Abstract

COVID-19 is currently the third leading cause of death in the United States, and unvaccinated people continue to die in high numbers. Vaccine hesitancy and vaccine refusal are fueled by COVID-19 misinformation and disinformation on social media platforms. This online *COVID-19 infodemic* has deadly consequences. In this editorial, the authors examine the roles that social media companies play in the COVID-19 infodemic and their obligations to end it. They describe how *fake news* about the virus developed on social media and acknowledge the initially muted response by the scientific community to counteract misinformation. The authors then challenge social media companies to better mitigate the COVID-19 infodemic, describing legal and ethical imperatives to do so. They close with recommendations for better partnerships with community influencers and implementation scientists, and they provide the next steps for all readers to consider. This guest editorial accompanies the Journal of Medical Internet Research special theme issue, “Social Media, Ethics, and COVID-19 Misinformation.”

The COVID-19 Infodemic

The COVID-19 pandemic continues to have a substantial impact worldwide, with over 266 million diagnosed cases and over 5 million deaths [1]. In 2021, depending on the month, COVID-19 was either the first, second, or third leading cause of death in the United States, alongside heart disease and cancer [2]. People are still dying from COVID-19 despite a vaccine surplus in wealthy countries, public health interventions to curb viral transmission, new therapeutic options, and the heroic efforts of frontline care providers. Why? Although we initially focused on a deadly and contagious virus, we were simultaneously overwhelmed by the deadly and contagious impact of online misinformation and disinformation about that virus [3]. Much like the COVID-19 pandemic itself, we face a widespread disease with long-term consequences: the COVID-19 infodemic.

The World Health Organization defines an infodemic as “too much information or false and misleading information” that “causes confusion, risk taking behaviors...and mistrust of health

officials" [4]. The United Nations Educational, Scientific, and Cultural Organization considers *fake news* a general term for false information that can be further defined by intentionality [5]. Misinformation consists of "information that is false but not created with the intention of causing harm," whereas disinformation is "information that is false and deliberately created to harm a person, social group, organisation, or country" often orchestrated with financial or political motives [5]. Both are prevalent across all social media platforms [6]. Together, these serve to undermine trust in governmental interventions, public health responses, expert guidance, and scientific facts about COVID-19 [7,8]. Accordingly, we define the COVID-19 infodemic as the overwhelming amount of complex and often contradictory information available about COVID-19, inclusive of substantial fake news about the origins of the virus, treatment options unsupported by rigorous clinical data, and baseless claims regarding adverse effects of lifesaving vaccines; these false narratives may be spread by authoritative institutions or influencers who are otherwise thought to be trustworthy, and they play a substantial role in shaping views and influencing human behaviors that can lead to poor health outcomes.

The clinical impact of the COVID-19 infodemic is profound. Effective strategies such as masking and social distancing have been undermined to the detriment of those at greatest risk. With several effective vaccines now available for SARS-CoV-2, vaccine hesitancy and vaccine refusal—two distinct problems with different causes and different solutions—have become major issues. Vaccine hesitancy is prolonged deliberation or delay in accepting vaccination, even when supply is ample; this differs from vaccine refusal, which is defined by the specific intent not to vaccinate, similar to the "anti-vax" movement adherents, in which people refuse all vaccines including childhood vaccinations. Both vaccine hesitancy and refusal are fueled by misinformation on social media, and vaccine misinformation that initially manifests offline can quickly spread to social media platforms; the misinformation exchange is bidirectional [9]. In fact, the US Surgeon General warned in 2021 that misinformation is the greatest threat to COVID-19 vaccination efforts [10]. COVID-19 misinformation and disinformation on social media increases vaccine hesitancy, lowers vaccination rates, and causes preventable deaths, especially among certain demographic populations [11,12]. The COVID-19 infodemic remains deadly, and we must act.

To address this, the Stanford University Ethics, Society, and Technology Hub and the Stanford Department of Emergency Medicine cosponsored INFODEMIC: A Stanford Conference on Social Media and COVID-19 Misinformation. INFODEMIC convened experts from the fields of social media, medicine, public health, and biomedical ethics with a goal of identifying new best practices to combat COVID-19 misinformation online [13]. The corresponding Journal of Medical Information Research theme issue, "Social Media, Ethics, and COVID-19 Misinformation" builds upon this work to discuss the impact of this infodemic and approaches to ending it. In this editorial, we will examine the role of social media companies (executives, financiers, leaders, and users) in health misinformation and their obligations to mitigate the COVID-19 infodemic.

The Role of Social Media

Recognition of social media's power to propagate fake health news came well before COVID-19, notably surrounding topics such as tobacco use, vaping, and recreational drug use [6]. However, 2020 was the *year of online disinformation*, with political and scientific misinformation and disinformation often reinforcing one another [14]. Social media companies and platform users both played a substantial role in the birth of the COVID-19 infodemic that year. The internet propagates knowledge rapidly and globally, typically without checks for accuracy, and facilitates the current infodemic. Social media companies attempt to self-police erroneous content on their platforms with variable success, both due to the overwhelming amount of COVID-19 information they must process and their reluctance to censor their users' posts. Information filters swiftly through various avenues on the internet, often accessed via search engines and social media algorithms. Google is the dominant search engine with over 3.5 billion global searches each day, allowing individuals to retrieve information from a wide array of sources [15]. Although it may appear that users pull information, search engines prioritize certain results, in effect pushing relevant information to the user [16]. Social media algorithms push selected content to billions of users as well (Table 1) [17]. The proprietary algorithms used by social media companies are routinely exploited to spread COVID-19 misinformation and disinformation, with certain content repeatedly presented to users who have specific profiling characteristics or search histories. These algorithms could be better optimized to reduce the online trafficking of harmful information that risks the public health.

Table 1. Approximate numbers of monthly users of several social media platforms.

Social media platform (company, location)	Approximate number of users
Facebook (Meta Platforms, Inc; Menlo Park, California)	3 billion
YouTube (Google LLC; San Bruno, California)	2.3 billion
WhatsApp (Meta Platforms, Inc; Menlo Park, California)	2 billion
Instagram (Meta Platforms, Inc; Menlo Park, California)	1.4 billion
Twitter (Twitter; San Francisco, California)	400 million

In addition to social networking, an increasing number of users consume news on social media platforms compared with traditional media outlets [18]. Individuals engage in social circles and networks on these platforms virtually, and they do

not leave—their beliefs are reinforced by information chosen for them and others like them by computer algorithms. Without intervention, there is exposure to new content but little to no exposure to new knowledge or ways of thinking. The algorithms used by social media companies create news echo chambers that can serve as a vector for misinformation by amplifying low credibility information sources. During the early COVID-19 pandemic, low credibility sources dominated both Twitter and Facebook posts related to COVID-19, topping traditional news and media outlets [19]. Online *bots* further confuse users and reduce their ability to discern truth from fake news. Bots are computer codes designed to appear as user profiles or credible news sources but are instead weapons for disinformation. Social media companies struggle to identify and remove bots that use even the simplest artificial intelligence, which take advantage of platform data and social media push algorithms. Thus, it is unsurprising that social media platforms fuel hoaxes and misinformation about the etiology and origins of COVID-19, its treatment, and its prevention through vaccines [19]. Social media companies could invest greater resources to combat these agents of the infodemic.

Moreover, health misinformation is not confined to COVID-19. In a 2021 systematic review, the greatest prevalence of health misinformation was found on Twitter and related to smoking, drugs, and vaccines [6]. Who is to blame? Many fingers can be pointed, and social media companies are among the culpable. *Top-down* misinformation from celebrities and other public figures that are allowed on these platforms exacerbates the problem. Celebrities account for 20% of online misinformation and 70% of the attention of platform users, compared to noncelebrity posts [19]. Social media companies benefit from increased user activity, and celebrity influencers are engaging. These attention-grabbing individuals enjoy unfettered reach to users because social media companies rarely place limits on their messaging, even when that messaging includes erroneous facts about COVID-19. The blurred lines between factual news and entertainment and falsehoods about COVID-19 could be labeled for users by social media companies through better oversight of their platforms.

An Obligation to Act

US-based social media companies are legally regulated by the US Federal Trade Commission in the same ways that any other US-based businesses are regulated. However, they are not subject to federal *social media regulations* of any kind—because there are none [20]. Social media platforms are private companies who set their own internal regulatory policies and are not subject to oversight by the US Federal Communications Commission (FCC) nor, specifically, Section 230 of the Communications Act of 1934 [21]. Subsection (c) (1) of the Act maintains that social media companies do not act as publishers of information, as do other media entities, absolving them of an obligation to monitor user-generated content on their platforms. There are no legal mandates to the manner or methods by which they self-govern, and any actions by these companies are simply made in good faith. However, they do maintain internal policies, some of which are intended to curb dissemination of different types of information that are harmful to the public welfare, ranging from COVID-19 misinformation to communications among terrorist organizations. These Good Samaritan policies determine what constitutes an acceptable use of their platforms and draw a line limiting certain types of social expression [22].

That said, social media companies are mostly unregulated, and some claim they should remain so, rather than be subject to FCC oversight as are television and radio companies. Current actions by these companies are voluntary, not compulsory, and often in response to external pressures. However, if companies do not meaningfully address misinformation and disinformation on their platforms, government oversight should be considered. Internal policies are an important first step, yet we continue to see blatantly false information that contradicts scientific evidence regularly posted across most social media platforms [3]. For example, a content analysis study that evaluated 1225 fake news stories found that social media platforms were responsible for disseminating half (50.5%) of the identifiable misinformation [3]. Social media companies are partly responsible for fueling the COVID-19 infodemic, and we believe that ongoing inaction or inadequate action to address it keeps them complicit. Given the stakes, failure to address health misinformation and disinformation should be viewed as a public health crisis, and the commensurate response should include government oversight of social media companies (similar to other media sources) in the name of the public good.

Beyond law and public policy, there are other interventions to consider. We maintain that there is an ethical obligation for social media companies to act. Bioethicists recognize the broader public health consequences of social media use and how bias is determined by the specific design and implementation of social media platforms [23]. Ethical frameworks guide moral decision-making and action/inaction, two of which are especially relevant for social media companies [24]. First, utilitarian ethics calls for decisions that positively affect the greatest number of people. This is also a bedrock of public health. The application of utilitarian ethics suggests that companies should make socially conscious decisions, even when inconvenient [25]. For example, social media companies can and should redesign their algorithms that have propagated the infodemic, even if such changes risk ad revenue and profits. Similarly, censorship of celebrity users who disseminate misinformation might decrease user engagement and activity with a platform, but these actions are needed to address the infodemic. Second, virtue ethics is reasoning based on the virtues of what makes a good person, or in this case a good company. Kaptein [26] defined corporate virtue ethics that include clarity, transparency, and sanctionability, among others. A *good* social media company that earnestly engages in self-regulation would exhibit many other virtues including honesty, courage, self-control, and integrity. When considering corporate virtues, and what makes a *good* social media company, it is worth noting corporate vices in the absence of *good*: deficiency, ambiguity, subversiveness, and opaqueness [26]. These vices are commonly associated with the current practices of social media companies, specifically when considering their algorithms that repeatedly drive dangerous content to users. These algorithms reinforce

COVID-19 misinformation for some users and cloister them from reports on legitimate scientific evidence.

It does not have to be this way. There is hope for "good social media companies," ones which take bold actions in the face of a global pandemic, and perhaps at their own expense. We think that social media companies could become allies after all, especially as their power to enact social change is unprecedented. Indeed, many companies are working to mitigate misinformation already. For instance, Twitter, Facebook, and Google Search remove content, add warning labels, and deactivate misleading accounts that promote disinformation. However, these companies must navigate the substantial influx of constantly changing information about COVID-19, struggling to discern between deceptive content, scientifically inaccurate *alternative facts*, and even genuine scientific disagreement [27]. That struggle deserves consideration. For example, a claim that SARS-CoV-2 is airborne may have been flagged as misinformation or disinformation in January 2020. Today, in early 2022, most scientists believe that the virus is airborne at least in certain environments and conditions. Would a social media company that removed a post claiming that SARS-CoV-2 is airborne have harmed the public or prevented important academic debate in the early days of the pandemic?

Acknowledging the genuine complexity of the situation does not undermine but rather illuminates the urgency of our call to action. In fact, recognizing the difficulties that social media companies have in fairly adjudicating misinformation implies that far more financial and human resources will need to be marshaled to sufficiently address the problem. Wealthy companies have invested some capitol toward these efforts, but they are capable of so much more. The volume of misinformation is impressive, and removed information is often quickly replaced by similarly harmful messages within a platform, stifling progress. In essence, social media companies are treading water, at best, and additional resources and initiatives are warranted. Such efforts may need to be strategically directed toward specific aspects of the infodemic, such as misinformation about the clinical severity of the virus or disinformation about the efficacy of the vaccine. Different strategies are warranted to address a range of fixed beliefs that may have developed at different stages of the pandemic; a singular approach by a social media company may be insufficient to change minds about the origins of the virus, its transmissibility, and its prevention, all at once. Each type of misinformation deserves a unique message in response, and these messages must be tailored to the cultural differences of users in certain communities.

Addressing the infodemic does not fall solely to social media companies, and we cannot rely only on a few people or a small number of entities to battle it. Key potential change agents also include elected government representatives, public health officials, research scientists, journalists, clinical ethicists, and physicians. However, for many constituencies, a general distrust of government and an underappreciation of science is magnified in part by social media, requiring a truly multidisciplinary response to the challenge [28]. Therefore, we believe that major impact could also result from effective messaging delivered by trusted community leaders who can, for example, reach communities of vaccine hesitant individuals online and in person: ministers, youth counselors, teachers, social and mental health workers, frontline workers, and others.

Finally, implementation scientists have been inadequately used as resources. Implementation science is the study of methods used to introduce research findings into a health care context. With respect to COVID-19, the methods used to introduce a new vaccine to the entire world's population represented an important and frequently missed opportunity [29]. During 2020, significant attention was given to the rapid development and testing of COVID-19 vaccines; relatively less attention was given to equally crucial areas, including how to equitably manufacture vaccines to scale and how to equitably distribute them [30]. The COVID-19 vaccine is widely accessible throughout most industrialized nations now, but the potential influence of implementation science remains no less important. A key tenet of implementation science is the use of different strategies to target different patient populations [31]. Especially in the face of stiffening vaccine hesitancy in certain communities and subpopulations, we believe that implementation scientists should be engaged to help guide strategies and actions of social media companies, and similarly to help other change agents such as elected officials. There is a social imperative and an ethical imperative to embrace the best available evidence and methods needed to improve COVID-19 vaccination rates. We recommend that social media companies seek the advisement of experts in implementation science as they develop strategies to combat vaccine and other COVID-19 misinformation.

Next Steps

Health misinformation and disinformation have been increasing rapidly for over a decade [14]. During the COVID-19 pandemic, substantial attention was initially focused on ensuring the distribution of the vaccines themselves but, unfortunately, *not the distribution of reliable information nor the mitigation of harmful misinformation and disinformation.* This has had long-lasting effects. Over time, some who have said "I won't wear a mask" now say, "I won't take a vaccine." Going forward, it is imperative that we move beyond our roles as scientists in a laboratory, physicians on the frontline, or strategists at social media companies. We must seek to expand our influence in health education and public health messaging more broadly. We must exit the silo of the house of medicine and meet patients and the public where they are at: online. As we do this, we need to rely on sound strategies gleaned from education and leadership literature to reach our patients effectively [8,32]. We need to identify evidence-based interventions that effectively dismantle online misinformation and then implement them [14].

If we want to create meaningful change, we cannot merely rely on the progress of clinical science alone. We must consider how best to implement and disseminate new discoveries to the public via social networks and offline communities. For many in science and medicine, this may mean engaging with mass media for the first time. That means personalizing our direct outreach to patients and communities, engaging with empathy, and seeking to understand before seeking change [33]. Moreover, we must resist a paternalistic approach in which we protect

patients from information but rather empower them to seek reliable information and make informed choices about their health. Fortunately, there are frameworks that can guide us. Bautista et al [33] proposed a two-step conceptual model for physicians seeking to refute misinformation—step 1: identification of the types and sources of health misinformation; and step 2: attempting to make private and public corrections, done strategically and respectfully. Meanwhile, Chou et al [34] urged physicians to partner with social media companies and influencers to address health misinformation online, teach the public to recognize potential misinformation, and cultivate better trust toward the medical community. Finally, Walter et al [35] confirmed that interventions to correct health misinformation are the most successful when they come from experts in a given field.

Complicated problems call for collaborative approaches. Social media companies, medical professionals, researchers, implementation scientists, and trusted messengers must form synergistic partnerships to successfully combat the COVID-19 infodemic and health misinformation and disinformation generally. Rather than focusing on assigning blame, change agents can be most effective by demonstrating their willingness to act and implement new best practices, regardless of whether or not they previously contributed to some of the problems we face today.

As you read the articles in this special theme issue of the Journal of Medical Internet Research, we urge you to reflect on expanding your own contributions beyond your current working environment. In Textbox 1, we offer several actionable next steps for social media companies and health care providers to combat COVID-19 misinformation. Consider how we all can better address the current COVID-19 infodemic and combat and prevent future ones. To truly win this battle, we must urgently convert our expertise into the right words and the right actions. Whether we find our patients in the clinical environment or on social media, we must protect them from the harms of misinformation and disinformation and help them benefit from the lifesaving medical and health information that we have to offer.

Textbox 1. Actions to address the COVID-19 infodemic.

Recommendations for social media companies

- Redesign social media algorithms to reduce the spread of COVID-19 misinformation
- Identify and remove harmful bots from platforms
- Censor sources of COVID-19 misinformation and disinformation
- Label erroneous content
- Promote sound science
- Support public health efforts
- Target culturally appropriate messaging to specific communities
- Direct users to local health clinics and COVID-19 resources

Recommendations for health care providers

- Engage patients on social media
- Offer COVID-19 content expertise to social media companies and online news media
- Commit to posting public health messaging online
- Identify and implement evidence-based interventions to combat health misinformation
- Partner with online influencers to disseminate accurate COVID-19 information
- Provide expert advice to mass media outlets
- Personalize direct outreach to patients and communities
- Seek to understand patients with empathy before seeking behavior change
- Empower patients to seek reliable health information and make informed choices
- Create synergistic partnerships with leaders in other disciplines

Authors' Contributions

Abstract

Background: There is a lack of evidence in the literature regarding the learning outcomes of immersive technologies as educational tools for teaching university-level health care students.

Objective: The aim of this review is to assess the learning outcomes of immersive technologies compared with traditional learning modalities with regard to knowledge and the participants' learning experience in medical, midwifery, and nursing preclinical university education.

Methods: A systematic review was conducted according to the Cochrane Collaboration guidelines. Randomized controlled trials comparing traditional learning methods with virtual, augmented, or mixed reality for the education of medicine, nursing, or midwifery students were evaluated. The identified studies were screened by 2 authors independently. Disagreements were discussed with a third reviewer. The quality of evidence was assessed using the Medical Education Research Study Quality Instrument (MERSQI). The review protocol was registered with PROSPERO (International Prospective Register of Systematic Reviews) in April 2020.

Results: Of 15,627 studies, 29 (0.19%) randomized controlled trials (N=2722 students) were included and evaluated using the MERSQI tool. Knowledge gain was found to be equal when immersive technologies were compared with traditional learning modalities; however, the learning experience increased with immersive technologies. The mean MERSQI score was 12.64 (SD 1.6), the median was 12.50, and the mode was 13.50. Immersive technology was predominantly used to teach clinical skills (15/29, 52%), and virtual reality (22/29, 76%) was the most commonly used form of immersive technology. Knowledge was the primary outcome in 97% (28/29) of studies. Approximately 66% (19/29) of studies used validated instruments and scales to assess secondary learning outcomes, including satisfaction, self-efficacy, engagement, and perceptions of the learning experience. Of the 29 studies, 19 (66%) included medical students (1706/2722, 62.67%), 8 (28%) included nursing students (727/2722, 26.71%), and 2 (7%) included both medical and nursing students (289/2722, 10.62%). There were no studies involving midwifery students. The studies were based on the following disciplines: anatomy, basic clinical skills and history-taking skills, neurology, respiratory medicine, acute medicine, dermatology, communication skills, internal medicine, and emergency medicine.

Conclusions: Virtual, augmented, and mixed reality play an important role in the education of preclinical medical and nursing university students. When compared with traditional educational modalities, the learning gain is equal with immersive technologies. Learning outcomes such as student satisfaction, self-efficacy, and engagement all increase with the use of immersive technology, suggesting that it is an optimal tool for education.

Introduction

Background

Educational technology is changing the way in which we learn today, and its purpose is to ultimately improve education [1,2]. The addition of educational technology to a curriculum needs to be developed and guided by informed, evidence-based research. Educational technology includes instructional software such as virtual reality (VR), augmented reality (AR), and mixed reality (MR), known collectively as immersive technology [3]. Immersive technologies should be built around effective teaching methods that provide an appropriate learning method and learning outcome [4]. Immersive technologies are thought to provide pedagogy based on the constructivist theory and experiential learning, creating an environment that aids visual learners and enables students to learn by doing, develop creativity, and increase understanding of invisible concepts [5]. The Association for Medical Education in Europe has previously published guidance on e-learning in medical education: "Designs for effective medical e-learning, therefore, need to mirror the dynamics and details of real-world practice as well as affording effective learning opportunities" [6].

Immersive technologies are defined as devices that provide sensory stimuli to provide a sense of realism and immersion in the interactions with the computer-generated world [7]. VR is a technology that allows the user to explore and manipulate computer-generated real or artificial 3D multimedia sensory environments in real time. It dates back to 1956, when Morton Heilig, a cinematographer, developed *the Sensorama*, a display box first used for background scenes in the Hollywood motion picture industry. This was the first head-mounted display to be developed. In the mid-1960s, Ivan Sutherland, an American Computer Scientist, went on to develop the concepts of VR further. He described *The Ultimate Display*, a VR system that could simulate reality [8], and his paper described core concepts that are the foundation of VR use today. Owing to the heterogeneity of the terminology used to describe VR, we can characterize VR as a "collection of hardware such as Personal Computer (PC), HMDs and tracking sensors, as well as software to deliver an immersive experience" [9]. In comparison, AR is an interactive experience of a real-world environment where the objects that reside in the real world are *augmented* by computer-generated perceptual information. Historically, the development of AR started in the 1960s; however, the term *AR* was not established until 1990. Although VR and AR share many technical aspects, the main difference is that AR does not construct a fully artificial environment and simply overlays computer-generated images onto images of the real world. Therefore, it uses machines that allow a physical view of the surrounding environment to be visible but enhanced with virtual images [10]. Finally, MR is the merging of real and virtual worlds to produce new environments and visualizations where physical and digital objects coexist and interact in real time [11].

Objective

To date, there has been a multitude of publications detailing the development and implementation of immersive tools, in addition to demonstrating the benefits of VR, AR and MR technology in medical, nursing and midwifery education [12-17]. This technology is thought to provide increased engagement and understanding during learning coupled with feedback mechanisms and design capabilities of varying difficulty levels [5]. In addition, it facilitates practice without the risk of human harm and also helps build professional skills and teamwork [18,19]. However, there is a paucity of evidence on the learning outcomes of these innovative educational tools.

As outlined by the Digital Health Education Collaboration, there is a need for a strong evidence base to guide the development of immersive educational tools so that the learning goals and outcomes are in line with national and international standards [20]. There have been an increasing number of systematic reviews documenting the use, application, and effectiveness of VR, AR, and MR in an effort to establish an evidence-based network of research for use in medical education. However, the results have been mixed; including a systematic review that looked at the effectiveness of AR in medical education which found that there was insufficient evidence to recommend its implementation into the curriculum. Similarly, another review looked at serious games used in medical education and found that the evidence was moderate to support the use of immersive technology, stating that it should not replace traditional learning tools [21-25]. Immersive technologies are used mainly as educational tools for complex topics such as anatomy and embryology and are thought to enhance the learning experience [26,27]. Are VR, AR, and MR as effective in delivering knowledge as well as an enhanced learning experience in comparison with traditional teaching tools such as 2D didactic presentations?

Therefore, the aim of this systematic review is to assess the learning outcomes of VR, AR, and MR across 3 health care student disciplines—medicine, nursing, and midwifery education—compared with traditional learning modalities. The learning outcomes include knowledge, skill development, and the learning perceptions of students, including satisfaction and self-confidence in learning along with engagement and motivational factors.

Methods

Purpose and Protocol

A systematic review of the available scientific literature was conducted to assess the learning outcomes associated with the application of VR, AR, and MR as educational tools compared

with traditional learning modalities for medical, nursing, and midwifery students in preclinical university education. The review protocol was registered with PROSPERO (International Prospective Register of Systematic Reviews) in April 2020 (CRD42020154598). The search results were reported according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [28] and the Cochrane Collaboration guidelines [29].

Eligibility Criteria

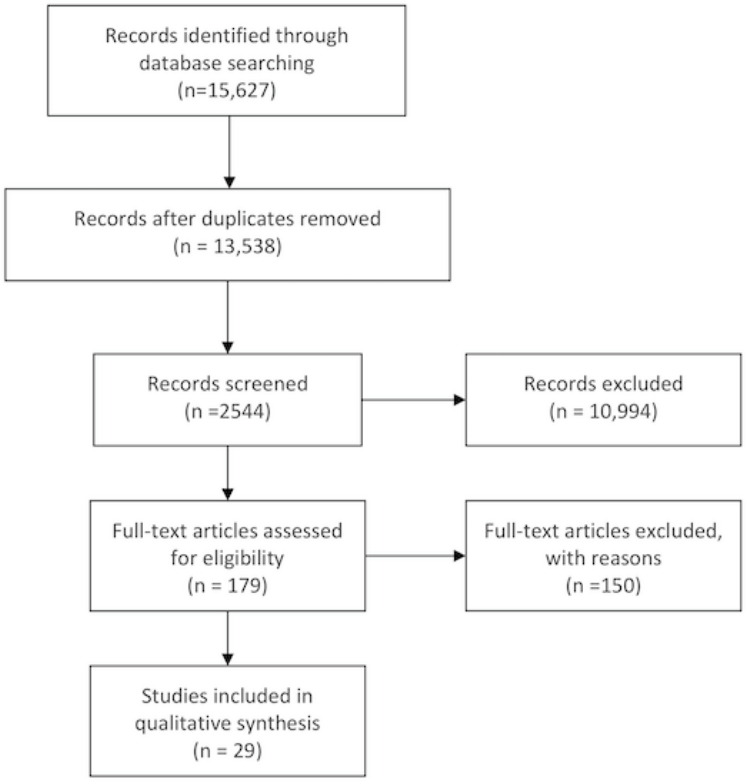
The eligibility criteria were based on the Population, Intervention, Comparison, and Outcomes criteria. The population selected for this review included preclinical university students enrolled in three educational disciplines: medicine, nursing, or midwifery courses only. Randomized controlled trials (RCTs) that implemented VR, AR, or MR technology in comparison with a control method were included. Owing to the heterogeneity of the definitions surrounding VR applications, we restricted inclusion to interactive 3D models requiring a headset, virtual patients (VPs), or VR learning environments. The primary outcomes included knowledge and reference to the learning experience, which involved engagement, satisfaction, and perceived learning experience. Only studies published in English were included.

Search Strategy

A large-scale search was undertaken because of the wide use of the various terminology to describe VR, AR, and MR and the technology surrounding their use in health care student education. The following method was used to identify empirical studies for inclusion in the systematic review. We conducted a comprehensive computerized database search of full-text articles published in English. Only RCTs assessing learning outcomes using VR, AR, or MR technologies in comparison with traditional learning models were included. The reason for this was that we wanted to review the learning outcomes of immersive technologies compared with traditional learning outcomes, including knowledge and learner experience. The fundamental study design of an RCT requires a control and an intervention group; therefore, we selected these types of studies for this review. Searches were conducted with predefined search terms (Multimedia Appendix 1) using the following electronic databases: PubMed, Embase, Web of Science, CINAHL, and ERIC. Medical Subject Headings terms included *virtual reality*, *augmented reality*, *educational technology*, *imaging*, *three dimensional*, *education*, and *teaching materials*. Search terms were connected using Boolean operators *AND* and *OR* to capture all relevant article suggestions. The latest search was conducted on March 8, 2021.

Databases were downloaded to EndNote reference manager software (Clarivate Analytics), which recorded citations and identified duplicates. A spreadsheet was created to record decisions and comments. Screening of articles was conducted by 2 researchers (GR and SC) in an unblinded, standardized approach (independently and in parallel). Titles and abstracts of studies sourced from electronic databases were reviewed according to the inclusion and exclusion criteria previously described. Subsequently, full texts of the included articles from the initial screening process were reviewed for eligibility according to the described inclusion and exclusion criteria. Differences of opinion were resolved through conversations between the reviewers. A schematic stepwise algorithm for the search strategy is shown in Figure 1.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flow diagram adapted for this study.



Data Collection

Microsoft Excel was used to build a data extraction form, which was divided into three categories: (1) study identification, (2) analysis of learning outcomes, and (3) study design. The first section included bibliographic information, the country of origin of the study, and a demographic description of the participants. The second section examined learning outcomes related to teaching strategies, relationships between technologies, and learning objectives. The third section evaluated the methodological quality of the study design.

Study Quality Assessment

We used the Medical Education Research Study Quality Instrument (MERSQI) to evaluate the study design of the RCTs [30]. The MERSQI is divided into several domains, including evaluation of study design, sampling, data type, validity, data analysis, and outcomes. The learning outcomes are based on the hierarchy of educational outcomes by Kirkpatrick and Kirkpatrick [31], which adopts a constructional framework using a 4-level model for evaluating educational effectiveness. The first level describes the participants' perception of the learning experience; knowledge, skills, and attitudinal change are assessed in the second level; changes in behavior are evaluated in the third level; and changes in health care or patient outcomes are evaluated in the fourth level.

Data Analysis

A narrative review of the results reported in the included studies on learning outcomes was conducted. The data in the final included studies did not allow for a formal meta-analysis as the studies were not sufficiently homogenous, given the stated research question and the use of different technologies and educational topics.

Results

Study Selection

We identified 15,627 articles from the primary database search. After duplicates were removed, there were 86.63% (13,538/15,627) of articles left for abstract review. Abstracts were screened and, of those 13,538 articles, 179 (1.32%) remained for a full paper review. Of those 179 articles, 150 (83.8%) were excluded, leaving 29 (16.2%) full papers for study inclusion. Details of the study selection process are displayed in Figure 1. In total, 29 RCT studies (N=2722) were included in this review. All studies were conducted in the past 10 years, with most studies (18/29, 62%) published within the past 3 years.

Study Designs

In total, 2722 students participated in the 29 RCTs. Of the 29 articles, 19 (66%) included medical students (1706/2722, 62.67%), 8 (28%) included nursing students (727/2722, 26.71%), and none of the studies involved midwifery students. Approximately 7% (2/29) of studies included both medical and nursing students (289/2722, 10.62%). The following disciplines were used to test the immersive technologies: anatomy, basic clinical and history-taking skills, neurology, respiratory medicine, acute medicine, dermatology, communication skills, internal medicine, and emergency medicine. A full list of the RCTs, basic demographic details, and immersive technology applications included in this review is outlined in Table 1.

Table 1. Randomized controlled trials included in this review of immersive educational tools.

Author	Setting	Application detail	Sample size, N	Purpose	Outcome
Seifert et al [32]	Germany	VP[a] cases (Moodle learning management system)	40	VP—basic clinical skills	Similar levels of long-term knowledge gained; participants assessed the learning experience and the comprehensibility of the seminars as either *very good* or *good*
Wang et al [33]	New Zealand	3D visualizer software (preloaded 3D hologram) on Microsoft HoloLens device	52	Anatomy teaching	There was no difference in knowledge acquisition between groups; only MR[b] group demonstrated higher retention in nominal and spatial types of information; increased engagement in 3DM[c] and MR group
Rossler et al [34]	United States	Virtual Electrosurgery Skill Trainer developed by the National Institutes of Health	20	Fire safety knowledge	No differences in knowledge; intervention group participants were noted to meet performance criteria for their assigned role in their perioperative team
Lombardi et al [35]	United States	Virtual heart activities using physiology software programs (Practice Anatomy Lab, Pearson Education, and Interactive Physiology)	29	Anatomy teaching	Plastic model group achieved significantly higher overall scores on initial and follow-up exams; attitude surveys demonstrated a higher preference for organ dissection
Padilha et al [36]	Portugal	Body Interact (simulation with VPs)	42	Respiratory medicine	Improved knowledge and higher levels of learning satisfaction in the intervention group; no statistically significant differences in self-efficacy perceptions
Blanie et al [37]	France	VP cases—LabForSIMS (simulation center) and a software designer (Interaction Healthcare)	146	Basic clinical skills	No significant educational difference was found; satisfaction and motivation were found to be greater with the use of SG[d]
Liaw et al [38]	Singapore	VP simulation—eRAPIDS, developed at the National University of Singapore	57	Clinical deterioration	No difference in knowledge acquisition; VP was rated positively
Menzel et al [39]	United States	Second Life (Linden Lab) virtual simulation environment (WALD[e] Island)	51	Cultural attitudes	No statistically significant differences between the learning formats
Gananasegaram et al [40]	Canada	Campbell's 3DM of the inner ear—publicly available data sets displayed on Microsoft HoloLens	29	Anatomy teaching	No difference in knowledge acquisition; HG[f] group rated higher for overall effectiveness, ability to convey spatial relationships, and learner engagement and motivation
Liaw et al [41]	Singapore	VR[g] (no details)	198	VP to teach MDT[h] rounds	Increased levels of self-efficacy and attitudes toward interprofessional team care
Moro et al [42]	Australia	Microsoft HoloLens, 3D Studio Max (Autodesk Inc), Unity 3D (Unity Technologies), Vuforia v5 plug-in for Unity (PTC Inc), Samsung Galaxy Tab 3 (Samsung Electronics), Visual Studio v2019	40	Physiology and brain anatomy	No difference in knowledge test scores; significant increase in dizziness using the HoloLens
Stepan et al [26]	United States	VR model of brain anatomy—brain CT[i] scans and MRIs[j], Surgical Theater, Oculus Rift VR system (Oculus VR)	66	Cerebral anatomy	No difference in anatomy knowledge; VR group found learning experience to be significantly more engaging, enjoyable, useful, and motivating
Hu et al [43]	Taiwan	Anatomy Master module of Medical Holodeck	101	Anatomy teaching	Significant improvement in ultrasound task performance and ultrasonographic image identification MCQ[k] tests in the VR group

Author	Setting	Application detail	Sample size, N	Purpose	Outcome
Engum et al [44]	United States	CathSim Intravenous Training System (CathSim) developed by HT Medical (Immersion)	93	Intravenous catheter training	Significant improvement in cognitive gains, student satisfaction, and documentation of the procedure with the traditional laboratory group compared with the computer catheter simulator group
Berg et al [45]	Norway	VR application developed by the authors with hired help for programming (Unity 2018.30f2) and video of the VR features	289	ABCDE basic resuscitation skills	Noninferiority of learning modality; more students in VR group reported liking the way they practiced and that it was a good way to learn; VR group scored high on the System Usability Scale
Kiesewetter et al [46]	Germany	VR learning environment CASUS	142	VP to teach clinical skills	Case formats with a VP did not affect knowledge gain or diagnostic accuracy [46]
Schoeb et al [47]	Germany	Instructions for catheterization displayed on Microsoft HoloLens	164	Catheter training	MR group had significantly better learning outcomes [47]
Noll et al [48]	Germany	AR[l] mobile app, iPhone operating system (iOS, Apple Inc)–based app mArble Derma (m-ARBLE-dermatology)	44	Dermatological teaching	No difference in outcomes between groups [48]
Liaw et al [49]	Singapore	3D virtual hospital developed—CREATIVE	120	Interprofessional skill training	No difference between groups in communication performance scores [49]
Ienghong et al [50]	Thailand	3D USS[m] images played on the downloaded phone app and AR	46	Emergency ultrasound skills	Better performance scores in VR flash card group [50]
Sobocan et al [51]	Slovenia	VP—no detail	34	Internal medicine skills	No difference in exam performance between groups
Kockro et al [52]	Switzerland	Virtual 3DM developed from MRI and CT scans and DextroBeam system (Bracco Advanced Medical Technologies)	169	Neuroanatomy	There were no significant differences in knowledge scores; participants rated the 3D method as superior to 2D teaching methods in four domains: spatial understanding, application in future anatomy classes, effectiveness, and enjoyableness [52]
Nickel et al [53]	Germany	Computer-based TM[n] developed using the open-source Medical Imaging Interaction Toolkit software developed by the German Cancer Research Center	410	Liver anatomy	3D group had higher scores, and participants had a preference for 3D training [53]
Berg et al [54]	Norway	ABCDE resuscitation application developed with help from hired programmers for Unity using Oculus Quest software (Oculus)	289	VP to teach clinical skills	Group self-practice of the ABCDE approach in multiplayer, immersive, interactive VR application was noninferior to practice with physical equipment [54]
Bogomolva et al [55]	The Netherlands	DynamicAnatomy AR application developed at the Department of Anatomy and Embryology at the Leiden University Medical Centre for Innovation	60	Anatomy teaching	No significant differences in knowledge scores [55]
O'Rourke et al [56]	United States	VP model simulation developed with a real patient in real time	60	Clinical skill—breaking bad news	No significant between-group differences on the POMS[o] 2 or salivary cortisol concentration following the SP[p] interaction; students had similar emotional and behavioral responses when delivering bad news to SP or vSP[q] [56]

Author	Setting	Application detail	Sample size, N	Purpose	Outcome
Du et al [57]	Taiwan	3DMs—Autodesk 3DS Max software (Autodesk Media and Entertainment) and Unity 3D developed into a VR gaming system for HTC Vive	18	Anatomy teaching	No significant differences in MCQ scores between groups; VR groups scored highly on the interest, competence, and importance subscales of the IMI[r]; both VR groups considered the system to be fun and beneficial to their learning; MP[s] group reported higher stress levels
Maresky et al [12]	Canada	Using TeraRecon (TeraRecon, Inc), Slicer, and The Body VR: Anatomy Viewer private beta version (The Body VR LLC) together with software provided by Sharecare VR (Sharecare Reality Lab)	42	Cardiac anatomy	VR group scored higher on knowledge
Issleib et al [58]	Germany	VR software developed in cooperation between the University of Hamburg and VIREED[t]—VR-BLS[u] course (using the Laerdal (mannequin)	160	Resuscitation training	Classic BLS training with a seminar and training sessions seemed superior to VR in teaching technical skills [58]

[a]VP: virtual patient.

[b]MR: mixed reality.

[c]3DM: 3D model.

[d]SG: simulation by gaming.

[e]WALD Island named for Lillian Wald, a public health nursing pioneer.

[f]HG: holographic.

[g]VR: virtual reality.

[h]MDT: multidisciplinary team.

[i]CT: computed tomography.

[j]MRI: magnetic resonance imaging.

[k]MCQ: multiple-choice question.

[l]AR: augmented reality.

[m]USS: ultrasound scan.

[n]TM: teaching module.

[o]POMS: Profile of Mood States.

[p]SP: simulated patient.

[q]vSP: virtual simulated patient.

[r]IMI: Intrinsic Motivation Inventory.

[s]MP: multiple-player.

[t]VIREED: Virtual Reality Education (medical virtual reality education platform).

[u]BLS: basic life support.

Study Characteristics

Approximately 76% (22/29) of authors used VR applications, which included virtual simulation scenarios and VPs. Approximately 17% (5/29) of articles used AR applications, which involved using the Microsoft HoloLens headset and mobile phone apps. There were 7% (2/29) of studies that used MR.

Of the 29 articles retrieved, 28 (97%) were from high-income countries and 1 (3%) was from an upper–middle-income country. Most studies originated in the United States (6/29, 21%) and Germany (6/29, 21%), followed by Singapore (3/29, 10%), Canada (2/29, 7%), Norway (2/29, 7%), Taiwan (2/29, 7%), Australia (1/29, 3%), France (1/29, 3%), the Netherlands (1/29, 3%), New Zealand (1/29, 3%), Portugal (1/29, 3%), Slovenia (1/29, 3%), Switzerland (1/29, 3%), Thailand (1/29, 3%), and Turkey (1/29, 3%).

Primary and Secondary Learning Outcomes

Learning outcomes were reported in all studies, including outcomes for both knowledge and the participants' learning experience. Knowledge was assessed via multiple-choice question tests, single best answer tests, general clinical knowledge tests, open-ended style tests, or objective structured clinical examinations. Of the 29 studies, 12 (41%) studies evaluated knowledge using multiple-choice question tests. Approximately 31% (9/29) of studies evaluated knowledge via

general clinical knowledge–based tests that used a variety of validated questionnaires such as the Maastricht Assessment of Simulated Patients questionnaire and the Attitudes toward Poverty scale questionnaire [39,56]. Approximately 10% (3/29) of studies assessed knowledge using open-ended style exam questions. Approximately 3% (1/29) of studies evaluated knowledge via an objective structured clinical examination–based exam. Of the 29 studies, 1 (3%) evaluated knowledge via a single best answer test, 1 (3%) did so via interprofessional skill assessment, and 1 (3%) did not specify the type of evaluation test. Approximately 90% (26/29) of studies reported on satisfaction, attitudes, perceptions, opinions, and general facts regarding the technology used. The learning experience was evaluated in various ways, including validated and nonvalidated instruments on satisfaction, engagement, and perceived learning outcomes. Approximately 3% (1/29) of studies used psychometric testing to evaluate the learning experience [33]. Another study measured salivary cortisol levels before and after the intervention to evaluate whether delivering bad news via a real simulated patient or a virtual simulated patient evoked the same psychological stress [56]. Approximately 66% (19/29) of studies used validated scales to assess the learning experience, namely, the Intrinsic Motivation Inventory [57], General Self-Efficacy Scale, Learner Satisfaction with Simulation Scale [36], and Diagnostic Thinking Inventory [51]. A full list of the validated scales used in the RCTs in this review is provided in Multimedia Appendix 2 [26,33,34,36-38,41,42,45-49,51,54-58]. Approximately 7% (2/29) of studies reported on behaviors as an outcome, and none of the studies reported patient or health care outcomes [51,56]. Only 3% (1/29) of studies reported on adverse health outcomes as part of their secondary outcomes [42].

Study Quality Assessment

The MERSQI scale scores ranged from 10 to 15, with a mean score of 12.64 (SD 1.6). The median was 12.5, and the mode was 13.5. The mean (SD) domain and item scores are illustrated in Multimedia Appendix 3. The mean domain scores were highest for study design (mean 1, SD 0), data analysis (mean 0.7, SD 0.46), and outcomes (mean 0.6, SD 0.21). The lowest-scoring domains included type of data (mean 0.5, SD 0), sampling (mean 0.3, SD 0.15), and validity of the evaluation instrument (mean 0.3, SD 0.27). All articles used an RCT (29/29, 100%) study design, which meant that all studies obtained the highest score in this domain.

Of the 29 studies, 1 (3%) was a double-center RCT, and the remaining 28 (97%) were conducted at a single site. In relation to participant response rate, 93% (27/29) of the studies had a high response rate of >75%.

The authors used appropriate statistical analysis in all studies according to the MERSQI [59]. In relation to the validity of the evaluation instrument, 66% (19/29) of studies used validated instruments and scales to assess learning outcomes, including satisfaction, self-efficacy, engagement, and perceptions of the learning experience.

Finally, according to classification using the criteria by Kirkpatrick [31] in the MERSQI scale, 97% (28/29) of studies assessed knowledge as the primary outcome, and 62% (18/29) of studies used a pre- and postlearning experience knowledge assessment.

Discussion

Principal Findings

The aim of this systematic review was to assess the current educational role of immersive technology in medical, midwifery, and nursing education at the university level compared with traditional learning modalities. Second, the review evaluated the associated learning outcomes of VR, AR, and MR and how they were evaluated. A total of 29 RCTs were selected for this review. The main findings of this study indicate that knowledge gain is equal when using VR, AR, or MR in health care student education compared with traditional learning modalities. In addition, VR, AR, and MR provide an enhanced learning experience based on the secondary outcomes of the studies included in this review [12,26,33,36,38,40,45]. This supports the current evidence that immersive educational technology is a useful and valuable learning tool in medical and nursing preclinical university education. The most common form of immersive technology used was VR. The favored use of VR may be due in part to the widespread availability of cost-effective 3D software and web-based material for the development of anatomy tools [14,60]. Comparators were present in every study and ranged from 2D didactic presentations to textbooks. All the studies retrieved involved medical and nursing students in preclinical university education. Interestingly, there were no studies involving midwifery students. Although there are studies involving midwifery students and immersive technologies in the literature, this review found no RCTs within this domain.

The MERSQI tool provided a standardized approach to evaluating the methodological quality of the studies included in this review [59], which resulted in a moderate level of evidence for these studies. The MERSQI tool also allowed us to classify the learning outcomes of the RCTs clearly, with knowledge identified as the most common primary outcome. Secondary outcomes were identified and included attitudes and opinions related to the learner experience (ie, satisfaction, self-efficacy, engagement, and perceptions of the learning experience). All studies were conducted in upper–middle-income or high-income countries, which may be because of the availability of more funding to support the purchase of such equipment. The articles identified for this review were published within the past 10 years, with most (19/29, 66%) being published in the past 3 years. This highlights the recent rise in interest in immersive technologies for use in preclinical university medical and nursing education. The International Data Corporation has forecasted the shipment of 36.7 million VR headset units by 2023 [61].

Anatomy was the most common topic taught with immersive technologies, which may be because of the ability of immersive technologies to enhance the understanding of complex body processes that cannot be visualized [24]. Subjects such as anatomy and embryology require students to translate 2D images into 3D concepts, which can be a cognitive challenge for those who have difficulty visualizing this transformation of images

[62,63]. Students may also mentally rotate complex structures inaccurately, leaving the mind to fill the gaps in any missing structures [64]. The introduction of immersive technology as an educational tool could automatically standardize this process for students and enhance the understanding of certain subjects such as anatomy and embryology. Similarly, midwifery education requires an understanding of complex concepts, such as fetal development in the womb. Therefore, this would be an important area for future research comparing traditional learning tools with immersive technologies.

VPs were developed in 41% (12/29) of the studies in this review. VPs play a key role in learning basic clinical skills for both nursing and medical education. In addition, they create an environment for repeated practice in a safe space without harm to patients [65,66]. Traditionally, clinical education relies on practicing diagnostic, therapeutic, and procedural skills on live patients. This can be difficult to balance on a day-to-day basis because of the fast-paced nature of medicine, time constraints for clinical teaching in busy wards, and competition between students [67]. In addition, over the past year, the experience of the global COVID-19 pandemic has vastly reduced access to bedside teaching for nursing, midwifery, and medical students [68]. Therefore, the availability and development of VPs and immersive learning environments can play a key role in the future as an adjunct to developing clinical skills for students at all levels and at any time [61].

The primary outcome in most studies (28/29, 97%) was knowledge. This review demonstrated that immersive technology is equally effective in knowledge gained by the student and, in some studies, reflects a higher level of knowledge retention. Regarding secondary outcomes concerning the learning experience, all studies reported overall positivity and higher satisfaction in learning, self-efficacy, and engagement with immersive technologies. Moreover, this review revealed the heterogeneity of tools and instruments used to evaluate secondary learning outcomes such as student satisfaction, self-efficacy, engagement, and learning perceptions. Several studies developed their own Likert-style assessment scales, whereas others used and adapted previously developed and validated scales for the assessment of secondary learning outcomes. According to the Association for Medical Education in Europe, “assessment tools selected should be valid, reliable, practical and have an appropriate impact on student learning” [69]. Perhaps this highlights the need for a standardized, validated instrument to be designed specifically for immersive technology in education for the evaluation of learning outcomes related to the students’ learning experience. For example, in simulation, the National League of Nursing developed a validated standardized scale to evaluate the use of simulation and student learning experience with simulation activity, including students’ satisfaction and self-confidence, perceived learning, and engagement [36]. Therefore, the development of a standardized instrument to evaluate learning outcomes, such as satisfaction, self-confidence, self-efficacy, and engagement, for immersive educational tools may be beneficial so that future research may be better informed by a more uniform approach to assessing learning outcomes.

Strengths and Limitations

This systematic review provides an up-to-date review on the learning outcomes of immersive technologies in university-level medical and nursing education. This study illustrates important findings on the use of immersive technologies that will provide a foundation for future research in this area. Knowledge gain with immersive technologies was shown in this review to be equal to or greater than that of traditional modalities, thus providing an evidence base for future curriculum developers and researchers alike to implement these immersive tools into university programs. A comprehensive search strategy and robust methodology support the strengths of this study. The use of the validated MERSQI tool to assess the study design of the included studies also adds to the strength of our study design.

Most of the reviewed studies developed their own bespoke immersive educational tool specific to their needs, with VR being primarily used. The favored use of VR may be due in part to the widespread availability of cost-effective 3D software and web-based material for the development of anatomy tools [14,60]. However, the development of these tools has financial and resource implications, including the time spent developing content for these devices. With the increased amount of content and material, there may be an opportunity to develop a universal platform that makes content sharable and available worldwide for health care education. This may reduce the barriers to accepting and implementing this technology in health care education.

Nevertheless, we recognize that there were also some limitations to this study. Common biases exist within the methodology section, including the study eligibility criteria, identification and selection of studies, data extraction, and study appraisal. Predefined search criteria and inclusion criteria were set out in the published protocol, which aimed to reduce these biases. Within the published literature, there is heterogeneity in how VR is defined, requiring us to confine VR to include the use of a headset, providing only an immersive experience, as opposed to a 3D visualization on a computer screen. Therefore, this may have resulted in the exclusion of studies involving a 3D animation or model on a computer screen that did not place the learner in an immersive environment. Furthermore, because of the initial large database of articles retrieved, we decided to only include RCTs, as they are regarded as the highest-quality study type and also included a comparator that was a traditional learning modality. This process was conducted by 2 independent reviewers (GR and SC), and full-text inclusion was dependent on agreement by both reviewers. During the study retrieval process, bias may have occurred because of the unavailability of some studies. Authors were contacted in cases of unavailable data; however, this may have led to data availability bias and unrepresented data. This study included only preclinical university students; therefore, the value of immersive technology in the postqualification setting is unknown.

Conclusions

In conclusion, this systematic review demonstrates that VR, AR, and MR are beneficial educational tools in preclinical medical and nursing university education. Immersive technology is equally effective in teaching and increases learner satisfaction,

self-confidence, and engagement. However, further research is required to explore the role of VR, AR, and MR in midwifery education. With the increasing availability of cost-effective immersive tools, the use of immersive technologies in health care student education is potentially very valuable.

Authors' Contributions

This study was part of a thesis by GR for an MD in Medical Education, University College Dublin, Ireland. GR and SC were involved in the writing of the study protocol drafts, development of the study design, data analysis, and writing of the manuscript. AR was involved in the data analysis, writing, and review of the manuscript. MH was a study supervisor and was involved in the review of the manuscript. EM was also a study supervisor and reviewed the manuscript. FMA was a study supervisor and was involved in the study design, writing, and review of the study protocol and manuscript.

Abstract

Background: Juvenile idiopathic arthritis (JIA) management aims to promote remission through timely, individualized, well-coordinated interdisciplinary care using a range of pharmacological, physical, psychological, and educational interventions. However, achieving this goal is workforce-intensive. Harnessing the burgeoning eHealth and mobile health (mHealth) interventions could be a resource-efficient way of supplementing JIA management.

Objective: This systematic review aims to identify the eHealth and mHealth interventions that have been proven to be effective in supporting health outcomes for children and young people (aged 1-18 years) living with JIA.

Methods: We systematically searched 15 databases (2018-2021). Studies were eligible if they considered children and young people (aged 1-18 years) diagnosed with JIA, an eHealth or mHealth intervention, any comparator, and health outcomes related to the used interventions. Independently, 2 reviewers screened the studies for inclusion and appraised the study quality using the Downs and Black (modified) checklist. Study outcomes were summarized using a narrative, descriptive method and, where possible, combined for a meta-analysis using a random-effects model.

Results: Of the 301 studies identified in the search strategy, 15 (5%) fair-to-good–quality studies met the inclusion criteria, which identified 10 interventions for JIA (age 4-18.6 years). Of these 10 interventions, 5 (50%) supported symptom monitoring by capturing real-time data using health applications, electronic diaries, or web-based portals to monitor pain or health-related quality of life (HRQoL). Within individual studies, a preference was demonstrated for real-time pain monitoring over recall pain assessments because of a peak-end effect, improved time efficiency (P=.002), and meeting children's and young people's HRQoL needs (P<.001) during pediatric rheumatology consultations. Furthermore, 20% (2/10) of interventions supported physical activity promotion using a web-based program or a wearable activity tracker. The web-based program exhibited a moderate effect, which

increased endurance time, physical activity levels, and moderate to vigorous physical activity (standardized mean difference [SMD] 0.60, SD 0.02-1.18; I^2=79%; P=.04). The final 30% (3/10) of interventions supported self-management development through web-based programs, or apps, facilitating a small effect, reducing pain intensity (SMD −0.14, 95% CI −0.43 to 0.15; I^2=53%; P=.33), and increasing disease knowledge and self-efficacy (SMD 0.30, 95% CI 0.03-0.56; I^2=74%; P=.03). These results were not statistically significant. No effect was seen regarding pain interference, HRQoL, anxiety, depression, pain coping, disease activity, functional ability, or treatment adherence.

Conclusions: Evidence that supports the inclusion of eHealth and mHealth interventions in JIA management is increasing. However, this evidence needs to be considered cautiously because of the small sample size, wide CIs, and moderate to high statistical heterogeneity. More rigorous research is needed on the longitudinal effects of real-time monitoring, web-based pediatric rheumatologist–children and young people interactions, the comparison among different self-management programs, and the use of wearable technologies as an objective measurement for monitoring physical activity before any recommendations that inform current practice can be given.

Introduction

Background

Juvenile idiopathic arthritis (JIA) is the most common rheumatic disease in pediatric populations [1]. Early diagnosis and active treatment are essential for maintaining physical function and psychological well-being. The treatments aim to control the disease, promote clinical remission, and prevent long-term disability [2-5]. However, to achieve these goals, the management of JIA should be multifactorial [6]. Pediatric-specific issues need tending, such as the use of antirheumatic medications in children and young people, growth retardation, pain and coping, school attendance, psychosocial functioning, dealing with parents, and, in the adolescent years, preparing for the transition to adult care [4,7,8]. For good reason, children and young people need to be closely monitored and supported by specialized rheumatology centers that provide interdisciplinary care using a range of pharmacological, physical, psychological, and educational interventions [6,9-12]. However, several barriers have been identified that hinder this current model of support, delaying the delivery of timely, individualized, and well-coordinated care.

There is an inadequate number of experienced pediatric rheumatologists (PRs) to meet demand and oversee care [7,13-18]. This has resulted in long waiting lists, the centralization of services into tertiary children's hospitals, and the need for many children and young people to travel long distances to access pediatric rheumatology centers [2,18] or care being delivered by a primary health care provider with no pediatric rheumatology training [2,5,14,18-20]. The World Forum on Rheumatic and Musculoskeletal Diseases clearly states that poor access to health care services can significantly impede diagnosis, appropriate treatment, and health outcomes [14], highlighting the need to overcome these barriers in the delivery of JIA management.

In addition, to achieve optimal health outcomes, children and young people need to adhere to their prescribed treatment plan [21,22], and parents need to support treatment recommendations [2,22]. However, suboptimal rates of adherence are commonly reported [22-24]. For example, a literature review of children and young people with chronic rheumatoid disease reported medication adherence rates as low as 38% and physical activity adherence rates of 40%, particularly during adolescence [22]. The primary reasons included the complexities of chronic disease management and medication schedules, time-consuming nonpharmacological treatments, lack of disease knowledge, and low satisfaction with the health care team [22]. These reasons are not surprising, as a recent systematic review identified 70 studies in which health information was inappropriately tailored to children and young people and their parents' level of health literacy, increasing their concerns and uncertainties about their condition, treatment options, and shared care decisions [25].

For JIA specifically, further reasons for nonadherence vary across treatment modalities [24] as follows: for oral medications, forgetfulness, taste, and long-term side-effects; for parenteral medications (injectables and infusions), pain and side-effects; and for physical and occupational therapy, forgetfulness, pain, and therapy not being considered necessary [24]. Fortunately, all these reasons are modifiable.

To uphold the expectations of rheumatology care, children and young people should be empowered to take an active role in their disease management by being provided opportunities to improve their health literacy and develop good self-management skills [2,10,25], particularly when considering the long-term benefits these skills will have across their life span. The development of self-management skills is also important as parents only hold a surrogate role in children's and young people's health care decisions; therefore, children and young people need to be prepared for their transition from pediatric to adult health care services [26].

A resource-efficient way of supplementing JIA management and the development of self-management skills could be to harness the burgeoning eHealth and mobile health (mHealth) interventions [27]. eHealth is described by the World Health Organization as an activity that delivers health-related information, resources, and services through electronic

technology and the internet [28]. mHealth is described as a subbranch of eHealth [28] that uses wireless technology to rapidly uptake, process, and communicate information to support health system efficiency and patient outcomes [29].

The number of studies exploring the potential of eHealth and mHealth interventions for chronic disease management is rapidly increasing. However, most are still at an early stage of development and are limited in their scientific rigor [30-35]; most have been conducted with adults rather than children and young people [31,35], which is interesting, considering that children and young people are experienced users of this form of technology and more likely to use a digital intervention or health app [36-38]. In fact, a recent systematic review identified that children and young people use the internet for at least 1 to 4 hours a day (9438/10,974, 86%) [37] and some type of app every day (719/719, 100%) [39]. Higher rates of use have also been reported for children and young people living with JIA who are at risk of poor psychosocial functioning compared with their peers (>1 hour a day) [36].

However, concerns have been raised about how children and young people use the internet [37,40]. Studies have established that children and young people have poor internet-searching skills, tend to use a 1-word search strategy, briefly skim through search-engine result pages [40], and lack the ability to appraise quality [33,36]. This limits their capacity to find high-quality, personally relevant health information and potentially exposes them to incorrect material [36] or results in them turning to apps and platforms not specifically developed as health resources such as YouTube, Tumblr, and Instagram [41].

Johnson et al [36] believe that for pediatric services to better support the needs of children and young people living with chronic illness, they need to be provided with accessible, developmentally appropriate, and high-quality health-related information. Children and young people with JIA (n=134) agreed, particularly those with low health-related quality of life (HRQoL), expressing an interest in being provided with supportive internet-based interventions [36]. In addition, children and young people participating in feasibility and usability studies and reporting on the delivery of health messages [42], exercise programs [43], symptom monitoring [44,45], and disease management [35,36,44] have also reported high levels of acceptability [42-44], usefulness [35], and satisfaction [43] when using these interventions. However, personal, technical, and device-related barriers have also been identified, which hinder their use [46]. Understandably, before a health care professional can prescribe a digital intervention, it has been suggested that they need at least 3 published papers demonstrating the intervention's effectiveness [47] to see whether the intervention works in a real-world setting [48].

Definition of Children and Young People

Internationally, pediatric services cater to children aged 0 to 12 years [49], and adolescents up to the age of 18 years (mean 18.7, SD 2.6 years), before they are transferred to adult services [50]. In this review, we use the term "children and young people" to broadly include all individuals in the age range of 1 to 18 years. We exclude neonates and infants (<1 year) [51].

Aim and Rationale

This systematic review aims to identify what eHealth and mHealth interventions have proven to be effective in supporting health outcomes for children and young people (aged 1-18 years) living with JIA. We anticipate that this review may aid the clinical use of eHealth and mHealth interventions and their integration in arthritis management.

Methods

Overview

This systematic review complies with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [52]. Before commencement of this review, a protocol for this review was registered on PROSPERO (CRD42018108985) [53]. Protocol questions 1, 2, and 4 were presented in a previous study [46], whereas question 3 is presented in this review [53]:

1. What types of eHealth and mHealth interventions have been used to investigate the health care of children and young people diagnosed with JIA?
2. What is the usability of eHealth and mHealth interventions for children and young people diagnosed with JIA?
3. What eHealth and mHealth interventions have proven to be effective in helping children and young people diagnosed with JIA?
4. Are the existing eHealth and mHealth interventions cost-effective for pediatric rheumatology?

Eligibility Criteria

Search Strategy

The search terms in this review were developed by SB after initially searching the National Center for Biotechnology Information Medical Subject Heading terms (Multimedia Appendix 1) [54]. The search terms were adapted to suit 15 health databases with the aim of gaining a broad range of interdisciplinary literature. These databases included MEDLINE or PubMed, Cochrane Library, Joanna Briggs Institute, AMED, CINAHL complete, Embase, JAMA, Informit Health, ProQuest database, PsycINFO, IEEE Xplore, SAGE Publishing, ScienceDirect, Scopus, and Web of Science. The search was conducted in October 2018 and July 2021 and was not restricted by language or year of publication to ensure the inclusion of all relevant studies. Further studies were retrieved from Google Scholar and JMIR and by hand searching reference lists.

Studies retrieved by the search strategy were exported to the web-based platform Covidence [55]. This allowed 2 authors (SB and AC) to independently review titles and abstracts—and then the full-text versions—against the inclusion and exclusion criteria via individual log-ins (Multimedia Appendix 2). The authorship and results of the studies were not masked. Any disagreements that arose were resolved through discussions between SB and AC.

Risk of Bias

The Downs and Black [56] (modified) checklist for randomized and nonrandomized studies was used to appraise study quality

[57]. Independently, 2 authors (SB and AF) rated 5 main assessment areas—the reporting, external validity, internal validity based on bias, internal validity based on cofounding and selection bias, and power—to provide an overall score out of 28. A score of 24 to 28 was graded excellent, 19 to 23 was graded good, 14 to 18 was graded fair, and <14 was graded poor [57]. Any disagreements between SB and AF in these ratings were resolved through discussion and re-examination of the study.

Summary Measures and Synthesis

To assist with data collection, a data spreadsheet was developed using Microsoft Excel to organize the data. Data collection included study characteristics, population, eHealth and mHealth interventions, outcome measurements, and study findings. Data collection was completed by 1 author (SB) and checked by all authors. A narrative synthesis method was used for methodological heterogeneity to identify and present common statistical descriptions [58]. All results were interpreted within the context of each study against the total number of studies and the considered risk of bias.

Where possible, data outcomes from similar studies were pooled, and a meta-analysis was performed to allow the comparison of an intervention group (IG) with a control group (CG). Baseline (time point 1) and end-of-study scores (time point 2) were entered into Review Manager software (RevMan version 5.4) to determine standardized mean differences (SMDs) and 95% CIs [59]. Forest plots were established using continuous data and a random-effects model because of the anticipated effect of clinical heterogeneity and to provide a summary of the distribution of effect [60]. A subanalysis was also conducted to reduce statistical heterogeneity. For the studies examining the same intervention and same fixed parameter, continuous data and a random-effects model were used to consider the common effect of the intervention [61].

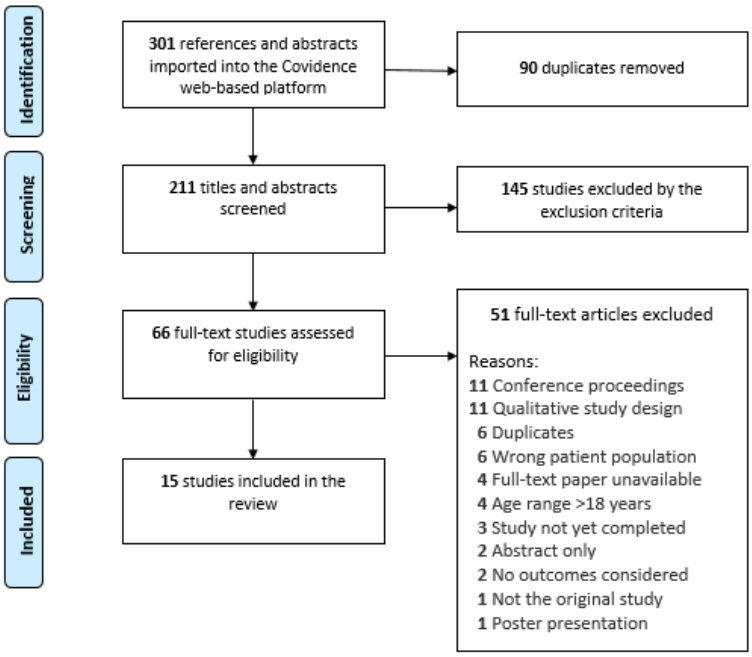
Finally, conclusions were drawn by visually inspecting forest plots and interpreting SMDs using the Hedge (adjusted) g. An effect size of 0.2 was considered small, 0.5 was considered medium, and 0.8 was considered large [62]. The presence of heterogeneity was also considered using I^2(I^2=100%×Q [chi-square]−df). A variation of 25% was reported as low, 50% was reported as moderate, and 75% was reported as high [63]. A P value of <.05 was considered statistically significant [64].

Results

Study Selection

The database search retrieved 301 studies. Of the 301 studies, 90 (29.9%) were duplicates; 145 (48.2%) did not meet the inclusion criteria based on their title or abstract; and 51 (16.9%) were excluded in the full-text screening because of study design, population, age range, outcomes, or the inability to gain the full text (eg, abstract only, conference presentations, and posters). Approximately 5% (15/301) of studies met the inclusion criteria to be introduced into this review (Figure 1) [65-79]. Of the 15 studies, only 1 (7%) was retrieved in a language other than English (Dutch), and an English version of the same study was attained through ResearchGate [72].

Figure 1. Summary of the study selection process using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.



Study Characteristics

Overview

The 15 studies included in this review were conducted in four countries: Canada [69,70,73-79], the Netherlands [65,67,68,72], the United States [66], and the United Kingdom [71]. These studies were published between 2008 and 2021 (Table 1) [65-79].

Table 1. Characteristics of the 15 studies showing population, intervention, control, outcomes, and study design.

First author and country	Population (N) and age range or mean (SD; years)	Intervention	Control (n)	Outcomes	Study design	Dropout (n)
Armbrust et al [65], the Netherlands	49; 8.7-10.8	Rheumates@Work	21[a]	Physical activity (effectiveness)	Multicenter observer blinded RCT[b]	7[c]
Connelly et al [66], United States	289; 12-18	Teens taking charge: managing arthritis on the web	144[d]	Self-management (effectiveness)	2-arm parallel group RCT	24[e]
Doeleman et al [67], the Netherlands	72; 10.6-16.4	EQ-5D-Y-5L[f] via Ruema2Go App	N/A[g]	HRQoL[h] monitoring to detect disease activity (efficacy)	Retrospective monocentric study	0[i]
Haverman et al [68], the Netherlands	176; mean 11.6 (SD 4.5)[j]	ePROfile	67	HRQoL (effectiveness) and PR[k] feedback (n=3)	Sequential cohort study	—[l]
Heale et al [69], Canada	31; 12.8-18.6	Wearable accelerometer using Misfit Flash	N/A	Physical activity (feasibility)	Pre- and postintervention design	3[e]
Lalloo et al [70], Canada	60; mean 15 (SD 1.7)[j]	iCanCope	29[d]	Self-management (feasibility and effectiveness)	2-arm pilot parallel group RCT	12[e]
Lee et al [71], United Kingdom	14; 7-16	My Pain Tracker	1 of 4 rotating groups[d]	Pain (effectiveness)	Randomized N-of-1 crossover trail	0
Lelieveld et al [72], the Netherlands	33; 8-12	Rheumates@Work	16	Physical activity (effectiveness)	Pilot RCT	0
Stinson et al [73], Canada	333; 12-18	Teens taking charge: managing arthritis on the web	169[d]	Self-management (effectiveness)	2-arm parallel group RCT	114[e]
Stinson et al [74], Canada	39; 12-17	iPeer2Peer Program	15[a]	Self-management (feasibility, usability, and effectiveness)	Pilot RCT	9[e]
Stinson et al [75], Canada	70[c]; age not available	eOuch	N/A	Pain (feasibility)	Correlational research	—
Stinson et al [76], Canada	101; 4-18	SUPER-KIDZ	N/A	Pain (efficiency) and PR feedback (n=15)	Descriptive design and 2-stage Delphi technique	—[m]
Stinson et al [77], Canada	46; 12-18	Teens taking charge: managing arthritis on the web	24	Self-management (feasibility)	Pilot RCT	9[c]
Stinson et al [78], Canada	13; 9-18	eOuch	N/A	Pain (feasibility and usability)	Descriptive study	3[n]
Stinson et al [79], Canada	112; 9-17	eOuch	N/A	Pain (feasibility and usability)	Prospective descriptive study	2

[a]Waitlist control.

[b]RCT: randomized controlled trial.

[c]Intention-to-treat analysis.

[d]Active control group.

[e]Excluded in final analysis.

[f]EQ-5D-Y-5L: EuroQol 5-dimensional youth 5-level.

[g]N/A: not applicable.

[h]HRQoL: health-related quality of life.

[i]Data from 4 children and young people were misinterpreted in the assessment and excluded from analysis.

[j]Age range not available.

[k]PR: pediatric rheumatologist.

[l]Not provided.

[m]Pain assessments were completed by parents instead of children (n=4; 4-7 years) and, therefore, excluded from the analysis.

[n]Dropouts (n=3) replaced in phase 2.

Participants

A total of 1438 children and young people (range 13-333) were included in this review [65-79]. Studies recruited children and young people from pediatric rheumatology centers or pediatric rheumatology departments within children's hospitals [65-70,72-79]; one of the studies recruited children and young people from the Childhood Arthritis Prospective Study [71].

Approximately 93% (14/15) of the studies reported on children and young people characteristics [65-74,76-79]. The mean age was 12.97 (SD 1.85) years, varying across studies between 9.7 years and 15.1 years. Most children and young people were female (887/1237, 71.7%) compared with males (350/1237, 28.29%), ranging from 62.9% to 96.7% [65-74,76-79]. The JIA subtypes were aligned with the International League for Rheumatology criteria [80]. Across the study population, the most common subtype of JIA that was reported was oligoarthritis, making up between 21% to 61% [65-74,76-79]. Approximately 7% (1/15) of the studies did not include these characteristics (N=70) [75], and 27% (4/15) of studies excluded the characteristics of children and young people lost during follow-up (n=123) [73,74] or excluded from the final analysis (n=8) [67,76]; (Multimedia Appendix 3 [65-79]).

Approximately 87% (13/15) of the studies considered disease activity [65-70,72-74,76-79]. Reporting either the mean range of disease (range 0.1 to 3.75) using the Physician Global Assessment, Juvenile Arthritis Disease Activity Score or 0-10cm Visual Analogue Scale [65,67-69,74,76-79], or the number of children and young people with low (range 60%-82.5%) scores, or moderate-to-high (range 17.4%-25%) scores [66,70,73], or the number of active (87%, 13/15) and inactive cases (13%, 2/15) [72].

Approximately 20% (3/15) of studies also included feedback from a range of pediatric rheumatology health care providers [67,68,76]. This included PRs (n=18; range 3-15) using eHealth interventions during consultations [68,76] or members of the Childhood Arthritis and Rheumatology Research Alliance (PRs and allied health) replying to a survey (survey 1:115 members; survey 2:157 members [73% replied to survey 1]) or attending a 2-day consensus conference (20 members; pediatric pain and rheumatology experts). Childhood Arthritis and Rheumatology Research Alliance members were from the United States and Canada [76].

Interventions

In total, 10 interventions were identified to support children and young people with JIA. The interventions were categorized according to their clinical aim to align with our research question, resulting in the formation of three themes: symptom monitoring, physical activity promotion, and self-management development.

Theme 1: Symptom Monitoring

Approximately 33% (5/15) of studies focused on self-reporting pain [71,75,76,78,79]. The interventions used included the following:

1. *My Pain Tracker*, an mHealth app aimed at monitoring pain 1 to 3 times a day or when needed [71]
2. *eOuch*, a customized electronic pain diary aimed at monitoring pain 3 times a day [75,78,79]
3. *SUPER-KIDZ*, a web-based assessment to self-report pain before consultations [76]

Approximately 13% (2/15) of studies focused on self-reporting HRQoL [67,68]. The used interventions included the following:

1. *EuroQol 5-dimensional youth 5-level questionnaire* (EQ-5D-Y-5L), accessed through the Reuma2Go health app aimed at remotely identifying disease activity and the need for treatment adjustments [67]
2. *ePROfile*, a web-based assessment (Kwaliteit van leven in kaart or quality of life map website) aimed at improving HRQoL discussion during rheumatology consultations [68]

Theme 2: Physical Activity Promotion

Approximately 20% (3/15) of studies focused on promoting physical activity [65,69,72]. The interventions used included the following:

1. A *wearable activity tracker*—using the commercially available *MisFit Flash*—aimed at improving physical activity levels (PALs) [69]
2. *Rheumates@Work*, a web-based behavioral and cognitive program aimed at delivering health information related to JIA and improving PALs [65,72]

Theme 3: Self-management Development

Approximately 33% (5/15) of studies aimed to develop self-management skills [66,70,73,74,77]. The interventions used included the following:

1. *Teens taking charge: managing arthritis online*, which is a web-based behavioral and cognitive program aimed at providing disease-specific information and self-management strategies to improve health outcomes [66,73,77]
2. *iCanCope*, a smartphone app aimed at tracking and improving pain self-management [70]
3. *iPeer2Peer Program*, a web-based peer-mentoring program aimed at facilitating positive role modeling and social support through video calls [74]

The expected level of engagement with the interventions varied from a few minutes before rheumatology consultations to 17 weeks [65-79]. Of the 15 studies, 14 (93%) required the children and young people to use the intervention at home (age range 7-18 years) [65-75,77-79], and only 1 (7%) was conducted in a clinical setting (age range 4-18 years) to monitor use [76]. For a more detailed description of each intervention, see Multimedia Appendix 4 [65-79,81].

Comparator or Control

Approximately 53% (8/15) of studies compared a pretested (time point 1) and posttested (time point 2) IG (455/904, 50.3%; range 17-144, median age 12.9, SD 2.09 years; female 322/455, 70.8%) with a CG (449/904, 49.7%; range 14-145, median age 13.4, SD 1.91 years; female 352/449, 78.4%) [65,66,68,70,72-74,77]. Of these 8 studies, 3 (38%) compared the IG with a CG receiving usual care (no eHealth or mHealth input) [68,72,77], 2 (25%) used a waitlist control method to allow all children and young people exposure to the intervention before study completion [65,74], and 3 (38%) compared the IG with an active CG also receiving a digital intervention [66,70,73].

One of the studies compared different real-time reporting schedules across 4 groups (n=12) with a median age of 12.5 years (range 10-14 years; female 9/12, 75%) [71].

Outcomes

Study outcomes varied according to the intervention stage of development (feasibility, usability, efficiency, and effectiveness) [65-79]. Health outcomes that considered an evaluation measurement to allow the quantitative comparison between groups, and an effectiveness analysis, were categorized to support the clinical aim of each intervention under the three intervention themes: symptom monitoring, physical activity promotion, and self-management development (Table 2).

Table 2. Formation of themes, evaluation criteria, and main outcomes supporting the delivery of the eHealth and mobile health interventions for juvenile idiopathic arthritis.

Theme (interventions aim)	Outcomes (evaluation measurement)
Theme 1: symptom monitoring	
Real-time pain	• Pain intensity, unpleasantness, interference using electronic VAS[a] 5 cm [75,78,79] and RPI[b] [75,78,79] • Pain location and descriptors: size (severity), throb rate (intensity), and emotion, PROMIS[c] and Pediatric pain Interference Scale–Short Form [71] • PedsQL[d] generic inventory—and arthritis module and PCQ[e] and Physician Rated Disease Activity Indices [79] • Children and young people aged 4-7 years: Faces Pain Scale–Revised; children and young people aged 8-18 years: NRS[f] (0-10 cm) [76], survey, and consensus conference [76]
HRQoL[g]	• EuroQol 5-dimensional youth 5-level questionnaire and 0-100 cm VAS (current health status) • Juvenile Arthritis Disease Activity Score with 71 joint count [67]
Pediatric rheumatology feedback	• HRQoL communication during pediatric rheumatology consultation, number of psychologist referrals, and PR[h] satisfaction [68] • Satisfaction questionnaire and 2-stage Delphi survey [76]
Theme 2: physical activity promotion	
Objective measurements	• Bruce Treadmill protocol for exercise capacity (endurance time) [65,72] • Accelerometer (Actical Phillips Respironics) for physical activity [65]
Self-reporting measurements	• A 7-day activity diary [65,72] • 3-Day Activity Recall to measure the metabolic equivalent values of activities and PROMIS [69] • PedsQoL (version 4) and pain and well-being (0-10 cm VAS); functional ability: CHAQ[i] [65,69] • School absenteeism, participation in physical education classes, and follow-up 3 and 12 months [65]
Functional capacity	• CHAQ [69] • Dutch version CHAQ38 [65]
Disease activity	• Disease and medication use records [72] • Disease activity 0-10 cm VAS [65] • Physician Global Assessment 0-10 cm or 0-100 cm VAS [69,72]
Theme 3: self-management development	
Pain reduction	• RPI [74,77] • Pain intensity [66,70,73] and interference [66,73] using an 11-point NRS (0-10) [66,70] • Tracking logs [70] • Follow-up at 3, 6, and 12 months [66,73]
HRQoL improvement	• PedsQL [66,70,73,74] • Juvenile Arthritis Quality of Life Questionnaire [77] • PROMIS: pediatric anxiety short form and depressive symptoms short form [66,73] • Perceived Stress Questionnaire [77] • Follow-up at 3, 6, and 12 months [66,73]
Functional capacity	• Child Activity Limitations Interview [70]
Health literacy	• Medical Issues, Exercise, Pain, and Social Support Questionnaire [66,73,74,77] • Children's Arthritis Self-Efficacy scale [66,73,74,77] • PCQ (behavioral and cognitive pain-coping strategies) [66,73] • Follow-up at 3, 6, and 12 months [66,73]
Adherence to prescribed treatment	• Child Adherence Report Questionnaire and Parent Adherence Report Questionnaire [73,77]

[a]VAS: visual analog scale.

[b]RPI: Recall Pain Inventory.

[c]PROMIS: Patient-Reported Outcomes Measurement Information System.

[d]PedsQL: Pediatric Quality of Life Inventory.

[e]PCQ: Pain Coping Questionnaire.

[f]NRS: numeric rating scale.

[g]HRQoL: health-related quality of life.

[h]PR: pediatric rheumatologist.

[i]CHAQ: Childhood Health Assessment Questionnaire.

Study Design

Study designs included two 2-arm parallel group randomized controlled trials (RCTs) [66,73], one 2-arm pilot parallel group RCT [70], 1 multisite observer-blinded RCT [65], 3 pilot RCTs [72,74,77], 1 randomized N-of-1 crossover trial [71], 1 descriptive study with 2-stage Delphi technique [76], 1 descriptive study with 2-phase testing [78], 1 prospective descriptive study [79], 1 retrospective monocentric study [67], 1 pre- and postdesign study [69], 1 correlational study [75], and 1 sequential cohort intervention study [68] (Table 1) [65-79].

Methodological Quality of Studies

Using the Downs and Black [56] (modified) checklist, the overall mean quality score of the 15 studies was 18.87 (SD 1.92) [65-79]. The scores ranged from 15 to 21, providing a fair-to-good score [57] (Multimedia Appendix 5 [65-79]). There were no disagreements between SB and AF that needed to be resolved by a third author (AC). The 2 areas in which study quality was consistently limited were power and sampling bias; 87% (13/15) of studies had insufficient power to detect a clinically significant effect [65,67-78], and convenience sampling and selection bias may have prevented full representation of the JIA population [68,72,75,79]. Children and young people were selected because of pain experience [66,70,78]; level of disease activity [65,66,69,71,75,78,79]; unlikelihood of medication changes [69]; no other comorbidities or cognitive impairments [65,66,69-71,73-75,77,79]; good visual acuity [75,79]; no hand deformities [75,79]; reduced PALs [65]; access to a computer, tablet, or phone or the internet [65,69,70,72,74]; and level of comprehension and ability to speak and read English [65,66,70,73-77,79], Dutch [72], Spanish [66], or French [73,77]. Methodological concerns were also seen in internal validity because of contamination or unreliable compliance [65-67,69-71,73,75-79].

Results of the Studies

Theme 1: Symptom Monitoring

Real-time Pain

Approximately 33% (5/15), fair-to-good–quality studies reported on real-time pain assessments [71,75,76,78,79]. Of these 5 studies, 3 (60%) reported on children and young people (aged 11.2-18 years) using *eOuch* to record their pain 3 times a day against the three pain rating measurements: intensity, unpleasantness, and interference [75,78,79], demonstrated a strong correlation (r=0.71-0.74, P<.01) between these pain measurements [79]. On average, pain scores reported were mild to moderate, interfering mostly with walking and least with school work, relationships with friends or family, and sleeping [78,79]. A good-quality study demonstrated changes in children's and young people's pain recordings throughout the day (interference P<.01, stiffness P<.01, and fatigue P<.01) and, week to week (intensity P<.01, unpleasantness P<.01, interference P<.01, and stiffness P<.01) [79]. Predicted changes in pain were also seen after a joint injection (medium effect size: 0.52-0.71); the main effect was for pain intensity [79]. A weak effect was reported for tiredness (r=0.24-0.26) and perceived ability to control pain (r=0.6-0.26) [79]; Multimedia Appendix 6 [71,75,78,79]).

Of the 5 studies, a further 1 (20%) fair-quality study reporting on the intervention *SUPER-KIDZ* that targeted children and young people aged between 4 to 18 years considered the pain dimensions that should be included in a pain assessment [76]. Using a 2-stage Delphi technique, the consensus view from health care experts (survey 1: n=115; survey 2: n=157; 2-day conference: n=20) concluded the inclusion of the characteristics of pain—intensity, location, frequency, duration, and the consequences of pain—and functional limitations [76].

Another 20% (1/5) of fair-quality studies reported on the frequency of recording real-time pain scores using *My Pain Tracker* [71]. Children and young people (aged 7-16 years) adherence rates were higher when pain was reported once a week (15/24, 63%) compared with when pain was reported once a day (85/168, 50.6%) or twice a day (127/336, 37.8%) or *as and when* pain was experienced (range 0-7 reports) [71]. There were no significant differences in pain interference scores because of reporting frequency (P=.77) or the different time points (weeks) across the study (r=−.004; P=.68). The children and young people qualitative results reported that they preferred once a day or *as and when* (6/14, 43%) reporting schedules [71] (Multimedia Appendix 6).

Real-time Pain Assessments Versus Recall Pain Assessments

Of the 5 real-time pain assessment studies, 3 (60%) fair-to-good–quality studies considered the correlation between *eOuch* real-time pain recordings and the Recall Pain Inventory short form [75,78,79]. For CPY (aged 11.2-18 years), a moderate to strong correlation (r=0.49-0.84) was reported between the real-time pain recordings and recall pain recordings (P<.01) [79], and the magnitude of changes in pain did not differ significantly when pain was defined as >0/100 or >0/30. However, when pain was defined as >0/10, there was weak *within-person consistency*, resulting in an 8% variance and a moderate association between the 2 assessments [75]. The same study also reported computed changes in pain (P=.02) against the judged assessment of pain (P=.004), finding both to be significantly similar, although the Recall Pain Inventory was higher and predictable [75]. Recall pain assessment measurements were mostly influenced by the children and young people peak pain score and the last real-time pain score. This finding appeared to be clinically significant (Multimedia Appendix 6).

Real-time Pain Scores Versus Other Commonly Used Pediatric Assessments

Of the 5 real-time pain studies, 1 (20%) fair-quality study compared real-time pain scores, using *eOuch*, with other pediatric tools (Pediatric Quality of Life Inventory [PedsQL]

Generic Inventory, PedsQL Arthritis Module, and Pain Coping Questionnaire). For children and young people (aged 9-17 years), a weak to moderate correlation (r=0.02-0.64) was seen, highlighting differences in the assessment tools, suggesting the need for specific pediatric pain assessments (Multimedia Appendix 6).

HRQoL Assessment Versus Disease Activity Assessment

Of the 15 studies, 1 (7%) good-quality study compared children and young people (aged 10.6-16.4 years) self-reporting HRQoL at home, using the *EQ-5D-Y-5L* assessment, with the commonly used clinical care tool Juvenile Arthritis Disease Activity Score with 71 joint count, which was completed by the PR during consultation to measure disease activity [67]. The HRQoL assessment (EQ-5D-Y-5L sum score) across all 5 levels (mobility, self-care, daily activities, pain or discomfort, and anxiety or depression) displayed satisfactory diagnostic accuracy (87%; 95% CI 76-94; P<.001), sensitivity (85%), specificity (89%), and predictive values (positive 88% and negative 86%) in identifying moderate to high disease activity [67]. This suggests that disease activity would not have been missed through remote monitoring of HRQoL, and treatment adjustments based on the current-to-treat guidelines (>1.5 for oligoarthritis and >2.5 for polyarthritis) could be applied [67].

PR's Feedback

Of the 15 studies, 1 (7%) good-quality study compared the preferred method of reviewing pain assessments by PRs (11/15, 73% female; 10/15, 67% practicing >10 years) [76]. *SUPERKIDZ* pain assessments were completed by children and young people (aged 4-18 years; with no help from parents) before the PR consultation using three different methods: a laptop or computer, a multimedia player, and a paper-based assessment. PRs (10/15, 67%) reported the electronic assessments to be more time efficient (P=.02) than the paper-based assessment and would recommend the use of web-based pain summaries to colleagues (9/15, 60%). There were no differences reported in developing pain management plans (10/15, 67%) [76].

Of the 15 studies, 1 (7%) fair-quality study reported on the PR's review of the web-based HRQoL assessment, *ePROfile*, during consultation [68]. PRs (n=5) reviewed 176 children and young people (mean 11.6, SD 4.5 years) tabulated answers and were satisfied with the care they provided for the IG compared with the care they provided for the CG, particularly in the areas of emotional support (first consultation [time point 1] P<.01 and second consultation [time point 2] P<.001) and meeting children and young people needs (time point 1 and time point 2 P<.001). PR satisfaction increased slightly in the second consultation compared with that of the first. PR evaluations reported *ePROfile* as useful (time point 1: 97/102, 95%; time point 2: 64/64, 100%), and the number of referrals increased (time point 1=9.2% and time point 2=4.3%) compared with the CG (3%). These results were not significant [68]. Parents also evaluated *ePROfile* as useful (time point 1: 57/65, 88%; time point 2: 37/46, 80%); however, parent satisfaction did not differ between the IG and CG, and children and young people (mean age 11.6, SD 4.5 years) reported the consultation as normal (time point 1: 47/48, 98%; time point 2 29/35, 83%). *ePROfile* was considered by the study authors as an efficient medium for monitoring HRQoL and was implemented in clinical use after the study [68].

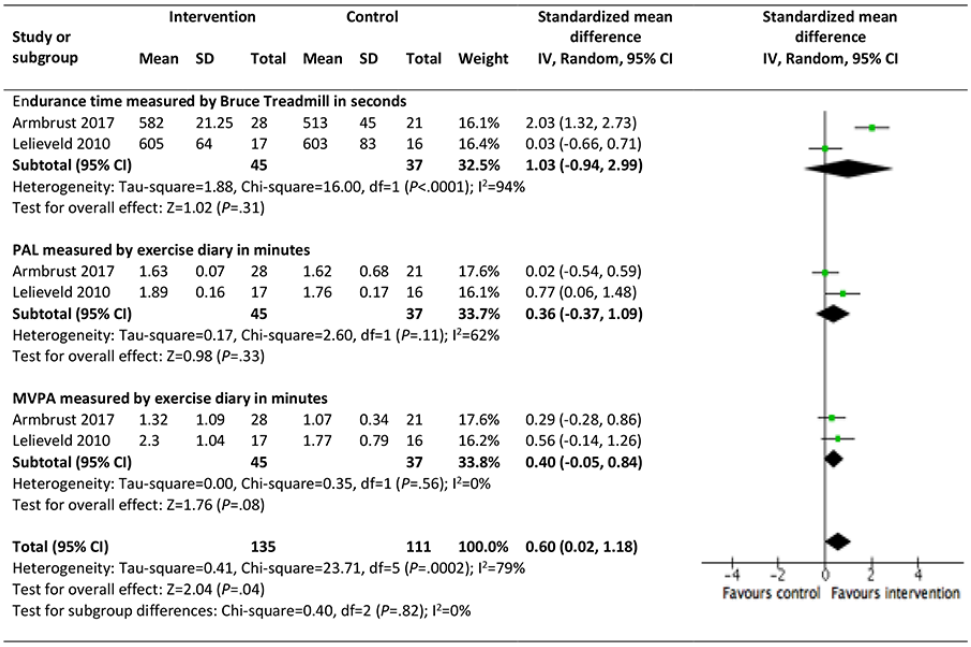
Theme 2: Physical Activity Promotion

Overview

Approximately 20% (3/15) of the fair-to-good–quality studies considered the interventions' effect on physical activity of children and young people [65,69,72]. Of these 3 studies, 1 (33%) fair-quality study reported on children and young people (aged 12.8-18.6 years) wearing an *activity tracker*, Misfit Flash, daily for 28 days. No significant differences in PALs were recorded [69].

The other 67% (2/3) good-quality studies reporting on children and young people (aged 8.7-12 years) who used the intervention *Rheumates@Work* were pooled in a meta-analysis [65,72]. Overall, a moderate effect (SMD 0.60, 95% CI 0.02-1.18, P=.40) was seen in physical activity (endurance time, PAL, and moderate to vigorous physical activity [MVPA]). However, there was high statistical heterogeneity between the studies (I^2=79%), suggesting a 79% variance across the studies, reducing confidence in these results (Figure 2) [65,72]. No changes were reported for pain intensity, disease activity, or functional ability [65,69].

Figure 2. Effectiveness of Rheumates@Work on the promotion of physical activity for juvenile idiopathic arthritis (aged 8-12 years). MVPA: moderate-to-vigorous physical activity; PAL: physical activity level.



Seasonal Intervention Effect

Of the 3 studies considering physical activity promotion, 1 (33%) good-quality study, *Rheumates@Work*, reported a seasonal intervention effect after comparing a winter IG to a summer IG. For the winter IG, a 24-minute reduction in rest was recorded using an accelerometer (Actical Phillips Respironics). This result was significant (*P*=.05) [65].

Follow-up

Of the 3 studies considering physical activity promotion, only 1 (33%) good-quality study, *Rheumates@Work*, considered follow-up after the study period [65]. At 3 months, for the IG, children's and young peoples' (aged 8.7-18 years) physical activity (endurance time and PAL) continued to improve, and by 12 months, it declined. However, this reduction did not reach the preintervention levels. Positive improvements were also reported for educational participation. At 3 months, school absenteeism decreased from 43% to 14% (*P*=.02) in the IG and increased from 24% to 29% (*P*=.60) in the CG. Children's and young peoples' participation in physical education classes also improved in the IG group, from 57% to 71% (*P*<.01) and from 62% to 67% in the CG (*P*=.01). However, these differences were not statistically significant [65].

Theme 3: Self-management Development

Overview

Approximately 33% (5/15) of fair-to-good quality studies assessed the health-related benefits of self-management development [66,70,73,74,77].

Pain Reduction

Of the 5 studies promoting self-management, all (100%) fair-to-good–quality studies monitored for changes in pain because of the intervention [66,70,73,74,77]. Of these 5 studies, 1 (20%) fair-quality study reported on children and young people (mean age 12, SD 1.7 years) using *iCanCope* [70]. The IG received a pain monitoring and self-management program, and the CG received pain monitoring only. Both groups reported a reduction in pain intensity (IG: 1.73-point reduction; CG: 1.09-point reduction), using a 0 to 10 numerical rating scale. These results were not statistically significant (*P*=.24) [70].

Of the 5 studies, 4 (80%) good-quality studies (children and young people aged 8-18 years) reporting on *Teens taking charge* and the *iPeer2Peer Program* were pooled for a meta-analysis [66,73,74,77]. A small postintervention effect was seen in the IG compared with the CG in reducing pain intensity (SMD −0.14, 95% CI −0.43 to 0.15; I^2=53%; *P*=.33). However, these results were not statistically significant, and moderate statistical heterogeneity was seen between the studies (Figure 3) [66,73,74,77]. No effect was seen on pain interference (Figure 4) [66,73].

Figure 3. Effectiveness of self-management programs in reducing pain intensity for children and young people (aged 12-18 years) with juvenile idiopathic arthritis.

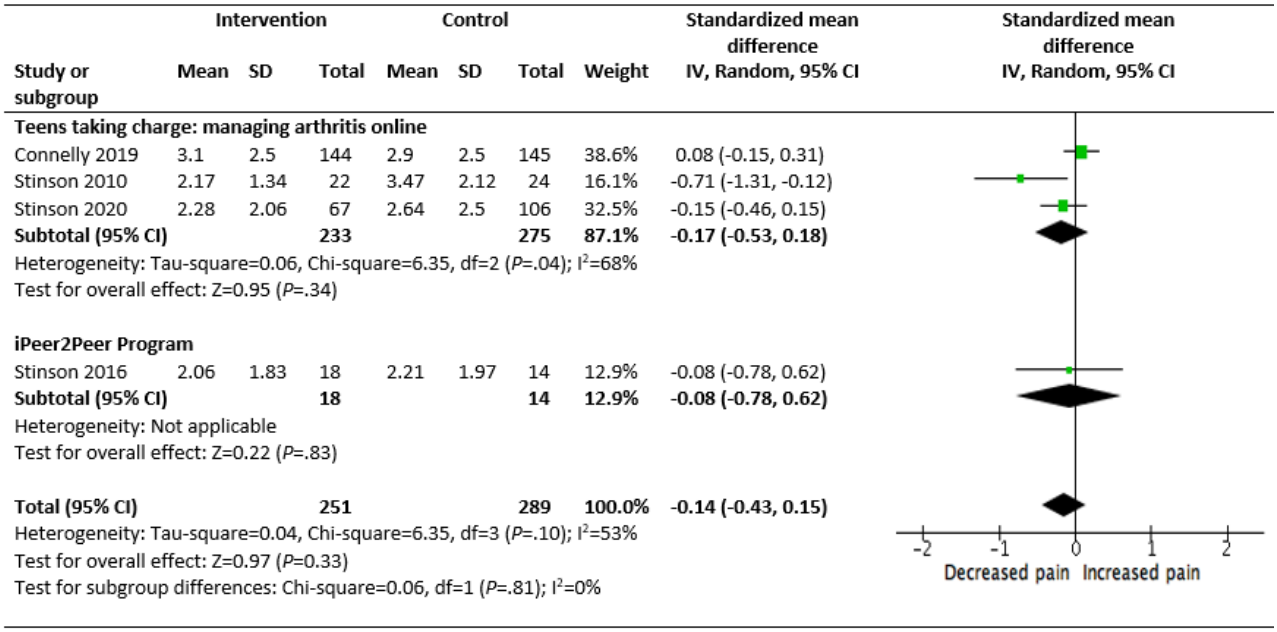


Figure 4. Effectiveness of Teens taking charge intervention in reducing pain interference for children and young people (aged 12-18 years) with juvenile idiopathic arthritis.

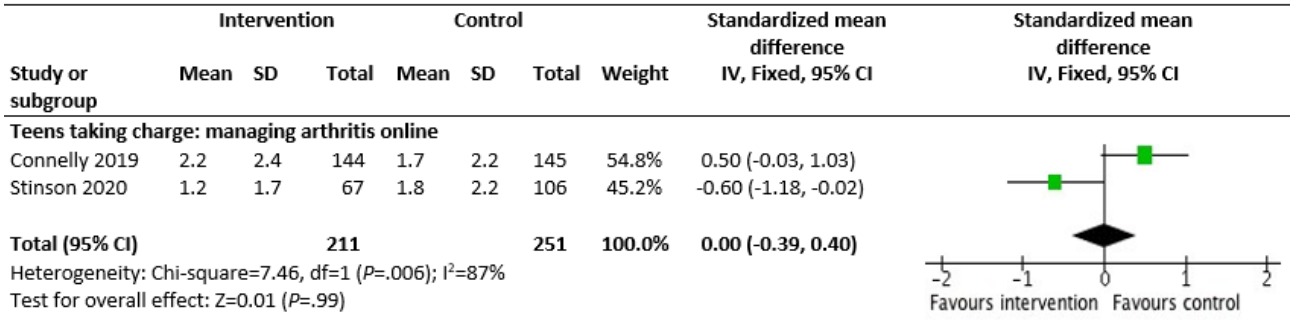
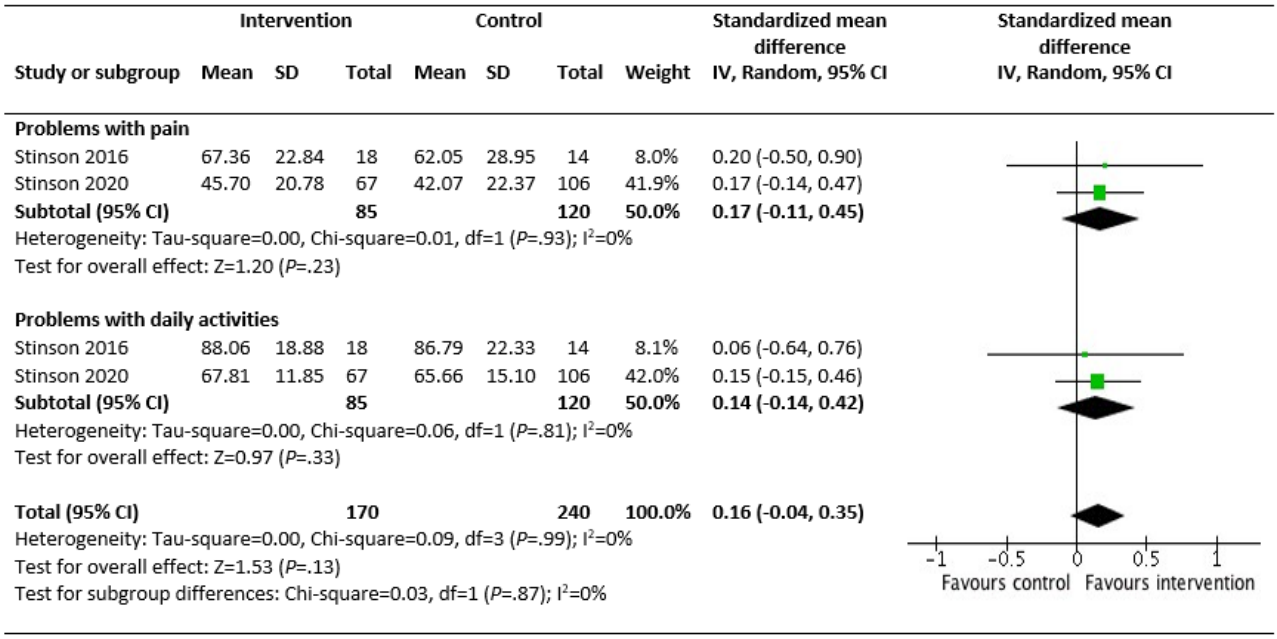


HRQoL Improvements

Of the 5 studies targeting self-management development, 4 (80%) fair-to-good–quality studies considered the intervention effect on HRQoL for the IG compared with CG (age range 8.7-18.6 years) [66,70,73,74,77]. Of these 5 studies, 4 (80%) good-quality studies, reporting on *Teens taking charge* and the *iPeer2Peer Program*, were pooled for a meta-analysis. No effect was demonstrated for HRQoL [66,73,74,77]. For *Teens taking charge*, a further subanalysis of the individual HRQoL domains (problems with pain, daily activities, treatment, worry, and communication), using the PedsQL, demonstrated a small effect in improving problems with pain and problems with daily activity (SMD 0.16, 95% CI −0.04 to 0.35; I=0%; *P*=.13) (Figure 5) [73,74]. This effect was not statistically significant. From the study outcomes excluded from the meta-analysis, no improvements were seen in anxiety, depression [66,73], or stress [77].

