface usability (4.6/5); personal relevance of information found (4.7/5); comprehension of information (4.8/5). • No *P* values stated.
Meppelink et al (2015) [52]	Observational study	Colorectal cancer screening messages divided into high-literacy and low-literacy groups, with and without illustrations	• Information recall, attitudes, intention to undergo screening	• Spoken messages about colorectal cancer screening improved recall (*P*=.03) and attitudes (*P*=.02) compared with written messages in individuals with lower health literacy. • Animations alone failed to improve recall, but when combined with spoken text, they significantly improved recall (*P*=.02).
Mayer et al (2003) [53]	Literature review	A theory designed to format multimedia content to optimize patient education	• Overloading, speed of content delivery, and misalignment of textual and visual cues	• Narration has better transfer of information than on-screen text. • Learner-controlled segments increase transfer of information. • Graphics and corresponding text should be aligned visually. • Signals also improve transfer. • No *P* values stated.
Stage of patient journey				

Study	Study type	Content	Outcomes pertaining to quality of web-based health care patient content	Main results
Biernatzki et al (2018) [54]	Cross-sectional descriptive	Evaluation of the informational needs of patients with diabetes	• Treatment process, course of disease, abnormalities of glucose metabolism, and diabetes through the life cycle	• Information needs among patients with diabetes is poorly investigated, although in high demand. • No *P* values stated.
Boyde et al (2009) [55]	Observational study	An investigation of the learning style and learning needs of patients with HF[l]	• Questionnaire identifying preferred learning modalities	• In total, 64% (55/86) of the participants reported a preference for multimodal learning style; 18% (15/86) preferred textual information; 11% (9/86) preferred auditory; and 7% (6/86) preferred kinesthetic. • Signs and symptoms were ranked as the most important topics to learn about. • No *P* values stated.
Hagenhoff et al (1994) [56]	Systematic review	Evaluation of the perceptions of both patients and nurses on the importance of educational content for patients with congestive HF	• Questionnaire evaluating the importance of the following categories: anatomy and physiology; psychology; risk factors; medications, diet, and activity; and other	• Patients and nurses rated all information as moderately to very important to learn. • Patients often rated information as more important than nurses did. • No *P* values stated.
Wehby et al (1999) [57]	Descriptive comparative study	Perceptions of RNs[m] and patients concerning educational content on HF were analyzed	• Ranking of categories of HF education in order of importance by patients and RNs	• "Patients perceived the subscales of general HF information, risk factors, medications, prognosis, and signs and symptoms as more important to learn than the RNs (*P*<.05)." • "Patients perceived diet information as less important to learn than the RNs (*P*<.05)." • "Patients perceived all eight subscales as more realistic to learn than the RNs (*P*<.05). Although not in identical order, both groups ranked education related to medication and signs and symptoms as the 2 priority areas." • "Diet information was ranked eighth by the patients and third by the RNs." • No *P* values stated.
Clark et al (2004) [58]	Descriptive correlational study	Examination of perceived learning needs of patients with heart failure after discharge	• "The Outpatient Heart Failure Learning Needs Inventory was used to rate the participants' perceptions of the importance of educational topics on a 5-point Likert scale."	• "The findings indicated that the subjects perceived signs and symptoms and medications as most important to learn and diet, activity, and psychological factors as least important to learn. These findings are consistent with previous research and provide a framework on which to base the development of educational programs for patients with heart failure. A significant finding was that nearly 25% of the screened patients were unable to participate because they were unaware that they had been diagnosed with heart failure." • No *P* values stated.
Kiliç B et al (2015) [59]	Descriptive comparative study	Qualitative analysis of questionnaires examining perceptions of RNs and patients concerning educational content on HF were analyzed.	• Themes related to the educational needs of patients about use of drugs. • Themes related to lifestyle changes. • Themes about the educational needs of the patients related to the characteristics of the disease ranking of categories of HF education in order of importance by patients and RNs.	• "In this study, HF patients stated that they mainly need information about the effects and purposes of the drugs they used. The need for information about the management of the symptoms that affect daily activities are considered 2nd and the educational needs about the disease itself are considered 3rd in importance." • No *P* values stated.

Study	Study type	Content	Outcomes pertaining to quality of web-based health care patient content	Main results
Solomon et al (2018) [60]	Qualitative study	To build an evidence-based web-based patient information resource for patients with HIV	• Transcribed interviews of stakeholders underwent qualitative content analysis	• The interviewees suggested that descriptions of all members of the health care team involved with HIV care be included on the website. • It was also suggested to organize the menu into health challenge categories for ease of navigation. • No *P* values stated.
Liu et al (2017) [61]	Umbrella review	Aimed to identify the current evidence on health education–related interventions for patients with acute coronary syndrome or type 2 diabetes	• Clinical outcomes, behavioral outcomes, psychosocial outcomes, and medical service use	• Nurses and multidisciplinary teams were the most frequent health care professionals to provide education, and most educational interventions were delivered after discharge. • Face-to-face sessions were the most common delivery formats of the patient educational interventions. • The psychoeducational interventions were found to be effective in reducing smoking and admissions for patients with acute coronary syndrome. • No *P* values stated.
Credibility and completeness				

Study	Study type	Content	Outcomes pertaining to quality of web-based health care patient content	Main results
Boyer et al (1998) [62]	Review	Review of *HONcode*[n], a guideline designed to raise the quality of web-based patient education data	• Guidelines to information providers, with the aim of raising the quality of web-based data available and helping to identify websites that are maintained by qualified people and contain reliable data.	• The HONcode mainly includes the following ethical aspects: the author's credentials, the date of the last modification with respect to clinical documents, confidentiality of data, source data reference, funding, and the advertising policy. • No *P* values stated.
Priyanka et al (2018) [63]	Observational study	Evaluation and analysis of web-based content pertaining to esophageal duodenoscopy for patients	• GQS, Health on Net, Flesch-Kincaid Reading Ease, and Flesch-Kincaid Grade Level	• Three websites were found to have high-quality, comprehensive, and authentic information: Healthline, Uptodate, and Emedicine. • In total, 13 sites yielded moderate quality of information. The mean Flesch-Kincaid Reading Ease score was 46.92. • The mean Flesch-Kincaid Grade Level was 11th grade. • No *P* values stated.
Couper et al (2010) [64]	Cross-sectional survey	Analysis of the perceived importance of sources of health information on the web	• Ranking of sources in terms of reliability and influence; use of the internet in age groups.	• Internet use was more common at younger ages, increasing from 14% among those aged 70 years or older to 38% for those aged 40-49 years. • Internet users rated health care providers as the most influential source of information for medical decisions, followed by the internet, family and friends, and media. • No *P* values stated.
Volk et al (2013) [65]	Cross-sectional survey	Evaluation of ongoing studies regarding what the standards for DAs for patients should be	• Voting system to develop criteria for DA standards	• The review comprised 13 manuscripts on topics including current frameworks used to create health care content, health literacy, and the role of patient stories. • No *P* values stated.

Textual Information

A study by Ernest et al [12] used the *DISCERN* Tool to evaluate the quality of written information regarding hormone treatment and surgery, which was found to be poor [66]. DISCERN is a validated tool developed by an expert panel through a process of panel debate and health care information analysis. It is noted to be the "first standardised index of quality of consumer health information" [66]. The DISCERN Tool comprises 15 key questions that investigate publication reliability and details of treatment choices, followed by overall judgment of quality. Each question is answered on a 5-point scale ranging from no to yes.

The study by Vivenkanatham et al [18] evaluated textual information on polymyalgia rheumatica. The study concluded that for web-based health care content to be effective, readability must be accessible to people of all literacy levels. Similar

conclusions on readability were also reached in the study by Maciolek et al [20], which reported that patient education materials are most effective when simple language accessible to a wide patient population is used. A quality assessment study of web-based content on rheumatoid arthritis analyzed the readability, applicability, and accessibility of patient education websites [21]. The mean reading level was found to be 12.1 (SD 2.3), according to the Flesch-Kincaid Readability Tool. This tool gives a measure of how difficult a passage written in English is to understand through analyzing factors such as word length, sentence length, and total number of syllables. It provides a grade level according to the US educational system ranging from fifth grade to college graduate [67]. The same study reported that 78% of the websites assessed were easy to navigate [21]. Importantly, only 33% of the websites were assessed to be user friendly for people who are visually or hearing impaired.

An evaluation of web-based information on disorders of sex development noted strengths, including the tendency of webpages to present focused information in chunks and in a logical sequence [12]. A semistructured interview study of general practitioners conducted by Hjelmager et al [13] revealed that health information technology apps require textual information that is targeted to patients and written with the input of health care professionals.

The study by Rofaiel et al [14] assessed the quality of website information about inflammatory bowel disease using the DISCERN score to assess reliability and the relevance of pertinent details. The mean DISCERN score for patient-searched websites was not statistically different from that for physician-recommended websites (3.21 vs 3.62, respectively; *P*=.16). Numerous studies [12,13,15-17] identified that readability, as analyzed by the Flesch-Kincaid Tool, of web-based information exceeded the recommended sixth to eighth grade reading levels [68].

In all, 3 studies evaluated the understandability and actionability of web-based patient information by using the validated Patient Education Materials Assessment Tool [12,17,20]. The tool comprises inventories (one for print and another for audiovisual content) that list desirable and undesirable characteristics of information and produce a numeric value for understandability as well as actionability (ie, how easy it is to act on given information). The scores range from 0% to 100%, and a higher score indicates that the text is more understandable or actionable. Web-based educational content pertaining to disorders of sexual development and tympanostomy tube placement yielded low actionability scores (mean scores 23% and 44.6%, respectively). Interestingly, a study by Maciolek et al [20] found that the Patient Education Materials Assessment Tool understandability score for academic institution patient educational material exceeded that for content created by private institutions (*P*=.02) and content from websites unaffiliated with a urologist (*P*=.01).

Discussion Boards or Web-Based Groups

The study by Cedars et al [27] reported on a study of patients with urethral strictures who participate in web-based discussions and share experiences to gain emotional support and find answers. Patients participating in these web-based groups were more often than not satisfied with their postoperative outcomes. These findings are supported by the study by Teaford et al [28], which explored the experiences of new mothers using a web-based postpartum forum. The study found that web-based forums provided a sense of community and a platform for sharing information. They identified five themes pertaining to the participants' concept of a web-based community: social support, anonymity, in-groups, drama, and entertainment.

However, the findings of a study by Castaneda et al [29] highlight the importance of exercising caution with web-based forums. The study evaluated the content of peripheral arterial disease eHealth forums and found that 15.1% of the medical advice given on such platforms was inconsistent with guidelines. Furthermore, the study found that 10 of the 18 posts related to negative personal experiences with health care providers.

It is important to note that there may be differences in patient engagement when comparing groups that are run by health care (or affiliated) professional service providers with those set up by patients or lay individuals themselves. A study comparing the difference between the effects of peer-led and moderated groups found that moderated groups were often more active and therefore had higher patient engagement.

Video-Based Content

The study by Pedersen et al [31] found that 4 participants who were interviewed after watching a 14-minute educational video on whiplash injuries felt reassured, particularly because the video aligned with information that they had received at the hospital. The study by Finnegan et al [32] reported that people who visited an information hub where videos were embedded in the webpage spent longer than 2 minutes on that webpage, indicating that visitors with average reading capability watch and listen to the video while browsing the text. The study also reported that this information hub's YouTube channel, which featured videos explaining the concept of herd immunity, was particularly successful, with visitors spending more than 6 minutes on that page [32].

In the context of managing health conditions, the study by Button et al [33] found that video-based content was particularly helpful for patients having physiotherapy for knee injuries because they were able to visualize the correct technique. Patient understanding and confidence were found to be improved by this intervention. In a separate study of 80 anesthetists using a Video-Assisted Patient Education intervention, 96% reported that patients felt that they had a better understanding of the information provided through the Video-Assisted Patient Education intervention, and 97.5% of the anesthetists felt that it was a useful form of patient education [34]. However, 46% noted increased anxiety caused by the intervention [34].

Interestingly, the study by Ferhatoglu et al [36] found in an evaluation of the quality of YouTube content on sleeve gastrectomy that patient experience and advertisement videos were significantly more popular than academic videos created by medical professionals, according to the Video Power Index (*P*<.001 and *P*<.003, respectively). The Video Power Index assesses video performance by comparing the video with leaders in its respective industry, measures its impact and effectiveness across all platforms, and facilitates strategies to cater to target

audiences [69]. The study by Erdem and Sisik [37] reported similar findings and found no significant association between video traction (*likes*, *dislikes*, or *views*) and usefulness of the content (Spearman rank correlation ρ=−0.038, *P*=.61; ρ=−0.003, *P*=.97; and ρ=−0.118, *P*=.12, respectively). Interestingly, the study found no significant correlation in usefulness to video length (ρ=−0.106; *P*=.16) in contrast to the findings of the study by Biggs et al [38], which concluded that medical videos categorized as useful had a mean length of 6 minutes and 51 seconds, with the videos rated in the top 10 having a mean length of 14 minutes and 47 seconds.

Similar to previous findings, a study conducted to assess the quality of YouTube videos on cataract surgery concluded that videos created by medical organizations such as the National Health Service were significantly more useful in terms of educating patients about the procedure than videos sourced by independent medical professionals and other sources (*P*<.001) [30]. The study by Bademci et al [40] similarly concluded that medical topic videos on deep vein thrombosis sourced from medical professionals and hospitals were significantly more useful than videos from other sources (*P*<.001).

In a study evaluating YouTube content on varicose veins, it was found that most of the videos were dominated by the private health care sector and that the video content presented a distorted view of treatment options, consequently leading to a skewed patient perception of the therapeutic options available to them [39]. Not only were 32% of these videos found to be of poor quality, but videos from private medical companies were also significantly more likely to favor minimally invasive surgery over ligation and stripping than videos from other sources. Once again, there was no significant association found between quality of content and viewing frequency.

Visuals or Pictographs

Pictographs are pictorial representations of words or phrases. The study by Christensen et al [41] described the value of pictographs in health communication. The study presents the results of building and testing the game *Doodle Health*, which is designed to produce pictographs through crowdsourcing. It found that this method of pictograph creation yielded positive feedback from focus groups with regard to usability and comprehension. Analysis of the feedback found that 62.2% of the participants praised the game, with a respondent describing it as “engaging and easy to use.” However, the study also found that people from diverse cultural backgrounds have different styles of communication, which may render visually presented information ineffective for minority groups. Crowdsourcing pictographs was suggested as a potential solution to this concern.

Device Accessibility

A study by Gogovor et al [42] concluded that the next generation of web-based educational health care programs should integrate apps for reasons of (1) accessibility, (2) flexibility, and (3) security and trustworthiness. Almost all the studies in our review used web-based platforms and required devices that accessed the web, with some studies requiring devices that accessed the video-sharing platform, YouTube, specifically.

A study by Lüchtenberg et al [43] found that only 18% (25/139) of the health information websites evaluated achieved a high standard of accessibility for users who are visually impaired as assessed by the Web Accessibility Initiative guidelines. The study concluded that web-based educational health care content should at least meet the requirements of priority 1 (level A) and preferably priority 2 (level AA) of the Web Accessibility Initiative guidelines. Developers can ensure accessibility by, for instance, having text alternatives for all nontext content and using high contrast ratios of text and images [36].

Few studies used smartphones exclusively to deliver information. Describing the benefits of using a smartphone, the study by Bashi et al [44] noted that smartphone adoption is becoming widespread, meaning more people can be reached; however, studies on how apps should deliver information in terms of interface and content is particularly lacking. The study by Noel et al [45] assessed the impact of a mobile medical app on plastic surgery patient care. A total of 60 patients answered questionnaires pertaining to the app, and the results supported the app’s utility from the patient’s perspective. The mean score for the app’s ability to answer patient questions was 4.1/5, and 20% of the patients were prevented from unnecessarily calling the emergency department. The use of a smartphone also enabled patients to access information from different locations and allowed for real-time disease management. A systematic review by Nicholas et al [46] revealed that of the 11 studies of apps providing patient information, only a third covered core psychoeducational principles. Furthermore, the average user ratings were not correlated with either comprehensiveness or adherence to best practice guidelines (ρ=−0.11, *P*=.80 and ρ=−0.02, *P*=.96, respectively).

Stage of Patient Journey

A qualitative study by Gogovor et al [42] using health care professionals and patient focus groups found that health care professionals suggested stratifying access to information according to *stage of advancement* in terms of their chronic pain management. A qualitative study of *Oneself*, a website designed for use by patients with chronic lower back pain, found it to be an effective adjunct to doctor-patient consultations because patients found that they were unable to have all their queries answered in the limited time of a consultation [49].

At different stages of a patient journey, decision aids may be used as adjunctive decision-making tools to support patients. In the study by Hagerman et al [50], the authors conducted semistructured interviews of 33 physicians to identify the desirable characteristics of decision aids. Of the 33 physicians, 20 (61%) stated that patients should be educated on the lack of urgency with regard to making a treatment decision. Of the 33 physicians, 28 (85%) agreed that decision aids should be provided to the patient after the consultation when the patient is at home. Furthermore, 36% (12/33) of the physicians deemed it *very* or *extremely* important that decision aids are designed to be used during and after consultations.

Tailoring information delivery to the stage of the patient journey is further supported by the results of the study by Kim et al [51] who developed a system to organize web-based disease-specific information according to a situational knowledge base model.

The approach categorizes information about a specific disease (eg, thyroid cancer) into sections corresponding to discrete clinical events (eg, presentation, fine-needle aspiration biopsy, and diagnosis). In all, 75 patients completed a questionnaire evaluating the website, which found mean usability to be 4.6/5, personal relevance of received information 4.7/5, and comprehension of received information 4.8/5.

Credibility and Completeness of Information

A study by Jamison et al [47] found that 86% of the apps for pain conditions reported were created with no involvement by health care professionals. A comprehensive study by Bae et al [30], assessing the quality of the content of YouTube videos for cataract surgery patient education, found that there was an abundance of videos simply showing patients undergoing a live procedure. More than 20% of the educational videos were commercial and hence potentially misleading. This may make it challenging to find high-quality, comprehensive educational videos on the web.

A study by Pithadia et al [35] used the American Academy of Dermatology guidelines as a benchmark to evaluate the accuracy of patient information YouTube videos on psoriasis treatments. It concluded that 12% of the videos contained high-quality patient education content, and most of them were not patient-centric. Similarly, the study by Ferhatoglu et al [36] used the *Journal of American Medical Association* benchmark criteria to assess the educational quality of sleeve gastrectomy YouTube videos and found that this score was significantly higher in university-affiliated physician videos than in other videos (P<.001).

The Health on the Net Foundation Code of Conduct (HONcode) presents a set of eight principles designed to set the quality standard for web-based patient information [62] (Textbox 1). A study by Laversin et al [70] compared 165 HONcode-certified websites with 165 noncertified websites. Only 0.6% of the noncertified websites conformed to the principles of the HONcode compared with 89% of the certified sites (P<.10). As the study followed certified websites 6 months after certification, the effect of the HONcode certification shows short-term sustainability.

Textbox 1. Quality standard (adapted from the study by Laversin et al [70]).

Eight Principles Designed to Set the Quality Standard for Web-Based Patient Information

1. Authoritative: qualifications of the authors indicated
2. Complementarity: information should support the doctor-patient relationship
3. Privacy: personal data collected by the site kept private
4. Attribution: cite all references
5. Justifiability: back up claims relating to benefits and performance
6. Transparency: accessible presentation, accurate email contact
7. Financial disclosure: identify funding sources
8. Advertising policy: clearly distinguish advertising from editorial content

Discussion

Principal Findings

In today's world of access to knowledge often being initially web-based, it is of importance for health care professionals to be able to create effective content. This is further emphasized in the current environment where minimum contact between patients and health care providers is required. We performed a wide scoping review of the literature to identify the features of web-based content and other telemedicine requirements that may improve quality of engagement with web-based health care content in this growing field. Using these results, we have developed a framework (Figure 2) to facilitate the development of web-based patient health care content. All the categories except for one (visual or pictograph) were reported on by 3 or more papers. We included the visual or pictograph category after discussion because it was felt to be a relevant and important means of communicating information. Although the features identified are, on reflection, intuitive, the framework arms the content creator with the best available strategies in making the content engaging and hence effective.

Figure 2. Infographic framework for modes of engagement for web-based health care content. HONcode: Health on the Net Foundation Code of Conduct; PEMAT: Patient Education Materials Assessment Tool.

Other similar frameworks such as the International Patient Decision Aid Standards (IPDAS) and the Standards for Universal Reporting of Patient Decision Aid Evaluation Studies (SUNDAE) checklists [65,71] have been developed for the evaluation of decision aids. However, to the best of our knowledge, this is the first framework to specifically focus on engagement with web-based content rather than a checklist approach to ensuring that decisions are made with appropriate consideration given to all relevant issues and options. A study design published by Knerr et al [72] aimed to evaluate patient behavior in response to a patient decision aid based on the IPDAS standards but has not reported results. Although patient decision aids can be a form of web-based content, efforts up to now have been directed toward ensuring transparency and trust in imparting information rather than ensuring the ability of web-based material to engage the user [73]. The need to engage

people in health care content has been overlooked. We propose that this framework be used to improve engagement, which in turn will improve adherence with medical treatment and hence improve outcomes. Nevertheless, the rigorous process used by the IPDAS and SUNDAE developers is one that we would be interested in following in refining and adapting the framework arrived at through this literature review.

Further work will involve a co-design process with all stakeholders (including patients) to refine the insights we have gained from the studies regarding engagement with web-based content. The personalization of health care content may have bearing on the issue of engagement. Studies have shown that it is possible to *segment* the population according to the likelihood of responding to health care messages [74,75]. Although our framework provides the best evidence available relating to engagement with web-based content, the holy grail may lie in developing further the field of psychographics for health care. Although researchers have investigated the way that segmentation affects a defined intervention, the effect of segmentation itself is yet to be assessed in a meaningful manner [75]. The internet is able to bring together varied but related content using the concept of the semantic web and the application of folksonomies [76]. The confluence of Web 3.0 (to crowdsource content relevant to a desired health care behavior), psychographic segmentation (including segmentation based on the proposed framework), and machine learning may provide a way forward. We have developed a Web 3.0 health care content platform (Health Shared) and intend to use it for this purpose.

Limitations

The findings of this review should be considered in the context of several limitations. The principal limitation is that most of the components of this suggested framework are not supported by strong evidence. The studies were heterogeneous in their aims, interventions, and outcomes, and some were of poor methodological quality. Few studies discussed the effect of the platform used on patient engagement—for example, smartphone app versus website versus commercial health care information—which may play a role in patient engagement. However, given that most of the studies discussed in the review were general scans of available websites, the framework developed is largely applicable to the website development platform. In addition, few studies describe the differences between informational sites and other modes-of-engagement systems that provide the ability for patient input and enable patients to contact their provider or providers; therefore, we were not able to compare these patient information platforms.

Furthermore, because only the PubMed database was searched, studies are likely to have been omitted from this review. Despite this limitation, the components of the framework are intuitive, and we believe that its application may be beneficial to health care providers and content creators. Evaluation and subsequent validation of the proposed framework by key stakeholders, including patients, clinicians, and content creators, would increase the robustness.

Conclusions

There is a paucity of high-quality data relating to the factors that improve users' quality of engagement with web-based health care content. Our framework summarizes the reported studies, which may be useful to health care content creators. Evaluation of the utility of web-based content to engage users is of significant importance and may be accessible through tools such as the Net Promoter score. Web 3.0 technology and development of the field of psychographics for health care offer further potential for development [75]. Future work may also involve improvement of the framework through a co-design process.

Although there are often specific health care issues needing to be addressed in response to crisis situations, we believe that this work is more generally important in facilitating patient activation and patient-supported self-management, which are two major pillars in how health care systems need to realign to keep up with increasing demand.

Authors' Contributions

UJ conceived the idea; LAO, EA, AA, NH, SL, and PN wrote the manuscript; and UJ, LAO, and PN reviewed and edited the manuscript.

Conflicts of Interest

UJ is the founder of Health Shared.

Abstract

Background: Oncological health care services are challenged by the increasing number of cancer survivors, long-term follow-up care, and fragmentation of care. Digital care platforms are potential tools to deliver affordable, patient-centered oncological care. Previous reviews evaluated only one feature of a digital care platform or did not evaluate the effect on enhancement of information, self-efficacy, continuity of care, or patient- and health care provider–reported experiences. Additionally, they have not focused on the barriers and facilitators for implementation of a digital care platform in oncological care.

Objective: The aim of this systematic review was to collect the best available evidence of the effect of a digital care platform on quality of care parameters such as enhancement of available information, self-efficacy, continuity of care, and patient- and health care provider–reported experiences. Additionally, barriers and facilitators for implementation of digital care platforms were analyzed.

Methods: The PubMed (Medline), Embase, CINAHL, and Cochrane Library databases were searched for the period from January 2000 to May 2020 for studies assessing the effect of a digital care platform on the predefined outcome parameters in oncological patients and studies describing barriers and facilitators for implementation. Synthesis of the results was performed qualitatively. Barriers and facilitators were categorized according to the framework of Grol and Wensing. The Mixed Methods Appraisal Tool was used for critical appraisal of the studies.

Results: Seventeen studies were included for final analysis, comprising 8 clinical studies on the effectiveness of the digital care platform and 13 studies describing barriers and facilitators. Usage of a digital care platform appeared to enhance the availability of information and self-efficacy. There were no data available on the effect of a digital care platform on the continuity of care. However, based on focus group interviews, digital care platforms could potentially improve continuity of care by optimizing the exchange of patient information across institutes. Patient-reported experiences such as satisfaction with the platform were considerably positive. Most barriers for implementation were identified at the professional level, such as the concern for increased workload and unattended release of medical information to patients. Most facilitators were found at the patient and innovation levels, such as improved patient-doctor communication and patient empowerment. There were few barriers and facilitators mentioned at the economic and political levels.

Conclusions: The use of digital care platforms is associated with better quality of care through enhancement of availability of information and increased self-efficacy for oncological patients. The numerous facilitators identified at the patient level illustrate that patients are positive toward a digital care platform. However, despite these favorable results, robust evidence concerning the

effectiveness of digital care platforms, especially from high-quality studies, is still lacking. Future studies should therefore aim to further investigate the effectiveness of digital care platforms, and the barriers and facilitators to their implementation at the economic and political levels.

Introduction

Background

Over the past few decades, the management of patients with cancer has considerably changed. Owing to earlier detection of cancer and improved treatment strategies, the number of cancer survivors has increased [1]. For this reason, patients with cancer currently require long-term follow-up care, similar to patients with chronic diseases. It is expected that the increased need of follow-up care, in combination with an overall increase of cancer patients due to an aging society, will intensify the use of health care services and increase health care costs [2]. Current health care systems cannot accommodate these increased demands and are deemed unsustainable [3,4]. An additional problem that requires a reevaluation of oncological health care services is the multidisciplinary, and sometimes multi-institutional, aspect of current care. This refers to the fact that cancer patients are usually cared for by multiple health care providers (HCPs), and that, as a result of centralization of complex care to high-volume centers [5], patients may receive parts of their treatment in multiple hospitals [6-9]. These aspects result in the fragmentation of cancer care [10].

The challenges facing cancer care are recognized by the World Health Organization [11] and the Health Program of the European Union [12], and have prompted them to think of different health care structures that enable the delivery of affordable, coordinated, patient-centered oncological care. A solution in restructuring health care for oncological patients could be found in telemedicine or electronic health (eHealth). Moreover, the COVID-19 pandemic, which led to the sudden forced implementation of telemedicine, has demonstrated the potential of telemedicine and eHealth to many patients and doctors [13]. These technologies therefore seem to be indispensable for sustainable care.

For these reasons, the time seems right to deploy eHealth much more widely in oncological care. An updated, accepted definition of eHealth is lacking, but eHealth can be perceived as an umbrella term for all digital communication and information technologies that aid in health care or health care services [14,15]. Over the past decades, multiple eHealth interventions have been developed to support oncological care [16,17]. The eHealth-based intervention of interest in this review is a digital care platform. We define a digital care platform as an eHealth-based tool that aims to increase coordinated and patient-centered care. A digital care platform incorporates several different features, which separately have been the subject of study elsewhere [18-21]. First, digital care platforms may provide patients with information specific to their situation. Second, they can provide an overview of the patients' personal health records, including appointments, medical results, and correspondence. Third, digital care platforms may also offer direct, secure messaging with HCPs (eg, electronic consultation [e-Consult]). We consider these three characteristics as key features of a digital care platform. Some additional features may include the registration of patient-reported outcomes (PROMs), a patient forum, the possibility to exchange patient-related information between different health care institutes, and enable communication between HCPs and general practitioners.

Studies on the use of eHealth-based tools and their effect on care processes have been previously described for patients with chronic diseases [22,23]. A recent systematic review by Tighe et al [23] indicated that digital platform–like interventions such as self-management tools have a positive effect on physical activity and disease-related quality of life. A systematic review by Kooij et al [22] indicated that digital interventions had positive effects on patient confidence and HCP satisfaction, but that firm conclusions on its clinical effects could not be drawn. Studies on the use of eHealth in oncological care have reported favorable results, as it has been associated with improved patient-provider communication [24]; improved coping with cancer-related symptoms such as fatigue, depression, anxiety, and physical activity [16,25-28]; and improved medication adherence and higher patient satisfaction [20,27]. Some studies have also reported favorable effects on quality of life [29,30]. However, these studies investigated the effect of only one feature of a digital care platform, for instance the registration of PROMs. Previous reviews did not study the digital care platform as a central part of the oncological health care service or the effect of digital care platforms on enhancement of information, continuity of care, or patient- and HCP-reported experiences. The effect on patient self-efficacy has only been studied for one feature of a digital care platform, namely self-management programs [25]. The outcome parameters of interest (ie, enhancing availability of information, self-efficacy, continuity of care, and patient-reported and HCP-reported experiences) can also be placed in the Quality of Care framework provided by the Institute of Medicine [31]. The six domains of quality of care are safe, effective, patient-centered, timely, efficient, and equitable care. Enhancing availability of information is a measure of effective and equitable care, self-efficacy is a measure of patient-centered care, patient-reported and HCP-reported experiences are measures of safe and patient-centered care, and continuity of care is a measure of efficient care and arguably also timely care.

Additionally, we did not identify any existing systematic reviews that focused on the barriers and facilitators that exist for the

successful implementation of a digital care platform in oncological care. This is important to assess so as to adequately determine the feasibility of a digital care platform as part of routine oncological care.

Objectives

The aim of this systematic review was two-fold: (1) to collect the best available evidence of the effect of a digital care platform on quality of care for oncological patients by focusing on enhancement of available information, self-efficacy, continuity of care (including communication), and patient-reported and HCP-reported experiences; and (2) to analyze the currently reported barriers and facilitators for implementation of a digital platform in oncological health care.

Methods

Protocol and Registration

This systematic review protocol was registered with the International Prospective Register of Systematic Reviews (PROSPERO; registration number CRD42020199282) [32] and was carried out according to the PRISMA (Preferred Reporting Items for Systematic Review and Meta-Analyses) guidelines [33].

Search Strategy

The PubMed (Medline), Embase, CINAHL, and Cochrane Library databases were searched for the period from January 1, 2000 until May 27, 2020. Search terms used included "neoplasms" and affiliated terms combined with "patient portal" or "digital care" or "eHealth." The aim of this search query was to provide search results on literature involving both the effect of a digital care platform on quality of care for oncological patients as well as barriers and facilitators for implementation. The exact search query is shown in Textbox 1.

Textbox 1. Search query.

(neoplasms [mesh] OR cancer* [tiab] OR tumor* [tiab] OR tumour* [tiab] OR neoplasm* [tiab] OR malignan* [tiab])

AND

("Patient Portals"[Mesh] OR "Telemedicine" [Mesh] OR Patient portal*[tiab] OR Patient platform*[tiab] OR Patient web portal*[tiab] OR Patient internet portal*[tiab] OR virtual care*[tiab] OR digital care [tiab] OR ehealth [tiab] OR e-health [tiab] OR econsult [tiab] OR e-consult [tiab])

Eligibility Criteria

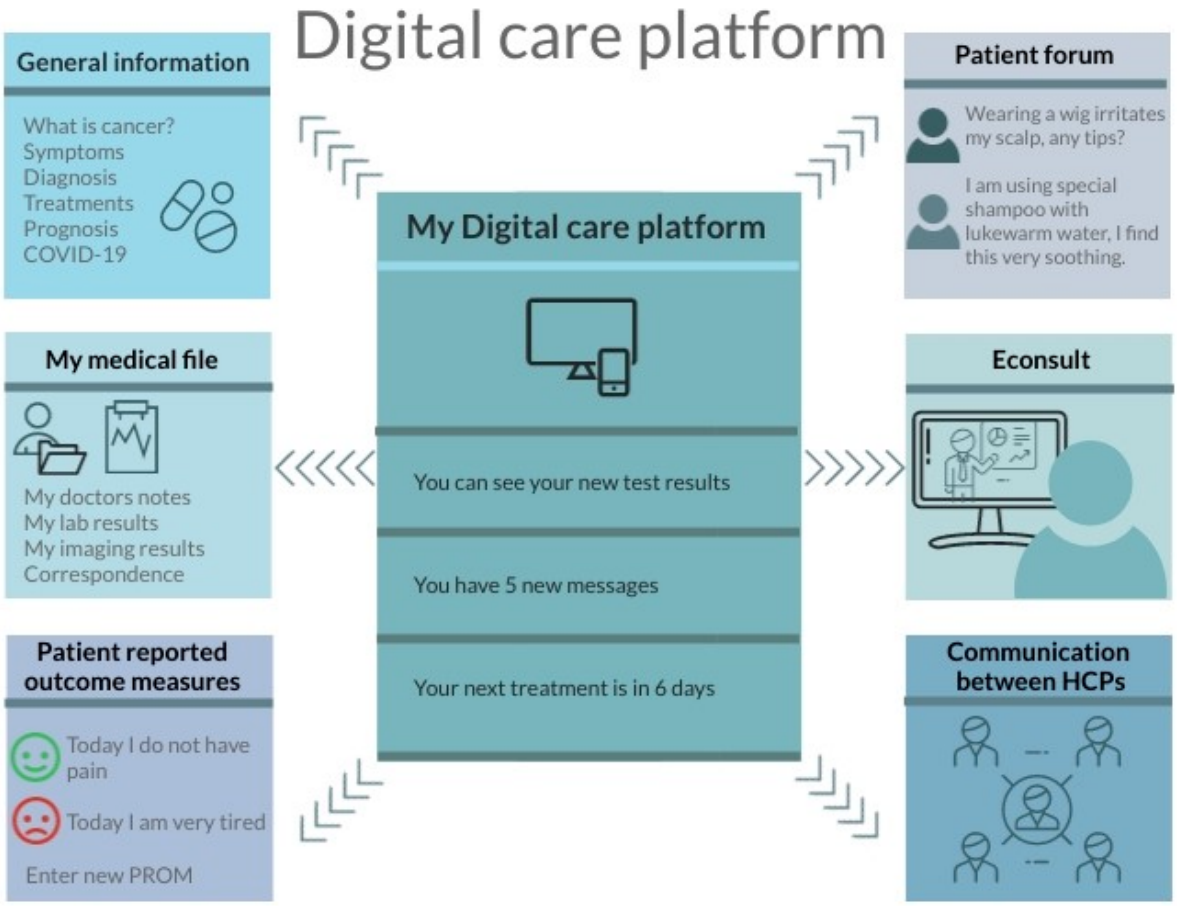
Studies of interest included randomized controlled trials (RCTs), prospective studies, and retrospective cohort studies. In addition, qualitative studies in which questionnaires were distributed or stakeholders were interviewed to investigate barriers and facilitators were also included. All studies were required to generate empirical data. Studies not written in English were also screened on the condition that they presented an English abstract. A translator could translate the full text if the abstract seemed to be eligible, thus avoiding a language bias. Systematic and narrative reviews, conference abstracts, and single case reports were excluded.

For our first objective, to collect the best available evidence of the effect of a digital care platform on quality of care, studies were required to involve oncological patients ≥18 years old. These clinical studies had to assess the effectiveness of a digital care platform. Although we provided our definition of a digital care platform in the Introduction, considering the exploratory stage of research of digital platforms in oncological care, we suspected that there would be a rather limited number of studies investigating such an extensive digital care platform. For this reason, for inclusion in our systematic review, a digital care platform was required to have at least two of the following key features: (1) provide general information concerning the disease as education (eg, symptoms, treatment, follow-up, prognosis); (2) provide patient-specific information concerning their medical file, such as planned appointments, treatments, and lab results; and (3) enable patients to communicate with their physician or specialized nurse via chatting, e-Consult, or email. Figure 1 depicts these and other features of a digital care platform.

Studies that did not involve a digital care platform with at least two of the three above-mentioned features and studies that provided insufficient or vague details concerning the digital intervention were excluded from the analysis to assess our primary objective.

For the second objective, identification of barriers and facilitators for implementation of a digital care platform in oncological care, studies were not required to involve a digital care platform that was already implemented. They could comprise studies that actually implemented a digital care platform and subsequently described the barriers and facilitators for implementation, but they could also comprise studies that identified barriers and facilitators based on a hypothetical discussion with stakeholders. In the latter case, the digital care platform in question was not yet implemented or developed.

Figure 1. Explanatory illustration of a digital care platform. Studies included in this systematic review were required to investigate a digital care platform with at least two of the following features: (1) general information provision, (2) electronic patient file, or (3) electronic consult (Econsult) with health care providers (HCPs). PROM: patient-reported outcome measure.



Study Selection

Two separate reviewers (JH and LV) screened the search output on titles and abstracts using Rayyan software [34]. During this screening process, the reviewers were blinded to each other's decisions. Studies with a contradictory judgment were discussed. In case of a remaining discrepancy, senior reviewers (RH and MS) were asked to arbitrate. The full texts of the selected studies were screened for eligibility. Reference lists of studies that were included after full-text screening were checked for additional eligible studies (snowball method). In cases in which multiple eligible studies reported on the same dataset (≥50% overlap of sample size), we excluded the article with the shortest follow-up.

Data Extraction and Analysis

Two authors (JH and LV) extracted data using a shared template. These data included: (1) author, year of publication; (2) country; (3) study design; (4) patient population, sample size; (5) platform that was the subject of the study; 6) features of the platform; and (7) the outcome parameters, including enhancement of available information, self-efficacy, continuity of care, and patient- and HCP-reported experiences. If possible, data were pooled; otherwise, synthesis of the results was performed qualitatively.

Barriers and facilitators for implementation of digital care platforms were categorized according to the framework of Grol and Wensing [35]. This framework categorizes barriers and facilitators at six different levels: (1) innovation, which involves advantages in practice, feasibility, credibility, accessibility, and attractiveness; (2) individual professional, which concerns the awareness, knowledge, attitude, motivation to change, and behavioral routines of the involved professionals; (3) patient, which involves knowledge, skills, attitude, and compliance of the patients; (4) social context, which concerns opinion of colleagues, culture of the network, collaboration, and leadership; (5) organizational context, which includes the organization of the care processes, staff, capacities, resources, and structures; and (6) economic and political contexts, which involve regulations, financial arrangements, and policies. The frequency of the barriers and facilitators mentioned, and the quality of the studies were used to prioritize barriers and facilitators.

Critical Appraisal of Evidence

The Mixed Methods Appraisal Tool (MMAT) version 2018 was used to critically appraise the included studies [36]. The MMAT is designed to help reviewers appraise the quality of empirical studies with different methods. These include quantitative RCTs, quantitative nonrandomized trials, quantitative descriptive studies, as well as qualitative and mixed methods studies. Each category includes five different quality parameters, all requiring to be assessed by answering "yes," "no," or "cannot tell" (maximum total score=5). Two authors (JH and LV) independently appraised all studies. In case of disagreement, RH and MS were asked to arbitrate. Studies with

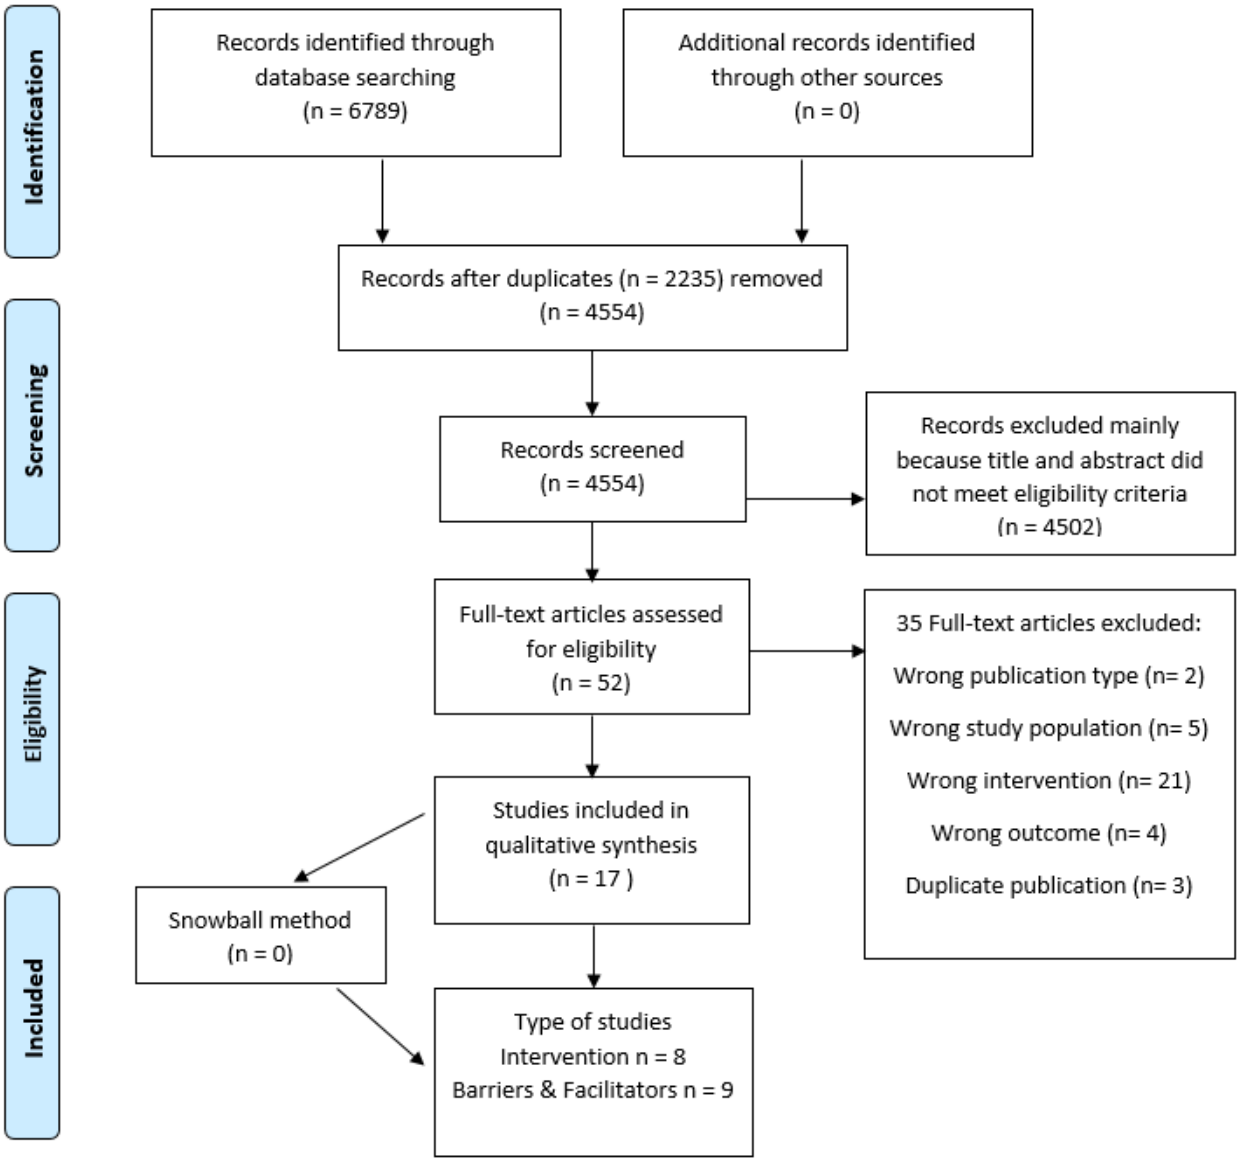
a total score of 1-2 were considered to be of low quality, a study with a score of 3 was considered to be of moderate quality, and studies with total scores of 4-5 were considered high-quality studies.

Results

Search Results

The initial search generated 6789 articles. After removal of duplicates and initial screening of titles and abstracts, 52 studies remained for full-text assessment. Of these 52 studies, 17 articles met our eligibility criteria and were included in this systematic review. Figure 2 depicts the PRISMA flowchart for the study screening process.

Figure 2. PRISMA flowchart.



Study Characteristics

Overview

Of the 17 included studies, eight were clinical studies that implemented a digital care platform and assessed its effect on at least one of the predefined outcome parameters [37-44]. Four of these clinical studies [39,42-44] also described barriers and facilitators for implementation. The other nine studies [45-53] only investigated barriers and facilitators for digital care platforms. None of the included studies was written in a non-English language. Table 1 and Table 2 show the baseline characteristics of the clinical studies and the barrier and facilitator studies included in this review, respectively.

[f]PROM: patient-reported outcome measure.

Study Design

Among the clinical studies, three were RCTs [37,38,41], two were mixed methods studies [39,42], and three were pilot or feasibility studies [40,43,44] investigating the use of the platform in a small cohort. The three RCTs included 450, 167, and 257 patients, respectively, and all assessed the effectiveness of different variations of a digital care platform [37,38,41]. For example, Baker et al [37] assessed the effectiveness of different components of a digital care platform by comparing patient groups using a platform with information only; a platform with information and support; and a platform with information, support, and coaching. The control group did not use a digital care platform but used the internet. An example of one of the mixed methods studies is that performed by Kuijpers et al [42], in which a digital care platform was implemented in a small cohort with a postintervention questionnaire, followed by focus group discussions. Studies solely investigating barriers and facilitators were mainly qualitative in nature, with the exception of three studies applying a mixed methods methodology [48,51,53] and one study using a quantitative methodology [50].

Patient Population

Breast cancer patients formed the majority of the study population of the clinical studies, with 75% of all studies including solely this patient population. The patient population was therefore mostly female, highly educated, and young (mean age 50 years) [37,38,42,43]. The other studies included patients with nonsmall cell lung cancer or a diverse group a of cancer patients such as those with renal cell cancer and sarcoma. One study [43] included two different patient groups, namely breast cancer and prostate cancer patients, and compared the use and effectiveness of the digital care platform between these two groups. The barrier and facilitators studies (Table 2) included patients with colorectal cancer, lung cancer, breast cancer, hematological cancer, and a variety of other cancer types.

Interventions

Within the eight clinical studies, five web-based platforms were distinguished. These platforms were all web-based and were not integrated in the electronic medical record (EMR). Seventy-five percent of the studies assessed a platform that also intended to improve self-management by, for instance, symptom monitoring, physical activity advice, or self-therapy [37,38,40-43]. Although each digital care platform had at least two of the three predefined criteria, heterogeneity concerning the platforms was observed. For example, the digital care platform described by De Regge et al [39] enabled HCPs, including general practitioners, to read their patients' medical records from other health care centers. This allowed them to gain insight into their patients' treatment trajectory and decision-making by other involved HCPs. Other platforms such as those described by Groen et al [40] and Kuijpers et al [42] did not have this feature, and provided personalized patient education material, an overview of upcoming hospital appointments, and tailored physical activity.

Methodological Quality

Quality assessment of the included studies is shown in Table 3. Of the clinical studies, four studies were of low quality [37,41,43,44], three of moderate quality [38,39,42], and one study was assessed as a high-quality study [40]. Regarding the barrier and facilitator studies, three studies were of low quality [49,51,53], one of moderate quality [48], and five were of high quality [45-47,50,52].

Outcome Measures

Enhancing Availability of Information

Five studies [39,40,42-44] reported on enhancing availability of general information on a digital care platform. In a high-quality feasibility study [40], the option to receive information was scored by patients with a mean of 7.1 (SD 1.5) on a scale of 1-10. The actual usage of information sections in the digital care platform differed among studies. One high-quality study reported the patient EMR to be the most used section of the digital care platform (mean 6.7, SD 4.7 logins during the 4-month study period) [40] and another study of moderate quality reported the opposite finding that the information section was rarely viewed (mean 0.75, SD 1.4 number of times participants consulted the information section) [39]. Needs of patients also differed, as Ruland et al [43] reported a significant difference (625 vs 271, *P*=.01) in the number of visits to the information section between breast cancer and prostate cancer patients, with breast cancer patients visiting this section more often. In this study, which was appraised as low quality, information comprehensibility of the digital care platform was rated with an overall mean score of 7.2 (SD 1.4) and usefulness was rated with a mean score of 6.5 (SD 1.7), both on a scale of 1-10 [43]. The main reasons for consulting the general disease-related information section of the digital care platform were to get help with problems and to get assurance. In addition to the information section, the platform's ability to directly communicate with a nurse was perceived as very useful, because it was perceived as easy-to-understand information. The nurses' contribution to a patient forum was reported as a trustworthy source of information [43] and therefore was highly valued by patients [44].

Self-Efficacy

Six studies investigated the effect of a digital care platform on self-efficacy [37,38,40-42,44] and all of them reported positive effects. Although the effects were not significant, a clear trend toward a positive effect on self-efficacy was reported. In the RCT performed by Børøsund et al [38], a moderate-quality study, patients using a digital care platform tended to score higher on self-efficacy compared with patients in the usual care group (mean difference 8.81, range 33-297, 95% CI –0.92 to 18.53, *P*=.08). Patients reported that a digital care platform was helpful in managing their health [44]. Groen et al [40] and Kuijpers et al [42], studies with high to intermediate quality, reported that access to general disease-related information and patients' EMRs enhanced patients' knowledge of their disease and their sense of control, based on questionnaires. Two RCTs showed that using a digital care platform increased patients' perceived ability to obtain and use health care information. The digital care platform also increased their comfort and activation level of dealing with physicians and health care situations compared to the patient group only using the internet [37,41]. However, both of these RCTs were categorized as low quality.

Continuity of Care

None of the included clinical studies reported specifically on continuity of care as a primary or secondary outcome parameter. However, three low/intermediate-quality studies [38,39,43] reported on the aspect of communication between patients and HCPs and among HCPs within the platform. A questionnaire-based pilot study [43] reported that the most valued feature of the platform (ie, Webchoice) as expressed by the study population was the ability to send messages to their HCPs. That same research group investigated the effects of their platform in an RCT and reported 40% use of the messaging service in this platform [38]. Patients perceived this feature to be useful and easy to understand. De Regge et al [39] reported that HCPs perceived the ability to exchange research results between HCPs (eg, HCPs in other hospitals and primary care) as valuable to patient care and a means to optimize continuity of care across institutes.

Patient- and HCP-Reported Experiences

Seven studies [37-40,42-44] reported on patient- or HCP-reported experiences. Patient satisfaction with the studied platform was considerably high in three intermediate/high-quality studies, with a mean rating of 3.9 (range 3.8-4.09) on a 1-5 scale [39,40,42]. A low-quality RCT that aimed to compare the effects of three different types of interventions and one control observed significantly higher patient satisfaction scores with their HCPs compared with those of the control group at 6 weeks (3.46 vs 3.17, *P*=.01) and 6 months (3.48 vs 3.28, *P*=.03) [37]. The majority of patients (75%-93%) stated that the platform was easy to use and that it was a valuable addition to their health care experience [40,42]. The most used features of the platform varied among studies, but mainly consisted of the personal medical records in intermediate/high-quality studies [39,40,42]. Only two clinical studies reported the experiences by HCPs. De Regge et al [39], an intermediate-quality study, reported that HCPs perceived the digital care platform as valuable compared to current care because it provides reliable, easy-to-access information for patients and because it enables the exchange of patient-related information between care providers. Despite these positive experiences, one-quarter of the physicians interviewed by Kuijpers et al [42], an intermediate-quality study, reported an increase in workload after installment of the digital care platform, varying from a few extra minutes to more than 10 minutes per patient, for additional explanations on information made available on the platform.

Barriers and Facilitators Levels

Overview

Table 2 presents the baseline characteristics of the studies describing barriers and facilitators. Tables S1 and S2 in Multimedia Appendix 1 present all barriers and facilitators identified in the included studies. The most prominent barriers and facilitators are discussed below. Figure 3 depicts the illustrative quotations found in the studies for each level.

Figure 3. Illustrative quotations mentioned in included studies concerning barriers (in red) and facilitators (in green) for implementation of a digital platform.

Innovation Level

Four studies [44,46,48,51] described technical challenges as a possible barrier for implementation. These included software development, functionality of the website, bugs, and log-on and internet access issues. A second barrier, concerning accessibility of the innovation, was patients' unawareness of the existence of the digital care platform, which led to limited or no use of the platform [53]. Despite these barriers, three studies showed that the use of a digital care platform is feasible [40,42,44]. Facilitators in practice were numerous: access to general and tailored medical information [42,45,47-49,52], full EMRs [39,42,45-48,50-52], and educational materials [42,47]. Moreover, the possibility to consult HCPs through interactive tools was mentioned to be a positive feature of a digital care platform that encouraged usage [43,44,47,48,50].

Individual Professional Level

The most frequently described barrier at the professional level was the concern of HCPs regarding the release of medical information on the digital care platform and the comprehensibility of medical jargon for patients [39,45,46,48,49,51,52]. Patients learning about a change in their health and well-being via a digital care platform was a fear expressed by all oncologists included in two studies [45,48]. The second most frequently described barrier, described in seven studies [39,42,45-47,49,51], concerned the fear of increased workload such as an increased burden of documentation, monitoring, and direct digital communication with patients [39,42,45,49].

Concerning facilitators, one study suggested that a digital care platform would not increase workload but would rather reduce workload by easing data management [46]. Another facilitator

mentioned was the ability to exchange information or medical results between different HCPs, including those in primary care such as general practitioners [39,46]. The optimization of data exchange between institutes could avoid or reduce repeated health assessments [46].

Patient Level

Three studies indicated that patients had concerns about the readability of the information (medical jargon) displayed on the digital care platform and whether medical results could be adequately understood without professional interpretation [45,46,48]. Some patients mentioned that this could increase anxiety [48,52].

Facilitators at the patient level were numerous, as indicated in Table S2 of Multimedia Appendix 1. In several studies, patients and oncologists mentioned that patients having access to the platform and their EMR could better prepare them for their doctor visit and enabled them to take on an active role during the consultation [45-47]. In addition, patients' willingness to communicate via digital resources facilitated implementation [53]. Lastly, improved patient-doctor communication was described as a facilitator, either by improved preparedness for doctor visits or by direct messaging [52].

Social Context Level

Three studies reported concerns on how a digital care platform could change the doctor-patient relationship [48] such as by increasing the patient's autonomous handling of information [46]. The digital care platform could make patients increasingly reliant on technology with decreased reliance on face-to-face communication [46,49]. This was feared as it may negatively influence the outpatient clinic visits as patients become more focused on discussing (irrelevant) details regarding available biomedical results rather than discussing values and preferences important for a follow-up treatment [48].

The change of the doctor-patient relationship was also mentioned as a facilitator. By enabling access to medical information, patients could become more actively involved in the management of their care and feel more comfortable to interact with their HCPs during consultations [42,45].

Organizational Context Level

Two studies mentioned the integration of the platform into existing systems as a barrier [44,47]. This would be especially relevant in cases in which the digital care platforms were also developed for other chronic diseases [47]. Limitations in time and resources were reported as another type of barrier [44].

A clear facilitator at the organizational level was the digital care platform's ability to exchange important patient information across health care institutes. HCPs emphasized the advantage of a digital care platform in improving the cross-sectoral availability of information about the patient to HCPs who are involved in the patient's treatment. It is suggested that the digital care platform could thereby diminish information loss, be of use in emergency situations where the rapid release of medical information is vital, and avoid repeated diagnostic investigations [46]. Organization of care could be improved as the improved availability of information promotes cross-boundary continuity of care and diminishes fragmentation of care [39,46]. Another facilitator at the organizational level was the early introduction of the digital care platform to the patient, preferably at diagnosis [44], and sufficient instructions concerning appropriate use of the platform for patients as well as HCPs [49].

Economic and Political Contexts Level

Data security and protection regarding the digital care platform were concerns reported by numerous studies [46,50,51,53]. During the development of the digital care platform described by Kildea et al [51], cybersecurity testing and legal issues were the most time-consuming processes. These legal issues involved the ownership of intellectual property [51] and liability [46,51].

Secure access was therefore identified as an important facilitator for a digital care platform [48]. Another facilitator, in the economical context, was that conferred by the optimized exchange of patient information between institutes, enabled with a digital care platform, and that unnecessary repeated diagnostic procedures and health assessments could be avoided [46].

Discussion

Principal Findings

A digital care platform for oncological patients has the potential to improve quality of care through the improved availability of information and positive effect on self-efficacy. Although continuity of care was not studied as a primary outcome in the identified studies, based on focus group interviews with HCPs, a digital care platform potentially improves continuity of care by optimizing the exchange of patient information across institutes. Patient-reported experiences such as satisfaction with the platforms were considerably positive. Our barrier and facilitator analysis indicated that the majority of barriers exist at the professional level. This included a concern of increased workload for HCPs and release of unattended medical information to patients. The majority of facilitators were identified at the patient and innovation levels. The patient's ability to become more informed, empowered, and involved in their care was identified as a prominent facilitator. Another relevant facilitator, at the organization level, is the digital care platform's potential to improve information exchange between HCPs across different institutes. This is relevant as this may improve continuity of care and diminish fragmentation of oncological care. Among the clinical studies, the majority were of low to intermediate quality. Regarding the barrier and facilitator studies, the majority were of high quality.

The positive effects of a digital care platform described in this review are consistent with prior research studying isolated features of digital care platforms [16,29,54]. A digital care platform seems to be a helpful medium in providing patients with general disease-related and personal information. This is a welcoming result as previous studies have described that a considerable number of patients are dissatisfied with information provision [55,56]. Moreover, 40%-80% of all medical information provided by the HCP during a consultation is forgotten or remembered incorrectly [57]. Therefore, the need of patients to read or reread medical information that is relevant

for their situation is an important facilitator for a digital care platform. In this systematic review, we identified studies that showed positive effects on self-efficacy, but no convincing clinically significant effects. In another systematic review, which studied the effectiveness of eHealth-based self-management tools, significant yet small effects on self-efficacy were described [25]. The authors explain that the tool was able to increase self-efficacy by enabling patients to enhance participation in their care trajectory. A more recent randomized trial refuted this finding [58]. In this RCT, the effect of an eHealth-based self-management tool (Oncokompas) was investigated in 600 cancer patients. At 3 and 6 months, patients were assessed on self-efficacy with the General Self-Efficacy scale. No significant effects on self-efficacy were observed (mean difference 0.5, 95% CI –0.4 to 1.4, *P*=.31). The authors partially attributed the lack of effect to the included patient population, which mostly consisted of patients diagnosed with cancer 2 years prior to the study. The authors suggested that this population is perhaps less in need of a self-management tool to increase self-efficacy as they have more experience and "know-how" compared with their newly diagnosed peers. The hypothesis that the effect of an eHealth-based tool may vary considerably depending on the patient population is important to consider for assessing the effectiveness of a digital care platform. In our systematic review, we included studies with patients in different stages of their disease trajectory and with different cancer types, and all effects regarding self-efficacy were positive but not significant. On the one hand, this aspect can be perceived as a limitation because the heterogeneity of patients may underestimate the effect of a digital care platform. On the other hand, it is a strength as we now have an overview of the effect of a digital care platform on self-efficacy of a broad cancer patient population, thereby increasing the generalizability of our results.

Similarity with prior work concerns the limited number of studies investigating combined features of a digital care platform. During the screening process of this review, we encountered numerous studies that only investigated one feature of the platform. This finding is similar to the findings of a review by Kruse et al [20], which concluded that many studies assessed the effect of one feature of a digital care platform and that a full platform was rarely studied in clinical practice. To adequately ascribe outcomes as an effect of the intervention, it is reasonable to first study an isolated feature of a digital care platform. However, it is absolutely vital to also study the combined features in a digital care platform for two key reasons: (1) because this is likely to be the eHealth intervention that is implemented in practice, and (2) because the effect of multiple features may not be equivalent to the sum of effects of a single feature.

The fact that we assessed the effects of digital care platforms that had at least two key features can therefore be considered a strength of this review. In addition, we assessed the effect of a digital care platform on quality of care parameters such as continuity of care, and described the patient- and HCP-related experiences. Other reviews did not, and instead only assessed the effect of a digital care platform with one feature or chose to study different endpoints such as fatigue, physical activity, depression, quality of life, and self-management abilities [20,25,29,30,54,59]. An additional strength is that we analyzed barriers and facilitators for implementation. This allows for a good understanding of what is needed for successful implementation. A final strength is that the search query was quite elaborate without exclusion of non-English articles, thereby minimizing the possibility of missing valuable studies. For these reasons, this systematic review provides a comprehensive overview of the best available evidence of the effect of a digital care platform on quality of care for oncological patients.

However, this systematic review also has some limitations. First, the included clinical studies were mostly early-stage, single-arm prospective studies where feasibility and acceptability were investigated. Although we did include three studies with a more advanced research methodology (ie, RCTs), these studies were all appraised as studies with low to intermediate quality. This makes interpretation of these RCTs quite challenging. One RCT reported a significant difference in patient satisfaction scores favoring a type of digital care platform [37]; however, the minimal difference (3.48 vs 3.28 on a 1-5 scale) puts into question the clinical relevance of this finding. A second limitation of this review concerns the heterogeneity of study designs and of the digital care platforms. Despite our predefined criteria of what a digital care platform should include, they were still quite different from each other with respect to the specific web format, options, and intended use, among other aspects. This heterogeneity precluded a pooled analysis with quantitatively measured outcome parameters. A third limitation concerns the study population and its representativeness. Three-quarters of the clinical studies included breast cancer patients. This study population mainly consists of well-educated females [60]. Indeed, 72%-73% of the breast cancer population in the studies included in this review had a college or university degree. It is plausible that a high education is an important factor for successful use of a digital care platform. For this reason, results of this review should be interpreted with caution and cannot simply be generalized to other cancer patients. A final limitation concerns the barrier and facilitator analysis. Studies included in this review almost exclusively focused on the barriers and facilitators mentioned by the end users of the platform (ie, the patients and HCPs). Evidently, their perspectives are crucial, but barriers and facilitators proposed by other stakeholders should also be investigated, such as stakeholders with an organizational, economic, and political background (eg, health insurers). This latter group can provide insight into what is required to realize the structural financing of a digital care platform.

Although there is a growing body of literature that describes the positive effects of digital care platforms, high-quality studies describing the effectiveness of these platforms integrated in oncological care are currently lacking. In addition, most studies implemented a digital care platform in one target patient population such as breast cancer patients. More evidence is required concerning the desirability and use of a platform in patients with other types of cancers and education levels. More specifically, it is important to investigate whether patients with a lower level of education can benefit from digital care platforms

to the same extent as their well-educated peers to avoid widened health disparities. The same applies to the patient population with limited internet access or internet skills. Studies in this review were performed in Australia, North America, and western Europe. The usefulness of digital care platforms in countries with low internet access is likely very different.

Concerning barriers and facilitators, future studies should aim to further elucidate barriers and facilitators at the organizational level and the economic and political levels. Ultimately, this is required for a digital care platform to become a successful eHealth-based tool in the improvement of quality of care for patients living with cancer.

Conclusion

Digital care platforms have a favorable effect on availability of information and enhancement of self-efficacy. Additionally, they could potentially serve as a valuable medium to improve continuity of care by optimizing communication between patients and HCPs and among HCPs. The vast majority of patients are positive about a digital care platform and its ability to meet their needs in improving the availability of information and patient involvement. Although these results are favorable, they were mostly generated by early-stage, nonrandomized studies with a specific patient population. To fully understand whether a digital care platform is able to increase quality of care by supporting the delivery of coordinated, patient-centered oncological care, more advanced studies such as RCTs are required, as well as studies investigating the barriers and facilitators at the economic and political levels.

Authors' Contributions

JH and LV were primarily responsible for the review and data extraction, and share first authorship. MS and RH contributed equally as senior reviewers and share last authorship. All authors contributed to and approved the final version of the paper.

Abstract

Despite recent and potent technological advances, the real-world implementation of remote digital health technology in the care and monitoring of patients with motor neuron disease has not yet been realized. Digital health technology may increase the

accessibility to and personalization of care, whereas remote biosensors could optimize the collection of vital clinical parameters, irrespective of patients' ability to visit the clinic. To facilitate the wide-scale adoption of digital health care technology and to align current initiatives, we outline a road map that will identify clinically relevant digital parameters; mediate the development of benefit-to-burden criteria for innovative technology; and direct the validation, harmonization, and adoption of digital health care technology in real-world settings. We define two key end products of the road map: (1) a set of reliable digital parameters to capture data collected under free-living conditions that reflect patient-centric measures and facilitate clinical decision making and (2) an integrated, open-source system that provides personalized feedback to patients, health care providers, clinical researchers, and caregivers and is linked to a flexible and adaptable platform that integrates patient data in real time. Given the ever-changing care needs of patients and the relentless progression rate of motor neuron disease, the adoption of digital health care technology will significantly benefit the delivery of care and accelerate the development of effective treatments.

amyotrophic lateral sclerosis; digital health care technology; e-health

Introduction

Remote digital health technology, ranging from simple mobile apps to implantable devices, will reform the delivery of care. Despite the recent technological advances in biosensors, mobile communications, and cloud computing, their real-world implementation remains to be fully realized [1]. Motor neuron disease (MND) is a debilitating disorder in which digital health care technology will benefit delivery of care [2,3] and also expedite the development of effective treatments [4-6]. Patients living with MND rapidly lose their functional independence, making travel, communication, and visits to specialist clinics for assessment of vital clinical parameters challenging [7]. This has been particularly the case during the COVID-19 pandemic [8,9]. The effects of the pandemic have focused attention on technological advances that increase the accessibility and personalization of care, and remote biosensors that optimize the collection of vital clinical parameters, irrespective of the patients' ability to visit the clinic, are poised to revolutionize the clinical encounter. These developments hold benefits for both research and care settings, driving the implementation of real-world use of remote digital health care technology in MND [2,10].

Notwithstanding, the following key barriers delay the adoption and wide-scale implementation of digital health care technology in MND [2]: (1) technical complexities, (2) low compliance rates, (3) time investment required, (4) high costs, and (5) legislation challenges. For clinical trials, adoption is further complicated by regulatory hurdles because of reduced auditability, consistency, and data quality [6,11,12]. Although there is considerable work underway in these areas that will facilitate the validation and initial adoption of digital technology in MND [4,5,13-15], it is also the case that device or platform incompatibility might further delay their wide-scale adoption and large-scale data aggregation. Therefore, there is a recognized need to open collaborations among clinicians, engineers, and technology companies that will support early implementation.

Here, we outline a road map that aims to (1) facilitate the identification of clinically relevant digital parameters; (2) mediate the development of benefit-to-burden criteria for innovative technology; and (3) direct the validation, harmonization, and adoption of digital health care technology in real-world settings.

The Need for Remote Technology in MND

Disease heterogeneity and rapid physical deterioration are key drivers in the delivery of care and monitoring of disease progression in clinical trials. Although MND is recognized as a clinical entity, it is better considered as a number of different subgroups with variable clinical presentations, different causes, and different disease trajectories. A flexible approach toward management is required such that the patient's clinical condition is monitored at intervals that best reflect both the needs of the patient and their family and the trajectory of the disease. As progression ultimately leads to severe disability, clinical attendance is increasingly burdensome [16], notwithstanding the known benefits of multidisciplinary clinics that include survival and optimal access to assistive devices or proven treatments [17]. Unfortunately, even in developed countries, attendance at multidisciplinary clinics is as low as 43%, and many of those who can attend are unable to return [18].

We illustrate the extent of this attrition process, as observed in a large clinical trial [19], in Figure 1. From the point of trial enrollment, almost 1 in 4 (184/750, 24.5%) patients failed to visit the clinic after 12 months, and more than one-third (271/750, 36.1%) were unable to provide reliable respiratory information. These figures are likely an underestimation of the attrition rates occurring at multidisciplinary clinics because clinical trials select for patients with better prognoses [20,21]. These high attrition rates affect the estimation of treatment benefit within clinical trials, reduce statistical power, and may lead to the continuation of an ineffective compound into a subsequent phase of clinical development.

Figure 1. Percentage of EMPOWER patients with missing information on clinical outcome measures. For each clinical visit in the EMPOWER study, we determined the number of patients that were on study medication and were alive (ie, number at risk). Subsequently, we calculated the proportion of missing observations per outcome measure. If the patient was no longer able to visit the clinic (as indicated by the number of missing in-clinic muscle strength assessments), ALSFRS-R data and blood samples were collected remotely by home visit or by phone. ALSFRS-R: Amyotrophic Lateral Sclerosis Functional Rating Scale-Revised.

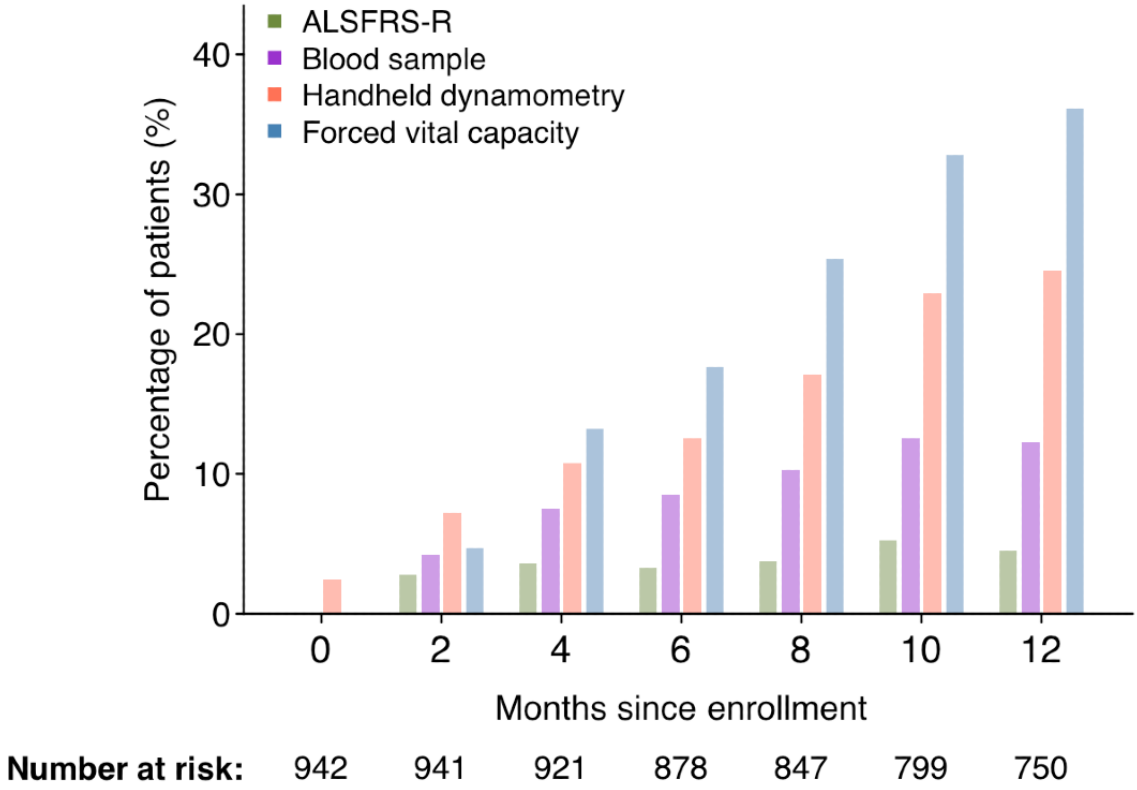

Figure 1 also demonstrates that outcomes that can be measured remotely, either by phone for the Amyotrophic Lateral Sclerosis Functional Rating Scale-Revised (ALSFRS-R) or by a home visit for a blood sample, can reduce attrition and may mitigate many of the current challenges. Remote data collection can be tailored to identify and accommodate the ongoing needs of patients and caregivers, thus shortening the time spent at the hospital or traveling to the hospital and personalizing visiting schemes [14,22]. This in turn can provide a communication channel between patients and health care providers that builds an iterative and shared decision-making process regarding the timing and management of interventions and the approaches to end of life [23]. For clinical trials, home-based monitoring of disease progression is likely to more accurately reflect the patients' true physical condition in free-living (ie, nonclinical) settings and lower the burden of monitoring. This in turn is likely to increase the number of patients who can participate in clinical research and provide real-world insight into the therapeutic value of experimental drugs [6,11,24]. Designing an information source that reflects the patients' true physical condition in near real time is therefore of significant value for all stakeholders.

A Road Map for MND

In this paper, we considered technology that assists with remote monitoring of MND disease progression or identifies critical health issues such as the development of respiratory or nutritional failure. To that end, we defined two key end products of the road map, as follows:

1. A set of reliable digital parameters to capture data, collected under *free-living* conditions at the patient's home, that reflect patient-centric measures and facilitate clinical decision making
2. An integrated open-source system that provides personalized feedback to patients, health care providers, clinical researchers, and caregivers

To achieve this, there is a need for input from all stakeholders, including those living with MND and those who (informally) care for patients with MND. To promote the uptake of new technology in real-world settings, we used a user-centered co-design approach that involves input from stakeholders (eg, patients, caregivers, physicians, ethicists, regulators, programmers, and researchers) at every stage of development [25]. There will be specific attention paid to patient, caregiver, and researcher access as well as international regulatory, financial, and licensing hurdles to ensure widespread implementation, sustainability, and growth [26]. For this road map, we have identified the following three key questions: (1) what to measure; (2) how to measure; and (3) how to implement? We outlined the requirements to answer each of these questions, considering the needs of the various stakeholders of the technology.

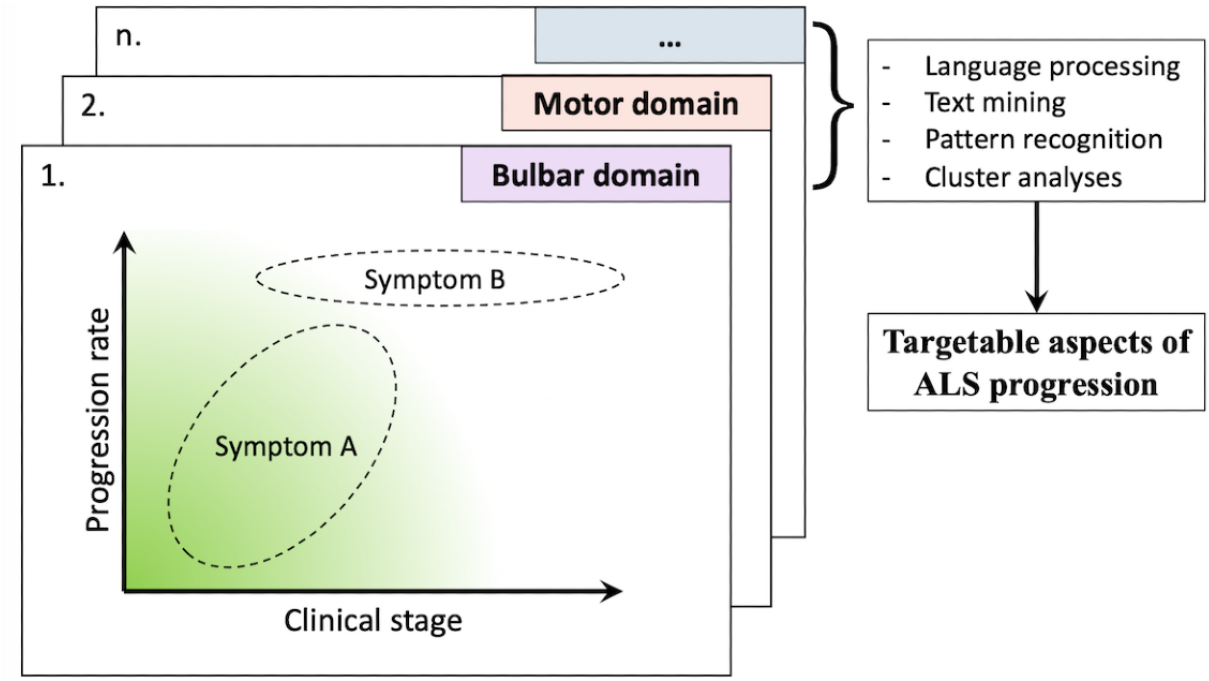
What to Measure?

Patient centricity is crucial to promote long-term adherence, where end points should focus on how aspects of MND affect daily living and distinguish between symptoms (ie, impairments) and activities (ie, disabilities). The clinician's input may help to prioritize end points in clinically relevant domains or supplement other aspects of MND that patients may not recognize as clinically important (eg, weight loss or cognitive and behavioral changes). This approach maximizes the likelihood of acquiring data that facilitate clinically relevant decision making and minimizes the collection of redundant information.

Workplan: What to Measure?

Information will be collected from three independent sources: (1) a systematic literature review summarizing and meta-analyzing all published symptomology associated with MND; (2) face-to-face in-depth interviews and focus group discussions with patients, caregivers, and physicians until data saturation is reached; and (3) a cross-sectional, population-based patient survey. We will apply a purposive and theoretical sampling strategy to ensure that we capture the complete range of disease patterns reported among patients with MND [27]. Videoconferencing will be used to ensure full patient participation at all meetings. In Figure 2, we illustrate two key elements that may help to disentangle the clinical heterogeneity observed among patients and guide sampling strategies or evaluate generalizability: clinical disease stage and progression rate. Some symptoms such as speech disturbances may only be prevalent in early clinical stages and will disappear over time owing to a complete loss of function (illustrated as *Symptom A*). Conversely, some symptoms may only be prevalent in patients with a certain disease type or progression rate (eg, symptoms related to spasticity in a primarily upper motor neuron, a slowly progressing subtype of disease, illustrated as *Symptom B*). Mapping the prevalence of symptoms in this 2D plane may help to disentangle a large part of the clinical heterogeneity in MND. Clinical stage can be defined by the King's clinical and Milano-Torino functional staging algorithms [28,29], whereas the progression rate is directly related to survival time and could be mapped by, for example, the patient's predicted prognosis [30].

Figure 2. Untangling clinical heterogeneity in motor neuron disease in a 3D framework. The prevalence of symptoms as reported by patients will be mapped according to their clinical stage and (predicted) progression rate. Clusters of symptoms will be defined into domains (eg, bulbar, motor, respiratory, and cognition) for creating a 3D map of motor neuron disease symptom heterogeneity. The map will be used to identify clinically relevant and targetable end points. ALS: amyotrophic lateral sclerosis.



A complete list of symptoms will be extracted from the interviews and focus group meetings, supplemented with data from the literature review, and by language processing and text mining from a population-based, cross-sectional survey asking open questions such as "What bothers you the most about your MND" and "In what way does this affect your daily living?" Information collection will be conducted in a multicenter, international setting to account for potential geographical, social, and cultural differences. Finally, a large range of statistical methods will be used for pattern recognition to cluster targets and end points, identify redundant information, and classify subgroups of patients with specific needs. Ultimately, this results in a 3D framework, as depicted in Figure 2, that orders a large part of the variability in symptoms among patients. Additional classification using, for example, cognitive or behavioral impairment or the presence of dementia may be applied to further elucidate heterogeneity in MND [31,32]. The 3D framework could help to evaluate the representativeness of the included population and quickly identify clinically relevant and targetable end points. The final list of targetable end points will be evaluated by patients, caregivers, and physicians for further refinement and prioritization.

How to Measure?

The second step is to translate the list of clinically relevant aspects of MND into digital parameters. For example, speech is a clinically relevant outcome in which a mobile speech app could serve to improve its objective assessment in a standardized manner. Critical aspects to consider here are, among other things, whether the mobile app requires an action-dependent or passive task (eg, repeat a fixed sentence vs record a daily 5-min conversation), the uniformity and precision of the digital voice parameters (eg, speaking rate vs volume vs perturbations) [33], the required number and length of measurements (eg, daily, weekly, or monthly follow-up), and whether direct supervision or caregiver assistance is required. These factors not only determine the burden for patients or caregivers but also establish the value of the obtained information for researchers and health care providers. The aim is to define selection criteria for digital technology that evaluates burden-to-information ratios and, based on these criteria, results in a standardized and protocolized set of digital metrics for MND.

Workplan: How to Measure?

We will conduct a series of systematic reviews to define a list of candidate technologies for each targetable aspect of MND. Naturally, the real-world use of the suggested technology could reveal insights that may not have been reported previously in the literature or by the supplier. Longitudinal studies are preferred because they not only evaluate test-retest reliability and the validity to capture disease progression of a digital parameter but they also provide information on patient adherence and the adequacy of the monitoring protocol (eg, obtaining daily, weekly, or monthly measurements). The latter is an often-overlooked aspect, although it has important consequences for all stakeholders. Naturally, a daily monitoring scheme would provide the most information about the disease for health care providers and researchers [5] but could disproportionally increase patient burden and lead to high (differential) attrition. A periodic monitoring scheme may be more successful, and a data-driven optimization of this trade-off, while accounting for patient and health care provider preferences, should be used.

As a practical illustration, in Table 1, we show the benefit of changing the monitoring frequency from monthly to daily for two end points: ALSFRS-R and daily physical activity [4]. The benefit of more or less frequent monitoring strongly depends on the end point, and as demonstrated by the ALSFRS-R, it could be questionable whether high-frequency monitoring is always beneficial. In addition, because of a difference in progression rates among patients, the monitoring frequency could be further optimized for each individual patient (eg, a patient who slowly progresses may require less frequent monitoring). Ultimately, the optimal monitoring scheme is likely to differ from digital end point to end point, and longitudinal data are essential to estimate a data-driven optimal burden-to-information ratio for each device or mobile app [4].

Table 1. Sample size estimates for the Amyotrophic Lateral Sclerosis Functional Rating Scale-Revised (ALSFRS-R) and daily activity with varying monitoring frequencies.[a]

Characteristic	ALSFRS-R	Daily activity
Monthly progression rate[b]	−0.06	−0.05
Between-patient variability, $\sigma^2_{between}$	0.06^2	0.04^2
Within-patient variability, σ^2_{within}	0.15^2	0.54^2
Required sample size (6-month follow-up), n (% difference)		
Monthly	226 (ref[c])	1208 (ref)
Biweekly	210 (−7)	805 (−33)
Weekly	199 (−12)	522 (−57)
Daily	187 (−17)	214 (−82)
Required sample size (12-month follow-up), n (% difference)		
Monthly	191 (ref)	322 (ref)
Biweekly	189 (−1)	251 (−22)
Weekly	187 (−2)	209 (−35)
Daily	185 (−3)	168 (−48)

[a]Daily activity was defined as the proportion of time that the patient was nonsedentary, as described elsewhere [4]. Sample size calculations are based on a standardized linear mixed model; data are based on 42 patients [4]. Sample size calculations assumed a target power of 80%, 2-sided α of 5%, and a 25% reduction in the progression rate; numbers are the required sample size per group [34].

[b]Progression rate is expressed as number of SD per month. Both the ALSFRS-R and daily activity were standardized to make a direct comparison possible. The ALSFRS-R has, on average, a faster progression rate, more variability between patients, and less variability within patients compared with daily activity.

[c]ref: reference.

There are circumstances in which digital technology may not appropriately quantify disease symptoms (eg, changes in mood or alterations in cognition). Therefore, an important aspect of the road map is to additionally develop scales and questionnaires that can be administered remotely to quantify clinically relevant, subjective symptoms [35]. It is important for these patient- and caregiver-reported outcome measures to consider elements such as the ease of engagement (eg, mobile apps with multiple verbal and nonverbal response formats), the length of questionnaires, the validity of questions (eg, differences between patient-reported and in-clinic outcomes), and the viability for digitization. Ultimately, it may prove critical to harmonize and integrate passive digital methods such as accelerometry with task-dependent methods and questionnaires to derive the most reliable and representative state of disease at any given time.

In addition, an important goal is to maximize the adherence and retention of the patient or caregiver. In two studies that reported on remote monitoring with personalized feedback in care settings [14,22], 80%-87% of the patients provided regular ALSFRS-R information. In two recent studies that solely monitored disease progression without providing care, this was reduced to 24%-56% [15,36]. It seems critical to provide an incentive to participate, where patients do not simply upload their data into the cloud but also receive something in return, such as care, tailored information, or personalized insights. An understanding of how best to retain patients in the digital environment (eg, by incorporating behavioral or motivational techniques) and which patient factors are related to digital uptake or adherence are fundamental to the success of the workplan. Finally, it is important to consider the geographical region and the local facilities and demographics. Older populations or patients from developing areas with minimal financial, technological, or educational facilities may encounter challenges when using devices. This could increase the risk of care asymmetries across populations and should be considered when comparing candidate technologies.

How to Implement?

A standardized format or platform for multiple digital metrics is not yet available, and a priority of the Treatment Research Initiative to Cure ALS will be to provide this technology [37]. This platform will solve the problem of collecting data relating to multiple domains while using multiple apps from different providers. Such a platform is essential because clinical decision making is often multidimensional and requires insight into various aspects of the patient simultaneously. The aim of this final part of the road map is to (1) integrate different data sources required by the end users and (2) deploy an open-source framework product in which one can flexibly integrate different third-party solutions, evaluate the performance of digital metrics compared with clinically relevant events, and allow in-depth analysis of health care expenditures and outcomes.

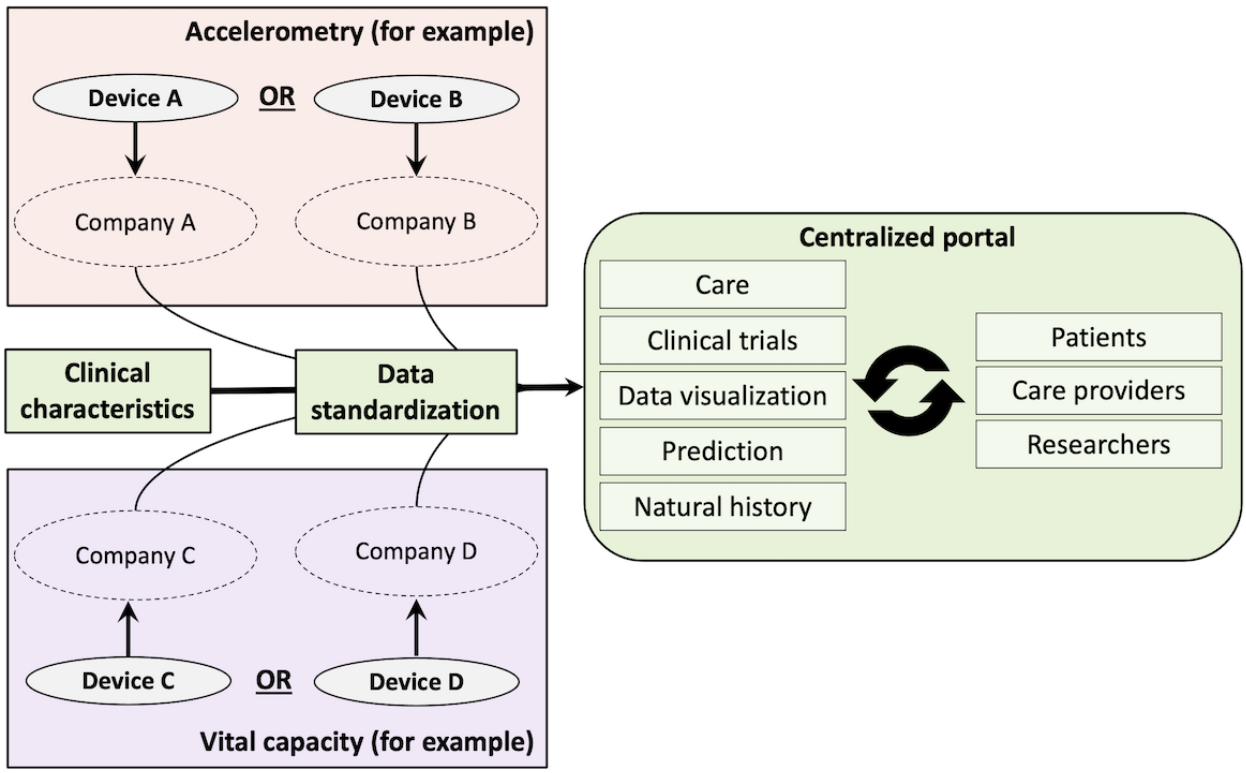
Workplan: How to Implement?

In Figure 3, we schematically illustrate the final product. The first step would be to standardize the metrics that are of interest across different devices. The standardized metrics are subsequently stored in a central database that acts as a single integrative platform. The capability of the device to allow uninterrupted, remote data access is therefore critical; the final selection of devices or mobile apps is likely an iterative process in close relationship with the *How to Measure* section. Although the concept is simple, this part of the road map may be the most challenging because of, among other things, privacy, regulatory, ethical, ownership, licensing, certification, and database challenges. A close collaboration among various industry, academic, funding, and regulatory parties has been initiated to provide a clear central and local governance and management structure with meticulous planning.

The next step is to translate the centralized data into useful information and disseminate insights to the relative end user. Given the extent of information acquired and the number of different stakeholders and settings, a customized approach will be required. Where a trialist may be primarily interested in a historical benchmark of group averages, clinicians and patients will be principally interested in individual disease patterns. These interests need to be carefully documented, and a dynamic, user-centered co-design approach is vital. It is important to evaluate how the implementation of digital parameters affects existing standard operating procedures and work practices or how health care professionals adhere to new MND technologies [38]. For care purposes, defining optimal *activation* or *flagging* rules is important for timely activation of additional care. For example, thresholds are needed for respiratory function (or decline in function) to alert the patient's health care provider or automatically refer the patient to a pulmonologist when the threshold is reached. Defining these rules can help to standardize remote monitoring of MND, and this requires the development of a disease-specific protocol based on MND guidelines and expert opinions [14].

In addition, efforts are required to evaluate different strategies for effective communication among users, for example, the implementation of chat functions between patients and health care providers or the provision of personalized information or feedback on the obtained measurements. By making use of open-source software platforms, tailored programs can be developed in a dynamic interface, while seamlessly integrating the continuously updating information from wearables and mobile apps. We have previously provided an example of such a platform for clinical trial design [39]. The platform and interactive platform will go through several stages before the product can be finalized, for example, prototype development, iterative testing phases, experimenting with varying key parameters (eg, user burden, monitoring frequency, different wording and timings, and different prompting regimes), pilot releases, and upgrading, taking into account the input from all users at every stage.

Figure 3. The harmonization and centralization of digital outcome data before dissemination. A schematic illustration of the integration of different devices from different third parties into a central database that acts as a single integrative platform is illustrated for vital capacity and accelerometry. Information and insights can subsequently be disseminated interactively to the respective end users.



Finally, only by real-world implementation can the true value of digital parameters and platforms be evaluated. For care settings, it is important to conduct dedicated studies to evaluate the cost-effectiveness of the digital health care technology and its effect on clinical outcomes. The gold standard would be randomized controlled trials, for example, allocating patients to usual care or digital assisted care or allocating hospitals in a cluster randomized study. An example of the former has been published previously, in which the authors evaluated the effect of home telemonitoring of noninvasive ventilation on the number of hospital visits [40], together with its cost-effectiveness [41]. Given the complexity of most eHealth interventions [13], such trials are challenging and it may not be immediately clear what an ideal efficacy end point would be (eg, survival time, number of hospital admissions, costs, or patient-reported indicators?). A key aspect for successful uptake is to have a financial model that is sustainable, while providing clinically relevant benefits to all stakeholders.

For clinical trials, the cost aspect may be of similar importance, and studies evaluating the gain in retention compared with cost would be highly insightful. Besides the potential reduction in attrition rates and gain in information quality, it will be necessary to determine whether digital metrics can ultimately replace the clinical efficacy end point (ie, surrogacy) and increase trial efficiency. The real-world systematic use of digital health care technology, alongside common clinical efficacy endpoints, is therefore a key first step. The potential use of real-world data originating from digital health care technology in clinical drug development has been recognized for regulatory purposes [42]. Nevertheless, important challenges remain, such as the design of interventional studies and challenges related to data availability, data quality, auditability, and the completeness of electronic phenotyping [43].

Data Security and Privacy Regulations

Given the current data security and privacy regulations for medical devices and personal data (eg, General Data Protection Regulation), data security and ethical hurdles will have a major impact on the developmental and operational aspects of the platform and on how the data may be used during (international) research projects or within care settings. These aspects are not only important for the platform itself but also apply to, for example, cloud services from third parties. How, when, and by whom data can be accessed need to be tailored and defined for each participating site individually to comply with local laws and regulations. Making use of existing infrastructures, for example, by integrating the platform into eHealth care services and requiring two-factor authentication could facilitate secure data access [14], but its feasibility depends on the available local facilities. In addition, considerations for using the data include obtaining consent to (1) share personally identifiable information for direct care only, (2) share personally identifiable information for research and care purposes, or (3) share anonymized data to be used for research only. Similarly, there is a need to address challenges in intellectual property and data ownership (eg, where the demarcation might be made between clinical and technical intellectual property).

An important consideration is the CE (Conformité Européenne) marking for medical devices and software. The disadvantage

of CE marking an entire ecosystem, as presented in Figure 3, is that it may significantly constrain the rate of change and evolution of the system. CE marking locks down the design, and any significant changes made to the system (eg, addition of new algorithms or devices) requires reapproval by external regulatory bodies. A consideration could be to use a mixed approach of using CE-marked devices and algorithms interconnected and facilitated by non–CE-marked software. This will require some design constraints to make it possible (eg, there can be no opacity in terms of non–CE-marked algorithms supporting clinical decision making), and achieving this goal will require careful design and partitioning from the outset. Another strategy is to consolidate and rationalize into a single CE-marked system once the ecosystem for ALS, including measurements, algorithms, and protocols, reaches maturity. These challenges will require dedicated strategies, which will need to be developed with the involvement of all relevant stakeholders and by obtaining expertise from ethicists, regulators, and data privacy officers. Ultimately, these discussions may affect the choice of measurement or device, indicating that the final set of digital parameters for MND is likely defined during a dynamic and iterative process rather than being fixed from the outset.

Conclusions

In conclusion, this road map aims to align the current developments in digital health care technology for MND and initiate a collaborative effort to mediate its wide-scale adoption across MND clinics and clinical trials. We defined the following three key questions, the answers to which are critical to achieve this aim: (1) what to measure; (2) how to measure; and (3) how to implement? Each question requires a dedicated study methodology to overcome potential implementation, adoption, or regulatory hurdles, which are summarized in Table 2.

Table 2. Summary of the road map for remote digital health technology for motor neuron disease (MND).

Question	Aim	Method	Result
What to measure?	To define clinically relevant, patient-centric, and targetable aspects of MND	• Inventorying symptomology associated with MND by systematic literature review, face-to-face in-depth interviews, focus group discussions, and population-based patient surveys	List of targetable end points for MND
How to measure?	To translate targetable end points for MND into digital parameters	• Candidate technologies are identified by systemic literature reviews. Standardized longitudinal studies are initiated to evaluate test-retest reliability and validity to capture disease progression and to assess protocol adherence.	Set of standardized and protocolized digital metrics
How to implement?	To centralize digital metrics in an integrative platform and disseminate user-dependent information	• Create a single database using open-source software platforms, reactive programming, and third-party cloud services • Initiation of dedicated studies to evaluate health care expenditures, cost-effectiveness outcomes, and surrogate biomarker value	Scalable and validated platform to provide tailored information for care and research settings

Given the ever-changing care needs of patients and the relentless progression rate of MND, aligning our current endeavors and facilitating the adoption of digital health care technology will significantly benefit the delivery of care and accelerate the development of effective treatments against this debilitating disease.

Conflicts of Interest

JE has a commercial interest in promoting the future use of remote digital technology platforms in Motor Neurone Disease. CJM has undertaken consultancy work for Biogen, Orion, Orphazyme, Merz and is supported by the NIHR Sheffield Biomedical Research Centre (BRC). SN is supported by the FightMND Mid-Career Research Fellowship. The remaining authors have no conflicts of interest to declare.

Abstract

Background: Technology, including mobile apps, has the potential to support self-management of long-term conditions and can be tailored to enhance adoption. We developed an app to support asthma self-management among people with limited health literacy in a web-based workshop (to ensure physical distancing during the COVID-19 pandemic).

Objective: The aim of this study is to develop and test a prototype asthma self-management mobile app tailored to the needs of people with limited health literacy through a web-based workshop.

Methods: We recruited participants from a primary care center in Malaysia. We adapted a design sprint methodology to a web-based workshop in five stages over 1 week. Patients with asthma and limited health literacy provided insights into real-life self-management issues in stage 1, which informed mobile app development in stages 2-4. We recruited additional patients to test the prototype in stage 5 using a qualitative research design. Participants gave feedback through a concurrent thinking-aloud process moderated by a researcher. Each interview lasted approximately 1 hour. Screen recordings of app browsing activities were performed. Interviews were audio-recorded and analyzed using a thematic approach to identify utility and usability issues.

Results: The stakeholder discussion identified four themes: individual, family, friends, and society and system levels. Five patients tested the prototype. Participants described 4 ways in which the app influenced or supported self-management (utility): offering information, providing access to an asthma action plan, motivating control of asthma through support for medication adherence, and supporting behavior change through a reward system. Specific usability issues addressed navigation, comprehension, and layout.

Conclusions: This study proved that it was possible to adapt the design sprint workshop to a web-based format with the added advantage that it allowed the development and the testing process to be done efficiently through various programs. The resultant app incorporated advice from stakeholders, including sources for information about asthma, medication and appointment reminders, accessible asthma action plans, and sources for social support. The app is now ready to move to feasibility testing.

Introduction

Background

Supported self-management for asthma (written action plans and regular review) is highly effective at improving control and reducing acute attacks [1-3]; however, globally, it is challenging to implement for 334 million people living with asthma [4-7]. One of the challenges is the need to tailor support for people with limited health literacy. Health literacy is defined as the degree to which individuals can obtain, process, and understand the necessary health information needed to make appropriate health decisions [8]. Studies have associated limited health literacy with erroneous health beliefs and poor adherence to self-management activities [9,10]. Malaysia has a high burden of limited health literacy in the general population [11], and asthma control is challenged by a lack of patient education, overreliance on unscheduled visits, and lack of action plan ownership [12-14].

The use of digital technologies for internet-based information is more common in the younger age group than in the middle and older age groups [15]. Malaysia's multigenerational household culture and strong family orientation have helped younger family members assist older generations in using digital technology to stay connected and find information [16]. The pandemic has further seen widespread adoption of digital technologies by a broader age group of users in diagnosis, prevention, and surveillance [17]. Three-fourth of Malaysians are now smartphone users, with most (60.9%) of them in the lowest income group [18]. Although health-related information-seeking behavior on the internet is greater in those with good health literacy [19], our previous qualitative work among people with limited health literacy suggests that a mobile app is a preferred medium to deliver supported self-management, including a pictogram-based asthma action plan and signposting to reliable asthma information sources.

Goals

For the aforementioned reasons, developing asthma self-management tailored to limited health literacy needs is an important context for the web-based design sprint workshop, as various studies have shown that the extensive use of pictograms, images, and prompts was appealing to participants and may improve the understanding of information in mobile apps [20-23]. However, it is essential to involve users early in the design stage, as some of the unique features that people want can be time-consuming and costly to build, and a balance may need to be found between desired features [24] and those with evidence-based recommendations [25,26].

Using a design sprint methodology, we seek to optimize user experience in app development by integrating patients into the 5-stage process of mapping, sketching, designing, developing, and testing [24,27]. We used the health literacy framework [8] to underpin the overall structure of the interventional work. The COVID-19 pandemic and physical distancing requirements meant that we had to conduct our workshop in a web-based format. In this study, we report the outcomes of the workshop deliberations and our experience of conducting a week-long remote 5-stage program attended by patients with asthma and health care professionals (HCPs).

Methods

Ethical Consideration

The workshop received ethical approval from the Medical Research and Ethics Committee of the Ministry of Health, Malaysia (ID: NMRR-19-3609-52292) and sponsorship approval by the Academic and Clinical Central Office for Research & Development at the University of Edinburgh (ID: AC20011). Informed consent was obtained from all the participants before the workshop.

Study Design

We conducted a 5-stage design sprint workshop using a web-based and qualitative research approach. We used the 5-stage design sprint process as a roadmap to develop the intervention. We adapted the methodology and constructed the workshop into five stages: (1) understanding and mapping problems, (2) sketching of solutions, (3) deciding on solutions to problems, (4) developing a prototype, and (5) testing a low-fidelity prototype [27,28]. The process was originally designed in the technology sector by the Google Ventures team for business start-up teams [27]. The involvement of the target population and early testing enhance intervention effectiveness and increase the likelihood of adoption at the implementation stage [24]. Owing to the rapid development and testing stages, this is an ideal concept for a low-resource setting, that is, time and cost [24].

Stakeholder (patient and HCP) discussions provided insights into self-management issues in stage 1, which informed mobile app development in stages 2-4. We recruited patients with asthma and limited health literacy to test the low-fidelity prototype in stage 5 and provided feedback through qualitative interviews. A low-fidelity prototype is a modeled prototype with limited technical functionality [29] that is quick to create and can be easily improved in the light of feedback in the testing stages. The details of each stage are listed in Table 1.

Table 1. Process, outcomes, and web-based adaptations of the workshop.

Stages and objectives	Process	Adaptations for web-based delivery of the workshop
Stage 1: understand and mapping problem		
• To identify the objectives of the prototype and the workshop • To map out problems from health care professionals and patients' perspectives which technology can help to solve	• As a team, we first discussed and agreed on the workshop's long-term goals for the workshop's prototype and aims through a structured discussion between the patients and health care professionals. • We listed a list of problems relating to self-managing asthma from stakeholders (patients and clinicians) point of views. • We constructed an end-to-end process of how patients cared for their asthma, and we targeted the problems we could potentially provide solutions for using the mobile app.	• Through a web conference site (Microsoft Teams), we brainstormed the long-term goal for the app and the workshop's aim. • In a separate browser, using a web-based board (Miro), we gathered the problems, potential solutions, and mapping of the target where the solutions can occur. Interviews were audio recorded during the workshop. • We considered scientific literature and previous study we have conducted as expert input.
Stage 2: sketch solution		
• To understand a broad range of problems and solutions concerning asthma self-management	• Focusing on the problems, each researcher reviewed existing ideas which we could potentially use and improve for the prototype. • The individual researcher then presented their findings and the reasons why the ideas being chosen. • Using this information, we then drew crude scenes with our contents which we believed would be suitable for the app. • After presenting the scenes and critical discussions, we voted on the best scene and content for the prototype.	• Reviewing and compiling sketches of ideas were done on Miro synchronously by all researchers. • We presented these sketches of ideas to the whole team on Microsoft Teams. • Individually, using colorful sticky notes and marker pens, we drew the crude scenes. We took photographs of these scenes and uploaded these on Miro. • Each researcher was given three blue dots for the voting, and they placed a dot on the best ideas.
Stage 3: decide the solution for the problem		
• To decide on solutions that answered our long-term objectives	• The winning scenes and content comprised topics on asthma education, asthma symptoms monitoring, and supporting people living with asthma. • We took the winning scenes from our sketches, and we constructed an end-to-end process (storyboard) on how these scenes and content would appear on an App. • The storyboard was first constructed in text form before we transformed it visually.	• The most voted ideas were put together, and we had another round of voting where each researcher was given a pink dot, and the team leader was given three purple dots on the web-based board (Miro). • The text and visual version of the storyboard was constructed as a group and through discussions on the web-based board (Miro) and Microsoft Teams.
Stage 4: prototype development		
• To build ideas for a low-fidelity prototype	• Each of the research members and the App developer was assigned roles to ensure the successful development of the low-fidelity prototype for the final day testing process.	• On Figma, a prototype development site, the low-fidelity prototype was developed. • Every researcher and the App developer completed their tasks (ie, content and language check) within Figma. • Brainstorming of prompts for the testing day was conducted on Google Sheets among the researchers. • Google sheet also was where a virtual scoreboard was set up for every researcher to capture the patient's evaluation of the prototype.
Stage 5: test low-fidelity prototype		

Stages and objectives	Process	Adaptations for web-based delivery of the workshop
• To validate the solutions for the patients through a qualitative method	• We tested the solutions to 5 patients using a concurrent think-aloud process. • We gathered verbal and visual feedback about the low-fidelity prototype from the patients, which we will use to build a high-fidelity prototype.	• Interviews were conducted through Microsoft Teams by a moderator, HS, with a patient observed by other researchers (whose video and audio function was turned off). • HS and each patient could see each other for an ice-breaking session at the start of the testing session. This session was essential to create rapport and to ensure the patient's readiness, mentally and technically. • The patient was then given a link to the prototype where they browsed through the prototype, gave comments and answered prompted questions. The patient's screen was shared within the MS Team. • The observers synchronously collected the patients' replies on the utility and usability prompts about the prototype during the interview on the virtual scoreboard and the observer's field notes. • The moderator had accessed to the scoreboard and would be able to pick up any point which needed further clarification. • The interviews were audio recorded, and browsing activities were video recorded.