Figure 5. Subanalysis of Teens taking charge intervention and the health-related quality of life domains: problems with pain and daily activities for children and young people (aged 8.7-18 years) with juvenile idiopathic arthritis.



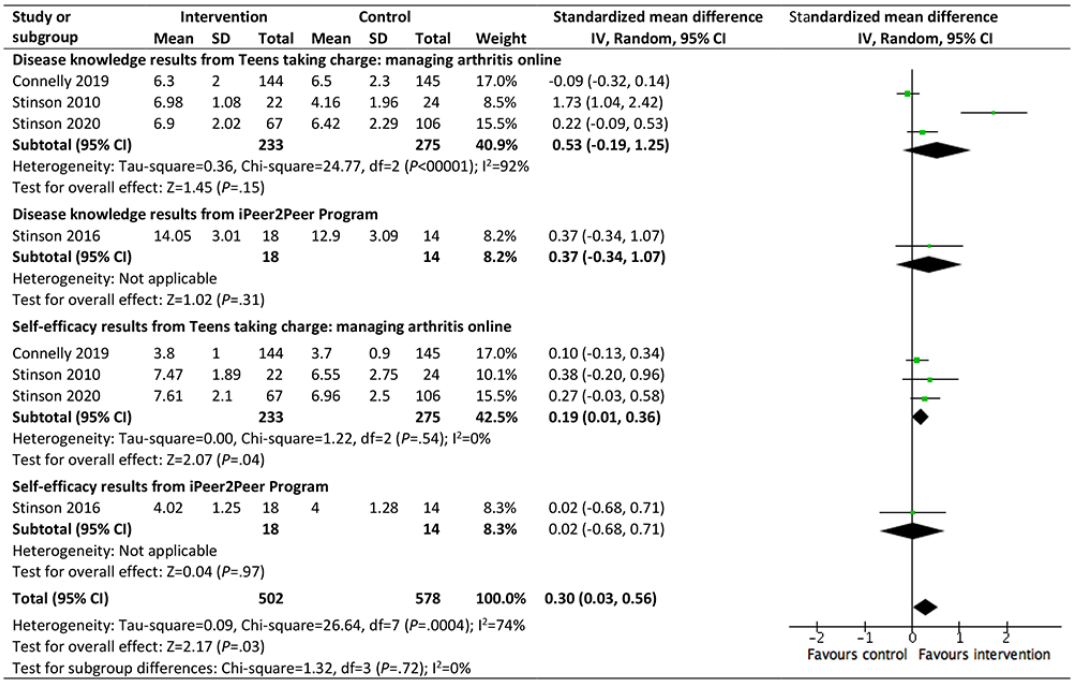
Follow-up

Of the 5 studies targeting self-management development, 2 (40%) good-quality studies considered follow-up after the study period at 3, 6, and 12 months [66,73]. In the Canadian *Teens taking charge* study, children and young people (aged 12-18 years) in the IG retained the improvements they gained during the study period for pain intensity and in the HRQoL domains of problems with pain and problems with daily activities. These results were not statistically significant. A significant improvement was seen in the domain of problems with treatment (*P*=.008) [73]. In the US *Teens taking charge* study, children and young people (aged 12-18 years) in the IG and CG continued to have a stable reduction in pain intensity and pain interference and improvements in HRQoL. The differences between the IG and CG were not significant [66].

Health Literacy

Of the 5 studies targeting self-management development, 4 (80%) good-quality studies, reporting on *Teens taking charge* and the *iPeer2Peer Program* (children and young people aged 8.7-18 years) and considering health literacy, were pooled in a meta-analysis [66,73,74,77]. A small, nonsignificant effect was seen in improving disease knowledge and self-efficacy (SMD 0.30, 95% CI 0.03-0.56; I^2=74%; *P*=.03); however, confidence in these results was reduced because of high statistical heterogeneity (Figure 6) [66,73,74,77]. No improvements were seen in pain coping strategies [66,73].

Figure 6. Effectiveness of self-management programs in improving disease knowledge and self-efficacy for children and young people (aged 12-18 years) with juvenile idiopathic arthritis.



Functional Ability and Adherence to Treatment

Of the 5 studies targeting self-management development, only 1 (20%) fair-quality study reported on functional ability. There was no improvement in pain-related limitations (*P*=.65) [70]. Another 40% (2/5) of good-quality studies reported on treatment adherence. No improvements were reported for medication, exercise, or splint adherence [73,77].

Adverse Events

Of the 15 studies, 3 (20%) fair-to-good–quality studies recorded adverse events [65,66,69]. *Teens taking charge* (age range 12-18 years) reported the highest number of adverse events (n=72), mostly related to infections (18/72, 25%) and arthritis-related flares (17/72, 24%) [66]. The more serious events involved hospitalization (9/72, 13%) or suicidal thoughts (4/72, 6%). There was no significant difference in adverse events between the IG and CG groups (*P*=.67) [66]. *MisFit Flash* (age range 12.8-18.6 years) also reported illness, injury, or pain (9/28, 32%), including arthritis-related ankle and knee pain (1/28, 4%). However, no significant difference was seen in functionality (mean Childhood Health Assessment Questionnaire score), pain, or active joint count during the study [69]. Whereas *Rheumates@Work* (age range 8-12 years) reported arthritis-related flares, affecting more children and young people in the CG (2/17, 12%) compared with the IG (1/16, 6%) [65].

Dropout

Of the 15 studies, 10 (67%) studies reported dropout rates (range 0-114) by children and young people (aged 8.7-18.6 years) [65,66,69,70,72-74,77-79]. Dropout reasons before study commencement included not being interested anymore [65,66,74], early withdrawal before allocation [66,77], not receiving allocation [65,70,77], not completing app orientation [70], technical issues [77], and no show and no reason [65]. Reasons during the study period included other health problems [65,69], school and extracurricular activities [69,78], discontinued use [66,74,77], did not complete final web-based measures [77], unable to reach [66], lost to follow-up [66,69,73,74,77,79], and removal because of lack of compliance [74]. No comparisons were made between age or gender [65,66,69,70,72-74,77-79].

Of the 15 studies, 7 (47%) studies reported both the IG and CG dropout rates [65,66,70,72-74,77]. A higher dropout rate was reported in the IG (119/455, 26.2%; range 0-76) compared with the CG (56/449, 12.5%; range 0-56) [65,66,70,72-74,77]. The Canadian *Teens taking charge* study reported the highest dropout rate (IG: 76/164, 46.3%; CG: 38/169, 22.5%) [73].

Discussion

Principal Findings

To the best of our knowledge, this is the first systematic review to evaluate the effectiveness of eHealth and mHealth interventions in supporting children and young people living with JIA. In total, 10 interventions were identified to support symptom monitoring, physical activity promotion, or self-management development for children and young people aged 4 to 18.6 years. These 10 interventions included 4 (40%) web-based programs [65,66,68,72,73,76,77], 3 (30%) health applications [67,70,71], 1 (10%) telecommunication application [74], 1 electronic diary (10%) [75,78,79], and 1 (10%) accelerometer compatible with a tablet or smartphone [69]. The methodological quality of the studies supporting these interventions ranged from fair [68-71,75,76,78] to good [65-67,72-74,77,79].

Theme 1: Symptom Monitoring (4-18 Years)

Pain assessment was the most common type of intervention used to support symptom monitoring. The interventions *My*

Pain Tracker and *eOuch* aimed to capture real-time data through children and young people self-reporting pain [71,75,78,79]. Monitoring pain is important as pain is the most frequently reported symptom by children and young people living with JIA [12,82]. Pain can dramatically interfere with physical functioning, coping mechanisms, and quality of life [12]. Stinson et al [79], through the use of *eOuch* pain diaries, demonstrated a correlation between pain intensity and the impact pain can have on emotional well-being (unpleasantness) and activities of daily living (interference), reinforcing the need for ongoing comprehensive pain monitoring, which could allow the health care team to make timely recommendations and prevent poor health outcomes [83-85].

However, there is no consensus on the required number of real-time assessments, per day or week [71,86,87], to ensure the collection of high-quality data and avoid the burden of momentary reporting [71]. Instead, a large variation, ranging from 2 to 9 times a day for children and young people, has been seen [87]. In this review, real-time pain monitoring ranged from 1 to 3 times a day [71,75,78,79] or when needed [71]. Lee et al [71], through *My Pain Tracker*, compared these reporting frequencies, finding that children and young people preferred once-a-week or when-needed pain assessments to avoid thinking about their pain. Although more details in pain data were collected from once-a-day reporting, and, for some children and young people, adherence to once-a-day reporting was easy as it became a routine [71], more research is needed on reporting frequencies.

Real-time pain monitoring also exposed differences between real-time pain and recall pain assessments [75]. Recall pain measurements were higher and predictive compared with average real-time pain measurements, influenced by the children's and young peoples' most intense pain and last pain score [75]. This is known as recall bias or peak-end effect [75,88]. This nonequivalence between real-time pain assessments and recall pain assessments adds significance to previous research by Stone et al [88], highlighting methodological concerns around relying on retrospective pain assessments, especially when considering the length between rheumatology appointments.

Longitudinal variances were also seen between real-time and recall pain monitoring [75]. Stinson et al [75] and Stone et al [88] both demonstrated a weak correlation with within-person data when pain was defined as >0/10, which is the most common pediatric pain scale. This suggests that real-time and recall pain assessments cannot be compared or used interchangeably when assessing long-term changes in pediatric pain [75]. Considering that the length of the studies in this review was only 2 to 8 weeks [71,75,78,79], further research on the longitudinal effects of real-time pain monitoring is needed.

The use of real-time symptom monitoring for children and young people is also supported by previous work in reducing the recall time to days, hours, or minutes [87], and importantly, a recent systematic review, reporting on real-time monitoring using mobile technology, suggests that it can be successfully implemented from the age of 7 years [87]. In addition, a study considering adults with chronic illnesses supports real-time monitoring for the identification of exacerbations, confidence in self-management, and prevention of hospital admissions [89]. In this review, the intervention *EQ-5D-Y-5L* endorsed this finding, as remote HRQoL monitoring identified, with satisfactory diagnostic accuracy (P<.001), moderate to high levels of disease activity, promoting the need for adjustments with prescribed treatments and rheumatology consultation frequency [67]. Further research is now needed on this web-based PR– children and young people interaction and the impact remote monitoring may have on safety [67,90].

In this review, 13% (2/15) of studies reported positive feedback from PRs after they reviewed web-based assessments during consultation [68,76]. PRs reported that *SUPER-KIDZ* pain assessments increased time efficiency compared with a paper-based assessment [76]. However, *ePROfile* increased PR satisfaction with the care they provided as the HRQoL discussion improved and the number of psychological referrals increased [68]. Although these findings were not significant, reviewing pain and HRQoL during consultation is important as children and young people with JIA have significantly lower HRQoL compared with that of healthy children and young people, and children aged 8 to 12 years with JIA have lower HRQoL than that of children with other chronic health conditions [9].

Interestingly, the use of web-based portals in adult rheumatology has been long standing. The Feed Forward System, for example, used in Sweden generates a patient's progress over a period and has been successfully used to guide health care provider recommendations and aid the development of patient self-management skills [91].

For JIA, feasibility studies considering web-based portals also support their use, reporting that this form of technology can increase children's and young peoples' (aged 5-22 years) feeling of control [92,93].

Regrettably, parents and children and young people did not report the same level of satisfaction with the *ePROfile* consultation as PRs [68]. Haverman et al [68] suggest that this may be as they are already happy with the quality of their care. Nonetheless, many factors that can influence children's and young peoples' opinions on digital assessments need to be considered. First, they can be influenced by the assessment experience; they need graphical and tailored feedback to encapsulate their results and catch their interest [94]. In addition, children and young people may not value and understand the importance of monitoring symptoms, disease, and general well-being (mood, fatigue, and functional ability) [44,95] or the need for a person-centered framework that builds partnerships between families and health care teams [92]. Further research on the use of web-based portals for children and young people is needed.

Theme 2: Physical Activity Promotion (8-18.6 Years)

In this review, 20% (2/10) of interventions, *Rheumates@Work* and the wearable *activity tracker*, Misfit Flash, aimed at improving self-management behavior by promoting physical activity for children and young people (aged 8-18.6 years) [65,69,72]. Of these 2 interventions, only 1 (50%)

Rheumates@Work, demonstrated a moderate but clinically meaningful effect on physical activity, improving endurance time, PAL, and MVPA for children and young people (aged 8-12 years) [65,72]. This finding is important as children and young people with JIA are less physically active [96,97] and spend more time in sedentary activities than their peers [96]. Improving physical activities helps to retain musculoskeletal function, muscle strength, and functional capacity [98].

In addition, increased physical activity did not exacerbate disease activity or pain in the IG compared with the CG [65,69]. In fact, no significant difference was reported [65,69], and absenteeism from school decreased [65]. These findings are encouraging, especially considering the related impact JIA can have on reducing academic performance, as depicted by Bouaddi et al [99] and Laila et al [100]. Although these findings are limited, they will add to the growing body of evidence reporting that exercise therapy is well-tolerated by children and young people with JIA [98,101,102], further supporting physical activity as a helpful and necessary treatment modality, improving adherence [24,103].

Theme 3: Self-management Development (8-18 Years)

In this review, 30% (3/10) of interventions—*iCanCope* [70], *Teens taking charge* [66,73,77], and the *iPeer2Peer program* [74]—supported self-management development for children and young people (aged 8-18 years). These interventions (including *Rheumates@Work* [65]) are typical behavior change technique interventions used for children and young people [31]. They support self-management through the development of disease-specific knowledge, goal setting, self-management strategies, and social support [66,70,73,74,77].

In this review, identified in the meta-analysis, children and young people participating in the self-management programs *Teens taking charge* and *iPeer2Peer Program* reported a small but nonsignificant improvement in pain intensity, disease knowledge, and self-efficacy scores [66,73,77]. However, high statistical heterogeneity was also seen within the results. This may be because of several reasons. First, a range of comparators was used for the CG. For example, in 2 of the 3 *Teens taking charge* studies, the IG was compared with an active CG rather than usual care. The CG also received an eHealth intervention 12 publicly available health education websites with phone support to support care. Improvements were then seen in both the IG and CG, reducing the mean difference between the groups [66]. Most digital studies primarily focus on a single intervention to demonstrate the intervention effect rather than comparing different digital interventions. However, it is this direct comparison that can reveal a more effective intervention [104]. The CG's intervention, the use of health care workers signposting quality health education websites to support self-management skills [105,106] and improve well-being [107], is supported in the literature. Therefore, acknowledging the improvements seen in the CG is important, as the use of publicly available websites can be a cost-effective solution for dissipating health information among the masses to support the delivery of health care [28]. For example, a study of adults living with chronic pain (n=20; aged 18-74 years) explained that if they had been provided with quality pain-related information, it might have prevented the desperation and anxiety they experienced, especially during the first few years [107].

Another explanation for the moderate to high statistical heterogeneity may have been that the studies were conducted in different countries, within different health care delivery systems, with different levels of pre-existing support [73]. Differences exist with the pediatric rheumatology workforce worldwide [7,13-18] and within publicly funded and self-funded health care systems [108,109]. Differences also exist in PRs' opinions on pediatric self-management and the use of an interdisciplinary approach to care [108]. Successful publicly available digital interventions may be a solution to transcending these boundaries and universally improving access to care [28,106]. Further comparisons between different self-management interventions is needed, especially when considering the dropout rates in this review, which, for the self-management programs, were higher in the IG [65,66,70,73,74]. These dropout patterns were similar to a recent systematic review predicting dropout rates in adults, with dropouts occurring at the beginning and over the course of the intervention [110].

There may also be no one-size-fits-all intervention, or there may be a need for a combination of interventions. For example, the *iCanCope* pain self-management application combined 2 interventions (real-time pain monitoring and self-management) and then compared this combination to standalone pain monitoring. This combination demonstrated a greater decrease in pain intensity scores (>1 point, 0-10 on the numerical rating scale) [70]. Although this finding was not significant, the inclusion of self-management programs could be clinically beneficial. Improving and providing effective educational interventions early in childhood should be when children and young people are beginning to develop their health behaviors [23]. Studies have shown that a high level of health literacy can support informed decision-making [111-113]; treatment adherence, especially for nonmedication interventions [113]; and the prevention of chronic health-related problems [22].

Unfortunately, not all the results of this review are promising. Across the studies, the interventions had no effect on pain interference [66,73], HRQoL [65,66,69,70,73,74,77], anxiety, depression, pain coping [66,73], disease activity [69,72], functional ability [65,69,70], or treatment adherence [73,77]. In addition, only 20% (3/15) of studies considered long-term follow-up [65,66,73]. More research is needed to gain wider health-related benefits.

Limitations

It is essential that several limitations are considered when interpreting the findings of this review. First, our search strategy was restricted to an academic context, using eHealth electronically indexed health databases that publish peer-reviewed journals, rather than apps within commercial stores. This means that our results may not provide a true reflection of the health apps available for JIA. This decision was based on the commonly reported shortcomings of health apps available to the general public that are related to data safety and lack of rigorous testing [114].

Second, the selection criteria in this review deviated from our systematic review protocol [53]. In the protocol, we outlined that the comparator or CG was to receive usual care, with no eHealth or mHealth input. Instead, we included 13% (2/15) of studies comparing an eHealth intervention to another digital intervention [66,73], as a preliminary pilot study of this intervention met our inclusion criteria to be included in this review [77]. This decision enabled us to provide the most up-to-date evidence for this intervention.

Third, our findings in this review supporting the use of real-time monitoring and web-based assessments were based on descriptive summaries. The use of a narrative, descriptive methodology to summarize, synthesize, and report the results is at risk of reporting bias. To reduce this risk, all authors internally reviewed all the stages of this review.

In addition, there were methodological concerns in the data reported by some studies because of performance bias. It was not possible to blind children and young people from the intervention, which could have resulted in a placebo effect. For example, *Rheumates@Work* reported improvements in both the IG and CG for MVPA and participation in physical education classes. Baseline testing may have made the CG more aware of the need to improve their physical activities [65]. The interventions' true effects may have also been overestimated, as activity levels entered by children and young people in the exercise diaries did not match the accelerometers. Overreporting exercise is not uncommon. Various correlations have been reported between exercise diaries and accelerometer recordings in the general population (r=0.52) [115]; among children and adolescents (reliable coefficient ranges r=0.5-0.93 and validity coefficient ranges r=0.03-0.88), with children being in the lower range [116]; and for JIA (light PAL and MVPA r<0.24; rest and PAL r=0.41) [117]. Unexpectedly, a 4% inaccuracy has also been identified in accelerometer recordings for JIA in light PALs (effect size 1.2) because of nonwearable periods (aquatic activities and ball games) [117]. Awareness of these possible variations enables correction. For example, Armbrust et al [117] recommend, for research purposes, the use of accelerometer recordings (7-19 days) and an activity diary (>13 days). Another feasible suggestion may be the use of wearable forms of digital technology (ie, a smartwatch) [27]; however, more research is needed to overcome the nonwearable periods such as contact sports [118] or while attending school [119].

Finally, the generalizability of our findings may be limited. We included 40% (6/15) of studies where several children and young people were categorized as unknown, not yet diagnosed, or other (55/1438, 3.82%; range 2-37) [68,70,73,76,77,79]. Dissecting the results to target children and young people specifically with JIA was not possible (Table 2). For a fair-quality study, which reported the highest number of children and young people in this category (37/101, 36.6%), our data extraction focused on the consensus view of pediatric rheumatology providers (PRs, allied health experts, and pain experts) rather than the children and young people [76], which is an area of research that is currently limited.

Conclusions

Evidence that supports the inclusion of eHealth and mHealth interventions in JIA management is on the rise; however, this evidence needs to be considered cautiously. Confidence in the results is reduced because of low sample size, wide CIs, high statistical heterogeneity, and no similar effect being seen across similar studies. More rigorous research is needed that focuses on the longitudinal effects of real-time monitoring, web-based PR–children and young people interactions, comparison of self-management strategies, and the use of wearable digital technology as an objective measurement for monitoring physical activity before any recommendations informing current practice can be given.

Abstract

Background: Hearing loss affects 1 in 5 people worldwide and is estimated to affect 1 in 4 by 2050. Treatment relies on the accurate diagnosis of hearing loss; however, this first step is out of reach for >80% of those affected. Increasingly automated approaches are being developed for self-administered digital hearing assessments without the direct involvement of professionals.

Objective: This study aims to provide an overview of digital approaches in automated and machine learning assessments of hearing using pure-tone audiometry and to focus on the aspects related to accuracy, reliability, and time efficiency. This review is an extension of a 2013 systematic review.

Methods: A search across the electronic databases of PubMed, IEEE, and Web of Science was conducted to identify relevant reports from the peer-reviewed literature. Key information about each report's scope and details was collected to assess the commonalities among the approaches.

Results: A total of 56 reports from 2012 to June 2021 were included. From this selection, 27 unique automated approaches were identified. Machine learning approaches require fewer trials than conventional threshold-seeking approaches, and personal digital devices make assessments more affordable and accessible. Validity can be enhanced using digital technologies for quality surveillance, including noise monitoring and detecting inconclusive results.

Conclusions: In the past 10 years, an increasing number of automated approaches have reported similar accuracy, reliability, and time efficiency as manual hearing assessments. New developments, including machine learning approaches, offer features, versatility, and cost-effectiveness beyond manual audiometry. Used within identified limitations, automated assessments using digital devices can support task-shifting, self-care, telehealth, and clinical care pathways.

Introduction

Background

Hearing loss affects 1.5 billion persons worldwide and is expected to increase by another billion by 2050 [1,2]. Hearing testing is the first step toward appropriate and timely treatment. Unfortunately, most persons affected with hearing loss are unable to access hearing assessments, with less than one hearing health professional for every million people in regions such as Africa [2,3]. Increasingly automated approaches (all aspects of the method associated with automated audiometry), including machine learning, are being developed and made available to provide self-administered hearing assessments. The term *automated audiometry* refers to all hearing tests that are self-administered from the point the test starts. More specifically, in this review, we define automated audiometry as calibrated pure-tone threshold audiometry in any setting (ie, hearing health care, occupational health, and community settings) that is self-administered from the point the test starts. Machine learning refers to model-based approaches that learn from examples (data) instead of being programmed with rules [4]. As the direct involvement of professionals is not required, automated approaches enable health care pathways with the potential to increase accessibility, efficiency, and scalability. Digital (health) technologies, including apps, smartphones, tablets, and wearables, can acquire data remotely; expand the reach and precision of clinicians; and facilitate more personalized hearing health care within a network of distributed expertise [5,6]. Recent examples of automated hearing assessments include clinical grade and consumer-grade applications [7]. General global health trends suggest that increased availability of diagnostic tools could lower health care costs and improve quality of life [8]. For example, in Parkinson disease, remote care based on wearables provides ecologically valid methods for monitoring and evaluating symptoms [9,10]. In tuberculosis screening in low-resource settings, an automated diagnosis can increase the sensitivity of identifying persons at risk while reducing costs [11]. Self-assessment using eHealth vision tools improves access to diagnosis and facilitates timely diagnosis, although consistent criteria for referring to the clinical pathway and validity and reliability of eHealth tools are still a concern [12].

Timely detection and treatment of hearing loss are essential to enable optimal outcomes and quality of life across the life span [2]. Untreated hearing loss restricts language development and educational potential in children and is associated with a more rapid cognitive decline in adults [13]. It may lead to social isolation, lower socioeconomic status, increased social disparities, and decreased health, resulting in lower quality of life at the individual level and substantial costs at the community level [14,15]. Importantly, treating hearing loss in midlife has been identified as the largest potentially modifiable risk factor for developing dementia in later life [16]. The global annual cost of untreated hearing loss is US $980 million [14]. Global health investment models indicate a significant return on investment in both hearing diagnosis and treatment [2]. The capacity of the entire clinical pathway should be increased as a bottleneck looms if the accessibility of diagnosis is increased faster than the availability of affordable treatment and rehabilitation.

Automated self-test options are important for detecting and diagnosing hearing loss to direct timely and appropriate treatments. The overwhelming majority of treatments are for permanent age-related and noise-induced hearing loss; however, a significant portion of the population requires medical treatment for hearing loss [1]. The onset of the COVID-19 pandemic has further emphasized the importance of self-testing approaches [17,18]. Automation on digital devices is a powerful enabler of alternative diagnostic pathways that can include home-based testing, low-touch service models outside traditional clinic settings, and decentralized community-based models that rely on task shifting to minimally trained facilitators [19].

Automation in hearing assessment is not a new concept and dates back to >7 decades [20]. In recent years, it has resurged with the convergence of digital technologies and machine learning approaches. The primary tool for hearing assessment is pure-tone audiometry, which describes the degree of hearing loss relative to normal hearing, expressed in decibels hearing level across specific frequencies (125-8000 Hz). Pure-tone audiometry can also differentiate the type of hearing loss, that is, sensorineural or conductive, when bone conduction and air conduction transducers are used. Machine learning–based threshold-seeking approaches, known as Bayesian active learning, have demonstrated their potential to optimize efficiency and increase the precision of automated hearing assessments [21]. The increased efficiency comes from the ability of these methods to target trials to those areas of the frequency space where the estimation has the greatest uncertainty [22,23].

Objective

In 2013, a systematic review that included 29 reports on automated audiometry showed that automated procedures have comparable accuracy with that of manual procedures when performing air conduction audiometry. Although a few validated automated procedures that included automated bone conduction audiometry had been reported, machine learning–based audiometry approaches had not been reported yet, and approaches were rarely validated in children or hard-to-test populations [24]. Since 2013, there has been significant work and innovation in this area, which calls for an update and extension of the previous review. This study aims to provide the current status of automation and machine learning approaches in hearing assessment using validated pure-tone audiometry with potential indicators of accuracy, reliability, and efficiency of these approaches.

Methods

We conducted a systematic scoping review of the peer-reviewed literature on automated and machine learning approaches to validate pure-tone threshold audiometry using digital technologies by considering accuracy, reliability, and efficiency. This review followed the methodological framework outlined by Arksey and O'Malley [25].

Identifying Potentially Relevant Records

A search across the electronic databases of PubMed, IEEE, and Web of Science was conducted to identify relevant reports from the peer-reviewed literature. Complementary and redundant search terms were applied to ensure thorough coverage and cross-checking of the search findings. In the PubMed database, medical subject headings and relevant keywords were collected to determine all records related to the study aim. The following synonyms of, and closely related terms to, automated audiometry were used: automatic audiometry, self-administered audiometry, self-assessment audiometry, and user-operated audiometry. The complete set of terms and the applied search strategy are provided in Multimedia Appendix 1. The IEEE database is engineering oriented, and only relevant keywords based on audiometry were used, as it was assumed that any result in audiometry would be highly associated with automated audiometry. The Web of Science database is known to index the PubMed and IEEE databases and was explored using search terms similar to the PubMed search. After preliminary explorations to identify appropriate keywords, we conducted a search on July 8, 2020, and updated it on January 12, 2021, and July 6, 2021. The search included all reports that met the inclusion criteria published from January 1, 2012, to June 30, 2021. The start date was chosen as we regard this scoping review as an extension and generalization of a previous (systematic) review by Mahomed et al [24], which included studies up to July 20, 2012.

Selecting Relevant Records

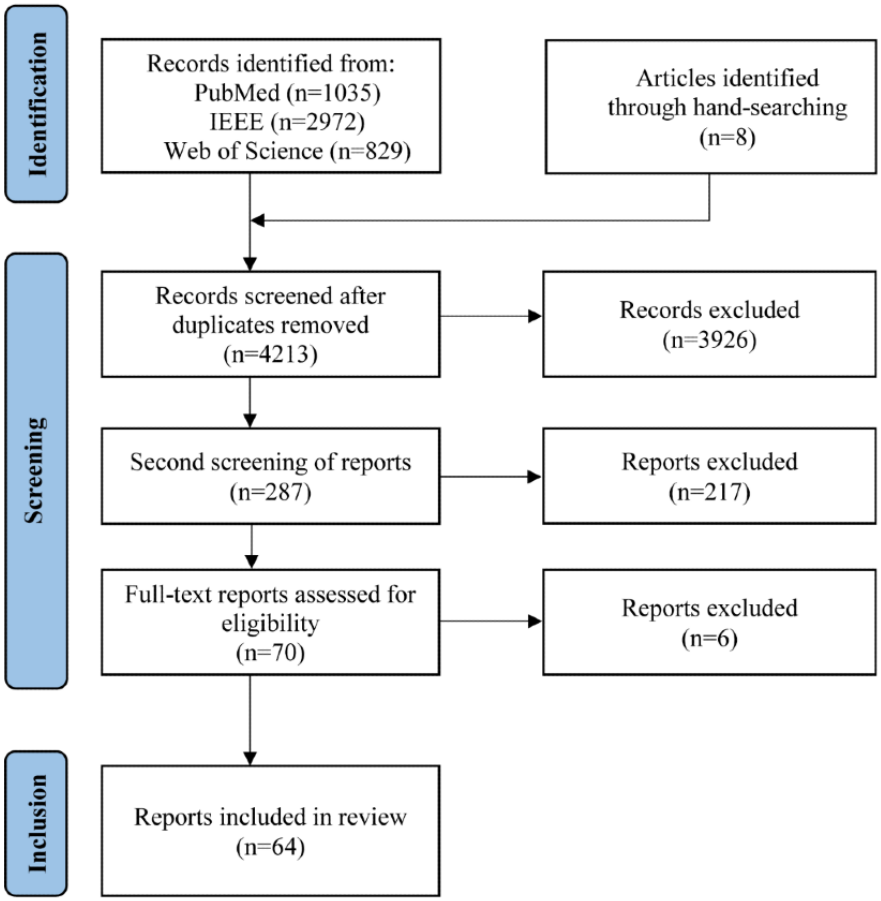
Reports had to meet the following three inclusion criteria: (1) the report had to be about automated or machine learning and pure-tone frequency-specific threshold audiometry, (2) it had to be written in English, and (3) the automated threshold audiometry had to be compared against the gold standard or reasonable standard. The gold standard is defined as manual audiometry in a sound booth according to the International Organization for Standardization standards. Automated audiometry also needed to be performed inside a sound booth, and the results needed to be compared with the gold standard. A reasonable standard for validation was defined as either a within-subject comparison between the gold standard and the automated audiometry in an unconventional setting (eg, a quiet room) or a within-subject comparison between a validated automated audiometry approach and an experimental approach of audiometry in the same unconventional setting.

We excluded reports on screening audiometry (eg, provided pass or refer as an outcome) rather than threshold audiometry, review papers, and studies reporting approaches that were not compared with the gold or reasonable reference standard.

The first phase of screening was based on the title. If the title indicated that content was within the scope of the research question (ie, automated or machine learning approaches in diagnostic hearing assessment), the report was included in the second screening phase. In the second phase, the abstracts of the remaining reports were assessed using the inclusion and exclusion criteria stated earlier.

Two researchers (LP and JWW) conducted the abstract screening. They were blinded from each other to avoid confirmation bias. After the screening, the researchers discussed any disagreements to reach an agreement. When in doubt, the report was admitted to the third, full-text review phase. In this phase, all the remaining reports were reviewed in full to determine whether the inclusion criteria were met. As can be seen in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram (Figure 1), the resulting selection of reports was complemented by additional reports. After some reports were clustered as having identical approaches (explained in *Collating Approaches, Summarizing, and Reporting the Results*), additional reports were added to avoid missing validation data of these clustered approaches. These additional reports were published before the inclusion date criteria (from before January 1, 2012) or did not appear in the search and were added based on the reference lists of the already included reports.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram of the screening process.



Extracting Data Items

A template for grading the reports was agreed upon by all the authors (Multimedia Appendix 2 [26]). Two researchers (LP and JWW) independently extracted information directly relevant to the scoping review question. In cases of disagreement, a consensus was reached after discussion between the 2 researchers. The compulsory data fields were test frequency and intensity range; response method; test equipment, including the type of transducers; calibration; hardware; test quality control; accuracy; reliability; efficiency; validation; and test population. In the report by Mahomed et al [24], the accuracy and reliability of manual and automated approaches demonstrated equivalent performances. Time efficiency had primarily been reported by comparing the testing times of manual and automated audiometry [27-29]. The reports on machine learning audiometry explicitly used the number of trials or stimuli needed to converge to a certain precision (eg, 5 dB) as a performance outcome [23,29]. Therefore, we added time efficiency as a necessary parameter. Where available, accuracy and reliability were expressed in decibels using the overall root mean square deviation (RMSD) between the automated approach and the gold (or reasonable) standard. On the basis of the study by Margolis et al [30] and the minimum acceptable accuracy recommended by clinical guidelines [31], RMSD values of 6 dB and 10 dB were chosen as criteria for desired and minimal accuracy, respectively. To establish a benchmark for an acceptable test duration, the mean testing time for conventional manual bilateral audiometry (air 7 and bone 5 frequencies) was estimated (Multimedia Appendix 3 [27-29,31,34,38]). For manual bilateral air conduction, based on the benchmark measurement times, a mean testing time of 5 to 10 minutes was considered acceptable, and for manual bilateral air and bone conduction, 10 to 20 minutes was considered acceptable. If testing times exceeded these ranges by >5 minutes, the time efficiency was assessed as a potential issue.

Data collected from the reports provided key information about the scope and details of each report, enabling the authors to assess commonalities between the approaches.

Collating Approaches, Summarizing, and Reporting the Results

When multiple reports described the same underlying approach, these reports were pooled into one approach cluster. The first report describing an approach and subsequent studies that validated or extended the approach were included. The name of the approach, citations to the initial report, or common authorships were used to cluster the reports. The grading table was completed for each cluster separately to provide a structure for the subsequent content analysis. In the last part of the grading table, under the heading *Validation Approach*, all validation studies are described together. For every approach cluster, a key contribution to the audiological field was derived from the associated reports. A key contribution is a finding or claim made by the authors significant to the approach in general, stated in

either the conclusion or the discussion section of a report in accordance with their objective.

Results

Overview

A total of 64 reports were included in this study. Of the 64 reports, 56 (88%) were included according to the inclusion and exclusion criteria, and 8 (13%) were added to the approach clusters. After clustering identical approaches, 27 approach clusters remained, including 2 that used machine learning. Extracted data items and grading of results on approaches are provided in Multimedia Appendix 4 [21,23,27-30,32-89]. The specifications of the reported accuracy, reliability, and time efficiency are described in Table 1.

Table 1. Review of the accuracy, test–retest reliability, and time efficiency for automated and machine learning audiometry approaches (2012-2021; N=27 approach clusters).

Type of transducer	Accuracy		Reliability (test–retest)		Time efficiency	
	Reported finding	Values, n (%)	Reported finding	Values, n (%)	Reported finding	Values, n (%)
Air conduction (n=23 approach clusters)						
	RMSD[a]<6 dB[b]	4 (17)	RMSD<6 dB	4 (17)	Acceptable testing time per (partial) audiogram	10 (43)
	RMSD<10 dB	7 (30)	RMSD<10 dB	1 (4)	Acceptable testing time and number of trials per audiogram	2 (9)
	Statistical equivalence	9 (39)	Statistical equivalence	9 (39)	Acceptable testing time and number of trials per frequency	1 (4)
	No statistical equivalence	3 (13)	Not reported	9 (39)	Testing time potential burden	1 (4)
	N/A[c]	N/A	N/A	N/A	Not reported	9 (39)
Bone conduction (n=1 approach cluster)						
	Statistical equivalence	1 (100)	Test–retest not reported	1 (100)	Not reported	1 (100)
Both air and bone conduction (n=3 approach clusters)						
Air conduction						
	RMSD<6 dB	2 (67)	RMSD<6 dB	1 (33)	Acceptable testing time per audiogram	2 (67)
	RMSD<10 dB	1 (33)	RMSD<10 dB	2 (67)	N/A	N/A
Bone conduction						
	RMSD<10 dB	1 (33)	RMSD<6 dB	1 (33)	N/A	N/A
	Statistical equivalence	2 (67)	Test–retest not reported	2 (67)	N/A	N/A
Air and bone conduction						
	N/A	N/A	N/A	N/A	Acceptable testing time per audiogram	1 (33)

[a]RMSD: root mean square deviation.

[b]dB: decibels.

[c]N/A: not applicable.

Accuracy

Accuracy is represented as a comparison against the gold standard or reasonable standard. Most of the automated techniques (14/27, 52%) expressed accuracy in RMSD. Other types of analyses used average differences and SD (10/27, 37%), average thresholds and SD (1/27, 4%) [32], linear regression and correlation coefficients (1/27, 4%) [33], and analysis of variance (1/27, 4%) [34]. The types of analysis used can be seen in Multimedia Appendix 5 [23,32-37,39,40,43,45,48-50,57-59,65,67,68,70,74,77,81,83-85].

Test–Retest Reliability

Test–retest reliability was reported for some automated and machine learning audiometry approaches. Of the 27 approaches, 17 (63%) did not report on test–retest reliability, and 7 (26%) expressed it in RMSD. Other statistical methods used were average differences and SD (6/27, 22%), Pearson product moment correlation coefficients (2/27, 7%) [35,36], standard of variance (1/27, 4%) [37], and repeated analysis of variance (1/27, 4%) [34].

Test Efficiency

Of the 27 approaches, 17 (63%) reported a measure for test efficiency based on the test duration. Test efficiency expressed

in testing time seems to be a standard metric, similar across studies and defined as the time from presenting the first stimulus until the final response of the participant, expressed in seconds or minutes. However, there were disagreement among reports on what to include in the measurement and what groups to use as a reference. Reported time-efficiency measures included the recorded time per frequency, recorded time per unilateral or bilateral air conduction audiogram (between 2 and 7 frequencies) in normal hearing or people with hearing impairment, or full air and bone conduction audiograms in people with hearing impairment. Of the 27 approach clusters, 13 (48%) approach clusters reported acceptable testing times; 3 (11%) approach clusters indicated the number of trials in addition to the testing time for either a bilaterally masked air audiogram [29], unilateral air audiogram [23], or per frequency [38]; 1 (4%) approach cluster that applied Bekesy tracking reported the testing time but was not in the acceptable range [39]; and 10 (37%) approach clusters did not report anything about the testing time.

Test Parameters and Specifications

All tests were self-administered from the point at which the test started. Approximately 15% (4/27) of approaches had the option of switching to a manual audiometry mode. Table 2 summarizes an overview of the test parameters and specifications of the 27 approach clusters, and Table 3 highlights the key contributions. Most of the approaches used adaptive procedures that relied only on the previous response (here referred to as partially adaptive procedures).

The most common example was the (modified) Hughson-Westlake staircase procedure (20/27, 74%), which is based on the classical method of limits [91]. Other partially adaptive procedures applied the method of adjustment, such as the Bekesy tracking method [39] or the *coarse-to-fine focus* algorithm [40]. There was a single report of an approach that did not define the threshold-seeking method but had a built-in protocol to alternate between ears during testing [35]. In contrast, fully adaptive procedures used a complete set of all previous responses. Examples include Bayesian active learning procedures (also referred to as machine learning audiometry; 2/27, 7%) [21,23] and maximum likelihood estimation (2/27, 7%) [37,38]. All machine learning audiometry methods applied active Bayesian model selection, which is a type of shallow machine learning that uses individual models. They apply supervised learning, as every data point is labeled by the participant [22].

Most of the approaches (20/27, 74%) used conventional calibration according to the International Organization for Standardization standards. Of the 27 approaches, 6 (22%) used an unconventional calibration technique. Patel et al [32] determined a reference equivalent threshold level for air conduction for a specific phone–headphone combination using manual audiometry as a reference. Masalski et al [41] used reference levels for calibration for smartphone and transducer combinations, collected under uncontrolled conditions in people with normal hearing. Other calibration techniques set the volume of the device to 50% [42], comparing and adjusting the output level to the input using a sound level meter [34,43], or using Thévenin-equivalent probe calibration [39].

Of the 27 approaches, 22 (82%) were validated in people with normal hearing and hearing impairment. Approximately 7% (4/56) of studies were performed in people with normal hearing [34,36,38]. One of the approach clusters was only validated in a population with hearing impairments using hearing aids as transducers [40]. Automated audiometry was applied across a range of populations. All approaches were applied to adults, except in the study by Patel et al [32] that only included children. Approximately 30% (8/27) approaches were validated in children, including 50% (4/8) of approaches that designed a child-friendly user interface [32,44-46]. Other test populations were older people [47], veterans [48], and persons exposed to occupational noise [49] or ototoxic substances [50]. Automated audiometry has also been applied as an alternative to traditional manual audiometry in low-resource environments [51-53]. The user interface plays an important role in making self-testing feasible in all populations and may require an iterative design process (including clinical pilot studies) [52,54].

Table 2. Description of test parameters and specifications for automated audiometry approaches (2012-2021; N=27).

Test parameters and specifications	Descriptions of approach clusters, n (%)
Threshold-seeking method (underlying algorithm to determine the thresholds)	
Hughson-Westlake (modified)	20 (74)
Machine learning	2 (7)
Bekesy tracking	1 (4)
Other method	4 (15)
Test range (limits of the frequency that can be tested)	
Clinical frequency range (125 Hz-8000 Hz)	18 (67)
Extended high frequencies range (125 Hz-16,000 Hz)	4 (15)
Reduced frequency range	5 (19)
Test range (limits of intensity that can be tested)	
Intensity range (0-100 dB[a] hearing level)	14 (52)
Reduced intensity range	10 (37)
Intensity range not reported	3 (11)
Masking (needed to prevent responses from the nontest ear and obtain the true threshold of the test ear)	
Automated masking	9 (33)
Manual masking	1 (4)
No masking	13 (48)
Masking not reported	4 (15)
Response method (method of recording participants' responses to test stimuli)	
Forced choice	9 (33)
Single response	13 (48)
Forced choice and single response	3 (11)
Not reported	2 (7)
Transducers (method of presenting stimuli, eg, insert phone or supra- or circumaural headphones)	
Air conduction transducers	23 (85)
Air and bone conduction transducers	3 (11)
Only bone conduction transducer	1 (4)
Calibration (unconventional calibration methods are explained in the text)	
Conventional calibration	20 (74)
Unconventional calibration	6 (22)
Calibration not reported	1 (4)
Digital devices (reported hardware needed to run the test)	
Portable audiometer	2 (7)
Computer based	9 (33)
Web-based (requires connectivity)	1 (4)
Smartphone- or tablet-based	1 (4)
Quality control measures (indicators of the reliability of the test)	
Detect false responses	5 (19)
Have noise control	6 (22)
Detect false responses and have noise control	7 (26)
Quality control measures not reported	9 (33)
Validation (highest level of validation reported for each approach cluster)	

Test parameters and specifications	Descriptions of approach clusters, n (%)
Gold standard	22 (82)
Reasonable standard	4 (15)
Proof of concept	1 (4)
Test population (hearing status)	
Normal hearing only	3 (11)
Hearing loss only	1 (4)
Normal hearing and hearing loss	23 (85)
Test population (age)	
Adults only	17 (63)
Children only	1 (4)
Adults and children	9 (33)

Table 3. Key contributions of the automated and machine learning approaches to the audiological field.

Approach cluster (lead author of first report, reports)	Approach cluster (name)	Key contributions to the field
Bean et al [55]	OtoKiosk	It has the potential to be used in test environments such as examination rooms as a clinical tool for identifying hearing loss via air conduction separating people with normal and impaired hearing.
Chen et al [40]	SHSA[a]	It is a hearing test that runs on a hearing aid, which has statistical equivalence to manual audiometry.
Colsman et al [36]	__[b]	Portable devices that use calibrated headphones result in much higher accuracies than uncalibrated devices.
Corry et al [34]	—	The reliability of audiometer apps should not be assumed. Issues of accuracy and calibration of consumer headphones need to be addressed before such combinations can be used with confidence.
Dewyer et al [33]	Earbone	It is a proof of concept for smartphone-based bone conduction threshold testing.
Foulad et al [43,51,56]	Eartrumpet	It is an iOS-based software app for automated pure-tone hearing testing without the need for additional specialized equipment, yielding hearing test results that approach those of conventional audiometry.
Jacobs et al [50,57]	Oto-ID	They are automated (remote) hearing tests to provide clinicians information for ototoxicity monitoring.
Kung et al [45]	Kids Hearing Game	It includes tablet-based audiometry using game design elements that can be used to test and screen for hearing loss in children who may not have adequate access to resources for a traditional hearing screening.
Liu et al [58]	—	A self-testing system comprising a notebook computer, sound card, and insert earphones is a valid, portable, and sensitive instrument for hearing thresholds self-assessment.
Manganella et al [35]	Agilis	It is an application that detects increased levels of ambient noise when it is programmed to stop the testing.
Margolis et al [30,46,59-61]	AMTAS[c]	AMTAS is designed to fit into the clinical care pathway, including air and bone conduction, and incorporates a quality assessment method (QUALIND) that predicts the accuracy of the test.
Margolis et al [48,62,63]	Home Hearing Test	It is developed and well-suited to provide increased access to hearing testing and support home telehealth programs.
Masalski and Krecicki [41,64,65]	—	It is an automated method that uses smartphone model–specific reference sound levels for calibration in the app. Biological reference sound levels were collected in uncontrolled conditions in people with normal hearing.
Meinke et al [66,67]	WHATS[d]	WHATS is a mobile wireless automated hearing test system in occupational audiometry for obtaining hearing thresholds in diverse test locations without the use of a sound booth.
Patel et al [32]	HearTest[e]	It is a novel, subjective, test-based approach used to calibrate a smartphone–earphone combination with respect to the reference audiometer.
Poling et al [39]	—	Specific Bekesy tracking patterns were identified in people who experienced difficulty converging to a reliable threshold.
Schlittenlacher et al [23]	—	Bayesian active learning methods provide an accurate estimate of hearing thresholds in a continuous range of frequencies.
Schmidt et al [37]	—	A user-operated, 2-alternative, forced choice in combination with the method of maximum likelihood does not require specific operating skills; repeatability is acceptable and is similar to conventional audiometry.
Song et al [21,29,68,69]	MLAG[f]	MLAG is a Bayesian active learning method that determines the most informative next tone, leading to a fast audiogram procedure and threshold estimation in a continuous range of frequencies, with the potential to measure additional variables efficiently.
Sun et al [70]	—	It is an active noise control technology to measure outside the sound booth.
Swanepoel et al [27,47,53,71-75]	KUDUwave	It is an automated portable diagnostic audiometer using improved passive attenuation and real-time environmental noise monitoring, making audiometry possible in unconventional settings.
Swanepoel et al [28,52,54,76-80]	HearTest[g]	It is a smartphone-based automated hearing test applicable in low-resource environments.
Szudek et al [42,81,82]	Uhear	It is an approach that is applicable to the initial evaluation of patients with sudden sensorineural hearing loss before a standard audiogram is available.
Van Tasell and Folkeard [83]	—	Method of adjustment and the Hughson–Westlake method embedded in automated audiometry can be considered equivalent in accuracy to conventional audiometry.

Approach cluster (lead author of first report, reports)	Approach cluster (name)	Key contributions to the field
Vinay et al [38,49]	NEWT[h]	NEWT, which is incorporated inside an active communication earplug, serves as a reliable and efficient method of measuring auditory thresholds, especially in the presence of high background noise.
Whitton et al [84]	—	It is a proof-of-concept study of several self-administered, automated hearing measurements at home, showing statistical equivalency to conventional audiometry in the clinic.
Yeung et al [44,85-89]	Shoebox	It is a method for threshold hearing assessments outside conventional sound booths and with an interface suitable for children.

[a]SHSA: smartphone-based hearing self-assessment.

[b]Not available.

[c]AMTAS: Automated Method for Testing Auditory Sensitivity.

[d]WHATS: Wireless Automated Hearing Test System.

[e]Smartphone-based hearing test app (not yet commercialized).

[f]MLAG: Machine Learning Audiogram.

[g]Automated hearing test commercialized by the hearX group.

[h]NEWT: The New Early Warning Test.

Discussion

Principal Findings

In 2013, evidence for automated audiometry demonstrated similar reliability and accuracy as that of manual audiometry. However, especially for children and bone conduction, the number of reports was limited [24]. In less than a decade, 22 novel approaches and developments across 5 existing approaches had appeared in 56 publications, adding to the 29 papers published before 2013. Promising new developments include the use of machine learning techniques for more time-efficient hearing assessment (2/27, 7%), use of tablets or smartphones as audiometer interface (15/27, 56%), and child-friendly user interfaces (4/27, 15%), including game design elements. The number of approaches that include bone conduction is still limited (4/27, 15%)—only 7% (2/29) more approaches were reported compared with the number reported in 2013 [24].

Accuracy

The required accuracy, reliability, and efficiency depend on the clinical aims and consequences. The ultimate aim of the automated hearing assessment is to deliver clinically actionable estimates of hearing status (ie, the clinician or patient acts appropriately for treatment, given the diagnostic test results). In fully adaptive procedures, the level of precision and confidence needed to conclude the assessment can be set to any level by choosing the proper termination criteria, resulting in different trade-offs. A study by Schmidt et al [37], for instance, aimed for high accuracy and reliability, whereas a study by Heisey et al [29] aimed for high efficiency with machine learning audiometry. Overall, a shift in the type of analysis to demonstrate the accuracy has been observed. In this review, the 2 major types of analysis included were RMSD (14/27, 52%) and average differences and SD (10/27, 37%). In the report by Mahomed et al [24], accuracy was primarily expressed in average differences (11/27, 41%) or thresholds and SD (11/27, 41%). In our view, RMSD is the preferred indicator for accuracy as it has clinical relevance [31], assuming it has already been demonstrated that there is no bias between the automated and manually determined hearing thresholds (eg, signed differences). In traditional clinical terms, automation is equal in accuracy to manual audiometry if the difference is within 6 dB RMSD. Of the 27 automated approaches, 6 (22%) meet this strict accuracy criterion. However, for many applications, the less strict 10 dB RMSD criterium is sufficient, which was achieved by 26% (7/27) additional automated approaches.

For bone conduction measurements, the accuracy was inherently lower than that of air conduction measurements because of conductor placement [30]. However, this reduced accuracy is typically sufficient to address the clinical question of whether conductive or mixed hearing loss is present, as well as choose and evaluate appropriate treatment. The technical feasibility of bone conduction assessments outside of a clinical setting (sound booth) remains difficult. Alternatively, this clinical question can be addressed with other tests, including tympanometry, otoscopy, or a combination of air conduction thresholds for tone and speech stimuli [90]. At least 13 automated techniques had accuracy comparable with that of traditional manual air conduction audiometry, as expressed in RMSD.

A limitation to the impact of achieved test accuracy is the high variation in the interpretation of audiograms by clinicians, regardless of whether those audiograms are determined using an automated or manual approach [92]. Automation can assist clinicians and patients in interpreting the measurement by data-driven automated reporting of accuracy and reliability (including signaling for suspicious outcomes) such as QUALIND [60] or by automated classification for diagnostic purposes (including the type and degree of hearing loss). Examples of automated classification include AMCLASS [93], Autoaudio [94], and data-driven audiogram classification [95].

Reliability

RMSD is also increasingly used as a measure of test–retest reliability. Of the 27 approaches that reported test–retest reliability, 8 (30%) used RMSD as a measure, whereas in 2013, this was only used in 2 (2/29, 7%) studies. Furthermore, 41% (11/27) of approaches did not report on test–retest reliability or used a measure of statistical equivalence that did not allow us

to assess the accuracy. Advances in automated audiometry that increase reliability include procedures to identify invalid responses (5/27, 19%), monitoring environmental noise (6/27, 22%), or both (7/27, 26%) to warn for invalid test conditions, making these tests applicable in more populations and environments. The reliability can be increased, for instance, by alternative response methods, including the forced-choice paradigm [37], or by using machine learning to account for lapses of attention [23]. Digital (health) technologies, including smartphones and tablets, lend themselves to quality control measures for increased reliability with the host of integrated sensors [6].

Efficiency

A fair indicator of efficiency is the overall time required to conduct a test. Most approaches (20/27, 74%) used the modified Hughson–Westlake procedure, of which some (7/20, 35%) showed a similar test duration to manual audiometry. Maximum likelihood procedures demonstrated a 45% reduction in test time in people with normal hearing [38]. Bayesian active learning methods can be extended by adding variables that share some interrelationships using a conjoint estimator that exploits nonlinear interactions between the variables [96]. The resulting machine learning–based automated procedures demonstrated a 30% to 70% reduction in test time compared with manual audiometry for air conduction audiograms in people with normal hearing and hearing impairment [29]. No machine learning approaches had incorporated bone conduction. Therefore, time-efficiency gains compared with full audiogram procedures are not available; however, one can assume that these will yield similar time-efficiency gains. Another indicator of test efficiency is the number of stimuli required to achieve the desired accuracy. This indicator is helpful in optimizing the threshold-seeking part of the approach. Reporting the equivalent time gains under operational conditions is recommended as this can be readily compared with other efficiency gains, including the reduced traveling time if a visit to the outpatient clinic can be replaced for an at-home test or time savings by automating other parts of the clinical care pathway such as interpretation of the outcome. Other aspects of efficiency beyond time that should be considered are cost reductions when enabling task shifting of professionals or the ability to test outside the sound booth.

Future Developments

To obtain an overall indicator of the technical maturity of an approach, developers should be encouraged to use the technology readiness level (TRL) to report the development phase of a technology. TRLs were initially developed in the aerospace industry to estimate the maturity of technology from basic concepts to flight-proven products [97]. To apply TRLs to automated audiometry, further adjustments can be made to fit the hearing health care sector to the version of biomedical TRLs created by the US Army Medical Research and Materiel Command [98]. For those approaches that are ready for operational use, certification (eg, Conformité Européenne and the United States Food and Drug Administration) can further stimulate clinical adoption and iterative improvements based on clinical feedback. In order to be cost-effective, timely, and responsive, certification for digital self-care approaches may need to be less stringent than those for clinical care. A study by Yeung et al [12] proposed alternative procedures for (fast) certification to keep up with the rapidly developing field of visual eHealth tools. Their recommendations might also be applicable to automated hearing assessments, including a rating by health agencies or nongovernmental organizations (eg, a repository of trusted approaches; see Psyberguide [99] as an example of mental health apps reviewed by experts) or adopting the Clinical Laboratory Improvement Amendments model to ensure that approaches comply with the basic requirements of usability, privacy, and security [12]. Following similar certification procedures in the visual and auditory domains may facilitate diagnosis across medical domains. In addition, standards on minimum quality and consensus on what metadata are needed in health applications to describe the test conditions and facilitate interpretation are currently missing.

Limitations

This scoping review included peer-reviewed reports from widely used and recognized scientific databases. A potential limitation is that some of the commercialized automated approaches may have been developed without peer-reviewed reports. Therefore, some automated approaches could be more mature than previously reported. There is no gold standard for reporting audiometry validation studies, which limits a consistent comparison among approaches. Finally, automated procedures may well be embraced by early adopters first, which could lead to projections on suitability that are overly optimistic for users with poorer digital proficiency.

Conclusions and Recommendations

Since 2013, an increasing number of automated audiometry approaches on digital devices have demonstrated similar accuracy, reliability, and time efficiency as conventional manual audiometry. New developments offer features, versatility, and cost-effectiveness beyond manual audiometry. Fully adaptive procedures, including machine learning techniques, seek hearing thresholds more efficiently. Inexpensive digital devices such as smartphones can be turned into audiometers, increasing accessibility and availability. Higher reliability is achievable by signaling invalid test conditions, and child-friendly user interfaces offer a solution to the hard-to-test population. These approaches can be implemented in the clinical care pathway, remote or virtual hearing health care, community-based services, and occupational health care to address the global need for accessible hearing loss diagnosis.

For successful adoption, standardized measures of accuracy, reliability, and efficiency are needed for comparative purposes. Certification and independent reviews may help prospective users select trustworthy approaches. Further reliability can be achieved by determining which difficult-to-test populations may not be appropriate for automated testing and how to detect and then triage these patients to specialized centers. More user-friendly and failsafe procedures that include remote surveillance and quality control can support automated hearing assessment at scale in specific populations and in concert with diagnostic assessments in other medical domains, including visual health and mental well-being [12,99]. Further contextual information, such as standardized metadata, is needed to help

clinicians interpret the context and limitations of test outcomes. If researchers and clinicians deal carefully with their limitations, automated hearing assessments can be designed such that they form an effective part of service delivery for many people who have or are at risk of hearing loss. Automated audiometry can be part of existing care pathways and also enable new service models, including task shifting to community health workers delivering decentralized care, virtual hearing health care, and over-the-counter or direct-to-consumer hearing aid dispensing.

Acknowledgments

The authors would like to thank On Ying Chan for her help during the development of the search string and Raul Sanchez-Lopez for his comments on the draft versions of the paper. In addition, the authors would like to thank Cris P Lanting and Lucas Mens for their suggestions over the course of this study.

Authors' Contributions

LP and JWW made equal contributions, shared first authorship, conducted the abstract screening, independently extracted information directly relevant to the scoping review question, and drafted the manuscript. LP, JWW, and DWS conceptualized the study. RE and DWS supervised the study, reviewed the results, and edited the manuscript. All authors contributed to the data interpretation.

Conflicts of Interest

DWS has a relationship with the hearX Group (Pty) Ltd, which includes equity, consulting, and potential royalties. DWS holds a patent for smartphone-based audiometry as an inventor.

Abstract

Background: As dementia progresses, symptoms and concerns increase, causing considerable distress for the person and their caregiver. The integration of care between care homes and health care services is vital to meet increasing care needs and maintain quality of life. However, care home access to high-quality health care is inequitable. eHealth can facilitate this by supporting remote specialist input on care processes, such as clinical assessment and decision-making, and streamlining care on site. How to best implement eHealth in the care home setting is unclear.

Objective: The aim of this review was to identify the key factors that influence the implementation of eHealth for people living with dementia in long-term care.

Methods: A systematic search of Embase, PsycINFO, MEDLINE, and CINAHL was conducted to identify studies published between 2000 and 2020. Studies were eligible if they focused on eHealth interventions to improve treatment and care assessment or decision-making for residents with dementia in care homes. Data were thematically analyzed and deductively mapped onto the 6 constructs of the adapted Consolidated Framework for Implementation Research (CFIR). The results are presented as a narrative synthesis.

Results: A total of 29 studies were included, focusing on a variety of eHealth interventions, including remote video consultations and clinical decision support tools. Key factors that influenced eHealth implementation were identified across all 6 constructs of the CFIR. Most concerned the inner setting construct on requirements for implementation in the care home, such as providing a conducive learning climate, engaged leadership, and sufficient training and resources. A total of 4 novel subconstructs were identified to inform the implementation requirements to meet resident needs and engage end users.

Conclusions: Implementing eHealth in care homes for people with dementia is multifactorial and complex, involving interaction between residents, staff, and organizations. It requires an emphasis on the needs of residents and the engagement of end users in the implementation process. A novel conceptual model of the key factors was developed and translated into 18 practical recommendations on the implementation of eHealth in long-term care to guide implementers or innovators in care homes. Successful implementation of eHealth is required to maximize uptake and drive improvements in integrated health and social care.

Introduction

Background

Dementia is a progressive, complex neurodegenerative condition with a multitude of types and clinical presentations. It is the leading cause of death in the United Kingdom [1] and is projected to have the highest global proportional rise (264%) in suffering associated with a need for palliative care [2]. Dementia is characterized by a complexity of care needs, which advance as the condition progresses [3]. These needs span multiple domains of health care, and multimorbidity is common [4]. Symptoms such as pain and breathlessness [5,6] cause significant distress for the person and their caregiver and increase toward the end of life [7].

Over half of the people with dementia (58%) die in care homes in England [8]. They are the main providers of end-of-life dementia care, with the average life expectancy on admission for a resident with dementia being 1 to 2 years [9]. The term *care home* in the United Kingdom refers to both residential and nursing homes. These differ with regard to the provision of input from health care professionals, with nursing homes providing additional access to 24-hour on-site nursing care. Care homes require the resources to deliver multidisciplinary care to meet these advancing and acute dementia-specific needs [10]. Providing access to good quality, continuous care throughout the dementia trajectory is essential. This can be achieved by integrating care homes with primary care, palliative care, and dementia care teams to enable multidisciplinary and specialist input on vital care processes [11].

Care needs change and develop over time and cause considerable distress if left unmet [6]. A comprehensive assessment by a multidisciplinary team to review medical, functional, mental, and social abilities is essential for this population with complex needs [12]. Interprofessional collaboration is also required to share clinical expertise and experience, best inform complex clinical decisions concerning treatment for multimorbidities, and deliver appropriate care [13]. Integrating these processes across services is widely acknowledged to improve person-centered treatment outcomes for older people with complex needs [11] and reduce detrimental transitions between settings occurring in the final years of life, such as unplanned hospitalization [14].

To integrate services and deliver continuous and coordinated care, established methods of communication are required to share information between systems about residents' care needs and outcomes. A way to facilitate this is through the use of eHealth [15], which is defined as "health services and information delivered or enhanced through the internet and related technologies" [16], encompassing an array of interventions that enable care to be delivered remotely.

The COVID-19 pandemic has had major implications for the use of eHealth in care homes. In response, former barriers to the integration of health and social care services in England have been liberalized, with restrictions on information sharing between services relaxed [17]. The pandemic highlighted the lack of systems for efficiently sharing information between services nationally and internationally [18,19]. This compromised the delivery of care to meet the escalating health care needs and residents' quality of life. Innovation was required to communicate between services for the comprehensive assessment of symptoms and management of care and outcomes. eHealth provides a way to do this [20].

Objective

There is little evidence to guide the design and implementation of eHealth resources to manage symptoms and concerns for people with dementia in care homes. The key task at hand is to understand how we can scale-up eHealth interventions to embed them in routine care. Despite positive findings regarding their benefit [21], eHealth interventions are yet to attain widespread implementation in care homes, and the way of effectively achieving this remains unclear. This study aimed to explore factors that influence the implementation of eHealth interventions to support assessment and decision-making regarding care and treatment for people with dementia in care homes.

Methods

Design

The review is reported in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses; Multimedia Appendix 1) guidelines. A systematic review, using narrative synthesis and thematic analysis, was conducted to identify common facilitators of and barriers to eHealth implementation in care homes. The synthesis followed the guidance of Popay et al [22], which provides a specific direction for reviews concerned with the implementation of interventions. The protocol for this review was registered on PROSPERO (International Prospective Register of Systematic Reviews; registration number CRD42020184587). Before registering this review, a search of PROSPERO was conducted to ensure that no similar reviews were underway. Our final search was performed in the week the review was registered (June 1, 2020). Originally, the scope of the review also included collecting data on intervention effectiveness and key components; however, given the breadth of evidence relating to these outcomes, the findings regarding effectiveness will be reported in a second review.

Search Strategy

A total of 4 databases (Embase, PsycINFO, MEDLINE, and CINAHL) were searched for studies published in English from January 2000, with the final search being on April 28, 2020. The year 2000 was chosen as the *cutoff* year to exclude eHealth that may be outdated in the context of today's technological

advancements. A search strategy was developed with the help of an information support specialist and informed by scoping the literature for the types of eHealth interventions currently in use (see Multimedia Appendix 2 for the full search strategy). A combination of Medical Subject Headings terms and keywords was used to develop a strategy based on the following concepts: *dementia* AND *care homes* AND *eHealth* AND *assessment* OR *decision-making*. The search strategy was complemented through reference chaining and citation tracking using Google Scholar, following the initial identification of studies from the database search. The eligibility criteria were developed using the PICO (population, intervention, control, and outcomes) acronym, following recommendations on its suitability and enhanced sensitivity when conducting qualitative systematic reviews [23]. The criteria are outlined in Textbox 1.

Textbox 1. Eligibility criteria.

Inclusion criteria

- Population: residents with a diagnosis of dementia residing in a long-term care facility; studies that included residents with dementia in a mixed population
- Intervention: eHealth interventions that aimed to facilitate comprehensive assessment of care home residents or improve decision-making about care and treatment; eHealth interventions that enable care coordination between practitioners and the sharing of information between settings to facilitate integrated working, such as between care homes and health care services
- Outcome: data relating to factors that influence or inhibit the implementation of eHealth interventions in care homes
- Comparator: no restrictors
- Study design: all study designs that reported data relating to implementation

Exclusion criteria

- Population: people with a diagnosis of dementia living at home or staying in short-term care or acute care settings; studies that did not mention dementia in the population
- Intervention: nondigitalized intervention studies; eHealth interventions that did not focus on aiding comprehensive assessment or supporting clinical decision-making; interventions that monitored clinical signs only, such as a motion sensor, or recorded biodata, for example, blood pressure remote monitoring, were out of scope
- Outcome: not applicable
- Comparator: not applicable
- Study design: opinion pieces

Study Selection Procedure

Studies identified from the search were exported to Endnote [24]. Duplicates were identified and removed. All titles and abstracts were screened by 1 researcher (JG). Approximately 20% were randomly selected for blinded double screening by 2 independent researchers (TA and EY) as a calibration process to test the application of the eligibility criteria. Once an agreement of 90% was confirmed between the reviewers, the eligibility criteria were applied to all identified studies. This was undertaken to screen for eligibility at the title and abstract screening and again at the full paper review. Discrepancies were resolved through discussion.

Quality Appraisal

The quality of publications was appraised using the Critical Appraisal Skills Programme (CASP) tool [25], which was appropriate for the study design. It was conducted by 1 author (JG) and reviewed independently by 2 authors (CE and ND). Where the design was not amenable to the CASP, alternative tools were used, including the Mixed Methods Appraisal Tool (MMAT) [26] and the Joanna Briggs Institute (JBI) critical appraisal tools [27]. No studies were excluded only on the basis of their appraised quality; rather, it was conducted to help understand and describe the studies.

Data Extraction

A standardized data extraction tool was developed in Microsoft Excel and informed by the review questions. Extracted data included study aim, country of origin, design, population of interest, setting, eHealth intervention (type, components, and summary), methods of data collection and analysis, outcomes regarding intervention implementation and conclusions, implications, and limitations. Implementation data were extracted from both the results and discussion sections to capture relevant findings relating to the authors' observations of why an intervention was or was not effective.

Data Analysis and Synthesis

A deductive thematic analytic approach was undertaken, underpinned by the adapted version of the Consolidated Framework for Implementation Research (CFIR) [28]. The original CFIR [29] comprises 5 broad theory-based constructs and 39 subconstructs within these: intervention characteristics, inner setting, outer setting, individual characteristics, and implementation process. It is a comprehensive and practical guide for assessing the potential factors that influence implementation. A recent adaptation of the framework added a sixth construct [28], *patient needs*, acknowledging the importance of person-centered care in health care interventions and the paucity of attention it frequently receives in

implementation frameworks. Given the nature of this review, the adapted CFIR was used.

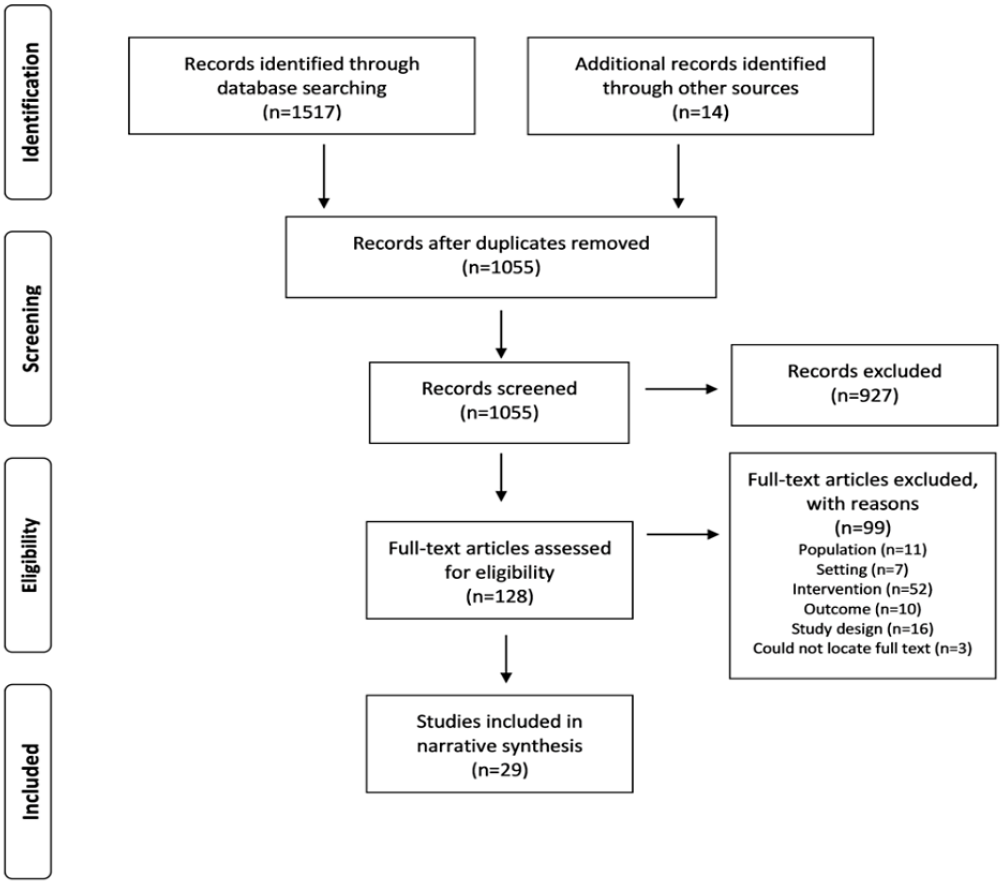
Preliminary synthesis involved tabulation to organize the findings and compare data across different studies. The data from each study were then mapped onto the framework. Common themes that arose across the studies in line with the subconstructs of the framework were then synthesized to form a narrative regarding facilitating elements of and inhibiting barriers to successful implementation. Where data did not align to a subconstruct, an inductive thematic analytic approach was undertaken to avoid biasing data and identify gaps in the framework when applying it to this context. The themes were then developed to identify additional constructs to adapt the framework to this specific context.

Results

Summary

A total of 1055 papers were screened by title and abstract, of which 128 (12.13%) full-text articles were assessed; of the 128 articles, 29 (22.7%) met the eligibility criteria for the review (Figure 1 [30]). The included studies reported 27 unique interventions that aimed to facilitate comprehensive assessment of care home residents or improve decision-making surrounding care and treatment, published between 2000 and 2020. The sample sizes ranged from 5 to 4171 for residents and 6 to 609 for carers. Approximately 31% (9/29) of studies omitted the number of participants.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart [30].



Of the 29 articles, the included studies comprised 7 (24%) randomized controlled trials, 7 (24%) quasi-experimental studies [31-37], 6 (21%) qualitative studies [38-43], 3 (10%) descriptive studies [44-46], 2 (7%) mixed methods studies [47,48], 2 (7%) cohort studies [49,50], and 2 (7%) cross-sectional studies [51,52].

All studies included adults with dementia, focusing specifically on requirements for people with dementia (11/29, 38%) [31,32,38-40,43,47,49,50,53,54] or within a mixed population (18/29, 62%) [33-37,41,42,44-46,48,51,52,55-59]. The average percentage of residents with dementia was 52.8% in the mixed population studies that reported the proportion (6/29, 21%) [35,37,44,46,55,56]. Approximately 41% (12/29) of studies did not delineate the proportion of residents with dementia [33,34,36,41,42,45,48,51,52,57-59] (see Table 1 for a summary of study characteristics).

Table 1. Summary of characteristics of included studies grouped by population residents.

Characteristics, study, and country of origin	Study design	Population (n)	Age (years), mean	Setting (n)	Type of eHealth intervention
Population with dementia and specific requirements					
Catic et al [49], United States[a]	Cohort	Dementia (46)	82.5	Nursing home (11)	Video consultation

Quality Appraisal

The included studies varied in their quality. In general, the CASP criteria for the experimental studies identified consistent reporting of clear and focused aims, with appropriate methodologies to address the research questions. Weaknesses were related to small sample size, evidence of selection and attrition bias, poor description of analysis, and nonblinding. Descriptive studies were generally well-reported (average 86% of MMAT criteria met) and quasi-experimental studies (average 77.7% of JBI criteria met). The weaker study design used mixed methods (average 50% of MMAT criteria met) and cross-sectional studies (average 56.2% of JBI criteria met). Weaknesses pertained to the management of confounding factors and the integration of qualitative and quantitative data. Multimedia Appendix 3 [31-59], details the quality appraisal results for each study using the respective appraisal checklist.

CFIR Constructs Associated With eHealth Implementation

Table 2 details the respective CFIR constructs and subconstructs that were identified as important determinants for implementation. The number of subconstructs identified per study ranged from 1 to 13, with a median of 6. No major differences in implementation requirements were identified between studies with a specific focus on requirements for people with dementia and studies reporting on dementia within a mixed population (Multimedia Appendix 4). Findings for each CFIR construct and respective subconstructs is presented in turn. Constructs that were identified in ≤2 studies are not presented as a narrative because of insufficient data.

Table 2. Factors identified to influence the implementation of eHealth interventions in a care home (N=29).

CFIR[a] construct and subconstructs	Definition in the context of care homes and integrated care for people with dementia	Total, n (%)
Intervention characteristics: aspects of eHealth that might affect implementation success		
Intervention source	How end users perceive the legitimacy of the eHealth source—whether it has been developed internally as a response to a problem in the care home or externally	0
Evidence strength and quality	Stakeholder perception of the strength of the evidence supporting the belief that eHealth will produce the desired outcomes from sources such as published literature	0
Relative advantage [36-39,47,48,54-56]	Whether stakeholders perceive eHealth as advantageous over current practice	9 (31)
Adaptability [37,40,48,49,52,55,59]	How interoperable eHealth is with current care home information technology systems	7 (24)
Trialability	Whether eHealth can be tested initially on a small scale, such as piloted in a small number of care homes	0
Complexity [36-38,40,41,44,45,47,48,53,54,56,58]	How simple and user-friendly end users perceive eHealth to be within routine care	13 (45)
Design quality and packaging	Stakeholder perception of the physical presentation of the eHealth intervention	0
Cost [36,37,47,49-51,53,54]	Cost associated with implementing eHealth	8 (28)
Patient needs: the extent to which resident needs are known and prioritized by the care home		
Clinical benefit[b] [34,36,38,39,41,45,47,48,52,55,58]	How clinically beneficial eHealth is perceived to be for the resident	11 (38)
Person-Centered care[b] [40,41,45,52]	Whether eHealth can be tailored to the individual needs of the resident and care home	4 (14)
Resident experience[b] [34,39,40,52,56,57]	The effect that eHealth has on resident needs and satisfaction with care	6 (21)
Outer setting: external influences on eHealth implementation		
Cosmopolitanism [37,43]	The degree to which the care home is networked with others	2 (7)
Peer pressure	Pressure experienced by the care home to implement eHealth	0
External policy and incentives [40,49,52-54]	External influences of implementation of eHealth for the care home	5 (17)
Inner setting: characteristics of the implementing care home		
Structural characteristics [35,37,43,52]	The social architecture, age, maturity, and size of the care home	4 (14)
Networks and communications [47]	The nature and quality of social networks and communication within a care home	1 (3)
Culture	Norms and values of the care home	0
Implementation climate	The capacity for change and shared receptivity of individuals to eHealth and the extent to which it will be supported within the care home	
Tension for change [32]	The extent to which stakeholders perceive current practices as needing change	1 (3)
Compatibility [36-38,40,47,51,52,54]	The degree of fit between the care home and eHealth in terms of values and existing workflows	8 (28)
Relative priority	Individuals' shared perception of the importance of implementation within the care home	0
Organizational incentives and rewards	Incentives to increase participation with eHealth such as awards and promotions for staff	0
Goals and feedback	The degree to which goals of eHealth are acted upon and feedback to staff	0
Learning climate [32,33,39,40,43,44,51,52,58,59]	A climate in which staff feel valued in the implementation process and comfortable to participate through encouragement by care home leaders	10 (34)
Readiness for implementation	Indicators of care home commitment to eHealth implementation	
Leadership engagement [31,32,37,39,43]	Commitment and involvement of care home managers and leaders in implementation	5 (17)
Available resources [32,33,35,36,39,41,42,44,46,48,51-53,59]	The level of care home resources dedicated to eHealth implementation, including money and staff time	14 (48)

CFIR[a] construct and subconstructs	Definition in the context of care homes and integrated care for people with dementia	Total, n (%)
Access to knowledge and information [31-33,35,37,38,40-44,48,51,52,54,56,59]	Access to sufficient eHealth training for end users	17 (59)
Individual characteristics: end-user individual beliefs, knowledge, and attitudes toward eHealth and implementation		
Knowledge and beliefs about the intervention [36,38,39,41,43,45-48,51-53,55,56,58,59]	End users' attitudes toward eHealth and its impact	16 (55)
Self-efficacy [33,36,38,41,47,56,59]	End users' belief in their own abilities to use the eHealth intervention	7 (24)
Individual stage of change	The phase an individual is in as they progress toward sustained use of eHealth	0
Individual identification with organization	End user's perception of their relationship with the care home	0
Other personal attributes [32,33,40,43,44,58,59]	Individuals' attributes that affect implementation such as staff willingness, experience, age, or grade	7 (24)
Process: stages of the implementation process that can impact its success		
Planning [32,38,42-44,46,48,51,54,56-59]	The degree to which tasks required for implementation of eHealth are agreed in advance	13 (45)
Engaging	Attracting and involving stakeholders in eHealth implementation	
Champions [32,35,37,43,48,58,59]	Individuals who are dedicated to driving the implementation of eHealth and overcoming resistance in the care home	7 (24)
End users[b] [32,33,37,39,40,42-44,54,59]	Other stakeholders, including end users and staff, within the care home	10 (34)
Opinion leaders	Individuals in a care home who have a formal or informal influence on others' attitudes toward implementation	0
Formally appointed internal leaders	Individuals from within the care home who are formally appointed to implement eHealth	0
External change agents	Individuals from outside the care home who formally influence implementation of eHealth	0
Executing [32,35,37,43,44]	The extent to which eHealth implementation is conducted as planned	5 (17)
Reflecting and evaluating [35,37,43,46,51,55,59]	Monitoring of eHealth implementation and feedback about its progress	7 (24)

[a]CFIR: Consolidated Framework for Implementation Research.

[b]Additional subconstructs identified inductively from the data.

Intervention Characteristics

This refers to aspects of the eHealth intervention that might affect implementation success in care homes and includes findings relating to intervention complexity, adaptability, and cost.

Relative Advantage

eHealth that is perceived as advantageous to an alternative system by improving access to emergency care [39], increasing efficiency [37,38,54,55], and reducing paperwork [47] is more likely to be adopted [48]. Barriers to uptake include a preference for face-to-face consultations [56] and increased time required to organize eHealth consultations [36].

Adaptability

eHealth is at an advantage if it aligns with data and technology already in use [37,40,51,52]. Concerns on patient privacy and electronic transfer of confidential information act as *institutional firewalls* [40,49] but can be overcome by encrypting data and assigning residents confidential numbers [49]. A way to increase the adaptability of a device is through the provision of customizable tools such as drop-down menus [40]. Incorporating a decision support system in eHealth interventions is advocated to respond to changes in individual residents' needs by providing alerts and directing staff to appropriate care [40,48,55].

Complexity

eHealth is more likely to be implemented if it is straightforward and user-friendly [36-38,40,41,44,45,47,48,53,54,56,58]. Simple devices are regarded as more reliable [36,40,48], and it is recommended that more advanced technology be used only where necessary [36]. Dual systems of paper-based and electronic devices should be avoided to minimize inconsistency [38] and the complexity of data recording [48]. Uptake is also influenced by the ease of access to eHealth [36,37,40,47,54,55], with portable tools improving ease of access [38,48] and thereby saving staff time [37,38,47,55]. However, some staff report that handheld devices are easy to break and misplace [47] and prefer a desktop computer [40]. Technological difficulties, including software and memory issues [47], inability of patients and physicians to see or hear each other [52,56], and difficulty in obtaining technical support despite frequently requiring it [36,56], can impede eHealth implementation [35,36,44,47,53,56,58]. Providing training and specialist technical support for staff are key to overcoming these barriers [40-42,44,46,53,56].

Cost

Cost is a major barrier to implementing electronic health records in care homes [52]; for an intervention to be implemented, the benefits must be perceived to outweigh the costs [36,51]. eHealth tools that incur no additional financial cost beyond staff time [37,49] and installation [54] can integrate with preassembled data [37], are cheaper to purchase than full-size computers [47], and are more likely to be adopted. Uptake is optimized by external funding [51,53,54] and intervention outcomes that minimize spending such as reduced resident transition between care settings, for example, unplanned hospitalization [36,49,53], or reduced antipsychotic prescriptions [50].

Patient Needs

This refers to the extent to which resident needs are known, prioritized, and pursued by a care home. A total of 3 novel subconstructs were identified inductively.

Clinical Benefit

An important contributor toward successful implementation is the perceived clinical benefit for residents [34,36,38,39,47,52,55,58]. eHealth interventions are reported to help staff *focus on the resident's condition* [47], better manage residents' symptoms and vital signs [34,55,58], improve safety around medication administration [55], enable staff to attend to residents in a timely manner, and identify common behavior patterns [38]. The positive impact of eHealth interventions to minimize burdensome care transitions has also been recognized. Reduced unplanned hospital transitions are suggested to improve residents' quality of life [45] by preventing disruption in care continuity with attendance to care needs in the care home [38]. Residents appreciate minimal journeys to acute care settings [52] and the benefit of emergency telemedicine sessions to deliver timely skilled health care interventions remotely [39]. Barriers to uptake of eHealth interventions pertained to opinions that the intervention little benefited residents [48] by inadequately monitoring and identifying resident change or deterioration and failing to improve assessment processes [41].

Person-Centered Care

Interventions must be tailored to the individual and accommodate changing resident needs if they are to be successfully implemented [40,41,52]. Given the heterogeneous population in care homes and variable incidence of dementia, eHealth interventions will not make a positive difference if they do not have the capacity to assist with dementia-specific needs when required [40,41,45]. Extra consideration must go into ensuring that technology is unobtrusive if used in the presence of this patient group [40,52] who may lack the capacity to understand the change in care. Where residents experience cognitive, visual, or hearing difficulties, eHealth must be tailored, such as through the provision of a larger monitor [52].

Resident Experience

A negative resident experience of eHealth obstructs implementation [39,40,57]. Dissatisfaction stems from devices interfering with the time spent with staff [57] and a switch from face-to-face to remote communication [56]. Staff report concerns that using eHealth in the presence of residents may be intrusive and dehumanizing [39,40]. Concerns tend to diminish with continued use of eHealth tools; however, over time, staff acknowledge that eHealth can improve care quality [39,52]. Other residents report no unintentional harm or negative effects on communication [57], with 1 study attributing positive findings to residents, reporting that they felt more *followed and cared for* [34].

Outer Setting

The outer setting is concerned with external influences on intervention implementation. This was least considered construct across the studies, with the main focus on the 'External policy and barriers' subconstruct. External barriers include policies on the medical liability of telemedicine [53], licensing requirements that do not allow physicians to consult across different parts of the country [49], and issues around reimbursement policies [52-54]. External financial support acts as an incentive to circumvent the additional cost barriers to implementation [40,53,54].

Inner Setting

The most commonly considered construct across the studies was the inner setting, referring to the internal characteristics of a care home. These focused on the 2 main subconstructs of implementation climate (compatibility and learning climate) and readiness for implementation (leadership, available resources, and access to knowledge).

Structural Characteristics

The structural characteristics of the care home setting that affect implementation success include the complex patient population, with the heterogeneity of residents' conditions affecting the compatibility between the intervention and the care home [35,60]. Care home size can also affect the uptake of an eHealth intervention, with larger homes facilitating uptake through more comprehensive provision of information technology services or inhibiting uptake with larger home leaders exhibiting more resistance to adoption and delivering training [43].

Implementation Climate

Compatibility

Portable eHealth devices that can be used at the point of care [38,40,54] and during nighttime hours [36] prevent disruption to workflow, thereby facilitating uptake [36,37,40,47,51,52,54]. Interventions are at an advantage if their goals are aligned with those of the care home, for example, improving advance care planning [37], and they may face resistance if they do not support existing practice [40]. Providing individually tailored implementation protocols [37] and delivering the intervention when care homes are maximally staffed can ease adoption [43,58].

Learning Climate

Creating a climate within the care home that encourages learning and active participation in the intervention is key [32,39,43,44,51,52,59]. Staff members in the frontline must be receptive [43] and participate if they are to influence patient outcomes [33,44] and affect care delivery [32]. Changes to

personnel at the site [44] and reluctance from staff [51,52,58,59] undermine a conducive learning climate. Hierarchical staffing can inhibit implementation [32,58] if junior staff feel they are unable to speak up [32] or access the new tools [40,43]. If a learning climate is not fostered, the staff lack practice in delivering an intervention [32] and opportunities to share and embed their learning to change practice [43].

Readiness for Implementation

Leadership Engagement

Organizational commitment from the top down is crucial [31,32,37,43]. Staff leaders and managers who collaborate with the research team [37] and *lead by example* through attending training and contributing to data collection [43] foster an engaged and cohesive workforce [39]. A lack of enthusiasm from management can lead to delays in implementation and reluctance from other staff [43]. Unwillingness and resistance from general practitioners to change practice also act as a barrier [32,39] and contribute to a fragmented learning climate [43].

Available Resources

Providing extra time for implementation planning [33,39,41,46,52] and end-user training [32,33,42,46,52] is required to accommodate a change in practice. A collective staff opinion of insufficient time to adjust to change hinders implementation [32,39,44,48,51,52,59]. Sufficient bandwidth is required to allow eHealth to function properly [35,36,44,53], and insufficient bandwidth can lead to significant *motion artefact* [44] and *jerky motion* images [53]. Additional space may be required for training, either within the home [42] or off site [32]. Equipment needs may include extra computers [42] and software [59], incurring further financial costs [32,51]. Reduced staffing [51], high staff turnover [44,58], and staff absence [43] obstruct the implementation of eHealth interventions. Limited resources can act as a barrier unless benefits can be demonstrated to outweigh costs [43,51]. Managers need to consider the additional resources required to accommodate adoption [43].

Access to Knowledge and Information

Providing adequate training to end users is crucial for promoting uptake [31-33,35,37,38,40-44,48,51,52,56,59]. A variety of educational methods are used, including interactive learning strategies [56], lectures, exercises, and group discussions [59]. Training is often provided through a cascaded learning *train-the-trainer* approach [37,43,48]. Preference varies as to receiving training *on the job* [31,40,42] or continuously over a designated period in the months leading up to implementation [35,37,48]. Training tailored to individual needs [38,40,48] can help facilitate uptake, whereas inadequate training can negatively influence perceptions of intervention benefits [32,48] and how staff disseminate knowledge to colleagues [32]. Incorporating a period of joint work and supervision from a qualified external expert can further facilitate the benefits of training [32].

Individual Characteristics

This pertains to end users' individual beliefs, knowledge, and attitudes toward eHealth and implementation. The findings focused on 3 main subconstructs.

Knowledge and Beliefs About the Intervention

Fostering a positive end-user attitude toward eHealth is key to ensuring willing adoption. eHealth tools that are perceived as high quality [45,48,53] and efficient [38,47,48,55], by cutting back on paperwork [47] and providing instant access to data [48], are more likely to be adopted. Interventions judged to improve staff understanding and knowledge [39,48,52,56,58] and benefit residents [36,39,48,58] are more likely to be used. eHealth devices that improve overall job satisfaction [45,48,55,56] while providing additional benefits, such as reducing staff anxiety [38], and social features that enrich staff lives outside of work [47] encourage use. Conversely, negative attitudes toward eHealth act as barriers to implementation. These include concerns regarding a lack of care improvement [39,41,45,58], a preference to deliver care in person [39,45,52,56], and concerns of inequity in health care provision, resulting in difficulty obtaining family consent [39]. Other barriers include a lack of positive impact on staff workload [36,41,45], concerns over increased time and effort because of implementation [36,39,51,52,58], and uncertainty about the purpose of eHealth and how it works [43,46]. This indicates the need for comprehensive training to highlight the benefits and importance of implementing the intervention [48].

Self-efficacy

Self-efficacy refers to an individual's belief in their own capabilities to implement an intervention. Low self-confidence in ability [47,56,59] and apprehension toward using new technology [38,47] can act as barriers to implementation. These can be overcome by providing sufficient training, which is tailored to individual needs [38,40,48], and on-hand technical support [36,56].

Other Personal Attributes

Other issues that affect implementation relate to staff willingness and commitment to ensuring that the intervention is executed as planned [32,33,44,59]. A lack of experience can also act as a barrier if senior members of staff consider more junior members to be less capable of participating [32,40,43,59] because of age, grade, educational background, or experience [32,59]. However, demonstrating that training designed for medical caregivers is effective across disciplines and grades should help dispel these notions [58].

Implementation Process

This concerned reporting on the stages of the implementation process that affect its success. A novel subconstruct was inductively identified to capture data related to engaging end users and other stakeholders.

Planning

Insufficient planning and preparation for change can result in overwhelmed staff perceiving eHealth to be incompatible with their care home [51], technology systems and facilities being

inundated [42], and essential care being omitted [46]. Poorly planned study timelines can lead to a low number of participants if enough time is not allocated to recruitment [58] and to implementation impact being undetected if insufficient time is allocated to following up and monitoring outcomes [48,57,59]. Time must also be allocated to prospectively explore different types of eHealth to ensure suitability [54]. Multiple strategies are required to initiate a change in behavior and routine practice [32,38]. Developing contingency plans to support the program [44,54] and establishing a team whose primary goal is to assist implementation can help facilitate uptake [59]. Staff members must be fully informed of the aim of the intervention [43] and have full clarity of their designated role to achieve maximum impact [56].

Engaging: Champions

Engaging individuals is key to successful implementation. This is often done through designating *champions*—individuals from within an organization responsible for driving and supporting implementation [32,35,37,43,48,58,59]. To be successful, there must be a sufficient number of assigned champions in each home [32]. They must be committed to the position [43] and not feel undermined by others in leadership roles [32]. Designating champions is often undertaken by the team manager [59] to ensure they are appropriately able to support other staff members [43,48].

Engaging: End Users

Engaging champions alone is insufficient; other staff members must be involved for successful implementation [33,37,39,40,42-44,54,59]. For a change in the quality of care to be observed, staff engagement must be sustained [43], with all disciplines, including frontline staff [33,54] and corporate leaders, committed to implementation [37]. Involving end users in the design and development of technology [39,40,59] and considering individual requirements is key if an intervention is to be embedded in a new context.

Execution

Low intervention fidelity is a challenge in complex care home settings [35], and residents often do not receive the intervention as planned [32]. Flexible protocols tailored to the care home environment should be developed [37,44]. Barriers to successful execution include lengthy gaps between initial contact with participants and data collection and intervention activity, which can undermine the coherence of the intervention [43].

Reflecting and Evaluating

Ongoing evaluation of progress is vital to ensure a new intervention is effectively embedded [37,43,46,51,55,59]. This can be done using routine data collected through the eHealth tool [43], through in-person visits to the home, monthly conference calls, or video status reports [35,37] to determine the effect and use of the intervention [46]. Receiving feedback can also motivate care home participation, with an absence of evaluative feedback leading to a feeling of being *short-changed* [43].

Discussion

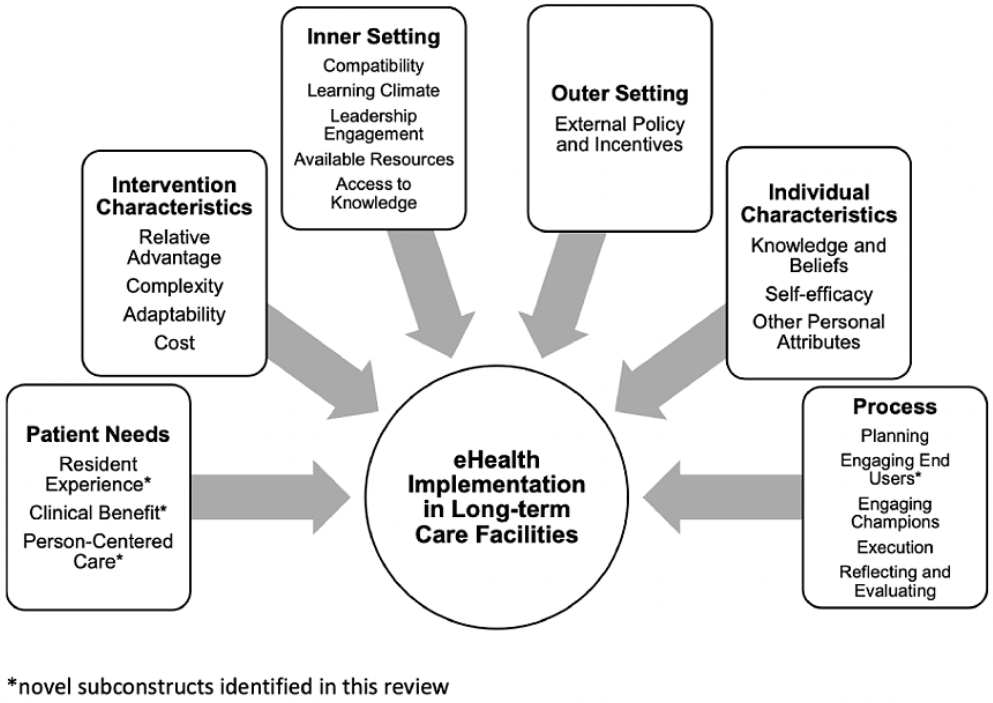
Principal Findings

This review investigated the key facilitators and barriers that influence the implementation of eHealth interventions to support comprehensive assessment and decision-making for people with dementia in care homes. Our findings inform a model of eHealth implementation in long-term care for people with dementia (Figure 2). We identified 4 novel subconstructs (denoted in the figure by an asterisk) required to adapt the CFIR to the care home context and use of eHealth to enhance integrated care for people with dementia. This modification enables the framework to accommodate the context-specific findings identified in this review and enhances its use when applied to implement eHealth in the care home context.

The 3 novel subconstructs—*resident experience*, *clinical benefit*, and *person-centered care*—were identified within the *patient needs* construct. No subconstructs have previously been delineated here, and the framework was previously not nuanced enough to capture the data and implementation requirements for this population. *Clinical benefit* was the most commonly identified theme, with the capacity to minimize burdensome transition between care settings as a key facilitator of implementation. This is echoed in the literature that highlights the adverse impact of burdensome care transitions, both on the resident [61] and on costs [62]. Although outcomes were not the focus of this review, eHealth interventions are more likely to be embedded if they can improve the delivery of integrated health care where it is required, enhance integrated care, and improve cost-effectiveness in the National Health Service [63].

Findings around the potential dehumanization of care reiterate a concern raised previously in relation to eHealth implementation [64]. Although the aim of eHealth is to enhance care delivery, entirely omitting in-person contact has clear disadvantages. Striking the right balance between delivering care face to face and virtually is crucial. Future research should focus on delineating the components of health care that must be delivered in person and identifying those that are more amenable to remote delivery to ensure that care quality is not compromised.

Figure 2. A model of factors that influence the implementation of eHealth in care for people with dementia.



The *engaging* subconstruct of the *implementation process* was also modified for the purpose of this review. None of the proposed subcategories of *engaging* (opinion leaders, formally appointed internal implementation leaders, champions, and external change leaders) were suitable for capturing data around engaging end users. The importance of involving end users throughout the implementation process is a key finding and is consistently advocated in the literature to help close the gap between research production and clinical practice [65,66]. Therefore, a novel subcategory titled *end users* was added to the CFIR. Contradictory findings regarding staff and resident preferences on the design and use of eHealth devices are an important indication that there is no *one-size-fits-all* approach to eHealth implementation. This inconsistency in preferences highlights the critical need to involve end users during intervention development to accommodate a range of requirements and enhance the likelihood of sustained implementation. Progressing the CFIR to include a subcategory suitable for data pertaining to all stakeholders' input increases its relevance and applicability for this context.

The most salient construct identified in this review was *inner setting* of the implementing organization. This is concurrent with the existing research on care homes. A systematic review by Goodman et al [67] identified many of the same factors that influence the readiness of care homes to participate in change. These include ensuring compatibility between the intervention and existing care home routine, providing sufficient training and resources, and engaging care home leaders. Both reviews highlight the significance of the organizational context on implementation success and the need to consider context in the planning stage to inform study design rather than retrospectively. This is contrary to a review of determinants for eHealth implementation with informal caregivers in the community [68], where few factors relating to context were identified as important. This indicates that factors influencing implementation may not be consistent across health care settings and stresses the importance of understanding specific contextual factors and tailoring implementation strategies accordingly.

One of the most prominent determinants of implementation identified in this review was the complexity of the intervention, consistent with previous findings highlighting ease of use as the most important facilitator of eHealth adoption. The nonadoption, abandonment, scale-up, spread, and sustainability framework [69] was developed specifically in response to the finding that eHealth, which is categorized as complex is rarely, if ever, successfully embedded in mainstream care. It aims to help innovators and implementers measure and minimize complexity in eHealth and scale-up and sustain innovation, and therefore, it could helpfully be used in this context.

Implications for Policy and Clinical Practice

Using the most salient subconstructs of the framework, a conceptual model was developed to highlight the most important factors that influence the implementation of eHealth interventions to enhance integrated care focusing on care processes of comprehensive assessment and decision-making about care and treatment (Figure 2). The findings can be translated into practical recommendations for organizations aiming to embed eHealth within long-term care settings for people with dementia (Textbox 2). The model indicates that for implementation to be successful, eHealth devices must be low cost, simple to use, and tailored to the care home setting and residents. It must be clinically beneficial to the residents, with special consideration of changing, multimorbid dementia-specific needs. Extensive planning and engagement of care home leaders, end users, and champions in the

development and implementation process are key to ensuring successful execution. Providing sufficient training and resources to ensure that care home staff feel valued, motivated, and optimistic about a change in practice is crucial to fostering a positive implementation climate.

Textbox 2. Practical recommendation for implementation of eHealth in long-term care for residents with dementia.

Consolidated Framework for Implementation Research constructs and practical recommendations for eHealth implementation

Patient needs

- eHealth should be tailored to the individual resident and accommodate changing and complex needs.
- It should be unobtrusive and not replace in-person contact or compromise care quality.
- eHealth must not just streamline workload but clinically benefit the resident and improve outcomes.

Intervention characteristics

- eHealth should be user-friendly and accessible to increase sustainability.
- eHealth that is interoperable with current systems is advisable to minimize installation cost and complex new learning for end users.
- Technical support should be easily attainable and readily available.