The web-based workshop discussions were conducted on a web conference platform (Microsoft Teams), and brainstorming of the idea was conducted on a web-based board (Miro). While conducting the exercise on the web-based board, the workshop participants remained connected to the web conference site to allow ongoing discussion. The web-based board was superseded by a prototype development (Figma) site in stages 4 and 5, whereas discussions remained on Microsoft Teams. The app developer supported information technology activities. Two weeks before the workshop, one of the researchers contacted each of the participants (patients and HCPs) to assess technical skills such as the ability to log on, use a meeting platform, and logistic issues such as the quality of the internet connection.

Setting

The workshop, which took place between June 22 and 26, 2020, was conducted through a secure web-based meeting platform using a virtual whiteboard to facilitate information sharing between the researchers and app developers. Our original plan for a face-to-face workshop was changed to a web-based format to overcome the restriction of the order of movement because of the COVID-19 pandemic; an additional advantage was that it allowed participants from different locations and time zones to participate.

The patients were from 2 urban public primary care clinics in central Malaysia. Asthma is managed in primary care clinics, although chronic and acute care management through the provision of an asthma action plan to support asthma self-management is uncommon. Malaysia has a dual health system, public and private, where the public health system provides the leading service for the population with copayment of Ringgit Malaysia, RM 1 (US $0.23) per visit.

Samples and Recruitment

Stakeholder Discussion (Stage 1)

A total of 3 patients and 2 HCPs who cared for asthma in the primary care settings, 2 app developers, 4 researchers from Universiti Putra Malaysia, and 1 from the University of Edinburgh were involved in the stakeholder discussion in stage 1 (Table 2).

Table 2. Summary of the stakeholders involved in each stage.

Stakeholder	Stage				
	1	2	3	4	5

2. Patients	✓				✓
3. Health care professionals	✓				
4. App developers	✓	✓	✓	✓	✓

[a]Stakeholder present.

Testing of the Prototype (Stage 5)

Five patients, recruited from the Klang Asthma Cohort, participated in testing the prototype at stage 5 (Table 2). The Klang Asthma Cohort database is one of the research outputs of RESPIRE (National Institute for Health Research Global Health Research Unit on Respiratory Health) in Malaysia. The database contains 1280 people with asthma recruited from

primary health care clinics in the Klang district. They provided consent to be called with invitations to participate in asthma-related research. Inclusion criteria for patients invited for this study were physician-diagnosed asthma, aged >18 years, smartphone user, limited health literacy, and were assessed by screening using the *Bahasa Malaysia* language version of the Health Literacy-Q47 scale [30]. The initial Health Literacy-Q47 scale [31] was translated and validated in Malaysia with a Cronbach α=.96 [30].

Data Collection

Demographic information was collected from the database of patients who agreed to participate. Stakeholders' discussions in stage 1 focused on challenges by patients and HCPs around (1) asthma education, (2) asthma self-management, (3) monitoring of symptoms, (4) emotional support or lifestyle advice, (5) social support, and (6) clinic set up (Multimedia Appendix 1).

In stage 5, we tested the prototype with 5 patients to assess its utility and usability using a set of semistructured questions in a concurrent think-aloud manner (Multimedia Appendix 2). During this session, HS, the main interviewer, guided the process. Four other researchers, PYL, SSG, ATC, and JW, observed the interview while the 2 app developers, Aidil Goh and Muhammad Marzuqi, managed the technical aspects of the sessions. The interviews took 1 hour and were conducted in *Bahasa Malaysia*, the patients' preferred language.

Qualitative interviews were audio recorded, other web-based discussions and browsing activities were video recorded, and web-based board exercises were captured and archived as described in Table 1. All interviews were transcribed verbatim.

Data Analysis

For this qualitative study, we used thematic analysis to obtain rich data from the stakeholders' discussions in stage 1 and the interviews in stage 5. The texts were analyzed iteratively using a deductive thematic analysis approach, as outlined by Braun et al [32]. The deductive thematic analysis seeks to answer the researcher's theory or analytical interest within the topic [32]. Phases in the thematic analysis included [32] (1) familiarization with the data by reading and rereading and noting down initial ideas (memoing), (2) duplicate coding (HS and JW) of one interview and comparing decisions to agree on standardizing the coding framework before coding all the transcripts, (3) discussing emerging themes with the research team, (4) reviewing themes with the wider research team and generating a map of the analysis (HP, SSG, PYL, ATC, or IY), (5) defining themes iteratively, and (6) presenting the deductive analysis with a selection of extracts. The data were organized using NVivo 11 (QSR International) qualitative data analysis software (HP and IY).

Results

Participants' Characteristics

Five patients (including 3 who attended stage 1) attended stage 5 (prototype testing). Table 3 summarizes the demographics of the patients involved in stage 5.

Table 3. Patients' demographic involved in stage 5.

ID	Age (years)	Gender	Education level	Health literacy score[a]	Use of pictorial asthma action plan at 6 months	Access to a digital device
P1	44	Female	Secondary	30	Yes	Smartphone and PC
P2	36	Male	Tertiary	32	No	Smartphone
P3	40	Female	Tertiary	17	Yes	Smartphone and PC
P4	38	Male	Tertiary	21	No	Smartphone
P5	19	Male	Secondary	31	No	Smartphone and PC

[a]Score less than 33 is considered as limited health literacy.

The Outcomes of Each Stage

Stage 1: Understanding and Mapping Problems

Overall, 3 patients and 2 HCPs (a family physician and a medical officer from Klang district) contributed to the stakeholder's discussion. The stakeholder discussion themes were categorized as relating to individuals, family and friends, society, and systems (Multimedia Appendix 3). The key problem used to inform the app design was education sources for asthma and support in the community, enabling self-management using pictorial action plans, reminders for medications, and asthma reviews or appointments. The log of history of asthma control, preventer intake, and information on expected best peak expiratory flow rate were features that could support patients during asthma review or appointment to discuss with their HCPs.

Stage 2-4: Sketching, Designing, and Developing the Prototype

Informed by the stakeholder discussion and findings of our previous qualitative study, we worked through the stages of sketching solutions and designed and developed the prototype (Multimedia Appendix 4). Through a round of voting in stage 3, solutions supporting self-management based on evidence-based practice were selected [3]. All winning solutions were clustered around four aspects of care: (1) education, (2) supporting self-management, (3) supporting behavior change, and (4) social support (Table 4). We created a storyboard for the prototype, and we developed the prototype app based on the storyboard, which was then tested in stage 5.

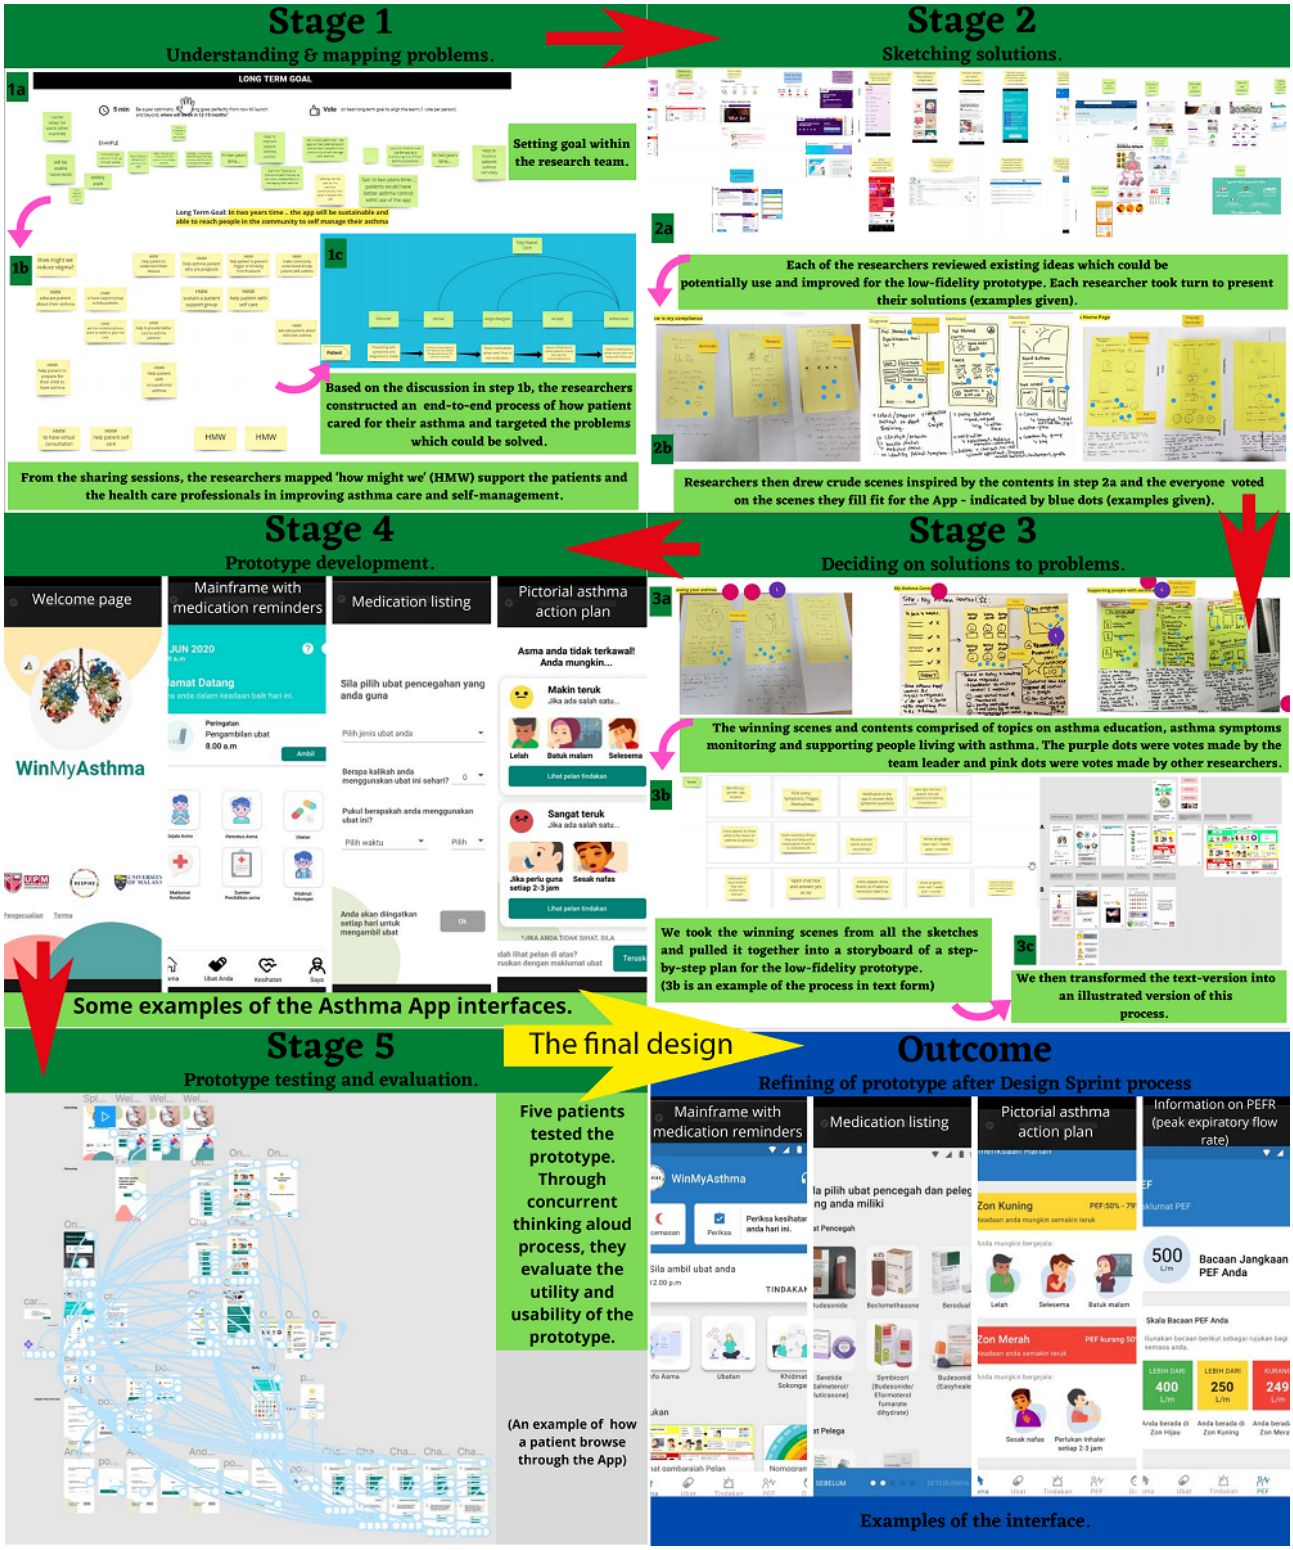
Table 4. Asthma App content and design features.

Main theme and section	Content	Features
Education		
About asthma, its symptoms and diagnosis; asthma medications	• Information in text and videos about asthma, symptoms, triggers, how the diagnosis is made, exacerbations and myths around asthma attack. Other information includes types of medications used to treat asthma, its function, and potential side-effects of the medications. There will be video-based instructions on the inhaler technique.	• The links to the Ministry of Health portal on asthma was provided under specific headings to facilitate the search for reliable information.
Supporting self-management		
Self-monitoring of symptoms	• Patients indicate any experience of asthma symptoms in the last 24 hours, which will translate into control and prompts to check the action plan.	• Tick-box list of potential asthma symptoms; ticking any one symptom will prompt a pop-up on advice to look at an action plan with a click button.
Asthma action plan	• A pictorial asthma action plan was used. Illustrations and wordings were validated in a series of discussions with stakeholders.	• List of zones are displayed, and patient choose which zone are appropriate for them.
Supporting behavior change		
Asthma medication and appointment reminder	• Patients provide information about medications and appointments which will trigger a reminder system at the timing of choice.	• Matrix of images of medications used and drop-down menu for frequency and timing
Asthma diary	• Asthma control and medication uptake will be recorded in the diary, including best PEFR[a].	• Monthly calendar, which displays asthma control and adherence
Reward system	• Achieving good asthma control and medication adherence will be translated into points.	• Display of scale of points achieved for good asthma control and adherence
Others		
Social support	• Information regarding support groups for asthma in Malaysia	• The links to various support groups available in Malaysia

[a]PEFR: peak expiratory flow rate.

The entire process is illustrated in Figure 1, and the decisions on the prototype content are summarized in Table 4. The app was written in the Malay language.

Figure 1. The Design Sprint process was undertaken on the web-based discussion board and meeting platform.



Stage 5: Testing Low-Fidelity Prototype

Patients who attended stage 1, along with 2 other patients, attended stage 5. Results are presented under the 2 main themes of utility (ie, app influence or support self-management) and usability (ease of use).

Utility

Patients commented that the app influenced the decision to self-manage in four ways: offering information, providing an accessible asthma action plan, motivating and supporting improved medication adherence, and promoting behavior change through a reward system.

Offering Information

Patients considered that the app provided essential information regarding asthma and how to manage it. P4 explained, “the information about asthma in the App is interesting and informative.” Although many were comfortable reading

text-based information, some preferred audio-visual formats such as videos. P5 explained, "the information about asthma, maybe it can be in the video, it's more interesting than just text."

Providing Accessible Asthma Action Plans

Patients felt that having an action plan on the phone made the plan accessible when needed. As P1 described, "when you need the plan, you just open the App in your phone and click on the plan [action], to see it." In this format, patients considered it easier to access and use the app-based plan than the paper-based action plan, which they may not carry unless they attend medical appointments.

Motivating and Supporting Improved Medication Adherence

The medication reminder function of the app was viewed as a good support for achieving good adherence to daily preventers. P5 stated, "It will be difficult not to remember taking the medications because of the reminder, and because I use the phone frequently, it is hard to ignore the reminder (chuckled)."

Promoting Behavior Change Through a Reward System

The app was designed to encourage behavior change through a positive reward system, where good asthma control and adherence to twice daily preventive inhalers would be awarded points, and the cumulative points were visualized clearly. Patients liked this approach. P1 was incredibly excited to see the reward points on the app: "wow, there is a reward points, this is great!" This excitement was shared with other patients who preferred to see the tangible results of their actions. P3 elaborated on how the reward system could influence behavior:

> *That's nice when I get points for taking the medications. I do want to see that I accumulate points and the scale moved further. And I can only do this if my control is good and if I take my medications.*

Usability

The patients could easily comprehend the information and instructions in the app. P2 elaborated on how he achieved this: "the instructions are accompanied with illustrations. It makes it easier to understand it." Although patients liked the use of illustrations and fewer words, the small font size used was challenging for some. P1 said:

> *[The] writing is small. I tried to put on my glasses, I still can't see it (chuckled).*

We used cartoon-based illustrations of the medications and in the steps of the asthma action plan. Some studies have suggested that the pictorial asthma action plan may be useful for patients with asthma other than adults. P3 suggested:

> *I think the illustrated plan can be appealing and useful for children and their carer. It's very easy to understand.*

Patients pointed out that a lack of navigational symbols meant that it was not always clear how to move from one interface to another. P4 stated his confusion:

> *There is no sign or indication on what to do next. I was a bit lost on what should I do now. Perhaps an arrow would help to tell that I can move forward.*

Otherwise, patients were mostly satisfied with the simple layout. P1 gave an example of this:

> *In terms of the layout, it's quite easy to navigate around the App. It's ok for me.*

The time spent using the app varied between 10 and 45 minutes. Some (younger) patients seemed comfortable navigating from one interface to the other and were keen to click buttons to explore the app functions. In contrast, others were dependent on symbols or prompted to navigate, which the app lacked at the testing stage.

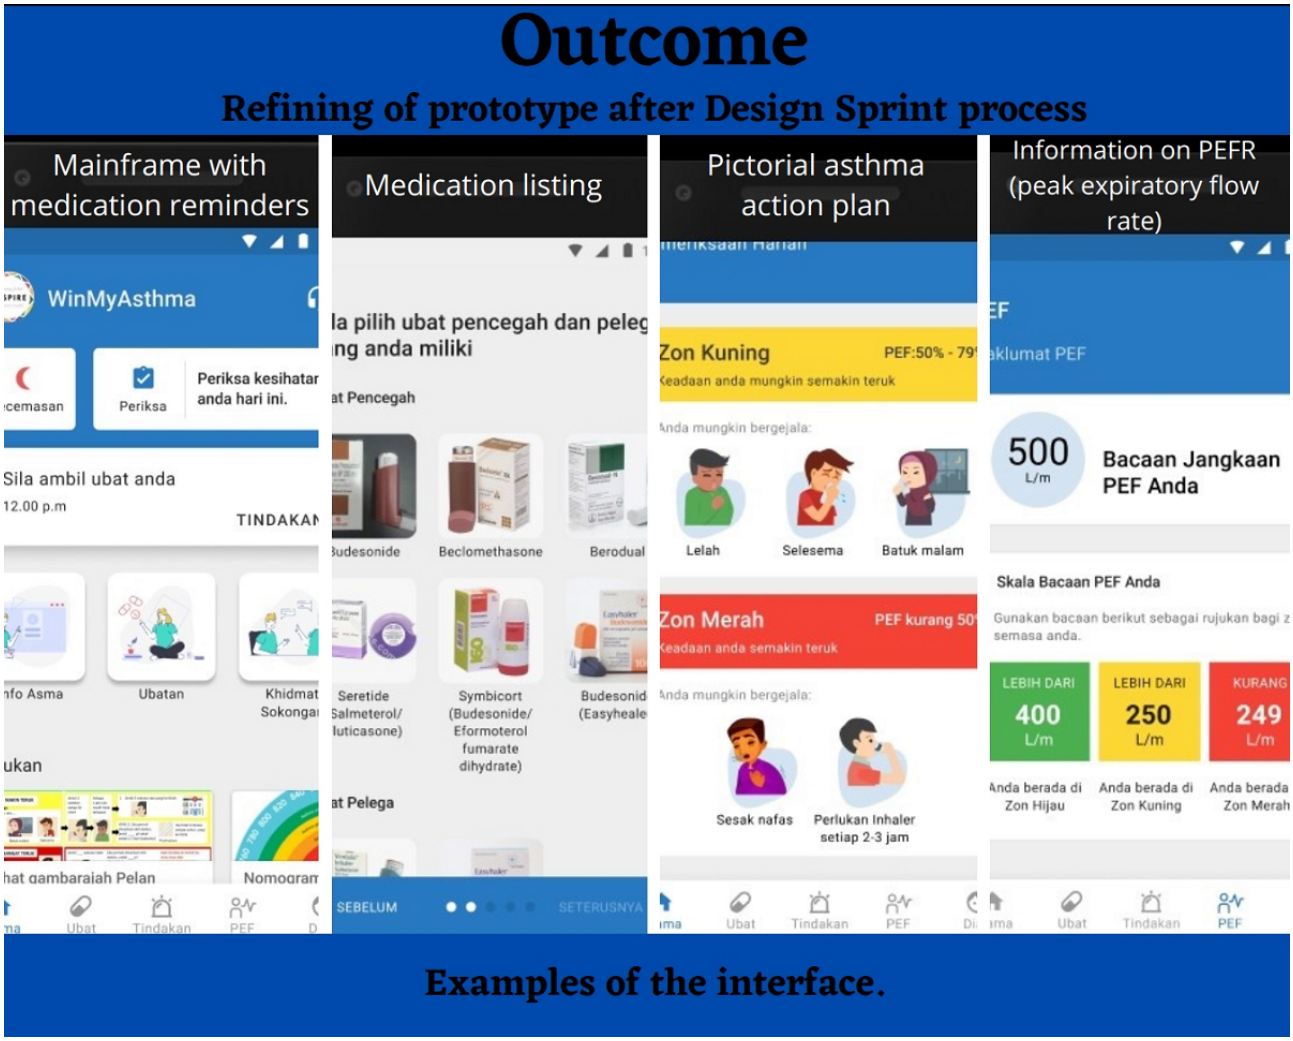
The language used in the app was generally satisfactory, although there was a linguistic misunderstanding of *breathlessness* and *wheeze* in the *Bahasa Malaysia* language. P4 described his confusion on the *Bahasa Malaysia* words for breathlessness and wheeze:

> *Mengalami sesak nafas (breathlessness) and lelah (wheezing), are different? I thought it's the same thing?*

After the Workshop

The design was refined and finalized after testing in stage 5 (Figure 2).

Figure 2. The finalized app design.



Discussion

Principal Findings

We conducted a design sprint workshop and employed a web-based format to ensure the safety of researchers and patients during the global pandemic. In this 5-stage workshop, we developed a low-fidelity prototype based on theoretical frameworks and refined it based on patient feedback during the design and testing stages. Patients described the resultant app to influence their ability to self-manage in four ways: offering information, providing accessible asthma action plans, motivating and supporting improved medication adherence, and promoting behavior change through a reward system. Specific usability issues were related to navigation, comprehension, and layout.

Strengths and Limitations

The involvement of stakeholders and the multidisciplinary approach at the development stage in the design sprint process are among the strengths of this study, which may increase the chances of the intervention meeting the needs of the target population. The 5-stage design sprint structure allowed the development and testing process to be performed quickly and efficiently at a low cost, which would likely be favorable in low-resource settings. Constructing a low-fidelity prototype offers many advantages in the initial stages of prototype development. It allows a quick gathering of requirements, ideas, and concepts and can be built rapidly [29]. The disadvantage was that the low-fidelity prototype lacked some core functionality (such as navigation features), so that the patients on day 5 gave feedback on a limited version of the app. Nevertheless, the feedback was beneficial and enabled the app to be refined after the workshop to produce a high-fidelity prototype.

The web-based approach connected people in different geographical locations and ensured safety during the global pandemic. We recognized that we do not have any participants aged >50 years, perhaps because this approach may be more appealing to younger age groups, although with limited health literacy, and it may not reflect the feasibility of using web-based methods for older age groups. We overcame limited internet access by providing an internet data voucher; however, we had to exclude those with no access to any digital devices. We provided training on the various platforms to be used in the workshop, thus overcoming the lack of digital skills. These strategies may assure researchers or intervention developers working in countries or settings with high levels of limited health literacy that this web-based methodology is of value.

The pandemic context may have explained the relatively small number of participants recruited during the testing stage. Some participants found it challenging to commit uninterrupted time to a web-based workshop while being *locked down* at home with their domestic or caring or *home-schooling* responsibilities. For comparison, face-to-face intervention design workshops have been reported with 14 participants in 5-day workshops [33] and 38 participants over 6 weeks [34].

Adaptation of the Design Sprint Workshop to a Web-Based Format

Patients with asthma and HCPs were recruited for a workshop in March 2020, but this could not occur because of the compulsory lockdown imposed by the local authorities in response to the COVID-19 pandemic. Therefore, we adapted the workshop to the challenges of a web-based format and its potential impact on participants' research experience [35]. A high-speed internet connection and technical skills in conducting this workshop were vital. To overcome some of these practical issues, we supported all participants with mobile web-based access through an RM 10 (US $2.42) internet data voucher to ensure that the participants would not bear the cost of internet access. Participants' experience with technologies was around social media, that is Facebook, video call, that is, WhatsApp, and information searching platforms, that is, Google and YouTube. We found a lack of experience with videoconferencing platforms and the software we planned to use during the testing day. Thus, we conducted training sessions for all participants to avoid technical problems during the workshop.

In the context of interviews, the literature suggests that web-based data collection can produce data of similar quality to face-to-face interviews [35]. Although using a web-based platform to interview patients was a new experience for the researchers, we found that the web-based programs eased discussions, and interviews took place quickly and effectively. Compared with traditional qualitative interviews, one advantage was that other researchers could observe the interview sessions on the web-based platform, and they could make concurrent fieldnotes. From the patient's feedback, although they knew they were being observed by additional researchers, being at their own home helped them forget about being observed and anxious.

In web-based discussions and interviews, dictation software has been used to capture audio data in text format, thereby avoiding transcription errors [36,37]. However, this was not possible in our context because the medium of interaction was the *Bahasa Malaysia* language, and the extensive use of colloquial language made it impossible to use any dictation software. Conducting research on the web raises concerns about participants' confidentiality and data security. We ensured that entry to the workshop was password-protected to control access to maintain the participant's confidentiality securely. The recordings were stored in a secure manner. For example, files from the workshop were encrypted and stored in a secure research data storage facility.

Web-Based Design Workshop and the Context of Limited Health Literacy in a Low-to-Middle–Income Country

Our app focused on designing a pictorial asthma action plan as a core strand of tailoring supported self-management for people with limited health literacy. Other features were a simple language for symptom assessment, education and information resources, provision of visual and audio medication reminders, and practical behavior change strategies such as a reward system. A clear message from our previous qualitative work was that participants wanted an interactive approach to support an asthma action plan with few words and clear pictures. Our original plan was to provide a paper-based pictorial action plan, but as it is not interactive, we reconsidered potential formats and decided to deliver the pictorial asthma action plan using a mobile app. Using a mobile app was seen as promoting a sense of autonomy to feel empowered in managing asthma.

Although previous reviews have reported a lack of interest in action plans [21], others have reported on the keenness of people to use action plans in mobile apps [38], although none have explored plans tailored for people with limited health literacy or the innovative pictorial representation of actions in a mobile app. In the United States, a study found that action plans were written at the literacy level of sixth-grade (11- to 12-year-olds), which will be a challenge to those without formal education or only receiving primary school education [39]. The same study also found that more graphics within an action plan may be needed to increase the ease of use [39]. In our web-based design workshop, the extensive use of images, icons, and the use of simple language were among the strategies used to overcome the challenge of understanding a written asthma action plan.

Recommendations for Practice, Policy, and Research

We outlined recommendations for practice, policy, and research based on this study in Textbox 1. On a practical level, to help researchers' concentration throughout the 5 days of the 7-hour workshops, we included frequent breaks and provided high-energy snacks. Each session was either 1 hour long with a 15-minute break or 45 minutes long with a 10-minute break. Committing to time in a workshop alone in front of the monitor can be challenging and mentally draining, so a week before the workshop, each researcher received a supply of high-energy snacks through the post. We also provided colored sticky notepads and permanent markers with similar tip sizes to ensure that all scanned sketches and writings were clear when uploaded on the web-based discussion board.

Textbox 1. Recommendations for practice, policy, and research.

Practice

- Although some participants only join the workshop for short periods, researchers and technical colleagues have to concentrate on the web for long periods. Adequate breaks, attention to nutrition, and general comfort are essential.
- The web-based platforms may be unfamiliar to many participants; training before the workshop gives confidence and helps reduce technical problems on the day.
- Owing to the relatively low cost and a short time spent from development to testing, the web-based design sprint methodology may be suitable for low-resource settings.
- Remote conduct ensured that high-risk stakeholders were shielded during a pandemic and overcame geographical barriers.

Policy

- The process is *a sprint* so that the end product can be developed to a short timescale to meet pressing deadlines.

Research

- The feasibility study of conducting a more extensive scale web-based intervention design program is necessary to ensure its practicality.

Conclusions

Working with people with limited health literacy enabled the development of an app that could support them in self-managing their asthma. Specific components included sources of information on asthma, pictorial asthma action plan, simple language, audio-visual prompts, and rewards for supporting adherence to daily therapy and scheduled reviews. Despite practical challenges, a 5-day web-based design workshop proved to be manageable, enabling meaningful engagement from patients and HCPs so that a prototype is now ready for feasibility testing.

Acknowledgments

This research was commissioned by the UK RESPIRE using UK Aid from the UK Government. The views expressed in this publication are those of the authors and not necessarily those of the National Institute for Health Research or the UK Department of Health and Social Care. The RESPIRE collaboration comprises UK grant holders, partners, and research teams as listed on the RESPIRE website. The authors are grateful to the study subjects for participating in this study. The authors would like to thank the experts from Pocket Pixel Sdn Bhd, Mohd Khalid IA, Goh A, and Zainal MM for their support in the conduct of this study.

Authors' Contributions

HS, HP, PYL, SSG, and IY were involved in formulating the ideas for the study. HS and JW planned and conducted training for the participants. HS, PYL, SSG, ATC, and JW conducted the workshop and collected the data. HS conducted data analysis, and all authors were involved in data interpretation. HS drafted the manuscript. All authors critically revised the manuscript for intellectual content. All authors read and approved the final manuscript.

Abstract

Background: Tobacco smoking is one of the biggest public health threats. Smartphone apps offer new promising opportunities for supporting smoking cessation in real time. This randomized controlled trial investigated the effectiveness of an app that encourages individuals to quit smoking with the help of a social network member (*buddy*) in daily life.

Objective: The objective of this study is to test the effectiveness of the SmokeFree buddy app compared with a control group with self-reported smoking abstinence and carbon monoxide (CO)–verified smoking abstinence as primary outcomes and self-reports of smoked cigarettes per day (CPD) as a secondary outcome.

Methods: A total of 162 adults who smoked participated in this single-blind, two-arm, parallel-group, intensive longitudinal randomized controlled trial. Around a self-set quit date (ie, 7 days before the self-set quit date and 20 days after) and 6 months later, participants of the intervention and control groups reported on daily smoking abstinence and CPD in end-of-day diaries. Daily smoking abstinence was verified via daily exhaled CO assessments. This assessment was administered via an app displaying results of exhaled CO, thus addressing self-monitoring in both groups. In addition, participants in the intervention group used the SmokeFree buddy app, a multicomponent app that facilitates social support from a buddy of choice.

Results: A significant reduction in CPD from baseline to the 6-month follow-up was observed among participants in both groups. Multilevel analyses revealed no significant intervention effect on self-reported and CO-verified daily smoking abstinence at the quit date and 3 weeks later. However, CPD was lower at the quit date and 3 weeks later in the intervention group than in the control group. No significant differences between groups were found for any outcome measures 6 months after the quit date. Overall, low app engagement and low perceived usefulness were observed.

Conclusions: Despite some encouraging short-term findings on the amount of smoking, the SmokeFree buddy app did not have beneficial effects on smoking abstinence over and above the self-monitoring control condition. Future studies should examine whether and what support processes can be effectively stimulated and how app use can be improved to better achieve this goal.

Introduction

Background

Smoking kills more than 8 million people each year and remains one of the leading preventable causes of premature death worldwide [1,2]. Cigarette smoking is a major risk factor for life-threatening diseases such as lung cancer, coronary heart disease, and stroke and other noncommunicable diseases [2]. Despite the evidence that quitting smoking is associated with rapid improvements in health and reduced risk for noncommunicable diseases, in 2017, every fourth person aged 15 years and older smoked in Switzerland [3]. The high relapse rates indicate that quitting is difficult [4]. Various socioenvironmental stimuli associated with smoking may lead to high-risk situations for relapse, even long after quitting [5]. Strengthening the capability to manage such high-risk situations (eg, cue-induced cravings) is crucial for smoking cessation interventions [6,7]. The use of mobile health technologies (eg, smartphone apps) offers promising opportunities for smoking cessation interventions in everyday life, with the potential to deliver support in situations when it is most needed [8,9].

Smartphone Apps to Promote Smoking Cessation

In Switzerland, 92% of adults owned a smartphone in 2018 [10]. Considering this high prevalence of smartphone use, delivering smoking cessation interventions using smartphone apps is a promising approach. With the widespread reach and proximity to the user, interventions are accessible in everyday life [11]. The location and time independence may reduce perceived barriers to treatment (eg, transportation, time, and cost) and make potential engagement convenient [11,12]. Furthermore, apps can provide interactive and tailored intervention features as well as an interactive platform to allow instant sharing of experiences and resources (eg, social support) [11,12]. All these factors contribute to the cost-effectiveness of smoking cessation app interventions [11].

Considering the potential of app interventions, existing apps predominantly provide simple tools (eg, calculators, calendars, trackers, or distractors) [13,14]. The majority of available apps had very little evidence-based content to support quit attempts, such that in 55% of the apps, no behavior change techniques (BCTs) [15] were present [16]. In addition to the content of the smoking cessation app, their effectiveness is less clear. In the context of text messaging interventions for smoking cessation, research has found that such interventions are effective in improving smoking cessation rates and reducing health service costs [17-19]. In contrast, despite the wide availability of smoking cessation apps and the rapid release of new apps [13], only a few studies have tested their effectiveness [17]. For instance, a smartphone decision aid app including behavioral support was compared with a simpler information-only app in a randomized controlled trial (RCT) across different countries [20]. The decision aid app significantly increased continuous smoking abstinence at 1, 3, and 6 months after quitting [20]. A recent review of five studies that tested the effectiveness of smoking cessation apps showed no clear evidence for increasing quit rates [17]. There is a lack of scientific evidence on the effectiveness of smoking cessation apps. We echo the conclusion of the authors that more RCTs with long-term follow-ups (at least 6 months; Russell Standard [21]) are needed to provide evidence on the effectiveness of smoking cessation apps [17]. Therefore, this RCT tests the effectiveness of the SmokeFree buddy app, which was part of the SmokeFree campaign of the Federal Office of Public Health in Switzerland. It is a multicomponent app that, in particular, aims to facilitate social support from a buddy of one's own social network.

App features that connect individuals who smoke with health care workers, smokers and ex-smokers, or persons from their own social network to foster social support resources are promising [5]. Social support is conceptualized as coping assistance, that is, the supporters' engagement in coping efforts through the provision of emotional help (eg, demonstration of understanding and valuing) and practical assistance (eg, advice and informational and instrumental support) [22]. Social support may help individuals cope with high-risk situations for smoking (eg, cue-induced cravings) or buffering stress while quitting [9,23]. Research shows that face-to-face individual counseling, group therapy, and telephone counseling that convey social support (eg, practical assistance by identifying high-risk situations or emotional help by encouragement) were found to be effective for smoking cessation [24-26]. Partner or peer support interventions, however, did not show clear effectiveness in smoking cessation [9,27]. These intervention approaches are very diverse, and one explanation is that these partner or peer interventions were not successful in increasing social support in the first place [27]. Furthermore, research shows that support receipt might have null or negative effects on recipients depending on the timing, content, and way how support is provided [28]. More evidence regarding partner or peer support interventions is needed [9,27,29]. Apps provide promising potential to enhance partner or peer support resources and availability during actual experiences in people's everyday lives [30]. Content analyses of smoking cessation apps, however, have found that apps rarely reference users outside of the app to a quit helpline or provide opportunities to reach out for social support [13]. Only 2.7% (6/225) of rated Android smoking cessation apps had content regarding social support [14]. This RCT tested the SmokeFree buddy app that fosters support resources from a buddy of choice. This app offers theory-based instructions for the buddy on how to support individuals who smoke during a quit attempt. The instructions may positively influence the quality of support, and the accessibility of the app is important for the ideal timing of support exchanges (ie, when it is most needed). In addition, individuals who smoke rely on persons from their own personal social network rather than on unacquainted buddies. This may influence the tailoring of support exchanges because a buddy of choice should know the target person and their needs better than a stranger [31].

Aims of This Study

Given the research gaps outlined above, this study aims to test the effectiveness of the SmokeFree buddy app in daily life. The SmokeFree buddy app was developed by the Federal Office of Public Health in Switzerland in collaboration with the Institute of Global Health of the University of Geneva, Switzerland. The app is designed to be used simultaneously by an individual who smokes and a personal buddy of choice. In brief, a chat function

is the direct communication channel for all text messages and connects the individual who smokes and the personal buddy. The individual who smokes can, for example, indicate the current mood state and intensity and can use notification buttons such as sending an emergency message, communicating craving to smoke, or communicating a lapse. The app then informs the buddy about text messages and notifications and the current mood or craving and provides them with the option of reacting immediately, for example, with a supportive message. The app further provides evidence-informed background information (eg, how to cope with craving) as well as preset supportive messages for the buddy, which can be customized or supplemented with a personal comment. A performance statistic shows the achievements to date (eg, number of smoke-free days), and a knowledge base contains information on smoking and quitting, which is also visible and accessible to the buddy. For more details about the SmokeFree buddy app, please refer to the study protocol [32].

This RCT examined whether the SmokeFree buddy app promotes daily abstinence rates and reduces the number of cigarettes smoked per day (CPD) in adult participants who smoke at a self-set quit date, 3 weeks later (end of intervention), and 6 months later in comparison with a control group (CG) that did not use the SmokeFree buddy app [32]. We hypothesized that adult participants in the intervention group (IG) will show higher daily abstinence rates and lower CPD at the self-set quit date, 3 weeks later (end of intervention), and 6 months later than those in the CG (hypothesis 1). Furthermore, our RCT uses intensive longitudinal data to test the app in participants' everyday lives, which additionally allows the analysis of the potential time effects of the intervention. Therefore, we additionally assumed a higher increase in daily abstinence rates and a higher decrease in CPD over time in the IG than in the CG (hypothesis 2). The hypotheses were prospectively registered (ISRCTN 11154315). The primary outcome measures were daily self-reported smoking abstinence and daily smoking abstinence using exhaled carbon monoxide (CO) [32]. This RCT assessed smoking abstinence objectively on a daily basis with the iCO Smokerlyzer (Bedfont Scientific Ltd [33]), a CO-monitoring device. The secondary outcome measure was self-reports of smoked CPD [32].

Methods

Overview

We conducted a single-blind, two-arm, parallel-group, intensive longitudinal RCT *smoking cessation with smartphone apps* (for a detailed description, please see the study protocol [32]). The trial consisted of a *baseline diary* (3 consecutive days), a background assessment, a *challenge diary* from 7 days before the self-set quit date until 20 days after the self-set quit date (28 consecutive days), and a *follow-up diary* 6 months after the self-set quit date (3 consecutive days). Participants were randomly allocated to the intervention (SmokeFree buddy app) or control condition (no SmokeFree buddy app). This trial was approved by the Ethics Committee of the Faculty of Arts and Social Sciences of the University of Zurich (reference number: 17.12.13) and was prospectively registered (ISRCTN11154315).

Participants and Procedures

Participants were adults who smoked at least one cigarette per day, intended to quit smoking during the study, and owned a smartphone with access to mobile internet. The exclusion criteria were insufficient knowledge of the German language, working in 24-hour shifts, use of a smoking cessation app, or participation in a professional smoking cessation program. Participants were recruited via advertisements in newspapers, web-based platforms, webpages, and flyers at the university, medical facilities, and local companies from April 2018 to August 2019 in Switzerland. The eligibility criteria were assessed using a web-based screening questionnaire. Participants started with a web-based end-of-day diary questionnaire for 3 consecutive days (*baseline diary*). After completion, participants were invited to the lab for a background assessment. The interviewer conducting the background assessment randomly assigned participants to one of the two groups (IG and CG), according to a computer-generated allocation sequence that was concealed in a set of sealed, numbered envelopes. Participants were blinded to the group assignment (ie, single-blind RCT; for the detailed randomization procedure, refer to the study protocol [32]). At the background assessment, all participants provided written informed consent, completed a questionnaire, and were asked to self-set a quit date (BCT *goal setting of behavior* [15]) within the next 6 weeks. The self-set quit date determined the start of the 28-day diary period (*challenge diary*), starting 7 days before their self-set quit date. Furthermore, all participants received a personal iCO Smokerlyzer and instructions on how to use it with the corresponding app to measure the exhaled CO daily. The first measurement of CO with the iCO Smokerlyzer was conducted at the background assessment. All participants were instructed to fill out an end-of-day diary (daily text message with link to questionnaire) and to measure the exhaled CO daily using the personal iCO Smokerlyzer for 28 consecutive days during the *challenge diary* phase (7 days before the self-set quit date, on the self-set quit date until 20 days after the self-set quit date). Six months after the self-set quit date, participants in the CG and IG were asked to participate in the *follow-up diary* phase, with end-of-day diaries and daily measures of exhaled CO using the personal iCO Smokerlyzer for 3 consecutive days. As an incentive for study participation, all adults who smoke received a personal iCO Smokerlyzer with a value of CHF 60 (US $63). Furthermore, with completion of the 6-month follow-up, participants were given entry into a lottery with a main prize of CHF 200 (US $209) and 40 prizes with a value of CHF 50 (US $52) shopping vouchers. Buddy participants were reimbursed with CHF 50 (US $52) at the completion of the study. On the basis of a power of 0.80 and a two-tailed type 1 error probability of P=.05, an a priori power analysis yielded a sample size of 128 to detect a 24% difference in smoking abstinence for the IG compared with the CG, drawing on meta-analyses of mobile phone interventions on short- and long-term smoking abstinence (rate ratios [RRs] between 1.7 and 2.1 [34,35]). Assuming an attrition rate of 25%, 6 months after the quit date resulted in a total sample size of 160 participants (80 participants per group). For more details, please refer to the study protocol [32].

Intervention

As described above, participants in the CG and IG set a self-set quit date and were instructed to fill out the end-of-day diaries and to measure exhaled CO with the iCO Smokerlyzer during the *challenge diary* phase. The CO Smokerlyzer app displayed participants' CO results and progress with smoking cessation and thus addressed the BCTs *feedback on behavior* and *self-monitoring of behavior* [15]. Only the IG participants were additionally introduced to the SmokeFree buddy app. Participants in the IG were instructed to identify a personal buddy of choice and to use the SmokeFree buddy app during the *challenge diary* phase (starting 7 days before the self-set quit date). The SmokeFree buddy app is available for free in the App Store and Google Play Store (version 4.0). The app comprises the following BCTs: *social support (emotional), social support (practical), social reward, feedback on behavior, self-monitoring of behavior, others monitoring with awareness, discrepancy between current behavior and goal standard, nonspecific reward,* and *information about health consequences* [15]. The buddy had to be a nonsmoker for at least 6 months, owning a smartphone with access to mobile internet. The exclusion criteria for the buddy were insufficient knowledge of the German language and working in 24-hour shifts. The buddy also provided informed consent and received a background questionnaire with instructions regarding the SmokeFree buddy app. The buddy participants were also instructed to fill out an end-of-day diary and to use the SmokeFree buddy app during the *challenge diary* phase (for 28 consecutive days) to interact with the participant who smoked. No recommendations regarding timing, frequency, and intensity of use were provided to participants who smoked and their buddies.

Measures

Primary Outcome: Daily Smoking Abstinence (Self-reported and CO Verified)

Participants indicated in a daily evening diary questionnaire whether they smoked that day or not by answering the question, "Did you smoke today (including only one puff)?" (coded as 0=yes and 1=no) [36,37]. To objectively assess smoking abstinence, participants were instructed each evening to assess exhaled CO with their personal iCO Smokerlyzer. The iCO Smokerlyzer is a CO-monitoring device that is used with a corresponding Smokerlyzer app [33]. At the end of the end-of-day diary questionnaire, participants were instructed to take a CO measurement with their personal iCO Smokerlyzer and the corresponding app. The Smokerlyzer app displayed the test values in parts per million (ppm) and automatically generated a result report. Participants were instructed to send their result report directly from the app via email to the study team and to report the ppm value in the end-of-day diary. The iCO Smokerlyzer test values were categorized as 1 for abstinent (0-6 ppm) and as 0 for not abstinent (>6 ppm) [33,38]. A recent study points to comparable results between the iCO Smokerlyzer and the more studied piCO$^+$ Smokerlyzer, which has been shown to validly distinguish between smokers and nonsmokers [38,39].

Secondary Outcome: CPD

If participants answered the smoking abstinence measure with yes (=today smoked), they were asked to report the number of cigarettes they had smoked that day. Otherwise, the daily number of cigarettes smoked was coded as 0 [37].

Covariates

The daily use of nicotine replacement products (NRPs) and a variable denoting whether days were weekdays or weekends were included as covariates in the sensitivity analyses. Research shows that using NRPs increases the probability of smoking cessation success [40], and smoking behavior has been shown to differ during weekends [41], which might be related to trigger exposure. NRPs were not provided to participants; however, the SmokeFree buddy app (ie, the knowledge base feature) incorporated encouragement to use NRPs for smoking cessation. Participants indicated in the daily diary whether they used NRPs or not by answering the question "Did you use nicotine replacement products today (eg, nicotine gum, nicotine patch, medications as for example Champix, etc)?" (0=no and 1=yes). Furthermore, with each timestamp of the daily diary, a variable was calculated, whether it was a weekend or not (0=no weekend and 1=weekend).

Data Analysis

Intention to Treat

In line with the outcome criteria recommended for smoking cessation trials (Russell Standard [21]), our final models included all randomized subjects (intention to treat). Participants who were lost to the *challenge* or *follow-up diary* phase were treated as smoking for the analyses, with the primary outcome variables of daily abstinence (0=not abstinent and 1=abstinent).

Analysis of the Intervention Effect at the Quit Date and End of the Intervention

To account for the nested structure of repeated measures within individuals, multilevel modeling was used [42]. To examine the intervention effect on the two dichotomous primary outcome measures, we ran logistic regressions using generalized linear mixed models (GLMMs). The continuous outcome measure, CPD, was a count variable that was highly skewed with a large number of zeroes. Therefore, we applied a GLMM for count outcomes using a negative binomial distribution with a logarithmic link function [43]. Owing to the logarithmic link function, regression coefficients are on a log scale and interpreted as RRs. The distance to an RR of 1 is interpreted as the percentage increase (above one) or decrease (below one) in the outcome for a one-unit increase in the predictor [44]. The specified multilevel models use all available diary entries using maximum likelihood estimations [42]. All analyses were conducted using SPSS 26.

To test our research question and corresponding hypotheses, all outcome measures were modeled as a function of *time*, *group* (coded as 0=CG and 1=IG; hypothesis 1), and *group by time* (hypothesis 2). For this purpose, a linear *time* variable for the 28 consecutive days of the *challenge diary* was created (in 1-day units). To test group differences at the quit date and 3 weeks later, the *time* variable was centered accordingly (centered on

the quit date: day 8=0 or centered on the last day: day 28=0). An initial graphic display of the data showed a discrete change in the outcomes at the quit date, indicating two qualitatively distinct phases before and after. To model this nonlinear trajectory over time (shift), a dummy-coded variable *quit* was computed (coded as 0=quit day and days after the quit date [days 8-28] and 1=days before the quit date [days 1-7]). To test group differences in this shift, we included an interaction term of the *quit* and the *group* variable (*group by quit*). Finally, to test for differential time effects before and after the quit date, we generated and added a second time variable reflecting an interaction between *quit* and *time* (ie, *quit by time* with the following coding: day 1=−7, day 2=−6, ..., day 7=−1, day 8=0, day 9=0, day 10=0, etc). No differential time effects of the two groups before the quit date emerged; therefore, this interaction was not included in the final model. In all analyses, we routinely included the grand-mean-centered CPD during the *baseline diary* phase as an indicator of nicotine dependence as a covariate. All models specified a maximal random effects structure, which, in the case of nonconvergence, was successively reduced until convergence was achieved [45].

Analysis of the Intervention Effects at Follow-up

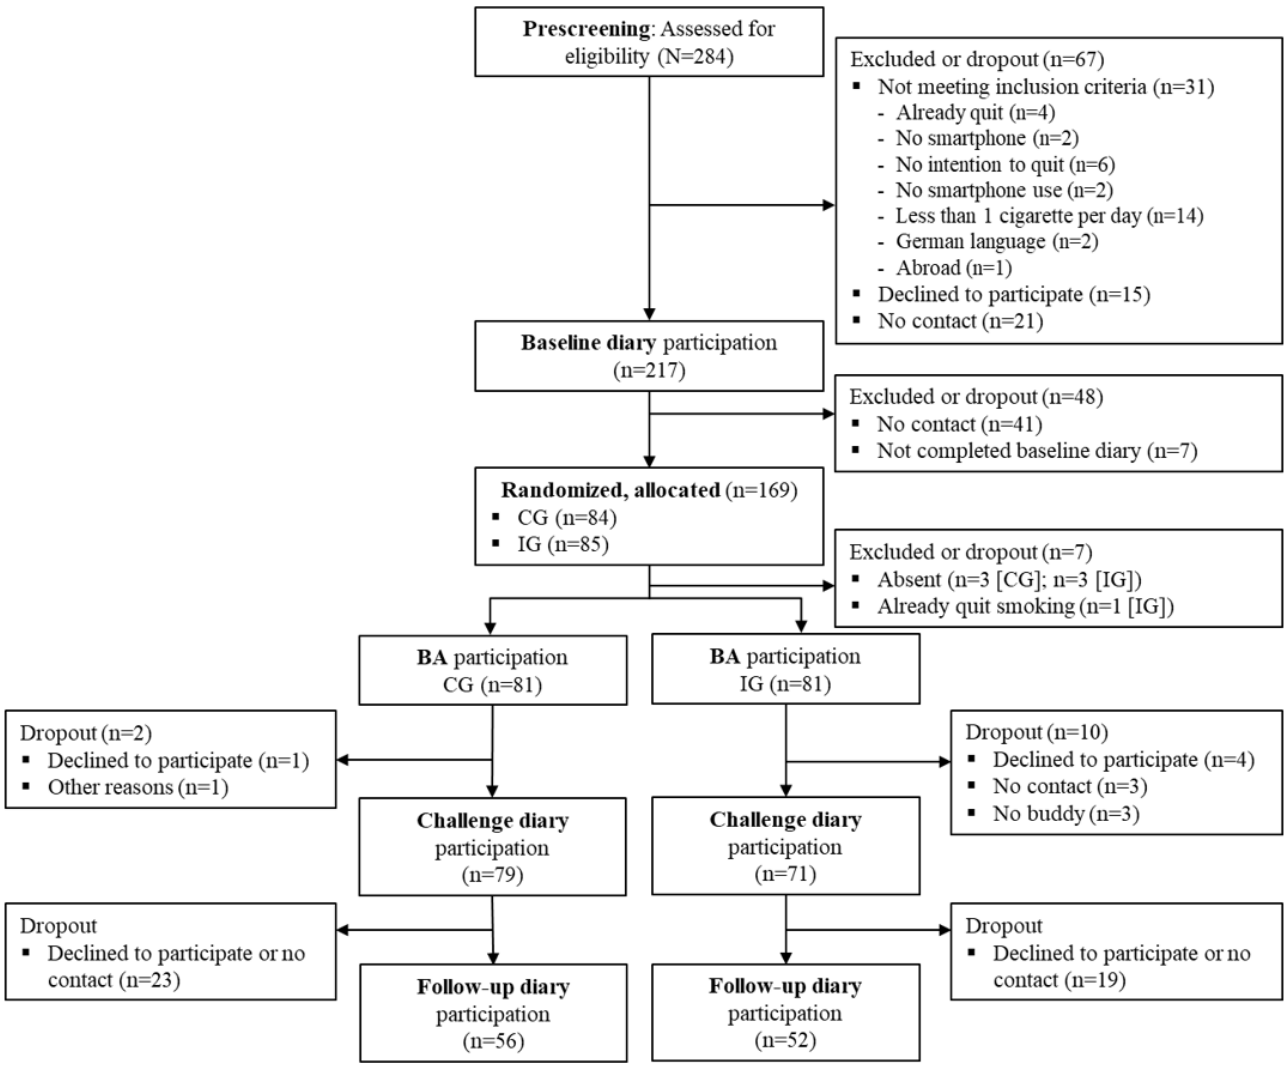
To investigate the intervention effect 6 months after the quit date, group differences regarding the primary and secondary outcome measures were examined by conducting independent samples two-tailed *t* tests (averaged days 1-3 of the *follow-up diary* phase per person). If variances were unequal between the groups, Welch *t* test was used. We used a Bonferroni-adjusted significance level to account for multiple comparisons.

Results

Sample

A total of 284 participants were screened, and 169 (59.5%) participants who completed the *baseline diary* were randomized to the CG (n=84 in total) and IG (n=85 in total; refer to Figure 1 for the participant flow).

Figure 1. Participant flow. BA: background assessment; CG: control group; IG: intervention group.



Overall, 162 randomized participants attended the background assessment, 81 in the CG and 81 in the IG. Table 1 displays the background characteristics of the participants in the CG and IG. Participants in the CG and IG did not differ on these variables at the background assessment (Table 1), proving successful randomization. The 162 participants had a mean age of 31.3

(SD 10.9) years and smoked 12.8 CPD (SD 7.1) before study participation. The majority of the participants were male (89/162, 54.9%). There were no significant background differences between groups regarding the intention and the desire to stop smoking reported at the background assessment as well as the self-regulation variables such as self-efficacy, action control, and social support receipt reported during the *baseline diary* (Table 1).

Of the 162 participants, 12 (7.4%) did not start with the *challenge diary*. By treating the dropout as smoking (intention to treat), the analyses of the primary outcomes had the maximum number of available data points (N=162; 3339/4536, 73.61% possible data points). Due to technical problems with the iCO Smokerlyzer, there were additional missing values for the CO-verified abstinence measure. CO measures were completely missing for 8 participants (103 missing data points). Additional missing CO values occurred due to various reasons, such as iCO Smokerlyzer did not work (57 days), iCO Smokerlyzer or smartphone forgotten (36 days), no time (5 days), or other unknown reasons (34 days). Therefore, the analysis of the CO-verified abstinence measure had 235 additional missing data points (n=154; 3104/4536, 68.43% possible data points). Secondary outcome data, CPD, were available for 97% (79/81) of the participants in the CG and 88% (71/81) of the participants in the IG (total n=150; 3003/4536, 66.2% possible data points).

Table 1. Baseline characteristics of the target persons in the intervention group and control group (N=162).

Variables	Intervention group (n=81)	Control group (n=81)	Intervention group vs control group[a]	*P* value
Gender, n (%)			0.2 (1)[b]	.64
Female	35 (43)	38 (47)		
Male	46 (57)	43 (53)		
Unmarried, n (%)	65 (80)	64 (79)	3.7 (2)[b]	.16
Higher education, n (%)	32 (40)	38 (47)	2.2 (3)[b]	.53
Employed, n (%)	35 (43)	41 (51)	3.1 (4)[b]	.54
Age (years), mean (SD)	31.32 (11.50)	31.32 (10.27)	0.00 (160)[c]	.99
Daily number of cigarettes (background assessment), mean (SD)	13.07 (7.33)	12.44 (6.83)	−0.57 (160)[c]	.57
Nicotine dependence, mean (SD)	3.33 (2.08)	3.56 (2.17)	0.67 (160)[c]	.51
Exhaled carbon monoxide (ppm[d]), mean (SD)	9.81 (6.34)	10.65 (9.05)	0.67 (139)[c]	.50
Intention to stop smoking, mean (SD)	5.40 (0.71)	5.33 (0.77)	−0.58 (160)[c]	.56
Desire to stop smoking, mean (SD)	5.00 (0.70)	4.95 (0.67)	−0.46 (160)[c]	.65
Baseline self-efficacy[e], mean (SD)	2.83 (1.34)	2.72 (1.24)	−0.55 (160)[c]	.59
Baseline action control, mean (SD)	2.48 (1.06)	2.75 (1.11)	1.54 (160)[c]	.13
Baseline social support receipt, mean (SD)	1.22 (1.87)	1.56 (1.85)	1.18 (160)[c]	.24

[a]Groups were compared for baseline characteristics using independent *t* tests for continuous data and chi-square tests for categorical data.

[b]Chi-square (*df*) values for categorical data.

[c]*t* test (*df*) values for continuous data.

[d]ppm: parts per million.

[e]Baseline variables were assessed during the *baseline diary* phase.

In total, 108 participants completed the *follow-up diary* phase (Figure 1). There were no significant differences in terms of background characteristics between participants who dropped out of the study and participants with follow-up data (Table S1 in Multimedia Appendix 1). By treating the dropout as smoking (intention to treat), the analyses regarding the primary outcomes included the full sample (N=162). Due to missing or not working iCO Smokerlyzer devices, the CO-verified abstinence measure was available for 86.4% (140/162) participants. Secondary outcome data were available for 66.7% (108/162) participants.

Descriptive Results

Table 2 shows the average CPD during the *baseline diary* phase and *challenge diary* phase and the 3 weeks and 6 months continuous abstinence rates by groups. The IG had a higher 3 weeks and 6 months continuous abstinence rate than the CG; however, these differences did not reach significance. For the CG, dependent *t* tests indicated a significant decrease in CPD from the baseline diary to the challenge diary *(postquit;* t_{72}=11.29; *P*<.001; *d*=2.66) and from the baseline diary to the follow-up diary (t_{55}=6.14; *P*<.001; *d*=1.66). The IG also showed a significant decrease in CPD from the baseline diary to the

challenge diary *(postquit;* t_{70}=13.25; *P*<.001; *d*=3.17) and from the baseline diary to the follow-up diary (t_{51}=6.51; *P*<.001; *d*=1.82). Figure 2 displays the means of the three outcome measures over the 28 days of the *challenge diary* by groups.

Table 2. Average cigarettes per day during the three diary phases and 3 weeks and 6 months continuous abstinence rates for the intervention group and control group (N=162).

Variables	Intervention group (n=81)	Control group (n=81)	Intervention group vs control group[a]	*P* value
CPD[b] baseline diary (N=162), mean (SD)	12.41 (7.50)	11.48 (7.08)	−0.81 (160)[c]	.42
CPD challenge diary prequit (n=149), mean (SD)	12.31 (7.29)	10.48 (6.15)	−1.67 (147)[c]	.10
CPD challenge diary postquit (n=144), mean (SD)	1.99 (4.03)	2.51 (3.14)	0.86 (142)[c]	.39
CPD follow-up diary (n=108), mean (SD)	6.13 (8.17)	4.99 (5.74)	−0.84 (91)[c]	.40
3 weeks continuous abstinence (ITT[d]) (N=162), n (%)	25 (30.9)	19 (23.5)	1.1 (1)[e]	.19
6 months continuous abstinence[f] (ITT) (N=162), n (%)	18 (22.2)	11 (13.6)	2.1 (1)[e]	.11

[a]Groups were compared for number of cigarettes per day and continuous abstinence rates using independent *t* tests for continuous data and chi-square tests for categorical data.

[b]CPD: cigarettes per day; the available data for the variable cigarettes per day varied due to dropout.

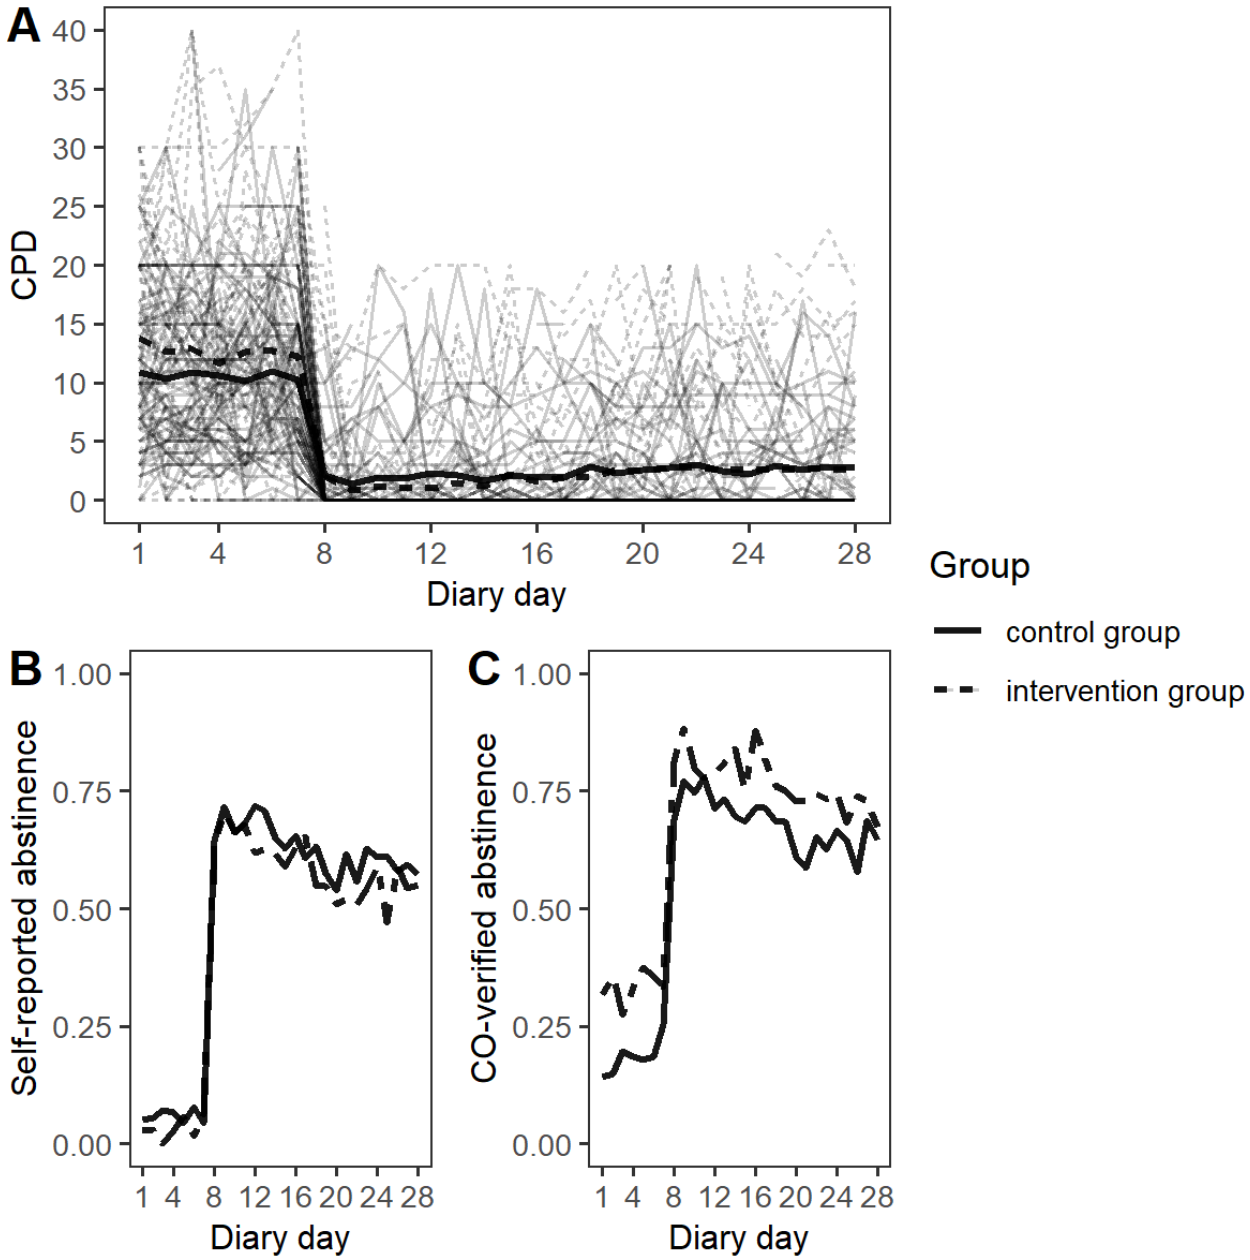
[c]*t* test (*df*) values.

[d]ITT: intention to treat; lost participants were treated as smoking (full sample).

[e]Chi-square (*df*) values.

[f]Six months continuous abstinence is defined as ≤5 cigarettes since quit date and no smoking during the follow-up diary phase (carbon monoxide verified).

Figure 2. Means of cigarettes per day (A), self-reported abstinence (B) and carbon monoxide–verified abstinence (C) over 28 days of the challenge diary phase by groups. CPD: cigarettes per day; CO: carbon monoxide.



Intervention Effects at the Quit Date and End of Intervention

The results of the three GLMMs are presented in Tables 3 and 4. In terms of daily self-reported smoking abstinence (GLMM 1), the intercept describes the probability of smoking abstinence for the CG at the quit date (77.4%, 95% CI 59.4%-88.9%). No significant *group* effect emerged: the IG (85.1%, 95% CI 42.4%-97.8%) did not report higher smoking abstinence than the CG. No significant *time* trend and no significant *group-by-time* effect were observed. This indicates that the daily self-reported abstinence was stable for both groups from the quit date on (disconfirming hypothesis 2), and the nonsignificant group difference on the quit date remained until the end of the intervention (disconfirming hypothesis 1; probability of abstinence on day 28: CG: 50.2%, 95% CI 17.2%-83.1% and IG: 74.2%, 95% CI 6.2%-99.2%). These results are not in support of our hypotheses. However, for both groups, a significant increase in the probability of daily self-reported abstinence from the phase before the quit date to the phase after the quit date occurred. Before the quit date, no difference was observed in the probability of daily self-reported abstinence between the CG (0.47%, 95% CI 0.05%-4.3%) and the IG (0.66%, 95% CI 0.1%-27.5%; to test group differences before the quit date, we recentered the time variable accordingly [centered on the first day: day 1=0]). The level-2 random effects indicated considerable variation between participants in the intercepts and trajectories over time (Table S2 in Multimedia Appendix 1).

Table 3. Fixed effects of generalized linear mixed models testing the effect of the intervention group versus the control group on daily self-reported abstinence and carbon monoxide abstinence (generalized linear mixed models 1 and 2).

Fixed effects	GLMM[a] 1[b] (daily self-reported abstinence) (N=162)			GLMM 2[c] (daily carbon monoxide abstinence) (n=154)		
	b[d] (SE)	*P* value	OR[e] (95% CI)	b (SE)	*P* value	OR (95% CI)
Intercept[f]	1.23 (0.43)	.005	3.43 (1.47-8.01)	3.37 (0.50)	<.001	29.21 (10.88-78.46)
CPD[g] (baseline diary)[h]	−0.10 (0.03)	.002	0.91 (0.85-0.97)	−0.14 (0.03)	<.001	0.87 (0.82-0.93)
Group (0=control group; 1=intervention group)	0.51 (0.61)	.40	1.67 (0.50-5.55)	−1.01 (0.69)	.14	0.37 (0.10-1.40)

[a]GLMM: generalized linear mixed model. Random effects are reported in Table S3 in Multimedia Appendix 1.

[b]Generalized linear mixed model 3 (negative binomial): n=150 persons with a maximum of 28 days; n=3003 out of 4536 possible diary entries.

[c]CPD: cigarettes per day.

[d]b: unstandardized regression coefficient.

[e]Intercept indicates level of the outcome for the control group at quit date (day 8).

[f]The grand-mean-centered cigarettes per day (cigarettes per day) during the *baseline diary* phase as covariate.

[g]Linear time trend centered on the quit date (day 8=0).

The GLMM 2 results with daily CO abstinence as an outcome confirmed the result pattern stated above. The intercept as the probability of CO abstinence for the CG at the quit date was 96.7% (95% CI 91.7%-98.7%). No significant *group* effect emerged: the IG (92.4%, 95% CI 50.1%-99.1%) did not report higher CO abstinence. No significant *time* trend from the quit date on and no significant *group-by-time* effect were observed. This indicates that the daily CO abstinence was stable for both

groups from the quit date on (disconfirming hypothesis 2), and the nonsignificant group difference on the quit date remained until the end of the intervention (disconfirming hypothesis 1; probability of CO abstinence on day 28: CG: 89.6%, 95% CI 69.2%-97% and IG: 87.6%, 95% CI 20.7%-99.3%). These results are not in support of our hypotheses. However, a significant increase in the probability of daily CO abstinence from the phase before the quit date to the phase after the quit date occurred for both groups. No significant group differences were observed in the probability of daily CO abstinence before the quit date between the CG (27.2%, 95% CI 3.9%-77.4%) and the IG (25.6%, 95% CI 0.2%-93.8%). The level-2 random effects indicated considerable variation between participants in the intercepts and trajectories over time (Table S2 in Multimedia Appendix 1).

In terms of CPD as an outcome (GLMM 3), the intercept describes the estimated CPD on the quit date in the CG. The average number of cigarettes smoked at the quit date in the CG was low, with about 1 cigarette (0.88) compared with about 12 CPD before the quit date. A significant difference emerged between the IG and CG (b=−0.71, SE 0.23; RR 0.49; *P*=.002). This result indicates that participants in the IG smoked approximately half of the number of cigarettes at the quit date compared with participants in the CG. A significant positive *time* trend (*time*; days 8-28), but no significant *group-by-time* effect emerged. This indicates that for both groups, CPD increased across days from the quit date on. The significant difference between groups remained until the end of intervention, with the CG reporting smoking on average 1.5 cigarettes and the IG on average half the amount (b=−0.73, SE 0.25; RR 0.48; *P*=.003). These results are in support of our hypothesis 1 but not in support of our hypothesis 2, assuming different time trends across groups. A significant decrease in CPD from the phase before the quit date to the phase after the quit date occurred. This nonlinear change in CPD was significantly greater for the IG. The level-2 random effects indicated considerable variation among the participants in the intercepts (Table S3 in Multimedia Appendix 1).

Sensitivity Analyses

We conducted sensitivity analyses of the intervention effect at the quit date and the end of the intervention to test whether results differed when controlling for the use of NRPs and a variable denoting whether days were weekdays or weekends (see the corresponding results in Tables S4 and S5 in Multimedia Appendix 1). Due to the additional covariates, we could only include participants with *challenge diary* entries (n=150). The result pattern of the models with daily CO abstinence (GLMM A2; Table S4 in Multimedia Appendix 1) and CPD (GLMM A3; Table S5 in Multimedia Appendix 1) as outcome remained the same. In the model with daily self-reported smoking abstinence (GLMM A1; Table S4 in Multimedia Appendix 1), an intervention effect emerged, such that the probability of self-reported abstinence on the quit date was significantly higher for the IG (92.6%, 95% CI 67.2%-98.7%) than for the CG (76.6%, 95% CI 61%-87.2%). This significant difference between groups remained until the end of the intervention (no difference in time trend between groups). The additional covariates were not the reason for the significant group effect on self-reported smoking abstinence, as the effect remained when running a model without the additional covariates (n=150; Table S6 in Multimedia Appendix 1; GLMM A4 and A5). These analyses excluded the dropout participants, that is, the 12 participants without *challenge diary* data (no intention to treat), and therefore estimated group differences less conservatively.

Intervention Effects at Follow-up

At the 6 months follow-up, regarding the outcome daily self-reported abstinence, we analyzed the full sample (intention to treat) and found no difference between the CG (mean 0.26, SD 0.42; n=81) and IG (mean 0.32, SD 0.46; n=81; t_{160}=−0.93; *P*=.36; *d*=−0.15). We found the same result pattern for the daily CO abstinence. No group differences emerged between the CG (mean 0.36, SD 0.47; n=67) and IG (mean 0.40, SD 0.48; n=73; t_{138}=−0.48; *P*=.63; *d*=−0.08). The same result patterns were found in the sensitivity analyses when excluding dropouts from the analysis (no intention to treat). For daily self-reported abstinence, no difference emerged between the CG (mean 0.37, SD 0.46; n=56) and IG (mean 0.50, SD 0.49; n=52; t_{106}=−1.40; *P*=.16; *d*=−0.27). In addition, for daily CO abstinence, no difference emerged between the CG (mean 0.55, SD 0.49; n=44) and IG (mean 0.67, SD 0.46; n=44; t_{86}=−1.13; *P*=.26; *d*=−0.24). On average, participants in the CG smoked fewer CPD during the *follow-up diary* phase than participants in the IG (Table 2). This difference was not significant (t_{91}=−0.84; *P*=.40; *d*=−0.18).

Intervention Fidelity

Of the 81 participants in the IG, 10 did not start the *challenge diary* (Figure 1). Of the remaining 71 participants, 1 did not find a buddy but started the *challenge diary* and used the SmokeFree buddy app alone. Excluding this participant did not change the result pattern. To measure app engagement, participants in the IG were asked if they used the SmokeFree buddy app on a daily basis. In addition, the daily perceived usefulness of the app was assessed. Furthermore, we had access to the Flurry Analytics account of the app developer. Flurry Analytics is a platform for tracking and analyzing users' app engagement (app sessions). Of 47 participants we obtained informed consent to analyze objective data of their SmokeFree buddy app use (Flurry Analytic). Overall, we observed low app engagement and low reported perceived usefulness (Table S5 in Multimedia Appendix 1). A total of 3 of the 71 participants indicated that they had never used the app through the *challenge diary* phase (no objective use data were available). Excluding these 3 participants did not change the result pattern.

Discussion

Principal Findings

The aim of this study is to examine the effectiveness of the SmokeFree buddy app, using an RCT with intensive longitudinal data and daily objective measures of smoking abstinence via exhaled CO in participants' daily lives. The SmokeFree buddy app group was compared with a CG that did not use the SmokeFree buddy app. Both groups set a quit date, filled in daily diaries, and measured exhaled CO with an app targeting self-monitoring and feedback on behavior. First, we

hypothesized that the IG will show higher daily abstinence and lower CPD at the quit date, 3 weeks later, and 6 months later than the CG (hypothesis 1). Second, we hypothesized a higher increase or decrease in the outcome measures over time from the quit date to 3 weeks later in the IG than in the CG (hypothesis 2).

Both groups significantly reduced their CPD from the baseline diary phase to the follow-up diary phase. The observed 6 months continuous abstinence rates (CO verified; Table 2) in the IG (18/81, 22%) and CG (11/81, 14%) were promising, as other recent RCTs of smoking cessation apps show continuous abstinence rates (6 months) from 7.8% [46], 10.2% [20] to 16.1% [47]. The CG was found to comparably reduce smoking and achieve similar abstinence rates as the IG. Therefore, our findings do not confirm hypothesis 1 with regard to daily abstinence rates. Regarding the secondary outcome, we found a significantly higher decrease from before to after the quit date in CPD for the IG and significantly lower CPD at the quit date and 3 weeks later, but not 6 months later, compared with the CG. Disconfirming hypothesis 2, we did not find differences in the increase or decrease in the outcome measures over time between the IG and CG. In both groups, the abstinence measures were low prequit, instantaneously shifted to a high level at the quit date, and remained stable during the 3 weeks postquit. In both groups, CPD was high prequit, instantaneously shifted to a low level at the quit date, and then slightly increased during the 3 weeks postquit (Figure 2). At the 6-month follow-up, CPD levels were approximately half of the CPD levels prequit (Table 2).

To our knowledge, this is the first RCT of an app for smoking cessation that focuses particularly on facilitating social support from a personally chosen buddy. Enhancing social support resources should theoretically help individuals to quit smoking [5,9]. There is evidence from intensive longitudinal studies that higher daily support receipt from one's partner was related to less daily smoking, and effects were more pronounced after a self-set quit date when support is theoretically most needed [23,37]. Previous intervention studies regarding partner or peer social support to improve smoking cessation, however, could not clearly demonstrate the effectiveness of smoking cessation compared with a CG [9,27]. An explanation is that these partner or peer support interventions were not capable of increasing social support in the first place [27]. Our findings match the results of these social support interventions, with no consistent evidence of its effectiveness [27]. The higher decrease and lower levels of CPD at the quit date and 3 weeks later might be explained by the presence of a buddy of choice which increased support and self-regulatory efforts (eg, self-monitoring and self-efficacy) to cope with single smoking events in the short term. However, the analysis of the secondary outcomes did not include all randomized participants. Excluding the 12 participants who did not start the challenge diary phase led to significant intervention effects on self-reported daily smoking abstinence at the quit date and the end of the intervention (Table S6 in Multimedia Appendix 1).

An explanation for the null effects of the intervention could be that the SmokeFree buddy app was compared with a CG that reported on their smoking and assessed CO on a daily basis, which is a strong self-monitoring intervention itself. It might be that the effect of the SmokeFree buddy app over and above the self-monitoring component was smaller than assumed. Another potential explanation for our inconsistent findings might be the low observed app engagement (Table S7 in Multimedia Appendix 1). At the end of the intervention, participants reported their reasons for potentially low app engagement. One reason often mentioned was the preference for established text messaging channels (WhatsApp and SMS text messages), phone calls, or face-to-face communication, which may have made the additional app medium redundant. Several participants also stated that they did not experience any benefits from using the app and did not feel the need to use the app more often. This is in line with reports of the low perceived usefulness of the app (Table S7 in Multimedia Appendix 1) and may have attenuated the evidence-informed support provision of buddy participants. Moreover, some participants also indicated that they generally use few apps, forgot to use the app, or stopped using the app due to relapse. Furthermore, other social exchange processes may have co-occurred, which may have been perceived as aversive or unwanted (eg, social negativity [48]) and so have no beneficial effects on smoking cessation.

Research has shown a general lack of engagement with digital interventions [49]. Low engagement with app content may limit the potential intervention effects [50]. An explanation for the low app engagement and inconsistent findings may be that the main content of the SmokeFree buddy app to enhance social support resources may not be attractive or fruitful for everyone, especially for individuals who do not rely on social relationships during health behavior change (eg, smoking cessation as *solo struggle*) [31,51]. In line with this, the intensive longitudinal data of this study indicate individual heterogeneity regarding the outcome measures at the quit date and in their time trajectories. Future studies should investigate the effects of the SmokeFree buddy app on hypothesized mechanisms to gain more insight into whether and what processes have been stimulated [32]. More research on the engagement with digital interventions and on factors most related to intervention effectiveness is needed (refer to the conceptual framework of Perski et al [50]). For instance, reminders have been found to be a simple strategy to increase user engagement with a digital smoking cessation intervention, such as tailored text messaging or email prompts [52,53]. In addition, human guidance (eg, by the study coordinator or health care worker) may also improve engagement with digital behavior change interventions [54] because human monitoring may lead to a certain accountability to one's actions or inactions (eg, supportive accountability) [55]. Finally, in the context of social support interventions, we have to deepen our understanding of how, for whom, and under what conditions social support beneficially influences smoking behavior [31].

Strengths and Limitations

This study had several strengths. First, the study provides the first experimental evidence of the SmokeFree buddy app, an app with a new approach of buddy support in everyday life compared with unacquainted buddies in other intervention studies. Second, we verified our primary outcome measure of

self-reported daily smoking abstinence with daily assessments of exhaled CO with the iCO Smokerlyzer. Third, the intensive longitudinal data are a major strength of this study. The daily assessment gave us a more precise display of smoking behavior and verification of continuous abstinence after a quit date compared with macrotime follow-ups only [56]. Furthermore, the intensive longitudinal study design allowed us to investigate the temporal developments of intervention effects and assess the heterogeneity of trajectories between individuals. We assessed self-reported app engagement during the study and measured it in real time. The daily diary design with daily CO measures increases the ecological validity of our data and is the first of its kind.

This RCT also had some limitations that need to be acknowledged. First, this RCT investigated a multicomponent app and thus is not able to disentangle the effects of individual intervention components. Future app intervention development should be guided by the multiphase optimization strategy [57] to identify effective social support components for smoking cessation first before running an RCT that evaluates a multicomponent intervention package [58,59]. Second, our data indicated low app engagement, which may have limited potential intervention effects.

Conclusions and Implications

Although the abstinence rates of this study are comparable with those of other studies of smoking cessation apps [17] and both conditions (IG and CG) led to significantly decreased CPD, we found that the SmokeFree buddy app was not superior to a CG with primarily self-monitoring components. The app provides evidence for a greater short-term reduction of CPD. There is a need for more research on the effectiveness of and the engagement with smoking cessation apps, considering the wide availability and the rapid release of new smoking cessation apps. App components aimed at enhancing beneficial social interactions with health care providers, partners, or peers to support smoking cessation require further investigation [60]. This study contributes to the scientific evidence on the effectiveness of smoking cessation apps in everyday life.

Abstract

Background: The volitional help sheet (VHS) for self-harm equips people with a means of responding automatically to triggers for self-harm with coping strategies. Although there is some evidence of its efficacy, improving acceptability and making the intervention available in a web-based format may be crucial to increasing effectiveness and reach.

Objective: This study aims to use the Theoretical Framework of Acceptability (TFA) to explore the acceptability of the VHS, examine for whom and under what circumstances this intervention is more or less acceptable, and develop a series of recommendations for how the VHS can be used to support people in reducing repeat self-harm.

Methods: We explored acceptability in two phases. First, our patient and public involvement partners evaluated the original VHS from a lived experience perspective, which was subsequently translated into a web-based format. Second, a representative sample of adults in the United Kingdom who had previously self-harmed were recruited via a YouGov survey (N=514) and were asked to rate the acceptability of the VHS based on the seven constructs of the TFA, namely, *affective attitude*, *burden*, *perceived effectiveness*, *ethicality*, *intervention coherence*, *opportunity costs*, and *self-efficacy*. Data were analyzed using descriptive statistics, one-tailed *t* tests, and binary logistic regression. A directed content analysis approach was used to analyze qualitative data.

Results: Participants in the web-based survey rated the VHS as positive (*affective attitude*; t_{457}=4.72; *P*<.001); were confident using it (self-efficacy; t_{457}=9.54; *P*<.001); felt they did not have to give up any benefits, profits, or values when using it (*opportunity costs*; t_{439}=−15.51; *P*<.001); understood it and how it worked (*intervention coherence*; t_{464}=11.90; *P*<.001); and were confident that it would achieve its purpose (*perceived effectiveness*; t_{466}=2.04; *P*=.04). The TFA domain *burden* appeared to be an important indicator of acceptability. Lower levels of perceived burden when using the VHS tool were more prevalent among younger adults aged 18-24 years (OR 3.63, 95% CI 1.50-8.78), people of White ethnic background (OR 3.02, 95% CI 1.06-8.613), and people without a long-term health condition (OR 1.53, 95% CI 1.01-2.30). Perceived modifications to further improve acceptability included improved formatting (*burden*), the feature to add new situations and responses or amend existing ones (*ethicality*), and clearer instructions and further detail about the purpose of the VHS (*intervention coherence*).

Conclusions: Our findings show high levels of acceptability among some people who have previously self-harmed, particularly among younger adults, people of White ethnic backgrounds, and people without long-term health conditions. Future research should aim to improve acceptability among older adults, people from minority ethnic groups, and people with long-term health conditions.

self-harm; implementation intentions; acceptability; online; volitional help sheet; digital health; mental health

Introduction

Background

Self-harm is a major public health concern that has a major impact on health care services [1,2] and is growing in prevalence in the United Kingdom [3]. Consequently, the management of self-harm is a widely recognized challenge, and developing preventative strategies is vital [4,5]. Self-harm may include self-harm with suicidal intent (suicidal attempts), self-harm without suicidal intent (nonsuicidal self-harm [NSSH]), or suicidal thoughts [6].

There are many reasons why people engage in self-harm [7] but common among them are triggers, such as feelings of defeat or entrapment [8] that increase the urge to self-harm. Providing people with a means of responding to such critical situations may lessen the likelihood of self-harm. Implementation intentions [9] may be valuable in this regard, as they automatize coping responses to trigger critical situations.

Implementation intentions are *if-then* plans that help people to link a critical situation (ie, *if*) with an appropriate response (ie, *then*). There is a wide body of research illustrating the effectiveness of implementation intentions [10], yet little research has examined the effectiveness of implementing intention-based interventions for reducing repeat self-harm. To help people reduce repeated self-harm, implementation intentions can help people recognize when they feel the urge to self-harm and provide alternative coping strategies. The if-then plans work by making automatic links [10] in memory between a critical situation ("If I am tempted to self-harm when I want to get some attention...") and an appropriate response ("...then I will do something else instead of self-harming"). Implementation intentions have been shown to be effective in reducing self-harm in people recently admitted to the hospital for self-harm [11]. In this study, participants were provided with a tool, the volitional help sheet (VHS), designed to assist with the formation of implementation intentions to reduce self-harm. The tool provides people with a list of critical situations where the urge to self-harm may be heightened, and a list of responses designed to increase the likelihood of not self-harming [12]. The development of the VHS for self-harm has been described elsewhere [11]. Briefly, the VHS provides a theoretically driven framework for participants to construct their own implementation intentions, drawing on theories of suicidal behavior [13], self-harm motivation literature [14], and the transtheoretical model of change [15]. However, previous research is limited by high rates of attrition at follow-up [11]. Other studies report that the effectiveness of implementation intentions for reducing repeat self-harm may vary as a function of self-harm history [16]. Given the likelihood of successful implementation and effectiveness of interventions may be dependent upon perceptions of acceptability [17,18], it is necessary to comprehensively examine the acceptability of the VHS for self-harm in further detail.

Intervention acceptability is an important consideration in the design, implementation, and evaluation of health care interventions [19,20]. The likelihood of successful implementation and effectiveness may depend on perceptions of acceptability [17,20]. For example, interventions perceived as acceptable by those delivering or receiving them are more likely to result in favorable outcomes, including adherence to treatment programs [18], support for public health policy [17], or acceptance of behavior change interventions [21]. The Theoretical Framework of Acceptability (TFA) [20] is an established guide for assessing the acceptability of interventions. It defines acceptability as "a multifaceted construct that reflects the extent to which people delivering or receiving a health care intervention consider it to be appropriate, based on anticipated or experienced cognitive and emotional responses to the intervention" [20]. The TFA comprises seven domains: (1) affective attitude (how individuals feel about taking part in an intervention), (2) burden (the amount of effort required to engage with an intervention), (3) perceived effectiveness (whether individuals perceive an intervention as likely to achieve its purpose), (4) ethicality (the extent to which an intervention fits with individuals' personal values), (5) intervention coherence (whether individuals understand an intervention and how it works), (6) opportunity costs (what is given up, such as time, to take part in an intervention), and (7) self-efficacy (how confident individuals are performing the intervention). The advantage of using the TFA, as opposed to more general approaches to investigating acceptability, is that the TFA allows a more systematic assessment of intervention acceptability, and this approach allows researchers to target specific TFA domains in future iterations of interventions (eg, addressing perceived burden of interventions) [22].

Objective

This study has three specific objectives: first, to evaluate the acceptability of the VHS from a lived experience perspective (patient and public involvement [PPI]) and redevelop the tool according to feedback; second, to examine for whom and under what circumstances the VHS is more or less acceptable; and finally, to develop a series of practice recommendations for how the VHS can be used to support people in reducing repeat self-harm.

Methods

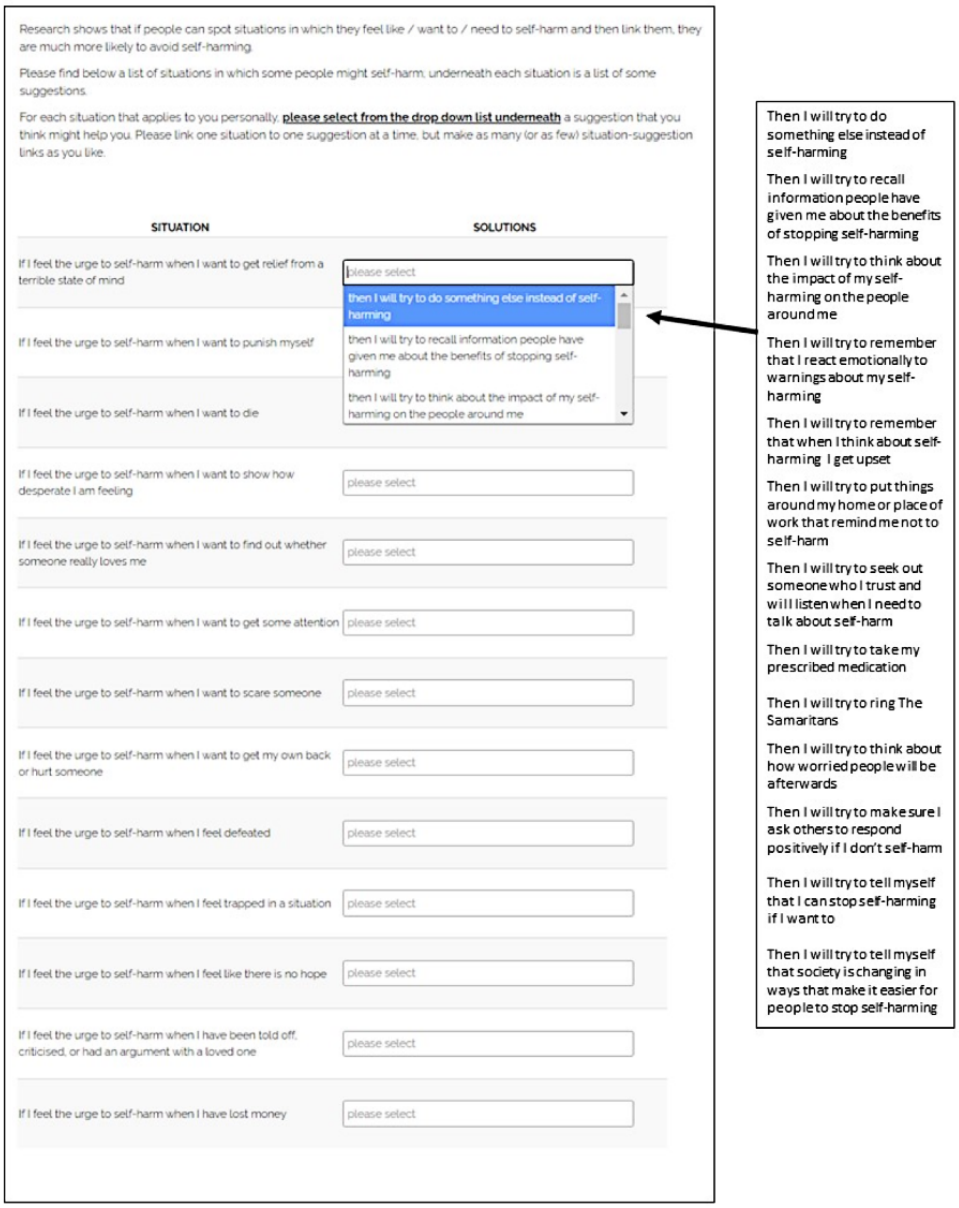
Overview

Ethical approval was obtained from the University Research Ethics Committee (ref: 2020-8446-15312), and informed consent was obtained from all participants. The VHS provides people with a list of critical situations where the urge to self-harm may be heightened, and a list of coping responses designed to decrease the likelihood of self-harming [12]. The development of the VHS for self-harm has been described elsewhere [11]. Briefly, the VHS provides a theoretically driven framework for participants to construct their own implementation intentions, drawing on theories of suicidal behavior [13], self-harm

motivation literature [14], and the transtheoretical model of change [15].

Acceptability was explored in two phases. In phase 1, the original VHS, used as part of a previous study [11], was distributed among a PPI group for initial feedback and translated to a web-based format by the research team. This was done by creating on a single webpage, as part of a web-based questionnaire, a list of situations alongside which participants could choose an appropriate response from a drop-down menu for each critical situation (a screenshot of the VHS is provided for illustrative purposes in Figure 1). As the intervention was presented on a single screen within the questionnaire, participants were able to print the VHS after participation. Participants were also given a physical copy of the VHS as part of the study. In phase 2, a national sample of people in the United Kingdom who had previously self-harmed was recruited via a survey panel company (YouGov), as part of a larger 6-month follow-up study examining the effectiveness of the VHS for reducing self-harm (ClinicalTrials.gov identifier: NCT04420546).

Figure 1. The volitional help sheet for self-harm.



Phase 1: PPI and Tool Development

The VHS has been shown to be effective for reducing self-harm in people recently admitted to the hospital following an episode of self-harm [11]. The researchers initially made minor changes to the VHS for translation into a web-based format, in line with a previous VHS delivered on the web [23]. To ensure that the intervention was suitable for as broad a population as possible, the VHS was evaluated from a lived experience perspective by members from a PPI group (n=10). The group was specifically trained to provide feedback on research methods and materials to be used as part of intervention delivery, and all members of the group had a history of self-harm, suicidal behavior, or receiving mental health services. The feedback from our PPI contributors was used to ensure that the VHS was understandable and sensitive to people's thoughts and emotions about self-harm (the majority of the PPI group had a history of self-harm). Participants provided (on hard copies of the VHS)

feedback and suggestions for improvements both on the wording of the instructions of the VHS, and the *critical situations* and *appropriate responses*. Previous deployments of the VHS have predominantly used paper and pencil, whereby participants are asked to physically draw a line linking any situations that applied to them, to one solution at a time (participants could make as many situation-solution links as they would like). On the basis of the feedback, amendments were made to the wording of 11 of the situations and nine of the solutions. Two solutions were removed because the group felt the wording was inappropriate ("Then I will tell myself that I can stop self-harming if I want to" and "Then I will make sure I am rewarded by others if I don't self-harm"). Two new situations ("If I feel the urge to self-harm when I have been told off, criticised, or had an argument with a loved one" and "If I feel the urge to self-harm when I have lost money"), and four new solutions ("Then I will try to ring The Samaritans," "Then I will try to think about how worried people will be afterwards," "Then I will try to make sure I ask others to respond positively if I don't self-harm," and "Then I will try to tell myself that I can stop self-harming if I want to") were added to the VHS. The final VHS, which included the two new situations and four new solutions, contained 13 situations and 13 solutions.

Phase 2: YouGov Survey

A national sample of adults in the United Kingdom who had previously self-harmed were recruited via a survey panel company (YouGov), as part of a larger study (ClinicalTrials.gov Identifier: NCT04420546) were invited to take part in a web-based questionnaire and were incentivized in accordance with the YouGov's point system (respondents accumulated points for taking part in surveys, which can be exchanged for cash or entry into a prize draw). To ensure that the final sample contained people with a prior history of self-harm, we asked a screen question: "Have you ever intentionally hurt yourself/self-harmed?" Response options were "yes, I have," "no, I have not," or "prefer not to say." The final sample was based on respondents answering, "yes, I have."

Following completion of the questionnaire (described below), participants were asked to complete the amended VHS to reduce self-harm (based on the feedback obtained from phase 1). Participants formed implementation intentions by linking critical situations with appropriate responses by choosing an appropriate response from a drop-down menu for each critical situation. Participants were free to make as many situation-response links as desired. Participants were then asked questions about their acceptability (n=514).

Measures

Sociodemographic Variables

Demographic variables, including age, gender, ethnicity, and social grade, were taken using the standard UK Office for National Statistics [24] measures.

History of NSSH, Suicidal Ideation, and Suicide Attempts

Three items drawn from the British Psychiatric Morbidity Survey [25]: "Have you ever seriously thought of taking your life, but not actually attempted to do so?" (suicidal ideation); "Have you ever made an attempt to take your life, by taking an overdose of tablets or in some other way?" (suicidal attempt); and "Have you ever deliberately harmed yourself in any way, but not with the intention of killing yourself? (ie, self-harm)" (NSSH). Response options for all questions were *Yes*, *No*, or *prefer not to say*. If respondents answered yes to any of the three questions, the timing of the last episode and frequency was asked.

Exposure to Death and Suicide

Participants were asked seven items [26,27] to establish whether any of their close friends or family had died, whether they had friends of family who had self-harmed, or who attempted or died by suicide (eg, "Has anyone among your family attempted suicide?").

Acceptability Measures

Only one study has deployed the TFA as a quantitative measure; Renko et al [28] assessed the acceptability of a training program to enhance teachers' physical activity promotion. However, the items were not sufficiently generic to adapt to the present purposes. Likert scale responses, with additional open-ended text questions to capture qualitative data with respect to each domain, were developed in line with the seven TFA constructs used to assess acceptability. Seven items were developed, for example, "On a scale of 0-10, how much effort was required to use the volitional help sheet?" (burden; *no effort*: 1 to *lots of effort*: 10). Item wordings were developed to closely resemble the definitions provided for each domain of the TFA [20]. The items used to measure each TFA domain are shown in Table 1.

For each of the seven TFA items, participants were invited to provide open-ended comments describing their experiences using the VHS with respect to each of the seven constructs of the TFA. Seven items were developed, corresponding to each of the TFA domains, for example, "Do you have any specific comments about how good or bad you felt when using the volitional help sheet?" (affective attitude). Participants' comments were combined, and content analysis was performed.

Table 1. The Theoretical Framework of Acceptability domains.

Domain	Question	Participant (n=514), n (%)	Values, mean (SD)	Comments (n=360), n (%)
Affective attitude	On a scale of 0-10, how good or bad did you feel when using the volitional help sheet?	476 (92.6)	5.50 (2.32)	33 (9.2)
Burden	On a scale of 0-10, how much effort was required to use the volitional help sheet?	471 (91.6)	5.09 (2.84)	78 (21.7)
Ethicality	On a scale of 0-10, how much was using the volitional help sheet a good fit with your personal values?	465 (90.5)	4.80 (2.68)	69 (19.2)
Self-efficacy	On a scale of 0-10, how confident were you about using the volitional help sheet?	468 (91.1)	6.16 (2.63)	37 (10.3)
Opportunity	On a scale of 0-10, to what extent did you give up any benefits, profits, or values when using the volitional help sheet?	440 (85.6)	2.95 (2.77)	38 (10.6)
Intervention coherence	On a scale of 0-10, how confident were you that you understood the volitional help sheet and how it works?	465 (90.5)	6.45 (2.63)	40 (11.1)
Perceived effectiveness	On a scale of 0-10, how confident were you that the volitional help sheet is likely to achieve its purpose?	467 (90.9)	5.24 (2.59)	65 (18.1)

Analyses

Quantitative data were analyzed using SPSS, version 26 (IBM Corporation). Descriptive statistics were used to summarize the sociodemographic variables. The chi-square test was used to compare our sample of people who reported a previous history of self-harm with general population data collected as part of the Adult Psychiatric Morbidity Survey [29]. In the absence of universally agreed criteria for determining acceptability with respect to deploying TFA quantitative measures, two approaches used in previous studies were adopted [30]. First, one-tailed *t* tests were used to assess how far above or below the neutral rating (5) people rated the seven TFA indicators. This measure was used to ensure that the neutral responses were accounted for. Second, the proportion of participants scoring at each point on the rating scale was assessed. These measures were used to assess the desirability and acceptability of the questionnaire according to each of the seven TFA domains. Binary logistic regression was used to explore the correlates of acceptability to identify which sociodemographic factors (gender, age, ethnicity, social grade, and recency of self-harm [past week or past year]; all dummy coded) were associated with higher or lower levels of perceived acceptability. Each of the main outcomes was recorded as a binary outcome (eg, high acceptability: 1 or low acceptability: 0). High acceptability was defined as scores above the neutral rating (ie, scores >5), and low acceptability was defined as scores ≤5, except for two domains (*burden* and *ethicality*) where high acceptability was defined as scores <5, and low acceptability was defined as scores ≥5.

Qualitative Analyses of Open‐Ended Comments

Participants were asked to rate the acceptability of the VHS based on the seven constructs of the TFA (described above): affective attitude, burden, perceived effectiveness, ethicality, intervention coherence, opportunity costs, and self-efficacy. Participants were invited to provide open-ended comments to each TFA question. A directed content analysis approach, which is suitable when the research uses an existing theory or framework to interpret the data, was used to identify and categorize instances of the TFA domains [31,32]. First, deductive coding was used to generate a content analysis framework in line with the TFA domains. Second, inductive coding was used to generate explanatory themes with respect to each TFA domain, whereby specific codes within each TFA domain were grouped into themes. Initial codes were generated and collated into potential themes by CK, who shared the coding framework and key illustrative quotes with CJA as the analysis progressed. Any areas of contention were discussed, and themes were refined accordingly to ensure the trustworthiness of the data. All the authors were involved in finalizing the main themes. NVivo, version 12 (QSR International) was used to organize the data. The codes focused on different aspects of acceptability with respect to using the VHS to reduce repeat self-harm, according to each TFA domain (eg, attitudes toward the intervention, and the perceived effort required to engage with the intervention). The themes were reviewed by coauthors, and there were no disagreements.

Results

Sample Characteristics

Overview

The total sample (n=514) comprised mostly women (331/514, 64.4%), 27.4% (141/514) were aged 18-34 years, 21.2% (109/514) were aged 35-44 years, 18.1% (93/514) were aged 45-54 years, and 33.3% (171/514) were aged ≥55 years. The majority of the sample was White (472/514, 91.8%), and 63.4% (326/514) were of higher social grade (nonmanual workers; Table 2). The characteristics of our sample closely resembled the characteristics of people who reported a history of self-harm according to the Adult Psychiatric Morbidity Survey of the general population [29] in terms of gender and age. However, our sample contained a lower proportion of people from a minority ethnic background compared with the national data.

Table 2. Sample demographics (N=514).

Variable	Population, n (%)	Value, mean (SD; range)	General population data (%)[a]	Chi-square difference between sample and population	*P* value

[a]According to the Adult Psychiatric Morbidity Survey of the general population [29].

[b]N/A: not applicable.

[c]BAME: Black, Asian, and minority ethnic.

[d]NSSH: nonsuicidal self-harm.

Prevalence of Suicidal Ideation, Suicide Attempts, NSSH, and Exposure to Suicide and Death

Overall, 75.9% (390/514), 41.2% (212/514), and 74.5% (383/514) of the total sample reported suicidal ideation, suicide attempts, and NSSH, respectively (Table 1). Furthermore, 7.4% (38/514) of the total sample reported suicidal thoughts in the past week, and 24.5% (126/514) of the sample reported suicidal thoughts in the past year. Few people reported suicide attempts in the past week (4/514, 0.8%), and 3.9% (20/514) reported a suicide attempt in the past year. With respect to NSSH, 5.1% (26/514) reported NSSH in the past week, and 13.2% (68/514) reported NSSH in the past year.

Over half of the sample (273/514, 53.1%) reported experiencing the death of a family member, over three-fourths (390/514, 75.9%) of the sample reported experience of the death of a close friend or relative, and 30.9% (159/514) of the sample reported experience of death by suicide of a close friend or relative. Of the total sample, 34% (175/514) reported exposure to a family member making a suicide attempt, and 36.8% (189/514) reported exposure to a suicide attempt by a close friend. Exposure to NSSH by a family member was reported by 29.8% (153/514) of the sample, and NSSH by a close friend by 41.6% (214/514) of the sample.

With regard to lifetime history of self-harm, our sample reported a higher prevalence of suicidal ideation (390/514, 75.9% vs 20.6%), suicide attempts (212/514, 41.2% vs 6.7%), and NSSH (383/514, 74.5% vs 7.3%) compared with national data. With regard to self-harm in the previous year, our sample reported a higher prevalence of suicidal ideation (126/514, 24.5% vs 5.4%) compared with national data; the prevalence of suicide attempts in the previous year more closely resembled national data (0.7% vs 20/514, 3.9%).

Overall Acceptability of the VHS

One-sample *t* tests showed that participants rated the VHS favorably on five of the seven indicators by scoring above or below the respective midpoints. Participants rated the VHS positively (*affective attitude*; mean 5.50, SD 2.32; t_{457}=4.72; *P*<.001); were confident using the VHS (*self-efficacy*; mean 6.16, SD 2.63; t_{457}=9.54; *P*<.001); did not have to give up any benefits, profits, or values when using the VHS (*opportunity costs*; mean 2.95, SD 2.77; t_{439}=−15.51; *P*<.001); understood the VHS and how it worked (*intervention coherence*; mean 6.45, SD 2.63; t_{464}=11.90; *P*<.001); and were confident that it would achieve its purpose (*perceived effectiveness*; mean 5.24, SD 2.59; t_{466}=2.04; *P*=.04). No significant differences were found for the two TFA domains: *burden* (mean 5.09, SD 2.84) and *ethicality* (mean 4.80, SD 2.68). The mean ratings for each of the seven constructs are listed in Table 2.

The proportion of participants scoring at each point on the rating scale of each TFA item is presented in Multimedia Appendix 1. There were two key findings. First, there was a high proportion of responses at the upper end of the *self-efficacy* and *intervention coherence* items, compared with other items (97/468, 20.7% and 110/465, 23.6% of participants, respectively, rating 9 or 10 on the 0-10 scales). Second, there was a high proportion of responses at the lower end of the opportunity costs item compared with other items (186/440, 42.3% of participants rated 0 or 1 on the 0-10 scale).

Associations Between Sociodemographic Variables (Age, Gender, Ethnicity, and Current Health Status) and Acceptability

Table 3 shows the binary logistic regression results of perceived acceptability of the VHS according to sociodemographic variables.

No significant differences were found between men and women in perceived acceptability of any of the TFA variables. Lower levels of perceived burden were more prevalent among people aged 18-24 years, compared with those aged 25-34 years (OR 3.63, 95% CI 1.50-8.78), and 35-44 years (OR 2.55, 95% CI 1.06-6.15), and among people of White ethnic background, compared with people from minority ethnic groups (OR 3.02, 95% CI 1.06-8.61). Higher levels of perceived burden were more prevalent among people who reported having a long-term health condition (OR 1.53, 95% CI 1.01-2.30), compared with those who did not report having a long-term health condition.

Table 3. Associations between sociodemographic variables and acceptability of the volitional help sheet, according to Theoretical Framework of Acceptability variables.

Variables	β (95% CI)						
	Attitude	Burden	Ethicality	Self-efficacy	Opportunity costs	Intervention coherence	Perceived effectiveness
Gender (women)	1.10 (0.75-1.61)	1.17 (0.80-1.71)	1.26 (0.84-1.87)	1.28 (0.87-1.88)	0.91 (0.53-1.58)	1.17 (0.79-1.74)	1.26 (0.86-1.86)

[a]*P*<.05.

[b]*P*<.01.

[c]NSSH: nonsuicidal self-harm.

Associations Among Prevalence of Suicidal Ideation, Suicide Attempts, NSSH, Exposure to Suicide and Death, and Acceptability

People who reported self-harm in the past year were more likely to report higher levels of burden (OR 1.64, 95% CI 1.11-2.41) than those who did not report self-harm in the past year. No significant differences were found for any of the TFA variables among people who had or had not self-harmed in the past week.

People who reported exposure to death (within their immediate family) were likely to perceive a lower burden (OR 0.62, 95% CI 0.43-0.89) compared with those who had not. People who reported exposure to a suicide attempt (within their immediate family) were more likely to report favorable attitudes toward the VHS (OR 1.53, 95% CI 1.04-2.25). People who reported exposure to a suicide attempt (by close friends) were more likely to report higher opportunity costs (the extent to which people gave up any benefits, profits, or values when using the VHS;

OR 1.77, 95% CI 1.03-3.03) compared with those who did not. People who reported NSSH (within their immediate family) were more likely to report higher levels of ethicality (fit with personal values; OR 1.53, 95% CI 1.02-2.30), self-efficacy (OR 1.51, 95% CI 1.00-2.27), and intervention coherence (confidence in understanding the intervention and how it works; OR 2.10, 95% CI 1.35-3.27), compared with those who did not. People who reported NSSH (by close friends) were more likely to report higher levels of intervention coherence (OR 1.53, 95% CI 1.03-2.27), compared with those who did not.

Qualitative Analyses of Open-Ended Comments

Overview

In all, 340 participants provided at least one open-text comment in response to the TFA items. After responses that were deemed invalid (eg, participants responding with *no comments*) were removed, all of the remaining responses (n=360 comments) were analyzed. Explanatory themes with illustrative quotes were presented within each TFA domain. With respect to opportunity costs, 38 comments were provided. The majority of comments were related to a lack of clarity with respect to this question. Consequently, the participants were unable to provide responses for this domain.

Affective Attitude

In total, 9.2% (33/360) of the comments were provided with respect to how good or bad participants felt about taking part in the intervention. Comments within this domain focused on *refinements to the intervention* and *the perceived relevance of situations and responses*. First, the suggested refinements were mainly with respect to general comments about the wording of the situations and responses. In particular, some participants suggested that some of the statements might induce negative thoughts about self-harm and act as a reminder of personal experiences of self-harm:

> *It brought back a lot of negative memories and feeling surrounding self-harm. Someone would need to be in a decent place in order to use it.* [P552, female]

Second, participants made reference to the importance of the intervention containing relevant situations to their own experiences where the urge to self-harm may be heightened and responses that are more appropriate. Some participants expressed a desire for more relevant options, as some participants had difficulty relating to either the situations or responses, and they did not link directly to their experiences:

> *I felt slightly frustrated. I don't know why. Maybe because I wanted more options.* [P348, male]

> *I felt that many of those situations were too specific and did not fit my experiences.* [P57, female]

Burden

In total, 21.6% (78/360) of the comments were provided with respect to the perceived effort required to use the VHS. Comments within this domain focused on *perceptions of usability* and *perceived technology-based challenges*. First, some participants reported specific features of the VHS that made it easy to use, including encouraging and promoting self-reflection as an important feature of the intervention. However, 13 participants reported the psychological effort required to engage with the VHS, such as difficulties in choosing an appropriate situation and response. Participants also described how situations or responses that were perceived to be not personally relevant added to the effort required to engage with the intervention: "Too much effort may result in people giving up completing it."

Second, participants described potential challenges of using a web-based platform that should be considered in future iterations of the intervention. First, due to the intervention being delivered on the web, 11 participants expressed technical or formatting difficulties that made it difficult to engage with the VHS. Technical issues included difficulties viewing on a mobile device or difficulties in selecting situations and responses from the drop-down menus. These were deemed minor and could be resolved in future iterations of the intervention:

> *I think it was just this interface made it difficult to scroll. I'm sure if it was on a different site it would be fine.* [P544, female]

> *I am doing it on the phone so is difficult to read sometimes.* [P339, male]

Ethicality

In total, 19.2% (69/360) of the comments were provided with respect to the extent to which using the VHS a good fit with an individual's personal values. Comments within this domain focused on *the perceived strengths of the intervention* and the *perceived importance of having modifiable statements*. First, participants reported that they recognized the situations and responses and indicated a good fit with their personal values. One participant reported that the practical approach to trying to reduce self-harm was a particular strength of the intervention. Another participant described how the intervention helped them focus on more positive thoughts when forming implementation intentions:

> *It identified to me other ways that I could keep thoughts positive.* [P571, female]

> *Practical without being patronising or guilt inducing.* [P348, male]

Second, there were a small number of participants, who responded negatively to the VHS in its current form; 15 participants perceived the situations and responses as a poor fit with their personal values (such as some of the solutions focusing on other people). In total, 6 respondents suggested acknowledging other situations and responses would strengthen the intervention, as would the feature to add new situations and responses or amend existing ones:

> *It makes the assumption that self harming is always bad.* [P437, female]

> *Like I said it makes me think I should be guilty for wanting to self harm.* [P101, female]

> *I don't really feel comfortable using other people as a solution I think examples of what to do instead (eg go for a walk) could be a way in the moment to realise thinks that might help.* [P709, female]

> *Self harming for attention/to hurt or worry others is attention seeking. There are other ways to seek attention. My own self harm was entirely hidden.* [P417, male]
>
> *I'd prefer something a bit more free-wheeling where I could add my own responses.* [P254, female]

Intervention Coherence

In total, 11.1% (40/360) of the comments were provided with respect to how confident respondents were that they understood the VHS and how it worked. Comments within this domain focused on *perceived clarity about the purpose of the intervention* and *perceived confidence in engaging with the intervention correctly.* First, 9 participants reported that they understood the intervention and were positive about its usefulness and helpfulness. However, the majority of the comments related to the need for improved clarity about the purpose of the VHS and how it works:

> *I believe I'm emotionally fairly intelligent and quite reflective so I believe I understood it fairly well.*
>
> *It was easy to understand but I imagine that some people would think they could only choose one option.* [P427, male]

Second, for some participants, a lack of clarity in how the VHS was described affected their confidence in using the intervention in the correct way. A need for clearer instructions for the VHS and, in particular, to help describe how the VHS is intended to work as a way of developing coping plans, was expressed:

> *The situation and the options were there but no idea how it is supposed to work to stop something that is not tailored towards a specific problem.* [P22, male]
>
> *I wasn't sure if I should have read all the options even the situations were not applicable to me. I apologise if I got that wrong.* [P387, male]

Perceived Effectiveness

In total, 18.1% (65/360) of the comments were provided with respect to how confident respondents were that the VHS is likely to achieve its purpose. Comments within this domain focused on *perceptions of when the intervention could be used* and *perceived receptiveness of people*. First, participants described how the VHS would be particularly helpful for people in specific contexts or under particular circumstances. Some participants believed that it may be helpful for people when the urge to self-harm was not at its height or as a preventative measure for self-harm: "I think in milder moments and before crisis point, it could help refocus the mind to a more positive and less destructive way of thinking."

Second, participants believed that the effectiveness of the VHS might depend on how receptive people are to the intervention, and they believed it would be effective for their own circumstances. Some participants expressed concerns that the purpose of the VHS was unclear and expressed a need for further guidance. Participants described how the intervention may induce negative emotions for some people, which may affect how people engage with the intervention:

> *I think for someone who self harms on instinct it would be useful to have solutions written down as a reminder.* [P249, female]
>
> *It requires a level of concentration which may be difficult to achieve if severely depressed.* [P422, male]

Self-efficacy

In total, 10.3% (37/360) of the comments were provided with respect to how confident respondents were about using the VHS. Comments within this domain focused on *perceptions of personal relevance* and *factors associated with engagement*. First, participants reported that the intervention was easy to use and navigate. However, others have reported that the likelihood of people using or needing a VHS may be dependent upon the relevance of the situations and solutions:

> *I felt like I learnt to use it. In some cases the situations and options did not fit "me."* [P549, male]

Perceptions of personal relevance were perceived to affect confidence in using the intervention. In some cases, participants reported that they had lower confidence in using the VHS because of some of the options not being relevant to their own circumstances; 3 participants expressed doubts that they were using the VHS correctly. Furthermore, one participant also described how motivation to engage with the intervention may differ depending on the situation presented:

> *Not sure on some of the questions, so put nearest guess to what I might do, most likely I would have selected a different option not available.* [P22, male]
>
> *Wasn't 100% sure about whether or not I could add the same motivation to different situations (I didn't).* [P254, female]

Discussion

Principal Findings

This paper describes the acceptability of a brief intervention based on implementation intentions to prevent and reduce self-harm. This is the first study to (1) apply the TFA to examine the acceptability of preventative strategies for self-harm, (2) examine for whom and under what circumstances the VHS is more or less acceptable for preventing and reducing self-harm, and (3) develop a series of recommendations for how the VHS can be used to support people to reduce repeated self-harm. This study has four key findings. First, the VHS was rated favorably on five of the seven TFA domains (*affective attitude*, *self-efficacy*, *opportunity costs*, *intervention coherence*, and *perceived effectiveness*). In particular, there was a high proportion of responses at the upper end of the *self-efficacy* and *intervention coherence* items, which suggests that participants understood the VHS and how it works, and they were confident in their ability to use it correctly. Furthermore, there was a high proportion of responses at the lower end of the opportunity cost item, which suggests that people anticipated no problems forming implementation intentions, nor did they have to give up something else, such as time, to engage with the intervention.

Second, with respect to sociodemographic variables, the TFA domain *burden* appeared to be an important indicator of

acceptability of the VHS. In particular, lower levels of perceived burden when using the VHS were more prevalent among younger adults (aged 18-24 years) than among older adults, and among people of White ethnic background, compared with participants from a minority ethnic background. This is consistent with national data showing higher rates of self-harm among younger adults [1,3] and among people of White ethnic backgrounds compared with other ethnic backgrounds [33]. Our intervention may benefit some vulnerable individuals. However, our results suggest that further modifications are required to increase acceptability among older adults and minority ethnic groups with respect to perceived burden. Moreover, higher levels of perceived burden were more prevalent among people who reported having a long-term health condition than among those who did not report having a long-term health condition. This may suggest that having the additional burden of a long-term condition may affect the perceptions of interventions designed to target mental health challenges. Given that 30% of the UK population reported living with a long-term condition and a mental health problem (approximately 4.6 million people) [34], this may consequently be an important target population for future studies.

Third, a history of self-harm was associated with perceived acceptability of the VHS. In our study, people who reported self-harm in the past year were more likely to report higher levels of perceived burden compared with those who did not report self-harm in the past year. The VHS has previously been found to be effective for people recently admitted to the hospital after an episode of self-harm [11]. Consequently, our findings suggest that the VHS could be improved further for people with a longer history of self-harm, to make the VHS less burdensome among people who have self-harmed relatively recently (ie, in the past year).

Fourth, our findings show that exposure to death and suicide is associated with perceived acceptability of the VHS. With respect to immediate family, people who reported exposure to death were more likely to report lower levels of perceived burden compared with those who did not. People who reported exposure to a suicide attempt were more likely to report favorable attitudes toward the VHS. Furthermore, people who reported exposure to NSSH were more likely to report higher levels of ethicality (fit with personal values), self-efficacy (confidence in using the VHS), and intervention coherence (confidence in understanding the intervention and how it works), compared with those who did not. With respect to close family and friends, people who reported exposure to NSSH were more likely to report higher levels of intervention coherence than those who did not. Wider research suggests that exposure to suicidal behavior may increase the risk of suicidal behavior through mechanisms such as imitation or social learning [26]. Our findings suggest that exposure to suicidal behavior may have positive effects on intervention acceptability and receptiveness to interventions, as they alleviate the perceived burden of interventions designed to support people in reducing repeat self-harm.

Overall, both our quantitative and qualitative findings suggest high levels of acceptability of the VHS. Consistent with the assumptions of the TFA that engagement in interventions may be dependent upon acceptability [20], our qualitative findings highlight: (1) factors that may affect engagement with the intervention and (2) suggestions to modify the intervention, which may increase acceptability.

With regard to the factors that may affect engagement with the intervention, there were a number of perceived challenges for participants when engaging with the intervention, which could be addressed in future iterations of the intervention, to further increase acceptability. The most commonly reported problems were related to (1) perceptions that statements might (for some people) induce negative thoughts about self-harm and act as a reminder of personal experiences of self-harm (*attitude*), (2) difficulties choosing an appropriate situation and response due to some being perceived as not personally relevant (*burden*), (3) technical issues including difficulties viewing on a mobile device or difficulties in selecting situations and responses from the drop-down menus (*burden*), and (4) perceptions of how receptive people are to the intervention (*perceived effectiveness*).

With regard to how to modify the intervention, in line with the respective TFA domains, there were a number of suggestions that may increase acceptability. The questions included (1) improved formatting of the intervention (*burden*), (2) the feature to add new situations and responses or amend existing ones (*ethicality*), and (3) clearer instructions and further details about the purpose of the VHS and how it works (*intervention coherence*).

Implications

Our findings suggest high levels of acceptability of the VHS. Participants reported that the VHS was easy to use, and encouraged and promoted self-reflection as a way of supporting people in avoiding future self-harm (*burden*). Minor technical issues were perceived to increase the intervention burden; however, these were judged by the research team to be minor issues. Interventions for self-care practices delivered web-based have been found to be acceptable and demonstrate some level of efficacy across a number of health conditions, including diabetes [35] and psoriasis [36]. This is important, as it suggests that technology-based interventions are perceived as an acceptable delivery mechanism for interventions targeting better management of long-term health conditions. Interventions for mental health problems delivered web-based are considered to be highly acceptable [37], and with further refinements, our intervention could be further developed and delivered as part of remote health care delivery [38,39]. However, further modifications and co-design are needed to make the VHS less burdensome for older adults and to explore specific requirements for people from minority ethnic groups and people with long-term health conditions. This could include clearer instructions about the purpose of the VHS and how it works, and improved formatting.

Our findings suggest that the VHS may be helpful for people in specific contexts or under particular circumstances. The timing of the last self-harm episode appears to be an important consideration when deploying the tool. The VHS was designed to be used as a support tool when someone has the urge to self-harm or immediately following an episode of self-harm [11]. Our findings suggest that further refinements are needed

for the tool to make it less burdensome (ie, requiring a lot of effort to engage with) for people who have self-harmed in the previous year. By making the tool easier to engage with, the tool may also be useful as part of long-term support strategies, such as when the urge to self-harm may not be at their height. It is encouraging that no gender differences in acceptability were found, and thus future research could explore the extent to which brief interventions for self-harm could be delivered by health care professionals, for example, research suggests that more emphasis should be placed on improving self-harm care for patients, with a focus on improving the implementation of self-harm management guidelines [40]. One possible route is to explore the use of the VHS alongside GP care, given that the recognition of primary care is an important place to potentially help people reduce repeat self-harm [41].

Strengths and Limitations

Previous studies examining the prevalence of self-harm have focused on general population samples [29] or adolescent samples [42]. To our knowledge, this is the first study to characterize a national community sample of adults who have previously self-harmed with respect to demographic variables, history of NSSH, suicidal ideation and suicide attempts, and exposure to death and suicide. This is important because knowing more about this community population allows more targeted preventative strategies for self-harm, with respect to specific subgroups who may benefit the most from interventions.

There was evidence of good acceptability of the VHS in line with the TFA domains. In the absence of a universally agreed criterion for TFA acceptability when deploying quantitative measures, we present an assessment criterion that fully operationalizes each of the seven TFA domains and can be used in future studies to assess perceived intervention acceptability. Further developments may be needed to increase perceived acceptability of the VHS for self-harm among older adults, people from minority ethnic groups, and people with long-term health conditions. This study had some limitations. Participants were identified from a pre-existing sample of the general public who reported a previous history of self-harm and were recruited and incentivized by YouGov to complete the questionnaire. Therefore, the sample may not be fully representative of a community with a history of self-harm. However, YouGov attempted to overcome this by seeking the widest possible variation in terms of demographic characteristics, according to people who reported a history of self-harm.

Due to a lack of available studies among community samples with a history of self-harm, we were unable to determine whether our sample is representative of this population. However, we were able to compare our sample with data from the Adult Psychiatric Morbidity Survey of the general population to compare demographic characteristics and self-harm outcomes among people who reported a history of self-harm. Our sample closely resembled the Adult Psychiatric Morbidity Survey data [29] in terms of gender and age. However, our sample contained a lower proportion of people from a minority ethnic background compared with the national data. Our sample also reported a higher prevalence of suicidal ideation (lifetime and past year), suicide attempts (lifetime), and NSSH (lifetime) compared with national data. We were unable to identify data on self-harm outcomes in the past week and NSSH outcomes in the past week or past year. Finally, due to the lack of an appropriate instrument to measure the seven TFA constructs, the research team developed a measure that could be deployed for the present purposes. It would be valuable to conduct follow-up work that examines the psychometric properties of the tool to determine whether it could be used in the context of other contexts.

Conclusions

A brief intervention based on implementation intentions has been shown to be effective in reducing self-harm in people recently admitted to the hospital after an episode of self-harm. Our findings show high levels of acceptability more generally in people who have previously self-harmed, particularly among younger adults, people of White ethnic backgrounds, and people without long-term health conditions. The intervention still has room for improvement with respect to further modifications around language and technical features, but with emphasis on other target populations. It is hoped that this intervention will provide a useful tool for both individuals to construct their own personalized implementation intentions and as part of long-term support for preventing self-harm delivered by health care professionals.

Abstract

Background: In the era of potent antiretroviral therapy, a high level of condomless anal intercourse continues to drive increases in HIV incidence in recent years among men who have sex with men. Effective behavior change strategies for promoting HIV-preventive behaviors are warranted. Narrative persuasion is a novel health communication approach that has demonstrated its persuasive advantages in overcoming resistance to counterattitudinal messages. The efficacy of narrative persuasion in promoting health behavior changes has been well documented, but critical research gaps exist for its application to HIV prevention.

Objective: In this study, we aimed to (1) capitalize on narrative persuasion to design a web-based multisession intervention for reducing condomless anal intercourse among men who have sex with men in Hong Kong (the HeHe Talks Project) by following a systematic development process; and (2) describe the main components of the narrative intervention that potentially determine its persuasiveness.

Methods: Persuasive themes and subtopics related to reducing condomless anal intercourse were initially proposed based on epidemiological evidence. The biographic narrative interview method was used to elicit firsthand experiential stories from a maximum variation sample of local men who have sex with men with diverse backgrounds and experiences related to HIV prevention; different types of role models were established accordingly. Framework analysis was used to aggregate the original quotations from narrators into collective narratives under 6 intervention themes. A dedicated website was finally developed for intervention delivery.

Results: A series of video-based intervention messages in biographic narrative format (firsthand experiential stories shared by men who have sex with men) combined with topic-equivalent argumentative messages were produced and programmed into 6 intervention sessions. The 6-week intervention program can be automatically delivered and monitored online.

Conclusions: We systematically created a web-based HIV prevention intervention derived from peer-generated stories. Strategies used to enhance the efficacy of the narrative intervention have been discussed within basic communication components. This paper describes the methods and experiences of the rigorous development of a narrative communication intervention for HIV prevention, which enables replication of the intervention in the future.

Introduction

Men Who Have Sex With Men as an Important Target for HIV Prevention

Although a steadily decreasing trend has been observed for the global HIV burden, the epidemic has continued to expand among men who have sex with men [1]. For example, in Hong Kong, HIV prevalence has increased to 6.54% among men who have sex with men in recent years, while the rate has remained lower than 0.1% in the general population [2]. Despite biomedical advances in antiretroviral therapy and growing access to care and treatment, there is a paradoxical rise in the HIV incidence rate among men who have sex with men that was found to be significantly associated with an increase in condomless anal intercourse [3,4]. The disproportionate risk is also fueled by a relatively low level of HIV testing [5,6]. More efforts are necessary to develop effective behavior change strategies for the promotion of HIV-preventive behaviors among this vulnerable population.

Gaps in Communicating Persuasive Messages on HIV Prevention

Although health communication is widely acknowledged as an important tool for HIV prevention [7], existing persuasive communications has failed to significantly stimulate behavior change [8]. Previous interventions drew heavily on classic health behavior change theories to improve cognitive determinants (eg, risk perceptions) [7]; however, such interventions are based on the assumption that message recipients are so-called *rational individuals*, and the influence of recipients' preexisting state in accepting and executing desirable behaviors are omitted [9,10]. Counterattitudinal messages, namely persuasive topics and arguments that differ from recipients' own values or beliefs [11], are largely used for health behavior promotion. For instance, interventions for HIV prevention are commonly developed to target high-risk groups who engage in unprotected sex or have a low intention to use condoms consistently. Recipients are prone to argue against advocated positions to protect their previously held values or beliefs [11,12], adhering to or even engaging in more of the discouraged behavior [13]. There has long been a need to overcome such resistance to persuasive messages about HIV prevention [14].

Theoretical Mechanisms Underlying Narrative Persuasion

Over the past decade, narrative persuasion has been recognized as a promising avenue for health communication [12]. A narrative refers to "a representation of connected events and characters that has an identifiable structure [15]." The traditional approach—argumentation—otherwise features expository and didactic communication, with a logical presentation of overt arguments and factual information in the form of reasons and evidence to put forth a claim [12,15,16]. The two communication styles are fundamentally different in terms of information processing. Instead of receiving carefully elaborated explicit persuasive arguments in argumentative communication [17], narrative processing typically involves engagement with narrative elements and identification with characters (ie, vicarious experience of characters' cognitive and emotional responses) as casually and chronologically related events unfold in a coherent manner [16,18,19].

Narrative persuasion is grounded in both the Extended Elaboration Likelihood Model [18] and the Transportation-Imagery Model [20]; narrative persuasion has the advantage (over argumentation) of inhibiting negative responses to counterattitudinal messages because fewer targets are available for counterarguments, given its structure, with implicit persuasive content embedded in narrative elements; (2) there is less processing capacity and motivation to critically scrutinize core arguments that are presented in narrative format; and (3) identification with narrative characters facilitates psychological distancing from the recipients' initial story-inconsistent positions [16,18,19,21].

Remarkably, the incorporation of argumentative support further bolsters narrative persuasion [22,23], facilitating cognitive elaboration, rehearsal, and repetition, which leads to an enduring persuasive impact [18,24,25]. Prefacing argumentative messages by narrative messages could potentially predispose recipients to positively process and comprehend the overtly persuasive arguments [26-28]. Recipients could first shift from existing positions temporarily through engagement with the narrative messages, and fully assimilate the advocated positions into their own value structures through positive elaboration of the subsequent argumentation messages [18].

Harnessing Narrative Persuasion for Behavioral Interventions

Existing empirical evidence supports the efficacy of narrative interventions in promoting health behaviors relative to argumentation or null controls [29,30]. Relatively fewer studies have examined the effect of a combination of narrative and argumentative messages about cancer screening [31-33], diabetes self-care [34], and vaccination [35]; most were found to be more effective in changing the target behavior and its theoretical determinants than a single message format.

Several studies [36-41] have applied narrative communication to HIV prevention, but there are some critical research gaps. First, most narratives took the form of fictional stories (eg, entertainment-education soap opera) that were scripted by researchers; its efficacy in improving HIV-preventive behaviors is controversial [36,37]. However, other narrative types, including experiential stories, have received little exploration. Second, some interventions involved multiple behavior change strategies (eg, condom distribution), and thus, made it difficult to isolate the specific effect of the narrative component [38]. Third, the majority of previous narrative interventions addressed heterosexual risk for HIV [39,40]; we suppose that efficacy of narrative interventions is higher among homosexual people because HIV prevention is more personally relevant to this population group, and personal relevance of a health topic can enhance narrative efficacy [41]. Finally, no studies have been conducted among Asian populations. More research on narrative persuasion in different contexts is warranted because shared stories inherently embody rich cultural information that shapes behaviors and responses to persuasive communication [9,42].

Utilizing Web-Based HIV Prevention Interventions for Men Who Have Sex With Men

Web-based technology has been recognized as a powerful tool to efficiently reach target populations and deliver behavioral interventions to enhance responses to the ongoing HIV epidemic among men who have sex with men [6]. A recent meta-analysis [43] of 44 studies across 12 countries and regions found that eHealth interventions effectively reduced condomless anal intercourse, reduced multiple sex partnership, and increased the uptake of HIV testing among men who have sex with men. Moreover, a considerable proportion of men who have sex with men actively use the internet for socializing and sex-seeking, which has been found to increase likelihood of condomless anal intercourse, and consequently, risk of HIV infection [44-46]. In Hong Kong, approximately 70% of men who have sex with men engage in sex-seeking online [47]. Hence, web-based interventions can seize the opportunity to promote HIV prevention among men who have sex with men at a crucial point when they tend to engage in risky sexual practices. In addition, Chinese men who have sex with men use the internet as the primary source of information about sexual health, HIV, and other sexually transmitted infections (STIs), and accept the use of eHealth in supporting their sexual health care [48].

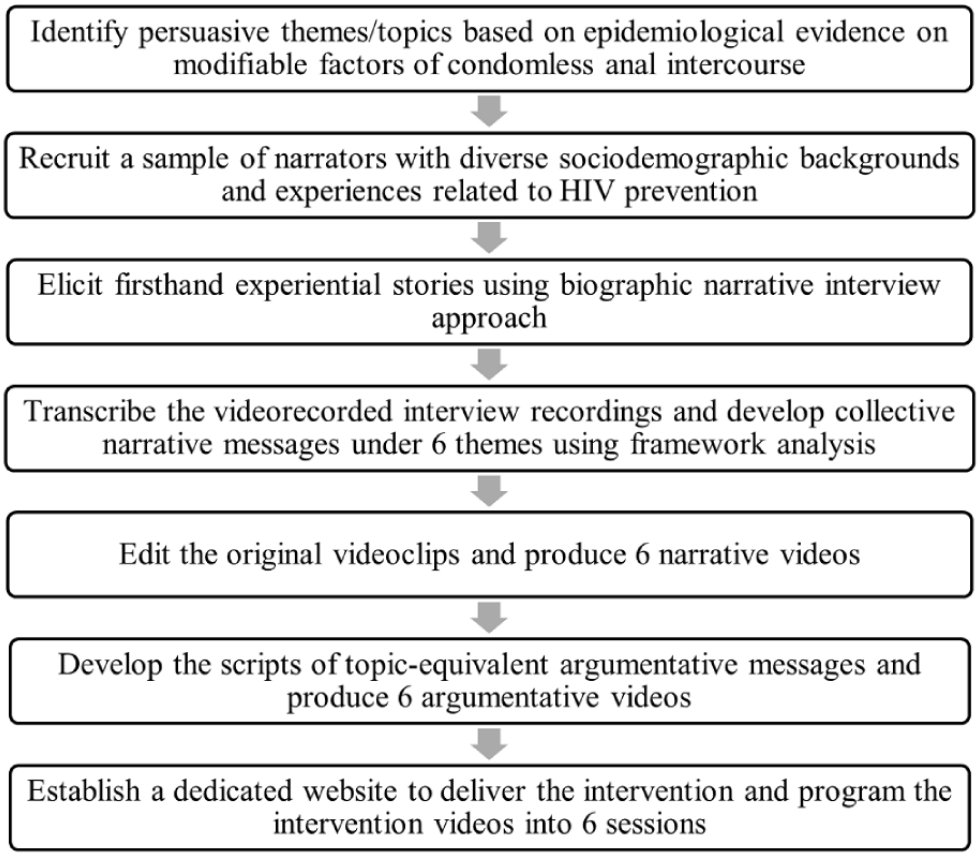
In this study, we developed a web-based narrative intervention for HIV prevention among men who have sex with men in Hong Kong (the HeHe Talks Project) to deliver a series of video-based persuasive messages to reduce condomless anal intercourse. Biographic narratives (firsthand experiential stories shared by local men who have sex with men peers) were combined with topic-equivalent argumentative messages.

Methods

Ethics and Procedure Overview

Informed consent was obtained from all participants involved in this project. Ethical approval was obtained from Joint Chinese University of Hong Kong–New Territories East Cluster Clinical Research Ethics Committee (reference number 2014.274-T). A roadmap of the development procedure is presented in Figure 1.

Figure 1. Procedure for developing the narrative intervention program (HeHe Talks).



Identifying Persuasive Themes and Subtopics

We conducted a review of modifiable and significant predictors of HIV/STI infection and condomless anal intercourse among local men who have sex with men in publications and government documents to inform topic selection. Factors were categorized into cognitive (eg, risk perceptions), interpersonal (eg, sex partnership), contextual (eg, substance use), and sexual practice–specific (eg, group sex). In addition, it has been suggested that HIV testing behavior should be addressed simultaneously, given its significant relationship with condomless anal intercourse among Chinese men who have sex with men [49,50]. Six session themes were initially proposed: knowledge about HIV/STI, condom use and partnership, condom use and risky contexts, condom use and substance use, efficacy of condom use, and HIV testing (Multimedia Appendix 1).

Qualitative evidence was obtained by conducting a focus group discussion with 5 Hong Kong men who have sex with men (age: range 28-38 years). The focus group was led by a public health researcher and a health psychologist and was used to assess knowledge, views, and information needs regarding HIV prevention and condomless anal intercourse. Most interviewees had university-level educations and above (4/5) and had full-time jobs (4/5); 2 interviewees reported consistent condom use for anal sex, and 1 had engaged in substance use–facilitated anal sex in the previous 6 months.

This focus group informed refinement of the intervention topics. For example, the participants emphasized the phenomenon of "complacency about HIV" among local men who have sex with men (ie, that strong belief about antiretroviral therapy efficacy contributed to low-risk perceptions and high motivation to engage in condomless anal intercourse). Proposed intervention topics were sent to several HIV specialists; we further revised the topics based on their feedback. For example, they suggested focusing on drug use other than alcohol consumption to address reducing substance use–facilitated condomless anal intercourse; accordingly, the subtopic *impact of alcohol use on condomless anal intercourse* was removed.

Recruiting Narrators and Operationalizing the Role Models

The Sabido entertainment-education strategy [25] was applied to establish 3 types of role models: (1) positive characters, who engage in consistent condom use while having anal intercourse and undergo regular HIV testing, and consequently, maintain sexual health; (2) negative characters, who engage in condomless anal intercourse and do not regularly undergo HIV testing, and are negatively affected (eg, infected with HIV or STI); and (3) transitional characters, who once engaged in risky sexual behaviors and suffered negative consequences and then adopted more positive attitudes and behaviors. Role modeling has been adopted in previous entertainment-education programs for HIV prevention [37,39]. Maximum variation sampling was used to recruit 2 to 3 HIV-positive and 6 to 7 HIV-negative narrators with different experiences and backgrounds [51].

Criteria for all narrators were (1) men who have sex with men; (2) age ≥18 years; (3) Hong Kong residents; (4) able to speak Cantonese fluently; and (5) of sufficient mental and physical capability to take part in a 2-hour interview. Criteria for HIV-positive narrators were (1) confirmed or high probability

of having acquired HIV by sexual transmission; (2) encountered negative experiences due to living with HIV; (3) once or currently undergoing antiretroviral treatment; and (4) having engaged in any condomless anal intercourse with male sex partners prior to the diagnosis. Criteria for HIV-negative narrators were (1) having undergone at least 1 HIV test in the previous year, with the most recent test having yielded a negative result; (2) consistently used condoms with male sex partners (in every sexual encounter in the previous year); and (3) having positive perceptions about condom use for HIV prevention. Prospective narrators were nominated and approached by the research team and a collaborating nongovernmental organization (AIDS Concern). A survey was administered to establish their eligibility and to create a profile for each individual, with background information (eg, age and sexual partnership) and specific experiences related to HIV prevention (eg, contracting HIV/STI infections, engaging in condomless anal intercourse).

Developing Persuasive Messages in Narrative and Argumentation Formats

Biographic-Narrative Interpretive Method [52,53] was employed to elicit narratives for the development of health promotion messages. A semistructured interview guide was drafted around the proposed topics and tailored to each narrator's profile. Two interviewers (MX and NK) and a professional camera operator were involved in the individual interviews with each of the selected narrators. One of the interviewers (NK) was a senior practitioner from the collaborating nongovernmental organization who had rich experience in providing community support services to local men who have sex with men; he took a leading role in the narrative interviews and preinterview negotiations, particularly with HIV-positive narrators, to ensure that the questions were delivered in a comfortable and respectful manner.

Interviewers first briefed the narrator on interview procedures and established rapport. Individual interviews started with a single question that was thematically or temporally focused, to elicit narratives of personal experiences, such as life after being diagnosed as HIV positive or an occasion of safe sex practices at a gay venue. Narrators were free to tell their story in the manner of their choosing (to provoke the narration within their own system of relevancy), and interviewers merely provided nondirectional facilitative support. Keyword notes were also taken to document the topics of interest arising in the original narrative, which helped inform follow-up questions for additional narrative to enrich the overarching story. After narrative-seeking questions, interviewers asked additional questions about topics that had not been raised or for purposes other than narrative extraction (eg, to make a persuasive appeal to the audience).

Videorecordings of the interviews were transcribed. Framework analysis was conducted to develop themed narrative messages using NVivo (version 11, QSR International) in 5 steps [54]: (1) familiarizing: carefully reading the transcripts and observational notes to gain a comprehensive understanding of the data; (2) framing: devising and refining a coding framework drawn on both predefined and emergent themes and subtopics; (3) indexing: systemically sorting original narrative quotations within the thematic framework; (4) charting: grouping indexed narratives from different narrators for each coded subtopic; (5) mapping: aggregating subtopics and corresponding quotations in a coherent manner under each of the 6 session themes to generate collective narrative messages. For each subtopic, argumentative messages were drafted based on the narrative content, by presenting didactic statements, factual claims, logical reasons, and statistical evidence.

Producing Intervention Videos and a Web-Based Delivery Platform

The videorecordings of the original narratives were segmented and re-organized to create 6 videos for the themes derived from the framework analysis. A background profile was presented for each narrator at first appearance in the videos; persuasive appeals from 1 or 2 narrators were used as epilogues. Videos were sent to the narrators to get their approval. Three male speakers (a nongovernmental organization staff and 2 research assistants) were invited to deliver scripted, videorecorded argumentative messages for each theme. Supplementary material, such as openings, subtitles, images, and background music, were added, and the finalized videos were programmed into 6 intervention sessions. Each included 2 videos with narrative (15-20 minutes) and argumentative (8-10 minutes) messages and a postvideo quiz set to enhance participants' dedication to intervention content. The narrative videos were longer than the topic-equivalent argumentative videos due to the inherent natures of storytelling (ie, portraying a series of events) and argumentation (ie, listing facts and evidence). A dedicated website was developed to deliver intervention sessions automatically, and a content management system was established for real-time monitoring of engagement in the program.

Results

Narrator Characteristics

A total of 36 men who have sex with men were screened, and 9 men were selected as narrators (Table 1). Two men, who had been diagnosed as HIV-positive 3 years prior, served as negative role-model narrators. The other men had recent HIV-negative test results (within 1 year): 3 men had never engaged in condomless anal intercourse with a male sex partner in their lifetime, and thus, served as positive role-model narrators; 4 men had once engaged in condomless anal intercourse but had consistently used condoms in the past year, and thus, served as transitional role-model narrators.

Narrators had varying sexual practices (Table 2): 3 had regular partners, and 5 had casual partners; 4 had engaged in both insertive (taking a top role) and receptive (taking a bottom role) anal intercourse; 6 had engaged in *casual fun*—anal intercourse with casual sex partners in collective sex environments (eg, gay saunas, group sex events [55]); 5 had engaged in *chem-sex*—anal intercourse while under the influence of psychotropic substances (eg, methamphetamine).

Table 1. Background characteristics of the 9 narrators.

Narrator (role model type)	Age (years)	Employment	Years as member[a]	HIV[b] status	History of other STIs[c] (type)	Type of HIV testing venues visited
A (negative)	24	Unemployed	Not disclosed	Positive	Yes (syphilis)	Community organization
B (negative)	24	Unemployed	>10	Positive	No	Public social hygiene clinic
C (transitional)	30	Full-time	>10	Negative	Yes (urethritis, pubic lice)	Public social hygiene clinic; community organization
D (positive)	38	Full-time	>10	Negative	No	Community organization; private clinic
E (transitional)	26	Full-time	>5	Negative	No	Public social hygiene clinic; community organization
F (transitional)	36	Full-time	>10	Negative	Yes (syphilis)	Community organizations
G (positive)	30	Full-time; Part-time	>10	Negative	No	Public social hygiene clinic; community organization
H (transitional)	32	Full-time	>10	Negative	No	Community organization
I (positive)	22	Student	>5	Negative	No	Community organization

[a]Period between self-identification as homosexual or bisexual and involvement in the local community of men who have sex with men.

[b]HIV: human immunodeficiency virus.

[c]STIs: sexually transmitted infections.

Table 2. Characteristics of the 9 narrators related to sexual practices (ie, anal intercourse with male sex partners prior to diagnosis or in the past year).

Narrator (role model type)	Sexual partnership	Sexual role	Consistent condom use[a]	Casual fun[b] (venue)	Chem-sex[c] (drug type[d])
A (negative)	Not recorded	Not recorded	No	No	No
B (negative)	Not recorded	Not recorded	No	Yes (gay sauna; private party)	Yes (meth, g water, foxy, rush poppers)
C (transitional)	Regular; casual	Top; bottom	Yes (recent)	Yes (gay sauna; private party)	Yes (rush poppers)
D (positive)	Regular	Top	Yes (lifetime)	No	No
E (transitional)	Casual	Top; bottom	Yes (recent)	Yes (gay sauna)	Yes (meth, g water, foxy)
F (transitional)	Casual	Bottom	Yes (recent)	Yes (gay sauna)	Yes (meth, foxy, ecstasy)
G (positive)	Regular	Top	Yes (lifetime)	No	Yes (rush poppers)
H (transitional)	Regular; casual	Top; bottom	Yes (recent)	Yes (gay sauna)	No
I (positive)	Casual	Top; bottom	Yes (lifetime)	Yes (gay sauna)	No

[a]The response *recent* referred to having once engaged in any condomless anal intercourse in lifetime but consistently using condoms within the past year; the response *lifetime* referred to having never engaged in condomless anal intercourse in lifetime.

[b]This refers to engaging in anal intercourse with casual sex partners at any local public venues.

[c]This refers to taking illicit drugs during or prior to anal intercourse.

[d]Meth, g water, foxy (ie, foxy methoxy), rush poppers, and ecstasy as slang for methamphetamine; gamma hydroxybutyrate/gamma butyrolactone; 5-methoxy-N,N-diisopropyltryptamine; inhalant alkyl nitrites; and 3,4-methylenedioxy-methamphetamine, respectively, were reported.

Topics and Contents of Persuasive Messages

There are 6 intervention sessions in total (Table 3); all sessions start with persuasive messages in the narrative format. The first session (A New Era of HIV Prevention) introduces the outcomes of HIV infection in the era of potent antiretroviral therapy. The HIV-positive peers narrate their experiences of receiving a diagnosis and living with HIV, with a focus on the severity of infections, negative influences on physical health and personal life, and co-infections with other STIs. The second session (Partnership and Protected Sex) includes experiences of condom use with different types of sexual partners, including actively negotiating condom use and making sexual decisions, resisting sexual pressure from partners, and balancing emotional relationships and safe sex practices. The third session (Casual Fun and Protected Sex) presents both obstacles to condom use experienced in high-risk contexts (eg, dark rooms in gay saunas and group sex parties) and practical skills for coping with unintentional condomless anal intercourse. The fourth session (Chem-Sex) focuses on potential exposure to psychotropic substances at local gay venues, negative influences of substance use on sexual practices and physical health, and problems related

to drug addiction. The fifth session (Efficacy of Condom Use) focuses on consistent and correct condom use for anal intercourse as well as its efficacy in preventing STIs. The last session (HIV Testing) includes experiences of undergoing HIV testing and counseling at different service sites and emphasizes the importance of regular testing while adhering to safe sex practices. Each narrative video ends with narrators appealing to the listeners. For example, the first session includes a positive message from a HIV-positive narrator; he talks about gradually accepting and recognizing his infection status, adhering to treatment, and having hope for a new future.

Table 3. An overview of topics in the narrative messages for each intervention session.

Themes and subtopics of narrative messages	Message sources (narrator and role model type)
Session 1: A New Era of HIV Prevention	
1. HIV diagnosis	A (negative) and B (negative)
2. Life impact of living with HIV	A (negative) and B (negative)
3. Problems encountered during HIV treatment	A (negative) and B (negative)
4. Co-infection with other sexually transmitted diseases	A (negative)
Session 2: Partnership and Protected Sex	
1. Active communication about condom use and assessment of partner(s)' HIV risk	D (positive), C (transitional), and E (transitional)
2. Assertive responses to unwanted condomless sex	A (negative), D (positive), G (positive), C (transitional), and E (transitional)
3. Barriers to condom use when in an emotional relationship	D (positive), G (positive), C (transitional), and E (transitional)
Session 3: Casual Fun and Protected Sex	
1. Risk of condomless sex with casual partners and norm about condom use at gay saunas	B (negative), D (positive), I (positive), C (transitional), E (transitional), and F (transitional)
2. Unintentional condomless sex encountered during casual fun	B (negative), D, I (positive), C (transitional), E (transitional), and F (transitional)
3. Contextual risk of group sex parties	B (negative), D (positive), C (transitional), and H (transitional)
Session 4: Chem-Sex	
1. Impact of drug abuse on sexual practices	B (negative), E (transitional), F (transitional), and H (transitional)
2. Impact of drug abuse on other health outcomes	B (negative), D (positive), C (transitional), E (transitional), and F (transitional)
3. Exposure to drugs when seeking sex	B (negative), D (positive), G (positive), I (positive), C (transitional), E (transitional), and F (transitional)
4. Drug addiction	B (negative), E (transitional), and F (transitional)
Session 5: Efficacy of Condom Use	
1. Protective efficacy of condom use	D (positive), G (positive), I (positive), and E (transitional)
2. Correct condom use	D (positive), I (positive), C (transitional), and E (transitional)
3. Consistent condom use	D (positive), G (positive), C (transitional), F (transitional), and G (transitional)
Session 6: HIV Testing	
1. Local HIV testing services	D (positive), G (positive), C (transitional), E (transitional), and H (transitional)
2. Regular HIV testing	A (negative), G (positive), I (positive), C (transitional), and H (transitional)

The topic-equivalent argumentative messages are delivered after narratives. For example, for the subtopic *Consistent condom use* (in Session 5), the narrative presents experiences of condomless sex and STI infections from an HIV-positive narrator, and the argumentative message is

> *If the sexual partner is HIV-positive, one could get infected through only a "single" episode of unprotected sexual encounter, ...research studies demonstrated that there was no significant difference in HIV risk between men who have sex with men who "inconsistently use condoms" and those who "have never ever used condoms."*

After videos, a quiz question is asked. For example, "According to the video messages, what type of immune cell was primarily attacked by HIV?" One correct response options ("CD4 cell") and 2 false response options ("CD3 cell" and "CD8 cell") are provided. Feedback and reinforcement are not given after the quiz, although users can return to the video during and after the quiz.

Web-Based Intervention Program

The program website can deliver the intervention automatically in a standardized manner: the 6 intervention sessions can be released sequentially on a weekly basis, and each session is accessible upon completion of the preceding session. Users can be assigned a unique password-protected account to access intervention content within a 6-week period, and activities are automatically recorded (eg, the dates and time of completing an intervention video). The program can also send out reminders when a new session is released, or users fail to engage in any activity for 2 to 3 weeks.

Discussion

General

We developed a theory-based and evidence-based narrative communication intervention for HIV prevention among men who have sex with men. The communication strategies used by this intervention program to enhance the potential narrative efficacy can be systematically discussed within the 4 basic components of health communication: message, source, recipient, and channel [12].

Message

Narratives took the form of firsthand experiential stories, in contrast to commonly used fictional stories [12]. To maintain the authenticity of personal experience narratives, which is the key to exploiting its advantages (ie, being perceived as credible, evoking high engagement and inhibiting counterarguing) over those of professionally generated stories in persuasion [15,56], we used well-developed methods for biographic narrative interviews to obtain stories [52]. The narrators were always given the space and time to narrate without any interruption; while the interviewers performed active listening by intermittently giving prompts, with nonverbal posture or empathetic and unobtrusive mirroring of the emotions expressed, throughout the storytelling. In addition, the intervention messages were produced by directly extracting biographic accounts from the videorecorded interview. Narratives conveyed in first-person are more effective than third-person narratives for STI prevention [35], because an individual is more likely to mentally embody characters' perspectives (ie, identification with characters) [57]. These strategies also strengthened the incorporation of cultural codes including visual presentations, language, and idioms that could heighten narrative engagement [58]. Furthermore, this narrative intervention featured subsequent provision of argumentative support. The argumentative messages were developed to match the themes and subtopics of the narrative messages, to reinforce the predisposition created by narrative persuasion but to avoid provoking counterargument [18].

Source

Collective narratives were extracted from a maximum variation sample of local men who have sex with men peers in this study to improve the comprehensiveness of persuasive content [15] and appeal to different audience segments [25]. The diversity of narrators allowed 3 types of characters to be established. The transitional role model was utilized the most in order to reduce selective avoidance of counterattitudinal messages about HIV prevention [19] and increase perceived homophily and realism of the characters, and thus, facilitate narrative processing [18], and enhance self-efficacy in changing risky sexual behaviors [59]. Positive and negative role models were also used to reinforce the consistency of condom use. Moreover, biographic narratives were a representation of the narrators' views of their own life-course, beliefs, interpretative schemata, and principles of judgement [52], which provided authentic and comprehensive portrayals of the characters, and in particular, avoided fostering negatively biased images of HIV-positive peers. For instance, the narrators with a history of HIV/STI shared their experiences of infection and risky sexual encounters as well as how they strived to adhere to treatments and improve their HIV-preventive behaviors.

Recipients

The targeted recipients are Chinese men who have sex with men, a highly marginalized community where members are strongly connected to each other [60]; social norms and community involvement have been found to be positively associated with their HIV-preventive behaviors [61,62]. To produce culturally authentic messages and engage the recipients [9], members of the local men who have sex with men community were actively involved throughout the intervention development, including determining persuasive topics, screening eligible narrators, assisting in narrative interviews, and generating and delivering intervention messages. Such participatory strategies can be applicable to other similar contexts where the community tend to share motives and values regarding health behavior.

Channel

The intervention comprises web-based videos. Video-based narratives have demonstrated strengths in building affection, facilitating identification with characters, and message elaboration, thereby promoting behavior changes [29,63,64]. Narrators' ability to organize and articulate stories in videorecorded interviews were carefully evaluated during the recruitment. The web-based delivery platform allows navigation of the content at the user's own pace without the presence of researchers; users are less likely to mask emotional responses and experience greater immersion when they view narratives alone [56].

Conclusions

In response to the call for innovative health communication approaches for HIV prevention, this paper describes the scientific rationale and rigorous procedure of applying narrative persuasion to promote HIV-preventive behaviors among men who have sex with men. This web-based narrative communication intervention can be easily replicated in other contexts and can be incorporated into comprehensive HIV prevention services.

Acknowledgments

This study was funded by the University Grants Committee of Hong Kong 2015-2016 General Research Fund (reference 14612615). We would like to express our heartfelt gratitude to all the narrators and participants in this project.

Abstract

Background: Atrial fibrillation (AF) is related to a variety of chronic diseases and life-threatening complications. It is estimated that by 2050, there will be 72 million patients with AF in Asia, of which 2.9 million will have AF-associated stroke. AF has become a major issue for health care systems.

Objective: We aimed to evaluate the effects of a web-based integrated management program on improving coping strategies, medication adherence, and health-related quality of life (HRQoL) in patients with AF, and to detect the effect on decreasing readmission events.

Methods: The parallel-group, single-blind, prospective randomized controlled trial recruited patients with AF from a medical center in northern Taiwan and divided them randomly into intervention and control groups. Patients in the intervention group received the web-based integrated management program, whereas those in the control group received usual care. The measurement tools included the Brief Coping Orientation to Problems Experienced (COPE) scale, Medication Adherence Rating Scale (MARS), the three-level version of the EuroQoL five-dimension self-report questionnaire (EQ-5D-3L), and readmission events 2 years after initiating the intervention. Data were collected at 4 instances (baseline, 1 month, 3 months, and 6 months after initiating the intervention), and analyzed with generalized estimating equations (GEEs).

Results: A total of 231 patients were recruited and allocated into an intervention (n=115) or control (n=116) group. The mean age of participants was 73.08 (SD 11.71) years. Most participants were diagnosed with paroxysmal AF (171/231, 74%), and the most frequent comorbidity was hypertension (162/231, 70.1%). Compared with the control group, the intervention group showed significantly greater improvement in approach coping strategies, medication adherence, and HRQoL at 1, 3, and 6 months (all $P<.05$). In addition, the intervention group showed significantly fewer readmission events within 2 years (OR 0.406, $P=.03$), compared with the control group.

Conclusions: The web-based integrated management program can significantly improve patients' coping strategy and medication adherence. Therefore, it can empower patients to maintain disease stability, which is a major factor in improving their HRQoL and reducing readmission events within 2 years.

Trial Registration: ClinicalTrials.gov NCT04813094; https://clinicaltrials.gov/ct2/show/NCT04813094.

KEYWORDS

web-based program; atrial fibrillation; coping strategy; medication adherence; readmission; health-related quality of life

Introduction

Atrial fibrillation (AF) is related to a variety of chronic diseases and life-threatening complications [1]. Owing to progressive aging of the population and the force of unhealthy lifestyles, the global incidence of AF is expected to achieve a twofold increase in the next decade [2]. According to the 2010 Global Burden of Disease Study report, approximately 33 million people worldwide suffer from AF [3]. It is estimated that by 2050, there will be 72 million AF patients in Asia, of which 2.9 million will have AF-associated stroke [4]. Compared with Europe and the United States, the population of AF has increased more rapidly in Asia [5-7], suggesting that AF has become a major issue for Asian health care systems.

The asymptomatic nature of AF often makes patients unaware of the subsequent stroke [2]. Nearly 40% of AF patients suffer from cerebrovascular accidents for this reason [1,8,9]. AF is the most common cause of cardioembolic stroke, which is particularly severe in terms of high mortality and serious disability [2]. The complications of AF lead to frequent visits to the emergency department, hospitalization and readmission, and impaired quality of life [10-12].

Anticoagulation is the preferred medical intervention to prevent stroke in patients with AF [7]. Nonetheless, a European clinical trial showed that nearly 40% of patients with AF withdrew anticoagulants within 1 year following the initiation of the treatment [13]. In fact, compliance to anticoagulants decreases with time in patients with AF [14], which is a major factor contributing to stroke in this population [15,16]. As such, anticoagulant incompliance worsens the prognosis of AF in terms of increased readmission and mortality rates [17-19]. Ensuring anticoagulant adherence in patients with AF is an important issue for stroke prevention and disease recovery.

AF frequently occurs in patients with multiple concurrent chronic diseases including hypertension, ischemic heart disease, and heart failure, which increase the number of medications used. Patients taking several medications have many adverse effects and tend to be noncompliant to treatments [20]. Therefore, advanced and integrated disease management programs are essential for AF patients to achieve successful disease control [21]. Prior studies support the use of eHealth to assist patients in conducting advanced disease management. A few randomized controlled trials had investigated the impact of eHealth on medication adherence in patients with AF for 3 months [22,23]. Although the use of eHealth management significantly improved medication adherence at 3 months after intervention, the long-term effects on medication adherence remain to be investigated [24]. Again, integrated management aims to improve patients' disease knowledge and empower patients to manage their disease [9,24,25]. Integrated management needs the involvement of patients and multidisciplinary AF teams. Multidisciplinary professionals using technological support such as eHeath provide disease information and self-care skills to AF patients [9]. As a result, advanced and integrated disease management programs are expected to improve medication adherence and disease control in patients with AF.

In this study, we aimed to evaluate the effects of a web-based integrated management program on improving coping strategies, medication adherence, and health-related quality of life (HRQoL) in patients with AF, and to detect its effect on decreasing readmission events. Therefore, we have two hypotheses. The first hypothesis is that the AF patients receiving the web-based integrated management program in the intervention group would use more approach coping strategies and improve their medication adherence and HRQoL compared with the patients in the control group. The second hypothesis is that the patients in the intervention group would have fewer 2-year readmission events than the patients in the control group.

Methods

Design

This study was a prospective, single-blind, randomized controlled trial with repeated measurements to determine the effects of a 6-month web-based integrated management program on improving the coping strategy, medication adherence, and HRQoL, and decreasing 2-year readmission events in patients with AF. Data were collected from October 2018 to January 2021. We collected the data at 4 time points: baseline (prior to randomization, T0), 1 month after beginning the intervention (T1), after completing 3 months of the intervention (T2), and after completing 6 months of the intervention (T3).

Participants

Participants were recruited from the cardiovascular outpatient department at a medical center in northern Taiwan through convenience sampling. Patients were included if they met the following criteria: (1) diagnosed with AF by cardiologists, (2) receiving anticoagulant treatment, (3) aged above 20 years, (4) able to speak and read Taiwanese or Mandarin to understand and follow instructions, and (5) able to use a mobile phone or computer correctly. The exclusion criteria included the following: (1) diagnosed with mental disorders or (2) involved in other clinical trials.

In total, 324 patients were screened in the cardiovascular outpatient department, and 258 patients were eligible to be included. Among the eligible patients, 26 patients refused to participate. The remaining 232 participants were randomly assigned into 2 groups by blocked randomization using a web-based system [26]. Finally, 116 participants were assigned into the intervention group and 116 participants were assigned into the control group. The patients in the intervention group received the web-based integrated management program, whereas those in the control group received consultations and were coached thrice by a research nurse over telephone.

Ethical Considerations

This study was approved by the Institutional Review Board of the participating hospital (IRB: 2-107-05-081; ClinicalTrials.gov NCT04813094) and conducted in accordance with the principles of the Declaration of Helsinki revised in 2000. A research nurse explained the research process to each participant and obtained informed consent from them. We ensured that the participants were kept anonymous. In addition, participants were informed that they had the right to withdraw from the study at any time for any reason.

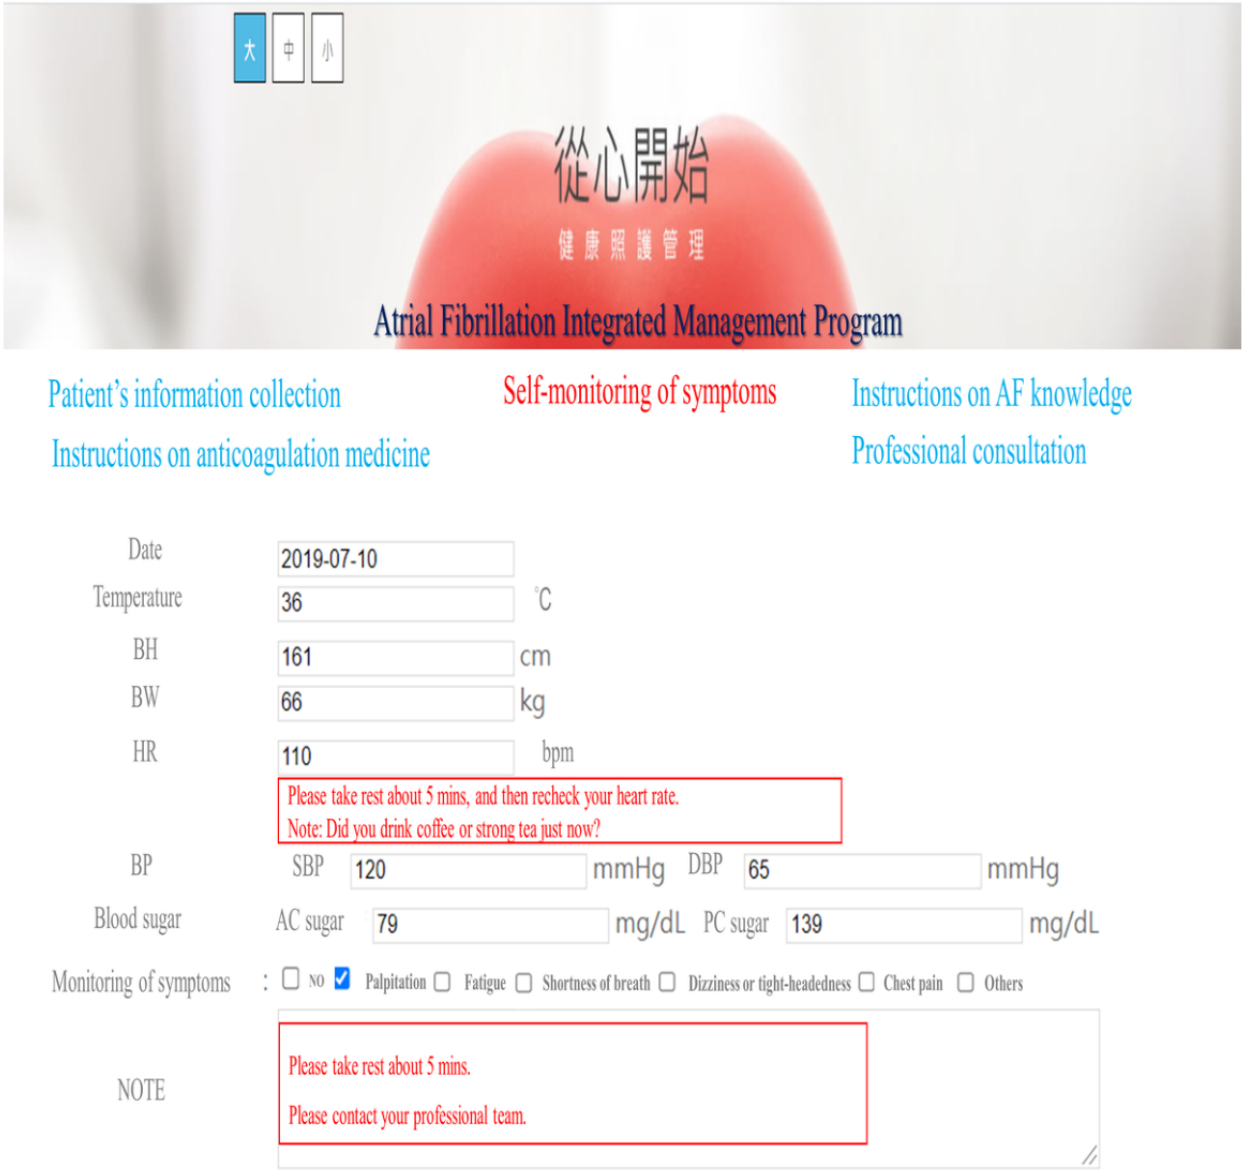
Study Interventions

The web-based integrated management program was conducted in the cardiovascular outpatient department. Participants had their own account and password to log in to the web-based program via mobile phones or computers. The program included five domains: patient information collection, instructions on AF knowledge, instructions on anticoagulation medicine, self-monitoring of symptoms, and professional consultation. In the patient information collection domain, the participants were able to provide and read their information, including age, gender, years of education, type of AF, modified European Heart Rhythm Association (mEHRA) classification, comorbidities, and use of anticoagulation medication. In the instructions on AF knowledge domain, participants were able to receive information about AF through texts and videos, including an introduction to AF, the risk factors and symptoms of AF, how to prevent stroke in patients with AF, and how to manage a healthy lifestyle. The videos were also available in Taiwanese and Mandarin. In the instructions on anticoagulation medicine domain, the participants were able to obtain descriptions about a variety of anticoagulant medicines. There was textual information about anticoagulant medicines, such as the effectiveness and adverse effects of these medicines, and precautions to be taken, as well as pictures of the corresponding medicines to serve as references for the participants. In the self-monitoring of symptoms domain, participants could provide record their symptoms every day, which could assist them in monitoring their disease progress and provide cardiologists with references to regulate their treatment. In the professional consultation domain, participants could receive consultations from multidisciplinary professionals on any issues related to AF at any time. All the participants had their own private consultations with clinical professionals. The research nurse also sent messages every day to monitor the participants' condition through the messaging function of this domain. When the participants had an emergency event, they could receive help to manage this situation through textual information or telephonic coaching (Figures 1 and 2).

After face-to-face presentations, we ensured that the participants fully understood the instructions for using this web-based program by the return demonstration method. We reviewed their understanding of the program at the next outpatient visit. In addition, we instructed participants on managing AF and anticoagulant treatment through the web-based program and provided the AF management manual to them.

Figure 1. Screenshot of the Atrial Fibrillation Integrated Management Program. BH: body height; BW: body weight; po: per os (Latin term meaning orally) QD: qaque die (Latin term meaning one a day).

Figure 2. Screenshot showing self-monitoring of symptoms. AF: atrial fibrillation; BH: body height; BW: body weight; HR: heart rate; BP: blood pressure; DBP: diastolic blood pressure; SBP: systolic blood pressure.



Control Group

Patients in the control group received standard instructions. The AF management manual was provided to them with explanations. In addition, we provided telephonic coaching thrice, which taught participants how to manage their disease at 1 month, 3 months, and 6 months after random assignment.

Measurements

The Clinical and Demographic Information Form

Demographic and clinical characteristics, including age, gender, education, marital status, type of AF, mEHRA classification, comorbidities, and use of anticoagulation medicine, were recorded before random assignment. The mEHRA classification was used to categorize AF patients according to their symptom severity. The mEHRA classification has five levels including class I, none; class IIa, mild; class IIb, moderate; class III, severe; and class IV, disabling [9].

Coping Strategies

The participants' coping strategies were measured using the Brief Coping Orientation to Problems Experienced (COPE) scale [27]. This 28-item instrument contains 2 subscales: approach coping (8 items) and avoidance coping (6 items). The approach coping strategies show how individuals actively seek resources to deal with their health problems (active coping, planning, positive reframing, acceptance, humor, religion, and using instrumental and emotional support). The avoidance coping strategies show how individuals attempt to divert attention away from events (self-distraction, denial, venting, substance use, behavioral disengagement, and self-blame) [28]. A higher score indicated that the patient often uses this coping strategy. In this study, the Brief COPE was translated into Chinese. The content validity for the Chinese version of the Brief COPE was examined by five cardiology experts. The

content validity index was 0.83. A previous study reported that the Cronbach α of each item ranged between .50 and .90 [27].

Medication Adherence

The participants' medication adherence was measured by the Medication Adherence Rating Scale (MARS) [29]. This instrument includes three domains: medication adherence behavior, attitude toward taking medication, and attitude toward the adverse effects of medication. Each item has two options. Participants choose an answer based on their prescription. The total possible score ranges from 0 to 10. A higher score indicates better medication adherence. In this study, the MARS was translated into its Chinese version. The content validity of the Chinese version was examined by five cardiology experts. The content validity index was 0.92. The Cronbach α of the MARS was .75 [29].

HRQoL Measurement

The participants' HRQoL was measured by the three-level version of the EuroQol five-dimension self-report questionnaire (EQ-5D-3L). The instrument includes 2 subscales: the EQ-5D descriptive system (5 items) and EuroQol visual analog scale (EQ-VAS). The EQ-5D descriptive system had five domains: mobility, self-care, usual activities, pain/discomfort, and anxiety/depression. Each item was rated at 3 levels: no problems at level 1 and extreme problems at level 3. The scores were converted into a single summary score. The EQ-VAS was a 20 cm visual analog scale to let participants self-assess their health status. The range of the EQ-VAS was from 0 to 100. A high score indicated the best state of health. We used the Chinese version of the EQ-5D-3L, which has adequate validity and reliability [30].

Readmission Events Within 2 Years

After recruiting the patients in the study, we followed their readmission events for 2 years. We collected these data through chart reviews of each participant.

Data Analysis

Statistical analyses were conducted using SPSS (version 23.0; IBM Corp). Categorical variables were reported as frequencies and percentages, and continuous variables with normal distributions were reported as means with SDs. The initial differences between groups for demographic characteristics and the baseline scores of each scale were examined with independent *t* and chi-square tests. The effects of the web-based integrated management program on the coping strategy, medication adherence, HRQoL, and readmission events were examined using a generalized estimating equation (GEE) [31]. The significance level was defined by a two-tailed *t* test with $P<.05$.

We used univariate logistic regression to assess the association between patient characteristics, including group assignment, and readmission events within 2 years and identify the predictor variables. The readmission event within 2 years was coded as the dependent variable with 1 denoting a readmission event within 2 years after intervention and 0 denoting no readmission event within 2 years after intervention. The predictor variables with $P<.20$ were eligible for inclusion in the multivariable logistic regression model for measuring the outcome. In the multivariable logistic regression model, predictor variables with two-tailed *t* tests and $P<.05$ were considered significant [32]. We used the GPower (Version 3.1, Heinrich-Heine-Universität [33]) procedure with an α value of .05, a medium effect size of 0.25, and sample size of 231 to conduct a post hoc statistical power analysis [33]. Finally, the statistical power of this study was greater than 0.8.

Results

Participant Characteristics

A total of 258 patients were recruited from the outpatient department of the study hospital according to the inclusion criteria. Of these patients, 26 refused to participate. At the end of the study, the complete data of 115 participants in the intervention group and 116 participants in the control group were included for the statistical analysis. One participant in the intervention group was lost to follow-up owing to emigration (Figure 3). The mean age of the participants was 73.08 (SD 11.71) years. Half of the participants were male (116/231, 50.2%), and over half of the participants were married (155/231, 67.1%). Most participants were diagnosed with paroxysmal AF (171/231, 74%), and the most frequent comorbidity was hypertension (162/231, 70.1%). Assessing the classification of AF symptoms through mEHRA indicated that 44.6% (103/231) of the participants were class I, 22.9% (53/231) were class IIa, 14.7% (34/231) were class IIb, and 17.7% (41/231) were class III. Approximately 36.4% (84/231) of the participants received rivaroxaban, and 27.3% (63/231) received apixaban. There were no significant differences in the demographic and clinical characteristics, and the baseline scores of each scale between the two groups (Table 1).

Effects on Coping Strategies

The GEE model analysis showed a significant difference in the scores of the approach coping subscale between the intervention and control groups at 1 month (β=.792; 95% CI 0.143-1.172; *P*<.001), 3-months (β=1.297; 95% CI 0.441-2.153; *P*=.003), and 6 months (β=1.902; 95% CI 0.882-2.922; *P*<.001) (Table 2 and Figure 4).

In addition, the intervention group showed a significantly higher decrease in the scores of the avoidance coping subscale at 1 month (β=–2.284; 95% CI –2.885 to –1.683; *P*<.001), 3 months (β=–2.602; 95% CI –3.511 to –1.694; *P*<.001), and 6 months (β=–2.982; 95% CI –4.096 to –1.869; *P*<.001) compared with the control group (Table 2 and Figure 4). These findings indicated that the web-based integrated management program helped participants to use more approach coping strategies and less avoidance coping strategies in managing their AF-related issues.

Effects on Medication Adherence

The GEE model analysis showed significant differences in the scores of the MARS between the intervention and control groups at 1 month (β=.326; 95% CI 0.034-0.618; *P*=.03), 3 months (β=.595; 95% CI 0.24-0.95; *P*=.001), and 6 months (β=.606; 95% CI 0.253-0.96; *P*=.001) (Table 3 and Figure 5). These results indicated that after receiving the web-based integrated management program, the AF patients showed significantly better medication adherence than that shown by the patients in the control group.

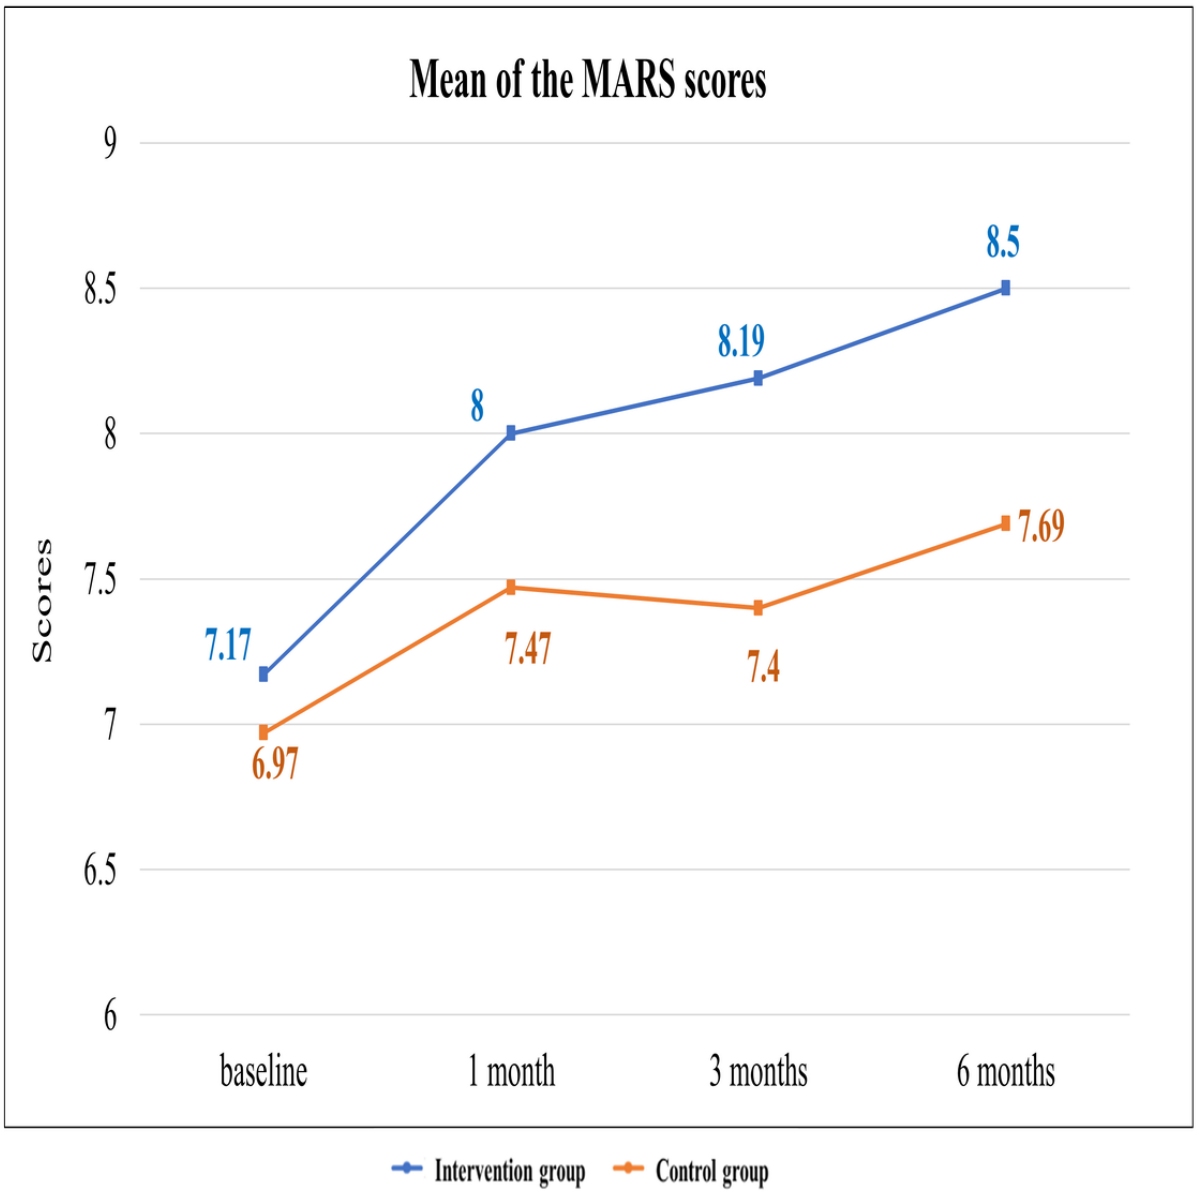
Figure 5. Mean scores of the Medication Adherence Rating Scale for participants in the intervention and control groups. MARS: Medication Adherence Rating Scale.



Effects on HRQoL

The GEE model analysis showed no significant difference in the EQ-5D scores between the 2 groups at 1 month (β=.042; 95% CI –0.014 to 0.980; *P*=.14). However, the patients in the intervention group showed significantly higher EQ-5D scores at 3 months (β=.082; 95% CI 0.028-0.137; *P*=.003) and 6 months (β=.19; 95% CI 0.13-0.25; *P*<.001) than the patients in the control group (Table 4 and Figure 6).

In addition, the GEE model analysis revealed significant differences between the 2 groups in the EQ-VAS scores at 1 month (β=2.071; 95% CI 0.551-3.592; *P*=.008), 3 months (β=3.838; 95% CI 2.169-5.506; *P*<.001), and 6 months (β=5.782; 95% CI 3.837-7.727; *P*<.001) (Table 4 and Figure 6). These results indicated that the AF patients receiving the web-based integrated management program showed a significantly higher HRQoL improvement than that shown by the patients in the control group.

Effects on Readmission Events Within 2 Years

During the study, we followed the readmission events within 2 years after intervention. A total of 34 readmission events occurred. There were 11 readmission events in the intervention group and 23 in the control group. The predictor variables with $P<.20$ were based on univariate logistic regression. The predictor variables meeting the criteria were patients aged over 65 years, the mEHRA IIa class, comorbidities such as valvular heart disease and heart failure, receiving clopidogrel, and group assignment (Table 5). According to the multivariate logistic regression model, the intervention group showed significantly fewer readmission events within 2 years (OR 0.406; 95% CI 0.178-0.926; $P=.03$) compared with the control group (Table 5). These results indicated that the patients with AF receiving the web-based integrated management program had a lower probability of readmission within 2 years, compared with the control group.

Table 5. Association between the web-based integrated management program and readmission events within 2 years (N=231).

Discussion

Principal Findings

The main findings of this study were that the web-based integrated management program significantly improved coping strategies, medication adherence, and HRQoL in patients with AF after 1, 3, and 6 months of intervention. In addition, the AF patients receiving the web-based integrated management program had a lower probability of readmission within 2 years after intervention compared with the patients not receiving this program.

The findings of this study identified that the AF patients receiving this program increased the usage of approach coping strategies and decreased the usage of avoidance coping strategies, as opposed to the patients in the control group. Individuals who used approach coping strategies were able to actively solve problems and conduct positive reappraisals [34]. As the patients were able to receive information immediately and appropriately through this web-based program, they became more confident in solving their problems. On the other hand, the patients in the control group received the manual for AF management to address their problems. They always complained that they did not have sufficient disease information and immediate discussions with clinical professionals when they faced problems. They resorted to using more avoidance coping strategies. Although avoidance coping strategies may be useful in temporarily reducing stress, they increase suffering and mortality, and decrease medication adherence and quality of life [35-37].

Furthermore, in our study, patients receiving the web-based program showed significant improvements in medication adherence and HRQoL, which resulted from the improved disease knowledge and empowerment to solve their problems. Wang et al pointed out three reasons why knowledge may improve medication adherence in patients with AF; first, they become more knowledgeable about the importance of anticoagulant treatment; second, they develop the ability to detect the adverse effects of anticoagulant medicines; third, they received more self-care information about managing the symptoms of AF and adverse effects of the medicines [38]. In addition, Ammenwerth et al suggested that integrated management with eHealth schemes can increase motivated lifestyles and adherence to medical recommendations, thereby improving the health status and HRQoL [39]. Our findings were consistent with those of previous studies [40,41]. All the findings proved that patients were able to manage their treatment and lifestyle by themselves through a web-based program providing positive coping strategies and sufficient disease knowledge and could therefore improve their medication adherence and HRQoL.

To test the second hypothesis that the patients in the intervention group would experience fewer 2-year readmission events than those in the control group, we followed the readmission status of AF patients for 2 years. Our findings showed significantly fewer readmission events within 2 years in patients who received the web-based integrated management program compared to those in the control group. Marcolino et al proposed that implementing web-based intervention programs can improve communication between patients and medical providers and provide assistance in disease management to promote health recovery of patients [42]. In our study, through the web-based integrated management program, direct communication between the patients/their families and health professionals was possible when the patients went back home. A randomized control trial involving patients with heart failure showed that using a remote medication monitoring system can greatly improve patients' medication adherence and reduce all-cause readmission events. It reduced the risk of readmission by 80% [43]. Our findings were consistent with these previous ones [44,45]. Because of the web-based integrated management program, we empowered patients to change their coping strategies and increase their compliance to medical treatment. Ultimately, it improved the HRQoL and long-term beneficial clinical effects in patients with AF in terms of reducing 2-year readmission events.

Conclusions

The study provides useful information for health care professionals regarding web-based integrated management programs for optimizing AF management. The most important findings of the study are summarized as follows: The web-based integrated management program can significantly improve patients' coping strategies and medication adherence, and help patients maintain disease stability, which has a major influence on improving the HRQoL and reducing adverse clinical events and readmission episodes. Overall, the program may improve the quality of patient care while reducing medical costs.

Limitations

Some limitations of this study should be considered. First, the sample may not reflect the entire AF population owing to the disease severity of most patients being mild or moderate. If AF patients had severe symptoms, they were hospitalized to receive medical interventions. Therefore, most of the AF patients in the community only had mild or moderate symptoms. However, they still had very limited knowledge on self-managing their symptoms. After receiving this program, they were able to take care of themselves, leading to decreased readmission events. Second, the single-center design limited the generalization of the findings. Third, factors that affect medication adherence and readmission, such as social support and economic status, were not included in the present study. As there were no differences in the educational levels and marital statuses of the patients in the intervention and control groups, we assumed that both groups of patients had similar social support levels and economic statuses. Nevertheless, future studies should examine these two factors and control their influence.

Acknowledgments

This study was supported by a grant from the Ministry of Science and Technology, Taiwan (MOST grant 107-2314-B016-013-MY3). This funding agency had no influence on the study design, data collection or analysis, decision to publish, or preparation of the manuscript.

Abstract

Background: Adherence to self-guided interventions tends to be very low, especially in people with depression. Prior studies have demonstrated that enhancements may increase adherence, but little is known about the efficacy of various enhancements in comparison to, or in combination with, one another.

Objective: The aim of our study is to test whether 3 enhancements—facilitator contact (FC), an online discussion board, and virtual badges (VB)—alone, or in combination, improve adherence to a self-guided, web-based intervention for depression. We also examined whether age, gender, race, ethnicity, comfort with technology, or baseline depression predicted adherence or moderated the effects that each enhancement had on adherence.

Methods: Participants were recruited through web-based sources and, after completing at least 4 out of 7 daily emotion reports, were sequentially assigned to 1 of 9 conditions—the intervention alone; the intervention plus 1, 2, or all 3 enhancements; or an emotion reporting control condition. The intervention was a positive psychological program consisting of 8 skills that specifically targeted positive emotions, and it was delivered over 5 weeks in a self-guided, web-based format. We operationalized adherence as the number of skills accessed.

Results: A total of 602 participants were enrolled in this study. Participants accessed, on average, 5.61 (SD 2.76) of 8 skills. The total number of enhancements participants received (0-3) did not predict the number of skills accessed. Participants who were assigned to the VB+FC condition accessed significantly more skills than those in the intervention only conditions. Furthermore, participants in arms that received the combination of both the VB and FC enhancements (VB+FC and VB+FC+online discussion board) accessed a greater number of skills relative to the number of skills accessed by participants who received either VB or FC

without the other. Moderation analyses revealed that the receipt of VB (vs no VB) predicted higher adherence among participants with moderately severe depression at baseline.

Conclusions: The results suggested that the VB+FC combination significantly increased the number of skills accessed in a self-guided, web-based intervention for elevated depression. We have provided suggestions for refinements to these enhancements, which may further improve adherence.

Introduction

Despite the fact that up to 20% of people in the United States will experience depression over the course of their lives [1], more than half will remain undiagnosed and untreated [2] for a variety of reasons including treatment cost and geographic inaccessibility [3,4]. Web-based self-help or self-guided (eHealth) programs can overcome potential barriers associated with conventional modes of treatment and may be particularly useful for individuals who might not otherwise seek out conventional face-to-face therapy [5]. However, eHealth interventions for depression also come with significant challenges. Retention in these web-based, self-guided interventions is low compared with other types of trials [6]. For example, previous studies reported retention rates as low as 43% posttreatment, with even lower rates with longer-term follow-up [7]. A recent review of retention in studies of smartphone-delivered interventions for mental health concluded that researchers can expect attrition of up to one-third of participants who enroll in the study [8]. In addition, adherence to intervention content—operationalized as the number of log-ins, duration of web exposure, or number of modules or exercises completed—is as low as 50% for web-based programs [7], and complete adherence to all components of smartphone-delivered interventions for depression was achieved by an average of only 34% of participants [8]. Predictors of poor adherence in web-based depression trials include higher baseline levels of depression [7], male gender [9,10], and lower levels of education [9]. Older age is sometimes found to be associated with better adherence [9,10] and sometimes poorer adherence [7]. Those with less frequent internet use at baseline (weekly to monthly compared with daily) may be more adherent to self-guided programs [10].

Social enhancements such as discussion boards that encourage users to generate and share content with each other can improve engagement [11-14]. Opportunities to earn points and badges can also increase motivation by providing virtual rewards to participants in the form of positive feedback [15-17]. More conventional enhancements, such as reminders via postcards or brief phone calls, can also increase participation [18,19], although other studies have found that similar enhancements such as personalization, interactivity, reminders, and text messages were not associated with better intervention adherence [20]. The discrepancy in these results suggests that specific automated enhancements, or combinations of automated and human-supported enhancements, may be necessary to maximize adherence to self-guided programs.

In this study, we tested the following three enhancements to a self-guided web-based intervention for people experiencing depressive symptoms: brief facilitator contact (FC), an online discussion board (ODB), and virtual badges (VB). These features were developed in previous phases of the program [21,22] and were selected based on research suggesting that personal contact, interactive components, and incentivizing participation increased engagement in web-based programs [7,23-29].

One enhancement was brief facilitator phone contact. Contact from study staff, a mental health professional, or another type of coach can provide a sense of obligation or accountability on the part of the participant and increase adherence to intervention content [29]. In eHealth interventions, this social presence, or sense that there is another human behind the intervention who is aware of the participant's engagement and may provide reminders or prompts, significantly improves adherence [30,31]. FC may increase user engagement by building rapport and connection to the intervention, providing feedback, or supporting meaningful use by tailoring the content or application of the material to participants' needs [32].

The second enhancement we tested was an ODB. Asynchronous discussion boards where participants can reflect on their experiences of learning the skills presented in the intervention and interact with other participants may provide a sense of peer support that improves the efficacy of the intervention. Although web-based support groups alone have not been particularly effective [33], from a collaborative learning perspective, the addition of a forum that allows participants to interact asynchronously with other participants and intervention content may help facilitate understanding and retention of the content and increase engagement with the targeted behaviors [34].

VB are a common form of gamification that increases engagement with an intervention [35] through the inclusion of playful, enjoyable, or competitive elements that boost adherence to a designated activity [36]. Although VB have been criticized for their emphasis on extrinsic motivation at the expense of intrinsic [35], there is evidence that gamified interventions are more engaging than those that do not contain such elements [37].

We hypothesize that the enhancements would increase adherence, operationalized as the number of sessions accessed,

and aim to explore whether the combination of enhancements had a significantly greater impact than any one alone. We also examine whether age, gender, race or ethnicity, comfort with technology, or baseline depression predict adherence or moderate the effects of each enhancement on adherence. Finally, we explore enjoyment ratings as predictors of use or engagement with each enhancement.

Methods

Participants

Detailed methods are described in the study by Cheung et al [22]. The study was approved by the institutional review board and preregistered through ClinicalTrials.gov (trial number: NCT02861755). All participants were recruited on the web through platforms such as ResearchMatch, Craigslist, and Reddit. Eligibility was determined using a web-based screener. To be eligible for the study, participants had to (1) have at least mild levels of depression, as indicated by a Patient Health Questionnaire-8 (PHQ-8) depression score of ≥5 [38]; (2) be aged ≥18 years; (3) have daily access to the internet; (4) own a mobile phone; (5) live in the United States; and (6) be able to read and write in English.

Procedures

Baseline and Randomization

After obtaining web-based consent, participants completed a baseline questionnaire and a 7-day run-in period in which they were asked to complete brief daily assessments of emotion. If participants completed the baseline assessment and at least 4 of 7 days of the run-in period, they were allocated to one of the nine study arms. We stratified participant allocation to a condition based on gender and the level of depressive symptom severity (PHQ-8 score: 5-9 [mild]; 10-14 [moderate]; 15-19 [moderately severe]; >20 [severe]) to ensure sufficient numbers of each group within each condition, and participants were sequentially assigned to the study arm after stratification.

The nine study arms varied according to the type and number of adherence enhancements. The nine conditions are as follows: (1) intervention alone, (2) intervention+FC, (3) intervention+ODB, (4) intervention+VB, (5) intervention+FC+ODB, (6) intervention+FC+VB, (7) intervention+ODB+VB, (8) intervention+FC+ODB+VB, and (9) the emotion reporting control condition.

Enhancements

In the FC conditions, the study staff called participants once per week to check their progress through the course. Specifically, following a prescribed set of questions, the staff member asked about the participant's experience learning that week's skills, using the home practice, and completing the daily emotion surveys; they probed for questions about the skills, accomplishments, barriers, and any difficulties with the technology. If the participant could not be reached by phone, the staff member sent an email with the same content in place of the call and encouraged the participant to reply if they had questions. Staff members were explicitly trained not to provide supportive counseling or skill training, but instead focused on discussing progress, challenges, and technology issues.

Participants who were assigned to the ODB had access to a virtual discussion board where they could participate anonymously using pseudonyms. The study staff provided prompts to seed the discussion board and were notified when a participant posted something. Posts were reviewed for inappropriate content and signs of extreme distress or suicidality.

In the VB condition, participants could earn flower badges that they could arrange in a garden plot. They received badges for completing activities such as creating a profile, reading a lesson, or logging in to the website for 7 consecutive days.

MARIGOLD Intervention

Conditions 1-8 received the MARIGOLD program, a positive psychological intervention that consisted of eight skills that specifically targeted positive emotions: noticing positive events, capitalizing, gratitude, behavioral activation, mindfulness, positive reappraisal, personal strengths, and acts of kindness. Additional details of the positive emotion skills intervention can be found elsewhere [21,22,39-43]. The skills were delivered over the course of 5 weeks in a self-guided, web-based format, and each week had associated home practice activities. Participants did not have access to all the skills at once; instead, 1 to 3 skills were released in each of the 5 weeks. Participants in conditions 1 to 8 also completed the same daily emotion reporting as the control condition (described in the following section).

Emotion Reporting Control

Participants in arm 9 were asked to log in to the website once per day for 49 days (the length of the other eight conditions) to report their emotions. Participants in the emotion reporting control arm completed approximately 20 of the 49 days of daily emotion reporting during the study period (mean 19.90, SD 18.01; range 0-50). They did not receive any of the intervention content and thus did not have adherence data as we have defined it; participants in the control condition will therefore not be included in the present analyses (we have included greater detail on the rates of retention for participants in the emotion reporting control arm and the comparison of daily emotion reporting in the emotion reporting control arm versus the other eight conditions in the supplemental analyses; Multimedia Appendix 1).

Measures

Adherence and Enhancement Ratings

The primary adherence outcome was operationalized as the number of skills (out of eight) accessed (see supplemental analyses in Multimedia Appendix 1 for analyses with other operationalizations of adherence [number of pages viewed and home practice completed] and study retention. Predictors of alternative operationalizations of adherence and of retention were essentially the same). In addition, we explored the evaluations of the enhancements, measured both quantitatively and qualitatively. Upon completion of the 5-week MARIGOLD study, participants completed postcourse surveys in which they provided feedback about the intervention content and

enhancements. Participants were asked to rate whether they enjoyed each enhancement they were assigned to receive (ie, FC, ODB, and VB) on a slider scale from 0 (*definitely not*) to 100 (*definitely yes*). Participants also asked open-ended questions regarding the benefits, drawbacks, and impact of each of the enhancements they received.

Predictors of Adherence and Enhancement Ratings

We also examined demographics, baseline depression, and comfort with technology as predictors of adherence and enjoyment of enhancements. Gender was assessed as *male*, *female*, *or other*, or *prefer not to answer*. Participants were asked whether they considered themselves Hispanic or Latino or Latina and how they self-identified their race (*Black*, *White*, *Asian*, *Native American*, *Pacific Islander*, and *mixed or other*). Age was calculated based on the date of birth. Depression was assessed using the PHQ-8 [38]. Finally, comfort with technology was assessed with six items that tapped a participant's overall frequency of and confidence with technology use (eg, "I am confident I can navigate websites") with response options ranging from 0 (*not at all confident*) to 10 (*totally confident*).

Analyses

Baseline Predictors of Adherence and Engagement With Enhancements

We first conducted an overdispersed (or quasi-) Poisson regression [44,45] to examine whether the number of enhancements received predicted the number of skills accessed. We then conducted the analyses predicting the number of skills accessed from the intervention arm, with the intervention only condition as the reference category.

We then conducted overdispersed Poisson regressions predicting the number of skills accessed from age, gender (1=female; male=0), race or ethnicity (with indicator variables to represent each race or ethnicity category), comfort with technology, and baseline depressive symptom severity (categorized as mild, moderate, moderately severe, and severe).

To further examine whether adherence to the study differed as a function of the combination of enhancements received, we conducted an additional overdispersed Poisson regression predicting each adherence outcome as a function of whether the participant received each enhancement (FC, ODB, and VB), the FCODB, FCVB, and ODBVB two-way interactions and the FCODBVB three-way interaction. The two-way and three-way interactions allowed us to explore whether receiving a specific combination of enhancements had a significantly greater impact than receiving any one enhancement alone.

Moderators of Adherence

We examined whether the effect of each enhancement on adherence was moderated by the following characteristics: age, gender (female vs male), ethnicity (Hispanic vs non-Hispanic), race (Asian, Black or African American, White, other race [Pacific Islander, Native American, and mixed or other]), comfort with technology, and baseline depressive symptom severity (mild, moderate, moderately severe, and severe). To examine this, overdispersed Poisson regressions predict adherence by whether the participants received each enhancement, with dummy variables representing each enhancement, the moderator of interest, and the two-way interactions between the moderator and each enhancement type (FC×moderator, ODB×moderator, and VB×moderator). Owing to power limitations, we did not test all 4 moderators in the same model or explored interactions among the moderators and combinations of enhancements.

Power Analysis

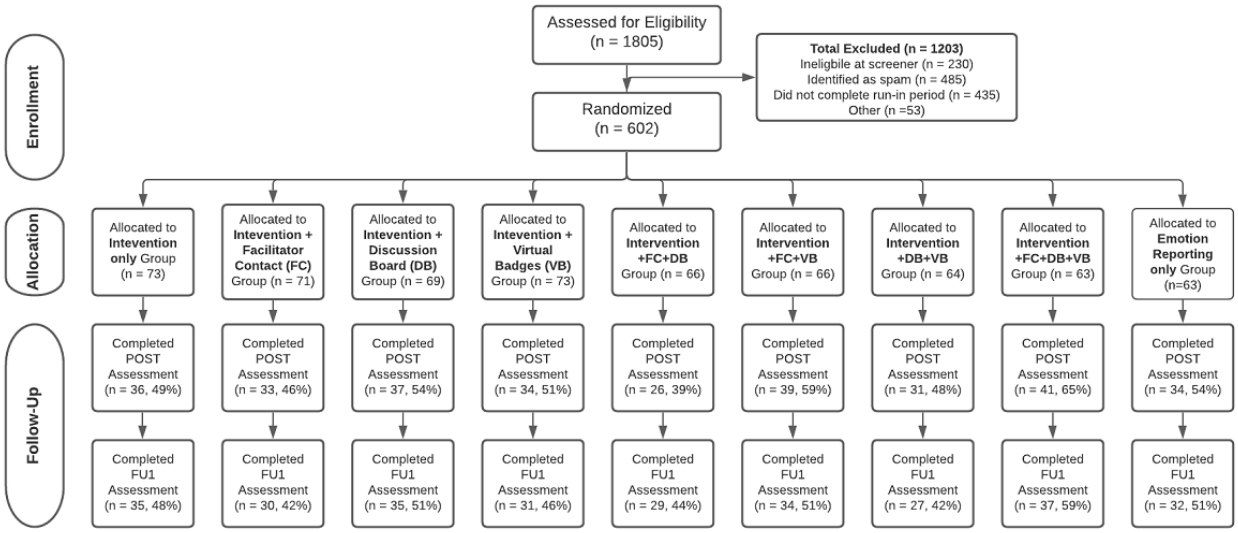
A sensitivity power analysis using the G*Power 3.1.9.6 software [46] revealed that the sample size for this study (N=539 participants across the eight intervention arms) was sufficient to detect a small effect size with adequate power. The minimum effect size necessary for this study was w=0.12, assuming an α significance criterion of P=.05 and power=0.80.

Results

Screening, Enrollment, and Randomization

Of the 1805 respondents who completed the screener, 1037 (57.45%) were deemed eligible and entered the run-in period. Of these, 58.05% (602/1037) completed at least 4 of 7 days of the emotion reports for the run-in and were sequentially assigned to one of the nine study conditions. Figure 1 shows the CONSORT (Consolidated Standards of Reporting Trials) diagram. There were 485 eligibility forms that were deemed spam. Most of these cases were identified because they enrolled in quick succession on the same day and had suspicious repeating patterns of first or last names. We sent additional screener questions to these cases and none completed them and therefore did not proceed to enrollment.

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) diagram. FU: follow-up.



Baseline Characteristics

Across the nine conditions, there were no differences in baseline demographics, depression, or comfort with technology (Table 1). The average age of the participants was 38 years (range 18-80 years). Three-fourths of the sample were female (422/573, 73.6%), three-fourths were White (421/573, 73.4%), and 43% (244/568) were college graduates. Compared with those who did not complete at least 4 of the 7 days of the run-in period, participants who completed the run-in were older (mean 37.95, SD 13.68 vs mean 36.03, SD 12.77; *P*=.04), more likely to be female (467/633, 73.7% vs 210/323, 65%; *P*=.008), and had lower baseline depressive symptom severity (PHQ-8: mean 13.85, SD 5.18 vs mean 15.34, SD 5.11); *P*<.001; Table S1 in Multimedia Appendix 1).

[c]ODB: online discussion board.

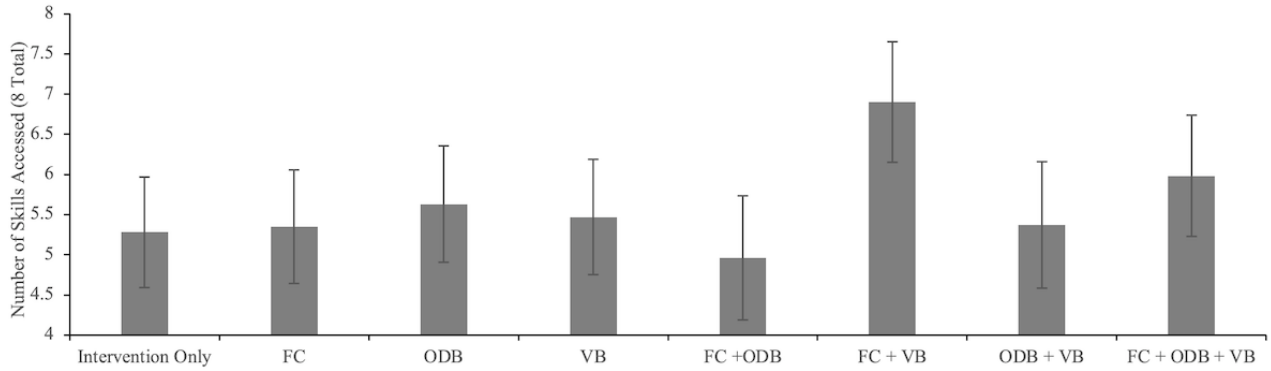
[d]VB: virtual badges.

[e]PHQ-8: Patient Health Questionnaire-8.

Adherence

Participants accessed, on average, 5.61 (SD 2.76) of 8 skills. The total number of enhancements that participants received (0-3) did not predict the number of skills accessed (1 enhancement vs 0: *P*=.63; 2 enhancements vs 0: *P*=.25; 3 enhancements vs 0: *P*=.19). We conducted an analysis predicting the number of skills accessed as a function of whether the participant received each enhancement and their two- and three-way interactions. There were no significant main effects for the FC (*P*=.24) or ODB (*P*=.36) enhancements. There was a significant main effect of receiving the VB enhancement, such that participants in the conditions that received VB (VB, VB+FC, VB+ODB, and VB+FC+ODB) had a greater number of skills (mean 5.90, 95% CI 5.52-6.31) relative to participants in groups that did not receive the VB enhancement (intervention only, FC, ODB, and FC+ODB; mean 5.30; range 4.96-5.67; χ^2_1=5.0; *P*=.03). This main effect, however, appeared to be driven by a significant VB by FC two-way interaction predicting the number of skills accessed (χ^2_1=5.5; *P*=.02) such that participants in arms that received the *combination* of both the VB and FC enhancements together (VB+FC and VB+FC+ODB) accessed a greater number of skills (mean 6.42; range 5.87-7.03) than participants who received either enhancement without the other (VB without FC: mean 5.42; range 4.92-5.98; *P*=.01; FC without VB: mean 5.15; range 4.67-5.68; *P*=.001). Furthermore, participants who received either VB or FC enhancement without the other did not differ in the number of skills accessed compared with participants who received neither enhancement (neither VB or FC: mean 5.45; range 4.98-5.98; *P*=.40 to *P*=.93). No other two-way or three-way interactions emerged with statistical significance (FC by ODB interaction: *P*=.17; ODB by VB interaction: *P*=.44; and FC by ODB by VB interaction: *P*=.94). Taken together, these findings suggest that receiving the VB and FC enhancements *in combination* increased the number of skills accessed, but receiving either the VB or FC enhancement without the other did not (Figure 2).

Figure 2. Number of skills accessed (n=8) as a function of condition. Error bars denote 95% CIs. FC: facilitator contact; ODB: online discussion board; VB: virtual badges.



The patterns of results were the same for other indicators of adherence (eg, pages viewed or home practice completed) and retention in the study. The details of these analyses are provided in Multimedia Appendix 1.

Moderators of Adherence

We examined age, gender, race, ethnicity, comfort with technology, and baseline depression as predictors of adherence and as moderators of the effects of each individual enhancement on adherence. As seen in Table 2, none of these baseline characteristics significantly predicted participants' adherence to the intervention content (*P*=.19 to *P*=.87).

Table 2. Overdispersed Poisson regression predicting adherence from baseline predictors.

Predictor	Number of skills accessed (n=8)	
	Odds ratio (95% CI)	*P* value
Age (years)	1.00 (0.99-1.00)	.79
Gender		
Female	1.08 (0.96-1.21)	.20
Male (reference)	—[a]	—
Ethnicity		
Hispanic	1.04 (0.91-1.19)	.60
Non-Hispanic (reference)	—	—
Race		
Asian	0.94 (0.78-1.13)	.50
Black or African American	1.09 (0.96-1.23)	.19
Other race[b]	0.97 (0.82-1.15)	.70
White (reference)	—	—
Comfort with technology	1.01 (0.97-1.04)	.78
Baseline PHQ-8[c]		
Moderate	1.05 (0.92-1.19)	.47
Moderately severe	0.99 (0.86-1.13)	.87
Severe	1.04 (0.90-1.22)	.58
Mild (reference)	—	—

[a]Not available (indicates reference value).

[b]Other race: the other race category constitutes those who identified as Pacific Islander, Native American, mixed, or other.

[c]PHQ-8: Patient Health Questionnaire-8.