Outer setting

- Policies that endorse eHealth use in care homes ease implementation, for example, rapid policy-driven implementation of remote consultations during the COVID-19 pandemic.

Inner setting

- eHealth tools should be tailored to care home settings to fit with existing workflow and care home values.
- Engaging care home leaders in the intervention is key to promoting enthusiasm and a cohesive working environment.
- Staff participation and learning about eHealth should be encouraged.
- Sufficient training should be provided for end users, which should be tailored to individual requirements.
- Additional resources need to be allocated to accommodate a change in practice. These include technological requirements such as bandwidth and equipment and extra staff time.

Individual characteristics

- Fostering a positive staff attitude toward eHealth is essential for uptake.
- The tool should benefit staff by easing workload, increasing knowledge, and improving job satisfaction.

Implementation process

- Preparation for change and consideration of implementation timelines, strategies, and contingency plans in advance is crucial.
- *Champions* should be designated in each care home to drive and support implementation.
- End users and other stakeholders should be engaged from an early point and consulted in the implementation process to accommodate individual requirements.
- Ongoing evaluation and reflection on uptake and adherence to eHealth should occur to inform any necessary developments and improvements.

CFIR Framework

The CFIR is a comprehensive determinant framework and is chosen to guide analysis owing to its previous application with eHealth interventions [68,70,71]. Generally, the extracted data were amenable to the CFIR, with no data left uncoded. However, 33% (13/39) of the subconstructs had no associated data (Table 2), concurrent with findings from a previous review of eHealth implementation across health care settings [70]. This consistency either suggests that some subconstructs are not relevant to implementing eHealth or highlights a limitation of the evidence base and lack of existing literature for this setting and population. These areas of uncertainty are important for informing future research, which should focus on identifying barriers to and facilitators of the implementation of these underresearched constructs.

Strengths and Limitations

A systematic approach to this review allowed for the rigorous and thorough identification of the relevant literature. Evidence synthesis was theory driven and guided by the CFIR, which has been built upon here to increase its relevance in eHealth and long-term care contexts.

Although this review specifies care home residents with dementia as its population of interest, only 38% (11/29) of the included studies had an exclusive dementia population. This was to reflect the real-world heterogeneous populations in care homes and include interventions that were suitable at an

organizational level rather than the individual level. Although there was no real difference in factors that influence implementation between dementia-specific and mixed populations, caution must be exercised when extrapolating these findings to homogeneous dementia populations.

Gray literature was not included in this review. This was because, when identified, it provided little data on the factors that influence implementation. This could have excluded relevant data on the eHealth interventions used in care homes. A recent scoping review on telehealth during the COVID-19 pandemic reported a rapid rise in eHealth during the pandemic [72].

Conclusions

To our knowledge, this is the first review to synthesize evidence on the implementation of eHealth interventions focusing specifically on improving assessment and decision-making in care homes for people with dementia. We adapted the CFIR and progressed its applicability for use in this context. We developed a conceptual model to demonstrate the most important factors to consider when designing and implementing an eHealth intervention and translated it into 18 practical recommendations for implementers, innovators, and organizations to implement eHealth for people with dementia in long-term care. Particular focus should be placed on the individual care home setting and on the consideration of resident and end-user needs when developing an implementation strategy for use in this context.

Acknowledgments

The authors would like to thank Adam Garside, an information support specialist at King's College London, who helped with the development of the search strategy. This project was funded by the Economic and Social Research Council (ESRC), National Institute for Health Research (NIHR), and ESRC/NIHR Dementia Initiative 2018 (grant reference number ES/S010327/1). CE is funded by a Health Education England/NIHR Senior Clinical Lectureship (ICA-SCL-2015-01-001). ND was supported by a fellowship from the Alzheimer's Society, United Kingdom (grant number AS-JF-16b-012). Abstract

Background: Digital health interventions have revolutionized multiple sclerosis (MS) care by supporting people with MS to better self-manage their disease. It is now understood that the technological elements that comprise this category of digital health interventions can influence participant engagement in self-management programs, and people with MS can experience significant barriers, influenced by these elements, to remaining engaged during a period of learning. It is essential to explore the influence of technological elements in mitigating attrition.

Objective: This study aimed to examine the study design and technological elements of documented digital health interventions targeted at people with MS—digital health interventions that were intended to support a program of engagement over a defined period—and to explore how these correlated with attrition among participants of randomized controlled trials (RCTs).

Methods: We conducted a systematic review and meta-analysis of RCTs (n=32) describing digital health self-management interventions for people with MS. We analyzed attrition in included studies, using a random-effects model and meta-regression to measure the association between potential moderators.

Results: There were no measured differences in attrition between the intervention and control arms; however, some of the heterogeneity observed was explained by the composite technological element score. The pooled attrition rates for the intervention and control arms were 14.7% and 15.6%, respectively.

Conclusions: This paper provides insight into the technological composition of digital health interventions designed for people with MS and describes the degree of attrition in both study arms. This paper will aid in the design of future studies in this area, particularly for digital health interventions of this type.

Introduction

Multiple sclerosis (MS) is a chronic neurological disease that affects over 2 million people globally [1]. The disease course of MS is highly variable and can be associated with a progressive decline in physical and cognitive function. The current treatment for MS involves the use of disease-modifying treatments and symptom management; however, the delivery of health care for MS is becoming increasingly supported by digital health interventions.

People with MS readily seek out web-based information on their disease and appear to do so at rates higher than those with other neurological conditions [2,3]. Further, many people with MS engage with digital technologies to manage their disease,

including exchanging medical information with health care providers or to assist in making and maintaining positive lifestyle changes [4]. Digital health interventions that support learning to self-manage MS and scaffold learning and practicing over a specific period of time are a particular subset of digital health interventions for people with MS. Evidence suggests that there are barriers to remaining engaged for the recommended duration in these interventions [5] and technological elements that could support engagement (such as interactivity, multimedia components, or feedback) can play a pivotal role in ameliorating attrition. Understanding the extent to which these technological elements may impact engagement by people with MS in such digital health interventions remains to be explored and is a necessary next step in designing and evaluating such digital health interventions.

We conducted a meta-analysis to address the following primary questions: (1) is there a difference in attrition for participants that were allocated to the intervention in randomized controlled trials (RCTs) of digital health interventions for people with MS between intervention and control arms? (2) How do study characteristics and technological elements of digital health interventions influence observed degrees of attrition?

Methods

Eligibility Criteria

Studies were eligible for inclusion in the review if they met each of the following predetermined criteria: (1) describe RCTs examining a treatment intervention or interventions for MS; (2) were delivered via a technological platform (ie, a "computer-assisted" or "web/internet-based intervention" or "eHealth/mHealth"), limited to a PC or to Mac, smartphone, and tablet devices. Interactivity and communication over a specified period of time were important components; therefore, episodic teleconferencing or telemonitoring and virtual reality–only interventions were excluded; (3) included study participants with a diagnosis of MS (any type); (4) reported attrition for those allocated to the intervention or control group upon conclusion of the intervention and study period, and the intervention and control arms were randomized from the same subject population; that is, no comparisons with healthy controls.

Search Strategy

A literature search was conducted on April 30, 2021, for published studies in the following databases: IEEE, Medline, Scopus, and CINAHL. The search contained terms related to identifying online interventions: (*online* OR *web-based* OR *internet* OR *digital* OR *virtual* OR *computer-assisted* OR *mhealth* OR *mobile* OR *smartphone* OR *ehealth* OR *telehealth* OR *telemedicine* OR *app*), a term identifying multiple sclerosis (*multiple sclerosis*), and a Medical Subject Headings (MeSH) term (*telemedicine*).

Reference lists and in-text citations were also screened for additional studies, as well as recommendations via correspondence from authors of other included studies.

Selection and Data Collection

Duplicates were first removed within and between databases. The remaining articles were then screened on the basis of their titles and abstract; thereafter, the eligibility of the final papers was confirmed following review of the full-text articles (Figure 1). Extraction of study characteristics and outcome data was conducted by authors WB and TW.

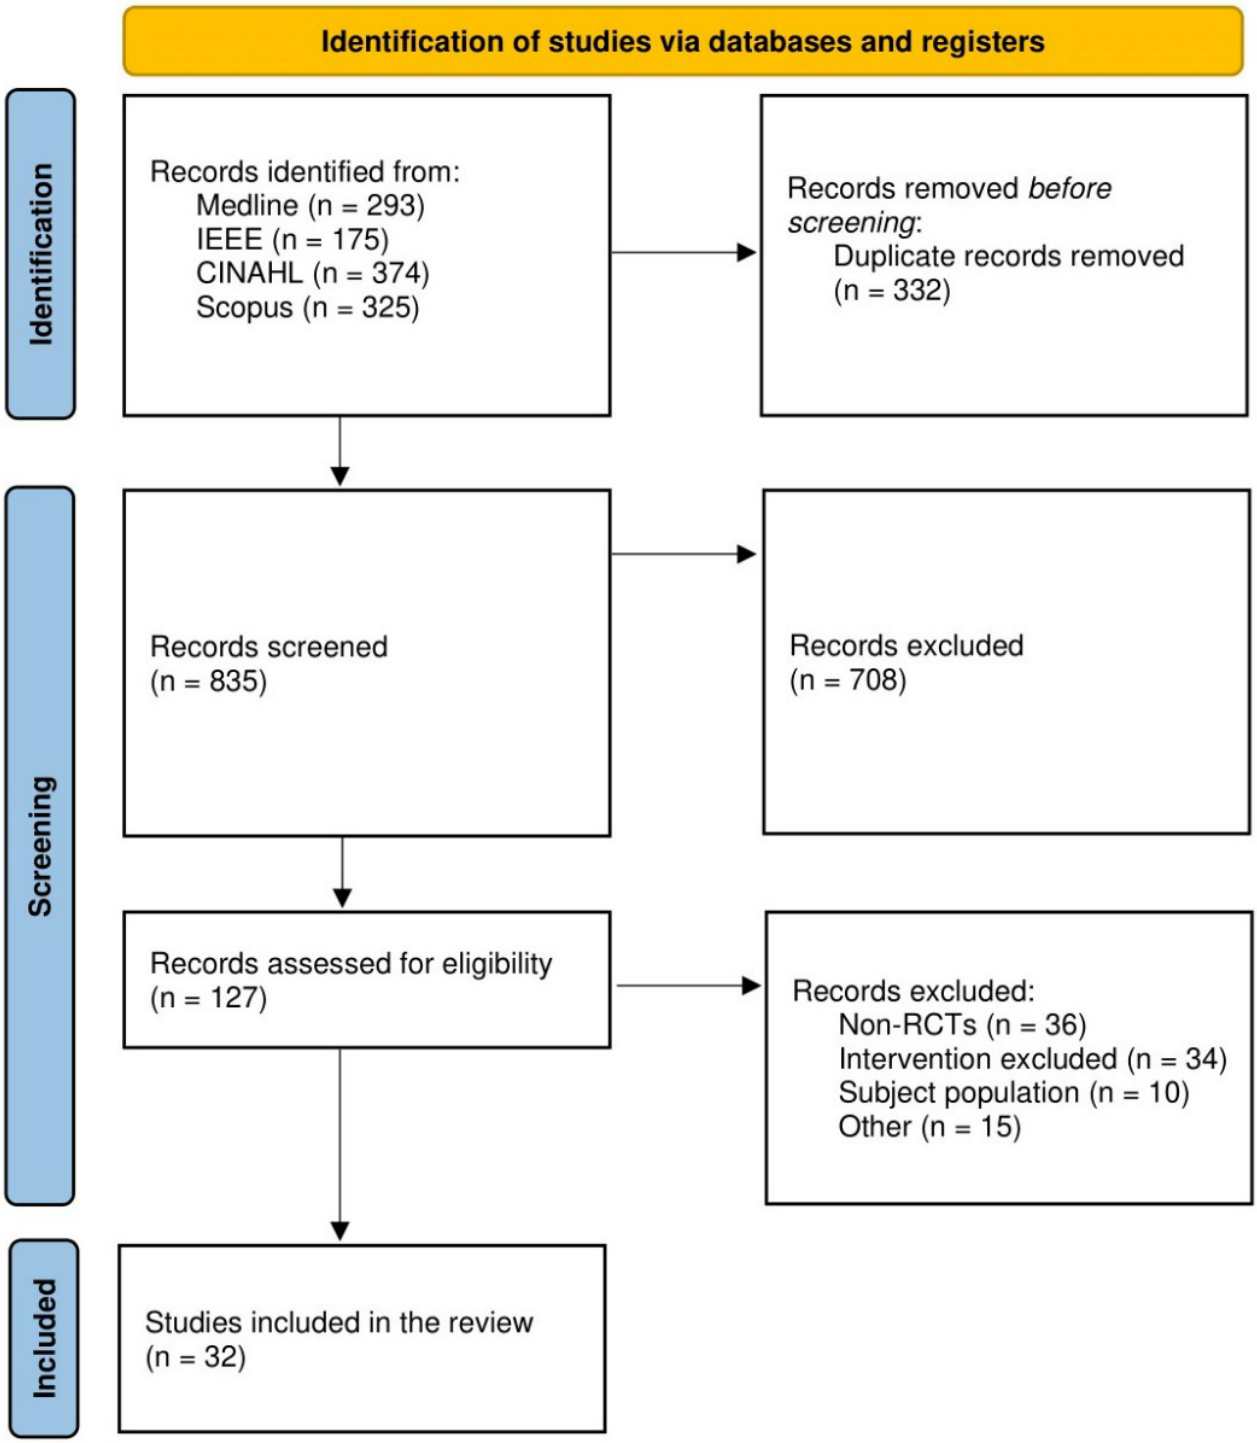
The following study characteristics were extracted: study design, study population, country, intervention type, control and comparison intervention, mean age of participants in both arms, percentage of female participants, years since diagnosis, length of intervention in weeks, number of sessions, length of time to final follow-up assessment in weeks, attrition in the intervention and control arms upon conclusion of the intervention, and primary outcome measures. In studies where there were multiple intervention or control arms, attrition data from intervention arms were combined and attrition data from control arms were combined for meta-analysis purposes [7].

Each study was scored on the basis of its technological elements by WB in accordance with the published manuscript. The scoring system used was adapted from Barakat et al [8], who developed it for use in web-based eTherapy programs targeted to eating disorders. Studies were scored in accordance with four domains:

- multimedia channels (written text="1," graphics/images="1," audio/voiceover="2," video="3," simulation/3D virtual reality="4");
- degree of user interactivity (questionnaires="1," quizzes="1," goal setting/to‐do list="2," homework tasks="3," user dashboard="3," forums="3," self‐monitoring tools="4," interactive exercises="4," virtual games="4," video coaching with professional="4");
- level of automated feedback (motivational pop‐ups="1," reminders="2," nonpersonalized feedback="3"), personalized feedback (telephone or email)= "4");
- technological device through which the program was made accessible (outdated technology; eg, compact disk read‐only memory (CD‐ROM)="1," modern technology; eg, tablet, desktop computer, laptop, and mobile phone="2").

The reporting of technological features of digital health interventions was often vague or absent in publications; therefore, it was necessary to survey each author regarding their examined web-based intervention to clarify scores in accordance with the system adapted from Barakat et al [8]. An email was sent out to authors who had not completed the survey. These authors were sent a summary of the initial scoring by WB and asked to confirm that all the elements listed were present in their study and to identify any that were missed. In total, 19 of the 32 studies responded and the remaining 11 provided additional elements that were not identified in the initial screen by WB. In total, 3 of the 33 studies [9-11] provided access to the program itself and provided confirmation of elements.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram [6]. RCT: randomized controlled trial.



Quality Appraisal

The methodological quality of the final studies included in the review was assessed by author WB using the Cochrane Risk of Bias tool 2 [12]. The tool uses five domains to assess the bias within study design: allocation concealment and random sequence generation, blinding of participants and study personnel, blinding of outcome assessment, incomplete outcome data, and selective reporting of data. Briefly, each domain is composed of questions, to which the response can be "yes," "possibly yes," "possibly no," "no," and "no information." Based on answers, each domain is scored as "low risk," "some concerns," or "high risk," whereby the overall judgement is made by the combination of all domains.

Statistical Analyses

Analyses were conducted using Stata (Stata/SE 16 for Mac, StataCorp).

Meta-analysis

The Stata command *meta* [13] was used for meta-analysis. The input variables required by *meta* were contained in a 2×2 table; that is, number of individuals who did and did not experience the "outcome event" in either the treatment or the control group.

To compare study attrition rates between the intervention groups and the control group, risk ratios were meta-analyzed using the default restricted maximum likelihood method. Log-transformed relative risk of attrition was computed separately for each study, weighted by the inverse of study variance, and pooled to create a summary effect. Studies with no loss to follow-up in one of the intervention or control arms were adjusted by adding 0.5 to each cell within a study's 2×2 table, enabled by meta-analysis settings within Stata. Studies with no attrition in both intervention and control arms were excluded from the meta-analysis as is best practice [14]. Heterogeneity was assessed using the I^2 statistic. Publication bias was assessed by funnel plots. Data were exponentiated and also presented as a Forest plot using the *meta forestplot* command in Stata.

Meta-regression

Meta-regression was used to examine the relationship between the log-transformed relative attrition rates, and various study characteristics, participant demographics, and intervention technological elements. Study characteristics included the type of control, type of intervention, duration of the study, and duration to the final follow-up. Type of control was dummy-coded as follows: wait-list, active control, usual care or active control computerized (1, 2, 3, 4). The type of intervention was dichotomized owing to small numbers of observations dummy-coded as follows: containing an exercise or physiotherapy condition or other (1, 2). The length of the intervention period was converted to years and evaluated as a continuous variable.

Demographic elements included the type of MS, mean age of the participants, female-to-male ratio, and years since disease onset. The type of MS was dummy-coded as either all MS types or relapsing-remitting MS (1, 2).

The intervention technological elements that could support engagement were as follows: multimedia channels, interactivity, and feedback; overall score was the sum of these 3 elements. This analysis omitted the element that assessed how the intervention was made accessible since all interventions used desktop computers. An attempt was made to further clarify whether interventions were designed to accommodate multiple platforms, but this remained unclear for many studies.

Variables were first examined individually and then jointly as a single meta-regression model informed by a directed acyclic graph.

Results

Results Overview

The database search retrieved 1167 articles, of which 187 were duplicates. After duplicates were removed, titles and abstracts of the remaining 835 were screened. Of these, 127 articles were obtained for full-text review. In total, 95 papers did not meet the inclusion criteria and were excluded after full-text review. Of the excluded papers, 34 were not applicable interventions, 36 were not RCTs, 10 had the wrong subject population, and 15 others were excluded for other reasons (Multimedia Appendix 1). In total, 32 papers that described 32 studies were eligible for meta-analysis.

Study Characteristics

Details of the study characteristics for the 32 included papers are reported in Table 1. Of the 32 studies, 10 were published before 2015, and the earliest paper was published in 2004. A total of 23 of 32 studies included all types of MS, 8 included only people with relapsing-remitting MS, and 1 included primary-progressive MS (PPMS). Two included any type of MS if fatigue was a symptom, 2 others included any type of MS if depression was a symptom, 1 assessed whether participants experienced migraines, and 1 only assessed whether participants experienced severe disability. The mean length of interventions was 14.0 (SD 10.2) weeks, and the mean length to last follow-up was 20.9 (SD 12.1) weeks. In total, 20 of 32 studies reported a high risk of bias upon quality appraisal with none reporting low risk (Figure 2).

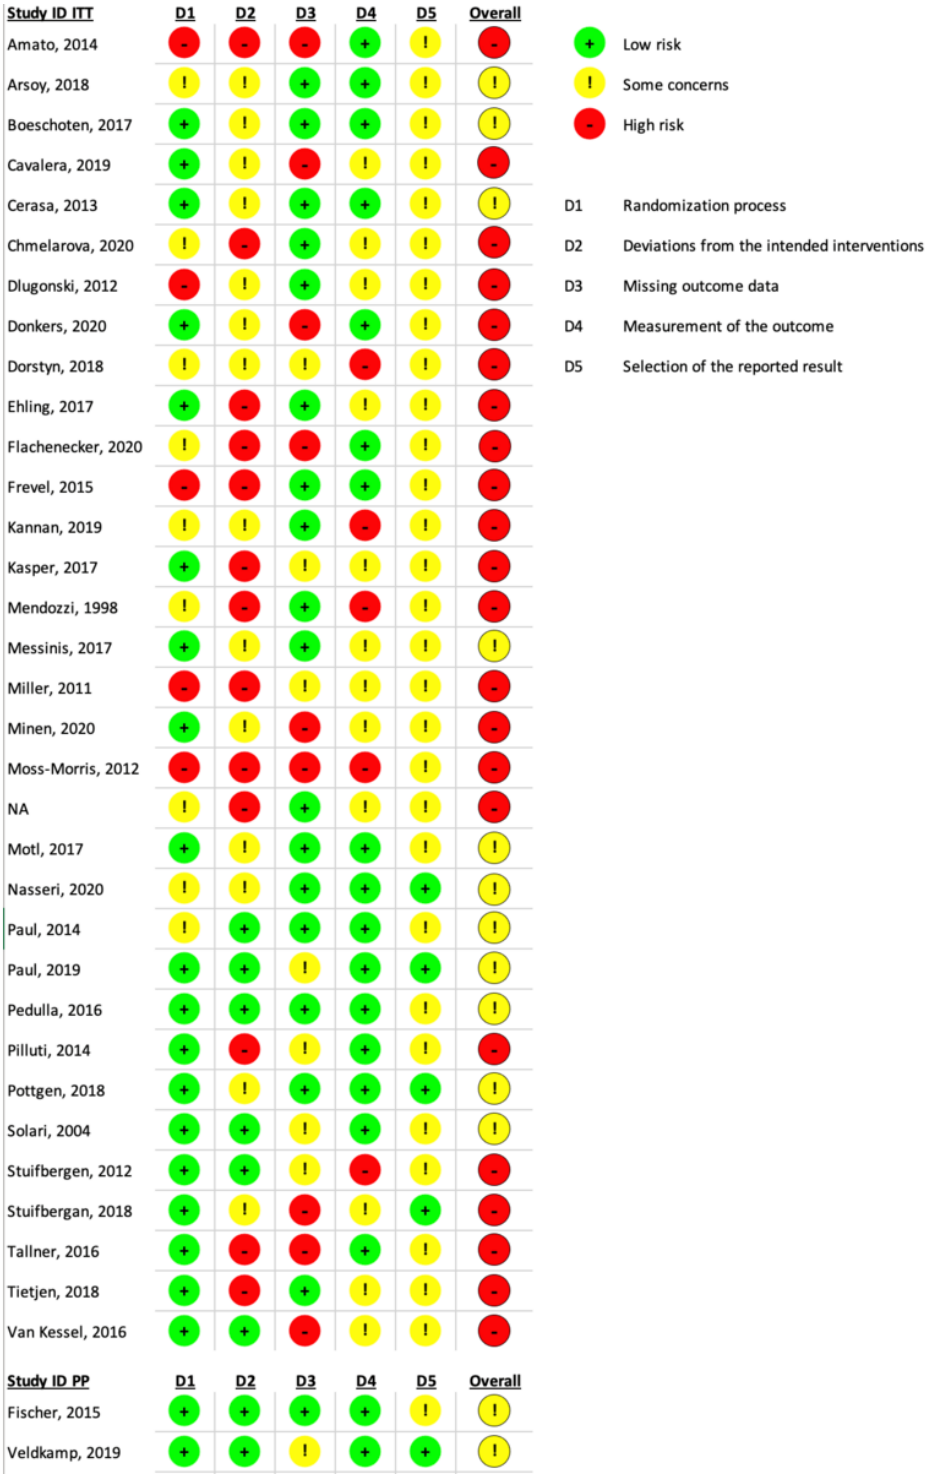
[a]N/A: not applicable.

Figure 2. Risk of bias assessment summary using the Cochrane Risk of Bias tool. ITT: intention-to-treat; PP: per-protocol.



Study Populations

The mean sample size across all 32 studies was 97.7 (SD 121.8). The smallest study contained 18 participants [19] and the largest 682 participants [41]. The median numbers of participants in the intervention and control arms at the final follow-up were 33 and 27, respectively.

Types of Digital Health Intervention and Control

All studies included a program aimed at people with MS delivered via web-based technology, with 2 studies [36,37] that included in-person components. The program ranged from 0.14 week to 52 weeks intended duration. In total, 15 of the 32 studies included a cognitive behavioral training element, 11 included an exercise training component, 2 included web-based physiotherapy, 1 included a fall prevention intervention, 1 included a program to build "returning to work" skills, 1 included a program to build health literacy, and 1 included a mindfulness intervention.

In total, 12 of the 32 studies used a wait-list control, while 7 studies used a usual care control. Eight studies used a noncomputerized active control, which included a physical activity regime [17-19,42], physiotherapy [11], modified version

of the intervention [38,39], or non–MS-specific psychoeducation [40]. Five studies used a computerized active control, which were all broadly modified versions of the intervention [26,33,35,41,43].

Digital Health Intervention Characteristics App

Complete scoring information for each individual study is available in Multimedia Appendix 2.

Multimedia

The mean multimedia score across all 32 studies was 3.5 (SD 2.2). In total, 29 of the 32 studies contained written text. Two of the remaining 3 studies that did not include written text were a gamified web-based cognitive training program [36,37], and 1 study described a web-based, asynchronous messaging system that uses electronic personal health records [42]. In total, 15 of 32 studies contained video or animation, half of all studies including images or graphics, and only one study used audio voiceover to augment written material [27].

Interactivity

The mean interactivity score across all 32 studies was 5.2 (SD 3.3). Eight of 32 studies contained homework tasks [9,27,32,34,36-38,40], which varied from set questions or self-directed learning to diary entries between course sessions. In total, 15 of 33 studies contained a self-monitoring component [10,11,15,16,18,21-25,31,32,38,42], which varied from a validated tool integrated within the program to generic mood-related questions and diary entries. Nine studies included interactive exercises or games [26,28,30,33,35-37,39,43], 5 studies contained goal-setting elements [15,21,22,24,38], 3 contained forums for interaction with other participants [20-22], 3 contained video coaching or interactive meditation by professionals [15,24,40], and 1 contained a questionnaire or quiz [32].

Feedback

The mean feedback score across all 32 studies was 2.8 (SD 2.4). In total, 14 of 32 studies included feedback [9-11,16,18,19,21,22,27,28,36,37,39,40], which ranged from personalized feedback from a trained staff member or professional to general feedback delivered automatically via the web-based platform. Reminders were included in 6 of 17 studies [15,17,20,25,32,42], which prompted users to complete the sessions, while 2 studies also included reminders on when new content was added or existing content was updated [21,22].

Meta-analysis

The final meta-analysis included 29 studies after 3 exclusions due to no attrition in both the intervention and control arms. Meta-analysis described an overall effect size of =–0.993 (95% CI 0.95-1.04) and a *P* value of .75, which indicates no statistical difference in the degree of attrition between the intervention and control arms (Figure 3). The test of homogeneity of study-specific effect sizes (*Q*) was rejected (*P*<.01). The data also suggested the presence of a medium level of heterogeneity between studies (I^2=50.50). There is evidence of publication bias as described by the funnel plot showing some asymmetry (Figure 4).

Figure 3. Individual effect sizes and forest plot of the difference in the degree of attrition between the intervention and control arms of the included studies within our analysis (negative values indicate greater attrition in the intervention arm than in the control arm and vice versa).

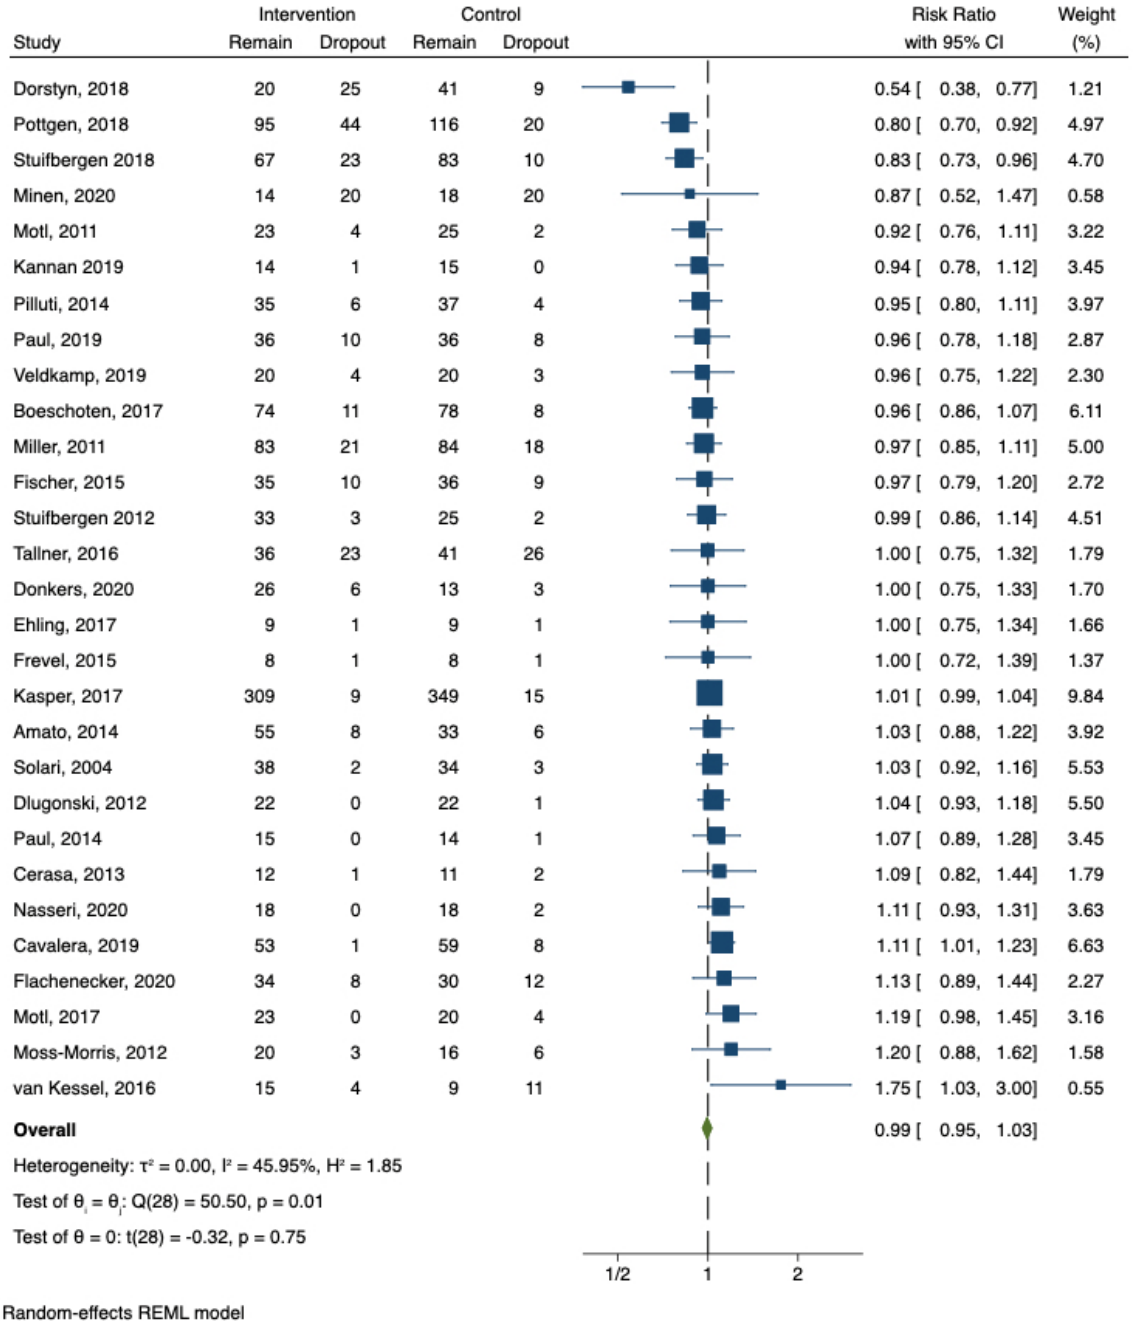


Figure 4. Contour-enhanced funnel plot of the relative attrition rates (>0 indicates a higher attrition rate in the intervention condition).

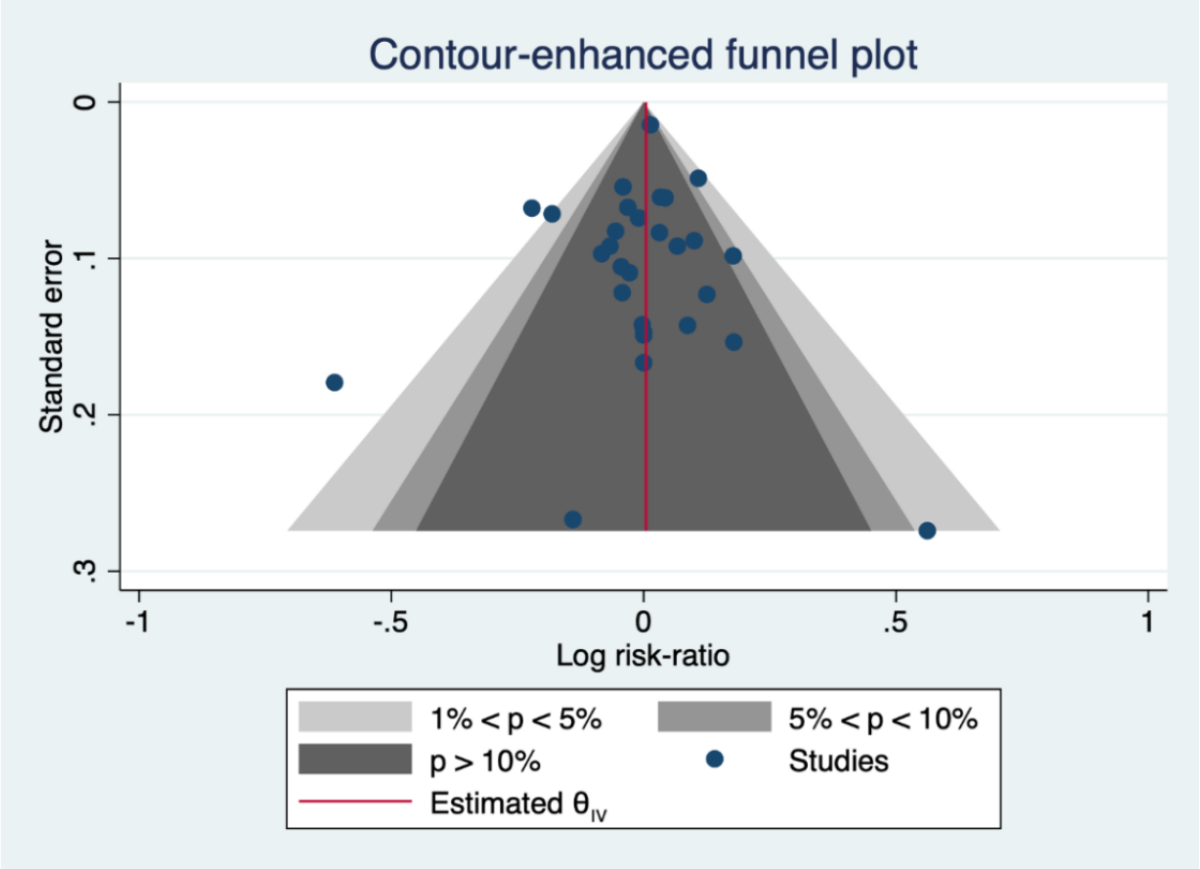

Meta-regression

Univariable Association

Univariable assessment of study characteristics and eHealth elements are described in Table 2. No significant association between length-of-treatment, weeks to last follow-up, type of control, MS type, feedback or interactivity, or attrition was observed. Lower attrition was observed when eHealth elements overall score and multimedia score were higher.

Table 2. Univariable meta-regression model describing the association between differential attrition and study characteristics.

Variables	Coefficient (95% CI)	*P* value
Length of treatment (years)	1.00 (1.00-1.00)	.88
Active control	1.03 (0.92-1.15)	.64
Usual care	1.07 (0.92-1.23)	.38
Active control computerized	1.06 (0.94-1.20)	.29
Relapsing-remitting multiple sclerosis	1.03 (0.93-1.14)	.60
Primary-progressive multiple sclerosis	1.12 (0.89-1.42)	.31
Non–cognitive behavioral therapy intervention	1.01 (0.92-1.10)	.88
Mean age (years)	1.00 (0.99-1.01)	.60
Female-to-male ratio	0.99 (0.99-1.00)	.01
Years since onset	1.01 (0.99-1.04)	.28
Overall score	1.00 (1.00-1.01)	.20
Multimedia subscore	*1.02* (*1.00-1.04*)[a]	*.03*
Interactivity subscore	1.00 (0.99-1.02)	.47
Feedback subscore	1.00 (0.98-1.02)	.79

[a]Italicized values are significant at *P*<.05.

Multivariable Models

Adjustment for other covariates did materially impact the association of overall score with attrition, which was significant (*P*<.01; Table 3). After adjustment, the multimedia subscore remained a significant association (*P*=.03; Table 4).

Table 3. Multivariable meta-regression model describing the association between overall score and attrition.

Variables	Risk ratio (95% CI)	*P* value
Overall score	*1.01 (1.00-1.03)*[a]	*.01*
Length of treatment (years)	1.08 (0.85-1.39)	.50
Active control	1.04 (0.88-1.22)	.46
Usual care	0.96 (0.79-1.16)	.64
Active control computerized	1.15 (0.97-1.37)	.09
Nonexercise intervention	0.97 (0.88-1.08)	.59
Relapsing-remitting multiple sclerosis	0.99 (0.88-1.12)	.84
Primary-progressive multiple sclerosis	1.11 (0.82-1.49)	.48
Female-to-male ratio	0.99 (0.99-1.00)	.13
Mean age (years)	1.00 (0.99-1.01)	.91

[a]Italicized values are significant at *P*<.05.

Table 4. Multivariable meta-regression model describing the association between multimedia subscore and attrition.

Variables	Risk ratio (95% CI)	*P* value
Multimedia subscore	*1.04 (1.00-1.08)* [a]	*.03*
Length of treatment (years)	1.14 (0.87-1.48)	.32
Active control	1.05 (0.89-1.24)	.53
Usual care	0.99 (0.82-1.20)	.94
Active control computerized	1.09 (0.93-1.28)	.28
Nonexercise intervention	1.01 (0.92-1.11)	.84
Relapsing-remitting multiple sclerosis	1.01 (0.90-1.14)	.80
Primary-progressive multiple sclerosis	1.06 (0.79-1.42)	.68
Female-to-male ratio	1.00 (0.99-1.00)	.34
Mean age (years)	1.00 (0.98-1.01)	.55

[a]Italicized values are significant at *P*<.05.

Discussion

Principal Findings

The aim of this systematic review and meta-analysis was to describe the study characteristics and technological components of digital health interventions that supported people with MS through a program of learning and practicing self-management, and then investigate any associations these factors may have with attrition. Our meta-analysis found no difference in attrition between participants allocated to intervention and control arms of the included RCTs. A multivariable association was found between degree of attrition and overall score, which was not observed in the univariable model, and between the degree of attrition and the multimedia subscore in both univariable and multivariable models. This suggests that among included studies, the interactivity subscore was the main driver in the association observed between overall score and degree of attrition; that is, the likelihood of attrition within the intervention arm compared with the control arm was associated with the inclusion of interactive elements such as self-directed tasks or self-monitoring.

Only 8 of the 32 studies described a design process or framework by which the intervention was developed. Development methods included engagement with the MS community [9,10,31,32,38], design with practitioners and allied health professionals [34], both [31], or followed a preset development plan [23]. There was no association observed between the number or type of technological elements used within the intervention and whether the study used or described a development framework. It is possible that a greater degree of consultation with the MS community during design phases does not necessarily lead to a great quantity of or more complex technological features. This highlights that while engagement with communities during the design phase is important, it is crucial to ensure this engagement is constructive and not perfunctory. Population preferences for number and type of

features require further exploration; however, our findings suggest that elaborate features are not necessarily what people with MS want in a web-based intervention of this kind.

Interestingly, length of intervention was not associated with attrition in either control or intervention arms. Intuitively, the longer the intervention itself, the greater the potential attrition from these studies, in which a negative relationship between attrition and length of treatment for self-management interventions for people with MS has been reported [45]. It is possible that the role of treatment length in attrition may only be true at longer time frames than in the included studies of both meta-analyses. Another likely variable is the number of sessions or time in contact with participants. It is possible that rather than the length of the intervention being a mediator, it is the time participants are exposed to the intervention ("dose"). Studies infrequently report these data; therefore, this needs to be addressed in future studies.

Another interesting finding is that the mean average attrition rates in the intervention and control arms were 14.7% and 15.6%, respectively, which is a useful figure for calculating sample sizes for future studies. A previous meta-analysis investigating attrition rates based on published studies of existing self-management interventions for people with MS reported pooled attrition rates of 16.8% and 14.4% for the intervention and control groups, respectively [45]. Interestingly, studies that used face-to-face delivery of interventions were described as having higher attrition rates. Our analysis supports their pooled data attrition rates, which indicates that there may not actually be a difference between face-to-face and non–face-to-face digital health interventions of this kind. Further, their meta-analysis described associations between attrition and sex, age, and length of intervention, which was not observed in our data set. As their data was pooled between face-to-face and other modes of delivery, it is possible that the web-based mode of delivery may be mediating that relationship in our analysis.

Importantly, 9 of 32 studies did not report any outcomes related to the use of the intervention or technological elements within their intervention; they only reported primary outcome measures related to health outcomes. In total, 15 of 32 studies reported logins, app use, or sessions completed, while only 4 studies reported any interactions between participants and technological elements that were not directly related to the primary outcome measure. This has implications of measuring the "dose" for digital health interventions, whereby factors not reported may have an impact on the outcome measures reported as well as on attrition. Studies describing digital health interventions should address this in the future.

Limitations

Technological elements were underreported in published papers as evidenced by the authors of 10 of 32 studies needing to be followed up to provide information not accessible within the papers. It is possible that this analysis failed to capture the entirety of the included technological elements present within these studies; however, this is unlikely with the follow-up procedure. The need for better reporting of digital health interventions is crucial in ensuring reproducibility and assessment of web-based interventions, especially as several accessible frameworks exist directed at digital tools [44,46] or more generally [47]. Providing access to explore the intervention itself—as 3 authors did for this study—may be another solution, although it is not feasible for some studies.

Digital health interventions are not new; however, there have been fewer published studies on their use in MS compared with other chronic conditions; a greater number of studies would make the meta-regression more reliable. Further stratification of participants may provide greater insight into the attrition in these interventions by accounting for digital literacy, level of access to technology infrastructure, and better general reporting of the intervention design overall.

While the scoring system used for technological component ratings in this review has previously been used and was created in accordance with guidelines for digital intervention development, this system is not yet validated. Several additions were made to this scoring system to accommodate features that were not included, and it is possible that these additions have compromised internal validity. Analysis was undertaken using the previous, unmodified scoring system and revealed no changes to the results using our modified scoring system; however, caution must be applied to interpreting these results before validation has occurred. Additionally, while the scoring was derived from both publication and authors themselves, it is possible there were inaccuracies due to misinterpretation or inability to recall.

It is possible that using qualitative methods and direct observations to understand the ways in which people with MS engage with technological components of these digital health interventions is a better predictor of attrition than merely quantifying and scoring the components themselves. Unfortunately, no studies provided the data required to carry out these analyses. It also possible that analyzing individual components of the subscores for multimedia, interactivity and feedback, rather than overall subscores themselves, may elucidate further associations; however, the weighting within these subscores of the different components aims to address this.

The inclusion criteria were also strict on the definition of the digital health interventions of interest to us. This excluded studies that were exclusively virtual reality interventions and those that were exclusively telemonitoring or conferencing. These exclusions may have biased our data. It is noteworthy that the category of digital health interventions of interest to us is not well-defined in the major taxonomy of digital health interventions published by the World Health Organization; the category *Interventions for Clients*, this describes "communication" but overlooks the structuring and scaffolding of interventions that would be better described as "education" [48].

Conclusions

In conclusion, this study describes no difference in the rates of attrition between participants allocated to the intervention and control arms in digital health interventions for people with MS. An association between overall technological elements score

and attrition was observed; however, the underlying mechanism is unclear. Future studies should further investigate the roles these elements play in retention in web-based interventions.

Acknowledgments

We would like to thank Cecily Gilbert for their assistance in refining our search strategy.

Authors' Contributions

WB, TW, GJ, KG, and SSY contributed to study design. WB contributed to literature search and in data collection and synthesis. WB and SSY were responsible for data analysis. All authors contributed to manuscript development and approval.

Conflicts of Interest

None declared.

Abstract

Background: There are a host of emergent technologies with the potential to improve hospital care in low- and middle-income countries such as Vietnam. Wearable monitors and artificial intelligence–based decision support systems could be integrated with hospital-based digital health systems such as electronic health records (EHRs) to provide higher level care at a relatively low cost. However, the appropriate and sustainable application of these innovations in low- and middle-income countries requires an understanding of the local government's requirements and regulations such as technology specifications, cybersecurity, data-sharing protocols, and interoperability.

Objective: This scoping review aims to explore the current state of digital health research and the policies that govern the adoption of digital health systems in Vietnamese hospitals.

Methods: We conducted a scoping review using a modification of the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines. PubMed and Web of Science were searched for academic publications, and *Th Vi n Pháp Lu t*, a proprietary database of Vietnamese government documents, and the Vietnam Electronic Health Administration website were searched for government documents. Google Scholar and Google Search were used for snowballing searches. The sources were assessed against predefined eligibility criteria through title, abstract, and full-text screening. Relevant information from the included sources was charted and summarized. The review process was primarily undertaken by one researcher and reviewed by another researcher during each step.

Results: In total, 11 academic publications and 20 government documents were included in this review. Among the academic studies, 5 reported engineering solutions for information systems in hospitals, 2 assessed readiness for EHR implementation, 1 tested physicians' performance before and after using clinical decision support software, 1 reported a national laboratory information management system, and 2 reviewed the health system's capability to implement eHealth and artificial intelligence. Of the 20 government documents, 19 were promulgated from 2013 to 2020. These regulations and guidance cover a wide range of digital health domains, including hospital information management systems, general and interoperability standards, cybersecurity in health organizations, conditions for the provision of health information technology (HIT), electronic health insurance claims, laboratory information systems, HIT maturity, digital health strategies, electronic medical records, EHRs, and eHealth architectural frameworks.

Conclusions: Research about hospital-based digital health systems in Vietnam is very limited, particularly implementation studies. Government regulations and guidance for HIT in health care organizations have been released with increasing frequency since 2013, targeting a variety of information systems such as electronic medical records, EHRs, and laboratory information

systems. In general, these policies were focused on the basic specifications and standards that digital health systems need to meet. More research is needed in the future to guide the implementation of digital health care systems in the Vietnam hospital setting.

Introduction

Digital health systems such as electronic health records (EHRs) and patient administration systems used in hospitals in high-income countries (HICs) have been adopted with the dual aim of increasing the quality of patient care and improving hospital finances through cost reductions and new revenue streams. These systems are commonly introduced in response to major government initiatives, often with significant public funding [1]. Despite major challenges and high-profile failures [2], HICs have now reached the point where secondary use of data from digital health systems can, in some cases, enable hospitals and health care systems to become *learning health systems*, using routinely collected data to facilitate research and quality improvement [3]. In recent years, data from hospital-based digital health systems have been used to develop and implement innovative artificial intelligence (AI) systems for monitoring patients and providing clinical decision support (CDS) to health care providers [4].

Although the adoption of digital health systems in low- and middle-income countries (LMICs) such as Vietnam has largely only taken place within the last decade, these solutions have the potential to support the development of universal health coverage and projects working toward addressing sustainable development goals [5,6]. However, in resource-constrained settings, new health care information technologies are often implemented with insufficient funding, infrastructure, regulations, and computer literacy of the staff who will be using them [7-9]. These challenges may be able to be mitigated through the use of open-source software [8,10], mobile technologies [11], and cloud-based data infrastructure [12]. The adoption of new policies and standards (such as Health Level 7's [HL7] Fast Healthcare Interoperability Resources [13]) may also enable simpler and more effective methods for health information exchange than was available to HICs in previous years [14].

Recent initiatives in Vietnam and other LMICs have sought to exploit the potential of digital technologies such as machine learning and low-cost wearable devices in improving critical care at an affordable cost [15,16]. For these innovations to attain scalability and sustainability, their research and development needs to consider the technical infrastructure and the regulatory frameworks that govern local technology adoption [5,6,15,16]. The Vietnamese government has recognized the role that digital health technologies can play in improving health care and optimizing administration processes [17], and along with building national health databases such as the national EHR system, new digital health policies and guidance have been promulgated by the Vietnam Ministry of Health (MoH) [18,19]. Awareness of the government's current regulations and future directions for digital health and the local research evidence in this area is important for the introduction of these emergent technologies in Vietnamese hospitals. This scoping review aims to map and summarize the academic literature and government policies in the field of hospital-based digital health systems in Vietnam. We have chosen a scoping review methodology as it allowed us to effectively explore and summarize information from a wide range of sources, given the rapidly evolving nature of digital health in Vietnam [20,21].

Methods

We conducted this review using a modification of the *PRISMA-ScR* (*Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews): Checklist and Explanation* guidelines [22].

Eligibility Criteria

The eligibility criteria are listed in Textbox 1.

Textbox 1. Eligibility criteria.

Inclusion criteria

- Policies and guidance documents from the government that regulate and guide the adoption of digital health systems in Vietnam's public hospitals. Academic publications that address digital health systems in Vietnam's hospitals
- Policies and guidance documents that are functioning or to be mandated
- Documents written in Vietnamese or English

Exclusion criteria

- Policies and guidelines that have been replaced by a newer version
- Policies and studies that only examine technical aspects of the digital solution without discussing its adoption and implementation in clinical settings
- Stand-alone apps or digital solutions that are implemented in the hospital settings but not linked with a particular hospital-based information system such as hospital information management systems and electronic medical records

Information Sources

We conducted searches on PubMed, Web of Science, and Google Scholar to identify academic literature. A structured search string (Multimedia Appendix 1) was built for the search on PubMed and Web of Science, and additional relevant publications identified during the full-text screening were retrieved and screened using Google Scholar.

A search of Vietnamese policies was conducted on the Th Vi n Pháp Lu t database [23]. A total of 10 search queries were built and executed separately (Multimedia Appendix 1). All document titles resulting from each of the search queries were extracted and compiled in a Microsoft Excel spreadsheet, from which all duplicates were removed. The MoH Electronic Health Administration's website was used to search for relevant documents that had not been found in the structured database search. Follow-up visits to the website were done throughout the study and at the end of the data-charting phase to identify newly released documents. Relevant documents that were referred to in the reviewed text but not found by the 2 former search strategies were searched for using Google.

No restriction on publication type and publication year was set.

Data-Charting Process

A data-charting form was developed based on the research objectives and guidelines from the PRISMA-ScR guidelines. A draft version of the data-charting form was piloted during the full-text screening, from which discussions were made to modify and finalize the charting form.

All the charting tasks were conducted by one researcher (DMT) using a Microsoft Excel spreadsheet. The charted data were then reviewed by another researcher (CP), and follow-up discussions were arranged to resolve any disagreements between the 2 investigators.

For academic literature, the charting form collected information about the publication year, methods, study population, or source of information reviewed (if the publication is a review), the study scope, the digital health domain being studied, the context that the domain was investigating, and key findings. The charting form of government documents sought to extract information about the domain of intervention, policy enactment time, the intended purpose of the policy, and the ministry that mandated the document.

Selection of Sources of Evidence

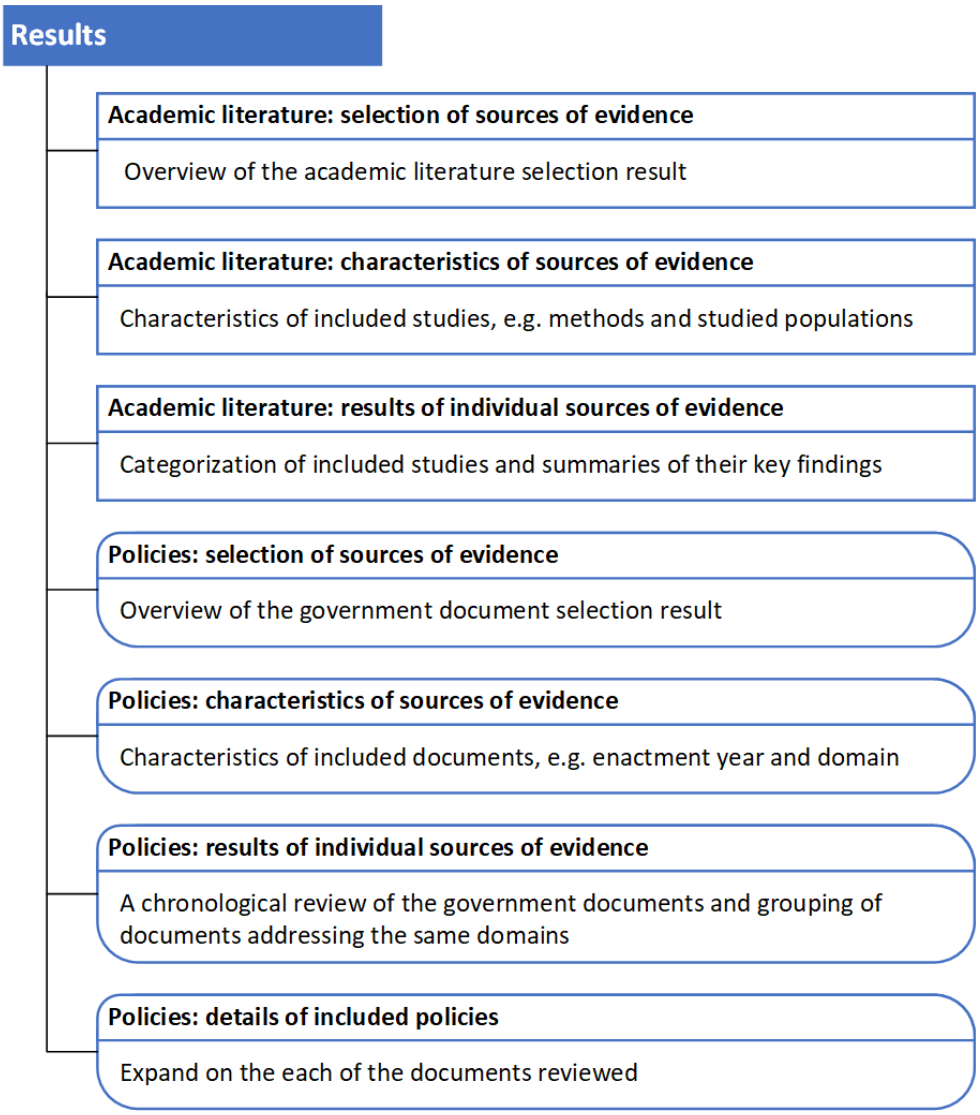
Academic publications were assessed through 3 steps including title, abstract, and full-text screening. Studies that did not meet the eligibility criteria in each step were ruled out from the screening list. Government policies and guidance were selected using a 2-stage process. In the first screening round, the title, introduction, and *scope and regulated entities* section of each document was screened to determine their eligibility. For documents that passed the first screening round, full text was screened in the second round. The selection was based on the eligibility criteria. Any uncertainty during the selection process was discussed between the authors for a final agreement.

Results

Overview

From the initial search results of 2033 academic publications and 266 government documents, 11 academic studies and 20 government documents were included in the review. We have organized the *Results* section into 2 major parts: academic literature and policies. Each part features the source selection process, characteristics of selected sources, and the results of individually selected sources. Figure 1 depicts the layout of the *Results* section.

Figure 1. Layout of the *Results* section. The branches represent the subsections in the *Results* section and the information included therein. Square boxes and round boxes denote the Academic Literature and Policies subsections, respectively.

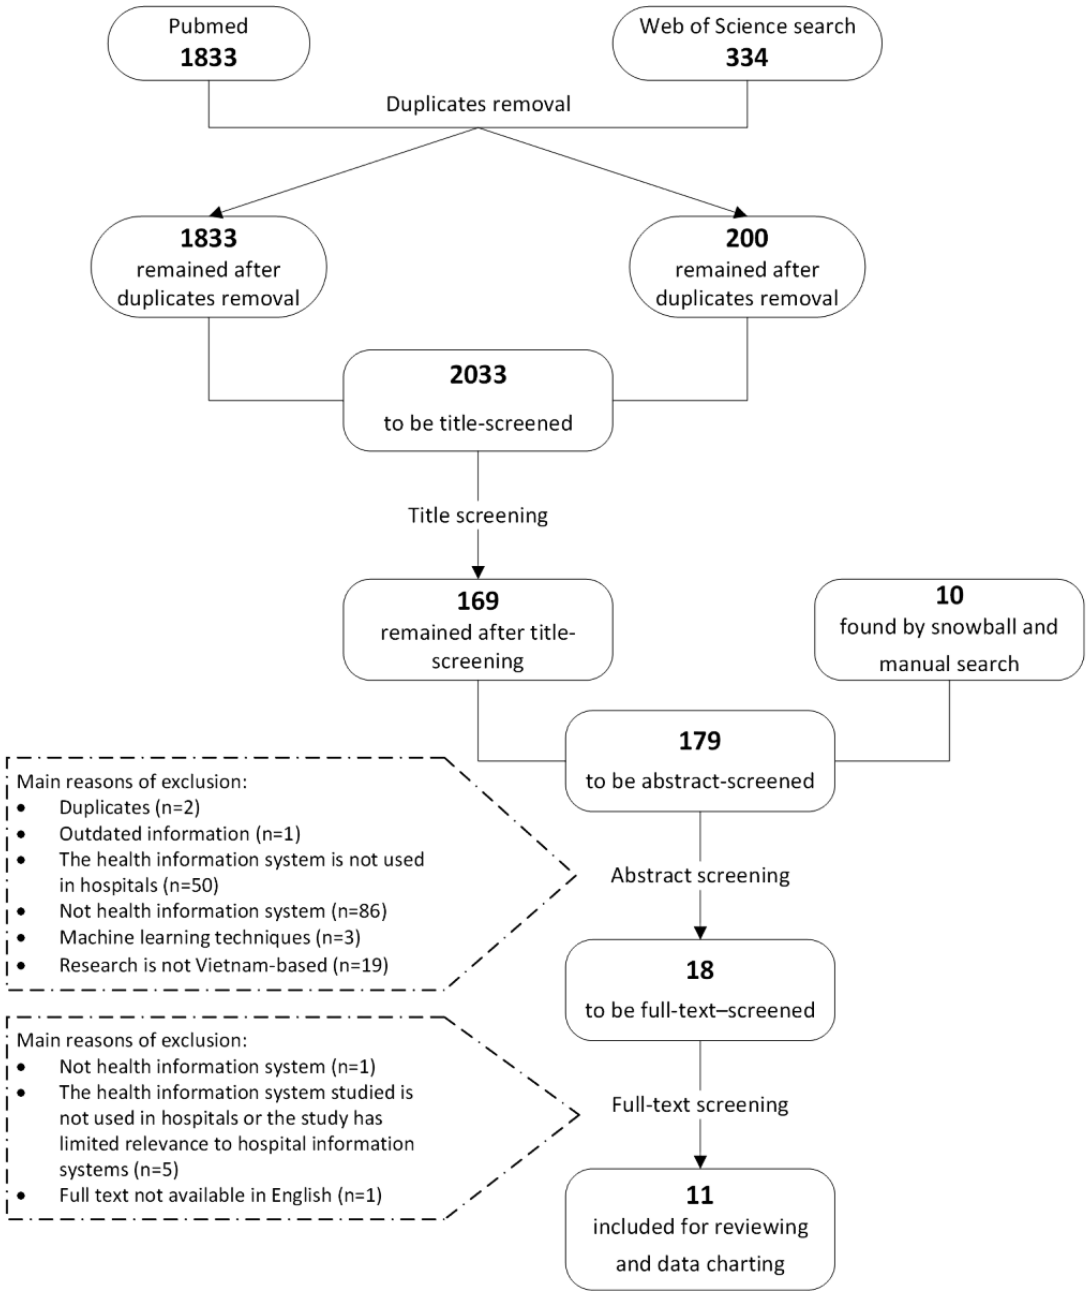


Academic Literature

Selection of Sources of Evidence

The PubMed and Web of Science searches of the academic literature returned 1833 and 334 articles, respectively. After the removal of duplicates, title screening was conducted on 2033 articles (1833 from PubMed and 200 from Web of Science), resulting in 169 marked *considered* for abstract screening. Titles were excluded if they did not imply any relation to the use of information technology (IT) in health care. In addition, the snowballing and manual search found an additional 10 studies, making it a total of 179 abstracts to be screened. The abstract screening ruled out 161 articles that did not meet the eligibility criteria and identified 18 articles eligible for the full-text review. The main reasons for exclusion during abstract screening were as follows: duplicated articles (n=2), the reviewed information was outdated to Vietnam's current digital health situation (n=1), the interventions studied were neither of health information systems (n=86) nor of hospitals' health information systems (n=50), the research was about machine learning techniques (n=3), and the research was not conducted in Vietnam (n=19). Of the full-texts screened, 11 articles were included in the final review. The full-text screening found 7 studies not eligible for the review, of which 1 did not examine health information systems, 5 studies investigated health information systems that were not implemented in hospitals or their findings were of limited relevance to the hospital information systems (HISs), and 1 study's full text was not available in English (Figure 2).

Figure 2. Summary of academic publication selection.



Characteristics of Sources of Evidence

Characteristics of each study including title, authors, publication year, methods, studied population or source of information reviewed, and study scope are summarized in Table 1.

Table 1. Summary of included studies.

Study title	Reference	Methods	Studied population or source of information reviewed	Study scope
Design of Laboratory Information System for Health Care in Vietnam BK-LIS	Vu et al [24]	Case study	Common laboratory test results in Vietnam's hospitals	Described how BK-LIS, a laboratory information system, was designed and developed to support the laboratory activities in Vietnam's hospitals
A Design of Renal Dataflow Control and Patient Record Management System for Renal Department Environment in Vietnam	Vu et al [25]	Case study	Hemodialysis systems in Bach Mai Hospital and E Hospital, 2 central-level hospitals in Vietnam	A case study of the development of BK-HD manager, an IT[a] solution that centrally manages the hemodialysis system in the hospital
Automatic Retrieving Data From Medical Equipment to Create Electronic Medical Records for an e-Hospital Model in Vietnam	Hai et al [26]	Case study	Electronic medical equipment commonly used in Vietnamese hospitals	Demonstrated technical solutions to automatically retrieve data from medical devices. The types of data include images and video data, laboratory test result data, and waveform data
Toward VNUMED for health care research activities in Vietnam	Vo et al [27]	Case study	EMRs[b] from hospitals in Vietnam	Introduced VNUMED, an intermediate database that gathers data from EMRs to support health care research, and related challenges for its development in Vietnam
EMR Visualization for Patient Progress Tracking: Interface Design and System Implementation	VO et al [28]	Case study	Gastroenterologists and EMR data in Thong Nhat central-level hospital	Described the development and testing of EMR visualization, a visualization tool for patient progress tracking, using data from the hospital's EMR system
Strategic Challenges Facing User- and Patient-Centered e-Health in Vietnam	Nguyen et al [29]	Review	IT use in health care in Vietnam before 2012	A review of the IT applications in Vietnam's health sector before 2012. Challenges in implementing patient-centered eHealth in Vietnam were discussed
English-Based Pediatric Emergency Medicine Software Improves Physician Test Performance on Common Pediatric Emergencies: A Multicenter Study in Vietnam	Lin et al [30]	Multicenter, prospective, pretest–posttest study	203 physicians from 11 hospitals across Vietnam	PEMSoft[c], a clinical decision support system, was tested against physicians' performance on a multiple-choice exam
Toward an Electronic Health Record System in Vietnam: A Core Readiness Assessment	Hochwarter et al [31]	Document analysis, participant observation, and in-depth interview	Participant observation and document analysis was conducted in a department of a top-level hospital in Vietnam; in-depth interview with an MoH[d] expert.	Investigation of the Vietnamese health system's core readiness for electronic health record implementation
Open-Source LIMS[e] in Vietnam: The Path Toward Sustainability and Host Country Ownership	Landgraf et al [32]	Reviewing the program reports	Reports from a national LIMS project using an open-source LIMS from 2008 to 2016	Described the building and scale-up of a national LIMS program for clinical and public health laboratories in Vietnam. Outcomes of the program and the lessons learned were discussed. A model for sustainability that could be applied to diverse laboratory programs was proposed
Electronic Health Record Readiness Assessment in Thái Binh Hospital, Vietnam	Nguyen [33]	Cross-sectional study using a scoring tool	Thái Binh provincial hospital	The study assessed the readiness for electronic health record implementation in Thái Binh hospital, Vietnam. The 4 main components of readiness included core readiness, technological readiness, learning readiness, and societal readiness
Artificial Intelligence vs Natural Stupidity: Evaluating AI[f] Readiness for the Vietnamese Medical Information System	Vuong et al [34]	Nonsystematic review	The literature about AI in medicine worldwide, the literature about eHealth in Vietnam, and the Joint Annual Health Review of Vietnam from 2012 to 2016	An overview of AI research and applications in medicine worldwide, proposing a framework to evaluate AI readiness. The assessment of AI readiness in Vietnam's health care sector using the proposed framework

[a]IT: information technology.

[b]EMR: electronic medical record.

[c]PEMSoft: Pediatric Emergency Medicine Software.

[d]MoH: Ministry of Health.

[e]LIMS: laboratory information management system.

[f]AI: artificial intelligence.

Results of Individual Sources of Evidence

The digital health domain that each study addressed, the context in which the domain was considered, year of data collection or reviewed evidence, and key findings of each study are presented in Table 2.

Among the 11 publications reviewed, 5 reported the development and testing of engineering solutions to gather, manage, or visualize data from the medical devices or information systems that were being used in the chosen hospitals. The 3 studies published in 2010 and 2011 described solutions to retrieve and manage data from laboratory devices or hemodialysis systems, whereas the 2 studies published in 2019 involved electronic medical record (EMR)-based solutions.

The other 6 articles addressed aspects of digital health implementation in Vietnam's health care system. Among these, no study examined a specific clinical information system in the hospital setting. EHR implementation was discussed in the 2 readiness assessment studies, in which one interviewed an MoH staff member, whereas the other study surveyed health care workers in a provincial hospital. These stakeholders recognized the benefits offered by EHRs and expressed positive attitudes toward EHR adoption. However, there was a lack of IT infrastructure, basic IT use among the hospital staff such as regular communication via email, and IT training capacity in place for EHR implementation. Lin et al [30] evaluated physicians' performance on a multiple-choice exam with the support of a system (CDS system [CDSS]). The participants improved their exam performance when using the CDS software compared with when not using the CDS software. However, the software was only used for testing purposes and not implemented in the studied hospitals. The national laboratory information management system program published by Landgraf et al [32] was largely used in public health laboratories rather than integrated into a hospital-based system. The 2 reviews by Nguyen et al [29] and Vuong et al [34] provided an overview of how health care facilities in Vietnam had implemented IT applications. Specifically, barriers for the development of patient-centered eHealth and AI in medicine in Vietnam were summarized, including the lack of national health databases, unstandardized data collection, and paper-based workflows. Importantly, most of the data analyzed in these 6 studies were collected in 2016 or earlier. The CDS performance and the EHR readiness assessments were conducted in the period from 2010 to 2014. The paper by Landgraf et al [32] was based on program reports from 2008 to 2016, whereas the review by Nguyen et al [29] provided insights into Vietnam eHealth before 2012. Discussions in the review by Vuong [34] were significantly carried out upon the analysis of the MoH annual reports from 2012 to 2016.

Table 2. Summary of the digital health domains and findings from academic publications.

Study	Digital health domain	Context in which the intervention was considered	Year of data collection or reviewed evidence[a]	Summary of findings relevant to digital health systems in hospitals in Vietnam
Vu et al [24]	Laboratory information system	Common laboratory test results in hospitals in Vietnam	2010 or earlier[b]	• Presented how a laboratory information system was designed to solve the paper-based laboratory result management.
Vu et al [25]	Hemodialysis management system	Hemodialysis systems in Vietnam's hospitals	2010 or earlier[b]	• A central management system for hemodialysis machines in 2 hospitals in Vietnam was designed and tested.
Hai et al [26]	Data acquisition from medical devices	Electronic medical equipment commonly used in Vietnamese hospitals	2011 or earlier[b]	• An engineering solution to automatically retrieve data from medical devices such as ultrasound, ECG[c], and laboratory devices for personal health records.
Vo et al [27]	A database of EMR[d] data	EMRs from hospitals in Vietnam	After 2019	• The lack of standardized EMR use among Vietnamese hospitals posed a challenge for data gathering and research. VNUMED is a database that aims to collect and standardize data from different EMR systems.
VO et al [28]	Data visualization for EMRs	Data in EMR from a Vietnamese hospital	Between 2015 and 2019[b]	• A data visualization app to track patient progress based on data collected from the local EMR system was developed and tested by the gerontologists as the end users. The testing results showed positive feedback from the end users regarding usability. The app was being updated for large-scale testing.
Nguyen et al [29]	Readiness for patient-centered eHealth	Health care in Vietnam before 2012	Before 2012	• Provided an overview of information technology applications in Vietnam's health care system from its beginning until 2011.
Lin et al [30]	CDS[e]	Physicians in hospitals	2010 to 2011	• The study provided evidence that CDS technologies can improve physicians' medical knowledge in the context of Vietnamese hospitals.

Hocwarter et al [31]	EHR readiness	Hospitals in Vietnam	2013	• Provided evidence on the core readiness to a national EHR including the following:
				  • Identification of needs for future changes that will be addressed by the EHR system.
				  • Challenges posed by the status quo that demanded an EHR system: the existing system of medical records; quality of the existing record-keeping practice; the numbering system for medical records; patient identification methods in medical records; use of daily admissions and discharge lists; medical record archiving after patient discharge; medical record preservation when in archive; practice of ICD-10[f] and use of ICD-10 in reality.
				  • Planning for the new EHR project by the Ministry of Health.
				• Integration of technology:
				  • Integration with the current services; plan to integrate the EHR system with the existing hospital information systems; use of health informatics standards; the use of defined interfaces or gateways in data exchange.

Landgraf et al [32]	Laboratory information system	Mainly district health centers and public health laboratories in provinces with a high prevalence of HIV	2008 to 2016	• Described the development, deployment, and operation of a national LIMS[g] project using an open-source LIMS. • Proposed factors for the sustainability of a health information system in Vietnam: (1) selection of appropriate technology, (2) capacity building and knowledge transfer, (3) financial viability, (4) leadership and management, and (5) alignment with national health strategies.

Study	Digital health domain	Context in which the intervention was considered	Year of data collection or reviewed evidence[a]	Summary of findings relevant to digital health systems in hospitals in Vietnam

Nguyen et al [33]	EHR readiness	A provincial hospital in Vietnam	2013 to 2014	• Provided evidence on EHR readiness in a Vietnamese provincial hospital, including the following:
				  • Core readiness: needs for change, planning, suitability of infrastructure, and integration of new technology with the existing services in the hospital.
				  • Technological readiness: need for information technology adoption and information technology infrastructure's capability to implement an EHR.
				  • Learning readiness: information technology training for hospital and implementation staff.
				• Societal readiness:
				  • Electronic communication with other organizations, data exchange between organizations, and sociocultural elements between health workers and patients.

Vuong et al [34]	Readiness for AI[h] in medicine	Health care of Vietnam	2012-2018 (mainly 2012-2016)	• Readiness for AI in medicine in Vietnam was assessed based on 3 factors: financial support, technological, and sociopolitical. In general, although AI in medicine research and political commitment was somewhat promising, the technical factor was seen as weak and inadequate.

[a]The period when primary data are collected or reviewed sources are published.

[b]On the basis of published year and reported grant period.

[c]ECG: electrocardiogram.

[d]EMR: electronic medical record.

[e]CDS: clinical decision support.

[f]ICD-10: International Classification of Diseases, Tenth Revision.

[g]LIMS: laboratory information management system.

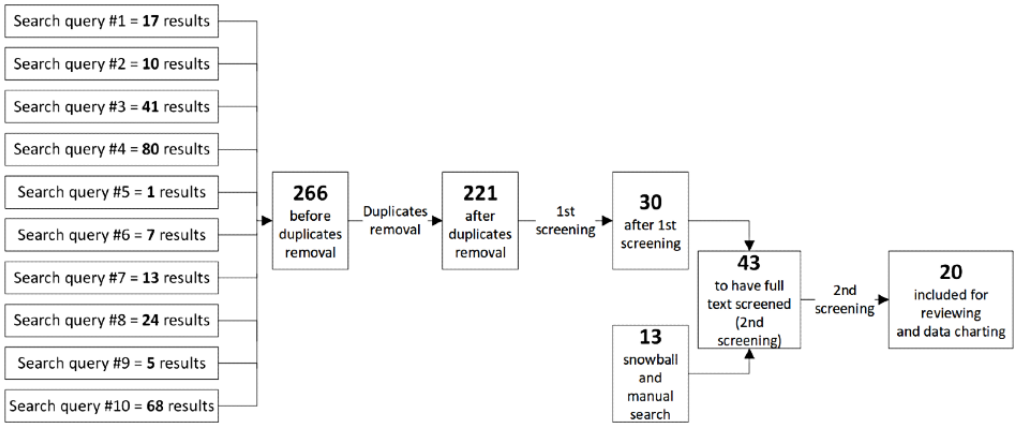
[h]AI: artificial intelligence.

Policies

Selection of Sources of Evidence

A total of 10 search queries on the *Th Vi n Pháp Lu t* database returned 266 results. After removing duplicate titles, there were 221 results remaining in the first screening round. In total, 30 articles were selected from this screening phase with 191 articles excluded for the following reasons: unrelated to HIS adoption (n=157), limited relevance to HIS adoption (n=13), not a policy or guidance document (n=5), expired (n=13), and documents whose contents are covered in an included policy (n=3; Figure 3). Manual scanning on the MoH's Electronic Health Administration website and snowballing from the reviewed documents helped identify 13 potential policies and guidance documents. Full text was screened for a total of 43 documents, which yielded 20 documents including for review and data charting.

Figure 3. Summary of government document selection.



Characteristics of Sources of Evidence

Table 3 presents an overview of the policies and guidance documents included. Characteristics of the documents were charted, including the enactment time points, policy ID numbers and titles, the digital health domains related to the policies, and the ministries that mandated the policies. Owing to the lengthy original titles, shorter denoted titles were created for easier reference of the documents in this paper.

Table 3. Summary of policy documents.

Valid from	Policy ID number and title	Denoted title	Domain	Ministry
December 2006	Decision 5573/QD-BYT year 2006 on Guideline for Hospital Information Management Systems [35]	The HIMS[a] Guidance	Hospital information management system	MoH[b]
June 2013	Decision 2035/QD-BYT year 2013 on Terminology Systems and Data Exchange Standards Recommended for Health IT[c] [36]	The Recommended Standards for HIT[d]	Standards for hospital information systems	MoH
October 2014	Decision 4159/QD-BYT year 2014 on Guidance on Ensuring Security of Electronic Health Data in the Health Sector [37]	The Cybersecurity Guidance	Cybersecurity in health organizations	MoH
March 2015 or January 2017[e]	Circular 53/2014/TT-BYT on Required Conditions for Provision of Health IT Activities [38]	The Required Conditions for HIT	Conditions for provision of health IT	MoH
October 2015	Decision 4495/QD-BYT year 2015 on Guideline for Developing Local Information Safety and Security Rules in Health Facilities [39]	The Guidance for Local Cybersecurity Policy	Cybersecurity in health organizations	MoH
October 2015	Decision 4494/QD-BYT year 2015 on Response Procedures for Information Safety and Security Issues in the Health Sector [40]	The Guidance for Cybersecurity Response	Cybersecurity in health organizations	MoH
September 2016	Decision 5004/QD-BYT year 2016 on The Architectural Framework of the Social Health Insurance Information System [41]	The Social Health Insurance EAF[f]	Electronic health insurance claim	MoH
June 2016	Decision 917/QD-BHXH year 2016 on Announcement of the Health Insurance Portal version 2 [42]	The Insurance Portal V2 Guidance	Electronic health insurance claim	Vietnam Social Security
September 2017	Decision 4210/QD-BYT year 2017 on Requirements for Standard and Format of Output Data Used in Management, Assessment and Reimbursement of Insurance-Paid Health Care Expenses [43]	The Claim Standardization Guidance	Electronic health insurance claim	MoH
August 2017	Decision 3725/QD-BYT year 2017 on Guidelines for Functionalities, Interoperability, Infrastructure and Human Resources for Establishing and Implementing Laboratory Information Systems at Healthcare Facilities [44]	The LIS[g] Guidance	LIS	MoH
February 2018	Circular 54/2017/TT-BYT on Assessment Criteria for Information Technology Implementation in Healthcare Facilities [45]	The HIT Maturity Model	HIT maturity	MoH
July 2018	Circular 39/2017/TT-BTTTT on Technical Standards for IT Implementation in State Organizations [46] (replaced circular 22/2013/TT-BTTTT)	The Recommended Standards for IT in State Organizations	Standards for IT applications in state organizations	MIC[h]
March 2018	Circular 48/2017/TT-BYT on Regulations on Data Exchange in Management and Reimbursement of Health Insurance Claims [47]	The Electronic Claim Regulations	Electronic health insurance claim	MoH
December 2018	Decision 7603/QD-BYT year 2018 on The Service Coding System for Healthcare Management and Health Insurance Reimbursement version 6 [48]	The Terminology and Service Coding System version 6	Electronic health insurance claim	MoH
October 2019	Decision 4888/QD-BYT year 2019 on The Smart Health IT Implementation and Development Scheme from 2019 to 2025 [49]	The Smart HIT Scheme	Digital health strategies	MoH
March 2019	Circular 46/2018/TT-BYT on Regulations for Electronic Medical Records [50]	The Regulations for EMRs[i]	EMRs	MoH
November 2019	Decision 5349/QD-BYT year 2019 on Implementation Plan for Electronic Health Record [51]	The EHR[j] Plan	EHRs	MoH
December 2019	Decision 6085/QD-BYT year 2019 on the eHealth Architectural Framework version 2.0 [52]	The EHAF[k] version 2	Architectural framework	MoH
December 2020	Decision 5316/QD-BYT year 2020 on The Digital Transformation in Health Care Scheme Until 2025 and Navigated Toward 2030 [53]	The Digital Transformation Scheme	Digital health strategies	MoH
May 2020	Decision 2153/QD-BYT year 2020 on Regulations on Creation, Utilization and Management of Health ID [54]	The Health ID Regulation	National health ID	MoH

[a]HIMS: Hospital Information Management System.

[b]MoH: Ministry of Health.

[c]IT: information technology.

[d]HIT: health information technology.

[e]March 2015 or January 2017: applicable since March 2015 for organizations that had not implemented any health information systems and since January 2017 for organizations that had implemented health information systems.

[f]EAF: electronic architecture framework.

[g]LIS: laboratory information system.

[h]MIC: Ministry of Information and Communications.

[i]EMR: electronic medical record.

[j]EHR: electronic health record.

[k]EHAF: eHealth architectural framework.

Results of Individual Sources of Evidence

A total of 20 government documents were combined into 11 groups based on the digital health domains or subjects that they addressed. These groups included hospital information management systems, general and interoperability standards, cybersecurity in health organizations, conditions for the provision of health IT, electronic health insurance claims, laboratory information systems (LISs), health IT (HIT) maturity, digital health strategies, EMRs, EHRs, and eHealth architectural framework (EHAF). Table 4 presents these policy groups and the main purpose of each policy. In the following section, we have summarized the policies and their objectives in chronological order.

Most of the digital health policies reviewed were released and came into effect after 2013, excluding the Hospital Information Management System (HIMS) Guidance, which was enacted in 2006. The HIMS Guidance was an instruction regarding the functionalities and standards for HIMS used in state health facilities [35]. In 2013, the MoH promulgated guidance for interoperability standards and terminology systems applicable for health information systems [36]. Some of these are mandatory such as the HL7 messaging version 2 or 3, Digital Imaging and Communications in Medicine, SDMX-HD (Statistical Data and Metadata Exchange–Health Domain), and International Classification of Diseases, Tenth Revision (ICD-10) Clinical Modification, whereas the others are recommended, including the HL7 Clinical Document Architecture, HL7 Continuity of Care Document, World Health Organization Anatomical Therapeutic Chemical, and Logical Observation Identifiers Names and Codes. Standards for general IT applications are guided by the Ministry of Information and Communications (MIC) [46].

The 3 Cybersecurity Guidance documents for state health organizations were published in 2014 and 2015. The Cybersecurity Guidance covers 16 components of an IT system in a health organization such as network, databases, applications, account management, and data transmission [37]. As organizations using IT systems are required to develop and implement their own cybersecurity policy, the Guidance for Local Cybersecurity Policy provides general instructions for the making of these local policies [39]. Finally, the Guidance for Cybersecurity Response is a standard procedure to identify, classify, report, and handle cybersecurity issues in health facilities [40]. In March 2015, the Required Conditions for HIT announced the essential criteria that organizations must meet when implementing HIT in Vietnam [38]. Accordingly, organizations must satisfy specific requirements for IT infrastructure, information security, IT workforce, and implementation of several technologies.

In 2016 and 2017, the MoH and the Vietnam Social Security (VSS) initiated the electronic social health insurance claim system, which was accompanied by the promulgation of several regulations and guidance. First, the Social Health Insurance Electronic Architectural Framework was published, describing the system's structure and operation [41]. A web-based portal was established, on which health providers can submit claims and check insurance information. To provide instructions for health facilities on using the portal, the VSS published the Insurance Portal V2 Guidance [42]. As claim data must be collected and formatted in a standardized manner, the Claim Standardization Guidance is intended to provide the necessary instructions for health facilities on claim preparation [43]. The Vietnam social health insurance system uses a national terminology and service coding system to form billing codes from medical documentation. In 2018, this coding system was in its sixth iteration [48]. Finally, the Electronic Claim Regulations defines the responsibilities of health providers and insurance agencies surrounding claim sharing and feedback [47].

Table 4. Main purposes of the policies.

Group of domains and denoted title	Purpose of the document	Valid from
Hospital information management system		
The HIMS[a] Guidance	A guidance for functionalities and standards of HIMSs	December 2006
General and interoperability standards		
The Recommended Standards for HIT[b]	A list of nomenclature systems and interoperability standards that the MoH[c] required or recommended for health information systems	June 2013
The Recommended Standards for IT[d] in State Organizations	A list of general IT standards that the MIC[e] required or recommended for health information systems	July 2018
Cybersecurity in health organizations		
The Cybersecurity Guidance	A comprehensive guidance of cybersecurity measures for health facilities	October 2014
The Guidance for Local Cybersecurity Policy	A guideline for developing organization information safety and security policies for health facilities	October 2015
The Guidance for Cybersecurity Response	A guidance for classifying, identifying, reporting, and handling cybersecurity issues in health facilities	October 2015
Conditions for provision of health IT		
The Required Conditions for HIT	Criteria that health facilities must satisfy when implementing digital health systems. Four areas addressed in the circular include IT infrastructure, information security, human resource, and specific criteria for some HIT systems	March 2015 or January 2017
eHealth insurance claim		
The Social Health Insurance EAF[f]	Explaining the architecture model for the social health insurance information system to be built by the MoH	September 2016
The Insurance Portal V2 Guidance	Announcing the launching of the Health Insurance Portal version 2 with an installation manual attached	June 2016
The Claim Standardization Guidance	A guidance for standardization of claims data including variable definition and data standards	September 2017
The Electronic Claim Regulations	Responsibilities of the health care organizations and the insurance agencies in electronic claim exchange and investigation	March 2018
The Terminology and Service Coding System version 6	A common list of health services with the relevant codes used in the social health insurance claim and reimbursement, updated to version 6	December 2018
LIS[g]		
The LIS Guidance	A guidance for functionalities and standards of LISs	August 2017
HIT maturity		
The HIT Maturity Model	Seven levels of HIT application applicable for health care organizations, made of 8 key components and capabilities. Criteria for each HIT level and component were provided herein.	February 2018
Digital health strategies		
The Smart HIT Scheme	Presenting the agenda to develop and implement digital and smart technologies in Vietnam's health care for the period from 2019 to 2025	October 2019
The Digital Transformation Scheme	Presenting the agenda to comprehensively implement IT in Vietnam's health care until 2025 and navigated toward 2030	December 2020
EMRs[h]		
The Regulations for EMRs	Criteria for EMR development and implementation to abide by Health Care Law and replace paper medical records	March 2019
EHR[i]		
The EHR plan	The national plan of the MoH to build and implement the EHR system in Vietnam	November 2019
The Health ID Regulation	The health ID system used for eHealth data of Vietnamese residents	May 2020
Architectural framework		

Group of domains and denoted title	Purpose of the document	Valid from
The EHAF[j] version 2	Explaining the architecture model of key IT systems and databases built by the MoH	December 19

[a]HIMS: health information management system.

[b]HIT: health information technology.

[c]MoH: Ministry of Health.

[d]IT: information technology.

[e]MIC: Ministry of Information and Communications.

[f]EAF: electronic architectural framework.

[g]LIS: laboratory information system.

[h]EMR: electronic medical record.

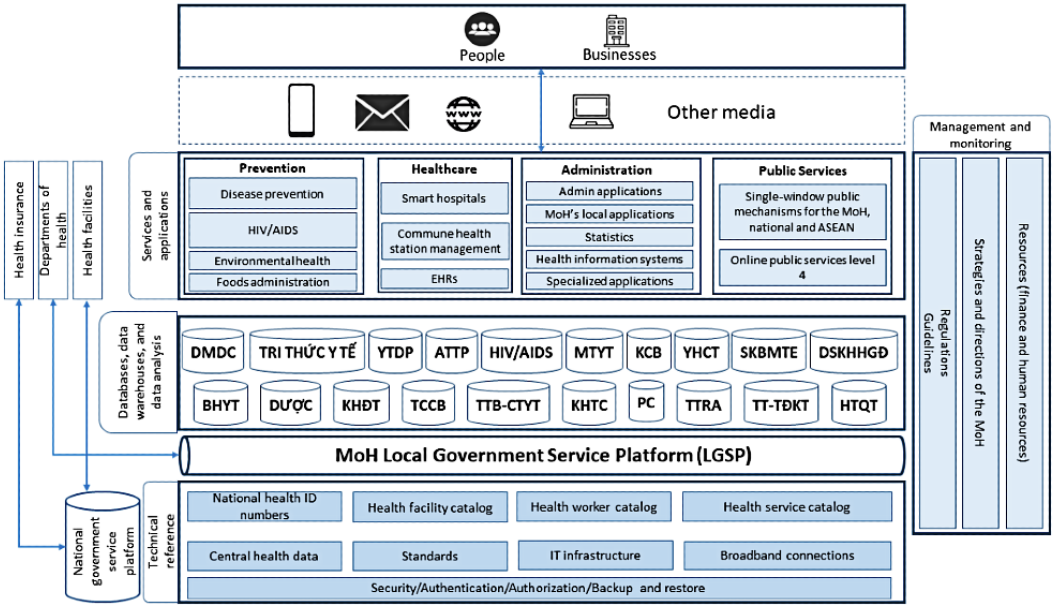
[i]EHR: electronic health record.

[j]EHAF: eHealth architectural framework.

Guidance for LISs was published in August 2017, addressing the functionalities and standards required for such systems in Vietnam [44]. From 2018 to 2020, the MoH issued several policies that govern key digital health systems such as the maturity model for HIT, EMRs, and EHRs. From February 2018, the *HIT Maturity Model* began to be used as a roadmap for health care organizations to build and upgrade their digital health system [45]. Similar to the Healthcare Information and Management Systems Society's Analytics Electronic Medical Record Adoption Model [55], this maturity model features 7 levels of HIT application, each of which is built on a specific set of criteria. The most basic level (level 1) only requires the implementation of HISs to manage outpatient services, whereas the highest level (level 7) defines a paperless environment that deploys a comprehensive range of HIT such as HIS, EMR, LIS, radiology information system and picture archiving and communication systems (RIS-PACS), and CDSS with interoperability between the systems. EMR adoption is governed by the *Regulations for EMRs*, enacted in March 2019 [50]. The circular sets out the requirements for EMRs so that their use abides by Health Care Law and is eligible to completely replace paper medical records. In the same year, the MoH announced a plan to roll out EHRs on a nationwide scale, starting in municipal cities [51]. Although EMRs serve inpatient care and can vary in their specifications depending on the specialty in which they are implemented, the EHR system can be seen as the digital version of the paper-based primary health record [56] and is a lifetime health document of every Vietnamese resident. Information in EHRs is mainly collected and updated by the district health facilities and outpatient clinics. The MoH has also announced the National Health ID system in the Health ID Regulation [54], in which each health ID number is unique and represents an individual for their lifetime.

An overall picture of the IT systems that the MoH has been developing is depicted in their EHAF, presented in Figure 4 (adapted from the Vietnam MoH [52]). The framework was first published in 2015 [57] and subsequently updated in 2018 [58] and 2019 with the EHAF version 2 [52]. According to the EHAF version 2, EMRs and EHRs are the 2 main components of the health care building block. In 2019, the MoH announced the Smart HIT Scheme, presenting an agenda to develop and implement digital and smart technologies in Vietnam's health care for the period from 2019 to 2025 [49]. By the end of 2020, the Digital Transformation Scheme was published, setting the goals to implement IT in multiple areas of the health sector including state administration, cashless payment and telehealth, disease prevention and primary care, and health care [53].

Figure 4. The Ministry of Health's eHealth Architecture Framework version 2.0 (adapted from the Vietnam Ministry of Health [52]). The following are English translations for the abbreviations—ATTP: food safety; BHYT: health insurance; DMDC: reference catalogs; DSKHHGD: population planning; D C: pharmacy; HTQT: international collaboration; KCB: health care; KHĐT: research and training; KHTC: finance; MTYT: environmental health; PC: legislation; SKBMTE: maternal and child health; Tri th c y t : health knowledge; TCCB: human resources; TTB-CTYT: medical devices and infrastructure; TTRA: inspection; TT-TĐKT: reward; YHCT: traditional medicine; YTDP: preventive medicine. EHR: electronic health record; IT: information technology; MoH: Ministry of Health.



Details of Included Policies

In the subsequent sections, we have expanded on the key policies in each digital health domain.

Architectural Framework: The EHAF Version 2

The framework is intended to guide the future developments of eHealth in the public sector, ensuring their compatibility with the current components and directed toward common goals.

The EHAF version 2.0 (decision 6085/QD-BYT year 2019 on the eHealth Architectural Framework Version 2.0 [52]) has 7 layers including the following:

1. End users (people and businesses)
2. Communication channels (means to communicate with applications and services of the MoH such as computers, smartphones, and information portals)
3. Services and applications layer. This layer comprises 4 building blocks including disease prevention, health care, administration, and public services
4. Databases and data analysis tools layer. This includes multiple databases specialized for each health area managed by the MoH, for example, traditional medicine, pharmacy, and health insurance
5. The MoH's Local Government Service Platform. This platform provides shared supporting services for the upper layers. The MoH's Local Government Service Platform is also able to communicate with other ministries and provinces through the National Government Service Platform
6. Technological infrastructure layer
7. Management and monitoring layer

An illustration of the EHAF version 2.0 can be found in Figure 4 (adapted from the Vietnam MoH [52]).

Digital Health Strategies

The Smart HIT Scheme

The Smart HIT Scheme (decision 4888/QD-BYT year 2019 on the Smart HIT Implementation and Development Scheme from 2019 to 2025 [49]) seeks to use digital health, particularly smart technology, in Vietnamese health care. The scheme highlighted the Industrial Revolution 4.0 concept and the technologies characterizing this era, for example, big data, AI, and the internet of things. Following the intention of the Vietnamese government to take advantage of this revolution, the scheme points out the readiness of Vietnam's health system for implementing digital health technologies along with the impact that these technologies can have on the health system. Finally, the scheme presents an agenda to promote and implement digital and smart health IT in Vietnam. The information relevant to the scope of this study is summarized in the subsequent sections.

The scheme aims to *implement and develop digital health and smart health technologies for a modern, high-quality, equitable, efficient, and internationally integrated health system* and *to promote residents' access to health information so that they can use a highly efficient health service and have their health continuously protected, taken care of, and promoted during their lifetime*. The following goals are specified:

1. Developing a smart health care and disease prevention system
2. Promoting IT implementation in health facilities for administrative process improvement and reducing hospital overload: adopting EMRs to replace paper records, using a cashless payment system for hospital billings, and establishing smart hospitals
3. Promoting IT implementation in health administration: installing the electronic office system, public portals, and

single-window information system of administrative procedures, promoting level 3 and level 4 web-based public service, building a smart health administration

To achieve these goals, the scheme proposes 9 areas of action from 2019 to 2025, including the following:

1. Building the regulatory framework, guidance, standards, and economic–technical norms
2. Building the health IT infrastructure
3. Building a smart health care and disease prevention system
4. Building a smart health care system
5. Building a smart health administration system
6. Developing the workforce
7. Promoting smart health IT research, development, and implementation
8. International cooperation
9. Educating the public's awareness of smart health care

In the scope of this study, we presented the detailed agenda of area 1—building the regulatory framework, guidance, standards, and economic–technical norms—and area 4, building a smart health care system (Textboxes 2 and 3).

Textbox 2. Area 1 of the Smart Health Information Technology Scheme: building the regulatory framework, guidance, standards, and economic–technical norms.

Area 1 of the Smart Health Information Technology Scheme

- Building eHealth architecture framework as a prerequisite for information technology implementation in the health system
- Developing regulations for the resident health ID system
- Developing standards for interoperability between health information technology (HIT) systems, that is, health station management software, electronic medical records, and electronic health records (EHRs)
- Developing economic–technical norms for HIT, in which HIT costs are a part of the total health service cost
- Building policy for managing and using electronic nomenclature and coding systems in the health system
- Building policy for using EHRs
- Developing regulations for cybersecurity and privacy protection for health information in the web-based environment
- Building human resource policies for HIT specialists

Textbox 3. Area 4 of the Smart Health Information Technology Scheme: Building a Smart Health Care System.

Area 4 of the Smart Health Information Technology Scheme

- Updating the management software and digital health systems in hospitals:
  - Develop health information systems that adhere to the national and international standards, in which interoperability between the information systems and between the information system and the digital devices (lab devices, imaging diagnosis devices, interactive screens, personal mobile devices, etc) is ensured
  - Standardizing the National Health ID system
  - Building smart hospitals—health care organizations consult the Health Information Technology Maturity Model to develop their smart hospital roadmap
- Electronic medical records (EMRs) are implemented in all health care organizations according to the EMR rollout timeline in circular 46/2018/TT-BYT on the *Regulations for EMRs*, aiming for paperless medical records and cashless payments in hospitals
- Establishing and scaling up information kiosks in hospitals
- Promoting artificial intelligence (AI) application in health care with the following priorities:
  - Building interoperability standards to implement the Internet of Medical Things as an infrastructure to operate clinical decision support systems (CDSSs)
  - Developing real-time CDSSs closely integrated with EMRs
  - Imaging diagnosis assistance
  - Surgery assistance
  - Encouraging businesses and health care organizations to build big data systems embedded with AI algorithm to support clinical decision-making
  - Disease diagnosis, treatment, and prevention with traditional medicines
  - Applying AI in specialties such as imaging diagnosis, cardiovascular diseases, respiratory diseases, orthopedics, cancer, obstetrics, and pediatrics

The Digital Transformation Scheme

The Digital Transformation Scheme (decision 5316/QD-BYT year 2020—The Digital Transformation in Health Care Scheme until 2025 and navigated toward 2030 [53]) seeks to implement IT in all aspects of health care as it defines digital transformation in health care as *the comprehensive application of information technology which prioritizes the cutting-edge digital technology that can make positive changes in all aspects of health care.*

The key 4 areas addressed in this scheme are state administration, cashless payment and telehealth, disease prevention and primary care, and health care. In the health care area, the scheme aims for 15% (210/1400) and 50% (700/1400) of hospitals in the country to successfully adopt paperless EMRs and cashless payment by 2025 and 2030, respectively.

Textbox 4 summarizes the areas and subareas of action set out in the scheme.

Area 5 (digital transformation in primary care and disease prevention) and area 6 (digital transformation in hospitals) are considered priorities over the others. We present details of area 1.2 (Textbox 5) and area 6 in subsequent sections.

Area 6, ie, Digital Transformation in Hospitals is largely similar to area 4 (building a smart health care system) of the Smart HIT Scheme. A comparison between these is shown in Table 5.

Textbox 4. Summary of areas of action in the Digital Transformation Scheme.

Areas of action

- Area 1: infrastructure development
  - Area 1.1: awareness education
  - Area 1.2: building the regulatory framework, guidance, standards, and economic–technical norms
  - Area 1.3: building and upgrading the information technology infrastructure
  - Area 1.4: building health databases
  - Area 1.5: building digital health platforms
  - Area 1.6: ensuring cybersecurity
  - Area 1.7: international cooperation, research, and innovations in digital health
  - Area 1.8: workforce development
- Area 2: implementing information technology in administration and public services
- Area 3: promoting investments in digital health from businesses and hospitals
- Area 4: digitalization in societies
- Area 5: digital transformation in primary care and disease prevention
- Area 6: digital transformation in hospitals

Textbox 5. Area 1.2 of the Digital Transformation Scheme: building the regulatory framework, guidance, standards, and economic–technical norms.

Area 1.2 of the Digital Transformation Scheme

- Publishing regulations and guidance for doing trials of novel digital health products; developing digital health platforms
- Developing regulations and standards for data exchange and interoperability between health information systems based on international standards
- Developing regulations for collecting and managing health data; building a decree for the national health database
- Providing guidance for digital health technologies; updating guidance for building smart hospitals and paperless hospitals
- Developing regulations for protecting security, safety, and confidentiality of health data in the web-based environment
- Developing regulations and guidance for electronic authentication in health care
- Implementing and updating the MoH's e-government structure
- Developing financial mechanisms for health IT services as part of the overall health care service and mechanisms for hiring health IT services
- Developing policies and regulations for telemedicine and e-prescription so that patients can use remote health care services

Table 5. Comparing area 4 (decision 4888/QD-BYT year 2019) and area 6 (decision 5316/QD-BYT year 2020).

Category	Area 4 of the smart HIT[a] scheme	Area 6 of the Digital Transformation Scheme
Updating management software and digital health systems in hospitals	Yes[b]	Yes
Standardizing the National Health ID system	Yes	Yes
Building smart hospitals based on circular 54/2017/TT-BYT	Yes	Yes
EMR[c] implementation based on circular 46/2018/TT-BYT	Yes	Yes
Building information kiosks	Yes	No
Promoting AI[d] application in health care	Yes	Yes
Conducting telehealth and web-based registration based on decision 2628/QD-BYT year 2020	No[e]	Yes
Implementing the national prescription management system in all health care organizations	No	Yes

[a]HIT: health information technology.

[b]The information was addressed in the document.