Next, we explored whether the enhancements had a greater effect on adherence depending on demographics, comfort with technology, or baseline depression. There was a significant baseline depressive symptom severity by VB two-way interaction in predicting the number of skills accessed, χ^2_3=8.6 (*P*=.04). Specifically, among participants with moderately severe depression (scores between 15 and 19 on the PHQ-8), receiving VB enhancement was associated with better adherence compared with those who did not receiving VB enhancement (B=1.09; *P*=.01). Two trends in the data that did not reach conventional levels of statistical significance are worth noting: for those in the mild (5-9) and moderate (10-14) range in the PHQ, there was also a positive association between the VB group and adherence (mild: B=1.00; *P*=.06; moderate: B=0.80; *P*=.10). At the highest level of depressive symptoms (scores >20); however, the association was in the opposite direction, with those who received the VB enhancement showing *lower* adherence compared with those who did not receive the VB enhancement (B=−1.21; *P*=.08). Given that the effects among participants in 3 of the 4 depression groups (mild, moderate, and severe but not moderately severe) did not reach statistical significance, caution is warranted in drawing conclusions based on these data.

Exploratory Analyses on Engagement With Enhancements

To better understand the responses to the three enhancements, we further explored the level of engagement and enjoyment ratings for each one.

Analysis of FC

For FC (n=266), study staff were able to contact 45.5% (121/266) of the participants in the FC enhancement conditions by phone at least once, and the average number of weeks that staff were able to reach participants by phone was 1 (SD 1.42; range 0-6). Facilitators were able to reach participants who were older, female, and more comfortable with technology and those who had baseline depression scores in the moderate and moderately severe range more frequently than those who were younger, male, less comfortable with technology, and had baseline depression scores in the mild range (*P*=.001 to *P*=.04; Table 3). The number of weeks that participants could be reached by phone was positively correlated with the number of skills accessed (Spearman r_{206}=0.32; *P*<.001).

Table 3. Overdispersed Poisson regressions predicting engagement with the virtual badges, facilitator contact, and ODB[a] enhancements from baseline predictors.

Predictor	Number of virtual badges		Facilitator contact phone contact		ODB posts	
	OR[b] (95% CI)	*P* value	OR (95% CI)	*P* value	OR (95% CI)	*P* value

[a]ODB: online discussion board.

[b]OR: odds ratio.

[c]Not available (indicates reference value).

[d]Other race: the other race category constitutes those identified as Pacific Islander, Native American, mixed, or other.

[e]PHQ-8: Patient Health Questionnaire-8.

Participants rated the facilitator phone calls as moderately enjoyable (mean 47.20, SD 32.64; range 0-100), and the qualitative feedback supported a wide range of responses such as “I liked hearing from a real person, because then I knew someone was paying attention to what I was doing in the course” versus “It got irritating to answer the same questions and it was frustrating and embarrassing because I hadn't done the skills.” Enjoyment ratings of FC were significantly correlated with staff contact by phone (Spearman r_{107}=0.27; P=.006) and the FC enjoyment ratings were positively associated with the number of skills accessed (Spearman r_{98}=0.25; P=.01).

Analysis of the ODB

Among participants assigned to receive the ODB enhancement (n=262), 25.2% (66/262) posted on the discussion board at least once, and slightly less than half 48.5% (127/262) liked or commented on a post at least once. Male participants posted a greater number of times on the ODB than female participants (P=.02). The number of times that participants posted on the ODB was positively correlated with the number of skills accessed (Spearman r_{198}=0.49; P<.001).

Enjoyment ratings for the ODB were also in the midrange (mean 45.53, SD 30.69; range 0-100), although the ratings varied greatly. Some participants appreciated connecting with other participants through the discussion board: “It was motivational to see others progress and be able to communicate with others.” However, for others, the ODB fell short of expectations: “There doesn’t seem to be much activity there.” Still others were in the middle ground and neither liked or disliked it: “I was able to connect with other people in the program but it wasn’t very personal, in the sense that I would just comment a few blurbs here and there but didn’t feel like I was doing much.” Those who rated the ODB as more enjoyable had more posts on the board (Spearman r_{101}=0.29; P=.003). However, participants’ ODB enjoyment ratings were not associated with the number of skills accessed in the program (Spearman r_{91}=0.10; P=.34).

Analysis of VB

Among participants who were assigned to receive a VB enhancement (n=260), the number of badges earned ranged from 9 to 192, with a mean of 17.29 (SD 16.48). All participants assigned to receive a VB enhancement earned at least one badge. As seen in Table 3, older participants and Hispanic participants

earned a greater number of VB than younger and non-Hispanic participants (P=.01 to P=.05). None of the other baseline characteristics significantly predicted the total number of VB (all P=.06 to P=.96).

For enjoyment ratings, participants rated the VB as moderately enjoyable (mean 50.90, SD 33.17; range 0-100). However, there was wide variability in enjoyment ratings, and the qualitative feedback for the VB reflected this range: "It is a visual point system that is cute and fun. It seems silly but I felt like I accomplished something when I got each flower." Others did not appreciate the whimsical garden plot calling it *childish* and *a waste of time*. Although the number of badges earned and enjoyment ratings of the VB enhancement were significantly correlated (Spearman r_{115}=.30; P=.001), participants' VB enjoyment ratings did not predict the number of skills accessed (Spearman r_{109}=0.14; P=.16).

Discussion

Principal Findings

Web-based, self-guided interventions hold significant promise for people with elevated depressive symptoms. Attaining acceptable levels of adherence to these programs is critical to effectiveness, yet this has proven to be a challenge. We developed and tested 3 enhancements that we hypothesized would, either alone or in combination, improve adherence to a self-guided positive psychological intervention for people with elevated depression. The enhancements were an ODB, VB, and FC. Participants in the eight conditions that received the intervention content also received 1, 2, or all 3 or no enhancements. Our results suggest that the combination of VB and FC is especially impactful and points to areas for future focus to improve adherence across the three enhancements.

For the ODB enhancement, participants had access to an online forum where they could anonymously post questions, share their experiences, and offer encouragement to other participants. Previous findings regarding the efficacy of discussion boards for improving adherence to web-based programs have been mixed. For example, one study found that an internet discussion board or support group resulted in *lower* adherence to the self-guided program compared with the self-guided program alone [47], although participants who were assigned to receive the discussion board had a greater reduction in depression at 6 months.

The engagement on the discussion board was quite low. Only a quarter of the participants posted on the board at least once, and qualitative feedback indicated that this low level of activity further discouraged participants from making use of the ODB. Therefore, it is perhaps not surprising that there was no indication that the ODB increased adherence to the program, either alone or in combination with other enhancements. Simple availability without engagement is not sufficient for an ODB to increase adherence to the intervention content. There are a number of ways that we could have increased engagement in the ODB, such as requiring participants to post as part of the home practice assignments or making it easier to navigate to the discussion board to lower the barriers to engagement.

VB is a form of gamification and is intended to increase adherence to the intervention content by providing rewards for completing activities on the platform, for example, reaching a goal for the number of log-ins or consecutive homework completions. Participants in the arm that received both VB and FC completed significantly more sessions than did those in the no-enhancement arm (Figure 2). Furthermore, participants in arms that received VB and FC together (VB+FC; VB+FC+ODB) accessed, on average, one more skill (mean 6.42) compared with participants who received either VB or FC without the other (mean 5.42; FC alone, VB alone, ODB+VB, and ODB+FC). Participants were of a mixed opinion on whether the VB were enjoyable, with 33.9% (39/115) giving the VB low enjoyment ratings (below 31 on a 0-100 scale) and 33% (38/115) providing high enjoyment ratings (between 70 and 100). Previous studies document similar challenges to the successful use of gamification elements, such as a lack of clarity on which behaviors are being rewarded or confusion over how progress was being illustrated [48-50]. Future work to make the badges more interpretable, enjoyable, and clearly linked to target behaviors will help to increase the impact of the VB on adherence to the intervention.

Our FC enhancement consisted of staff contacting participants by phone once per week for a brief check-in regarding any challenges they were experiencing while completing that week's skills and answering questions or concerns they had. We included the FC component based on studies showing that contact with a person improves adherence to self-guided, web-based interventions [18,23,27,51,52]. Although receipt of the FC alone did not significantly improve adherence to the program, when combined with VB, there was an improvement such that those participants who received *both* FC and VB completed more of the intervention sessions compared with those who did not. The average number of times a facilitator was able to reach a participant was one, and fewer than half of the participants were ever reached by a facilitator by phone. The data indicate that the more participants enjoyed the FC, the more skills they completed, and as with VB, there was a wide range of enjoyment ratings for FC, leaving a lot of room for improvement. One easy change that may increase participants' enjoyment of the FC condition, and as a result improve the impact of FC on adherence, is to vary the questions that are asked each week and word them so they do not come across as judgmental. Qualitative feedback indicated that participants found these questions repetitive and, especially if they had not completed the home practice that week, somewhat shaming. Furthermore, some participants may prefer email over phone contact, and providing an email contact option could increase the impact of the enhancement. Other ways to improve the impact of the FC condition could include improving the *supportive accountability* [29], such as setting clear expectations and goals for engagement with the platform, and tailored performance monitoring that is supportive rather than shaming. In addition, clarifying the expertise of the facilitators and increasing trust could enhance the impact of FC [29].

Aside from the content of the enhancement, a simple count of the number of enhancements the participant was assigned to (up to 3) was not predictive of adherence. On the basis of our

data, it is not necessarily better. However, the combination of VB and FC increased adherence compared with either enhancement alone. It may be that the FC helps encourage people to engage with the platform, with the phone call providing a reminder and the facilitator providing someone to be accountable. Once participants are on the platform, the VB reinforce that engagement and provide some extrinsic motivation to remain engaged [29].

We explored potential moderators of the effect of each enhancement and found that depression influenced whether VB enhancement was associated with adherence. Specifically, among those with moderately severe baseline depression (PHQ-8 scores between 15 and 19), those who received the VB enhancement demonstrated better adherence than those who were not assigned to a VB condition. For those in the mild and moderate range of the PHQ-8 (scores between 5 and 14), the direction of the effect was the same but did not reach statistical significance. For participants with severe baseline depression (>20), the effect was in the opposite direction, such that VB were associated with (nonsignificantly) poorer adherence. Although this interaction should be interpreted with caution given the marginal significance and the very small number of participants in this group (those with the highest levels of depression who received the VB), this pattern was also apparent in our analyses with the proportion of intervention completed as an outcome (the number of pages viewed as a proportion of the total possible number of pages; Multimedia Appendix 1). It may be that for people with severe clinical depression, the badges were off-putting, and extra thought should be put into this form of gamification for people with the highest levels of depression. Of note, other studies of web-based depression interventions tend to exclude people who have scores in the severe range [10,20] so would not have picked up this potential demotivating effect of VB for people with the highest levels of depression.

Limitations

There are several limitations to consider in this study. First, the sample was recruited from all web-based sources and likely differed from clinic-based samples or those referred by medical providers. The sample was predominantly made up of non-Hispanic White individuals and females, which significantly limits the generalizability of the findings. Furthermore, participants needed to complete 4 of 7 daily emotion reports as part of a *run-in* to be assigned to a condition in which only 58.05% (602/1037) of the participants were able to accomplish. Although run-in periods are often used in clinical trials [53], by including only those who demonstrated adherence to the study protocol, we may have artificially enriched our sample with participants who were more likely to be adherent to the intervention. Comparison of those who completed the run-in to those who did not indicate that those who completed were older, more likely to be female, and less depressed than those who consented but did not complete the run-in. We also ran a large number of statistical tests and did not control for multiple comparisons. However, our analyses were hypothesis-driven and appropriate for this stage of intervention development. Finally, we tested the enhancements in the context of a positive psychological intervention, and the content may have influenced adherence, although we do not have a way to test this possibility in this study.

These findings lead to several suggestions for future self-guided interventions and potential adherence enhancements. First, the program and enhancements were feasible even for people with very high levels of depression. Unlike most previous studies of web-based programs for people with depression, we included participants with the highest levels of depression. The findings demonstrate that people with severe levels of depression can also engage in programs like this, and their inclusion in the study sample suggested important differences in terms of response to enhancements. Second, the combination of VB and FC was associated with better adherence than either enhancement alone. Researchers should go beyond single enhancements to improve adherence and consider including combinations of enhancements that may be more effective than any one enhancement alone. Furthermore, it may be helpful to offer participants a choice of which enhancements they want to access. Providing participant control over which enhancements they receive from the outset could increase feelings of engagement and investment in the program. Finally, as the technology for intervention delivery progresses, there are new possibilities for better-engaging participants. Future work may consider more immersive approaches such as virtual reality [54] and approaches such as SMS text messages [55] or chatbots [56] that foster a sense of social connection and may encourage stronger engagement with the intervention content.

Self-guided web-based interventions hold great promise to help people living with depression, and creative approaches to better engage participants will provide greater benefit to more people as the programs are more widely disseminated. Despite low levels of engagement with the FC enhancement, the results of our randomized trial suggest that the combination of VB and FC may be especially effective at improving adherence to the intervention, which in turn, may increase the impact of the intervention on well-being and bode well for future programs that incorporate enhancements such as these.

Abstract

Background: The human papillomavirus (HPV) vaccination rate in Japan has fallen to nearly zero since the suspension of governmental proactive recommendations in 2013, owing to the development of purported adverse events.

Objective: This study aimed to evaluate the effects of a brief web-based educational intervention using the theory of behavioral insights on the willingness of adults to consider the HPV vaccine for their daughters and sons.

Methods: We recruited 1660 participants aged 20 years or older in March 2018 via a webpage and provided them with a 10-item questionnaire related to the following aspects: awareness regarding HPV infection and vaccination, willingness for immunization, and actions for prevention. We randomly stratified participants based on sex and age with or without a brief educational intervention involving scientific information presented in an easy-to-read format.

Results: Only 484 (29.2%) of the respondents were aware of the benefits of HPV vaccination. Although only 352 (21.2%) of the respondents displayed a willingness for immunization of their daughters, there were 40 (4.8%) more respondents in the intervention group with this willingness (adjusted odds ratio [aOR] 1.32, 95% CI 1.04-1.69). In a subanalysis, the willingness toward vaccination for daughters in men was significantly higher in the intervention group (aOR 1.46, 95% CI 1.05-2.02). However, such a difference was not observed among women (aOR 1.20, 95% CI 0.83-1.73).

Conclusions: This study suggests that a brief web-based educational intervention increases the willingness of adults to consider the HPV vaccine for their children, especially among men. Thus, providing adequate information to men may be a useful strategy to improve the currently low rates of HPV vaccination.

human papillomavirus; human papillomavirus vaccination; behavioral insights; behavioral change; web-based randomized controlled trial

Introduction

Background

In Japan, the human papillomavirus (HPV) nonavalent vaccine was approved by the Pharmaceuticals and Medical Devices Agency (PMDA) for girls aged 9 years or older in July 2020 [1]. The corresponding quadrivalent inoculation was ratified for boys in the same age group in December 2020 [1]. Nevertheless, the level of awareness regarding HPV, the resultant cancer (cervical cancer [CC]), and the vaccine needs to be higher in the Japanese population [2,3]. Although vaccination is the exclusive means of preventing HPV infection, the immunization rate has fallen below 1% owing to subsequent adverse events [4], which are regarded as functional disorders. These cases were reported repeatedly in Japanese media in sensational ways [2,4]. As a result of the dissemination of misinformation and the misunderstanding of the HPV vaccine, most Japanese people have distrust toward the HPV vaccine [2]. Thus, the immunization rate of the bivalent or quadrivalent HPV vaccine for the target population from the 6th grade of elementary school students to the 1st grade of high school students was 0.8% in 2018 [5]. This has persisted from 2013 for almost 8 years [4-6].

According to the strategy of the World Health Organization devised in 2019 for controlling CC [7], by 2030, 90% of girls worldwide would be vaccinated with the HPV vaccine by the age of 15 years. Malaysia, Mexico, Bhutan, Brunei, and Rwanda have achieved an immunization rate of 90% or higher in the target population [7]. Furthermore, in Australia, the success of two national programs, the National Cervical Screening Program (NCSP) and the Australian National HPV Vaccination Program (NHVP), resulted in achievement of the threshold for rare cancer in 2020 [8]. By 2028, the estimated number of cases would be less than 4 per 100,000 [9], which is the threshold for elimination [8].

In addition to HPV-related cancers, vulvar, anal, and throat malignancies may be prevented by the vaccine [9,10]. A Japanese research group provided evidence of a significant reduction in the incidence of cervical intraepithelial neoplasia grade 3 or higher in vaccinated women [11].

Specific information regarding the effects and adverse events of HPV vaccines needs to be fully disseminated to the Japanese population. Considering this, approximately 40% of the population is willing to be vaccinated [2]. Therefore, it is critical to disseminate adequate scientific knowledge regarding the beneficial effects of the vaccine so that people in the target age group actually take the vaccine.

Goal of the Study

Vaccine awareness programs are necessary, and campaigns through the media and social network services can play significant roles [2,4]. In an information-overloaded society, people frequently make decisions related to health issues based on a bunch of information [12]. Therefore, it is critical to consider the influence of behavioral insights to promote change [13]. This broadly refers to concrete approaches based on the knowledge of behavioral science and economics. The Easy, Attractive, Social, and Timely (EAST) principles are a simple way of applying behavioral insights to interventions and have been used to change human awareness and behavior [13]. This study aimed to assess the effects of these behavioral insights utilizing brief scientific information on vaccine benefits, along with statistics on CC.

Methods

Study Design and Participants

We recruited a total of 1660 participants in March 2018 via a specially designed webpage for this study. These were registered members of the research panel owned by Macromill Inc (Tokyo, Japan). The participants were 20 years old or above as on March 12-13, 2018. They were recruited until the target sample size was fulfilled. We randomly assigned each participant to respond to an identical questionnaire after (intervention group) or prior to (control group) providing behavioral insights material (BI-material) featuring brief scientific information presented in an easy-to-read format (as displayed in Figures 1 and 2).

Figure 1. Flow diagram of the randomization. BI-material: behavioral insights material featuring brief scientific information presented in an easy-to-read format.

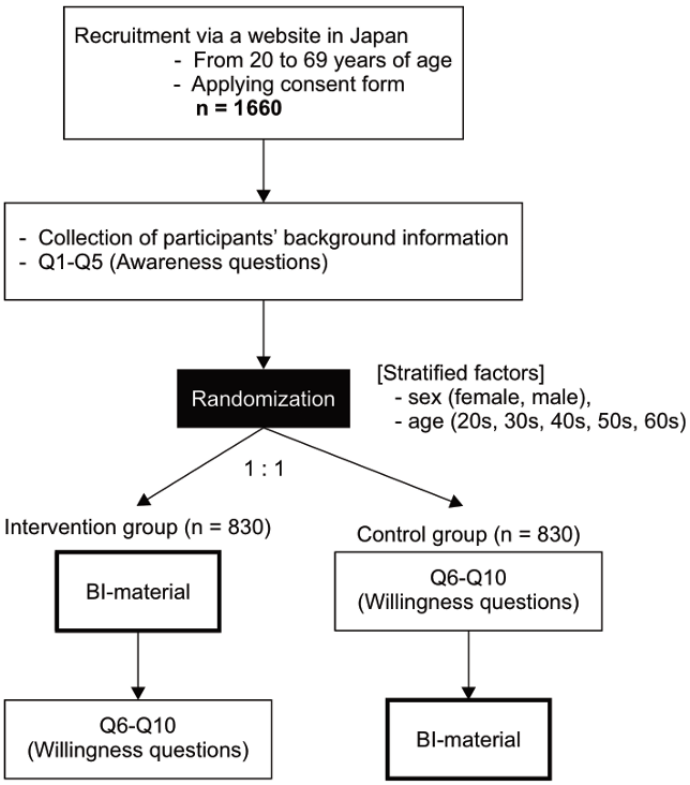

Figure 2. Behavioral insights material.

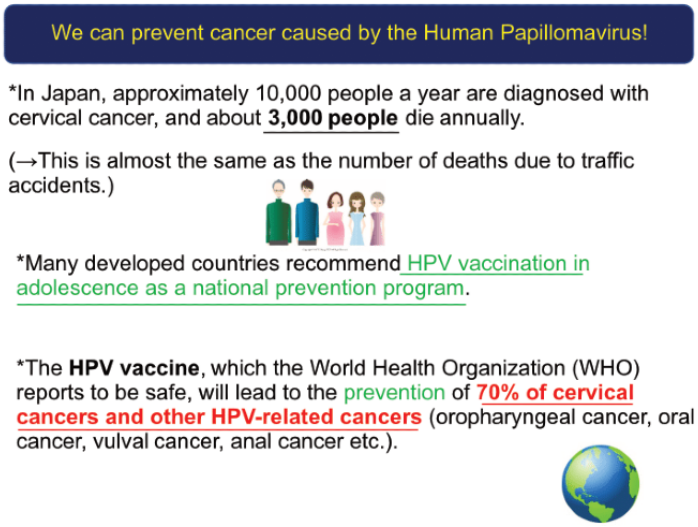

Informational Material and Behavioral Insights

Informational materials are designed primarily to increase effectiveness; they are based on a specific purpose rather than a template. In this study, first, we provided one-page BI-material containing three sentences, which were deemed to be in line with scientific evidence and objective facts associated with the theory of behavioral change and economics. This theory was suggested and represented by Richard Thaler [14]. The first sentence of our material reflected the Japanese epidemiological data on CC (Figure 2), which was intended for the framing effect [15,16]. For example, a statement like “Cervical cancer is the 11th most frequent malignancy among women in Japan” or “2.8% of women diagnosed with cervical cancer die” does not emphasize the deterioration in health. Therefore, this would not contribute to general behavior change. Additionally, we applied the prospect theory by drawing similarities between the number of deaths due to CC in Japan and fatalities due to traffic accidents. Second, to promote a change in the consciousness of participants, the presentation of social norms was included as part of the EAST framework (S-social) in the second sentence of the BI-material (Figure 2). This was employed for devising behavioral insights of greater effectiveness [17]. Third, heuristics (awareness of prejudice and intuition) [18] hypothesized a reduced interest in male participants in case the HPV immunization focused exclusively on CC. Therefore, it was conveyed that non-CC HPV malignancies are preventable

through HPV vaccination [9]. The first author (YS) is one of the specialists of the behavioral design team in Yokohama, which was established as the first nongovernmental nudge unit in Japan [19]. Thus, this BI-material was created given the behavioral insights methodology.

Randomization

Participants were randomly allocated (1:1) to each group. The intervention was performed using an automatic web-based allocation system stratified by the sex (female/women and male/men) and age (20s, 30s, 40s, 50s, and 60s) of the participants. Randomization was performed by the web-research system of Macromill Inc. Participants and investigators were blinded to the distribution (double-blinded). Once the upper limit of each stratum was reached, new participants could not be added to the web system. This ensured uniform distribution of the stratification factors. In the intervention group, we provided the BI-material prior to answering questions related to preventive awareness, following consent for the online study. The control group was provided with the same material as that provided to the intervention group after all responses were completed.

Questionnaire

The participant demographics included age, sex, marital status, number of children, sexual experience, household income, medical background, education, and tobacco use. For female participants, we also collected information regarding HPV vaccination history and previous pap screening. Medical background was defined as follows: a respondent who had a history of working as a medical professional (medical doctor, dentist, nurse, or allied health care professional) or who attended medical school.

The respondents completed a 10-item questionnaire. The first half determined HPV awareness as background information, and the second half addressed willingness to receive HPV vaccines and undergo screening tests. The respondents were instructed to answer “Yes” or “No” for each question.

The awareness questions were as follows:

Q1. It is possible to detect both cancer and precancerous lesions through CC screening.

Q2. Sexual experience is associated with HPV infection.

Q3. CC screening is necessary for women even after vaccination.

Q4. I have heard of the benefits of the HPV vaccine.

Q5. I have heard of the adverse events associated with the HPV vaccine.

The willingness questions were as follows:

Q6. If you have/had a daughter, do/would you consider getting her vaccinated against HPV?

Q7. If you have/had a son, do/would you consider getting him vaccinated against HPV?

Q8. Would you consider undergoing a pap smear? If male, will you want your family or partner to undergo a smear test?

Q9. Would you undergo the cancer screening tests recommended by the government?

Q10. Do you plan informing family members, friends, or others about cancer prevention and screening (through Facebook, LINE, Twitter, etc)?

Statistical Analysis

Tests Performed

Statistical evaluation comprised the Student *t* test, the chi-square (χ^2) test, and multiple regression analyses. These were performed using SPSS, version 27 (IBM Corp).

Power and Statistical Significance

The sample size was calculated as 80% powered to detect a 10% effect in the intervention group (increased from 40% in the control group to 50% in the intervention group) with a two-sided *P* value of .05. *P* values less than .05 were regarded as significant. The hypothetical baseline willingness rate in the control group was determined based on our previous study [2]. The sample size was calculated as 776 when the effect of the intervention estimated a 10% increase. The number of participants recruited was double of the calculated sample size because of the difficulty in estimating the baseline willingness and the intervention effect.

Odds Ratio

The adjusted odds ratios (aORs) related to the background knowledge level from the binominal logistic regression were analyzed to assess differences in both groups. In the subanalysis, questions Q2 and Q4, for which the responses showed a significant difference in the rate of awareness between the two groups (data not shown), were included as covariates in the aOR in the analysis for men. Questions Q1, Q2, and Q5, for which the responses showed a significant difference in the rate of awareness between the two groups (data not shown), were included as covariates in the aOR in the analysis for women.

Ethical Approval and Funding

The study protocol was approved by the Institutional Research Ethics Committee of Yokohama City University School of Medicine (A180200004). The trial registration number is UMIN000049745. We received research funding from the Japan Agency for Medical Research and Development (grant number 15ck0106103h0102). The survey was outsourced to Macromill Inc.

Results

Analysis of Participant Demographics

From March 12 to 13, 2018, 1660 participants were recruited. Stratifying factors, such as sex and age, were evenly allocated. The following variables displayed no significant differences between the intervention and control groups: marital status (*P*=.96), children (*P*=.84), household income (*P*=.58), sexual experience (*P*=.26), education (*P*=.44), medical background (*P*=.50), and tobacco use (*P*=.64) (Table 1).

[c]HPV: human papillomavirus.

[d]Pap: Papanicolaou test.

[e]Only female participants aged 20 years or older (n=830).

HPV Awareness Analysis

For questions Q1 to Q5 regarding HPV awareness, the recognition rate for Q2 was significantly higher (by 7.8%) in the control group than in the intervention group. For questions Q4 and Q5, the values in the intervention group were significantly higher (by 6.5% and 6.6%, respectively) than those in the control group (Table 1).

Only 484 (29.2%) of the respondents were aware of the benefits of HPV immunization (Q4), whereas 543 (32.7%) were aware of the adverse effects (Q5).

Willingness to Consider Children's Vaccination

Only 352 (21.2%) of the respondents displayed a favorable attitude toward HPV immunization for their daughters (Q6). However, an additional 40 (4.8%) participants responded affirmatively in the intervention group (aOR 1.32, 95% CI 1.04-1.69) compared to those in the control group (Table 2). For Q7, there were additional 33 (3.9%) satisfied respondents willing to consider vaccination for their sons in the intervention group (aOR 1.38, 95% CI 1.05-1.80) compared to those in the control group (Table 2).

The number of respondents expressing a desire to receive a screening test (Q8) (*P*=.37) or to communicate HPV-related issues (Q10) did not increase (*P*=.17) (Table 2).

Table 2. Comparison of attitudes toward human papillomavirus vaccination and screening tests according to intervention.

No	474 (28.6)	229 (27.6)	245 (29.5)				
Q9. Would you undergo the cancer screening tests recommended by the government?							
Yes	1128 (68.0)	574 (69.2)	554 (66.7)	1.12 (0.91-1.37)	.29	1.12 (0.91-1.38)	.30
No	532 (32.0)	256 (30.8)	276 (33.3)				
Q10. Do you plan informing family members, friends, or others about cancer prevention and screening (through Facebook, LINE, Twitter, etc)?							
Yes	760 (45.8)	396 (47.7)	364 (43.9)	1.17 (0.96-1.42)	.12	1.15 (0.94-1.40)	.17
No	900 (54.2)	434 (52.3)	466 (56.1)				

[a]OR: odds ratio.

[b]*P* value estimated using binomial logistic regression analysis.

[c]Q2, Q4, and Q5 were included as covariates in the adjusted OR.

[d]HPV: human papillomavirus.

[e]Pap: Papanicolaou test.

Sex-Wise Attitudes Toward HPV Vaccination

Table 3 presents the subanalysis results according to sex.

Differences were identified in Q6 (men: aOR 1.46, 95% CI 1.05-2.02 vs women: aOR 1.20, 95% CI 0.83-1.73) and Q7 (men: aOR 1.53, 95% CI 1.08-2.18 vs women: aOR 1.21, 95% CI 0.80-1.83). The willingness to consider vaccination for daughters in men was significantly higher in the intervention group (by 8.2%, *P*=.02; Multimedia Appendix 1); however, such a difference was not observed in women (*P*=.22; Table 3, Multimedia Appendix 2).

In an overall comparison between men and women irrespective of intervention, the willingness to consider vaccination for daughters in men was significantly higher than that in women (25.1% vs 17.3%, *P*<.001), and the willingness to consider vaccination for sons was also higher in men than in women (20.1% vs 12.8%, *P*<.001).

In the intervention group, higher rates were identified in men than in women for Q6 (29.2% vs 18.1%, *P*<.001) and Q7 (23.9% vs 13.0%, *P*<.001). While in the control group, differences were not identified between men and women for Q6 (21.0% vs 16.6%, *P*=.11) and Q7 (16.4% vs 12.5%, *P*=.11).

Table 3. Comparison of attitudes toward human papillomavirus vaccination and screening tests according to sex.

Variable	Yes response vs other			
	OR[a] (95% CI)	*P* value[b]	Adjusted OR[c] (95% CI)	*P* value[b]
Q6. If you have/had a daughter, do/would you consider getting her vaccinated against HPV[d]?				
Men	1.55 (1.13-2.13)	.01	1.46 (1.05-2.02)	.03
Women	1.11 (0.77-1.59)	.58	1.20 (0.83-1.73)	.33
Q7. If you have/had a son, do/would you consider getting him vaccinated against HPV?				
Men	1.60 (1.13-2.26)	.01	1.53 (1.08-2.18)	.02
Women	1.04 (0.70-1.57)	.84	1.21 (0.80-1.83)	.38
Q8. Would you consider undergoing a pap[e] smear? If male, will you want your family or partner to have a smear?				
Men	1.05 (0.78-1.42)	.76	1.04 (0.77-1.42)	.78
Women	1.15 (0.85-1.56)	.36	1.18 (0.87-1.61)	.30
Q9. Would you undergo the cancer screening tests recommended by the government?				
Men	1.01 (0.76-1.34)	.94	1.02 (0.76-1.36)	.92
Women	1.25 (0.93-1.69)	.15	1.31 (0.96-1.79)	.09
Q10. Do you plan informing family members, friends, or others about cancer prevention and screening (through Facebook, LINE, Twitter, etc)?				
Men	1.27 (0.96-1.67)	.09	1.24 (0.94-1.64)	.13
Women	1.08 (0.82-1.42)	.58	1.11 (0.84-1.47)	.47

[d]HPV: human papillomavirus.

[e]Pap: Papanicolaou test.

Discussion

Principal Findings

We conducted a web-based randomized controlled trial (RCT) to assess the benefits of BI-material employing brief scientific information and its ability to motivate individuals to consider the HPV vaccine for their children. Our results showed that providing brief scientific information could increase the willingness to consider HPV vaccination for daughters and sons. This effect was observed typically among male participants. Similar minor interventions may potentially modify mindsets favorably. However, such brief digital information failed to affect the mindset in women. A possible reason why the intervention was more effective among men than women is that women had a more negative image toward HPV vaccination. There was a significant difference between men and women in the awareness level. Overall, 45.7% of women responded that they know about the adverse events of HPV vaccination, while this rate was 19.8% in men (data not shown). Such awareness might have influenced the difference in the intervention effect.

In terms of the COVID-19 pandemic, a difference in awareness of prevention strategies was observed between men and women [20]; therefore, it is essential to build a method appropriate for sex subgroups to transform general behavior via the internet and social networking services.

Comparison With Prior Work

According to a systematic review regarding the effect of the pedagogical approach on social awareness or action, more reliable and validated studies are required to change the perception or mindset of the target population [21]. This paves the way for mitigating hesitancy toward vaccination [21]. Therefore, this RCT may be valuable to ensure a change in public attitudes toward vaccination.

A systematic review revealed that general communication about childhood vaccination resulted in a positive change by 20%; however, this excluded the HPV vaccine [21]. In contrast, the brief educational intervention was observed to improve the willingness to consider the HPV vaccine for daughters and sons, with aORs of 1.32 and 1.38, respectively (Table 2). Therefore, when compared to the review data of the in-person approach [21], the aORs were not small. Furthermore, the BI-material was designed by a specialist of behavioral insight, resulting in a moderate cost; therefore, this intervention is more reliable and cost-effective than those used in previous studies.

A US RCT reported that education through social media is effective for improving general awareness regarding vaccination. However, the study was limited to a sample of 58 participants [22]. A phase 2 Japanese trial evaluated how the extent of intervention affected HPV vaccination acceptance and reported that providing appropriate medical information resulted in

beneficial effects [23]. Thus, this study proved the utility of effective and adequate guidance in improving vaccine acceptance. There is a paucity of literature on the efficacy of pragmatic educational materials for HPV vaccination promotion [22]. Therefore, more extensive trials focusing on the mode of endorsing HPV vaccination like our trial are required for evidence-based promotion.

Limitations

We recognize several limitations in this study. First, the sustainability of effective change was not evaluated. Typically, with respect to health issues, taking action requires time. Therefore, a study should assess not only a change in mindset, but also the appropriate course of action. We have already performed an RCT (UMIN000039273) assessing the sustainability of general acceptance and concrete behavior for HPV vaccination. Second, the impact of the study on the behavioral outcome was unclear; specific vaccination functioning needs to be tracked. Third, selection bias was present as the respondents were Japanese individuals enrolled by an internet survey company.

Based on the sex-wise subanalysis, improved information in male participants may be the key to improve the rate of HPV vaccination in Japan. Additionally, video-based content with patient feedback is expected to result in a broader impact. Thus, a varied approach for men and women may be required.

Conclusions

Inference of the Study Findings

Our study revealed a positive outlook toward HPV vaccination following a brief web-based educational intervention, especially among men. Such an approach is extremely effective to overcome challenges related to communication and information overload.

Impact of the Findings

A brief web-based educational intervention based on the theory of behavioral insights increases the willingness of Japanese adults to consider the HPV vaccine for their daughters and sons.

Acknowledgments

The authors would like to thank the members of the research group affiliated to Niigata University, Osaka University, and Yokohama City University for their cooperation. We would like to thank Editage (http://www.editage.jp) for English language editing. Abstract

Background: Effective, resource-efficient treatment is urgently needed to address the high rates of pediatric and adolescent obesity. This need has been accelerated by the COVID-19 pandemic. The use of a mobile health tool as an early intervention before a clinic-based multidisciplinary weight management program could be an effective treatment strategy that is appropriate during a pandemic.

Objective: This study aims to assess the effectiveness of and adolescent engagement with a mobile app–based lifestyle intervention program as an early intervention before enrollment in a clinic-based multidisciplinary weight management program.

Methods: This prospective single-cohort study involved adolescents, aged 10-16 years, who were overweight and obese (defined as BMI percentile above the 85th percentile). Participants used the mobile Kurbo app as an early intervention before enrolling in a clinic-based multidisciplinary weight management program. Kurbo's health coaches provided weekly individual coaching informed by a model of supportive accountability via video chat, and participants self-monitored their health behavior. The implementation of Kurbo as an early intervention was evaluated using the reach, effectiveness, adoption, implementation, and maintenance framework by reach (number who consented to participate out of all patients approached), implementation (Kurbo engagement and evaluation), and effectiveness as measured by the primary outcome of the BMI z-score at 3 months. Secondary outcome measures included changes in body fat percentage, nutrition and physical activity levels, and quality of life at 3 months. Maintenance was defined as the outcome measures at 6-month follow-up.

Results: Of the 73 adolescents who were approached for enrollment, 40 (55%) of adolescents were recruited. The mean age was 13.8 (SD 1.7) years, and the mean BMI z-score was 2.07 (SD 0.30). In the multiethnic Asian sample, 83% (33/40) of the participants had household incomes below the national median. Kurbo engagement was high, with 83% (33/40) of participants completing at least 7 coaching sessions. In total, 78% (18/23) of participants rated the app as good to excellent and 70% (16/23) stated that they would recommend it to others. There were no statistically significant changes in BMI z-scores at 3 months (*P*=.19) or 6 months *(P*=.27). Participants showed statistically significant improvements in measured body fat percentage, self-reported quality of life, and self-reported caloric intake from the 3-day food diaries at 3 and 6 months.

Conclusions: The use of Kurbo before enrollment in an outpatient multidisciplinary clinical care intervention is a feasible strategy to expand the reach of adolescent obesity management services to a low-income and racially diverse population. Although there was no significant change in BMI z-scores, the use of Kurbo as an early intervention could help to improve quality of life and reduce body fat percentage and total caloric intake.

Introduction

Background

Mirroring global trends, the prevalence of overweight among Singaporean adolescents increased from 2.2% in 1975 to 15.9% in 2016. Overweight adolescents are at a higher risk for adult obesity as well as short- and long-term medical and psychosocial complications [1]. To address this concern in a resource-efficient manner, experts have proposed a staged care approach for the management of adolescents who are overweight and obese. Those who are less successful in reaching a healthy weight through less-intensive interventions, such as mobile health (mHealth) apps [2], are then recommended for higher stage interventions. mHealth apps have the potential for broad reach and adoption among Singaporean youth because of their low cost, widespread internet availability, and high levels of smartphone ownership [3-5]. Given the current COVID-19 pandemic, mHealth is a timely and essential tool to engage adolescents when in-person services are unavailable and when COVID-19 response strategies contribute to decreased physical activity and increase other unhealthy lifestyle behaviors [6,7,8].

The commercially available mHealth weight management program, Kurbo, has provided individualized health coaching, educational videos on nutrition and physical activity, and self-monitoring to improve diet and physical activity behaviors [9]. Prior research among Kurbo users showed that increased engagement with the Kurbo features, including the web-based coaching sessions, was associated with greater weight loss, suggesting that Kurbo may be appropriate as an early-stage intervention among adolescents with obesity [10].

Objectives

Therefore, the primary objective of this study is to examine the implementation of Kurbo as an early intervention for adolescents with obesity before enrollment in a clinic-based multidisciplinary weight management program in Singapore. The evaluation used the relevant dimensions of the reach, effectiveness, adoption, implementation, and maintenance evaluation framework [11].

Methods

Study Design

This was a prospective, single-arm study that conducted evaluations at three time points: baseline, 3 months, and 6 months. A total of 40 participants, with informed parental consent and child assent, were enrolled in the study at the point of referral to the KK Women's and Children's Hospital (KKH) weight management clinic (WMC). Participants were enrolled between October 2018 and March 2019. All study procedures were approved by the Singhealth Centralized Institutional Review Board. The study was registered at ClinicalTrials.gov (NCT03561597).

Multidisciplinary WMC Clinic

KKH is an 830-bed tertiary pediatric teaching hospital that provides two-third of the government-subsidized pediatric care in Singapore. The adolescent WMC is a physician-led multidisciplinary clinic where adolescents with overweight and their families engage with a multidisciplinary care team consisting of physicians, dietitians, exercise physiologists, and psychologists to set and monitor behavioral goals to manage obesity-related comorbidities. The KKH WMC protocols and outcomes have been previously published, with a historical dropout rate of 58% [12].

The usual waiting time for a first visit to the WMC clinic varies from 4 to 8 weeks after the initial referral. For this study, WMC providers had access to information about participants' Kurbo progress through an administrator site during this period. This allowed for monitoring safety concerns and guiding discussions during clinic visits. After the first WMC visit, dietary recommendations and counseling were provided by the dietitian according to the recommended nutritional guidelines. Physical activity counseling was also performed by exercise trainers based on the World Health Organization guidelines on physical activity and sedentary behavior.

Study Participants

Adolescents, referred to the WMC, aged 10-17 years with a BMI percentile above the 85th percentile [13], were eligible for enrollment. Adolescents with secondary causes of obesity, such as Cushing syndrome, those whose parents were non-English speakers, and those without smartphone access were not eligible for enrollment. Study participants were asked to download the Kurbo app onto their mobile phones and enroll in the app at the point of study enrollment. The participants had free access to the Kurbo program.

Kurbo Program

Kurbo is a mobile app developed to aid adolescents and their families with weight management through dietary self-monitoring and weekly coaching sessions (Figure 1). The details of the Kurbo mobile app and use of supportive accountability in the coaching program have been described previously [10,14]. In short, the Kurbo program consists of a mobile app for self-monitoring of eating, physical activity behaviors, and weight and individualized coaching sessions by Kurbo-certified behavioral coaches. The mobile app's data-driven platform provides users with feedback via push notifications, text messages, and emails. Using the traffic light diet to categorize foods [15], Kurbo promotes the gradual reduction of high-calorie (red) foods over time. Study participants were asked to use the mobile app to log their daily food intake and were encouraged to gradually reduce their *red* food consumption and increase consumption of *green* food. They were also recommended to monitor their daily physical activity levels and to work toward the recommended 60 minutes of moderate-to-vigorous physical activity (MVPA) each day.

Weight tracking and uploading into the app were recommended at least weekly. Individualized coaching included a weekly check-in with the coach for 15 minutes via video, phone, or text over a 12-week period. Participants were paired with the same coach for the duration of the program. Coaches monitored participants' self-report of weight, physical activity, and dietary behaviors and provided individualized feedback based on the information provided. After each coaching session, coaches emailed a copy of the session summary and a tailored plan for the coming week.

Figure 1. Screenshot of Kurbo app.

Measures

Demographic and parental characteristics were obtained at the baseline. Questionnaires and food diaries were obtained through self-reports using physical forms during the study visits.

Evaluation

The implementation of the Kurbo program as an early intervention was evaluated using the relevant dimensions of reach, effectiveness, adoption, implementation, and maintenance framework [11] as follows: (1) reach, number who consented to participate out of all patients approached; (2) implementation, program engagement as detailed for the 12-week program and program evaluation; (3) effectiveness, measured by 3-month BMI *z*-score changes from baseline and changes in blood pressure, nutritional intake physical activity levels, quality of life, and disordered eating behaviors as defined below; and (4) maintenance, measured using the identical outcomes at 6 months and 3 months after the program conclusion. Throughout the 12-week program, we also recorded the weekly frequency of information entered for meal consumption, body weight, physical activity, and coaching sessions. We evaluated satisfaction with the Kurbo program through solicitation of participants' feedback on ease of program navigation and overall use as well as their likelihood to recommend Kurbo to others.

Anthropometric and Blood Pressure Measurements

Height, weight, waist circumference [16], body fat percentage [17], and blood pressure were measured by trained staff at each study visit in the clinic. Height was measured to the nearest 0.1 cm via a stadiometer (Seca, Model 220). Weight was measured to the nearest 0.1 kg using a medical weighing scale without shoes and in light clothing. Body fat percentage was assessed

using bioimpedance analysis (Impedimed, DF50 Body Composition Analyser). Blood pressure was measured using an electronic sphygmomanometer (Dinamap model 8101, Critikon Inc). Anthropometric measurements were taken at baseline and at 3 and 6 months.

Nutritional Intake

Adolescents' daily total caloric intake and fruit and vegetable consumption were assessed using a 3-day food diary that has been previously validated for use with Singaporean adolescents [18,19]. The food diary was administered at baseline and at 3 and 6 months.

Physical Activity Levels

Physical activity was assessed using a wGT3X+ ActiGraph accelerometer. Participants wore the accelerometer for a 7-day period at baseline, 3 months, and 6 months. The ActiGraph data were processed using ActiLife 6 software. The Puyau cutoff point of 3200 counts per minute was used to estimate the time spent in MVPA. When 20 minutes of consecutive zeros were present in the accelerometry data, it was assumed that the monitor was not being worn at that time. All days with >500 minutes of valid data were included in the analysis [20-22].

Psychosocial Outcomes

Self-reported questionnaires were administered to adolescents at baseline, 3 months, and 6 months. The Pediatric Quality of Life Inventory (PedsQoL; UK version 4) was administered to evaluate physical, emotional, school, and social functioning. The Eating Pattern Inventory for Children (EPI-C) [23] was used to assess four dimensions of psychological eating behavior: external eating, emotional eating, dietary restraint, and parental pressure to eat. Higher scores were indicative of concerning behavior in each dimension. Both the PedsQoL and EPI-C have been validated in adolescent cohorts, including overweight adolescents [24,25].

Statistical Analysis

Data were analyzed using SPSS version 9.3 for Windows (IBM Corp). BMI was computed as kg/m^2, and the BMI z-score was calculated using the L, M, and S parameters published by the Centers for Disease Control and Prevention [13]. Baseline demographic, anthropometric measurements, and parent characteristics were compared between study completers and those who dropped out of the study using the Wilcoxon rank-sum test and two-sample, 2-tailed *t* tests for nonnormal and normal continuous variables, respectively, and the Fisher exact test for categorical variables. Changes in anthropometric measurements, quality of life, disordered eating behaviors, MVPA, total caloric intake, and blood pressure measurements between the first visit and months 3 and 6 were compared using paired-sample *t* tests. Linear regression was used to determine the association between BMI z-scores at 3 months (primary outcome) and the number of WMC visits attended during the Kurbo program. The level of statistical significance was set at $P<.05$.

Results

Implementation of Kurbo Program as an Early Intervention

Reach

Of the 73 eligible participants, 40 (55%) were consented and enrolled in the study. The mean age of the participants was 13.8 (SD 1.7) years. Among this, 58% (23/40) of the enrolled adolescents were male, 45% (18/40) were Chinese, 33% (13/40) were Malay, and 13% (5/40) were Indian. Of 40 participants, 32 (80%) were referred to WMC as a result of opportunistic screening during medical visits for nonobesity-related conditions and 8 (20%) were referred specifically for obesity-related comorbidities. Moreover, 65% (26/40) of participants had a family history of metabolic diseases, and 83% (33/40) of accompanying parents were overweight or obese. Overall, 83% (33/40) of participants had household income less than the national median monthly household income of SGD 9500 (US $7125) [26], and approximately one-third had a monthly household income below SGD 2000 (US $1500). Half of the accompanying parents had a secondary school–level education or less. Other baseline characteristics of the participants are summarized in Table 1. There were no significant differences in baseline characteristics between those who completed the study and those who dropped out (Table 1). In total, 53% (21/40) of adolescents completed the 3-month assessment, and 50% (20/40) completed the 6-month assessment (Figure 2).

Engagement and Evaluation

Overall, 83% (33/40) of participants completed at least 1 health coaching session. Participants completed a median of 7 (IQR 2-10) weekly sessions. Initial participant engagement across all Kurbo components was initially high but decreased over time (Figure 3). During the 12-week program, participants logged mean of 4.1 (SD 2.1) weight measurements. On average, participants tracked mean *green foods* 3.8 (SD 3.9) times and *red foods* 4.6 (SD 3.7) times and recorded physical activity 3.2 (SD 2.6) times each week. In addition, 18% (7/40) of participants did not engage in any health coaching session, weight, meals, or physical activity tracking.

A total of 23 participants completed the evaluation of Kurbo and individual components, as shown in Figures 4 and 5. Participants rated communication with the health coach as the most user-friendly and useful component. A total of 21 participants reported following the health coaches' advice to a moderate-to-large extent. The participants did not report difficulties in using the app. Moreover, 18 participants rated the app as good to excellent, with 16 participants stating that they would recommend it to others.

Figure 3. Number of participants who logged in at least one weight, food, or physical activity by week.

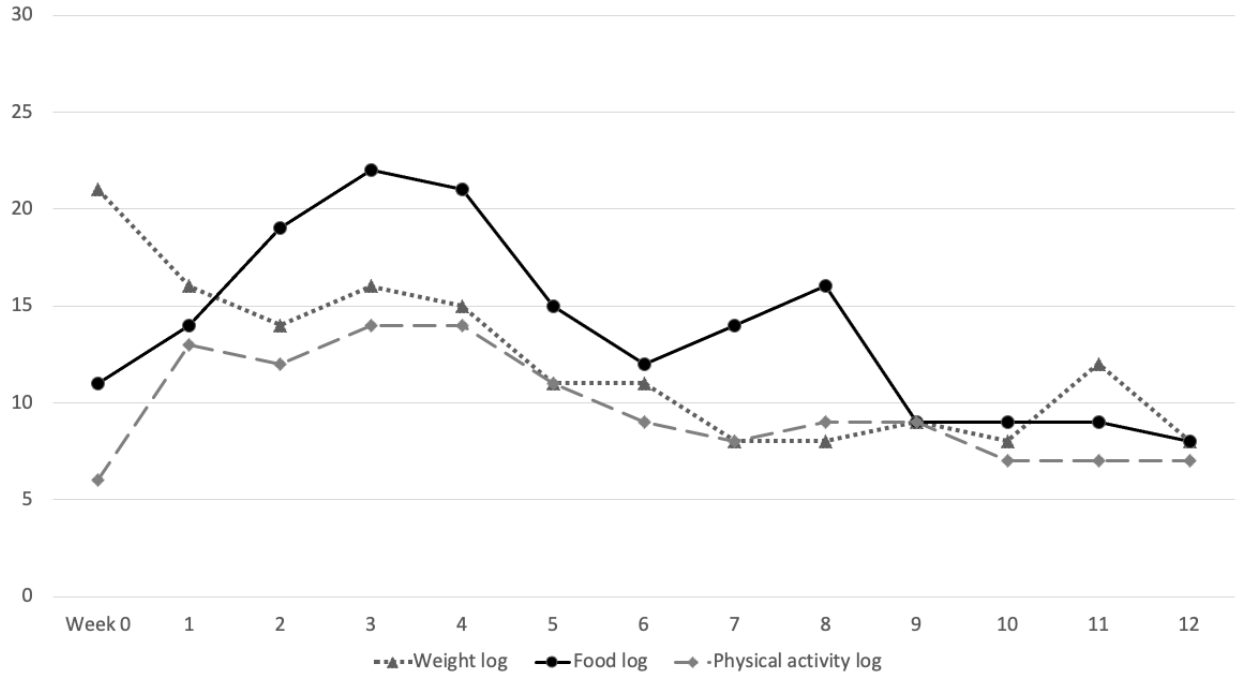

Figure 4. User-friendliness of the various components of Kurbo where 1=very difficult and 5=very easy.

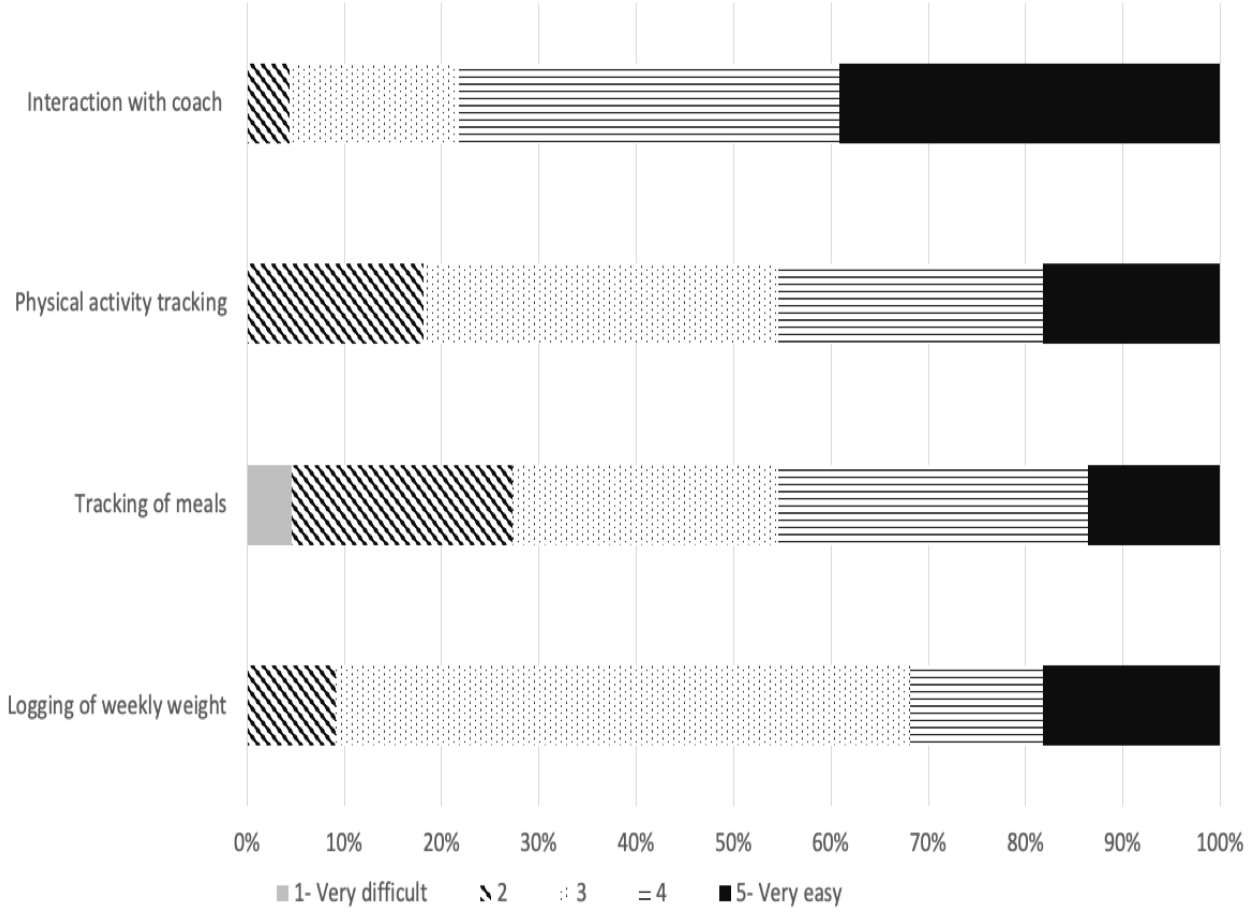

Figure 5. Usefulness of the various component of Kurbo where 1=not useful and 5=very useful.

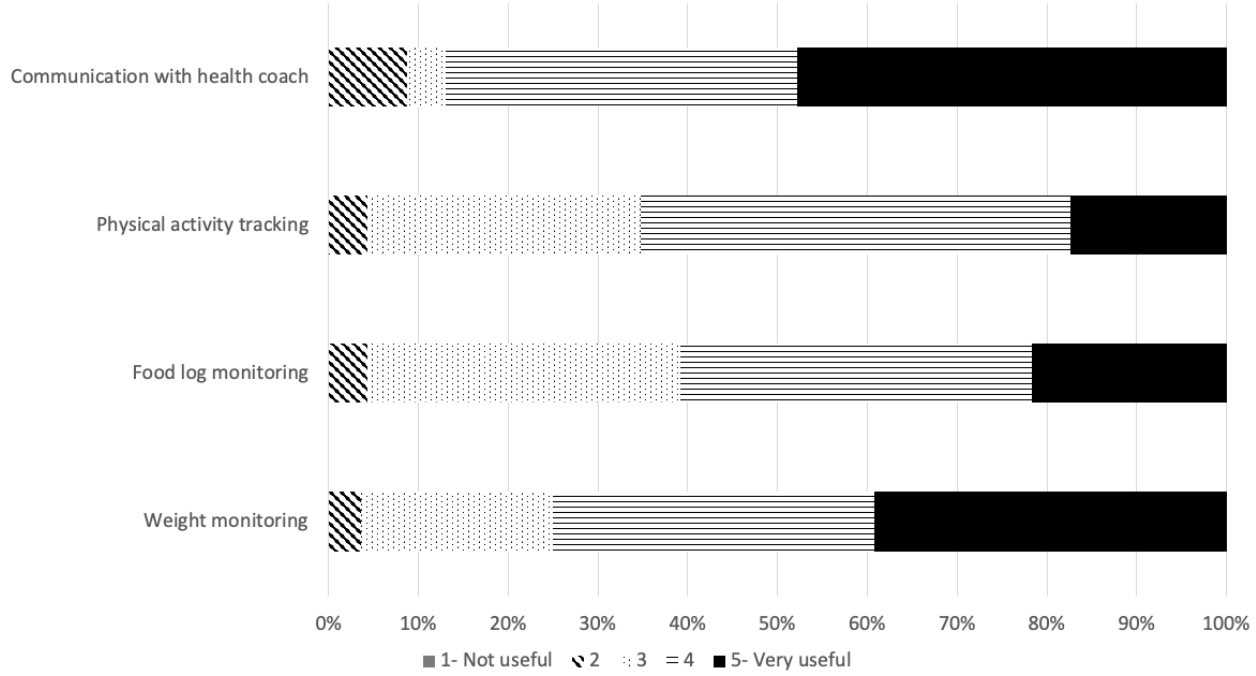

Effectiveness (3-Month Outcome) and Maintenance (6-Month Outcome)

Anthropometric and Blood Pressure Outcomes

There were no significant changes in BMI z-score (primary outcome) at either 3 or 6 months. However, there was a significant reduction in body fat percentage at both 3 months (−1.3%; 95% CI −2.5% to −0.2%; *P*=.03) and 6 months (−2%; 95% CI −3.6% to −0.4%; *P*=.02; Table 2). After adjusting for multidisciplinary weight management visits during engagement with Kurbo *P*, there was no significant difference in BMI z-scores at 3 months (F_{27}=0.406; *P*=.53). No significant differences were detected at 6 months for blood pressure, waist circumference, or waist-to-height ratio (Table 2).

Table 2. Changes in adolescents' anthropometric and blood pressure (N=40).

Variable	Baseline to 3 months (n=21)		Baseline to 6 months (n=20)	
	Value, mean (SD; 95% CI)	*P* value	Value, mean (SD; 95% CI)	*P* value
Body mass (kg)	2.7 (4.74; 0.5 to 4.8)	.02	3.59 (4.55; 1.45 to 5.71)	.002
BMI z-score	0.045 (0.15; −0.024 to 0.114)	.19	0.035 (0.14; −0.028 to 0.098)	.27
Waist circumference (cm)	1.1 (6.74; −1.9 to 4.2)	.45	0.3 (6.21; −2.6 to 3.2)	.84
Waist-to-height ratio	−0.003 (0.040; −0.20 to 0.015)	.75	0.004 (0.038; −0.014 to 0.022)	.67

[a]BP: blood pressure.

Eating and Physical Activity Behaviors

The 3-day food diary revealed significant reductions in caloric intake at 3 months (mean −300, SD 456; 95% CI −576 to −24; *P*=.04) and 6 months (mean −332, SD 517; 95% CI 598 to −66; *P*=.02; Table 3) [5]. Moreover, the time spent in MVPA (minutes) at 6 months increased (mean 5.3, SD 4.8; 95% CI 0.88-9.75; *P*=.03; Table 3).

Table 3. Changes in adolescents' health behavior and psychosocial parameters (N=40).

Variable	Baseline to 3 months (n=21)		Baseline to 6 months (n=20)	
	Value, mean (SD; 95% CI)	*P* value	Value, mean (SD; 95% CI)	*P* value
Total (kcal/day)	−300 (457; −576 to −24)	.04	−332 (518; −598 to −66)	.02
Servings of vegetables per day	−0.17 (0.50; −0.5 to 0.1)	.24	−0.0 (0.79; −0.4 to 0.4)	.99
Average moderate-to-vigorous physical activity per day (minutes)	1.47 (10.03; −4.3 to 7.2)	.59	5.3 (4.78; 0.88 to 9.75)	.03
Adolescents Pediatric Quality of Life Inventory				
Total	2.4 (13.11; −3.1 to 7.9)	.38	1.4 (11.67; −4.2 to 7.0)	.61
Physical	4.0 (13.56; −1.7 to 9.8)	.16	1.0 (11.60; −4.6 to 6.6)	.72
Emotional	6.5 (23.34; −3.4 to 16.3)	.19	9.7 (20.58; −0.2 to 19.7)	.05
School	8.3 (18.28; 0.6 to 16.1)	.04	6.9 (13.52; 0.2 to 13.7)	.04
Psychosocial	6.3 (14.52; 0.2 to 12.5)	.04	6.5 (12.98; 0.2 to 12.7)	.04
Eating Pattern Inventory for Children				
Dietary restraint	0.033 (0.42; −0.15 to 0.21)	.72	0.00 (0.48; 0.23 to −0.23)	.99
External eating	−0.087 (0.82; −0.44 to 0.27)	.62	−0.19 (0.65; −0.50 to 0.12)	.22
Parental pressure to eat	0.116 (0.54; −0.12 to 0.35)	.31	0.018 (0.66; −0.30 to 0.33)	.91
Emotional eating	0.00 (0.79; −0.34 to 0.34)	.99	0.171 (0.67; −0.15 to 0.49)	.28

Psychosocial Outcomes

At 3 months, adolescents' self-reported quality of life improved in the school (mean 8.3; 95% CI 0.6-16.1; *P*=.04) and psychosocial (mean 6.3; 95% CI 0.19-12.5; *P*=.04) domains (Table 2). These improvements persisted for 6 months. There were no significant changes in eating patterns, including dietary restraint, external eating, parental pressure to eat, and emotional eating subscales.

Discussion

Principal Findings

This pilot study is one of the few studies to evaluate the implementation of a multicomponent mobile app as an early intervention before enrollment in an adolescent WMC. The Kurbo pilot was successful in reaching a low-income and racially diverse population. Although there was no significant reduction in BMI z-scores, there were significant improvements in fat percentage, total caloric intake, and quality of life, suggesting potential benefits of enrolment and the need for a more formal randomized trial.

Obtaining a reach of 58% is comparable with that of other pediatric obesity studies [27]. Moreover, the high percentage of minority, lower education, and low-income enrollees suggests that Kurbo is more likely to reach disadvantaged populations than traditional in-person programs. Given the high rates of obesity among children of lower socioeconomic status, this is a significant advantage of Kurbo.

Kurbo participants completed a median of 7 (IQR 2-10) coaching sessions. This level of engagement is considered very low (<10 hours of intervention time) based on the US Preventive Special Task Force criteria [28]. This may account for the lack of BMI changes among our participants. However, this lack of engagement is not unique to Kurbo, as other programs, including clinic-based programs, have shown similar levels of engagement [29-31].

Our results show that the maximal period of engagement with Kurbo occurred in the first 7 weeks, which corresponded to the period between the initial WMC referral and the first WMC clinic visit. This suggests that Kurbo may be helpful in engaging participants as an early intervention before the first WMC visit. Early engagement may account for the increase in WMC attendance at 6 months (20/40, 50% attendance) compared with our historical rate of 42.1% (51/121). The use of a mobile app as an early intervention also provided mutual benefits to both the health care provider team and Kurbo health coaches. The administrator platform allowed the multidisciplinary team to gain a better understanding of patient progress in health behaviors and weight before presenting to the clinic. This allowed for more targeted discussions about barriers that adolescents faced in the management of obesity and more efficient care. Kurbo health coaches were able to highlight any concerns that they faced during the health coaching sessions of the health care team.

A challenge with Kurbo as an early intervention was the high attrition rate. Although the study's dropout rate of 50% (20/40) is less than the in-clinic rate of 57.8% (70/121), it suggests that strategies need to be crafted to reduce attrition if Kurbo is to be successfully used as an early-stage intervention. Further research on the reasons for attrition is recommended.

Despite the lack of changes in BMI z-scores, a significant improvement in quality of life is an important finding. Quality of life among adolescents with overweight is lower than that among normal-weight peers [25] and youth with other chronic conditions [32]. Improvement in quality of life has been reported

with participation in other obesity treatment programs, even in children who do not achieve significant weight loss [33]. Given the prevalence of weight-based victimization experienced by adolescents with obesity in school [34], the improvement in the school dimension of quality of life is promising. Improvement in quality of life is critical, as it has been associated with improved long-term health indicators, with lower use of health care resources and greater long-term weight reduction [35]. To the best of our knowledge, improvement in self-reported quality of life has not previously been reported with the use of a mobile app to address adolescent obesity, which should be validated in future research.

Reassuringly, our study found no measured increase in disordered eating behaviors, as measured by the EPI-C. On the basis of these results, the integrated model of a mobile app with multidisciplinary adolescent obesity management is unlikely to increase disordered eating behaviors despite concerns for the development of disordered eating habits with the use of mobile apps [36].

Limitations

This study had several limitations. The study had a small sample size and a high attrition rate. Second, as this was a feasibility study, the study did not include a control group.

Conclusions

In this pilot study, the use of the Kurbo mobile app as an early intervention before a multidisciplinary clinical care for adolescent obesity treatment is feasible in a low-income and ethnically diverse Asian population. Although there was no significant change in the BMI z-score, Kurbo showed promise in improving quality of life and reducing body fat percentage and total caloric intake. Given the promising outcomes in several dimensions, further research using more rigorous trial designs should be conducted to evaluate the effects of Kurbo as part of an early, stepped care intervention for adolescents with obesity.

Acknowledgments

The authors thank Kurbo for providing the data for this study. Kurbo was not involved in the design of the study, the analysis and interpretation of the data, or the preparation and submission of this manuscript. The authors wish to thank the patients and their families for their participation in the study and members of the pediatric weight management team for their contribution to the study. The study was funded by the Pediatrics Academic Clinical Programme/Tan Cheng Lim Fund grant PAEDACP-TCL/2017/CLIN/006.

Conflicts of Interest

EAF is on the scientific advisory board for WW Int (formerly Weight Watchers), the company that now owns Kurbo.

Abstract

Background: College environments promote high-volume or binge alcohol consumption among youth, which may be especially harmful to those with type 1 diabetes (T1D). Little is known about the acceptability and effectiveness of interventions targeting reduced alcohol use by college students with T1D, and it is unclear whether intervention framing (specifically, the narrator of intervention messages) matters with respect to affecting behavior change. Interventions promoted by peer educators may be highly relatable and socially persuasive, whereas those delivered by clinical providers may be highly credible and motivating.

Objective: The aim of this study is to determine the acceptability and impacts of an alcohol use psychoeducational intervention delivered asynchronously through web-based channels to college students with T1D. The secondary aim is to compare the impacts of two competing versions of the intervention that differed by narrator (peer vs clinician).

Methods: We recruited 138 college students (aged 17-25 years) with T1D through web-based channels and delivered a brief intervention to participants randomly assigned to 1 of 2 versions that differed only with respect to the audiovisually recorded narrator. We assessed the impacts of the exposure to the intervention overall and by group, comparing the levels of alcohol- and diabetes-related knowledge, perceptions, and use among baseline, immediately after the intervention, and 2 weeks after intervention delivery.

Results: Of the 138 enrolled participants, 122 (88.4%) completed all follow-up assessments; the participants were predominantly women (98/122, 80.3%), were White non-Hispanic (102/122, 83.6%), and had consumed alcohol in the past year (101/122, 82.8%). Both arms saw significant postintervention gains in the knowledge of alcohol's impacts on diabetes-related factors, health-protecting attitudes toward drinking, and concerns about drinking. All participants reported significant decreases in binge drinking 2 weeks after the intervention (21.3%; odds ratio 0.48, 95% CI 0.31-0.75) compared with the 2 weeks before the intervention (43/122, 35.2%). Changes in binge drinking after the intervention were affected by changes in concerns about alcohol use and T1D. Those who viewed the provider narrator were significantly more likely to rate their narrator as knowledgeable and trustworthy; there were no other significant differences in intervention effects by the narrator.

Conclusions: The intervention model was highly acceptable and effective at reducing self-reported binge drinking at follow-up, offering the potential for broad dissemination and reach given the web-based format and contactless, on-demand content. Both

intervention narrators increased knowledge, improved health-protecting attitudes, and increased concerns regarding alcohol use. The participants' perceptions of expertise and credibility differed by narrator.

Introduction

Background

Effective management of chronic conditions such as type 1 diabetes (T1D) is affected by individual-, family-, community-, and health care system–level features [1]. For adolescents and young adults with T1D who may struggle to meet glycemic targets [2], disease self-management (eg, blood glucose monitoring) and risk behaviors (eg, alcohol consumption and poor diet) are some of the many factors that influence the achievement of glycemic targets [3,4]. The transition to college may be a particularly vulnerable period, as self-management processes are disrupted, risk behaviors rise, and access to support and supervision from family and health care providers diminishes [5].

Clinical studies in the United States have found that 1 in 3 youths with T1D may drink alcohol by the time they reach high school [6]. Postsecondary education (eg, college or university) students with T1D may be especially vulnerable to initiating or intensifying alcohol use, as many reside in settings that are ill-prepared to identify and support their health needs [7]. *Alcogenic* college environments [8-10] create social pressures that foster alcohol use [11,12]. Despite the risks associated with alcohol consumption and T1D [13,14], college-aged youths with T1D have poor alcohol-related health literacy [15,16] and engage in risky alcohol use [8,17]. There is a dearth of evidence-based interventions to minimize alcohol-related risks in youths with T1D in general [3,16,18] and fewer targeting those in college [19].

Given the high potential for alcohol-related health harm, it is critically important to identify how best to engage college students with T1D around harm reduction [20]. Consistent with the students' developmental status, successful interventions may require a patient-centered focus and peer or provider directives, reinforcing the value of health-protecting behavior [21-24]. A digital approach to delivering specialized information may be especially advantageous in situations where college students are distanced from their specialty care or where college health services may be underresourced for the provision of chronic disease–specific guidance [25]. The digitally oriented nature of this age group suggests that the students will be highly receptive to such delivery [26]; however, even digital materials may benefit from delivery by a compelling spokesperson who can appropriately frame the educational materials. Communication sciences and behavioral economics posit different ways in which the presentation of information can affect decision-making; thus, understanding the acceptability and impact of different narrators for delivering harm reduction messages may optimize their effects. Peer delivery could be especially meaningful if college students with T1D personally identify with the narrator and feel supported regarding the distress arising from contravening social norms that encourage drinking. Conversely, provider delivery may be highly salient—clinician expertise, gravitas, and the grounding of guidance in diabetes science may be impactful for shaping health beliefs and behaviors.

Objective

The aims of this study are to understand the acceptability of a digital health intervention for addressing alcohol use risk among college students with T1D and to test the relative salience of two types of narrators for its delivery and framing. Consistent with a stepped approach for designing behavioral interventions [27,28], we undertook a pilot trial to evaluate the acceptability and impacts of the intervention overall and measure the relative salience of competing versions of the intervention, with one version delivered by a peer educator and another delivered by a specialty care provider (ie, a medicine-pediatric endocrinologist). The intervention coupled diabetes-related medical science and social-emotional content, building on formative work indicating that both elements are considered high priorities for substance use–related interventions targeting adolescents and young adults with chronic conditions [22]. Given prior evidence about the effectiveness of peer support for diabetes self-management [29-34], we hypothesized that exposure to peer delivery of this information would show higher acceptability and impacts on knowledge, attitudes, and behaviors than provider delivery.

Methods

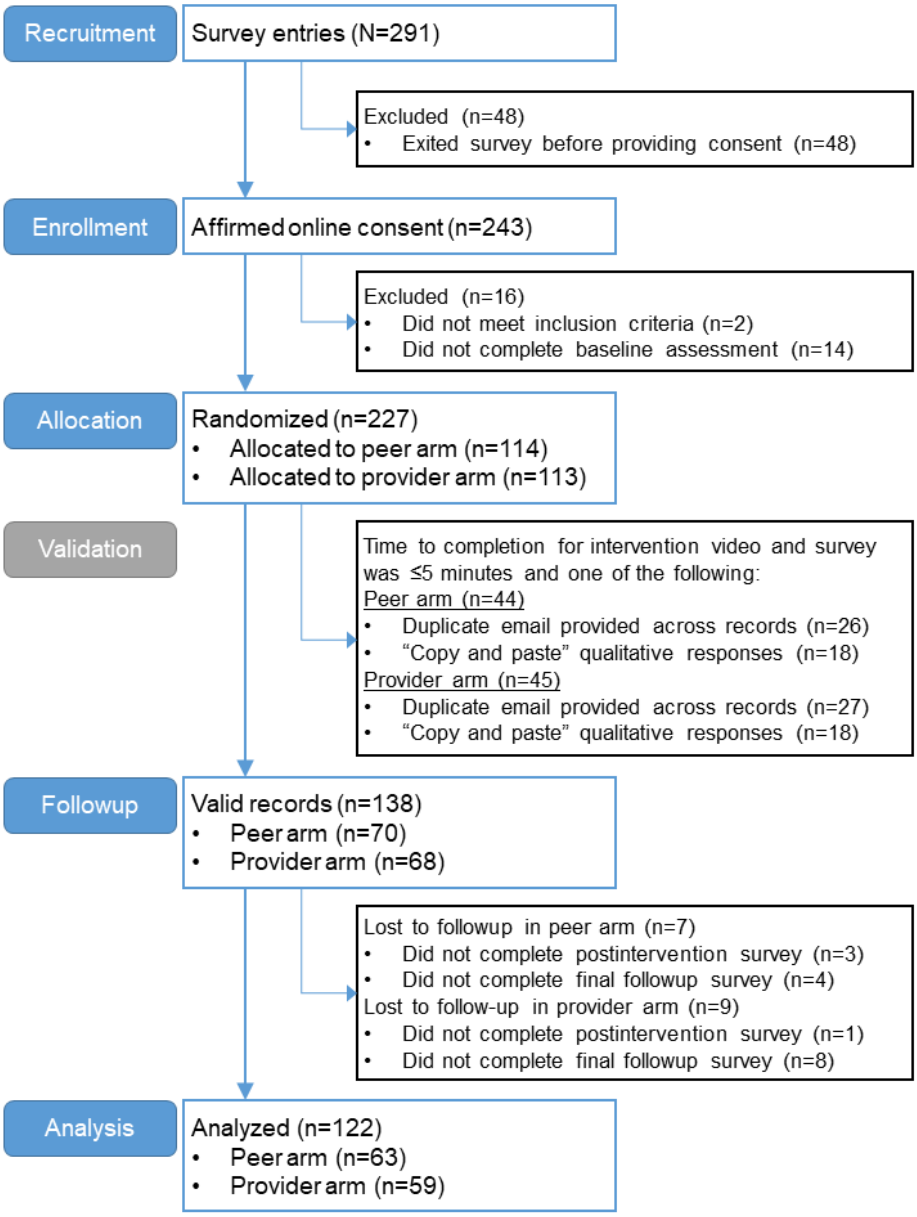
Overview

We implemented a pilot trial to test two competing versions of a novel psychoeducational intervention targeting alcohol-related knowledge, attitudes, and behaviors of college students with T1D from the United States and Canada. The approach to engaging participants has been previously reported [35]. For the pilot, we randomized the narrators delivering and framing the educational materials. Both structured and open-ended survey data were collected. This study was approved by the institutional review board.

Recruitment and Consent

The participants were recruited from two diabetes advocacy groups through social media, direct email newsletters, and a website banner. The recruitment messages were linked to a website with additional study details and safety resources. The website, in turn, transferred interested individuals to a REDCap (Research Electronic Data Capture) survey hosted on secure servers; the website and survey were accessible on a smartphone, tablet, or computer. After entering the survey, the individuals completed the web-based informed consent (or assented with a waiver of parental consent for those aged 17 years). Additional details of recruitment procedures and study implementation, including an evaluation of sampling procedures and generalizability, have been previously published [35] and are summarized in the CONSORT (Consolidated Standards of Reporting Trials) diagram (Figure 1).

Figure 1. Trial CONSORT (Consolidated Standards of Reporting Trials) diagram showing participant flow through each stage of the randomized trial from recruitment through analyses.



After providing consent, the respondents answered screening questions to ascertain eligibility (aged 17-25 years, received a diagnosis of T1D, and currently attending, enrolled at a college, or university), and those who met the inclusion criteria (hereafter *participants*) were directed to complete the remainder of the baseline survey.

Intervention and Assessments

Upon completion of the baseline survey, the participants were automatically randomized to receive one of two brief psychoeducational videos narrated by either an endocrinologist (provider) or a college student with T1D (peer educator). A REDCap module executed stratified randomization based on sex, year in college, and alcohol use in the past year. The intervention video included educational content about the effects of alcohol on physical and psychological functioning in persons

with T1D and addressed the social aspects of alcohol use through visually rich, annotated graphics that described how and why youths with T1D choose to limit alcohol use in social settings; overall, the video had a harm reduction rather than abstinence focus that did not specifically call for abstinence or suggest safe limits in use.

To develop the psychoeducational content for the intervention, we conducted qualitative interviews using a semistructured interview guide grounded in social cognitive theories of risk-taking among adolescents with chronic conditions [22]. The topics covered daily experiences of the patient's medical condition; information about personal, social, situational, and clinical factors affecting decision-making regarding alcohol use; and preferences for clinical communication about substance use. The results of the qualitative interviews, in combination with prior epidemiological investigations to ascertain salient concerns, motivations, and consequences of alcohol use [6,9,22,36-38], informed the development of an intervention containing patient-centered, accessible information regarding disease-specific concerns and goals while also addressing the complexity of navigating chronic disease management and alcohol use in the setting of adolescent-typical peer pressures and impulses. Clinically accurate content to address disease-specific concerns related to alcohol use within the context of T1D (eg, the effects of alcohol on glucagon efficacy and identification of hypoglycemic symptoms) was developed with input from pediatric endocrinologists, chronic disease epidemiologists, and a developmental behavioral pediatrician specializing in addiction medicine and treating adolescent substance use. Experiential or *slice of life* observations about alcohol use and living with T1D were also incorporated into the intervention using illustrative quotes taken from formative qualitative research [22], with content designed to address the main social and psychological concerns of the target group. Drawings created by an artist embedded in the study team aided in the explanation of both clinical and social-behavioral concepts and were included in the intervention.

Before testing, the intervention underwent formative evaluation through iterative rounds of piloting (for accessibility and acceptability) with patients representing the target group (ie, adolescents and young adults with T1D presenting for routine clinical care to an outpatient hospital clinic). Feedback on the intervention was collected in a structured session with trained members of the research team. The formative evaluation also included a review by pediatric endocrinologists to ensure the accuracy of clinical and health-related content before moving to video production and with stakeholders representing the advocacy organizations through which the study samples were to be recruited. The visual intervention content was then overlaid with the corresponding audio explanation, narrated by either a peer or provider narrator. The narration scripts were identical for both the peer and provider versions of the intervention, with the exception of the initial narrator introductions containing narrator-specific identification (ie, the narrator's name and role or credentials). The peer and provider narrators were purposefully selected to be of the same gender and same race, and they were similarly styled to reduce the influence on audience perceptions related to factors other than the narrator's role. Other than the narrator, all video content was identical. The final versions of the intervention (approximately 7.5 minutes in duration) were uploaded to a private channel on a video hosting site and embedded within the REDCap survey so that the participants could automatically view the video without having to exit the survey.

The participants completed a brief survey immediately after viewing the video, and 2 weeks after completion of the *initial* session (baseline survey, intervention video, and immediate postintervention survey), they were sent a follow-up survey through email (automated through REDCap, with up to two additional reminders). The participants received a US $20 gift card for completion of each of the two sessions (initial and follow-up). Of the 138 valid responses at baseline, 134 (97.1%) completed the immediate postintervention survey, and 122 (88.4%) subsequently completed the follow-up assessment. Compared with the participants with complete follow-up, those lost to follow-up were older at diagnosis (13.3 years vs 10.6 years; P=.04; data not shown); no other significant differences were observed.

Covariates

The participants provided sociodemographic data (eg, age, sex, race or ethnicity, parental education, health insurance, enrollment status, school year, living arrangement, and region of college or university attended) and clinical information (eg, age during diagnosis or disease duration, last glycated hemoglobin [HbA_{1c}] value, current insulin pump use, current continuous glucose monitoring [CGM] device use, average blood glucose tests per day, average HbA_{1c} tests per year, and self-rated health) at baseline.

Self-reported Alcohol Use (Primary Outcome)

The participants self-reported alcohol use behaviors at baseline and follow-up assessments, including validated measures of binge use during the past 2 weeks (defined as having 3, 4, 5, or more drinks containing alcohol on one occasion, depending on age and sex threshold [39]). The participants identified any recent events or breaks that were atypical for their schedule in response to novel questions. The events were grouped into those potentially associated with a greater likelihood of drinking (eg, spring break spent with friends) or those with a reduced likelihood of drinking (eg, midterms or final examinations).

Knowledge, Attitudes, and Concerns Toward Alcohol Use (Secondary Outcomes)

The secondary outcomes relied on novel test batteries that were developed for a series of related studies and informed by clinical reviews and epidemiologic insights [6,22,40,41]. During all three assessments, the participants were asked about their knowledge of the potential impacts of alcohol use on diabetes (10 items with responses of "true," "false," or "don't know"), attitudes toward drinking with diabetes (six items rated from "strongly disagree" [score=1] to "strongly agree" [score=10], with two items only asked among drinkers), and concerns about the potential impact of alcohol on diabetes (seven items rated from "not concerned" [score=0] to "very concerned" [score=6]). To summarize knowledge, the number of correct items was determined. To summarize attitudes and concerns, the mean

score across all items was determined for each; higher scores reflected health-protecting attitudes toward drinking or greater concern about the impact of alcohol. Although the measures were novel and not previously validated, they demonstrated reasonable internal consistency (Cronbach α=.9079 for concerns and .6462 for attitudes).

Intentions and Impressions (Secondary Outcomes)

At postintervention and follow-up assessments, the participants were asked about their impressions of the video (13 items rated from "strongly disagree" [score=1] to "strongly agree" [score=10]) and their intentions (10 items rated from "definitely will not" [score=1] to "definitely will" [score=8], with two items only asked among drinkers). To summarize impressions and intentions, the mean score across all items was determined for each; higher scores reflected more favorable impressions of the intervention (ie, acceptability) or greater intention to engage in lower-risk behaviors. The measures demonstrated reasonable internal consistency (Cronbach α=.8581 for impressions and .8294 for intentions). For aligning with intentions, the participants were asked at the final follow-up to specify actual behaviors, including (1) if they had talked in the past 2 weeks with friends, health care providers, or someone else about how alcohol affects diabetes and (2) the frequency with which they tested their blood sugar before, during, or after drinking during the past 2 weeks.

The participants were also prompted with open-response questions on their diabetes care or alcohol use, first impressions of the video (after the intervention), and final thoughts about the video (final follow-up). The participants who endorsed learning something new or having unanswered questions were prompted for further clarification. These open-ended questions were intended to complement the quantitative impression measures by providing a more subjective and nuanced perspective on intervention acceptability.

Analytic Approach

The analyses followed a mixed methods protocol, investigating structured survey data and thematically coding optional comment data. Quantitative analyses were performed using SAS version 9.4 (SAS Institute Inc). Statistical significance was set at $P<.05$. All individuals who were randomized into the study and completed the follow-up were included in the analyses (N=122). Differences in characteristics between the arms were assessed using appropriate bivariate tests (Table 1). Differences in outcomes between the arms at baseline and follow-up were evaluated using bivariate tests (Table 2). Multivariate mixed effects models estimated the intervention effects on the outcomes overall (main effects models) and by arm (interaction models; Table 3); adjusted predictive margins were output from these models to visualize the intervention effects (Figure 2). Adjusted regression analysis models controlled for age at survey, age at diagnosis, sex, race or ethnicity, parent education, last HbA_{1c} value, and CGM device use, while accounting for repeated measures; the models for alcohol use outcomes were additionally adjusted for atypical events affecting the likelihood of drinking. We selected measures for covariate adjustment based on their known association with alcohol use behaviors (eg, age and sex), known association with diabetes knowledge (eg, HbA_{1c} value), or imbalance across treatment arm (eg, parental education). We additionally evaluated the secondary outcomes (change in knowledge, attitudes, and concerns from baseline to after the intervention) as predictors of the overall change in binge drinking (at final follow-up vs baseline). The participants' responses to the open-response questions were analyzed using an iterative process, including open coding, to identify emergent themes [22] and refinement of the coding scheme over several rounds of joint review with 3 coders (RKT, LEW, and ERW). Disagreements were resolved through discussion and consensus. Themes that reflected consistent commonality across the responses or important distinctive motifs were specified; illustrative quotes for each theme were selected and summarized as context to understand the impacts of the intervention (Multimedia Appendix 1). All 122 participants provided a textual response for their impression of the video, and 91 provided a textual response for the remaining optional prompts; the response rates did not differ by arm (P=.40).

[a]All models were adjusted for age at survey, age at diagnosis, sex, race or ethnicity, parent education, last glycated hemoglobin value, and continuous glucose monitoring device use. Models for binge use additionally adjust for atypical events that affect the likelihood of drinking. The *peertime interaction* coefficient represents the difference in the change over time for the peer arm versus the provider arm (only included in *Interaction* models); this indicates if the effect of the intervention differed by arm. When not statistically significant at *P*<.05, results from the *Main Effects* column are preferred.

[b]Self-reported past 2-week binge alcohol use was modeled with a binomial distribution. Odds ratios are shown instead of β coefficients.

[c]These are models in which this term was not included.

[d]The knowledge summary score indicates the number of correct items out of a total of 10 items, modeled with a normal distribution.

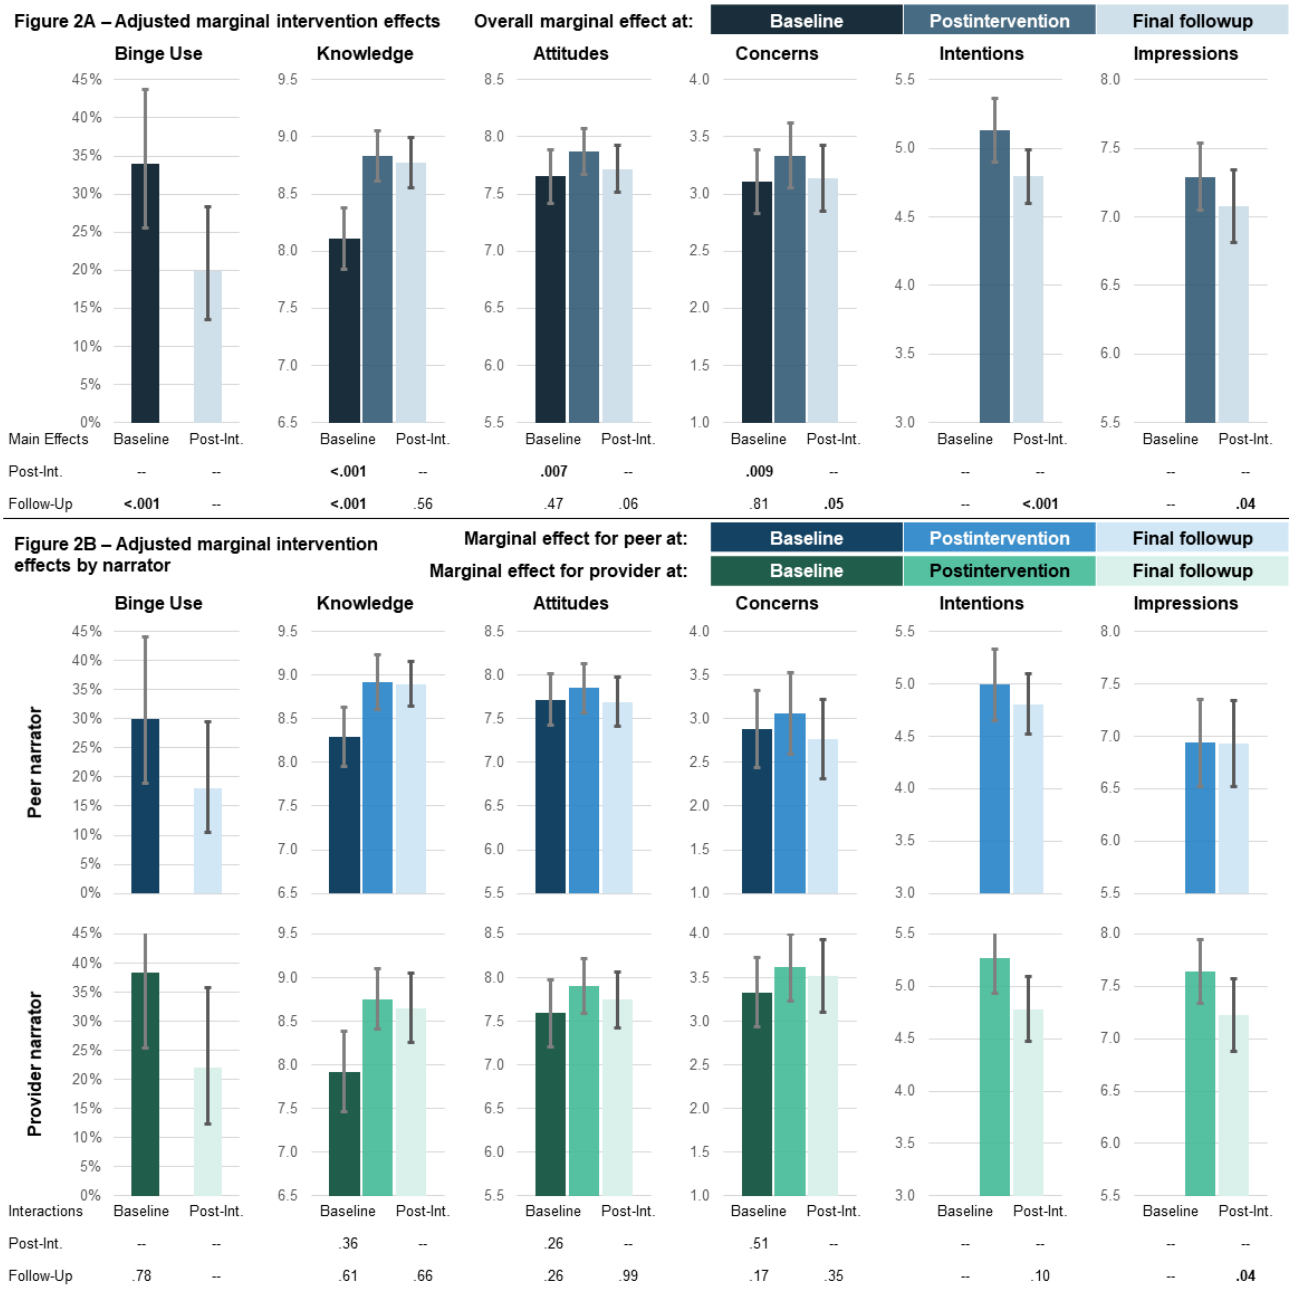
[e]The attitude summary score (average of six items for drinkers and four items for nondrinkers, scored from "strongly disagree" [score=1] to "strongly agree" [score=10]) was modeled with a normal distribution.

[f]The concern summary score (average of seven items, scored from "not concerned" [score=0] to "very concerned" [score=6]) was modeled with a normal distribution.

[g]The intention summary score (average of 10 items for drinkers and eight items for nondrinkers, scored from "definitely will not" [score=1] to "definitely will" [score=8]) was modeled with a normal distribution.

[h]The impression summary score (average of 12 items, scored from "strongly disagree" [score=1] to "strongly agree" [score=10]) was modeled with a normal distribution.

Figure 2. Adjusted marginal intervention effects (y axis) both overall (A, main effects models) and by treatment arm (B, interaction models) across time points (x axis). Adjusted marginal means or probability and 95% CIs were output from multivariate mixed effects models as described in the Methods section. In panel A, the *P* values indicate the statistical significance for the overall intervention effect across time; for example, the intervention reduced the prevalence of binge drinking at final follow-up compared with baseline at *P*<.001. In panel B, the *P* values indicate the statistical significance for the difference in the intervention effect across time by arm (interaction); for example, the reduction in the prevalence of binge drinking at final follow-up compared with baseline was not significantly different by treatment arm at *P*=.78.



Results

Sample Characteristics

The participants were aged 20.46 (SD 1.44) years; 80.3% (98/122) were women, 83.6% (102/122) were White and non-Hispanic, 68.9% (84/122) had a parent with a bachelor's degree or higher, 82.8% (101/122) used insulin pumps, 60.7% (74/122) used CGM devices, their last HbA_{1c} value was 7.65 (SD 1.20), and 82.8% (101/122) self-reported past-year alcohol use (Table 1). The characteristics were largely balanced across the peer (63/122, 51.6%) and provider (59/122, 48.4%) arms, except for the fact that the peer arm participants reported higher parental education (*P*=.02) than their counterparts.

Knowledge, Attitudes, and Concerns

Despite the participants' high baseline knowledge (participants averaged 8.11, SD 1.58 correct items out of 10; Table 2), there was a significant adjusted improvement in correct knowledge items of +0.72 after the intervention (95% CI 0.50-0.95; *P*<.001;

Table 3; Figure 2) and +0.66 at follow-up (95% CI 0.42-0.91; *P*<.001); the improvements after the intervention and at follow-up were not significantly different by arm (*P*=.36 and *P*=.61, respectively). The improvements were driven by an increased understanding of the impact of alcohol on the liver, the distinction between being drunk and low blood glucose, the interaction between alcohol and glucagon, and alcohol-related dehydration (Multimedia Appendix 2).

The participants saw adjusted improvements in health-protecting attitudes of +0.22 after the intervention compared with baseline (95% CI 0.06-0.37; *P*=.007; Table 3; Figure 2); overall improvements after the intervention were similar by arm (*P*=.26). Attitudes did not differ between the follow-up and baseline (+0.06, 95% CI –0.10 to 0.22; *P*=.47). Postintervention changes were driven by attitudes related to telling friends that they cannot drink because of diabetes, and at follow-up, fewer college students agreed that college students with diabetes could drink if they are careful (Multimedia Appendix 2).

The participants reported adjusted increases in concerns about alcohol of +0.23 after the intervention versus baseline (95% CI 0.06-0.40; *P*=.009; Table 3; Figure 2); improvements after the intervention were similar by arm (*P*=.51). Concerns were not different at follow-up versus baseline (+0.03, 95% CI –0.19 to 0.25; *P*=.81). Postintervention changes were driven by increased concern for the effectiveness of glucagon while drinking, whereas increased concerns about the impact of alcohol on HbA_{1c} tests were greater for those in the provider arm than for those in the peer arm (Multimedia Appendix 2).

Intentions and Impressions

Adjusted overall intentions to engage in lower-risk behaviors decreased from after the intervention to final follow-up (–0.33, 95% CI –0.51 to –0.15; *P*<.001; Table 3). Positive impressions of the intervention decreased for those in the provider arm (–0.42, 95% CI –0.74 to –0.10; *P*=.01), whereas those in the peer arm had lower impressions than those in the provider arm (–0.71, 95% CI –1.25 to –0.17; *P*=.01), but their impressions were stable over time (interaction +0.41, 95% CI 0.02-0.80; *P*=.04). The adjusted ratings of narrator knowledge and trust were significantly higher for the provider arm than for the peer arm (Multimedia Appendix 2). After the intervention, the provider arm participants also rated their trust in the information presented and willingness to share this video more highly than the peer arm participants. The provider arm was significantly more likely to decrease their rating of whether they learned something new from after the intervention to follow-up than the peer arm. Intentions to tell their friends about the effect of alcohol on diabetes and to ask their provider about diabetes and alcohol use were stable for the peer arm but more likely to decrease at follow-up for the provider arm.

Alcohol Use Outcomes

Overall, the intervention was associated with a 52% adjusted relative reduction in self-reported binge drinking (odds ratio [OR] 0.48, 95% CI 0.31-0.75; *P*=.001; Table 3; Figure 2) from baseline to follow-up, with no significant difference across narrators (*P*=.78). The change in concerns from baseline to after the intervention was significantly associated with a reduction in binge drinking at follow-up (OR 0.71, 95% CI 0.58-0.88; data not shown), whereas the changes in knowledge and attitudes were not (knowledge OR 0.93, 95% CI 0.75-1.15; attitudes OR 0.90, 95% CI 0.70-1.15).

Qualitative Outcomes

Overall, the qualitative responses suggested that the participants seemed to derive value from the intervention, with four primary themes emerging (Multimedia Appendix 1). First, the youth want disease-specific information about alcohol and have various sources of knowledge acquisition, including through the intervention. Some participants were disappointed that they had not previously been exposed to information about the impact of alcohol on diabetes from other sources (such as their care providers), whereas others expressed appreciation for receiving this new information during the study. However, the information was not novel to all participants, and some described prior acquisition of knowledge through sources such as the internet or peers, as well as their health care teams. Second, the youth noted the influence of personal safety on alcohol use decision-making and the desire for harm reduction messages, as well as new safety practices motivated by the intervention. The participants recognized the prevalence of alcohol use among college students with T1D, expressing a preference for video content encouraging safe and responsible use rather than complete abstinence. Some participants commented upon current safety practices such as drinking with friends and checking their blood sugar while consuming alcohol, whereas others discussed new behaviors inspired by the video, such as recognition of their need to monitor and adjust for their own alcohol intake limits. The third theme encompasses the appeal of intervention content that is not only developmentally appropriate and affirming of personal experiences but also contains an authoritative voice and is professionally produced. Many participants remarked upon their ability to relate to the video because of the relevance of the information and trustworthiness of the speakers, whereas others yearned for more personal stories, easily digestible content, and improved production quality. Finally, the youth addressed factors complicating diabetes and alcohol use management at college, including the need for and role of adequate systems of support. The participants elucidated ongoing challenges faced by youth with T1D, such as social isolation from peers without T1D, inadequate access to specialists on campus, and difficulty balancing their health with other competing priorities during the college years.

Discussion

Principal Findings

This pilot trial demonstrates that a novel, web-based psychoeducational intervention reduces self-reported binge drinking 2 weeks after the intervention among college students with T1D, irrespective of the narrator. Both narrators improved knowledge of the effects of alcohol and temporarily affected attitudes toward and concerns about drinking, although the provider narrator was more highly rated regarding subject knowledge and trustworthiness. Given measurable reductions in binge drinking at follow-up, this brief video intervention

demonstrates promise for mitigating risky alcohol consumption among college students with T1D, and the web-based format is suitable for delivery across numerous settings.

The substantial reduction in binge alcohol use observed for the participants in both arms suggests that both peer and provider narrators can motivate behavioral change. However, the mechanisms by which the narrator affects change may be different. The provider narrator appeared to quantitatively *win out* over the peer narrator with respect to perceived knowledge and trustworthiness, suggesting that delivery of factual content may be enhanced by the aura of clinical authority or that some youths strongly trust and respond to perceived medical experts. Prior qualitative work reported that youths living with chronic conditions conveyed an emphatic preference for the inclusion of information about alcohol use in subspecialty care and reported thinking that their specialty care team know them and their disease best [22]; current qualitative findings echo this and indicate high respect for providers' authority on this topic. The peer narrator appeared to better motivate the intention of the participants to speak with others about the effects of alcohol on their diabetes, suggesting that emotional processing and sharing of experiences may be important for motivating behavioral change and reinforcing knowledge gains. The qualitative findings also supported the participants' desire for narrator and content relatability, as the participants responded positively to hearing their own experiences reflected by their peers. Subtle differences in secondary outcomes by narrator underscore the need for purposeful, well-designed future work to tease out the components that produce cognitive, affective, and behavioral changes, including over a longer time horizon, using insights from pilot work to design and refine a robust intervention suitable for testing in a traditional, controlled trial, consistent with best practice recommendations for behavioral trials [42].

Future work should evaluate delivery on a longer timescale and determine if greater personalization might solidify and sustain the effects to extend the promising results from this pilot. As changes in concerns about alcohol and diabetes (an intermediate outcome predicting a reduction in binge use) were not sustained at the final follow-up, the single-dose intervention appeared to alert the participants to possible dangers, generating a near-term response of increased concern. The lack of sustained change may reflect recalibration of concern, given time to absorb new information (knowledge and experience), growth in perceived self-efficacy for navigating drinking, or retrenchment from the initial state of alarm. A model that delivers multiple doses (boosters) may help to reinforce and sustain the response; hence, future studies should investigate changes over longer periods for a single and possibly multiple-dose intervention. Both narrators in this trial were unknown to the participants; intervention delivery from someone with whom participants have an established relationship, such as a trusted provider [43] or close friend, may also boost intervention effects; however, these designs would limit the scalability of a broadly diffusible digital intervention. Alternatively, the effectiveness of a one-time interaction may be enhanced by providing youths with the opportunity to subsequently discuss the intervention's educational content with a trusted provider or peer.

Although in-person anticipatory conversations between adolescents or young adults and their diabetes care teams about the effects of alcohol on their health and strategies for avoiding risk may be the gold standard for delivering a preventive intervention, this model may not be practical. Providers are increasingly tasked with covering a myriad of topics during short clinical encounters [44], and health guidance is increasingly delivered through web-based channels. Therefore, understanding the acceptability and effects of electronic interventions is vital [45]. Prior work has demonstrated that web-based information and diabetes support can augment clinical care [46] and improve quality of life [47]. This study demonstrates that digitally delivered interventions can effectively engage college students with T1D and provide them with vital health information, a promising model for larger-scale dissemination [25,48]. Future research and implementation studies are needed to evaluate the long-term effectiveness of digital tools and build evidence around best practices for content and delivery [49,50].

Finally, many of the participants noted that they would have liked to receive this intervention earlier (ie, before they began drinking or matriculated to college). As the intervention materials were not specific only to college, the current intervention might be generalizable for use with younger individuals or young adults not attending college, and such extensions could be tested. However, as this intervention was designed to focus on harm reduction, further investigation, including with respect to timing of or age at delivery, is needed to determine if these materials are suitable for the goal of preventing drinking initiation.

Limitations

This study includes several limitations. First, as with all internet-based recruitment, the underlying population (*denominator*) [51] is unclear, making it difficult to characterize sample representativeness and imposing constraints on generalizability. Although a prior methodological evaluation identified that this approach yields a sample that is representative of the sampling frame [35], this sample likely does not represent all college students with T1D (eg, this cohort included predominantly women, and most of the participants were privately insured, had higher pump and CGM use, and also had better self-reported glycemic control than other similarly aged cohorts [52]). This sample may be socioeconomically advantaged, with well-managed diabetes; hence, the findings may be indicative of a *best case scenario*. Second, this study was designed as a pilot trial to gauge the acceptability and relative impacts of the narrator and lacked a nonintervention control group. The observed effects could stem from test-retest bias, carryover effects, or regression to the mean; future controlled evaluations might mitigate these concerns. Third, all outcomes (and diabetes status) were self-reported, and only the alcohol use questions relied on validated items. To our knowledge, there are no pre-existing validated tools to assess knowledge, attitudes, and concerns regarding the intersection of alcohol use and diabetes. The survey items were extensively pretested and have been used in other surveys [6,37,38]; however, they may be subject to measurement errors and other biases stemming from self-reporting. Despite the use of validated

items for alcohol use, self-reported behaviors are subject to social desirability bias, which may result in misclassification. Finally, although the intervention videos were made to be maximally comparable (eg, same-gendered, same-race, and similarly styled narrators), other differences may have existed that differentially affected the response to the intervention, including among certain participant subgroups (eg, men respond differently to female narrators). Relying on an actor or more professional video editing, qualitatively noted by some participants, may diminish the potential differences.

Conclusions

We demonstrate the acceptability and impacts of a psychoeducational intervention for mitigating binge alcohol use among college students with T1D. We further determine that peer and provider narrators have similar short-term impacts as framing devices for this educational content. As this pilot demonstrates the feasibility of delivering this intervention to a hard-to-reach group through web-based channels, similar outreach methods could be used to deliver this content more broadly. In light of these promising findings, future work should further test these materials against the control of *care as usual* and should determine what further modifications are needed to enhance intervention effects.