[c]EMR: electronic medical record.

[d]AI: artificial intelligence.

[e]The information was not addressed in the document.

EMRs: The Regulations for EMRs

EMR refers to the clinical record system used in hospitals' inpatient departments. They are locally managed by health care institutions and different from the EHR system, which is centrally managed on the national database and intended for use by the commune health facilities and outpatient clinics (circular 46/2018/TT-BYT on *Regulations for EMRs* [50]).

This circular is the first official guidance for EMRs in public health care facilities. It ensures that the use of EMRs can uphold the equivalent law and can legitimately replace paper-based medical records. Health care organizations are eligible to discontinue paper-based medical record–keeping if they can satisfy all the criteria in this circular, which concern the following areas:

1. Content specifications
2. EMR creation and update
3. Storage and backup
4. Access right and secondary use
5. Patient identification
6. Digital or electronic signatures
7. Basic functionalities
8. Adherence to interoperability and IT standards
9. Data security and confidentiality
10. Nomenclature system

A total of 4 essential criteria that must be prioritized are as follows:

- Each patient's EMR is provided with an ID number that is unique in the health organization.
- All information that a traditional medical record collects can also be recorded by EMRs.
- Each EMR must have a digital signature of the one who is responsible for the information entered in that record.
- Data stored in an EMR system are protected by Section 2, Article II of Cyber information Security Law [59].

In addition, the circular also provides the criteria for paperless lab test and imaging diagnosis management with LIS and picture archiving and communication system. Full details of this document can be found in Multimedia Appendix 2.

HIT Maturity: The HIT Maturity Model

Overview

The MoH put into effect the *HIT Maturity Model* (circular 54/2017/TT-BYT on Assessment Criteria for IT Implementation in Health Care Facilities [45]) as a roadmap for HIT implementation in health care facilities. Health care organizations are required to evaluate their current HIT maturity using this model and report the evaluation results to the MoH. The baseline results are a requisite for health care organizations to set goals for their next maturity level. An overall HIT maturity level depends on the maturity level of the individual domains, which are as follows:

1. IT infrastructure
2. Administration and operation software
3. HIS
4. RIS-PACS
5. LIS
6. Nonfunctionality standards
7. Security and information safety
8. EMR

In addition, there are specific capabilities that are required for each maturity level. An organization's overall HIT maturity can range from *HIT level 1* to *HIT level7*.

There are 7 levels (1 to 7) applicable for the IT infrastructure domain and the HIS domain, and 2 levels (basic and advanced) applicable for the other domains (administration and operation software, LIS, nonfunctionality standards, security and information safety, RIS-PACS, and EMRs). The 7 levels of HIT maturity are summarized in subsequent sections. An overview of all the 7 levels can be found in Table 6.

Table 6. Levels of health information technology (HIT) maturity.

	Information technology infrastructure	HIS[a]	LIS[b]	RIS-PACS[c]	EMR[d]	Administration and operation software	Security and information safety	Nonfunctionality criteria	Extra capabilities
HIT level 7	Level 7	Level 7	Advanced	Advanced	Advanced	Advanced	Advanced	Advanced	• "Paperless" hospital if all relevant criteria are met • CDSS[e] level 3 supporting doctors' decisions related to treatment protocols and treatment results using suitably customized templates • Data in CDR[f] is analyzed to improve care quality, patient safety, and care efficiency • Clinical data can be readily shared for stakeholders in care coordination based on HL7[g] standards • Continuous reports of hospital services using the data collected
HIT level 6 (smart hospital)	Level 6	Level 6	Advanced	Advanced	Basic	Advanced	Advanced	Advanced	• CDSS level 2 providing: evidence-based warnings for treatment; that is, health and medicine advice, drug information and interaction check, and initial order and prescription violation identification rules • All structured forms; that is, progress notes, consultation notes, problem lists, and discharge summaries are digitalized • Closed-loop management of drugs, using identification technologies to assist drug administration
HIT level 5	Level 5	Level 5	Advanced	Advanced	N/A[h]	Basic	Basic	Basic	• PACS[i] can replace physical films
HIT level 4	Level 4	Level 4	Advanced	Basic	N/A	Basic	Basic	Basic	• PACS allows doctors to access images outside the imaging department • Electronic ordering • Electronic management of inpatient orders
HIT level 3	Level 3	Level 3	Basic	N/A	N/A	Basic	Basic	Basic	• Electronic records having digital vital sign records, nursing notes, medical procedures, and surgical procedures are stored in CDR • CDSS level 1 assisting electronic prescription (new or historic prescription) • Pharmacy information available in the hospital network and supported with CDSS
HIT level 2	Level 2	Level 2	N/A	N/A	N/A	N/A	N/A	N/A	• A CDR consisting of normenclature and coding systems, pharmacy, orders, and test results (if available) • Data in CDR can be shared between stakeholders for care coordination

	Information technology infrastructure	HIS[a]	LIS[b]	RIS-PACS[c]	EMR[d]	Administration and operation software	Security and information safety	Nonfunctionality criteria	Extra capabilities
HIT level 1	Level 1	Level 1	N/A	N/A	N/A	N/A	N/A	N/A	• Patient's information can be accessed electronically

[a]HIS: hospital information system.

[b]LIS: laboratory information system.

[c]RIS-PACS: radiology information system-picture archiving and communication system.

[d]EMR: electronic medical record.

[e]CDSS: clinical decision support system.

[f]CDR: clinical data repository.

[g]HL7: Health Level 7.

[h]N/A: not applicable.

[i]PACS: picture archiving and communication systems.

HIT Level 1

HIT level 1 includes level 1 of IT infrastructure and level 1 of HIS, which aims to provide electronic access to patient data. This IT infrastructure level essentially requires workstation computers, a local area network, and an internet connection while HIS manages outpatient and pharmacy data, and sends claim data to the health insurance claim system. Adoption of MoH's terminology and service coding system is compulsory.

HIT Level 2

HIT level 2 is an upgrade of IT infrastructure and HIS from level 1 to level 2. This will add to the pre-existing system a dedicated server and the laboratory modules that manage laboratory orders and results. HIT level 2 particularly aims at building a clinical data repository (CDR) of pharmacy data, laboratory orders, test results, and the terminology and service coding system. Data in the CDR can be accessed by multiple stakeholders engaging in patient care.

HIT Level 3

HIT level 3 requires an upgrade of IT infrastructure and HIS from level 2 to level 3. Added components include LIS, administrative applications, and cybersecurity solutions at a *basic* level. At this level, more security and storage infrastructures are provided, including firewall devices, security solutions, and specialized storage. CDR capacity is increased to cover vital sign data, nurse notes, and medical procedures. Health care organizations would start implementing CDSS level 1 to assist doctors with drug information via the facility's intranet.

HIT Level 4

HIT level 4 comprises level 4 IT infrastructure, level 4 HIS, advanced LIS, and a basic level of RIS-PACS, administration and operations software, cybersecurity, and nonfunctional standards. Organizations at this HIT level can manage their imaging diagnosis data electronically using RIS-PACS. Although a basic RIS-PACS has yet to discontinue physical film archiving [50], it offers essential functionalities such as integration with imaging diagnosis machines and HISs, digital image viewing, and measurement. An advanced LIS can manage test samples and supplies, integrate with the HIS, and send out alerts for abnormal test values. A storage network (a storage area network or a network-attached storage), a queue management system with display screens, will complement the IT infrastructure. Outpatient orders from doctors can be made electronically, whereas all inpatient orders will be managed in the digital system.

HIT Level 5

HIT level 5 differs from HIT level 4 in level 5 IT infrastructure, level 5 HIS, and *advanced RIS-PACS*. The advanced level of RIS-PACS is able to conduct multi-site consultation, allowing images to be viewed on multiple devices such as laptops and mobile phones. Furthermore, the *Regulations for EMRs* allow paperless image management if health care facilities have *advanced RIS-PACS* with an eligible storage capacity [50]. At level 5, HISs can manage emergency rooms, operating theaters, appointments, and follow-ups and can integrate electronic patient card.

HIT Level 6

Transitioning from HIT level 5 to HIT level 6 requires organizations to implement a *basic* EMR system in addition to upgrading their IT infrastructure, HIS, administration and operation software, security and data safety, CDSS, drug management, and nonfunctional standards to an *advanced* level. Hospitals qualified for HIT level 6 or higher are certified as a *smart hospital*. The basic EMR system provides inpatient medical records and can integrate with other clinical information systems. Mobile devices working on wireless local area network, hospital security cameras, and backup storage systems are needed to meet level 6 IT infrastructure.

Hospitals at HIT level 6 can receive and use data from multiple information systems such as drug information and interactions, treatment protocols, and nutrition. Clinical information can be accessed via mobile devices. In addition, HIT level 6 features several extra capabilities including a level 2 CDSS, a safe medicine management procedure, and increased digitalization of clinical documents. Level 2 CDSSs can warn doctors of drug interactions and potential treatment risks based on the most updated evidence. The medicine management system provides a closed and automatic medicine management procedure using automated dispensing systems and digital identification devices,

for example, barcodes and radio frequency identification. All structured clinical forms such as progress reports, consultation notes, problem lists, and discharge summaries are digitized.

HIT Level 7

At HIT level 7, all 8 domains are at their highest level. Organizations are now equipped with information kiosks and network monitoring systems. A level 7 HIS provides functionalities to manage EMRs, professional procedures, control information kiosks, and support cashless payment. EMR systems at the *advanced* level have dedicated functionalities to manage medical records including increased storage duration, syncing records, and restoring records. Data stored in the EMR system are better protected and can be exchanged under international standards such as HL7. According to the *Regulations for EMRs* [50], an *advanced* EMR system with qualified storage capacity is eligible to replace the paper-based medical record system. Data from CDR are analyzed to improve quality of care, patient safety, and service efficiency. Insights for operational activities can be continuously generated to inform hospital departments such as inpatient, outpatient, and emergency departments. Organizations at this HIT level can exchange data using HL7 standards. Finally, level 3 CDSSs can support a wider range of diagnosis and treatment decisions (Table 6).

Conditions for Provision of Health IT: The Required Conditions for HIT

The Required Conditions for HIT (circular 53/2014/TT-BYT on Required conditions for provision of health IT activities [38]) can be seen as a summary of the criteria that health care facilities need to satisfy when implementing eHealth systems.

This circular announces the conditions and requirements that health care facilities operating in Vietnam must abide by when implementing and operating health IT systems. Health IT activities, as defined in the circular, involve *providing, transferring, collecting, analysing, storing and exchanging health care data through the IT infrastructure*. The conditions specify 4 areas related to health IT implementation: IT infrastructure, information security, human resource, and operational requirements (Multimedia Appendix 3).

General and Interoperability Standards

This group included 2 guidance documents, one from the MIC and one from the MoH. Although the former addressed the general technical standards that IT applications in state organizations need to adopt, the latter revolved around the national and international standards targeted at health information systems.

The Recommended Standards for HIT

In June 2013, the MoH published decision 2035/QD-BYT (year 2013—Terminology systems and data exchange standards recommended for health IT [36]) recognizing the terminology systems and technical standards applicable for health IT systems. Some terminologies and standards are required, whereas others are recommended for adoption in public health care organizations. It is strongly advised in the decision that all public facilities should adopt these systems, and information systems not matching them should plan for relevant transitions. Table 7 presents the standards and nomenclature systems recommended in the decision.

In addition to the standards, the MoH instructs IT systems in the health sector to follow other relevant IT standards from the MIC that were addressed in circular 01/2011/TT-BTTTT, which was then replaced by the new version, circular 22/2013/TT-BTTTT.

Table 7. Standards and nomenclature systems for health information technology systems.

Categories and standard names	Reference	Guidance
Administrative nomenclature		
The list of official administrative units in Vietnam	Decision 124/2004/QD-TTg year 2004 and its amendments	Compulsory
The list of ethnic groups in Vietnam	Decision121-TCTK/PPCD year 2004 and its amendments	Compulsory
The list of occupations in Vietnam	Decision 114/1998/QD-TCTK year 1998 and its amendments	Compulsory
International classification and coding for diseases and medical services		
ICD-10-CM[a]	WHO[b]	Compulsory
ICD-O-3[c]	WHO	Recommended
ICD-10-PCS[d]	WHO	Recommended
ATC[e]	WHO	Recommended
LOINC[f]	Regenstrief Institute	Recommended
International interoperability standards		
Health Level 7 messaging version 2.x or 3.0	Health Level 7	Compulsory
DICOM[g] version 2.0	The National Electrical Manufacturers Association	Compulsory
SDMX-HD[h]	WHO	Compulsory
HL7 CDA[i]	Health Level 7	Recommended
HL7 CCD[j]	Health Level 7	Recommended
ELINCS[k]	The California HealthCare Foundation	Recommended

[a]ICD-10-CM: International Classification of Diseases, Tenth Revision, Clinical Modification.

[b]WHO: World Health Organization.

[c]ICD-O-3: International Classification of Diseases for Oncology, Third edition.

[d]ICD-10-PCS: International Classification of Diseases, Tenth Revision, Procedure Coding System.

[e]ATC: Anatomical Therapeutic Chemical.

[f]LOINC: Logical Observation Identifiers Names and Codes.

[g]DICOM: Digital Imaging and Communications in Medicine.

[h]SDMX-HD: Statistical Data and Metadata eXchange–Health Domain.

[i]HL7 CDA: Health Level 7 Clinical Document Architecture.

[j]HL7 CCD: Health Level 7 Continuity of Care Document.

[k]ELINCS: EHR-Lab Interoperability and Connectivity Specification.

The Recommended Standards for IT in State Organizations

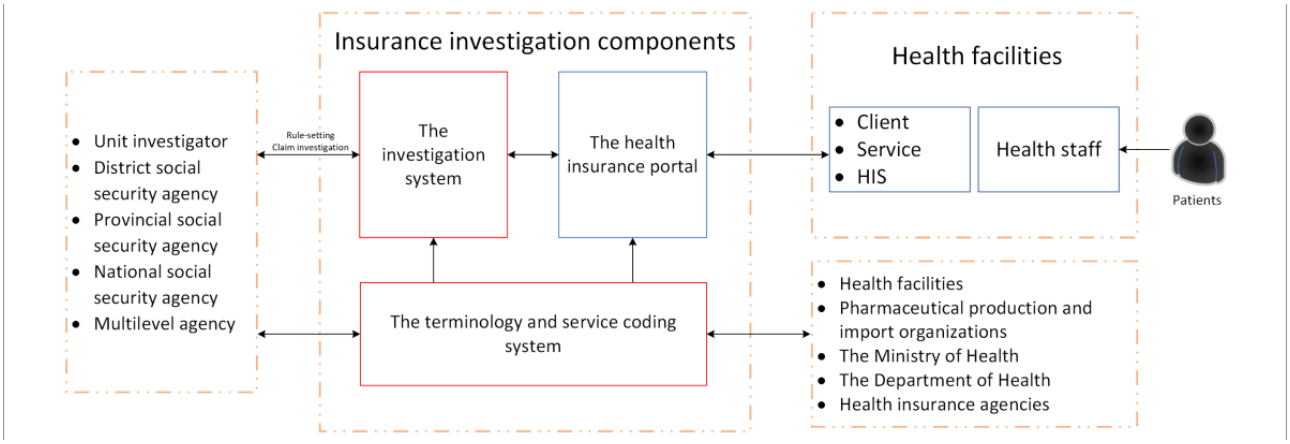
The MIC released circular 39/2017/TT-BTTTT (Technical Standards for IT Implementation in State Organizations [46]) as guidance for the adoption of technical IT standards in state organizations. Its first version is circular 22/2013/TT-BTTTT, released in 2013. The circular advises on 5 categories of standards such as connection, data integration, information access, information security, and public key infrastructure. The MIC encourages systems currently not adopting the standards in this circular to carry out transitions by July 2018. A detailed list of the standards is shown in Multimedia Appendix 4.

Electronic Health Insurance Claim

The Insurance Portal V2 Guidance

Decision 917/QD-BHXH year 2016 (Announcement of the health insurance portal version 2 [42]) from the VSS announces the health insurance portal version 2 and provides detailed guidelines on connection configuration and structuring data sets. The guideline is intended for use by health care facilities and provincial health insurance agencies who are responsible for regular data upload to the portal. The VSS health insurance claim and investigation structure are presented in Figure 5.

Figure 5. The Vietnam Social Security health insurance and investigation structure. HIS: health information system.



The guideline demonstrates 3 protocols that claim data can be submitted, each of which is accompanied by detailed instructions such as setting up connections, properly formatting data, and uploading data to the portal:

- Via web service connection—supports a variety of data submission including clinical data, service validation, monthly reports, health insurance ID checking, examination history, and referral receipt from other facilities.
- Data sync from client software—supports syncing clinical data to the system.
- Direct data entry on the portal—supports clinical data entry to the system.

The portal also offers functionalities for checking health insurance account information, viewing information of previous hospital visits, and checking referral documents between health care facilities.

The Electronic Claim Regulations

The MoH-mandated circular 48/2017/TT-BYT (Regulations on data exchange in management and reimbursement of health insurance claims [47]) as an official regulatory document for web-based health insurance claims and investigation for health care organizations. The circular essentially articulates the responsibilities of health care facilities and the health insurance agency as well as relevant rules in sending data and follow-ups. The fundamental technical requirements previously described in the VSS's guidelines are also outlined in the document (Multimedia Appendix 5).

The Claim Standardization Guidance

The health insurance portal requires claim data to be formatted as XML, encoded with Unicode Transformation Format–8-bit (UTF-8), and relevant data sets to be standardized for efficient management and assessment. To support organizations in preparing claim data, the MoH has delivered data formatting guides and continuously updated them. The latest release is found in decision 4210/QD-BYT year 2017 (Requirements for standard and format of output data used in management, investigation and reimbursement of insurance-paid health care expenses [43]). Claims for groups of health services are recorded into separate data sets. Data sets from the same patient are linked through a unique ID number coded as *MA_LK*. The instructions include data item, data type, the allowed maximum length, and guidance for data collection.

The scope of the document is as follows:

- Guidance for claims of general health services
- Guidance for claims of medications
- Guidance for claims of medical procedures and supplies
- Guidance for claims of imaging diagnosis and laboratory test services
- Guidance for claims of follow-up interventions
- The official groups of services by cost
- The official hospital department codes
- The official accident and injury codes
- The official medicine bid packages and package codes

The Terminology and Service Coding System Version 6

The Service Coding System for Health Care Management and Health Insurance Reimbursement (decision 7603/QD-BYT year 2018 on the Service Coding System for Health Care Management and Health Insurance Reimbursement version 6 [48]), or the terminology and service coding system, was first piloted in 3 cities in Vietnam in 2015 [60]. Since then, it has been continuously updated, with version 6 [48] being the most up-to-date. The system features nomenclatures of health services, their standardized codes, regulated prices, and the ICD-10 codes with Vietnamese instruction. The terminology and service coding system has been made compulsory for use in health information systems of state health facilities and web-based health insurance claim activities. The 11 nomenclature groups provided in version 6 are as follows:

- Technical service codes
- Department codes
- Inpatient bed codes
- Half-day bed codes in chemotherapy and radiotherapy
- Medication codes
- Traditional medication codes
- Traditional diagnosis codes
- Medical supply codes
- Blood product codes
- ICD-10 codes
- Laboratory test codes

Cybersecurity in Health Organizations: The Cybersecurity Guidance

In October 2014, the MoH promulgated decision 4159/QD-BYT year 2014 (Guidance on ensuring the security of electronic health data in health organizations [37]) detailing the required measures to safeguard cybersecurity in health facilities. These regulations are applicable for organizations that conduct health IT activities in the web-based environment, including managing, using, storing, and exchanging health information. In general, the measures and recommendations addressed by this decision aim to maintain 3 characteristics (Textbox 6) in digital health implementation The 16 cybersecurity areas covered in the guidance can be found in Multimedia Appendix 6.

Textbox 6. Characteristics in digital health implementation safeguarded by The Cybersecurity Guidance.

Security

- Only authorized users can access the health information.
- Passwords and access keys are encrypted during access and transmission and are saved at the health care facilities.

Integrity

- Information can only be deleted or edited by authorized users. Information is preserved during storing and transmission.
- Integrity is maintained in the management, use, storage, and transmission of information, in which changes are not allowed without authorization from the administration unit.
- Measures to ensure integrity must be applied in accessing, entering, storing, using, processing, transferring, extracting, and recovering data.

Availability

- Uninterrupted operation of the information technology (IT) system is ensured.
- Information can be accessed quickly in response to authorized requests.
- Human resource personnel operating the IT system is ensured.
- Policies for managing and implementing the IT system are developed, publicized, and adhered to (Multimedia Appendix 6).

LISs: The LIS Guidance

Decision 3725/QD-BYT year 2017 (guideline for implementation of LIS in health care facilities [44]) guides the technical features and functionalities of an LIS used in health care facilities.

The guideline first highlights the essential points that organizations need to consider when implementing or developing an LIS:

- LIS's capability to communicate and integrate with other information systems in the hospital or health care system.
- Laboratory test results and related information can be exchanged and linked between different laboratories in a facility and with other facilities.
- LIS's design and technical documents to allow for easy repair, maintenance, and upgrade.
- Technical standards recognized in circular 22/2013/BTTTT and decision 2035/QD-BYT year 2013, where applicable, must be adopted for LISs.
- Advanced technologies are encouraged for implementing LISs.
- Facilities must ensure the necessary conditions for managing and operating LISs such as safety, data security, IT infrastructure, and human resources (Multimedia Appendix 7).

HIMS: The HIMS Guidance

In 2006, the MoH released the decision 5573/QD-BYT year 2006 (Requirements and functional modules for hospital management software (HMS) [35]) to guide the adoption of HMS in Vietnam's public and private health care facilities. The guideline addresses the key requirements that an HMS should meet in the regulatory and clinical context of Vietnam. An HMS's functional modules and detailed instructions for each module are also presented in the document (Multimedia Appendix 8).

Electronic Health Records

Overview

The EHR system aimed to create and maintain a lifetime EHR for every Vietnamese resident. It differed from EMR systems that are managed by hospitals. EHR contents were developed based on the paper-based personal health record's standardized template. Each EHR profile is identified by a unique health ID number.

The EHR Scheme

Overview

In decision 5349/QD-BYT year 2019 (The EHR Scheme [51]), the MoH presents the scheme for setting up and implementing the EHR system on a national scale. Accordingly, an EHR is the digital version of health records that are created, displayed, updated, stored, and exchanged using electronic devices. Health records are the medical documents that keep health care information of a person for their lifetime and are regulated by the MoH. The ultimate goal of this scheme is to provide every Vietnamese citizen with an EHR while step-by-step establishing a population health database in the National Health Data Center.

The scheme requires the manufacturers to apply specific standards for the EHR software. Textbox 7 lists the requirements for EHR systems according to the EHR Scheme.

Every EHR profile will have a national health ID number that is unique for every citizen. The National Health ID system is guided by decision 2153/QD-BYT year 2020 [54].

For data ownership, the government's administrative bodies (the MoH and the relevant Provincial Department of Health) own and manage the data generated during EHR use. EHR providers or EHR developers have responsibilities to hand over data, software source codes, and other tools that allow the MoH or the Department of Health to continue the EHR service with another provider.

Textbox 7. Summary of requirements for electronic health record systems.

Category and requirements

- The electronic health record (EHR) software's design must meet the required standards:
  - The EHR software can collect all the data in a standard paper health record guided in decision 831/QD-BYT year 2017 (the standard template of personal health record for primary health care)
  - The EHR software can export data to XML files that follow the guidance set out in decision 4210/QD-BYT year 2017 (Standards for claim data submitted to the web-based health insurance system)
  - The EHR software can satisfy the regulations in circular 48/2017/TT-BYT year 2017 (regulations for data sharing in health insurance claim)
  - Compatible with Health Level 7 standards
  - The EHR software can use the National Health ID system and is interoperable with related health information systems
- EHR functional modules
  - Health service provision functionality
  - Administrative management functionality
  - Information infrastructure management functionality
- Personal information protection
  - Protection of personal data in EHRs abides by Section 2, Chapter II of the Electronic Data Safety Law

Per the timeline announced in the scheme, the MoH aims to reach an EHR coverage of 80% in the population of central government provinces by the end of 2020 and a coverage of 95% in Vietnam's population by the end of 2025. Following are the steps to install and implement EHRs:

- Developing EHR software
- Installing EHR software in health facilities
- Providing EHR training for health workers
- Creating EHRs and collecting data for EHRs using the pre-existing data at health facilities or via interviews
- Continuously updating data to EHRs at health facilities
- Making use of data collected in EHRs
- Maintaining the EHR system

Technical documents and guidance to operate and manage EHRs will be built to guide EHR use at health facilities, including the following:

- Interoperability specifications with the National Health ID system and related health information systems.
- Policies for using, managing, operating, and ensuring data safety for the EHR system.
- Policies for creating, updating, and making use of EHRs.
- Financial mechanisms for maintaining and operating the EHR system.

The Health ID Regulation

Decision 2153/QD-BYT year 2020 (Regulations on creation, use, and management of health identification [54]), released in May 2020, announced that the social insurance ID will be the national health ID. These ID numbers are nationally unique for each patient and represent a set of identification data for that patient. Each identification data set includes the patient's full name, date of birth, gender, place of birth ID, and health insurance ID. Health ID is intended to be used with EHR, EMR, and other health information systems as a common patient identifier system.

Discussion

Principal Findings

This review explored the current state of digital health research and policies in Vietnam to inform the implementation of digital systems used in hospital care. Nearly half of the hospital-based studies were case reports of engineering solutions; 1 study assessed physicians' performance with assistance from a CDS software; 2 explored readiness to adopt EHRs; and 2 provided a high-level review of Vietnamese eHealth. The data analyzed in these studies were mostly collected in 2016 or earlier. These findings suggest a lack of research studies that investigate and inform the implementation of digital health systems in Vietnamese hospital settings.

Government policies in Vietnam have paid significant attention to digital health over the past 5 years. The MoH has set out specific regulations for EMR use and a maturity framework that shapes the development of digital health systems in hospitals.

Other national projects have occurred, such as the electronic insurance claim system, the nationwide rollout of an EHR, and a national health ID system. International standards such as HL7v2 messaging, ICD-10, and recently HL7's Fast Healthcare Interoperability Resources have been consistently recommended. Guidance documents have also addressed measures to ensure cybersecurity in health organizations. These policies are guided by an architectural framework and digital health strategies that ultimately aim to leverage IT, especially smart technology, in all aspects of the sector.

Of all the policies reviewed, the *Regulations for EMRs* and the *HIT Maturity Model* can be seen as the key policies for HIT application in Vietnam's hospitals. Although the previous national efforts focused on administrative systems such as the HIMS [35], these policies aimed to promote the adoption of clinical systems such as EMR, laboratory information management system, and RIS-PACS. At this nascent stage of HIT adoption, Vietnam has been focusing on building the necessary infrastructure and emphasizing the role of HIT in achieving a more efficient paperless environment. This is reflected in the recent digital health agenda, which highlighted the crucial role of EMRs in replacing paper medical records [49,53]. A major theme that the Regulations for EMRs addressed is the eligibility of transitioning to a completely paperless environment for EMR systems, as well as LIS and RIS-PACS [50]. Although this is a practical and well-defined motivation for EMR adoption, the World Health Organization recommended the true benefits of EMRs, such as improved data quality, timely access to information, and increased care quality, should be proven to encourage buy-in from health care workers [61]. Thus, future policies may seek to link EMR and HIT adoption with such benefits through clearly defined quality indicators to ensure meaningful HIT use. Lessons learned from some countries also recommend that financial incentives, when possible, should be made to increase EMR adoption [62-64].

The *HIT Maturity Model* defined a wide spectrum of HIT implementation levels that are applicable for hospitals of various digitization stages. Although the *Smart HIT Scheme* and the *Digital Transformation Scheme* aimed to establish smart hospitals (HIT level 6) in the next few years, there may be a need for further policy development that takes into account the Vietnamese context as an LMIC. The *Assessment of HIT Maturity* conducted in 2019 showed a large dispersion of HIT maturity across the top-level hospitals directly governed by the MoH, among which 19% (8/42) were only at HIT level 1, most hospitals (20/42, 48%) were at HIT level 3, and only 2% (1/42) of hospitals was at HIT level 5 [65]. A readiness assessment conducted by the MoH in 2017 revealed that among 36 MoH-governed hospitals, only 11 (31%) had EMR systems, 14 (39%) had some forms of CDS software, and over half of these hospitals lacked specialized IT workforce and information security capacity [66]. Given the low HIT maturity levels that these high-rank hospitals held, HIT implementation and readiness in smaller hospitals can be even poorer. It is likely that rural hospitals will struggle to reach even the most basic levels of digital maturity owing to a lack of funding, IT workforce, and infrastructure. Therefore, future policies may need to recommend further support for small and rural hospitals to reduce these gaps in digital maturity.

The 2 digital health strategies aim to promote AI in health care through applications such as CDSSs integrated with EHR systems, imaging diagnosis, and surgical support. New regulations, guidance, and standards are to be released to inform these adoptions [53]. Some of these intended policies are regulations for trials of novel digital health products, guidance for digital health technologies, and guidance for protecting web-based health data, to name a few. New regulation frameworks, along with an increased use of EMRs and EHRs in Vietnam's hospitals, will be important facilitators for the development and implementation of AI for hospital care in Vietnam. However, there is currently a lack of research to inform appropriate and sustainable use of these technologies in Vietnam. Local context factors such as disease burden, health care practices, and infrastructure constraints should be considered for future AI research and implementation, as highlighted by Schwalbe and Wahl [5], Wahl et al [6], and Alami et al [67]. Future digital health research should seek to investigate these factors to best guide HIT and AI development and application in Vietnam's hospitals.

Limitations

This review was limited to the context of hospital-based digital health systems and does not cover the more extensive academic literature on community-based systems and the use of national systems for monitoring infectious disease outbreaks and other public health interventions. Academic studies were only searched on international databases, hence this study did not cover publications in Vietnamese journals that are not registered in these databases.

At the time this study was conducted, the digital health policy landscape in Vietnam was experiencing significant changes with new policies likely to be released and the existing policies being subject to modifications over the next year. Therefore, this scoping review should be viewed as a snapshot of this area at the end of 2020.

Conclusions

Quantity and areas of research studies about digital health systems in hospitals in Vietnam are limited with little evidence to inform the implementation of new technologies in hospital care. The policies developed over the past 5 years to inform the adoption of digital health systems in Vietnam are comprehensive and will be useful for hospitals. They focus on guiding the basic functionalities and largely follow international standards and guidelines. Further research is needed to ensure that policies and guidelines can deal in detail with issues not encountered in HIC settings or that may be specific to the Vietnamese context.

Acknowledgments

This study was supported by the Wellcome Trust United Kingdom WT217650/Z/19/Z. Documents' full-texts on *Th Vi n Pháp Lu t* database was accessed through a registered paid account provided by the Oxford University Clinical Research Unit. Original government documents in Vietnamese were interpreted and summarized in English by DMT. English translations of some government documents purchased from *Th Vi n Pháp Lu t* were consulted during the interpretation. Search on Web of Science was conducted through the access from the Bodleian Health Care Libraries.

The members of the *Vietnam ICU Translational Applications Laboratory (VITAL)* group are as follows:

Abstract

Background: In recent years, virtual reality exposure–based cognitive behavioral therapy (VRE-CBT) has shown good treatment results in (subclinical) anxiety disorders and seems to be a good alternative to exposure in vivo in regular cognitive behavioral therapy (CBT). However, previous meta-analyses on the efficacy of VRE-CBT on anxiety disorders have included studies on specific phobias and subthreshold anxiety; therefore, these results may not be generalizable to patients with more severe and disabling anxiety disorders.

Objective: The objective of our study is to determine the efficacy of VRE-CBT on more severe anxiety disorders, excluding specific phobias and subthreshold anxiety disorders. Meta-analyses will be conducted to examine the efficacy of VRE-CBT versus waitlist and regular CBT. Our secondary objectives are to examine whether the efficacy differs according to the type of anxiety disorder, type of recruitment, and type of VRE-CBT (virtual reality exposure either with or without regular CBT). Furthermore, attrition in VRE-CBT and CBT will be compared.

Methods: Studies published until August 20, 2020, were retrieved through systematic literature searches in PubMed, PsycINFO, and Embase. We calculated the effect sizes (Hedges *g*) for the difference between the conditions and their 95% CIs for posttest and follow-up measurements in a random effects model. A separate meta-analysis was performed to compare attrition between the VRE-CBT and CBT conditions.

Results: A total of 16 trials with 817 participants were included. We identified 10 comparisons between VRE-CBT and a waitlist condition and 13 comparisons between VRE-CBT and a CBT condition. With regard to risk of bias, information on random sequence generation, allocation concealment, and risk of bias for selective outcome reporting was often absent or unclear. The mean effect size of VRE-CBT compared with waitlist (n_{co}=10) was medium and significant, favoring VRE-CBT (Hedges *g*=−0.490, 95% CI −0.82 to −0.16; *P*=.003). The mean effect size of VRE-CBT compared with CBT (n_{co}=13) was small and nonsignificant, favoring CBT (Hedges *g*=0.083, 95% CI −0.13 to 0.30; *P*=.45). The dropout rates between VRE-CBT and CBT (n_{co}=10) showed no significant difference (odds ratio 0.79, 95% CI 0.49-1.27; *P*=.32). There were no indications of small study effects or publication bias.

Conclusions: The results of our study show that VRE-CBT is more effective than waitlist and as effective as CBT in the treatment of more severe anxiety disorders. Therefore, VRE-CBT may be considered a promising alternative to CBT for patients with more severe anxiety disorders. Higher-quality randomized controlled trials are needed to verify the robustness of these findings.

Introduction

Background

Exposure-based cognitive behavioral therapy (CBT) is known as the *gold standard* for treatment of patients with anxiety disorders as its efficacy has been well-established by extensive research [1,2]. Despite its efficacy, potential disadvantages concern CBT being time- and cost-inefficient, impracticable, or considered too aversive by patients [3]. Virtual reality exposure–based cognitive behavioral therapy (VRE-CBT) offers an alternative to regular CBT and has several advantages. It allows immersion within a feared virtual environment that is tailored to the individual patient while being offered within a convenient and safe clinical setting. In VRE-CBT, the therapist can ensure complete control over the content and dose of feared stimuli and therefore optimize individualized pacing through exposures. Moreover, each step of VRE-CBT can be repeated as often as needed before proceeding to the next feared situation, thereby facilitating the complex processes responsible for the effect of exposure therapy. Attrition rates between VRE-CBT and CBT do not seem to differ [4]. However, it was shown that most of a clinical sample with phobic disorders (76%) preferred VRE-CBT over exposure in vivo, and refusal rates of those who were offered VRE-CBT (3%) were substantially lower compared with refusal rates of those who were offered exposure in vivo (27%) [5].

In recent years, many studies have been conducted on the efficacy of VRE-CBT on anxiety disorders and have shown good treatment results. A total of 5 meta-analyses on the efficacy of VRE-CBT versus control conditions, consisting mostly of studies on specific phobias, have been published. They consistently show a clear superiority of VRE-CBT versus nonactive control groups (ie, waitlist) [6-10] and similar [6,7,9,10] or larger [8] effects of VRE-CBT versus CBT conditions incorporating in vivo exposure. In addition, Opris et al [6] showed good stability of VRE-CBT results over time, similar to those of CBT, and a dose-response relationship with more sessions yielding a larger treatment effect. Although it has been questioned whether VRE-CBT induces significant behavior changes in real life [8], Morina et al [7] showed that treatment gains after VRE-CBT generalize well to real-life situations as measured by means of behavioral laboratory tests and recordings of behavioral activities in real life [7]. Considering the advantages of VRE-CBT and its promising results in previous meta-analyses, it is not surprising that a significant expansion of VRE-CBT in mental health care is both predicted and advocated to occur in the coming years [11]. However, these meta-analyses have limited generalizability to patients with more severe and disabling anxiety symptoms—a diagnosis of an anxiety disorder according to the criteria of the Diagnostic and Statistical Manual of Mental Disorders, Fourth and Fifth Edition (DSM-IV and DSM-V, respectively), and the International Classification of Diseases, 10th and 11th Revision (ICD-10 and ICD-11, respectively), established by a structured diagnostic interview, excluding specific phobias. First, most previous meta-analyses included studies that completely [7], largely, or partly [6,8-10] focused on specific phobias. However, specific phobias are generally less severe than more disabling anxiety disorders such as social anxiety disorder (SAD), posttraumatic stress disorder (PTSD), panic disorder (PD), and agoraphobia (AGO). Second, the inclusion of studies in previous meta-analyses was not restricted to samples with a formal anxiety disorder diagnosis (following DSM or ICD criteria), thereby including subthreshold anxiety disorders that are less severe. Carl et al [9] also stated that "The applications for clinical settings are clearer when conclusions can be drawn from clinical samples." The experience with and effects of VRE-CBT may be different for patients with more severe symptoms. On the one hand, they might be more reluctant to expose themselves to feared situations with regular CBT and may favor and benefit most from a controlled exposure therapy setting, such as in VRE-CBT. On the other hand, treating these more severe anxiety disorders with VRE-CBT may be far more challenging than treating milder symptoms. VRE-CBT for the treatment of more severe anxiety disorders requires more varied and elaborate virtual settings while still ensuring a high sense of presence (the feeling that one is actually present in the virtual world). For example, rather than fear of a specific situation or object, treatment of AGO generally requires exposure to various public places (eg, streets, shops, and public transport). In addition, for SAD, it may be essential that VRE-CBT also incorporates interaction through verbal and nonverbal behavior of others in response to the behavior of the patient as SAD centers on the perception of negative evaluation. In addition to the predominance of studies targeting specific phobias, most previous meta-analyses also included nonrandomized studies, thereby possibly leading to biased results. Ultimately, there is a lack of evidence for the efficacy of VRE-CBT in the treatment of more severe and formal anxiety disorders. Hence, a careful examination of research is necessary to prevent unjustified expansion of VRE-CBT in clinical settings.

We conducted a meta-analysis to determine whether the positive results of VRE-CBT as reported in earlier meta-analyses are sustained when focusing solely on more severe anxiety disorders (according to DSM-IV, DSM-V, ICD-10, or ICD-11 criteria): PD with or without AGO, AGO, SAD, generalized anxiety disorder (GAD), obsessive-compulsive disorder (OCD), or PTSD, limiting our inclusion criteria to studies with a formal diagnosis to avoid heterogeneity in our sample.

Objectives

Our main objective is to examine the efficacy of VRE-CBT on anxiety severity compared with (1) waitlist and (2) CBT at posttest and follow-up measurements (if available). Our secondary objectives are to examine whether efficacy differs according to the type of anxiety disorder, type of recruitment, and type of VRE-CBT (virtual reality exposure [VRE] with or

without regular CBT). Furthermore, the feasibility of VRE-CBT has been evaluated by comparing the attrition of VRE-CBT and CBT.

Methods

Study Selection

Studies published until August 20, 2020, were retrieved through systematic literature searches in PubMed, PsycINFO, and Embase (see Multimedia Appendix 1 for the complete search strings) for studies that randomized patients with anxiety disorders into VRE-CBT, active control condition, or an inactive control condition and compared the effects of these treatments. A librarian and IvL conducted the search by combining search terms indicative of anxiety disorders (PD with or without AGO, AGO, GAD, SAD, OCD, and PTSD) with terms indicative of VRE therapy. Furthermore, we checked the reference lists of the retrieved articles and previous meta-analyses and reviews for additional studies.

The inclusion criteria were (1) adult patients (aged >18 years); (2) at least one VRE-CBT condition; (3) random assignment to conditions; (4) comparison with waitlist or CBT without virtual reality (VR); (5) measure of outcome related to anxiety; (6) a primary diagnosis of an anxiety disorder according to DSM-IV, DSM-V, ICD-10, or ICD-11 criteria established by a structured diagnostic interview, excluding specific phobias; and (7) original empirical findings. Consistent with the DSM-IV or DSM-V classification, PTSD and OCD were also included even though these are no longer classified as anxiety disorders in the DSM-V. No date restrictions were applied. Articles consisting of only abstracts or not presenting original data were excluded, as were studies with a crossover design. No language restrictions were applied.

In total, 2 authors (WS and IvL) independently assessed the list of titles and abstracts that resulted from the literature search for eligibility. WS and IvL independently examined full texts and selected eligible randomized controlled trials (RCTs). Discrepancies were resolved by consulting and discussing with a third author (NB). This meta-analysis was conducted in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [12].

Data Extraction

In total, 2 authors (WS and IvL) independently extracted the data from the selected articles. This information included characteristics of the study population (mean age and range and gender), classification instrument, recruitment method, primary outcome, and conditions (sample size, number of dropouts, number of sessions, and follow-up in months for each condition).

For studies using more than one validated outcome measure, we selected the reported primary outcome measure. When undefined, we selected the domain-specific outcome that was most frequently used in the included trials for that type of anxiety disorder as the primary outcome measure.

For each study, the mean and SD of the primary outcome on posttest and follow-up measurements were used to calculate the effect sizes. For the study of Pitti et al [13], the effect size was calculated using the mean and *P* value of the between-group comparison as SDs were not available. Discrepancies in data extraction were resolved through discussion and by studying the original article. In case of a lack of clarity or missing data, the authors of selected studies were contacted.

Risk of Bias Assessment

In total, 2 authors (WS and IvL) independently assessed the risk of bias in the included studies. Differences were resolved through discussion. Five areas of risk of bias according to the Cochrane tool for assessing risk of bias were rated [14]: (1) random sequence generation, (2) allocation concealment, (3) blinding of outcome assessment, (4) incomplete outcome data, and (5) selective reporting. The criterion of blinding of participants and personnel was omitted as blinding is not possible in these psychological interventions. We assessed all areas as having low, high, or unclear risk of bias. Incomplete outcome data were assessed by evaluating attrition rates in all the comparison groups. Attrition was defined as all randomized patients who dropped out of the treatment. If attrition rates were >30% and no appropriate methods were used to minimize biased comparisons among groups (intention-to-treat analyses), the study was coded as being at high risk of bias for incomplete outcome data. Selective outcome reporting was assessed by evaluating differences in primary outcomes between publication and trial registration, if available. If no trial registration was available for a study, the study was coded as being at unknown risk for selective outcome reporting. We computed a summary score for each study by summing the number of items scoring high risk of bias, which could range from 0 to 5, with low scores indicating low risk of bias.

Meta-analysis

Meta-analyses were conducted to assess the effect of VRE-CBT on the severity of anxiety symptoms when compared with waitlist and CBT conditions. We calculated the effect sizes (Hedges *g*) for the difference between the conditions and their 95% CIs for posttest and follow-up measurements if data were available. For the follow-up date, we chose the longest follow-up period available. The effect sizes were based on intention-to-treat analysis, if available. Otherwise, completer analysis results were used. Heterogeneity among the studies was examined using the Cochran *Q* test and Higgins I^2 statistics [15]. The possibility of publication bias was evaluated by visual inspection of the funnel plot and Egger test [16] and using the Duval and Tweedie trim and fill procedure [17]. Random effects models were used as heterogeneity across the studies was expected, for example, because of variations in the number of sessions, treatment protocols, recruitment setting, and type of anxiety disorder.

Predefined subgroup analyses were conducted for type of anxiety disorder and method of recruitment (community, clinical, or both). Meta-regression analyses were used to estimate the impact of year of publication, quality of the individual studies (risk of bias), and treatment duration (in sessions). We conducted sensitivity analyses excluding outliers and studies in which the VRE-CBT condition included additional CBT elements or sessions with psychoeducation, cognitive restructuring, interoceptive exposure, and exposure

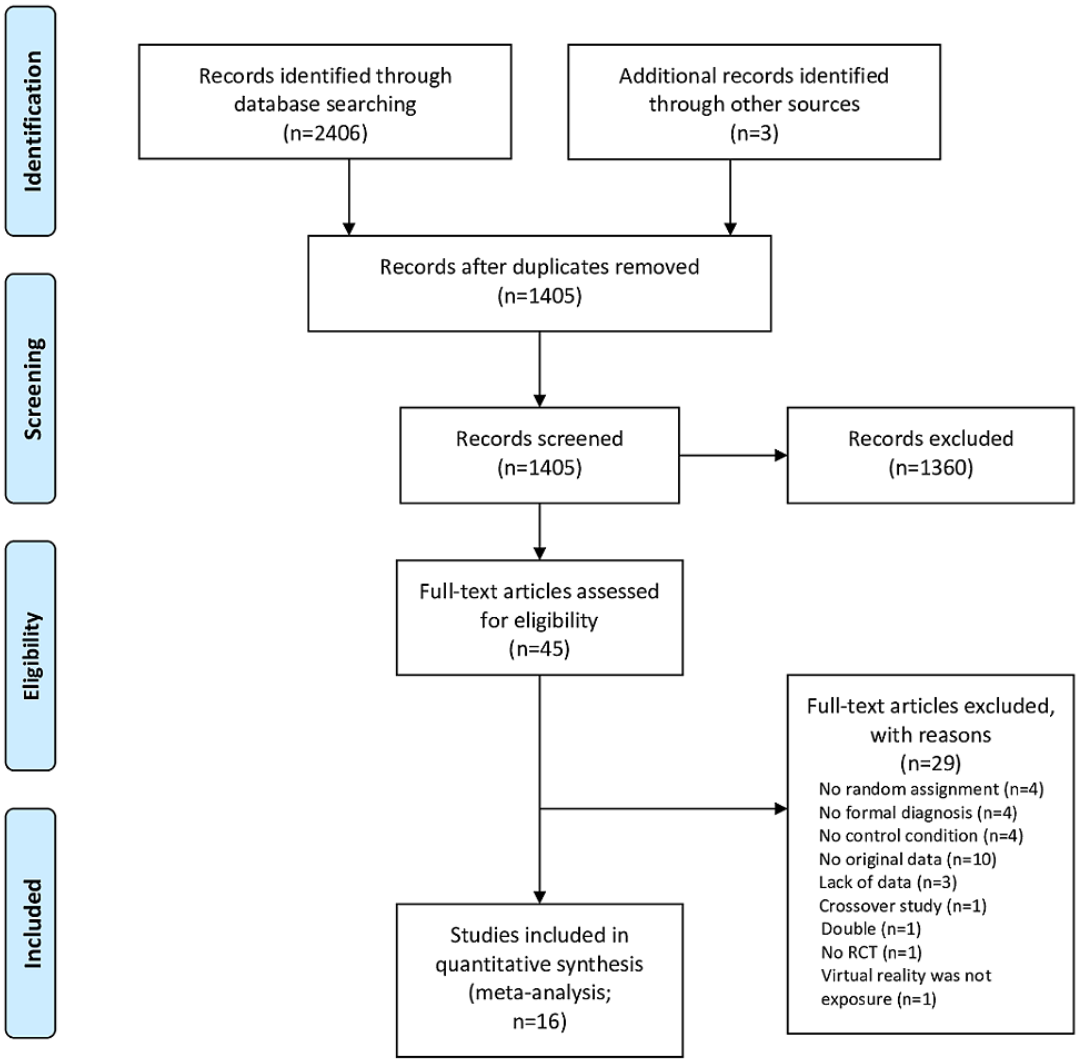
in vivo. A separate meta-analysis was performed to compare the dropouts between the VRE-CBT and CBT conditions to assess the feasibility of VRE-CBT. Odds ratios indicated the odds of participants dropping out from the VRE-CBT versus CBT. The analyses were performed using Comprehensive Meta-Analysis (version 2.2; Biostat Inc) [18].

Results

Study Inclusion

After removal of duplicates, the literature searches resulted in a total of 1405 papers for consideration. A total of 2 papers (2/1405, 0.1%) were identified from checking references. After screening the titles and abstracts, of the 1405 papers, 45 (3.2%) full-text articles were retrieved for a more detailed evaluation of eligibility. Figure 1 shows the flowchart of the inclusion process following the PRISMA guidelines [19]. Subsequently, of the 45 articles, 26 (58%) were excluded as they did not meet the inclusion criteria for various reasons. In addition, 3 studies (3/45, 7%) were excluded because of missing data for analyses despite efforts to acquire these data by contacting the authors (for specific reasons, see Figure 1). Finally, 16 studies were included in the meta-analysis.

Figure 1. Flowchart of study inclusion. RCT: randomized controlled trial.



Study Characteristics

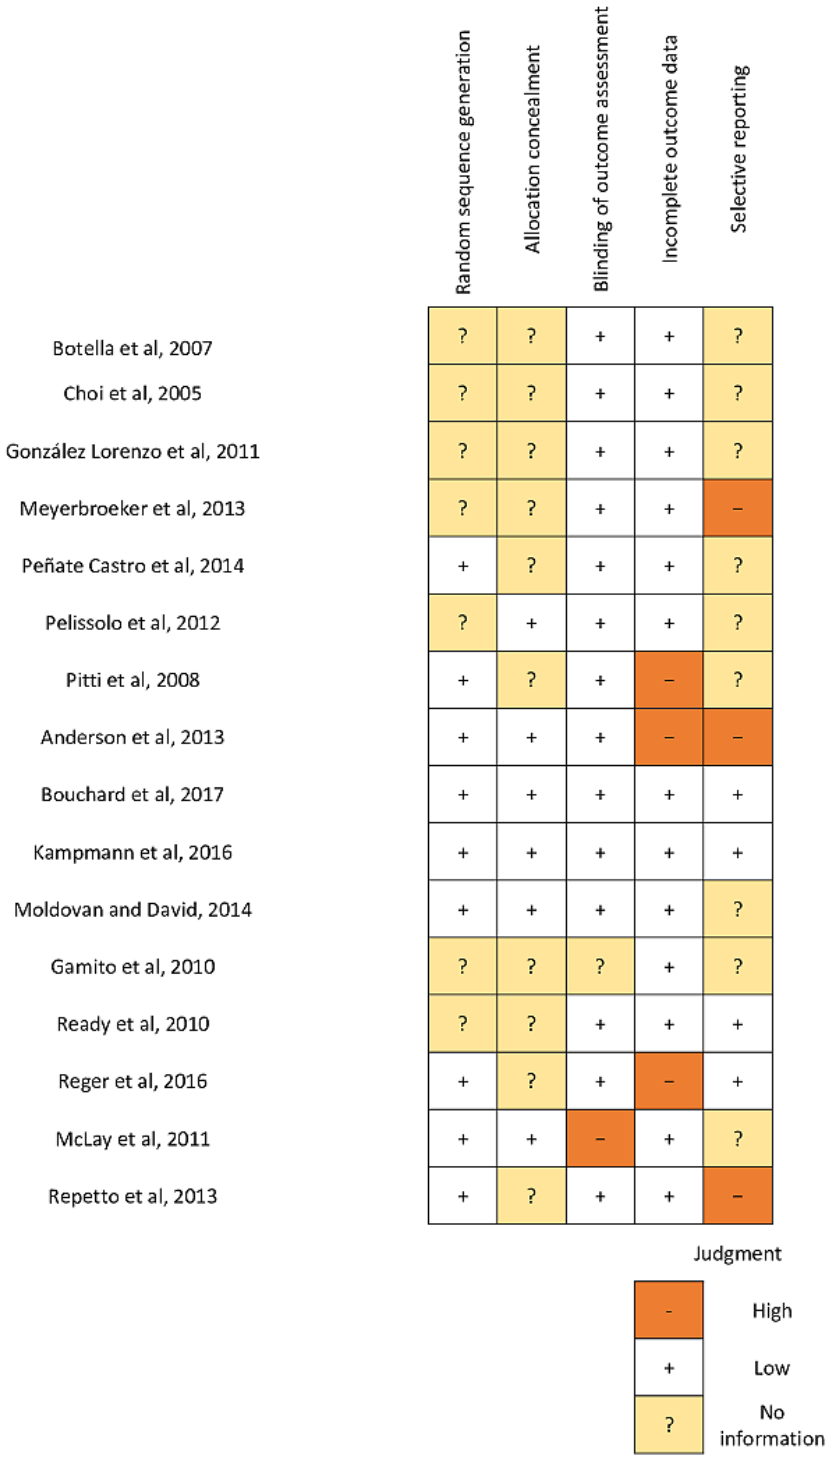
A total of 16 trials were included in Multimedia Appendix 2 [13,20-34]. These trials entailed 10 comparisons between VRE-CBT and a waitlist and 13 comparisons between VRE-CBT and a CBT condition. The number of participants per study ranged from 10 to 162 (12/16, 75% of the studies had <25 participants in each arm). Follow-up data were available for 38% (5/13) of the comparisons between VRE-CBT and a CBT condition and ranged from 6 to 12 months. Of the 16 studies, 7 (44%) focused on PD with or without AGO, 4 (25%) focused on SAD, 4 (25%) focused on PTSD, and 1 (6%) focused on GAD. None of the screened studies on OCD were included as they did not meet our inclusion criteria.

Risk of Bias

In each trial, 5 areas of risk of bias were rated as low, unclear (because of lack of information), or high risk of bias. As blinding of participants and personnel was not possible, all studies had a high risk of performance bias; therefore, this was not reported

(see Figure 2 for the risk of bias summary). Information on random sequence generation and allocation concealment was absent or not reported clearly in 44% (7/16) and 63% (10/16) of the trials, respectively. Of the 16 trials, 9 (56%) were scored with unclear risk of bias for selective outcome reporting as registration in a trial database could not be found.

Figure 2. Risk of bias summary [13,20-34].

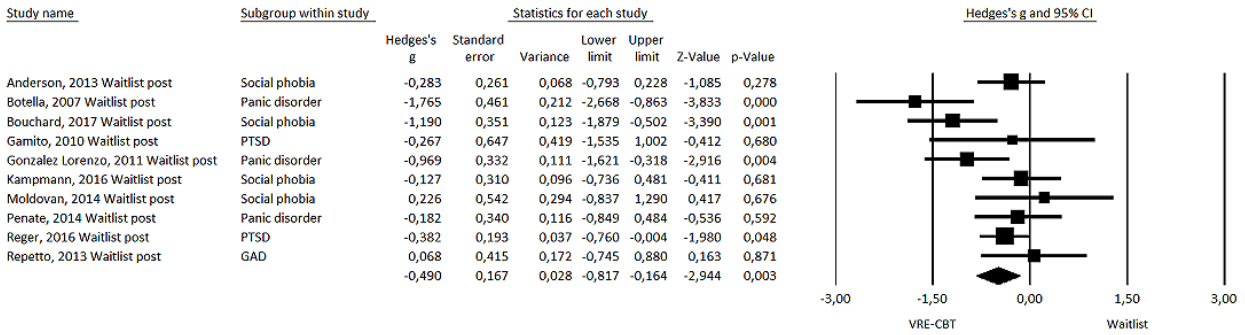


Effect Size: VRE-CBT Versus Waitlist at Posttest Measurement

The mean effect size of VRE-CBT on symptoms of anxiety when compared with waitlist control at posttest measurement (n_{co}=10) was medium and significant, favoring VRE-CBT (Hedges g=−0.490, 95% CI −0.82 to −0.16; P=.003; see Figure 3 for the forest plot). There was moderate heterogeneity (I^2=56%). Effect size decreased after exclusion of 1 potential outlier [20] (Hedges g=−0.391, 95% CI −0.66 to −0.12; P=.005),

with low heterogeneity (I^2=33%). Sensitivity analysis excluding studies in which VRE-CBT included additional CBT elements or sessions (n_{co}=6) showed a decrease in the effect size to Hedges *g* of −0.255 (95% CI −0.49 to −0.02; *P*=.03). Sensitivity analysis excluding 1 study with medication (antidepressants; n_{co}=9) as part of the intervention and control conditions showed a decrease in the effect size to Hedges *g* of −0.432 (95% CI −0.78 to −0.09; *P*=.01).

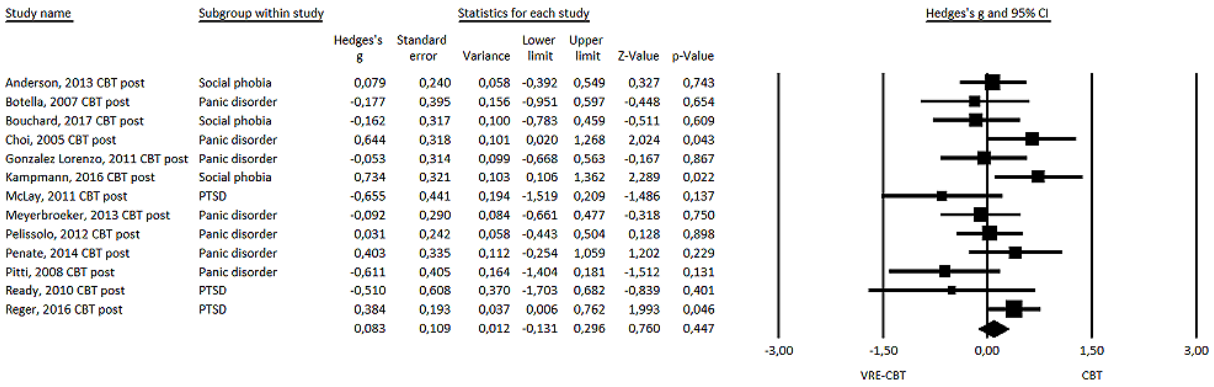
Figure 3. Forest plot of virtual reality exposure–based cognitive behavioral therapy versus waitlist at posttest measurement [20,22,24,26-30,32,34]. GAD: generalized anxiety disorder; PTSD: posttraumatic stress disorder; VRE-CBT: virtual reality exposure–based cognitive behavioral therapy.



Effect Size: VRE-CBT Versus CBT at Posttest Measurement

The mean effect size of VRE-CBT on symptoms of anxiety when compared with CBT at posttest measurement (n_{co}=13) was small and nonsignificant, favoring CBT (Hedges *g*=0.083, 95% CI −0.13 to 0.30; *P*=.45) with low to moderate heterogeneity (I^2=36%; see Figure 4 for the forest plot). Sensitivity analysis excluding studies in which VRE-CBT included additional CBT elements or sessions (n_{co}=6) showed a nonsignificant increase in the effect size to Hedges *g* of 0.209 (95% CI −0.14 to 0.56; *P*=.24). Sensitivity analysis excluding 1 study with medication (antidepressants; n_{co}=12) as part of the intervention and control conditions showed a similar effect size of Hedges *g* of 0.09 (95% CI −0.14 to 0.33; *P*=.34).

Figure 4. Forest plot of virtual reality exposure–based cognitive behavioral therapy versus cognitive behavioral therapy at posttest measurement [21-28,31-33]. CBT: cognitive behavioral therapy; PTSD: posttraumatic stress disorder; VRE-CBT: virtual reality exposure–based cognitive behavioral therapy.



Effect Size: VRE-CBT Versus CBT Condition at Follow-up (6-12 Months)

In total, there were 5 studies (5/16, 31%) with follow-up assessments that were compared with CBT. Of the 16 studies, 3 (19%) only conducted follow-up assessments after 6 months [24,27,31], 1 (6%) had 6- and 12-month assessments [25], and only 1 (6%) had a 12-month follow-up [20]. For the meta-analysis, the longest follow-up period was used. The mean effect size of VRE-CBT on symptoms of anxiety when compared with CBT (n_{co}=5) remained nonsignificant at follow-up (Hedges *g*=−0.082, 95% CI −0.40 to 0.24; *P*=.61; I^2=0).

Subgroup Analyses and Meta-Regression Analyses

Subgroup analyses were performed for the type of anxiety disorder and type of VRE-CBT (VRE either with or without regular CBT). Type of anxiety disorder (SAD: n_{co}=3; PD with or without AGO, or AGO: n_{co}=7; and PTSD: n_{co}=3) was a significant moderator (*P*=.005) for the comparison between VRE-CBT and waitlist, although this result was most likely affected by the high heterogeneity within 2 of the small

subgroups—PD with or without AGO, or AGO (I^2=75%) and SAD (I^2=59%). Only 1 GAD study (1/16, 6%) was available; therefore, we did not include this study in the analysis.

We were not able to conduct planned subgroup analyses for type of recruitment (community, clinical, or both) as there was only 1 study (1/16, 6%) with community recruitment, which did not allow for subgroup analysis.

Meta-regression to estimate the impact of year of publication (*P*=.16), treatment duration (in sessions; *P*=.85), and quality of the individual studies (risk of bias; *P*=.32) showed no significant effects in the comparison of VRE-CBT with waitlist control. In the comparison with CBT, year of publication (*P*=.44), treatment duration (in sessions; *P*=.07), and quality of the individual studies (risk of bias; *P*=.50) also showed no significant differences.

Comparison of Attrition Between VRE-CBT and CBT

A separate meta-analysis was conducted to compare the dropouts between VRE-CBT and CBT conditions to assess the feasibility of VRE-CBT. The dropout rates between the 2 conditions (n_{co}=10) showed no significant difference (odds ratio 0.79, 95% CI 0.49-1.27; *P*=.32).

Publication Bias

We conducted the Egger test for asymmetry of the funnel plot for the comparison between VRE-CBT and waitlist. Visual inspection of the funnel plot seemed to show some asymmetry, which could indicate small study effects. The Egger regression intercept test was not statistically significant (intercept=−0.53, 95% CI −4.09 to 3.03; *P*=.74). The Duval and Tweedie trim and fill procedure showed that adjustment for potentially missing studies (n=1) was associated with the effect size slightly increasing from −0.51 (95% CI −0.84 to −0.17) to −0.56 (95% CI −0.88 to −0.22; Figure 5). The Egger test for the comparison between VRE with and without CBT also showed some asymmetry. The Egger regression intercept test was not statistically significant (intercept=−2.15, 95% CI −4.60 to 0.30; *P*=.08). The Duval and Tweedie trim and fill procedure showed that adjustment for potentially missing studies (n=3) was associated with the effect size increasing from 0.09 (95% CI −0.13 to 0.30) to 0.19 (95% CI −0.04 to 0.42; Figure 6), with largely overlapping CIs.

Figure 5. Trim and fill adjusted funnel plot of virtual reality exposure–based cognitive behavioral therapy versus waitlist (the white circles represent the observed studies, and the black circles represent the imputed studies). Std diff: Standard difference.

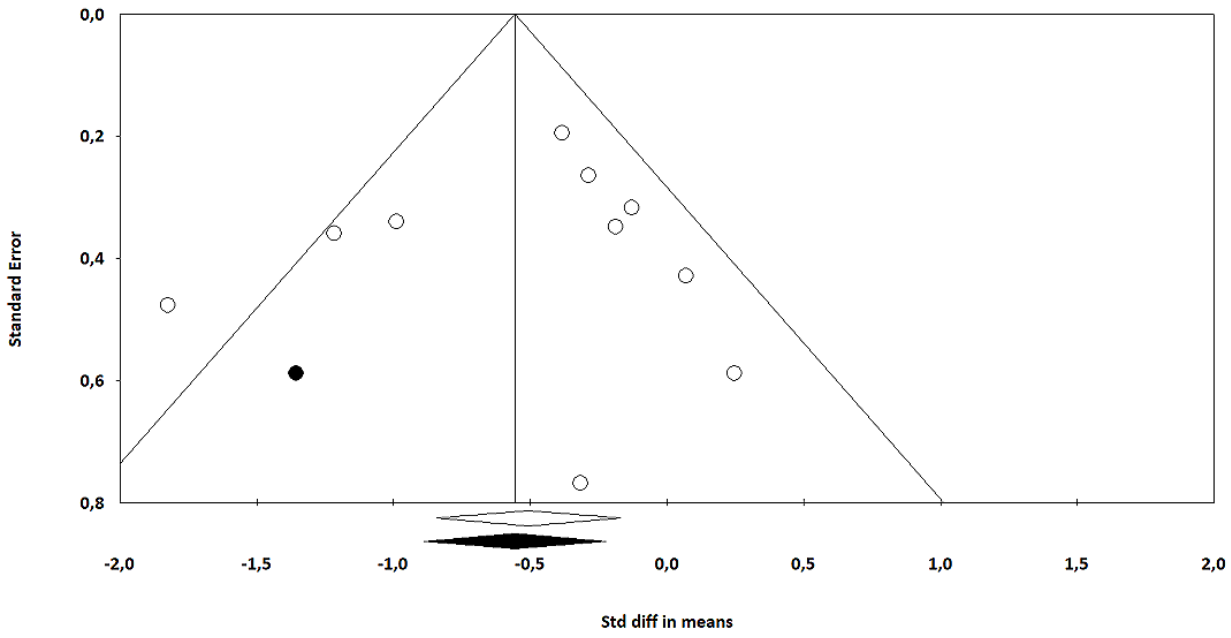


Figure 6. Trim and fill adjusted funnel plot of virtual reality exposure–based cognitive behavioral therapy versus cognitive behavioral therapy (the white circles represent the observed studies, and the black circles represent the imputed studies). Std diff: Standard difference.

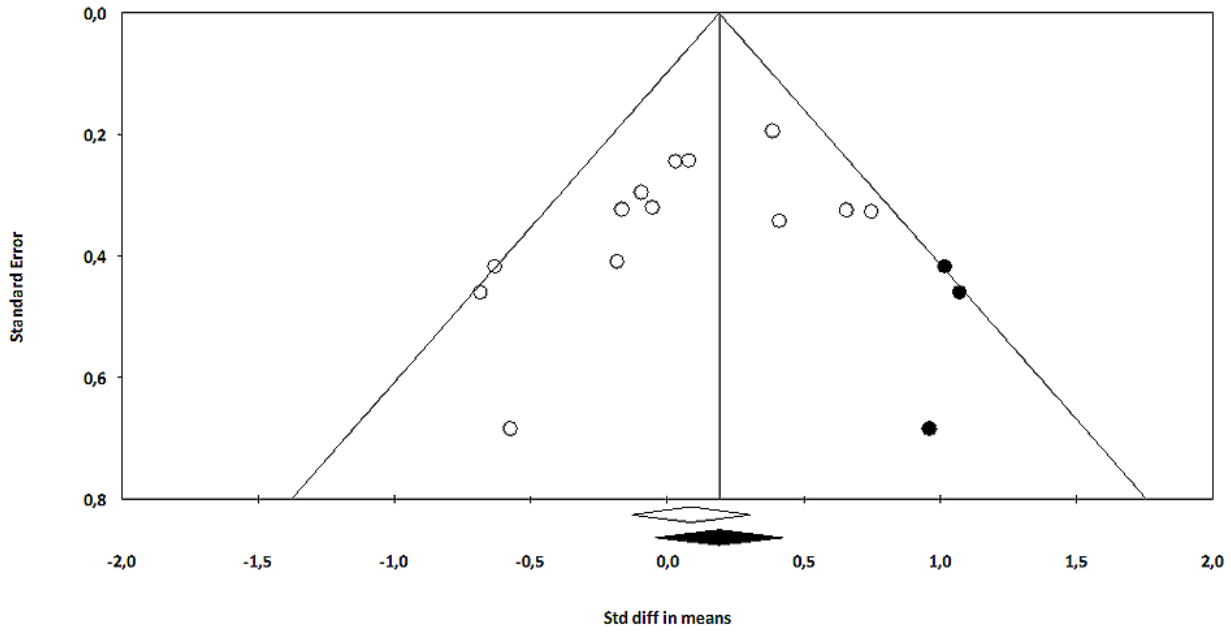

Discussion

Principal Findings

This is the first meta-analysis of VRE-CBT for anxiety disorders focusing solely on patients with more severe anxiety disorders with a formal diagnosis, excluding specific phobias. The meta-analysis, consisting of 16 VRE-CBT trials including 817 patients with anxiety disorders, showed a medium effect size compared with waitlist conditions. In the comparison between VRE-CBT and CBT, no significant differences were found between posttest and follow-up measurements. These findings are somewhat less positive than findings from previous meta-analyses as the effect sizes of VRE-CBT were lower in our meta-analysis. We found an effect size (Hedges *g*) of −0.49 of VRE-CBT versus waitlist compared with an estimated Hedges *g* of 0.88 and 0.79 in the meta-analyses by Carl et al [9] and Fodor et al [10], respectively. It can be hypothesized that their higher effect size is a result of the inclusion of specific phobias and subthreshold anxiety disorders. Specific phobias seemed to account for the larger effect sizes in the meta-analysis by Fodor et al [10], in which high effects of VRE-CBT for specific phobias and fight anxiety, and moderate or small effects for SAD and PTSD were found. However, in the study by Carl et al [9], this was not the case. Thus, the influence of specific phobias on the effect size is inconclusive. With regard to subthreshold anxiety disorders, neither study requested that participants be formally diagnosed with anxiety disorders. Therefore, it can be assumed that less severe cases were also included. It could be argued that people with less severe anxiety are easier to treat, and a greater effect can be reached in treatment. On the other hand, the reverse may also be true—with more symptoms at the start of treatment, greater gains can be made. Fodor et al [10] conducted sensitivity analyses that were restricted to patients with an anxiety disorder diagnosed with a clinical interview or a cutoff score on a questionnaire, which resulted in a smaller effect (Hedges *g*=0.72). This finding seems to support the hypothesis that people with less severe disorders might benefit more from treatment with VRE-CBT. With regard to the role of CBT elements or CBT sessions in 56% (9/16) of the VRE-CBT studies, sensitivity analyses with only pure VRE studies showed that pure VRE studies without additional CBT elements showed lower effect sizes in the comparison with the waitlist condition, indicating that adding CBT elements (such as psychoeducation, cognitive restructuring, interoceptive exposure, and exposure in vivo) to VRE is advised for optimizing effects.

Compared with the other studies, it is more difficult to interpret the effect size of the only study on GAD [34] in this meta-analysis as the VRE-CBT in this study mostly consisted of progressive muscle relaxation and autogenic techniques, and only 2 of 8 sessions consisted of exposure therapy. Furthermore, exposure itself differed from regular exposure-based interventions in GAD. It involved exposure to preselected words or images related to personal stressful events, although in regular CBT treatments patients with GAD are exposed to worries about hypothetical scenarios describing their worst fear [35]. It is possible that more focused exposure could lead to better results in future VRE-CBT studies for GAD.

We found no difference in attrition between VRE-CBT and CBT, which is in line with the findings of Benbow and Anderson [4], who conducted a meta-analysis on attrition between VRE-CBT and CBT across 46 studies with a combined sample size of 1057 participants. Fodor et al [10] also found that VRE-CBT yielded similar dropout rates to other interventions. These findings also suggest that VRE-CBT does not mitigate attrition.

The heterogeneity of the studies was low to moderate and did not seem to influence the results. We found no indications of small study effects or publication bias.

The risk of bias assessment in our study showed that, in many studies, it was difficult to assess risk of bias because of lacking or unclear information on random sequence generation and allocation concealment and because of lack of registration in a trial register. Keeping this in mind, it is difficult to interpret our results from the meta-regression, in which we found no significant effect of the total risk of bias score. Fodor et al [10] also used the Cochrane tool [14] for assessing the risk of bias in their meta-analysis on VRE-CBT in anxiety and depression, and they found that most studies had high or uncertain risk of bias across domains. In exploratory subgroup analyses, they also did not find differences between studies with high, uncertain, and low risk of bias, but these results must be interpreted with caution, as there were only few studies with a small risk of bias. Furthermore, previous research on adherence to study quality criteria in VRE-CBT studies on anxiety disorders by McCann et al [36] showed that the studies met an average of 2.85 (SD 1.56) of 8 quality criteria for research design, but study quality did not affect the effect size. It may be concluded that better reporting of quality in VRE-CBT RCTs is needed before conclusions can be drawn on the effect of quality on effect sizes.

Limitations

This meta-analysis has some limitations. First, there were a limited number of trials per diagnosis (ie, none on OCD and only 1/16, 6% on GAD) and per method of recruitment (only 1/16, 6% recruited in the community) and few studies with follow-up outcome data (5/16, 31%). Subgroup analyses showed that *type of anxiety disorder* was a significant moderator in the waitlist comparison, but no conclusions can be drawn from this result, as there was high heterogeneity within the subgroups, expressing excessive clinical diversity and therefore showing no true effect. Second, we did not investigate the sense of presence or other indicators of interaction, although presence may influence the effectiveness of VRE-CBT. Ling et al [37] found a positive relationship between sense of presence and anxiety disorders, which was stronger in studies with participants with a formal anxiety disorder than in nonclinical populations. Third, 3 studies (3/45, 7%) were excluded because of missing data for analyses despite efforts to acquire these data by contacting the authors. This may have influenced the estimations.

Clinical Implications

There are some clinical implications of the findings in this meta-analysis and for the position that VRE-CBT holds in the treatment of more severe anxiety disorders. Patients should be made aware of the state of the current evidence regarding VRE-CBT relative to alternatives to be able to make a shared decision with the therapist. The advantages of VRE-CBT over CBT may play a role in this decision. Bouchard et al [27] used a Specific Work for Exposure Applied in Therapy scale (evaluating topics such as cost, time, planning, and difficulties), which showed that VRE-CBT was more cost-efficient and practical for therapists than CBT with in vivo exposure. In addition, VRE-CBT offers a large potential for exposing patients to situations and stimuli that are too complex, costly, or challenging for in vivo exercises. It can be hypothesized that when these applications are exploited accordingly, it creates the potential to increase the effectiveness of VRE-CBT above and beyond in vivo exposure.

Furthermore, there are some specific concerns regarding VRE-CBT that clinicians should take into account: the use of the VR simulators can cause simulator sickness, appropriate training and supervision are needed, and technical support should be available in case of technical problems. In addition, although lower-cost options are becoming available, such as using smartphones as VR viewers, they still need to be evaluated [38]. Regarding improving VRE-CBT, developing VR that can be customized precisely to a patient's needs with a better sense of presence and interaction may lead to even better outcomes.

Conclusions

In conclusion, the results of our study show that VRE-CBT is as effective as CBT in the treatment of more severe formal anxiety disorders. However, VRE-CBT studies in this meta-analysis not only were limited in number but the quality of reporting was also poor. Therefore, awaiting further high-quality data, VRE-CBT may be considered a promising alternative to CBT, especially for patients who prefer VRE-CBT over CBT [5].

Future research should focus on conducting high-quality RCTs. Subsequently, examining for which patients or anxiety disorders VRE-CBT or CBT works best could be a next step in research.

Abstract

Background: The internet has now become part of human life and is constantly changing people's way of life. With the increasing popularity of online health information (OHI), it has been found that OHI can affect the physician-patient relationship by influencing patient behaviors.

Objective: This study aims to systematically investigate the impact of OHI-seeking behavior on the physician-patient relationship.

Methods: Literature retrieval was conducted on 4 databases (Web of Science, PubMed, China National Knowledge Infrastructure, SinoMed), and the time limit for literature publication was before August 1, 2021.

Results: We selected 53 target papers (42 [79%] English papers and 11 [21%] Chinese papers) that met the inclusion criteria. Of these, 31 (58%) papers believe that patients' OHI behavior can enable them to participate in their own medical care, improve patient compliance, and improve the physician-patient relationship. In addition, 14 (26%) papers maintain a neutral attitude, some believing that OHI behavior has no significant effect on doctors and patients and others believing that due to changes in the factors affecting OHI behavior, they will have a negative or a positive impact. Furthermore, 8 (15%) papers believe that OHI search behavior has a negative impact on doctors and patients, while 6 (11%) papers show that OHI reduces Chinese patients' trust in doctors.

Conclusions: Our main findings showed that (1) OHI-seeking behavior has an impact on patients' psychology, behavior, and evaluation of doctors; (2) whether patients choose to discuss OHI with doctors has different effects on the physician-patient relationship; and (3) the negative impact of OHI on China's internet users is worthy of attention. Due to the low quality of OHI, poor health information literacy, short physician-patient communication time, and various types of negative news, patients' trust in doctors has declined, thus affecting the physician-patient relationship. Improvement of people's health information literacy and the quality of OHI are important factors that promote the positive impact of OHI on the physician-patient relationship.

Introduction

About 4.66 billion people worldwide have access to the internet [1]. The internet has gradually become part of human life, constantly changing people's lifestyle. As the availability and immediacy of information services provided by the internet continue to improve, and patients' private information can be concealed to a certain extent, internet health information services have become increasingly attractive [2]. In addition, the lack of medical resources makes people choose to obtain health information online to meet their own health information needs [3]. The online health information (OHI) that patients search for on the internet mainly includes information about diseases, nutrition, treatments, physical and mental health, etc [4,5]. The uneven quality of OHI has a major impact on patients. The credibility of information perceived by patients affects whether the patients use the internet as a frequently used and preferred information source [6]. Physicians are still the most popular source of health information, but the internet has gradually become another important source of health information [7].

OHI seeking can influence physician-patient relationships and patient compliance. Patients who can obtain more health information can better follow the treatment process and enjoy better therapeutic effects [8]. The rapid development of the internet has changed the access of patients to health information and affected the existing physician-patient relationship, which to a large extent determines the medical result that patients receive [9]. As mentioned before, patients choose to obtain health information online to meet their own needs. At the same time, the health information search results provided by the internet show that extreme situations, for example, advice that is contrary to the standard medical opinion or complex data provided by health care professionals, leads to misinterpretation, confusion, and other problems for patients [10]. Of course, the availability of health information on the internet is transforming many patients from passive medical service consumers to those who can participate in the medical process, which brings new challenges for many physicians [11,12]. When patients carry a lot of health information in a short consultation, can physicians deal with it as usual?

With the continuous development of the internet, the physician-patient relationship has attracted much attention. In terms of importance, the relationship between patients and physicians is second only to that of family [13]. It is viewed as extremely or very important by 67%, exceeding relationships with spiritual advisors, pharmacists, coworkers, and financial advisors [13]. Due to the patients' lack of understanding of diseases and communication barriers between physicians and patients, some patients cannot understand the results of diagnosis and treatment of the disease and the treatment behavior, which causes a series of problems [14]. Physician-patient communication is a complex clinical behavior whose main goal is to share medical information to improve the education of clinical diagnosis, treatment, and specific diseases [14]. The quality of physician-patient communication affects the physician-patient relationship. In the past, physicians made decisions and patients obeyed them, which constitutes the traditional physician-patient relationship [15]. Patients and medical staff advocate the transition to mutual participation, that is, shared power and responsibility [15]. Previous studies have shown that processing patients' OHI-seeking behavior in daily consultation can improve the quality of medical services [16]. In an ideal physician-patient relationship, patients should be guided instead of looking for OHI independently [17]. However, at present, patients are mainly looking for OHI by themselves, and they are unable to control the quality of information and other aspects.

In China, the total population is about 1.4 billion [18]. As of June 2021, the number of internet users reached 1.011 billion, and the internet penetration rate reached 71.6%. The “Healthy China” strategy is China’s priority development strategy [19]. By implementing internet medicine, the Healthy China strategy promotes the mobility of medical services, enhances the operation efficiency of the overall medical and health system, and optimizes the allocation of medical resources [19]. Due to China's large population and the impact of COVID-19, China's demand for medical resources is growing exponentially. Increasingly more doctors and patients are seeking health information through internet platforms, effectively breaking the time and space restrictions and giving China's unbalanced medical resources a chance to be redistributed [20]. Considering that OHI may have a positive or a negative impact on the physician-patient relationship, which is important in medical care, this study aims to examine the impact of OHI on the physician-patient relationship in China.

In recent years, studies on health information seeking have been increasing. It is of great significance to understand the impact of the current health information seeking on the physician-patient relationship. Thus, the purpose of this study is to systematically review the current studies on the impact of OHI seeking on the physician-patient relationship.

Methods

Literature Retrieval

In this study, English references were obtained from the databases Web of Science and PubMed. The PubMed database contains references related to medicine and life sciences. Web of Science includes the most influential core academic journals on natural science, engineering technology, biomedicine, and other research fields. Chinese references were obtained from the databases China National Knowledge Infrastructure (CNKI) and SinoMed. The CNKI is China's largest full-text journal database, while SinoMed focuses on collecting the biomedical literature in China.

After consulting with librarians, the search strategy for this paper consisted of all possible keywords related to 4 topics: (1) online OR internet OR web OR network, (2) wellness information OR health information, (3) search* OR seek* OR inquiry OR query, and (4) physician-patient communication OR doctor-patient communication OR physician-patient relation* OR doctor-patient relation* OR physician-patient interaction OR doctor-patient interaction OR physician-patient trust OR doctor-patient trust. The papers were published before August 31, 2021. Combinations of these keywords were

searched in the 4 databases to make the literature search as comprehensive as possible. In addition, we searched the PubMed database separately with Medical Subject Headings (MESH). The Mesh terms were “patient-physician relations” and “internet.”

This systematic review conforms to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement (Multimedia Appendix 1).

Inclusion and Exclusion Criteria of Publication Standards

To make the coverage of this study comprehensive enough, the types of papers included were journal papers, conference papers, and academic dissertations. Paper retrieval covered all regions and languages, but only papers with full text in English or Chinese were retained. Papers involving only OHI-seeking studies or only physician-patient relationship studies were excluded. We also excluded all nonempirical research papers, including reviews, research on websites, and research commentaries. Then, we evaluated the quality of the included papers. We used the Critical Appraisal Skills Programme quality assessment tool for qualitative studies, which comprises 10 questions [21] (Multimedia Appendix 2). We also used a quality assessment tool for quantitative studies that comprises 14 questions customized by Tan et al [22] (Multimedia Appendix 3). Papers with a quality assessment score lower than 0.7 were excluded.

Paper-Screening Process

The literature screening in this study was independently carried out by 2 researchers. They screened the titles and abstracts, respectively, and read the full text to extract opinions. We compared the 2 researchers' screening results and the consistency of the extracted views, discussed the discrepancies to ensure the consistency and integrity of results, and used quality assessment tools to assess the quality of the papers. Endnote 20 was used to merge related search results and delete duplicate papers.

Data Extraction and Management

The research data of papers were independently extracted by 2 researchers according to the predesigned table. It mainly included the following information: country, research design method, sample size, respondents, and conclusion. Where there was ambiguity, the 2 researchers discussed it and reached an agreement.

Results

Characteristics of the Papers

In this study, we searched the PubMed and Web of Science databases and retrieved 10,303 and 9345 records, respectively, for a total of 19,648 initially searched records and 15,801 (80.42%) exported records that remained after duplication removal using Endnote 20. According to the screening criteria, whether the papers discussed OHI seeking and the physician-patient relationship, 173 (1.09%) papers were included according to the title and abstract for further screening. Through the application of inclusion and exclusion criteria, of these 173 papers, 72 (41.6%) did not involve the impact of the physician-patient relationship; 7 (4%) were reviews; for 9 (5.2%), the original text could not be obtained; 19 (10.9%) did not have health information seeking as the main research object; 13 (7.5%) had full text in languages other than English; 10 (5.8%) were on nonempirical research; and 1 (0.6%) focused on physicians. The screening process is shown in Figure 1.

Finally, we included 42 of 173 (24.2%) English papers in the study; see Table 1. From the perspective of literature research methods, most of the studies were carried out in the form of questionnaires and interviews, and there were 11 (26%) studies in which research models and hypotheses were first proposed and questionnaires were designed for verification to study the mechanism of OHI seeking affecting the physician-patient relationship from different perspectives [11,23-32].

Figure 1. Flowchart of the selection process (English papers). OHI: online health information.

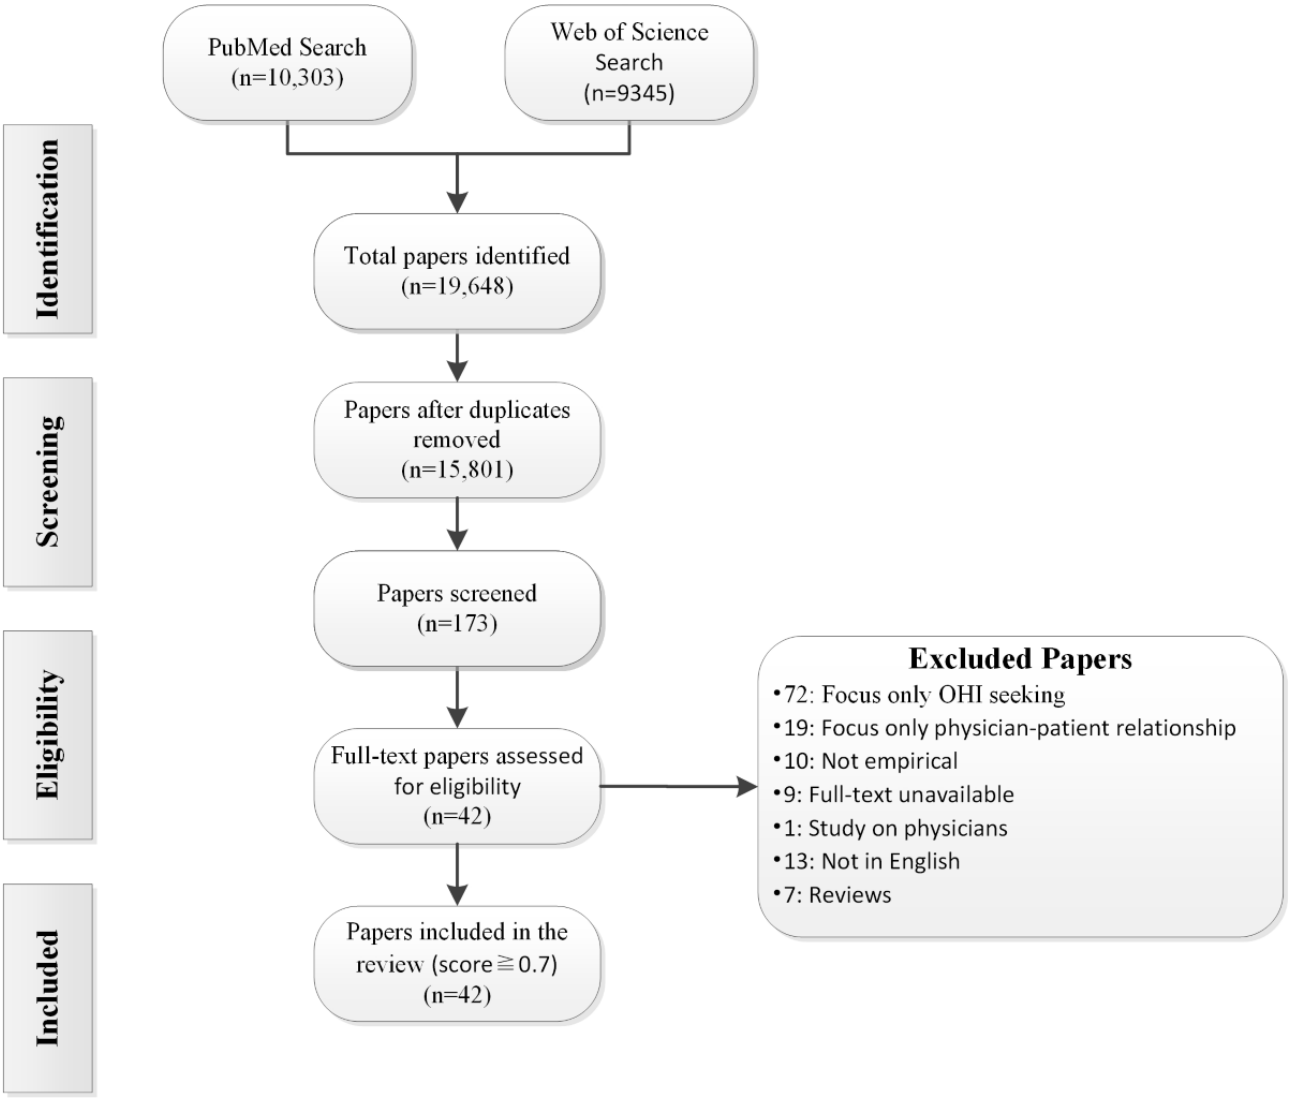

Table 1. Summary of included English papers (n=42).

Number	Reference	Country	Method	Participants, n	Participant characteristics	Factors affecting OHI[a] use covered in this paper (Y=yes/N=no)	Impact of OHI seeking on patients covered in this paper (Y=yes/N=no)	OHI seeking affects patients' evaluation of physicians covered in this paper (Y=yes/N=no)	Discussion of OHI and physician-patient relationship covered in this paper (Y=yes/N=no)
1	[33]	United Kingdom	Semistructured interview	22 (12 [55%] female, 10 [45%] male)	Adult patients with psychosis	Y	Y	N	Y

[a]OHI: online health information.

[b]OHC: online health community.

With searching in the CNKI and SinoMed, there were 5440 initially searched papers, of which 5219 (95.94%) exported papers in Chinese remained after duplication removal using Endnote 20. Of these, 88 (1.69%) papers were included according to the title and abstract for further screening. Through the application of inclusion and exclusion criteria, of these 88 papers, 54 (61%) did not involve the impact of the physician-patient relationship; 10 (11%) did not have health information seeking as the main research object; 7 (8%) were on nonempirical research; for 3 (3%), the original text could not be obtained; and 1 (1%) focused on physicians. The screening process is shown in Figure 2. All 13 (15%) papers met the quality rating except for 2 (15%). Finally, 11 of 88 (13%) Chinese papers were included in this study; see Table 2.

The conclusions of these papers were divided into 5 themes: (1) factors that affect patients' use of OHI, (2) the impact of OHI on patients, (3) OHI seeking affecting patients' evaluation of physicians, (4) discussion with physicians about OHI affecting the physician-patient relationship, and (5) the impact of OHI seeking on the physician-patient relationship, including positive effects, negative effects, and neutral views (Table 3). The neutral view refers to no significant effect or both positive and negative effects.

[a]OHI: online health information.

Factors Affecting the Use of OHI

Studies show that education level, income, gender, age, health literacy, culture, and other factors can affect people's use of OHI [12,26,33,34,39,42,49,51,56]. Five papers showed that users with high education level and high income are more willing to use OHI [12,33,34,39,42,62]. This population has relatively high health literacy and can better deal with OHI. Patients with difficulties in understanding health information are less likely to ask questions or seek guidance during consultation. Gantenbein et al [12] found that women are more willing to conduct OHI searches, while Aref-Adib et al [33] found that young male psychiatric patients are more likely to discuss health information with their physicians. De Looper et al [26] and Drug et al [56] found that younger patients engage more in OHIS, but Waring et al [51] did not observe the age difference possibly because the large age-grouping scope could not reflect the difference between the elderly and the young. In addition to personal factors, Chiu et al [59] found that the cultural environment of patients may also affect the communication on health factors. In a hierarchical culture of patients and physicians, patients are unwilling to ask questions for fear that the physicians would be unhappy. Instead, they choose to listen to the advice of physicians [59]. In this paper, we only included papers studying the relationship between physicians and patients; however, maybe many other factors also affect the use of OHI by patients.

Impact of OHI Seeking on Patients

Several studies have shown that OHI can enhance the communication ability and decision-making ability of patients. The study conducted by Iverson et al [36] showed that 46% of patients said they would change their health-related behaviors after searching for health information online. After searching the health information online, patients have a certain understanding of their own health status and disease treatment and can better understand the medical terms used by physicians when talking with them [25,38,59]. Murray et al [44] showed that people who discuss health information with physicians often have higher self-assessment ability to assess their own health. Liang et al [61] showed that patients who think that OHI is important and helpful to health decision making are more inclined to think that it will be beneficial to the physician-patient relationship.

However, some patients may show some negative effects after OHI query. Aref-Adib et al [33] found that some patients may have concerns over what they read and that they change medication adherence and behavior without communication with the physicians. Another concern raised by OHI seeking is related to the quality of OHI, such as the credibility and limitations of information [40]. OHI will affect patients' decision making, but patients still regard physicians as the main source of health information [47]. Due to the uneven quality of OHI and the lack of quality control, in addition to patients lacking medical information literacy, the judgments made by patients based on OHI are generally unscientific and difficult to be recognized by doctors, which may have a negative impact on the physician-patient relationship [62].

OHI Seeking Affects Patients' Evaluation of Physicians

The impact of OHI is mainly reflected in patients' trust in and satisfaction with physicians [42]. Patients' satisfaction with physicians is composed of many factors, among which the the main influencing factors are related to the actual communication between patients and physicians [23]. However, most patients are afraid to challenge their doctors, so they are reluctant to discuss their OHI [41]. Patients' satisfaction with OHI has a direct and positive impact on psychological safety [34], while psychological safety might have a direct and positive impact on patients' trust in physicians [24]. When patients use the network health community, the trust relationship among

community members also affects patients' trust in and satisfaction with physicians [71]. Liu [68] showed that continuous use of online health communities (OHCs) increases users' satisfaction with medical services.

Discussion With Physicians About Health Information Affects Physician-Patient Relationships

After OHI seeking, some patients choose to share health information with their physicians. Part of the motivation for discussing health information with physicians is that patients want to meet their psychological and emotional needs [42]. Iverson et al [36] showed that 73% of patients like to discuss OHI with physicians mainly because they think physicians are willing to discuss OHI. The willingness of physicians to discuss health information with patients is crucial. After discussing their concerns about OHI with physicians, the patients' medication adherence and behavior remain unchanged and the anxiety caused by OHI reduces [33]. In addition, after discussing OHI with physicians, patients' satisfaction with physicians significantly improves [39]. People who discuss OHI with their physicians think it has a positive impact on the disease and their relationship with their physicians [7].

However, some studies have also proved that the main reason patients do not actively discuss health information with physicians is the fear of challenging physicians' authority [33,35,38,40,42,43,59]. Patients worry that when they talk about OHI, or express some opinions that physicians cannot refute, the physicians will feel criticized [35]. Of course, there are also some health care professionals trying to maintain the existing authority by not discussing OHI [45]. Guanghua [62] showed that the negative impact of OHI is greater, which creates greater obstacles in the communication between doctors and patients in China.

OHI Seeking Affects Physician-Patient Relationships in China

A total of 53 papers were included in this study, of which 31 (58%) hold that OHI seeking has a positive impact on the physician-patient relationship, 14 (26%) have a neutral view, and 8 (15%) have a negative influence. It is worthy of in-depth study that 6 (11%) papers showed that OHI seeking has a negative impact on the physician-patient relationship in China. Therefore, the negative impact of OHI on China's internet users is worthy of attention. Due to the large population of China, the time for each patient to communicate with the doctor is short, and patients choose to search online for health information more for convenience than for accuracy or authority [67]. Some studies have shown that the inclusion of some wrong medical information and reports of malignant incidents in the physician-patient relationship have a negative impact on physician-patient trust, confirming media depression theory [67,69,70]. Feifei [64] found that for ordinary patients, due to the professional barriers of medical knowledge, it is difficult for them to distinguish between true and false after receiving false health information on the internet. This causes patients to question doctors and leads to difficulties in the physician-patient relationship [64]. Therefore, it is important to improve patients' health information literacy and the quality of OHI.

Discussion

Principal Findings

Based on the review of the included studies, we found that there are many factors that affect patients' choice of OHI, such as gender, age, education level, income, health literacy, and culture [33,34,39,42,49,51]. People with high income, education level, and health literacy are more likely to use OHI. The age difference is mainly between the young and the old. There is a digital divide between the elderly and the young [72]. One study found that older people prefer to choose people as sources of information, such as health care providers, pharmacists, relatives, and retired community workers [73]. From the perspective of patients, most of them think that OHI seeking does not affect the physician-patient relationship; some patients think it has a positive impact on the physician-patient relationship, and a few patients think it may have a negative impact on the physician-patient relationship [46]. As the impact of OHI seeking on the physician-patient relationship may be restricted by social and cultural factors, it may have adverse effects in a culture with distinct levels of patients and physicians [59].

The mechanism of OHI seeking affecting the physician-patient relationship is relatively complex. According to the study findings, OHI seeking can enhance patients' understanding of medical knowledge and enhance their decision-making ability and communication ability with physicians. At the same time, OHI seeking can also have an impact on patients' own psychology. Good quality of health information has a positive impact on the psychological safety of patients. Bylund [74] found that high satisfaction with OHI can promote patients' psychological security when communicating with physicians. Psychological safety has a certain impact on the distrust in the physician-patient relationship so as to affect the relationship [75]. Side effects of drugs and other information cause anxiety in patients. As the internet provides an opportunity to communicate with others about their concerns, anxiety tends to increase [76]. A small number of patients even have drug compliance changes and changes in their own medical behavior [76]. Previous studies have shown that that OHI can affect the consistency of communication between physicians and patients and the compliance of patients [33].

It is important that patients discuss health information with their physicians. Patients will seek OHI to prepare for seeing a doctor, fully participate in the decision making, and actively supplement their information during the process of seeking medical service [77]. However, this will also cause anxiety and a series of changes, such as compliance change and medical behavior change [33]. If patients do not discuss health information with physicians, the negative effects on some patients might even worsen. If patients discuss health information with physicians, these negative effects can be eliminated and alleviated. The survey results show that discussing health information with physicians is beneficial to patients' satisfaction with and trust in physicians. We must admit that patients need to discuss their health information with physicians to better promote the physician-patient relationship and improve medical services

[78]. Good physician-patient communication can improve the clinical outcomes of some diseases [79].

Several studies have mentioned that patients are afraid to discuss health information with physicians because they are afraid of challenging the authority of physicians and even of conflicts with physicians. The OHC is not well received by the professional medical staff. They have doubts about the quality of a lot of OHI and whether they can explain the medical information to the patients in a better way [16]. Patients tend to remain silent if they do not feel the physician's willingness to discuss OHI with them. When patients consult about traditional and nontraditional therapies, many physicians react defensively, resulting in adverse effects on patients' trust in them and the communication between physicians and patients [80]. Some physicians try to maintain their authority as physicians by avoiding discussing OHI [45]. Due to the widespread popularity of OHI, physicians should be aware that many patients seek OHI before consultation, and actively discuss and exchange OHI with patients [81].

Of the included 53 papers, 21 (39.6%) studied the impact of OHI seeking on the physician-patient relationship in China, of which 2 (9%) papers specifically mentioned that cultural factors play a potential role in OHI seeking for physician-patient relationships [59,62]. In the culture of hierarchical physician-patient relationships in China, the patient fully follows the physician's recommendations [59]. The popularity of OHI allows patients to play a more important role in the medical process. However, under the medical environment of "more patients, fewer physicians" in China, the communication time between each physician and patient is too short [62]. If the doctor cannot convince the patient and deny the patient's opinion directly without explanation, the conflict weakens the authority of the doctor and exacerbates the negative impact on the physician-patient relationship [62].

Several papers have shown that the internet usage time could reduce the patient's trust in the doctor [66,67]. Medical corruption, medical malpractice, physician-patient conflict, and other contents are more likely to spread among Chinese patients. Various types of negative news is frequently pushed to patients. The negative factors in the physician-patient relationship are magnified. The media often blame medical disputes on medical personnel, which exacerbates patients' distrust of doctors. In addition to negative news, the low quality of OHI has a negative impact on the physician-patient relationship [61,82].

OHI is a double-edged sword for the relationship between physicians and patients. It is becoming increasingly important in the relationship between physicians and patients. With high-quality OHI, it is relatively easier to have a positive impact on patients, thus promoting the physician-patient relationship. With the rapid growth and wide use of medical websites, there are important problems about the necessity of quality control [83]. The pattern of patients' access to health information is changing from passive recipients to active service seekers [77]. Health care professionals should not only discuss health information with patients but also guide them to correctly seek and use health information. Patients who can reasonably understand OHI can reduce the burden of physicians in the consultation and improve the communication [63].