Acknowledgments

The authors wish to acknowledge the generous funding support for this project and the investigator efforts provided by the Boston Children's Hospital Research Faculty Council Awards Committee Pilot Research Project Funding FP01017994 (coprimary investigators: LEW and ERW), the Agency for Healthcare Research and Quality K12HS022986 (primary investigator: Jon Finkelstein), Conrad N Hilton Foundation Clinical Research 20140273 (coprimary investigators: SL and ERW), and the National Institute of Diabetes and Digestive and Kidney Diseases K01DK116932 (primary investigator: LEW). The funders had no involvement in the design, data collection, interpretation, or reporting of the results. The authors wish to acknowledge Dr Courtney N Sandler, MD, MPH, and Hannah Hast, PT, DPT, for their assistance with the intervention video.

Authors' Contributions

LEW and ERW conceptualized and designed the study. LEW, ERW, and SL designed the data collection instruments and interventions. KMM and EBN collected data; LEW and ERW coordinated and supervised the data collection. LEW carried out all analyses; RKT carried out qualitative analyses; KMM and EBN assisted with data management and interpretation. LEW drafted the initial manuscript, and all authors critically reviewed and revised the manuscript. All authors approved the final manuscript as submitted and agree to be accountable for all aspects of the work.

Abstract

Background: Despite the popularity of maternal and infant health mobile apps, ongoing consumer engagement and sustained app use remain barriers. Few studies have examined user experiences or perceived benefits of maternal and infant health app use from consumer perspectives.

Objective: This study aims to assess users' self-reported experiences with maternal and infant health apps, perceived benefits, and general feedback by analyzing publicly available user reviews on two popular app stores—Apple App Store and Google Play Store.

Methods: We conducted a qualitative assessment of publicly available user reviews (N=2422) sampled from 75 maternal and infant health apps designed to provide health education or decision-making support to pregnant women or parents and caregivers of infants. The reviews were coded and analyzed using a general inductive qualitative content analysis approach.

Results: The three major themes included the following: app functionality, where users discussed app features and functions; technical aspects, where users talked about technology-based aspects of an app; and app content, where users specifically focused on the app content and the information it provides. The six minor themes included the following: patterns of use, where users highlighted the frequency and type of use; social support, where users talked about receiving social support from friends, family and community of other users; app cost, where users talked about the cost of an app within the context of being cost-effective or a potential waste of money; app comparisons, where users compared one app with others available in app stores; assistance in health care, where users specifically highlighted the role of an app in offering clinical assistance; and customer care support, where users specifically talked about their interaction with the app customer care support team.

Conclusions: Users generally tend to value apps that are of low cost and preferably free, with high-quality content, superior features, enhanced technical aspects, and user-friendly interfaces. Users also find app developer responsiveness to be integral, as it offers them an opportunity to engage in the app development and delivery process. These findings may be beneficial for app developers in designing better apps, as no best practice guidelines currently exist for the app environment.

Introduction

Background

Globally, there is a growing demand for, and use of, mobile smartphone apps to disseminate maternal and infant health information and self-management tools effectively to pregnant and postpartum women [1-5]. This increase in acceptance of digital technologies is attributed to the fact that women find it extremely convenient to seek answers to their questions, with easy access to health-related information throughout the day [6]. Furthermore, these technologies may provide important social support, especially when pregnant women feel isolated, time constrained, or need reassurance [6], and apps have shown the potential to produce positive health behavior changes [7]. Maternal and infant health apps frequently appear on the Apple App and Google Play stores' list of most downloaded apps, and some have been downloaded over 5 million times [8].

Although popular, consumers often rate maternal and infant health apps lower (ie, fewer star ratings) than other categories of apps [9]. Moreover, the percentage of users who discontinue (ie, uninstall) the use of health-focused apps in general approaches 50% [10]. This disconnect between popularity, ratings, and use may be driven by several factors. One reason could be price—maternal and infant health apps are priced higher than apps targeting other populations and health conditions [9]. Alternatively, app efficacy may be a challenge. Apps with unclear or inaccurate consumer decision support could lead to poor end user choices and potentially undesirable outcomes [11]. Most maternal and infant health-focused apps are developed by non–health care organizations [12]. Furthermore, popular maternal and infant health apps typically include only a minority of behavior change techniques that are found to be useful in health promotion [13]. Apps often fail to provide sources of their information and lack warnings pertaining to the use of this information [5], or the reasons could be related to design and usability. Overall, end users have discontinued apps because of the time-consuming data entry process, hidden costs, use difficulty, lack of data privacy, and lack of maintained interest [10]. User commentaries from women's health apps indicate that women are in favor of apps that are easy to use, contain new information, and are motivational, whereas areas that need improvements are associated with the quality of graphics, download speed, compatibility with other devices, ability to transfer data onto newer versions, and certification or affiliation with credible organizations [9].

Objectives

Mobile technology can be an effective platform for delivering resources and interventions, but consumer engagement remains a barrier for uptake and continued use [14]. Therefore, it is imperative to consider the consumer's perspective on these apps to improve the utility of such resources [14]. The objective of this study is to assess users' self-reported experiences with maternal and infant health apps, perceived benefits, and general feedback by analyzing publicly available user reviews on two popular app stores—Apple App Store and Google Play Store.

Methods

Study Design

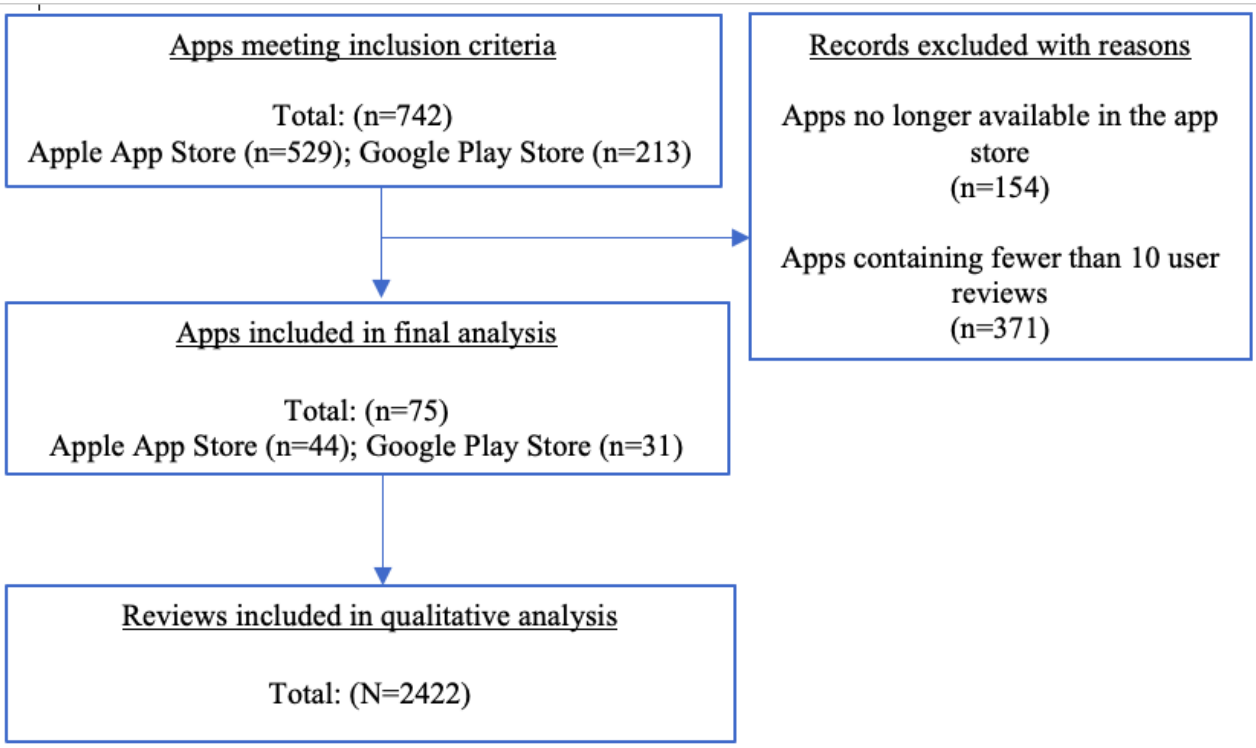
We conducted a qualitative assessment of publicly available user reviews from a sample of maternal and infant health apps available in the Apple App Store and Google Play Store. We followed a four-step process to create a data set of user reviews from a set of maternal and infant health apps that offer health education or decision-making support to pregnant women or parents or caregivers of infants. First, we populated a database with the set of available maternal and infant health apps by systematically fetching app details from the Apple App Store [15] and Google Play Store [16] using a Java-based scraper program called Node.js (OpenJS Foundation) [17]. Through this automated process, data are retrieved from the web using http in a central database [18]. Scraping programs automate the extraction of information displayed to users in the same way that chart reviewers record details from a medical chart. Second, we identified an inclusive list of relevant keywords that users might search for when locating apps related to maternal and infant health. Third, we scraped the two app stores for candidate apps and merged and deduplicated the resultant apps first within stores and then across stores. We then applied inclusion and exclusion criteria to identify apps that were eligible for the study. Inclusion criteria were as follows: (1) app description written in English; (2) target users judged as to-be pregnant women, to-be parents, and other caregivers of infant children as primary users; (3) listed in the medical, health and fitness, books and references, and education categories in the Apple App Store or listed in the medical, health and fitness, books and references, education, and parenting categories in the Google Play Store; and (4) described as intending to provide health education and user decision-making support. Exclusion criteria were as follows: (1) app description written in any language other than English; (2) inadequate or no app description provided; (3) target users judged as health professionals, providers, and students in health professions as primary users; (4) listed in all other categories; (5) described solely for purposes such as gestational age or due date calculators, identifying baby names, and shopping for baby products; and (6) apps meant to be used by members and patients associated with special programs (eg, fitness centers, clubs, or other paid memberships) or health care facilities (eg, a clinic or hospital). Fourth, we sampled a set of user reviews from the candidate maternal and infant health apps. The data reflected the app store content as of February 2018. Steps 1 to 3 are described in detail elsewhere [12]. The Indiana University Institutional Review Board approved this study as nonhuman subjects' research.

Search Strategy

The three steps listed earlier resulted in a total of 742 eligible maternal and infant health apps (Figure 1). Of these, 20.8% (154/742) were no longer available in the app stores at the time

of data collection (and therefore excluded). Apps with fewer than 10 (371/742, 50%) reviews were also excluded to obtain a robust set of reviews for analyses. From the 217 resulting apps, a simple random sample of 75 (34.6%; 44 Apple App Store and 31 Google Play Store) apps were selected. The sample size was sufficient to achieve data saturation. Each app name was entered into an individual scraper search. Each scrape resulted in maximum allowed user reviews of 50 from the Apple App Store and 40 user reviews from the Google Play Store (ordered by the most recent review). The upper limit per app was set at 40 user reviews for a total sample of 2422 user reviews (Figure 1) to maintain consistency across platforms. In addition to the text of the user reviews, the scraper program returned the star rating, price, and review date (see Multimedia Appendix 1 for a list of apps included in this study). Finally, using a general inductive content analysis approach, we qualitatively analyzed user reviews, where the underlying themes were identified from the data.

Figure 1. Schematic representation of the user review selection process for qualitative analysis.



Data Analysis

Descriptive Summary

Descriptive statistics were used to summarize the app characteristics such as app price, user star ratings, app platform, and review characteristics such as publication date and length of reviews.

Qualitative Analysis

User reviews were analyzed using a general inductive content analysis approach [19,20]. In this approach, themes were derived from data, as opposed to using preconceived categories [21]. First, 2 coders (RB and KSW) undertook a joint reading of a random sample of 30 user reviews to establish consistency in the textual unit of analysis, identification of categories, and formation of themes [20]. Next, the same 2 coders independently read and identified the preliminary codes from a new sample of 200 user reviews. Through joint reading sessions, these preliminary codes were refined, collapsed, assigned descriptive labels, and arranged into a coding framework to be applied to the sample. To assess coding consistency, both the coders independently analyzed a new sample of 100 user reviews. Agreement between the coders was high (κ=0.89). The 2 coders independently coded the remaining sample and met regularly to resolve any coding discrepancies and discuss the themes that were detected in the data. All data management and analyses were conducted in Dedoose 8.0.39 (SocioCultural Research Consultant, LLC) [22].

Results

Description of Apps and Reviews

Of the apps that were included, 75% (56/75) were free. Of the paid apps, the prices ranged from US $0.99 to US $8.99, with an average price of US $3.14 and a median of US $2.99. These prices reflected one-time payments to download the app, not monthly or annual subscription fees. More than half (44/75, 59%) of the apps were from the Apple App Store, and the remaining were from the Google Play Store. The average star rating for all apps was 4.1, with a range of 2.5-5.0. The oldest review in the data was written on July 5, 2009, whereas the latest review was published on February 13, 2018. The longest user review was 403 words long, and the shortest was only 1 word. Three major and six minor themes (present in less than 10% of the reviews) were identified in the data (Figure 2). The definitions of the themes, along with the frequency of occurrence, are presented in Table 1.

Figure 2. Summary of themes identified from qualitative content analysis.

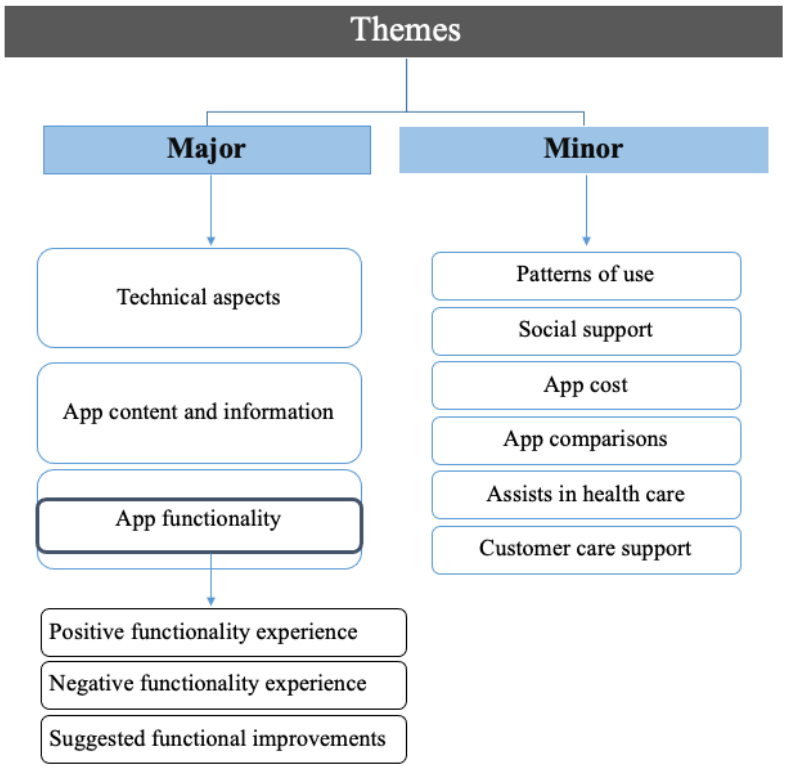


Table 1. Prevalence of major and minor themes identified in the data (N=2422).

Themes[a]	Definition	Reviews, n (%)
Major		
App functionality	The user specifically talks about app functions and features and what it does either positively or negatively.	2119 (87.49)
Technical aspects	The user specifically talks about aspects pertaining to how an app operates either positively or negatively, that is, privacy, security of data, or other technology-based aspects.	510 (21.05)
App content	The user specifically talks about the app content and information it provides.	349 (14.41)
Minor		
Patterns of use	The user highlights the frequency and type of use—whether the app is used for the first pregnancy or the app is being used for a long time.	219 (9.04)
Social support	The user specifically talks about receiving support from friends and family or offering support to other women while using the app.	207 (8.54)
App cost	The user specifically talks about the cost of an app, ie, cost-effective, or a waste of money.	201 (8.3)
App comparisons	The user compares the app with other apps in the market.	104 (4.29)
Assists in health care	The user specifically highlights the role of the app in offering clinical assistance.	77 (3.18)
Customer care support	The user specifically talks about their interaction with the app customer care support either positively or negatively.	44 (1.82)

[a]These themes were not exclusive.

Major Themes

App Functionality

Around 87.49% (2119/2422) of user reviews focused on commenting on the functionality of apps, such as app features, indicating that users frequently discuss the functionality of an app while using them. The discussion about app functionality featured three main subthemes: (1) positive functionality experience, (2) negative functionality experience, and (3) suggested functional improvements.

Positive Functionality Experience

A majority of the reviews focusing on app functionality indicated an overall positive experience with the functionality of the app. Many of the positive reviews were geared toward an app's overall design and app features describing these apps as useful, helpful, and easy to use. Users mainly elaborated on

app features that assisted in data recording and tracking of data pertaining to infant needs such as feeds, milk pumps, diaper changes, and sleep, akin to a *one-stop shop.* Some of the other tracking features focused on recording the height and weight of the infant, monitoring the trends over time, and keeping a log of immunization and other health histories:

> *Best tracking all app ever! ibabylog is the best app I have! It helps me track everything from nap times, to meal times, to dirty diapers. Its best feature is that it helps you keep intact with breast feedings. You can track everything in between like medication, doctor visits, growth, anything you can think of. I love this app and I recommend it big time!*

Users have also expressed a general preference toward the feature of data sharing and synchronizing of data between two or more devices:

> *Awesome App! My wife has been using MammBaby on her iPhone and now I am using it on my Android phone. It is definitely the easiest one to use and sharing feature is awesome!*

Some of the other features that have received favorable attention include baby heartbeat self-reported monitors, contraction timers, week-by-week fetal development stages, and diet or exercise tips and recommendations:

> *With countless pregnancy and newborn resources on the market, it can be hard for parents to know where to turn for information. This app is created by experts, for parents. As a mother, I appreciate the easy-to-understand and reassuring information found in the app. Like most pregnancy apps, the week-by-week updates are perfect. And the contraction timer came in handy on the big day! Thank you, Lamaze, for cutting the fuss and giving parents what we really need: power to make the best decisions for our family!*

Negative Functionality Experience

A frequent complaint pertained to app features that did not meet user expectations. Reviewers expressed concerns over apps that presented inaccurate calculations to users, that is, wrong due dates or height, weight, or percentile calculations:

> *Inaccurate Percentile Calculation, I don't know how they're trying to calculate the percentiles by age, but it's clearly not working. None of the percentiles in the app have matched up with either the hospital's or the pediatrician's data for my son--by a long shot! Even without the doctor's records telling me he's somewhere near the 75th percentile, it's obvious that an 8 lbs. boy is NOT in the 30th percentile for weight for his age at 13 days old, as the app reports.*

Users also highlighted issues pertaining to loss of data or inability to synchronize data:

> *Have to leave app running or else you lose your contractions data. Isn't that kinda the point in having a contraction app? I will be deleting this one and finding something that actually will track my contractions.*

Similarly, there were complaints about apps with no updates or poor updates:

> *Terrible update! Before this last update on 7/30, the app was fantastic! But now I HATE IT! It's too cutesy and it's hard to tell anything anymore! The photo section is far too large now when that is not the information that I need. The daily schedule section is MUCH more confusing, and I can't see any patterns. I will be deleting and finding a new app now! It is so confusing now. They went with trying to make it look cute instead of functional. Horrible app!!!!*

Finally, users reported that they discontinued the use of an app with inadequate features, with limited ability to track data, modify an inaccurate entry, or lacking flexibility in using conversion metrics, that is, mg to oz or kg to lbs:

> *I deleted it after one time, this app is terrible. It just tells you how much weight you should gain. It doesn't track your weight or monitor your progress. It doesn't even save any information. You can find this same information on several sites or easily figure it out on your own. And either way, if you want to keep track, you would have to do it yourself anyway. I deleted the app after the first time I tried it and realized it was useless.*

Suggested Functional Improvements

Along with critiquing an app's functionality and features, users often provided additional recommendations pertaining to features that could be added to improve their overall experience with the app. Reviewers often had a bucket list of requests to customize an app and tailor it to their specific needs and requirements. Textbox 1 provides a summary of suggestions for functional improvements. Some of the more common recommendations focused on data visualization or trends data (for height, weight, feedings, or immunizations), ability to export or print data, additional tracking facilities, or capabilities to synchronize data between two or more devices.

Textbox 1. Suggested functional improvements for maternal and infant health apps.

Requested Features and Direct Quotes

- Export data
  - "Helpful, but...I would love to be able to export or print data. Otherwise helps me keep track of my preemie between Dr visits."
- Data visualization and trends data
  - "The only thing that would make it better in my opinion would be to have a graph of each activity to show any types of trends. Knowing that my baby has slept 14% more in this 7-day period vs the last 7 days is maybe interesting, but not helpful when I'm trying to see any patterns of when he's sleeping and for how long. Having a graph that shows when he sleeps each day for a week would be so helpful for getting into more of a natural routine with the baby."
- Additional data tracking: symptoms, weight, illness, pumping, feeding, and medications
  - "Wish it had a medicine tracker and reminder, Wish the app helped with keeping track of when a dose of the medication was given and help with reminders for the next dose."
- Alerts, alarms, and reminders
  - "A Great App!! I use this app all the time! I pretty much rely on it! The only thing I've noticed that I'd like them to add is an alarm feature for medicines."
- Data synchronization between devices and data integration across apps
  - "I wish they could allow for other apps to feed info into it. For example, I use a digital thermometer that connects to my phone. If it could sync with this app it would be perfect!"
- Edit or delete incorrect data entries
  - "I wish I could edit time entries in case I look to see which side but forgot to click a new entry. But overall, great and easy to use."

Technical Aspects

The second most common theme (510/2422, 21.05%) that users discussed in their reviews were associated with the technical aspects of an app, such as how an app operates. Users preferred apps with a user-friendly app interface, free from advertisements or forced ratings, and those that did not occupy a large space in the phone memory.

However, most of the comments were geared toward technology failures, such as apps that crashed or froze on users, thereby rendering them useless for further use:

> *Unfortunately, it crashes frequently (usually in the middle of the night when I'm trying to time nursing sessions) and multiples times in a row at that (I think my record is 7). Incredibly irritating when you're sleep deprived, it's 2 am, and all you want to do is get back to sleep not continuously open an app all, so it can hang for 30 seconds then crash.*

Users have also criticized certain apps that were extremely slow to load the information or content or stream videos:

> *Generally good, a little slow, switched to this app once the written log from our lactation consultant ran out of space. It's been very helpful for tracking feedings and diapers. I find, however, that it runs really slowly sometimes in terms of entering information and the nursing/pumping timer.*

Other reasons cited as causes for discontinuing app use were inability to register oneself, not available offline, and other glitches associated with synchronizing data or loss of data:

> *It no longer lets me register or log in, and every time I open it I get the message that its opening for the first time, with a long wait. I probably won't use it when I'm in labor because of this.*

A few users also recommended certain technical improvements that would help enhance their overall experience with the app. These recommendations pertained to app availability on multiple devices and app platforms, or making an app esthetically pleasing (improved user interface, fonts, or image quality):

> *LOVE, I absolutely love this app, I just wish they would make it Apple Watch compatible as well!*

App Content and Information

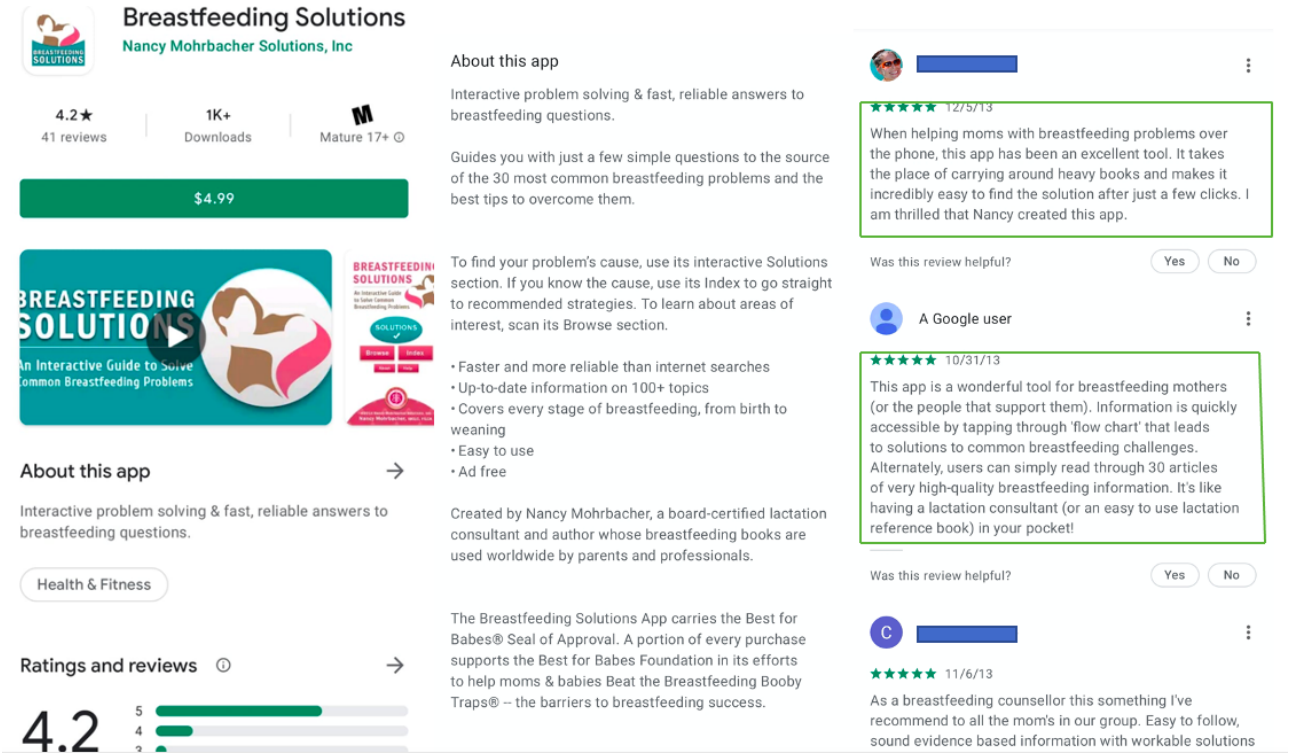
Reviews related to app content or information typically referred to the *wealth of information* these apps had to offer. Users appreciated apps providing detailed information, daily or weekly tips and reminders, latest and updated content, and evidence-based articles:

> *An evidence-based app you can trust, the information provided by Lamaze comes from evidence-based research, so you know you're not getting the "fluff" that you read in other pregnancy or parenting apps.*

New parents expressed their satisfaction with apps that met their increased information needs. A few users also suggested that certain apps were better organized and offered greater support as opposed to seeking information on the internet. Other users indicated greater satisfaction with using an app for information seeking over the traditional use of books (Figure 3):

> *Yes! Love love love this app, used it for my first pregnancy and it put me at such ease being a first time mom, I love how they have something to say everyday because you get so anxious being pregnant and just want the baby and this app helps you calm down and understand every stage. I love that you can put pictures at the bottom and see your progress before the birth of your child.*

Figure 3. User reviews centered around app content and information.



However, not all users found the content of these apps to be beneficial. Some users articulated a general dislike toward apps that had very brief content, contained basic information that could be found on the internet, or comprised a number of typos or grammatical errors, making it incomprehensible. This was especially true for paid apps, where users had higher expectations in terms of content quality:

> *Underwhelming application., I cannot speak to the integrity of the information this application gives you, A friend of mine told me to purchase it as I was expecting. For the price I expected much more. The Videos section simply opens their YouTube page in a web browser. And the very limited information the application gives you could fit on one sheet of paper. I was expecting for suggestions on how to deal with or enrich my child's experience during her leaps, but instead I only found a very brief description of what was happening developmentally. Certain aspects of the application just don't work at all, you can tell this application was outsourced to international developers for whom English is a second language. I would perhaps give this application three stars if it were free, but considering I paid for it I was expecting more. I'm sure all the information in this app can be found online with little effort. Save your money on this one.*

A few users were also disapproving of apps that contained unrelated information or were very narrow in scope; for example, they covered a selective range of topics that were not applicable to many:

> *I didn't put five stars because I disapprove the zodiac stuff, I don't find it useful, fun, or educational (on the contrary).*

Furthermore, there were reviews that offered suggestions to improve the app content. Most of the recommendations were geared toward offering content in a different language and adding additional content:

> *I've got a son with one of the rarest of rare genetic diseases that I thought would be awesome for this app it's called Spinal Muscular Atrophy Respiratory Distress also known as (Smard 1).*

Some recommendations were also for simplifying the information to account for the lay audiences:

> *Hard to understand, the information is correct. However, it would be extremely helpful to nursing mommies if they understood what the medical mumbo jumbo meant!*

Minor Themes

Patterns of Use

Over 9.04% (219/2422) of the reviewers described their patterns of app use by identifying the length, duration, and frequency of use. Some of them were long-term users, using these apps for multiple pregnancies. Users have also highlighted their frequency of use, with some users using these apps almost daily.

In addition, most app users tend to be first-time parents who use maternal and infant health apps for information seeking, tracking their pregnancy or infant needs, or connecting with other parents for moral support:

> *Great app! I don't normally write reviews for apps but this app is amazing. I am a new mom and I use it throughout the day, every day. I use it to keep track of feeding and sleeping trends.*

Social Support

Over 8.54% (207/2422) of all reviews referred to apps that acted as a safe haven for users, as these apps connected pregnant women and mothers to a larger community of app users, thereby offering social support that is typically needed by many during this period. First-time mothers especially found these communities encouraging and useful to lessen their anxieties over issues where they had minimal experience:

> *Awesome video blogs, never seen video blogs from other moms before and it helped me feel like I wasn't the only one. Same goes for the forum. Really good to connect to other moms.*

However, a few reviewers were not satisfied with their interactions within such communities. A handful of women faced some level of cyberbullying by others in these communities, especially those who had differing perspectives or values pertaining to childcare. Such negative experiences were geared toward the strong opinions, biases, and immaturity of other users.

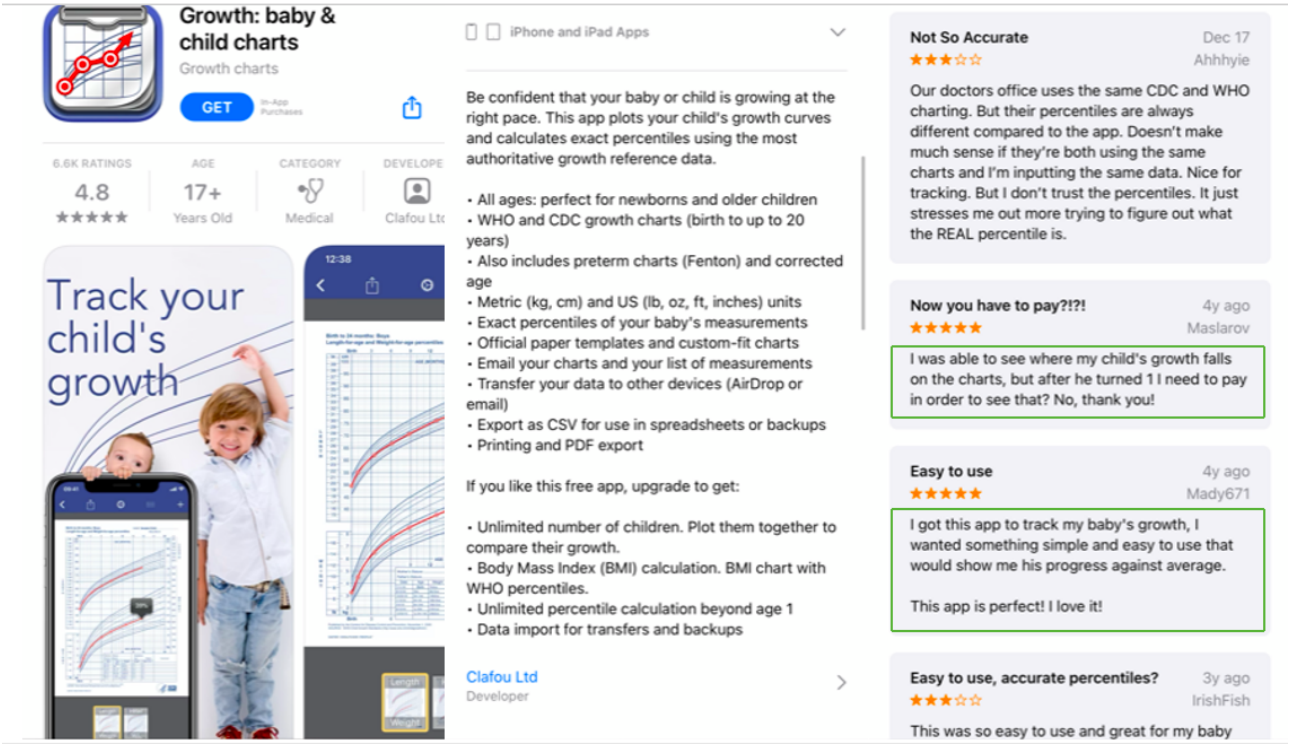
Users also expressed an overall appreciation for apps that had the capability to synchronize their data with other caregivers, especially their spouses, family members, or significant others. These features helped parents stay abreast with their infants' activities at all times:

> *Great app, I didn't know a lot about pregnancy and it has helped a lot with the different stages. It has even given my wife some comfort because I know things when she asks me questions.*

App Cost

Generally speaking, app users preferred apps that were free or had a very low cost associated with it (Figure 4). Users were willing to purchase apps with enhanced capabilities, such as data synchronization on multiple devices, additional tracking features, or data visualization functions. Users were also willing to pay for a *pro* version to eliminate advertisements and pop-ups and appreciated apps that were esthetically appealing.

Figure 4. User reviews centered around app cost and ease of use.



However, users were disapproving of apps that were labeled as free on the app store but offered very limited functionalities and required an upgrade (pro version) to enjoy additional features. Users called such apps *misleading*, *unfair*, or *false advertising*. Similarly, users were very critical of apps that were paid and did not meet their expectations. Users associated price with quality, thereby voicing extreme distress if the app faced any technical issues, provided basic information, or contained mediocre features:

> *Lot of glitches, poor info, no matter what article I click on- every other page starts with the same header: "Article good fats from bad ones" and then an incomplete sentence about using safe household cleaners...I tried to leave a review ON one of these pages- because EVERY page asks you for a review, and it said "sorry we couldn't complete your review right now." I cannot imagine who would pay 6.99 for this. (Or that they raised the price from 4.99???) I*

downloaded it for exercises but they don't have videos to show the exercises so I'm better off just going back to YouTube.

App Comparisons

Approximately 4.29% (104/2422) of users compared certain app features, either in a positive or negative context, with other apps that they used in the past or were currently using. Users also compared paid apps with apps that were offered for free to establish whether the app was worth the purchase or not:

Meh, Really...I have a ton of other baby apps that give more details on my baby's development and what I should be eating. This app is lacking a lot of details I wouldn't waste my money on going "premium." I'll stick with the bump and nurture. Thanks.

Assists in Health Care

Approximately 3.18% (77/2422) of app users established the role of maternal and infant health apps in health care management. Consumers especially found these apps useful for keeping track of infants who were underweight, short for age, premature at birth, or with congenital birth defects. They confirmed the role of these apps in recording accurate data that could then be reported effectively to their pediatrician:

I have used this for the last six months with no troubles. It's quick, intuitive, and easy. I have three kids and this baby was a newborn ICU baby, and this made life simpler with multiple caretakers/doctors who want all the details (and not great communication between all the people involved in baby's life.) and exhaustion from all the demands. What a lifesaver!

A minority of reviews were initiated by the health care professional, where they specified either using these apps for information seeking or monitoring patients' progress. Health care professionals have also provided recommendations for certain apps to their patients.

Customer Care Support

Users particularly cared about customer care responsiveness in addressing their questions, promptness in fixing issues, as well as fulfilling their requests for additional features. Consumers expressed distress over situations where they paid for an app but did not receive adequate developer support:

Doesn't work at all, I purchased this app and was so excited after reading the reviews. However, this app is crap! Took my money but does not work at all, nothing. Stays on one page and that's it. I can't get in touch with app support either. Don't waste $$$ or time. I have tried reinstalling it several times and still crap.

Discussion

Principal Findings

To our knowledge, this is the first study to evaluate consumer preferences for mobile apps targeted toward maternal and infant health using publicly available user review data. The elements of maternal and infant health apps that users were most interested in were related to the functionality of apps, that is, app features. Users were satisfied with apps that offered advanced features such as data monitoring and tracking or data synchronizing abilities across different devices. Similarly, users were highly critical of apps that did not meet user expectations in terms of their functionality and were prompted to discontinue the use of apps with limited functionalities. A large number of comments were concerned with the loss of data or inability to edit an incorrect entry. The overall emphasis on app functionality is consistent with previous literature that highlights the role of user satisfaction with app functions as one of the major caveats in consumer app use [14,23]. In addition, users also offered suggestions or recommendations in terms of app features that would improve their overall experience with the app. This is again consistent with previous reports in other domains [14,24,25], indicating that consumers are not fully content with the available features and their needs are often inadequately addressed.

Consumers prefer apps that are easy to use, with an esthetically pleasing interface, and occupy less memory space. The reasons cited for discontinuation of app use centered around technical issues such as crashing or freezing of apps while in use, slow download speed, and too many pop-ups or forced ratings [9,26,27]. An app that crashes often is deleted by users before any engagement with key functions has occurred [23]. Thus, app developers may give careful consideration to the technical aspects of these apps before releasing them for use. One of the major aspects of consideration for app use is the quality of information or content provided by these apps. When it comes to content, users typically value tailored information pertaining to their condition and actionable solutions for its effective management. Pregnant women and new mothers often seek information from apps on topics such as establishing breastfeeding, solving breastfeeding problems, infant health issues, and topics that are uncomfortable to discuss with health care providers [28]. Overall, women reported a positive experience with pregnancy apps, but a few reported issues with what they perceived as validity, accuracy, and timeliness of the information that was being presented by certain apps.

App cost was recognized as an important consideration for app adoption and use. Most users preferred free apps; however, users were willing to pay for apps if they offered sophisticated features and comprehensive information and were of superior quality. These results are consistent with those of previous studies on maternal and infant health apps [12]. Although some users discussed a negative experience with app-based communities, most women expressed their enthusiasm in terms of the social support they received from fellow mothers undergoing similar experiences. Women value peer experiences and knowledge on important topics such as breastfeeding or infant care and, in turn, offer similar support to others in need. Women often use these platforms to discuss topics that are sensitive in nature, such as sexual activity during and after pregnancy or feelings of hopelessness [29]. The anonymity offered in such communities provides an opportunity to raise issues that they otherwise would not discuss with family, friends, or health care professionals during in-person visits [29]. Aside from being a part of an ongoing community of app users, women

have also cherished the ability to engage their partners and other family members in maternal and infant health care and support. Information seeking during pregnancy and postpartum was relatively higher among first-time mothers who use these apps to track stages of pregnancy on a weekly basis or monitor infant development. Women also report using these apps for multiple pregnancies, and some engage with maternal and infant health apps almost daily.

Increasingly, women are using maternal and infant health apps to assist them in health literacy, monitoring, self-management, as well as consumer decision-making. Reviewers elucidated the role of maternal and infant health apps in improving patient-provider communication by aiding in data tracking, which helps improve recall and increase preparedness for doctor visits. Certain apps offer additional features where users can print reports or directly email them to their providers. This increased use of mobile apps during pregnancy and postpartum periods also highlights the importance of providing evidence-based information, especially because of the vulnerable nature of these phases. Very few reviewers discussed the availability of evidence-based content or expressed a desire to identify the scientific sources of information that are being presented to them. This may be credited to the fact that users are more concerned with the overall appeal of an app in terms of functionality, features, content, or usability, as opposed to verifying the credibility of this information. Therefore, health care professionals, app developers, and policy makers may consider strategies to review and promote apps to consumers based on information accuracy and trustworthiness. Future research may focus on evaluating the quality of maternal and infant health app content and information.

Furthermore, there is increased satisfaction among users whose needs and viewpoints were adequately addressed by the app developers. This highlights the fact that consumers value increased involvement in the app development and delivery process, which may increase their engagement and long-term use.

These results may provide meaningful information for app developers and other stakeholders regarding consumer needs and expectations pertaining to maternal and infant health apps, which are often complex and multidimensional. App developers may also consider strategies to collaborate with health care professionals for app content development and technical experts for app interface and usability to provide evidence-based information with superior functionality to users at low cost.

Strengths and Limitations

A major strength of this study is that it analyzes consumer attitudes and perspectives toward maternal and infant health apps using a large and diverse sample of publicly available user review data from Apple App and Google Play stores. This study uses a systematic approach of sampling a comprehensive set of user reviews for analysis. Importantly, to our knowledge, this is the first study that uses this particular methodology and sampling strategy to study users' perspectives on maternal and infant health apps.

This study had some limitations. First, it is likely that user reviews on the app store may not be representative of the larger population of app users. User opinion on a given app may be affected by gender, economic status, education level, or other demographics. However, these data elements were not publicly available and were not considered to draw conclusions. The study, therefore, uses information similar to what would normally be available to consumers in a *real-world* context before downloading an app. In addition, the study used a random sample of user reviews using a strategic approach to capture a more diverse sample of app users, which probably could not be achieved using other exploratory methods such as interviews or focus groups. Second, our results may not be generalizable to apps belonging to other health domains; for example, app use for monitoring infant needs may not be applicable to other populations such as for diabetes or weight loss. Third, the motivation to post may be to give a negative review to express dissatisfaction with the app [30]. However, in our random sample of apps, positive reviews were more common, which is consistent with previous reports [14,31]. Finally, there is a possibility of fake reviews to increase the app demand [32]; however, the large number of reviews per app should compensate for this challenge.

Conclusions

This review extends the literature by emphasizing the features of maternal and infant health apps that are particularly important to users. These results may be beneficial for app developers to consider during app development. Overall, consumers value low-cost apps that have high-quality content, superior features, and smooth technical aspects and are easy to use. Users consider app developer responsiveness an integral part of app use, as it empowers them in the process of app development and delivery. These consumer perspectives are essential for mobile health sustenance, as no best practice guidelines currently exist for the app environment. Users are increasingly using apps for health care management and informed decision-making. Thus, health care professionals, app developers, and policy makers may consider strategies to review and promote evidence-based and trustworthy apps to consumers. Future studies may focus on assessing user experiences by using other qualitative methods to garner detailed perspectives on long-term app use. This study should also be replicated in other health domains to gain a greater sense of consumer perspectives in the field of mobile health. Future studies may also focus on developing a framework for consumers to evaluate app quality for effective app comparisons and use decisions.

Acknowledgments

The authors would like to thank the Department of Health Policy and Management at Indiana University Richard M Fairbanks School of Public Health and Regenstrief Institute, Inc, for their ongoing support during the research process. KSW was supported by a training grant (award T15LM012502) from the National Library of Medicine of the National Institutes of Health.

Authors' Contributions

The primary author, RB, proposed and completed this study as part of her doctoral dissertation. The coauthors KSW, JRV, BED, TC, and CAH (chair) contributed significantly to the acquisition, analysis, and interpretation of data; rigor of the methodology and analysis; and writing of the manuscript.

Conflicts of Interest

JRV is a founder and MND equity holder in Uppstroms, a health technology company. Other authors have declared no conflict of interest.

Abstract

Background: Osteoarthritis is a disabling condition that is often associated with other comorbidities. Total hip or knee arthroplasty is an effective surgical treatment for osteoarthritis when indicated, but comorbidities can impair their results by increasing complications and social and economic costs. Integrated care (IC) models supported by eHealth can increase efficiency through defragmentation of care and promote patient-centeredness.

Objective: This study aims to assess the effectiveness and cost-effectiveness of implementing a mobile health (mHealth)–enabled IC model for complex chronic patients undergoing primary total hip or knee arthroplasty.

Methods: As part of the Horizon 2020 Personalized Connected Care for Complex Chronic Patients (CONNECARE) project, a prospective, pragmatic, two-arm, parallel implementation trial was conducted in the rural region of Lleida, Catalonia, Spain. For 3 months, complex chronic patients undergoing total hip or knee arthroplasty and their caregivers received the combined benefits of the CONNECARE organizational IC model and the eHealth platform supporting it, consisting of a patient self-management app, a set of integrated sensors, and a web-based platform connecting professionals from different settings, or usual care (UC). We assessed changes in health status (12-item short-form survey [SF-12]), unplanned visits and admissions during a 6-month follow-up, and the incremental cost-effectiveness ratio.

Results: A total of 29 patients were recruited for the mHealth-enabled IC arm, and 30 patients were recruited for the UC arm. Both groups were statistically comparable for baseline characteristics, such as age; sex; type of arthroplasty; and Charlson index, American Society of Anesthesiologists classification, Barthel index, Hospital Anxiety and Depression scale, Western Ontario and McMaster Universities Osteoarthritis Index, and Pfeiffer mental status questionnaire scores. Patients in both groups had

significant increases in the SF-12 physical domain and total SF-12 score, but differences in differences between the groups were not statistically significant. IC patients had 50% fewer unplanned visits (P=.006). Only 1 hospital admission was recorded during the follow-up (UC arm). The IC program generated savings in different cost scenarios, and the incremental cost-effectiveness ratio demonstrated cost-effectiveness.

Conclusions: Chronic patients undergoing hip or knee arthroplasty can benefit from the implementation of patient-centered mHealth-enabled IC models aimed at empowering patients and facilitating transitions from specialized hospital care to primary care. Such models can reduce unplanned contacts with the health system and reduce overall health costs, proving to be cost-effective. Overall, our findings support the notion of system-wide cross-organizational care pathways supported by mHealth as a successful way to implement IC for patients undergoing elective surgery.

Introduction

The progressive aging of populations has led to an increased burden of chronic diseases [1]. Osteoarthritis (OA) is one of the most disabling chronic diseases in developed countries. Worldwide estimates show that 10% of men and 18% of women aged >60 years have symptomatic OA [2]. Knees and hip are the most affected locations. Among the people with OA, 80% have movement limitations and 25% are disabled to perform major activities of daily living [2]. OA is associated with increased comorbidities and mortality. More than half of people with OA have another chronic medical condition, and approximately one-third of people have five or more chronic conditions [3].

Total hip arthroplasty (THA) and total knee arthroplasty (TKA) are effective surgical treatments for end-stage OA, improving joint function and health-related quality of life (QoL) [4]. Since 2000, the number of hip and knee replacements has increased rapidly in most countries in the Organization for Economic Co-operation and Development [5]. On average, hip replacement rates increased by 30% between 2007 and 2017, and knee replacement rates increased by 40% [5]. Comorbidities are independent predictors of increased postoperative complications and nonhomebound discharge in patients undergoing shoulder, hip, or knee arthroplasty [6] and are associated with physical function and pain after primary TKA [6].

So far, the strategies aiming to improve the outcomes of elective surgeries have mainly focused on enhanced recovery protocols, prehabilitation, and postoperative rehabilitation protocols, which have been proven effective for lower limb arthroplasty [7,8]. Nevertheless, there are aspects of the entire care process that can still be improved. Traditional care models suffer from care fragmentation, with the different care levels failing to communicate effectively. After transitioning from hospital care to primary care, patients can have changes in prescribed drugs or repetition of tests because of a lack of communication across health settings [9]. Moreover, traditional models still focus on diseases rather than patients, which makes patients and their caregivers passive actors in the process [9]. Therefore, there is a need for a profound redesign of how care is provided to chronic older patients to ensure quality and sustainability [10]. Integrated care (IC) models aim to increase health efficiency through defragmentation of care, including the promotion of collaboration across settings, promotion of patient-centeredness, and prioritization of preventive strategies [11]. Interestingly, the use of eHealth tools could be the key to enabling such models [12], as demonstrated by projects such as Personalized Connected Care for Complex Chronic Patients (CONNECARE) [13] or BeyondSilos [14], which have proven the feasibility of eHealth-enabled IC in the Catalan setting. The adoption of efficient IC models can result in better outcomes for THA and TKA. In this regard, a 2017 systematic review on the benefits of telerehabilitation after orthopedic surgery showed promising results for patients undergoing THA or TKA [15]. More recently, Jonker et al [16] confirmed the feasibility of perioperative eHealth interventions for the management of older surgical patients. However, there are very few initiatives that fully embrace the use of eHealth-enabled IC models in older patients undergoing THA or TKA.

The CONNECARE project is a European Union Horizon 2020 Research and Innovation project aiming to co-design, develop, deploy, and evaluate a novel smart and adaptive organizational IC model for complex chronic patients (CCPs) [17]. From 2016 to 2019, the project co-designed an organizational model for IC and an eHealth platform supporting it by means of an iterative patient-centered process involving patients and stakeholders across different health settings. The resulting IC model promoted collaboration among professionals in different care settings (hospital specialists, family physicians, and social workers), prioritizing home-based prevention strategies over institutional reactive care and fostering patient empowerment. A Smart Adaptive Case Management (SACM) system is offered as a web-based platform to professionals from different settings, and a patient-empowering mobile health (mHealth) self-management system allowing for three-level monitoring features and advanced communication is offered to patients.

As part of the CONNECARE project, a novel mHealth-enabled IC model was implemented in Lleida, Spain, targeting older CCPs undergoing elective THA or TKA. The existing care model for THA and TKA in Lleida is an enhanced recovery after surgery (ERAS) pathway based on different interventions to reduce perioperative stress; maintain and support homeostasis and physiological function; and accelerate the achievement of discharge criteria, including minimizing complications and readmission [18,19]. Although it produces good results with low transfusion, low complications, and decreased length of

stay, it is limited by the scarce communication between professionals in different care settings, mostly hospital and primary care professionals, with different electronic medical records (EMRs) systems in hospitals and primary care centers (Argos SAP and ECAP [20], respectively). Therefore, we hypothesized that the new mHealth-enabled IC model could result in better outcomes for our patients.

This paper describes the results in terms of effectiveness and cost-effectiveness of the implementation of an mHealth-enabled IC model for the prevention of hospital readmissions in CCPs undergoing THA and TKA.

Methods

Study Design

This was a prospective, pragmatic, two-arm, parallel implementation trial comparing usual care (UC) with a 3-month mHealth-enabled IC intervention. The study was conducted from July 2018 to August 2019 at the University Hospital of Santa Maria (Lleida, Spain) and its network of primary care centers. This corresponds to a large rural area accounting for more than 236,000 citizens with a life expectancy of 80 and 86 years for men and women, respectively [21].

Target Population

The eligibility criteria were home-dwelling patients elected for primary THA or TKA at the University Hospital of Santa Maria; aged >65 years; being defined as CCP (Charlson index score ≥3, taking four or more pills per day, and having had contact with the health system at least two times in the last 12 months); being classified according to the American Society of Anesthesiologists (ASA) classification as ASA II (mild systemic disease) or ASA III (severe systemic disease); and successfully passing a basic technological test, aimed to ensure the availability of internet connection at home as well as patients' or caregivers' competence with the use of a smartphone, tablet, or computer. The basic technological test can be found in Multimedia Appendix 1 [20,22].

Recruitment

The recruitment was done in several waves to match the pace of the CONNECARE project technological developments. In each wave, consecutive potential participants were contacted by a case manager during preoperative assessment at the anesthesiology outpatient clinic. The case manager explained the study protocol and obtained informed consent. These patients formed the intervention arm. After the recruitment of each patient included in the intervention arm, an active search for a control with similar characteristics from the surgery waitlist of the Orthopedics Department of University Hospital of Santa Maria began. This enhanced the similarity of patients in the intervention and control arms, although it implied a certain lag in the recruitment of controls (from some days to few weeks). All patients and their caregivers, regardless of study arm, received a face-to-face explanation about the study and provided informed consent.

Intervention

Patients in the intervention arm were attended using an IC model, including (1) preliminary assessment of the patient's health status using several questionnaires, tests, and indices specific to their main chronic diseases and social needs; (2) a self-management app, with status and performance reports, a virtual coach with customizable automated feedback, and full communication with the care team; (3) a Fitbit Flex 2 digital activity tracker [23], fully integrated into the self-management app; (4) a patient's profile in the SACM web-based platform, accessible to all members of the care team (family physicians, hospital surgical team, and social workers) and used to coordinate professionals in the different settings and enable a communication channel among them and with the patient, when needed; and (5) assignment of a case manager in charge of supervising the whole process and being the main patient contact point. Additional details on the CONNECARE IC model and the supporting eHealth platform can be found in Multimedia Appendix 1. Patients in the control arm were attended using care as usual, being managed from primary care after hospital discharge. After discharge from the initial 90 days of UC or IC management, all patients had 3 months of additional passive follow-up.

Data Collection

Variables characterizing the patients were collected at recruitment using the SACM on tablet and/or desktop computers. Collected variables included main baseline characteristics, such as age, sex, main chronic diseases, Charlson index of comorbidities [24], ASA scores [25], Barthel index for activities of daily living [26], Hospital Anxiety and Depression scale [27], assessment of the dwelling characteristics, main medications, Pfeiffer mental status questionnaire [28], and tobacco and alcohol consumption.

The cost estimation of the IC program and used health care resources is described in Multimedia Appendix 1. Briefly, IC costs included the costs of newly required medical personnel (hospital-based nurse case managers) and the costs of licensing and running the IC platform. In contrast, the one-off costs associated with the development of the IC model and supporting technology or the tuning of the system were not considered. Similarly, the required restructuring of health care professionals' time to include new tasks related to the IC model was assumed to be covered by the health system at no additional cost, as we assumed that such restructuring would not imply any additional time. Costs associated with the use of health care resources, such as medical visits and hospital admissions, were based on official data from the Catalan Health Department [22]. All costs were originally in Euros (€) and were converted into US $ (conversion used: €1=US $1.21).

The main outcomes were (1) intervention effectiveness, as measured by the changes in the 12-item short-form survey (SF-12) health questionnaire's physical and mental domains (baseline vs discharge) [29]; (2) use of health care resources after 6 months; and (3) cost-effectiveness, based on the improvement in QoL relative to costs, assessed by means of the incremental cost-effectiveness ratio (ICER). The source of health information was the EMR, and the collected information

included hospital admissions, emergency room visits, visits to primary care, and visits to hospital specialists.

Statistical Analyses

Participants' baseline characteristics were described by n (%), mean (SD), or median (P25-P75), as appropriate. Comparisons between IC and control patients' baseline characteristics were performed using the chi-square test, *t* test, or Kruskal-Wallis test, as appropriate. A paired *t* test comparing baseline with discharge was used to assess changes in the SF-12 domains. Linear regression models were used to assess the differences in the changes experienced by IC and control patients. Negative binomial regression models were used to assess the differences in the number of visits and admissions. Models were adjusted for age, sex, and Charlson score. ICER was calculated in relation to the SF-12 total score. Sensitivity analyses assuming two different scenarios, 150% and 200% estimated cost of the IC program, were performed to explore the cost-effectiveness performance of the IC model under unplanned increases in the implementation costs. Data analyses were conducted using Stata version 12.1 (StataCorp). The threshold for significance was set at a *P* value of .05. All *t* tests were two-tailed.

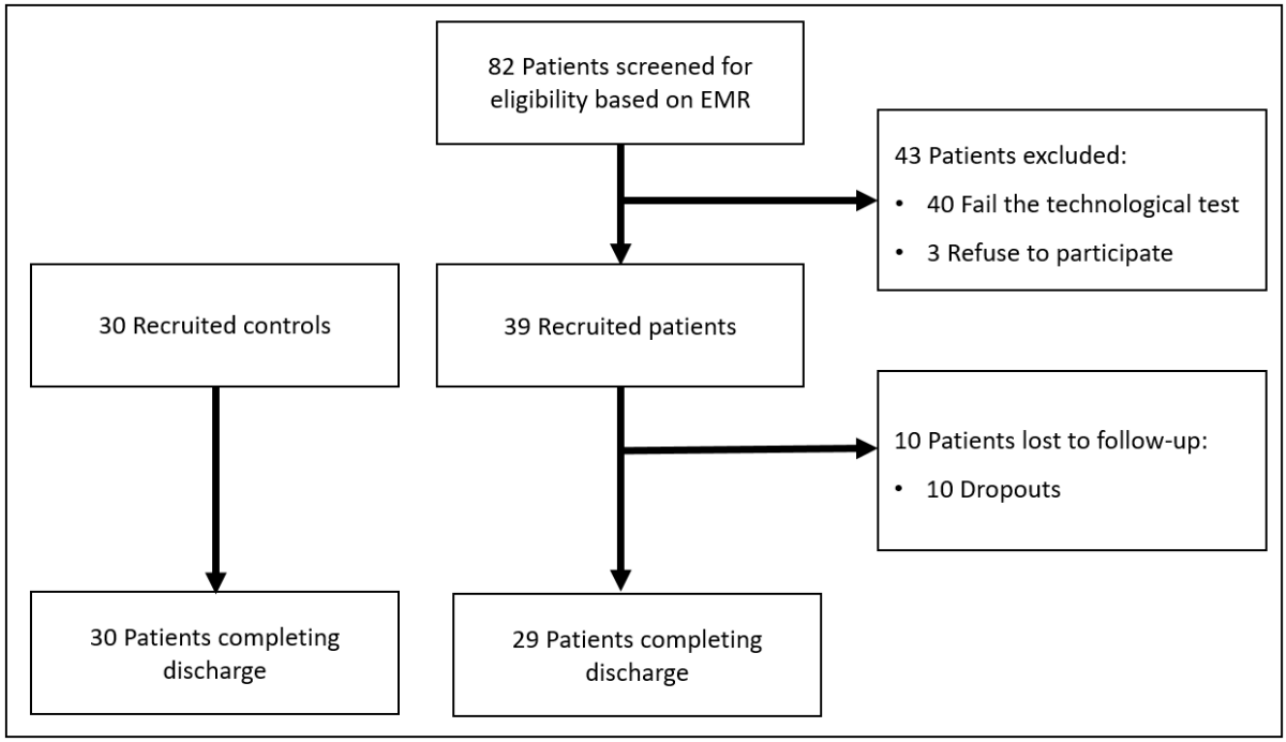
Ethical Considerations

This study was approved by the Ethics Committee of Hospital Arnau de Vilanova (CEIC-1685), and all patients provided written informed consent. All collected data were handled and stored in accordance with the current national and international legislation.

Results

Up to 82 patients were screened for eligibility. Of them, 49% (40/82) failed the technological test because they did not have an internet connection and 4% (3/82) refused to participate. Therefore, 39 patients were recruited for the mHealth-enabled IC arm and 30 for the UC arm. Final analyses were based on 29 IC and 30 control patients who completed the follow-up (Figure 1).

Figure 1. Study flowchart. EMR: electronic medical record.



The baseline characteristics of the patients are presented in Table 1. Although the proportion of knee surgeries was slightly higher in the IC arm, no significant differences were found in the baseline characteristics of the patients in the two arms.

Table 1. Baseline characteristics of the patients in the usual care and integrated care arms (N=59).

Characteristic	Usual care (n=30)	Integrated care (n=29)	*P* value[a]
Sex (male), n (%)	8 (27)	12 (41)	.23
Age (years), mean (SD)	74 (8)	72 (9)	.46
Charlson score, mean (SD)	4.3 (1.7)	4.2 (1.5)	.81
American Society of Anesthesiologists class, n (%)			.52
II	10 (33)	12 (41)	
III	20 (67)	17 (59)	
Western Ontario and McMaster Universities Osteoarthritis Index score, mean (SD)			
Pain	9.5 (3.4)	9.6 (3.8)	.93
Function	38.7 (12.8)	39.8 (14.2)	.77
Stiffness	2.3 (2.1)	3.0 (2.8)	.29
Barthel score, median (IQR)	95 (90-100)	100 (95-100)	.16
HAD[b] scale anxiety score, mean (SD)	6.2 (4.9)	5.0 (3.9)	.34
HAD scale depression score, mean (SD)	5.0 (2.3)	5.1 (2.9)	.88
Pfeiffer intact intellectual functioning, n (%)	30 (100)	27 (93)	.14
Surgery location: knee, n (%)	22 (73)	26 (90)	.11

[a]Chi-square test, *t* test, or Kruskal-Wallis equality-of-populations rank test, as appropriate.

[b]HAD: Hospital Anxiety and Depression.

Table 2 shows the changes in QoL (SF-12 domains) from baseline to discharge. Regardless of the study arm, all patients showed a substantial increase in the SF-12 physical domain. The analysis of the differences in differences in QoL between IC and control patients showed no differences. Stratification according to the surgical location (hip or knee) reported similar findings.

Table 2. Changes in health status in the usual care and integrated care arms.

12-item short-form survey score	Baseline, mean (SD)	Discharge, mean (SD)	Change, mean (SD)	*P* value
Physical				
UC[a]	27.9 (6.4)	42.0 (7.7)	14.1 (9.0)	<.001[b]
IC[c]	29.9 (10.0)	45.3 (9.8)	15.4 (11.7)	<.001[b]
Difference	2.0 (2.2)	3.3 (2.2)	1.4 (3.2)	.79[d]
Mental				
UC	48.1 (14.2)	50.2 (13.5)	2.0 (11.9)	.35[b]
IC	52.1 (14.2)	52.8 (12.9)	0.8 (15.2)	.79[b]
Difference	3.9 (3.6)	2.6 (3.6)	−1.3 (5.1)	.94[d]
Total				
UC	76.1 (15.6)	92.2 (18.1)	16.1 (14.8)	<.001[b]

Difference	5.9 (4.5)	6.0 (4.5)	0.1 (6.3)	.94[d]

[a]UC: usual care.

[b]Paired *t* test comparing baseline and discharge measures.

[c]IC: integrated care.

[d]Linear regression predicting the difference in the changes experienced by each arm, adjusted by age, sex, and Charlson index.

Table 3 shows that IC patients had 50% fewer unplanned visits than patients in the UC arm, either when considering visits

directly related to the surgical procedure or any visits. One patient in the UC arm required hospital admission, whereas no admissions were recorded among IC arm patients.

Table 3. Total use of health services during the follow-up period (N=59).

Health service	Usual care (n=30), mean (SD)	Integrated care (n=29), mean (SD)	*P* value[a]	Adjusted *P* value[b]
All unplanned visits	1.4 (1.5)	0.7 (1.0)	.03	.006
Unplanned visits directly related to the surgery procedure	0.8 (1.2)	0.4 (0.7)	.10	.02
All hospital admissions	0.03 (0.2)	0 (0)	N/A[c]	N/A
Hospital admissions directly related to the surgery procedure	0.03 (0.2)	0 (0)	N/A	N/A

[a]Negative binomial regression model.

[b]Negative binomial regression model adjusted for age, sex, and Charlson comorbidity index.

[c]N/A: not applicable.

The analyses of within-trial costs and cost-effectiveness for all unplanned visits and hospital admissions are summarized in Table 4 and those for unplanned visits and hospital admissions related to the arthroplasty procedure are summarized in Table 5. The IC program generated savings from €109.88 (US $132.96) to €126.99 (US $153.66) per patient, depending on the nature of unplanned visits and hospitalizations. The IC program was cost-effective according to ICER, performing similar in terms of QoL gain while reducing overall expenses because of the reduction of unplanned visits and hospital admissions.

Table 4. Changes in health-related quality of life, within-trial costs (average cost per patient), and cost-effectiveness considering all unplanned visits and hospital admissions.

Variables	Usual care (n=30)	Integrated care (n=29)	Difference	ICER[a]
Changes in the 12-item short-form survey score, mean (SD)	16.1 (14.8)	16.2 (14.3)	0.1 (6.3)	N/A[b]

Total costs per patient (US $)	249.93	116.97	−132.96	−1661.94

[a]ICER: incremental cost-effectiveness ratio; incremental cost associated with one additional point gain in the 12-item short-form survey.

[b]N/A: not applicable.

[c]Costs based on the Catalan Institute of Health official pricing.

Sensitivity analyses assuming two different cost scenarios, 150% and 200% estimated cost of the IC program, thus exploring cost-effectiveness under unplanned increases in the implementation costs, showed savings and cost-effectiveness, as shown in Tables S1 and S2 in Multimedia Appendix 1.

Discussion

Principal Findings

The prospective assessment of the implementation of an mHealth-enabled IC program for TKA and THA management showed a reduction in the number of unplanned contacts with the health system after the surgery; generated substantial savings for the health system, while not having any negative impact on QoL or clinical outcomes; and demonstrated cost-effectiveness.

Strengths and Limitations

The implemented IC model had several strengths that must be highlighted. First, there was an effort to involve all the stakeholders from different organizations that would be actors in a large-scale deployment of the mHealth-enabled IC program since the very early stages. This is key, as the lack of cooperation among professionals, teams, and organizations is a recurrent barrier for effective IC implementation [11]. Second, informal caregivers played a role in the IC process, as close relatives of the patients can be their link with the health system. Moreover, informal caregivers can play a key role in facilitating the use of self-management apps in older patients. Third, the self-management app for patients (allowing active monitoring, communication with the care team, and a virtual coach with customizable automated feedback) enhanced doctor-patient relationships [30] and facilitated early detection of any problem in the surgical recovery process [31]. Fourth, the assessment and promotion of patients' physical activity is an effective way of preventing any mobility impairment, which is found in one-third of people aged >65 years [32]. Finally, the region selected for the deployment of the IC program, a large rural area, was especially appropriate as their citizens can benefit the most from community-based IC initiatives that can avoid unnecessary travel to the hospital.

Regarding this study, several strengths and limitations should be noted. Among the strengths, we note the use of a prospective study design with a comparator arm; the use of objectively measured endpoints, such as visits and admissions, in contrast to patient-reported outcomes; and cost and cost-effectiveness assessments. Concerning the limitations, the technological platform supporting the implemented IC model showed substantial improvements throughout the implementation period. This implied that patients recruited near the end of the implementation study had a richer IC experience than those recruited at the very beginning. Similarly, this had an impact on health care professionals, who had to cope with a platform under development and not fully integrated with existing EMRs. Nevertheless, participating patients and professionals showed great acceptability of the IC model and setting [33]. Moreover, directly participating in a dynamic development and implementation process fostered professionals' engagement and allowed them to propose changes and new features to be developed, which resulted in not a single professional dropping out of the study. Next, the limited number of patients involved in the study had an impact on statistical power. Nevertheless, the current number of participants sufficed to show a significant reduction in robust endpoints, such as unplanned visits and hospital admissions, and showed the cost-effectiveness of the IC program. Finally, only direct costs were considered, although the inclusion of indirect or societal costs would most likely favor the cost-effectiveness of the IC model.

Comparison With Existing Literature

This study aimed to assess the impact of the implementation of an IC model in three domains: (1) patients' QoL, (2) patients' use of health services, and (3) health economics. Regarding the QoL domain, the IC model performed as good as the UC arm in the differences-in-differences analysis. This result is in line with the mixed results found in a 2017 review on the impact of IC interventions on QoL [34]. However, it is worth noting that the great increase in QoL obtained after a successful THA or TKA is likely to mask any minor increase in QoL caused by being managed in an IC model. Next, regarding the use of health services, patients in the IC model required 50% fewer unplanned visits after the surgery. This corresponds to the upper margin of benefits reported in reviews about IC interventions between 2000 and 2015, which reported significant reductions in hospital activity ranging from 15% to 50% [35]. These excellent results could be in line with the notion of system-wide cross-organizational care pathways as a successful way to implement IC, in contrast to smaller and narrow interventions [9]. Finally, regarding health economics, IC generated savings from €109.88 (US $132.96) to €126.99 (US $153.66) per patient and was deemed cost-effective. This is in line with reviews stating the potential cost-effectiveness of IC in the management of chronic diseases [36]. However, these savings are lower than the range of US $584-$1434 obtained when applying the same IC model to CCPs with chronic obstructive pulmonary disease or heart failure [13], who are more prone to experiencing unplanned visits and hospitalizations.

When specifically focusing on THA and TKA, previous studies have suggested the usefulness of the different potential components of an eHealth IC model, including telerehabilitation [15], care pathways [18,37], education [38], patient-centeredness [39], mHealth continuous monitoring [40,41], and cross-setting integration [42]. However, to our knowledge, this study is the first to include all these components in a single mHealth-enabled IC model. Overall, our results are similar to or better than those reported in these previous studies, suggesting a moderate additive effect of combining the reported interventions into a single mHealth-enabled IC model.

Implications for Research and/or Practice

The World Health Organization has already stated the need for patient-centered IC models to satisfy the health needs of older populations with chronic diseases while keeping costs sustainable [29,43]. With this premise in mind, the CONNECARE project tackled the task of iteratively co-designing a mHealth-enabled IC model with the participation of all key stakeholders: patients; hospital-based surgeons, anesthesiologists, nurses, physiotherapists, and case managers; primary care physicians and nurses; social caregivers; and

managers, technical staff, developers, and researchers. This multidisciplinary team envisioned a system-wide cross-organizational patient-centered care pathway, in line with the principles of the 2015 World Report on Ageing and Health [1]. The experience acquired during the co-design and testing process allows us to highlight some key features that future IC models for the management of older citizens undergoing THA or TKA should consider (1) a common cross-setting web-based platform is key for a successful coordination of care across settings and patient monitoring; (2) the habilitation of functional communication channels for the patients can be a key source of savings, as most savings are achieved through the avoidance of unplanned visits; and (3) involving informal caregivers, such as younger family members, can facilitate the adoption of mHealth tools, such as sensors and self-management apps, and make the overall user experience very satisfactory [44]. Moreover, it is key to ensure access to an internet connection at home, as this was the main criterion halting the participation of potential users.

Conclusions

The implementation of a patient-centered mHealth-enabled IC model for the management of patients undergoing THA or TKA successfully empowered patients, effectively connected the different care settings involved, reduced unplanned contacts with the health system, reduced health costs, and was cost-effective. This supports the use of mHealth tools for the implementation of system-wide cross-organizational IC models.

Acknowledgments

This work was supported by the European Union's Horizon 2020 Research and Innovation Program (under grant agreement GA-689802). JDB acknowledges receiving financial support from the Catalan Health Department (Pla Estratègic de Recerca i Innovació en Salut 2016: SLT002/16/00364) and Instituto de Salud Carlos III (Miguel Servet 2019: CP19/00108), which is cofunded by the European Social Fund, *Investing in your future*. Funding organizations had no role in the design and conduct of the study; collection, management, analysis, and interpretation of the data; preparation, review, or approval of the manuscript; and decision to submit the manuscript for publication. The authors would like to express their sincere gratitude to all the participating patients and their caregivers as well as to all the involved health and social care professionals. All of them were key in the co-design of the integrated care model and its implementation in the region of Lleida.

Authors' Contributions

JDB, EV, NN, FP, FM, FB, and GT participated in the conceptualization of the project. JC, RD, MT, MM, EV, AF, MOB, and GT conducted the data collection. MM, EV, and JDB participated in the data curation. JDB conducted all statistical analyses. JC and JDB wrote the original draft of the manuscript. All authors reviewed the final manuscript. JDB, EV, FM, FB, and GT secured funding for the project. The CONNECARE-Lleida Group consists of: Maria Aguilà Balastegui, Sandra Alexandre Loxano, Laila Al-Jouja Llorente, Tomás Alonso Sancho, Enrique Aparicio Bañeres, Ana Arce Vila, Jose Maria Baron Burriel, Ramon Bascompte Claret, Albert Bigorda Sague, Emilia Blanco Ponce, Maria Boldú Franque, Àngels Bosch Roig, Carmen Bravo Santiago, Alba Capdevila Sarramona, Aida Castelló Corretge, Montse Coma Gassó, Fina Cregenzan Ortiz, Dolors Del Pozo Garcia, Mireia Falguera Vilamajó, Pere Farre Pagés, Yolanda Fauria Garcia, Anabel Fusalba Canales, Jara Gayan Ordas, Sergi Godia Lopez, Irene Gomez Companys, Jessica Gonzàlez Gutierrez, Anna Gort Oromí, Carme Jorge Tufet, Mercé Lavega Llorens, Laia Llort Samsó, Maria Rosa Lopez Cervelló, Belen Malla Clua, Josep Maria Marsol Mas, Teresita Martí Ribes, Diana Martin Capella, José Maria Martínez Barriuso, Esther Mateus Solé, Ramon Mazana Novellon, Petra Merino De los Santos, Miquel Mesas Julio, Sonia Minguet Vidal, Nuria Moles Porta, Luis Miguel Montaña Esteban, Dolors Morera Roset, Meritxell Moyà Oro, Irene Muñoz Del Campo, Francisco Nicolás Sánchez, Inés Ortiz Catalán, Mireia Ortiz Valls, Sonia Ortiz Congost, Jose Maria Palacin Peruga, Eugeni Paredes Costa, Pablo Pastor Pueyo, Ana Pérez Sainz, Antonio Plana Blanco, Anna Planas Hiraldo, Pepita Pont Aldoma, Marife Quelle Alonso, Rebeca Ramirez Molinero, Maria Àngels Revés Juanbaro, Anna Ribé Miró, Eva Ribó Caubet, Rebeca Rodriguez Corbaton, Marina Rué Florensa, Oscar Sacristán García, Irene Sanmartí Forns, Maria Cruz Sanz Martinez, Neus Sendra Bordes, Maria Cruz Urgelés Castillón, Laia Utrillo Montagut, and Montse Vidal Ballesté.

Abstract

Background: The assessment of behaviors related to mental health typically relies on self-report data. Networked sensors embedded in smartphones can measure some behaviors objectively and continuously, with no ongoing effort.

Objective: This study aims to evaluate whether changes in phone sensor–derived behavioral features were associated with subsequent changes in mental health symptoms.

Methods: This longitudinal cohort study examined continuously collected phone sensor data and symptom severity data, collected every 3 weeks, over 16 weeks. The participants were recruited through national research registries. Primary outcomes included depression (8-item Patient Health Questionnaire), generalized anxiety (Generalized Anxiety Disorder 7-item scale), and social anxiety (Social Phobia Inventory) severity. Participants were adults who owned Android smartphones. Participants clustered into 4 groups: multiple comorbidities, depression and generalized anxiety, depression and social anxiety, and minimal symptoms.

Results: A total of 282 participants were aged 19-69 years (mean 38.9, SD 11.9 years), and the majority were female (223/282, 79.1%) and White participants (226/282, 80.1%). Among the multiple comorbidities group, depression changes were preceded by changes in GPS features (*Time*: $r=-0.23$, $P=.02$; *Locations*: $r=-0.36$, $P<.001$), exercise duration ($r=0.39$; $P=.03$) and use of active apps ($r=-0.31$; $P<.001$). Among the depression and anxiety groups, changes in depression were preceded by changes in GPS features for *Locations* ($r=-0.20$; $P=.03$) and *Transitions* ($r=-0.21$; $P=.03$). Depression changes were not related to subsequent sensor-derived features. The minimal symptoms group showed no significant relationships. There were no associations between sensor-based features and anxiety and minimal associations between sensor-based features and social anxiety.

Conclusions: Changes in sensor-derived behavioral features are associated with subsequent depression changes, but not vice versa, suggesting a directional relationship in which changes in sensed behaviors are associated with subsequent changes in symptoms.

Introduction

Background

Behaviors such as levels of activity and social engagement are associated with common mental health conditions such as depression and anxiety [1-4]. Retrospective evaluations of these behaviors through self-report measures or interviews rely heavily on retrospective recall, which is subject to systematic biases [5,6]. Even more accurate methods, such as ecological momentary assessment (EMA), which acquire self-reported experiences in the course of peoples' lives [7,8], have not proven practical over extended periods outside of research settings [7]. Accelerometry data from wearable devices that measure activity levels have also been associated with depression [9], but many people stop wearing the devices within the first weeks [10].

Smartphones are becoming ubiquitous. As of 2019, 81% of Americans owned a smartphone [11], as did 76% of people in countries with advanced economies, and 45% in emerging nations [12]. Smartphones are fully integrated into our lives, supporting a growing number of activities. Smartphones contain embedded networked sensors that provide continuous, objective data without user effort, which can be used to produce behavioral markers. A growing body of research suggests that these sensor data can be associated with common mental health problems [13]. Location features derived from GPS actual measurement of patterns of locations visited, time in locations, and travel in phone communications such as text messaging and phone and app use have been associated with depression, anxiety, and social anxiety [14-17].

The potential for personal mobile sensing to improve our understanding of the relationship between behavior and mental health, as well as to advance clinical care, has been widely recognized [18]. However, although there is promise, research to date has had a number of weaknesses. Many of these studies have been conducted in small, relatively homogenous groups, such as students [15,16,19-21]. Although there has been some specificity, with location features tending to identify depression [14,15,19,22,23] and communication features tending to predict social anxiety [17], there have also been a few studies that have found the opposite [16,24]. This may be because of the heterogeneity in symptoms and comorbidities [25], which are common and have not been considered in existing research [13].

To date, studies have focused on using sensed behavioral features to estimate a person's state, either the presence or absence of a condition or symptom severity. With some exceptions, they have generally not evaluated the capacity for sensed behavioral features to predict whether symptoms will increase or decrease in the future. Among the few studies that have examined the capacity of sensed features to predict symptom change, one small study of 18 patients with bipolar disorder found that greater inconsistencies in rates of typing on a smartphone keyboard were related to future greater depressive symptom severity [26]. Relative to studies that use sensed behavior to estimate a person's state, the temporal relationship between sensed behaviors and symptom change has received relatively little attention.

Objectives

In this study, we examine the temporal relationship between changes in sensor features and subsequent changes in mental health symptoms in a large sample of participants. The aim of this exploratory study is to evaluate whether changes in classes of smartphone sensor features were associated with changes in symptom severity for depression, anxiety, and social anxiety, across all participants as well as within groups clustered based on symptoms.

Methods

Participants

Participants were recruited from July 15 to July 26, 2019, through ResearchMatch, a National Institute of Health-funded volunteer network, and the Center for Behavioral Intervention Technologies research registry. Participants were included if they were US citizens and residents, age ≥18 years, could read English, and had an Android smartphone. Participants were excluded if they endorsed, via self-report, having been diagnosed with a severe mental illness, defined as bipolar disorder, schizophrenia, or other psychotic disorder. Participants were compensated for completing measures at set assessment points as well as for completing EMA check-ins. Compensation for completing assessments increased as the study period progressed, such that participants were compensated relatively less for early assessment points and relatively more for assessments toward the end of the study. No single assessment was compensated at more than US $32.50 per assessment time point. Recruitment was advertised as a study on depression and deliberately oversampled depressed participants such that at least 50% of the sample experienced at least moderate depression symptom severity according to the 8-item Patient Health Questionnaire (PHQ-8).

Procedures

Participants downloaded the Passive Data Kit [27] mobile app, which unobtrusively collects phone sensor data and administers surveys. Web-based questionnaires were administered every 3 weeks. Participants were enrolled in the study for 16 weeks. All procedures were approved by the Northwestern University Institutional Review Board, and informed consent was obtained from all participants before participation.

Measures

Participants completed web-based symptom severity assessments at baseline and every 3 weeks until the end of the study period (ie, weeks 4, 7, 10, 13, and 16). Symptom measures included depression severity (PHQ-8) [28], generalized anxiety disorder (Generalized Anxiety Disorder 7-item scale [GAD-7]) [29], and social anxiety disorder (Social Phobia Inventory [SPIN]) [30]. The PHQ-8 was administered as an EMA survey after the baseline assessment point and, subsequently, had one additional assessment point (week 1) relative to other symptom measures.

Phone sensor data included GPS coordinates sampled once every 5 minutes, communication information (ie, phone logs and duration, text message logs, and length), and open apps. Assessment weeks occurred every 3 weeks, during which

participants were asked each evening to label the semantic location (type of location) that they had visited for more than 10 minutes [31]. A series of maps identifying each location were presented, and participants selected the category of each place (eg, home, work, errand, entertainment, place of worship, etc).

Data Analyses

Phone Sensor Feature Transformation

Overview

We considered four categories of phone features for our analysis: GPS-derived movement and location information, semantic locations, app use, and phone-based communication (calls and texts).

To increase interpretability and reduce the number of sensor features, we aggregated features first based on their phone sensor source, as different sensor sets provide unique information. Within each sensor set, we used unit weightings that maximized the interpretability for each feature aggregation. Where possible, we used existing theory to guide our unit aggregations. All sensor features were standardized (mean-centered with unit variance) across the full sample and averaged to produce sensor groupings within the four sensor categories. A full list of features, feature calculations, and their groupings can be found in Multimedia Appendix 1.

GPS-Derived Location and Movement

Following the methodology of Saeb et al [20], we computed high-level features from GPS data that measure participant movement, including location variance (variability in GPS location), total unique location clusters, location entropy (variability in time spent at location clusters), normalized entropy, total distance traveled, average velocity, and circadian movement (extent to which sequence of locations followed a 24-hour pattern). The features were aggregated into *Locations* (location cluster and location variance; represents the number and variability in locations visited), *Time* (total entropy, normalized entropy, and circadian movement; represents the variability in time spent across locations), and *Transitions* (distance traveled and velocity; represents travel between locations).

Semantic Location

Labels for semantic location categories included home duration, work duration, shopping duration, social activities duration (eg, friends' homes and entertainment), religious activities duration (eg, place of worship), and exercise location duration (eg, gyms). During the nonassessment weeks, semantic labels were assigned to locations visited using GPS coordinates assigned during the assessment weeks. This allowed us to estimate the daily duration of time participants spent in each semantic location category.

Communication

The number of incoming and outgoing calls and texts, call duration, and text message length were summed to obtain daily aggregates. The feature groups were *Calls* and *Text Messages*.

App Use

Apps running in the foreground of the phone were sampled every 5 minutes. We aggregated to produce daily app use duration measurements. We grouped apps of interest into 3 categories based on previous theory that certain apps facilitate active use, whereas others elicit more passive use [32,33]. This theoretical underpinning resulted in 3 categories of app use that were manually constructed using unit weighting. Final categorizations included: *Active Apps* (eg, messaging, email, and maps), which required active engagement to complete the primary essential task of each app, *Information Consumption Apps* (eg, YouTube and web browsers) where the primary purpose was more passive consumption of information or entertainment and *Social Apps* (eg, Facebook, Instagram, and Snapchat), which were considered social media apps, and were generally considered as a unique category of apps [34].

Population Clustering

Heterogeneity in underlying symptom patterns may impede the ability to observe clinically meaningful relationships between sensor features and symptom severity [13,35]. We used a data-driven approach, performing k-means clustering on the baseline PHQ-8, GAD-7, and SPIN items [36]. We chose k=4 using the elbow heuristic to choose the number of clusters (Multimedia Appendix 2). Qualitative analysis of these clusters showed that the 4 groups roughly corresponded to (1) a *Minimal Symptom* cluster (n=88), comprising participants characterized by low mean scores on all outcome measures; (2) a *Depression andSocial Anxiety* cluster (n=71) that included participants with predominantly moderate severity scores on the PHQ-8 and the SPIN, but low scores on the GAD-7 measures; (3) a *Depression and Anxiety* cluster (n=69), characterized by generally moderate-severe symptoms on the PHQ-8, moderate symptoms on the GAD-7, but mild ratings on the SPIN; and a (4) *Multiple Comorbidities* cluster (n=54) characterized by elevated ratings across all three symptom measures, with a substantial proportion scoring in the severe range.

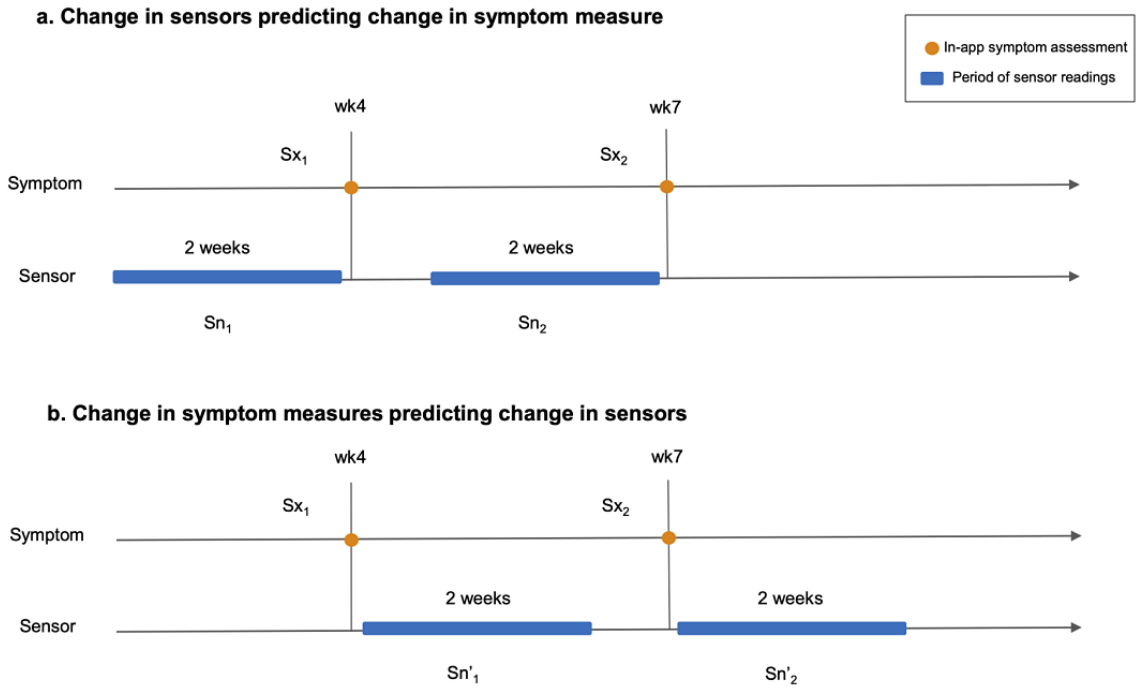
Statistical Methods: Correlation of Changes in Sensors to Changes in Symptom Severity

Figure 1 shows the strategy we used to lag, by 2 weeks, repeated measure correlations [37] of the changes in phone sensor features with changes in symptom severity. The 2-week window for sensor features, consistent with previous research [14,20], was used to allow for sufficient quality of sensor readings to match the retrospective time spans of self-report questionnaires and to maximize data available for analysis while preventing overlapping data sources (ie, symptom outcomes and concurrent sensed behavioral data) from being used at different time points. For the PHQ-8, we had six check-ins across the entire study, yielding five pairs of changes for each participant, whereas for GAD-7 and SPIN, we had five check-ins, yielding four pairs of changes for each participant. For analyses, in which changes in sensor features were used to estimate subsequent symptom severity, Sn_2-Sn_1 was correlated with Sx_2-Sx_1. For analyses in which changes in symptom severity were used to estimate changes in subsequent sensor features, Sx_2-Sx_1 was correlated with $Sn'_2-Sn'_1$. To correct for multiple comparisons, we

computed adjusted *P* values using the Benjamini-Hochberg procedure to control the false discovery rate [38].

If one assessment check-in was missing from a given pair of check-in dates, we used a within-person mean-fill method for the missing assessment. Any pair of assessment check-ins that had missing phone sensor data was discarded from analyses. Power calculations revealed that a sample size of 255 would be required to detect an effect size (correlation, $|\rho|$) of 0.2 at an α of .05 and power (β) of .90.

Figure 1. The sensor window preceding (a) and proceeding (b) the assessment check-ins. Correlations are run as corrected (Sx_2-Sx_1, Sn_2-Sn_1) and corrected (Sx_2-Sx_1, $Sn'_2-Sn'_1$).

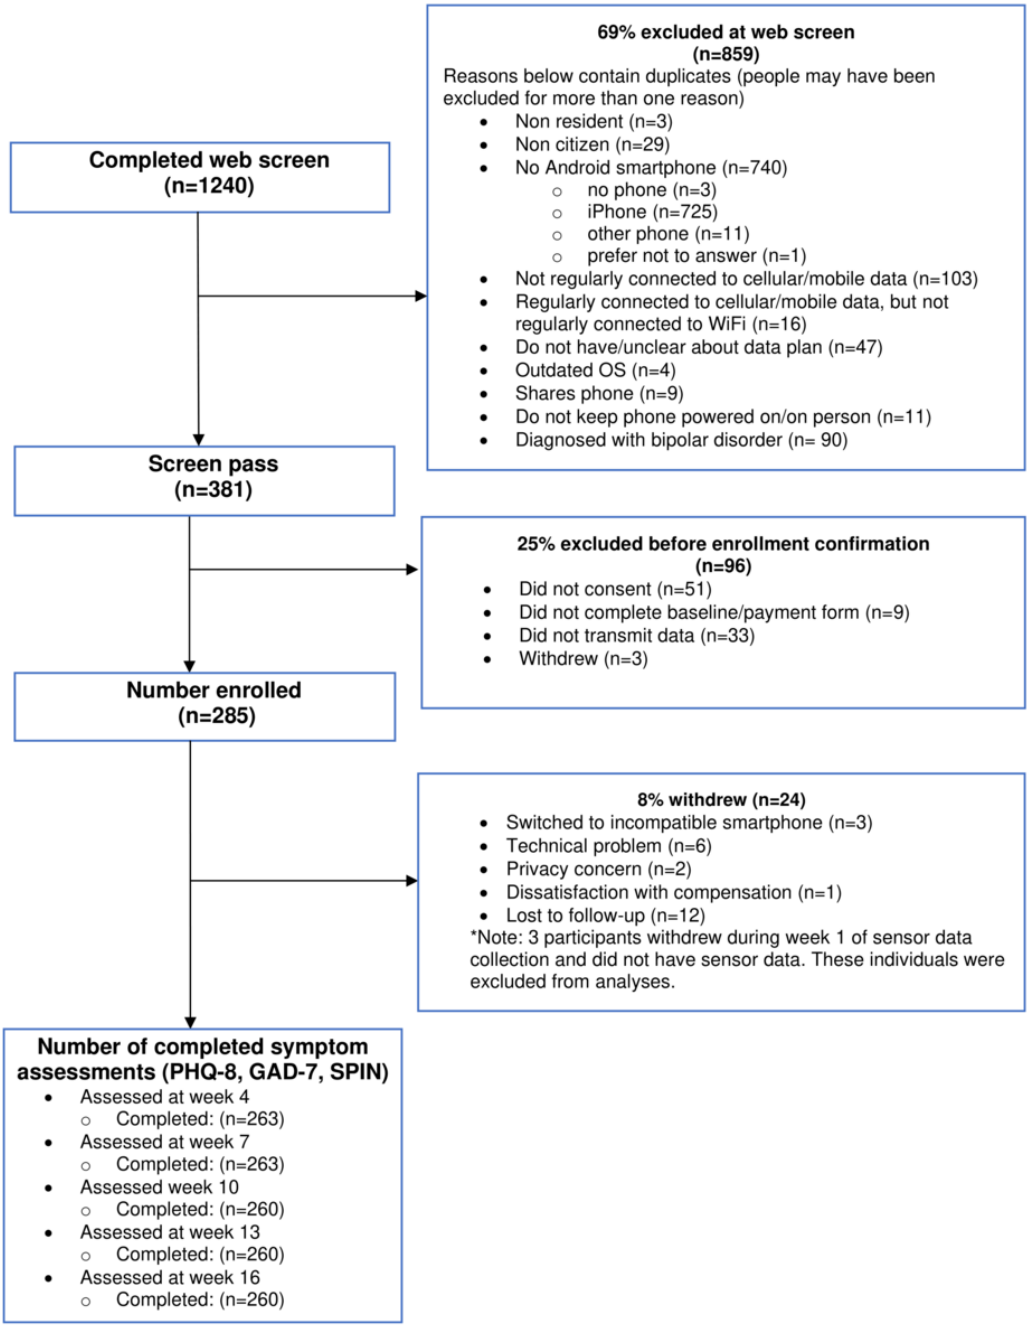


Results

Participants

The flow of participants in this study is shown in Figure 2. Participant demographic and baseline symptom severity characteristics across the entire sample and participant clusters are detailed in Multimedia Appendix 3.

Figure 2. Participant flow diagram. GAD-7: Generalized Anxiety Disorder 7-item scale; PHQ-8: 8-item Patient Health Questionnaire; SPIN: Social Phobia Inventory.



Symptom Change Over Time

Ordinary least square regression revealed no significant change in symptom severity as a function of time (PHQ-8: *P*=.80; GAD-7: *P*=.83; SPIN: *P*=.57). However, there was substantial within-participant variability depending on the symptom measure, with mean SDs of 2.66, 3.50, and 5.90, for the PHQ-8, GAD-7, and SPIN, respectively.

Association Between Sensor-Derived Behavioral Feature Changes and Subsequent Symptom Severity Change

Overview

Table 1 displays the repeated measure correlations primary outcomes by symptom cluster.

[a]There were no significant associations between sensor features and subsequent 8-item Patient Health Questionnaire (PHQ-8) symptoms or PHQ-8 symptoms and subsequent sensor features within the *minimal symptoms* group. There were also no significant associations between sensor features and subsequent Generalized Anxiety Disorder 7-item scale (GAD-7) symptoms or GAD-7 symptoms and subsequent sensor features for any subgroup.

[b]dof = n (k − 1), where n is the total number of participants and k is the average number of observations per participant.

[c]Repeated measures correlation coefficient.

[d]Benjamini-Hochberg corrected *P* values. Identical *P* values are due to the recursive definition of the Benjamini-Hochberg correction; it is possible for corrected *P* values to be identical, especially for nonsignificant correlations.

[e]PHQ-8: Patient Health Questionnaire-8 item.

[f]Full results are provided for Patient Health Questionnaire-8 item results in the full sample only to display all sensed behavioral features. Thereafter only relationships with corrected *P*<.1 are displayed.

[g]SPIN: Social Phobia Inventory.

Location Features

Patterns in individuals' movements were associated with subsequent changes in psychological symptoms, specifically depressive symptoms. Changes in GPS-derived *Location* were negatively associated with changes in the PHQ-8 in two of three symptom clusters, *Multiple Comorbidities* (r=−0.36; P<.001), *Depression and Anxiety* (r=-.20; P=.03), and the full sample (r=−0.17; P<.001) and trended toward significance in the *Depression and Social Anxiety* cluster (r=−0.16; P=.08), but the results were not statistically significant. Changes in GPS-derived *Time* were negatively associated with changes in PHQ-8 within the *Multiple Comorbidities* cluster (r=−0.23; P=.02) and the full sample (r=−0.12; P=.003) and trended toward significance in the *Depression and Social Anxiety* cluster (r=−0.16; P=.08), but the results were not statistically significant. Changes in GPS-derived *Transitions* were negatively correlated with changes in PHQ-8 for the *Depression and Anxiety* cluster (r=−0.21; P=.03) and the full sample (r=−0.12; P=.003) and trended toward significance in the *Multiple Comorbidities* cluster (r=−0.18; P=.07), but the results were not statistically significant. There were no significant relationships for the *Minimal Symptom* cluster for the PHQ-8 and no significant relationships between GPS features and subsequent changes in the GAD-7 or SPIN.

Certain types of semantic locations were also associated with PHQ-8 changes. In the depression and social anxiety cluster, there was a trend toward significance for *Social Activity Duration*, which was negatively correlated with changes in the PHQ-8 (r=−0.17; P=.08), but the results were not statistically significant. Within the *Multiple Comorbidities* symptom cluster and the full sample, *Exercise Location Duration* was positively associated with subsequent changes in PHQ-8 scores (*Multiple Comorbidities* cluster: r=0.39, P=.03; full sample: r=0.18, P=.005). This unexpected association between changes in exercise locations and changes in PHQ-8 was likely due to a preponderance of individuals who spent no time in exercise-based locations (ie, zero change in *Exercise Location Duration* from zero time spent in exercise locations), thus overweighting the data of some individuals who saw increased time spent in exercise-based locations with increased PHQ-8. There were no significant relationships within the minimal symptom cluster for the PHQ-8, and no significant relationships were found between semantic location features and subsequent changes in the GAD-7 or SPIN.

Telephone Calls

Within the *Depression and Social Anxiety* baseline cluster, increases in calls were associated with increases in SPIN scores (r=0.25; P<.001).

App Use

Changes in *Active App Use* were negatively correlated (r=−0.31; P<.001) with changes in PHQ-8 scores within the *Multiple Comorbidities* cluster.

Association Between Changes in Symptom Severity and Subsequent Change in Sensor-Derived Behavioral Features

There were no significant correlations between changes in any symptom severity measures and subsequent changes in sensor-derived behavioral features.

Missing Data

Across all treatment weeks, missingness (ie, the number of missing observations/total number of possible observations for

all 282 participants) was higher for the PHQ-8 (277/1692, 16.37%) assessments than for the GAD-7 (104/1410, 7.38%) and SPIN (104/1410, 7.38%). PHQ-8 assessments were administered through our smartphone app, whereas the GAD-7 and SPIN were administered through REDCap (Research Electronic Data Capture) [39]. In addition, across symptom outcome measures and relative to baseline symptom levels (Multimedia Appendix 3), those with missing assessments tended to have slightly higher baseline symptom severity (PHQ-8 range: 10.94-12.82; GAD-7 range: 9.95-11.5; and SPIN range: 24.52-27.48).

Discussion

Principal Findings

Changes in numerous phone sensor–derived behavioral features were associated with subsequent changes in mental health symptoms among people with elevated symptoms of depression. However, changes in symptoms were not associated with subsequent changes in behavioral features. GPS location features were fairly consistently and negatively, albeit modestly, related to subsequent changes in depression severity across symptom groups. This is consistent with a number of previous relatively small studies showing correlations between GPS features and depression [14,19,20,22,40,41]. This larger study confirms these earlier findings, and importantly, indicates a directional relationship in which GPS features are associated with subsequent increases or decreases in depressive symptoms, but not with anxiety or social anxiety.

The types of locations (work, shopping, etc) people visited were less consistently related to changes in depression. This does not necessarily mean that specific locations are unimportant at the individual level: one person may like shopping, whereas another may detest it. However, this suggests that patterns of movement through geographic space, irrespective of the destinations or locations to which one travels, are indicators of symptom change among people with depression. We speculate that this may reflect a loss of motivation expressed through geographic movement. Perhaps more speculatively, it may also be that changes in neurocognitive mechanisms, such as executive control, affect, and motivation, impact both depression and basic mechanisms involved in movement through geographic space [42,43].

The different constellations of symptoms that participants experience impact the salience of some sensed behaviors in predicting outcomes. For example, only within participants in the *Depression and Social Anxiety* symptom cluster was the amount of time spent in locations related to social activities associated with (at the trend level) subsequent change in depressive symptoms, suggesting that although locations are generally useful for depression prediction, social activities may be particularly useful when social anxiety symptoms are present. *Active App Use* (texting, email, and mapping) was associated with depression change among those with multiple and more severe comorbidities. Although GPS features were generally useful, features integrating time and location were not useful among those with comorbid generalized anxiety, and features measuring transitioning between locations were not useful for those with comorbid social anxiety. Thus, there was support for the notion that symptom constellations are important considerations for some features.

Increases in telephone calls were associated with increases in social anxiety symptoms among clusters characterized by depression and social anxiety. This finding notwithstanding, the capacity for sensor-derived features to be associated with changes in social anxiety symptoms was not as consistent as that for depressive symptoms. Furthermore, we did not find any associations between sensor-derived features and generalized anxiety symptom changes.

These findings indicate that sensor-derived behavioral features, which are objective and can be acquired with reduced participant effort, can be a useful tool for investigating the role of some behaviors in changing depressive symptom severity. There has been much speculation about the clinical potential of mobile sensing [18,44]. The effect sizes are modest, albeit consistent with many other studies that have examined the use of sensed behavioral features to estimate the presence or severity of symptoms [16,19]. This study does not support the use of phone sensor data alone in monitoring symptom changes in mental health populations; however, phone sensor data may be useful in conjunction with other networked sensing tools such as wearables. Phone sensor data may be useful for digital mental health interventions [45]. Just-in-time adaptive interventions [46,47] use individualized data to predict risk and deliver context-aware intervention material that is adaptive. These approaches are increasingly applied in digital health interventions, such as identifying when to send messages to increase physical activity such as step counts [48]. The promise of delivering motivational messages at opportune moments that reinforce behavioral activation strategies, such as visiting someplace new, spending more time outside of the home or work, or engaging socially, has the potential to improve engagement with these tools and reduce depression.

Limitations

This study had several limitations. First, the exploratory nature of this study requires interpreting results with caution and necessitates that future work must explicitly test the a priori hypotheses arising from these results. Next, although we establish significant temporal relationships between sensed behavior changes and subsequent changes in symptom severity, our study is not experimental and does not establish causal relationships. Furthermore, our sensor feature aggregations were limited to single sensor sources and were constructed to maximize interpretability; however, future studies that use data-driven aggregations are necessary to help inform feature aggregations across sensor modalities. Although aggregating across sensor modalities presents a challenge for interpretability, future work that examines cross-sensor aggregations could yield improved estimation of sensed behaviors and, subsequently, more robust associations with changes in symptoms. In addition, although these findings provide some support for the hypothesis that sensed behavior change is associated with subsequent changes in depression and not vice versa, this study examined the associations between changes in sensor features and subsequent changes in symptom severity measures lagged by

2 weeks, and therefore should not be generalized to periods beyond the 2-week window. Another limitation is that our sample only included those who used Android devices and agreed to participate in this research. App use and communication data are not readily available for iOS devices. Regarding data missingness, across all the surveys, individuals who had missing data had higher baseline symptom severity than the overall sample, though not dramatically so; thus, data were missing not at random. These missingness rates are in line with established criteria that are often used as the standard for good trial data [49]. Finally, although we controlled for multiple analyses, we nonetheless caution against overinterpretation of more isolated findings that need to be replicated in future studies.

Conclusions

The ubiquity of smartphones with networked sensors has opened up new opportunities to identify behavioral markers related to mental health that can be acquired continuously and effortlessly. Changes in movement through geographic space were consistently associated with subsequent changes in depressive symptoms; however, there was no evidence that changes in depression were associated with subsequent changes in sensed behaviors. This supports a directional relationship in which changes in movement patterns precede symptom change, but symptom change does not precede changes in movement behaviors.

Abstract

Background: When using a smartwatch to obtain electrocardiogram (ECG) signals from multiple leads, the device has to be placed on different parts of the body sequentially. The ECG signals measured from different leads are asynchronous. Artificial intelligence (AI) models for asynchronous ECG signals have barely been explored.

Objective: We aimed to develop an AI model for detecting acute myocardial infarction using asynchronous ECGs and compare its performance with that of the automatic ECG interpretations provided by a commercial ECG analysis software. We sought to evaluate the feasibility of implementing multiple lead–based AI-enabled ECG algorithms on smartwatches. Moreover, we aimed to determine the optimal number of leads for sufficient diagnostic power.

Methods: We extracted ECGs recorded within 24 hours from each visit to the emergency room of Ajou University Medical Center between June 1994 and January 2018 from patients aged 20 years or older. The ECGs were labeled on the basis of whether a diagnostic code corresponding to acute myocardial infarction was entered. We derived asynchronous ECG lead sets from standard 12-lead ECG reports and simulated a situation similar to the sequential recording of ECG leads via smartwatches. We constructed an AI model based on residual networks and self-attention mechanisms by randomly masking each lead channel during the training phase and then testing the model using various targeting lead sets with the remaining lead channels masked.

Results: The performance of lead sets with 3 or more leads compared favorably with that of the automatic ECG interpretations provided by a commercial ECG analysis software, with 8.1%-13.9% gain in sensitivity when the specificity was matched. Our results indicate that multiple lead-based AI-enabled ECG algorithms can be implemented on smartwatches. Model performance generally increased as the number of leads increased (12-lead sets: area under the receiver operating characteristic curve [AUROC] 0.880; 4-lead sets: AUROC 0.858, SD 0.008; 3-lead sets: AUROC 0.845, SD 0.011; 2-lead sets: AUROC 0.813, SD 0.018; single-lead sets: AUROC 0.768, SD 0.001). Considering the short amount of time needed to measure additional leads, measuring at least 3 leads—ideally more than 4 leads—is necessary for minimizing the risk of failing to detect acute myocardial infarction occurring in a certain spatial location or direction.

Conclusions: By developing an AI model for detecting acute myocardial infarction with asynchronous ECG lead sets, we demonstrated the feasibility of multiple lead-based AI-enabled ECG algorithms on smartwatches for automated diagnosis of cardiac disorders. We also demonstrated the necessity of measuring at least 3 leads for accurate detection. Our results can be used as reference for the development of other AI models using sequentially measured asynchronous ECG leads via smartwatches for detecting various cardiac disorders.