Limitations

This study has a wide range of retrieval. When references were included, the focus was on whether health information seeking has an impact on the relationship between physicians and patients. Papers studying the impact of health information seeking on patients were not included, which may have led to missing potential research. In addition, due to the lack of a large number of studies and more reliable evidence, we could not reach a strong conclusion about how health information seeking affects the physician-patient relationship.

Conclusion

This study mainly focused on the effects of OHI on the relationship between physicians and patients. There are many factors influencing people's use of OHI, and young, female, highly educated, and high-income patients are more willing to search OHI. OHI seeking can affect patients' mentality and behavior. Through understanding OHI, patients can have a better understanding of medical knowledge, improve self-confidence during communication, and enhance self-decision-making behaviors. However, some OHI can lead to negative emotions and even change patients' health behaviors, due to the uneven quality of OHI. OHI seeking also affect patients' evaluation of doctors, including patients' trust in and satisfaction with physicians. OHI users choose to discuss OHI with doctors, which is beneficial to the physician-patient relationship in most cases. However, due to the subjective consciousness of patients, they may be concerned that it might affect the authority of physicians, which is the reason some patients do not initiate the discussion of health information. Moreover, the negative impact of OHI on China's internet users is worthy of attention; due to the low quality of OHI, poor health information literacy, short physician-patient communication time, and various types of negative news, patients' trust in doctors has declined. At present, China's vigorous promotion of "internet + medical health" and the reform of the hierarchical medical will be of great significance to improving the physician-patient communication model and promoting harmonious physician-patient relationships. At the same time, improving people's health information literacy and the quality of OHI is the crucial step in facilitating the positive effects of OHI on the physician-patient relationship.

Acknowledgments

The authors thank the State Key Program of the National Social Science of China (grant no. 17AZD037) and the Natural Science Foundation of Hunan Province (2019JJ80032) for their assistance in this study. We also appreciate the support of all participants.

Abstract

Background: Many children with mental health problems do not receive professional help. Despite the frequent use of digital health interventions (DHIs) such as websites or web-based service navigation platforms, their effects on parents' mental health literacy, help seeking, or uptake of professional services are unclear.

Objective: This study aims to provide a systematic review and narrative synthesis to describe whether DHIs improve the aforementioned parental outcomes.

Methods: Databases, including CINAHL, Embase, MEDLINE OVID, PsycINFO, and PubMed (2000-2020), were accessed. Studies were included if they evaluated quantitative changes in mental health literacy, help seeking, or the uptake of services by parents of children with mental health problems. Theoretical frameworks, sample sizes, participant demographics, recruitment, interventions, DHI use, results, and health economic measures were used for data extraction.

Results: Of the 11,379 search results, 5 (0.04%) studies met the inclusion criteria. One randomized controlled trial found the reduced uptake of services after using a DHI coupled with a telephone coach for a child's behavioral problem. Of 3 studies, 2 (66.7%) found statistically significant improvement in mental health literacy for attention-deficit/hyperactivity disorder but had no control group. One study found nonsignificant improvement in mental health literacy and help-seeking attitudes toward anxiety and depression compared with those in active controls. All studies were rated as having a high or serious risk of bias. Search results were affected because of a single reviewer screening articles, overall low-quality studies, and a lack of consistent nomenclature.

Conclusions: There is no high-quality evidence that DHIs can improve parents' mental health literacy, help seeking, or uptake of services. More research is needed to evaluate DHIs by using rigorous study designs and consistent measures.

Introduction

Background

Mental health problems are common among children [1,2]. They include internalizing problems, such as anxiety and lowered mood, and externalizing problems, such as hyperactivity, oppositional defiance, and aggression. Around half of these problems can progress to mental health disorders that are associated with adverse outcomes, including early school dropout, criminal justice system involvement, lower life satisfaction, poorer relationships, and lower earning potential [3-9]. Fortunately, there is a range of evidence-based treatments that have been shown to improve mental health problems in children, including the use of websites or web-based programs or other digital health interventions (DHIs) [10-13]. A DHI can be defined as the digital delivery of health information, such as through websites or apps, for health-related purposes [14]. Many of these treatments, including those delivered by DHIs and face-to-face interventions, focus on improving parenting—a key modifiable risk factor for these problems [15]. Despite treatments being available, many children with mental health problems do not receive professional help [2,16-18].

There are several recurrent barriers that prevent children receiving professional help. These barriers can be viewed along the help-seeking process, as parents need to recognize their child's problem and acknowledge their need for additional support, be aware of treatment options, overcome stigma in accessing treatment, and ultimately access available services or treatments [2,19,20]. A lack of problem recognition and awareness of available treatments reflect inadequate mental health literacy, which has been defined as the "knowledge and beliefs about mental disorders which aid their recognition, management or prevention" [21]. Mental health literacy is important because it is linked to actions and mental health outcomes [22]. For children, especially young children, parents play a large role in recognizing the child's problem and facilitating help seeking (Figure 1).

Ideally, we should be able to improve parents' knowledge of mental health problems in children and where to find available and accessible services to help their children. This could be done by improving their mental health literacy, a known modifiable factor of help seeking [23]. However, previous research on interventions designed to improve mental health literacy and help seeking has been hampered by a lack of consistent measures of mental health literacy and a lack of focus on parents [22,24,25]. For parents, a US study with 165 children with mood disorders and other mental health comorbidities showed that face-to-face mental health literacy interventions can improve the quality of services accessed by families compared with waitlist control. The quality of services was measured by consensus among a group of blinded expert clinician researchers [26]. However, this intervention was intensive (8 group sessions lasting 90 minutes each) and may have been affected by attrition bias, as only 74% of participants completed the 18-month follow-up. In addition, several families dropped out of the waitlist control group after their child's symptoms improved, underscoring the need for controlled trials to account for the natural history of some mental health problems improving over time.

Digital delivery of this educational material to parents, such as through a DHI, may prove to be an effective, accessible, scalable, and desirable way to improve parents' mental health literacy and help seeking. Most parents search the web for health information and seek out the lived experience of other parents through forums, such as those on Facebook [27,28]. As parents seek out this information on the web, money and resources are devoted to building websites, apps, and platforms to help parents better understand their child's mental health and where to receive help. Child mental health websites, such as childmind.org, can have enormous reach with a recent mental health campaign reaching 275 million people [29].

The World Health Organization states that DHIs have many perceived benefits, including enhanced reach, accessibility, scalability, desirability, reduced stigma, and perceived cost-effectiveness [14]. DHIs' perception of cost-effectiveness comes from the potential for near-infinite scalability at low cost and targeted early intervention [14,30,31]. However, data on cost-effectiveness are rarely collected, despite recommendations to measure the economic impact as part of any DHI evaluation [32,33].

DHIs have been shown to improve mental health literacy in adults, based on the findings of 2 systematic reviews [34,35]. However, these reviews, which included a combined total of 28 studies, only included 1 study with parents.

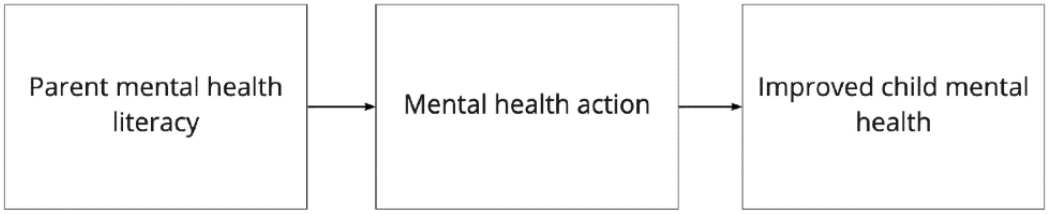
The single-parent study was a randomized controlled trial that found that a convenience sample of parents recruited from a single workplace improved their mental health literacy from a DHI [36]. This lack of focus on parents in previous reviews is important because parents are the agents of change for their child's mental health. Unlike adults seeking help for themselves, parents' willingness to receive help for their child's mental health problem is influenced by unique factors, such as whether the child participates in mental health treatment, or whether the treatment is framed in terms of child development [37,38]. With half of all adult mental health disorders originating in childhood, it is crucial to determine how DHIs can improve parents' mental health literacy, help seeking, and uptake of mental health services for their children [9].

However, there have been no consistent positive effects on parental help-seeking attitudes, with some low-quality studies finding a positive effect of DHIs, but most found no effects [34,35]. Studies in these 2 reviews had some limitations, specifically the common use of convenience sampling, the predominant focus on young people, lack of consistent measures, and low-quality evidence.

Recently, a universal education program delivered via SMS text messaging improved mental health literacy in the parents of adolescents compared with care as usual control. However, this study did not include parents of younger children or parents who were identified as having an adolescent with a mental health problem, who may be more likely to benefit from an intervention that facilitates help seeking [39].

Little is known about the effects of a DHI on the mental health literacy of parents, especially parents of young children, and even less is known about the effects on help seeking and uptake of services and cost-effectiveness. This is despite the frequent use of DHIs by parents and low uptake of services among many children with a mental health problem.

Figure 1. Link between parent mental health literacy and child mental health outcomes (adapted from a study by Jorm [22]).



Objectives

In this study, we aim to conduct a systematic review of the literature to understand (1) whether DHIs targeting parents of children aged 2 to 12 years with a mental health problem improve mental health literacy and (2) whether the use of DHIs is associated with changes in parental help seeking or uptake of mental health services for their child. We also aim to report the cost-effectiveness of such DHIs.

Methods

The systematic review was registered with PROSPERO (CRD42020130074). We conducted and reported a systematic review according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [40].

Eligibility

We included studies that evaluated a DHI delivered directly to parents of children aged 2 to 12 years, with quantitative data reporting on outcomes of mental health literacy (specifically knowledge of treatment), help seeking (attitudes, intentions, and behaviors), or uptake of mental health services. Quantitative data were chosen to narratively synthesize the impact of DHIs on mental health literacy, help seeking and uptake of services.

For this review, we defined a DHI as a consumer-facing intervention using information communication technology targeting parents. The intervention could deliver information as a static webpage, a web-based parenting program, a web-based social network, a native mobile app, or other content delivered using digital means (other than telehealth). This definition was included in the PROSPERO registration.

We included DHIs targeting children with and without a mental health condition as long as the DHI was delivered as part of a program where some families were identified as having a mental health concern for their child. We included children aged 2 to 12 years. This age range was selected because of their likely dependence on parents to receive help for their mental health and the long-term impact of these early years on the well-being into adulthood [9]. We required a minimum of 1 outcome question on mental health literacy focusing on any of the following: knowledge of treatment, help seeking, or uptake of services.

Study designs included randomized controlled trials, quasi-randomized trials, and uncontrolled single-cohort studies. We restricted our analysis to articles published between January 2000 and December 2020 and written in English. We excluded conference proceedings and gray literature.

Data Sources and Search Strategy

We developed our search strategy after consultation with a research librarian at The Royal Children's Hospital, Melbourne, Australia. A pilot search was performed in MEDLINE OVID, followed by a review of keywords and further development of the search strategy. We searched the electronic databases CINAHL, Embase, MEDLINE OVID, PsycINFO, and PubMed in late 2019 and repeated the search in January 2021 to identify any more recent publications.

We also reviewed the reference list of the included studies to identify additional studies for full-text review. All search results were compiled in Endnote and then exported to Covidence for screening. The search strategy used for all the databases is given in Multimedia Appendix 1.

Study Selection

One author (DP) screened the titles and abstracts of all articles produced from the search against the eligibility criteria. The full text of the remaining articles was obtained and screened again against the inclusion criteria. Any concerns about study eligibility were resolved in discussions with the supervising author (HH) during fortnightly supervision meetings. If there was insufficient evidence from the full-text study on whether it met the inclusion or exclusion criteria, DP attempted to contact the authors to obtain relevant information.

Data Collection Process

Two authors (DP and MG) independently extracted data from the included studies using a pre-existing data collection form for intervention reviews from Cochrane [41].

Data Items

Data extracted included study design; number of participants; type of comparison (where relevant); setting; recruitment; age and sex of participants and their children; the intervention, including the theoretical basis (a factor that may influence the success of a help-seeking intervention) [42] and measures of DHI use; outcome measures and whether they are validated measures; results; and economic outcomes. The data extracted were compared for accuracy, and the supervising author (HH) resolved any disagreements. Where possible, we calculated the effect sizes of the interventions and included these in Table 1.

Table 1. Primary outcomes of the interventions.

Study	Design	Sample, n	Intervention	Timing of measures	Primary outcome	Measure	Outcome	*P* value	Validated measure
Montoya et al [43]	Pre or post single cohort	35	DISCERN tool assessing popular Spanish websites about ADHD[a] treatment	Unspecified time points pre, post parents using the DISCERN tool	Mental health literacy: ADHD specific knowledge and motivation for treatment	• The ADHD-knowledge and motivation for treatment questionnaire (ADHD-KMT). • Basic knowledge subscale	• Pre: mean 49.09 (SD 9.46) • Post: mean 63.21 (SD 9.45) • Cohen *d*=1.49	• <.01	No
Ossebaard et al [44]	Pre or post single cohort	195	Web-based decision aid on ADHD treatment	Pre, post intervention, though exact timing unclear	Mental health literacy: ADHD knowledge and treatment	• "Would you please rate your knowledge on ADHD and its treatment possibilities" with a response on a 1-10 numerical scale	• Pre: mean 6.2 (SD 1.9) • Post: mean 6.5 (SD 1.9) • Cohen *d*=0.16	• .60	Unclear
Ryan et al [45]	Pre or post single cohort	172	Information-based website on ADHD management	Baseline: 28 days post-baseline	Mental health literacy: ADHD knowledge	• ADHD Knowledge and Opinions Survey-Revised (AKOS-R) – adapted • Lower score (min: 30; max: 60)=higher knowledge	• Wilcoxon signed rank test showed a statistically significant moderate increase in knowledge; Z=−4.799; Cohen *d*=−0.503	• <.01	No

Study	Design	Sample, n	Intervention	Timing of measures	Primary outcome	Measure	Outcome	*P* value	Validated measure
Sapru et al [46]	Nonrandomized controlled trials	27	3× PowerPoint presentations emailed to participants	Pre and post intervention, though exact timing unclear	Mental health literacy and help-seeking attitudes for depression	• Understanding mood disorders questionnaire • Lower incorrect score=higher knowledge	• Median number of incorrect scores: Intervention: Pre 7, post 1; Control: Pre 7.5, post 4 • Within-group difference (pre or post) in PowerPoint group: Wilcoxon signed-rank test showed statistically significant improvement in responses (Z=−2.30; *P*=.04) • Comparison between PowerPoint group and control (in-person group): One-way ANOVA showed no statistically significant improvement difference in responses	• Within-group difference (pre or post) in PowerPoint group: *P*=.04 • Comparison between PowerPoint group and control (in-person group): *P* value not reported	Not reported
				Pre, post intervention, though exact timing unclear	Mental health literacy and help-seeking attitudes for anxiety	• Understanding of anxiety disorders questionnaire • Lower incorrect score=higher knowledge		• Within-group difference (pre or post) in PowerPoint group: *P*=.04 • Comparison between Power Point group and control (in-person group): *P* value not reported	Not reported

Study	Design	Sample, n	Intervention	Timing of measures	Primary outcome	Measure	Outcome	*P* value	Validated measure
							• Median number of incorrect scores: Intervention: Pre 9, post 2; Control: Pre 6.5, post 3.5 • Within-group difference (pre or post) in PowerPoint group: Wilcoxon signed-rank test showed statistically significant improvement in responses (Z=−2.30, *P*=.04) • Comparison between PowerPoint group and control (in-person group): one-way ANOVA showed no statistically significant improvement difference in responses		
Sourander et al [47]	Randomized controlled trial	464	Strongest Families' Smart website and 11× weekly 45-minute telephone coaching sessions	6 months, 12 months, and 2 years after randomization	Uptake of services in the past 6 months	• Past service use evaluated using a yes or no question: "asking the parents if the child had received any behavioural treatment in the last 6 months"	• Number of participants reporting uptake of services: Intervention: 28 (18%); Control: 46 (28%); OR 1.8 [95% CI 1.1-3.1]	• .02	No

[a]ADHD: attention-deficit/hyperactivity disorder.

Risk of Bias

The included studies were assessed for quality against 1 of 2 instruments. For nonrandomized studies, we assessed the risk of bias using the Risk of Bias in Nonrandomized Studies of Interventions tool [48]. For randomized studies, we assessed bias using the revised Cochrane tool for assessing risk of bias in randomized trials [49]. The quality assessment was conducted independently by DP and MG. They compared their assessments and resolved any disputes by discussion or through the input of the supervising author (HH).

Summary Measures

Whenever possible, we presented the outcome data of mental health literacy, help seeking, and uptake of services consistently, with parametric continuous data compared using means, nonparametric continuous data presented using medians, and categorical data presented as proportions. We also attempted to group the outcome data by validated and unvalidated measures.

Synthesis

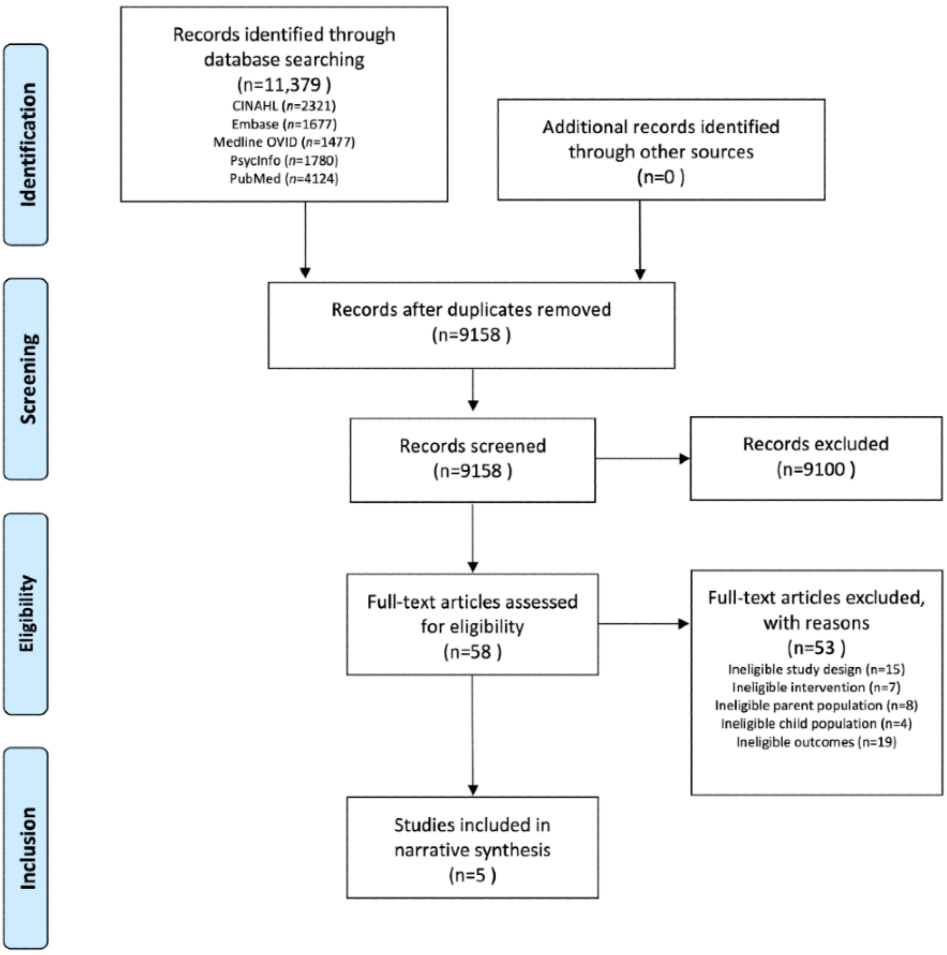
Owing to the heterogeneity in outcome measures, we could not conduct a meta-analysis. Accordingly, we used a narrative synthesis to describe the effects of the DHIs.

Results

Search Results

Through the search strategy detailed in the previous section, a total of 11,379 potentially eligible articles were identified. Of the 11,379 articles, 5 (0.04%) met all inclusion and exclusion criteria (Figure 2). The primary author (DP) reviewed the reference list of these included studies, which revealed no additional studies meeting inclusion and exclusion criteria.

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram of search results and study selection.



Description of Included Studies

Of the 5 included studies, 1 (20%) was a randomized controlled trial [47], 1 (20%) was a nonrandomized trial of 2 interventions [46], and 3 (60%) were uncontrolled before and after studies [43-45] (Table 2).

All 5 studies were published between 2010 and 2018. There were 893 participants across the 5 studies, with the number of participants ranged from 27 to 464. The mean age of the children ranged from 4 to 10 years across the 5 studies. All studies were published in Europe or North America. Outcome measures included knowledge of attention-deficit/hyperactivity disorder (ADHD) treatment, knowledge and help seeking for anxiety and depression, and uptake of treatment for a child's behavioral problem.

A total of 3 studies included participants with concerns about, or a recent diagnosis of, ADHD [43-45]. Another study included only participants who were parents of children with high-level disruptive behavior on the Strengths and Difficulties Questionnaire and who recognized that their child had a problem [47]. The final study included participants who were referred to a tertiary center for management of the child's anxiety or depressive disorder, although the authors did not describe how the disorder had been diagnosed [46].

Participants were sampled using a variety of techniques. Of the 5 studies, 2 (40%) used consecutive sampling techniques to approach participants attending a scheduled universal health appointment [47] or a tertiary hospital mental health outpatient clinic [46]; 1 (20%) used a convenience sample of participants who had already attempted to access the intervention evaluated in the study [44]; and 1 (20%) used a convenience sample in which participants were selected by their child's physician or from a local advocacy group [43].

Table 2. Study description.

Study	Country	Design	Sample, n	Participants	Recruitment	Intervention	Comparator	Theoretical basis for the intervention	Digital health intervention use	Economic outcomes
Montoya et al [43]	Spain	Single cohort pre or post study	35	Parents of children with a recent diagnosis of ADHD[a]	Parents selected by their child's physician or from a local advocacy group	Use of the DISCERN tool to assess the quality of 10 popular Spanish websites about ADHD treatment	Nil	Not reported	• Not reported	Not reported
Ossebaard et al [44]	Netherlands	Single cohort pre or post study	195	Parents of children with a recent diagnosis of ADHD	The web-based decision aid invited visitors to the website to participate in the study	Web-based decision aid on ADHD treatment	Nil	Yes	• About 7500 unique visits • About 6 minutes on site • About 8-9 clicks to navigate	Not reported
Ryan et al [45]	United Kingdom	Single cohort pre or post study	172	Parent or carer of a child with confirmed or suspected ADHD	Invited to attend if attending one of 3 pediatric outpatient clinics for suspected or confirmed ADHD	Information based website on ADHD management	Nil	Not reported	• Never used the website: 62 (41%) • 1-2 times: 50 (33%) • 4-5 times: 27 (18%) • 5-6 times: 6 (4%) • 7+ times: 8 (5%)	Not reported

[a]ADHD: attention-deficit/hyperactivity disorder.

Description of the Included Interventions

Of the 5 interventions, 4 (80%) were delivered on the web through a website [43-45,47] and 1 (20%) was delivered via a series of PowerPoint presentations [46]. These PowerPoint presentations were emailed to each family every week for 3 weeks. The topics of the three PowerPoint presentations were (1) introduction and treatment options, (2) interpersonal illness and communication skills, and (3) problem solving and personal reflection [46].

A total of 2 (40%) web-based interventions were delivered with a cointervention [43,47]. One (20%) of these cointerventions consisted of 11 consecutive weekly telephone coaching sessions, in addition to access to the Strongest Families Smart Website [47]. This website features 11 sessions containing tailored content, exercises, and instructional videos and requires parents to complete knowledge and experience-based questions. This content is designed to help parents develop skills to promote positive behavior and a positive relationship with their children [47]. Another study by Montoya et al [43] used a cointervention. In this study, parents evaluated popular ADHD websites against the DISCERN instrument [50] to assess the quality of written consumer health information available on ADHD treatment [43].

The remaining 2 (40%) interventions consisted of a website focused on ADHD [44,45]. A study by Ossebaard et al [44] trialed a web-based decision aid designed to help support parents and caregivers through the decision-making process of ADHD treatment. The average visitor, which included participants and nonparticipants, visited the website for an average of 6 minutes [44]. The final ADHD website contained information on the management of ADHD [45]. The website was funded by the pharmaceutical company Shire, which was disclosed to the participants. The participants could access the website for 1 month, and most of the participants accessed the website once or twice during that time [45]. For these 2 ADHD websites, postintervention outcomes were measured immediately following the intervention [44], 30 days after the intervention started [45], or 2 years after the intervention commenced [47].

Of the 5 studies, 2 (40%) did not specify precisely when they recorded postintervention outcomes [43,46].

Effect on Mental Health Literacy, Help Seeking, and Uptake of Services

Mental health literacy outcomes were the most common outcome assessed by the included studies, with 80% (4/5) of the studies measuring some form of mental health treatment knowledge (Table 1). The most common mental health problem assessed by the knowledge measures was ADHD [43-45], followed by depression and anxiety knowledge and help-seeking attitudes studied by Sapru et al [46]. Only 1 (20%) study measured the parent-reported uptake of mental health services [47].

ADHD Knowledge

Despite 60% (3/5) of the studies intending to measure ADHD knowledge and all through survey responses, each study used a different measure. None of these measures were validated. An adapted version of a validated measure was used by Ryan et al [45], but the authors did not provide a description of how it had been adapted and whether it was still valid. All of the ADHD knowledge studies were uncontrolled pre-post studies, and all showed an improvement in parent ADHD knowledge scores, 2 (40%) of which were statistically significant [42,49].

In addition, changes in knowledge among those who accessed the website and those who did not were assessed by Ryan et al [45]. Their study [45] showed that those who accessed the website at least once had a moderately significant improvement in knowledge compared with those who never accessed the *ADHD and You* website.

Of note, evaluation of a web-based decision aid by Ossebaard et al [44] was affected by a large number of missing data. From the 7500 unique views to the site, all of whom were invited to participate in the study, only 195 participants were enrolled, leading to potential selection bias. In addition, of these 195 participants, only 12 (6.2%) provided outcome data before and after the intervention, leading to potential attrition bias.

Depression and Anxiety Knowledge and Attitudes to Help Seeking

The only study that evaluated anxiety and depression-based mental health literacy and help-seeking attitudes was carried out by Sapru et al [46]. One measure was used for anxiety, and another for depression, with each measure assessing both knowledge and help-seeking attitudes within the same instrument. It was not reported whether these tools had been validated for this population.

Both the anxiety and depression measures showed an improvement in median scores of the intervention (web-based) compared with those of the control (in-person) group, although this difference was not significant in a small sample size.

Missing data and high attrition rates were again common, with outcome data provided for only 38% (5/13) of the intervention participants and 57% (8/14) of the control participants. The authors did not report why so many families failed to initiate or complete the programs and outcome measures. Two of the authors were contacted but did not provide further clarification on reasons for the missing data.

Uptake of Mental Health Services

Only 1 (20%) study measured the uptake of mental health services, which was also the largest study and had the longest follow-up of 2 years [47]. A study by Sourander et al [47] asked parents to self-report whether they had received any behavior treatment for their child in the previous 6 months. This measure was recorded at 6, 12, and 24 months after starting the 11-week intervention. The authors did not report whether this measure had been validated. Fewer parents in the intervention group, consisting of a website and 11 weekly telephone coaching sessions, reported that their child had accessed behavioral treatments (28/160, 17.5% participants) than did parents in the control group (46/164, 28% participants; odds ratio 1.8, 95% CI 1.1-3.1; P=.02). This reduction in the uptake of behavioral treatments occurred in the context of a small but significant

improvement in the child's behavior in the intervention group compared with the control group.

Cost-effectiveness

No studies reported on the cost-effectiveness or costs of the DHIs.

Assessment of Risk of Bias

One randomized controlled trial was rated as having a high risk of bias in 1 domain because of missing data, giving it an overall rating of high risk (Table 3) [47].

A total of 4 study designs were nonrandomized, with 3 (75%) of these studies [43,45,46] rated at serious risk of bias and 1 (25%) [44] rated at critical risk of bias (Table 4). The studies were rated at serious risk of bias because of a lack of identification of, or control for, potential confounders; potential for bias in selection of participants; and lack of objective outcome measures. The large number of missing participants also contributed to attrition bias and subsequent critical risk ratings.

Table 3. Risk of bias of randomized studies using the Cochrane tool for assessing risk of bias in randomized trials (RoB 2).

Study	Randomization process or selection bias	Deviations from intervention	Missing outcome or attrition bias	Measurement of outcome or detection bias	Selection of reported result or reporting bias	Overall
Sourander et al [47]	Low	Low	High	Some concerns	Some concerns	High

Table 4. Risk of bias in nonrandomized studies using the Risk of Bias in Non-randomized Studies–of Interventions (ROBINS-I) tool.

Study	Confounding	Selection of participants	Classification of interventions	Deviations from intended interventions	Missing data	Measurement of outcomes	Selection of reported result	Overall
Montoya et al [43]	Serious	Low	Low	Low	Low	Moderate	Moderate	Serious
Ossebaard et al [44]	Serious	Critical	Low	Low	Critical	Serious	Moderate	Critical
Ryan et al [45]	Serious	Low	Low	Low	Moderate	Serious	Moderate	Serious
Sapru et al [46]	Serious	Serious	Low	Low	Moderate	Moderate	Moderate	Serious

Discussion

Principal Findings

This study identified 5 studies of DHIs for parents of children with a mental health problem, measuring changes in mental health literacy, help seeking, or uptake of services.

Of those measuring mental health literacy, 80% (4/5) of the studies showed an improvement in parent knowledge. However, most of these studies focused on ADHD knowledge and were of low quality.

Of the 5 studies, 1 (20%), using a very small sample size of parents, measured both mental health literacy and help-seeking attitudes and used a nonrandomized control group, showing a nonsignificant trend to improved knowledge and help-seeking attitudes for child's anxiety and depression. For this study, the mental health literacy and help-seeking attitudes outcomes were evaluated using the same measure and results were not presented separately, precluding conclusions about whether this improvement was predominantly because of changes in knowledge or attitudes.

The only large randomized controlled trial measured uptake of services and found the use of a website coupled with a telephone coach, reduced uptake of services for the child's behavior, whilst simultaneously improving child behavior compared with a control group at 24 months follow up [47]. Despite the widespread use of websites and apps to help parents understand their child's mental health or find services to help their child, only one study evaluated a universally accessible website [43]. Of the 5 studies, 2 (40%) had a comparison group, and neither of these studies compared the DHI to an existing and previously evaluated face-to-face, web-based, or school-based intervention. Thus, the comparative efficacy, feasibility, and cost-effectiveness of DHIs and face-to-face interventions remain unclear.

Of the 5 studies, 2 (40%) reported using theory to inform the design of the DHI. Although there is no evidence to definitively support the use of theory in designing a DHI, it is recommended to use a theory, or theories, to inform the design of health promotion interventions, and it may be beneficial for DHIs targeting help seeking [42,51].

None of the studies reported health economic outcomes of the interventions, such as development costs, implementation expenses, or potential financial benefits from the intervention on the family or health services. The overall quality of the papers was low, with only 20% (1/5) of the studies being a randomized controlled trial. All studies were rated as either high risk of bias on the revised Cochrane tool or serious or critical risk of bias on the Risk of Bias in Nonrandomized Studies of Interventions tool.

In addition, the lack of consistent and validated measures made a meta-analysis impossible and limited our ability to compare efficacy among the interventions. The lack of consistent measures has been described previously [24].

This is the only review showing the impact of DHIs on mental health literacy, help seeking, and referral uptake in parents of children with mental health problems. We searched a wide range of databases, hand searched references from included articles, and attempted to contact authors where data were missing. This study included all quantitative studies evaluating a DHI across multiple time points and thus presented a wider scope of included study designs than existing review articles on DHIs for mental health literacy or help seeking. Finally, this was the only study that extracted data on the theoretical basis of the intervention and economic outcomes.

Limitations

We included only studies with quantitative outcome measures. We recognize that we could have used categorical coding of qualitative data (eg, positive, neutral, or negative impact) to include qualitative research. This could be an area for future research. In addition, qualitative studies may provide more nuanced data into the effectiveness or otherwise of DHIs in this area, particularly on factors influencing help-seeking attitudes, intentions, and behaviors. In addition, a single reviewer (DP) evaluated all search results against the inclusion and exclusion criteria, which may have resulted in studies being missed at the screening stage. However, hand searching of references within these papers revealed no new studies, suggesting that it is unlikely that we missed any published studies. The studies included were of poor quality; therefore, the results must be interpreted with caution. This review only included peer-reviewed journals and did not include a search for gray literature. As such, there is potential for publication bias in the results. Finally, a lack of consistent nomenclature around help seeking and uptake of services may have resulted in the search strategy missing some studies that measured these outcomes.

Impact

There is no high-quality evidence that DHIs improve parent mental health literacy, help seeking, or uptake of services, even for the most studied area of ADHD. There is low-quality evidence that parents' mental health literacy can be improved through the use of DHIs. There is also evidence that the use of a website and telephone coach may reduce the long-term uptake of mental health services for preschool children with disruptive behavior. The economic benefit of any DHI targeting parent mental health literacy, help seeking, or uptake of services remains unknown. This study cautiously supports the use of DHIs, especially ADHD websites, to improve parent mental health literacy. There is no evidence that any DHI can improve help seeking or uptake of services for children with a mental health problem.

Future Research

Despite the widespread availability, enthusiasm for, and use of DHIs among parents, there is little rigorous evidence regarding the effect of DHIs on parent mental health literacy, help seeking, and uptake of services for their children. There is an urgent need to develop, implement, and rigorously evaluate DHIs designed to improve these outcomes, including an economic evaluation of their effects. Websites targeting parent mental health literacy, especially for mental health problems other than ADHD, should be evaluated to establish whether they increase mental health literacy. Ideally, this evaluation would compare new and previously evaluated interventions using validated measures of parent mental health literacy.

Researchers should conduct randomized controlled trials of new and existing DHIs, including existing interventions that are already frequently accessed by parents. Comparison of face-to-face and school- or community-based interventions would also prove helpful in understanding the role of DHIs within the broader context of child mental health services [25]. Outcomes should include validated measures of parents' knowledge of mental health problems in children and mental health actions, such as help seeking and uptake of services [25]. Consistent use of validated measures would allow a comparison of interventions and meta-analysis of their effects [52]. Research focusing on help seeking and uptake of services is especially important, given that so many children with mental health disorders are not receiving professional help. Until such research is conducted, we do not know whether a DHI can improve the uptake of mental health services among parents of children with mental health problems. A systematic review of qualitative studies may provide additional information on the influence of DHIs on parents' help-seeking behaviors.

Conclusions

This review found low-quality evidence that DHIs may increase mental health literacy for ADHD and increase mental health literacy and help-seeking attitudes toward anxiety and depression. Overall, the heterogeneity of measures and high risk of bias across studies impacted our ability to confidently interpret these findings. We highlight the gap between parents' frequent use of web-based sources of health information and the paucity of published evidence on the effect of these DHIs on help seeking, the uptake of services, and cost-effectiveness.

Acknowledgments

The authors would like to thank Ms Poh Chua, a research librarian at The Royal Children's Hospital, Melbourne, Australia, for her help in developing the search strategy for this review. In addition, they would like to thank Associate Professor Emma Sciberras for her assistance in conceptualizing this paper. DP was funded by the National Health and Medical Research Council Postgraduate Scholarship (grant 1189935). HH was supported by the National Health and Medical Research Council Practitioner Fellowship Award 1136222. The Victorian Government's Operational Infrastructure Support Program supported research at the Murdoch Children's Research Institute.

Authors' Contributions

DP conceptualized and designed the study, searched the literature, extracted data, conducted a quality appraisal, drafted the initial manuscript, and reviewed and revised the manuscript. MG extracted data, conducted a quality appraisal, and reviewed and revised the manuscript. HH conceptualized and designed the study, supervised the data extraction and quality appraisal, and reviewed and revised the manuscript. All authors approved the final manuscript as submitted and agreed to be accountable for all aspects of the work.

Conflicts of Interest

None declared.

Abstract

Background: Recent meta-analyses suggest the use of technology-based interventions as a treatment option for obesity in adulthood. Similar meta-analytic approaches for children are scarce.

Objective: The aim of this meta-analysis is to examine the effect of technology-based interventions on overweight and obesity treatment in children and adolescents.

Methods: A systematic literature search was performed using MEDLINE (PubMed), Scopus, and Cochrane Library for randomized clinical trials to identify interventional studies published between January 2000 and February 2021.

Results: In total, 9 manuscripts from 8 clinical trials of 582 children or adolescents were considered eligible. BMI, BMI z-score, and other BMI-related baseline metrics during and after intervention were considered as primary outcomes. In 7 of 8 studies, a technology-based intervention was applied in addition to conventional care. Of the 8 studies, 6 studies were conducted in the United States, 1 in Australia, and 1 in northwestern Europe. In total, 5 studies included adolescents, whereas the rest addressed children aged 9 to 12 years. Intervention duration ranged from 3 to 24 months. Significant differences between groups in BMI metric changes were reported by 5 of the 8 studies. Pooled analysis revealed an overall significant decrease in BMI metrics in the intervention group (standardized mean difference –0.61, 95% CI –1.10 to –0.13; *P*=.01). Subgroup analysis revealed that significance was lost in case of no parental involvement (standardized mean difference –0.36, 95% CI –0.83 to 0.11; *P*=.14). The small number of clinical trials found, the varying study quality, and the study heterogeneity are some limitations of this review.

Conclusions: The studies reported herein describe functional and acceptable technology-based approaches, in addition to conventional treatments, to enhance weight loss in young populations.

Introduction

Background

Excess weight in childhood and adolescence has remained one of the most important global public health challenges since emerging as a concern several decades ago [1]. The urgent need to reverse the course of childhood obesity has led to significant growth in research regarding the efficacy of childhood obesity interventions [2]. Various interventions have been tested so far, from school-based interventions to comprehensive behavioral programs with multiple components, delivered by a multidisciplinary team [3,4]. Such models of treatment—even when effective—are often inconvenient, burdensome, and

inaccessible in some cases. New computer- or mobile-assisted information and communication tools can provide useful means to develop smart digital health interventions that could tackle childhood obesity [5,6]. Data collected through internet-linked systems, electronic health records capturing clinical or demographic information, and sensors or smartphones tracking dietary behaviors provide the opportunity to generate useful knowledge regarding users' health, behavior, and progress [7].

A previous meta-analysis with 83 randomized clinical trials (RCTs) has suggested the use of technology-based interventions as a treatment option for obesity in adulthood with potential benefits in weight loss [8]. For children and adolescents, there is only 1 meta-analysis on eHealth overweight and obesity interventions, where parents or caregivers were the agents of change [9]. The meta-analysis included interventions, such as behavioral websites with nutrition information, interactive voice response sessions, or telemedicine via videoconferencing. The fact that most of the eligible technological facilities lacked an interaction with users and the self-monitoring component is considered a limitation. Other meta-analyses examined the effect of web-based or mobile-based interventions on children commenting on modifications in obesogenic behaviors, such as sedentary lifestyle or unhealthy nutritional habits and not on core outcomes such as BMI [10,11]. Therefore, this systematic review and meta-analysis examines the effect of technology-based interventions on overweight and obesity treatment in childhood and adolescence.

Objectives

The objective of this meta-analysis is to determine whether such interventions, delivered mostly on top of conventional care, could be more effective in improving the weight status of children or adolescents with overweight or obesity compared with conventional care or no care. The research hypothesis in this study is that technology-based interventions are effective in weight management and in case of direct comparison with conventional care, at least equivalent to conventional care.

Methods

Search Strategy

Following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2009 guidelines, a computer-assisted systematic literature search (not a registered protocol) was performed by 2 independent researchers (M Kouvari and M Karipidou) using MEDLINE (PubMed), Scopus, and the Cochrane Library for RCTs examining the effect of technology-based versus conventional interventions on weight management of children and adolescents with excess weight. The search strategy was mainly based on Medical Subject Headings terms as follows: *(obesity* OR *overweight* OR *body mass index* OR *weight* OR *diet* OR *nutrition)* AND *(mobile health* OR *ehealth* OR *mhealth* OR *mobile technology* OR *Internet* OR *cellular phone* OR *cellular phones* OR *smartphone* OR *telecommunications* OR *mobile applications* OR *web-based* OR *mobile apps* OR *portable electronic app* OR *portable software app* OR *text message* OR *SMS* OR *short message service* OR *portable game* OR *computers, handheld* OR *PDA* OR *personal digital assistant* OR *social media* OR *social media health* OR *Twitter* OR *tweets* OR *Facebook* OR *Instagram* OR *mobile fitness apps* OR *online social networking* OR *virtual reality* OR *avatars* OR *online gaming* OR *video games)* AND *(pediatric* OR *child* OR *adolescent* OR *youth)* AND *(clinical trial* OR *pilot study* OR *randomized controlled clinical trial)*. The search was limited to publications in English from January 1, 2000, to February 1, 2021. Reference lists of retrieved articles were also considered when these were relevant to the issue examined yet not allocated in the basic search. The relevance of the studies was assessed using a hierarchical approach based on the title, abstract, and full manuscript.

Titles and abstracts of the identified studies were independently screened by 2 researchers (M Kouvari and M Karipidou), and duplicates were removed. Full-text copies of papers were assessed for eligibility (M Kouvari and M Karipidou), with any disagreements resolved by a third researcher (EB). Data for each included study were extracted by 1 researcher (M Kouvari) and cleaned and checked by another (M Karipidou). The 2 researchers (M Kouvari and M Karipidou) extracted data using a standardized extraction form to ensure that it adequately captured trial data. For papers in which additional information was required, the corresponding authors were contacted via email.

Selection Criteria

Studies were selected based on the inclusion and exclusion criteria presented in Textbox 1.

Quality Assessment of Selected Studies

The quality assessment of the selected validation studies was independently implemented by 2 researchers (M Kouvari and M Karipidou) using the Consolidated Standards of Reporting Trials statement [12]. Any differences were discussed, and a decision was made by consensus.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Study design: controlled clinical trials with at least one arm with a technology-based intervention controlled by a second arm with a conventional care intervention or without any intervention
- Sample: children and adolescents with overweight or obesity (defined through BMI or validated growth charts) aged ≤18 years
- Intervention: technology-based intervention for children or adolescents with or without parents' or families' support
- Outcome: BMI, BMI *z*-score, and other BMI-related metrics (eg, BMI-SD score) at baseline, during the intervention, and at the postintervention phase were considered as the primary measurements for this meta-analysis

Exclusion criteria

- Review articles
- Letters to editors
- Editorials
- Articles based on studies with adults
- Articles providing only feasibility or acceptance level of the applied technology-based interventions or outcomes related only to obesogenic behaviors
- Articles in which the technology-based intervention was applied only to parents
- Articles in which the control group included the use of technology
- Articles in which the technology-based intervention was not interactive with the user, for example, telemedicine or it had only an informative character, for example, a website
- Articles with inadequate statistical information

Effect Size Measurements

The outcome of interest in this meta-analysis was the difference between the web-based intervention and the control group with regard to the potential changes from cumulative frequency distribution in BMI or BMI z-score or BMI-SD score. Studies that reported BMI-related metric results as change scores or baseline and final values; SD, SE, or CIs; and number of participants in each intervention group were included in the meta-analysis. The mean change was calculated where required, and SDs were calculated from SE or 95% CI where SD was not reported [13]. Finally, missing SDs of the changes from baseline were calculated using an imputed correlation coefficient [13].

Data Analysis

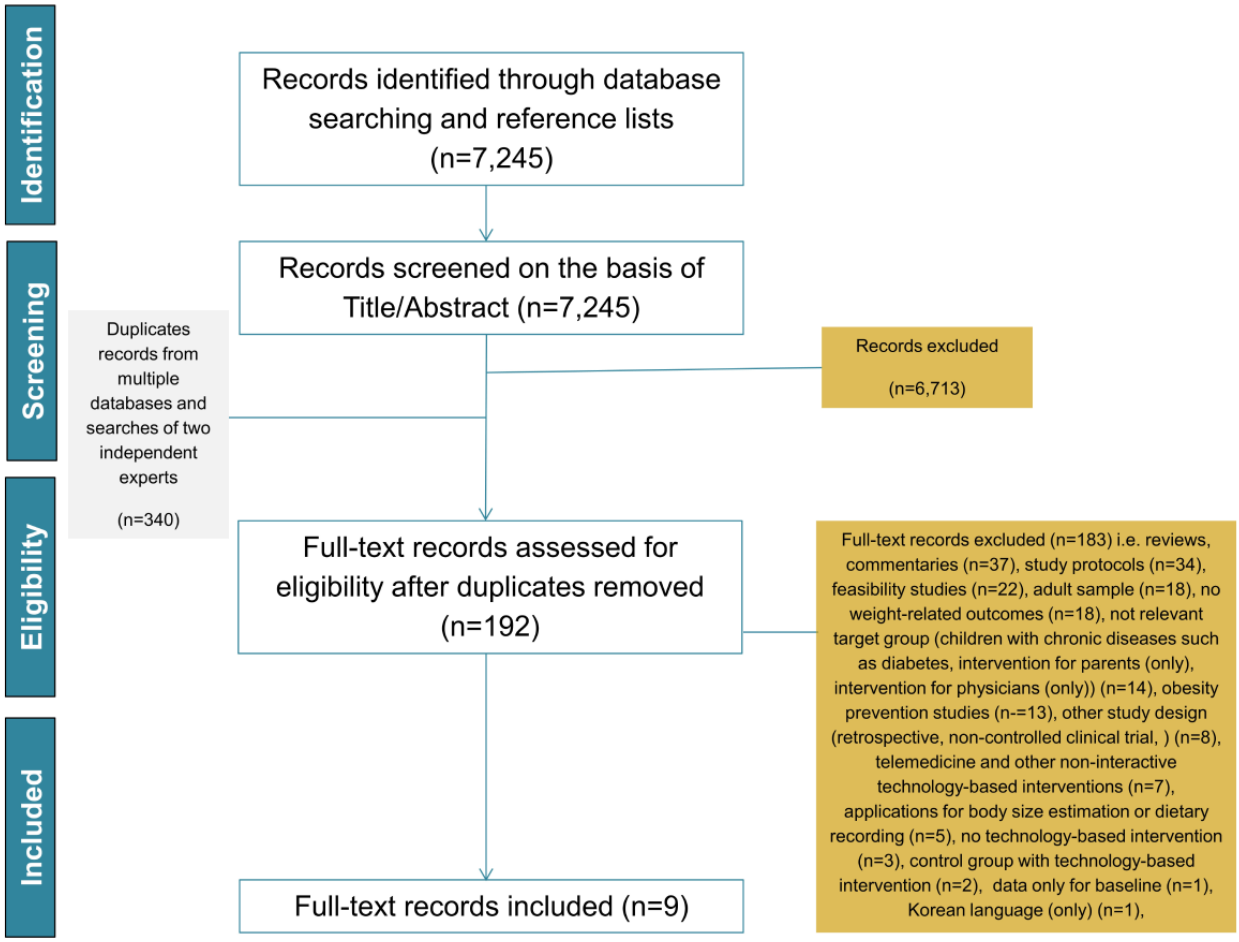
Standardized mean difference (SMD) was used to enable the inclusion of BMI-related metrics in the same meta-analysis. In a study that reported >1 BMI metric, BMI was used. Pooled values of SMDs between the technology-based intervention and the control group and 95% CIs as the recommended summary statistics of the effect size were calculated using either a fixed or random effects model. The fixed effects model was used when sample heterogeneity was <50%, and the random effects model was used when heterogeneity was >50%. Heterogeneity assessed the null hypothesis that all studies evaluated the same effect and was evaluated using the chi-square test. Inconsistency (I_2) was calculated to quantify the total variation consistent with interstudy heterogeneity, ranging from 0% to 100%. A *P* value of <.10 for the chi-square test and I_2 >50% reflected a significant heterogeneity [14]. Estimates of the effect size measures were weighted by the inverse of their variances. The random effects model (DerSimonian and Laid method) was used in the presence of heterogeneity. In contrast, fixed effects models were used to calculate effect size estimates for studies that lacked heterogeneity. Subgroup analysis of prespecified groupings was performed for the following study characteristics: duration of follow-up (3-24 months), parental involvement, and type of intervention (web based vs mobile based and others). In subgroup analyses, only the last follow-up values were considered. In studies with multiple follow-ups, only the last follow-up time was considered for the estimation of the overall effect size. Possible publication bias was assessed using a contour-enhanced funnel plot of each trial's effect size against the SE. Funnel plot asymmetry was evaluated using the Begg and Egger tests [15]. Stata software, version 14 (StataCorp LLC) was used for all statistical analyses.

Results

Flow of Included Studies

A literature search flow diagram is presented in Figure 1. Initially, 7245 papers were retrieved and selected for evaluation. Then, 6713 manuscripts were removed based on their titles and abstracts as they were irrelevant to the scope of this work, accompanied by 340 duplicate records from multiple databases and searches that were also excluded. Among the rest (n=192), 9 manuscripts from 8 studies (ie, 2 separate articles were published based on 1 study regarding 2 follow-up periods) were considered relevant; 183 manuscripts were excluded, as they did not meet the inclusion criteria of this systematic review.

Figure 1. Flow diagram describing the literature review process.



General Characteristics of the Selected Clinical Trials

The characteristics of the eligible clinical trials for this meta-analysis are presented in Multimedia Appendix 1 [16-24]. In total, 582 children and adolescents participated in the selected 8 studies with a range of cultural or ethnic groups, including African American, Chinese American, White, and others. Of the 8 studies, 6 (75%) studies were conducted in the United States [16-22], 1 (13%) in Australia [23], and 1 (13%) in northwestern Europe (Netherlands) [24]. Moreover, 75% (6/8) of studies were conducted within the last decade [16-19,23,24], whereas the remaining 25% (2/8) of studies were conducted earlier [20-22]. Most of the selected studies addressed adolescents [16,17,20-23], whereas the rest had children aged 9-12 years as the target group [18,19,24]. The length of interventions ranged from 3 months [16,19,24] to 4 months [20], 6 months [17,18], and 24 months [21-23]. All studies were 2-arm controlled clinical trials, in which technology-based interventions were controlled for 1 conventional care intervention, except for 2 studies in which no intervention was implemented in the control group [16,19,24].

Description of the Technology-Based Interventions

Of the 8 studies, 4 (50%) examined the effect of a mobile health (mHealth) intervention with or without sensors [16,17,19,24], 3 (38%) studies used a web-based intervention [18,20-22], and 1 (13%) study used an SMS text messaging intervention accompanied by telemedicine [23]. Focusing on mobile-based interventions, they also addressed nutrition-related issues and unhealthy dietary behaviors [16,17,19,24], whereas in 38% (3/8) of studies, physical activity and screen time were also taken into account [16,19,24]. In 1 study with web-based interventions, participants were enhanced to increase their physical activity level via a gamification method [18]. The other 2 web-based interventions, following a family-oriented approach, provided nutrition education accompanied by physical activity tips and counseling regarding healthy body image [20-22]. The SMS text messaging intervention along with telemedicine and group sessions focused on weight loss and weight loss maintenance, covering issues from nutrition and physical activity to body image and psychological well-being [23]. The level of parental involvement varied among the selected studies. In 6 (75%) of the 8 studies, there was participation of parents in the intervention group [18-24] accompanied by a similar participation of parents in the control group, with the exception of 2 (25%) studies [18,19]. In 7 (88%) out of 8 interventions, a hybrid approach was followed, which means that the technological tools—of any kind—were examined as supportive of conventional care treatment [17,19-24]. In 7 (88%) of the 8 studies, there was support from health care practitioners, such as dietitians, physicians, pediatricians, and psychologists [17-24]. Participants in the intervention group (children or adolescents alone or with their parents) attended weekly, biweekly, or monthly face-to-face sessions with health professionals [17,19-24] or videoconferences [18]. These sessions included goal setting, motivation techniques,

individualized feedback based on the technology-based dietary or physical activity records, and enhancement to use the digital tools provided.

Primary and Secondary Outcomes of the Selected Clinical Trials

Different measures of weight status and adiposity were used in the selected studies, with most of them using multiple measures. In total, of the 8 studies, 5 (63%) used BMI z-score [17-20,23], 3 (38%) used BMI [16,19,21,22], 3 (38%) used BMI percentiles [17,19,21,22], 2 (25%) used body fat [18,21,22], 1 (13%) used waist-to-hip ratio [23], and 1 (13%) used BMI-SD score [24]. Other metrics included modifications in obesogenic behaviors, such as dietary habits [16,18-20,22-24], physical activity habits and/or screen time [16,18,19,22,23], and physical examination or biochemical metrics [18,23]. All studies included psychological and self-efficacy metrics related to diet, physical activity, well-being, or healthy body image. With the exception of 25% (2/8) of studies [16,23], the remaining studies provided information on participants' satisfaction and compliance with the technology-based intervention.

Risk of Bias Within Selected Studies

The results of the risk of bias assessment for all included studies are summarized in Table 1. The selected eligible studies were of moderate quality, meeting on average, approximately 6 out of the 9 quality criteria. In particular, all studies except 1 had a well-documented randomization process [17]. In all studies, except for 1 study [22], the baseline characteristics were presented. All studies used a valid method to assess the main outcome of interest, that is, BMI, whereas only 4 (44%) out of 9 studies reported blinded assessment of the outcome of interest [16,18,20,23]. All studies except 1 [23] met the dropout rate cut-off points (ie, ≤20% for <6 months and ≤30% for ≥6 months). Regarding the quality of statistical analysis, on average, the selected studies met 2 out of 9 criteria. Specifically, all studies except 3 used intention-to-treat analysis [17,20,24]; all studies except 2 reported adequate statistical power [17,19], whereas only 4 studies provided adjusted differences between groups [16-18,23].

[a]Quality assessment was performed based on the Consolidated Standards of Reporting Trials statement.

Separate Outcomes of Selected Studies

Overview

The separate outcomes of the eligible clinical trials are summarized in Multimedia Appendix 2 [16-24].

Weight and Adiposity Outcomes

Of the 8, 5 (63%) studies reported significant differences between groups in BMI metrics from baseline to the end of intervention [18,20,21,23,24]. The intervention duration of these studies was >6 months, and all of them addressed not only children or adolescents but also their parents. Significant reductions in body fat [22] and waist-to-hip ratio [23] were observed in interventions with a 2-year duration.

Diet-Related Outcomes

The 7 studies reporting modifications on dietary intake and behaviors revealed a significant difference between groups with regard to improvement in at least one dietary outcome. In particular, a decrease in consumption of sugar-sweetened beverages [16], lower carbohydrate intake [18], increased fruit consumption [19], decreased meat and fruit juice intake [23], better adherence to a healthier dietary pattern [20,24], and lower consumption of food products with high-fat content [21,22] were observed.

Physical Activity–Related Outcomes

Among the 5 studies that provided input on changes in participants' physical activity level, 1 (20%) study revealed a

significant decrease in screen time [16], whereas the remaining 4 (80%) studies highlighted increases in physical activity level in terms of hours per day or the intensity of exercise [17,20,21,24].

Physical Examination and Biochemical Metrics

In 1 (50%) of the 2 studies with physical examination and biochemical measurements, significant reductions in blood pressure and cholesterol levels were observed [18].

Psychological Health–Related Outcomes

All studies provided input on the effect of technology-based intervention over the control group on participants' psychological health. Of the 8 studies, 7 (88%) studies observed that participants in the intervention group increased their self-efficacy in relation to diet [16,19,20] and physical activity [16,18,20], decreased unhealthy eating behaviors related to dieting or weight or body image [22,23], and ameliorated their self-esteem [23,24].

Usability and Acceptability of the Technology-Based Intervention

Of the 6 studies providing information on the level of compliance of participants with the technology-based intervention, 5 (83%) reported moderate to high levels of usability and acceptability of the technology-based intervention [17-20,24]. Nevertheless, the added value of the technology-based intervention over typical care was not clear considering the similar dropout rates between the 2 groups (dropout rate in the intervention group: 12.9%, range 0%-41%, vs dropout rate in the control group: 12.6%, range 0%-36%; *P*=.96), excluding studies in which the control group had no intervention [18,19]. Among the 6 studies, 1 (17%) revealed that children assigned to the technology-based intervention receiving SMS text messages were less likely to withdraw from the study than children who did not receive this service [24].

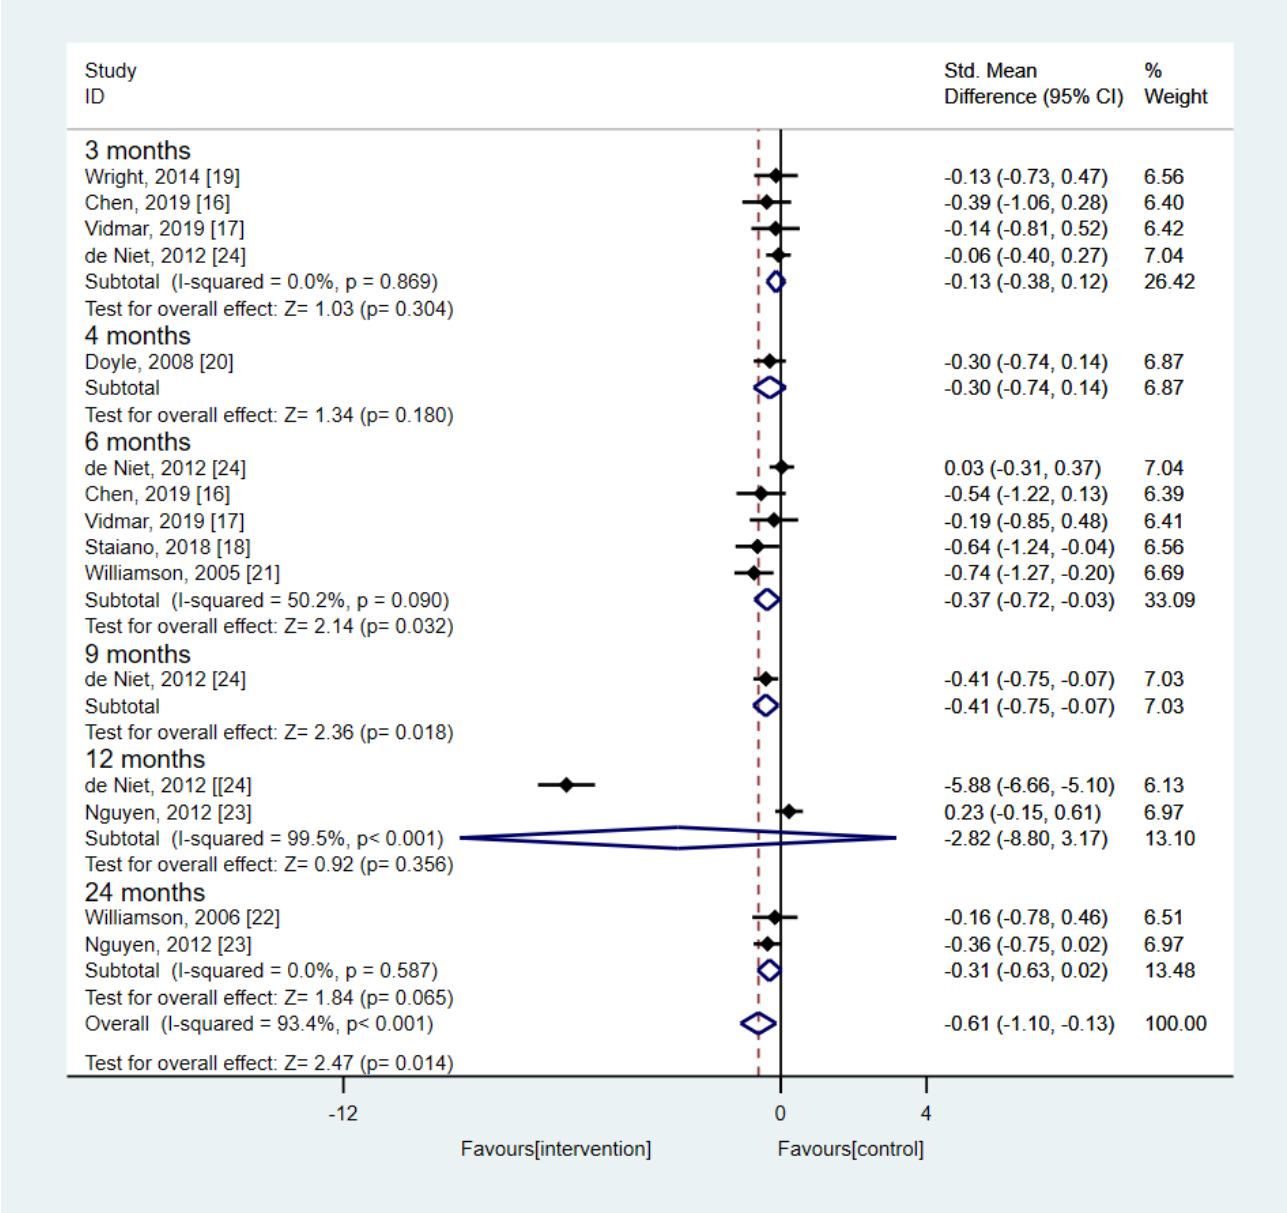
Synthesis of BMI-Related Outcomes

Overview

A meta-analysis was conducted on pooled data from 9 manuscripts (8 studies in total), which compared technology-based intervention groups with control groups. The meta-analysis results are presented in Figures 2-4.

As presented in Figure 2, a significantly higher decrease in the BMI-related metric was observed (SMD –0.61, 95% CI –1.10 to –0.13; *P*=.01). Compared with the other follow-ups, this was more evident after a 6-month follow-up in the technology-based intervention group when compared with the control group (SMD –0.37, 95% CI –0.72 to –0.03; *P*=.03), whereas a favorable effect of the technology-based interventions was also found after 24 months; however, statistical significance was not reached (SMD –0.31, 95% CI –0.63 to 0.02; *P*=.07).

Figure 2. Results from the random effects meta-analysis concerning the effect of the technology-based interventions on BMI-related metrics according to the study follow-ups. In case of studies with multiple follow-ups, only the last follow-up time was considered for the estimation of the overall effect size.

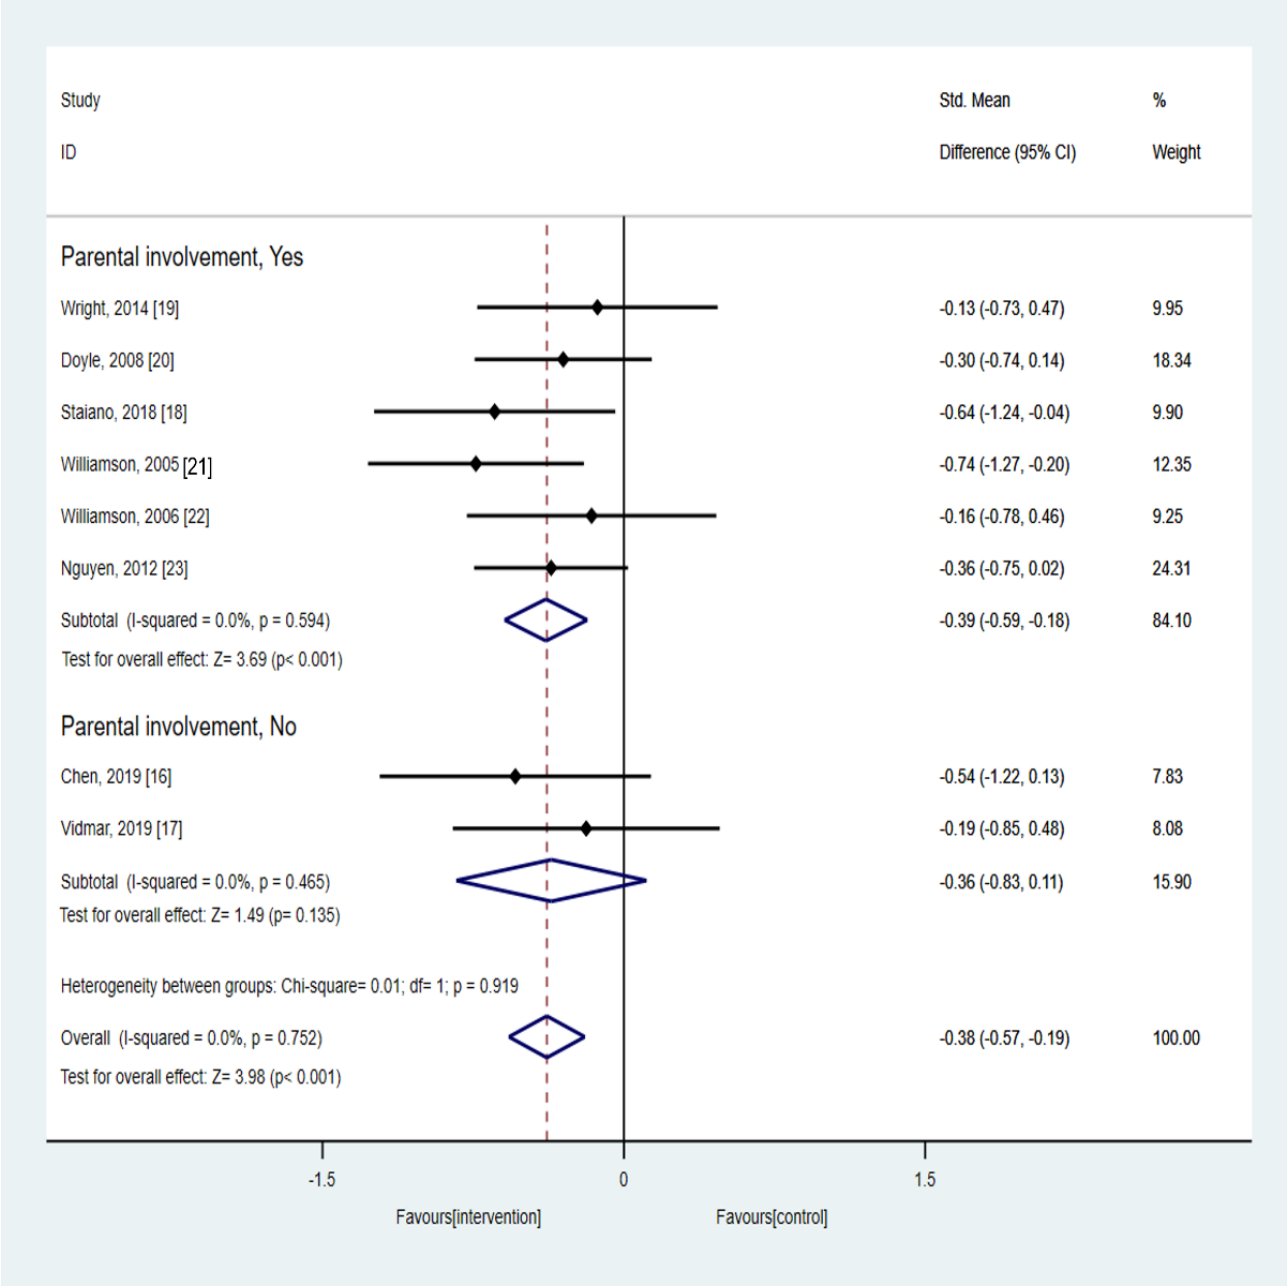


Sensitivity Analysis

Of the 8 studies, 2 (25%) had a control group without any intervention. Hence, we repeated the aforementioned analysis, excluding these 2 studies. The overall outcome remained significant (SMD –0.65, 95% CI –1.20 to –0.10; *P*=.02), whereas the 6-month outcome remained marginally significant (SMD –0.32, 95% CI –0.71 to 0.07; *P*=.10).

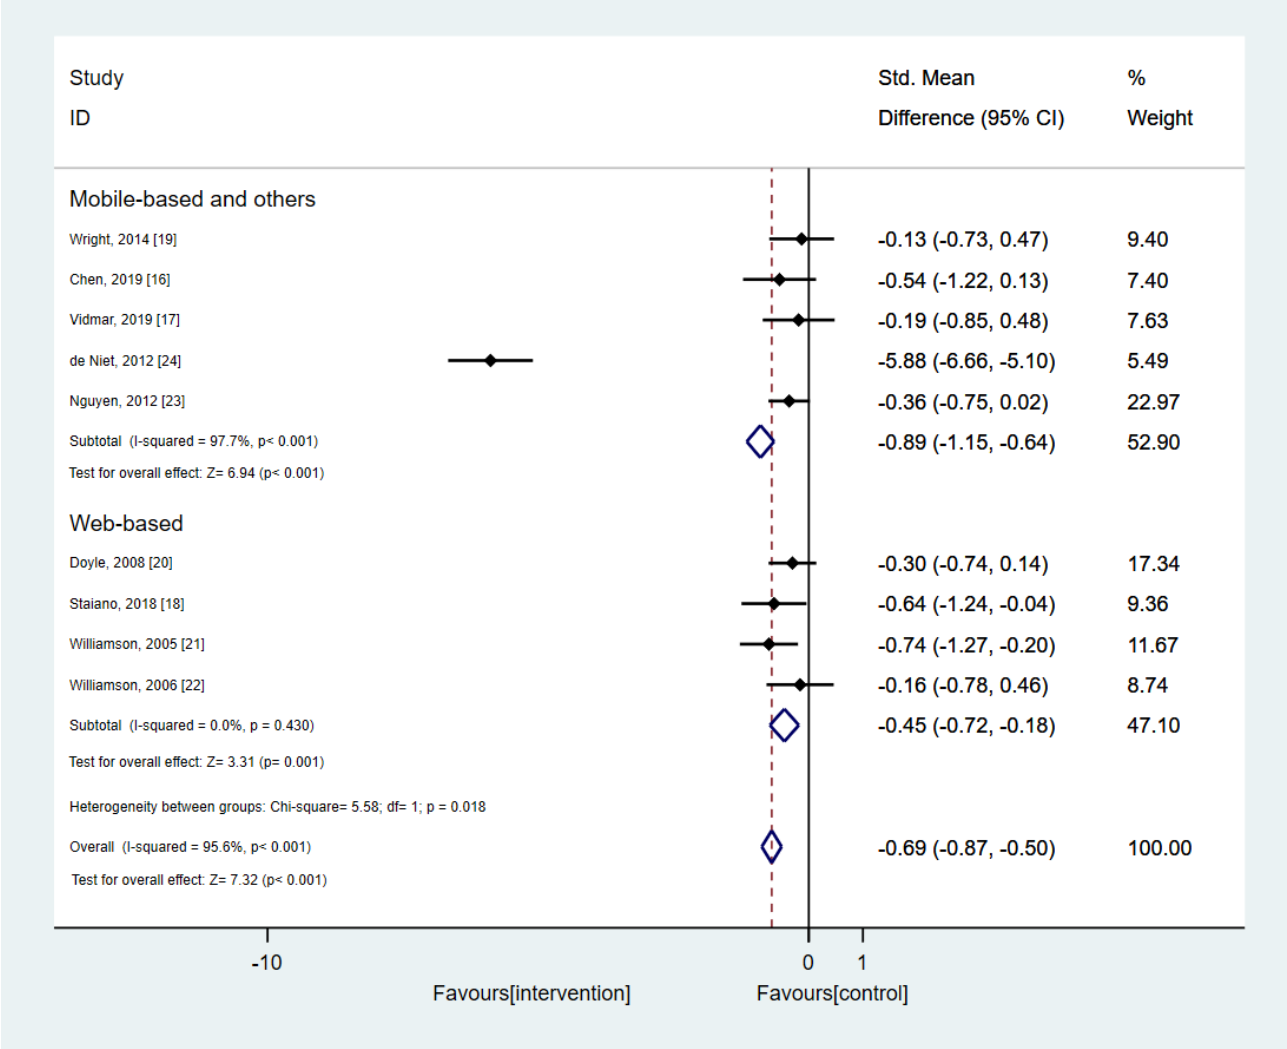
A subgroup analysis was conducted based on parental involvement, and the results are shown in Figure 3. The meta-analysis revealed a significantly higher decrease in the BMI-related metric in the technology-based intervention group than in the control group only in case of parental involvement (SMD –0.39, 95% CI –0.59 to –0.18; *P*<.001). In the case of no parental involvement, no significant difference between groups was observed (SMD –0.36, 95% CI –0.83 to 0.11; *P*=.14).

Figure 3. Results from the subgroup analysis according to the parental involvement of the technology-based intervention concerning its effect on BMI-related metrics. In case of studies with multiple follow-ups, only the last follow-up time was considered for the estimation of the overall effect size.



Another subgroup analysis performed in this study was related to the type of technology-based intervention used. The results are shown in Figure 4. Interventions were grouped as web-based, mobile-based, and others. A statistically significant decrease in the BMI-related metric in the intervention group compared with that in the control group was observed both in the case of mobile-based and other interventions (SMD –0.89, 95% CI –1.15 to –0.64; *P*<.001) as well as in the case of the web-based interventions (SMD –0.45, 95% CI –0.72 to –0.18; *P*=.001).

Figure 4. Results from the subgroup analysis according to the type of the intervention concerning its effect on BMI-related metrics. In case of studies with multiple follow-ups, only the last follow-up time was considered for the estimation of the overall effect size.



Discussion

Principal Findings

This meta-analysis revealed that an intervention that combines conventional care with technological facilities could be an effective method for weight management of children and adolescents with overweight or obesity and is probably more effective than conventional care alone. These observations were more evident in the case of interventions lasting at least six months. The selected studies included eHealth and mHealth technologies, such as interactive web platforms, mobile apps, gaming, and SMS text messaging with or without sensors and were accompanied or not accompanied by other contact forms such as telemedicine, emails, and informative websites. The focus of these technologies was more or less related either exclusively or in combination with improvement in dietary habits, enhancement of physical activity, or the increasing of users' self-monitoring potential. The type of technological means used in each intervention, that is, mobile-based or web-based, did not seem to alter the final outcome. Parental involvement was related to greater outcomes of the intervention, particularly in children; however, it was not possible to isolate the separate contribution of parents to the final outcome.

Strengths and Limitations

To the best of our knowledge, this is the first meta-analysis to examine the effect of technology-based interventions on weight management in childhood and adolescence using strict eligibility criteria, such as the existence of a control—without any kind of technology—group, the exclusion of technology-based interventions without an interactive—with the user—character, and the exclusion of studies providing the effect on weight-related metrics of normal-weight children or adolescents (obesity prevention spectrum). However, several limitations exist, including the restriction to articles published only in English, the small number of clinical trials found with varying study quality, heterogeneity of the studies, inadequacy of the power to detect an outcome in some studies because of the small number of participants, varying aims between studies, and all but 2 studies being conducted in the United States. Finally, no definite conclusion can be drawn on whether the actual difference in weight management was caused by the different techniques used or by the differences in other intervention characteristics (eg, number of sessions).

Comparison With Prior Work

To date, technology-based health interventions for weight management in young people have been reported as a rapidly developing research area; although promising results have been produced, more research is definitely in order [25]. Hitherto, studies have described technologies with the potential to promote healthy behaviors related to nutrition or physical activity in children and adolescents [26,27]. The pooled higher reduction in adiposity metrics observed in this study in favor of technology-based intervention groups were observed with improvements in users' dietary habits, physical activity level, and screen time and with better psychological health regarding body image, self-esteem, or weight- and dieting-related stress. Examining the actual efficiency and added value of technology-based methods over conventional interventions in childhood obesity management remains a challenging research field for many reasons. Most interventional studies combine eHealth or mHealth interventions with other mostly conventional treatments (hybrid approach), thus making the efficacy of technology-only approaches to affect adiposity outcomes difficult to ascertain [9,26]. In most studies selected for this meta-analysis, the digital behavior change intervention was examined on top of conventional care and matched for conventional-only care, revealing an advantage of the former in weight loss. On the other hand, digital behavior change interventions have not been generated to replace the role of health professionals and the multifaceted treatments required for management of excess weight in childhood and adolescence but rather to support them, showing potential as an additional tool for patient monitoring and designing tailor-made interventions through the selection of more valid information and plausibly weight loss maintenance in the postintervention phase [28,29].

Another issue examined in this study was related to parental involvement in technology-based interventions. Active enrollment of parents was reported in 6 (75%) out of 8 studies [18-24], accompanied by a similar participation in the control group, with the exception of 2 studies [18,19]. Interestingly, 2-8 studies without parental involvement did not achieve significant modifications in adiposity metrics. Although many reasons could be responsible for this nonsignificance, such as the fact that lower combined sample size in the 2 studies could lead to greater CIs and higher *P* values, this finding may imply that the participation of families in childhood obesity management programs remains of high importance even in or especially in interventions with advanced technological means. Currently, interventions that target parents to tackle obesity in early life stages are presented as effective, especially when it comes to preschoolers, that is, children <5 years [30-33]. On the other hand, the studies in this meta-analysis were designed for children >9 years and principally adolescents, which may challenge the level of parental involvement. Preschool-aged children are rarely targeted in such technology-based interventions. The MINISTOP RCT is probably the very first study to apply a 6-month technology-based weight loss intervention to children <5 years, using their parents as the primary target group. Although no significant differences in adiposity metrics between the control and intervention groups were observed, children and parents assigned to the technology-based group seemed to significantly ameliorate their nutrition and physical activity habits [34]. Considering the fact that technological approaches and parental involvement are usually presented as effective practices to tackle excess weight in childhood, their combination into 1 tailor-made weight loss intervention may result in multiple positive outcomes.

The studies in this meta-analysis provided input on the usability and acceptability of technology-based interventions. Most of them reported a moderate to high level of adherence to the intervention using different criteria and metrics, such as the level of user enjoyment, the frequency of app use, or the number of SMS text messages received [17-20,24]. Nevertheless, based on the dropout rates, no significant differences were observed between the intervention and control groups in most cases. This evidence regarding the usability of technology-based interventions is based largely on the use of SMS text messaging using a mobile- or web-based approach. However, the latest technological advances include the emergence of smartphone apps [29], interactive platforms [35], and exergaming [36]. Such facilities have increased in popularity, offering a unique opportunity to implement large-scale obesity treatment interventions in youth [37]. The current orientation for improving adherence to treatments in pediatrics focuses on motivation, problem-solving skills, and reduction of posttreatment influence, resorting to several novel youth-friendly technological approaches [26]. For instance, studies have described the best placement and accuracy of mobile devices and sensors to record dietary intake or physical activity and ways to lessen user burden [26]. Reward-type incentives, provision of social connections and multiplayer capabilities, short- and long-term motivational techniques, and personalized feedback are also suggested as means to enhance user acceptability, efficiency of the intervention, and probably maintenance of positive outcomes even in the postintervention phase [26]. Focusing on gamification, many video games have been created with the aim to modify children's or adolescents' dietary habits or physical activity status, such as *Let's Move! (To move!)*, *Counting Carbohydrates with Lenny*, *LeapBand*, or *Zamzee*, where users interact with virtual characters that—creating a fascinating environment—enhance them to complete a series of relevant activities and challenges [38]. Finally, early involvement of key stakeholders in the intervention development stage seems to be detrimental for the delivery of a technological tool that will be well-accepted by the target group—even more when it comes to younger ages [39].

Conclusions

Studies reported herein describe functional and acceptable technology-based approaches, on top of conventional care, to enhance weight loss in overweight or obese children and adolescents through the promotion of a healthy lifestyle and improvement of users' well-being. However, the large heterogeneity in study designs, settings, intervention components, and outcomes probably eliminates the strength of this conclusion. Finally, this field is advancing so quickly that the technology used is often no longer state of the art; interventions that use the full range of novel technologies, such

as ubiquitous sensing and real-time feedback, are currently being developed and pilot tested. Therefore, similar meta-analytic approaches should be repeated on a regular basis.

Abstract

Background: Heart failure (HF) is a clinical syndrome with high incidence rates, a substantial symptom and treatment burden, and a significant risk of readmission within 30 days after hospitalization. The COVID-19 pandemic has revealed the significance of using eHealth interventions to follow up on the care needs of patients with HF to support self-care, increase quality of life (QoL), and reduce readmission rates during the transition between hospital and home.

Objective: The aims of this review are to summarize research on the content and delivery modes of HF posthospitalization eHealth interventions, explore patient adherence to the interventions, and examine the effects on the patient outcomes of self-care, QoL, and readmissions.

Methods: A restricted systematic review study design was used. Literature searches and reviews followed the (PRISMA-S) Preferred Reporting Items for Systematic Reviews and Meta-Analyses literature search extension checklist, and the CINAHL, MEDLINE, Embase, and Cochrane Library databases were searched for studies published between 2015 and 2020. The review process involved 3 groups of researchers working in pairs. The Mixed Methods Appraisal Tool was used to assess the included studies' methodological quality. A thematic analysis method was used to analyze data extracted from the studies.

Results: A total of 18 studies were examined in this review. The studies were published between 2015 and 2019, with 56% (10/18) of them published in the United States. Of the 18 studies, 16 (89%) were randomized controlled trials, and 14 (78%) recruited patients upon hospital discharge to eHealth interventions lasting from 14 days to 12 months. The studies involved structured telephone calls, interactive voice response, and telemonitoring and included elements of patient education, counseling, social and emotional support, and self-monitoring of symptoms and vital signs. Of the 18 studies, 11 (61%) provided information on patient adherence, and the adherence levels were 72%-99%. When used for posthospitalization follow-up of patients with HF, eHealth interventions can positively affect QoL, whereas its impact is less evident for self-care and readmissions.

Conclusions: This review suggests that patients with HF should receive prompt follow-up after hospitalization and eHealth interventions have the potential to improve these patients' QoL. Patient adherence in eHealth follow-up trials shows promise for successful future interventions and adherence research. Further studies are warranted to examine the effects of eHealth interventions on self-care and readmissions among patients with HF.

Introduction

Background

Heart failure (HF) affects an estimated 64 million people worldwide [1]. It poses a burden on the health care system in general and on primary care specifically because the total number of patients with HF is increasing, reflecting the chronic course of the disease as well as population growth and aging [2,3]. Symptomatic HF is a complex clinical syndrome with a symptom burden of dyspnea and fatigue [4] and can be troublesome for patients and their families because of frequent hospitalizations and symptom and treatment burden negatively affecting their quality of life (QoL) [5-7]. QoL is understood as a multidimensional and subjective concept that includes physical, functional, emotional, and social well-being [8]. Effective self-care behavior is essential for patients with HF [9,10]. Self-care in the context of HF is an overarching concept based on three key concepts: (1) self-care maintenance (eg, compliance with medication regimens and following diet and physical activity recommendations), (2) self-care monitoring (eg, regular weighing), and (3) self-care management (eg, changing diuretic dose in response to symptoms) [10]. Upon discharge from the hospital, many patients transition from care provided by health professionals in a safe hospital setting to individual self-care at home [11]. This period, when patients transition between hospital and home, is a vulnerable and stressful time for patients with HF and many struggle to perform recommended self-care and navigate the health care system, particularly when posthospitalization care is poorly executed as a result of inadequate coordination of resources or follow-up [5,7]. Of any diagnosis, HF is associated with the highest 30-day all-cause readmission rate (approximately 20%), whereas nearly 35% of the patients with HF are readmitted within 90 days [2,6]. During this phase, the lack of resources for following up or poor medical education leaves this population vulnerable to deterioration and rehospitalization [12]. Posthospitalization HF disease management programs include education, self-management, weight monitoring, sodium restriction or dietary advice, exercise recommendations, and medication review [13]. In addition to social and psychological support with a high degree of care coordination, as well as the higher intensity of follow-up, these components may be important for better self-care behavior, increased QoL, and reduced readmission rates [4,13,14]. The impact of the COVID-19 pandemic has raised the requirement for, and importance of, eHealth solutions as a tool for health care professionals to perform such follow-up of patients with HF [15]. Insight into ensuring a more seamless eHealth care service from inpatient to outpatient care for patients with HF is necessary if they are to achieve adequate self-care support and feel safe [15,16]. eHealth care service is defined as "health services and information delivered or enhanced through the internet and related technologies" [17] and holds the potential to increase the efficiency and quality of health care services [18]. In this review, eHealth comprises digital solutions to deliver health care services, including patient education; telemonitoring of weight, blood pressure, and heart rhythm; and social and emotional support. Previous research suggests that the use of posthospitalization eHealth interventions to follow up on patients may promote self-care for people with long-term illness [18]. Several recent reviews have summarized the findings from eHealth follow-up interventions for patients with HF and provided information about the efficiency of such interventions. Auener et al [19] investigated the effects of telemonitoring programs on different aspects of health care use from 16 randomized controlled trials (RCTs) and 13 nonrandomized studies. All studies included weight as a parameter, whereas only 4 included electrocardiography measures as a physiological parameter. The results revealed that telemonitoring has the potential to reduce hospitalization rates. However, the number of non–emergency department visits increased in most of the studies [18]. Ding et al [20] extracted 18 telemonitoring strategies from 26 RCTs involving patients with HF. Some strategies were commonly used, such as call center support and daily weight monitoring, whereas others, including nurse support, interventions for depression and anxiety, and exercise interventions, were seldom used. Telemonitoring strategies involving medication support and mobile health (mHealth) interventions were associated with improvements in all-cause mortality or hospitalization outcomes [20]. A systematic review conducted in 2017 identified 39 relevant RCTs of telemedicine, largely based on assessments of symptoms, weight, heart rate and rhythm, and blood pressure, and found that telemonitoring was associated with reductions in all-cause mortality of 20% and HF hospitalization of 37% [21]. In contrast, nurse-based telephone-supported care seemed to provide little benefit, and only a reduction in the rate of HF-related admission was noted compared with the control group. However, a combination of home-based teletransmission and nurse-based telephone reinforcement may be encouraged [21]. Although these reviews generally support the effectiveness of eHealth interventions for patients with HF, the outcomes mainly focus on readmission and health care use, and only one of them focuses specifically on the hospital-to-home transition phase [21]. Moreover, they mostly lack information about self-management, QoL, and participants' adherence to the eHealth interventions. Adherence to self-management and medication regimens is crucial during the transition from hospital discharge to home to prevent hospital readmission and achieve improved health outcomes and QoL [22-24]. Therefore, the success of an intervention aiming to support patients' chronic disease management depends on patient adherence to the intervention components [25]. Intervention adherence refers to the degree to which the behavior of trial participants corresponds to the intervention assigned to them [26]. Adherence varies according to the patient's health status, treatment regimens, access to support, and psychological factors such as motivation and beliefs. The long-term success of interventions depends on patients assuming responsibility for their own health and can

be achieved with the aid of coordinated measures such as patient education and regular follow-up contacts [26]. An accurate assessment of intervention adherence is warranted to verify whether changes in health outcomes are due to a particular intervention [26].

There is a knowledge gap concerning the synthesis of recent posthospitalization eHealth follow-up interventions for patients with HF focusing on outcomes of self-care, QoL, and adherence to the interventions. Therefore, this restricted review will investigate eHealth interventions that may better prepare patients for the period after hospital discharge, strengthen their self-care and QoL, reduce readmissions, and help them to recover well. Furthermore, the review will address the issue of adherence and discuss how it may affect intervention outcomes. Therefore, the aim is to summarize the most recent information about the content and delivery mode of HF posthospitalization eHealth interventions, explore patient adherence to the interventions, and systematically investigate the effects on patient outcomes of self-care, QoL, and readmissions.

Research Questions

The a priori research questions were designed according to the FINER framework, which states that a review research question should be feasible, interesting, novel, ethical, and relevant [27].

Our research questions were as follows:

- What are the content and delivery modes of posthospitalization eHealth interventions for patients with HF?
- What is the reported adherence to posthospitalization eHealth interventions in HF?
- Which effects can be expected from posthospitalization eHealth interventions on self-care, QoL, and readmissions of patients who have received treatment for HF?

Methods

Reporting Standards

This study used a framework proposed for restricted systematic reviews [27]. The restricted systematic review framework is proposed to be applicable when conducting a rapid review because it consists of core steps that are minimum requirements for systematic reviews, thereby accommodating factors such as a short time frame and limited resources [28]. Such factors are important to consider when conducting a literature search and review as part of developing complex interventions [29]. The framework comprises six core steps: (1) literature search, (2) study selection, (3) data extraction, (4) critical assessment of the included studies, (5) data synthesis, and (6) publication [28].

Step 1: Literature Search and Search Terms

The literature search was performed as part of a more extensive review study on eHealth interventions in noncommunicable diseases. This paper reports the results from HF populations. A research librarian performed comprehensive literature searches in the CINAHL, MEDLINE, Embase, and Cochrane Library databases. To ensure that our results reflect current conditions and avoid repeating previous review efforts, this rapid review was limited to data published between 2015 and 2020 in English or a Scandinavian language. Searches were performed in the publication title or abstract. Appropriate search terms, including relevant Medical Subject Headings, were closely matched with the Population, Intervention, Control, and Outcome elements (see next section). Documentation of the search strategy and search terms is presented in Multimedia Appendix 1. The search strategy also included manually hand searching the reference lists of the included studies and relevant background material. The searches were performed on March 20, 2020.

A Priori Eligibility Criteria

Key components of the synthesis are encapsulated by the Population, Intervention, Control, and Outcome framework [30].

- Population: patients initially treated for HF
- Intervention: posthospitalization eHealth follow-up services
- Control: standard care and nondigital follow-up services
- Outcomes: self-management and self-care, QoL, and readmissions

The inclusion and exclusion criteria are displayed in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Empirical intervention studies
- Populations of adult patients with heart failure
- eHealth interventions from hospital to home
- Patient outcomes of self-care, quality of life, and readmissions
- Experimental and quasi-experimental randomized and nonrandomized controlled trials
- Pre–post design with a comparison group
- Peer-reviewed studies
- Published in English

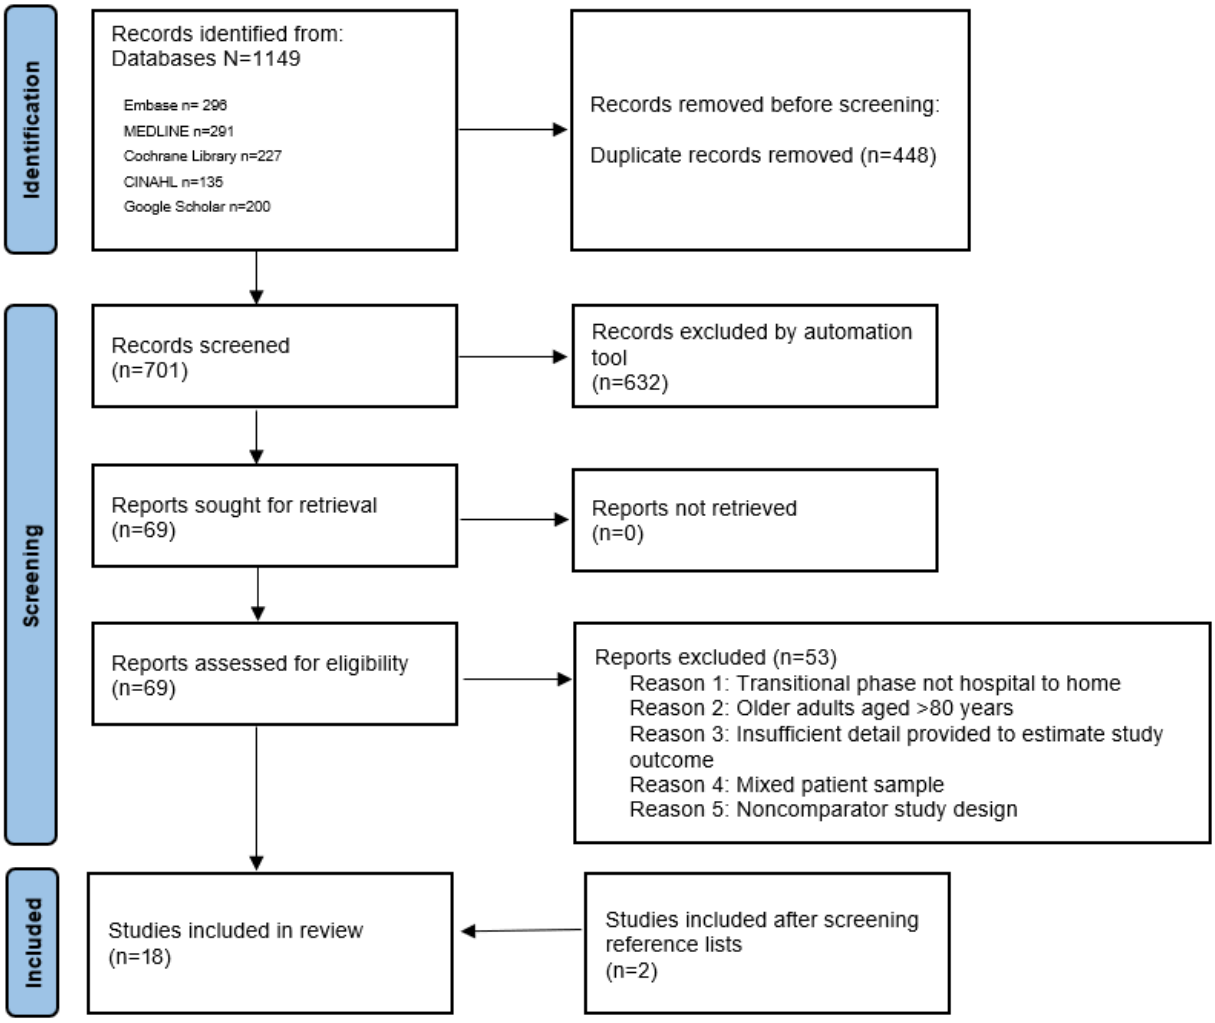
Exclusion criteria

- Review studies, study protocols, book chapters, and conference contributions
- Children and adolescent patients
- Older adults (aged >80 years)
- Community health care services context
- >3 months since hospital discharge
- Insufficient detail provided to estimate study outcome
- Mixed patient samples
- Noncomparator study designs

Step 2: Study Selection

After removing duplicates using EndNote (Clarivate), a member of the research team (AMLH) carried out an initial broad review of all included titles and abstracts, using the a priori inclusion and exclusion criteria. Next, the abstracts verified for potential inclusion were reviewed for full-text extraction by all authors, divided into 3 review teams. Full-text articles were extracted for 9.8% (69/701) of the abstracts. Finally, team members resolved conflicting opinions by assessing reasons for exclusion and deciding whether to include the study. The results of the data search and selection process are displayed in a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart (Figure 1) [31].

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow chart of the study selection process.



Step 3: Data Extraction

An Excel spreadsheet (Microsoft Corp) was created to ensure consistent data extraction, including data fields of publication identifiers, study design, study context and participants, eHealth intervention or program, and outcomes. The review teams used the spreadsheet to extract relevant data from the included articles. Any inconsistency within the group was resolved through assessment by a reviewer from one of the other groups.

Step 4: Critical Assessment of Included Studies

To minimize bias, an assessment of internal validity of the included studies, risk of bias (eg, over- or underestimation of intervention effect), and potential conflicts of interest were examined using the Mixed Methods Appraisal Tool (MMAT) [32]. The MMAT, which aims to appraise the methodological quality of included studies in systematic reviews, consists of a checklist of qualitative, quantitative, and mixed methods studies [32]. For this review, checklists for randomized and nonrandomized research designs were used. Each checklist is initiated with 2 screening questions to allow for further assessment, and each list contains 5 assessment criteria to be answered with *Yes*, *No*, or *Can't tell*. A total score of 7 constitutes a *Yes* response to the screening and assessment criteria [32]. The developers recommend that the MMAT be used to describe only the study quality and to avoid excluding studies based on total scores [32].

To assess data quality, each review team member independently rated the studies, followed by a discussion to achieve consensus. For 10% (2/18) of the included studies, the quality scoring was verified through independent scoring by 2 reviewers (IMM and AMLH). The quality of included studies was above moderate (ie, of the 7 criteria, 6 [86%] were answered with *Yes*; Textbox 1).

Step 5: Data Synthesis

The findings on service content and delivery mode, adherence, and the effects of posthospitalization follow-up eHealth interventions were systematically analyzed by using thematic analysis as well as searching for patterns, themes, and categories across studies, which were then narratively summarized as suggested by Whittemore and Knafl [33]. Because of the heterogeneity of the study designs, participants, and outcome measures, meta-analysis was not recommended. Thus, the effects on patient outcomes were reviewed and reported narratively.

Step 6: Publication

The results from this restrictive systematic review will be published, including all appendices and added data. In addition, the study's findings will be disseminated in relevant clinical settings and websites.

Results

Overview

The literature search process is outlined in Figure 1. The search yielded a total of 1149 references (ie, records screened for 2 patient populations); after the removal of 318 (27.68%) duplicates, 831 (72.32%) titles and abstracts were assessed for inclusion. Of the 831 titles and abstracts, 701 (84.4%) titles pertaining to eHealth interventions for patients with HF were screened for eligibility using the web tool [34]. Of the 69 studies evaluated for eligibility in full text, 16 (23%) met all inclusion criteria and were included. Screening the reference lists of the included studies yielded another study and screening the reference lists of relevant background material identified a further study. Finally, this review included 18 studies.

Study Characteristics

Detailed characteristics of the included studies are displayed in Table 1. All studies were published between 2015 and 2019. Of the 18 studies, 10 (56%) were performed in the United States [35-44]. Although RCT was the predominant study design, 11% (2/18) of the studies applied a quasi-experimental method [37,43]. Among the 18 studies, enrollment of patients with HF to the posthospitalization eHealth service varied from recruitment at the hospital before hospital discharge to recruitment within 3 months of recent hospitalization (Textbox 1). In 56% (10/18) of the studies, all patients were recruited upon hospital discharge to an intervention with a duration of 14 days to 12 months [35,37,38,40-42,44-47]. In 22% (4/18) of the studies, patients were recruited after recent (within 30 days) hospitalization to an intervention with a 3- to 12-month duration [39,43,48,49]. In another study, patients with HF were enrolled during hospitalization or within 3 months of discharge for an HF exacerbation, and the intervention lasted for 3 months [36]. In 17% (3/18) of the studies, patients were recruited at hospital discharge or at the HF outpatient clinic to an intervention with a duration of 3-9 months [50-52].

Table 1. Characteristics of included eHealth intervention studies involving patients with heart failure (HF; N=18).

Study (country)	Design	Sample size			Content, focus, and mode of instruction	Duration	MMAT[a] scores out of 7, n (%)
		Total sample (N)	I[b], n (%)	C[c], n (%)			
Athilingam et al [35] (United States)	RCT[d]	18	9 (50)	9 (50)	Telemonitoring (HeartMapp); daily measures of weight, heart rate, blood pressure, and HF symptoms. HF education: 10 modules, home visit after 2-3 days by a nurse. A phone call to all participants. Nurses checked the dashboard daily to monitor participants' progress.	30 days	2 (29)
Comin-Colet et al [45] (Spain)	RCT	178	81 (45.5)	97 (54.5)	Telemonitoring and telephone support. Daily measures of weight, heart rate, and blood pressure. HF nurses reviewed alarms and alerts from the system every day.	6 months	6 (86)
Dunbar [36] (United States)	RCT	134	70 (52.2)	64 (47.8)	Telephone support; education and counseling on diet, medications, self-monitoring, symptoms, and physical activity; self-monitored blood glucose level and weight; self-care with follow-up home visits and telephone counseling.	6 months	4 (57)
Evangelista et al [37] (United States)	Quasi-experimental	42	21 (50)	21 (50)	Telemonitoring and telephone support; daily measures of weight, heart rate, and blood pressure. Telemonitoring provided alerts and feedback in the case of worrisome responses to questions or if vital signs were outside of preset limits. The research nurse communicated with the patient through teleconferencing and collaborated with the patient's primary care provider to facilitate a plan of action. Telephone support as usual to the control group.	3 months	7 (100)
Frederix et al [46] (Belgium)	RCT	160	80 (50)	80 (50)	Telemonitoring; daily measurements of weight, heart rate, and blood pressure were forwarded to a central computer. If the recordings were outside of predefined alert limits, both the general practitioner and HF clinic were alerted by email. At that moment, per protocol, the general practitioner (or cardiologist) was asked to visit or contact the patient and adapt the treatment if they felt that it was necessary. The HF nurse contacted the patient by telephone 1-3 days after the alert to verify whether the intervention had been effective.	6 months	6 (86)
Gallagher et al [38] (United States)	RCT	40	20 (50)	20 (50)	Telemonitoring; electronic measurement of adherence to loop diuretics. A licensed clinical social worker reviewed adherence data daily during the first 7 days after discharge and weekly after that and then contacted participants who were nonadherent for ≥2 days per week.	30 days	7 (100)

Study (country)	Design	Sample size			Content, focus, and mode of instruction	Duration	MMAT[a] scores out of 7, n (%)
		Total sample (N)	I[b], n (%)	C[c], n (%)			
Hwang et al [48] (Australia)	RCT	53	24 (45.3)	29 (54.7)	Telemonitoring and telephone support; participants were instructed to self-monitor and verbally report their blood pressure, heart rate, and oxygen saturation levels at the start of each rehabilitation session. The intervention group received electronic education sessions.	3 months	7 (100)
Jayaram et al [39] (United States)	RCT	1521	756 (49.7)	765 (50.3)	Telephone calls are used for technical support by interactive voice response; symptoms and daily weight; patients were instructed to call a toll-free number daily for 6 months, respond to a series of automated questions regarding their symptoms, and enter their daily weight. They were also provided with educational materials.	6 months	6 (86)
Kotooka et al [47] (Japan)	RCT	181	90 (50)	91 (50)	Telemonitoring and telephone support, measurement of weight, heart rate, and blood pressure daily. Physicians could provide telephone guidance, change medications, and order hospital readmission if required. Full-time nurses monitored acquired data on a secure website. Telephone support from a physician as usual.	15 months	6 (86)
Kraai et al [50] (Netherlands)	RCT	176	83 (47.2)	93 (52.8)	Telemonitoring and telephone support; daily measurement of weight, heart rate, and blood pressure. HF nurses automatically received notifications by mobile phone and email and then discussed symptoms and treatment with patients within 2 hours.	9 months	6 (86)
Köberich et al [51] (Germany)	RCT	110	58 (52.7)	52 (47.3)	Telephone support; nurse-led symptom monitoring, education on signs and symptoms of worsening HF, HF-specific diet, and fluid restriction. When seeking help, patients were advised to use a diary to document body weight, blood pressure, heart rate, and edema on a daily basis. If necessary, after discharge from the hospital, patients received 4 telephone calls within 3 months about changes in HF-related symptoms and treatment.	3 months	5 (71)
Lycholip et al [49] (Netherlands)	RCT	118	58 (49.2)	60 (50.8)	Telemonitoring and telephone support; daily measurement of body weight, blood pressure, and heart rate. HF nurses automatically received notifications by mobile phone and email and, within 2 hours, discussed the symptoms and treatment with the patients. An HF nurse provided education on HF.	9 months	6 (86)

Study (country)	Design	Sample size			Content, focus, and mode of instruction	Duration	MMAT[a] scores out of 7, n (%)
		Total sample (N)	I[b], n (%)	C[c], n (%)			
Masterson- Creber et al [40] (United States)	RCT	67	41 (61.2)	26 (38.8)	Telephone support MI[e]: a tailored intervention at discharge to improve self-care, involving a home visit and follow-up calls. A nurse used the MI approach to identify client-directed self-care goals. Participants received written educational material.	3 months	6 (86)
Ong et al [41] (United States)	RCT	1437	715 (49.7)	722 (50.3)	Telemonitoring and telephone support; weight, heart rate, and blood pressure were measured daily. A total of 9 telephone health coaching calls over 6 months, generally from the same call center nurse.	6 months	5 (71)
Pedone et al [52] (Italy)	RCT	96	50 (52/1)	46 (47.9)	Telemonitoring and telephone support; measurement of blood pressure, oxygen saturation, weight, and heart rate daily; a geriatrician evaluated the data received every day. Participants received education on medical treatment and lifestyle counseling by telephone.	6 months	6 (86)
Ritchie et al [42] (United States)	RCT	511	253 (49.5)	258 (50.5)	Interactive voice response and telephone support; symptoms and body weight measured daily; E-Coach intervention: an intervention with condition-specific customization and in-hospital and postdischarge support by a care transition nurse, interactive voice response, postdischarge calls, and care transition nurse follow-up.	2 months	7 (100)
Srivastava et al [43] (United States)	Cohort–control	1067	197 (18.5)	870 (81.5)	Telemonitoring and telephone support; measurement of heart rate and blood pressure daily. Data were monitored on weekdays by a telehealth nurse who analyzed the data for abnormalities and lack of response; if clinical data caused concern for declining health status, a phone call was initiated to the patient. All patients also received a monthly follow-up call.	12 months	6 (86)
Young et al [44] (United States)	RCT	105	54 (51.4)	51 (48.6)	Telephone support: the patient-activated care at home intervention contained a variety of formats (eg, verbal, written, and visual) with 12 weeks of post discharge education sessions delivered by telephone. Besides self-management workbooks, each subject was provided with a self-management toolkit, including a calendar for weight and daily salt-intake logging, a step-on weight scale with large and bright readings, and an electronic pill organizer reminder alarm.	6 months	6 (86)

[c]C: control.

[d]RCT: randomized controlled trial.

[e]MI: motivational interview.

Themes Derived From Data Analysis

In the following section, the data analysis results are presented, thereby answering the research questions concerning intervention content and delivery mode, intervention adherence, and the effects of eHealth on patient outcomes.

Delivery Mode and Content of Posthospitalization eHealth Follow-Up Interventions

In all, 2 different modes of delivering an eHealth service were identified (Table 1). The specific technologies identified included (1) structured telephone calls and (2) telemonitoring or telemonitoring in combination with telephone support.

Structured Telephone Call

Of the 18 studies in our review, 6 (33%) included structured telephone calls to deliver the intervention to patients with HF [36,39,40,42,44,51]. Of these 6 studies, in 2 (33%), interactive voice response devices were used to examine the patients' symptoms and vital sign registrations [39,42]. In these studies, patients were instructed to call a toll-free number daily for 6 months, respond to a series of automated questions about their symptoms, and enter their daily weight. Responses that met prespecified criteria triggered a variance within the system. Conflicts were then flagged for immediate attention by on-site clinicians [39].

Nurses performed all telephone calls. Four dominant categories of content and use of the telephone-supported HF interventions were identified as follows: (1) keeping logs: encouraging patients to keep logs for monitoring symptoms, blood pressure, and weight; (2) goal-setting skills: teaching patients goal-setting skills to manage their condition or behavior changes; (3) problem-solving skills: teaching patients problem-solving skills to manage their condition; and (4) advice about when to seek help in case of worsening HF. In addition, education and counseling were combined with follow-up home visits in 17% (1/6) of the studies [36], whereas in another study, customized HF education was provided on the patient's response to questions on symptoms and self-management [40]. Each intervention session lasted 15-50 minutes. In the trial conducted by Ritchie et al [42], support calls were provided to patients only when required, whereas in 67% (4/6) of the studies, 4-10 calls were delivered for 2-4 months [36,40,44,51].

Telemonitoring

Of the 18 included studies, 12 (67%) included a telemonitoring program. In 75% (9/12) of these studies, weight, heart rate, and blood pressure were measured daily [35,37,41,45-47,49,50,52]. Athilingam et al [35] also included a medication tracker in their HeartMapp app and physiological exercises to reset the autonomic nervous system and improve functional capacity. Pedone et al [52] included oxygen saturation in addition to measuring blood pressure and heart rate daily. These studies also used assessments of symptoms related to HF and action plans for clinical decisions based on out-of-limit alerts from the data monitoring. In 75% (9/12) of the studies, nurses specialized in HF care and telemedicine, or care transition performed the daily data monitoring [35,37,41,43,45-47,49,50]. Of the 12 telemonitoring studies, 2 (17%) provided patients with automated feedback triggered by out-of-limit alerts [35,39]. In cases where these alerts indicated possible mild to moderate decompensation, nurses could promote diuretic dose adjustments following specific protocols [45] and alerts could be routed to clinicians (eg, physicians and cardiologists) who evaluated the data and contacted patients if necessary. For cases in which out-of-limit alerts indicated severe decompensation, patients were advised to call the emergency number or go to the nearest hospital emergency department [35,37,41,43,45-48,50]. In 17% (2/12) of the studies, clinicians (physicians and geriatricians) conducted data monitoring and management simultaneously [39,52]. Of the 12 studies, 1 (8%) was a telerehabilitation investigation in which participants were guided to self-monitor and verbally report their blood pressure, heart rate, and oxygen saturation levels at the start of each rehabilitation session [48]. Finally, 75% (9/12) of the telemonitoring studies provided the participants with telephone support to either follow up on alerts generated from the patient's registrations of symptoms and vital signs [43,45,49,50], technical support [48], and follow-up of control group or as usual care [37,47] or to provide patient education [41,52].

Adherence to Posthospitalization Follow-Up eHealth Interventions in HF

Of the 18 included studies, 11 (61%) reported patients' adherence to the intervention [35,38,41,42,44,45,47-50,52]. In 91% (10/11) of these studies, adherence was reported as a secondary study outcome, whereas in 9% (1/11) of the studies, adherence was included as a primary outcome [38]. Overall, adherence levels were reported at a rate of 72%-99%. Among the studies using telephone support as a delivery mode, 33% (2/6) included measures of adherence with adherence levels of 86% [42] and 84% (T1) and 86% (T2) [44]. Details regarding reported adherence are provided in Table 2.

Table 2. Reporting intervention program adherence in the included studies (N=18).

Study	Adherence reported	Definition and assessment of adherence	Adherence results
Athilingam et al [35]	Yes	Duration for which the participants accessed intervention features.	Adherence was low, with only 72% of the participants completing the 30-day follow-up.
Comin-Colet et al [45]	Yes	Daily automated telemonitoring of biometrics and symptoms using the intervention platform.	Adherence was very high, with missed biometric daily transmissions less than 1% of the expected number of daily transmissions.
Dunbar et al [36]	No	—[a]	—
Evangelista et al [37]	No	—	—
Frederix et al [46]	No	—	—
Gallagher et al [38]	Yes	Adherence to loop diuretics in the 30 days after discharge. Nonadherence=adherence <88%. Adherence was calculated as the percentage of days on which the correct number of doses was taken as prescribed, irrespective of dose timing.	Median correct dosing adherence was 81%, and 33% of the participants were classified as adherent. Reasons for nonadherence were identified as follows: ran out of pills, out of usual routine, side effects, and did not know the correct dose.
Hwang et al [48]	Yes	Attendance rates were categorized into adherent (>80%), partly adherent (20%-80%), and nonadherent (<20%), based on the proportion of sessions attended by each participant.	Of the 51 participants who attended the rehabilitation programs, 49 (96%) were categorized as adherent or partly adherent. None of the intervention participants were nonadherent.
Jayaram et al [39]	No	—	—
Köberich et al [51]	No	—	—
Kotooka et al [47]	Yes	Adherence was measured as the number of days that each patient measured their body weight and blood pressure in a month.	The mean rates of adherence at 1, 6, and 12 months after randomization were 96%, 90%, and 91%, respectively.
Kraai et al [50]	Yes	Adherence of patients to telemonitoring was assessed by daily weighing and measuring of blood pressure.	The median adherence rate was 95% (range 87%-99% for the total study period).
Lycholip et al [49][b]	Yes	Adherence of patients to telemonitoring was assessed by daily weighing and measuring of blood pressure.	The median adherence rate was 95% (range 87%-99% for the total study period).
Masterson-Creber et al [40]	No	—	—
Ong et al [41]	Yes	Telemonitoring adherence: percentage of total days during 30 and 180 days; telephone coaching adherence: percentage of total days during 30 and 180 days.	Overall, 83% (591/715) of the intervention participants used telemonitoring equipment.
Pedone et al [52]	Yes	Percentage of the total amount of expected symptom measurements.	On average, 62% of the scheduled measurements were completed (weight once a day, blood pressure and heart rate twice a day, and peripheral oxygen saturation thrice a day); adherence was best for pulse oximeter (70%) and worst for the scale (56%); 64% of the participants completed at least half of the scheduled measurements.
Ritchie et al [42]	Yes	Total (100%) adherence was defined as answering all interactive voice response system calls. Optimal adherence: daily response to the interactive voice response during the first 7 days. Answering a call was defined as a patient completing the questions of the call.	Of the patients with HF, 144 (86%) received a total intervention dose.
Srivastava et al [43]	No	—	—
Young et al [44]	Yes	Frequencies of self-reported self-management behaviors of daily weighing, following a low-sodium diet, taking prescribed medications, exercising, and attending follow-up appointments.	Participants in the intervention group who received the patient-activated care at home intervention had significantly higher self-reported adherence to self-management behaviors; 84% at 3 months and 86% at 6 months reported not missing any doses in the previous week, compared with 68% at both time points in the control group.

[a]Data not available.

[b]Same study population and intervention as in the study by Kraai [50].

Effects From Follow-Up Interventions on Patient Outcomes

Overview

Of the 18 included studies, only 1 (6%) investigated all 3 patient outcomes of interest to this review (ie, QoL, readmissions, and self-care behavior) [45]. Included in 61% (11/18) of the studies, QoL was the most frequently analyzed patient outcome, followed by readmissions in 56% (10/18) of the studies. Self-care was explored in 44% (8/18) of the included studies. Details concerning the effects of eHealth interventions are provided in Table 3.

Table 3. Effects of intervention programs on patient outcomes of quality of life (QoL), self-care, and readmissions (N=18).

Study	Sample size n (%), I[a]/C[b]	Baseline	Postbaseline measures		Outcome

Impact on QoL

QoL was included as a patient outcome in 61% (11/18) of the studies among patients with HF [35-37,39-41,45,47,48,50,51]. Of these 11 studies, 4 (36%) found that an eHealth intervention significantly improved patients' *overall QoL* [36,37,45,48]. Of these 4 studies, 3 (75%) contained telemonitoring combined with telephone support and with an intervention duration of 3-6 months [35,43,45], whereas the study by Dunbar et al [36] provided only telephone support lasting for 6 months. In both the studies by Jayaram et al [39] and Ong et al [41], the QoL was nonsignificant at the first postbaseline data collection. In contrast, QoL was significantly improved in both studies 6 months after beginning the intervention [39,41]. Of the 3 studies recruiting participants later than at discharge (ie, within 30 days after discharge), 2 (67%) reported significant effects from an eHealth intervention on QoL [39,48].

Self-care Behavior

Self-care was investigated in 39% (7/18) of the studies [35,37,38,44,45,49,51]. Athilingam et al [35] and Evangelista et al [37] both reported on self-care measured by the Self-Care of Heart Failure Index, which included the subscales self-care maintenance, self-care management, and self-care confidence. *Self-care management* was found to be significantly increased by eHealth interventions in both studies; in addition, Evangelista et al [37] found that *self-management maintenance* also seemed to be significantly improved. The subscale *self-care confidence* was enhanced to a significant degree by an eHealth intervention in 14% (1/7) of the studies [35]. Comin-Colet et al [45] used the Self-care Behavior Scale to study self-care behavior in patients with HF who were remotely followed by the Home Tele-HealthCare platform, with the authors detecting a marginally significant difference between the intervention and control groups. Köberich et al [51] and Lycholip et al [49] measured self-care behavior by using the European Heart Failure Self-care Behavior Scale. Of the 7 studies, 1 (14%) found significant improvements from the eHealth interventions on self-care behavior [51], whereas Lycholip et al [49] determined that such interventions did not influence self-care behavior; this study recruited patients within 14 days after discharge [49]. Finally, in the study by Gallagher et al [38], self-care was defined as medication adherence, with no significant effect from the eHealth intervention being noted. The studies showing significant effects on self-care behavior delivered the interventions for 30 days to 6 months. Of the 7 studies, only 1 (14%) did not include digital monitoring of symptoms and vital signs [46].

Readmissions

Of the 18 studies, 10 (56%) included readmissions as a patient outcome [38,41-47,50,52]. A significant reduction in readmissions associated with eHealth interventions was detected in 30% (3/10) of these studies [45,46,52]. All the studies combined telemonitoring and telephone support as the intervention delivery mode, and the intervention lasted for 6 months. Comin-Colet et al [45] found a significant reduction in readmissions in the HF intervention group compared with controls. The study by Frederix et al [46] identified a significant reduction (P=.04) in days lost to HF-related readmissions among patients in the intervention group but not for all-cause readmissions (P=.26). Pedone et al [52] revealed a significantly (P=.04) higher risk of readmissions (42%) at 180 days in the control group compared with 21% for patients with HF who were given remote follow-up. None of the studies that recruited patients later than discharge achieved significant effects on readmissions [43,44,47].

Discussion

Summary of Evidence and Comparison With Prior Work

In this restricted systematic review, we have evaluated and synthesized the findings from 18 posthospitalization follow-up eHealth interventions targeting QoL outcomes, self-care, and readmissions of patients with HF. To summarize, patients with HF were enrolled in the interventions upon or after hospital discharge. Interventions were delivered mainly by telephone or email and focused on patient education and counseling, social and emotional support, and self-monitoring of vital signs and symptoms. Posthospitalization eHealth follow-up for patients with HF holds potential for improving their QoL, whereas a positive impact on self-care and readmissions is less evident.

Some of the included studies used more traditional tools to follow up with patients, such as the telephone. Because of its familiarity and ease of use, the telephone may be appropriate to contact patients remotely. Individuals at risk of low eHealth literacy, such as older or less educated patients, may benefit from using a more traditional eHealth tool such as the telephone [53]. However, when comparing the effects on patient outcomes from studies using eHealth solutions other than the telephone as the delivery mode, telephone interventions do not stand out as more or less appropriate. We found that telephone interventions as a delivery mode effectively improved patients' self-care behaviors, but the effects on QoL and readmissions were less promising. This finding suggests that self-care follow-up is likely to be more important than the specific mode of follow-up.

Most studies in this review included features that required patients to monitor their vital signs and report health behaviors and symptoms. Giving patients with HF a more active role in their healing processes through posthospitalization eHealth interventions may promote their experience as true partners in shared decision-making, improve their well-being, and result in better adherence to treatment [54]. However, the value of eHealth interventions as part of health care for patients who are chronically ill may vary. Runz-Jørgensen et al [55] found that patients with multimorbidity and more significant illness and

treatment burden perceived eHealth interventions as more favorable than those with less complex disease and treatment. This result may be explained by considering the burdens of HF [55]. Patients with HF are vulnerable because they require regular and ongoing disease monitoring and management to reduce the risk of deterioration, and many fragile patients with HF have limited access to the health care system. The COVID-19 pandemic has forced health care systems to re-evaluate reimbursement for eHealth solutions to promote more widespread adoption of HF care [15,56,57].

We believe that for patients with HF to perceive the eHealth follow-up service as appropriate and be willing to use it, the timing of the introduction of the service is a crucial factor. In our review, patients were primarily enrolled in the eHealth interventions upon hospital discharge, ensuring patient support immediately after release. However, of the 18 included studies, 5 (28%) recruited patients during the first 4 weeks after discharge, demonstrating that eHealth interventions significantly increased QoL but had little impact on readmissions and self-care. Nevertheless, the findings of the effects from eHealth follow-up on patient outcomes suggest that patients with a severe heart condition benefit from prompt posthospitalization follow-up. It may be essential to provide patients with HF with self-care support at discharge to avoid 30-day readmission.

Remote monitoring as a feature of eHealth interventions may include parameters for detecting symptom and illness deterioration, successfully reducing readmissions among patients with HF [19-21]. However, in our study, the effects on readmissions from remote monitoring were inconclusive. For monitoring to be successful, aspects of measurement reliability and frequency, patient interface and adherence, and prompt interpretation by health professionals need to be considered [58]. Most of the included studies involving remote monitoring also provided contact with health care professionals, mainly nurses, who regularly stayed in touch with patients by either telephone calls or email. Koivunen and Soranto [59] identified communication and patient–nurse relationships as essential factors of telehealth in nursing practice. Patient–nurse interactions enable nurses to inquire about and assess patients' self-care needs and symptoms, express empathy, and increase patients' sense of security [58]. Another vital aspect of the patient–nurse interaction in the included eHealth interventions was whether the technology was acceptable to patients. Lack of required engagement among patients may be attributed to the nature of the technology [60], and patient adherence to the system is crucial for an intervention's success. Ding et al [61] found high adherence to the intervention component of weight monitoring (6 out of 7 days) in their recent telemonitoring RCT of patients with HF (published after our literature research). The intervention resulted in a significant improvement in self-management related to health maintenance, medication adherence, and diet [61]. We found that intervention adherence in most of the remote monitoring studies with patient–nurse interaction was 81%-99%. Comin-Colet et al [62] found that despite low expectations among patients before entering a telemedicine HF care intervention, adherence and satisfaction levels were high during the intervention, likely because of the HF care teams' proactive engagement with patients [62]. Clinicians who practice patient-centered communication adopting the patient's perspective may contribute to increased adherence levels in patients with HF, particularly during care transitions such as discharge from hospital to home, which to many patients can be confusing and demanding related to follow-up on treatment regimens [63]. The World Health Organization states that the quality of the treatment relationship is an essential determinant of adherence [26].

eHealth interventions have excellent potential to reinforce patient education on self-care [53]. Most of the reviewed studies in this review provided patients with education or counseling delivered by nurse specialists before the trial or during the trial, covering disease- and treatment-specific topics, psychosocial issues, and health behavior change. These studies seem to support improved self-care from eHealth interventions that include an educational aspect. Although the educational focus of many eHealth and mHealth interventions is illness management [64], a more holistic approach to self-care education not limited to only disease management is suggested. According to Lewis et al [65], addressing the holistic needs of patients with comorbidities using eHealth technology supports more patient-centered health care. Interestingly, of the 18 included studies, only 1 (6%) assessed changes in patients' knowledge at the completion of the intervention period. This study found that an HF education program involving iterative teaching tools expanded patients' HF knowledge [35]. This finding is in line with a review by Bashi et al [64], in which only 2 of the 15 mHealth interventions included an evaluation of patient knowledge as a study outcome. On the contrary, a recent Cochrane review of mHealth-delivered educational interventions for patients with HF found no evidence of a difference in HF knowledge or other patient-reported outcomes [66]. However, validated tools of patient knowledge can be an efficient measure of intervention success, and an assessment of patient knowledge as part of eHealth protocols is recommended [66].

Limitations

Several limitations should be mentioned. First, heterogeneity in the included studies made meta-analysis impossible, and a qualitative thematic analysis was applied. Such an analysis is prone to interpretation bias [33]. Second, the included eHealth interventions pertain to the transition phase between hospital and home, thus limiting generalizability to all stages of follow-up of patients with HF. Third, although most of the included studies indicated good methodological quality, most of them did not apply a blinded randomization process, and 50% (9/18) of the studies did not report adherence to the intervention.

Conclusions

This review identified 18 studies of posthospitalization follow-up interventions in patients with HF. Most of the included studies enrolled patients in eHealth interventions upon hospital discharge to ensure support in the critical post–hospital discharge period. The most common mode for posthospitalization follow-up was telemonitoring with telephone support. Patients received education or counseling about their disease, psychosocial issues, and health behavior changes. Most

studies also required the patients to monitor vital signs and report their health behaviors and symptoms.

The findings of the effects of interventions on patient outcomes such as QoL, self-care, and readmissions propose that patients with HF should receive prompt follow-up after hospital discharge. eHealth interventions, including patient education, support, and self-monitoring, have the potential to improve QoL, but it is less clear how eHealth interventions affect self-care behavior and readmissions in populations of patients with HF.

Aspects of measurement reliability and frequency, user interface and adherence, and prompt interpretation by health professionals need to be considered to ensure successful monitoring in eHealth interventions. These findings are important to inform future intervention studies to support patients with HF after discharge from the hospital. eHealth interventions have the potential to improve well-being, adherence to treatment, and patients' experiences of being engaged partners in shared decision-making.

Systematic reviews of the literature are recommended during the planning and development of complex interventions [29]. The findings from this review will be used to inform the development of a post–hospital discharge follow-up service addressing the burden of treatment and self-management among patients with HF.

Abstract

Background: Symptoms of anxiety are common in pregnancy, with severe symptoms associated with negative outcomes for women and babies. Low-level psychological therapy is recommended for women with mild to moderate anxiety, with the aim of preventing an escalation of symptoms and providing coping strategies. Remotely delivered interventions have been suggested to improve access to treatment and support and provide a cost-effective, flexible, and timely solution.

Objective: This study identifies and evaluates remotely delivered, digital, or web-based interventions to support women with symptoms of anxiety during pregnancy.

Methods: This mixed methods systematic review followed a convergent segregated approach to synthesize qualitative and quantitative data. The ACM Digital Library, Allied and Complementary Medicine Database, Applied Social Sciences Index and Abstracts, Centre for Reviews and Dissemination database, the Cochrane Central Register of Controlled Trials, the Cochrane Library, CINAHL, Embase, Health Technology Assessment Library, IEEE Xplore, Joanna Briggs Institute, Maternity and Infant Care, MEDLINE, PsycINFO, and the Social Science Citation Index were searched in October 2020. Quantitative or qualitative primary research that included pregnant women and evaluated remotely delivered interventions reporting measures of anxiety, fear, stress, distress, women's views, and opinions were included.

Results: Overall, 3 qualitative studies and 14 quantitative studies were included. Populations included a general antenatal population and pregnant women having anxiety and depression, fear of childbirth, insomnia, and preterm labor. Interventions included cognitive behavioral therapy, problem solving, mindfulness, and educational designs. Most interventions were delivered via web-based platforms, and 62% (8/13) included direct contact from trained therapists or coaches. A meta-analysis of the quantitative data found internet-based cognitive behavioral therapy and facilitated interventions showed a beneficial effect in relation to the reduction of anxiety scores (standardized mean difference −0.49, 95% CI −0.75 to −0.22; standardized mean difference −0.48, 95% CI −0.75 to −0.22). Due to limitations in the amount of available data and study quality, the findings should be interpreted with caution. Synthesized findings found some evidence to suggest that interventions are more effective when women maintain regular participation which may be enhanced by providing regular contact with therapists or peer support, appropriate targeting of interventions involving components of relaxation and cognitive-based skills, and providing sufficient sessions to develop new skills without being too time consuming.

Conclusions: There is limited evidence to suggest that women who are pregnant may benefit from remotely delivered interventions. Components of interventions that may improve the effectiveness and acceptability of remotely delivered interventions included

providing web-based contact with a therapist, health care professional, or peer community. Women may be more motivated to complete interventions that are perceived as relevant or tailored to their needs. Remote interventions may also provide women with greater anonymity to help them feel more confident in disclosing their symptoms.

Introduction

Symptoms of anxiety are common in pregnancy and have been reported across all 3 trimesters [1,2]. Recent reviews have reported worldwide prevalence rates of 15% to 20% in the antenatal period, with higher rates reported in low- to middle-income countries, particularly among poorer women with gender-based or psychiatric risks [3-5]. Risk factors for developing anxiety during pregnancy include demographic and socioeconomic factors (lack of partner support, young age, lower education, smoking, and being overweight), psychological factors (past mental health concerns, reduced emotional well-being, stressful events, low self-esteem, and negative coping styles), and obstetric factors (previous pregnancy loss and complications in pregnancy) [6,7]. Antenatal anxiety is reported to be associated with postpartum depression, reduced rates of breastfeeding, prematurity, and preterm birth [8,9].

Facilitated self-help and low-intensity psychological interventions are recommended as the first-line treatment option in pregnancy within a stepped care approach [10]; however, there are limited data on the effectiveness of interventions for the antenatal period [11]. Vigod and Dennis [12] discussed that interventions delivered via the internet might present a solution for overcoming the barriers of access to treatment for perinatal mental health disorders, such as a lack of specialist psychological and psychiatric support, the cost of services and transportation, and childcare requirements. Interventions can be delivered as unguided resources to support or replace patient–provider interactions or as guided interventions that may include live interactions over telephone or video or contact with therapists using digital messaging. Web-based interventions and peer discussion groups may benefit women by reducing the stigma of mental illness in pregnancy, addressing treatment barriers, and strengthening social support mechanisms. Web-based therapist-assisted interventions may offer women flexibility and convenience and be more efficient than the delivery of one-on-one therapy [12]. In particular, the use of mobile technology is thought to offer a low-cost solution for improving treatment accessibility and sustainability. In high-income countries, between 84% and 99% of people aged <35 years own a smartphone, which would include women in their prime reproductive years [13,14].

A recent review of internet-delivered psychological interventions for perinatal anxiety and depression [15] included 2 cognitive behavioral therapy (CBT) interventions for women with fear of childbirth [16] and symptoms of anxiety and depression [17]. Improvement in symptoms was reported, and participant satisfaction was positive in both studies. A scoping review of mobile health apps and text-based interventions for perinatal anxiety and depression (n=26 publications from 22 studies) [14] identified 1 intervention focused solely on anxiety and 9 interventions for both depression and anxiety. Intervention strategies included peer support, psychoeducation, and active therapy.

Anxiety symptom screening for maternity care, which, in the United Kingdom, uses a simple 2-item measure (Generalized Anxiety Disorder [GAD] 2 items) [18], is recommended to identify where women may need further support or referral for specific diagnosis by specialist mental health professionals. Locating interventions that can be integrated within current maternity care structures was a key motivation in the design of this review. Maternity care providers require guidance on the aspects of care that can be safely and effectively delivered via remote interventions and consider the implications in terms of acceptability, fidelity, and equitability [19-21]. The COVID-19 pandemic presented a further motivation for this review, considering the impact of the pandemic on women's mental health and identifying innovative ways of delivering safe, effective, and equitable care [22,23]. In this review, we seek to identify the types of remotely delivered interventions that are available and have been evaluated to improve the symptoms of anxiety in women who are pregnant. We include a broad concept of common anxiety disorders in pregnancy, including pregnancy-specific anxiety and fear of birth, and a range of intervention strategies, including psychological, mind–body, education, and social support. The review aims to answer the following questions:

- What remotely delivered, digital, or web-based interventions have been evaluated and reported in the research literature to improve the symptoms of anxiety in women who are pregnant?
- How effective are remotely delivered, digital, or web-based interventions in reducing the symptoms of anxiety in pregnancy?
- What are women's views, attitudes, and experiences of accessing and participating in remotely delivered anxiety interventions during pregnancy?

Methods

Overview

A mixed methods systematic review was conducted following the established Joanna Briggs Institute (JBI) methodological guidance [24]. This approach supported the broad research aim and enabled evidence from diverse study designs to provide a comprehensive and detailed understanding of the current

evidence base [25,26]. The review adopted a convergent segregated mixed methods approach [27] in which the search and synthesis process for the different study designs included in the review were conducted concurrently. Qualitative and quantitative evidence were initially analyzed separately, followed by comparison and integration of qualitative and quantitative data to form an overarching synthesis. Before commencement, the review protocol was registered on the PROSPERO (The International Prospective Register of Systematic Reviews) database (CRD42020195887).

Eligibility Criteria

Papers were included if the following criteria were met:

1. Participants included women who are pregnant of all parities across the 3 trimesters of pregnancy; women who are pregnant and under the care of specialist mental health services for severe and enduring mental health conditions were excluded
2. Evaluated the following types of interventions: mind–body interventions (relaxation, yoga, meditation, mindfulness, hypnotherapy, and imagery), social support interventions (supportive interactions, group discussions, peer support, telephone support, and exercise), educational interventions (birth preparation, educational sessions, educational materials, psychoeducational interventions, and antenatal classes), psychological interventions (CBT, mindfulness CBT, group CBT, interpersonal psychological therapy, nondirective counseling, therapy, and problem-solving therapy), and interventions that have been remotely delivered, including web-based materials, via telephone, computer software, digital apps, and digital forums
3. Comparators or control groups (CGs) included usual antenatal care or other types of interventions
4. Interventions were considered appropriate and capable of being introduced into maternity care
5. Outcome evaluations included measures of anxiety, fear, stress, distress, and women's views, feedback, and opinions
6. Study methods included quantitative or qualitative primary research, including mixed methods studies involving any number of participants

Information Sources and Search Strategy

A search of the following electronic bibliographic databases was undertaken (October to November 2020): the ACM Digital Library; Allied and Complementary Medicine Database; Applied Social Sciences Index and Abstracts; Centre for Reviews and Dissemination database; the Cochrane Central Register of Controlled Trials; the Cochrane Library; the Cochrane Depression, Anxiety and Neurosis Group's Trials Register; CINAHL; Embase; Health Technology Assessment Library; IEEE Xplore; JBI; Maternity and Infant Care; MEDLINE; PsycINFO; and the Social Science Citation Index. References cited in existing systematic reviews and meta-analyses and reference lists of identified studies were searched to identify additional potentially relevant studies.

The search was limited to studies published since 2000 focusing on women who are pregnant and written in English. This reflects the period in which digitally delivered interventions were available in maternity care.

Titles and abstracts of papers were screened independently by 2 reviewers (KE and SC) against the inclusion and exclusion criteria to identify potentially relevant papers. Potentially relevant papers were retrieved and read in full to identify papers for inclusion in the systematic review. The papers identified for inclusion were agreed upon following discussions with the entire review team. A PRISMA (Preferred Reporting Item for Systematic Reviews and Meta-Analyses) flowchart (Figure 1) [28] was completed to summarize the study selection process. Reference management (RevMan, Version 5.4; The Cochrane Collaboration, 2020) software was used to organize and catalog the references.

Search terms used in the review are summarized in Textbox 1.

Risk of Bias and Quality Assessment

The quantitative experimental study designs were independently assessed by 2 reviewers using the Cochrane Collaboration Effective Practice and Organization of Care tool for assessing the risk of bias [29]. This assesses the risk of selection, performance, detection, attrition, and reporting biases. The RevMan (version 5) software package was used to assist the organization and presentation of the data. The Critical Appraisal Skills Program for qualitative and cohort studies, the Critical Appraisal Skills Program for qualitative and cohort studies [30], The National Heart, Lung, and Blood Institute Quality Assessment Tool for Before–After (Pre–Post) Studies with No Control Group [31], and the JBI Checklist for Quasi-Experimental Studies [32] were also used to assist the methodological assessment of studies for inclusion in the systematic review analysis. Although no studies were excluded on the basis of quality, the quality assessment was used to identify the strengths and limitations of the review [24].

Data Extraction

Data extraction forms were designed and piloted. Extraction was completed by 2 independent researchers (KE and SC). Data extraction tables comprising numerical and textual data were produced to present the study characteristics, results, and quality assessments.

Data Synthesis

Tables were produced to present the study characteristics, results of interest, risk of bias ratings for randomized controlled trials (RCTs), and quality ratings for the included papers. This is presented alongside a narrative description of the data. A meta-analysis of quantitative data from the included experimental studies was conducted [29]. Considerations for performing meta-analysis included assessing the risk of bias of the studies and performing a qualitative assessment of clinical homogeneity. To evaluate statistical heterogeneity, the Q statistic and I^2 index were used [33]. A random effects model was identified as the most appropriate method of analysis, and subgroup analysis was planned for subsets of intervention designs, participants, and methods of delivery. The standardized mean difference (SMD) was presented as the summary statistic for continuous data for anxiety and other outcomes, with 95% CIs and 2-sided *P* values calculated for each outcome where possible. A Grading of Recommendations Assessment, Development and Evaluation (GRADE) assessment [29,34] of the quantitative review findings was conducted, and a GRADE Confidence in Evidence from Reviews of Qualitative research (GRADE-CERQual) assessment of the qualitative studies [35] was planned, although there were insufficient data to perform a GRADE-CERQual assessment.

Following the convergent segregated approach [27], quantitative findings were translated into narrative statements that were then compared, contrasted, and juxtaposed against the qualitative findings and integrated to configure synthesized findings to address the research questions. The synthesized findings were then interpreted and configured into overarching themes to develop explanation, understanding, and coherence between the synthesized findings as a whole [26,36].

Results

Details of the included qualitative and quantitative studies, population, intervention components, and delivery are presented in Multimedia Appendix 1 (TIDieR [Template for Intervention Description and Replication] checklist) [37].

Quality Assessment

The risk of bias assessments for quantitative experimental studies are presented in Figures 2 and 3. Studies were assessed as having a high or moderate risk of bias against the risk of bias standards for studies with a separate CG [29]. A cohort feasibility study [16] was assessed as moderate for methodological quality, which was mainly attributed to a lack of reporting of the recruitment strategy and the small sample size. The 3 qualitative studies were assessed using a moderate to high methodological quality score. Moderate scores were allocated to studies assessed as having limited reporting of (1) researchers' reflexivity and (2) Sampling and context [38,39].

Figure 2. Risk of bias table with assessments of the experimental studies [16,17,38-41,43-47,49-52,62].

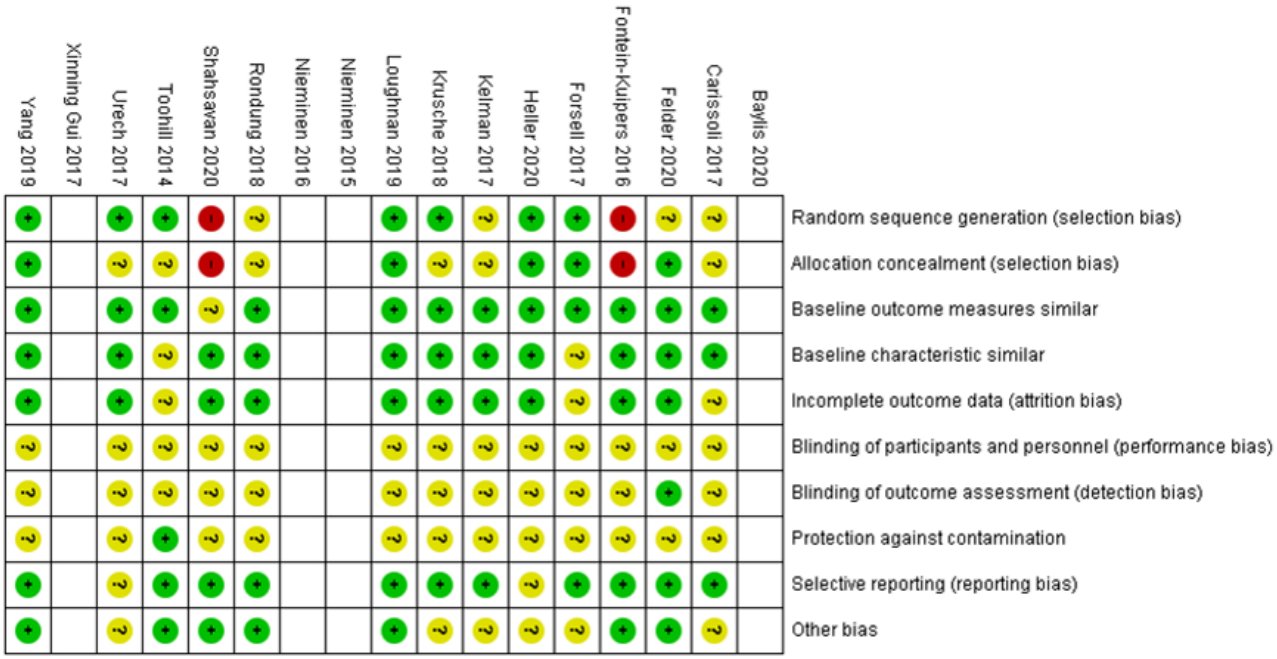

Figure 3. Risk of bias summary of the quantitative experimental selected studies.

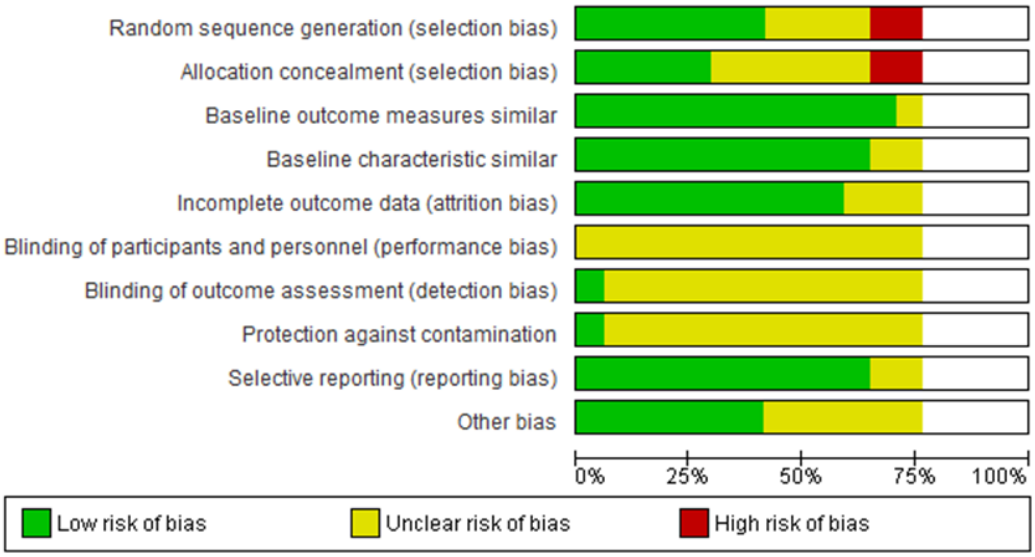

Results From the Quantitative Studies

Overview

Of the 16 included studies, 14 (88%) were conducted in Australia, China, Iran, Italy, the Netherlands, Sweden, Switzerland, the United States, and the United Kingdom. Of the 14 studies, 10 (71%) were RCTs, 2 (14%) were quasi-experimental studies, 1 (7%) was a controlled study, and 1 (7%) was a cohort study. Participants ranged from 28 to 433, with a total of 2339 participants across all included quantitative studies. Study populations included a general population of women who were pregnant (no psychological screening criteria), women with high anxiety and depression self-report scores, women with high fear of childbirth, women with insomnia, and preterm labor.

Study Rationale

In all the included studies, the authors stated that the effectiveness of cognitive-based or mindfulness approaches had been demonstrated in wider populations using traditional face-to-face sessions, with some evidence of effectiveness for internet-based CBT (I-CBT) approaches for anxiety and depression. Studies that focused on supporting women with fear of birth reported on the associations among anxiety, stress, and fear of birth. The authors hypothesized that CBT-based interventions would also lead to an improvement in women's fear of birth symptoms. Approximately 14% (2/14) of studies were focused on addressing birth outcomes. Urech et al [40] discussed the association between anxiety and preterm birth, suggesting psychological therapy as potentially helpful in improving birth outcomes. Shahsavan et al [41] reported an association between maternal requests for cesarean section and fear of birth, stating that addressing fear of birth symptoms may lead to a reduction in the prevalence of cesarean birth. Many of the included studies provided a rationale for developing remotely delivered interventions related to (1) flexibility, (2) cost-effectiveness, (3) potential reach, (4) accessibility, (5) availability, and (6) ubiquity. The flexibility of remotely delivered interventions was considered particularly relevant during pregnancy. The authors suggested that barriers to accessing traditional treatment, such as childcare issues, access to transportation, and limited time, could be overcome by providing interventions that women could access at the time of their choosing. Many studies have reported a lack of suitably trained therapists to meet the demand for psychological services, highlighting the accessibility of I-CBT as an advantage for increasing access to care for all women in all locations. Approximately 14% (2/14) of studies [17,42] discussed that remotely delivered interventions might provide women with greater anonymity and be more acceptable to women who may be reluctant to disclose their symptoms or seek support from health care professionals (HCPs) because of the stigma of mental health conditions in pregnancy, providing women with greater anonymity. The propensity of women who are pregnant for accessing web-based information and the ubiquity of smartphones, tablets, and computers was highlighted as further motivation for developing remotely delivered interventions for this population.

Comparators or CGs

Carissoli et al [43] conducted a pragmatic controlled trial, with the intervention group (IG) receiving a psychological well-being mobile app in addition to childbirth classes. The CG was randomized to receive only childbirth classes. Felder et al [44] recruited women with symptoms of insomnia. The CG was reported to receive standard care for insomnia, which the authors state may have included medication, psychotherapy, herbal supplements, counseling, and support groups. Urech et al [40] recruited women with diagnosed preterm labor for a cognitive behavioral stress management program. The CG received the same duration of web-based sessions and were asked to write short stories, listen to radio plays, answer specific questions, or perform quiz games. Other psychological, psychoeducation, and mindfulness intervention studies stated standard or usual antenatal care as the control condition [17,41,42,45-48,52]. The study by Rondung et al [49] compared I-CBT for women with fear of birth with standard care, which the authors described as including midwife-led fear of birth counseling, delivered face-to-face over 2 to 4 sessions. Kelman et al [50] compared internet-delivered compassionate mind training with I-CBT in a proof-of-concept RCT.

Intervention Components in the Included Studies

Interventions included psychological (CBT and problem solving), mindfulness, and educational designs. Many of the interventions adopted a multidimensional approach with cognitive behavioral techniques, relaxation, and educational intervention components. Most were delivered via web-based platforms where women could complete exercises and modules in their own time. Of the 13 interventions, 8 (62%) interventions included direct contact from trained therapists or coaches via feedback or answering questions, and 1 (8%) intervention was delivered via telephone [46]. Interventions lasted for 2 to 30 weeks (Multimedia Appendix 2). Participants were recruited by various methods: HCP referral during routine clinical appointments or self-recruited via advertisements in print and social media. Eligibility screening was conducted in 79% (11/14) of the studies, which included anxiety symptoms, depression, fear of birth, insomnia, or preterm labor (Multimedia Appendix 3). For studies reporting inclusion rates (as a percentage of the enrolled population), all 29% (4/14) of studies that used criteria based on fear of birth measures reported inclusion rates <10%. The 29% (4/14) of studies that used criteria based on anxiety or depression screening tools reported inclusion rates between 19% and 46%. Studies that did not apply psychological screening inclusion measures reported inclusion rates ranging from 76% to 90%.

Intervention Completion Rates Reported in the Included Studies

Shahsavan et al [41] reported an adherence rate of 93.72% across an 8-week I-CBT intervention. Adherence to the intervention program was measured as the number of log-ins and time spent on the designed software gathered via web - logging per unique user ID. Loughnan et al [53] and Yang et al [45] reported completion rates of 72% across all 3 sessions for an I-CBT intervention and 84% for a mindfulness intervention. The remaining 54% (7/13) of interventions that provided relevant

data reported falling attendance rates across the time frame of the intervention. Approximately 36% (5/14) of studies (I-CBT and problem-solving interventions) maintained completion rates of approximately ≥50% at week 5 to week 6 time points and included women with elevated symptoms of anxiety, depression, fear of birth, or insomnia [16,17,42,44,46]. Approximately 14% (2/14) of studies reported completion rates of <30% by week 3 on the intervention program: the study by Rondung et al [49], which involved I-CBT for women with high fear of birth scores, and the study by Krusche et al [47], which involved mindfulness for a general population of women who are pregnant. Fontein-Kuipers et al [48] reported the number of women who completed third trimester postintervention measures for an intervention delivering coping skills, resources, and personalized feedback (CG 56% and IG 64%). Across the 64% (9/14) of studies reporting full intervention completion data, all 56% (5/9) of studies that maintained completion rates >50% across the whole intervention reported significant improvement in anxiety scores between the IG and CG groups [16,41,44,46,53]. The 44% (4/9) of studies where completion fell <50% (at weeks 2-5) reported nonsignificant differences between the IG and CG groups [17,42,47,49].

Reported Acceptability and Satisfaction

Approximately 29% (4/14) of the studies assessed participant acceptability or satisfaction through feedback and satisfaction questionnaires; all received positive feedback, and women considered they had benefitted from participating. Loughnan et al [52] reported that after 1 to 2 sessions, most participants found the I-CBT intervention logical and considered it would be useful for their symptoms of anxiety and depression. Following completion of the intervention, most women were satisfied with the program, which they assessed as good quality, relatable, and useful in helping them manage their symptoms. Women could relate to the fictional characters experiencing anxiety and depression presented in an illustrated story. The authors reported that just over half of the participants preferred the web-based delivery of the program rather than other methods of intervention delivery. Forsell et al [17] reported that women who completed the I-CBT intervention felt satisfied, and most rated the treatment as helpful and important. Heller et al [42] reported that most women found the guided problem-solving intervention satisfying and would recommend the intervention to others. The website and feedback of coaches were rated as fairly good to excellent by most participants. The mindfulness intervention by Yang et al [45] was reported as beneficial by most of the participants who reported that it helped them feel relaxed and calm, become fully aware of fetal movements, and relieve discomfort. Some women reported that learning to maintain an accepting attitude was challenging, and daily mindfulness practice was onerous.

Reported Findings for Anxiety and Fear of Birth Scores in the Included Studies

Studies used various self-report outcome measures for anxiety and fear of birth symptoms, including the following:

- GAD 7-item (GAD-7) scale [18]
- Patient Health Questionnaire 9 item [54]
- Hospital Anxiety and Depression Scale—Anxiety subscale [55]
- Depression Anxiety Stress Scale [56]
- State–Trait Anxiety Inventory [57]
- Pregnancy-Related Anxiety Test [58]
- Pregnancy-Related Anxiety Questionnaire [59]
- Wijma Delivery Expectancy/Experience Questionnaire [60]
- Fear of Birth Scale [61]

Outcome scores as reported in the included papers are provided in Multimedia Appendix 3.

Meta-analysis of Anxiety Postintervention Scores

Studies used different anxiety measures to assess intervention outcomes (GAD-7, Hospital Anxiety and Depression Scale—Anxiety subscale, Pregnancy-Related Anxiety Test, Pregnancy-Related Anxiety Questionnaire, Patient Health Questionnaire-9 item, State–Trait Anxiety Inventory, and Depression Anxiety Stress Scale); therefore, SMDs were used as the summary statistic [33]. The results from 43% (6/14) of the studies that provided sufficient outcome data for postintervention anxiety scores were pooled and indicated statistical heterogeneity among the studies and clinical heterogeneity between the intervention type, duration, and the characteristics of participants (Figure 4). Subgroup analyses were conducted on studies of interventions with similar characteristics, such as I-CBT and facilitated interventions, which provided sufficient data and were assessed as having sufficient clinical and statistical homogeneity to perform a meta-analysis (Figures 5 and 6) [33].

For the 23% (3/13) I-CBT interventions that provided sufficient data to be included in the meta-analysis, a beneficial effect was observed in relation to the reduction of anxiety scores (SMD −0.49, 95% CI −0.75 to −0.22), with low statistical heterogeneity among the studies (I^2=0%; P=.87). For facilitated interventions, beneficial effects were observed in relation to the reduction of anxiety scores (SMD −0.48, 95% CI −0.75 to −0.22), although there was substantial statistical heterogeneity among the studies (I^2=65%; P=.02). However, the pooled number of participants was relatively small (n=228 and n=848, respectively), and studies were assessed to have an unclear risk of bias. Therefore, the results of the meta-analysis should be interpreted with caution (Table 1).

Findings From the Qualitative Studies: Women's Engagement and Experiences of Interventions

A total of 3 qualitative studies were included in this review. Of the 3 studies, 2 (67%) included participants of experimental intervention studies [38,39], and 1 (33%) reported women's narratives from a web-based forum [51]. The study by Gui et al [51] was included in the review as the web-based forum was considered by the review team to fit with the eligibility criteria of an intervention, and the study provided useful and relevant data on women's concerns, anxiety, stress, and fear during pregnancy.

Baylis et al [39] interviewed women (n=19) who had participated in the I-CBT intervention to support women with a fear of childbirth [49]. The women were interviewed in the postnatal period. The study aimed to describe women's experiences of guided I-CBT for fear of childbirth and describe the content of that fear. The authors reported that women's fears were focused on losing control in labor, fear for their life, or

the health of the baby. I-CBT was reported to offer a supportive and flexible treatment, although most women would have preferred CBT to be delivered face-to-face. Remote delivery made it difficult for women to maintain their motivation. The I-CBT intervention was not tailored to women's specific situations or fears, and women could not always relate to the content within the sessions. However, women said it helped them to think in different ways about the imminent birth, understand their fear, work with their emotions, and cope with uncertainty. Learning the skills to *step outside* of themselves and observe what was going on helped women relieve their fears. The interactions with the psychologist through emails received positive comments and were described as supportive and encouraging. Individual contact made the treatment more personal, and the relationship with the psychologist was reported by some women as the most important part of the therapy. For some women, contact by email was preferable to meeting a stranger in an unfamiliar hospital setting and made it easier to disclose their fears. Other women would have preferred meeting the psychologist in person; this was thought to have resulted in women feeling more supported and motivated to complete the program and helped them create a warm and trusting relationship. Some women actively sought out alternative ways of addressing their fear of childbirth, including face-to-face midwife-led counseling, particularly when they needed to process previous traumatic birth experiences. Some women contacted a psychologist, attended antenatal classes, or attended antenatal yoga sessions.

Nieminen et al [38] conducted a thematic analysis of narratives completed by nulliparous women participating in an I-CBT intervention for fear of childbirth [16]. This study aimed to describe women's expectations of childbirth before and after I-CBT. The authors reported six main themes: fear, self-confidence, coping, the partner, the staff, and the baby. Themes were identified within three domains: my own role, the role of others, and attitude toward the baby. Women reported that, following I-CBT, their complete focus on fear, as well as anxiety and hopelessness, was replaced by an expectation that reflected increased confidence. Women described positive and more realistic expectations regarding themselves, their partners, and the staff that would look after them in labor. Before I-CBT, women provided very few comments about the health of the baby in labor and were more focused on their anxiety and on surviving painful labor and delivery, which some women described as a *nightmare*. Following I-CBT, women still reported uncertainty about the outcome of labor and birth; however, their attitude toward their fear had changed to become more manageable and less isolating. They developed self-confidence and strategies to cope with pain and seek support from partners and care providers.

The study by Gui et al [51] analyzed narratives from women who were pregnant and posting within a web-based community across the 3 trimesters of pregnancy. The study reported women's motivations for seeking web-based support, which surrounded (1) having limited access to care providers (delay in accessing advice); (2) wanting to access alternative sources of advice and information; (3) having little social support; (4) experiencing conflict between pregnancy information and their own experiences; and (5) seeking general advice, reassurance, and emotional support. The authors reported that across all 3 trimesters, women who were pregnant closely monitored their symptoms, fetal movements, body shape, and test results. Women reported emotional stress about maintaining their pregnancy, adjusting their lifestyle, managing medication for mental health conditions, and managing family relationships. Participation in web-based peer support provided a strategy for women to manage their stress and anxiety. Emotional stress remained a concern for women in the third trimester, which is mainly related to fear and anxiety about the upcoming birth, personal relationships with family members with regard to preparing for the birth, and extreme physical discomfort because of their progressing pregnancy. The authors stated that women's motivations for seeking web-based support were greater for women with particular symptoms who needed to access information immediately. The number of posts that contained statements about emotional stress was slightly larger than the number of posts that directly asked for emotional support, which the authors concluded was because of differences in the way women cope with stress (ie, some women actively seek social support, whereas others prefer to vent their feelings).

Synthesis of Quantitative and Qualitative Evidence

The evidence from the quantitative studies (14/16, 88%) and the qualitative studies (3/16, 18%) were synthesized to draw overall conclusions and provide insight to guide the design of future studies. The synthesis findings are presented in Textbox 2 and relate to the research questions.

Textbox 2. Synthesis of the qualitative and quantitative evidence.

Quantitative, qualitative, and synthesized evidence

How effective are remotely delivered interventions in reducing symptoms of anxiety?

- Quantitative evidence: There was limited evidence of effectiveness for cognitive behavioral therapy and facilitated interventions for women with symptoms of depression, anxiety, and fear of birth. Interventions may be more effective when interventions are targeted at women with psychological symptoms; interventions include facilitation and contact with therapists, health care professionals, or peer communities; completion rates are sustained above 50% across all sessions; and interventions include cognitive skills and relaxation or meditation.
- Qualitative evidence: There was limited evidence from 2 studies to suggest that internet-based cognitive behavioral therapy interventions can be beneficial in helping women develop coping strategies for dealing with uncertainties and accessing support from partners and health care professionals. Limitations of remotely delivered interventions include a lack of tailoring to specific fears and anxieties; a lack of motivation and encouragement to complete modules; an inability to form secure, trusting professional relationships; content is perceived as onerous.
- Synthesized findings: Overall, there is limited evidence to suggest that interventions are more effective when women are motivated to maintain regular participation in interventions. Strategies to maintain participation include the following:
  - Personalization: achieved by providing regular contact with therapists and health care professionals to discuss individual circumstances, symptoms, or concerns; consider animated therapists as a proxy for human therapist interactions
  - Relatable: designing and targeting interventions to women with particular symptoms; providing peer forums; presenting content as stories and vignettes
  - Skills and techniques: include components of relaxation and cognitive-based skills
  - Achievable: sufficient sessions to develop new skills without being too time consuming

What are women's views on remotely delivered interventions in reducing the symptoms of anxiety?

- Quantitative evidence: There is limited evidence to suggest that attrition rates were higher in studies that did not include therapist and health care professional or peer support components and were not targeted at women with symptoms of anxiety, depression, or fear of birth. Participants in 2 internet-based cognitive behavioral therapy interventions reported they were satisfied with the intervention and considered it helpful to manage their symptoms.
- Qualitative evidence: There was limited evidence from 2 studies to suggest that internet-based cognitive behavioral therapy interventions for fear of birth were valued by women if they offered flexibility and strategies for coping with their anxiety and fear and provided access to individual support from therapists. Women with fear of birth would have preferred individualized advice that was not readily available via remotely delivered therapy. Although some women felt more confident in disclosing their fears via remote messaging, many women would have preferred and actively sought alternative face-to-face treatment.
- Synthesized findings: Overall, there is very limited evidence to suggest that some women may prefer face-to-face therapy to help them stay motivated and receive individualized, tailored advice to manage their fears surrounding pregnancy and childbirth. However, for other women, remotely delivered interventions that provide some contact with a therapist, health care professional, or peer community may provide adequate human interaction to be of benefit. Remote interventions may also provide women with greater anonymity to help them feel more confident in disclosing their symptoms. There is limited evidence from the qualitative and quantitative evidence to suggest that women value interventions that resonate with their experiences. Women may be more motivated to complete interventions that are perceived as relevant to their needs and situations.

Discussion

Principal Findings

This paper presents a systematic review of remotely delivered interventions to improve symptoms of anxiety in women who are pregnant and presents a meta-analysis of the preliminary efficacy of these interventions on self-reported anxiety scores. Within the 16 included studies, numerous intervention designs were evaluated. Of the 16 studies, 10 (63%) evaluated I-CBT interventions targeting women with fear of birth, anxiety and depression, preterm birth, and insomnia; 2 (13%) reported mindfulness interventions for women who are pregnant and having symptoms of anxiety and depression; and the remaining 4 (25%) included psychoeducation for women with fear of birth, problem solving for women with anxiety and depression, psychological well-being, and a web-based forum for a general population of women who are pregnant. Remotely delivered interventions included in the meta-analysis achieved some beneficial effect in relation to the reduction of anxiety scores, although these findings need to be interpreted with caution as sample sizes were relatively small, and studies were assessed to have an unclear risk of bias.

The need to increase the reach and improve timely access to therapeutic and supportive treatment for women with psychological symptoms was reported as the main rationale for conducting the studies. In the United Kingdom, suicide is the second largest cause of maternal deaths, and women with a mental health diagnosis are overrepresented among women who die during pregnancy or the postnatal period [62]. Within the UK maternity services, low-level psychological therapies are recommended as the first-line treatment option for women with mild to moderate mental health conditions [63]. Improving Access to Psychological Therapy programs are available for many women who are pregnant in the United Kingdom, with recommended treatment interventions starting within 6 weeks of referral [64]. Women have reported positive experiences of Improving Access to Psychological Therapy support, although

barriers to accessing services have been identified, including reluctance to disclose difficulties because of stigma and fear of custody loss, as well as lack of clear information and support, with referrals from HCPs such as general practitioners, midwives, and health visitors [65]. This review has identified that for some women, remotely delivered interventions provide a sense of anonymity, which enables them to feel more confident in disclosing their symptoms. However, qualitative studies assessing women's feedback on remotely delivered interventions reported a lack of face-to-face contact with therapists and a lack of tailoring information and interventions to women's specific circumstances as barriers to the effectiveness of interventions. The quantitative data suggested that interventions were more effective in improving anxiety symptoms when interventions included individual contact from a therapist, HCP, or peer web-based forums.

Social learning and social comparison theory can be facilitated by providing social forums to foster a sense of connectivity and cooperation. Many women participate in web-based forums during pregnancy to discuss their worries and concerns and regularly access web-based information to monitor their well-being and assist in decision-making [51,66]. The inclusion of social support mechanisms as a component of remotely delivered interventions has been recommended for individuals with serious mental health concerns [67].

Therapeutic alliance has been reported as fundamental to the success of face-to-face psychological therapies and requires a strong bond between the care provider and client to foster shared understanding and collaboration on tasks and goals [67]. A systematic review of technology-based mental health interventions identified that users could experience therapeutic alliances with digital interventions if they are personalized and interactive, providing automated feedback that emulates reciprocal trusted relationships [68]. Numerous systematic reviews have identified that remotely delivered anxiety interventions are more effective when therapists provide support and guidance [69-71]. The impact of facilitator or therapist training has mainly been evaluated in digital interventions for symptoms of depression. Remotely delivered guided interventions were reported to be beneficial in improving symptoms of depression and found no association between the qualifications or level of facilitator training and outcomes [72-74]. In pregnancy, increasing midwives' and maternity care providers' awareness of remotely delivered interventions could assist signposting women to effective interventions. Remotely delivered interventions can be enhanced by midwives offering support and encouragement to improve intervention uptake and completion and providing pregnancy-specific information and advice tailored to women's particular circumstances. Midwives may need brief, additional training to support this role; however, in addition to supporting women's experience of the intervention, midwives' involvement would reflect contemporary policy drivers related to the continuity of carer (Better Births). A central tenet of the Midwifery Continuity of Carer models is the development of a collaborative relationship and provision of personalized care. Compared with conventional care, the provision of continuity of carers enables midwives to get to know women better, increase mutual trust, and facilitate access to specialist services.

Of the 16 included studies [44,53], 2 (13%) evaluated unguided I-CBT interventions for women with anxiety and depression and women with insomnia. Both studies reported an improvement in postintervention between-group anxiety symptoms for the IGs. Both studies included fictional characters in the form of a digital therapist [44] and fictional characters to narrate anxiety and depression experiences and help teach CBT skills. Rehm et al [75] reported that avatars were used as autonomous digital therapists to facilitate clinical interviews and assessments, provide psychoeducation, or signpost to other services. Digital therapists, not controlled by human clinicians, can be represented as a realistic-looking human avatar or as a 2D animated character. Participants have reported that they were willing and felt comfortable sharing information with therapist avatars [75], although there is very limited evidence, and further research is required in the perinatal context.

None of the included studies were solely targeted at improving symptoms of anxiety, which may reflect a greater focus on broader concepts of psychological well-being and respond to the reported comorbidity and associations between common mental health and psychosocial and physical health concerns in the perinatal period [76-78]. Although a multidimensional approach has been reported as an important factor in promoting psychological well-being in pregnancy [79], interventions targeting 1 condition may not be effective for the other comorbid conditions [80]; the underpinning theory of change needs to be defined for each condition before further testing the mechanisms of change.

The 31% (5/16) of studies that maintained completion rates ≥50% across the entire intervention reported significant improvement in anxiety scores between the IG and CG groups compared with studies where completion rates fell <50% (weeks 2-5). Of the 4 studies where completion fell <50%, 3 (75%) were developed for the general population of women who are pregnant and 1 (25%) for women with severe symptoms of fear of birth. Studies that maintained relatively high completion rates were targeted at women with symptoms of anxiety, depression, insomnia, or fear of birth and used established, validated screening tools with recommended cutoff scores to identify women with mild, moderate, and severe symptoms. A systematic review of antenatal interventions to reduce maternal distress also reported that interventions delivered to women with symptoms of distress were more effective than preventative interventions for women with little or no symptoms at baseline [81]. However, because of the heterogeneity of target populations included in the review, there is currently insufficient evidence to draw conclusions about the effectiveness of targeted interventions compared with universal interventions for women with symptoms of anxiety during pregnancy.

Overall, the content of interventions was well-documented, with most of the studies reporting the material content provided in each module. Of the 13 interventions, 10 (77%) included cognitive skills, and 69% (11/16) of studies included mindfulness or relaxation techniques. The amount of time taken to complete modules was not well-documented, and some

authors reported the average time women accessed websites and portals, whereas other authors reported the amount and types of information provided. Women reported that intervention content and homework exercises felt too onerous at times, and they found it difficult to remain motivated. In future studies, assessing and reporting the amount of time spent completing intervention modules would help inform optimal intervention content. Overall, the information about the ways in which interventions were developed and tailored to the population was limited, and many authors simply stated that interventions were amended from traditional CBT interventions to meet the needs of a pregnant population or to fit within the timescale of pregnancy. Conducting a needs assessment in the target population is an essential stage in intervention development to improve potential effectiveness [82]. O'Mahen et al [83] explored women's needs to inform the modification of CBT for perinatal depression. The authors reported that an increased focus on interpersonal strategies is required to help women seek out normalizing information that counters rigid beliefs about motherhood from other mothers. Considerations of women's ethnicity and socioeconomic status are also required to address particular worries and concerns and improve the relevance of the intervention content. Similar studies are required to inform the tailoring of interventions for women with symptoms of anxiety during pregnancy. Only 19% (3/16) of the included studies provided demographic data relating to the ethnicity of participants, and from these studies, most of the participants were White. The recent MBRRACE-UK: Saving Lives, Improving Mothers' Care report has highlighted inequalities in maternity care, with Black and Black British and Asian and Asian British babies up to twice as likely to be stillborn or die neonatally, suggesting that safety initiatives are failing to reach many women from higher risk ethnicities [84]. A low rate of participation among ethnic minority groups reduces the generalizability of mental health research findings, affects the development of effective interventions, and further widens health inequalities. Urgent attention is required to address inequalities in mental health provision for Black, Asian, and minority ethnic women, and researchers need to develop relevant, tailored interventions and recruitment strategies that reflect the diversity of the population.

Limitations

This review adopted a broad approach, including different types of interventions for different populations of women who are pregnant. This limited the utility of the study findings as different measurement instruments were used by the authors, and there was insufficient data to calculate outcome scores across all included studies. As a meta-analysis of postintervention anxiety scores was only achievable for a small subgroup of studies, the aim of the study to assess the effectiveness of interventions was only partially achieved. However, low-powered analysis based on a small number of studies can provide useful insights by exploring interesting relationships that may emerge and highlighting deficiencies in a topic that requires further attention [85]. The overall quality of the included studies was rated as moderate; the small sample sizes and heterogeneity of interventions and study populations resulted in overall low quality of evidence for the quantitative studies. There were insufficient qualitative studies to conduct a narrative synthesis, which further limited the qualitative findings and the synthesis of qualitative and quantitative evidence. We did not locate any studies that focused solely on anxiety symptoms in pregnancy, and most quantitative studies were not powered to detect significant changes in anxiety scores. Studies not published in English were excluded from this review.

Conclusions

The introduction of remotely delivered interventions has the potential to improve symptoms of anxiety in women who are pregnant. The results of the review are limited and need to be interpreted with caution, as the findings of the review were predominantly based on small sample sizes with heterogeneity between intervention designs, delivery, and sample populations. The synthesized findings highlighted components of interventions that may improve the effectiveness and acceptability of remotely delivered interventions. Most women valued individual web-based contact from a therapist or HCP to maintain motivation and access individualized information. There was some evidence of effectiveness for interventions that provided some form of facilitation and access to peer support. Overall, there was limited evidence to suggest that interventions are more effective when women are motivated to maintain regular participation. Interventions targeting women with psychological symptoms were more likely to maintain participation across the intervention time frame and report improvements in anxiety scores. Although there was some limited evidence of the benefits of remotely delivered interventions described as CBT or mindfulness, most studies included a multicomponent approach and provided cognitive and mind–body content. Most women reported satisfaction with the interventions and provided positive feedback. Some women may prefer and actively seek face-to-face therapeutic interventions. However, for some women, remotely delivered interventions provide women with greater anonymity to help them feel more confident in disclosing their symptoms. Interventions provided a timely and flexible approach and provided women with strategies for coping with their symptoms. Future research is required to identify ways that interventions can be tailored to meet the particular needs of diverse populations of women who are pregnant to improve their relevance and ensure equitable access. Researchers need to consider the structures of maternity care in which interventions are implemented to assist in signposting women and need to maximize the potential for maternity care professionals to provide encouragement, support, and motivation, enhancing the digital therapeutic approach.

Abstract

Background: With the world's population aging, more health-conscious older adults are seeking health information to make better-informed health decisions. The rapid growth of the internet has empowered older adults to access web-based health information sources. However, research explicitly exploring older adults' online health information seeking (OHIS) behavior is still underway.

Objective: This systematic scoping review aims to understand older adults' OHIS and answer four research questions: (1) What types of health information do older adults seek and where do they seek health information on the internet? (2) What are the factors that influence older adults' OHIS? (3) What are the barriers to older adults' OHIS? (4) How can we intervene and support older adults' OHIS?

Methods: A comprehensive literature search was performed in November 2020, involving the following academic databases: Web of Science; Cochrane Library database; PubMed; MEDLINE; CINAHL Plus; APA PsycINFO; Library and Information Science Source; Library, Information Science and Technology Abstracts; Psychology and Behavioral Sciences Collection; Communication & Mass Media Complete; ABI/INFORM; and ACM Digital Library. The initial search identified 8047 publications through database search strategies. After the removal of duplicates, a data set consisting of 5949 publications was obtained for screening. Among these, 75 articles met the inclusion criteria. Qualitative content analysis was performed to identify themes related to the research questions.

Results: The results suggest that older adults seek 10 types of health information from 6 types of internet-based information sources and that 2 main categories of influencing factors, individual-related and source-related, impact older adults' OHIS. Moreover, the results reveal that in their OHIS, older adults confront 3 types of barriers, namely individual, social, and those related to information and communication technologies. Some intervention programs based on educational training workshops have been created to intervene and support older adults' OHIS.

Conclusions: Although OHIS has become increasingly common among older adults, the review reveals that older adults' OHIS behavior is not adequately investigated. The findings suggest that more studies are needed to understand older adults' OHIS behaviors and better support their medical and health decisions in OHIS. Based on the results, the review proposes multiple objectives for future studies, including (1) more investigations on the OHIS behavior of older adults above 85 years; (2) conducting more longitudinal, action research, and mixed methods studies; (3) elaboration of the mobile context and cross-platform scenario of older adults' OHIS; (4) facilitating older adults' OHIS by explicating technology affordance; and (5) promoting and measuring the performance of OHIS interventions for older adults.

KEYWORDS

older adults; online health information seeking; health information behavior; aging technology; systematic scoping review

Introduction

During the past decade, the rapid development of information and communication technologies (ICTs) has increased laypeople's access to health information sources and is constantly reshaping their health information–seeking behaviors [1]. Online health information seeking (OHIS) serves multiple purposes, such as understanding disease symptoms, assessing disease risks, finding treatment choices, managing chronic conditions, and preparing for patient-doctor communication [2]. Studies have revealed that OHIS has become one of the most common everyday life experiences across the entire lifespan [3].

In recent decades, the aging of the world population has led to significant demographic transitions that have never occurred before in human history. Societies with large aging populations face great challenges to their health care sectors with respect to an increasing prevalence of chronic conditions among older adults and a sharply rising demand for health care resources. As older adults are more likely to experience illness and chronic conditions than younger people, they have a greater need for health information [4]. With the world population aging, increasing numbers of health-conscious older adults are seeking health information to make better-informed health decisions [5]. Many hopes are placed on ICTs to empower the aging population, promote public health, and alleviate the burden of health care systems. However, there is some skepticism regarding whether older adults really benefit from current technological advancements [6]. Although some studies have found that the adoption and use of ICTs to address health concerns have remained at a relatively low rate among older adults [7], other studies suggest that older adults are increasingly engaged in internet surfing [8]. These mixed results suggest that the OHIS behavior of older adults is still insufficiently investigated.

Despite scattered empirical studies on the topic, few scoping or systematic reviews have directly addressed the OHIS behaviors of older adults and synthesized this body of knowledge. Chang and Huang [9] recently reviewed antecedents that predict general consumers' OHIS behaviors (ie, health status, self-efficacy, health literacy, availability, credibility, emotional responses, and subject norms). Although the review found that age is a significant moderator of the correlations between the antecedents and OHIS, it provided few details on older adults' health information behaviors. Hunsaker and Hargittai [8] synthesized quantitative literature on general internet use among older adults. Although their review addressed the relationship between older adults' health and internet use, OHIS was neither specified nor teased out from the general internet use behaviors. Therefore, the type of health information sought by the participating older adults and the factors that influenced older adults' OHIS reported in the literature are unclear. Waterworth and Honey [10] reviewed 8 empirical studies of OHIS among older adults and discussed facilitators of and barriers to older adults' OHIS. However, the number of studies included in this review was limited, and it can hardly provide a comprehensive understanding of OHIS among older adults.

Gaps in the existing research indicate that a systematic scoping review on older adults' OHIS is necessary because it will not only enhance our knowledge of human information behaviors and practices but will also inform better health information system designs and ensure better information services for older adults. Motivated by the existing research gaps, this systematic scoping review examines the state of research on older adults' OHIS and reveals the types and sources of health information that the older adults seek, factors that influence older adults' OHIS, barriers to older adults' OHIS, and interventions that are available. The purpose of this systematic scoping review is to provide our readers with an overview of how OHIS among older adults has been studied and present implications for future research. It aims to answer the following questions:

1. What types of health information do older adults seek and where do they seek health information on the internet?

2. What are the factors that influence older adults' OHIS?

3. What are the barriers to older adults' OHIS?

4. How can we intervene and support older adults' OHIS?

Methods

Literature Search

This review follows the guidelines of the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) [11]. We were also inspired by the recommended framework for conducting systematic reviews in information-related fields by Okoli [12]. The bibliographic database search strategies were developed after consulting an academic librarian at the first author's university.

First, we searched the following databases: Web of Science; Cochrane Library database; PubMed; MEDLINE; CINAHL Plus; APA PsycINFO; Library and Information Science Source; Library, Information Science and Technology Abstracts; Psychology and Behavioral Sciences Collection; Communication & Mass Media Complete; ABI/INFORM; and ACM Digital Library. These databases were chosen because they cover the academic disciplines (eg, medicine, medical informatics, communication, psychology, and information and library science) that are most likely to study older adults' OHIS behaviors. Second, the search queries contained the following categories and keywords: people (older adults, elderly, aging, senior, seniors, older people, aged 60, aged 65), behavior (find, search, seek, access, retrieve), place (internet, online, web), object (information), and attribute (health, medicine, drug, nutrition, diet, wellness, illness). Specific queries were run in the topic, title, and abstract fields, depending on the database (see Multimedia Appendix 1). The initial search was performed in November 2020. Third, we captured additional articles using Google Scholar by tracking the citations and references in the articles found in the databases and in other relevant reviews. In addition, we supplemented relevant articles by searching Google Scholar directly. All the studies identified during the database searches were imported into the reference management software Zotero, and duplicates were removed.

Eligibility Criteria

We developed a series of inclusion and exclusion criteria to identify articles relating to older adults' OHIS behaviors. The inclusion criteria were as follows: (1) The articles should pertain to health-related contexts, including areas such as health, mental health, diet, and nutrition. (2) The article should describe OHIS behaviors (eg, general OHIS, selection and use of health information sources, and adoption and use of health information). (3) The article should focus on older adults (Note that although the search strategies indicated 2 commonly accepted lower age boundaries, 60 and 65 years, to identify older adults, it did not exclude other ways to describe the population); studies that clearly mentioned the population of older adults or contained explicit, equivalent claims were eligible. (4) The research should be empirically based. (5) The articles should have been published in a peer-reviewed journal or in conference proceedings. (6) When we identified more than 1 paper published by the same author on the same topic, we selected only the most recent one. (7) The articles should be written in English.

Our exclusion criteria were as follows: (1) The articles did not pertain to a health-related context. (2) The articles were not about OHIS behaviors; for instance, some articles focused only on general ICT use or adoption behaviors, were more concerned with technology-related rather than information-related issues or addressed only older adults' health literacy or eHealth literacy and did not investigate their OHIS. (3) The articles did not focus on older adults; we specifically excluded articles that treated age merely as a predictor or moderator in studying the OHIS of the general population, as it is evident that age influences people's OHIS behaviors. (4) The articles were not based on empirical research; this criterion helped eliminate opinion pieces, brief communications, editorial commentaries, and reviews. (5) The articles were not peer-reviewed (eg, a self-archived manuscript). (6) The articles were not written as full papers (eg, abstracts, posters, or letters). (7) The articles were not written in English.

Screening Procedure

The procedure for screening articles was based on the eligibility criteria. The initial search used database search strategies and identified 8047 publications. After duplicates were removed, the data set consisted of 5949 publications for screening.

The screening involved 3 stages. In the first stage, all the 3 authors reviewed the titles and abstracts of a sample of 300 articles from the search results, and then discussed and refined the screening criteria. In the second stage, we selected another 300 articles randomly from the search results as a test set. The feasibility criteria were verified independently by 2 of the authors (SS and MZ). Intercoder agreement (κ=0.816) indicated satisfactory reliability. Discrepancies were discussed and resolved by involving the third author (YZ), and the eligibility criteria were further refined accordingly. In the third stage, author MZ screened the remaining articles based on the eligibility criteria using the titles and abstracts, and author SS validated the results. Discrepancies were resolved by involving author YZ. The whole screening procedure resulted in 279 articles for full-text analysis.

To read and code the full-length articles downloaded from the databases, we used the MAXQDA 2020 software, which is designed for analyzing computer-assisted qualitative and mixed methods data, texts, and multimedia data. During the full-text analysis, we excluded 211 articles by applying the eligibility criteria. The remaining 68 articles were retained, and 8 more eligible articles were identified through citation tracking with the assistance of Google Scholar. In total, 75 articles were selected for the systematic scoping review.

Data Extraction and Analysis

We used Excel (Microsoft Corporation) to extract and record the basic information of the articles in the sample, including the author(s), title, publication year, publication name, and publication type (eg, journal vs conference). We used thematic content analysis in an iterative manner to identify the evidence regarding our research questions [13]. Several lists of codes were generated during 2 rounds of full-text coding procedures. In the first round, all the authors participated in the open and selective coding processes until a coding schema emerged and converged. In the second round, MZ coded the full texts by applying the coding schema, and SS validated all the codes. The intercoder reliability of the thematic content analysis reached 85%. Discrepancies were solved by involving YZ in the discussion.

Results

Basic Characteristics of the Included Articles

After screening, the final sample consisting of 75 articles was obtained, as shown in Figure 1. The articles were published between 1997 and 2020 (see Multimedia Appendix 2). Trend observations revealed that the number of publications in this subject area increased over time and that the OHIS of older adults began to receive considerable attention in the last 3 years (see Figure 2). The articles in the sample were mostly published after 2006 (n=69, 92%), which relates closely to the boom in social media. Of all the articles, 72 (96%) were published in journals, and the remaining 3 (4%) were published in conference proceedings. The articles originated from 17 countries (based on the first author's affiliations), with the top 3 being the United States (n=44, 58.67%), Australia (n=5, 6.67%), and China (n=4, 5.33%). The top 4 journals publishing these articles include the Journal of Medical Internet Research (n=8, 10.67%), Educational Gerontology (n=4, 5.33%), Journal of Health Communication (n=3, 4%), and Library & Information Science Research (n=3, 4%), indicating the multidisciplinary nature of the sample.

Figure 1. Screening procedure. ACM: Association for Computing Machinery; APA: American Psychological Association; CINAHL: Cumulative Index to Nursing and Allied Health Literature; ICT: information and communication technology.

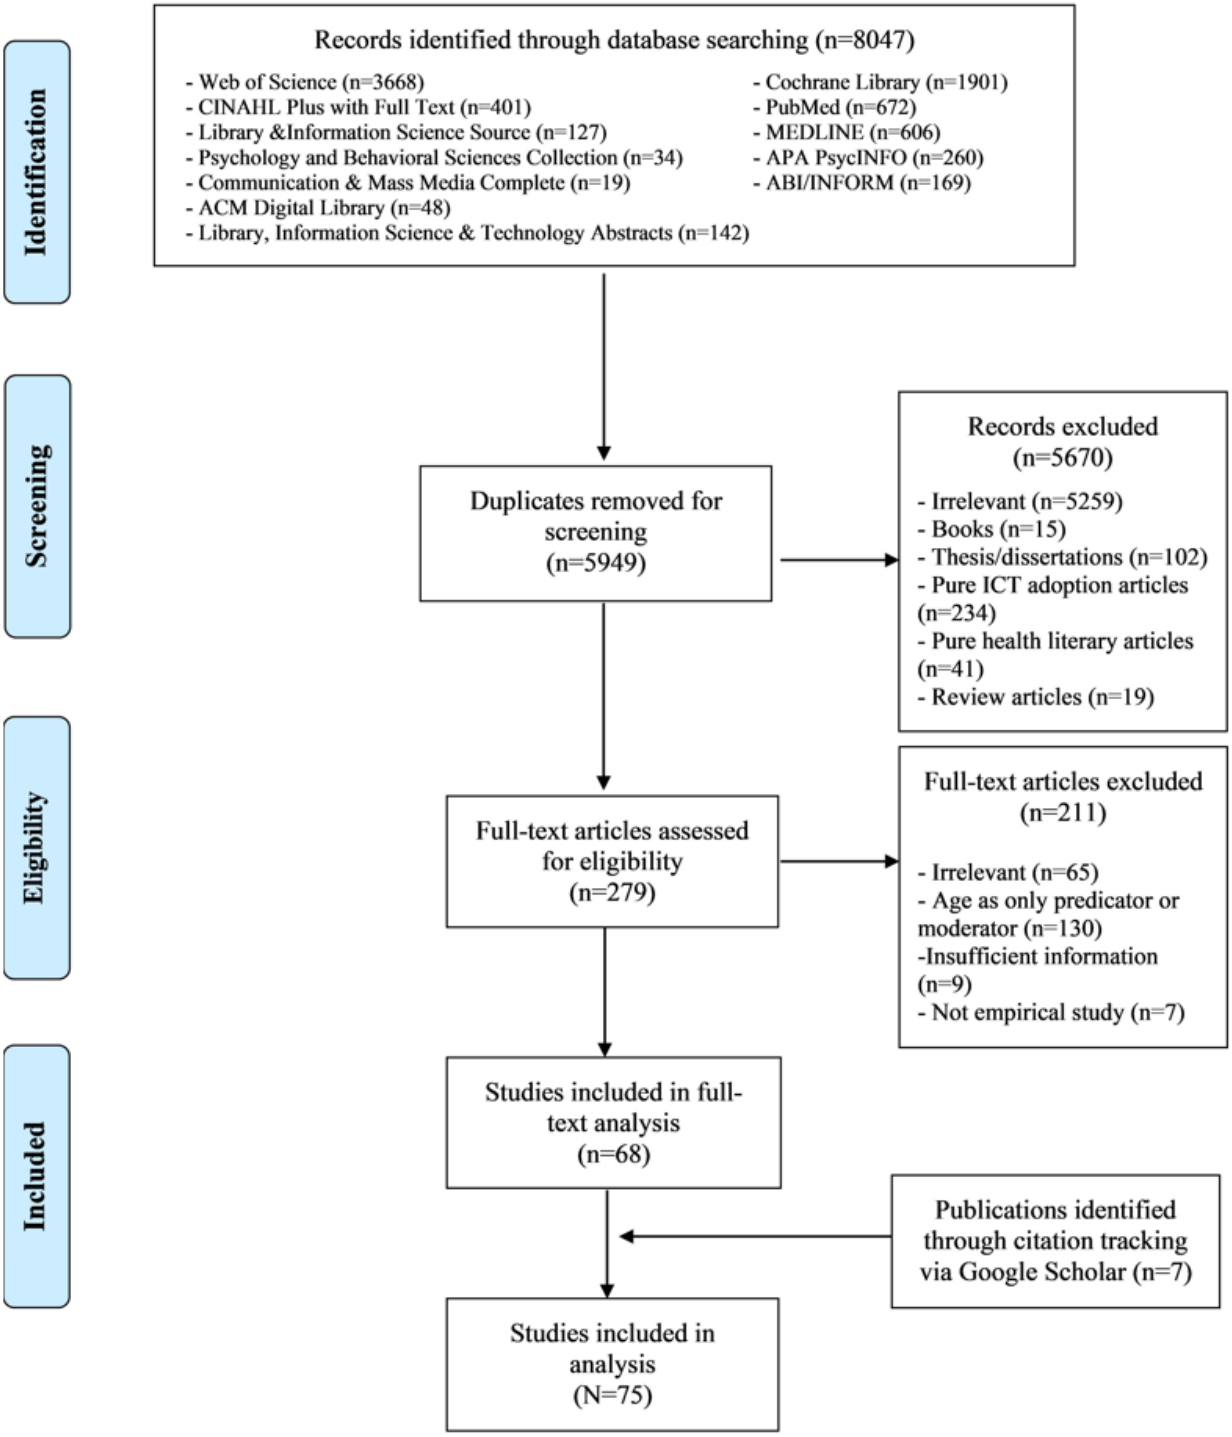

Figure 2. Distribution of publication years.

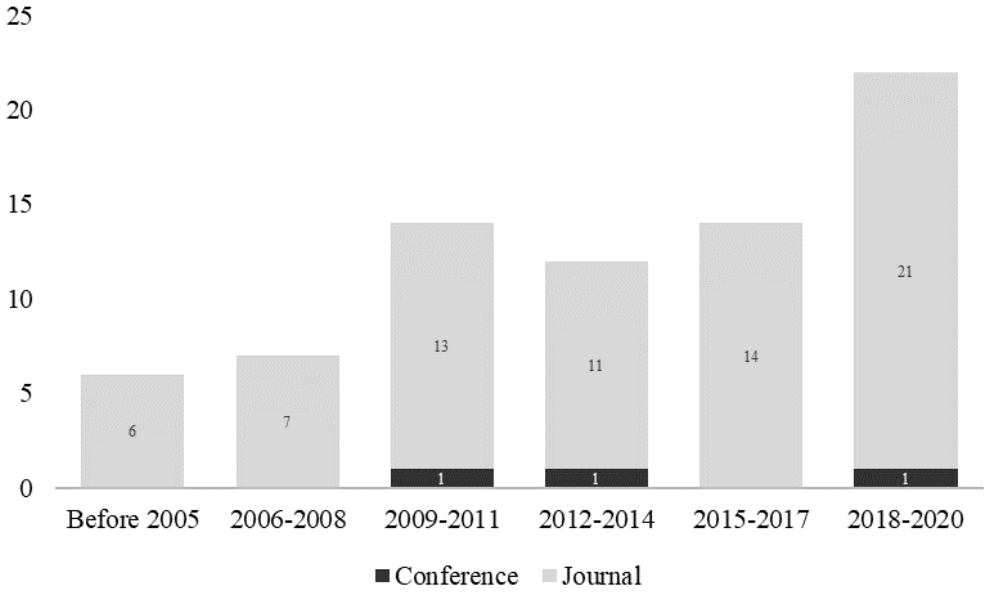

The systematic scoping review first investigated how the included 75 articles defined the target population of older adults. The cutoff ages for defining older adults were determined. More than half of the articles used samples of older adults aged above 60 years. Furthermore, 16 articles (21.33%) defined older adults as those aged 65 years and above, and 23 (30.67%) had cutoff ages ranging from 60 to 64 years. In addition, we noted some papers that defined the older adult group more loosely. For example, the cutoff age in 17 articles (22.67%) ranged from 50 to 54 years, and 14 articles (18.67%) used samples with minimum ages ranging from 55 to 59 years. Moreover, 5 of the articles (6.67%) did not specify precise age distributions.

The research methods varied across the 75 studies. Regarding methodological approaches, we found that 45 studies (60%) used quantitative approaches, 22 (29.33%) employed qualitative approaches, and 8 (10.67%) were based on mixed methods designs, using a combination of quantitative and qualitative methods. As for specific methods, surveys (n=28, 37.33%) and interviews or focus groups (n=25, 33.33%) were the primary methods used, followed by secondary data analysis (n=6, 8%) and experiments (n=4, 5.33%). In terms of data sources, most of the studies were based on primary data (n=65, 86.67%) and a few on secondary data (n=10, 13.33 %). Concerning the types of data, we found 59 studies (78.67%) based on cross-sectional data and 16 (21.33%) based on longitudinal data.

Internet-Based Health Information Types and Sources

Information types and information sources are 2 frequently reported aspects of information in OHIS studies [14]. For our analysis, we adapted the typologies of health information types from Kent et al [15] and Ramsey et al [16]. The results presented in Table 1 suggest that older adults often search the internet for information on specific diseases because they want to obtain a general idea of their condition before diagnosis or treatment so that they know what to expect and can be better prepared to face stressful situations [17]. The health problems mentioned in these 75 articles are mainly cancer (n=10, 13.33%), mental health problems (n=5, 6.67%), chronic conditions (n=4, 5.33%), and physical diseases (n=4, 5.33%). Aside from this disease information, the most frequently mentioned types of information are related to medication or treatment, nutrition or exercise, medical research, disease symptoms, and health promotion. Some articles mentioned that older adults also use the internet to seek support groups or interpersonal advice, health insurance information, health news, and health policy information. Of note is that more than half of the articles (n=40, 53.33%) used the umbrella term health information, without specifying any type of health information content. Furthermore, the types of content were not mutually exclusive. For example, a single article might mention more than 1 type of information (eg, older adults seeking information for cancer-related symptoms and medication).

Table 1. Types of health information mentioned in the articles (N=75).

Type of health information	Number of articles (n)
General health information	40
Specific diseases	23
Medication/treatment	21
Nutrition/exercise	13
Medical resource	12
Disease symptoms	9
Health promotion	8
Support groups/interpersonal advice	4
Health insurance	4
Health news/policies	3

Most of the articles in the sample (n=58, 77.33%) used the general internet to represent all the web-based sources of health information. Further, 26 articles (34.67%) described health websites as sources of internet-based health information for older adults; among these, the owners of the websites varied, consisting of educational, commercial, government, and nonprofit entities. Moreover, general search engines such as Google were the third most frequently mentioned sources in the studies (n=17, 22.67%), suggesting that older adults often use general search engines to start OHIS [18-20]. Further, 11 articles (14.67%) mentioned older adults' use of social media (eg, Facebook, Twitter) and blogs in OHIS. Only 3 articles (4%) addressed older adults' use of patient portals, and 2 articles (2.67%) were about older adults' use of mobile internet services. Table 2 shows the health information sources mentioned in the studies.

Table 2. Internet-based health information sources mentioned in the studies (N=75).

Source of internet-based health information	Number of articles (n)
General internet	58
Health websites (eg, WebMD, Mayo Clinic)	26
General search engines (eg, Google, Yahoo)	17
Social media/blogs (eg, Facebook, Twitter)	11
Patient portals	3
General mobile	2

Factors That Influence Older Adults' OHIS Behaviors

Among the 75 articles, 35 (46.67%) treated OHIS as a variable or construct. These articles quantitatively measured OHIS with various scales or proxy variables. Among them, 27 (36%) regarded OHIS as a dependent variable and explored the antecedents of older adults' OHIS. Further, 4 (5.33%) treated OHIS as an independent variable, and the remaining 4 (5.33%) treated OHIS as neither a dependent nor an independent variable but provided only descriptive analyses. Because the articles that employed quantitative approaches primarily concerned the antecedents of older adults' OHIS, we summarize the antecedents in Table 3.

We summarize the main influencing factors that appeared in the investigations. The antecedents of older adults' OHIS fall mainly into 2 categories, namely individual-related characteristics and source-related characteristics. Within the individual-related characteristics, 12 subcategories were observed, including demographics, anxiety, beliefs, attitudes, self-efficacy, personality, health status, medical history, health care service availability, source experience, health literacy and motivations. Among the source-related characteristics, credibility, usefulness, and ease of use were the 3 most frequently mentioned factors.

Table 3. Factors influencing older adults' online health information seeking behaviors.

[a]ICT: information and communication technology.

Barriers to OHIS of Older Adults

Rather than treating OHIS as a variable, 40 of the 75 articles (53.33%) treated OHIS as a process. Of these studies, 29 (38.67%) explored the barriers that older adults encounter during OHIS. The results suggest that older adults may experience many barriers preventing successful OHIS, as shown in Table 4. In the prior studies, we identified 3 main types of barriers (ie, individual, social, and ICT), 11 subtypes, and 38 specific issues.

Table 4. Barriers to older adults' online health information seeking behavior.

Barrier types	Studies
Individual barriers	
Functional decline	
Vision impairment	[20,34]
Physical challenges (eg, back pain, knee injury)	[47,48]
Illness conditions	[32,35,36]
Low literacy	
English language literacy	[49,50]
Basic health knowledge	[51,52]
Digital literacy	[53,54]
Information literacy	[52,55,56]
Health literacy	[24,33,43]
eHealth literacy	[27,57]
Low self-efficacy	
Low efficacy and anxiety associated with computer use	[18,49,58,59]
Low efficacy in reading and learning	[49,60,61]
Low efficacy in OHIS[a]	[62,63]
Low efficacy in health information evaluation	[55,62]
Negative attitudes	
Attitude toward internet use	[39]
Attitude toward technology	[42]
Privacy concerns	[20,61,64]
Health beliefs	
External locus of control	[45]
Fatalistic beliefs	[31]
Social barriers	
Social stigmas	
Stigma of mental health problems	[65]
Stigma of sex-related health problems	[66]
Lack of social support	
Lack of informational support	[66,67]
Lack of organizational support (eg, health care services)	[17,50,68]
Lack of instrumental support (eg, instructions on computer use)	[57,65]
Lack of intergenerational support (eg, not living with children)	[49,69]
Lack of peer support (eg, hard to get support from friends)	[70,71]
ICT[b] barriers	
Lack of IT[c] infrastructure	
Lack of ICT devices	[29]
Low accessibility to medical records	[71]
Problematic information quality	
Misinformation	[64,72]
Conflicting health information	[73,74]

Barrier types	Studies
Irrelevant information	[65,73]
Information overload	
Overwhelming health information on the internet	[20,48,71]
Overwhelming extraneous information and pop-ups	[58,64,70]
Unsatisfactory user experiences	
Unsatisfactory interactivity and navigability	[75,76]
Unsuitable font sizes	[72,75]
Dense text and lack of visual elements	[76,77]
Confusing layouts	[51,72,75]
Insufficient ease of use	[39,45,78]
Frustrating user experiences	[51,56,59]

[a]OHIS: online health information seeking.

[b]ICT: information and communication technology.

[c]IT: information technology.

Regarding individual barriers, some studies found that older adults' OHIS could be hindered by age-related functional decline, including vision impairment, poor eye-hand coordination, physical challenges (eg, back pain), and illness. Moreover, some studies reported several aspects indicating low literacy among older adults that prevented effective OHIS, including limited English language skills, lack of basic health knowledge, limited digital literacy, undeveloped information literacy, and low health or eHealth literacy. Moreover, some studies found that older adults' perceptions of low self-efficacy regarding computer use, reading, learning, and evaluation of health information reduced their willingness toward OHIS. Other findings revealed that negative attitudes toward internet use or general technology and privacy concerns about using technology decreased older adults' intentions to search information on the internet. The results also revealed that beliefs regarding the external locus of the control of health care and fatalistic beliefs reduced older adults' active OHIS.

As for social barriers, studies suggested that older adults may have some social stigma concerning OHIS when it comes to mental and sex-related health problems. Moreover, older adults often report a lack of social support in their OHIS, including informational, organizational (eg, health care services), instrumental (eg, instructions on computer use), intergenerational (eg, support from children), and peer support (eg, support from friends).

In terms of ICT use, analysis of the studies revealed that many older adults do not possess information technology devices, and they reported low accessibility to medical records. Moreover, the quality of general health information on the internet is problematic. Older adults are likely to encounter misinformation, conflicting information, and irrelevant information during their OHIS. Furthermore, they often confront information overload when reading health information due to overwhelming amounts of irrelevant information or pop-ups. Moreover, older adults' OHIS may lead to some unpleasant and frustrating user experiences, such as unsatisfactory interactivity and navigability, unsuitable font sizes, dense text lacking visual elements, confusing layouts, and complicated site designs.

Interventions for Older Adults' OHIS

Given the abovementioned barriers, it is essential to provide older adults with additional support to facilitate their OHIS. We identified 11 studies (14.67%) among the 75 that used educational training programs to facilitate and intervene in older adults' OHIS, as shown in Table 5. Among these, 10 of the 11 studies provided offline workshops, and 1 conducted an online workshop. The offline workshops were conducted in community settings (eg, public libraries, schools, or medical centers) and included face-to-face instruction. We identified only 1 study that used an internet-based tutorial to improve older adults' ability to distinguish high-quality internet-based health forums from low-quality ones. Among the 11 articles, 9 described training programs with multiple sessions, each lasting 2 to 3 hours, and the duration of the programs varied from 1 to 4 months; the other 2 studies used 1-time training sessions.

Table 5. Interventions to support older adults' online health information seeking behaviors.