Introduction

Wearable devices, simply referred to as "wearables," are smart electronics or computers that are integrated into clothing and other accessories that can be worn on or attached to the body [1]. The consumer adoption of wearable technology for health care services is skyrocketing owing to increasing interest in personalized health management, disease prevention, and fitness [2,3]. One such technology is continuous/day-to-day measurement of single-lead electrocardiograms (ECGs) via smartwatches or other portable/handheld devices [4-6]. These devices can provide a novel opportunity for facilitating timely diagnostics by extending the availability of ECG measurement to the general population outside the hospital.

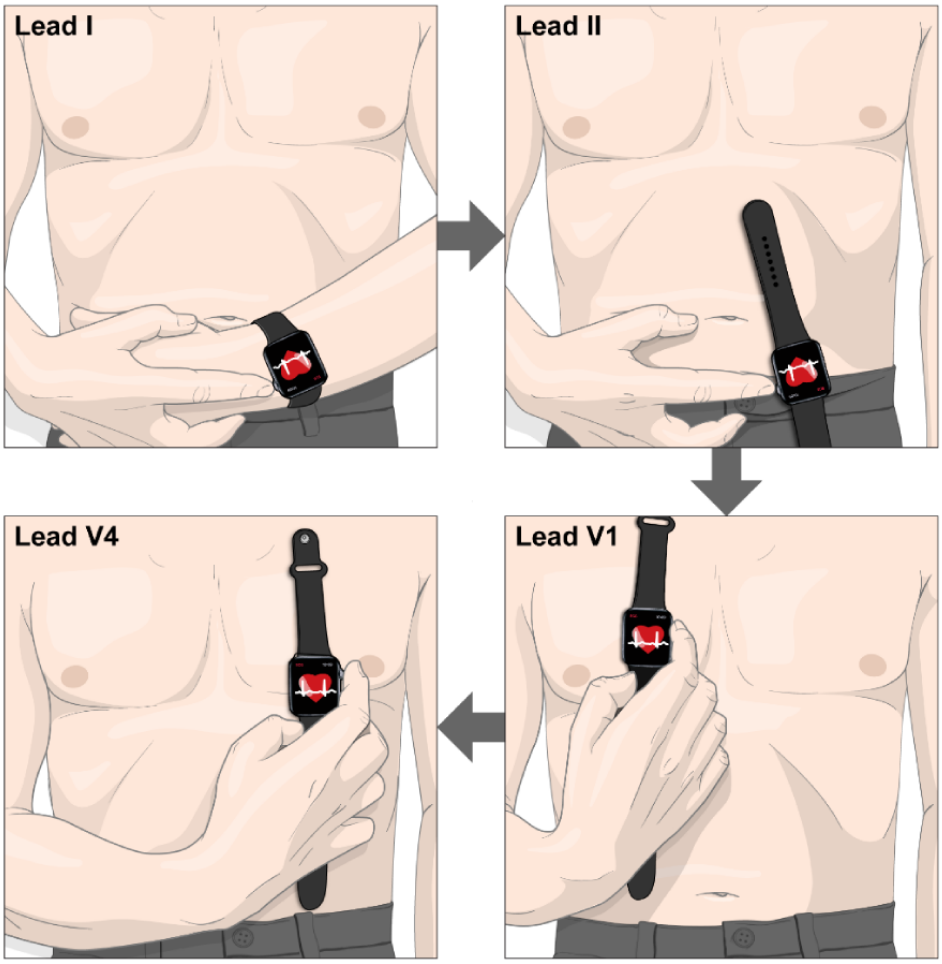
Smartwatches and other portable/handheld ECG devices measure single-lead ECG when the 2 electrode detectors are attached to 2 different parts of the body [5]. However, useful information from other leads can potentially be neglected when only a single lead is evaluated [7]. Analyzing electrical activity of the heart from different spatial locations by measuring multiple leads is necessary for accurate and robust detection of cardiac disorders, such as myocardial infarction, pulmonary embolism, and acute left or right heart failure [8,9]. Accordingly, the standard 12-lead ECG is the most commonly used assessment among physicians for evaluation of the heart.

Previous studies have explored the possibility and described the methodology of measuring multiple ECG leads using smartwatches [9,10]. Multiple ECG leads can be obtained from smartwatches by sequentially placing the smartwatch on different parts of the body (Figure 1). The ECG signals from different leads are asynchronous when measured in this way. There are also reports evaluating the concordance of multiple-lead ECG obtained by smartwatches compared with the standard 12-lead ECG in detecting conditions related to ischemic heart disease when read by physicians [11-13].

To the best of our knowledge, previous studies on automated diagnosis or classification of ECGs using artificial intelligence (AI) have utilized either single-lead ECGs or synchronous multiple-lead ECG signals as input [14-19]. Application of asynchronous ECG signals for AI model development is largely unexplored. Such an application needs to be assessed to ensure that multiple lead-based AI-enabled ECG models can be implemented on smartwatches. Moreover, the adequate number of sequentially recorded leads from smartwatches that would ensure sufficient diagnostic power of the AI-enabled ECG model needs to be verified.

In this study, we aimed to develop an AI model for detecting acute myocardial infarction using asynchronous ECG lead sets and then compare the performance of our model with that of an automatic ECG interpretation provided by a commercial ECG analysis software. Such a model could prove the feasibility of AI-enabled ECG algorithms on smartwatches. As a prerequisite to develop such a model, we derived asynchronous ECG signals from standard 12-lead ECG reports to simulate a situation similar to the sequential recording of ECG leads via smartwatches. Moreover, we aimed to find the optimal number of leads for sufficient diagnostic power by randomly masking each lead channel during the training phase and validating/testing our model with various targeting lead sets (and masking the remaining lead channels).

Figure 1. Example of measuring multi-lead electrocardiogram (ECG) from a smartwatch. Multiple-lead ECG can be obtained from smartwatches by sequentially placing the smartwatch on different parts of the body. The figure depicts an example of measuring leads I, II, V1, and V4 sequentially. Lead I can be recorded with the smartwatch on the left wrist and the right index finger on the crown. Then, after removing the smartwatch from the left wrist, lead II can be recorded with the smartwatch on the left lower quadrant of the abdomen and the right index finger on the crown. Next, leads V1 and V4 can be recorded with the smartwatch on the fourth intercostal space at the right sternal border and fifth intercostal space at the midclavicular line, respectively, with the right index finger on the crown in both cases.



Methods

Ethics Approval

The Institutional Review Board of Ajou University Hospital approved this study (protocol AJIRB-MED-MDB-20-597) and waived the requirement for informed consent because only anonymized data were used retrospectively.

Data Sample and Labeling

We utilized standard 12-lead ECG reports collected from General Electric (GE) ECG machines at Ajou University Medical Center (AUMC), a tertiary teaching hospital in South Korea. These ECG reports of AUMC originally exist as PDFs and are stored in a database. Thus far, the ECG database contains a total of 1,039,550 ECGs from 447,445 patients, collected between June 1994 and January 2018. A previous study extracted raw waveforms, demographic information, and ECG measurement parameters/automatic ECG interpretations made by the GE Marquette 12SL ECG Analysis Program from these reports [20]. In these reports, each lead is 2.5 seconds in duration and sampled at 500 Hz. We also collected clinical data, such as emergency room visit time or the diagnosis of the patients, from the AUMC Electronic Medical Records database.

For our study, we identified and extracted ECGs recorded within 24 hours from each visit to the emergency room between June 1994 and January 2018 from patients aged 20 years or older. For each visit to the emergency room, all diagnoses made during the stay in hospital were collected. If either International Classification of Diseases, Tenth Revision (ICD-10) code I21 (acute myocardial infarction) or I22 (subsequent ST elevation and non-ST elevation) was entered, the ECGs for those visits were labeled as having acute myocardial infarction. For visits that had neither of the 2 ICD-10 codes entered, the ECGs for those visits were labeled as not having acute myocardial infarction.

We split the data into training/validation (80%) and independent hold-out test (20%) sets, and then further split the training/validation set into training (85%) and validation (15%) sets. To reduce ambiguity, we excluded patients whose time of registration for the ICD-10 codes for acute myocardial infarction (I21 or I22) was either “null” (meaning that the registration time was not entered and thus is unknown) or not within 24 hours of ECG measurement.

After model development, we compared the performance of our model with that of the automatic ECG interpretation provided by the GE ECG analysis program. To derive the performance of the automatic ECG interpretation for detecting acute myocardial infarction, we categorized the interpretations in 2 different ways. First, the automatic ECG interpretation was categorized as myocardial infarction if the interpretation included at least one of the following three phrases: “ACUTE MI,” “ST elevation,” and “infarct.” The second categorizing criterion consisted of the 3 phrases in the first labeling criterion along with the following three phrases: “T wave abnormality,” “ST abnormality,” and “ST depression.” We thus derived 2 distinct performance indices from these 2 categories.

Deriving Asynchronous Lead Sets From ECG Reports

Multimedia Appendix 1 shows an example of a standard 12-lead ECG report used at AUMC. These ECG reports are asynchronous as a whole while being synchronous when grouped into 4 subsets of 3 leads each. The x-axis of the ECG report represents time flow; the waveforms on the left side are recorded earlier than those on the right side. The total recorded time of this ECG report is 10 seconds. In Multimedia Appendix 1, leads I, II, and III are shown to have been recorded 2.5 seconds earlier than leads aVR, aVL, and aVF, which were recorded 2.5 seconds earlier than leads V1, V2, and V3, which in turn had been recorded 2.5 seconds earlier than leads V4, V5, and V6.

As previously mentioned, asynchronous ECG lead sets can be derived from ECG reports to simulate a situation similar to the sequential recording of ECG leads via smartwatches. For example, a 4-lead subset consisting of leads I, aVR, V1, and V4 from the ECG report is completely asynchronous. According to the Einthoven law and Goldberger equation, for the 6 limb leads (leads I, II, III, aVR, aVL, and aVF), the remaining 4 leads can be calculated even if only 2 leads are available [21,22]. Here, we trained/validated our AI model by randomly masking each lead channel and then tested our model with various target lead sets (while masking the remaining lead channels) to determine the optimal number of leads for sufficient diagnostic power. The tested lead sets are specified in Multimedia Appendix 2. For the multiple-lead sets, we included lead I in all cases, given that lead I is the most basic lead channel that can be measured from a smartwatch: lead I can be measured by placing the right index finger on the crown without removing the smartwatch from the left wrist. The lead channels in each 4-, 3-, and 2-lead set are completely asynchronous. Thus, the lead channels included in the 4-lead sets were leads I and II (calculated from leads aVR, aVL, and aVF) for the limb leads and all the possible combinations of 2 precordial leads that could be derived from the ECG report while maintaining complete asynchrony. The lead channels included in the 3-lead sets were leads I and lead II (calculated from leads aVR, aVL, and aVF) for the limb leads and 1 precordial lead. The lead channels included in the 2-lead sets were lead I and either lead II (calculated from leads aVR, aVL, and aVF) or 1 precordial lead. We also tested 2 single-lead cases (lead I or II).

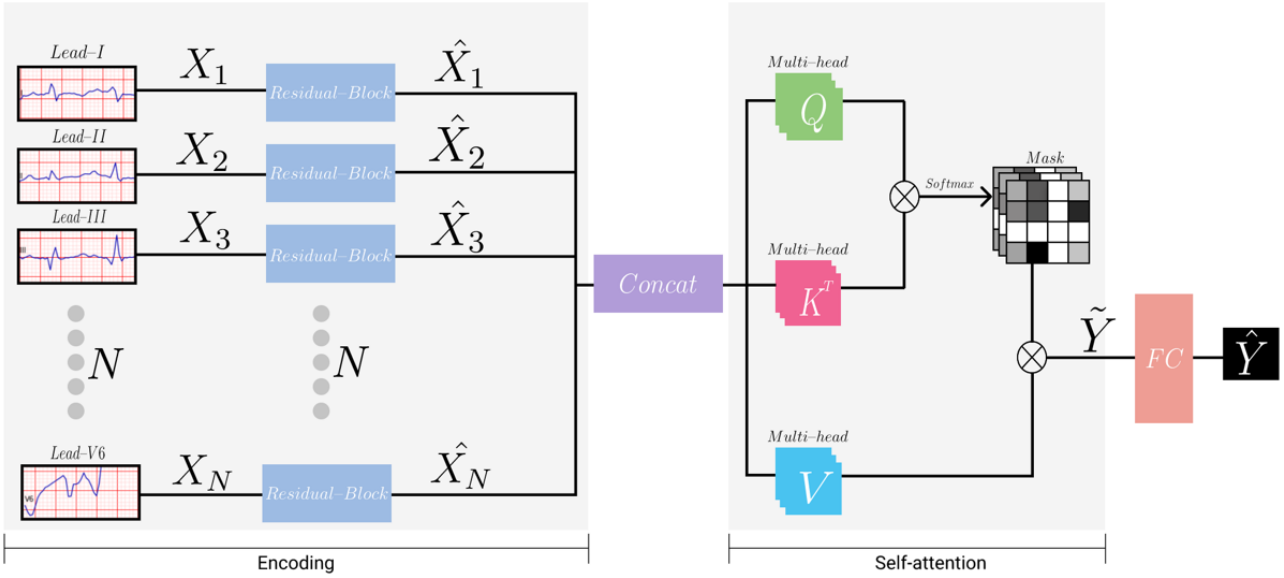
Primary and Secondary Aims of the Study

Our primary aim was to develop an AI model for detecting acute myocardial infarction from asynchronous ECG signals, which outperforms the automatic ECG interpretation provided by the GE ECG analysis program. Our secondary aim was to determine the optimal number of leads required for sufficient diagnostic power. Model performances were assessed using the following statistics: area under the receiver operating characteristic curve (AUROC), area under the precision-recall curve (AUPRC), sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV).

Neural Network Architecture and Training

Figure 2 illustrates the architecture of the neural network model used in our study. The model was divided into two phases: encoding and self-attention.

Figure 2. Illustration of the neural network's architecture. The encoding phase encodes each lead channel with a weight-shared structure. The self-attention phase captures the relation between each lead channel.



Encoding Phase

The model took the input of 2.5 seconds from each 12-lead ECG channel, which was downsampled from 500 Hz to 250 Hz. Each lead was processed in a separate but weight-shared encoder. Details of the architecture of the encoder are summarized in Multimedia Appendix 3. The encoder consisted of 16 residual blocks with 2 or three 1-dimensional convolutional neural network (CNN) layers in each block [23]. Every CNN layer was followed by a batch normalization layer and a ReLU activation function. All the CNN layers had a kernel size of 7 and the "same" padding. In the first residual block, the output of the first ReLU activation function was connected to the block's output via a pooling layer. In the following 15 residual blocks, the input and output of each block were connected via skip connection. CNN layers with a stride of 2 were applied every 2 or 4 residual blocks. The depth (number of features) of the CNN layers increased by a factor of 2 per 4 residual blocks. For example, a stride described as "2,1,1" in Multimedia Appendix 3 implies that there are 3 CNN layers in that block and the stride of those CNN layers are 2, 1, and 1, respectively. The "Length" and "Depth" columns in Multimedia Appendix 3 are the length and depth of the output of each block. Each feature of the final output of the encoder was average pooled to obtain length=1.

Self-attention Phase

To capture the associations among each lead channel, we utilized a multi-head self-attention module that consisted of queries, keys, and values. Each query, key, and value represented a single dense layer that took all output from the encoder (ie, ) [24]. We computed the dot products of the query with all keys and applied a softmax function to obtain $N \times N$ attention matrices, where N is the number of lead channels. During the training phase of the model, to ensure generalization and applicability for any lead combinations (eg, various 4-, 3-, 2-, and single-lead sets), we randomly masked each lead channel on the attention matrices. Meanwhile, we masked all the lead channels except for the specific targeting leads during the inference phase. For instance, if the target leads were I and V1, we masked all other leads but leads I and V1 during the inference phase. Any lead combinations can be set as target leads. The specific combinations that we tested are specified in Multimedia Appendix 2. After acquiring the attention matrices, we computed the dot products of the values with attention matrices such that the model could reflect the relation between leads. Afterward, these outputs from all the multi-heads were concatenated and linearly projected so that the final output dimension of the multi-head self-attention module became 512 (the same as the original input of the multi-head self-attention module).

We then flattened the output of lead channels before feeding them into the classifier. The classifier had 2 layers of dense layers, which reduced the dimension from 6144 (512 × 12) to 1, followed by a sigmoid layer that calibrated the probability of acute myocardial infarction (ie, ) range from 0 to 1. We split the data into training/validation (80%) and independent hold-out test (20%) sets, and then further split the training/validation set into training (85%) and validation (15%) sets. For training, we used the Adam optimizer with a batch size of 32 and a learning rate of 0.001. We also applied weight decay and several data augmentation techniques, including random Gaussian noise, time scaling, and signal masking, to prevent overfitting. To tune the hyperparameters, we utilized validation data sets with extensive experiment settings (ie, 12-, 4-, 3-, 2-, and single-lead settings). We implemented the model using the Pytorch library.

Results

Data Set Characteristics

From the AUMC ECG database, we extracted 97,742 patients aged 20 years or older with 183,982 ECGs recorded within 24 hours from each visit to the emergency room (Figure 3). After applying the exclusion criteria, we included 76,829 patients with 138,549 ECGs in the training and validation data set, and 19,109 patients with 34,371 ECGs in the test data set. The data set characteristics are summarized in Table 1. The proportion of ECGs labeled as acute myocardial infarction was 1.78% for the training and validation data set, and 1.61% for the test data set.

Figure 3. Patient flow diagram. The patients were split into training and validation (80%) and test (20%) data sets. ECG: electrocardiogram, ICD-10: International Classification of Diseases, Tenth Revision.

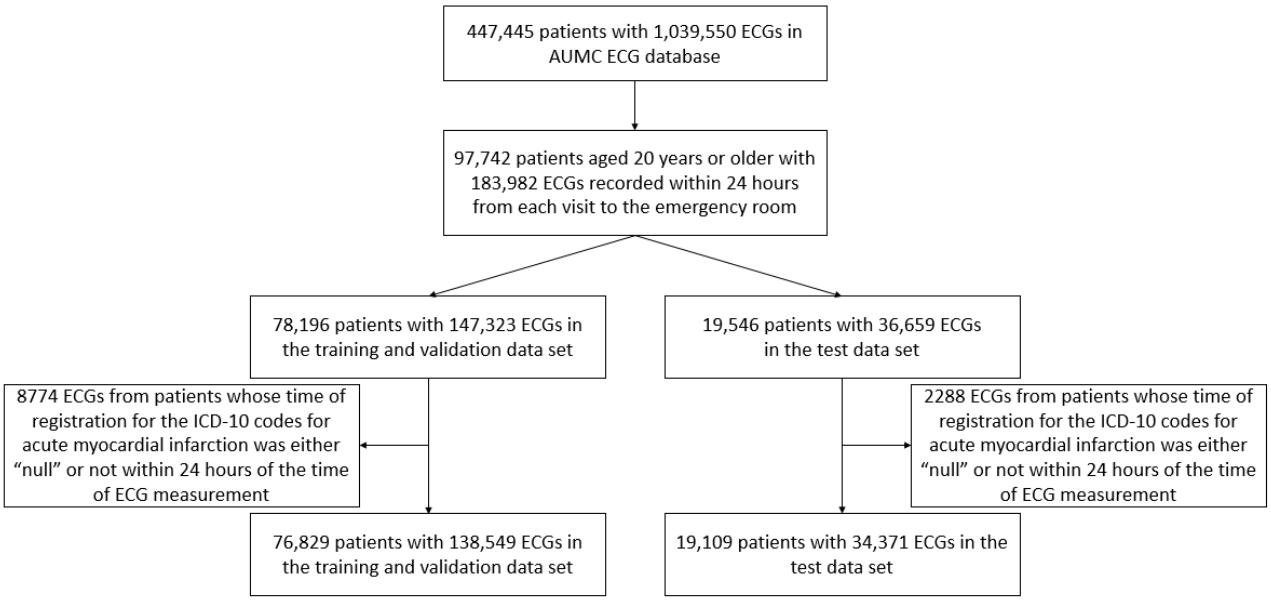


Table 1. Data set characteristics.

Characteristics	Training and validation (n=138,549)	Test (n=34,371)
Patients, n	76,829	19,109
Age (years), mean (SD)	59.00 (16.98)	59.00 (16.95)
Sex		
Male		
Electrocardiographs, n	75,552	18,426
Patients, n	40,662	10,043
Female		
Electrocardiographs, n	64,097	15,945
Patients, n	36,170	9066
Acute myocardial infarction, n	2465	554

Model Performance

Figures 4 and 5 show the receiver operating characteristic (ROC) and the precision-recall (PR) curves for the various target lead sets. The dots indicate the performance of the automatic ECG interpretations provided by the GE ECG analysis program. The sensitivity, specificity, PPV, and NPV of the first labeling criterion of the automatic ECG interpretation were 0.579, 0.866, 0.066, and 0.992, respectively. The corresponding values of the second labeling criterion of the automatic ECG interpretation were 0.765, 0.647, 0.034, and 0.996, respectively. Lead sets with 3 or more leads had a better performance than the automatic interpretations: their corresponding ROC and PR curves consistently lay above the corresponding dots of the automatic ECG interpretations. Similarly, the single-lead sets had worse performance than the automatic ECG interpretations: the corresponding ROC and PR curves lead sets lay below the corresponding dots of the automatic ECG interpretations. For the 2-lead sets, some of the ROC and PR curves lay above and some below the corresponding dots of the automatic ECG interpretations, which implied that not all the 2-lead sets had a better performance than the automatic interpretations.

Figure 4. ROC curves for the various target lead sets. The plot on the upper left shows the average ROC curves according to the number of leads. The solid lines depict the average ROC curves, and the shaded areas depict 1 SD of the ROC curves. The rest of the plots show the ROC curves for the 12-, 4-, 3-, 2-, and single-lead sets, respectively. In all plots, the performance of the automatic ECG interpretations is depicted as dots. AUROC: area under the receiver operating characteristic curve; ROC: receiver operating characteristic curve.

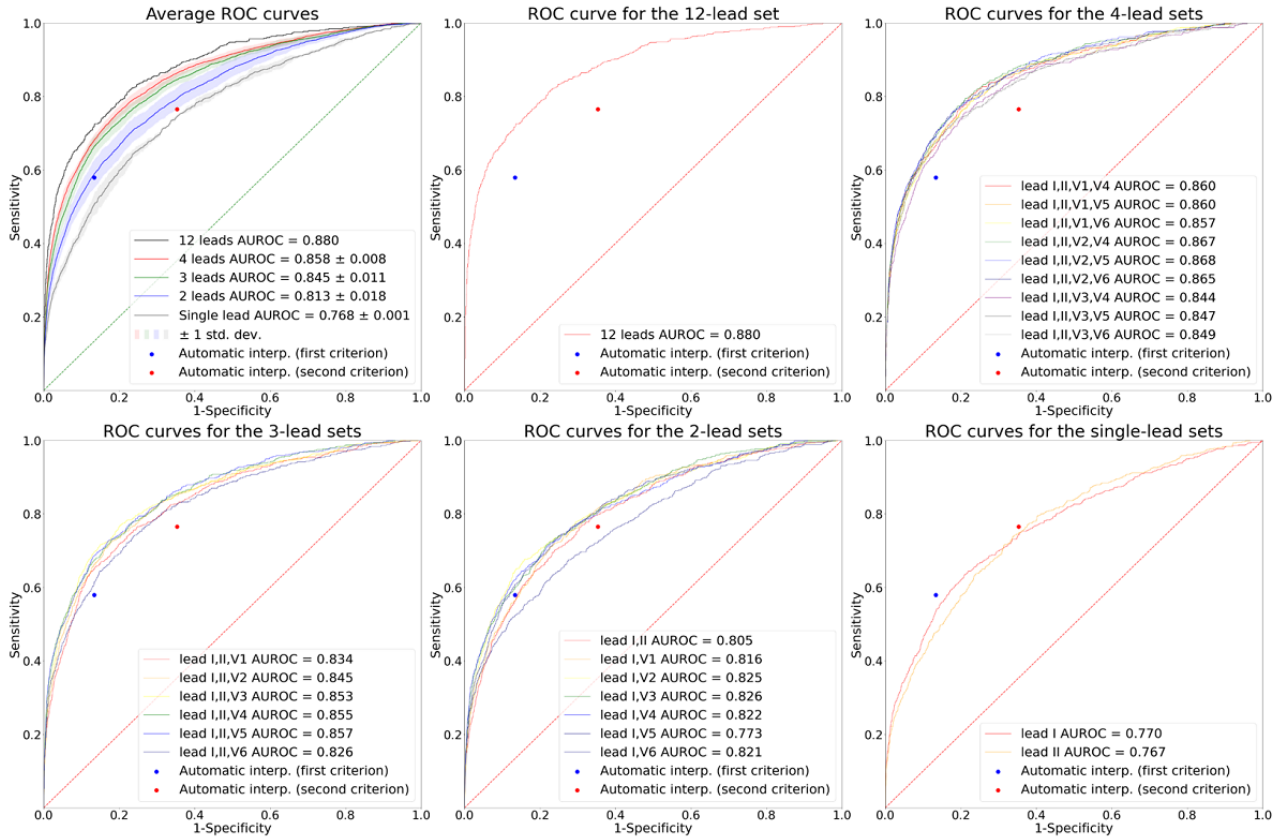

Figure 5. PR curves for the various target lead sets. The plot on the upper left shows the average PR curves according to the number of leads. The solid lines depict the average PR curves, and the shaded areas depict 1 SD of the PR curves. The rest of the plots show the PR curves for the 12-, 4-, 3-, 2-, and single-lead sets, respectively. In all plots, the performance of the automatic ECG interpretations is depicted as dots. AUPRC: area under the precision-recall curve; PR: precision-recall.

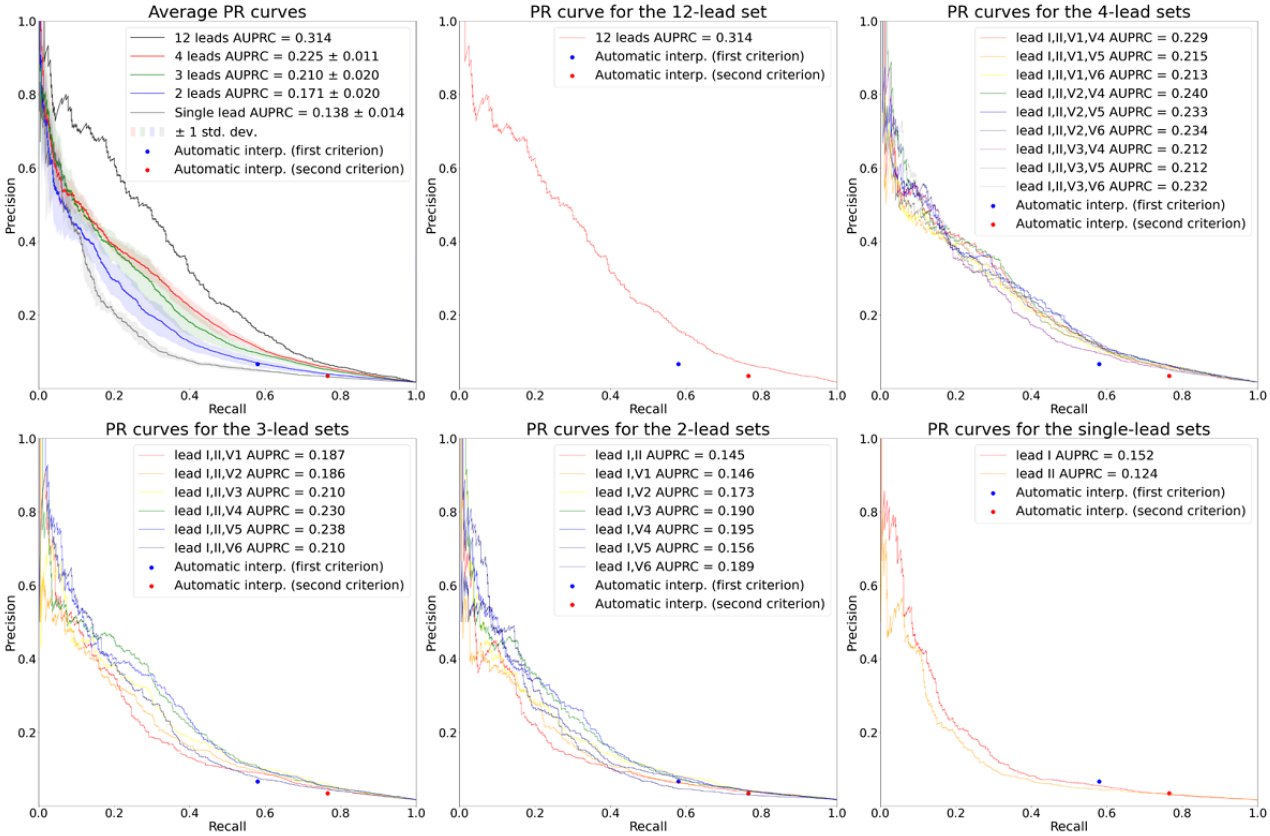

The average AUROCs for the 12-, 4-, 3-, 2-, and single-lead sets were 0.880, 0.858 (SD 0.008), 0.845 (SD 0.011), 0.813 (SD 0.018), and 0.768 (SD 0.001), respectively. The average AUPRCs for the 12-, 4-, 3-, 2-, and single-lead sets were 0.314, 0.225 (SD 0.011), 0.210 (SD 0.020), 0.171 (SD 0.020), and 0.138 (SD 0.014), respectively. These values indicate that the average AUROC and AUPRC increased as the number of leads increased. All the comparisons of AUROCs between ROC curves having the median AUROC from lead sets with different numbers of leads ("12-lead set" vs "4-lead set [leads I, II, V1, V5]" vs "3-lead set [leads I, II, V3]" vs "2-lead set [leads I, V6]" vs "single-lead set [lead I]") were statistically significant at a significance level of .05, as revealed through the DeLong test [25]. All the comparisons of AUROCs between ROC curves having the highest AUROC from lead sets with different numbers of leads ("12-lead set" vs "4-lead set [leads I, II, V2, V5]" vs "3-lead set [leads I, II, V5]" vs "2-lead set [leads I, V3]" vs "single-lead set [lead I]") were also statistically significant at a significance level of .05, as revealed through the DeLong test.

When we set the thresholds of the lead sets to match the specificity of the first labeling criteria of the automatic ECG interpretation (specificity=0.866), the 12-, 4-, and 3-lead sets demonstrated an average gain in sensitivity of 13.9%, 10.2% (SD 1.6%), and 8.5% (SD 2.7%), respectively (Table 2), compared to the automatic ECG interpretation, while maintaining a high NPV above 0.99. The results for the second labeling criteria (specificity=0.647) revealed average gains in sensitivity of 11.9%, 9.8% (SD 1.2%), and 8.1% (SD 1.5%) for the lead sets with 12, 4, and 3 leads, respectively (Table 2), while maintaining a high NPV above 0.99. The sensitivities of the 2-lead sets were, on average but not consistently, slightly higher than those of the automatic ECG interpretations when the thresholds of the 2-lead sets were set to match the specificities of the automatic ECG interpretations. Single-lead sets had lower sensitivities than the automatic ECG interpretations when the specificities were matched.

Table 2. Average sensitivity, positive predictive value, and negative predictive value according to the number of leads when the thresholds were set to match the specificity of the first or second labeling criteria of automatic electrocardiogram interpretation.

	Sensitivity		Positive predictive value		Negative predictive value	
	At specificity=0.866 (first labeling criteria)	At specificity=0.647 (second labeling criteria)	At specificity=0.866 (first labeling criteria)	At specificity=0.647 (second labeling criteria)	At specificity=0.866 (first labeling criteria)	At specificity=0.647 (second labeling criteria)
Automatic electrocardiogram interpretation	0.579	0.765	0.066	0.034	0.992	0.996
12-lead set	0.718	0.884	0.081	0.039	0.995	0.997
4-lead sets, mean (SD)	0.681 (0.016)	0.863 (0.012)	0.077 (0.002)	0.039 (0.001)	0.994 (0.000)	0.997 (0.000)
3-lead sets, mean (SD)	0.664 (0.027)	0.846 (0.015)	0.075 (0.003)	0.038 (0.001)	0.994 (0.000)	0.996 (0.000)
2-lead sets, mean (SD)	0.589 (0.038)	0.794 (0.030)	0.067 (0.004)	0.036 (0.001)	0.992 (0.001)	0.995 (0.001)
Single-lead sets, mean (SD)	0.505 (0.029)	0.745 (0.001)	0.058 (0.003)	0.033 (0.000)	0.991 (0.001)	0.994 (0.000)

Discussion

Principal Findings

In this study, we developed an AI model for detecting acute myocardial infarction by randomly masking each lead channel during the training phase and testing the model using various target ECG lead sets with the remaining lead channels masked. First, we found that the performances of lead sets with 3 or more leads compared favorably with that of the automatic ECG interpretations provided by the GE ECG analysis program, with a 8.1%-13.9% gain in sensitivity when the threshold was set to match the specificity of the automatic ECG interpretations, and with the ROC and PR curves lying above the corresponding dots of the automatic ECG interpretations. Only some of the 2-lead sets compared favorably with the automatic ECG interpretations. When only a single lead was evaluated, acute myocardial infarction could be underdiagnosed; thus, useful information from other leads could potentially be neglected. Indeed, single-lead sets performed worse than the automatic ECG interpretations.

Multiple-lead ECG is necessary for the accurate and robust detection of cardiac disorders, particularly acute myocardial infarction. Given that multiple-lead ECGs can be obtained by smartwatches only in an asynchronous manner, our results imply that multiple lead-based AI-enabled ECG algorithms can be implemented on these devices. Such implementation could facilitate timely diagnostics to enhance outcomes and reduce mortality among cardiovascular disease populations outside the hospital.

Second, we found that model performance generally increased as the number of leads increased (12-lead set: AUROC 0.880; 4-lead sets: AUROC 0.858, SD 0.008; 3-lead sets: AUROC 0.845, SD 0.011; 2-lead sets: AUROC 0.813, SD 0.018; single-lead sets: AUC 0.768, SD 0.001). With smartwatches, measuring additional leads would only take less than a minute, and the benefit of doing so would greatly outweigh the risk. In an emergency situation, we suggest measuring at least 3 leads (ie, I, II, and V5) and ideally more than 4 leads (ie, I, II, V2, and V5) to minimize the risk of failing to detect acute myocardial infarction occurring in a certain spatial location or direction.

Previous studies on automated diagnosis or classification of multiple-lead ECGs using AI have used synchronous ECG signals as input. The results from these studies are insufficient for the evaluation of the feasibility of multiple lead-based AI-enabled ECG algorithms on smartwatches since only asynchronous ECG signals can be obtained from smartwatches. To the best of our knowledge, our study is the first to utilize asynchronous ECG signals for AI model development. Future studies could aim at developing AI models with asynchronous ECG signals for detecting cardiac disorders other than acute myocardial infarction, such as cardiac arrhythmias or contractile dysfunctions.

Our study has important medical and economic impacts. First, our model can significantly reduce time to diagnosis, and consequently reduce time to reperfusion, which is the elapsed time between the onset of symptoms and reperfusion and is critical to the clinical outcome of the disease [26]. The ECG is commonly the first diagnostic test in the evaluation of myocardial infarction, and it should be acquired as early as practicable [27]. Traditionally, the bulky ECG equipment and the need for a trained physician for diagnosis have required the transfer of patients to hospitals, even in emergency situations. This practice greatly delays time to diagnosis, which would be most ideal if made directly in the field. With our model implemented on smartwatches, reliable preliminary diagnosis can be made even before contact with emergency services, thereby greatly reducing the time from the onset of symptoms to diagnosis. With the preliminary diagnosis already made, patients can be promptly triaged to the most appropriate form of treatment after accounting for geographical factors and available facilities [26]. The final diagnosis should be made by a trained physician after arriving at the appropriate facility, but with the aid of our model, the time required for the entire process can be greatly reduced. The threshold for a positive result from our model can be altered to balance between over- and undertriage. Second, our model has the potential to greatly reduce mortality and the related economic burden due to acute myocardial infarction. Untimely diagnosis or treatment results in increased myocardial damage and mortality. The extent of myocardial salvage is greatest if patients are reperfused in the first 3 hours after onset of symptoms [28]. For every 30-minute delay in coronary reperfusion, the relative 1-year mortality rate

increases by 7.5% [29]. Our model can reduce mortality due to acute myocardial infarction by facilitating timely diagnosis and reperfusion. Consequently, the economic cost caused by lost productivity from premature mortality due to acute myocardial infarction, which is estimated to be US $40.5 billion annually in the United States, can also be reduced [30]. Third, since our study indicates the feasibility of multiple lead-based AI-enabled ECG algorithms on smartwatches, it can promote the development of AI models with asynchronous ECG signals for detecting cardiac disorders other than acute myocardial infarction, thus accelerating market growth in this field.

Strengths and Limitations

Our study has several strengths. First, our model only takes ECG as input and does not require other additional clinical data. This implies that our model is highly applicable in real-world, real-time settings where no medical practitioners are available. Smartwatches are the only requirement for applying our model. Second, our model is theoretically implementable with all smartwatches, which further strengthens our study in terms of real-world applicability. That is, creating a mobile software app that activates the ECG hardware, instructs the wearer on how to measure the leads, preprocesses the measured leads to satisfy the input conditions of our AI model (eg, resampling the ECG to 250 Hz, snipping 2.5 seconds from each lead), and runs our AI model, would be sufficient for real-world implementation. We believe that with the aid of mobile app developers, such an app would not be technically difficult to develop. We leave this as a subject for further study. Third, we did not exclude ECGs on the basis of waveform abnormalities. This implies that our model is applicable regardless of ECG abnormalities, thereby greatly enhancing the generalizability to real-world settings. Fourth, our model was trained, validated, and tested with a very large data set of 172,920 ECGs recorded from 95,938 patients. A large enough data set can reduce overfitting to the training set, thus increasing generalizability to other data sets [31,32]. Fifth, as mentioned in the Methods section, our model is applicable to any lead combinations (eg, various 4-, 3-, 2-, and single-lead sets). This is because we randomly masked each lead channel on the attention matrices during the training phase. Thus, users would be able to choose any lead combination in accordance with their preferences or situation.

However, our study also has some limitations. First, our labeling method might be problematic. The diagnosis of acute myocardial infarction does not ensure that the patient's initial ECG in the emergency room would show explicit signs of acute myocardial infarction. Thus, some ECGs labeled as acute myocardial infarction in our data set might not explicitly show signs of acute myocardial infarction. Nevertheless, our model showed high performance, with our 12-lead set having an AUROC of 0.880. Second, the 12-lead set is not completely asynchronous. When grouped into 4 subsets with 3 leads in each subset, the ECGs are asynchronous intersubset-wise, while being synchronous intrasubset-wise. Thus, the maximum number of leads that can compose a completely asynchronous lead set in our study was 4. The diagnostic capacity of a model tested with 5 or more completely asynchronous lead sets needs to be evaluated in future studies. Third, our model cannot be deemed as a confirmatory test. The final confirmatory diagnosis should be made by a trained physician after the patient arrives in hospital. However, with the preliminary diagnosis made by our model, patients can be efficiently triaged to get the most appropriate form of treatment after accounting for geographical factors and available facilities, even before contact with emergency services. Finally, our model was not validated with external data sets. In future studies, external validation should be performed to ensure the reliability of our model in new environments.

Conclusions

In conclusion, this study shows the feasibility of multiple lead-based AI-enabled ECG algorithms on smartwatches for the automated diagnosis of cardiac disorders by developing an AI model for detecting acute myocardial infarction with asynchronous ECG signals. We also showed that measuring at least 3 leads, and ideally more than 4 leads, is necessary for accurate detection. Our results show that single-lead sets lack diagnostic performance. From our results, we look forward to the development of other AI models that detect various cardiac disorders using sequentially measured, asynchronous ECG leads from smartwatches. Such models, along with our model, can facilitate timely diagnostics to enhance outcomes and reduce mortality among various cardiac disease populations outside the hospital.

Abstract

Background: A rise in the recent trend of self-managing health using consumer health technologies highlights the importance of efficient and successful consumer health technology trials. Trials are particularly essential to support large-scale implementations of consumer health technologies, such as smartphone-supported home tests. However, trials are generally fraught with challenges, such as inadequate enrollment, lack of fidelity to interventions, and high dropout rates. Understanding the reasons underlying individuals' participation in trials can inform the design and execution of future trials of smartphone-supported home tests.

Objective: This study aims to identify the enablers of potential participants' trial engagement for clinical trials of smartphone-supported home tests. We use influenza home testing as our instantiation of a consumer health technology subject to trial to investigate the dispositional and situational enablers that influenced trial engagement.

Methods: We conducted semistructured interviews with 31 trial participants using purposive sampling to facilitate demographic diversity. The interviews included a discussion of participants' personal characteristics and external factors that enabled their trial engagement with a smartphone-supported home test for influenza. We performed both deductive and inductive thematic analyses to analyze the interview transcripts and identify enabler themes.

Results: Our thematic analyses revealed a structure of dispositional and situational enablers that enhanced trial engagement. Situationally, clinical affiliation, personal advice, promotional recruitment strategies, financial incentives, and insurance status influenced trial engagement. In addition, digital health literacy, motivation to advance medical research, personal innovativeness, altruism, curiosity, positive attitude, and potential to minimize doctors' visits were identified as the dispositional enablers for trial engagement in our study.

Conclusions: We organized the identified themes for dispositional and situational enablers of trial engagement with a smartphone-supported home test into a research framework that can guide future research as well as the trial design and execution of smartphone-supported home tests. We suggest several trial design and engagement strategies to enhance the financial and scientific viability of these trials that pave the way for advancements in patient care. Furthermore, our study also offers practical strategies to trial organizers to enhance participants' enrollment and engagement in clinical trials of these home tests.

Introduction

Background

Consumer health care technologies (CHTs) that could potentially transform the health care industry require proper assessment and evaluation before large-scale use. In 2013, the US Food and Drug Administration (FDA) issued guidelines named *Mobile Medical Applications Guidance for Industry and Food and Drug Administration Staff* to regulate a rapidly growing number of mobile consumer health apps [1]. Furthermore, the FDA defined *mobile medical applications* as medical devices that are mobile apps or as an accessory to regulated medical devices that require FDA approval [1]. Personal health information is increasingly intertwined with clinical applications. In addition, CHTs are increasingly being looked at as a means to support the effective execution of home-based medical diagnostic tests [2-4] and medical procedure preparation kits (eg, colonoscopy preparation) [5]. As a result, an increasing number of CHTs will require assessment and evaluation (eg, clinical and premarket trials). Premarket trials are often an integral part of health care product development, even when regulatory assessments are not formally required. Developers and vendors may seek to pretest CHTs with target users for usability, feasibility, and economic viability [6]. Specifically, they provide ways to evaluate the CHT's impact on health outcomes and assess efficacy and safety before releasing it to the general population [7]. Trials can also provide opportunities for refinements to improve CHTs before their availability for commercial use [8]. Overall, trial engagement involving CHT is an interesting user behavior that deserves more attention in research to facilitate the assessment of health care innovations for the suitability for general use.

We define a potential trial participant as someone willing to try the technology before it becomes available for public and wider-scale use. Trial engagement refers to a potential trial participant successfully completing a trial. Research generally reports inadequate trial engagement as a significant challenge to CHT trial success [9]. For example, potential trial participants may perceive trial participation as a risky activity and may not be willing to enroll [10]. In addition, potential trial participants may determine that incentives or compensation are inadequate compared with their perceived risk of participating in the trial [11]. Even after enrollment, the participants' lack of engagement in trial activities and high dropout rates can impede trial success [12]. In the context of CHT, studies show that inadequate enrollment and engagement can be very costly for CHT manufacturers and researchers involved [13-15]. By and large, trial engagement is crucial for determining the validity, feasibility, and success of CHT clinical trials [16-18].

Unfortunately, there is a lack of research to provide guidance regarding people's perceptions and attitudes toward engaging in CHT trials. Current research that addresses engagement in clinical trials focuses primarily on evaluating attitudes toward traditional in-person trials of pharmaceutical interventions such as pharmaceutical trials [19] and randomized control trials for interventions and care processes related to serious health conditions such as cancer [20-22], cardiovascular disease [23,24], and lung disease [25].

Indeed, there is a shortage of behavioral research related to trials that evaluate engagement in CHT trials involved in the clinical or self-care process [26]. Within the realm of CHT, health apps offer tools, procedures, and communications to support mobile health care practices [27,28]. Moreover, very few studies in the medical informatics literature have explored clinical trials involving health apps [29], and few of the existing studies aim to identify enablers for health apps. Consumer perceptions or beliefs about the trial attributes that influence clinical trial engagement are known as enablers [30]. One notable exception in the medical informatics literature includes a 2-pronged research study, which proposed a recruitment framework for eHealth clinical trials using cost-effective and time-efficient trial recruitment strategies [18,31]. However, the study did not consider the attitudes of potential trial participants toward the trial. Another notable exception is a study that examined the perceptions and experiences of women engaging in a digital technology–based clinical trial in the context of physical activity interventions [32]. The study identified critical factors that enabled participants' continued engagement in physical activity after the trial period but did not investigate the enabling factors for their trial participation. In a different study context, Cohen et al [33] tried to understand patient compliance during 2 digital trials involving 2 pathologies, Parkinson disease and Huntington disease, each lasting 6 months. The study measured patient compliance metrics, namely, daily app-based medication reporting during the 6-month trials; however, it did not attempt to understand the factors that enabled participants' trial engagement.

Identifying engagement enablers can inform future trial design and execution, thereby enhancing the scientific and financial feasibility of CHT trials. Among the increasing technological capabilities associated with CHT innovation is using a smartphone to support home-based diagnostic tests, referred to as smartphone-supported home tests (Smart-HT). This study focuses on trial engagement in the context of CHT used for home-based diagnostics or Smart-HT (ie, diagnostic tests that a user can carry out with the support of a smartphone) [34-37]. Smart-HT usually requires FDA approval and has growing market potential and patient interest. Smart-HT comprises a diagnostic testing kit and a software component (eg, a mobile app providing one or more of the following features: instructions, education about the test or health situation, an indication of results, and results messaging). The user is required to simultaneously perform the necessary physical procedures to complete the test and understand the software component to use Smart-HT to achieve the desired outcome—diagnosis and enablement for the next steps in care.

The growing interest in at-home diagnostics, combined with their potential implications for future pandemic preparedness, merits the focused study of Smart-HT. The at-home diagnostic market is predicted to value >US $6 billion by the end of 2027; the market is anticipated to have a compound annual growth rate of 3.98% during the forecast period of 2020 and 2027 [38]. A recent survey (the 2018 Deloitte Center for Health Solutions) indicated that most people are interested in engaging with new care channels, such as at-home diagnostic testing. Overall, 51% of respondents reported being comfortable using at-home tests

for their current health concerns and identifying potential future health issues. Furthermore, 44% of respondents reported being comfortable using mobile apps connected to at-home diagnostic tests to track and monitor their health trends [39].

Objective

The purpose of this study is to identify the enablers of potential participants' trial engagement in clinical trials of CHT, in particular, Smart-HT trials. We use flu@home, a Smart-HT in trial that comprises a test kit and a mobile app to facilitate home-based testing for the diagnosis of influenza, as our instantiation of CHT to address the following research question: What enablers influence trial engagement for Smart-HT?

The paper is structured as follows. First, we discuss the Smart-HT context of the study (flu@home pilot) used to inform the enablers of Smart-HT trial engagement. We provide details on the interview phase of the pilot, where qualitative data were collected and analyzed to inform the results of this study. Second, we present our results in the form of a Smart-HT trial engagement research framework based on our evidence and provide a discussion of the identified enablers for Smart-HT trial engagement. Finally, we discuss the implications of this study for trial organizers and researchers.

Methods

Smart-HT Context: flu@home

This study leverages the context of influenza (or *flu*) using an instantiation of Smart-HT called flu@home, which has the potential to allow individuals to self-diagnose influenza. Influenza, a contagious respiratory infection caused by influenza viruses, is a serious global health threat with an estimated 1 billion cases each year, of which 18% of people die worldwide [40]. Influenza imposes a substantial economic burden, including health care costs and productivity losses, accounting for US $87 billion in the United States alone [41]. Infectious diseases, including influenza, call attention to the need for speedy diagnosis and patient treatment or isolation [3]. In addition, the drugs available for treating influenza are most effective when used within 48 hours of identifying symptoms [42]. Smart-HT offers an expedient and effective way of diagnosing influenza at home without exposing others to the virus (eg, at a physicians's office).

The Smart-HT in this study, flu@home, comprises two components: a test kit (adapted from the Quidel QuickVue Influenza A+B test) and a mobile app to facilitate testing (Figure 1). The at-home rapid diagnostic testing kit includes materials for an individual to self-test for influenza using a low nasal swab. The testing involves taking a sample from inside one's nose and processing it using a lateral flow assay (Quidel Corporation). The mobile app was available for participants to download on the iOS platform for use on smartphones and tablets. Multimedia Appendix 1 contains detailed information about the technical details associated with the flu@home mobile app.

The flu@home pilot study included two phases: the comparative accuracy phase and the interview phase (Figure 2). The study design was approved by the University of Washington institutional review board STUDY00007627.

Figure 1. Screenshots of flu@home app.

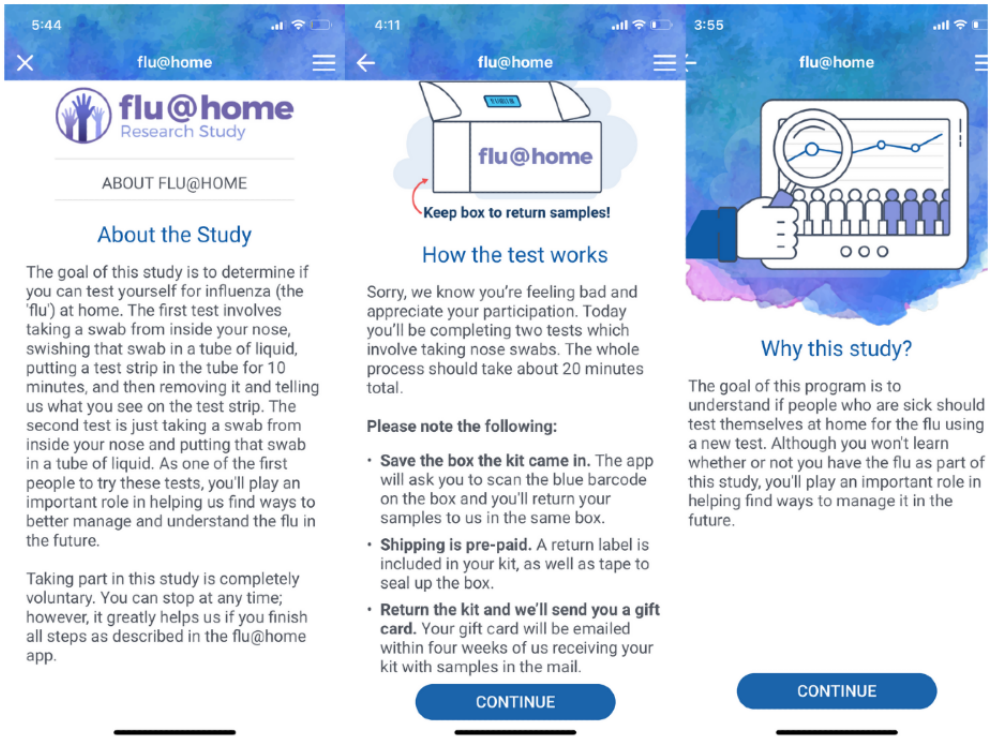

Figure 2. Phases of flu@home pilot study.

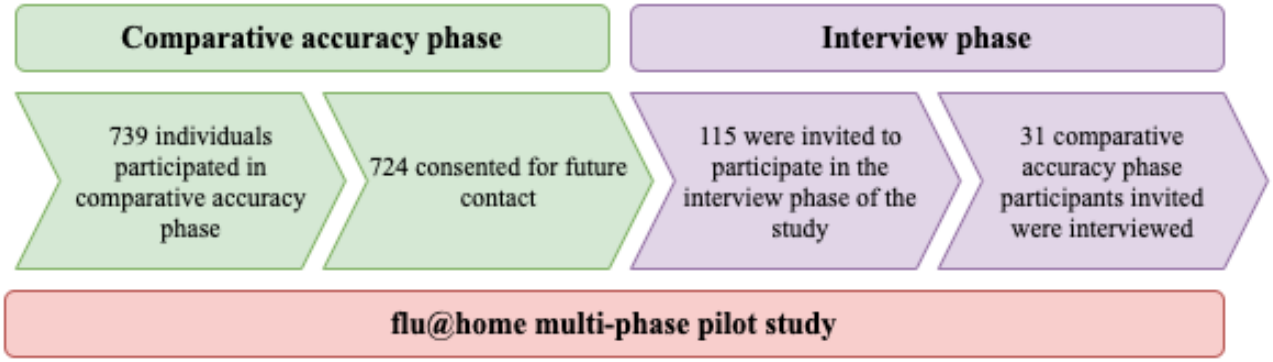

During the comparative accuracy phase, participants engaged with flu@home. The inclusion criteria for the comparative accuracy phase of the flu@home pilot study involved eligible participants who were aged ≥18 years, spoke English, had an iPhone or iPad, and had an influenza-like illness, defined as the presence of a cough and at least one or more of the following symptoms: fever, chills or sweats, muscle or body aches, or feeling tired or more tired than usual. Two videos were provided to participants as part of this study: one for recruitment purposes (study overview) and the other for providing step-by-step instructions to engage in the trial (Multimedia Appendices 2 and 3 contain the videos). Trial participants (N=739) completed the following workflow: (1) downloaded the flu@home app to enroll in the trial and order a test kit, (2) completed the consent form and a survey about their symptoms and exposure risk, (3) received a test kit by mail and followed the app instructions to conduct the rapid diagnostic test, and (4) shipped a second nasal swab sample to the research laboratory for reference standard testing. Of the 739 individuals who participated in the comparative accuracy phase of the flu@home trial, 97.9% (724/739) trial participants consented to be contacted for further phases of research.

During the interview phase, we conducted semistructured interviews with a sample of individuals who completed the comparative accuracy phase. We used phenomenology to guide this phase to construct a rich understanding of participants' experiences with flu@home and identify the enablers of Smart-HT trial engagement [43]. Phenomenology, described as the science of phenomena, explores human experience to elicit meanings for individuals through the analysis of their experiences and perceptions [44]. In line with this paradigm, we conducted in-depth interviews that covered experiences and perception questions related to (1) personal characteristics that enabled participants to complete flu@home trials; (2) attitudes toward health and medical research; (3) perceptions toward flu@home, mobile apps, and the overall trial; and (4) factors that enabled their Smart-HT trial engagement.

To fulfill the purposes of this study, we reported results from the interview phase related to understanding the enablers of potential participants' Smart-HT trial engagement. In the following sections, we further describe the data collection and data analysis procedures pertinent to the interview phase.

Data Collection

To meet the eligibility (inclusion) criteria for the interviews, individuals must have participated in the comparative accuracy phase of the pilot and consented in the flu@home app to be contacted for future study efforts. However, participation in the interview phase was not dependent on individuals completing the final steps in the flu@home workflow (ie, it is possible that some participants never mailed their sample to the laboratory; however, they would still be eligible if they opted in for future contact in the app). The flu@home test results were deidentified, so we were unable to determine how many eligible participants may not have performed the final step of mailing back their test results for analysis.

We consulted the literature to determine the total number of participants for the interviews. Data saturation, the point at which additional data collection no longer generates a new understanding [45], is the most common guiding principle for determining the total number of participants in qualitative research [46]. Prior interview study designs reached saturation in as few as 10-40 interviews [47-52]. In considering precedence and study design, we determined a minimum of 20 trial participants to be an adequate and appropriate target number of interviews.

Participants were invited to participate in the interviews via email and offered a US $25 gift card for completing the interview. To ensure diversity in the interviewee sample, we recruited participants in three waves. We followed purposive sampling to maintain diversity in the representation of trial participants in terms of age, race, and geographic location. First, we sorted the trial participants into age groups (18-24 years, 25-34 years, 35-44 years, 45-64 years, and ≥65 years) and randomly selected participants from each age group to send interview invitations. In the two subsequent waves of recruitment, we adjusted the proportion of participants recruited from each age group to ensure sample representation from all age groups. Attempts to fulfill purposeful sampling resulted in 115 invitations to participate and 31 actual interviews. Table 1 details the demographics of the trial participants who were invited and interviewed for the study.

Table 1. Demographics of interview participants in the study.

Characteristics	Invited to participate in study	Completed the interview
Total, n (%)	115 (100)	31 (100)
Age (years), n (%)		
18-24	12 (10.4)	3 (10)
25-34	34 (29.6)	6 (19)
35-44	38 (33)	11 (36)
45-64	21 (18.3)	8 (26)
≥65	10 (8.7)	3 (10)
Ethnicity, n (%)		
White individuals	78 (67.8)	21 (68)
Black or African American	10 (8.7)	6 (19)
Asian	8 (7)	0 (0)
Native Hawaiian or Other Pacific Islander	1 (0.9)	1 (3)
American Indian or Alaska Native	16 (13.9)	1 (3)
N/A[a], other, or prefer not to say	2 (1.7)	2 (6)
Geographic representation, n (%)		
West	43 (37.4)	14 (45)
Midwest	21 (18.3)	5 (16)

Northeast	32 (27.8)	4 (13)
Southeast	17 (14.8)	7 (23)

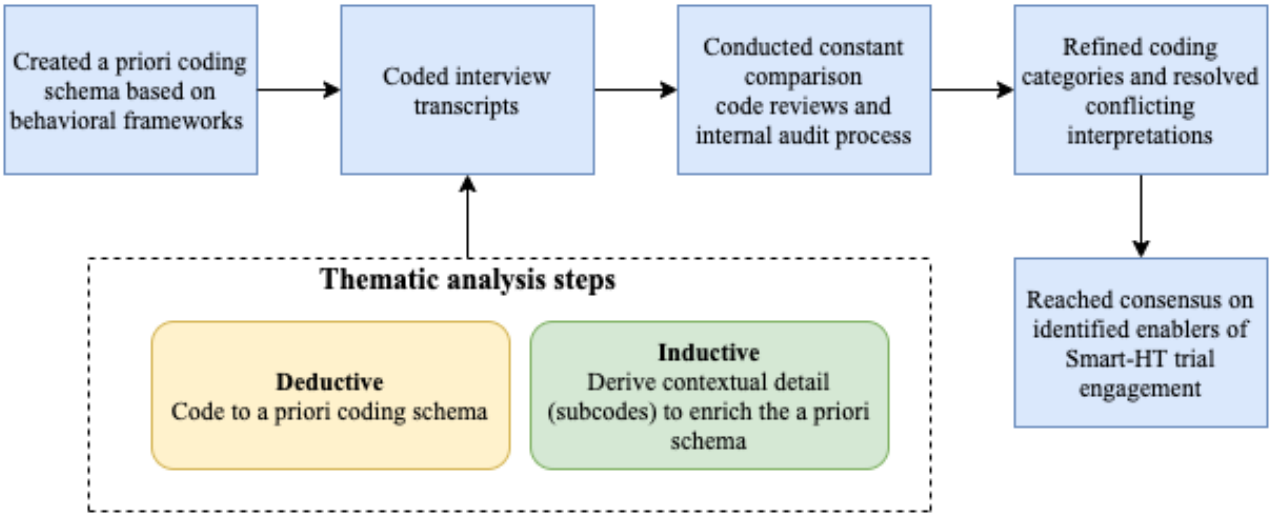
[a]N/A: not applicable.

Semistructured interviews were conducted via the web-based video conferencing tool Zoom from August 12, 2019, to December 19, 2019. Zoom has been an effective means of data collection in various health-related studies [53]. Participants had the option of being on or off camera. Each interview lasted between 40 and 60 minutes. Of the 3 research team members (in a rotating fashion), 2 were present during the interviews, providing direct experience with the actual interviews to the 3 team members subsequently engaged in the analysis process. Of the 2 team members participating in the interview, 1 served as the lead interviewer, whereas the other served the role of *active listener* and notetaker. The *active listener* was invited to ask any follow-up questions needed for clarification during the interview. The 3 team members alternated in serving the primary interviewer and listener roles for each interview. The 2 team members participating in the interview debriefed immediately after each interview to review highlights relevant to the study, establishing early key points to consider for coding purposes. Interviews were recorded and transcribed, and all personal identifiers were removed before analysis. We uploaded deidentified interview transcripts to Dedoose version 7.0.23, a software for qualitative data analysis.

Data Analysis

We conducted a thematic analysis [54] to code the deidentified transcripts. Thematic analysis is defined as a method for identifying, analyzing, organizing, describing, and reporting themes within a data set [55]. To ensure the validity and reliability of the thematic analysis results, we followed the Lincoln and Guba [50] criteria for conducting qualitative research. Specifically, we established confirmability, dependability, and credibility through procedures such as researcher triangulation, code reviews, expert feedback, and resolution meetings [50,56]. We took a hybrid approach to thematic analysis by including both deductive and inductive coding [57]. Figure 3 illustrates this process.

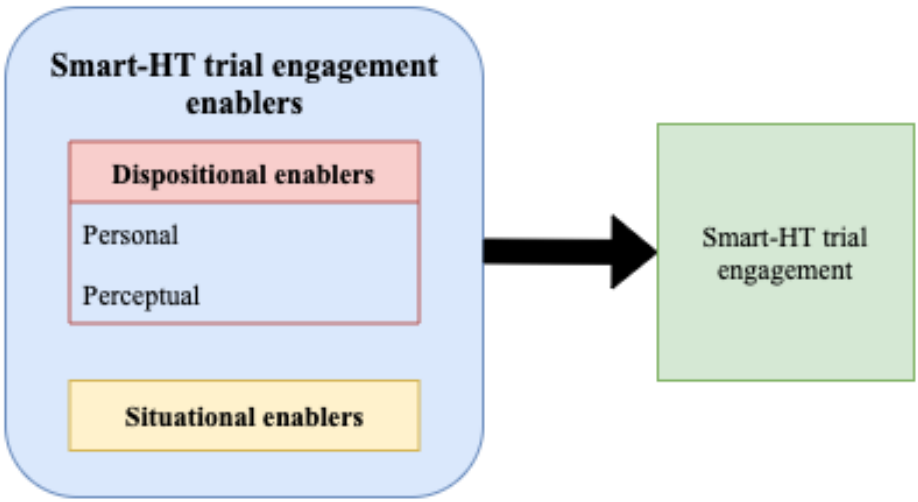
Figure 3. The qualitative thematic analysis process that guided the deductive and inductive coding of the interview transcripts. Smart-HT: smartphone-supported home tests.



We developed the a priori coding schema based on widely used behavioral frameworks that explain an individual's behaviors and actions [58-61] and categorized the factors into dispositional and situational enablers. Specifically, we relied on attribution theory, the digital health engagement model proposed by O'Connor et al [61], and the technology acceptance model [60] to identify generalized enabler constructs that align with our context to include in our a priori coding schema. On the basis of this foundation, our resulting a priori coding schema recognized the possibility of personal, perceptional, and situational factors. Situational enablers referred to external events or environmental factors that contributed to participants' Smart-HT trial engagement [58,59]. Personal enablers related to an individual's abilities, traits, and beliefs, whereas perceptional enablers referred to their perceptions that enabled their Smart-HT trial engagement. To further refine our schema and acknowledge relationships in existing research, we decided to group the personal and perceptional enablers we find in the data as *dispositional*.

Dispositional enablers referred to trial participants' behaviors and perceptions, whereas situational enablers were independent of participants' behavior. We used the skeletal a priori coding schema (Figure 4) as a starting point for the thematic analysis. Using the schema facilitated an initial, agreed-upon conceptual basis for the research team to begin analysis and then determine the operational definitions for each identified variable based on the schema [62,63].

Figure 4. A priori coding schema for thematic analysis. Smart-HT: smartphone-supported home tests.



We started our thematic analysis with a deductive approach [57]. During this analysis step, 2 of our team members independently coded the interview transcripts using the a priori coding schema (Figure 4). We were also open to additional high-level constructs emerging from our study that would extend the a priori schema. To capture key content within each a priori theme (ie, parent code), we extended and enriched the a priori schema codes (ie, parent codes) with inductively identified subcodes (ie, child codes). Explicitly, as we encountered new content during the coding process, we updated our coding schema with additional subcodes to further define the general themes in the a priori schema to the Smart-HT context. These practices further defined and specified associated constructs in

the a priori coding schema and continued until thematic saturation of the Smart-HT trial enablers was reached.

We used the constant comparison method of analysis [63,64] to refine and triangulate the coding. The constant comparison procedure included 2 coders and an internal auditor serving. A research team member with >17 years of qualitative research methods expertise, familiar with the study constructs and context but not engaged in the detailed coding process, served as our internal auditor to ensure expertise, understanding, and independence from the specific assignment of quotes to codes and initial code labels. The team held recurring meetings to compare initial coding determinations to ensure agreement on high-level codes and ratify the addition of subcodes (child codes) supporting the constructs in the initial coding schema. The team also refined the code labeling (names of codes) as needed to ensure understandable terms and themes. The ratification of subcodes included a general review of supporting quotes to support discussion points.

Although various studies finalize coding on this consensus [65], we chose to extend our rigor to support our findings further. Specifically, as a final step, our internal auditor also reviewed the holistic structure, labeling, and syntax of the final reconciled schema and performed a code review of 100% of the coded quotes to ensure alignment with the final coding structure. Any identified issues were brought back to the collective team for final disposition. As noted in prior literature, a feedback process, such as this internal audit process, can serve as a crucial *reader resonation* strategy to further enhance the validity of qualitative findings [66].

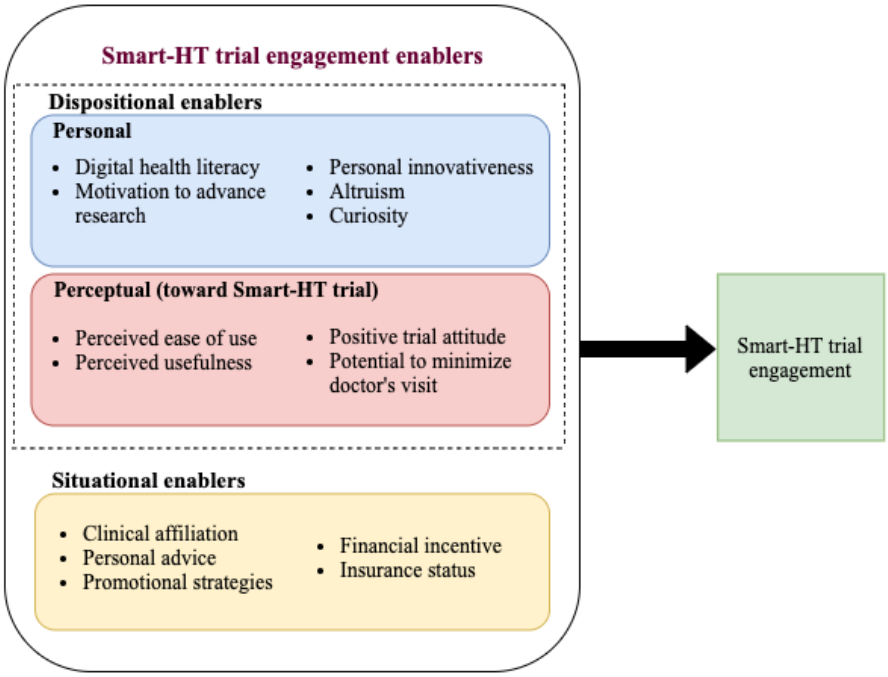
There were no noted major conceptual differences in the constant comparison and final internal review process. Reconciliation and arbitration were primarily focused on combining some subcodes or refining the labels and definitions of added codes. In particular, the team sought to refine the labels, where appropriate, to terms used in generally related research. In completing the process, there were no exceptions to reaching consensus, and, thus, code reviews and resolution meetings established the confirmability and dependability of the findings. We present our results as a research framework for enablers of Smart-HT trial engagement in the following section.

Results

Overview of Results

We synthesized our results into a research framework (Figure 5) that presents pertinent dispositional and situational enablers for Smart-HT trial engagement. This section details our thematic analysis findings under each of the broader enabler themes (dispositional and situational). We include evidence trace tables providing a representative participant quote to demonstrate the study's identified themes, as found in the data in Multimedia Appendix 4. Tables S1, S2, and S3 provided in Multimedia Appendix 4 present the evidence trace table for personal enablers and perceptional and situational enablers, respectively. The research team collectively selected the quotes from the multiple options coded as both a good conceptual fit and easy for the reader to understand outside of providing extensive interview text and context.

Figure 5. Evidence-based smartphone-supported home tests trial engagement research framework. Smart-HT: smartphone-supported home tests.



Dispositional Enablers

Our results supported characterizing dispositional enablers into personal and perceptional.

Personal Enablers

Our results identified the following personal enablers for Smart-HT trial engagement: digital health literacy, motivation to advance medical research, innovativeness, curiosity, and

altruism. Table S1 in Multimedia Appendix 4 presents the evidence trace table for personal enablers identified in the study.

In general, the interviewees in this study were digital health literate. Interviewees commonly expressed their ability to seek, find, understand, and apply health information from a wide range of web-based sources such as Google, health care websites, and WebMD, among others. Moreover, some interviewees even noted their familiarity with using wearables (eg, Apple Watch) and telemedicine for taking care of their health, which evidenced their adequate degree of *digital health literacy.*

Our inductive thematic analysis emphasized *motivation to advance medical research* as a prominent enabling factor in trial engagement for Smart-HT. The data revealed that participants hoped that their feedback after the flu@home trial might benefit vaccine development in the future. An interviewee explained that offering feedback and data that further medical research is vital for the greater good.

Remarkably, nearly all the interview participants acknowledged that they were *inherently innovative*. Their perception of Smart-HT as an innovative and transformative technology seemingly encouraged them to engage in the trial. Our analysis further identified *curiosity* in a relatively new technology (ie, a Smart-HT) as a personal enabler for individuals to engage in the trial. In addition to being curious about the trial and technology, interviewees indicated how their *altruistic notions* encouraged them to participate in the trial.

Perceptual Enablers (Toward Smart-HT Trial)

Our analysis revealed the importance of trial participants' perceptions of Smart-HT in their trial engagement for Smart-HT. The perceptual enablers identified in the study (Table S2 in Multimedia Appendix 4) include ease of use, usefulness, positive attitude, and potential to minimize physician visits.

The interviewees perceived the overall Smart-HT trial to be easy to follow and self-explanatory. For example, many described their use of nasal swabs to self-test for influenza as an *easy process.* Participants also stressed how the test kit packaging with vials to hold to swabs made the whole Smart-HT trial engagement process simpler. Interviewees also commented on the mobile app's interface that guided them with the instructions required to complete the trial as not complicated and that it served the intended purpose.

In addition, *the perceived usefulness* of the Smart-HT and the value of their participation in advancing research seemed to have encouraged interviewees' Smart-HT trial engagement. Interviewees perceived their trial engagement with flu@home as a *useful* exercise contributing to public health management in enhancing the Smart-HT functionalities for large-scale commercial use. Participants also indicated that flu@home was *useful* in reducing the spread of disease in the future.

Overall, the interviewees cited a *positive attitude* toward home-based testing and their trial engagement for the Smart-HT (*positive trial attitude*). Many expressed optimism toward Smart-HT and found it to be a promising and innovative technology with potential uses. Excitement at being offered to be a part of the Smart-HT trial was also a common theme among the interviews. Several interviewees reported their interest in engaging in a trial for a promising Smart-HT that could minimize traditional physician's visits for illness diagnosis. In addition, most interviewees explained how getting a physician's appointment when most needed could be a hassle that they would readily forego for a Smart-HT.

Situational Enablers

Situational enablers referred to external events or environmental features that enabled trial engagement for the Smart-HT. Our analysis revealed clinical affiliation, personal advice, promotion strategies, financial incentives, and insurance status as situational enablers for Smart-HT trial engagement. We present a representative quote for each of the situational enablers identified in this study (Table S3 in Multimedia Appendix 4).

Clinical affiliations of the health care entities associated with the trial prominently influenced interviewees' willingness to engage in the Smart-HT trial. Several interviewees explained that the reputable institutions associated with flu@home's development and the trial execution enhanced their perceived trust in the trial, which resulted in their trial engagement.

Furthermore, interviewees expressed their propensity to trust *personal advice* or recommendations from friends and family members to participate in these Smart-HT trials. A few interviewees shared details about who recommended them to the Smart-HT study. The list of personal recommenders identified included friends, spouses, and family members.

Considering the voluntary nature of trial participation, we identified the salience of effective *promotion and recruitment strategies* in enabling individuals' engagement in the Smart-HT trial. Interviewees detailed how they found out about the Smart-HT study on the web and described how web-based advertising could be a helpful recruitment mode. In addition, the interviewees offered meaningful insights into preferred future web-based recruitment and promotion strategies. From our analysis, social media emerged as a popular recruitment pathway to achieve the desired trial participation. The data also included references to a web-based forum or an email list where people could volunteer for these trials.

The *financial incentive* that was offered in the form of a gift card provided by the research study at completion notably incentivized and compensated the participants to engage in the Smart-HT trial. An interviewee also emphasized how *lack of insurance* coupled with symptoms and incentives encouraged Smart-HT trial engagement.

Discussion

Overview

In this qualitative study, we explored the enablers of trial engagement with a home-based diagnostic supported by a CHT, referred to as Smart-HT. We identified dispositional and situational enablers of Smart-HT trial engagement that can inform future Smart-HT trial design and execution. In the following sections, we discuss these enablers, along with recommendations for trial organizers and researchers.

In reviewing the following discussion of enablers, it is worth considering that many CHTs in various health care contexts involve a software component and are rooted in a traditional health care service offering. Additional forms of CHTs may elicit similar trial engagement responses as those who responded to the Smart-HT context. Therefore, it is plausible that the identified Smart-HT dispositional and situational enablers we discuss may apply to a majority of CHT trials, in general, and merit testing in other CHT contexts.

Dispositional Enablers

Personal Enablers

With clinical trials facing challenges in the form of low retention and high dropout rates of trial participants, our results point to the need for increased attention on personal enablers in future Smart-HT trial recruitment efforts. In alignment with prior studies on digital health technologies [67,68], individuals with digital health literacy (eg, prior experience with digital health tools) generally tended to have a positive experience with Smart-HT. In our study, individuals generally reported to be digitally health literate and did not encounter any major issues during the Smart-HT trial. Experience with accessing health care on the web seemed to have enabled participants to engage with Smart-HT in the trial. Digital health literacy of potential trial participants could inform their Smart-HT trial engagement behaviors. Therefore, as part of the participant recruitment efforts, trial organizers may want to develop screening criteria to recruit individuals with proficient digital health literacy among the target appropriate populations. To reach those with no relevant digital health tool experience, we suggest that the trial organizers offer appropriate training and general promotion concerning Smart-HT use to enhance Smart-HT trial engagement.

Smart-HT trial engagement was also enabled by the trial participants' willingness to play a role in advancing medical research. These results are in line with a survey conducted on public perceptions in the United States toward clinical trials in which 86% of the sample noted that they would participate in clinical trials for advancing scientific research [69]. In the future, researchers should make use of appropriate advertising channels to communicate the potential value of the Smart-HT trial in advancing medical research to prospective trial participants. An increase in the perceived value of the trial might further motivate prospective participants' Smart-HT trial engagement intentions.

Personal attributes, such as inherent innovativeness, curiosity, and altruistic notions, enabled participants' Smart-HT trial engagement. These findings offer practical implications for Smart-HT trial designers and trial organizing entities, as they inform successful trial participant recruitment in future trials. For instance, researchers in future trials could extend a short survey as part of the screening criteria to measure personal innovativeness [70] and curiosity [71] as part of the Smart-HT trial recruitment processes. Potential trial participants who are relatively more innovative and curious about the Smart-HT (in the trial) could then be screened, thereby enhancing the Smart-HT trial engagement and success. We also propound that future trial designers could highlight their choice of individuals who explore and are curious about new technologies in their recruitment campaigns. For instance, clear recruitment messages such as "Do you want to try a new and transformational healthcare technology?" and "Are you interested in contributing to your community" could further encourage potential trial participants' Smart-HT trial engagement.

Perceptual Enablers (Toward Smart-HT Trial)

The successful design of the accompanying mobile app enabled the overall success of the Smart-HT trial. The mobile app instructions were perceived to be self-explanatory and easy to use and enabled the participants' Smart-HT trial engagement**.** Easily understood and navigable mobile app interfaces with clear and step-by-step instructions (which in this case included videos) are critical to ensuring that trial participants complete the trial successfully and do not withdraw from the study because of frustration with the test procedures or technology. This finding further strengthens this study's contribution as it points to the potential of Smart-HT. Namely, the addition of a technology component to a trial or even an existing home diagnostic test to comprise a Smart-HT has the potential to alleviate some of the concerns of errors or process misunderstanding surrounding home diagnostic self-testing in the absence of clinical supervision. The addition of technology to facilitate procedural success can further inform future trials. Future researchers could examine whether trials involving tests and home-based preparation procedures (eg, blood test) combined with the easy-to-use app would have better trial engagement outcomes than trials involving diagnostic tests accompanied by no apps or complicated apps.

Our findings suggest a few considerations regarding the specific design of apps to support trial procedures. First, trial mobile app developers could ensure that the trial's aims and objectives are adequately communicated through the app pages to enhance the Smart-HT trial engagement. Second, the app should contain a frequently asked questions section that addresses the common concerns or risks surrounding the trial. Third, the app should provide an option to call a research coordinator to answer any questions that may arise during the trial. Fourth, interactive videos demonstrating the step-by-step study procedures (eg, nasal swab process) may stimulate and inspire potential trial participants to engage. All these design elements may reduce trial drop-off.

In line with our findings, prior research on the trialability of new technologies has shown that a positive attitude [72,73] toward the technology can ease concerns surrounding a trial of relatively new technology like Smart-HT. Removing this concern eliminates a barrier to motivating individuals to engage with Smart-HT. Furthermore, Smart-HT trial engagement was perceived to contribute to public health management in our study. These findings have significant implications for trial organizers and mobile app developers who could highlight how a specific trial could advance and benefit public health in addition to advancing medical research. Consequently, educating potential trial participants about positive trial consequences may manifest in a positive attitude toward the Smart-HT and the overall trial, encouraging the Smart-HT trial engagement.

Another interesting perceptional enabler theme that emerged from our analysis was the perceived potential of the Smart-HT

to minimize a physician's visit. Smart-HT offers a fundamental change from traditional health care encounters for diagnostic testing. The potential role of Smart-HT in reducing the need to seek face-to-face appointments encouraged the interviewees to engage in the trial. Therefore, Smart-HT trial engagement may be enhanced if potential trial participants are convinced that the Smart-HT is transformational and offers solutions to the existing problems they face in the health care system (eg, access to testing and getting physician's appointments). Researchers in future trials should inform potential trial participants about the possible innovations and improvements that may be solved by the Smart-HT in trial.

Situational Enablers

Awareness of the trial's clinical affiliations enabled Smart-HT trial engagement in our study. The brand reputation associated with these health care and research institutions encouraged potential participants to trust the trial as legitimate and, thus, influenced their trial engagement. These findings are in line with a survey conducted on the perceptions toward clinical trials [69]. For example, 38% of the nationwide sample cited a lack of trust in trials as one of the primary reasons for not considering clinical trial participation. In addition, 91% of the same sample said that the competence and reputation of the trial conducting institutions play an essential role in their decision to participate in a trial. These findings could potentially inform future trial designers and mobile app developers. For example, future recruitment strategies could include detailed descriptions of the trial organizing institutions' previous research breakthroughs and research quality (in terms of patents or publications) that could persuade potential trial participants to perceive the trial as legitimate and to engage in it.

Most of the trial participants heard about the Smart-HT trial in our study from social media. Our analysis affirmed that web-based advertising and recruitment strategies could be effective modes of potential participant recruitment. Web-based medical forums where potential trial participants could volunteer to engage in an advertised trial could offer a potential future mode of participant recruitment for Smart-HT trials. Sending Smart-HT trial invitations using emails to a list of potential trial participants could also enable the Smart-HT trial engagement. Therefore, Smart-HT trial organizers should dedicate significant efforts toward web-based recruitment using available channels such as web-based medical forums, email lists, health care blogs, and social media [74,75].

Personal recommendations to engage in the Smart-HT trial (in the form of referrals from friends and family) and the financial incentive offered for participating in the trial seemed to have motivated some interviewees' engagement. In the future, mobile app developers could add a functionality, allowing one to invite others to sign up for the trial through the app itself. Many interviewees affirmed financial incentives as a critical factor that influenced their Smart-HT trial engagement. Although considering the perceived criticality of financial incentives, there may be value in offering additional incentives for referring other potential participants to the Smart-HT trial. Referral promotions could solve the issues of inadequate participant enrollment and retention rates.

Some participants attributed their trial engagement for the Smart-HT to their lack of health insurance. This study highlights the opportunity to engage participants in Smart-HT clinical trials to improve their access to needed health care. We also identified practical issues for trial designers in terms of trial advertising and recruitment efforts. One of the interviewees explained how the absence of trial participation costs encouraged her to enroll in the Smart-HT trial. Therefore, emphasizing that the Smart-HT trial is free and does not require health insurance in the advertisements and recruitment messages may increase engagement. These techniques could draw the attention of potential trial participants who may assume that they are ineligible for trial as they lack health insurance. Simultaneously, we caution the Smart-HT trial organizers that it would be unethical to coerce potential trial participants to sign up for a clinical study they would otherwise be reluctant to do.

Overall, our evidence-based research framework (Figure 5) highlights the cruciality of the trial participants' personalities, beliefs, and perceptions as drivers of their Smart-HT trial engagement. Our analysis and the resulting framework may help Smart-HT researchers and trial organizers gain valuable insight into the phenomenon of trial engagement. We also encourage future research studies that extend our framework by examining the relative significance of the enablers presented using quantitative research methods.

Limitations

We focused on one example of CHT, Smart-HT, an instantiation of flu@home to identify the dispositional and situational enablers of trial engagement in our study. Although we feel that our results may carry to other CHT trial situations, we did not test other CHT contexts. Therefore, this choice may limit the generalizability of the study's findings. Specifically, trial participants for CHTs that differ from Smart-HT may elicit a different or an extended set of their trial engagement enablers. Although we expect most of the identified dispositional enablers to influence trial engagement for other CHTs and Smart-HTs, there could be additional situational enablers relevant to the functionality and context of the specific technology used. We encourage future research to investigate and enrich the framework in other contexts such as mobile health apps and Smart-HT for other health conditions and clinical trials. Our study focuses on offering an evidence-based Smart-HT trial engagement framework for Smart-HT that requires FDA approval. Future research is required to investigate the enablers for trial engagement for other health and wellness technologies that may not formally require FDA approval or undergo approval through different FDA routes for devices. The need for approval and situation influences resulting in social desirability response bias might have minimally influenced the qualitative study's findings [76]. We encourage future studies to empirically test and extend our evidence-based Smart-HT trial engagement framework using quantitative research methods such as surveys.

Conclusions

Premarket clinical trials play a crucial role in evaluating and assessing medical devices and technologies for effectiveness and safety before their approval and release to the general population. However, inadequate trial engagement remains an

issue that leads to failure in CHT trials. In the field of CHT, there is a dearth of research exploring the factors leading to CHT trial engagement. This exploratory qualitative study reports enablers of trial engagement for Smart-HT, a promising form of CHT, using an instantiation to diagnose influenza, namely, flu@home.

Our study adds to the understanding of people's perceptions toward Smart-HT trials by delineating an organized series of enablers that can impact the decision to participate in a Smart-HT trial. Clarification on these dispositional and situational enablers contributes to behavioral research associated with Smart-HT trials and can inform future Smart-HT trial design and engagement strategies. In addition, our study offers practical implications for trial organizers in the form of trial promotional and recruitment efforts. An important example is developing screening criteria to recruit innovative, curious, and altruistic individuals with proficient digital health literacy among the target population. Our study also confirms the benefit of creating relevant promotion materials that showcase Smart-HT's usefulness, ease of use, benefits, trial organizer's reputation and clinical affiliations, the trial's role in advancing medical research, and finally, Smart-HT's role in solving existing health care issues. Understanding and accounting for a series of internal and external enablers when targeting potential trial participants can address the issue of inadequate Smart-HT trial engagement, thereby leading to effective evaluation of health technologies and timely release of them to the general population.

Acknowledgments

Efforts that helped shape this paper were partly supported by the Seattle Flu Study, funded by Gates Ventures. The funder was not involved in the design of the study, nor did they have any ownership over the management and conduct of the study, the data, or the rights to publish. The content is solely the responsibility of the authors and does not necessarily represent the official views of the Seattle Flu Study investigators. We acknowledge John Tamerius and Quidel Corporation for donating the testing materials for the flu@home pilot. The authors would like to acknowledge Audere for developing the flu@home mobile app and Shawna Cooper for providing app content for this publication.

Abstract

Background: The standard of care in general wards includes periodic manual measurements, with the data entered into track-and-trigger charts, either on paper or electronically. Wearable devices may support health care staff, improve patient safety, and promote early deterioration detection in the interval between periodic measurements. However, regulatory standards for ambulatory cardiac monitors estimating heart rate (HR) and respiratory rate (RR) do not specify performance criteria during patient movement or clinical conditions in which the patient's oxygen saturation varies. Therefore, further validation is required before clinical implementation and deployment of any wearable system that provides continuous vital sign measurements.

Objective: The objective of this study is to determine the agreement between a chest-worn patch (VitalPatch) and a gold standard reference device for HR and RR measurements during movement and gradual desaturation (modeling a hypoxic episode) in a controlled environment.

Methods: After the VitalPatch and gold standard devices (Philips MX450) were applied, participants performed different movements in seven consecutive stages: at rest, sit-to-stand, tapping, rubbing, drinking, turning pages, and using a tablet. Hypoxia was then induced, and the participants' oxygen saturation gradually reduced to 80% in a controlled environment. The primary outcome measure was accuracy, defined as the mean absolute error (MAE) of the VitalPatch estimates when compared with HR and RR gold standards (3-lead electrocardiography and capnography, respectively). We defined these as clinically acceptable if the rates were within 5 beats per minute for HR and 3 respirations per minute (rpm) for RR.

Results: Complete data sets were acquired for 29 participants. In the movement phase, the HR estimates were within prespecified limits for all movements. For RR, estimates were also within the acceptable range, with the exception of the sit-to-stand and turning page movements, showing an MAE of 3.05 (95% CI 2.48-3.58) rpm and 3.45 (95% CI 2.71-4.11) rpm, respectively. For the hypoxia phase, both HR and RR estimates were within limits, with an overall MAE of 0.72 (95% CI 0.66-0.78) beats per minute and 1.89 (95% CI 1.75-2.03) rpm, respectively. There were no significant differences in the accuracy of HR and RR estimations between normoxia (≥90%), mild (89.9%-85%), and severe hypoxia (<85%).

Conclusions: The VitalPatch was highly accurate throughout both the movement and hypoxia phases of the study, except for RR estimation during the two types of movements. This study demonstrated that VitalPatch can be safely tested in clinical environments to support earlier detection of cardiorespiratory deterioration.

Introduction

Background

Failure to recognize and act on physiological indicators of deterioration in hospital wards is a well-recognized problem [1-3]. Current practice involves manual measurement of vital signs and the use of early warning scores. However, the acquisition of these measurements can be time consuming for health professionals in a busy ward [4]; therefore, the desired monitoring frequency of observations is often not achieved [5]. This is identified as a limitation of periodic monitoring systems, as they are dependent on the frequency of vital sign observations [6]; of more concern is that even when the ideal frequency is achieved, patients might deteriorate between observation sets [7]. Continuous vital sign monitoring using wearable devices may overcome these limitations and improve timely detection of deterioration [8-10]. However, recent observational studies and pilot randomized controlled trials of wearable monitoring devices were inconclusive, and large randomized clinical trials of ambulatory monitoring devices are required to demonstrate improved patient outcomes [1,8,11,12]. This may be because of limitations in currently available ambulatory monitoring devices; for instance, it has been demonstrated that the detection and reduction of noise and artifacts during movement can be challenging in this type of monitoring [13]. Therefore, there is a need for diagnostic accuracy studies addressing motion artifacts to support the development of reliable wearable devices [3,9,14,15].

The VitalPatch [16] is a wireless, battery-operated chest-worn wearable biosensor that records heart rate (HR), electrocardiography (ECG), HR variability, R-R interval (the time elapsed between two successive R-waves of the QRS signal on the electrocardiogram), respiratory rate (RR), body temperature, skin temperature, fall detection, activity (including step count), and posture (body position relative to gravity including fall detection) [17,18]. This device (Figure 1) was well tolerated by users because of its wearability and low impact on activities [19,20]. However, validation studies regarding the VitalPatch showed mixed results [3]; for HR, the mean bias was within acceptable ranges for all validation studies [14,18,21-23] and within acceptable limits of agreement (LoA) in 3 studies [18,21,22]. For RR, the mean bias was also acceptable; however, all studies reported LoA outside of the clinically acceptable range [14,18,21-23].

Figure 1. Picture of a VitalPatch device.

This work is a substudy of our virtual high dependency unit (vHDU) hypoxia study [24]. In the main protocol, our goal was to determine the specificity and sensitivity of currently available ambulatory pulse oximeters for the detection of hypoxemia. In this substudy, the aim is to assess the VitalPatch estimation accuracy during several simulated movements and in controlled hypoxic conditions against gold standard measurements, ECG for HR [25] and capnography for RR [26].

Objectives

The primary outcome is accuracy, defined as the mean absolute error (MAE) of the VitalPatch HR and RR estimation versus gold standard recording of HR (3-lead ECG) and RR (capnography) in healthy volunteers during movement and during induced hypoxia (down to peripheral oxygen saturation [SpO_2] of 80%). In line with the American National Standards Institute/Association for the Advancement of Medical Instrumentation (ANSI/AAMI) EC13:2002 standard [27], we defined the MAE of the patch estimates to be clinically acceptable if the rates are within 5 beats per minute (bpm) and 3 respirations per minute (rpm) [3,21,22,27].

Methods

This manuscript follows the Guidelines for Reporting Reliability and Agreement Studies [28].

Study Design

This was a prospective, observational, cross-sectional cohort study that validated the HR and RR of a single-lead ECG chest patch. The VitalPatch HR is computed via the detection of Q wave, R wave, and S wave complexes from a single-lead ECG waveform. The RR is derived from combined information from three sources, that is, an embedded algorithm uses a weighted average of two characteristics of the ECG signal: (1) Q-, R-, and S-wave amplitude modulation and (2) respiratory sinus arrhythmia (as both ECG-derived signals change during inspiration and expiration), and (3) changes in the accelerometer signal induced by chest movement during respiration [23,29,30]. We compared the HR and RR estimates with the *gold standard* HR derived from 3-lead ECG and RR determined from capnography measurements, respectively. The protocol for the full study has been published [24].

Participants

The screening process and inclusion and exclusion criteria are described in the study protocol [24]. Participants were recruited consecutively from the Oxford area, United Kingdom, between June 18 and August 8, 2019. The study sessions took place at the Cardiovascular Clinical Research Facility, John Radcliffe Hospital, Oxford, United Kingdom.

Device Placement

After the participants provided written informed consent, an arterial line was inserted into the participant's nondominant radial artery. The participants were then fitted with a VitalPatch in a modified lead-II configuration on the left midclavicular line over the intercostal space (as recommended by the vendor), a nonambulatory Philips MX 450 pulse oximeter (dominant arm), a 3-lead ECG (standard configuration) for acquisition of HR, and a nasal cannula for acquisition of RR, both connected to the Philips monitor. The participants were continuously monitored with these devices throughout the study session by trained health care professionals with appropriate resuscitation facilities.

Test Methods

Stage 1: Movement Phase

The participants were considered *at rest* after fitting all the devices (variable duration between participants). The participants then moved into a chair and were asked to complete a series of consecutive motion conditions: 20× sit-to-stand (STS), 2-minute tapping at 2 Hz, 2-minute rubbing at 2 Hz, 20 times drinking from a plastic cup, 50 times turning pages, and a set of predefined table activity tasks [24]. STS was considered a dynamic activity, whereas the remainder were considered *sedentary activities*.

Stage 2: Hypoxia Exposure Phase

Following the movement phase, participants were placed in a semirecumbent, supine position and wore a tight-fitting silicone facemask connected to a hypoxicator unit (Everest Summit Hypoxic Generator). During this phase, oxygen saturations from the *clinical standard* Philips monitor guided the titration of the hypoxicator by a senior anesthetist from the research team. Oxygen (7%) in nitrogen was used to further lower the fraction of inspired oxygen, if required [24]. The inhaled fraction of inspired oxygen was also monitored using an in-line gas analyzer. Participants were gradually desaturated to reach stable prespecified target SpO_2 levels of 95%, 90%, 87%, 85%, 83%, and 80%. These levels were selected to allow sufficient data points for different hypoxia levels. SpO_2 stability was subjective for each target window, that is, a senior anesthetist decided when a stable oxygen level was achieved.

Data Collection

For each participant, the following information was recorded in the case report form: age, sex, height, weight, skin type (Fitzpatrick scale [31]), baseline HR (Philips MX 450 3-lead ECG), and arterial oxygen saturation. Data from all participants were identified using a study number.

All data collection devices (wearables, tablets, laptops, and physiological monitors), and respective software, were synchronized to the same time server at the start of each study session day. Continuous HR and RR data (sampled at 0.25 Hz) from the VitalPatch were sent via Bluetooth Low Energy to an Android tablet–based data capture system, developed in-house. Once the VitalPatch is connected to the tablet, it updates its internal clock and timestamps each sample internally. The Phillips MX 450 3-lead ECG data were collected in real time on a laptop using the ixTrend version 2.1 software (ixcellence GmbH) [32]. For each step of the *movement phase* and prespecified oxygen saturation level of the *hypoxia phase*, the corresponding start and stop time stamps were recorded both in the in-house data capture software and on the respective case report forms [24].

Data Analysis

Sample Size

Our sample size calculation was based on recommendations from the International Organization for Standardization 80601-2-61:2019 (as the primary objective of the original study was the assessment of pulse oximeter accuracy). For our secondary analysis of the VitalPatch, we aimed to have approximately 30 complete patient data sets to ensure sufficient data points for analysis and validation testing using the VitalPatch and gold standard (Philips monitor) continuous data.

Statistical Analysis

To analyze the agreement between the VitalPatch and the gold standard during the movement phase, we compared 40-second median HR and RR estimates from the VitalPatch with simultaneous 40-second median HR and RR estimates from the Phillips monitor from each movement task interval (±20 seconds at the start and at the end, respectively, to accommodate for the 40-second window size). For the hypoxia phase (100% to 80% saturations), 40-second median HR and RR estimates were also sampled for both devices from the start until the end of hypoxia testing. For each window, simultaneous 40-second median SpO_2 estimates from the Philips monitor were also calculated per participant (our pulse oximetry hypoxia study suggested a negligible mean bias between the Philips SpO_2 and arterial oxygen saturation). The 40-second window was chosen as the VitalPatch outputs instantaneous HR and RR estimates every 4 seconds, which gives 10 points per median estimate; the Philips monitor outputs both at 1 Hz. Therefore, this represents the comparison of a 10-point median with a 40-point median centered on the same sample, which is reasonable.

For each phase, descriptive summaries for both devices are shown (number of data points and mean and SD values of HR and RR) and the MAE and root mean square error (RMSE) were computed for these vital signs. However, MAE was the metric used to determine HR and RR accuracy, in accordance with the ANSI/AAMI EC13:2002 standard [27]. It was defined as clinically acceptable if ≤5 bpm and 3 rpm, respectively. Both MAE and RMSE 95% CIs were determined via bootstrap using 10,000 replicates [33].

Bland-Altman plots, the corresponding mean bias, and the 95% LoA (SD 1.96) were also analyzed [34]. Finally, the Pearson correlation coefficient and associated *P* value [35] were reported. All statistical tests were conducted using R v3.6.1 (R Foundation for Statistical Computing) [36].

Missing Values

Participants in whom it was not possible to achieve hypoxemia (SpO_2<90%) were excluded from the analysis to avoid different sample sizes or participants in the movement and hypoxia phases. All the included participants had complete data from the movement phase. If there were any technical issues during an activity, it was repeated until complete data were obtained. For clinical reasons, this was not possible in the hypoxic phase. Participants with intermittent missing data (if not significant) were included. We did not use imputation in this study, given that the median was calculated for consecutive 40-second windows without data on either the VitalPatch or reference device excluded from the analysis.

Results

Participants

The flow diagram of the data set collected in this study is shown in Figure 2. A total of 42 participants were recruited, of which 29 (69%) were included in our analysis. The demographic descriptors are listed in Table 1. Exemplar HR and RR traces collected in the movement and hypoxia phases for one participant are shown below.

Figure 2. Participant flowchart. ABG: arterial blood gas.

[a]rpm: respirations per minute.

[b]bpm: beats per minute.

[c]SaO_2: arterial oxygen saturation.

[d]BP: blood pressure.

Movement Phase

The movement phase lasted approximately 13 minutes for each participant. The exemplar HR and RR traces shown in Figure 3 confirm higher variability during the STS movement. The scatter and Bland-Altman plots for HR and RR in Figure 4 also show a higher mean bias and LoA for the dynamic activity (STS) versus one of the sitting movements (using a tablet). Scatter and Bland-Altman plots for all movement tests can be found in Multimedia Appendix 1. Table 2 lists the performance

metrics for the complete movement phase. The VitalPatch HR showed marginal overestimation throughout the sitting activities, with a mean MAE ranging from 0.55-0.84 bpm, RMSE from 0.89-1.32 bpm, bias from 0.06-0.32 bpm, and with a correlation of approximately 1 (P<.001) throughout. In the dynamic activity (STS), there was an increase in the MAE, 2.69 (95% CI 1.58-3.63) bpm, and RMSE 5.75 (95% CI 3.83-7.94) bpm, mean bias 1.92 (95% LoA −8.75 to 12.59) bpm, with a correlation of approximately 0.95 (P<.001).

[a]$P<.001$.

[b]MAE: mean absolute error.

[c]RMSE: root mean square error.

[d]LoA: limits of agreement.

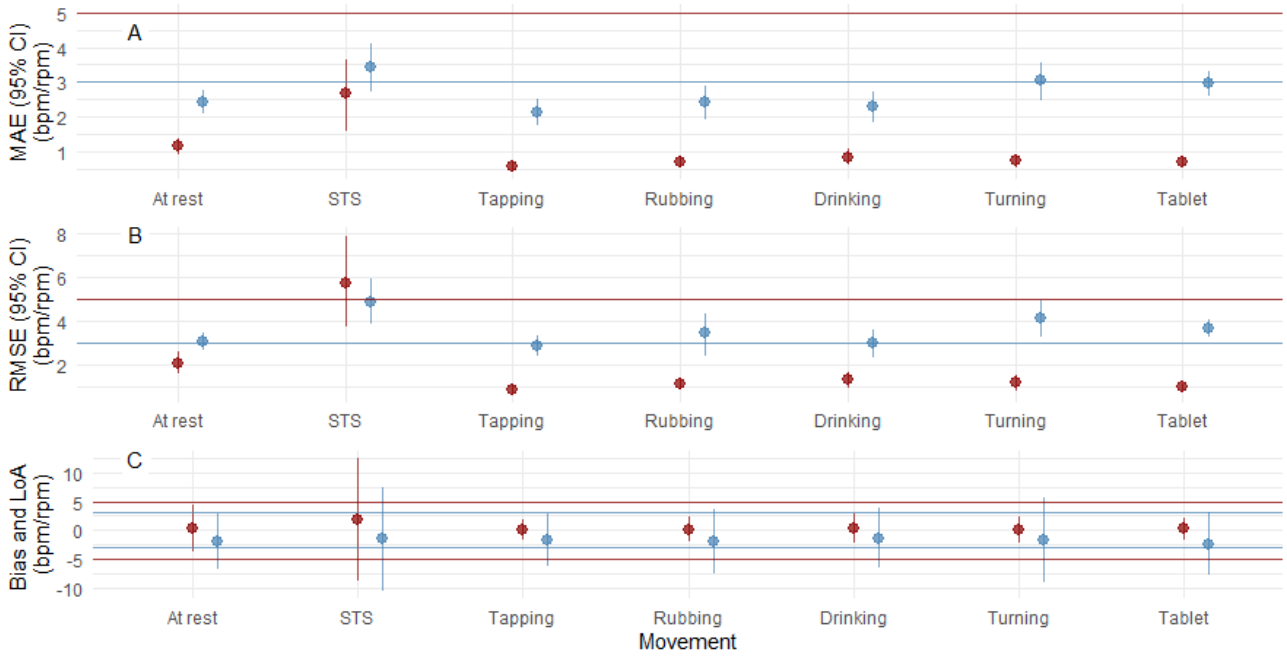
[e]bpm: beats per minute.

[f]STS: sit-to-stand.

[g]rpm: respirations per minute.

In contrast, a consistent underestimation was observed for RR throughout the sitting activities. MAE ranged from 2.14-3.05 rpm, RMSE from 2.86-4.13, mean bias from −1.68 to −2.43 rpm, and the correlation coefficient from 0.53-0.74 ($P<.001$). During the dynamic activity, the MAE was 3.45 (95% CI 2.71-4.11) rpm, RMSE was 4.89 (95% CI 3.91-5.92) rpm, mean bias was −1.59 (95% LoA −10.7 to 7.53) rpm, and the correlation was 0.56 ($P<.001$). An overview of the MAE, RMSE, and mean bias (LoA) for all movements is shown in Figure 5.

Figure 5. Accuracy and Bias (mean bias) plots for all movement tests. Red: heart rate; horizontal red line represents acceptable limits. Blue: respiratory rate; horizontal blue line represents acceptable limits. (A) MAE (95% CI) plot, (B) RMSE (95% CI) plot, (C) bias LOAs. bpm: beats per minute; LoAs: limits of agreement; MAE: mean absolute error; RMSE: root mean square error; rpm: respirations per minute; STS: sit-to-stand.



The VitalPatch HR estimation was within clinically acceptable accuracy, achieving a MAE 0.72 (95% CI 0.66-0.78) bpm and a RMSE 1.16 (95% CI 1.02-1.29) bpm in the hypoxia phase. Figure 6 shows an exemplar participant during the hypoxia phase, and Figure 7 shows the scatter and Bland-Altman plots for HR and RR. The mean bias was 0.49 (95% LoA −1.58 to 2.56), and the correlation was approximately 1 (P<.001). Although more variable, the RR was also within the acceptable accuracy achieving a MAE 1.89 (95% CI 1.75-2.03) rpm and a RMSE 2.92 (95% CI 2.64-3.2) rpm. A minimal mean bias of −0.08 (95% LoA −5.8 to 5.65) and a correlation of approximately 0.72 (P<.001) were observed.

Figure 6. Exemplar heart rate (A) and respiratory rate (B) traces during the hypoxia phase for one participant (vHDU-H-29). red: VitalPatch heart rate; blue: VitalPatch respiratory rate; black: Philips 3-Lead electrocardiography heart rate (A) and capnography respiratory rate (B); brown horizontal line: target hypoxia levels. bpm: beats per minute; HR: heart rate; rpm: respirations per minute; RR: respiratory rate.