Study	Main objective	Intervention format	Intervention setting	Intervention evaluation measures
Malone et al [20]	To improve the health literacy skills of older adults	Educational program: Participants could attend every class offered at their library or could select the classes most appropriate to their personal needs and interests. No. of participants: 110	5 local libraries	Method: Pre- vs postsession surveys Qualitative analysis with descriptive statistics: Participants' confidence in their OHIS[a] increased, and the overall response to the program was positive.
Bertera et al [67]	To increase access to and use of 2 prominent health websites: MedlinePlus.gov and NIHSeniorHealth.gov	2-step training: (1) Training of internet navigators: 13 hours of basic training in computer skills over 13 weeks, plus a 4-hour specific training on 2 health websites and training on how to support peers during the process. No. of participants: 8 (2) Training of older adults living in affordable housing: 2-hour session on basic computer skills and use of 2 specific health websites. No. of participants: 42	A computer learning center located in the community	Method: Pre- vs posttest surveys, face-to-face interviews A significant improvement in the ability to use a computer or navigate the web was observed (P<.001). The average navigational skills self-efficacy score for health web sites (P<.001) and computers (P<.001) improved.
Chu et al [68]	To assist older adults with retrieving and evaluating health information resources on the internet	Educational program: 2-hour sessions once a week over 5 weeks. Partnering with Seniors for Better Health: Classes included 2 components, computer literacy and health information search strategies. No. of participants: 112	A computer lab offered at a facility of the YWCA[b] in Houston	Method: Pre- vs posttest surveys; survey conducted 6 weeks after training Participants experienced reduced computer anxiety and increased confidence and sense of self-efficacy when retrieving and evaluating internet-based health information (P<.001).
Campbell [79]	To improve the ability to locate health information	Workshops: 2-hour sessions once a week over 5 weeks The sessions used constructivist teaching techniques and self-directed learning. No. of participants: 70	A large suburban public library and 2 community centers for older adults	Method: Posttest interview Qualitative assessment by asking participants questions such as "Did your levels of participation in your health care change since you began using the internet?"
Campbell and Nolfi [80]	To teach older adults to access health care information on the internet	Workshops: 2-hour sessions once a week over 5 weeks No. of participants: 42 Follow-up survey 1 year after the workshops No. of participants: 27	A large suburban public library and 2 community centers for older adults	Method: Pre- vs. posttest surveys; survey 1 year after the training Statistically significant differences were found between baseline and 5-week follow-up results for MHLC[c] in males (P=.02) and females (P=.05), as well as for Krantz HOS[d] information seeking scores (P=.05).
Hoffman-Goetz et al [81]	To improve the internet search skills of adults aged 50 years and older	Workshops: 2-hour workshops once a month, over 4 months. The maximum number of participants per workshop was 15. Total No. of participants: 44	Public library with computer stations, led by a researcher, librarian, and university-based investigators	Method: Pre- vs posttest surveys Participants' search difficulty decreased after the workshops (P<.001). Participants' understanding of the internet improved after the workshops (P<.001).
Leung et al [82]	To improve basic skills for searching health information on the internet	Workshops: 3-hour training course The number of participants per workshop was 30. Total No. of participants: 88	Local university and company, instructed by nursing lecturer and students	Method: Postsession telephone interviews 1 month after the workshop Participants' confidence level in seeking health information was significantly associated with the level of satisfaction with the workshop (P<.001).
Campbell [83]	To improve health literacy skills among low-income, minority, and older adults	Workshops: 2-hour sessions once a week over 5 weeks No. of participants: 36	Computer labs in 2 low-income, minority residential buildings	Method: Pre- vs posttest surveys, survey 6 months after the training Participants experienced reduced anxiety concerning computers and increased confidence in locating health information.

Study	Main objective	Intervention format	Intervention setting	Intervention evaluation measures
Xie and Bugg [84]	To teach older adults to access and use high-quality internet-based health information	Educational program: 2-hour sessions twice a week over 4 weeks. The maximum number of participants per workshop was 7. Total No. of participants: 100	Public libraries	Method: Pre- vs posttest surveys Participants showed significantly reduced computer anxiety (P<.001), increased interest in computers (P=.001), and improved efficacy (P<.001) from pretraining to posttraining.
Chu and Mastel-Smith [85]	To enhance older adults' ability to grasp and manage health-related information retrieved from the internet and act accordingly	Educational program: 2-hour sessions once a week over 5 weeks. No. of participants: 12	A parish-sponsored, older adult leisure learning center	Method: Pre- vs posttest surveys; survey conducted 6 weeks after the training Participants experienced reduced anxiety, increased confidence, and a sense of self-efficacy at the end of the 5-week program and 6 weeks after program completion (P<.001).
Fink and Beck [86]	To improve the eHealth literacy of adults aged 50 years and older	Educational programs: 70 minutes to complete an educational online program and answer questions. No. of participants: 64	Internet-based setting	Method: Experimental group vs control group survey comparison Compared to the control group, the experimental group participants rated higher usability and learned more information on a new website.

[a]OHIS: online health information seeking.

[b]YWCA: Young Women's Christian Association.

[c]MHLC: multidimensional health locus of control.

[d]HOS: health opinion survey.

Further, 4 of the 11 programs were guided by established theories, models, or concepts (eg, the self-efficacy theory and the health belief model). All the studies involved some form of evaluation, including postsession surveys or interviews, pre- versus postintervention comparisons, and experimental versus control group comparisons. In addition, 5 studies evaluated the effectiveness of the intervention outcomes from a longitudinal perspective over a period ranging from 1 month to 1 year to the competence of the program. Among all the studies, 9 statistically assessed the effects of the intervention. Measures varied across the studies; these included opinions from surveys on the internet, self-efficacy in seeking health information, and anxiety regarding computer use. All the articles reported some positive outcomes of the intervention programs.

Discussion

Principal Findings

This systematic scoping review provides an overview of OHIS behaviors among older adults, as shown in Figure 3. Overall, the findings of this paper reveal core elements of OHIS among older adults. First, the types and sources of health information that older adults search for were clearly presented. Then, a portion of the studies explored the main factors influencing older adults' OHIS behaviors, which can be categorized as individual-related and source-related characteristics. Then, we identified the barriers to OHIS behavior in older adults from existing literature, including individual barriers, social barriers, and ICT barriers. Finally, this paper provides an in-depth analysis of the interventions mentioned in some of the included papers to support OHIS behaviors among older adults. We believe that the framework of this paper can, to some extent, help researchers to better position their research objectives in future studies so that the objectives correspond to specific dimensions for in-depth empirical investigation.

Regarding the first research question, the results show that older adults sought various types of health information on the internet, including information about specific diseases, medication and treatment, nutrition and exercise, medical resources, disease symptoms, health promotion, support groups and interpersonal advice, health insurance information, and health news or policies. The information sources included health websites, general search engines, social media and blogs, patient portals, and mobile devices. The types of health information sought differed from those that interest young people. According to a recent systematic review [87], adolescents and youths (<24 years) search the internet for daily health-related issues, physical and psychological well-being, sexual health, social problems, and culturally sensitive topics. Compared to the adolescent and youth population, older adults tend to search more for disease-related health information topics.

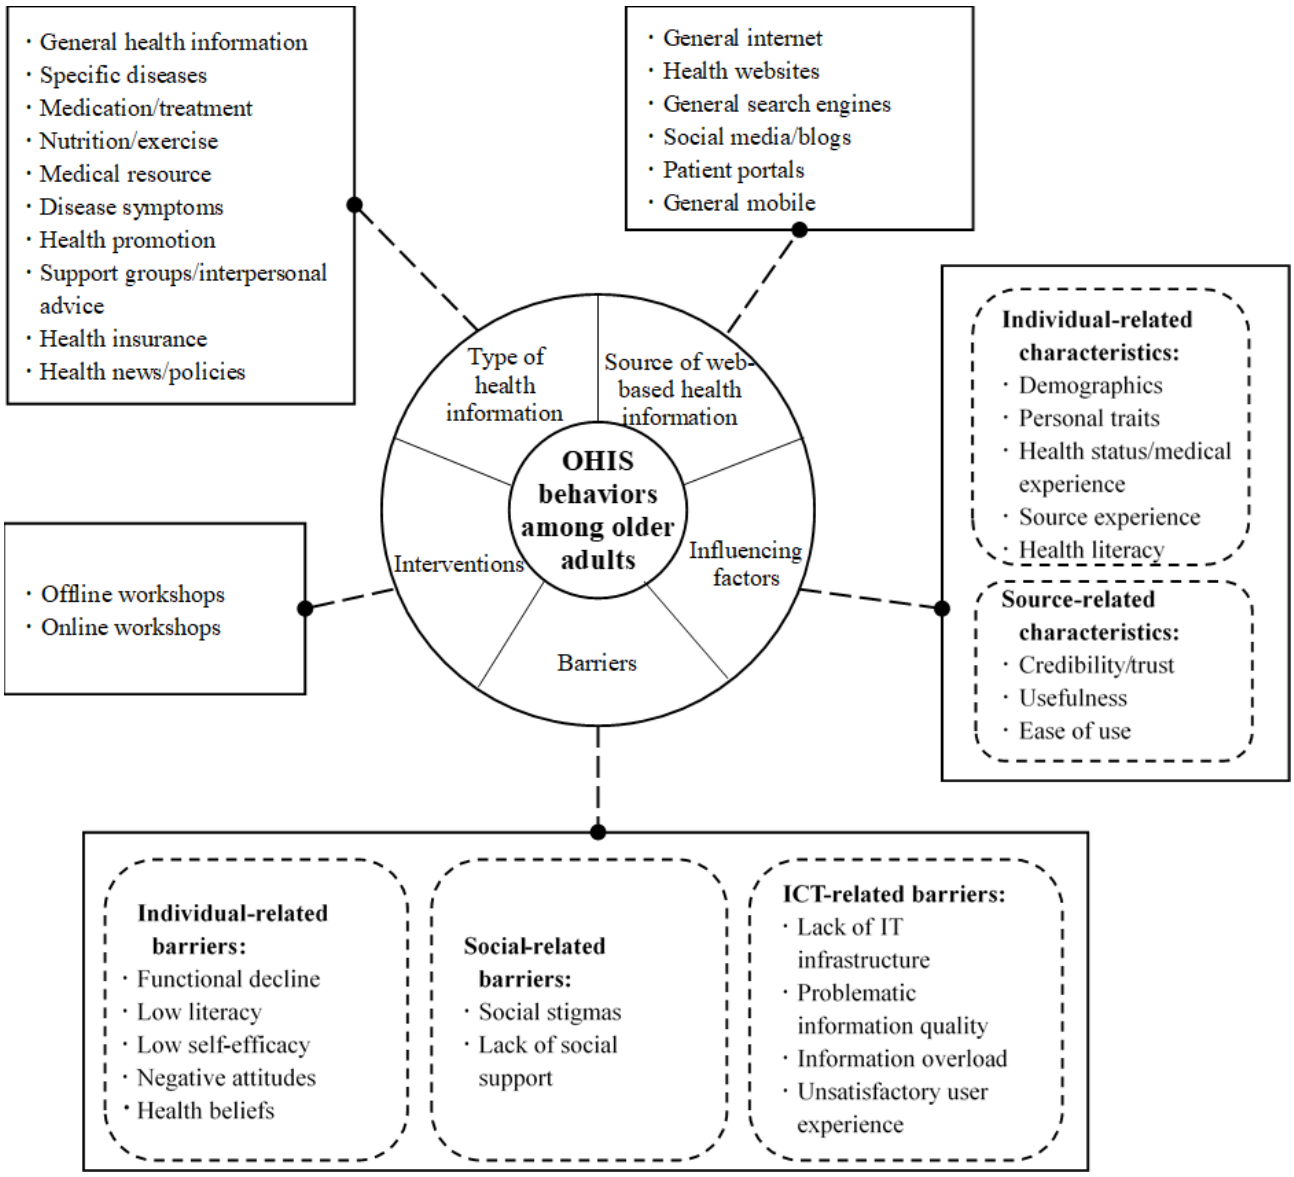
As for the second research question, the results point to 2 main types of factors influencing older adults' OHIS: individual-related characteristics and source-related characteristics. The individual-related characteristics include demographics, anxiety, beliefs, attitudes, self-efficacy, personality, health status, medical history, health care service availability, source experience, health literacy, and motivations. Among the source-related characteristics, credibility, usefulness, and trust were the 3 factors most frequently mentioned in the studies. We noted that the primary factors influencing older adults' OHIS differ from those influencing young adults. A systematic review of studies investigating young adults' (<24 years) OHIS [87] revealed that the most frequently mentioned influencing factors were gender, age, educational status, emotional characteristics, engagement in risky behaviors, and eHealth literacy.

The results for the third research question reveal that older adults might encounter 3 types of barriers during their OHIS, including

individual barriers (eg, low literacy), social barriers (eg, social stigmas), and ICT-related barriers (eg, lack of ICT devices). These barriers may hinder effective OHIS behaviors of older adults. The results suggest some differences from the findings on young adults' OHIS. For the adolescent and youth population (<24 years), the main barriers to OHIS include online privacy and concerns about information credibility [87]. Although some studies report low health literacy among adolescents [88], older adults seem to have more difficulties in this respect than adolescents [89,90].

As for the fourth research question, the review found that many intervention programs have been created to support older adults' OHIS; they primarily use educational training workshops in offline and online formats. Most training programs contained multiple sessions, with each session lasting 2 to 3 hours; the duration of the programs varied from 1 to 4 months, and all the programs reported at least some positive effects in support of older adults' OHIS.

Figure 3. Overview of principal findings. ICT: information and communication technology; IT: information technology; OHIS: online health information seeking.



Implications for Future Research

Overall, this systematic scoping review identified the need for more in-depth research on older adults' OHIS. As can be seen from the aforementioned evidence, a subset of studies have treated OHIS as a variable or construct and focused on exploring the factors influencing OHIS in older adults. Other studies treat OHIS as a process and investigate how the older adults search the internet for health information. However, given the complexity of the health conditions of older people and a projected future intensification of information overload, older adults will encounter more serious problems when searching for health information on the internet, such as how to select from among multimodal information sources, how to express health information needs, and how to evaluate health misinformation. Considering the growing population of older adults, the importance of internet-based information seeking for overall public health, and the lack of best practices, more research on this topic is needed. In this section, we propose

several directions for future research based on gaps identified in the review.

Investigations on the OHIS Behavior of Older Adults Above 85 Years

With the accelerating pace of global aging, the population of older adults is steadily growing. Instead of classifying the large population of older adults as one group, researchers are advocating for a more precise segmentation of this population, such as the youngest-old (65 to 74 years), middle-old (75 to 84 years), and oldest-old groups (above 85 years) [91]. Regarding OHIS, the age distribution of the samples in this systematic scoping review indicates that the exploration of OHIS by the oldest-old group is very limited [92]. Most articles included in this review have focused on the youngest- and middle-old groups [30], whereas there is a lack of research on the health information needs and behaviors of the oldest-old group. Future OHIS research can be appropriately skewed toward the oldest-old group to consider the physiological and psychological characteristics, the unique information needs, and explore the influences, processes, and health outcomes of the OHIS of this group more empirically within the framework of everyday information mastering [93].

Conducting More Longitudinal, Action, and Mixed Methods Research

As for research methods, most current studies use cross-sectional data collection methods and pay little attention to longitudinal approaches. In future, more consideration can be given to the adoption of longitudinal methods, such as the experience sampling method and the ethnographic approach. In particular, for intervention studies on OHIS behaviors in older adults, educational training programs with long time spans could provide data to improve OHIS performance and the health literacy of older adults. More participatory action research at the community level would enrich the network of actors in OHIS for older adults and engage more participants, thereby promoting interdisciplinary and collaborative health information practices in this population. In addition, future studies might consider more mixed methods approaches to leverage the advantages of qualitative and quantitative approaches and triangulate primary data with secondary data. Existing mixed methods studies have been conducted mainly based on quantitative questionnaire analyses as well as qualitative focus groups, and a richer mix of methods is to be further explored for this topic in future. Finally, as prior studies have relied heavily on self-reported data, future studies could consider more behavioral data using methods such as eye-tracking and electroencephalograms.

Elaboration on Mobile Context and Cross-platform Scenario of Older Adults' OHIS

Information types and information sources are the essential contextual factors in OHIS [94-96]. However, this review found that most studies on older adults' OHIS do not clearly explain what health-related information was involved or from where the information was gathered. In terms of information types, current studies mainly focus on searches for disease and treatment information. More studies are needed to address other types of health information that older adults might seek, such as information on environmental health and disease prevention.

Regarding information sources, studies are needed to investigate older adults' use of mobile devices for OHIS. With the development of the mobile internet and the internet of things, OHIS scenarios for older adults are changing. Mobile device–based health information access can more effectively meet the health information needs of older adults, facilitate daily health monitoring and self-tracking, and improve context-driven, health-related decision-making among older adults. For example, increasing numbers of older adults are seeking health information on their smart phones through short video apps like TikTok [97,98]. Furthermore, in addition to searching for health information on their mobile devices, increasing numbers of older adults are using mobile social apps to create content [99]. Future research could focus more on the relationship between OHIS and health-related content generation by older adults.

In addition, further exploration of complicated OHIS scenarios is needed. For example, with the popularity of wearable devices and the development of various health-related vertical search platforms, a portion of the older adult population with higher information literacy will become more proficient at searching for a full range of health information using various smart devices and immersive technologies [100], such as interacting with information through voice recognition and gesture control. Thus, explorations of cross-platform and cross-device seeking behaviors in OHIS by older adults are needed. Meanwhile, in addition to active information seeking, more types of seeking behaviors, such as passive exposure, information encountering, and surrogate health information seeking [101,102], deserve attention and further investigation. In particular, the influences and positive outcomes of searching as learning during OHIS by older adults is a topic worth exploring.

Facilitating Older Adults' OHIS by Explicating Technology Affordance

This review revealed that current research on factors influencing OHIS in older adults focuses more on demographic issues and individual-related characteristics than on source-related factors. In recent years, increased emphasis has been placed on aging-friendly designs in human-computer interaction [103], and the user experience–oriented design of various social apps and smart devices is centered on the needs and behavioral preferences of older adults, with an interest in meeting their personalized requirements. We believe that the affordance of technology in aging-friendly design is also a highly influential factor for promoting OHIS in older adults. It would be fruitful to integrate the uses and gratifications theory with the affordance lens to better promote the positive impact of new media platforms on older adults' information-seeking behaviors [104,105]. More attention needs to be placed on the ease of use, usability, and sociability of aging-friendly information sources and information systems. In particular, in the upcoming human-centered artificial intelligence era, older people's perception of the trustworthiness of multimodal information sources and their trust in algorithm-based content recommendations will continue to change. Therefore, the age-appropriate design of OHIS needs to constantly break away

from stereotypes of older people and re-establish a more adaptive mental model. The lens of the affordance theory could be applied to help situate OHIS for older adults in the context of information practices, promoting deep reflection on the interaction of actors with sociocultural environments and on the mediated nature of technology [106]. For instance, an OHIS platform should provide rich technology affordances for older adults and provide targeted support for active health information access, information encounters, and information avoidance problems in different sociocultural environments. Future research could focus more on how technology affordance can better mediate older adults' OHIS gratification by attempting to build a more detailed affordance typology [107]—such as handling, effecter, and motivational affordances—to measure older adults' gratifications for OHIS using social media.

Promoting and Measuring the Performance of OHIS Interventions for Older Adults

The results show that older adults encounter many barriers in OHIS; thus, many intervention programs have been created to support their searching. However, current intervention programs still leave considerable room for improvement. First, current educational training programs are generally small-scale ones, making it difficult to reach a wide group of older adults; most programs are offline workshops, and there are few internet-based programs. Future OHIS interventions for older adults need to offer more technology-mediated web-based programs and provide richer formats than workshops and tutorials, such as distance education for older adults using gamification and immersive technology. Moreover, most current intervention programs operate in the United States; older adults living in less developed countries or areas received less attention. Future studies on OHIS in older adults must involve more trans- and cross-national, or regional and cross-cultural comparative studies to further explore the influence of sociocultural factors on older adults' OHIS behaviors. We also recommend that more information and communication technology for development (known as “ICT4D”) projects focus on upgrading OHIS and improving the same for older adults [108], thereby better promoting health literacy and health mobility for older adults in developing countries and regions.

In particular, researchers need to draw more on the design science research paradigm. Design science research is an innovative and often iterative problem-solving process that builds and evaluates artifacts [109]. In our research context, the purposeful artifacts could be search systems, training courses, workshops, tutorials, or citizen science programs. In the building phase of artifact development, most units of analysis relate to offline workshops and neglect other types of artifacts. It is also noteworthy that current intervention studies lack a theoretical lens, and only a few studies have designed interventions based on theoretical foundations. Future interventions for older adults' OHIS need to embrace the theoretical considerations that design science research has been advocating [110]. In the evaluation phase of artifact development, current studies lack long-term assessments of intervention effects. Future studies should consider more participatory action research to iteratively test the effects of OHIS interventions on older adults and select some specific health domains—such as chronic diseases, cancer, and mental health—for attempting to verify the actual effects of OHIS interventions on information literacy, health literacy, and health outcomes of older adults. In addition, future studies could contemplate providing various forms of support based on the perspectives of older users, allowing them to participate in the project design process and thus help them overcome search barriers.

Limitations

This systematic scoping review has several limitations. The first one is in terms of search sources. Owing to the interdisciplinary nature of OHIS research in older adults, although we tried to search multiple databases using relevant keywords and consulted academic librarians to improve our search strategy, it was nevertheless inevitable that some literature would be missed, especially relevant research in unofficially published conference proceedings. The backward and forward strategy can be further used to expand the literature search sources in future [111]. Second, in terms of the literature type, this review mainly focuses on empirical studies, whereas some opinion papers, descriptive cases, and short communications on OHIS for older adults were excluded from our literature pool, and some complementary analyses of such nonresearch articles can be conducted in future. Finally, in terms of the analytical approach for searching literature, this study did not conduct a comparative chronological analysis of the literature in different periods, which to a certain extent could not fully reveal the impact of technological and sociocultural changes on older adults’ OHIS behavior. In future, the introduction of knowledge graphs can be considered to map the themes of the literature at different stages.

Conclusions

This review provides an overview of how older adults’ OHIS has been studied. It reveals that older adults search for various types of health information on the internet using different types of web-based sources and that their OHIS is jointly influenced by source-related and individual-related factors. Their difficulties in searching arise from individual, social, and ICT-related barriers. Some educational intervention programs that support older adults’ OHIS have been initiated in the form of web-based and offline workshops. Furthermore, the review reveals that the topic of older adults’ OHIS is understudied, although the number of studies is increasing. Nevertheless, more studies are needed to understand the problems associated with older adults’ interactions with health information and better support them in their decision-making when they are searching for medical and health information on the internet. Based on the findings of the review, the authors propose several objectives for future research.

Acknowledgments

We thank the anonymous reviewers and editors for their helpful comments on the manuscript. The study was supported by the National Science Foundation of China (grants 72074112, 72174083, and 71774083).

Abstract

Background: Mental disorders are normally diagnosed exclusively on the basis of symptoms, which are identified from patients' interviews and self-reported experiences. To make mental health diagnoses and monitoring more objective, different solutions have been proposed such as digital phenotyping of mental health (DPMH), which can expand the ability to identify and monitor health conditions based on the interactions of people with digital technologies.

Objective: This article aims to identify and characterize the sensing applications and public data sets for DPMH from a technical perspective.

Methods: We performed a systematic review of scientific literature and data sets. We searched 8 digital libraries and 20 data set repositories to find results that met the selection criteria. We conducted a data extraction process from the selected articles and data sets. For this purpose, a form was designed to extract relevant information, thus enabling us to answer the research questions and identify open issues and research trends.

Results: A total of 31 sensing apps and 8 data sets were identified and reviewed. Sensing apps explore different context data sources (eg, positioning, inertial, ambient) to support DPMH studies. These apps are designed to analyze and process collected data to classify (n=11) and predict (n=6) mental states/disorders, and also to investigate existing correlations between context data and mental states/disorders (n=6). Moreover, general-purpose sensing apps are developed to focus only on contextual data collection (n=9). The reviewed data sets contain context data that model different aspects of human behavior, such as sociability, mood, physical activity, sleep, with some also being multimodal.

Conclusions: This systematic review provides in-depth analysis regarding solutions for DPMH. Results show growth in proposals for DPMH sensing apps in recent years, as opposed to a scarcity of public data sets. The review shows that there are features that can be measured on smart devices that can act as proxies for mental status and well-being; however, it should be noted that the combined evidence for high-quality features for mental states remains limited. DPMH presents a great perspective for future research, mainly to reach the needed maturity for applications in clinical settings.

mental health; digital phenotyping; sensing apps; data sets; sensor data

Introduction

Background

Mental health issues have a high prevalence, with 1 in 10 people worldwide experiencing them at any one time [1] and common mental disorders such as depression being closely linked to suicide [2]. Mental disorders are "generally characterized by some combination of abnormal thoughts, emotions, behavior and relationships with others" [3]. Examples are depression, schizophrenia, excessive anxiety and stress, disorders caused by drug and alcohol abuse, and personality and delusional disorders. These disorders pose a significant burden on societies, both emotionally and financially. For example, the cost of mental health disorders in the European Union is estimated at €600 billion (~US $451 billion), or 4% of gross domestic product [4]. COVID-19 has had a further negative impact on global mental health [5].

Mental disorders are usually diagnosed exclusively on the basis of symptoms, which are identified from patients' interviews and self-reported experiences. Sometimes these experiences are gathered using ecological momentary assessment (EMA) solutions [6], but mostly therapists rely on patients remembering such experiences during sessions. EMA solutions are used as a research method to collect, at fixed or random moments, reports from individuals about perceptions of their behaviors and feelings, and what they have done or experienced. It is well known that the intervening time and current state of the patient bias his/her memory of the experience. In addition, biological tests to assist diagnosis remain hard to be developed [7]. Based on the need to develop solutions able to objectively diagnose and monitor mental health, different solutions have been proposed, such as mobile apps [8,9] and machine learning (ML) solutions [10], which are even more indicated today due to the global pandemic situation [11,12]. Digital phenotype solutions are examples that can expand the ability to identify and diagnose health conditions from the interactions of people with digital technologies [13]. Specifically, digital phenotyping of mental health (DPMH) [14] seems to be a promising approach not only to deal with the problem of diagnosing the issue, but also to be applied to the treatment.

The omnipresent adoption of pervasive devices, including smartphones and wearable sensors, provides novel opportunities for tracking mental health status and disorders. Digital phenotyping refers to the "moment-by-moment quantification of the individual-level human phenotype in-situ using data from smartphones and other personal digital devices" [15], thereby removing limitations created by the aforementioned bias in self-reports.

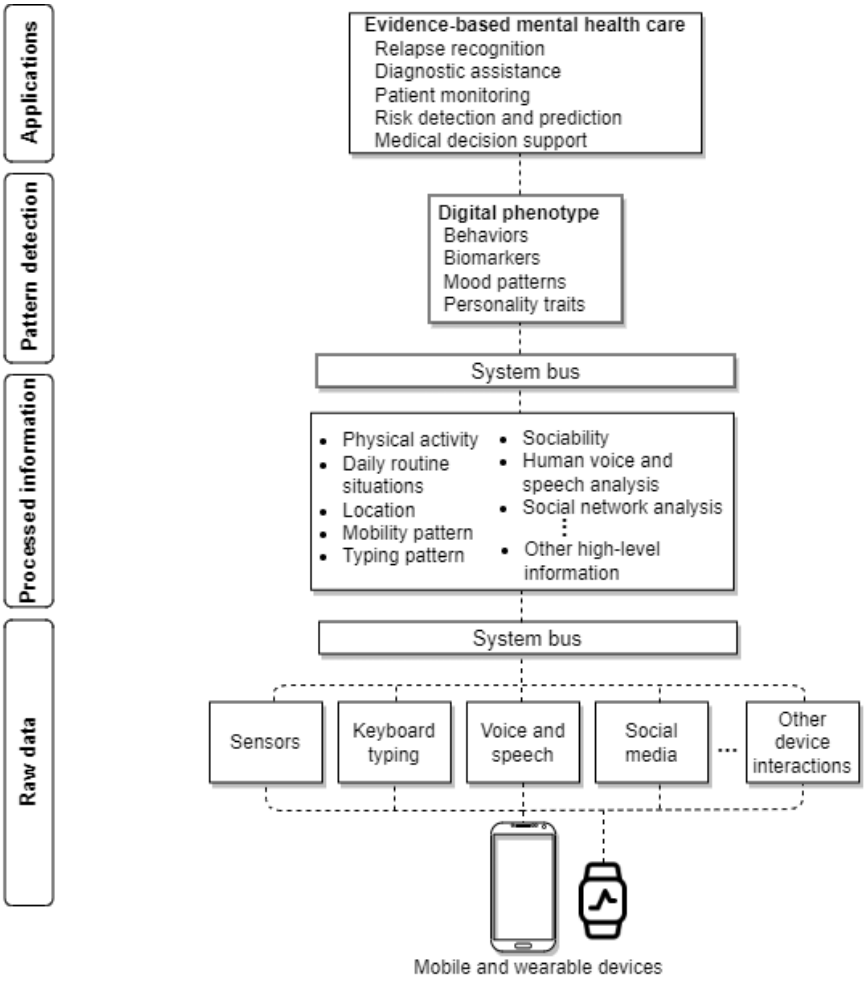
DPMH solutions require collecting and analyzing large amounts of different types of social and behavioral data that can represent experiences of the users and their interactions with people, places, and devices. These context data can be passively gathered, for instance, from ubiquitous sensors, social media, and health care systems [16]. After collection, pieces of raw data are usually preprocessed and transformed into useful data or data sets to be mined [17]. For example, these data sets may be analyzed or used as input to build ML models [18], including for DPMH, to produce valuable insights and evidence. Therefore, DPMH sensing apps are primarily responsible for collecting and preprocessing data, with the data sets produced being important for developing such models. This study systematically reviews the sensing apps and data sets for DPMH.

Definitions

In the last few years, the number of smart devices, that is, mobile (eg, smartphone, tablet) and wearable (eg, smart band, smartwatch) devices, has grown globally. They have enabled the development of research in the health area, including mental health [10]. The term "digital phenotype", defined by Jain and colleagues [13], refers to the identification of human behavior patterns, whereas "digital phenotyping" is a monitoring approach that can collect patients' behavioral markers passively [19]. Therefore, DPMH solutions aim at collecting multimodal pieces of information from digital devices using sensing apps to combine them with electronic medical records to objectively contribute to the identification of symptoms of mental disorders. In this context, sensing apps are tools for mobile and wearable devices used to collect useful user information.

Our vision of the digital phenotyping process organized in layers is presented in Figure 1. The process starts at the first layer with the collection of raw data from different sources (eg, global positioning system [GPS] sensors, keyboard inputs, voice, and social media). These data can be collected both actively, in which user inputs are explicitly required, and passively [20], which only requires the user's permission to access context data. In the next layer, these data are processed to provide high-level information. High-level information represents not only human behaviors (eg, sociability, physical activity) and habits (eg, mobility, sleep) but also other information of interest for professionals (eg, environmental context, mood). Next, human behavioral patterns that compose digital phenotypes (eg, biomarkers, mood patterns) can be recognized using computational tools (eg, ML, data mining, statistical models). Finally, we visualize the application layer, which corresponds to digital phenotypes used by health professionals for evidence-based mental health care.

Figure 1. The process of digital phenotyping.



Related Work

Since the aforementioned concepts were proposed in the literature, many research studies have been performed. For this reason, researchers have also reviewed different aspects regarding this research topic. Table 1 presents a list composed of related reviews.

Table 1. List of related review articles.

Study	Description
Garcia-Ceja et al [10]	A survey on mental health monitoring using mobile and wearable sensors focused on multimodal sensing and machine learning solutions.
Cornet and Holden [21]	An SLR[a] on passive sensing using specifically smartphones focused on health and well-being.
De-La-Hoz-Franco et al [22]	An SLR aimed at finding data sets composed of sensor data for human activity recognition.
Trifan et al [23]	This SLR aimed to identify studies on the passive use of smartphones for generating outcomes related to health and well-being. It identified that one of the areas most explored by mobile passive sensing is mental health.
Seppälä et al [24]	An SLR on mobile solutions focused on uncovering associations between sensor data and symptoms of mental disorders (ie, behavioral markers).
Liang et al [14]	A comprehensive survey addressing different topics on DPMH[b].
Benoit et al [20]	This SLR sought to map DPMH tools that use machine learning algorithms across the schizophrenia spectrum and bipolar disorders.
Antosik-Wójcińska et al [25]	This work presents an overview of studies about smartphone systems focused on monitoring or detecting bipolar disorder.

[a]SLR: systematic literature review.

[b]DPMH: digital phenotyping of mental health.

This review differs from the previous ones in the following aspects: First, instead of focusing on a specific mental state/disorder, this review presents an overview of how different types of devices and detection modalities have been used to monitor a wide variety of different mental states within the DPMH area. Second, this review covers not only active collection solutions, which are emphasized in most reviews, but also passive sensing proposals. Third, this review focuses on the technical features of sensing apps and data sets (eg, size, sensors used to collect data, and types of context data). Technical features can be identified to serve as a basis for the use or development of new apps (eg, physical and virtual sensors used to collect data, operating systems for which the apps were developed, types of context data collected, inferred information). Finally, not all previous reviews were conducted systematically. Our article therefore provides researchers with an overview of the available technological framework for DPMH and can serve as a preliminary guide for current and further research.

Objectives and Research Questions

This systematic review intends to provide a technical characterization and summary of sensing apps and public data sets for DPMH. By "public" we mean data sets that are available for free download for use in other research endeavors. These 2 topics (ie, sensing apps and public data sets) are jointly addressed in this review as complementary content. When researchers do not have access to DPMH data sets, they need sensing apps. This paper therefore can be a starting point not only to gain knowledge on the current sensing apps for DPMH (which consequently enables the development of new solutions), but also to find reusable ones. Therefore, the objectives of this article are to (1) present results from a systematic search on digital libraries and data set repositories, and then identify and categorize them by considering their characteristics; (2) summarize their main features (measurable pieces of data that can be used for analysis or creation of ML models, such as data collection time stamp, context data produced by DPMH solutions, and data self-reported by users), which are useful for researchers, either mental health or information technology ones, to conduct further investigation and comment on their usefulness; and (3) identify trends in and research opportunities for DPMH. Results of this systematic review are also relevant for data engineers and ML specialists who make efforts in developing DPMH solutions.

To achieve the objectives of this systematic review, we defined the following research questions for sensing apps (SA-RQs) and data sets (DS-RQs):

SA-RQ1: What context data are collected through DPMH sensing apps?

SA-RQ2: What high-level information can be inferred from the context data collected by DPMH sensing apps?

SA-RQ3: How is the identified high-level information used to support mental health?

DS-RQ1: What features are available in public data sets for DPMH?

DS-RQ2: What high-level information can be derived from public data sets for DPMH?

Methods

Design

This study was conducted based on the guidelines for systematic literature reviews in software engineering proposed by Kitchenham and Charters [26]. This review followed 3 main phases: planning, conducting research, and dissemination of results. These phases were supported by the *Parsif.al* [27] tool, which provides an online shared work environment for planning and executing systematic reviews. In this section, we present how this review was planned and conducted.

Search Strategy

The search aimed to identify data sets and studies that have presented sensing apps capable of collecting data. Two (JM and IM) researchers conducted an exhaustive search on January 14, 2021, on data set repositories and digital libraries. The search for data sets was performed in 20 repositories (Multimedia Appendix 1). The search for articles reporting sensing apps was conducted in the following digital libraries: ACM Digital Library, DOAJ, IEEE Xplore, Web of Science, PubMed, PsycInfo, ScienceDirect, and Scopus. These databases were selected because they collect reliable studies related to mental health informatics.

We designed the search strings to retrieve data sets and articles presenting sensing apps for DPMH (Table 2). These search strings were carefully designed to meet the research focus. In the string to search data sets, we defined the 2 main terms (ie, mental health and digital phenotyping) and decided to use Boolean "OR" as the link for them to get comprehensive results. The search string for articles was developed based on the review objective, research questions, and their motivations. We used keywords and their synonyms to maximize results. To avoid missing papers, we evaluated the suitability of the string in a pilot search, in which we used those studies developed by Liang et al [14] (ScienceDirect) and Torous et al [15] (PubMed) as control articles. This pilot search was able to retrieve the cited studies, thus demonstrating its ability to find articles relevant for this review. At the end of the search, duplicate data sets and articles were identified and removed using the *Parsif.al* tool.

Table 2. Keywords and their synonyms.

Search	Source	String
Data sets	Data set repositories	"mental health" OR "digital phenotyping"
Sensing apps	Digital libraries	("mental health" OR "mental disorder*" OR "mental illness" OR "mental state" OR "mental disease") AND ("mobile device" OR "smartphone*" OR "wearable device*" OR "sensor*" OR "wearable*" OR "mobile application*" OR "mobile health" OR "mHealth" OR "mobile phone*" OR "sensor data") AND ("passive detection" OR "data collection" OR "digital phenotype" OR "digital phenotyping" OR "digital health" OR "monitoring" OR "passive sensing")

Selection Criteria

A set of selection criteria was defined to track research articles and data sets. Textbox 1 presents the selection criteria for scientific studies with sensing apps and data sets. Importantly, no date range limits were applied to the literature included in the review. In the selection of scientific articles, criterion EC1 excluded studies presenting the development of EMA apps, and papers that do not present a new DPMH solution (eg, studies using a DPMH solution previously described/published in another paper). For data set selection, criterion EC1 excluded those data sets that were not publicly available, that is, those protected and not accessible to be reused by other researchers.

In the selection phase, 2 researchers (JM and IM) performed the data set selection process based on the inclusion and exclusion criteria. In a second step, the same 2 researchers independently performed the study selection process. This process consisted of 3 sequential phases: (1) study screening by means of metadata analysis (ie, title, abstract, and keywords); (2) full-text analysis of the articles selected in the screening phase; and (3) conducting backward snowballing [28]. Next, the level of agreement between the selections was calculated using the Cohen κ coefficient [29]. In the end, the 2 researchers conducted discussions to resolve selection conflicts and, when there was no consensus, judges (2 other authors, namely, AT and DV) deliberated on the disagreements.

Textbox 1. Selection criteria.

Inclusion criteria (IC)

Scientific articles

IC1: Primary studies that present pervasive solutions to collect data for digital phenotyping of mental health.

IC2: Full papers.

IC3: Papers in English language.

Data sets

IC1: Available to be downloaded and used in other research studies (ie, public data set).

IC2: Focused on mental health or specific mental disorders.

IC3: Relevant data (eg, behavioral, physiological, social) for mental health collected through pervasive technologies.

IC4: Content in English language.

Exclusion criteria (EC)

Scientific articles

EC1: Articles presenting research on digital phenotyping of mental health without involving a proposal of a pervasive solution.

EC2: Gray literature.

EC3: Articles that have other publications with a more current and complete version of the proposed solution.

Data sets

EC1: Not publicly available.

EC2: With no content related to mental health.

EC3: Data on treatments of patients with mental disorders without using pervasive devices.

EC4: Content in languages different from English.

EC5: Online surveys on ethnographic characteristics and prevalence of mental disorders.

EC6: Composed exclusively by multimedia data (eg, video, audio) or electroencephalography data.

Data Extraction

In this step, data were extracted from the selected articles and data sets to answer the research questions defined in this review. For this purpose, a data extraction form was designed by 2 authors (JM and IM) and validated by the judges. Specifically, we designed the items in the form to extract relevant information presented by the reviewed studies and data sets, thus enabling

us to answer the research questions, and identify open issues and research trends. Multimedia Appendix 2 presents the items in the data extraction form.

Results

Study Selection

An overview of the review process with results is presented in Figures 1 and 2. In Figure 2, 8 digital libraries were used to search for scientific articles that presented sensing apps for DPMH. A total of 2374 articles were returned. We removed 926 duplicate articles. The inclusion and exclusion criteria from Textbox 1 were applied to select 26 selected studies. The Cohen κ statistical test showed an agreement level of ≈0.87 between researchers, which is considered an almost perfect agreement [29]. Next, researchers used the 1-level backward snowballing approach and added 5 articles. This resulted in 31 articles for inclusion in the data extraction process.

In Figure 3, 20 data set repositories were searched to return 2581 data sets with 471 duplicates that were removed. After applying selection criteria (Textbox 1) and resolving conflicts, 8 data sets remained for analysis.

Figure 2. PRISMA-based flowchart describing the selection of studies.

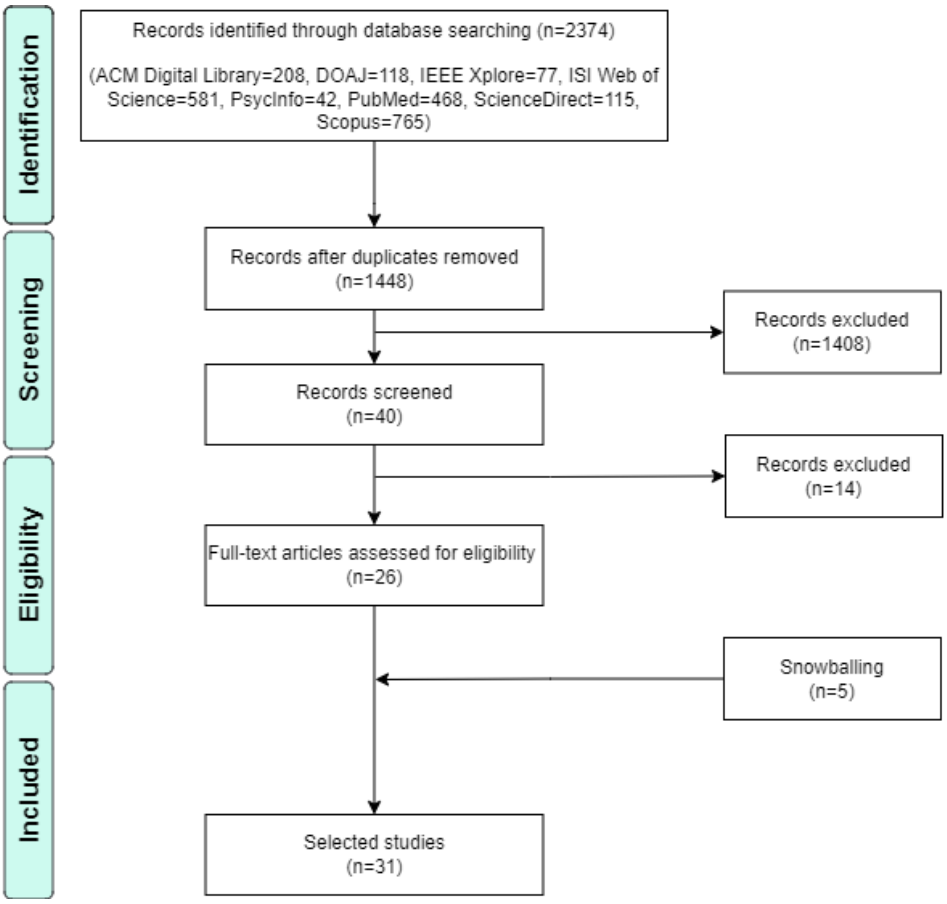


Figure 3. Flowchart describing the selection of data sets.

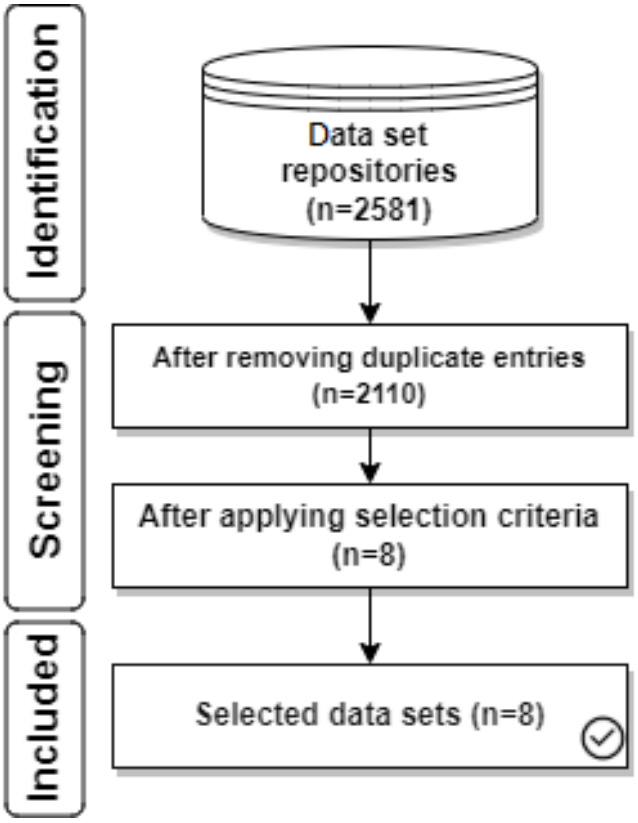


Sensing Apps

Table 3 summarizes the 31 apps identified, which are presented in ascending order by year of publication. Multimedia Appendix 3 presents the full version of the table. Context data sources are categorized as follows to present the sensors used by the apps based on the work by Palaghias et al [30]: ambient (eg, microphone, camera), positioning (eg, GPS, Wi-Fi), virtual (eg, phone calls, SMS text messages), and inertial (eg, accelerometer, gyroscope). Table 3 also presents high-level information inferred and types of analyses performed on the collected data. Apps that do not infer information (ie, defined as "It does not infer information") are only intended to collect data from smart devices. In this case, collected data are usually sent to servers for analysis. These apps are flagged as "Raw data collection" in Table 3.

Table 3. Summary of reviewed sensing apps.

App	Context data source	High-level information	Type of analysis
Funf [31]	Positioning, inertial, and virtual	It does not infer information	Raw data collection
Mobilyze [32]	Positioning, inertial, virtual, and ambient	Mood, emotions, cognitive/motivational states, physical activity, social context	Mental state prediction
Purple Robot [33]	Positioning, inertial, and virtual	It does not infer information	Raw data collection
AWARE [34]	Positioning, inertial, and virtual	It does not infer information	Raw data collection
Sensus [35]	Positioning, inertial, virtual, and ambient	It does not infer information	Raw data collection
MOSS [36]	Positioning and virtual	Physical activity, mobility, device usage, sociability, app usage	Mental state classification
Beiwe [15]	Positioning, inertial, virtual, and ambient	It does not infer information	Raw data collection
EVO [37]	Positioning, inertial, and virtual	It does not infer information	Raw data collection
CrossCheck [38]	Positioning, inertial, virtual, and ambient	Sleep, sociability, mobility, physical activity, device usage	Mental state prediction
SituMan [39]	Positioning and inertial	Daily routine situations (eg, working, studying)	It recognizes daily routine situations using fuzzy logic
EmotionSense [40]	Positioning, inertial, virtual, and ambient	Semantic locations, physical activity, sociability	Correlation analysis and mental state classification
StudentLife [41]	Positioning, inertial, virtual, and ambient	Sociability, mobility, physical activity, device usage	Correlation analysis
Undefined [42]	Positioning, inertial, and ambient	Physical activity, mobility, and sociability	Correlation analysis
AMoSS [43]	Positioning	Mobility	Mental state prediction
eB2 [44]	Positioning and virtual	Mobility	Mental state classification
EARS [45]	Positioning, inertial, virtual, and ambient	It does not infer information	Raw data collection
SleepGuard [46]	Inertial and ambient	Posture/position of body when sleeping	Mental state classification
Moment [47]	Virtual	It does not infer information	Mental state classification
TypeOfMood [48]	Virtual	It does not infer information	Mental state classification
RADAR-base [49]	Positioning, inertial, virtual, and ambient	It does not infer information	Raw data collection
SHADO [50]	Positioning, inertial, and ambient	Physical activity, mobility, sleep, sociability	Correlation analysis and mental state classification
InSTIL [51]	Positioning, inertial, virtual, and ambient	It does not infer information	Raw data collection
Lamp [52]	Positioning	Physical activity	Correlation analysis
SOLVD [53]	Positioning, inertial, virtual and ambient	Mobility, sociability, context of daily life (eg, duration of sleep)	Correlation analysis
STDD [54]	Inertial, virtual, and ambient	Physical activity, mood, sociability, sleep	Mental state classification
Moodable [55]	Positioning, virtual, and ambient	Sociability and mobility	Mental state classification
Cogito Companion [56]	Positioning and Virtual	Mood, stress level, and well-being	Mental state classification
Strength Within Me [57]	Virtual	Sleep, mobility, and sociability	Mental state prediction
EuStress [58]	Ambient	It does not infer information	Mental state prediction
Mood Triggers [59]	Positioning, inertial, virtual, and ambient	Mobility and sociability	Mental state prediction
Data Collector [60]	Positioning and inertial	Physical activity and mobility	Mental state classification

Data Set Characterization

Table 4 shows the 8 selected data sets in descending order by number of participants. Two of them have sleep quality data: data sets DS1 and DS7, in which the data are derived from activity trackers such as Fitbit, smartwatches, and smartphones. We identified 2 data sets (DS3 and DS5) with data collected from various sensors, which we refer to as multimodal. We identified 2 data sets (DS3 and DS5) that were generated by the StudentLife [41] and Beiwe [15] sensing apps, respectively, shown in Table 3.

Table 4. Summary of DPMH data sets.

Data set	Study	High-level information	Features	Device type/operating System	Number of participants	Study duration	Size
DS1[a] [61]	[62]	Sleep quality	Fitbit data (eg, heart rate, sleep duration, sleep time, wake time)	Watch Fitbit	482	3-11 nights	392.32 KB
DS2 [63]	[64]	Activity	Actigraph (time stamp, activity measurement from the actigraph watch)	Actigraph watch	55	Average 12.6 days	4.3 MB
DS3 [65,66]	[41,67]	Multimodal (stress, sleep, mood, physical activity, sociability, well-being)	Self-report questionnaires, activity, audio, Bluetooth encounters, conversation, lightness, GPS[b] coordinates, phone charge, screen on/off, Wi-Fi IDs	Smartphone (Android)	48	66 days	230 MB/5 GB
DS4 [68]	[69,70]	Sociability	Self-reports, battery level, Bluetooth encounters	Smartphone (Android, iOS)	32	4 weeks	9.7 MB
DS5 [71]	[15]	Multimodal (mobility, sociability, sleep)	Self-report questionnaires, accelerometer, app logs, Bluetooth encounters, call logs, GPS coordinates, power state, Wi-Fi	Smartphone (Android, iOS)	6	3 months	776.7 MB
DS6 [72]	[73]	Mood, depression symptoms	Self-report questionnaires	Smartphone (Android, iOS)	3	14 days	2.7 MB
DS7 [74]	—	Sleep quality	Start, end, sleep quality, time in bed, wake-up time, sleep notes, heart rate, number of steps	Wearable device and smartphone (iOS)	1	4 years	66.11 KB
DS8 [75]	—	Mood	Self-reported mood	Mobile social network (Twitter app)	1	2 years	131 KB

[a]DS: data set.

[b]GPS: global positioning system.

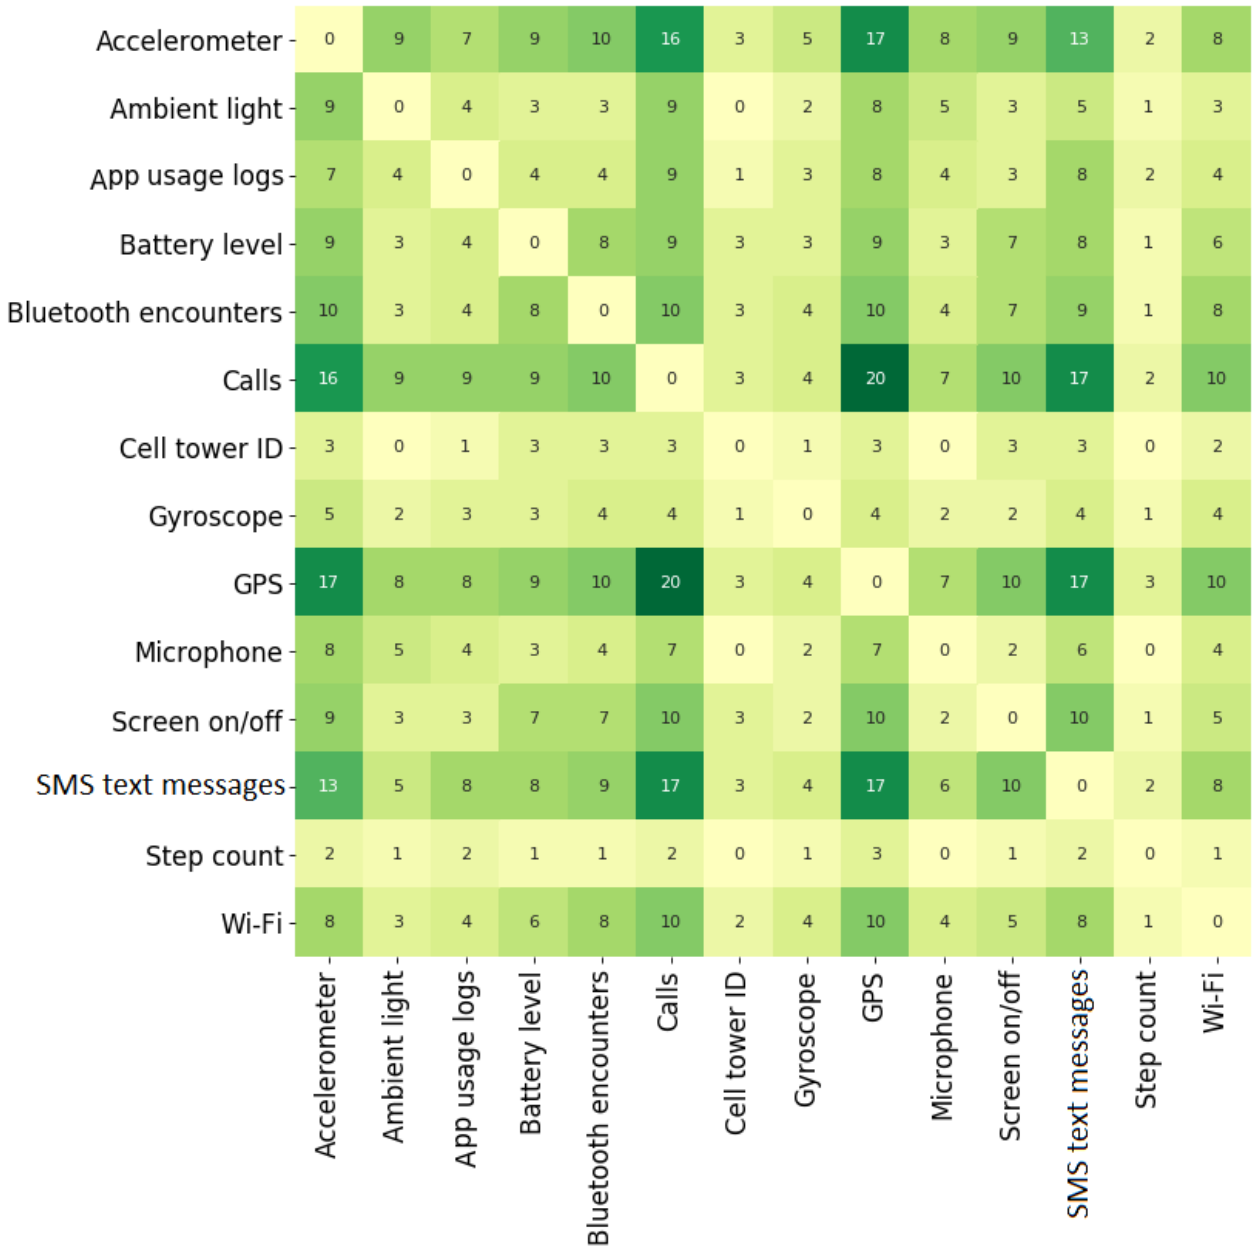
Data set DS1 [61] presents sleep data (eg, total sleep time and sleep efficiency) obtained from Fitbit Charge HR activity trackers used by 482 individuals [62], while data set DS2 [63] includes actigraphic data collected from patients with unipolar and bipolar disorders and 32 healthy controls [64]. Data set DS3 [65,66] contains data gathered from different sensors and EMA questionnaires collected from smartphones of 48 undergraduate and graduate students over 66 days [41,67]. Data set DS4 [68] comprises Bluetooth device scan, battery level, and EMA data collected at regular intervals for 4 weeks [69,70], while data set DS5 [71] presents passive data (eg, GPS, Wi-Fi, Bluetooth, and accelerometer) and active data (EMA survey responses) collected over 3 months [15]. Data set DS6 [72] contains EMA assessments of depression symptoms using the 9-item Patient Health Questionnaire (PHQ-9) [73]. Data set DS7 [74] presents sleep data collected through the Sleep Cycle mobile app [76]. Finally, data set DS8 [75] presents values extracted from Twitter posts collected from a person using Exist [77] over 2 years.

Context Data Collected by DPMH Sensing Apps (SA-RQ1)

Sensing apps identified in this review collect context data from mobile and wearable devices to support DPMH. At a high level, the sensors that measure context data can be seen as physical and virtual sensors [78], which generate a diversified set of behavioral data. Physical sensors are hardware components embedded or connected to devices responsible for collecting context data. Some examples are accelerometers to measure user activity, light sensors to measure ambient light levels, and GPS to collect user's locations. Virtual sensors represent software components capable of recording interactions of individuals with devices or using a number of physical sensors (or other virtual ones) to construct a higher-level feature. Examples of such sensors are social interaction sensors that may use Bluetooth encounters (ie, co-location information between individuals or places), Wi-Fi network, and sound data to infer social activity; and user–device interaction sensor, which measures user interactions with devices (eg, call logs, SMS text messages, app usage, screen on/off).

Figure 4 presents a heat map of the combination of context data sources for the 31 sensing apps, showing the most used sensors in DPMH solutions. In this analysis, we investigated the frequency of the combination of each type of context data source, highlighting the main sets of sensors explored by the sensing apps. For example, Bluetooth encounters are often combined with accelerometer (n=10), battery level (n=8), calls (n=10), GPS (n=10), screen on/off (n=7), SMS text messages (n=9), and Wi-Fi (n=8), while app usage logs are often combined with accelerometer (n=7), calls (n=9), GPS (n=8), and SMS text messages (n=8). We also identified from this analysis that step count (Fitbit), cell tower ID, and gyroscope are combined less often with other context data sources. The analysis of the combination of context data sources (Figure 4) demonstrates an interest in performing data fusion to identify multiple high-level information and emphasizes the combination of context data sources resulting from the interest in monitoring such information. For example, we identify an interest in recognizing sociability information by combining call logs with Bluetooth encounters (n=10) and SMS text messages (n=17). We also recognize that GPS is often combined with Wi-Fi (n=10) to recognize mobility aspects. In addition, the interest in monitoring multiple high-level information in the same app resulted in different combinations of context data sources. For example, the combination of GPS with call logs (n=20), accelerometer (n=17), and screen on/off (n=10) is a result of an interest in monitoring sociability, physical activity, and device usage patterns, respectively.

Figure 4. Context data sources used in the reviewed studies. GPS: global positioning system.



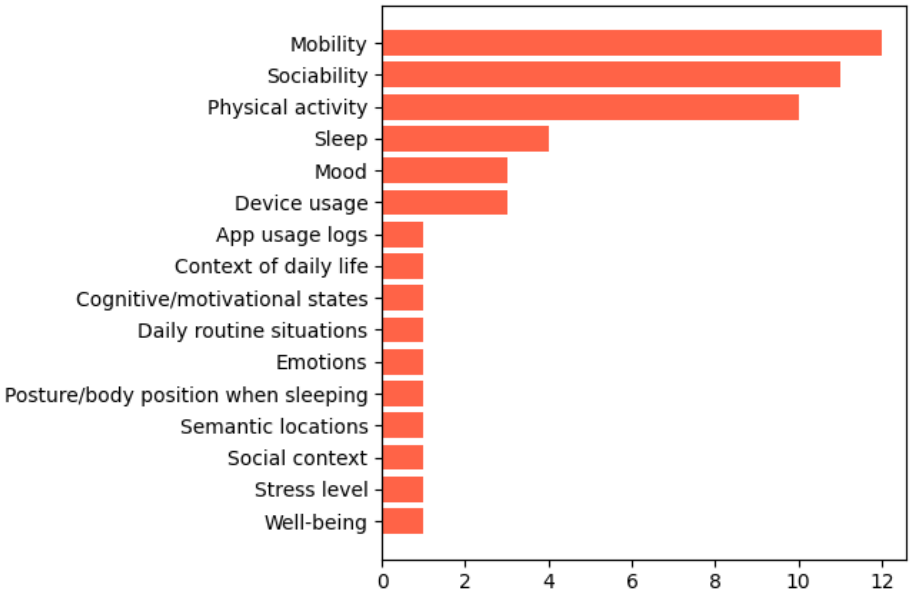
High-Level Information Identified by Sensing Apps (SA-RQ2)

From the context data collected by sensing apps, researchers can extract high-level information representing different types of situations (eg, sociability, mobility). Table 3 presents the situations of interest identified from context data. Sensing apps aimed to identify information related to the physical and environmental aspects of the monitored individuals, such as mobility patterns [38] (eg, places visited, total distance traveled, time spent in locations), physical activities (activity type and duration), daily routine situations (eg, working, studying), and environmental context (eg, ambient temperature).

Figure 5 shows the types of high-level information generated by the sensing apps. The 3 types of information that stand out are human behavioral patterns related to mobility, sociability, and physical activity (n≥10). Information about the individual's condition was also derived, such as mood and sleep quality.

Researchers also explored information about device usage, which was derived from logs such as calls, SMS text messages, screen on/off events, and app usage. In general, studies have been able to build apps that achieve promising results of performance metrics (eg, accuracy, sensitivity, specificity) in identifying useful high-level information for mental health professionals. By contrast, there are some researchers developing apps that have not transformed context data into high-level information (ie, they focus only on raw data collection), and these are not shown in Figure 5.

Figure 5. High-level information summary.

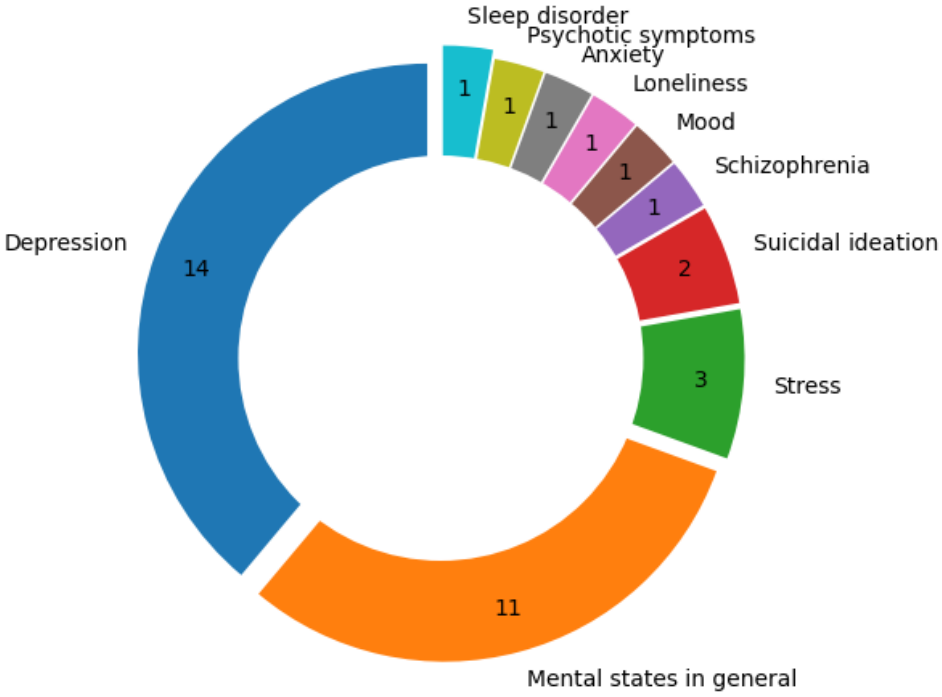


Support for Monitoring Mental Health (SA-RQ3)

The sensing apps identified used high-level information to provide a variety of mental health services. Table 3 shows the types of analyses performed based on the high-level information identified. Some apps infer daily routine situations and send recommendations in real time [58], thus aiming to provide tools to improve services of health professionals. Most approaches to support mental health monitoring were as follows: correlation, classification, and prediction. Correlation analyses associate features extracted from high-level information with mental states of the monitored individual, that is, they aim to find evidence that identified behaviors have significant correlations with psychological well-being [79]. Researchers also used identified behaviors to design ML models capable of classifying and predicting mental states [32,80], which can be used as decision support tools for health professionals. Lastly, some studies [31,81,82] did not report on additional analyses, but concentrated on describing the features of their sensing apps to facilitate DPMH research.

Figure 6 shows the mental states/disorders studied by DPMH research. Apps classified as "Mental states in general" did not focus on a specific mental disorder; instead, they are generic to be used in studies for different mental health disorders. We found 14 articles with a focus on individuals with depression. Other mental states/disorders are schizophrenia, mood, suicidal ideation, stress, loneliness, anxiety, and psychotic symptoms, all with between 1 and 3 studies returned in our search. We identified 11 articles that did not specifically address a particular mental disorder in their studies.

Figure 6. Mental states/disorders targeted by sensing apps.



Features Available in Data Sets (DS-RQ1)

The selected data sets have several types of features extracted from context data collected by sensing apps. These features model various aspects of human behavior that can be applied to the development process of new tools for monitoring and intervention in mental health. Table 4 presents the features available in the selected data sets. Data sets DS1 and DS7 contain features related to sleep. They provide information such as sleep start and end, sleep quality, time in bed, wake-up, sleep notes. Data sets DS4 and DS8 have features related to the social aspect such as self-reports of social interactions and Bluetooth encounter data, while data sets DS6 and DS8 provide actigraph data and self-reports, respectively. Data sets DS4 and DS5 have features capable of modeling more than 1 human behavior (ie, multimodal), thus providing data from different sources. These sources provide multimodal context data that can be fused to generate meaningful high-level information [10]. Moreover, multimodal data sets can support DPMH research under different aspects of interest for professionals, such as patient's mobility and sociability.

Possible High-Level Information Derived From Data Sets (DS-RQ2)

The selected data sets have features capable of modeling different types of human behavior. Therefore, to understand the potential for applying these data to DPMH, we identified high-level information that can be derived from these data sets based on the available context data. Table 4 presents high-level information inferred. Explicitly, these data sets can model the situations listed in Textbox 2.

Additionally, some data sets contain high-level information such as mood, mental status, and mental disorder symptoms. These types of information are self-reported by participants using questionnaires (eg, PHQ-9) and EMA solutions through smart devices.

Textbox 2. Situations modeled by data sets.

Sociability

This can be quantified using context data that allow characterizing social relationships of the participants such as interactions on online social networks, and face-to-face and device-mediated interactions [83]. These data sets contain context data such as posts on social networks, Bluetooth encounters, global positioning system (GPS) coordinates, or conversational activity inferred from microphone signals.

Physical activity

This is routinely measured using accelerometer and GPS data, resulting in either a log of user physical activities or an aggregate measure of energy expenditure.

Sleep

This is mostly measured in terms of sleep quality and sleep duration of the participants. In general, these data sets have features such as sleep quality, total sleep time, time in bed, and wake-up inferred from contextual data such as heart rate and screen on/off logs, and ambient light.

Multimodal

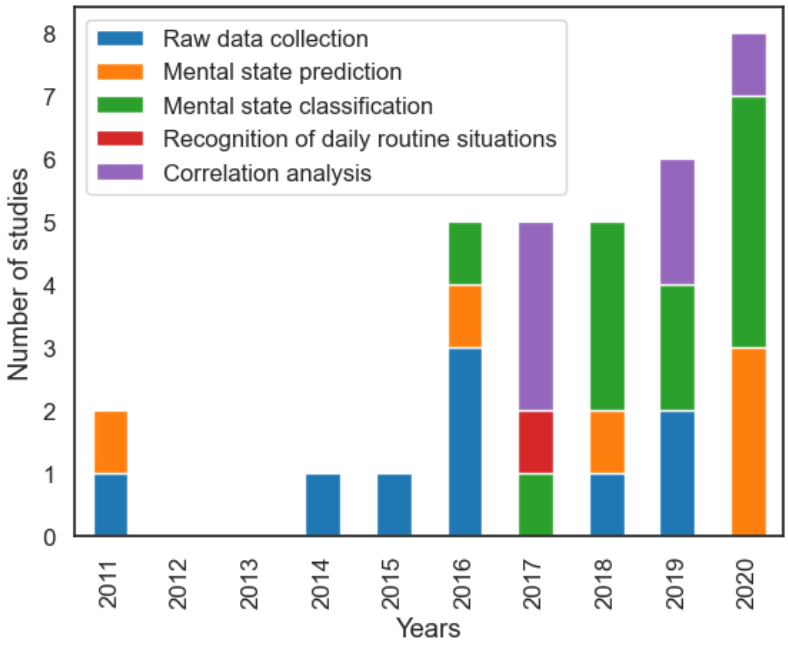
These data sets comprise several types of context data (eg, accelerometer, ambient light, battery level, Bluetooth, GPS, screen on/off, questionnaires [9-item Patient Health Questionnaire]), which allow characterizing more than 1 behavior of the participants such as sociability, mobility, and physical activity.

Discussion

Principal Findings

Our review shows that there are features that can be measured on smart devices that can act as proxies for mental status and well-being, but it should be noted that the combined evidence for high-quality features for mental states remains limited. Researchers have conducted several types of analysis on the data collected. In principle, we recognize a trend to design features from the data collected (Figure 7) to train ML models capable of classifying mental states/disorders (n=11) and predicting future mental states/disorders (n=6). We also note a substantial effort in analyzing correlations between features designed from the collected data and mental states/disorders (n=6). This type of analysis aims to find evidence of the viability and usefulness of DPMH for clinical practice. Furthermore, there are apps that only collect raw context data (n=9) to be analyzed subsequently, and 1 app (SituMan [39]) focused on the recognition of daily routine situations.

Figure 7. Number of published studies by year and types of analysis.



The literature mostly reports on the measurement of mobility, sociability, sleep, physical activity, and mood. Mobility represents high-level information derived from the movement sequence of individuals. These patterns are identified by processing GPS and Wi-Fi samples, which allow for the recognition of mobility traces. Sociability is measured using context data sources such as call logs, SMS text messages, Bluetooth encounters, and microphone data. These pieces of data allow identifying physical and virtual social interactions. Sleep information is measured by contextual data fusion such as ambient light, movement activity, screen on/off, and ambient sound. In addition, researchers have used Fitbit data to recognize sleep quality. Physical activity is recognized using data from inertial sensors (eg, accelerometer, magnetometer, gyroscope), making it possible to classify different types of activities such as walking, running, and stationary. Finally, mood has been

recognized using different context data sources, such as accelerometer and heart rate monitor of wearable devices, combined with self-reports.

The different ways in which these features are inferred and reported make it impossible to compare results across studies, or combine data sets to achieve greater statistical power. For this reason, we believe the research community would benefit from a clear standard on the measurement of these behaviors. The data sets identified and studies in this review provide an interesting starting point for such consensus building. Particularly, the StudentLife data set [41] has been explored by many studies that propose solutions capable of supporting mental health professionals. Different solutions have used this data set to detect human behavioral patterns and perform association, classification, and prediction of mental states. For example, by using the StudentLife data set, Saeb et al [80] analyzed the correlation between mobility patterns identified from GPS samples and depressive symptoms reported by students. Farhan et al [84] designed a multiview biclustering model using various features (accelerometer, screen state, light, conversation data, and GPS) to identify clusters representing behavior subgroups. Morshed et al [81] developed a computational method to predict mood stability from behavioral features (eg, frequency of conversation, number of location changes, and duration of different physical activities) extracted from accelerometer, microphone, GPS, and Wi-Fi. Recently, de Moura et al [82,83] developed a solution capable of detecting sociability patterns and routine changes in social event streams (ie, conversation events).

A related issue is the predominance of solutions developed for Android OS, for which all apps have a version. This is expected as Android provides an open development platform, different from iOS, with significantly more flexibility to gather the data of interest. The divergent approaches to sensing on iOS and Android yield further issues in terms of standardization and the collection of comparable results across large cohorts, invariably with both Android and iOS users.

Our review further shows that studies use a mix of smartphone-based sensing and wearable device sensing. The latter may be useful where smartphones do not provide quality data (eg, for heart rate, physical activity during sport, or sleep quality), but do pose an issue in terms of interpretability of data given the variety of wearable devices available on the market, each of which use different algorithms. The interpretability of resulting information is further confounded as some of the most popular devices use proprietary algorithms to measure the behaviors of interest or provide aggregate data. Standards would need to consider the commercial pressure for device manufacturers that results in algorithms being proprietary and thus making it difficult to compare information from different devices.

Regarding the year of publication of the studies, most articles (n= 9) have been published in the last 3 years (Figure 7). These data reveal a growing trend in the number of solutions proposed for DPMH.

Research Opportunities

From this review, we are able to identify different research opportunities for DPMH sensing apps, which are open issues for further investigation.

Wearable-Based Solutions

Raw data have been generated mainly in smartphones, so few sensing apps have taken advantage of the potential of wearable devices to produce monitored individual's data ubiquitously. Wearables are capable of providing a lot of useful information about human behavior [79]. For example, wearable devices such as smartwatches and wristbands can collect users' context data even when they are performing intense physical activities such as running and swimming. Therefore, as these devices are smaller, meaning more imperceptible to the user, they can enrich the physiological data collection [85].

Explainable Models With a Focus on Human Behavior

DPMH sensing apps that perform data analysis to design intelligent models have used traditional ML algorithms in different tasks [20]. These models sometimes lack transparency, which is not helpful for mental health professionals because evidence in decision support tools is required to be explainable. Although traditional ML models are very useful for generating valuable information that supports mental health treatment, an explanation of how they generate their outputs is desirable. This is fundamental because professionals need to interpret the patient's behavior to perform assessments and interventions. Therefore, explainable models [86] seems to be the way to apply machine and deep learning techniques more suitable to DPMH.

Real-Time Inference Engines

Most sensing apps perform offline data analysis after collecting raw data (eg, to create ML models, to correlate self-reports with context data). Therefore, few solutions provide inference engines to produce high-level information in real time. These generated situations of interest are useful to have a better insight into the patient's behavior and to allow interventions to adapt to this information in real time. This is crucial in extreme cases such as signs of suicidal ideation, but generally useful where the goal is to implement ecological momentary interventions or just-in-time interventions that rely on just-in-time information on user status. In this sense, both rule-based engines (eg, fuzzy logic [39], complex event processing [82]) and ML-based approaches [20] are promising tools to process context data efficiently and infer high-level information in DPMH.

Extensible Solutions

Sensing apps are not able to be customized for use in other research. Although general-purpose (eg, Sensus [35]) and reusable (eg, Beiwe [15] and SituMan [39]) apps can be applied to other research, none of the solutions identified in this review is extensible. Proposals of framework, middleware, and library are examples of extensible solutions that provide services, reusable code, and are prepared to be modified or consumed by apps. They would be very useful to allow DPMH researchers to extend solution's capabilities to different requirements. Therefore, this could reduce costs and time for research in specific scenarios.

By analyzing the results of the public data set review, we clearly identify the scarcity of data sets (n=8). This low number may be related to the privacy of information collected from study participants. DPMH researchers should possibly be concerned about whether collected data will become public, which could enable to identify participants from them. DPMH data sets may have sensitive personal information about the mental health treatment or monitoring, hence ethical issues arise [87]. Moreover, ethics committees where studies are recorded may restrict the sharing of collected data to the public. This barrier can generate great difficulty for the development of new research, because new ML models and engines for inferring high-level information are not possible to be designed and trained. Differential privacy seems to be a promising tool to break this barrier [88].

Another open issue is the standardization of data sets. Currently, there is no standard for data representation (eg, data type, precision, file format) and collection (eg, frequency, duration, presence of time stamps). As a result, data sets cannot be combined, nor can we easily compare the performance of different approaches or algorithms. Proposals for standardization would be a major contribution to the DPMH field.

It is beneficial for such standardization that there are efforts to design general-purpose sensing apps. We propose that the research community should endeavor to work on such apps collaboratively and make these apps available on a non-for-profit basis. This could not only result in an efficient use of commonly agreed standards, but would also reduce the wasteful effort of developing custom sensing apps. Such initiatives, however, are difficult to start and maintain, as has been shown by brave endeavors such as Beiwe [15], Funf [31], Purple Robot [33], and Sensus [35], which show that keeping such platforms up-to-date is an expensive process that can only be warranted if continued use guarantees continued resources for maintenance and further development.

Notwithstanding the benefits we believe would be derived from such standards, it should be acknowledged that self-reports will likely remain an important modality to improve the quality of automatically measured behaviors, or to measure behaviors or states that cannot be automatically measured. An opportunity that is not widely leveraged is using the automatically measured behaviors to trigger such self-reports. This would allow self-reports to be more appropriate to the user's context, further inform automated measures in case sensor measurements do not provide a clear enough picture, and be less intrusive. Software for such a functionality has been proposed previously [39,89], and we believe such a functionality should be part of standardized tools for capturing DPMH.

Finally, data sets are composed of few study participants. It may be difficult for researchers in attracting participants to the research and, at the same time, making them remain until the end of the study. The low number of participants can potentially compromise the use and validation of some data contained in the data sets, and this directly reflects the use of data sets in other DPMH surveys, where it requires a high number of participants to be validated.

Limitations and Future Work

A first limitation is that data sets and articles published in languages other than English were not included in this review. Second, the search for sensing apps was restricted to 8 digital libraries, although we searched 20 sources with numerous public data sets. Finally, our review is limited by studies reported in the published literature and data sets available to be downloaded.

In addition, we did not focus on security and privacy aspects of DPMH apps in this review. Therefore, our plans include a systematic analysis on the security and privacy features provided by DPMH apps. As this is an extremely sensitive aspect in the development of new functionalities for current and new DPMH mobile systems, a particular characterization with deeper analysis is required. Therefore, we plan to dedicate efforts on this topic for further investigation.

Conclusions

In this article, we described a systematic review that resulted in a deep analysis of 31 sensing apps and 8 public data sets for DPMH. Results showed a growth in DPMH sensing apps in recent years as opposed to a scarcity of public data sets. We answered the research questions, then showing, for example, the most used context data and their respective sources, the different types of high-level information generated by the analysis of the collected data, the features available in data sets, and the mental disorders that researchers have focused. From the results, we were able to identify trends and open issues that hinder the development of research in the DPMH area. As a consequence, by considering the growth in proposals for DPMH sensing apps and the impact of the COVID-19 outbreak on global mental health, we believe that DPMH presents a great perspective for future research not only to overcome open issues discussed in this review, but also to reach the needed maturity for application in clinical settings.

Abstract

Background: Simple visualizations in health research data, such as scatter plots, heat maps, and bar charts, typically present relationships between 2 variables. Interactive visualization methods allow for multiple related facets such as numerous risk factors to be studied simultaneously, leading to data insights through exploring trends and patterns from complex big health care data.

The technique presents a powerful tool that can be used in combination with statistical analysis for knowledge discovery, hypothesis generation and testing, and decision support.

Objective: The primary objective of this scoping review is to describe and summarize the evidence of interactive visualization applications, methods, and tools being used in population health and health services research (HSR) and their subdomains in the last 15 years, from January 1, 2005, to March 30, 2019. Our secondary objective is to describe the use cases, metrics, frameworks used, settings, target audience, goals, and co-design of applications.

Methods: We adapted standard scoping review guidelines with a peer-reviewed search strategy: 2 independent researchers at each stage of screening and abstraction, with a third independent researcher to arbitrate conflicts and validate findings. A comprehensive abstraction platform was built to capture the data from diverse bodies of literature, primarily from the computer science and health care sectors. After screening 11,310 articles, we present findings from 56 applications from interrelated areas of population health and HSR, as well as their subdomains such as epidemiologic surveillance, health resource planning, access, and use and costs among diverse clinical and demographic populations.

Results: In this companion review to our earlier systematic synthesis of the literature on visual analytics applications, we present findings in 6 major themes of interactive visualization applications developed for 8 major problem categories. We found a wide application of interactive visualization methods, the major ones being epidemiologic surveillance for infectious disease, resource planning, health service monitoring and quality, and studying medication use patterns. The data sources included mostly secondary administrative and electronic medical record data. In addition, at least two-thirds of the applications involved participatory co-design approaches while introducing a distinct category, *embedded research*, within co-design initiatives. These applications were in response to an identified need for data-driven insights into knowledge generation and decision support. We further discuss the opportunities stemming from the use of interactive visualization methods in studying global health; inequities, including social determinants of health; and other related areas. We also allude to the challenges in the uptake of these methods.

Conclusions: Visualization in health has strong historical roots, with an upward trend in the use of these methods in population health and HSR. Such applications are being fast used by academic and health care agencies for knowledge discovery, hypotheses generation, and decision support.

KEYWORDS

interactive visualization; data visualization; secondary health care data; public health informatics; population health; health services research

Introduction

Background

As digital medicine advances, visualization applications in population health increasingly provide ways for researchers and practitioners to explore and communicate findings [1], supporting knowledge discovery from disparate large data sources [2]. Visual analytics (VA) has been defined as the "science of analytics reasoning facilitated by visual interfaces" [3], and it is an interdisciplinary field combining visualization, statistical analysis, and advanced analytics such as machine learning and cognitive sciences [4]. A specific approach within VA is the use of interactive visualization, which Ola and Sedig [2] define as computational tools that store, process, and visually represent data, to facilitate interactive exploration. Interactive visualization increases the potential for big data use in health care by supporting sense making, knowledge discovery, and hypothesis generation [2,5]. Simple visualizations such as scatter plots, heat maps, and bar charts typically present 2 facets of the data, displaying attributes and relationships between 2 variables such as a disease condition and risk factors. Interactive visualization methods allow for presentation of multiple related facets such as risk factors to be studied simultaneously, leading to insights through exploring trends and patterns [2,5].

Population health research involves the study of data related to health outcomes and determinants of population health [6,7], whereas health services research (HSR) studies the health system in relation to access, quality, costs, and patient outcomes [8,9]. Both fields involve the analysis of large secondary data sources such as clinical databases, administrative data sets, and electronic medical records (EMRs) [10-12]. In a prior review, we summarized evidence on VA applications in these interrelated fields of health care [13]; this review complements it by reviewing the evidence on interactive visualization applications in population health and HSR.

Recent systematic reviews have summarized visualization methods in varied areas of health care. Among the most cited reviews, the study by West et al [1] synthesized literature on the use of visualization approaches for exploratory analysis of electronic health records (EHRs). Similarly, another well-cited review by Carrol et al [14] summarized the literature on visualization and analytics tools used in infectious disease epidemiology, particularly in relation to geographic information systems (GIS), molecular epidemiology, and social network analysis methods. Islam et al [15] offered a comprehensive view on data mining and theoretical approaches in health care. Wu et al [16] summarized evidence on visualization and analytic technologies for characterizing evaluation methods in health informatics, an area primarily concerned with clinical care. The

most recent related review by Chung et al [17] focused on visual approaches in mental health care policy and systems. To our knowledge, interactive visualization applications have not been studied as a body of literature separate from data visualization and VA; hence, this review is the first systematic synthesis on the subject.

Rationale for a Companion Review

This companion review is our second synthesis of literature on visualization and analytics tools, techniques, and approaches in population health and HSR. Our first publication focused on VA methods in these areas, where we offered an updated definition of VA in health care as "an approach, method, or application for analytic reasoning, exploration, knowledge discovery, and sense making of complex data, using one or more interactive visual interfaces, employing analytic and visual engines" [13]. As part of VA applications, analytic engines involve advanced machine learning, database querying, and manipulation.

Interactive visualization applications typically engage a front-end visual engine such as Tableau [18], Qlik [19], and PowerBI [20]. Although all VA methods carry a visualization component, which may or may not be interactive, interactive visualization applications typically do not involve or report an analytic component. Hence, this companion review on interactive visualization applications illustrates the state of evidence in population health and HSR, focusing on contemporary methods, approaches, tools, and co-design from real-world use cases. This review will be helpful for health care researchers, practitioners, and decision-makers to understand and adopt visualization-based data analysis.

Objectives

The primary objective of this scoping review is to describe and summarize the evidence on interactive visualization applications, methods, and tools being used in population health and HSR and their subdomains in the last 15 years, from January 1, 2005, to March 30, 2019. Our secondary objective is to describe the use cases, metrics, frameworks used, settings, target audience, goals, and co-design of applications.

Methods

Review Methodology and Protocol

Scoping reviews outline the size and scope of available literature and identify the quality and extent of research evidence [21]. We briefly describe the methodological processes relevant to the second part of the review in this section, whereas further details can be found in the published protocol [22]. We primarily followed the guidance provided by the Joanna Briggs Institute [23], as well as the framework for conducting scoping reviews described by Arksey and O'Malley [24], with improvements suggested by Levac et al [25] and Peters et al [26], while using the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist provided by Tricco et al [27] for reporting. The major steps were as follows: determining the research question, identifying relevant studies, abstracting data, and summarizing and reporting the results. The operational concepts and definitions are presented in Textbox 1.

Textbox 1. Operational concepts and definitions.

Concepts and definitions

- Population health, adapted from Kindig and Stoddart [6] and Kindig [7]
  - "The health outcomes of a group of individuals, including the distribution of such outcomes within the group," includes "health outcomes, patterns of health determinants, and policies and interventions that link these two"
- Health services research, adapted from the Canadian Institutes of Health Research [8] and National Libraries of Medicine filters for health services research [28]
  - Research with the "goal of improving the efficiency and effectiveness of health professionals and the health care system"
  - Access to services
  - Utilization of services
  - Cost of services
- Domains of population health and health services research, adapted from Islam et al [15]
  - Clinical populations include a health condition
  - Epidemiologic includes disease distribution and dynamics
  - Demographic includes population-related characteristics such as age and gender
  - Spatiotemporal includes events over time and space
- Problem categories, based on subject area and the aim or aims of the application
  - Epidemiologic monitoring or surveillance
  - Resources and services monitoring and planning
  - Medication use patterns
  - Visualization methodologies
  - Epidemiologic data exploration
  - Health service monitoring, planning, and quality
  - Patient or care pathways
  - Public or patient communication
- Interactivity, adapted from Ola and Sedig [29] and Pike et al [30]
  - Ability to reflect changes in the visual representation, based on one or more variables available on the analytic interface
  - Tasks such as filtering, determining ranges, and finding anomalies, clusters, and the like by providing menus, dropdowns, and other options on the visualization interface
- Tools
  - Software for developing an application
- Use case
  - Use of the application or method to one or more data sets
- Goal of the application, adapted from Islam et al [15]
  - Whether the application was meant for decision support, knowledge discovery, or both
- Analytic capability, adapted from Islam et al [15]
  - Descriptive or predictive analytics or visual exploration of data
- Functions of the visualization presentations from the Graphic Continuum by Schwabish and Ribecca [31]
  - Spatial
  - Change over time
  - Flow

- Distribution
- Ranking
- Magnitude
- Correlation
- Part to whole

- Co-design, adapted from Ward et al [32]
  - Encompasses the partnership of health workers, patients, and designers who aspire toward change, depending on shared knowledge to achieve "better outcomes or improved efficiency"
  - Whether any participatory approach toward co-design was reported by the authors
  - Embedded research: applications developed in response to an expressed need within a health care organization
- Settings and target audience
  - On the basis of the location of the application developed and the overall objectives of the reported application
  - Categories include academia, government health care units, and industry
- Subject of applications
  - Exploratory word frequency analysis of included articles to yield major subject areas for which applications were developed or any other related finding using a word cloud
- Applications in current use, public availability, innovation, and limitations
  - For ascertaining whether the application could be adapted or replicated in future
  - Public availability to ascertain whether the application was developed for the public

Eligibility Criteria

Eligible articles included peer-reviewed published journal and full conference papers in English related to use cases of interactive visualization in population health and HSR. We included articles on spatiotemporal visualization but excluded articles presenting cartographic methods and tools for GIS because these were outside the scope of the research objectives. Similarly, we did not include articles on human-computer interaction, user design, and articles without a use case. Non–peer-reviewed work such as editorials, conference abstracts, and short articles were excluded. The eligibility criteria are presented in Textboxes 2 and 3.

Textbox 2. Inclusion criteria.

Inclusion criteria

- Peer reviewed journal or full conference papers
- From January 1, 2005, to March 30, 2019
- Population health or health services research related
  - Articles with population level or health services research metrics: incidence, prevalence, events over time, and space, access, cost, utilization, disease or condition distribution, as well as social or multiple determinants of health
- Interactive visualization used for a use case with one or more data sets

Textbox 3. Exclusion criteria.

Exclusion criteria

- Articles not in English
- Editorials, projects, reviews, book chapters, short papers, or reports
- Articles on computer vision and medical imaging
- Studies conducted in clinical settings without a population level or health services component, such as from a single hospital or unit
- Articles on device or sensor data, without a population level or health services research component
- Studies reporting a visual analytics component or analytic engine

Sources of Evidence and Search Strategy

The search strategy, its conceptualization, and steps for operationalization are detailed in the review protocol [22]. The search was externally peer reviewed using the Peer Review of Electronic Search Strategies Guideline [33] and included an extensive list of search terms and their variants to cover all related concepts of population health, HSR, visualization, analytics, and interactivity [22]. The 6 databases searched, their platforms, and results are summarized in Table 1. We further hand searched 10 relevant journals, in addition to internet searches [22]. We used the Covidence (Veritas Health Innovation Ltd) platform for screening citations [34] and EndNote (Clarivate) for reference management [35].

Table 1. Databases and search results (N=14,099).

Database name	Search results, n (%)
MEDLINE (life sciences and biomedicine)	4633 (32.86)
Embase (life sciences and biomedicine)	1880 (13.33)
Web of Science (multidisciplinary)	5396 (38.27)
Ei Compendex (engineering and technology)	1267 (8.99)
IEEE Xplore (engineering and technology)	151 (1.07)
Inspec (engineering and technology)	772 (5.48)

Data Charting and Synthesis of Results

In all, 2 independent reviewers screened articles at each stage of the review, including title and abstract screening, full-text screening, and data abstraction. A third reviewer acted as an arbiter in case of conflicts and for validating the data abstracted for their content and level of detail.

The data abstraction encompassed the major concepts in 6 major themes: (1) study characteristics (country, problem category, settings, and target audience), (2) tools and techniques used, (3) data type and visualization methods, (4) domains of population health and HSR, (5) innovation of the application and its current availability and use, and (6) if the application was co-designed with the target audience.

Results

Selection of Sources and Presentation of Results

We identified 14,099 articles from the 6 databases searched. Given the varied sources of the articles, we adapted the method described by Bramer et al [36] for removing duplicate references using EndNote X9 [35]. Among the 14,099 articles, we considered major citation details and identified, double-checked, and removed 2078 (14.74%) duplicates, comparing the title, identifiers, publication platforms, and abstracts. From the remaining 12,021 articles, another 711 (5.91%) duplicates were removed after importing into Covidence [34]. We excluded 96% (10,819/11,310) of the references during the title and abstract screening and 89% (435/491) of the articles during the full-text screening. We did not find additional articles from reference lists of recent systematic and narrative reviews, hand searches of individual journals, and internet searches. Hence, of the initially identified 14,099 articles, we have summarized 56 (0.39%) for reporting in this review. The reasons for exclusion during the full-text-screening are detailed in the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram (Figure 1), whereas the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews reporting checklist is presented in Multimedia Appendix 1.

We have also summarized our results in a visual format using a publicly accessible Tableau dashboard, a screenshot of which is presented in Figure 2 [37]. The abstracted data and complete workbook are available to support replication, adaptation, and further analysis. Operational concepts for each category and reported theme are detailed in the *Methods* section (Textbox 1).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart for article selection. VA: visual analytics.

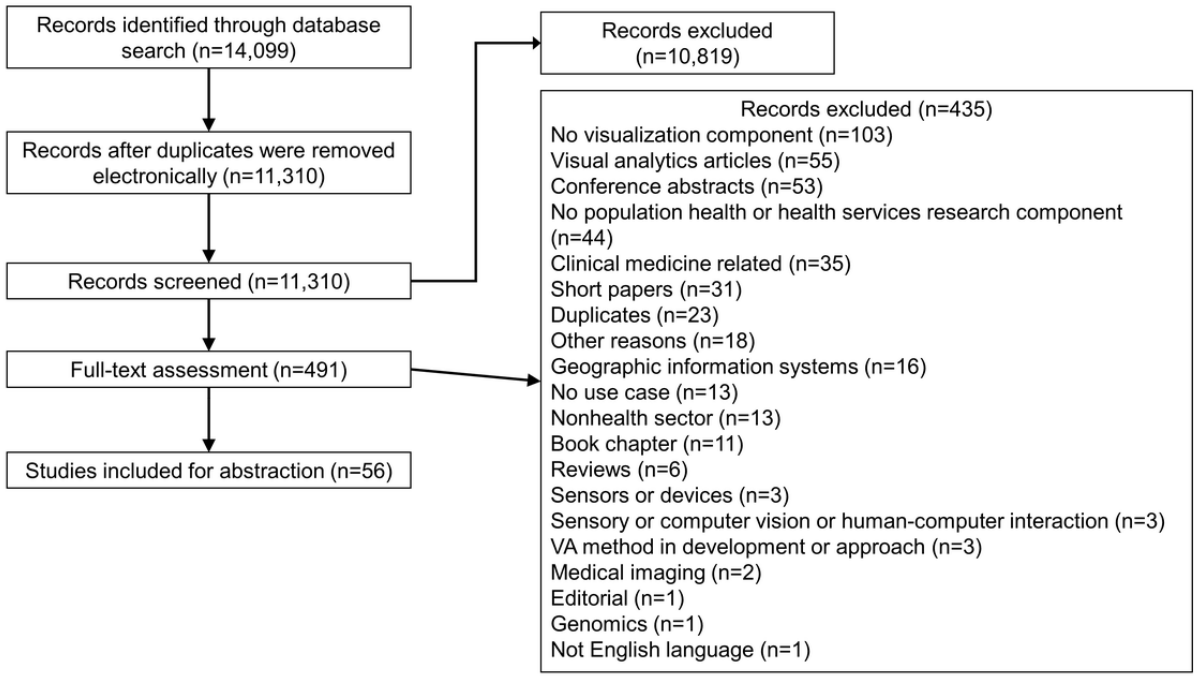

Figure 2. Screenshot of the results presented as a Tableau dashboard.

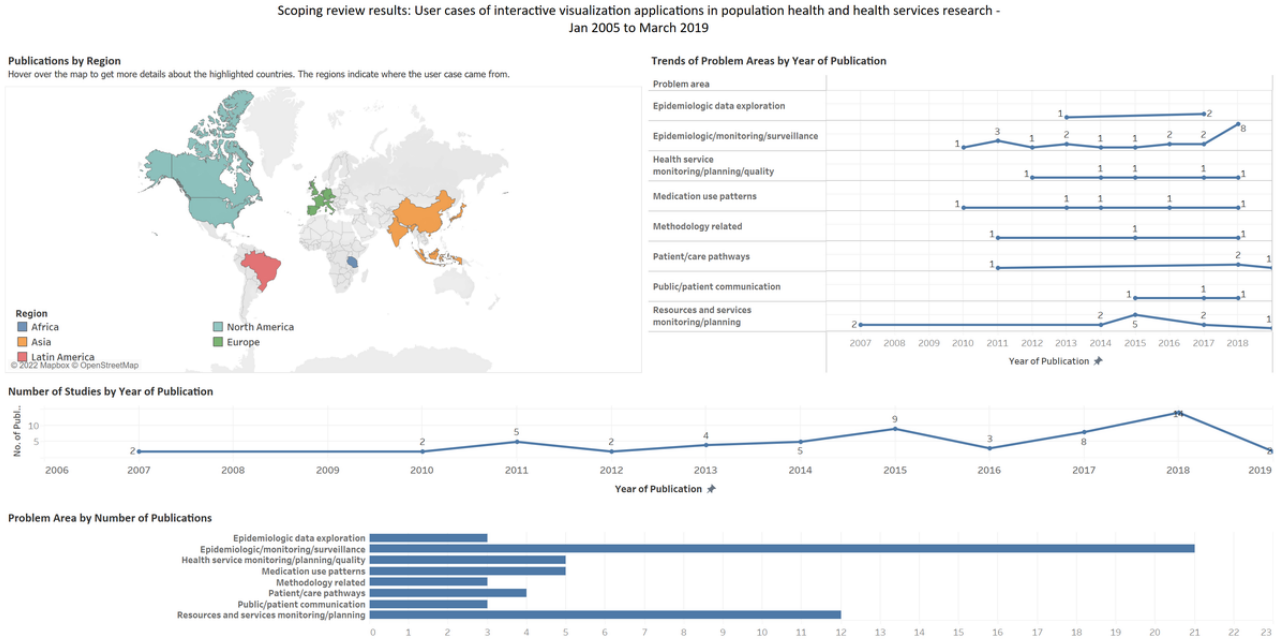

Study Characteristics, Settings, and Target Audience

The 56 articles summarized were from 21 countries, including the United States (30/56, 54%), the United Kingdom (4/56, 7%), India (2/56, 4%), Indonesia (2/56, 4%), and Canada (2/56, 4%). Of the 56 articles, there was 1 (2%) each from the Netherlands, Spain, Puerto Rico, Czech Republic, Malaysia, France, Portugal, Tanzania, Slovenia, China, Germany, Brazil, Italy, Japan, and Korea, whereas 1 (2%) study included a comparison of health indicators from the United States, the United Kingdom, Costa Rica, Sweden, Croatia, Japan, Hong Kong, and China. Details on countries, settings, and target audiences are presented in Multimedia Appendix 2 [38-93], whereas these are summarized in Tables 2 and 3. Study settings included government ministry or health unit (39/56, 70%), academia (18/56, 32%), and industry (2/56, 4%). There was overlap between the government health unit and academia (1/56, 2%) and between the government health unit and industry (2/56, 4%).

The included studies often had more than one target audience. These were population or public health practitioners (53/56, 95%), clinicians (24/56, 43%), policy makers and decision-makers (21/56, 38%), public and patient groups (12/56, 21%), data scientists (5/56, 9%), and industry (2/56, 4%).

Table 2. Settings of the studies (N=56).

Setting	Values, n (%)	Study
Government; ministry; health department	39 (70)	Alibrahim et al (2014) [38], Barrento and De Castro Neto (2017) [39], Basole et al (2015) [40], BenRamadan et al (2017) [43], BenRamadan et al (2018) [44], Bjarnadottir et al (2016) [46], Brownstein et al (2010) [47], Henley et al (2018) [52], Hosseinpoor et al (2018) [53], Jia et al (2015) [56], Kirtland et al (2014) [58], Ko and Chang (2018) [59], Kubasek et al (2013) [61], Lanzarone et al (2016) [62], Lopez-DeFede et al (2011) [63], Mahler et al (2015) [64], Marshall et al (2017) [65], Mitrpanont et al (2017) [67], Moni et al (2015) [68], Monsen et al (2015) [69], Monsivais et al (2018) [70], Mozumder et al (2018) [71], Pachauri et al (2014)[73], Palmer et al (2019) [74], Pike et al (2017) [76], Podgornik et al (2007) [77], Pur et al (2007) [78], Raghupathi and Raghupathi (2018) [79], Ratwani and Fong (2015) [80], Rodriguez-Fernandez et al (2016) [81], Rowlingson et al (2013) [82], Shen et al (2018) [84], Sims et al (2011) [85], Sopan et al (2012) [86], Toyoda and Niki (2015) [87], Valdiserri and Sullivan (2018) [89], van der Corput et al (2014) [90], Wang and Yao (2018) [92], and Zhang et al (2011) [93]
Academia	18 (32)	Becnel et al (2019) [41], Benítez et al (2017) [42], Bieh-Zimmert et al (2013) [45], Bjarnadottir et al (2016) [46], Cesario et al (2012) [48], Chui et al (2011) [49], Haque et al (2014) [50], Happe and Drezen (2018) [51], Hsu et al (2018) [54], Iyer et al (2017) [55], Kaushal et al (2018) [57], Krause (2015) [60], Martinez et al (2016) [66], Ortiz-Zuazaga et al (2015) [72], Pickle and Carr (2010) [75], Semple et al (2013) [83], Tsoi et al (2018) [88], and Wang et al (2011) [91]

Health Care Domains, Metrics, and Categories of Problems Addressed by the Applications

Among the domains of health, the categories overlapped, with articles falling under population health (38/56, 68%), HSR (29/56, 52%), and both population health and HSR (11/56, 20%). Among the articles in the population health category, their subdomains included clinical populations with 1 condition of interest (23/56, 41%), demographic population (28/56, 50%), epidemic monitoring and modeling (11/56, 20%), and spatiotemporal (16/56, 29%). For HSR, these included access to services (16/56, 29%), utilization (23/56, 41%), and costs (4/56, 7%).