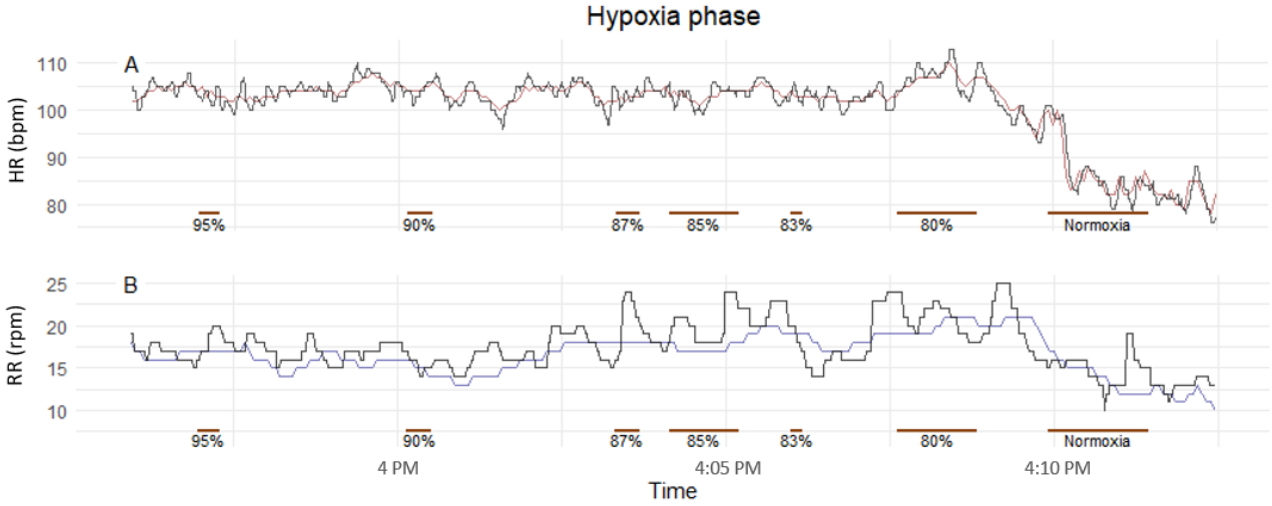


Figure 7. (A and C) Scatter plots and (B and D) Bland-Altman plots for heart rate (A and B in red) and respiratory rate (C and D in blue) during the full hypoxia phase. bpm: beats per minute; rpm: respirations per minute; SpO_2: peripheral oxygen saturation.

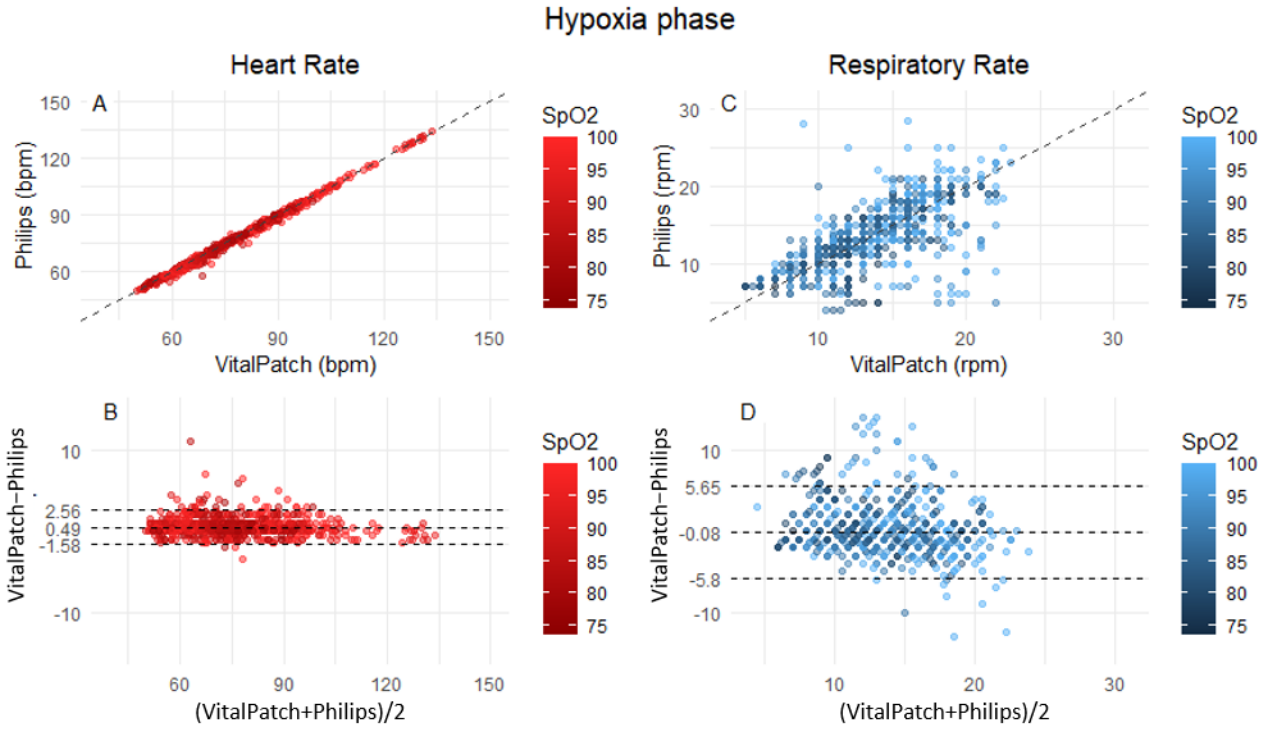
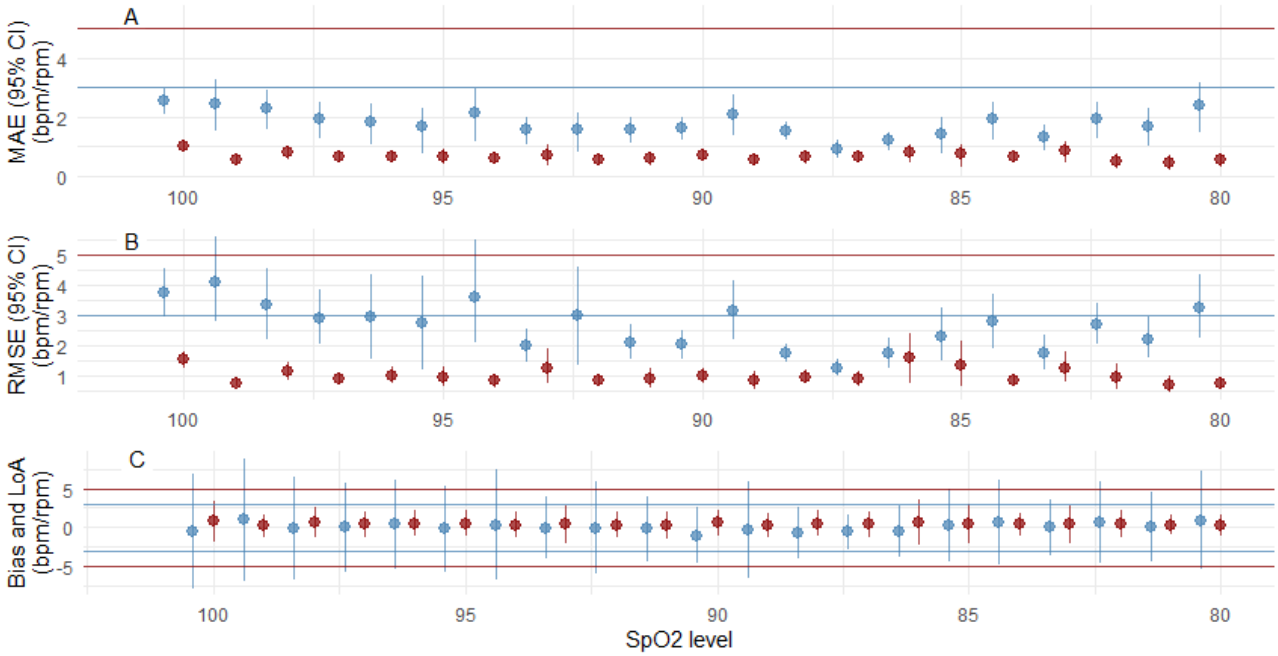


There were also no significant differences in the error metrics between the SpO_2 subgroups (normoxia, SpO_2 100% to 90%; mild hypoxia, SpO_2 85%-89.9%; and severe hypoxia, SpO_2<85% [24]), as shown in Multimedia Appendix 2. Finally, Figure 8 shows the MAE, RMSE, and mean bias (LoA) computed for each oxygen saturation level from the hypoxia phase.

Figure 8. Accuracy and Bias (mean bias) plots for the hypoxia phase. Red: heart rate; horizontal red lines represent acceptable limits Blue: respiratory rate; horizontal blue line represents acceptable limits. (A) MAE (95% CI) plot, (B) RMSE (95% CI) plot, (C) bias LOAs. bpm: beats per minute; LoA:s limits of agreement; MAE: mean absolute error; RMSE: root mean square error; rpm: respirations per minute; SpO_2: peripheral oxygen saturation.



Discussion

Principal Findings

The key findings from this study were as follows: (1) The VitalPatch HR estimation was well within acceptable accuracy limits when compared with the gold standard device (Philips 3-lead ECG), (2) The VitalPatch RR estimation was also in agreement with the gold standard device (Philips capnography) for most of the movements and throughout the full hypoxia phase, and (3) there was no impact on the HR and RR estimation performance when participants were exposed to induced hypoxia. These findings support the clinical use of VitalPatch in patients with reduced baseline saturation or *at risk* of hypoxia.

Accuracy testing during motion is important before clinical use, as we aim to implement an ambulatory monitoring system that promotes patient mobility and independence without compromising safety. Our results suggest that the VitalPatch can measure HR with high accuracy and minimal bias during simple movements (mimicking in-hospital patient movements). Reliability was reduced during STS activity but was still within acceptable limits. These results agree with the results of previous clinical validation studies when compared with a reference standard device in healthy volunteers [18,23] and surgical patients [21,22]. When compared with nurse manual measurements in surgical patients [14], VitalPatch meets the accuracy criteria for HR estimation.

The MAE of the VitalPatch RR estimation was comparatively higher, especially during the movement phase. However, it was also mostly within the prespecified limits (except for the STS and turning a page movements), in agreement with previous studies [14,18,21-23]. High variation during STS was expected as it is a dynamic activity, potentially creating several artifacts that could affect VitalPatch accuracy during this test [21,22]; however, a high MAE for RR was not expected for the *turning pages* activity (even if close to the 3-rpm threshold). We postulate that the latter may have created a low-frequency periodic artifact that influenced both the ECG and accelerometer waveforms (both used in the computation of the RR estimate by the VitalPatch).

The most recent study showed that the VitalPatch tended to overestimate RR with a bias of 4.4 rpm [22], but previous studies showed a predominant RR underestimation [14,18,21]. Our study seems to agree with the latter, as VitalPatch mostly underestimated RR throughout the movement phase and varied in the hypoxia phase. However, in contrast to these previous studies, we collected vital signs from healthy participants.

This study also assessed the VitalPatch reliability during a controlled hypoxia phase, and our results suggest that there is no impact on this patch's reliability for HR and RR measurements during periods of reduced SpO_2 levels. The VitalPatch estimates followed the gold standard HR and RR variations caused by the controlled desaturation of the participants during the hypoxia phase, reliably, supporting its use in clinical populations with reduced baseline saturation or *at risk* of hypoxia.

Limitations

This study had some limitations. First, the participants were healthy volunteers in a controlled environment that is not representative of hospitalized patients. In addition, the main study was powered to assess the accuracy of SpO_2 and not that of HR and RR. Although the range required to validate RR was achieved (10 to 30 rpm is required [18] and 4 to 31 rpm was collected), the HR range achieved in this substudy was 40 to 150 bpm, a subset of the range required to validate its accuracy, 30 to 200 bpm [27].

Comparison With Prior Work and Future Research

The ANSI/AAMI EC13:2002 standard [27] only requires that a measure of systematic error (eg, mean bias or MAE) be below the clinically accepted limits. In more recent studies, MAE has been used because it is less susceptible to outliers than the mean bias [18,23,30]. Analyzing the RMSE results, which combines both the systematic and random errors, we note that they follow the trend of those of the MAE metric as the RMSE was also higher during the STS activity for both variables and for the *turning pages* movement for RR. In our study, the LoA (also a measure of random error) seemed to be within the acceptable range when compared with the results of other studies [14,18,21-23] (except for the aforementioned cases). Previous studies reported higher LoA (defined as out of the acceptable range by the authors) for RR when compared with reference standard devices both in healthy volunteers (−10.1 to 6.5) [18] and surgical patients (−15.8 to 11.2) [21] and (−4.4 to 13.3) [22], and when compared with nurse manual measurements in surgical patients (10.32 to 9.04) [14].

In this study, the VitalPatch was subjected to robust testing, during movement and under induced hypoxia, against a gold standard in a controlled environment. Our results suggest that this device can be safely tested in clinical environments (within the collected input range for each vital sign). Our results will inform future phases of our vHDU research project, aiming to develop an accurate wearable system for monitoring ambulatory patients in hospitals.

Conclusions

In conclusion, the VitalPatch was highly accurate throughout movement tests except for the measurement of RR during the STS activity and the *turning pages* movement. This device was also reliable throughout the hypoxia phase, with no significant MAE or bias differences in hypoxic levels. This study demonstrated that VitalPatch can be safely tested in clinical environments to support earlier detection of clinical deterioration.

Acknowledgments

CMA, MS, LY, MH, and SV were funded by the National Institute for Health Research (NIHR) Oxford Biomedical Research Centre. The views expressed are those of the authors and not necessarily those of the National Health Service, the NIHR, or the Department of Health. AS is currently supported by the NIHR Doctoral Research Fellowship (NIHR-DRF-2017-10-094). The authors would like to thank all the volunteers who participated in this study.

Authors' Contributions

Authorship was determined in accordance with the International Committee of Medical Journal Editors guidelines. CMA, SV, PP, LT, and PW drafted the initial protocol. CMA, SV, EK, JE, LY, OG, CR, MP, and MS conducted the study procedures and data acquisition. AS and MH provided medical coverage on the study days. CMA and MS conducted statistical analyses. CMA drafted the manuscript, and all the authors reviewed and approved the manuscript. The funders had no role in the study protocol design or in the collection, management, analysis, and interpretation of the data or the writing of the final report.

Conflicts of Interest

PW and LT report significant grants from the NIHR, United Kingdom, and the NIHR Biomedical Research Centre, Oxford, during the conduct of the study. PW and LT report modest grants and personal fees from Sensyne Health outside the submitted work. LT work part-time for Sensyne Health and hold shares in the company. PW was previously Chief Medical officer for Sensyne Health and has shares in the company. Sensyne Health have provided research support to his university department.

Abstract

Background: Multidisciplinary treatment (MDT) and adjuvant therapy are associated with improved survival rates in breast cancer. However, nonadherence to MDT decisions is common in patients. We developed a smartphone-based app that can facilitate the full-course management of patients after surgery.

Objective: This study aims to investigate the influence factors of treatment nonadherence and to determine whether this smartphone-based app can improve the compliance rate with MDTs.

Methods: Patients who had received a diagnosis of invasive breast cancer and had undergone MDT between March 2013 and May 2019 were included. Patients were classified into 3 groups: Pre-App cohort (November 2017, before the launch of the app); App nonused, cohort (after November 2017 but not using the app); and App used cohort (after November 2017 and using the app). Univariate and multivariate analyses were performed to identify the factors related to MDT adherence. Compliance with specific adjuvant treatments, including chemotherapy, radiotherapy, endocrine therapy, and targeted therapy, was also evaluated.

Results: A total of 4475 patients were included, with Pre-App, App nonused, and App used cohorts comprising 2966 (66.28%), 861 (19.24%), and 648 (14.48%) patients, respectively. Overall, 15.53% (695/4475) patients did not receive MDT recommendations; the noncompliance rate ranged from 27.4% (75/273) in 2013 to 8.8% (44/500) in 2019. Multivariate analysis demonstrated that app use was independently associated with adherence to adjuvant treatment. Compared with the patients in the Pre-App cohort, patients in the App used cohort were less likely to deviate from MDT recommendations (odds ratio [OR] 0.61, 95% CI 0.43-0.87; *P*=.007); no significant difference was found in the App nonused cohort (*P*=.77). Moreover, app use decreased the noncompliance rate for adjuvant chemotherapy (OR 0.41, 95% CI 0.27-0.65; *P*<.001) and radiotherapy (OR 0.49, 95% CI 0.25-0.96; *P*=.04), but not for anti-HER2 therapy (*P*=.76) or endocrine therapy (*P*=.39).

Conclusions: This smartphone-based app can increase MDT adherence in patients undergoing adjuvant therapy; this was more obvious for adjuvant chemotherapy and radiotherapy.

breast cancer; adherence; multidisciplinary treatment; adjuvant treatment; smartphone-based app; mobile phone

Introduction

Background

Breast cancer has the highest prevalence rate among malignant diseases in women worldwide [1]. Typically, comprehensive treatment for breast cancer includes locoregional and systemic therapy approaches. The former refers to surgery and radiotherapy, and the latter comprises chemotherapy, targeted therapy, endocrine therapy, and other promising strategies such as immunotherapy [2]. Moreover, multidisciplinary treatment (MDT), which involves physicians from different disciplines with specialized knowledge working as team to discuss the treatment of a given patient, has become a standard care modality that can promote clinical decision-making and improve the overall quality of treatment [3]. To date, nearly 70% to 80% of nonmetastatic breast cancers are curable because of the continuous improvement of therapeutic strategies and MDT discussions [4].

Despite the proven efficacy of adjuvant treatment, patients may have difficulty initiating or pursuing a treatment plan because of the relative complexity of the overall therapy. A cancer registry study demonstrated that the nonadherence rate for adjuvant therapy was approximately 30% for early breast cancer [5]. Meanwhile, it has been reported that nearly one-third of patients discontinued endocrine therapy during 5 years of treatment [6]. Noncompliance was associated with an increased risk of recurrence and poorer clinical outcomes [7,8]. Thus, it is essential to identify the reasons for nonadherence and use effective interventions to improve adherence.

Mobile Health Intervention

Currently, the use of mobile devices to conduct health control and management has become increasingly popular and has the opportunity to affect health behaviors, especially in the condition of chronic disease and cancer setting among adolescents [9]. For example, sharing treatment experiences on the web can help alleviate isolation and emotional distress [10]. Active and regular self-monitoring using the digital app also helps to improve health-related outcomes, such as pain management for cancer [11]. Studies have also argued that the change in actual behavior is modest, and there is a lack of research focusing on effectiveness and acceptability [12,13]. New technologies such as artificial intelligence, virtual reality, and machine learning have also been tailored in health care settings to optimize disease outcomes [14]. Therefore, we launched a smartphone-based app called the *full-course management system* in November 2017, which enabled sustained communication between outpatients and medical workers and provided personalized management according to MDT discussions. Using this app, we aimed to facilitate the postoperative management of patients with breast cancer.

Objective

In this study, we aimed to determine the potential factors that influence patient compliance with MDTs. Meanwhile, we aimed to evaluate whether this smartphone-based app could improve patients' adherence to MDT for early breast cancer patients.

Methods

Data Processing and Cohort Sorting

Patients with a diagnosis of breast cancer who received MDT discussion for adjuvant treatment decisions between March 2013 and May 2019 at Shanghai Ruijin Hospital were retrospectively reviewed. Data on demographic and clinicopathological characteristics as well as follow-up information were retrieved from the Shanghai Jiao Tong University Breast Cancer Database. The inclusion criteria were as follows: (1) female patients with a diagnosis of primary breast cancer and (2) patients who received surgical treatment. Patients were excluded if they met the following criteria: (1) forgone or had missing MDT discussion data, (2) pathologically confirmed without invasive lesions, or (3) missing clinicopathological characteristic data. Patients were then divided into 3 cohorts according to the year of diagnosis and use of the smartphone-based management system. The Pre-App cohort included patients who received a diagnosis between March 2013 and October 2017. The App nonused cohort included patients who received a diagnosis between November 2017 and May 2019 without using the app. The App used cohort referred to patients who received a diagnosis between November 2017 and May 2019 and who had applied the smartphone-based app within the adjuvant treatment setting. It is worth noting that the use of the app was entirely up to patients' willingness, and at least one time of logging record identified from the backstage system would be defined as app used.

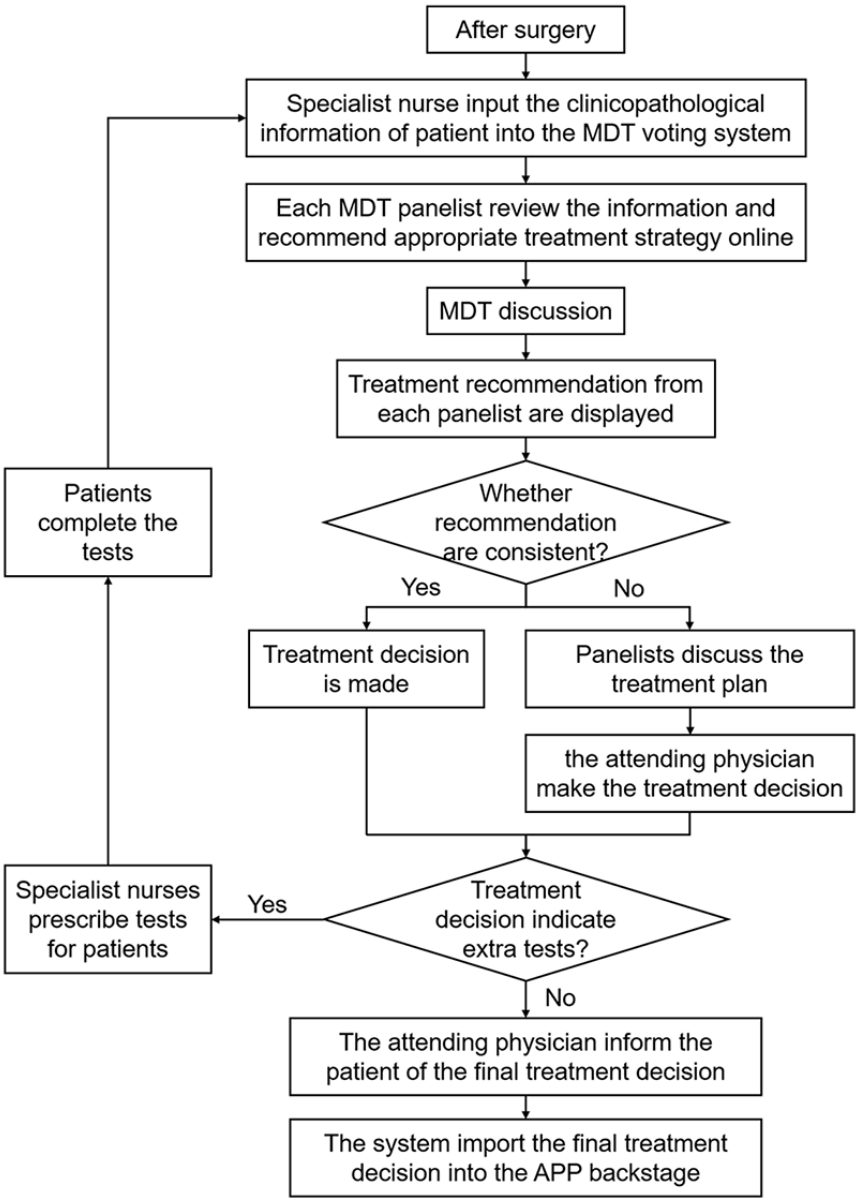
Ethics Approval and Consent to Participate

The study was approved by the Ethical Committees of Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, and informed consent was waived because of the retrospective design of this study. All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards.

MDT Discussion

After breast cancer surgery, an MDT discussion session was held to determine the adjuvant treatment strategy for each patient. In brief, the MDT panel members reviewed the medical history of each patient in advance and selected treatments on a given webpage. The MDT panelists consisted of breast surgeons, medical oncologists, pathologists, radiation oncologists, and oncology nurses. When the MDT meeting was held, a physician reported the cases and displayed the treatment results of each panelist for each patient. If the treatment results were consistent, a treatment decision was made. If the treatment decisions were inconsistent, the panel members discussed the treatment plan, and the attending physician made the final treatment decision for the patient. The flowchart of the MDT is shown in Figure 1.

Figure 1. Flowchart of multidisciplinary treatment. MDT: multidisciplinary treatment.



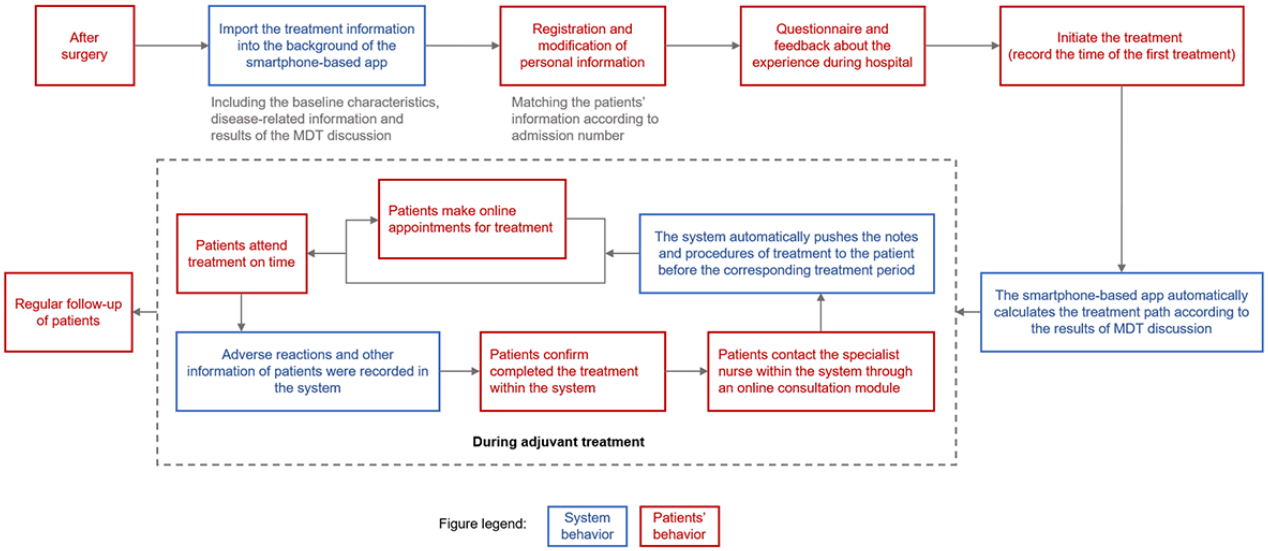
Smartphone-Based Full-Course Management App

The smartphone-based app consists of the following features:

1. Login, logout, setting, and modification of personal information
2. Full-course management included registering for information on the surgical treatment, viewing the results of the MDT discussion, generating the treatment process according to the MDT discussion, receiving the reminder of the treatment, confirming the completion of the treatment, filling in the follow-up information, and consulting a specialist nurse.
3. Questionnaire and feedback

The operational flow of the app is illustrated in Figure 2. In brief, after discharge from the hospital, the baseline characteristics and surgical and pathological information of the patients were uploaded to the system. Then, the patients completed the registration through the smartphone app and initiated the first course of treatment. The system then automatically calculated the treatment schedule according to the MDT recommendation and pushed notifications to patients periodically. After completing each cycle of therapy, patients were required to confirm the treatment-related record on the app. During the entire course of treatment, patients communicated in real time with specialist nurses via this app.

Figure 2. The operation flow of the smartphone-based app. MDT: multidisciplinary treatment.



Measurement of Nonadherence

Treatment adherence was assessed by physicians via outpatient procedures, by follow-up specialists, or by nurses via phone calls. The routine follow-up interval was as follows: (1) every 3 months within the first 2 years after surgery, (2) every 6 months between 3 and 5 years, and (3) once a year after 5 years.

Treatment adherence was evaluated in all patients according to whether their actual treatment was the same as the results of the MDT discussion. Nonadherence was defined as follows: (1) patients refused to receive the prescribed regimen recommended by the MDT, (2) patients received a different regimen with the MDT recommendation, or (3) patients failed to complete the full course of treatment. Adherence was investigated in each therapeutic modality, including chemotherapy, radiotherapy, anti-HER2 (human epidermal growth factor receptor-2) therapy, and endocrine therapy, and then overall compliance was calculated.

Statistical Analysis

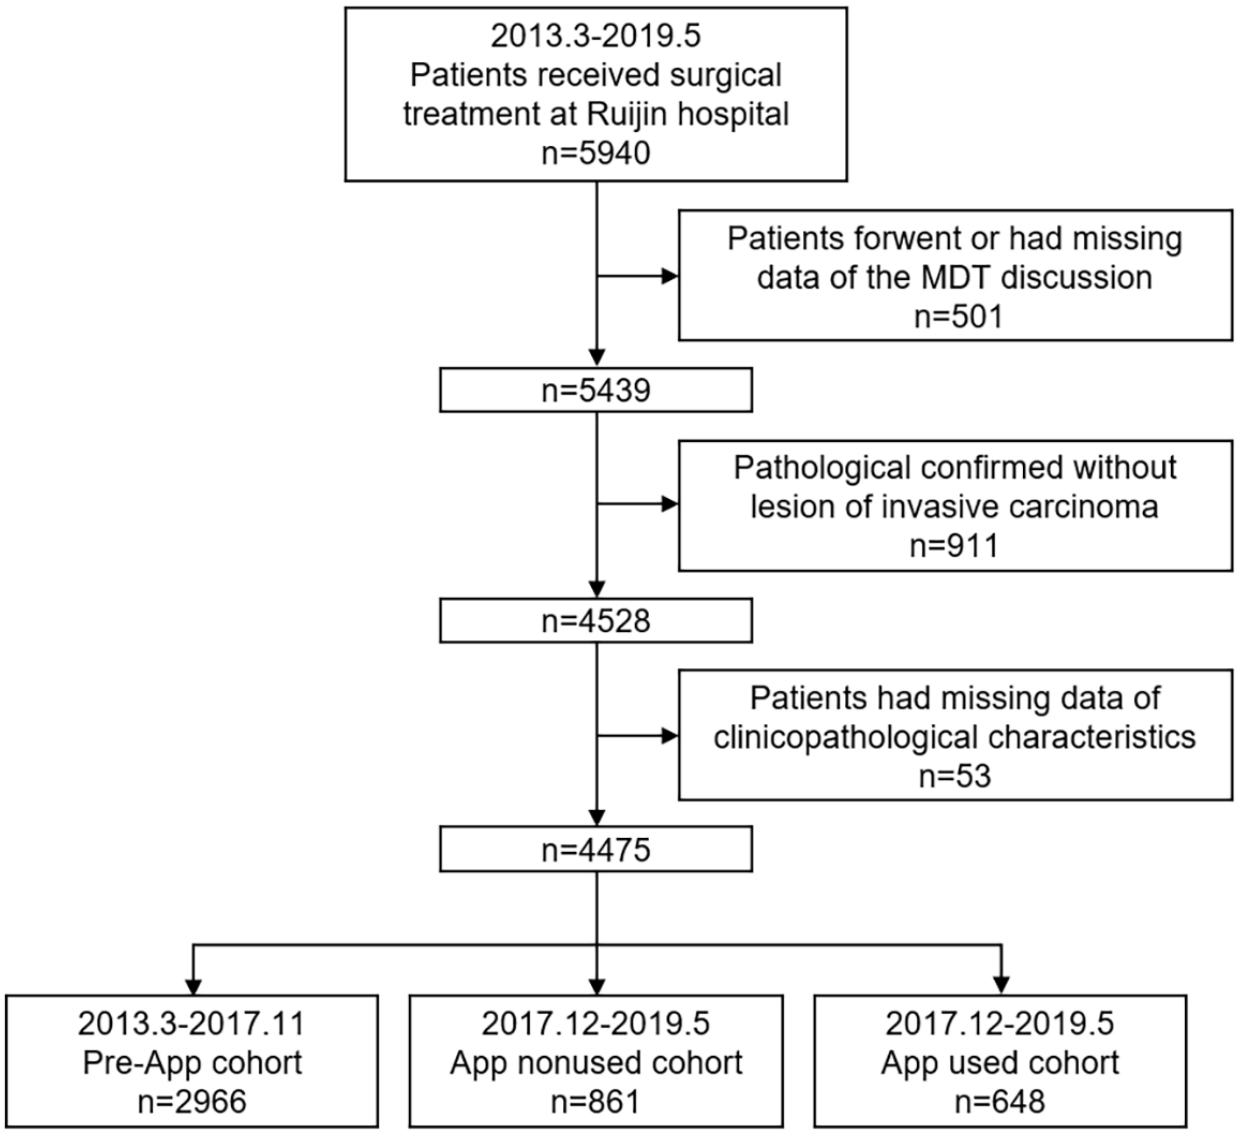
The chi-square test was used to evaluate the differences in patient characteristics among the three app-related groups and between the adherence and nonadherence groups, as well as to compare the difference in treatment adherence among the 3 app-related groups. A multivariate logistic regression model was used to identify the features associated with treatment compliance. Odds ratios (ORs) with 95% CIs were used to evaluate the influence of app use on patient adherence. Interactive analyses were performed to illustrate the effect of app use on compliance among patients with different clinicopathological features. Statistical analyses were performed using IBM SPSS version 25 and GraphPad Prism 8 (GraphPad Prism, Inc).

Results

Baseline Characteristics

A total of 5940 patients were reviewed, and 4475 were included in the study (Figure 3). There were 66.28% (2966/4475), 19.24% (861/4475), and 14.48% (648/4475) of patients in the Pre-App, App nonused, and App used cohorts, respectively.

Figure 3. Flowchart. MDT: multidisciplinary treatment.



Among 4475 patients, 1662 (37.14%) were aged 50 years or older, 2304 (51.49%) were aged between 50 and 70 years, and 11.73% (509/4475) of patients were older than 70 years. A total of 64.31% (2878/4475) of patients underwent mastectomy for the breast, and 66.2% (2940/4475) of patients underwent sentinel lymph node biopsy for the axillary region. Regarding the molecular subtype, there were 20.63% (923/4475), 42.53% (1903/4475), 12.97% (540/4475), 11.17% (500/4475), and 13.61% (609/4475) of tumors classified as luminal-A like, luminal-B like (HER2-negative), luminal-B like (HER2-positive), HER2 positive, and triple negative, respectively (Table 1). When using the American Joint Committee on Cancer staging system to classify the disease, 44.71% (1954/4475) were stage I, 42.08% (1839/4475) were stage II, and 13.2% (577/4475) were stage III. Altogether, 84.46% (3780/4475) of patients received the treatment regimen assigned by MDT, which was defined as adherence.

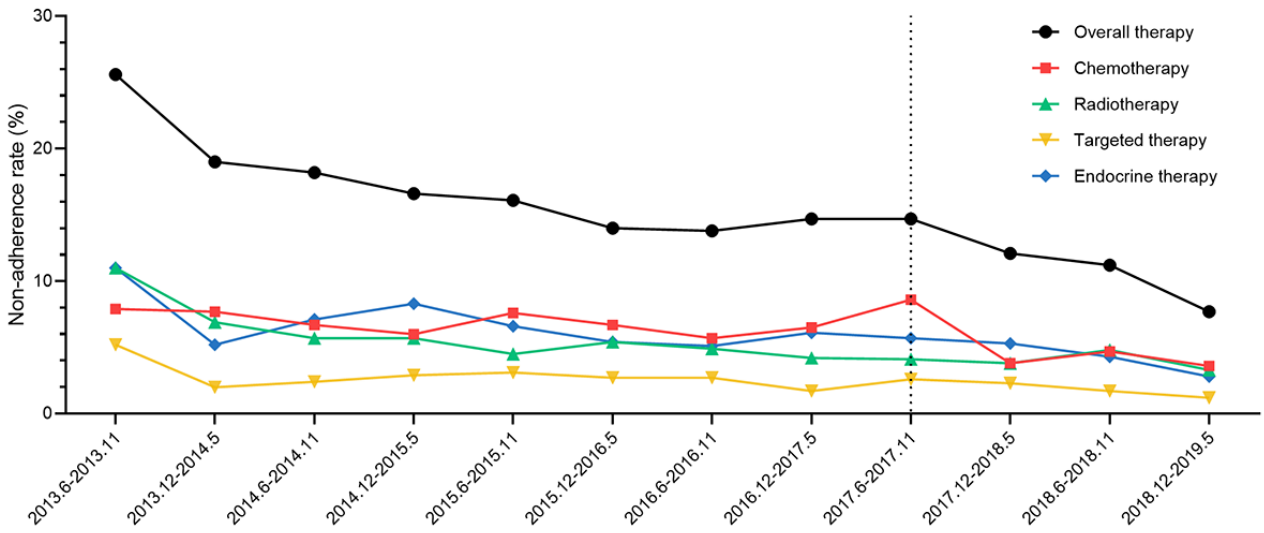
[j]TNM: tumor, lymph node, and metastasis.

[k]A total of 105 patients had missing data of tumor, lymph node, and metastasis stage.

Factors Associated With Treatment Adherence

The rate of nonadherence decreased by year, which was approximately 27.4% in 2013 and 8.8% in 2019 (Figure 4).

Figure 4. Trend of noncompliance rate to multidisciplinary treatment recommendations by year. The dotted line indicates launch of the smartphone-based app.



In the univariate analysis, diagnosis year, demographic characteristics, medical history, surgical type, as well as the staging and characteristics of tumors were significantly associated with adherence to MDT. Moreover, regarding smartphone-based app use, the nonadherence rate was 17.6% in the Pre-App cohort, 13.24% in the App nonused cohort, and 9.1% in the App used cohort (P<.001; Tables 2 and 3; Table S1 in Multimedia Appendix 1).

[a]In 1028 patients with HER2-positive breast cancer.

[b]In 3337 patients with hormone receptor–positive breast cancer.

Multivariate analysis demonstrated that diagnosis year, age, educational level, axillary surgery, lymph node status, HER2 status, and molecular subtype were significantly associated with patients' adherence to the MDT recommendation. Notably, the use of the smartphone-based app was also an independent factor associated with patient compliance (*P*=.02). Compared with the patients in the Pre-App cohort, patients in the App used cohort were less likely to violate the treatment plan (OR 0.60, 95% CI 0.43-0.87; *P*=.007). However, there was no significant difference in adherence rates between the App nonused cohort and the Pre-App cohort (OR 0.96, 95% CI 0.70-1.29; *P*=.77; Table 4).

Table 4. Multivariate analysis of factors associated with nonadherence.

Characteristics	Odds ratio (95% CI)	*P* value
Diagnosis year (per year)	0.88 (0.81-0.94)	<.001
Age (years)		<.001
50-70 vs ≤50	1.08 (0.88-1.31)	.45
>70 vs ≤50	2.85 (2.19-3.70)	<.001
Educational level (high school or higher vs middle school or lower)	0.76 (0.64-0.91)	.002
Menopausal status (post vs pre)	1.01 (0.72-1.41)	.96
Family history of breast cancer (yes vs no)	0.70 (0.48-1.00)	.05
Axillary surgery (ALND[a] vs SLNB[b])	0.72 (0.55-0.96)	.03
Tumor size (>2 cm vs ≤2 cm)	0.83 (0.62-1.09)	.18
Lymph node status (positive vs negative)	1.40 (1.04-1.88)	.03
Pathological subtype (Non-IDC[c] vs IDC)	0.77 (0.58-1.02)	.07
Tumor grade		.15
III versus I or II	1.19 (0.97-1.45)	.10
Unknown versus I or II	1.36 (0.84-2.20)	.21
PR[d] status (positive vs negative)	0.86 (0.66-1.12)	.28
HER2[e] status (positive vs negative)	2.04 (1.34-3.10)	.001
Ki-67 index (≥14% vs <14%)	0.96 (0.73-1.26)	.75
Molecular subtype		<.001
Luminal-B like (HER2 negative) versus Luminal-A like	1.83 (1.29-2.59)	.001
Luminal-B like (HER2 positive) versus Luminal-A like	1.60 (1.16-2.21)	.005
HER2 positive versus Luminal-A like	N/A[f]	N/A
Triple negative versus Luminal-A like	2.11 (1.41-3.14)	<.001
TNM[g] stage		.02
Stage II versus stage I	1.35 (1.08-1.69)	.008
Stage III versus stage I	1.57 (1.09-2.25)	.01
Group according to app use		.02
App nonused cohort versus Pre-App cohort	0.96 (0.70-1.29)	.77
App used cohort versus Pre-App cohort	0.61 (0.43-0.87)	.007

[a]ALND: axillary lymph node dissection.

[b]SLNB: sentinel lymph node biopsy.

[c]IDC: invasive ductal carcinoma.

[d]PR: progesterone receptor.

[e]HER2: human epidermal growth factor receptor 2.

[f]N/A: not applicable.

[g]TNM: tumor, lymph node, and metastasis.

Patient Adherence According to Treatment

Adjuvant Chemotherapy

Among 4475 patients, 310 (6.93%) patients did not adhere to the adjuvant chemotherapy decision, and the nonadherence rates were 7.9%, 6.2%, and 3.5% in the Pre-App cohort, App nonused, and App used cohorts, respectively (*P*<.001; Table 3; Table S1 in Multimedia Appendix 1). In the multivariate analysis, older age, luminal-B–like tumors, HER2-positive breast cancer, and triple-negative breast cancer were significantly associated with a lower compliance rate. Pathologically diagnosed noninvasive ductal carcinoma was associated with good compliance (*P*=.003). Moreover, compared with the patients in the Pre-App cohort, patients in the App used cohort (OR 0.41, 95% CI 0.27-0.65; *P*<.001) but not in the App nonused cohort (OR 0.74, 95% CI 0.54-1.02; *P*=.07) were less likely to not follow

MDT-recommended chemotherapy (Table S2 in Multimedia Appendix 1).

Adjuvant Radiotherapy

There were 5.45% (244/4475) patients who did not receive adjuvant radiotherapy according to the MDT discussion, and the discordance rates were 6%, 6%, and 2.3% in the 3 groups, respectively (*P*=.001; Table 3; Table S3 in Multimedia Appendix 1). Multivariate analysis demonstrated that later diagnosis year, age, educational level, Ki-67 index, and lymph node status were significantly related to patient adherence (Table S4 in Multimedia Appendix 1). When compared with the patients in the Pre-App cohort, patients in the App used cohort were less likely to not follow the MDT recommendation (OR 0.49, 95% CI 0.25-0.96; *P*=.004). However, there was no significant difference between the App nonused cohort and the Pre-App cohort (OR 1.38, 95% CI 0.86-2.22; *P*=.18) in terms of adjuvant radiotherapy.

Adjuvant Target Therapy

Among 1028 patients with HER2-positive breast cancer, 118 (11.48%) patients violated the anti-HER2 treatment strategy. The nonadherence rates were 13.4%, 8.1%, and 6.6% in the Pre-App, App nonused, and App used cohorts, respectively (*P*=.02; Table 3; Table S5 in Multimedia Appendix 1). In multivariate analysis, only diagnosis year, age >70 years, and educational level were independent factors of treatment adherence (Table S6 in Multimedia Appendix 1). However, app use was not independently associated with MDT adherence to adjuvant targeted therapy (*P*=.76).

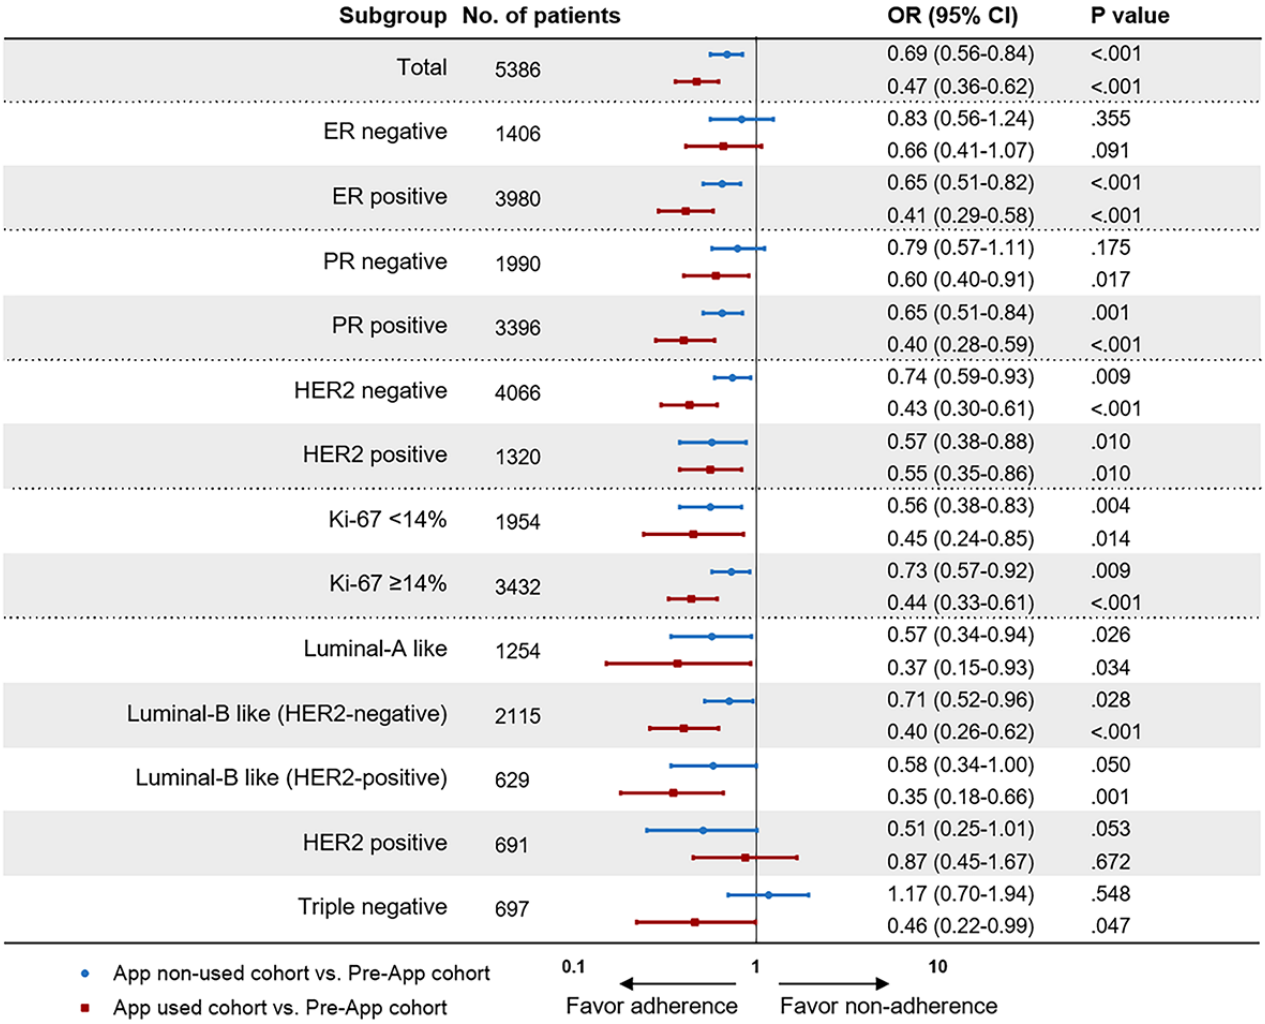
Adjuvant Endocrine Therapy

A total of 3337 patients received a diagnosis of hormone receptor–positive breast cancer, among whom 256 (7.67%) did not follow the doctors' recommendations for endocrine therapy within the follow-up period. The noncompliance rates were 8.8%, 6.5%, and 3.6% in the 3 groups (*P*<.001; Table 3; Table S7 in Multimedia Appendix 1). Multivariate analysis revealed that patients with early diagnosis years, aged >70 years, and with luminal-B–like (HER2-positive) breast cancer were less likely to adhere to the endocrine therapy recommendation (Table S8 in Multimedia Appendix 1). The use of the app was not significantly associated with treatment compliance (*P*=.54).

Subgroup Analysis

Subgroup analyses of MDT-recommended treatment compliance according to clinicopathological parameters were also performed (Figure 5). Age (interaction *P*<.001), menopausal status (interaction *P*<.001), and comorbidity (interaction *P*=.007) were significantly associated with app use and MDT compliance. In patients older than 70 years, those who did not use the app were more likely to be nonadherent (OR 2.01, 95% CI 1.31-3.09; *P*<.001). Meanwhile, use of apps was associated with better adherence in postmenopausal patients (OR 0.54, 95% CI 0.38-0.77; *P*<.001) and patients with comorbidities (OR 0.46, 95% CI 0.28-0.74; *P*<.001). However, there were no significant interactions between the group setting and cancer-related characteristics, including the molecular subtype or tumor, lymph node, and metastasis stage.

Figure 5. Effect of the app use on multidisciplinary treatment compliance in the entire population and stratified according to clinicopathological features. Odds ratios (OR) and 95% CIs for multidisciplinary treatment compliance (an OR<1 indicates a higher compliance rate) are shown. The compliance rate of patients in the Pre-App cohort was used as a reference. CIs have not been adjusted for multiple comparisons. Significant interactions were observed between patient groups and age, menopausal status, as well as comorbidities. ER: estrogen receptor; HER2: human epidermal growth factor receptor-2; OR: odds ratio; PR: progesterone receptor.



Discussion

Principal Findings

In this study, we included 4475 patients with early-stage breast cancer who had undergone an MDT discussion after surgery and found that sociodemographic factors together with clinicopathological factors were associated with MDT compliance in terms of adjuvant treatments. More importantly, the novel smartphone-based app designed for full-course management of patients with breast cancer could improve patients' adherence to MDT recommendations for adjuvant treatment, which will help us better manage breast cancer adjuvant treatment after MDT and improve disease outcomes for these patients.

MDT in Breast Cancer

Currently, MDT has gradually become an integral part of standardized treatment modalities for breast cancer worldwide. It could be conducive to evidence-based decisions for clinicians and provide a convenient medical treatment process for patients [15,16]. Our previous studies demonstrated that MDT discussion could also lower the relative risk of relapse by 16% and the risk of death by 11% in patients with breast cancer [7]. However, a major difficulty after the MDT meeting and during the treatment process was maintaining patient compliance. Data from the Pennsylvania and Florida cancer registries demonstrated that nearly 30% of the patients did not pursue the recommended treatment. The reported nonadherence rate during the 5 years of adjuvant endocrine therapy ranged from 10% to 40% [17-20]. Our study reported a nonadherence rate of 14.6%, and real-world nonadherence to adjuvant therapy may still be underestimated because of loss of patient follow-up and self-reporting methods [8].

Treatment Noncompliance in Breast Cancer

Influence Factors of Noncompliance

Noncompliance is a complex and multifaceted phenomenon that is influenced by demographic, socioeconomic, psychological, and clinical-related factors [21-24]. Several studies including our study have documented that age-specific factors were associated with a lower compliance rate [17,25,26]. This was because weakness and fragility due to old age may

influence tolerance to medical interventions. Regarding disease-related factors, receiving axillary lymph node dissection (ALND), HER2-positive, unfavorable molecular subtype, and advanced tumor, lymph node, and metastasis stage were associated with lower compliance. These patients usually require more complex and aggressive regimens, and their confusion about the therapeutic procedure as well as anxiety about adverse reactions may lead to treatment absence [27]. Moreover, the literature reported that health insurance and employment status were correlated with intravenous chemotherapy adherence [28,29]. Our study demonstrated that educational level was an influencing factor of compliance. These results indicate that economic level was positively related to treatment adherence. Jacobs et al [30] found that cancer-related symptom severity, but not sociodemographic or psychosocial constructs, could influence patients' compliance with oral chemotherapy. The size of enrollment and the delivery method of chemotherapy may have caused differences between the studies. Furthermore, the modifiability of psychological status renders it a key to improving patient compliance [31], but we failed to include this factor in the study because of the difficulty in emotional evaluation during regular follow-up.

Interventions to Improve Patients' Compliance

Withdrawal from treatment was associated with increased recurrence and impaired survival [32]. Our previous study showed that noncompliant patients had 1.8 times the risk of disease relapse and 2.5 times all-cause mortality than those who received the planned treatment [7]. Thus, tailoring enhanced interventions to improve patient adherence is of great importance. Liu et al [33] showed a large difference in patient adherence (59% vs 94%) between those receiving provider-patient communications and those not receiving provider-patient communication. In SWOG S1105, unidirectional text messaging failed to reduce the early discontinuation of adjuvant aromatase inhibitor therapy in women with early-stage breast cancer, suggesting that long-term adherence may call for personalized behavioral interventions and sustained management [34]. A meta-analysis by Lin et al [35] analyzed the influence of psychosocial factors on oral anticancer medication adherence in patients with breast cancer and indicated that using patient-centered interventions and building sustainable relationships may contribute to improved compliance.

Mobile Health Apps

Purpose of Mobile Health Apps

During the treatment process, patients may face complex procedures, unfamiliar treatment-related effects, and numerous changes in psychology and lifestyle. Thus, they need a platform to interact with medical workers, provide feedback on treatment-related problems, and gain informational support. With the popularization of mobile communication, a number of mobile health apps designed for prevention and early diagnosis of disease, management of disease, and survival support and enhancement, greatly facilitate breast cancer health care. As acknowledged, the treatment of breast cancer involves more than surgery; thus, our app was designed for the management of postoperative treatment. Until 2018, approximately 600 apps were designed for breast cancer prevention and management [36]. Those apps designed for providing disease-related information, managing disease, raising awareness, and preventing disease, and the majority of the target population of these apps were patients with breast cancer.

Features and Innovations of Our App

We published an app that engages physicians and oncology nurses in the long-term management of patients after surgery. Our app relies on the most popular social networking platform in China-WeChat, and patients do not need to download and install the software, which ensures convenience and accessibility. Meanwhile, the app was connected to our MDT decision support system [37], and the treatment information of patients can be directly imported into the full-course management app system without manual operation, which could improve efficacy and reduce errors. More than half of the previous apps were developed by nonmedical professors, which may leave concerns regarding the accuracy and validity of the information [36,38]. Our app was designed by health care and computer science professionals, which ensured the credibility of the information and reliability of operation. Several studies have reported that mobile intervention only had modest effects on patients' actual behavior, especially using the most common type of intervention-text messaging [34,39]. We found that after adjusting for the diagnosis year, patients using the smartphone-based full-course management app had a nonadherence rate of only 9.1%, lower than 17.6% in the Pre-App cohort, and 13.24% in the App nonused cohort. The effectiveness of our app may be because, in addition to regular treatment reminders, it supports interactive communication between patients and specialist nurses, which enables the patients to resolve the problem during treatment in a timely manner. The importance of two-way communication has also been demonstrated by Hwang et al [40], who designed an e-monitoring app allowing patients to upload the picture of wounds and consulting doctors on web, and it can decrease the number of clinical visits.

Patient Engagement

Patient engagement was expected to be related to the effectiveness of the digital intervention. Perski et al [41] found that the target behavior, as well as the mechanism of action, may influence engagement. At present, there is a lack of a uniform standard definition of engagement. In this study, we defined the use by logging detected from the backstage system for at least one time, as well as the reasons for patients not to use this app, including not owning a smartphone, older age, being treated in the local hospitals, and refusing to follow the MDT recommendation. Stubbins et al [42] emphasized the importance of providing real-time feedback via the app to improve patients' engagement and adherence. Our app has a feedback function, tending to investigate and improve user experience. A previous review summarized studies using interventions to improve patients' endocrine therapy drug uptake, which should last for years, and all published studies failed to prevent medication discontinuation [43]. Our app was also not effective for targeted or endocrine therapy. Indeed, with the prolongation of treatment, user retention for

smartphone-based apps is another great challenge [44], and further efforts are still needed to minimize user fatigue to enhance patients' long-term engagement.

Economic Factors

There has been growing interest in economic evidence. Although our app is funded by a government project and is completely free for the public to use, the economic status could still potentially influence the use of mobile communication. However, there is a lack of uniform standards to evaluate the economic outcomes, and cost-effectiveness analysis is still insufficient [45,46].

Limitations

In this study, we developed a novel and effective smartphone-based app that can decrease patients' prescription-deviating behaviors during treatment. One strength of this study is the large sample size of the included patients. There are several other potential limitations of this study. First, as a retrospective study, there may be a selection bias among patients. Thus, a prospectively designed study is warranted to validate the influence of this app on patient adherence and long-term survival. Second, there is still a lack of standard methods for evaluating adherence. Further efforts are needed to achieve consensus in the assessment of compliance, including time, frequency, and detection method. Third, the economic status of patients was difficult to assess in this study, which may have greatly influenced the results. Tailoring appropriate criteria to evaluate the financial situation of patients should be considered in the future. Last but not least, the follow-up time is still too short for some of the patients right now because they have not completed adjuvant endocrine therapy for at least 5 years, and the results of continued follow-up are worth expecting. There were also some points that deserve consideration in the development of health care–related apps. First, standardized quality measures for medical apps are lacking, and corresponding scales or rules should be developed. The apps should be comprehensively measured and rated by medical workers, software engineers, and users to improve the quality of apps. Second, the economic impact and long-term effectiveness of apps should be constantly tracked, and novel features warrant consideration to meet patients' needs and ensure user engagement.

Conclusions

We included a large number of patients with early-stage breast cancer within the MDT discussion and found that treatment adherence was independently associated with smartphone-based app use, which can serve as a useful intervention to improve patient compliance with MDT. Prospective studies are needed to validate the effectiveness of smartphone-based full-course management apps in improving patient outcomes to integrate this app into routine MDT clinical practice for breast cancer.

Acknowledgments

The authors would like to thank Yidong Du for her significant contribution to the data input, management, and follow-up. This work was funded by financial support from the National Natural Science Foundation of China (81772797, 82072937) and Shanghai Municipal Education Commission–Gaofeng Clinical Medicine Grant Support (20172007).

Authors' Contributions

JY and XC contributed to the conception and design of the study; JW and OH organized the database; JY performed the statistical analysis and wrote the first draft of the manuscript; KS and XC contributed to manuscript revision and funding acquisition, and they read and approved the submitted version.

Abstract

Background: Supporting healthy lifestyle changes is a key aim of cardiovascular and pulmonary rehabilitation programs. SMS text messaging programs have demonstrated effectiveness in cardiovascular disease risk reduction, weight loss, increasing physical activity, and smoking cessation. The optimization of SMS text messaging programs may deliver greater population benefits as mobile phone use becomes ubiquitous. Visual messaging (ie, image-based messages) has the potential to communicate health messages via digital technology and result in enhanced engagement.

Objective: This study aims to determine and understand patient preferences for lifestyle-focused visual text messages that support cardiovascular and pulmonary rehabilitation.

Methods: A discrete choice experiment was conducted in a 4-stage iterative process to elicit patient preferences for visual message features. Attribute and level development yielded 3 attributes (purpose, image type, and web address), and 16 choice sets were subsequently constructed according to a full factorial design. Patients participating in cardiovascular and pulmonary rehabilitation were surveyed (on the web) for their preferences regarding the visual message choice sets. Respondents were asked to choose among 16 pairs of visual messages regarding key lifestyle behaviors, namely, physical activity and nutrition. The data were analyzed using a conditional logit model.

Results: There was a total of 1728 observations from 54 unique respondents. Two factors that were associated with patient preference were gain-framed purpose compared with no purpose (odds ratio [OR] 1.93, 95% CI 1.40-2.65) and real images compared with cartoon images (OR 1.26, 95% CI 1.04-1.54). A loss-framed purpose was less preferred than no purpose (OR 0.55, 95% CI 0.42-0.74). Overall, patients preferred positive images that were colorful and engaged with text that supported the image and had a preference for images of real people rather than cartoons.

Conclusions: A discrete choice experiment is a scientific method for eliciting patient preferences for a visual messaging intervention that is designed to support changes in lifestyle behaviors. SMS text messaging programs that use visual aids may result in greater patient satisfaction by using a gain frame, using real images, and avoiding a loss frame. Further research is needed

to explore the feasibility of implementation and the health and behavioral outcomes associated with such visual messaging programs.

Introduction

Background

Noncommunicable diseases (NCDs) are the leading cause of disease burden worldwide [1]. Two major NCDs—cardiovascular disease (CVD) and chronic respiratory disease—have negative impacts on quality of life [1], health care costs [2], and worker productivity [3,4]. NCDs are generally defined by their persistent effects on health, which require long-term management [5]. NCD disease burden is largely manageable by addressing the following four key modifiable risk factors: tobacco use, alcohol misuse, physical inactivity, and diet [5]. Chronic disease management programs, also known as rehabilitation, offer group exercise and education sessions with the aim of improving key modifiable risk factors [6,7]. The benefits of both cardiac and pulmonary rehabilitation are well evidenced, which include reduced mortality, improved quality of life, and reduced hospital admissions [7,8]. However, uptake and attendance rates are poor, estimated to be between 10% and 30% globally [9,10] because of logistical barriers of time and distance [11,12].

The rapid advancement of mobile technology presents an opportunity to increase participation in existing rehabilitation programs and support self-management. There are >4.7 billion mobile phone users worldwide [13], and SMS text messaging has become an inexpensive and simple way for people to communicate. Strong evidence supports the effectiveness of SMS text messaging interventions to promote smoking cessation [14], weight loss [15], and increased physical activity [16]. A randomized controlled trial is currently underway to evaluate the effectiveness of a text message support program for patients with CVD and chronic respiratory disease [17]. This is based on a previous randomized controlled trial, the Text Me study, which showed that a lifestyle-focused SMS text messaging intervention was effective in improving cardiovascular risk factors in patients with coronary heart disease [18]. Given that visual aids have been found to enhance the engagement and understanding of health messages [19], it is possible that a visual messaging program could demonstrate similar, if not better, outcomes to previous SMS text messaging interventions for different populations; however, this is a relatively unexplored area. Researchers have explored the application of visual aids in technologies aimed at healthy behavior change, such as websites [20,21] and mobile apps [22-24]. However, there is a paucity of research investigating how visual aids may look like in a mobile messaging format. To the best of our knowledge, only one other study [25] has examined whether visual-based mobile phone messages could be used to support healthy lifestyle behavior change. However, this was tested in a cohort of young, healthy university students with no chronic disease, and the messages were stylistically simple. Therefore, we explored the feasibility of an infographic-style visual message containing both images and text. As an infographic-style visual message is made up of many characteristics (eg, color, type of image, and intention), we also investigated patient preferences with regard to the differing characteristics of this specific format. This project, which explored the use of visual aids in mobile messaging, represents a novel expansion in the growing field of persuasive health technology, which aims to use technology to support positive behavior change [26].

Understanding patient preferences regarding various aspects of SMS text messaging interventions is important for improving them. Qualitative methods such as focus groups are commonly used to gather patients' perspectives, as used by the authors of the Text Me trial to investigate why participants found the intervention useful [27]. These methods are robust; however, when trying to understand what patients like and dislike about certain features of infographic-style visual messaging (ie, whether they prefer this type of image over another), alternative methods may be better suited. For example, one SMS text messaging intervention used a quantitative method called a discrete choice experiment (DCE) to elicit patient preferences for various aspects, such as the frequency of messaging [28]. DCEs are a quantitative survey method and have been used to measure patient preferences for health care services and products [29]. DCEs define health care products and services by their attributes (ie, characteristics), where each attribute has various levels. For example, one attribute of a health care product could be price, and its levels could be US $1, US $2, and US $5. DCEs then present respondents with a choice set containing 2 or more alternatives to choose from, where each alternative is described by a different attribute-level combination. When a respondent chooses an option, their preferences for certain attributes can be estimated, and the relative weighting of attributes can be calculated [30]. Although this is a robust preference elicitation method, no DCEs to date have been used to explore the preferences for visual messaging in a population of patients with CVD and chronic respiratory disease.

Objectives

Therefore, the overall aim of this study is to understand the preferences of patients with CVD and chronic respiratory disease for lifestyle-focused visual-based messages.

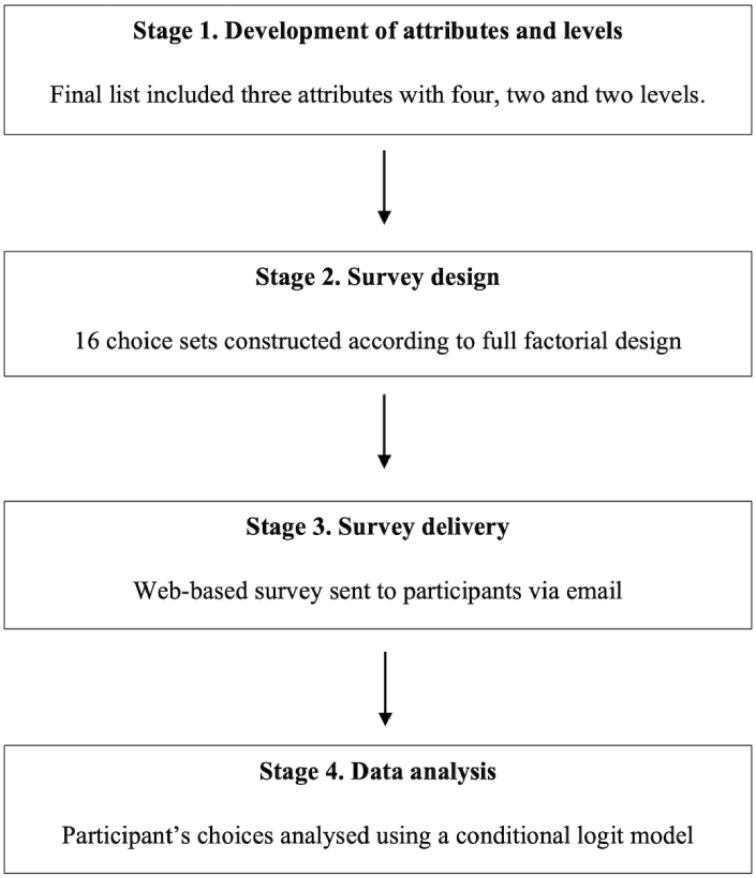
The first objective is to determine which visual messaging attribute levels were preferred by patients with CVD and chronic respiratory disease using a DCE. The second objective is to explore the reasons why patients preferred or not preferred certain visual messages using a single open-ended question.

Methods

Study Overview

This study was conducted as part of the process evaluation component of an integrated text messaging (ITM) study [17]. Ethics approval was obtained from the Ethics Review Committee of the Sydney Local Health District (HREC/16/RPAH/362), Sydney, Australia. To address the first objective of determining which visual messaging attribute levels influenced participants' choices, a DCE was conducted. This DCE followed the ISPOR (International Society for Pharmacoeconomics and Outcomes Research) guidelines on conjoint analysis methods [31]. The following stages were conducted and are described in the following sections: (1) the development of attributes and levels, (2) survey design, (3) survey delivery, and (4) data analysis (Figure 1). For addressing the second objective of exploring the reasons why certain visual messages were preferred or not preferred over others, a single open-ended question was asked after each choice set. This is described in the final section of the *Methods* section.

Figure 1. The four stages of the discrete choice experiment.



Stage 1: Development of Attributes and Levels

The development of attributes and attribute levels was carried out in two steps. First, a list of potential attributes was generated by examining the literature and discussing with experts from SMS text messaging interventions (AT, JR, and RR) [32,33]. Eight attributes were identified on the basis that patients might find them preferable: education (simple steps on how to perform a behavior) [28], framing (explaining the positive or negative outcomes of performing a behavior) [34-36], call to action (a command to perform a behavior) [37], testimonial (stories of similar people performing certain behaviors), color, mood (the overall emotional feeling), URL (a link to a web address), and a credibility indicator (acknowledgment of information as coming from a credible source) [28]. After the attributes were identified, they were reviewed independently by the research team (AT, JR, and RR), and their suggestions were then incorporated into the revised list of attributes and levels. Following DCE guidelines [29], which recommend no more than 6 attributes to minimize survey burden, we combined similar defined attributes. For example, the *URL* and *credibility* attributes were combined into a new attribute, *URL to a credible source*, because the internet site used was of high quality. Where attributes could not be combined together, they were redefined as attribute levels. For example, the attributes *color*, *mood*, and *framing* were redefined as levels *gain-frame* and *loss-frame* underneath a new attribute called *purpose*. A visual message with the *gain-frame* attribute level was specified by bright, saturated colors to create a positive mood and contained text explaining the benefits of performing the health behavior. On the other hand, a visual message with the *loss-frame* attribute level was specified by dark, unsaturated colors to create a negative mood and contained text explaining the losses of not performing the health behavior. The final list of attributes and levels derived from this iterative process is outlined (Textbox 1).

Textbox 1. Included attributes and levels of this discrete choice experiment.

Message purpose

- None (no additional information)
- Educational (simple instructions for performing health behaviors)
- Gain-frame (benefits of health action are explained)
- Loss-frame (losses of not performing health action are explained)

Image type

- Not real-life images (eg, cartoons, icons, and stick figures)
- Real-life images (eg, real-life people, objects, and places)

URL link

- Without (no web address provided)
- With (web address provided)

Stage 2: Survey Design

Given the small number of attributes and levels (3 attributes at 4, 2, and 2 levels), we decided to use a full factorial design consisting of 16 choice sets. However, no orthogonal array was available to fit this design, and so, the *idefix* package (Rstudio Inc v3.6.0) [38] was used to generate an appropriate survey design that randomized and balanced the various attribute-level profiles. The result was a DCE design with a DB-error (Bayesian D-error) efficiency of 0.4%. Once the survey design was specified, visual messages were crafted according to the required attribute-level combinations of each choice set. The content of the visual messages was sourced from the original SMS text messages developed for the ITM study (developed based on the published process) [17,39] along with stakeholder websites. The ITM SMS text messages themselves were developed based on the behavior change taxonomy of Michie et al [40]. Therefore, our visual messages were directly adapted from these original ITM SMS text messages. The first 8 choice sets centered around the message *go walking*, and the latter 8 centered around *eat healthy*. Visual messages were constructed according to the level specified for each attribute. For example, for the attribute levels *educational*, *nonreal*, and *with URL*, the actions required to follow the proposed health behavior would be explained, a cartoon image would be inserted, and a URL link would be attached (Figures 2 and 3). Similarly, for the attribute levels *gain-frame*, *real image*, and *without URL*, a real-life photograph would be inserted, and bright saturated colors would be used to emphasize the benefits of taking that certain health action (Figures 2 and 3). Different variations in font, sizing, and layout were considered for each visual message. After an iterative design process for refinement, 32 visual messages were selected. Each choice set was preceded by the question stem "If you were going to improve your diet or your level of physical activity, which visual message would you prefer to receive?"

Figure 2. Example of a choice set from the discrete choice experiment survey.

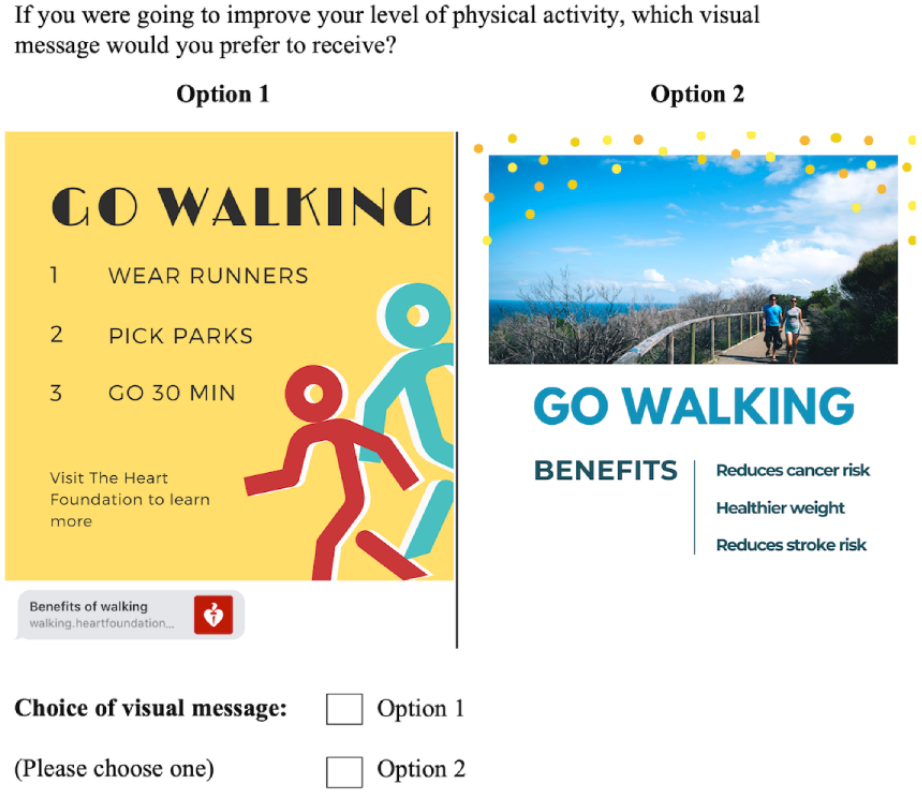


Figure 3. Example of a "go walking" choice set from the discrete choice experiment survey.

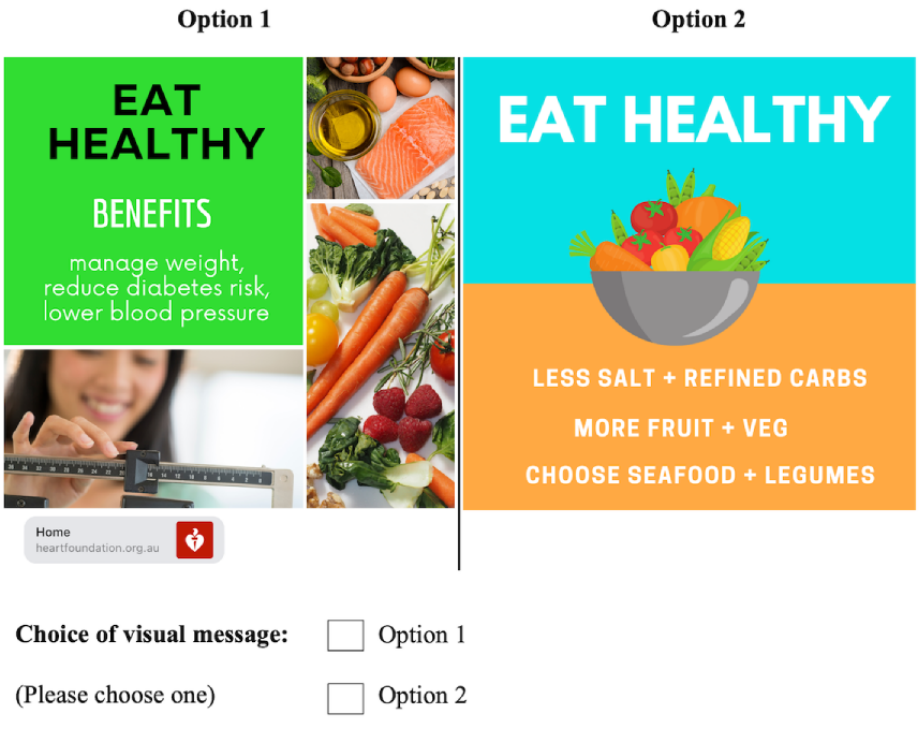


Stage 3: Survey Delivery

Before the delivery of the web-based survey to participants, it was pilot tested among the research team. The aim was to explore the acceptability of the DCE survey, the time taken to complete it, and the ease of understanding. Once refinements were made, a link to the web-based survey was sent to 141 participants via their nominated email address. These participants had already been recruited as part of the ITM study [17]. Eligible respondents consisted of adults with a medical history of CVD (including coronary heart disease, cardiomyopathy, peripheral arterial disease, and stroke) or chronic respiratory disease (chronic obstructive pulmonary disease, chronic bronchitis, emphysema, chronic asthma, and bronchiectasis). These participants were recruited from 6 rehabilitation clinics across Sydney, Australia. Eligible respondents were identified by clinical rehabilitation staff and invited to participate in the ITM study. Participants provided informed consent to participate in message feedback and improvement. Of the 141 participants, 54 (38.3%) people responded to the survey. Out of the 54 respondents, 6 (11%) respondents did not fully complete all questions.

Stage 4: Data Analysis

Overview

Data analysis was informed by the ISPOR guidelines on appropriate statistical methods for DCEs [41]. Analyses were performed using SAS v9.4 (SAS Institute). Patient characteristics were summarized as mean and SD for continuous variables and number and percentage for categorical variables. To analyze the DCE, a conditional logit model, also known as McFadden's choice model [42], was used, and odds ratios (ORs) and 95% CIs were estimated. The conditional logit model is based on the random utility theory, which states that choices are made because they bring utility to the individual [43]. It was assumed that the patients would choose the visual message (1 or 0) that maximizes their utility depending on the attributes. This was formulated as follows:

$$U\ (1,\ 0) = \beta_1\ educational + \beta_2\ gain\text{-}frame + \beta_3\ loss\text{-}frame + \beta_4\ real\ image + \beta_5\ URL + \quad \textbf{(1)}$$

Single Open-ended Question

For addressing the second objective, participants were asked an open-ended question to explore the reasons why certain visual messages were chosen or not chosen over others. After each choice set, participants were asked, "What did you like or dislike about the visual message you have chosen?" Participants typed their responses in a free text box (Figures 2 and 3). An inductive thematic analysis was conducted to analyze these responses [44]. First, the research team familiarized themselves with the data by reading through the responses. Second, a set of initial codes was generated, and each response was tagged with one or more of these codes. As this was an iterative method, new codes were added as new elements came up in the data. Next, the codes were grouped under themes, which were defined as patterns that describe something significant or interesting about the data. These themes were then reviewed, and definitions were developed. Overlapping themes were separated, and subthemes were developed. The interactions between themes were also examined.

Results

Overview

We received 54 surveys that resulted in a total of 1728 observations.

Respondent Characteristics

Most of the study sample (mean age 69.7 years, SD 8.7) was male (34/54, 62%), was of White ethnicity (43/54, 84%), and was diagnosed with CVD (32/54, 59%; Table 1). The median level of education in the cohort was diploma certification.

Table 1. Baseline demographic and clinical characteristics (N=54).

Demographic	Values
Age (years), mean (SD)	69.7 (8.7)
Gender, n (%)	
Men	34 (62)
Women	20 (37)
Ethnicity[a,b], n (%)	
White	43 (84)
Aboriginal or Torres Strait Islander, Chinese, Japanese, Malay, South Asian[c], Arab or Persian, Black African, Sub-Saharan African, or Native American Indian	6 (12)
Other	2 (4)
Education[a,d], median (IQR)	5.0 (4.0-7.0)
Clinical disease type, n (%)	
Diagnosed with CVD[e]	32 (59)
Diagnosed with chronic respiratory disease	22 (41)

[a]As baseline data were collected from previous medical records, we collected all available data at the time of extraction.

[b]Ethnicity data were only available for 51 participants.

[c]Bangladesh, India, Nepal, Pakistan, or Sri Lanka.

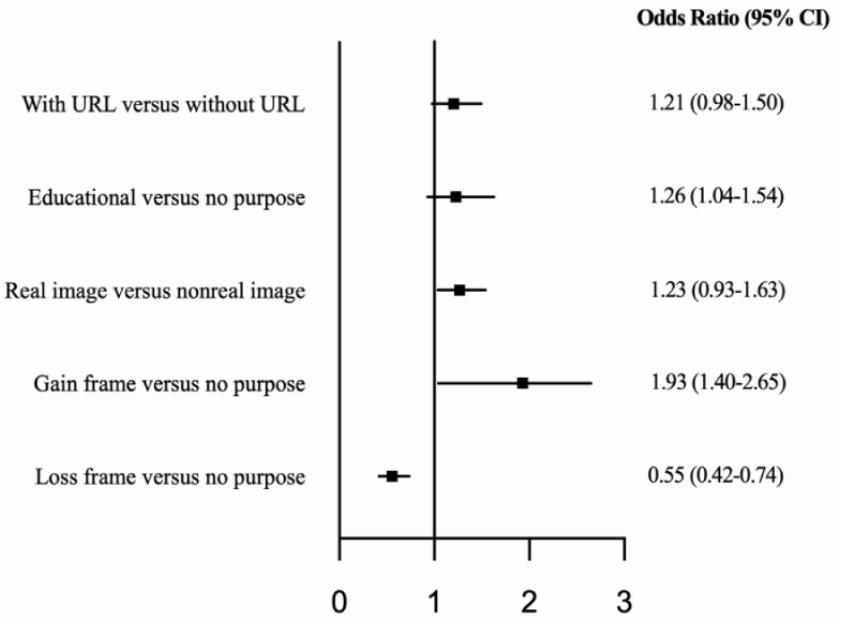
[d]Education data were only available for 51 participants.

[e]CVD: cardiovascular disease.

Visual Messaging Attribute Levels That Influenced Preferences

As per the first objective, a DCE was used to determine which visual messaging attribute levels influenced preferences. According to the conditional logit model, the following three attribute levels significantly influenced participant preferences: a gain frame, a loss frame, and real images. Visual messages with a gain-framed purpose were approximately 93% more likely to be chosen over messages with no specific purpose (OR 1.93, 95% CI 1.40-2.65; Figure 4). Conversely, visual messages with a loss-framed purpose were approximately 45% less likely to be chosen than messages compared with no purpose (OR 0.55, 95% CI 0.42-0.74). Visual messages with a real image were 26% more likely to be chosen than messages with a nonreal image (OR 1.26, 95% CI 1.04-1.54).

Figure 4. Attribute levels of visual messages, which influenced participant choice.



Reasons for Choosing Certain Visual Messages

As per the second objective, an open-ended question was asked after each choice set to explore the reasons why certain visual messages were preferred over others. The inductive thematic analysis resulted in the following six themes and subthemes: positive emotions (positivity, healthy, and cheerfulness), visual appeal (colorful, engaging image, high brightness, and high contrast), ease of understanding (clarity, large font, relationship between image and message, and concise), usefulness (benefits explained, informative, encouraging, and URL link), image reality (natural beauty, real people, and real food), and disliked features (forced to make a choice, irrelevant, condescending, negative emotions, and ignoring mental health). Illustrative quotations are provided in Table 2, and the conceptual patterns and relationships among the themes are shown in Figure 5.

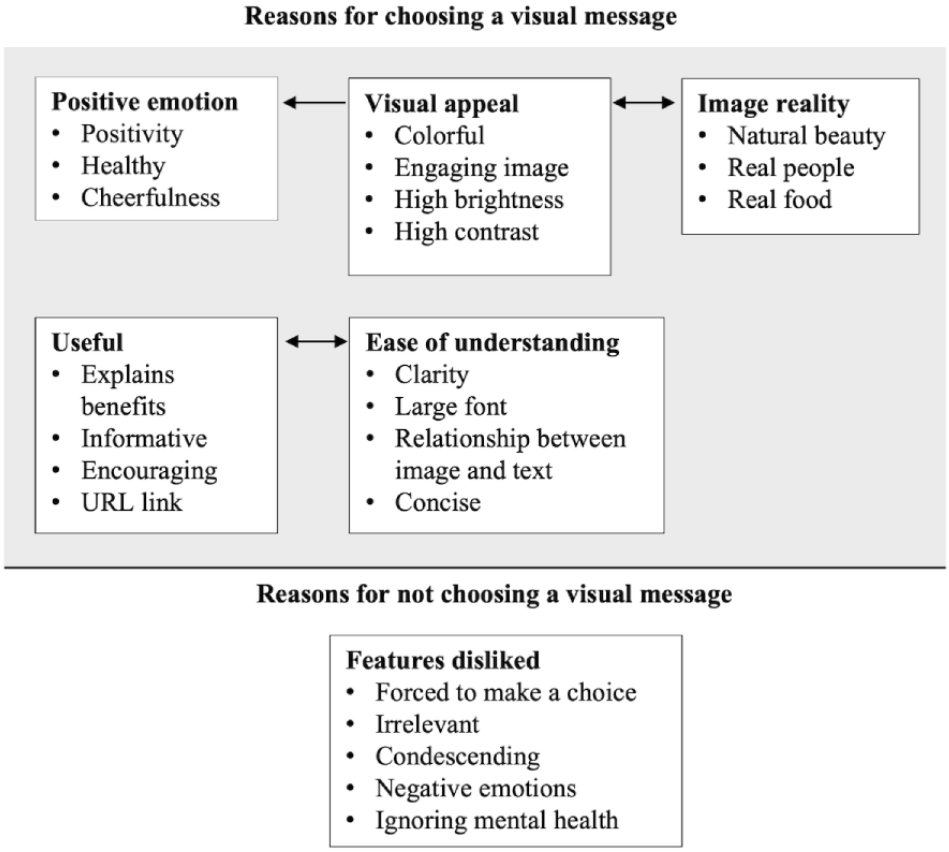
Table 2. Illustrative quotations of what participants liked and disliked about the visual messages.

Theme	Quotations	Participant characteristics (gender, age, and disease type)
Positive emotions		
Positivity	"Stands out with a more positive vibe."	Male, 56 years, COPD[a]
Cheerful	"Much cheerier–colour probably."	Female, 66 years, CVD[b]
Visual appeal		
Colorful	"Bright colours encourage people to look, read and absorb idea."	Male, 53 years, CVD
Engaging image	"Photo of good-looking food makes me want to eat better."	Female, 57 years, COPD
Ease of understanding		
Simplicity	"Clear. Easy to read."	Male, 29 years, CVD
Relationship between image and message	"Photos supported text clearly and effectively. Good clear message."	Male, 48 years, CVD
Usefulness		
Benefits explained	"It explains what the things [benefits] that you can get from walking."	Male, 43 years, COPD
URL link	"Links to Heart Foundation [website]."	Male, 36 years, CVD
Image reality		
Nature images	"The real outdoor picture instantly draws you to a feeling of health, fresh air and sunshine."	Female, 42 years, COPD
Real people	"I'd rather see photos of people than cartoonish drawings. The other option is very unattractive!"	Female, 66 years, CVD
Features disliked		
Forced to make a choice	"Neither is that good. Need to give reason rather than lecture or order exercise."	Male, 56 years, CVD
Condescending or offensive tone	"Both are terrible assuming people are idiots."	Female, 57 years, CVD
Negative emotions	"Yet again try to stay away from negative images."	Male, 40 years, CVD

[a]COPD: chronic obstructive pulmonary disease.

[b]CVD: cardiovascular disease.

Figure 5. Illustrative quotations of what participants liked and disliked about the visual messages.



Discussion

Principal Findings

To our knowledge, this is the first study to examine the preferences of patients with CVD and chronic respiratory disease for varying characteristics of lifestyle-focused visual-based messages to be sent digitally. As per the first objective, this study used a DCE to determine whether 3 visual messaging attribute levels significantly influenced participant preferences: gain frame, loss frame, and real images. As per the second objective, this study analyzed the responses to a single open-ended question and discovered the reasons for choosing or not choosing certain visual messages. The reasons for choosing a visual message included positive emotion, visual appeal, image reality, ease of understanding, and usefulness. The reasons for not choosing a visual message included irrelevant information, condescending tone, and negative emotions. These findings have important design implications for infographic-style health messages, suggesting that gain-framed messages with lifelike photos are likely to be well received by patients with CVD and chronic respiratory disease.

Comparison With Prior Work

This study found that framing had a strong influence on participants' preferences; gain-framed messages were liked, and loss-framed messages were disliked. This proclivity toward gain framing and aversion to loss framing is a well-known phenomenon reported in the health communication literature. It is unclear why framing effects occur. Therefore, understanding how framing can effect preferences may inform future implementation of visual messaging programs. It has been suggested that the framing effect depends on the type of behavior being communicated. For example, Rothman and Salovey [45] discovered that gain-framed messages are more effective than loss-framed messages in promoting disease-preventing behaviors. In support of this idea, a meta-analytic review of 94 studies demonstrated that gain-framed messages were slightly more effective than loss-framed messages in promoting disease-preventing behaviors [46]. Rothman and Salovey [45] also discovered that loss-framed messages were more effective than gain-framed messages in promoting disease-detecting behaviors. They proposed that this occurs because of prospect theory [47], which states that people will be risk averse when considering actions with guaranteed benefits and risk seeking when considering actions with potential losses. In this study, two disease-preventing behaviors (walking and healthy eating) were communicated to participants, and it was found that gain-framed messages were preferred. In line with the work of Rothman and Salovey [45], we suggest that the observed framing effect is because of the fact that the behaviors being promoted are disease preventing and that if they were disease-detecting behaviors, then loss-framed messages would be preferred over gain-framed messages. Therefore, when incorporating framing appeals into health messages, it is important to consider what type of behavior is being advocated so that the message is well received by participants.

Another line of research has proposed that framing effects may depend on the individual's disposition. For example, Covey [48] suggested that framed messages that are congruent with

an individual's motivation are likely to be preferred, that is, gain-framed messages are more persuasive when the recipient is reward oriented, and loss-framed messages are more persuasive when the recipient is threat aversive. It is unknown what the motivational status of this population is, although some evidence suggests that the patients undergoing cardiac rehabilitation are likely to be threat aversive as they have undergone a major coronary event and would want to avoid it again in the future [19]. In that case, the findings of this study contradict the findings of Covey [48]; however, this is difficult to tease out, as we do not know whether this population is threat aversive or reward oriented. Therefore, it is unknown whether the framing effects in this study are mediated by the disposition of the participants. Future research is needed to test whether the motivational status of people with chronic diseases might mediate framing effects.

In discussing framing effects, one study found little impact because of message framing. Niu et al [25] examined the impact of framed SMS text messages on encouraging healthy eating practices. They discovered that participants' cognitive responses did not differ between gain-framed and loss-framed messages, that is, there was no observable difference because of framing. However, there are at least 3 factors that may explain the discrepancy in findings between this study and the study by Niu et al [25]. First, the studies had different aims; this study sought to understand one's choices, and the other examined one's cognitive processes. Second, different methodologies were used; this study used a DCE, and the other study used a questionnaire. Finally, the samples were different demographically and clinically; this study examined an older cohort with chronic disease, and the other study examined a group of young, healthy undergraduates. These three factors may explain why this paper discovered a strong response to framing and why Niu et al [25] saw virtually no response to framing.

Although framing was an influential design attribute, there were other factors that may have accounted for the large difference in preferences for gain-framed and loss-framed messages. For example, certain colors may have attracted some respondents to that particular visual message. In this DCE, bright saturated colors were used when designing gain-framed messages. In contrast, dark colors were used when designing loss-framed messages. The purpose of the color was to accentuate the respective gains and losses that the supposed action would bring. Color, hue, and saturation preferences have been demonstrated [19,49], which may have influenced the participants' choices. The findings of the thematic analysis support the idea that messages with positive colors are preferred. Therefore, the strong preference for gain-framed messages was likely influenced by the use of positive colors.

Our results highlight that adapting messages into a digital visual format requires the consideration of several design features. For example, the use of images is a key design feature. As the digital age advances, capturing and communicating photographs will become easier and can be used in mobile health (mHealth) interventions. Although it is understood that visual media can impact the processes leading to behavior change [19,25], no studies to date have examined whether the type of image might have a different impact. This study found preferences for real images over nonreal ones in a population of cardiac and pulmonary rehabilitation patients. It is known that photos of people are powerful, persuasive tools as viewers can establish a relationship with the subject [50,51]. They elicit immediate emotional reactions that can affect their behavior. The effects of visual images on behavior change have also been reported when there are demographic similarities between the subject in the photograph and the viewer [52]. It is unknown whether this effect also applies to patients with chronic diseases. Future studies can examine whether visual image tailoring may influence the reception of visual messages.

Text is another important element of visual messages. In this study, we paired brief textual information with images. In general, participants preferred these messages to messages with no text as the text explained the visual message of the photo in a manner that was simple and easy to understand. This finding adds to the current understanding of effective infographic-style health messages. In fact, simplicity as a design principle has been identified as an important factor influencing user acceptability of mHealth technologies in patients with CVD [53]. However, messages that were too simplistic and contained no textual information were generally disliked. Instead, what patients seemed to prefer was a textual message that gave meaning to the visual aid in a clear and concise way. Factors such as font sizing, colors, layout, and positioning all contribute to how the text in a visual message is perceived and should be carefully considered to maximize clarity.

An interesting feature (further research to evaluate) used in this study's visual messages was a URL link. The purpose of this was to act as a means for people to pursue more information. The presence of the URL link also serves as a credibility indicator. The addition of a URL link is a benefit of SMS text messaging as a communication modality. Not only can respondents see the website address, but those with internet capabilities are also able to follow the link immediately and view the website's information. The findings from this study were aligned with those of past studies examining the role of visual aids in supporting chronic disease education. Visual aids have been used across a variety of formats, including print materials, websites, and mobile apps, to support the education of patients with CVD and chronic respiratory disease [20,22,24,54-57]. However, it is unknown whether visual-based messages can be used. The findings from this study suggest that there is great potential for visual messages that combine real images with a simple lifestyle-focused message to be well received by patients undergoing chronic disease rehabilitation.

The strength of this study lies in its DCE methodology. DCEs have many advantages over traditional surveys in eliciting preferences. First, DCE is an accepted survey method. The benefit is that best practice guidelines were able to be followed both in experimental design and also in statistical analysis [31,41]. Although the DCE originated in economics [30] and has been widely used to determine preferences for health services and products [29], this is the first instance of a DCE being used to explore the preferences for visual messaging. This only highlights the versatility of a DCE and its future potential to be used more widely in examining patient preferences in the field of mHealth interventions.

Another key advantage of DCE is its quantitative analysis. Rather than using a traditional questionnaire that yields qualitative results, DCE can measure preferences [29]. Of course, learning about patient preferences is enhanced by both qualitative and quantitative methods. In fact, qualitative methods such as focus groups are highly recommended when developing an initial idea of attributes, which the target population may care about [33]. The full power of the DCE is realized when the attributes are numeric. This allows for powerful analyses, where choice can be graphed as a dependent variable of attribute variables. However, in this study, the attributes were categorical variables (message purpose, image type, and URL link); thus, this type of analysis was not possible. Nevertheless, quantitative results were obtained in the form of an OR, allowing the relative size of the attributes to be ascertained.

DCE is also a robust method, as it indirectly measures preferences. Participants were asked to choose the message they preferred but not directly told of the different attributes that comprised each message. This reduced participants' bias, as they have to consider which message they actually prefer by comparing the two. Alternative preference elicitation methods could have also been used. For example, multiprofile best-worst scaling is a method in which the participant is asked to rank several choices from best to worst [58]. A variant of this method is single-profile best-worst scaling, in which a participant is presented with a single option and asked to state the best and worst aspects. Therefore, the DCE is a robust quantitative method that holds great potential for future studies on patient preferences for mHealth interventions.

Limitations

One of the limitations of this study was the lack of a no-choice alternative. Participants were offered to choose between two visual messages with no choice to opt out. This is an important limitation as thematic analysis of the free text responses revealed that some participants did not like either visual message, suggesting that they would have likely chosen the opt out if it was offered. In choice sets where there was no clear preference for the participant, an opt out would improve the validity of the results and better reflect their preferences. Therefore, future DCEs exploring patient preferences for visual messaging should use a no-choice alternative.

Another limitation of this study was that some attributes might have been missed in the DCE. Attribute selection is an important step in running a DCE [31]. However, as DCEs work best when focusing on only a few attributes, other attributes may have been excluded from the survey. Therefore, there may have been attributes that influenced patient preferences but were not tested in the DCE. To ensure that all attributes are captured in the survey, it is useful to use qualitative methods, such as focus groups and interviews [33]. Owing to COVID-19, these face-to-face qualitative methods were not possible, limiting the scope of possible attributes that this DCE could have examined. In the future, given the uncertainties of the current health situation, we would like to conduct qualitative interviews over the phone or via videoconferencing to obtain valuable participant input in the development of visual messages.

In relation to the design of the visual messages, although they were developed using a systematic and iterative process, we did not pilot test them before seeking consumer feedback. Therefore, we have identified this as a limitation and, in the future, would like to test different variations of font, sizing, and layout to determine optimal combinations. In relation to the 87 participants who were sent the survey link but did not open it, there is no way of knowing their preferences, so we cannot assume that they disliked the messages from the fact that they did not open the survey.

The fourth limitation was the number of choice sets. The DCE guidelines state that the ideal number of choice tasks is 8-16 [29]. This survey was constructed with 16 choice tasks, which were thought to be an acceptable length for respondents. However, there were a number of partially completed surveys, suggesting that there were too many choice tasks. Therefore, a shorter survey may have resulted in more completions. Instead of using a full fractional design, future DCEs should use a fractional factorial design, which will allow the number of choice tasks to be reduced so that the survey is less burdensome to participants.

The strength of the investigation was limited by the small sample size. Therefore, the results are not generalizable to a wider population of people undergoing both cardiac and pulmonary rehabilitation. The small sample size also meant that data analysis was limited. In this study, a conditional logit model was used to examine the associations between the choice outcome and the visual message attributes [42]. With a larger sample size, a different model could have been used, namely, a multinomial logit model, which examines associations between the choice outcome and demographic characteristics as well as the visual message attributes. Other DCEs have used a multinomial model to examine whether preferences are influenced by age, sex, ethnicity, income, and education [28]. Future DCEs with sufficiently large sample sizes should investigate the effect of demographics on preferences. Finally, a limitation arises from the fact that this research was an additional substudy with recruitment from the ITM trial, which was not specifically designed to test visual messages [17].

Conclusions

This study explored the preferences for lifestyle-focused visual messages in patients with CVD and chronic respiratory disease and found that message framing and image type were important characteristics. Framing was the most important factor that influenced preferences. A strong preference for gain-framed messages with real images was shown. As such, when designing visual messaging interventions for patients with chronic conditions, these attributes may influence the acceptability of messages. Owing to COVID-19 restrictions, the DCE was delivered on the web. Further research is needed to deliver visual media content using digital technology and determine whether the identified preferences actually hold. Future studies can examine the implementation of these visual messages and their effects on chronic disease rehabilitation health and behavioral outcomes.

Acknowledgments

The authors thank all of the staff and participants who supported and participated in this study and the integrated text messaging study. This work was supported by a National Heart Foundation 2015 New South Wales Cardiovascular Research Network Research Development Project grant (grant 101134). JR was supported by the National Health and Medical Research Council Career Development Fellowship (Application ID: 1143538). SRP was supported by the National Health and Medical Research Council of Australia and the National Heart Foundation Early Career Fellowship (Application ID: 1157438). KH was supported by a National Heart Foundation Postdoctoral Fellowship (Application ID: 102138).

Authors' Contributions

MC and RR managed the data collection. MC and KH conducted the data analysis and interpretation. MC, SRP, AT, and JR contributed to the conception of the study, the study design, the interpretation of the data, and the drafting and critical revision of the manuscript. All authors approved the final version of the manuscript.

Abstract

Background: Health and fitness apps have potential benefits to improve self-management and disease control among patients with asthma. However, inconsistent use rates have been reported across studies, regions, and health systems. A better understanding of the characteristics of users and nonusers is critical to design solutions that are effectively integrated in patients' daily lives, and to ensure that these equitably reach out to different groups of patients, thus improving rather than entrenching health inequities.

Objective: This study aimed to evaluate the use of general health and fitness apps by patients with asthma and to identify determinants of usage.

Methods: A secondary analysis of the INSPIRERS observational studies was conducted using data from face-to-face visits. Patients with a diagnosis of asthma were included between November 2017 and August 2020. Individual-level data were collected,

including age, gender, marital status, educational level, health status, presence of anxiety and depression, postcode, socioeconomic level, digital literacy, use of health services, and use of health and fitness apps. Multivariate logistic regression was used to model the probability of being a health and fitness app user. Statistical analysis was performed in R.

Results: A total of 526 patients attended a face-to-face visit in the 49 recruiting centers and 514 had complete data. Most participants were ≤40 years old (66.4%), had at least 10 years of education (57.4%), and were in the 3 higher quintiles of the socioeconomic deprivation index (70.1%). The majority reported an overall good health status (visual analogue scale [VAS] score>70 in 93.1%) and the prevalence of anxiety and depression was 34.3% and 11.9%, respectively. The proportion of participants who reported using health and fitness mobile apps was 41.1% (n=211). Multivariate models revealed that single individuals and those with more than 10 years of education are more likely to use health and fitness mobile apps (adjusted odds ratio [aOR] 2.22, 95%CI 1.05-4.75 and aOR 1.95, 95%CI 1.12-3.45, respectively). Higher digital literacy scores were also associated with higher odds of being a user of health and fitness apps, with participants in the second, third, and fourth quartiles reporting aORs of 6.74 (95%CI 2.90-17.40), 10.30 (95%CI 4.28-27.56), and 11.52 (95%CI 4.78-30.87), respectively. Participants with depression symptoms had lower odds of using health and fitness apps (aOR 0.32, 95%CI 0.12-0.83).

Conclusions: A better understanding of the barriers and enhancers of app use among patients with lower education, lower digital literacy, or depressive symptoms is key to design tailored interventions to ensure a sustained and equitable use of these technologies. Future studies should also assess users' general health-seeking behavior and their interest and concerns specifically about digital tools. These factors may impact both initial engagement and sustained use.

KEYWORDS

mobile apps; smartphone; patient participation; self-management; asthma

Introduction

Smart mobile technology has revolutionized how we communicate, share, and consume content, seeping into many different sectors of society, including health care [1]. With the democratization of smartphone use, with 3.8 billion smartphone users worldwide [2], the market of specific apps has experienced a boom. Often free, easy to download, and easy to use, mobile apps have an extensive application in social, educational, and entertainment fields and naturally in the fields of self-management and health behavior change [3]. According to the software application industry, around 500 million smartphone users worldwide were using a health and fitness app in 2015; and by 2018, an estimated 50% of the 3.4 billion smartphone and tablet users, including health care professionals, consumers, and patients, would have downloaded one [4]. The total global mHealth market is predicted to reach the US $100 billion mark in 2021, which constitutes a 5-fold increase from 2016 [5]. In this context, it is hypothesized that apps may become ubiquitous solutions impacting a large number of patients, often capitalizing on gamification strategies and social interaction [6]. In particular, health and fitness apps are a promising approach for improving self-management behaviors in patients with asthma, a prevalent long-term condition with potential social and economic impacts [7,8], which requires a range of self-management skills in everyday life [9]. Indeed, around 1500 mobile apps are targeting patients with asthma in both the Apple App Store and the Google Play Store [10]. A systematic review published by Unni et al [11] suggests that the use of mobile apps by patients with asthma may have benefits across a range of outcomes, including medication adherence and asthma control.

However, the current use of smart devices and apps among patients with asthma remains unexplored, as emphasized by a position paper of the European Academy of Allergy and Clinical Immunology, highlighting the lack of published studies on the use of mHealth in allergic diseases [12]. While there are more than 100 papers published over the last 5 years, they either evaluate the characteristics of specific apps (rather than their use) or focus on the impact of asthma-specific apps.

A recent study reported that smart device ownership levels in patients with asthma are similar to those of the general population, that three-quarters of patients had downloaded/used a general app, yet only one-third had ever used a health and fitness app [13]. A significant variability exists in usage among different racial/ethnic and sociodemographic groups. Nonetheless, this evidence comes mainly from studies conducted in the United States and does not address specific disease contexts [14-18]. The use of health and fitness apps in the asthma context can be explored through the lens of the conceptual model developed by Andersen et al [19], which proposes that the use of health services is driven by three dynamics: predisposing factors (eg, age and gender), enabling factors (eg, socioeconomic level, education, and literacy), and need (eg, clinical characteristics and severity of disease).

The purpose of this study is to evaluate the use of health and fitness apps by patients with asthma and to identify determinants of usage. Specifically, we will investigate the following: (1) the proportion of patients with asthma using health and fitness apps and (2) the relationships among predisposing, enabling and need factors, and using mHealth apps.

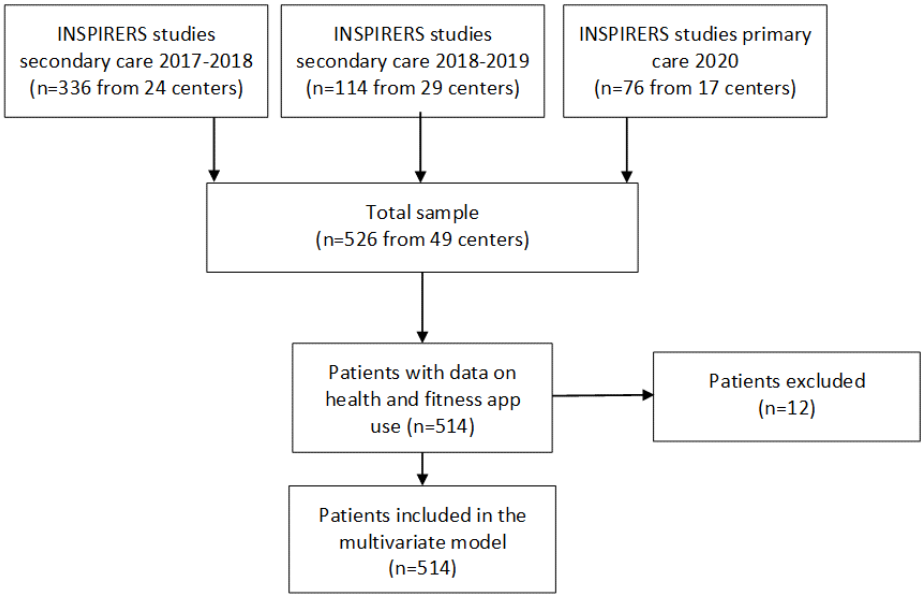
Methods

Study Design

A secondary analysis of INSPIRERS observational studies involving 32 secondary care centers (allergy, pulmonology, and pediatrics departments) and 17 primary care centers in Portugal was performed (Figure 1), as part of the INSPIRERS project. The design of the INSPIRERS observational studies was

disseminated through email contacts, social networks, and oral communications at national meetings/conferences, and physicians/centers interested in being part of the study contacted the research team. A convenience sample of adolescents and adults with persistent asthma was recruited for the INSPIRERS studies between November 2017 and August 2020. Depending on the study, each center was asked to recruit a minimum of 2-10 patients. The 3 INSPIRERS observational studies address the topic of adherence to asthma inhalers among adolescents and adults with persistent asthma (Figure 1). Further details on the project setting and methods have been previously published [20,21]. This study is reported in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines [22].

Figure 1. INSPIRERS studies flowchart.



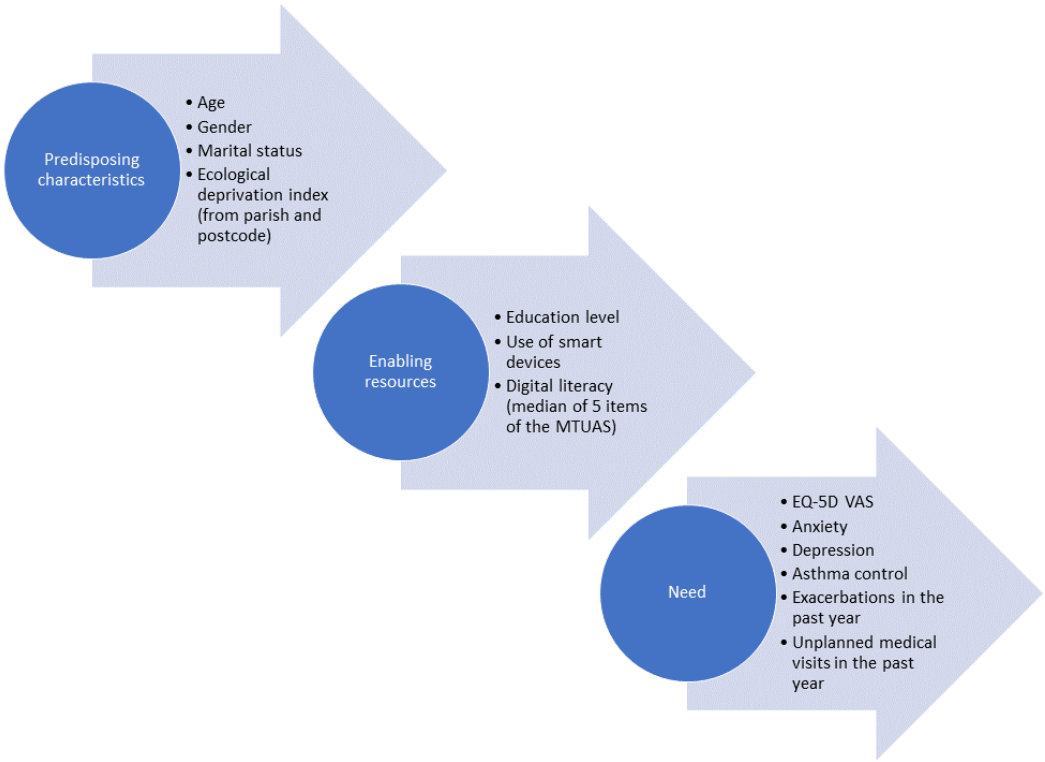
Participants and Data Collection

Data were collected using a questionnaire during a face-to-face visit. The questionnaire had a section to be completed by the physician addressing patients' asthma characteristics and a set of questions to be self-completed by the patient, as detailed below. Patients were included if they had a previous medical diagnosis of persistent asthma, were at least 13 years old, and had an active prescription for an inhaled controller medication for asthma. Patients were excluded if they had a diagnosis of a chronic lung disease other than asthma or a diagnosis of another significant chronic condition with possible interference with the study aims.

Users and nonusers were defined as individuals who answered "yes" or "no," respectively, to the question "Have you ever downloaded and used a health and fitness app?" Health and fitness apps were defined as a range of apps related to personal fitness, workout tracking, diet and nutritional tips, health and safety, etc. In accordance with the conceptual model proposed by Andersen et al [19], variables collected included predisposing factors, enabling factors, and need (Figure 2). Predisposing factors included demographic data (ie, age, gender, marital status, parish, and postcode), and enabling factors included education level, use of smart devices, and digital literacy, both collected from patients. Digital literacy was defined as the median of 5 items of the Media and Technology Usage and Attitudes Scale (MTUAS, ie, use of the GPS, browsing the web, taking pictures, gaming, and checking social networks) rated by frequency of use in a 10-point Likert scale (1=never to 10=all the time) [23]. Additionally, socioeconomic level was explored as an enabling factor, which was defined as the Portuguese ecological deprivation index, extracted from the patient residence information (civil parish/postcode), and categorized into 5 quintiles (Q1=least deprived to Q5=most deprived) [24]. Need variables included smoking status, patients' perceived overall health status (from EQ-5D Visual Analog Scale [VAS], ranging from 0 [worst imaginable health state] to 100 [best imaginable health state]) [25], the presence of anxiety or depression (cut-off≥8 in the Hospital Anxiety and Depression Subscales) [26], and physicians' input, including asthma control level (uncontrolled, partially controlled, or well controlled according to the classification of the Global Initiative for Asthma [27]), number of exacerbations (episodes of progressive increase in shortness of breath, cough, wheezing, or chest tightness, requiring a change in maintenance therapy) in the past year [28], and the number of unplanned appointments in the past year.

Age was categorized into age bands (13-18,18-30, 30-40, 40-50, 50-65, and ≥65 years). Other continuous variables (socioeconomic level, median digital literacy, and overall health status) were categorized into quartiles.

Figure 2. Variables collected included predisposing factors, enabling factors, and need according to the Andersen et al [19]. MTUAS: Media and Technology Usage and Attitudes Scale; VAS: Visual Analog Scale.



Data Analysis

Counts and proportions were calculated for each variable. Multivariate logistic regression with the Enter method was used to ascertain the determinants of being a user of a health and fitness mobile app (dependent variable) in accordance with Andersen et al's [19] conceptual model. Categorical variables, such as gender, age, marital status, educational level, socioeconomic level, use of smart devices, digital literacy, overall health status, smoking status, presence of anxiety or depression, and asthma status were explored as independent variables, irrespective of significance in preliminary univariate logistic regressions. We assessed model fit using the pseudo-R2 Nagelkerke method and tested for evidence for poor model fit using the Hosmer–Lemeshow test. In addition, to assess the increasing contribution of each covariate to the model, we adopted a stepwise approach to build models starting from 1 covariate until including all covariates in the full models. For each model, we computed the described goodness of fit statistics. The quality of the final model was also assessed using the Aikake Information Criterion. Adjusted odds ratios and 95% CIs were calculated. Statistical analyses were conducted using R and the "glm" package. The map of Portugal was created using Paintmaps [29].

Ethics Approval

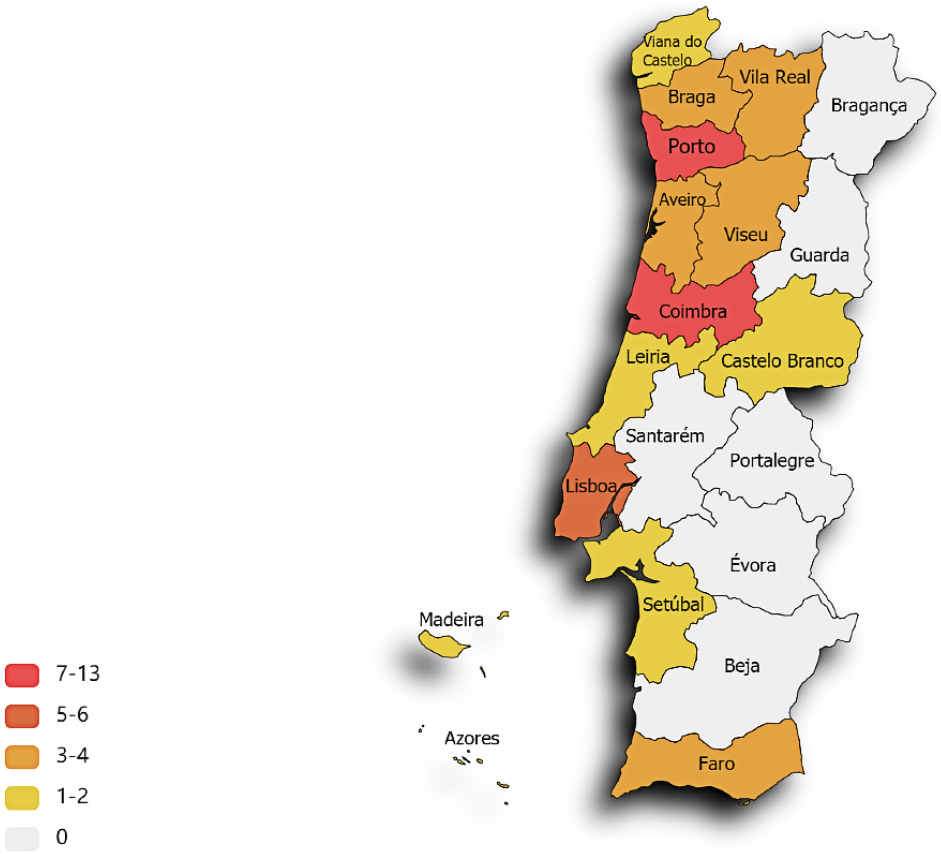
The studies were approved by the ethics committees of all participating centers. The studies were conducted in accordance with the ethical standards established in the Declaration of Helsinki. Eligible patients were approached by physicians during medical visits and invited to participate. Written informed consent was obtained before enrollment. Adult patients signed a consent form; adolescents signed an assent form and a parental consent form was also obtained.

Results

A total of 526 patients attended a face-to-face visit between November 2017 and August 2020 at the 49 recruiting centers. Of those, 12 did not answer the question "Have you ever downloaded and used a health and fitness app?" and were excluded (Figure 1). The recruiting centers included 12 of the 18 Portuguese districts, which represented 9,189,723 inhabitants (89% of the total national population) [30]. A detailed overview of the distribution of the participating centers by district is provided in Figure 3.

The majority of the subjects were ≤40 years old (66.4%, n=341) and 63.4% (n=326) were female. Most participants were single (58.0%, n=298) and had at least 10 years of education (57.4%, n=295). Approximately one-third were in the 2 lower quintiles of the socioeconomic deprivation index (29.9%, n=154). Regarding general health status, as assessed by EQ-5D VAS, 69.8% (n=359) of the participants reported a score of ≥70. Most of the subjects were never smokers (75.5%, n=388). The prevalence of anxiety and depression symptoms in the sample was, respectively, 34.4% (n=177) and 11.9% (n=61).

Figure 3. Number of participating centres per district.



Asthma was well controlled among 51.0% (n=262) of participants. While 50.8% (n=261) of participants had 1 or more asthma exacerbations during the last year, most of the participants did not have any unplanned appointments (66.1%, n=340) or inpatient admissions (94.2%, n=484). The proportion of participants who reported using health and fitness mobile apps was 41.1% (n=211). A full description of the sample, as well as the characteristics of the nonuser and user groups, is provided in Table 1.

Characteristics of both users and nonusers were explored using multivariate logistic regression. The aORs show that single individuals and those with more than 10 years of education are more likely to use health and fitness mobile apps (aOR 2.22, 95%CI 1.05-4.75, and aOR 1.95 95%CI 1.12-3.45, respectively). Higher digital literacy scores were also associated with higher odds of being a user of health and fitness apps, with participants in the second, third, and fourth quartiles showing, respectively, aORs of 6.74 (95%CI 2.90-17.40), 10.30 (95%CI 4.28-27.56), and 11.52 (95%CI 4.78-30.87). Participants with depression symptoms had lower odds of using health and fitness apps (aOR 0.32, 95%CI 0.12-0.83). No significant associations were found with gender, age, socioeconomic level, general health status, smoking status, anxiety, and asthma control (including level of control, number of inpatient admissions, or number of exacerbations). A detailed overview of the multivariate analysis is provided in Table 2.

Table 1. Characteristics of the participants according to their use of health and fitness mobile apps (N=514).

Characteristics	Nonusers (n=303), n (%)	Users (n=211), n (%)	Total, n (%)

[a]Confidence intervals could not be calculated. Reference means the category used as reference (ie, to which other categories are compared). The Hosmer–Lemeshow Test yielded a *P* value of .21, χ^2_8=10.9, Aikake Information Criterion of 542, and coefficient of determination (R^2) of 48%.

[b]Italicized *P* values are significant.

Discussion

Principal Findings

Use of health and fitness mobile apps was positively associated with a single status, >10 years of education, and higher digital literacy scores, and negatively associated with depressive symptoms. No significant associations were found with other variables, including gender, age, socioeconomic level, general health status, smoking status, anxiety, and asthma control.

Comparison With Previous Studies

According to our results, single participants are more likely to use health and fitness apps. In a recent mixed methods study, Zhou et al [18] explored the barriers to and facilitators of the use of mobile health apps and found that single users had less strong concerns about information security and privacy and less desire to have stringent security protection, which could contribute to higher usage levels in this group.

Consistent with our findings, previous studies have described educational attainment as an important predictor of use of mobile devices and apps [14-16]. However, the relationship may be more complex than initially predicted, as in another study by Carroll et al [14] where both patients with a degree and those with less than high school education were significantly associated with a reduced likelihood of using health apps. The reasons for the educational differences are not fully understood but may reflect the effect of digital skills and confidence, and social norms related to the perceived value of using health and fitness apps [16].

A significant association between digital health literacy and use of health and fitness apps was also found. Digital health literacy has been previously shown to affect the use of health apps [17]. However, comparisons between different studies are limited by the heterogeneity of tools used to evaluate patients' digital health literacy; therefore, standardization of the assessment methods used is recommended in the future. It is also important to note that although individuals with low general health literacy tend to use less health information technology [31], previous evidence has shown that tailored approaches including apps programmed with computer-animated characters, text, and graphics to provide health communication and education could be a widely accepted option for these patients [32].

Interestingly, our study found a negative association between the use of health and fitness apps and the presence of depressive symptoms. Despite the breadth of research exploring the determinants of use of mental health apps [33-35], there was a lack of evidence specifically exploring the impact of the presence of mental health symptoms on usage rates. However, several studies show that patients with depressive symptoms often exhibit poor engagement with health services, and health care avoidance [36,37], and such behaviors may also contribute to a lower interest and usage of health and fitness apps by these groups of patients. This finding opens a new research avenue, and future work should explore the drivers for this effect and should involve patients with mental health problems in the co-design of digital solutions and interventions that promote both early and sustained use. The other needed variables, such as the ones related to asthma control, were not significant in explaining mHealth behaviors, although they showed a similar trend to the one observed with the variable depression. This is in line with previous asthma mHealth studies showing that patients with worse asthma control engage less with the tested apps [15,38]. Regarding age, odds ratios were higher for patients

aged 18-30 years (1.93, 95%CI 0.97-3.89), but no significant differences were detected, despite the *P* value being close to the significance threshold (*P*=.06). Increasing the sample size in future studies could help further explore this effect and to confirm or exclude a potential type II error [39]. Previous studies found that younger adults were more likely to engage with health apps [14-16] and suggested that the effect of age likely reflects both social norms and cohort effects, such as the increased exposure to these devices and apps at younger ages [14]. Previous evidence also suggests that younger adults seem to have higher digital health literacy levels, which can contribute to increased use of digital solutions [40]. While it is recognized that the use of digital health solutions by older persons could improve patient engagement and reduce both financial burden and pressure on health systems, usage rates among this group remain low. According to a mixed methods study conducted by Fox et al, this digital health divide is deepening owing to older adults' perceived inability and unwillingness to use digital technologies, stemming from mistrust, high-risk perceptions, and a strong desire for privacy [41].

Finally, no significant associations were found with gender. Previous literature shows mixed evidence on this subject: while some studies had found a higher use among male subjects [15], others reported the opposite [14,16]. The reasons for gender differences in some samples are unclear but may reflect sample-specific differences in health-seeking behavior, and interest and participation in healthy lifestyle interventions in general.

Strengths and Limitations

This study has several strengths. It is the first national-level study performed in Portugal, evaluating the use of health and fitness apps among patients with asthma, covering the majority of the geographic regions of the country. A comprehensive set of individual-level characteristics was collected and analyzed, which allowed us to explore the impact of a range of sociodemographic factors, health literacy, and cofactors such as general health status and asthma status. Although no power calculation was performed (which was associated with the secondary analysis nature of this study), the overall large sample size contributes to the robustness of these findings.

Other limitations also need to be acknowledged. Intrinsic to the study design using convenience sampling, a potential selection bias cannot be excluded. This can possibly explain the low number of patients above 65 years of age. Nevertheless, this risk was mitigated by sampling patients from different health care settings, centers, and geographic regions. Health and fitness app use was patient-reported; therefore, a potential information bias cannot be excluded either. As an alternative, future studies could use patient log-in as a measure of app use. Furthermore, digital literacy was assessed using selected items of MTUAS scale, not the complete instrument. This choice emerged as a mitigation measure to reduce the data collection burden and allow us to efficiently collect data on an aspect seldom reported in the literature. Future studies should explore the possibility of including complete validated tools, such as MTUAS [23] or the eHealth Literacy Scale [42]. We also need to consider that although the questionnaires were independently answered by the study participants, they were provided to them by their family physicians provided during an in-person visit, which may have influenced them to give desirable responses, namely those related to their general health status and asthma control.

Finally, most subjects included in this study were relatively young, had at least 7 years of education, were in the 3 higher quintiles of the socioeconomic deprivation index, had an overall good health status, and had good asthma control. Consequently, attempts to generalize these findings to other populations that do not share the same characteristics need to be cautious. Future studies should consider involving patients with specific needs (ie, lower education attainment, lower sociodemographic levels, poorer overall health status, or poorer asthma status control) and evaluate the replicability of these findings.

Conclusions

Our results show a negative association with low literacy and the presence of depressive symptoms, highlighting the need for future research to explore the effect of disparities on app use, particularly among those with lower digital health literacy or mental health issues. Importantly, such studies should also assess participants' general health-seeking behavior (ie, interest and participation in healthy lifestyle interventions in general) and the key constructs of their acceptance the unified theory of acceptance and use of technology) [43,44]. This theory was developed through a consolidation of the constructs of 8 previous models (theory of reasoned action, technology acceptance model, motivational model, theory of planned behavior, a combined theory of planned behavior/technology acceptance model, model of personal computer use, diffusion of innovations theory, and social cognitive theory), and includes four constructs: performance expectancy, effort expectancy, social influence, and facilitating conditions. Gender, age, experience, and voluntariness of use have been suggested to moderate the impact of the 4 key constructs on usage intention and behavior [43,44].

A better understanding of which patients with asthma are (and are not) using general health and fitness apps is key to design tailored mHealth interventions to improve sustained use by this specific group of patients. Additionally, this knowledge can also inform high-level delivery strategies to ensure that these solutions reach out comprehensive groups of patients with asthma, thus improving rather than entrenching health inequities within this population.

Acknowledgments

This study was funded by the European Regional Development Fund through the following programs: POCI-01-0145-36 FEDER-029130 ("mINSPIRE—mHealth to measure and improve adherence to medication in chronic obstructive respiratory diseases - generalisation and evaluation of gamification, peer support and advanced image processing technologies") cofunded

Abstract

Background: Information and communication technologies, including mobile health (mHealth), can help isolated communities address environmental health challenges. The Puerto Rican island of Culebra has faced multiple sociopolitical and economic factors that have distressed the island's environment and health. *Culebrenses* are technologically engaged and have demonstrated a use of technology that transcends socioeconomic barriers. As a result, technological interventions could potentially help manage environmental risks on the island.

Objective: This study aims to test and evaluate the potential benefits of an mHealth tool, termed ¡mZAP! (*Zonas, Acción y Protección*), for engaging communities with environmental risks through technology.

Methods: Participants using ¡mZAP! (N=111) were surveyed. Bivariate analyses were used to examine associations of mHealth use with sociodemographics, technology use, an adapted environmental attitudes inventory, and the multidimensional health locus of control. Logistic regression was used to examine associations between attitudes toward environmental health risks and mHealth use.

Results: Higher positive attitudes toward the environment were significantly associated with the use of ¡mZAP! (odds ratio 5.3, 95% CI 1.6-17.0). Environmental attitudes were also associated with the multidimensional health locus of control *powerful others* subscale (*P*=.02), indicating that attitudes toward the environment become more negative as feelings controlled by others increase. Participants felt that the authorities would resolve the challenges (63/111, 56.7%).

Conclusions: Perceived lack of control could present barriers to collective actions to address salient environmental health challenges in communities. The ongoing dependency on government-based solutions to community problems is worrisome, especially after the hurricane experiences of 2017 (which may potentially continue to be an issue subsequent to the more recent 2020 earthquakes).

community engagement; environmental health risk; epidemiology; ICT; mHealth; mobile phone; Puerto Rico

Introduction

Background

Information and communication technologies (ICTs), including mobile health (mHealth), can help isolated communities address environmental health challenges [1,2]. The World Health Organization considers environmental risks a public health priority [3]. Social and ecological determinants of health, along with environmental health challenges, often exacerbate pre-existing health disparities [4]. Traditional health paradigms have been changed by mHealth tools to address such health disparities. For example, a study used a mobile app termed *FAITH!* (Fostering African American Improvement in Total Health) to improve cardiovascular health among an African American church community (n=86) in the United States following a multiphase community-based participatory research design [5]. Other examples include using a web-based intervention for smoking cessation among low socioeconomic status populations in the United States (n=1440) [6] and an mHealth tool to reduce health care access gaps among marginalized rural populations in Laos (n=983) and Thailand (n=1158) [7].

The benefits of using ICTs to address environmental risks following crowdsourcing approaches have been successfully implemented in the United States using the mobile phones of users [8,9]. Mobile phones are also being used to engage populations in new and innovative learning modalities [10,11]. Previous studies have shown that mobile tools such as cell phones can help users develop positive attitudes toward the environment [12,13]. Mobile tools facilitate engaging with users by using their devices (eg, smartphones and smartwatches) as part of the solution to existing environmental challenges [8,13].

Although the use of technology has transcended socioeconomics barriers, providing digital access to different levels of society, a significant gap perpetuates digital access disparities among marginalized communities worldwide [14-16].

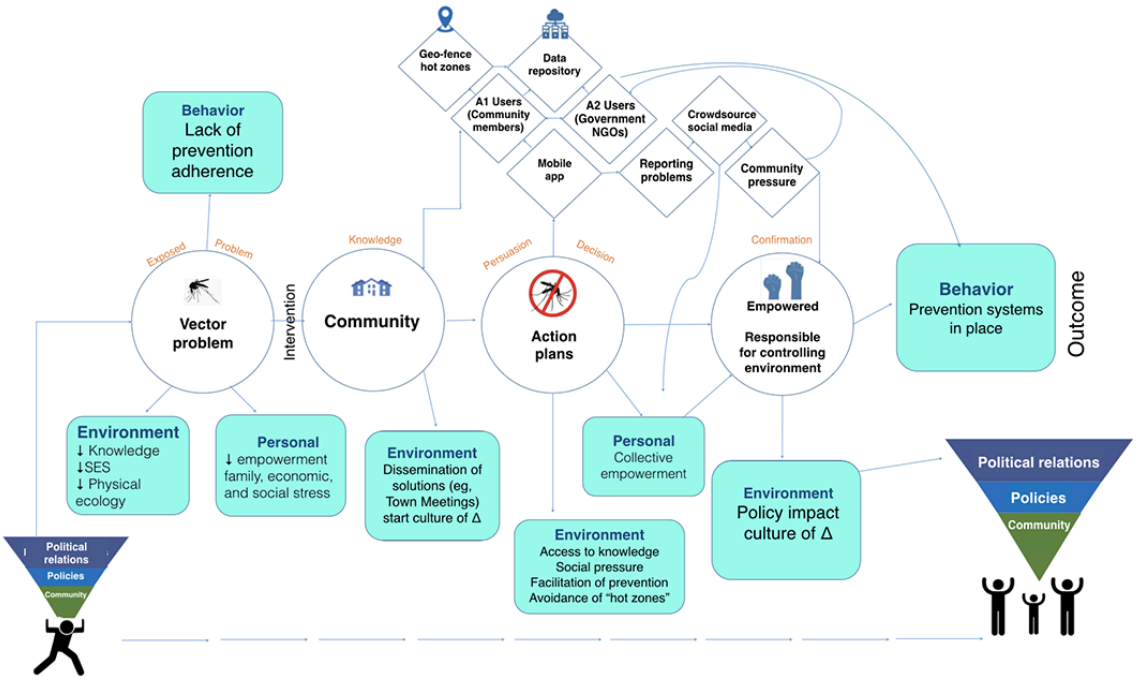
The power of being interconnected via modern technology (eg, social media, cell phones, and the internet) has been shown to (1) catalyze sociopolitical changes [17,18], (2) close the gap in physical distances [19], (3) foster the development of health advances [20], and (4) provide access to information [21]. In contrast, the use of technology has also been linked to the spread of misinformation, resulting in the exacerbation of social injustices among marginalized groups. For example, WhatsApp was used in Maceió, Brazil, to diffuse conspiracy theories about vaccines as the cause of microcephaly in children testing positive for the Zika virus [22,23]. Thus, communities often have untapped and unrecognized resources that may be mobilized to work with the government sector, health programs, and nonprofit organizations to address risks in their environments [24].

Many communities, particularly islands, are dependent on ICT to reduce the impact of their geographical and societal isolation [25]. Island communities face many social and health challenges that are not necessarily faced by other communities, which can intensify risk [26-28]. The remote island of Culebra, off the eastern coast of Puerto Rico's *Big Island* (*Isla Grande*), is geographically and systemically isolated from the rest of Puerto Rico. Culebra's isolation also results in limited political power because of the small population, leading to a system of dependency that negatively impacts health access, utilities, waste management, transportation, water safety, and air and soil contamination, which is common in rural and isolated areas [29-33].

Hurricanes Irma and María in 2017 demonstrated this dependency, with Culebra losing connection to the national electrical grid for more than a year [34] and having difficulties in resuming ferry and other island services. Although impacted by these challenges, *Culebrenses* have a strong history of collective engagement against social injustices, such as facilitating the US Navy's exit from the island in 1975 and protesting against maritime transportation policies [35]. In addition to this community engagement, *Culebrenses* are technologically engaged and have demonstrated a use of technology that transcends socioeconomic barriers [36]. As a result, technological interventions could potentially help manage environmental risks on the island.

This study was guided by a multi-theoretical framework (social cognitive theory [SCT] and the diffusion of innovations theory) which, along with community-centered design methodology, can (1) provide a model for behavioral changes and (2) guide the process to understand the adoption of this mHealth tool better [37-39]. This study also followed a human-centered design framework that provides an inclusion process whereby users are central and active agents necessary for the conception, testing, implementation, and evaluation of solutions to Culebra's environmental health risk challenges [40]. The SCT addresses behavior change and the effect of the community members' environment [41]. The SCT also helps identify community problems and priorities, allowing for an in-depth understanding of personal factors, current community behaviors, and environmental influences associated with environmental health risks that can affect community-wide behavioral change. The diffusion of innovations theory facilitates the process of development and sustainability [42]. Owing to the complexity of these two theories, a theoretical framework model titled *Community-Centered Environmental Health Risk Control Model* was developed for this study (Figure 1).

Figure 1. Community-centered environmental health risk control model. NGO: nongovernmental organization; SES: socioeconomic status.



Objective

Following this theoretically informed model facilitated the work as part of a community-driven research project to collaborate with community partners to implement a tailored, community-centered, and crowdsourced ICT termed ¡mZAP! (*Zonas, Acción y Protección*) as part of a community-driven approach to assess the ability of ICTs to engage islanders in collective environmental actions. Specifically, in this study, we evaluate the ability of psychosocial, environmental attitudes, and technological variables to predict the use of the ¡mZAP! app.

Methods

Overview

We used a prospective design to assess the ¡mZAP! app use. The study surveyed community participants at baseline to capture their perceptions and attitudes toward the environment, access to and use of technology, community actions toward environmental challenges, knowledge about vector-borne diseases, and health control in Culebra, Puerto Rico. App registrants were followed prospectively for 3 months (November 2018-February 2019) to assess the use of ¡mZAP!

The Archipelago of Culebra

Culebra is an archipelago municipality located on the east coast of Puerto Rico, 17 miles from *Isla Grande* (*Big Island*—as it is commonly referred to in Puerto Rico by the residents of outer islands; Figure 2). On the basis of the 2018 US Census annual estimates of the resident population, Culebra has an estimated population of 1500 [43]. Culebra's geographical location provides a unique, biodiverse ecosystem of drylands, mangroves, lagoons, white sand beaches, and coral reefs, all in almost 12 square miles [35,44]. Largely owing to this biodiversity and geographical location, tourism is Culebra's primary economy.

Culebra also presents another face; for many decades, this set of islands has experienced marginalization by the United States and from the local government [33,35], including military bombing drills that left unknown contamination and pollution effects [29-31], unreliable maritime transportation [45], environmental hazards [46], high presence of vector agents (mosquitoes) [35], and the lack of a proper health care facility [32,47].

Figure 2. Map of Culebra in relation to the rest of Puerto Rico.

¡mZAP! App

The ¡mZAP! app was designed and developed as a community-oriented ICT to stimulate collective action to mitigate environmental health risks (eg, trash and mosquitoes). This study design involved direct input from community organizations and community members in Culebra, including women's advocacy organizations, sports organizations, private businesses, health organizations, and schools, primarily through focus group and qualitative engagement processes, as previously described [48].

In this app, users may take actions to identify, report, and address community-based priorities such as abandoned structures, trash, stray animals, stagnant water, mosquito breeding grounds, and pests. Although not directly relevant to environmental issues, a feature to track ferry and ship locations was included to further incentivize app use as the community had identified maritime transportation as a major challenge.

Survey

A survey was deployed at baseline using the REDCap (Research Electronic Data Capture, Vanderbilt University) platform version 9.0, which also hosted the survey data. As defined in previous studies, the REDCap database is a secured, encrypted, and Health Insurance Portability and Accountability Act–compliant data capture application developed for large-scale research projects [49].

The survey contained adaptations of two previously validated instruments and original items self-administered by participants via the mobile app tool. The survey aimed to better understand users' attitudes toward the environment, community technology use, and community challenges. Questions related to community health, demographic characteristics, the environment, attitudes toward community actions, and technology use were included. Consistent with recommendations for pretesting and pilot-testing of surveys evaluating mHealth interventions [49,50], the survey was pretested with approximately 10 iterations with feedback from 4 bilingual Latinos from the author's institution and volunteers from the target community.

¡mZAP! Databases

The ¡mZAP! app was built as a cross-platform mobile and web-based app using the *Ionic* framework by an app developer that worked as part of the ¡mZAP! core team at the University of Rochester. *Ionic* is an open-source toolkit that facilitates the building of mobile apps and web-based applications using a single coding structure (eg, HTML, Cascading Style Sheets, and JavaScript), eliminating the need to create a new coding process for each mobile and web-based platform. An integration of *Angular*, a Google-maintained platform, was used to build the app across mobile and web-based systems (eg, iOS and Android). *Firebase* software was used as a database repository. *Firebase* is a Google-based software with the capacity to secure file uploads and downloads, including images, videos, and other user-generated data under Google encrypted (AES256 and AES128) and cloud storage. The ¡mZAP! mHealth tool back-end process was built to assign each user a unique ID linking all the data generated by users while using the app. This process facilitated a better understanding of ¡mZAP! users' behaviors. An application programming interface was used to access the REDCap survey directly from the app. Unique user identifications and email addresses were used to merge the two databases (¡mZAP! use and the REDCap survey). A weekly data transfer stored participants' app use to secure servers at the lead author's institution.

Sample Size Calculation

This study was powered to detect an effect size of 3.0 (α=.05 and β=.20) of app use by the environmental attitudes' category. We estimated that 50% of participants with positive attitudes toward the environment would use the app and 25% of participants with negative attitudes would use ¡mZAP! On the basis of these calculations, the sample size required for this study was 116 participants.

Participants and Study Implementation

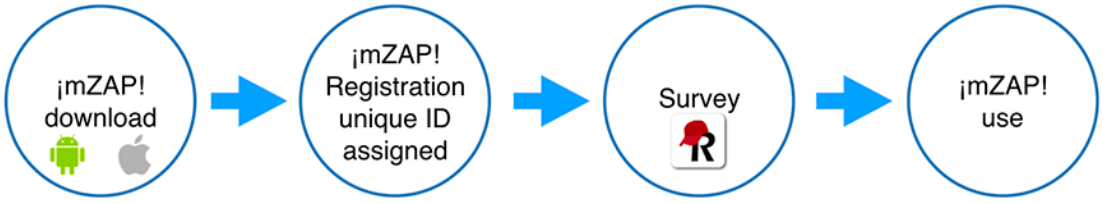
Eligible participants were ≥18 years and self-reported living in Culebra for at least 6 months before the start of the study. Survey questions were administered in Spanish, which is the primary language of the island.

Participants were recruited at baseline following a snowball sampling methodology [51], community meetings, flyer distributions, and social media posts. During in-person visits, eligible participants were invited to download the ¡mZAP! app and complete the survey during the registration process before starting the use of app functionalities (Figure 3). Participants completed the survey using their devices, and via REDCap, the surveys were uploaded to the University of Rochester's firewall-protected, encrypted cloud-based servers. Participants did not receive any compensation for completing the survey or using ¡mZAP! For recruitment purposes, a local area code telephone number and a unique email address were acquired, and a Facebook fan page was created specifically for the project, enabling participants to reach the research team for questions and concerns about the project. This study adhered to the Reporting of Studies Conducted using Observational Routinely Collected Data guidelines and checklist to ensure the inclusion of all components deemed necessary for a scientific research report [52].

¡mZAP! was launched in a series of in-person community meetings in fall of 2018 and was disseminated among community members during a 3-month trial period (November 2018-February 2019). A total of 124 people downloaded the app (Apple iOS 53/124, 42.7% and Android 71/124, 57.3%). Out of the 124 people, 116 (93.5%) participants started registration; 5 (4%) respondents did not meet the inclusion criteria of being a resident of Culebra and were excluded. Out of the 116 participants, 111 (95.7%) participants successfully registered and completed the survey.

This study was reviewed and approved by the institutional review board of the first author's (RSRB00073777) university and followed the 1964 Declaration of Helsinki and its subsequent amendments. HealthproMed, a federally qualified health center in Culebra, reviewed the study protocol and approved the study. An information letter was electronically provided to the participants during their registration for the app.

Figure 3. ¡mZAP! user implementation process. ¡mZAP!: Zonas, Acción y Protección.



Measures

Overview

The study data included two distinct databases: ongoing baseline survey data and ¡mZAP! use data. The app documented user actions and collected data within a 3-month period. *¡mZAP! use* was defined as any action by users within the mobile app (eg, reports, comments, messages, likes, and resolves) during this follow-up period. Multiple user data points were synchronized by random user unique identification, which traced each user's behavior while using the ¡mZAP! tool.

The Environmental Attitudes Inventory

The environmental attitudes inventory [53] scale was adapted (adapted environmental attitudes inventory [a-EAI]) to assess participants' attitudes toward the environment. This environmental scale was developed to evaluate the multidimensional nature of environmental attitudes and the perceptions or beliefs of participants regarding the natural environment and associated factors. For this study, 12 items from the environmental attitudes inventory scale were selected and combined for the a-EAI summary scale. We converted the EAI summary scale to a standardized *t* score with mean 50 (SD 10) [54]. In addition to analyzing the a-EAI as a continuous variable, we reduced the a-EAI to discrete categories with tertiles as the cutoff.

The Wallston Multidimensional Health Locus of Control

The multidimensional health locus of control (MHLC) scale assesses perceptions of control over one's health. The MHLC scale has been used in previous studies to measure the influences and perceptions of community members regarding external factors that affect health outcomes [55]. A Spanish-validated version of the MHLC was used in this study [56]. The three subscales were MHLC internal (internal health locus of control), MHLC external (powerful others health locus of control), and MHLC chance (chance health locus of control) [57]. The rationale for using the MHLC was that perceptions of health control could be associated with overall control and a positive inclination to act against environmental health risks. The subscale scores were standardized using the Streiner and Norman [54] method.

Community Environmental Priorities, Technology Use, Mosquito Knowledge, and Demographics

For addressing community environmental priorities, two additional sections were incorporated from previous study findings [48,49,58] to assess the use of technology, environmental challenges, community resolutions, and access to technology at home (eg, cell phones and the internet).

Data Analysis

The survey data were exported from REDCap, cleaned, and analyzed using SPSS Statistics (IBM Corporation) version 25 [59]. Chi-square tests and analysis of variance were used to test bivariate associations among all key variables. Odds ratios (ORs) with 95% CIs were used to examine the magnitude of the association of predictor variables, including the main predictor variable (attitudes toward the environment, a-EAI) and the primary outcome (use of ¡mZAP!). Forced and forward stepwise logistic regression models [60] were generated to control for potential confounders that were marginally associated (ie, $P<.25$) with a-EAI and mZAP! use. Where necessary, $P<.05$ was considered significant.

Results

Study Sociodemographic Characteristics

In total, 110 participants completed the download of ¡mZAP! and the intake survey. As Table 1 shows, most (71/110, 64.5%) of the survey participants were aged >35 years. In addition, 65.4% (72/110) had completed a higher education degree and 68.5% (76/111) had lived in Culebra for >11 years. An equal number of females and males participated in the study (n=54 each). A comparison of the study sample with the US Census 2013-2017 American Community Survey in Puerto Rico [43] revealed no statistically significant differences between the study population and the population of the municipality of Culebra regarding gender and ethnicity (data not shown), suggesting that the study sample was similar to the overall population of Culebra.

Table 1. Sociodemographics and technology attitudes among ¡mZAP! (Zonas, Acción y Protección) study survey participants in Culebra, Puerto Rico, 2018-2019 (N=110).

The use of technologies brings us closer to the community	37 (33.9)
The constant use of technology limits the community work	43 (39.1)
The technology cause problems in the community	36 (32.7)

Technology and Community Characteristics Among ¡mZAP! Survey Participants

As Table 1 shows, every participant reported owning a cell phone, and 96.3% (105/110) of participants also had a data plan as part of their cell phone plan. With respect to technology at home, 87.3% (96/110) of participants reported having internet access at home, with 66% (63/95) using cell phone data plans for connecting to the internet. Most of the participants owned more than one cell phone (62/83, 74.6%), used electronic devices for up to 5 hours daily (89/110, 80.9%), and had negative perceptions about cell phone reception (99/110, 90%). In addition, 95.5% (105/110) of participants reported being social media users, with WhatsApp being the most used daily social media network (99/105, 94.3%), followed by Facebook (89/105, 84.8%) and Instagram (43/105, 40.1%).

In a series of statements about the relationship between technology and the community, 90.9% (100/110) of participants believed that technology is a tool that can be useful daily and 60% (66/110) agreed that technology could facilitate the resolution of problems in the community. Participants disagreed or were undecided about the role of technology in bringing communities closer (72/110, 65.4%), whether using technologies was an impediment for individuals to do community work (67/110, 60.9%), and whether technology caused community problems (74/110, 67.3%).

Attitudes Toward the Environment and Predictors

On the basis of the responses on the a-EAI scale, participants often disagreed with items reflecting negative statements about protecting the environment. For example, 44.2% (49/116) disagreed with “One of the most important reasons to keep lakes, beaches and rivers clean is so that people have a place to enjoy water sports,” and 46.8% (51/109) disagreed with “Modern science will not be able to solve our environmental problems.” Most participants agreed with or were ambivalent about items that reflected positive inclinations toward the environment; for example, “Protecting the environment is more important than protecting peoples’ jobs” (65/109, 59.6%) and “I would like to join and actively participate in an environmentalist group” (73/110, 66.4%). When comparing a-EAI with sociodemographic variables, as shown in Table 2, having a higher educational level (OR 4.5, 95% CI 1.2-16.3) and having lived fewer total years in Culebra were significantly associated with a stronger positive attitude toward the environment (OR 3.0, 95% CI 1.2-7.6).

Table 2. Associations of the a-EAI[a] with sociodemographics, technology attitudes, and knowledge about mosquito-borne diseases among ¡mZAP! (Zonas, Acción y Protección) study survey participants in Culebra, Puerto Rico, 2018-2019.

Collective Action Strategies

A series of questions on the importance of community actions to address environmental risks were posed. As shown in Table 3, most participants (79/108, 73.1%) believed that environmental problems are not typically resolved among community members. Similarly, 58.3% (63/108) of participants expected the government to resolve environmental problems. Other participants expressed that these problems would be resolved by the community (29/108, 26.9%) or would be resolved without making any effort to fix them (28/108, 25.9%). No statistically significant associations were found among the series of items on community actions and a-EAI scale scores.

Table 3. Associations of the a-EAI[a] with community environmental actions resolutions among ¡mZAP! (Zonas, Acción y Protección) study survey participants in Culebra, Puerto Rico, 2018-2019 (N=108).

How does generally environmental differences or problems get resolved in your community?	Total participants, n (%)	a-EAI, n (%)		Odds ratio (95% CI)	*P* value[b]

[a]a-EAI: adapted environmental attitudes inventory.

[b]*P* value of chi-square test.

[c]N/A: not applicable for reference groups.

Multidimensional Health Locus of Control

Most participants reported moderate beliefs about health control, MHLC internal (76/118, 64.4%), MHLC *powerful others* (78/108, 72.2%), and MHLC chance (71/108, 65.7%; data not shown). No statistically significant associations were found between the a-EAI and MHLC subscales. In contrast, when comparing MHLC subscales with the a-EAI as a scale score, as MHLC *powerful others* scores increased, overall a-EAI scores decreased (*P*=.02; data not shown). This association indicates that attitudes toward the environment become more negative as the sense that one's health is controlled by *powerful others* (eg, parents, doctors, and authorities) increases.

¡mZAP! User's Characteristics and Predictors

Of the 14 participants who used the ¡mZAP! app, 5 (36%) participants used the app more than once; 11 (78%) participants used the app to report environmental health risks, including trash, stray animals, mosquito breeding grounds, abandoned structures, and deposits of stagnant water; and 2 (14%) participants commented on reports. Of the 14 users, 3 (21%) used the tool to report the maritime transportation location (location of the ferries). In addition, of the 14 ¡mZAP! users, 9 (64%) expressed the expectation that the government would resolve the environmental challenges in the community.

Equal proportions of women and men used ¡mZAP! As shown in Table 4, most users (11/14, 79%) were aged >35 years, lived in Culebra for >11 years (10/14, 71%), and had completed higher education (10/14, 71%). No statistically significant differences were found between nonusers and users in terms of sociodemographic variables. Although not significant, several variables had substantial ORs (ORs>1.5): age (OR 2.2, 95% CI 0.5-8.4), educational level (OR 1.6, 95% CI 0.4-6.5), cell phone number per household (OR 2.2, 95% CI 0.5-10.6), household type of internet access (OR 1.8, 95% CI 0.7-5.2), daily hours spent using electronic devices (OR 2.8, 95% CI 0.8-9.3), and *the use of technologies helps to fix community problems* (OR 3.1, 95% CI 0.9-10.0).

Table 4. Association of ¡mZAP![a] use with sociodemographics, technology attitudes, and knowledge about mosquito-borne diseases among ¡mZAP! study survey participants in Culebra, Puerto Rico, 2018-2019.

[a]¡mZAP!: Zonas, Acción y Protección.

[b]*P* value of chi-square test.

[c]N/A: not applicable.

[d]a-EAI: adapted environmental attitudes inventory.

No item from the MHLC was statistically significantly associated with the use of the ¡mZAP! app, including when compared with each subscale's total score (MHLC subscale 1 [internal health locus of control], MHLC subscale 2 [powerful others health locus of control], and MHLC subscale 3 [chance health locus of control]; data not shown).

Higher positive attitudes toward the environment were significantly associated with using the ¡mZAP! app (OR 5.3, 95% CI 1.6-17.0). To assess potential confounding factors, we selected variables that were marginally associated with a-EAI and the use of the ¡mZAP! app, although none of the variables met the statistical criteria for remaining in the model. Clinically relevant sociodemographic variables (education level and age) were forced into the logistic regression model and showed no confounding between environmental attitudes and the use of ¡mZAP! app.

A statistically significant ($P<.01$) association persisted when comparing the highest tertile of a-EAI versus the other two tertiles and ¡mZAP! app use (adjusted OR 5.4, 95% CI 1.4-20.4). The Hosmer and Lemeshow goodness-of-fit test [60] was not statistically significant ($P=.89$), validating the tested model.

Discussion

Principal Findings

This study was followed by the *Community-Centered Environmental Health Risk Control Model*. This theoretically informed model facilitated the process of learning about *Culebrenses'* environmental health priorities and, more importantly, the implementation of their community perspectives in the development of ¡mZAP! app as an mHealth tool tailored to the community and by the community. This new model contributes to our understanding of behaviors that can lead to better ICT use among community members, and this model can be adopted in future studies worldwide.

The main findings of this study are as follows: (1) ¡mZAP! users were five times more likely to have stronger environmental attitudes than ¡mZAP! nonusers; (2) a negative relationship between environmental attitudes and the MHLC *powerful others* was observed; and (3) an expectation that the government will meet the needs of *Culebrenses* was found.

The study results also suggest that *Culebrenses* have a strong use of ICT, where most participants spend up to 5 hours daily using electronic devices. In contrast, this study also found important aspects of *Culebrenses'* potential interpretations of and implications for their attitudes toward the environment. For example, participants with a low perception of health control were also more likely to have a less positive attitude toward the environment. This association indicates that attitudes toward the environment become more negative as the sense that one's health is controlled by *powerful others* increases. Higher scores on the MHLC *powerful others* subscale have been previously demonstrated to affect health outcomes negatively [61,62]. This relationship could also lead people to become disengaged in efforts to protect their environment. People may hold conflicting beliefs because most participants agreed with or were ambivalent about items that reflected positive inclinations toward the environment.

As described in previous studies, *Culebrenses* expressed a feeling of *being forgotten* by the Puerto Rican government, which could partly explain why *Culebrenses* have a sense of pride and ownership with respect to Culebra [48]. As a result, *Culebrenses* could demonstrate a greater inherent consciousness of protecting natural resources, the environment, and fragile

ecosystems, which are also the island's main tourist attractions. The results of this study help to empirically reaffirm Culebra's positive community attitudes and beliefs toward the environment. Although the intentions to protect the island were in the minds of community members, these intentions did not necessarily translate into the use of ¡mZAP! to protect the environment and address environmental health risks that affect islanders.

This study suggests that less time spent living in Culebra was associated with stronger positive attitudes toward the environment. This finding is important, particularly considering that most ¡mZAP! users have lived in Culebra for >11 years. Perhaps these results suggest that the longer one lives in a location, the more likely one is to be disincentivized to engage in behaviors to respond to community environmental challenges. For example, *Culebrenses* have been exposed to many environmental health risks in the past, including solid waste polluting beaches, improper land development, air pollution, and most notably, the US military bombing practices [35,63-67]. Although the community advocated against these environmental injustices in the past [66,67], the ongoing repercussions of these challenges [31,68] have potentially resulted in reduced enthusiasm. ¡mZAP! users had higher positive attitudes toward the environment, which could also translate into an increase in environmental conscientiousness.

Participants' beliefs that government agencies are responsible for responding to environmental risks and community discrepancies related to environmental challenges help us better understand *Culebrenses*' perceptions of lack of control over the community's health. Societal issues that affect the community's poor health outcomes extend into the social and ecological determinants of health [69,70]. The ongoing dependency on government-based solutions to community problems is worrisome, especially after the hurricane experiences of 2017 (which may potentially continue to be an issue subsequent to the more recent 2020 earthquakes).

The catastrophic impact of hurricanes Irma and María and the inappropriate responses of the Puerto Rican and US governments may have cemented this perception of lack of control. Community members experienced the isolation of being disconnected from the main island of Puerto Rico and the exacerbation of an unreliable maritime transportation system, resulting in a societal crisis where health access, common goods, and food became scarce [71,72].

Culebrenses' dependency systems and the way social injustices from the past and the present may have resulted in the perception of lack of control, which was associated in this study with negative environmental attitudes, can undermine the good intentions of community members to protect their land. Therefore, implementing community-driven approaches to address environmental health risks or health disparities may not be sufficient to ensure a successful mHealth tool intervention, especially when other social conditions work as oppressors. Socioecological conditions force community priorities to be in constant transformative change. This transformative change was especially true after the 2017 hurricane season in Culebra, where the emergence of new challenges such as rebuilding destroyed properties became a new top priority for *Culebrenses*.

Previous studies suggest that new mobile apps are used between 4% and 20% of the time, with an average session app use of <1 minute. Furthermore, 51% of apps are deleted after the first week of use [73-78]. In this study, only 12.6% (14/111) of participants adopted the use of ¡mZAP!. Although the number of initial users was small, it may be noteworthy that 36% (5/14) of participants used the mHealth tool more than once. These adoption and reuse rates are typical when compared with the adoption rates of other mobile apps. In addition, identifying proper champions on the island to promote ¡mZAP! presented a challenge that could have also affected the use of the mHealth tool. Early identification of community champions has been previously studied as an approach to develop and increase trust between community members and investigators, facilitating an engaging process and a successful community-based research intervention [79-81].

This research study lacked sufficient power to detect some potentially meaningful and theoretically driven associations. The observed associations that were not statistically significant but which had ORs >1.5 can, therefore, be useful for hypothesis generation and to inform future studies. Therefore, in a larger sample, certain relevant predictor variables would have statistically significant associations with the primary outcome, such as age, education level, cell phone number and type of internet per household, daily use of electronic devices, and the perception of how technology contributes to help fixing community problems.

The results of this study provide some support for suggesting that people used ¡mZAP! and were taking self-directed action by using ICTs to address environmental health challenges in Culebra. These results, although limited, confirm the objective of this study to assess the ability of ICTs as tools to engage islanders in collective actions that address environmental health risks. However, for other *Culebrenses*, although they may have similar intentions to protect the environment, existing higher community priorities and potential oppressive challenges, including health care and maritime transportation access, prevent them from translating their intentions into actions.

Limitations and Strengths

Although this pilot study may offer some insight into directional relationships via statistically significant associations in this sample, interpretation of results is limited because of the small sample size, which restricted power. There may have been a selection bias, including volunteer bias. The data collected for this study reflect a one-time *snapshot* where questions were self-administered by participants, potentially generating respondent bias. The hurricane disasters of 2017 may have substantially affected community perceptions and priorities to the extent that the development of ¡mZAP! was affected in unexpected ways.

The empirical findings concerning perceived lack of control and government dependency systems support conclusions about how these situations could have a stronger influence on people's behaviors. These behaviors could lead to a perpetuation of the

challenges associated with this population's unique social determinants of health. The results from this study should be further qualified by the fact that people who are less familiar with technology may not be as represented in this study as those who are more familiar (eg, those who are younger and have higher education). These contextual factors are important in future research to ensure the potential adoption and success of any ICT.

The study results might only apply to the users of the ¡mZAP! app, a tool that proactively focuses on environmental health risks. Anecdotally we know that some community members were positively affected by the tool (social influence from other users). The perceptions and priorities of nonusers are likely to differ. Future studies could explore the relationship between offline and internet-based generations to address communities' environmental priorities.

This study had several strengths. Existing partnerships with collaborators in Puerto Rico facilitated access to the target population and necessary local ethical review and approval. The study addressed key goals and objectives of Healthy People 2030, including "Use health communication strategies and health information technology to improve population health outcomes and health care quality, and to achieve health equity" [82]. This is the first study to provide an overview of *Culebrenses'* intentions to protect the island's environment in the context of mHealth resource use. In addition, this study provides a unique perspective on how people in remote and underresourced communities perceive environmental health risk and how those perceptions affect the use of rapidly advancing mobile technologies, which can help decrease barriers to access to health in rural areas [2,83,84]. In conclusion, the study findings demonstrated the capacity to stimulate collective action by using ICTs as a novel and engaging approach in underresourced rural locations.

Implications and Future Research

Future research studies should seek to better understand the factors preventing the use of ¡mZAP! and other ICTs, including changes in the community's perceptions and priorities after natural disasters or other major community-wide challenges. It is important to explore how ICT use can support, facilitate, or even drive collective community actions. For example, there are multiple community-based centers, groups, and institutions, including a federally qualified health center, a women's health community organization, and other grassroot-level environmental organizations that can be supplied with ¡mZAP! and other mHealth ICT–related mobile technologies. These tools could be coupled with educational materials and community-based initiatives aimed at increasing positive perceptions of the environment by community members in this rural setting.

Future research should work toward a better understanding of community members' priorities and addressing pre-existing social determinants, such as those found in this study. Although other social determinants of health in this study, including colonialism, were not assessed, this research establishes a contributing baseline to further investigate the relationship between health or environmental disparities and the sociopolitical power imbalances that affect community islands such as Culebra [85,86]. As community-driven interventions have been successful in the past, with the understanding that community work takes time to develop, the findings of this study can serve as a foundation for future community and ICT research in Culebra and other locations with similar environmental health conditions.

Acknowledgments

The authors would like to thank the community of Culebra, in particular the collaborators in this study from the Amigos de la Reserva Natural Caño Luis Peña organization (Nicolás Gómez Andujar, Abimarie Otaño, and Alfredo Montañez), Dulce María del Río Pineda and MariCarmen Carbonell from the Mujeres de Islas organization, HealthproMed Inc, Escuela Ecológica de Culebra, Abbie White-Thomas (Abbie's School), Foundation for a Better Puerto Rico, José D Pérez from the Municipality of Culebra, Office of Emergencies Management, and Yahaira Rivera, former Culebra's social worker from the Administración de Servicios de Salud y Contra la Adicción. The authors would also like to acknowledge Ahona Shirin, Matthew Quick, Derek Guo, and Astghik Baghinyan for their contributions to this manuscript. The authors are also thankful to The Dye Lab, including the ¡mZAP! (Zonas, Acción y Protección) developing team, Michael Kelly, and Noah Wilson. This study was funded by the University of Rochester, School of Medicine and Dentistry, Department of Obstetrics and Gynecology Pilot Research Award and the University of Rochester, Office of Equity and Inclusion supported journal publication fees. At the time of this work, the corresponding author (JGPR) was enrolled in a doctoral program and accessed REDCap (Research Electronic Data Capture) resources supported by the University of Rochester, Clinical and Translational Science Awards, award numbers TL1TR002000 and UL1TR002001 from the National Center for Advancing Translational Sciences of the National Institutes of Health. The content of this work is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Abstract

Background: Hypertension is a long-term medical condition. Electronic and mobile health care services can help patients to self-manage this condition. However, not all management is effective, possibly due to different levels of patient engagement (PE) with health care services. Health care provider follow-up is an intervention to promote PE and blood pressure (BP) control.

Objective: This study aimed to discover and characterize patterns of PE with a hypertension self-management app, investigate the effects of health care provider follow-up on PE, and identify the follow-up effects on BP in each PE pattern.

Methods: PE was represented as the number of days that a patient recorded self-measured BP per week. The study period was the first 4 weeks for a patient to engage in the hypertension management service. K-means algorithm was used to group patients by PE. There was compliance follow-up, regular follow-up, and abnormal follow-up in management. The follow-up effect was calculated by the change in PE (CPE) and the change in systolic blood pressure (CSBP, SBP) before and after each follow-up. Chi-square tests and *z* scores were used to ascertain the distribution of gender, age, education level, SBP, and the number of follow-ups in each cluster. The follow-up effect was identified by analysis of variances. Once a significant effect was detected, Bonferroni multiple comparisons were further conducted to identify the difference between 2 clusters.

Results: Patients were grouped into 4 clusters according to PE: (1) PE started low and dropped even lower (PELL), (2) PE started high and remained high (PEHH), (3) PE started high and dropped to low (PEHL), and (4) PE started low and rose to high (PELH). Significantly more patients over 60 years old were found in the PEHH cluster ($P \leq .05$). Abnormal follow-up was significantly less frequent ($P \leq .05$) in the PELL cluster. Compliance follow-up and regular follow-up can improve PE. In the clusters of PEHH and PELH, the improvement in PE in the first 3 weeks and the decrease in SBP in all 4 weeks were significant after follow-up. The SBP of the clusters of PELL and PELH decreased more (–6.1 mmHg and –8.4 mmHg) after follow-up in the first week.

Conclusions: Four distinct PE patterns were identified for patients engaging in the hypertension self-management app. Patients aged over 60 years had higher PE in terms of recording self-measured BP using the app. Once SBP reduced, patients with low PE tended to stop using the app, and a continued decline in PE occurred simultaneously with the increase in SBP. The duration

and depth of the effect of health care provider follow-up were more significant in patients with high or increased engagement after follow-up.

Introduction

Background

Hypertension is a lifestyle-induced chronic disease that affects health-related quality of life. Once the disease deteriorates, it may cause complications such as stroke, myocardial infarction, cardiac failure, and renal failure [1]. Controlling hypertension requires patients to follow long-term self-management plans, including measuring and recording blood pressure (BP), taking medicine, conducting physical activities, and healthy eating. These plans should preferably be established with guidance from the health care providers and be followed continuously for hypertension control [2].

The rapid pace of electronic and mobile technology development has promoted the implementation of out-of-hospital health care services [3-5]. Mobile health (mHealth) service is defined as the use of mobile phone and wireless technologies to support medical and public health care services [6]. Abundant evidence supports the introduction of mHealth services into chronic disease control and promoting positive patient behavior [4,7-10]. Although recent studies have demonstrated efficacy for some mHealth services, some have performed poorly [11-14]. Thus, there are mixed results for using mHealth services to support patient self-management of hypertension in the community [15,16].

Patient engagement (PE) is essential for bringing an improvement of health outcomes using the mHealth app [11,17,18]. PE refers to the activation of a patient to engage with the interventions that are designed to promote positive health behavior [19]. In a study of a hypertension self-management app, Toto-Ramos et al [20] found that the patients with sustained PE, as measured by the number of weeks that the patients engaged with the app, experienced significant reduction in systolic blood pressure (SBP). Goyal et al [21] evaluated the behavior of daily blood glucose reading of patients and found a significant relationship between increased number of readings and improved glycated hemoglobin. In comparison with the traditional methods, mHealth service is advantageous in improving PE for self-management of hypertension [22,23]. For example, Kaplan et al [24] designed an mHealth app to facilitate PE in managing hypertension. The app provides a mobile platform for recording and tracking self-measured BP, periodic reminders to measure BP, and wireless BP measurement devices. Their research resulted in significant improvement in BP for patients and a high level of PE.

In the mHealth field, complex PE patterns emerge when mobile apps are used for self-management. Some patients register but never use the app, some use it intermittently, and others frequently use it for a long period of time. PE can be objectively measured as amount, duration, breadth, and depth of using the mHealth app [11], and it can also be subjectively measured as interest, intrigue, focus, inattention, enjoyment, pleasure, etc [25]. In a study of pain management with a mobile app, Rahman et al [26] used a clustering technique to identify PE patterns with the app. They measured PE by 3 key usage features: duration of app use, frequency of app use, and the number of usage records. They then used a K-means clustering algorithm to find groups of patients as indicated by PE because the PE pattern reflects the behavioral characteristics of patients using the app. Sanatkar et al [27] also used a clustering technique to analyze the mHealth app usage data so as to distinguish PE with the app in an e-mental health community. They measured 5 usage features of PE: number of user logins, number of daily trackers used, number of learning activities started and completed, and number of reminders received. Distinct usage patterns were observed in the frequency of using the app.

To date, the studies on patterns of PE and the associations between these PE patterns and health outcomes have usually used various types of static count data (eg, number of logins and number of records). However, PE is a dynamic, ongoing process [28]. The change of this dynamic process cannot be captured simply by analyzing count data captured at a single date point in the cross-sectional data analysis. Longitudinal change is useful for identifying trends through analyzing the time series data. Furthermore, as hypertension management requires long-term efforts, understanding the trends of PE is important for the long-term successful management of hypertension.

Health care provider follow-up can offer continuous and personalized attention to guide patient's self-management behavior in response to the patient's current BP level [29]. Without health care provider support, it is difficult for patients to maintain BP control and high levels of PE with an mHealth app [30], which has often resulted in a high level of dropout [31,32]. Therefore, follow-up by health care providers is recommended by the hypertension management guideline in order to know, track, and intervene in patient's hypertension self-management in the long-term [33-35]. In the traditional outpatient management model, follow-up often takes the form of home visits by health care providers to promote PE and then achieve BP control. Despite its proven benefits for hypertension management, follow-up is not fully implemented by health care providers due to the high human resources required for patient follow-up.

In comparison with the traditional format of follow-up, mHealth health care provider follow-up is a low-cost, convenient means of follow-up, and patient's BP, medication, exercise, diet, etc., can be checked in the office. In a series of our previous studies into hypertension management service [36,37], after receiving

the BP data that a patient entered through the mobile app, the server could automatically conduct BP data analysis, with the web-based platform reporting the patient's BP condition to the health care provider and reminding the health care provider which patients needed to follow-up. In response to different patient health statuses, health care providers can conduct follow-up through calling and sending short SMS text messages. Our previous study designed 3 types of follow-ups: compliance follow-up, regular follow-up, and abnormal follow-up [36,37]. These were conducted to improve compliance, track BP status, redesign a new plan, and respond to the abnormal BP of patients.

To date, few studies have explored the effect of health care provider follow-up on PE and BP control in mHealth services for hypertension management [23]. It is not clear if follow-up is effective, which type of follow-up is effective, when the follow-up effect emerges, if there is a differential effect of follow-up in different patient groups, and how long the follow-up effect lasts [28,38]. Answers to these questions are essential for informing the implementation of value-based health care and providing optimal outcomes in improving the quality and reducing cost of hypertension management.

Objective

The aim of this study was to explore the patterns of PE with a hypertension management service and the effect of health care provider follow-up on PE and BP within the first 4 weeks of mHealth app usage. This included 3 objectives: (1) to discover the patterns of PE with the mHealth app and the association between a series of related variables (age, gender, education level, the mean SBP, and the number of follow-ups) and the PE pattern, (2) to explore the health care provider follow-up effect on PE, and (3) to examine the effect of follow-up on SBP in each PE pattern.

Methods

Description of the mHealth App

Blood Pressure Assistant (BPA) is a mHealth hypertension self-management app available for patients in the General Hospital of Ningxia Medical University [36,37,39]. BPA was launched in 2015, and since then, 2129 patients have registered to use the app. The mHealth app was designed in accordance with a customized care pathway in compliance with the Chinese guideline for hypertension management. The care pathway defines tasks for hypertension management for patients and health care providers.

In this care pathway, each patient is required to register and provide basic demographic information (ie, name, gender, date of birth, and education level). The patient is then assigned to a health care provider, who is responsible for formulating a tailored management plan, conducting follow-up, and supervising patients' uploaded data. The management plan includes the frequency of self-measured and recorded BP, and recommendations for medication, physical activities, and diet. The patient's uploaded data includes self-measured BP, medications taken, physical activities, and diet records. The most important task for health care providers is to track patient's current BP level through the web-based platform and use mobile phones for patient follow-ups to assist in BP control. There are 3 types of follow-ups. (1) Compliance follow-up is performed as a response to the identified low patient compliance with the hypertension management plan [36]. In this case, health care providers need to remind the patient to measure and record BP on a regular basis. (2) Regular follow-up is conducted on regular basis in order to check the BP level and decide whether or not to maintain or update the management plan [37]. (3) Abnormal follow-up is required when patient's self-measured BP data are abnormal [36]. Health care providers need to check and understand the causes of abnormal conditions and intervene in a timely manner. With consent, the health care provider enrolls the patient they manage into the mHealth hypertension management program in an online community. Patients can use the app to check their self-management plans. Their main task is to measure and record BP data on a daily basis.

Data Collection

Statement of Ethics

Ethical approval was granted by the Ethic Committee for the Conduct of Human Research at General Hospital of Ningxia Medical University (#NXMU-GH-2017-273). Patients in this study signed the informed consent forms.

Sample

All data were stored and extracted from the BPA server, which contains the demographic information, self-management plans, patient-uploaded data, and follow-up records of health care providers. The primary data set included 2129 patients. We selected the patient records based on the following criteria: patients were at least 18 years of age; patients registered to the app between March 27, 2016, and July 10, 2019 (as the main functions of the app were consistent during this period, this could ensure that the patient's behavior was not affected by the changes in app functions); and patients continuously measured and recorded BP more than 4 weeks after registration (as the control of BP requires at least a 4-week observation period according to the relevant guidelines) [33-35].

Data Extraction

We extracted 3 types of data from the database: demographics, BP records, and follow-up records. The demographics information included the patient identification, data of birth, gender (male and female), and education level (primary or secondary school, high school, or university and above). The BP record data included SBP, diastolic blood pressure, and the uploaded date (containing year, month, day, minute, and second). Due to the high correlation between SBP and diastolic blood pressure, only SBP was used for analysis. The information specific to the follow-up records included patient ID, follow-up type (compliance follow-up, regular follow-up, and abnormal follow-up), and follow-up date.

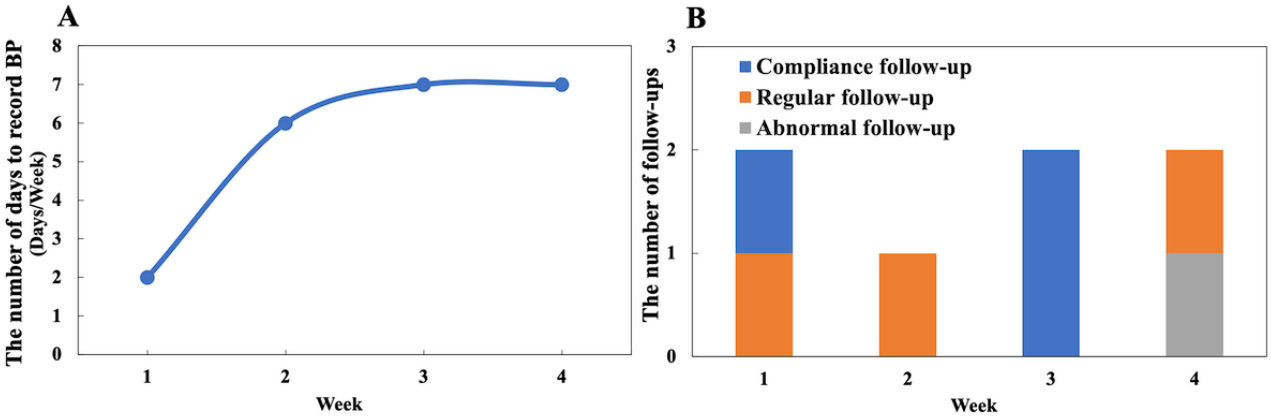
Data Analysis

Measuring PE

In accordance with the hypertension management guidelines [33-35], we defined the time unit of observation as 1 week. The behavior of measuring BP is a basic behavior in hypertension

management because other behaviors (eg, taking medicine, doing physical activities, and eating healthy) need to be based on patient's current BP level. Therefore, in this study, patient engagement was indicated by the number of days that a patient recorded self-measured BP per week (see Figure 1). The analysis period was the first 4 consecutive weeks after the initial patient registration.

Figure 1. Example of patient engagement and follow-up for a patient within 4 weeks. (A) Example of patient engagement. (B) Example of the number of different types of follow-ups. BP: blood pressure.



Cluster Analysis

Cluster analysis was conducted to group the patients into different PE patterns. K-means algorithm (Python 3; Python Software Foundation) was used to cluster patients by PE [40]. Dynamic time warping was used to calculate the similarity of PE between patients because this feature was represented as time series data [41]. We then used silhouette score to determine the optimal number of clusters [42]. The silhouette score measured the distance between clusters based on the distance between the PE of patients as determined by dynamic time warping. A higher silhouette score indicates tighter clusters, where each cluster is completely separate from the others.

Characterizing the Clusters

An optimal clustering result was reached based on the silhouette score of a different number of clusters. For each cluster, we analyzed the demographic features (the distribution of age, gender, and education level); BP features, including the distribution of mean SBP in the first week (representing the initial BP conditions in hypertension management) and the trend of weekly mean SBP; and follow-up features (the distribution of the number of the 3 types of follow-ups in each of the 4 weeks; see Figure 1).

The Effect of 3 Types of Follow-ups on PE and SBP

The follow-up effect was calculated by the change in PE (CPE) and the change in SBP (CSBP) before and after each follow-up, which were defined as follows:

where PE_{i+1} is PE in the week after a follow-up event, PE_i is PE in the week of the follow-up even, SPB_{i+1} is the mean SBP in the week after a follow-up event, SPB_i is the mean SBP in the week of the follow-up event, and N is the number of follow-ups performed by health care providers.

Statistical analysis was conducted in SPSS version 24 (IBM Corp). Chi-square test was performed to evaluate the statistical significance of associations between the clusters and the discrete variables (demographic, BP, and the number of follow-ups). Pairwise comparisons were conducted using the z scores to compare difference in the proportion of discrete variables between the clusters. Analysis of variance (ANOVA) was employed to analyze the changes in outcome parameters (CPE and CSBP) after follow-up in each of the 4 weeks. Once a significant change was detected, Bonferroni multiple comparisons were further conducted to examine the differences between the clusters. A P value <.05 was used to determine whether the difference was statistically significant.

Results

PE Patterns

A total of 562 patients met the selection criteria and were included in the study. We found that the silhouette score was the highest with 4 clusters of patients (see Figure 2). Hence, we accepted the 4-cluster output of K-means (see Table 1) for further analysis. The PE of each cluster within 4 weeks was significantly different (P<.001).

Figure 2. Comparison of the silhouette score for the different numberd of clusters (range from 3 to 7).

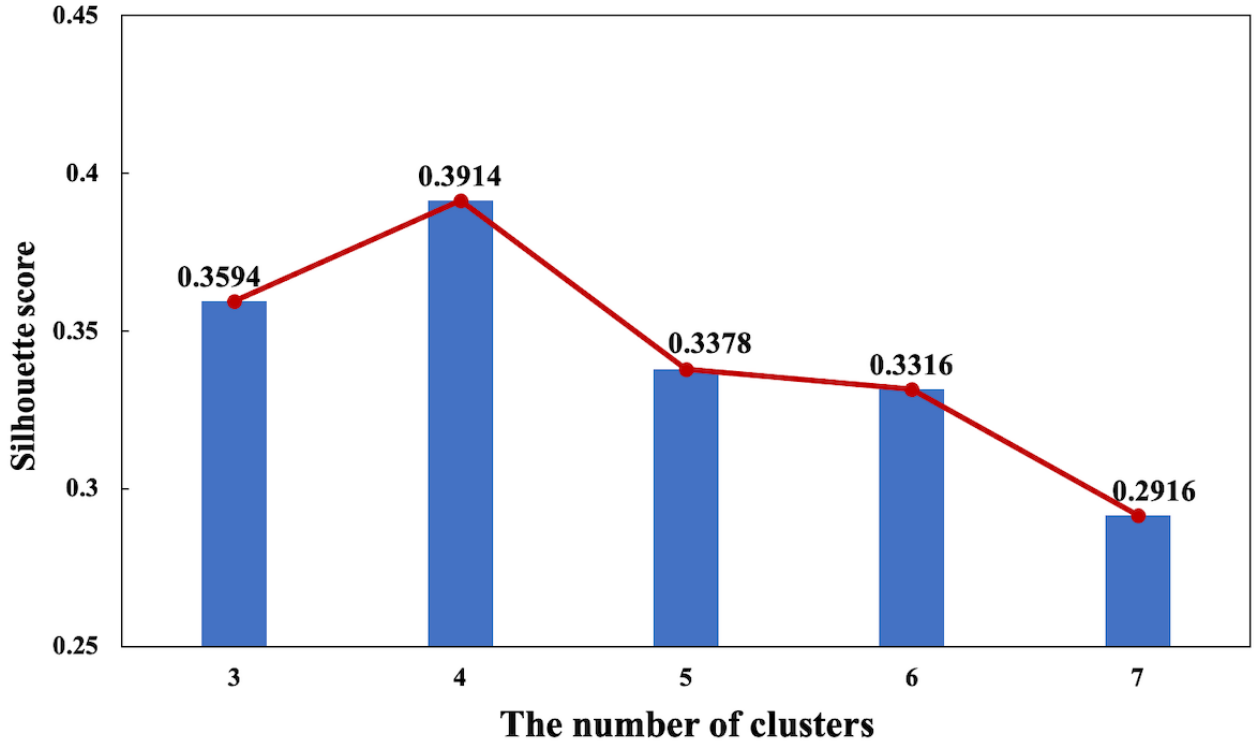


Table 1. Comparison of PE in the 4 clusters.

PE[a] (Days/week)	PELL[b], mean (SD) (n=183)	PEHH[c], mean (SD) (n=142)	PEHL[d], mean (SD) (n=148)	PELH[e], mean (SD) (n=89)	*P* value
Week 1	1.9 (1.1)	6.4 (1.1)	5.8 (1.2)	2.4 (1.3)	<.001
Week 2	0.8 (1.3)	6.6 (0.8)	4.8 (1.9)	3.5 (2.0)	<.001
Week 3	0.8 (1.3)	6.4 (0.9)	3.2 (2.1)	4.3 (2.0)	<.001
Week 4	0.6 (0.8)	6.3 (0.9)	1.8 (1.3)	4.6 (1.5)	<.001

[a]PE: patient engagement.

[b]PELL: patient engagement started low and dropped even lower.

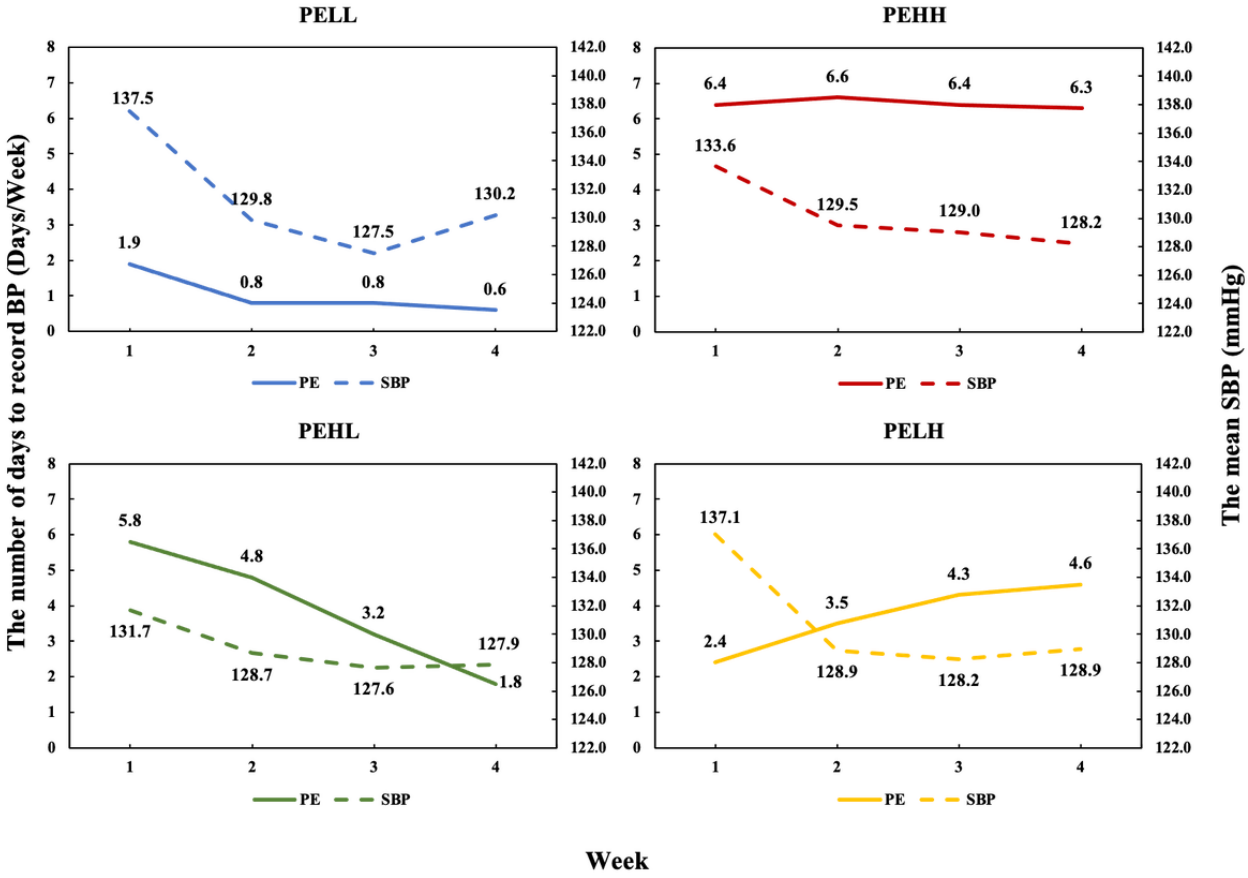
[c]PEHH: patient engagement started high and remained high.

[d]PEHL: patient engagement started high and dropped to low.

[e]PELH: patient engagement started low and rose to high.

There were 4 distinctive change patterns of PE (see Figure 3). The first cluster contained 183 patients. They started recording their BP 1.9 days/week (SD 1.1 days/week) and then decreased every week to around 0.6 days/week (SD 0.8 d days/week) in the fourth week. We referred this cluster as “PE started low and dropped even lower” (PELL) cluster. The second cluster contained 142 patients who were consistently active engaging in BP recording throughout the whole period. On average they recorded the BP for more than 6 days per week. Therefore, we referred them as the “started high and remained high” (PEHH) cluster. The third cluster contained 148 patients who started with a high level of recording (5.8 days/week, SD 1.2 days/week) that then decreased every week to around 1.8 days/week (SD 1.3 days/week) in the fourth week. We referred them as the “PE started high and dropped to low” (PEHL) cluster. The fourth cluster contained 89 patients who began recording self-measured BP 2.4 days/week (SD 1.3 days/week) and gradually increased every week to around 4.6 days/week (SD 1.5 days/week) in the fourth week. We referred them as the “PE started low and then rose to high” (PELH) cluster.

Figure 3. The patient engagement patterns of the 4 clusters and the 4-week mean SBP curve of the 4 clusters. BP: blood pressure; SBP: systolic blood pressure. PELL: patient engagement started low and dropped even lower; PEHH: patient engagement started high and remained high; PEHL: patient engagement started high and dropped to low; PELH: patient engagement started low and rose to high.



The Demographics, SBP, and Follow-up Characteristics of the PE Patterns

The Association Between Demographic Factors and the PE Pattern

The distribution of age, gender, and education level in each cluster is presented in Table 2. The majority of patients (387/562, 68.9%) were between 40 and 60 years old. Chi-square test found a statistically significant association between age and the PE pattern (P=.001). There was no significant difference in the distribution of patients under 60 years old in each PE pattern, but there were many more patients aged over 60 years old in the PEHH cluster than in the other clusters (P<.05).

Chi-square test did not find a statistically significant association between the PE pattern and gender or education level. There were many more male patients (338/562, 60.1%) using the BPA than female patients. Moreover, 50.5% (284/562) of patients had a university degree.

Table 2. The distribution of demographic characteristics in each cluster.

Characteristic	PELL[a] (n=183)	PEHH[b] (n=142)	PEHL[c] (n=148)	PELH[d] (n=89)	*P* value
Age, n (%)					.001
18<age≤40	24 (13.1)	14 (9.8)	27 (18.2)	11 (12.4)	
40<age≤60	131 (71.6)	86 (60.6)	104 (70.3)	66 (74.1)	
Age>60	28 (15.3)	42 (29.6)	17 (11.5)	12 (13.5)

[c]PEHL: patient engagement started high and dropped to low.

[d]PELH: patient engagement started low and rose to high.

The Association Between the Initial BP Conditions and the PE Pattern

The mean SBP in the first week represented the initial BP conditions in hypertension management. The chi-square test showed a statistically significant association between the mean SBP in the first week and the PE pattern (*P*<.001; see Table 3). *z* scores identified a significantly higher proportion of patients with high SBP (between 160 mmHg and 179 mmHg) in the PELL cluster in the first week than in the PEHL cluster (*P*<.05). The majority of patients (316/562, 56.2%) had a mean SBP between 120 mmHg and 139 mmHg in the first week.

Table 3. The distribution of the first week mean SBP in each cluster (*P*<.001).

SBP[a]	PELL[b], n (%) (n=183)	PEHH[c], n (%) (n=142)	PEHL[d], n (%) (n=148)	PELH[e], n (%) (n=89)
SBP<120	19 (10.4)	13 (9.2)	23 (15.5)	7 (7.9)
120≤SBP≤139	90 (49.2)	91 (64.1)	91 (61.5)	44 (49.4)
140≤SBP≤159	53 (29.0)	35 (24.6)	32 (21.6)	34 (38.2)
160≤SBP≤179	16 (8.7)	3 (2.1)	2 (1.4)	4 (4.5)
SBP≥180	5 (2.7)	0 (0)	0 (0)	0 (0)

[a]SBP: systolic blood pressure.

[b]PELL: patient engagement started low and dropped even lower.

[c]PEHH: patient engagement started high and remained high.

[d]PEHL: patient engagement started high and dropped to low.

[e]PELH: patient engagement started low and rose to high.

The Trend of Weekly Mean SBP in Each PE Pattern

Across 4 weeks of management, the mean SBP of all 4 clusters declined at different rates (see Figure 3). Pairwise comparisons of the mean SBP between 4 weeks in each cluster revealed that in the clusters of PELL (*P*=.002), PEHH (*P*=.006), and PELH (*P*<.001), the mean SBP had significantly reduced from the second week. In the PEHL cluster, the significant reduction of SBP appeared from the third week (*P*=.02). The PELL cluster experienced a greater reduction in the mean SBP in the third week compared to the other clusters, but the SBP of users in this cluster increased more than did the others in the fourth week.

The Number of Follow-ups in Each PE Pattern

The amount of the 3 types of follow-ups were significantly different (*P*=.03) in the 4 clusters (see Table 4). Abnormal follow-up was performed significantly less frequently (*P*<.05) in the PELL cluster than in the clusters of PEHH and PEHL. The distribution of follow-up in each of the 4 weeks was not significantly different in the 4 clusters. Most (338/680, 49.7%) follow-ups were performed in the first week.

Table 4. The distribution of the number of 3 types of follow-ups and the number of follow-ups in each of the 4 weeks in each cluster.

Value	PELL[a] (n=183)	PEHH[b] (n=142)	PEHL[c] (n=148)	PELH[d] (n=89)	*P* value

The Effect of Follow-up on PE and SBP in Each PE Pattern

The Effect of Each Type of Follow-up on PE

The results of ANOVA revealed the significant main effects of cluster (F=15.09; P<.001) and type (F=5.442, P=.005), and the cluster–type interaction effect (F=2.60; P=0.02) on PE (see Table 5). Bonferroni multiple comparisons found that after the 3 types of follow-up, the CPE between the 4 clusters had the following statistically significant differences: (1) for the compliance follow-up, PE in the PELL cluster had a significantly larger drop than did the PEHH (P=.02) and PELH (P<.001) clusters, and improvement in PE in the PELH cluster was significantly higher than that of the PELL (P<.001) and PEHL (P<.001) clusters; (2) for the regular follow-up, PE in the PEHL cluster had a significantly larger drop than did the clusters of PELL (P=.01), PEHH (P=.01), and PELH (P<.001); and (3) for the abnormal follow-up, the decrease in PE in the PEHL cluster was significantly lower than that of the PEHH cluster (P=.01). Compliance follow-up improved PE in the PEHH and PELH clusters. Regular follow-up improved PE in the PELH cluster.

Table 5. The effect of 3 types of follow-ups on patient engagement and the effect of follow-up in each of the 4 weeks on PE. Multiple comparisons of the 4 clusters (at the .05 level).

CPE[a] (Days/week)	PELL[b], mean (SD) (n=183)	PEHH[c], mean (SD) (n=142)	PEHL[d], mean (SD) (n=148)	PELH[e], mean (SD) (n=89)	*P* value
Type

[e]PELH: patient engagement started low and rose to high.

[f]The given cluster is significantly different from the PELL cluster.

[g]The given cluster is significantly different from the PEHH cluster.

[h]The given cluster is significantly different from the PEHL cluster.

The Effect of Follow-up on PE in Each of the 4 Weeks

The results of ANOVA revealed the significant main effects of the cluster (F=10.335; P<.001) and time (F=2.870; P=.04), and the cluster–time interaction effect (F=5.168; P<.001) on PE (see Table 5). Bonferroni multiple comparisons found that after the follow-up in each of the 4 weeks, the CPE between the 4 clusters had the following statistically significant differences: in week 1, the improvement in PE in the PELH cluster was significantly higher than that of the clusters of PELL (P<.001), PEHH (P=.03), and PEHL (P<.001); in week 2, the PE in the PEHL cluster had a significantly larger drop than that of the clusters of PELL (P=.001), PEHH (P=.01), and PELH (P<.001), and the improvement in PE in the PELH was significantly higher than that of the clusters of PELL (P=.01), PEHH (P=.01), and PEHL (P<.001); and in week 3, the PE in the PEHL cluster had a significantly larger drop than that of the PEHH (P=.02) and PELH (P=.01) clusters. Follow-up improved PE in the PEHH and PELH clusters in first 3 weeks and only in the second week in the PELL cluster, but had no effect on the PEHL cluster in any of the 4 weeks.

The Effect of Each Type of Follow-up on SBP

The results of ANOVA revealed significant main effects of cluster (F=2.789; P=.04) and type (F=1.137; P=.32), but no cluster–type interaction (F=0.956; P=.46) effect on SBP (see Table 6). The mean SBP of all 4 clusters of patients reduced after 3 types of follow-ups except for the abnormal follow-up in the PELL cluster. Bonferroni multiple comparisons showed that after the compliance follow-up, the PELH cluster had a significantly higher level of SBP decline than did the PEHL cluster (P=.003).

Table 6. The effect of 3 types of follow-ups on systolic blood pressure and the effect of follow-up in each of the 4 weeks on systolic blood pressure. Multiple comparisons of the 4 clusters (at the .05 level).

[f]The given cluster is significantly different from the PEHL cluster.

[g]The given cluster is significantly different from the PEHH cluster.

The Effect of Follow-up on SBP in Each of the 4 Weeks

The results of ANOVA revealed significant main effects of cluster (F=2.697; P=.045) and time (F=7.561; P<.001), but no cluster–time interaction effect (F=1.600; P=.11) on SBP (see Table 6). Bonferroni multiple comparisons showed that the PELH cluster in the first week had a significantly higher level of SBP decline than did the PEHH (P=.001) and PEHL (P<.001) clusters. The SBP decreased within the first 2 weeks in all 4 clusters and continued to fall in the PEHH and PELH clusters over 4 weeks. Overall, the SBP was more reduced in the PELL (–6.1 mmHg) and PELH (–8.4 mmHg) clusters than in the others in the first week.

Discussion

Principal Findings

PE Patterns

This study explored patterns of PE with the hypertension self-management app and identified the effect of health care provider follow-up on PE and SBP in each PE pattern in the first 4 weeks after registration. For the first time, we found 4 dynamic trends of PE in a sample of 562 patients who used the mHealth app to record self-measured BP. Two clusters started with a high level of engagement, with one remaining at a high level throughout and the other dropping. Two clusters started with low engagement, with one increasing the level of engagement and the other dropping.

The majority of patients (387/562, 68.9%) were mainly between 40 and 60 years old. There was no difference in the distribution of patients under 60 years of age in each PE cluster; however, there were more patients aged over 60 years in the continuously high engagement cluster than in the other clusters. This may suggest that the patients over 60 years of age were more likely to engage in recording self-measured BP using the mHealth app for hypertension self-management. This may be attributed to the high level of awareness of the risk of hypertension because age is an important contribution factor to the development of hypertension [16,43]. Our finding is consistent with that of Goyal et al [15] in which older participants completed more planning challenges for chronic disease management than did younger participants. However, the finding of Kruse et al [10] was not consistent with our observations. They found that patients over the age of 65 years were less likely to use the mHealth service due to problems understanding the information, difficulty using technology, and inability to access the internet [10].

In this study, there were more male patients than female patients, which may be attributed to males being more prone to using mHealth services for hypertension management [44,45]. However, we did not find a significant difference in the proportion of males and females in each PE pattern. It appears that, although more males used the mHealth services than did females [44], they had the same level of PE with the mHealth service. Abd-alrazaq et al [30] found that gender did not affect intention to use the mHealth service, which was in line with our findings. However, Chung et al [46] found that females with heart failure were more adherent to the sodium-restricted diet than males, and Goyal et al [15] found that PE levels among female users with chronic disease were slightly higher than those among male users. Therefore, the gender differences in PE with mHealth apps does not appear to be conclusive.

The relationship between PE and SBP in the PELL cluster is worth noting. Patients in the PELL cluster reported a higher

SBP in the first week, and after 3 weeks of management, the SBP decreased more compared with the other clusters. Patients then began to stop using the app, and this decline in PE continued simultaneously with the increase in SBP. It may be the case that patients felt they reached the BP goal and ceased use of the app [27,47]. This may give evidence to suggest that controlling BP requires continuous engagement in hypertension self-management [35].

The Effect of 3 Types of Follow-ups on PE and SBP

Health care provider follow-up is essential for the prevention and treatment of hypertension. It is necessary to understand which type of follow-up is effective for which patient group [2]. Compliance follow-up, which was provided when the patients showed signs of reducing compliance in recording self-measured BP, had a positive effect on PE in the PEHH and PELH clusters. Regular follow-up, which was provided at a fixed interval, only had a positive effect on PE in the PELH cluster. These follow-ups might have been taken as the cue for engagement behavior for these patients, who may have awareness of hypertension self-management, but need cues for action. Interestingly, abnormal follow-up had no effect on any cluster of patients despite it being performed when the patient's BP was abnormal. These findings suggest that different types of follow-ups had different effects on patients' behavior of recording self-measured BP.

The content and method of follow-up are important to achieving a follow-up effect [48-50]. One study showed that health care providers have individual inherent preferences for the type of follow-up content to be provided to the patient [18]. Abd-alrazaq et al [30] found that the health care provider factor was related to patients' intension to engage in mHealth services. In our study, follow-up was performed through the mobile phone after health care providers received a reminder from the mHealth app. Other ways to improve PE, such as routine reminders combined with games, have yielded higher user engagement [16], and users seem to prefer simple, short voice messages over text messages because of communication trust and increased accessibility [51]. Cechetti et al [52] developed and implemented an mHealth app with a gamification method for hypertension management, which proved to be effective in promoting PE [52].

The mean SBP of all 4 clusters of patients reduced after 3 types of follow-ups except for abnormal follow-up in the PELL cluster. We also found abnormal follow-up was performed less frequently in the PELL cluster than in the others. This may be attributed to patients in the PELL cluster having a low level of engagement in recording self-measured BP, which resulted in the mHealth app not detecting the patient's abnormal BP condition and reminding the health care provider to follow-up. The PELH cluster developed positive PE and achieved SBP control after 3 types of follow-ups. This is in agreement with the observation that follow-up can motivate patients to engage in self-management. Positive feedback from PE after follow-up has been shown to be beneficial for BP control [53-55].

The Effect of Follow-up in Each of the 4 Weeks on PE and SBP

One study reported that 74.84% of app-only users stopped using an mHealth physical activity management app by day 43 [56]. This suggests that the duration of patient "stickiness" with the fully automatic mHealth services is limited and needs to be complemented by human support to keep momentum. Little is still known concerning the extent and duration of the effect of health care provider follow-up on self-management of hypertensive patients. This study found that the effect of follow-up on the PEHH and PELH clusters lasted until the third week, only had a small impact on the PELL cluster in the second week, and had no effect on the PEHL cluster at any time point. The effect duration of different types of follow-ups varied across each PE pattern. This may suggest that a fixed care pathway based only on patient's BP level would not work for all types of patients. Chronic disease management also needs to consider the patient's behavior and personal preferences. Our results support the design of patient-centered follow-up plans that incorporate social behavioral characteristics and preferences of patients into chronic disease management [14].

After 4 weeks of mHealth services being used, the mean SBP of all 4 clusters decreased. Interestingly, in the first week, the PELL and PELH clusters had a higher level of decline in SBP than did the other clusters. This may be the reason why the PELL cluster was complacent and did not actively engage in recording self-measured BP. Taking the advice of the health care providers may motivate those in the PELH cluster to increase their level of engagement. In the first 2 weeks, all 4 clusters of patients experienced a decline in SBP. Only the PEHH and PELH clusters maintained the SBP reduction through the fourth week, supporting the notion that hypertension management requires ongoing effort in monitoring BP to help patients improve their awareness of their own condition.

Strengths and Limitations

The strength of this study was that, first, the study used the longitudinal data collected in the first 4 weeks of patient registration with the mHealth service, which is informative for characterizing the changing trend of PE with hypertension management under an mHealth service. The findings are useful for continuous improvement of mHealth services for hypertension management. To the best of our knowledge, no other study has used longitudinal data to describe patterns of PE with a hypertension self-management app. Second, we analyzed the effect of health care provider follow-up on PE and SBP in each PE pattern. Our findings revealed the relationship between PE, BP, and health care provider follow-up. This provides evidence to support the further design of appropriate types of follow-ups for patients. Finally, we observed PE from real-world patients, which can reveal patient behavior in a natural setting, rather than recruited patients who would be more likely to overcome the burden associated with research work [57]. This helped to generate implementable, practical insights for the engagement of actual patients in daily hypertension management.

The study had 4 limitations. First, we excluded patients who used the app for fewer than 4 weeks after registration. This

might have produced a bias toward more positive findings of PE with the mHealth app and thus may limit the generalizability of our findings to those patients who drop out of the mHealth service early. Second, we only investigated the PE trend with the mHealth service in the first 4 weeks of hypertension management. Future study can further investigate the PE pattern after this period of time. Third, we defined PE as the behavior of recording self-measured BP. There are many other usage behaviors, such as taking medicine, engaging in physical activities, and keeping a healthy diet, which should be analyzed in future studies. Fourth, the different engagement behaviors could have arisen from various demographic and social psychological characteristics of patients (such as marital status, profession, anxiety, depression), so these factors need to be considered in future studies.

Conclusions

By analyzing the 4-week log data from a hypertension self-management app, BPA, this study identified the 4 distinct PE patterns in using an mHealth app for hypertension self-management. We also characterized the different effects of 3 types of health care provider follow-up on PE and SBP. Results showed how patients engaged with the mobile app and how health care provider follow-up affects or does not affect their engagement and BP. Our findings may inform the design and help strengthen health care provider follow-up strategies to improve outpatient engagement with mHealth apps for hypertension management. Future work needs to clarify the long-term engagement of patients with hypertension health care services. The indicators of PE should be broadened to include multiple types of usage behavior, and the effect of patient provider follow-up needs to be associated with patients' various demographic and socio-psychological characteristics.

Abstract

Background: In the United States, the number of people experiencing homelessness has continually increased over the last 3 years. Homelessness is associated with poor health, and people experiencing homelessness are often burdened with high rates of chronic and mental health conditions, functional limitations, and cognitive impairment. Despite the high burden of chronic illness and functional limitations, there is limited literature exploring self-management among homeless populations.

Objective: This study aims to investigate how access to smartphone technology facilitates self-management, including the attainment of social needs within the context of homelessness.

Methods: A secondary analysis of 33 exit interviews from 2 feasibility studies related to mobile health interventions among people experiencing homelessness was conducted. Iterative thematic analysis was used to identify themes representative of participants' experiences using smartphone technology.

Results: Collectively, participants revealed not only how the context of homelessness constrained their ability to engage in activities necessary to self-manage health and meet social needs but also how consistent and predictable access to the tools available through a smartphone changed their behaviors and outlook. The global theme of *empowered by technology* was identified and defined as how having a smartphone with a plan for unlimited text, calling, data, and transportation allowed participants to navigate homelessness and facilitated self-management.

Conclusions: People experiencing homelessness used the tools on a smartphone to make decisions, take action, solve problems, and use the resources—skills necessary for fulfilling tasks required for effective self-management. Further, consistent access to smartphone technology and transportation empowered participants to meet the requirements for the attainment of social needs.

Introduction

Background

In the United States, the number of people experiencing homelessness has continually increased over the last 3 years, with a 3% increase from 552,830 in 2018 to 567,715 in 2019 [1]. This number is likely to increase during the ongoing COVID-19 pandemic [2]. Homelessness is associated with poor health, and people experiencing homelessness are often burdened with high rates of chronic and mental health conditions, functional limitations, and cognitive impairment [3-5]. Furthermore, the rates of disability are high among people experiencing homelessness. In 2016, almost 50% of people

experiencing homelessness had some type of disability compared with 20% of the general US population [6].

The reasons for poor health are multifactorial and include risk factors that increase the risk of homelessness in the first place, such as early life poverty, mental illness, and substance use disorders. However, many risk factors are secondary to the conditions of homelessness, such as poor nutrition, exposure to communicable diseases, harsh living conditions, and violence [7,8]. Many people experiencing homelessness face difficulties in connecting to and accessing appropriate health and social services because of social and psychological barriers such as stigma, lack of trust in health care providers, and transient lifestyles [9-11]. Furthermore, people experiencing homelessness struggle to meet the basic needs such as food, shelter, and transportation, resulting in self-management of chronic health conditions being overlooked or neglected [12-14]. These barriers and competing priorities contribute to adverse outcomes, including reliance on emergency departments (EDs) or hospitals for nonemergent health care services and increased risk of 30-day hospital readmissions [15-17].

Self-management has been defined as "the ability of the individual, in conjunction with family, community, and health care professionals, to manage symptoms; treatments; lifestyle changes; and psychosocial, cultural, and spiritual consequences of health conditions" [18] and requires patients to perform a variety of day-to-day tasks to manage symptoms, treatments, and consequences of chronic conditions [19]. A component of self-management also includes developing the skills needed to devise, implement, evaluate, and revise plans to take charge of one's own health [20]. Given that self-management requires planning ahead, dedicated resources, and access to information, it is not surprising that homelessness poses unique barriers to successful self-management. For example, people experiencing homelessness have described poor sleeping conditions, limited food choices, limited income, and a lack of access to storage as barriers to self-management [21].

Despite the high burden of chronic illness and functional limitations, there is limited literature exploring self-management among homeless populations. To the extent that self-management has been investigated among people experiencing homelessness, outcomes are encouraging [22-24]. In addition, Merdsoy et al [21] explored the perceptions, needs, and preferences for self-management among men experiencing homelessness. They found that the majority of participants perceived self-management as important, but complex challenges related to homelessness, including lack of social support and limited access to communication technology, dictated unique self-management support needs [21].

Given the distinct context of homelessness and the importance of social support and access to information and communication for effective self-management, smartphone technology may be a useful tool to facilitate self-management activities among people experiencing homelessness. In the United States, smartphones are ubiquitous. For people experiencing homelessness who often encounter many barriers to communication and information seeking, smartphones allow for multiple resources in one tool, helping overcome access barriers. Prior evidence suggests that the connectivity provided by smartphones can decrease social isolation and facilitate communication between peers, family, and service providers [25]. In addition, pilot studies have investigated using phone calls for improving medication adherence [26], apps for improving mental health [27], and text messaging for appointment reminders [28] and improving physical activity [29] among people experiencing homelessness. This burgeoning body of evidence suggests that people experiencing homelessness are welcoming and supportive of using smartphone technology to address their health care issues, and smartphone technology has also been identified as a feasible tool for self-management support among people experiencing homelessness [25].

Objective

The purpose of this study is to investigate how access to smartphone technology facilitates self-management, including the attainment of social needs within the context of homelessness. The methods and results are reported in accordance with the Consolidated Criteria for Reporting Qualitative studies checklist [30].

Methods

Overview

This study is a secondary analysis of exit interviews from 2 pilot studies investigating the preliminary outcomes of two mobile health interventions among people experiencing homelessness [25]. Both studies were conducted in Austin, Texas, United States. The first pilot study was a 4-month study designed to improve care coordination and reduce acute health care utilization among people experiencing homelessness [25]. The second was a 1-month study designed to improve medication adherence among people experiencing homelessness. In each study, participants were recruited from 3 churches that provided services to people experiencing homelessness. Convenience sampling was used, and potential participants were referred by community partner site staff or volunteers to the research team for study eligibility and screening (for eligibility criteria for each study, refer to Textbox 1). At baseline, the first author (WT) administered a series of baseline assessments to collect demographic data and self-reported health history, medication adherence, social support, and recent hospitalizations or ED visits. Upon enrollment into the study, participants received a study-assigned smartphone activated with a plan for unlimited text, calling, data, and public transportation.

Exit interviews were conducted between February and June 2019 with 16 people experiencing homelessness who participated in the first study and between August and September 2019 with 17 people experiencing homelessness who participated in the second study. The semistructured interviews included questions about participating in the study, having and using a smartphone, ED or hospital visits during the study period, and medication use. The interviews allowed participants to share their experiences with smartphone technology and how access to a smartphone with a data plan and access to unlimited public transportation affected their daily lives and routines. For this secondary analysis, investigators focused on the component

of the interview in which participants described how they used their smartphones to accomplish various daily tasks. Interviews were conducted by the first author (WT) in quiet, private locations in church-based entities from which the participants had been recruited. Interviews were digitally recorded, and a team of graduate students transcribed and verified each interview. Both studies were approved by the university institutional review board, and informed consent was obtained before participant enrollment.

Textbox 1. Inclusion criteria for research studies.

Study 1

- Aged ≥18 years
- Currently experiencing homelessness (defined as where the person had slept most nights in the previous 30 days)
- Currently prescribed at least two medications for chronic health conditions (self-report)
- Diagnosis of at least one chronic health condition (self-report)
- At least two hospitalizations or emergency department visits in the past 6 months (self-report)
- Score of at least 10 on the Patient Health Questionnaire-9

Study 2

- Aged ≥18 years
- Currently experiencing homelessness (defined as where the person had slept most nights in the previous 30 days)
- Currently prescribed at least two medications for chronic health conditions (self-report)
- Diagnosis of at least one chronic health condition (self-report)
- At least two hospitalizations or emergency department visits in the past 6 months (self-report)
- Score of at least 4 on the Rapid Estimate of Adult Literacy in Medicine-Short Form

Data Analysis