The visual applications for these health care areas used different metrics in combination with the major categories, including prevalence (23/56, 41%), space and time (20/56, 36%), incidence (19/56, 34%), resources (6/56, 11%), mortality (4/56, 7%), hospitalization (1/56, 2%), events over time (1/56, 2%), and air quality (1/56, 2%).

The problem categories addressed by the applications included epidemiologic monitoring or surveillance (21/56, 38%), resources and services monitoring or planning (12/56, 21%), health service monitoring or planning or quality (5/56, 9%), medication use patterns (5/56, 9%), patient or care pathways (4/56, 7%), visualization methodologies (3/56, 5%), epidemiologic data exploration (3/56, 5%), and public or patient communication (3/56, 5%).

Application's Analytic Capability, Goal, and Frameworks Used

There was overlap in the analytic capability of the tools with applications capable of descriptive analytics (53/56, 95%), predictive analytics (4/56, 7%), and visual exploration of complex data sets (37/56, 66%). Regarding the goal of the visualization application, there was overlap between knowledge discovery (56/56, 100%) and decision support (47/56, 84%). Of the 56 articles, 6 (11%) used a framework in their methods for developing the application. These frameworks are summarized in Table 4. Multimedia Appendix 3 [38-93] lists the analytic capability and goals of each application.

Table 4. Articles mentioning the use of methodological frameworks (N=6).

Author and year	Methodological frameworks used in developing interactive visualization applications
Alibrahim et al (2014) [38]	Display principles for visual monitoring by Few et al [94]
Bieh-Zimmert et al (2013) [45]	Ten guidelines by Kelleher and Wagener [95]
Monsen et al (2015) [69]	Followed the Omaha System [96]
Ratwani et al (2015) [80]	Visualization principles (overview, zoom and filter, and details on demand) based on theories from Shneiderman [97] and Chen [98]
Semple et al (2013) [83]	For developing the web app, the 5-stage user-centered design model described by Kinzie et al [99] was used
Wang et al (2011) [91]	Align, Rank, and Filter Framework used for user interaction by Wang et al [100]

Data Characteristics: Source, Structure, Type, and Use Cases

Data sets used in the visualization applications were single (40/56, 71%) or multiple (16/56, 29%), and they were structured (48/56, 86%) or semistructured (8/56, 14%). The sources of data included administrative (45/56, 80%), spatiotemporal (17/56, 30%), EMR or EHR or medical records (15/56, 27%), registry (10/56, 18%), web or social media (2/56, 4%), and sensor data (1/56, 2%). Multimedia Appendix 4 [38-93] details the data types and sources with the primary tools used to develop the application.

Visualization: Primary Types, Presentation, and Tools

Regarding the functional aspects of the interactive visual presentations, the categories included spatial (31/56, 55%), change over time (9/56, 16%), flow (8/56, 14%), distribution (2/56, 4%), ranking (2/56, 4%), magnitude (2/56, 4%), correlation (1/56, 2%), and part to whole (1/56, 2%).

The primary visual presentations included choropleth map (19/56, 34%), thematic map (10/56, 18%), event timeline (7/56, 13%), network map (4/56, 7%), Sankey diagrams (3/56, 5%), area chart (1/56, 2%), parallel coordinates (1/56, 2%), column bars (1/56, 2%), circular weighted graph (1/56, 2%), line (1/56, 2%), dot strip plot (1/56, 2%), ring map (1/56, 2%), table (1/56, 2%), scatterplot matrix (1/56, 2%), bar (1/56, 2%), histogram (1/56, 2%), arc (1/56, 2%), and heat map (1/56, 2%). The relative distribution of visual presentations and software tools by problem category is provided in Figure 3. For details on the functional types and visual presentations included in each article, please refer to Multimedia Appendix 5 [38-93].

The different visualization software tools used included Tableau (7/56, 13%); D3.JS (5/56, 9%); ArcGIS and Instant Atlas (3/56, 5% each); R/R-Shiny, Open Street Map, Google Maps application programming interface (API), SQL, and Java-based application (2/56, 4% each); and MS Power BI, SigmaJS, RESTful API, CNGI, Lifelines2, AtlasPR, Circos, IBM Watson Analytics, SAS BI, Pajek, Gephi, pChart, Three Table View, Python, and QuantumGIS (1/56, 2% each). Some articles did not mention the visualization tool (13/56, 23%). Figure 4 shows a screenshot from the Tableau results dashboard with the primary visualization tools and heat map of problem category and visual presentation. This interactive dashboard is also available on the Tableau results dashboard [37].

Figure 3. Types of visualizations, primary software tool, and visualization type by problem area (screenshot).

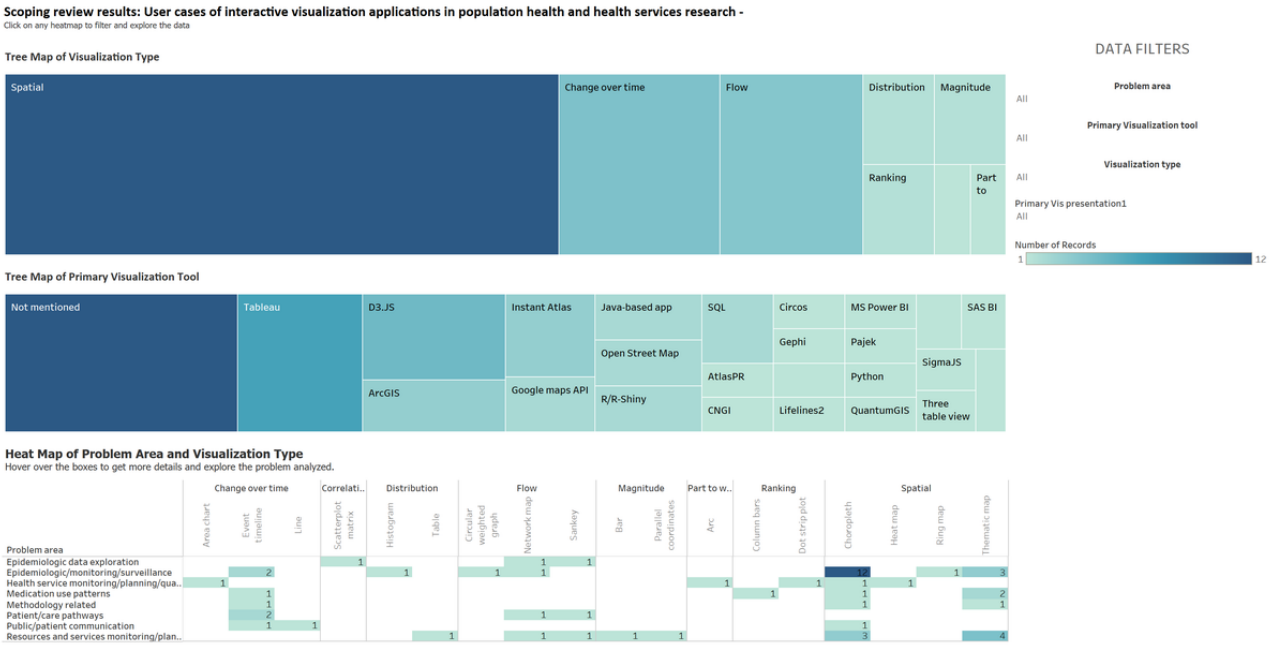

Figure 4. Primary visualization presentations by health care problem area.

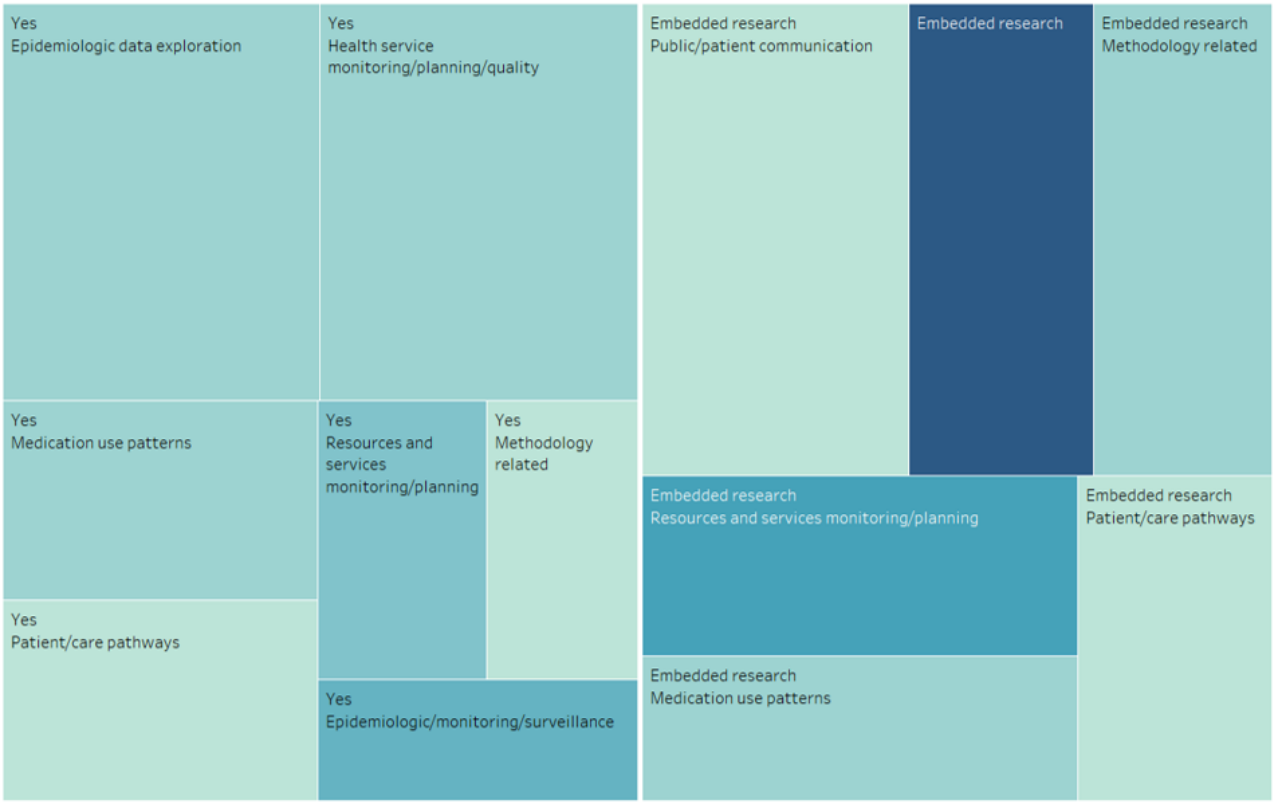
Application Co-design

For participatory approaches to application development, some articles (35/56, 67%) mentioned co-design. Among these (20/35, 57%) were applications that were part of embedded research at health care organizations. Other articles (20/56, 37%) did not mention this aspect. Application co-design was found in the problem categories of epidemiologic monitoring or surveillance (13/56, 23%), resource and service monitoring and planning (8/56, 14%), medication use patterns (4/56, 7%), visualization methodology (3/56, 5%), epidemiologic data exploration (2/56, 4%), health service monitoring or planning or quality (2/56,

4%), patient or care pathways (2/56, 4%), and public or patient communication (1/56, 2%). Figure 5 shows a tree map of co-designed applications and embedded research.

Figure 5. Co-designed applications and related health care areas (screenshot).



Applications in Current Use and Public Availability

Most of the applications were mentioned as being currently available and in use (31/56, 55%). Related to public access, a third of the applications were available to the public (18/56, 32%). There were applications using free or open source tools (18/56, 32%) and those using proprietary tools (19/56, 34%), or the tools were not mentioned (18/56, 32%).

Discussion

Significance of the Review

Data visualization in health has a lengthy history going back to the influential work of John Snow and Florence Nightingale in the 19th century. The field of interactive visualization has developed in parallel with computing power and the availability of large, complex health care data sets for diverse audiences such as clinicians, public health researchers, practitioners, and decision-makers [1,41], with considerable progress made in design methodologies [14]. Our review is a novel synthesis and summary of the literature from a vast body of research that had not previously been covered.

In this methodological review, we aim to capture the current state of knowledge and evidence on the topic of *interactive visualization applications* in population health and HSR, distinguishing them from conventional graphical presentations in health care and the related field of VA. We explored areas in population health and HSR to ascertain where these techniques have been used and identified trends and opportunities for the use of these applications.

As population health and health services researchers and practitioners, our perspective and interest in pursuing this research question were based on developing an in-depth understanding of the state of evidence on the use of visualization-based approaches for big health care data analyses. We anticipated that the review would help diverse audiences in population health and HSR learn from practical applications, inform future research endeavors, and help introduce the analytic method to researchers and students. We discuss our findings in this section with these overarching aims, contrasting the findings from previous reviews in other areas of health care using visualization approaches.

Gaps and Opportunities for Application Co-design

Data visualization aims to convey information *at a glance*, although it assumes that the audience has expertise and visual literacy on the subject matter [101]. In their review of visualization-based applications in infectious disease epidemiology, Carrol et al [14] summarize the audience's information needs and learning behavior and point to 3 important barriers to relaying information to target audiences: (1) time constraints, (2) prior knowledge, and (3) cognitive load [14]. Hence, the design process is imperative for an effective application that allows the user to successfully understand the presented data. Various methodologies outlining effective design requirements and experiences from stakeholders to create new products and solutions have been explored [102-104]. For our

scoping review, we opted to use the term *co-design*, which is more commonly used in health care literature, as opposed to *design thinking* and other related terms [13].

In this review, we found that at least two-thirds of the applications involved co-design approaches, involving stakeholders for developing interactive visualization applications. This was in contrast to a smaller proportion of co-designed VA applications (18%), which were mostly prototypes developed by and for data scientists at academic centers [13]. In line with this finding, more than half of the interactive visualization applications were developed in-house within health care organizations. We termed these initiatives *embedded research* as part of co-designed applications to indicate that these were initiated within the organizations in response to an identified data-driven need for knowledge generation and decision support. We could not find such applications in the VA literature [13]. This indicates an important trend because participatory design and development in health has proven to be a key element in better viability and uptake in planning and implementation of services [105,106].

Notably, a third of the articles in this review did not mention a co-design method, which could be due to authors either opting to omit it or because these were covered elsewhere. We recommend that future research indicate whether the application used co-design approaches. It is important to describe the context in adequate detail to appreciate stakeholder needs, experience, and satisfaction. Furthermore, to map and present methods in sufficient detail, we suggest using established frameworks such as the Munzner Nested Process [107] or Design Thinking for Visualization [108] as reporting tools.

Contrasting Interactive Visualization and VA Applications

Through our recent work in studying visualization methods and applications in population health and HSR, we establish that the fields of interactive visualization and VA share communities of practice, methods, and approaches, but they are conceptually separate with important differences. We highlight the major ones here.

We found that interactive visualization applications were initiated by and targeted at researchers and practitioners within government health care organizations tasked with health services delivery, planning, and policy advice. In contrast, most of the VA applications were from and developed for data scientists [13]. In addition, most interactive visualization applications were developed using front-end engines, especially proprietary tools not requiring an advanced knowledge of coding [13]. Most VA methods and applications were prototypes developed using different combinations of tools, with a very small number using proprietary software [13]. Related to theoretical or conceptual frameworks, VA applications offered 13 different frameworks, whereas we could not identify any of these in this review of interactive visualization applications. However, the latter applications mentioned the use of frameworks at different stages of developing the applications. VA applications also expressly mentioned statistical and machine learning techniques as part of the analytic engine, whereas interactive visualization applications mostly used simple descriptive aggregative techniques. In another distinction, most VA applications were prototypes, whereas most interactive visualization applications were developed for knowledge generation and decision support [13].

Both the VA and interactive visualization techniques seem to have originated from North America and Europe [13]. The top 3 countries identified for VA applications were the United States (24/55, 44%), Canada (5/55, 9%), and Germany (3/55, 5%). The top countries for interactive visualization applications were the United States (30/56, 54%), the United Kingdom (4/56, 7%), and Canada and Indonesia (2/56, 4% each). Both our reviews indicated that most of the applications for both methods were descriptive analytics, with an overlap with exploratory analyses of complex data sets (23/55, 42% for VA and 37/56, 66% for interactive visualization), and a small proportion for predictive analytics. The application goals were comparable, with most being knowledge discovery (35/55, 80% for VA and 56/56, 100% for interactive visualization) or decision support (44/55, 80% for VA and 47/56, 84% for interactive visualization), with considerable overlap (29/55, 53% for VA and 47/56, 84% for interactive visualization). The data sets used for both types of applications were single (32/55, 58% for VA and 40/56, 71% for interactive visualization) and structured (40/55, 73% for VA and 48/56, 86% for interactive visualization). There were no unstructured data sets used for interactive visualization applications. Both types of applications used a small number of semistructured data sets (5/55, 9% for VA and 8/56, 14% for interactive visualization).

As population health and HSR are overlapping concepts, many articles in both reviews overlapped with their foci, methods, and the metrics studied. Among the VA articles, almost all (54/55, 98%) had a population health focus, whereas a third (18/55, 33%) were on HSR. There was a smaller overlap among the interactive visualization applications, with approximately two-thirds (38/56, 68%) focusing on population health and approximately half (29/56, 52%) on HSR.

Comparing the subdomains of population health and HSR, the 2 major categories of articles in the VA review focused on spatiotemporal aspects (27/55, 49%) compared with approximately a third (16/56, 29%) for interactive visualization applications. The next largest subdomains in VA included clinical populations focusing on a condition or cluster of conditions (17/55, 31%) or epidemic monitoring and modeling (18/55, 33%). Among the HSR articles for VA, these were mostly for health services' utilization (15/55, 27%), access to care (10/55, 18%), or costs (2/55, 4%). Conversely, in the interactive visualization literature, the most common subdomain for population health was the study of a demographic population (28/56, 50%), followed by a clinical population (23/56, 41%), and epidemic monitoring and modeling (11/56, 20%). There was a similar trend toward the use of both interactive visualization in HSR, with the most common subdomains being health services' utilization (23/56, 41%), followed by access (16/56, 29%) and costs (4/56, 7%).

The categories of problems have important similarities and variations with epidemiologic surveillance for infectious disease being the major category that the applications targeted (38%

for both VA and interactive visualization). The next problem categories for VA applications were medical record pattern identification (20/55, 36%), population health monitoring (9/55, 16%), and health system resource planning (2/55, 4%). For interactive visualization applications, these included resources and services monitoring or planning (12/56, 21%), health service monitoring or quality (5/56, 9%), and medication use patterns (5/56, 9%).

Interactive visualization applications mostly used administrative and EMR or EHR data sources. This can be attributed directly to the availability of data within health care organizations. VA applications were developed using varied data sources, including administrative (19/55, 35%), EMR or EHR (17/55, 31%), spatiotemporal (16/55, 29%), social media (8/55, 15%), and simulation data (6/55, 11%); for interactive visualization applications, the data sources were secondary administrative data (45/56, 80%), social media (2/56, 4%), and sensor data (1/56, 2%).

Comparing tools in current use, about a third (21/55, 38%) of the VA applications were in use at the time of publication, whereas others were either not available or were prototypes. Moreover, a few (7/56, 13%) applications were accessible for public use, while less than a third were developed using free open source tools (13/56, 24%). Among the interactive visualization applications, more than half (31/56, 55%) were mentioned as being in current use, whereas about a third (18/56, 32%) were available to the public, and the same proportion were developed using free or open source tools. There was a greater proportion of use of proprietary tools (19/56, 34%) for interactive visualization applications compared only a 10th of VA applications (5/55, 10%).

The trend for the use of visual presentations was toward the use of different maps in both applications. Choropleth maps were the most frequently used for interactive visualizations (13/56, 24%), followed by thematic maps (10/56, 18%), event timelines (7/56, 13%), and network maps (4/56, 7%). VA applications showed a similar trend with thematic maps (17/55, 31%), timelines (8/55, 15%), and heat or choropleth maps (6/55, 11%). This corresponds to the findings of the review by Chung et al [17] on visualization methods in the area of mental health systems, which indicated that the most common means of presenting data was through maps [17].

Because of the differences in the methods involved in developing the applications, software tools varied greatly. VA tools were a mix of software tools used for the analytic and visual engines, whereas interactive visualization applications reported visual engines alone. However, there were still similarities in the use of tools. Tableau was the most frequently reported tool for interactive visualization applications (7/56, 13%), followed by D3.JS (5/56, 9%); ArcGIS and Instant Atlas (3/56, 5% each); and R/R-Shiny, Open Street Map, Google Maps API, SQL, and Java-based applications (2/56, 4% each). The most common tools found for VA applications were R-based tools (7/55, 13%), followed by D3.JS (4/55, 7%); SQL (4/55, 7%), Java-based tools (3/55, 5%); and Python-based tools, HTML 5, or Google Maps API (2/55, 4% each). Front-end visual engines such as Tableau were used by only 1 VA application in combination with Weka as the analytic engine.

Finally, an issue that we identified in both our reviews was the lack of reporting detail in the articles, which is important for the replicability and adaptation of the methods used in developing applications. We suggest using part of the VA Reporting Checklist that we presented in our previous work on VA, particularly around the details on the *visualization engine* for the standard reporting of interactive visualization applications [13].

Recent Trends of Using Interactive Visualization Methods

Our results showed that thematic mapping, including choropleth maps, was the most common visual presentation across all problem categories of population health and HSR. This was particularly the case for epidemiologic monitoring and surveillance. The recently created COVID-19 dashboards fall into the same category of applications [109]. Mapping also surfaced as a popular method for health resource monitoring, particularly for the planning of health care services [41,56,62,64,67,73,77,78,80,87,110,111].

Among different conditions of interest, a significant number of applications were developed for studying trends in cancer [43,44,52,61,71,88]. Being a worldwide population health issue, the greater use of interactive visualization methods in cancer could be due to the availability of dedicated registries and secondary administrative data [88]. In global health, applications focused on surveillance of communicable diseases [47], outreach campaigns [64], methods to examine health inequalities [53], and effects on health from global climate change [61]. In HSR, 6 applications directly or indirectly highlighted inequities in health, particularly in regard to effective planning and advising policy [43,53,63,70,82,89]. There was 1 article examining social determinants of health in HIV [63].

As two-thirds of the applications were focused on the visual exploration of complex data sets, this indicated a clear trend toward the use of this technique for exploratory analyses. Although most applications were meant for descriptive analytics and visual exploration of complex data sets, of the 56 applications, 4 (7%) were also capable of predictive analytics [39,68,71,93]. The methodological frameworks that were applied to developing the applications pertained to visual monitoring [38], level of detail in visual presentation [80], use of scientific publication visualizations [45], information management [69], user-centered web-based applications [83], and user interaction [91].

Opportunities for Future Applications and Research

Experts highlight the preference of researchers for interactive graphics to facilitate data exploration and abstraction, and they suggest greater, varied learning opportunities from the use of interactive visualization tools [14].

In comparison with standard, traditional statistical analyses, interactive visualization techniques can play an important complementary role through knowledge generation as well as establishing associations and causality. Interactive visualization

methods enable a *data* discourse, leading to in-depth data-driven insights, while having the advantage of improved perception with reducing cognitive load [2,5]. This interplay of direct data manipulation and analysis allows simultaneous study of trends and patterns in the analytic process, while formulating and testing hypotheses [13,112]. Furthermore, these methods are considered apt for studying correlations in high-dimensional data with a large number of time points [112]. This translates into a powerful technique for using big health care data, allowing a deep exploratory dive without an a priori hypothesis to identify data-driven trends and patterns.

In this review, although we observed various applications of interactive visualization, we found limited evidence of its use in global health. Given the massive open access data sets available from agencies such as the World Bank and the World Health Organization (WHO), research can focus on studying a plethora of population health and HSR indicators [113,114]. The WHO's Global Health Observatory provides population health–related data and statistics from 194 member states, particularly on nutrition, virological surveillance, workforce, and health systems, whereas the World Bank's open data repository features macroeconomic and social indicators such as gender and aid effectiveness. The methods can be helpful in ecologic studies, such as those comparing indicators across and within nations.

Related to this is another major opportunity for the use of interactive visualization in studying inequities, especially those rooted in social determinants of health. Although the social determinants of health have become a major focus for investigating structural inequities, we found only 1 article examining related aspects in the HIV sector [63]. Social determinants of health are defined by the WHO as "conditions in which people are born, grow, live, work and age...shaped by the distribution of money, power and resources at global, national and local levels" [115]. This is especially relevant for investigating structural inequities related to issues of access and use based on race, gender, disability, income distribution, and indigenous populations [116,117]. Taking Canada's example, investigating proximal factors for health among indigenous populations is one of the priority areas for improving health care [116]. Furthermore, high-quality Canadian data can be used to investigate inequities to better understand gaps in access and use of services by underserved populations. This can be done through national administrative data sources such as the Canadian National Ambulatory Care Reporting System, Discharge Abstract Database, and Hospital Morbidity Database, which store data for emergency and ambulatory care [118], as well as hospital inpatient discharges and day surgery [119].

Another major opportunity comes from the extension of using multiple data sources for studying patient journeys and care pathways. With the increasing use of EMR and EHR technologies, especially in primary care, there is an opportunity for researching patient populations along the continuum of care. Another such example is from the United Kingdom's Clinical Practice Research Datalink database, which forms the largest collection of anonymized primary care patient records [120]. In Ontario, Canada, the Electronic Medical Record Administrative Data Linked Database offers high-quality linked data for exploring trends and patterns in care and its provision with the advantage of capturing quality of care measures involving prescriptions and investigations [121].

In a recent review on visualization approaches for supporting mental health systems and policy research, Chung et al [17] indicate that there is a gap in studies that influence policy. Although policy was not our main area of focus for this review, the work indicates that there is an opportunity for informing and advising policy based on the use of big data, especially in the important area of mental health services.

Although the potential for the use of interactive visualization tools for bringing together disparate data sources is valued, there are related concerns for data interpretation, quality, accuracy, and handling [1,14]. Meeting the needs of diverse users and interdisciplinary teams as well as promoting the understanding of visual approaches are 2 related and important challenges to be cognizant of [1,14]. Researchers indicate that understanding the value of these techniques among health care organizations and public health agencies is key to realizing the potential of these methods regarding decision support [17].

Implications and Value-add From the Review

Our work is unique in several respects. Complementing our work on VA applications in population health and HSR [13], this review amalgamates the findings from studies on interactive visualization applications, while delineating the literature to construct a holistic picture on the use of visualization approaches in these areas of health care. Interactive visualization is an increasingly popular method, especially for embedded research within health care organizations. Although traditional statistical methods inform causality and associations of various conditions, interactive visualization presents a complementary opportunity for knowledge discovery, hypotheses generation, and decision support using big health care data.

As a novel method, we present findings from both our scoping reviews on VA and interactive visualization in a dynamic, interactive, and visual format using Tableau dashboards [37,122]. In the interest of greater transparency and replicability, we provide the abstraction database with relevant fields for adaptation and further analysis [37].

We highlight opportunities in areas of research that could benefit from visualization-based methods to promote the understanding and uptake of the methods among the communities of research and practice. This work would also prove useful in further developing visualization-related analytic methods.

Limitations

Although there are several important limitations that we are cognizant of in reporting this review, we made extensive efforts to identify relevant literature, delineate the body of literature on interactive visualization applications, incorporated rigor in our methods through all stages, and went through extensive steps toward validation to present our findings.

We cast a wide net in our literature search covering 6 databases, published the study protocol, and had our search strategy externally peer reviewed. However, we may have missed relevant literature residing in subject-specific databases such

as those of digital art, mathematics, geography, and computer science. In addition, our review was limited to peer-reviewed literature from journal articles and full conference papers, and we focused on health care–related databases. We did not include CINAHL and ACM Digital Library because we could not find unique articles, separate from MEDLINE and IEEE Xplore, during the pilot searches.

In addition, in line with the first review on VA, this literature synthesis is limited to articles published between January 1, 2005, and March 30, 2019. We situate and report the review within the same period as the one on VA applications to complement and contrast findings. Many COVID-19–related visualization products that surfaced later are not included in this review for both reasons of feasibility and the subject being extremely specialized and falling under *outbreak analytics*. However, we plan a rapid analysis of COVID-19–related visual products later in the year. Although we describe interactive visualization applications, we allude only briefly to the challenges in the use of these methods because this was beyond the scope of this review.

Conclusions

Visualization in health has strong historical roots. This systematic literature synthesis informs the state of evidence and trends toward the use of interactive visualization methods in the important and interrelated areas of population health and HSR. We note a significant trend in the use of interactive visualization applications being used in health care organizations, which we term *embedded research*. Such applications are being used by academic and health care agencies for knowledge discovery and generation, as well as decision support. Many of these applications have been co-designed with relevant stakeholders. Although we found a wide array of applications in different subdomains of population health and health services, there are multiple opportunities for the use of these methods in investigating global- and national-level indicators and social determinants of health, as well as constructing patient journeys for a holistic picture of the continuum of care.

Acknowledgments

This review is part of the doctoral work under JAC's Canadian Institutes of Health Research Health System Impact Fellowship 2018-19 and 2019-20. JAC, IAB, MCM, MI, AK, JSM, and LT are Health System Impact Fellows cofunded by the Canadian Institutes of Health Research and their host organizations. The Fellows' host organizations are mentioned in the author affiliations. SJ holds the Toronto Rehabilitation Institute Chair at the University of Toronto.

Authors' Contributions

All authors contributed significantly to the conceptualization and reporting of the review. JC, IAB, AB, and JSM mainly wrote and revised the manuscript in consultation with the others. SA, MB and MI contributed to data abstraction. MI and JC validated the abstracted data. JC provided conceptual guidance on the Tableau visual dashboards, whereas AB and SFAT contributed significantly to the co-design, usability testing, and revisions to present the results. All authors reviewed the manuscript and its subsequent revisions.

Abstract

Background: The need to include individuals with lived experience (ie, patients, family members, caregivers, researchers, and clinicians) in health research priority setting is becoming increasingly recognized. Social media–based methods represent a means to elicit and prioritize the research interests of such individuals, but there remains sparse methodological guidance on how best to conduct these social media efforts and assess their effectiveness.

Objective: This review aims to identify social media strategies that enhance participation in priority-setting research, collate metrics assessing the effectiveness of social media campaigns, and summarize the benefits and limitations of social media–based research approaches, as well as recommendations for prospective campaigns.

Methods: We searched PubMed, Embase, Cochrane Library, Scopus, and Web of Science from database inception until September 2021. Two reviewers independently screened all titles and abstracts, as well as full texts for studies that implemented and evaluated social media strategies aimed at engaging knowledge users in research priority setting. We subsequently conducted a thematic analysis to aggregate study data by related codes and themes.

Results: A total of 23 papers reporting on 22 unique studies were included. These studies used Facebook, Twitter, Reddit, websites, video-calling platforms, emails, blogs, e-newsletters, and web-based forums to engage with health research stakeholders. Priority-setting engagement strategies included paid platform–based advertisements, email-embedded survey links, and question-and-answer forums. Dissemination techniques for priority-setting surveys included snowball sampling and the circulation of participation opportunities via internal members' and external organizations' social media platforms. Social media campaign effectiveness was directly assessed as number of clicks and impressions on posts, frequency of viewed posts, volume of comments and replies, number of times individuals searched for a campaign page, and number of times a hashtag was used. Campaign effectiveness was indirectly assessed as numbers of priority-setting survey responses and visits to external survey administration sites. Recommendations to enhance engagement included the use of social media group moderators, opportunities for peer-to-peer interaction, and the establishment of a consistent tone and brand.

Conclusions: Social media may increase the speed and reach of priority-setting participation opportunities leading to the development of research agendas informed by patients, family caregivers, clinicians, and researchers. Perceived limitations of the approach include underrepresentation of certain demographic groups and addressing such limitations will enhance the inclusion of diverse research priority opinions in future research agendas.

KEYWORDS

social media; research priority-setting; knowledge user; scoping review

Introduction

Background

The need to meaningfully engage individuals with lived experience (ie, patients, family members, caregivers, clinicians, researchers, and other advocates; henceforth referred to as knowledge users) in the conduct of health research—defined as research that includes clinical and basic medical sciences, such as care-based research, systems research, and preventative research—is being increasingly recognized by the scientific community. In particular, it is recognized that these individuals should be included at the onset of the research process, with the aim of developing research that meets the needs of individuals with lived experiences [1]. In fact, the lack of involvement of these individuals in such research priority setting has been identified as a key contributor to difficulties in effectively translating research findings into clinical practice and policy [2].

In parallel, the use of social media—defined as any web-based platform or mobile app through which users can engage with others—is gaining considerable traction within the research community, as researchers increasingly access Facebook, Twitter, and YouTube to support participant recruitment and other research activities [3]. The benefits of research-related social media use include enhanced connectivity between researchers and participants and the potential for rapid diffusion of scientific knowledge to target audiences [4]. The nature of web-based survey methods may also enhance anonymity for participants within the research process, potentially promoting the collection of more valid data [5]. Particularly, data collected via the web may be less vulnerable to contextual biases that can arise in focus group settings or when researchers administer surveys in-person [5].

In light of such potential benefits, a growing body of literature describing the use of social media to elicit and prioritize research uncertainties from knowledge users is emerging [6]. However, there remains sparse methodological guidance on how best to conduct social media efforts and their corresponding effectiveness in developing knowledge user–built research agendas [7].

Objective and Research Questions

Through this knowledge user–driven scoping review, we aim to identify studies that implemented and evaluated social media campaigns that promote participation in setting priorities for health research to address three overarching research questions:

1. What social media–based strategies have been used to enhance knowledge user participation in health research priority setting?
2. What metrics (direct and indirect) have been used to assess the effectiveness of these social media campaigns in securing knowledge user participation?
3. From the perspectives of those conducting social media–based research priority-setting campaigns, what are the benefits and limitations of the method, as well as recommendations for future campaigns?

Methods

Overview

An internal protocol was developed for this review. Our reporting process was conducted in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for scoping reviews) guidelines [8].

Search Strategy and Selection of Studies

A comprehensive search strategy was developed in consultation with a tertiary hospital librarian (LR). We conducted tailored searches in PubMed, Embase, Cochrane Library, Scopus, and Web of Science. We searched all databases from their inception to September 14, 2021. Multimedia Appendix 1 shows the search strategy. Intradatabase and interdatabase duplicates were removed electronically. Using Covidence (Veritas Health Innovation), titles and abstracts were screened independently by 2 trained authors (KH and SS) according to our eligibility criteria. In cases of conflicting opinions on eligibility, studies were moved to full-text screening. Full-text articles were then screened independently by 2 authors (KH and SS). Any eligibility disagreements were resolved by consensus through discussion by at least three authors (AC, KH, SS, and LJ). The reference lists of relevant studies were also scanned to find other applicable papers.

Selection Criteria

We included studies (1) that discussed strategies to promote social media–based health research priority setting among key stakeholders and knowledge users and (2) measured the effectiveness of such strategies directly or indirectly. There were no restrictions on the language, country, and year of publication, nor the research content focus, as priority-setting research is cross-disciplinary. Although no explicit restrictions were placed on the language, the included studies were dominated by English language–based social media campaigns. We defined social media as any web-based platform or mobile app through which users can interact and engage with others. We defined knowledge users as patients (or potential patients), caregivers, clinicians, and other advocates (eg, health researchers). We excluded (1) studies where the purpose of the social media campaign did not include knowledge user engagement (eg, social campaigns used to disseminate smoking cessation information to knowledge users) [9]; (2) studies where the research prioritization campaign did not involve social media (dissemination techniques solely involved telephone calls, flyer distribution, etc); and (3) abstracts, dissertations, protocols, systematic reviews, scoping reviews, or case studies.

Data Extraction and Management

A standard electronic data collection form was created and piloted with our group, after which data extraction occurred independently (KH and SS). Discrepancies between the collected data were resolved through discussion with 3 authors (LJ, SS, and KH).

Data Analyses

We used descriptive statistics to summarize quantitative study data and an inductive thematic analysis to synthesize qualitative data [10]. Our data collection form was uploaded to NVivo (version 12.6.0; QSR International) for analysis and was read through multiple times by 2 authors (KH and SS) who had previous experience with thematic analyses. One author (SS) then coded qualitative text within the table on a segment-by-segment basis. At frequent meetings, a second author (KH) reviewed the coding decisions using a constant comparative approach adapted from Thorne [11]. As a group, we (KH, SS, and LJ) then collapsed these codes into subthemes and themes based on the between-code relationships and in accordance with our research questions.

Results

Overview

Figure 1 outlines our study identification process. Overall, 23 papers reporting on 22 unique studies were included in this review. The number of published studies increased steadily over time until 2020, which was the last complete publication year (Figure 2).

Included studies were conducted in 46 countries, most commonly in the United States (11/23, 48%), the United Kingdom (7/23, 30%), and Canada (5/23, 22%). Studies described participation by 13,640 individuals (median 332; range 31-4601), with sample size data missing from 4% (1/23) of the studies. Across studies, the median percentage of female participants was 77.28% (7404/9581). Sex data were missing from 52% (12/23) of the studies. Age data were variably reported and missing from 57% (13/23) of the studies; therefore, data were not collated. Sex data were missing from 39% (9/23) of the studies. Included studies used a variety of social media platforms to gather research priorities, including websites, emails, Facebook, Twitter, e-newsletters, web-based flyers, Survey Monkey, ExpertLens, blogs, YouTube, Choicebook, Instagram, WhatsApp, Snapchat, and web-based forums. The most common platforms used in the included studies were websites (12/23, 52%) and Facebook (9/23, 39%). The median length of a study's social media campaign, when reported, was 3.5 months (range 1-24 months). Table 1 summarizes the characteristics of the included studies.

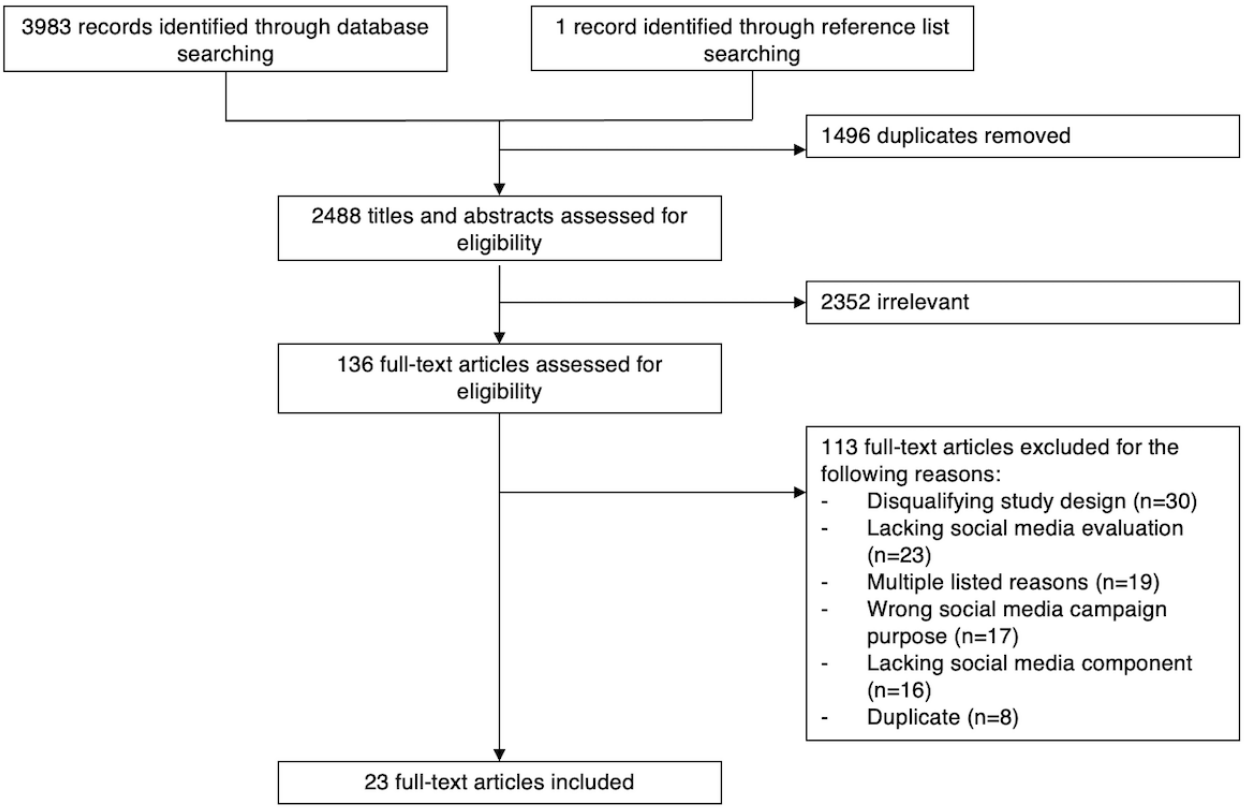

Figure 2. Social media–based research prioritization publication trend.

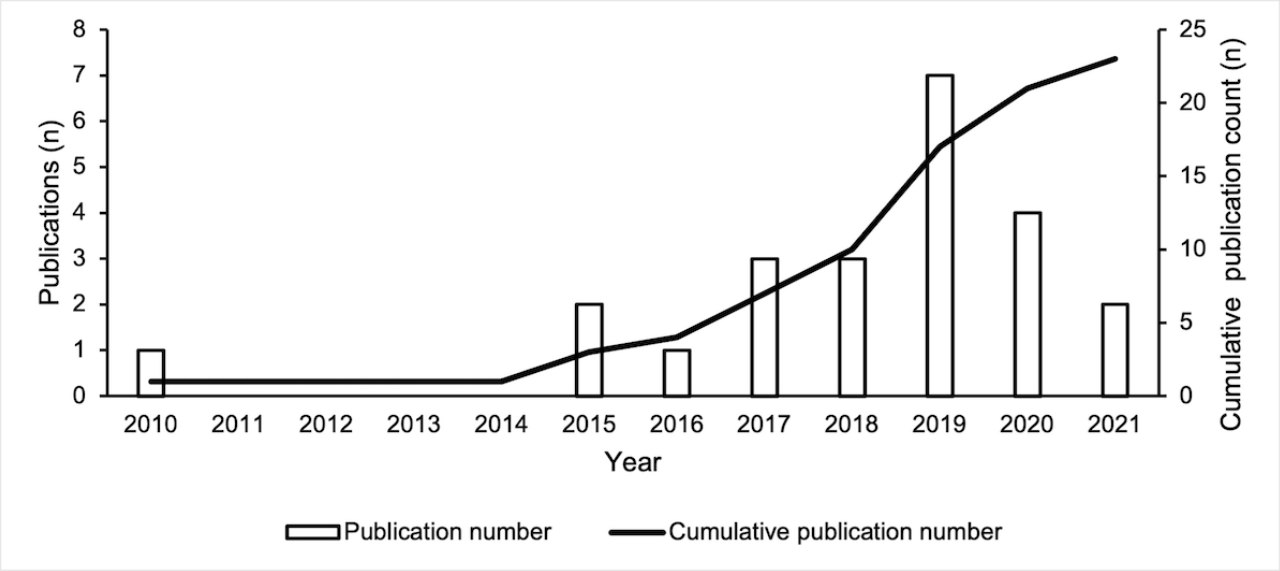

Table 1. Study characteristics (N=23).

Study	Year; country	Sample, N	Age and sex	Social media platform	Social media target group	Purpose for social media use	Duration of social media use	Social media outreach (eg, emails sent and posts made)	Social media analytics (outcomes)	Survey response rate	Outcomes of campaign in terms of research-priority gathering
Allsop et al [12]	2019; 32 countries within Africa	51	Not stated	Website and emails	Members of the African Palliative Care Association and individuals who work in palliative care	To identify (1) current mobile health use in palliative care, (2) potential barriers to use, and (3) priorities for research development	May to August 2016 (4 months)	101 organizations were emailed with web-based survey links	Not stated	51 (100%) survey responses (50.5% response rate)	Research priorities successfully identified
Correll et al [13]	2020; United States	365	Not stated	Website, emails, and other	Patients and caregivers of children (age ≥13 years)	To identify what research topics were most important to patients and caregivers of children with JM[a], JA[b], and cSLE[c]	November 2016, January 2017, and March 2017 for JM, AF[d], and LFA[e], respectively (5 months)	19,176 emails were sent	Not stated	441 survey responses	Research priorities successfully identified
Dyson et al [14]	2017; Canada and Portugal	110	Median age 35 years; 90% (99/110) women, 10% (11/110) men	Website, Facebook, and Twitter	Caregivers of children aged 0-17 years	To identify the outcome priorities of parents of children who had experienced an acute respiratory infection	December 2013 to March 2014 (4 months)	Creation of website, Facebook, and Twitter page or posts with embedded survey links	Website visits (5207); 3.9% view rate	110 (100%) survey respondents	Research priorities successfully identified
Dyson et al [15]	2017; Canada and Portugal	110	Median age 35 years; 90% (99/110) women, 10% (11/110) men	Website, Facebook, and Twitter	Caregivers of children aged 0-17 years	To identify the outcome priorities of parents of children who had experienced an acute respiratory infection	December 2013 to March 2014 (4 months)	Creation of website, Facebook, and Twitter page or posts with embedded survey links	Survey site visits (5027); Facebook page likes (104); and Twitter following (52 new followers)	110 (100%) survey respondents	Research priorities successfully identified

Study	Year; country	Sample, N	Age and sex	Social media platform	Social media target group	Purpose for social media use	Duration of social media use	Social media outreach (eg, emails sent and posts made)	Social media analytics (outcomes)	Survey response rate	Outcomes of campaign in terms of research-priority gathering
Eberman et al [16]	2019; United States	4601; 87 (1.89%) for focus groups, 4514 (98.11%) for survey	Age not stated; 55.05% (2533/4601) women, 43.40% (1997/4601) men, and 0.61% (28/4601) no indication	Newsletters via email	Athletic trainers	To identify research priorities and unify research with clinical practice to improve patient care and advance the profession	January 30, 2017 to March 16, 2017 (2 months)	48,752 emails were sent	Started the survey (5131, 10.5%); agreed to participate (4514, 9.3%); and completed the questionnaire (3910, 86.6%)	4514 (100%) research participants (9.3% response rate)	Research priorities successfully identified
Han et al [17]	2019; United States	332	Median age 51 years; 100% (332/332) women	Newsletters via web, website, Facebook, Twitter, web-based flyers, and emails	Females aged ≥18 years	To identify diabetes type 1 or 2 or prediabetes health research priorities	November 2016 to June 2017 (8 months)	904 website posts	Survey link clicks (421); comments on posts (904); total likes (530); total searches (167); and resource download (671)	332 (100%) research participants	Identified high priority research areas for women living with diabetes
Han et al [18]	2017; United States	332	Median age 49 years; 100% (332/332) women	Newsletters via web, website, Facebook, Twitter, web-based flyers, and emails	Females aged ≥18 years	To identify diabetes type 1 or 2 or prediabetes health research priorities	Not stated	551 emails were sent	Tag clicks (497); reposts and comments (872); voted for posts (540); searched for resources (167); and downloaded resources (671)	332 (100%) survey respondents (84% response rate)	The researchers identified 11 high priority categories of topics that were discussed on the DiabetesSistersVoices community

Study	Year; country	Sample, N	Age and sex	Social media platform	Social media target group	Purpose for social media use	Duration of social media use	Social media outreach (eg, emails sent and posts made)	Social media analytics (outcomes)	Survey response rate	Outcomes of campaign in terms of research-priority gathering
Healy et al [19]	2018; United Kingdom and Ireland	790	Age not stated; 71% (561/790) women, 28.98% (229/790) men	Website, emails, and Twitter	People invited to participate in a randomized trial or participated in Trial Steering Committees, front line randomized trials staff and investigators, and people familiar with trial methodology	To identify priority research questions related to trial recruitment	July 2016 to August 2016 (1 month)	Not stated	Not stated	790 (100%) respondents	List of top 10 trial recruitment uncertainties, determined by those directly involved in trials, were identified
Kim et al [20]	2018; United States	360	Age not stated; 60% (216/360) women, 40% (144/360) men	ExpertLens (ie, expert opinion forums), emails, and other	Patient, patient advocate, clinician, and researcher stakeholders	To determine engagement of stakeholders in research related to heart failure, obesity, and Kawasaki disease	18 months	Not stated	Not stated	84% response rate	Research priority successfully identified
Kriss et al [21]	2019; United States	207	Not stated	Email	Experts in global, regional, and national or subnational health	To identify research priorities for achieving disease elimination goals in the context of measles and rubella	October 17 to November 4, 2016 (approximately 1 month)	774 emails were sent	Not stated	207 (100%) respondents	Four main research priorities within the field of measles and rubella
Morris et al [22]	2015; United Kingdom	475	Not stated	Website, newsletters, and emails with embedded links	Children with neurodisability, caregivers, and clinicians	To identify and prioritize research questions regarding ways to improve the health and well-being of children and young people with neurodisability	Not stated	Creation of website and emails were sent with embedded links	Not stated	369 respondents (78% response rate)	Successfully established top 3 research priorities

Study	Year; country	Sample, N	Age and sex	Social media platform	Social media target group	Purpose for social media use	Duration of social media use	Social media outreach (eg, emails sent and posts made)	Social media analytics (outcomes)	Survey response rate	Outcomes of campaign in terms of research-priority gathering
Morse et al [23]	2021; United States	31	Mean age 15 years; 55% (17/31) women, 45% (14/31) men	Email and social media platforms (not specified)	Parents of children with medical complexity	To (1) ascertain parents' perceived characteristics of child pain experiences, (2) determine the extent to which parents feel that caregivers adequately address pain, and (3) identify ways in which pain collaboration between parents and caregivers may be improved	August 2018 to February 2019 (6 months)	Posting institutional review board–approved message on primary investigator's social media page	Social media post shares (n=30)	Not stated	Established research priorities
Normansell et al [5]	2015; United Kingdom	57	Not stated	Survey Monkey, Facebook, Twitter, website, and other	Patients, caregivers, and health care professionals with expertise in this discipline	To identify research priorities in asthma	August 6 to September 5, 2014 (1 month)	Not stated	"Obtained a large number of responses in a short timeperiod with potentially wide geographical reach"	Not stated	Developed a list of priority Cochrane Reviews
Oesophago-Gastric Anastomosis Study Group [24]	2020; United Kingdom	363	Not stated	WhatsApp and email	OGAA[f] committee, national leaders, and engaged clinicians from high-, low-, and middle-income countries	To prioritize future research areas of unmet clinical need in RCTs[g] to reduce anastomotic leaks	September to November 2019 (3 months)	Posted on organizations' social media accounts	Not stated	Not stated	Established research priorities

Study	Year; country	Sample, N	Age and sex	Social media platform	Social media target group	Purpose for social media use	Duration of social media use	Social media outreach (eg, emails sent and posts made)	Social media analytics (outcomes)	Survey response rate	Outcomes of campaign in terms of research-priority gathering
Rowbotham et al [25]	2019; worldwide	482	Not stated	Twitter	Patients, their caregivers, and clinicians	To identify research priorities for cystic fibrosis	March 2016 to January 2017 (10 months)	320 tweets	Twitter followers gained (n=732); total number of views (n=151,000); engagements with hashtag (n=1806); and followers (n=1160)	Not stated	Top 10 list for research in CF[h] was established
Russell et al [26]	2016; Canada	96	Not stated	Facebook	Family members of children	To exchange knowledge on project planning and research direction and translate research knowledge on disabilities and medical complexity	June 2014 to March 2015 (10 months)	432 Facebook posts were published	96 Facebook members; posts were generally seen by all group members; median likes (n=3); and comments (n=4)	49 respondents (51% response rate)	Provided researchers with an opportunity to consult families of children with special needs to receive guidance and hear issues that are important to them. Research priorities not identified
Salmi et al [27]	2020; United States	36	Not stated	Twitter, emails, blog posts, and Facebook groups	Patients with brain tumor and their care partners (ie, family members and friends who care for patients)	To describe the use of Twitter to complement in-person stakeholder engagement and report emerging themes from qualitative analysis of tweet chats on quality of life needs and palliative care opportunities for patients with brain tumor	April 2018 (1 month)	Two 60-minute scheduled live chat on Twitter	417 tweets by participants in first session and 355 tweets by participants in second session	N/A[i]	Research priorities, in the form of qualitative themes, were successfully identified

Study	Year; country	Sample, N	Age and sex	Social media platform	Social media target group	Purpose for social media use	Duration of social media use	Social media outreach (eg, emails sent and posts made)	Social media analytics (outcomes)	Survey response rate	Outcomes of campaign in terms of research-priority gathering
Shalhub et al [28]	2020; United States, United Kingdom, and Canada	300	Not stated	Blogs and website	Patients and their caregivers	To understand patient needs and determine the research methods best suited to study the adverse health implications associated with vascular Ehlers-Danlos syndrome	January 2018 and April 2018 (2 months)	Not stated	Facebook members in secret group (n=363) and Facebook followers (n=80,573)	Not stated	Optimal modality for research participation and methodologies for building trust in the research teams were identified
Shields et al [29]	2010; Canada	>800	Not stated	Choicebook, message board, blog, YouTube, Facebook, and email	Residents of and health service providers in northwestern Ontario	To engage the disperse population of northwestern Ontario in health care priority setting	Not stated	YouTube video welcome message; weekly blogs; and weekly participation update reports	“Hits” on website platform (n=2500); website views (n=2000); and >800 participants	Not stated	Findings identified new or additional research priorities for health network
Siefried et al [30]	2021; Australia	47	Mean age 42 years; 45% (21/47) women, 45% (21/47) men, and 5% (2/47) other or preferred not to say	Newsletter, emails with embedded links, Twitter, and website	Consumers, family, friends, caregivers, clinicians, researchers, policymakers, industry, research funders, institutions, organizations, law enforcement, border control, and other community members interested in the topic of methamphetamine	To identify clinical research priorities for methamphetamine and emerging drugs of concern in Australia, to guide the work of the National Centre for Clinical Research on Emerging Drugs	February 2019 to March 2019 (1 month)	Newsletter with embedded link were sent to mailing list and recipients of emails were invited to forward the email to other interested parties	Not stated	Not stated	Research themes and priorities were successfully identified

Study	Year; country	Sample, N	Age and sex	Social media platform	Social media target group	Purpose for social media use	Duration of social media use	Social media outreach (eg, emails sent and posts made)	Social media analytics (outcomes)	Survey response rate	Outcomes of campaign in terms of research-priority gathering
Sinclair et al [31]	2019; Croatia, France, Germany, Italy, the Netherlands, Poland, Portugal, Spain, and the United Kingdom	80	Mean age 38 years; 94% (75/80) women, 6% (5/80) men	ConnectE-people (e-forum), Facebook, YouTube, Twitter, WhatsApp, Snapchat, and Instagram	Parents of children with illness	To identify the research priorities of parents of children with Down syndrome, cleft lip or cleft palate, congenital heart defects, or spina bifida	Approximately 2 months	105 parents were invited to secret Facebook group	92% (74/80) of participants accessed the survey through social media and Facebook members (32)	54 (68%) respondents (51.4% response rate)	Top 10 list of research priorities were successfully identified
Sylvia et al [32]	2018; United States	4103	Age range between 18 and 86 years; 78.21% (3209/4103) women, 19.01% (780/4103) men	Website and web-based forums	Patients, caregivers, clinicians, and other advocates	To understand research topics that are of most interest to individuals with mood disorders	May 2015 to May 2017 (24 months)	Not stated	4103 (100%) users enrolled into the web-based community (via the website)	Not stated	Research priority agenda in the area of mood disorders were successfully identified

Study	Year; country	Sample, N	Age and sex	Social media platform	Social media target group	Purpose for social media use	Duration of social media use	Social media outreach (eg, emails sent and posts made)	Social media analytics (outcomes)	Survey response rate	Outcomes of campaign in terms of research-priority gathering
Wojcieszek et al [33]	2019; Australia, New Zealand, Africa, Asia, Europe, North America, South or Central America, the United Kingdom, and Ireland	79	Not stated	Emails with embedded link	Individuals involved in stillbirth research, clinical practice, and advocacy	To identify research priorities and explore potential methodologies to inform care in subsequent pregnancies following a stillbirth	June 2018 to August 2018 (1.5 months)	124 email invitations were sent	Not stated	79 (100%) respondents (64% survey response rate)	Five priority research topics were successfully identified

[a]JM: juvenile myositis.

[b]JA: juvenile arthritis.

[c]cSLE: childhood-onset systemic lupus erythematosus.

[d]AF: Arthritis Foundation.

[e]LFA: Lupus Foundation of America.

[f]OGAA: oesophago-gastric anastomosis audit.

[g]RCT: randomized controlled trial.

[h]CF: cystic fibrosis.

[i]N/A: not applicable.

Research Question 1: Social Media–Based Strategies Used

Table 2 shows the particular social media strategies used to enhance knowledge user engagement in research priority-setting exercises grouped by platform. Of studies using email as their primary social media platform [12,16,17,19,23,24,27,29,30,33] study teams emailed messages with embedded research prioritization survey links (including to researchers' existing mailing lists) and integrated tell a friend tool in emails to prompt recipients to invite colleagues to participate. Facebook-specific methods to engage stakeholders included embedding survey links within Facebook posts, using the platform's boosting feature (ie, paid advertisements), and hiring a Facebook advertising specialist. Informational Facebook pages were also used and involved private and public question-and-answer pages and a resource center with links to relevant documents [5,17,14-18].

Twitter-specific methods to engage participation included the use of hashtags within tweets and question-and-answer threads for prospective participants [5,14,15,17-19,25,31]. In addition, Salmi et al [27], hosted live chats on Twitter, in which host Twitter accounts tweet about predefined topics with questions during a set period, to which Twitter users respond via tweets and engage in discussions with each other. A web-based forum strategy led to the creation of a space where families and researchers could share ideas on the priority-setting research project [31]. Informational videos were created and hosted on YouTube for people potentially interested in contributing research priorities and were later posted on other platforms [28,29]. For studies involving blogs, researchers posted stories and internal updates related to the project to enhance interest in participation [28,29]. Studies also distributed e-newsletters to existing networks, sending them monthly to promote participation [16-18,28,30]. In addition, several studies used posts on Reddit and websites and web-based connection with the research team through video-calling platforms (eg, Skype, WhatsApp, or FaceTime or video chat on Facebook Messenger) to promote participation in priority-setting research [22,28,32].

Table 3 summarizes techniques to disseminate actual web-based research priority-setting surveys through social media. Snowball recruitment, in which current participants' friends and family were approached for participation, was used [14,15,29,30]. Study teams also provided partner organizations with toolkits, templates, and promotional materials [5,12,13,15,17,23,29]. Then, organizations could use these materials to support the

broadcasting of participation opportunities through social media. Individuals embedded in research prioritization exercises, such as steering group members, were additionally asked to promote the participation opportunity to their networks via social media [12-16,19,23,30], including by providing such individuals with preworded statements to tweet [19].

Table 2. Social media platform strategies.

Social media platform and specific strategy	Strategy description	Representative quotes	Studies providing evidence
Blogs			
Blog post stories	Posting insightful stories related to the priority-setting research project with the goal of promoting participation	• "Weekly blogs by the chief executive officer profiling stories that are particularly moving or insightful, as well as internal news on the project."	Shields et al [29]
Project news posting	Posting internal news or updates related to the priority-setting research project	• "Some organisations or individuals promoted the study on Twitter or a blog."	Dyson et al [14]
Emails			
Embedded links	Embedding survey links within emails to promote participation in the priority-setting research project	• "Invitations to participate in the research and a link to the online survey (in the relevant language) were sent via email. Those approached to complete the survey were identified using membership lists of the African Palliative Care Association (APCA)."	Allsop et al [12], Correll et al [13]; Han et al [18], Kriss et al [21], Siefried et al [30], and Wojcieszek et al [33]
Mailing list distribution	The use of an existing mailing list to promote participation in the priority-setting research project	• "A link to an initial electronic survey (created using REDCap) was emailed to members of Cure JM[a], AF[b] and LFA[c] patient and family members and posted on their respective social media sites. The ranking survey was emailed to the Cure JM, AF, and LFA listservs and a link was posted on their respective social media sites."	Allsop et al [12], Correll et al [13], Han et al [17], Siefried et al [30], and Wojcieszek et al [33]
Peer-to-peer dissemination	Using a *tell a friend tool*, which invites friends and colleagues to participate (peer-to-peer messaging) in the priority-setting research project	• "Tell a Friend tool to invite friends or colleagues to participate, using e-mail-based peer-to-peer messaging."	Shields et al [29]
Reminders to participate	Sending email reminders to individuals about the opportunity to participate in the priority-setting research project	"We sent an initial e-mail on Tuesday, January 30, 2017, at 12:00 PM EST to potential participants and, on subsequent Tuesdays between 10:00 AM and 12:00 PM EST, sent 5 weekly reminders to those who had not yet responded."	Eberman et al [16], Han et al [17], Kriss et al [21], and Wojcieszek et al [33]
Reminders to finish survey	Sending email reminders to individuals who began the survey but only partially completed it	• "Reminder emails were sent to non-responders and to individuals who began the survey but only partially completed it."	Kriss et al [21] and Wojcieszek et al [33]
Facebook			

Social media platform and specific strategy	Strategy description	Representative quotes	Studies providing evidence
Embedded links to create ease of participation	Embedding simple and direct links within Facebook posts to external sites related to participation in the priority-setting research project	• "Simple 'How to Participate' area that provided a visual menu of the ways to get involved, with simple links to take participants directly to the tools. Resource Centre page with access to links, documents and reports to help participants deepen their knowledge of the technical health challenges in the region."	Normansell et al [5] and Shields et al [29]
Engagement of advertising strategists	Hiring a Facebook advertising strategist to plan the social media campaign used for promoting participation in the priority-setting research project	• "Tactica Interactive, a digital media enterprise, was hired to broaden our sampling frame via a Facebook advertising strategy."	Dyson et al [15]
Providing participation explanation	Creating a Facebook section that explains how to participate in the priority-setting research project	• "Simple 'How to Participate' area that provided a visual menu of the ways to get involved, with simple links to take participants directly to the tools."	Dyson et al [15]
Use of private and public pages	Creating both public and private Facebook groups to allow private discussion among participants in the priority-setting research project	"Announcement of the vEDS[d] Collaborative survey was disseminated via vEDS public and private social media pages." • "Secret Facebook groups, providing optimal security, were set up for newly recruited research-aware parents (RAPs) to communicate privately and confidentially with each other and for the research team to generate questions and to interpret findings."	Dyson et al, [14], Shalhub et al [28], and Sinclair et al [31]
Providing project explanation	Creating a section on Facebook page dedicated to explaining the priority-setting research project and how participation could have an impact	• "'About our Project' section to provide participants with specific details on how their participation would affect the North West LHIN[e] decision-making and the second IHSP[f]."	Shields et al [29]
Question and answer	Using and moderating a web-based question-and-answer thread on Facebook to promote discussion topics regarding research participation	• "To encourage engagement and re-engagement, the site moderator used online question and answer threads to keep promoting new discussion topics and emailed a weekly topic to all the registered users to encourage them to come back."	Han et al [17] and Sinclair et al [31]

Social media platform and specific strategy		Strategy description	Representative quotes	Studies providing evidence
	Resource center	Creating a resource center with links to documents and reports on the Facebook page	• "'Resource Centre' page with access to links, documents and reports to help participants deepen their knowledge of the technical health challenges in the region."	Shields et al [29]
	Private and secret groups	Creating private Facebook groups to allow private discussion among participants in the priority-setting research project	• "Announcement of the vEDS Collaborative survey was disseminated via vEDS public and private social media pages"	Shalhub et al [28] and Sinclair et al [31]
Newsletter				
	Distribution through the researcher's existing network	Distributing newsletter to an existing network to promote participation in the priority-setting research project	• "To increase our reach and the likelihood of participation, the NATA[g] marketing team distributed our recruitment announcement and link to volunteers via the ''Range of Motion'' newsletter to all registered attendees 5 and 6 weeks before the conference."	Han et al [18], Eberman et al [16], and Siefried et al [30]
	Frequent promotion	Sending monthly newsletters to promote participation in the priority-setting research project	• "Social media promotion through Facebook and Twitter and monthly electronic newsletters from DiabetesSisters."	Han et al [18] and Han et al [17]
Web-based forums	Idea sharing	Creating forums through which families and researchers could share their ideas related to the priority-setting research project	• "Moderated online group where families and researchers can share ideas related to research."	Russell et al [26]
Reddit	Posting of promotional material	The use of Reddit as a social media platform used to promote participation in the priority-setting research project	• "Announcement of the vEDS Collaborative survey was disseminated via vEDS public and private social media pages."	Shalhub et al [28]
Twitter				
	Hashtags	Using Twitter hashtags to attract participants and generate conversation among relevant stakeholders	• "A bespoke Twitter account was set up @questionCF with the associated hashtag #questionCF. This was managed by members of the steering group and aimed to promote the online surveys and increase participation."	Rowbotham et al [25]
	Question and answer	Creating a post for inviting participants to ask questions about the priority-setting research project, which was moderated by steering group members	"A bespoke Twitter account was set up @questionCF with the associated hashtag #questionCF. This was managed by members of the steering group and aimed to promote the online surveys and increase participation."	Rowbotham et al [25]

Social media platform and specific strategy		Strategy description	Representative quotes	Studies providing evidence
	Live chats	Host Twitter accounts tweeting about predefined topics with questions over a set period, during a scheduled chat, to which Twitter users respond via tweets and engage in discussions with each other. Tweets from participants are limited to 280 characters and participants typically include an assigned hashtag in their tweet, thus allowing aggregation of the conversation.	• "The tweet chat hosts (@BTSMchat and @HPMchat, respectively) tweeted the 4 predefined topics (Table 1) with questions over a 60-minute period during a scheduled chat. The hosts alerted tweet chat participants that the transcript of the chat would be subject to qualitative analysis and used to inform research. One tweet question was posted roughly every 15 minutes. Twitter users responded to the questions and engaged in discussions with each other. On Twitter, responses are limited to 280 characters, and participants were instructed to add the #BTSM or #HPM hashtag to aggregate the conversation."	Salmi et al [27]
YouTube	Welcome video	Using YouTube to create a personal welcome message on Facebook pages, inviting users to participate in the priority-setting research project	• "On the site's home page, YouTube video personal welcome message."	Shields et al [29] and Shalhub et al [28]
Website	Posting of promotional material	Discussing the use of websites with survey as a social media platform used to promote participation in the priority-setting research project	• "We created an online and social media presence via a study website (Outcomes in Child Health)..." • "We collaborated with organisations interested in ARI[h] and patient engagement to advertise our research via websites and other channels..."	Allsop et al [12], Dyson et al, Normansell et al [5], and Sylvia et al [32]
Video calling	Digital connection to promote participation	Discussing the use of video-calling or internet-based face-to-face interactions to promote participation in the priority-setting research project	• "Discussed details about the project and the parents' research needs through face-to-face social media platforms such as Skype, WhatsApp, FaceTime, or via video chat on Facebook Messenger to build trust."	Sinclair et al [31]

[f]N/A: not applicable.

Research Question 2: Measurement of Social Media Campaign Effectiveness

Across all the 23 included studies, 21 (91%) claimed to be successful in conducting health research priority-setting exercises via social media–based methods.

The direct effect of social media campaigns in securing stakeholder participation in research priority-setting was assessed as the (1) number of survey responses [12,14,15,20,33], (2) number of survey responses within a set period [14,15,20,33], (3) proportion of surveys fully completed [21], and (4) number of visits to external survey administration sites [14,15].

Indirect metrics for campaign effectiveness were (1) audience reach (ie, extent to which the survey sample was characteristic of the target population [13-15], number of countries and local communities represented in the sample [12,21], and number of national associations and external organizations contacted [12]);

(2) campaign interaction (ie, number of clicks and impressions on posts [14,15,18,23,25,27], frequency of post views [26], volume of comments left by target stakeholders [26], number of searches for campaign pages or downloads of resources [17,18], number of bespoke hashtag clicks or uses [25,27], and Google Analytics [18]); (3) participant satisfaction [17,28,31]; and (4) platform-specific methods (ie, number of website views or likes [12,14,15,17-19,21,29], number of registered participants in an email chain or total number of delivered emails [12,13,16,19,21,29,33], new followers and likes on Facebook pages [14,15,17,18,26], and Twitter followers gained [14,15,25]).

Research Question 3: Benefits, Limitations, and Recommendations

Benefits and Limitations of Social Media–Based Research Priority Setting

All included studies (23/23, 100%) successfully gathered research priorities from key stakeholders and knowledge users using social media–based participant recruitment. Cited benefits related to social media use were the capacity to elicit participation from many knowledge users [14,15,17,18,27,31], the speed at which research priorities were gathered, the sense of community developed [17,31], peer-support offered to patients and family members [17,26,28,31] by social media campaigns, and the capacity for dissemination of health-promoting resources from health care professionals to patients. A cited limitation of social media–based methods was that web-only methods may limit the participation of individuals with limited or no access to technology, limited leisure time to engage with social media, and lower socioeconomic status and of older age [12-15,17].

Recommendations for Successful Social Media–Based Research Priority Setting

To improve the effectiveness of social media campaigns, authors recommended focusing on the campaign's graphic design components and style of messaging [26,31,32], creating opportunities for the target audience to personally interact with the team leading the campaign [31], and using platform-specific paid advertisements (ie, also termed *boosts*) [18,28].

Design-related recommendations included implementing illustrative and graphical sophistication, such as posts containing words, text, and video [31] and establishing a tone and style of graphics to create a consistent brand [26,32]. Messaging recommendations were to post some content that is not directly related to research, but of interest to community members—especially if these posts are community-led [22,26,31]; to avoid phrases that do not foster inclusivity and may separate the researchers from the target audience (ie, *us* vs *them* semantics); and to minimize scientific jargon in posts. Interaction-related recommendations involved using moderators [17,26], especially community members to build the authenticity of the campaign [27]; initiating conversations with perspective participants to *break the ice*; using software that supports face-to-face interaction between researchers and the community [31]; allowing peer-to-peer sharing (ie, providing community members with capacity to invite colleagues to participate) [17,22,26,28,29,31,33]; and using platform-specific boosts (eg, Facebook boosts) [18,28]. This last strategy corresponded with the highest recruitment and enrollment yields.

Recommendations to address the limitation that social media may prevent priority-setting participation by some groups were also suggested. These included implementing a hybrid of electronic and nonelectronic survey dissemination methods to increase the representation of those without access to technology [12,17,18], developing web-based materials with simple navigation requirements to allow participation by individuals with less experience with the web [30], and intentionally tailoring social media strategies (eg, hashtags and boosts) for subpopulations of individuals whom study teams identify as being underrepresented in research prioritization project data sets [13-15,17,21,25,32].

Discussion

Principal Findings

Recognizing the importance of engaging key stakeholders in developing research agendas, we sought to use the extant literature to understand how social media might support research priority-setting, how effectiveness of the method might be measured, and the method's benefits and drawbacks. We show that multiple social media strategies, which differ depending on the social media platform, have been used to promote participation in research priority setting—with strong success rates in generating research agendas. Metrics to quantify the reach of these strategies included the number of impressions on posts (eg, likes and other reactions) and the volume of comments left by stakeholders. In addition to the benefits, limitations of the use of social media in research priority-setting were also identified. Results from this review can guide methods for research priority-setting by patients, family caregivers, health care professionals, and other advocates and support the engagement of these stakeholders in developing future research agendas.

Social Media Platform Strategies and Dissemination Techniques

Social media–based strategies that incorporated platform-specific amplification (eg, Facebook boosts) and components that encouraged active engagement by participants (eg, question-and-answer forums and shared resources) enabled researchers to reach a broad audience of possible participants. This finding agrees with the literature showing that Facebook [34] health promotion posts receiving a paid boost reached significantly more users. Hashtags were also used in the included studies to increase visibility of tweets, which aligns with previous research showing hashtag use as effective in influencing social media conversations related to mental health [35] and in cases where the desired participant pool is small [36].

Our finding that snowball sampling is used to disseminate priority-setting surveys and expand participant pools aligns with other research showing that options to like, tag, or share posts expand a social media campaign's reach [37]. This method may be particularly advantageous in cases where the campaign target

audience is a specific and relatively small group (eg, people with lived experiences of less common diseases) and campaign participants may have contacts within their social network who they can engage in the process. Our results also suggest that there are priority-setting advantages in asking relevant external organizations and internal research and clinical team members to circulate survey links and use their personal or organization-affiliated social media accounts to expand reach.

Measurement of Social Media Campaign Effectiveness

We identified several metrics used by researchers to evaluate the effectiveness of social media campaigns, including the number of post impressions, frequency of viewed posts, volume of comments left by stakeholders, and number of times a bespoke hashtag was clicked or used. The heterogeneity in metrics likely reflects the exponentially growing number of social media platforms. However, the collection and interpretation of these social media impact metrics support ongoing consideration of the campaign's effectiveness and subsequent content adjustments to maximize campaign reach and engagement [35].

Benefits and Limitations of and Recommendations for Social Media Campaigns in Research

Commonly identified benefits of priority-setting via social media include the speed at which participation opportunities can be disseminated and the capacity to build a sense of community among participants—possibly enhancing engagement. Research has also indicated that social media may be particularly useful in targeting information at some rarely reached groups such as individuals with depression [38]. In addition, moderators might humanize the campaign, build possible participant's trust, and enhance campaign engagement by these individuals [39].

In contrast, limitations of social media–based methods for priority-setting research include the uncertainty of who is being captured through the posts [40]. Our study found that researchers commonly cite fears that social media–based methods may unexpectedly include or exclude the research priority perspectives of certain groups. In these cases, there are limited ways to assure that the recruited team of participants is the valid group of people that will render reliable results. This is problematic from ethical and methodological (ie, sampling bias) points of view and its mitigation requires careful planning. Moreover, when survey links are disseminated via social media, the true number of individuals that are reached cannot be calculated. This is because not all users will engage (ie, like, comment, and share) with the post [13,20]. In addition, although the platform analytics (ie, number of follows, comments, and likes on posts) are often used as an indication of survey engagement, these data may not be representative of the sample that opens the survey link or completes the survey.

Recommendations were also made to establish a consistent tone and branding, with a focus on using attractive graphic designs within priority-setting research campaigns. This consistency may increase the recognizability of the research project and authenticity to the effort, resulting in increased participation in priority-setting research efforts [41].

Limitations of Our Study

The definition of social media varies substantially in the literature and some definitions used did not meet our inclusion criteria. Our conclusions regarding the recruitment for priority-setting research projects may differ from those arising if a different definition was used. Varying definitions of *social media* may also have rendered our decision-making process during the screening phase susceptible to error. However, we screened in duplicate with good consistency and used third-party arbitration of discrepancies. Finally, amid the COVID-19 pandemic, the number of studies adapting to web-based research methodologies, especially using social media, may have increased after the search strategy was performed. Considering such rapid growth, it is important to note that this review is a snapshot at a particular point in time that does not account for novel methods that may have emerged after our search.

Recommendations for Practice and Future Research

Social media appears to be an effective means to recruit and involve participants in the research process. Thus, researchers should consider using web-based social networking as a method to recruit knowledge users, collect data, and translate knowledge into practice. The study team's efforts to build knowledge user trust in prioritization efforts, including by humanizing the campaign through moderating chats and engaging with participants, may improve engagement. On the basis of our findings, efforts can be supported by optimizing the visual representation of data through illustrative posts containing text and graphics. Moreover, to enhance participation by a wide group of knowledge users, researchers should focus on developing accessible and inclusive web-based materials. In addition, investing in platform-specific boosts (eg, Facebook boosts) and paid advertisements may be an effective tactic to enhance participant recruitment and enrollment.

Given the relatively recent emergence of digital platforms, social media–based methods are understudied compared with traditional recruitment means. We have identified some possible limitations of the method, such as potential limited access to individuals of lower socioeconomic status or older age. However, few studies have determined the extent to which these limitations impact prioritization efforts and, in the case of older adults, contrary evidence exists indicating good engagement with social media and technologies [42]. Should the identified limitations of social media–based priority-setting be significant, research into ways to mitigate these shortcomings is needed. Further research is needed to understand how to enhance the capacity of social media recruitment to capture representative samples. More research is also needed to understand which social media strategies and dissemination techniques are likely to be successful for research prioritization efforts, with the understanding that these strategies and techniques are likely to change over time as new social media platforms and features become available. Finally, given the highly public nature of information exchange on social media, considerations of the data privacy and security implications of social media–based research prioritization efforts are needed.

Conclusions

In this review, we synthesized the rapidly emerging data assessing the effectiveness of social media strategies to engage knowledge users in research priority-setting efforts across several social media platforms. The benefits of social media–based recruitment included the speed at which participation opportunities can be disseminated and the sense of community built among participants. As it is likely that social media–based research methods, including for research priority-setting, will be increasingly used by the scientific community, lessons and recommendations from this review can support scientists to more fully engage those who are most impacted by health research in setting associated research agendas.

Abstract

Background: Studies have shown a high prevalence of depression during pregnancy, and there is also evidence that cognitive behavioral therapy (CBT) is one of the most effective psychosocial interventions. Emerging evidence from randomized controlled trials (RCTs) has shown that technology has been successfully harnessed to provide CBT interventions for other populations. However, very few studies have focused on their use during pregnancy. This approach has become increasingly important in many clinical areas due to the COVID-19 pandemic, and our study aimed to expand the knowledge in this particular clinical area.

Objective: Our systematic review aimed to bring together the available research-based evidence on digitalized CBT interventions for depression symptoms during pregnancy.

Methods: A systematic review of the Web of Science, Cochrane Central Register of Controlled Trials, CINAHL, MEDLINE, Embase, PsycINFO, Scopus, ClinicalTrials.gov, and EBSCO Open Dissertations databases was carried out from the earliest available evidence to October 27, 2021. Only RCT studies published in English were considered. The PRISMA (Preferred Reporting Items of Systematic Reviews and Meta-analyses) guidelines were followed, and the protocol was registered on the Prospective Register of Systematic Reviews. The risk of bias was assessed using the revised Cochrane risk-of-bias tool for randomized trials.

Results: The review identified 7 studies from 5 countries (the United States, China, Australia, Norway, and Sweden) published from 2015 to 2021. The sample sizes ranged from 25 to 1342 participants. The interventions used various technological elements, including text, images, videos, games, interactive features, and peer group discussions. They comprised 2 guided and 5 unguided approaches. Using digitalized CBT interventions for depression during pregnancy showed promising efficacy, with guided intervention showing higher effect sizes (Hedges g=1.21) than the unguided interventions (Hedges g=0.14-0.99). The acceptability of the digitalized CBT interventions was highly encouraging, based on user feedback. Attrition rates were low for the guided intervention (4.5%) but high for the unguided interventions (22.1%-46.5%). A high overall risk of bias was present for 6 of the 7 studies.

Conclusions: Our search only identified a small number of digitalized CBT interventions for pregnant women, despite the potential of this approach. These showed promising evidence when it came to efficacy and positive outcomes for depression

symptoms, and user feedback was positive. However, the overall risk of bias suggests that the efficacy of the interventions needs to be interpreted with caution. Future studies need to consider how to mitigate these sources of biases. Digitalized CBT interventions can provide prompt, effective, evidence-based interventions for pregnant women. This review increases our understanding of the importance of digitalized interventions during pregnancy, including during the COVID-19 pandemic.

KEYWORDS

pregnancy; antenatal depression; systematic review; cognitive behavior therapy; digital interventions; COVID-19

Introduction

It is estimated that one-fifth of mothers experience depression during pregnancy [1]. This has been strongly associated with postnatal depression [2,3] and linked with several adverse health and psychosocial outcomes for both the mother and child. These include preterm delivery [4,5], difficulties in mother-child interactions, impaired cognitive and psychomotor development [6], and altered fetal brain development [7,8]. Pregnant women experience changes to psychological symptoms due to complex biological and psychological interactions throughout the pregnancy period [9]. Therefore, recognizing depression symptoms during pregnancy at an early stage and preventing future risk of depression should be considered an important global public health challenge.

There is evidence that psychosocial treatment, cognitive behavioral therapy (CBT), and interpersonal psychotherapy are effective in treating depression during pregnancy [10]. The US Preventive Services Task Force [11] reviewed pharmacological and nonpharmacological interventions for depression during pregnancy and postnatal periods. It reported that CBT was effective and stated that global studies had not reported harmful outcomes for either mothers or infants. A randomized controlled trial (RCT) of 217 pregnant women in the United States showed that CBT significantly reduced depression during pregnancy when it was compared with standard care [12]. Concerns about the safety of using selective serotonin reuptake inhibitors during pregnancy and their effect on offspring have been reported, such as altering brain circuits [13], increasing the risk for later depression [14], and increased problems with motor and language development [15]. These highlight the need to study psychosocial interventions.

There is huge gap between what pregnant women need and the human resources that are available to provide such services. Very few women seek help with mental health issues during pregnancy [16]. Barriers to seeking help have included individual factors, such as lack of motivation, time constraints, or they just decided not to seek care [16,17]. Social factors have included stigma and lack of social support, and practical issues have included lack of money or childcare. There are also structural barriers, like lack of information about services, treatment provider responsivity, and treatment accessibility issues [16-20]. The World Health Organization's Mental Health Atlas also reported unequal and limited availability of mental health services and resources across the world [21]. Depression is common during pregnancy, and it needs to be treated without delay. The Institute of Medicine recognized the different spectrum of interventions for mental health based on the risk for the target population: prevention (universal, selective, indicated), treatment (case identification, standard treatment for known disorders), and maintenance (compliance with long-term treatment, aftercare) [22]. Focusing on pregnant women with different depression risk levels is essential, given that less than three-quarters of pregnant women are screened for depression [23].

Digitalized interventions provide an effective way of reaching people and have the potential to overcome barriers, such as the fear of being stigmatized, practical reasons, and treatment availability [24-28]. Digitalized interventions are also becoming increasingly important, as mental health services struggle to deal with the considerable increase in demand for services due to the COVID-19 pandemic. This health emergency began at a time when resources were already scarce, and the number of referrals is now increasing. The use of digital interventions has increased during the COVID-19 pandemic, especially during physical distancing measures, and this has highlighted the increased role it can play in self-care and remote care. Digital interventions have the potential to improve the health outcomes of pregnant women and their experiences with care [29].

To our knowledge, no review has specifically focused on digitalized CBT interventions for depression symptoms during pregnancy. We note that 4 broader reviews on psychosocial interventions have been conducted in the past 5 years, and these can be divided into 2 categories. One review focused on any psychosocial interventions during pregnancy [30], and 3 reviews focused on psychosocial interventions throughout the broad perinatal period, namely pregnancy and the postnatal period [31-33]. The aim of the study by Li et al [30] was to carry out a systematic review and meta-analysis of any psychotherapies for pregnant women that focused on depression, anxiety, and quality of life. However, the authors only identified 2 RCTs on digitalized CBT. It was notable that their review did not include important search terms widely used for digital or internet interventions, such as web-based interventions, digital health, internet, and online interventions [34]. The other 3 reviews mainly identified interventions during the postnatal period. Lee et al [32] did not find any digitalized CBT interventions during pregnancy, while the other 2 studies [31,33] only found limited evidence. It is important to note that none of those 4 broader reviews contained extensive discussions of digitalized CBT interventions.

We decided that a new review was warranted, given the broad nature of previous systematic reviews and the increasing need for, and emergence of, digitalized CBT interventions for depression symptoms during pregnancy. Our systematic review aimed to evaluate the efficacy and acceptability of digitalized CBT interventions for depression symptoms during pregnancy. This review had 2 specific aims. The first was to evaluate the efficacy of digitalized CBT interventions during pregnancy by comparing the effect sizes between studies. The second was to assess the acceptability of digitalized CBT interventions by looking at attrition rates and feedback from participants.

Methods

This systematic review was conducted in accordance with the PRISMA (Preferred Reporting Items of Systematic Reviews and Meta-analyses) [35] and the Synthesis Without Meta-analysis [36] reporting guidelines. The review protocol was prospectively registered with PROSPERO (the International Prospective Register of Systematic Reviews).

Search Strategy

Relevant peer-reviewed papers published in English were identified by comprehensively searching key electronic databases from the earliest available evidence to October 27, 2021. These were the Web of Science, Cochrane Central Register of Controlled Trials, CINAHL, MEDLINE, Embase, PsycINFO, Scopus, ClinicalTrials.gov, and EBSCO Open Dissertations databases. The backward snowballing technique was also used to identify potentially relevant papers [37]. This involved looking at the reference lists of the selected papers to see if any more papers could be identified. The search strategy was created and refined based on consultation with a library information specialist (in Multimedia Appendix 1).

Inclusion and Exclusion Criteria

The inclusion and exclusion criteria used to screen the articles were based on PICOS (population, intervention, comparator, outcome, and study design) [38].

Population

Studies were only included if the pregnant women were at least 18 years old. Studies were excluded if they combined samples of pregnant and nonpregnant women, male partners, or those aged younger than 18 years. Given that we focused on the broad spectrum of interventions for depression (prevention [universal, selective, indicated], treatment [case identification, standard treatment for known disorders], and maintenance [compliance with long-term treatment, aftercare] [22]), this may include a population of pregnant women with different depression risk groups.

Intervention

We focused on digitalized CBT interventions that primarily used technological platforms to target depression, such as the internet, computers, mobile phones, and virtual reality. The term digitalized CBT was based on 2 previously established definitions. First, we used the umbrella term digital, as it covers the full spectrum of digital technology, such as the internet, electronic devices, and mobile phones [39]. Second, we referred to the definition of technology-empowered CBT outlined by Wolters et al [40]: "CBT-based interventions integrating technology varying from basic online bibliotherapy to online self-help therapy, therapist-supported computerized CBT, smartphone applications (apps), traditional CBT delivered via telephone or videoconferencing, and combinations of these forms." We only included interventions that began during pregnancy, but some of them also provided follow-up support during the postnatal period. We included any depression symptom intervention across the Institute of Medicine's spectrum of interventions for mental health based on the risk of the target population: prevention (universal, selective, indicated), treatment (case identification, standard treatment for known disorders), and maintenance (compliance with long-term treatment, aftercare) [22]. Both guided and nonguided interventions were included. We excluded studies on psychosocial interventions that began postnatally and those that primarily evaluated nondigitalized CBT interventions, such as face-to-face group interventions and those with telephone support but no digital element.

Comparisons

Studies that compared digitalized interventions with standard treatment, waiting lists for treatment, and secondary or other interventions were included.

Outcome

Studies were included if the primary outcome was at least one validated measure of symptoms of depression during the perinatal period.

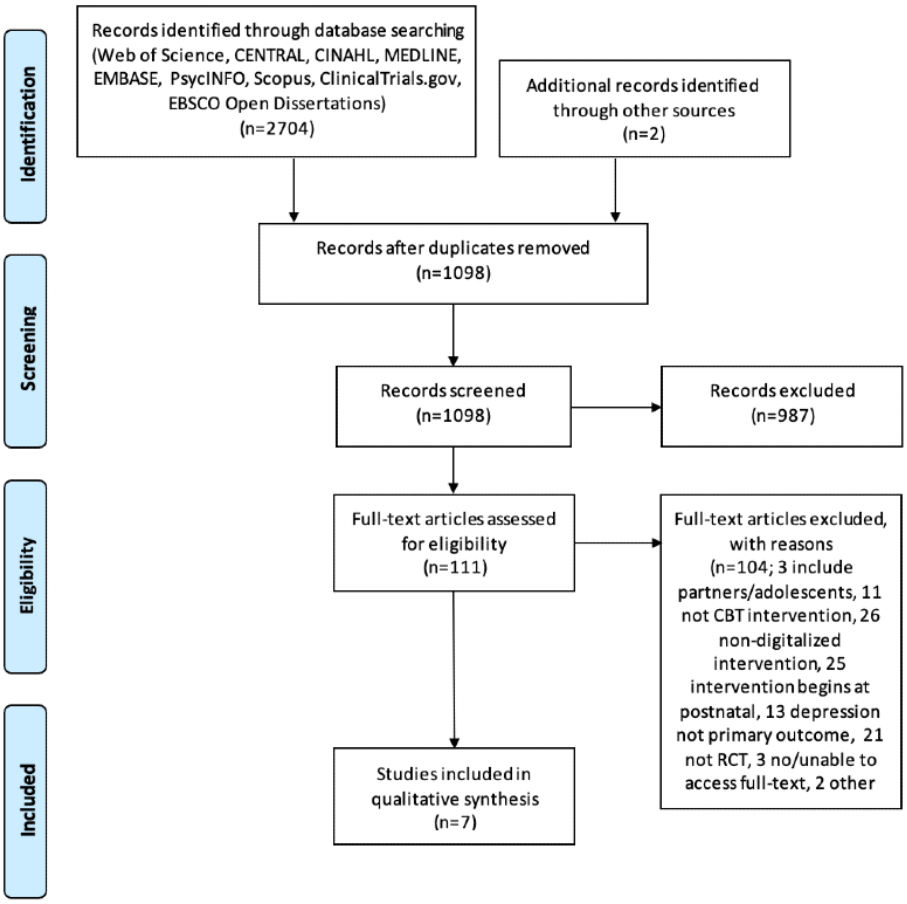
Study Design

Our review only included RCTs, as this research design is considered to be the gold standard for studying the effectiveness of interventions. RCTs are also considered to be the cornerstone for evidence-based practice [41], as they can be used to inform policy and practice decisions [42]. Only studies with full texts published in English were included. Nonrandomized, quasi-experimental, or pure qualitative studies were excluded and so were research protocols and case studies.

Study Selection and Retrieval Process

Figure 1 displays the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow diagram for the screening and study selection processes. The search and screening processes were independently conducted by 2 reviewers (WMAWMY and OW) based on the titles and abstracts and after any duplicates were removed. Any disagreements were discussed with a senior researcher (HMM). Next, the 2 reviewers independently conducted full-text assessments based on the predefined inclusion and exclusion criteria. Both reviewers cross-checked the papers that were suggested for inclusion, and any disagreements were discussed and resolved with the senior researcher (HMM) and professor (AS). The list of excluded studies with their reasons for exclusion are available in Multimedia Appendix 2.

Figure 1. PRISMA (Preferred Reporting Items of Systematic Reviews and Meta-analyses) flow diagram.



Quality and Risk of Bias Assessment

The methodological quality of the included studies was assessed using the Revised Cochrane risk-of-bias tool for randomized trials (ROB2) [43]. This tool addresses specific domains that can influence the risk of bias in an RCT. It asks a series of questions to enable users to evaluate the potential risk of bias in RCTs based on 5 domains: the randomization process, deviations from the intended intervention, missing outcome data, outcome measurements, and how the reported results were selected. The process evaluates each domain and enables the user to reach an overall judgement, namely a low or high risk of bias or some concerns. According to the tool guidelines, identifying a high risk of bias for any individual domain will produce an overall high risk of bias. Some concerns about any individual domain will lead to the paper being categorized as some concerns or a high overall risk [43]. The risk of bias assessments were independently conducted by 2 reviewers (WMAWMY and OW). Any discrepancies were discussed and agreed with the senior researcher (HMM) and professor (AS). The specific reasons for the 3 categorizations, namely low, some concerns, or high, were recorded in a Microsoft Excel spreadsheet template provided with the ROB2 tool.

Data Extraction and Synthesis

A customized data extraction Excel spreadsheet was used by the reviewers. Data that were extracted from each of the final 7 papers included the author, year of publication, country, recruitment, sample size, and randomization. We also extracted the name, type, and mode of the intervention, screening method, primary depression scale, other mother-related outcomes, infant-related outcomes, number of sessions and duration, intervention start and end points, funding sources, brief synopsis, CBT elements, type of therapeutic guidance, and other support, such as technical or peer support. The research team also extracted and calculated the between-group effect sizes and 95% CIs after the intervention, user feedback, and the postintervention attrition rates. The Hedges g effect sizes were either extracted, if provided, or calculated using the 2020 Effect Size Calculator from the Center for Evaluation and Monitoring [44]. We extracted the means, standard deviations, and sample sizes of the intervention and control groups at the postintervention assessment point, during pregnancy. The effect sizes were interpreted as small (≤0.32), moderate (0.33 to 0.55), or large (≥0.56) [45]. The acceptability of the interventions was assessed according to the Theoretical Framework of Acceptability [46]. This suggests that intervention acceptability can be assessed at 3 time points: before, during, and after an intervention has been delivered [46]. In addition, the attrition rate percentage was calculated using the total number of subjects dropped out in the intervention group post-intervention over the total number of subjects in the intervention groups at baseline, after randomization. The data extraction was conducted by the first author (WMAWMY) and then independently checked by the second reviewer (OW) for accuracy and completeness. Disagreements were resolved through consensus discussion with a senior researcher (HMM). WMAWMY also

contacted authors of included studies with a request for missing or additional information (in Multimedia Appendix 3).

Results

The electronic searches and hand searches yielded 2706 titles, and 7 were included in this study after the duplicates were removed and the screening process was carried out [47-53]. All of the papers were published between 2015 and 2021, and 5 were published in 2019 or 2021. Figure 1 provides a flow diagram of the screening processes and study selection.

Characteristics of the Included Studies

Table 1 summarizes the characteristics of the 7 studies: 2 were from the United States, 2 were from China, and there was 1 each from Australia, Norway, and Sweden. The papers covered a total of 2830 participants, and the sample sizes ranged from 25 to 1342 at the time of randomization. The 7 studies assessed 7 different interventions. The Swedish Internet Cognitive Behavior Therapy for Antenatal Depression program had 42 participants, and the intervention, which was delivered via a secure online platform, consisted of reading material, assessments, homework, and worksheets [49]. Videos, graphics, and an online diary book were used by the Chinese Internet-based Mindful Self-Compassion Program with 314 participants [50]. The Mothers and Babies Internet Course had 852 participants, making it the second largest study. Coordinated from the United States, but with a worldwide reach, it provided fully automated online lessons that included information pages, short audio and video clips, images, and worksheets [47]. The American-based Sunnyside Group-based Internet Intervention was an online website with various interactive tools and games that facilitated learning and peer interaction. It was the smallest study, with 25 participants [48]. Mamma Mia was by far the biggest program, with 1342 Norwegian participants. It was a fully web-based intervention that combined text, pictures, pre-recorded audio files, and user input [51]. The Australian MUMentum Pregnancy Program had 87 participants. This featured a virtual online clinic and used an illustrated story centered around fictional characters [52]. The final study was the Chinese smartphone-based Mindfulness Behavioral Cognitive Therapy, with 168 participants, delivered through a smartphone app. It consisted of thematic curriculum provided through text, audio, and visual materials [53].

Two of the studies, from the United States [47] and Norway [51], employed a universal approach, and the other 5 studies used an indicated approach. Three studies recruited participants directly from hospitals: the Chinese study from a reproductive mental health multidisciplinary clinic [50], another Chinese study from the obstetrics clinic of a tertiary hospital [53], and the largest Norwegian study via midwives during regular maternal check-ups [51]. The other 4 studies combined diverse recruitment strategies, using advertisements on social media and online forums and in newspapers, mass emails, Google Ads, and flyers distributed at maternity clinics and hospitals. None of the studies screened participants using population-based approaches. Four studies screened participants during recruitment using different measures and cut-off scores. The Swedish study used a Montgomery-Åsberg Depression Rating Scale (MADRS) [54] score of 5 to 35 and no or a low risk of suicide [49]. The Chinese study used an Edinburgh Postnatal Depression Scale (EPDS) [55] score of ≥9 [50], while the other Chinese study used an EPDS score of ≥9 or Patient Health Questionnaire (PHQ)-9 [56] of ≥4 [53]. The small American study used PHQ-8 scores of 5 to 14, which indicated no diagnosis of major depression [48]. When it came to measuring depression, 6 studies used the EPDS, as either the only measure or one of the outcome measures. However, the EPDS outcome cut-off scores used for probable depression differed: 4 studies used >9 points [47,50,51,53], and 2 studies used >12 points [49,52]. Other studies used the PHQ-9, Center for Epidemiological Studies-Depression [57], MADRS-Self Report, and Beck Depression Inventory II [58] to measure depression outcomes. The studies also assessed various other mother-related outcomes, but only 2 studies reported infant-related or mother-infant attachment outcomes. These were the Chinese study [50], which used the Infant Behavior Questionnaire Revised-Very Short Form [59] and the Australian study [52], which used the Maternal Antenatal Attachment Scale [60]. Five studies [48-50,52,53] also assessed anxiety as secondary outcomes, using the Generalized Anxiety Disorder 7 scale [61], the State-Trait Anxiety Inventory [62], or the Inventory of Depression and Anxiety Symptoms [63].

Interventions Used by the Studies

Table 2 summarizes the description of each intervention, while Figure 2 compares the earliest starting point to the latest end point for each intervention. All the digitalized study interventions were delivered on the internet but varied in terms of their session structure and duration, the type of support provided, and the duration. Six interventions were delivered via a website, and only 1 [53], which was recently published, was delivered via a smartphone app. The shortest intervention, from Australia, lasted for 4 weeks and was comprised of 3 brief unguided internet-based CBT (iCBT) sessions [52], while the largest Norwegian intervention, Mamma Mia, had the longest duration, of 11.5 months, and provided sessions during pregnancy and postnatal periods [51]. Two of the 7 interventions were guided, as they incorporated an element of therapeutic guidance. The Swedish intervention was provided by CBT-trained therapists, who were not mental health professionals, on a fully digital platform [49], but no telephone guidance was provided. The level of therapeutic guidance provided by this guided iCBT varied, and messages sent via the internet platform were responded to within 48 hours during weekdays. The Chinese intervention did not detail the type of guided instructions that were provided [50]. In addition to therapeutic guidance, several of the guided and unguided interventions employed other forms of support, such as peer support discussion groups or platforms, as well as technical support by the research team members. Table 3 shows a brief synopsis and the CBT elements of the 7 interventions.

Table 3. Brief intervention synopsis, themes, and cognitive behavioral therapy (CBT) elements.

Author(s) and country	Brief synopsis	Themes	CBT elements
Guided			
Forsell et al [49], Sweden	The iCBT[a] Internet Psychiatry Clinic is an intervention for antenatal depression and is an adapted version of iCBT for depression. The platform is a form of guided self-help treatment consisting of reading material (about 75,000 words), assessments, homework, and worksheets via a secure online platform. The platform can be accessed anytime and anywhere using a computer or mobile device with an internet connection. There are 10 modules of guided self-help by nonexpert therapists trained in CBT.	Introduction, being pregnant, behavioral activation, cognitive restructuring, relationships, anxiety and worry, sleep problems, and summary and relapse prevention	Psychoeducation (depression, CBT, myths, facts, and physiological changes), behavioral activation (positive and negative reinforcement behaviors), cognitive restructuring (negative automatic thoughts, acceptance, cognitive biases), psychoeducation (relationships, communication, role transition, anxiety and fear of labor and sleep), and homework
Guo et al [50], China	Mindful Self-Compassion Program (MBSP) is aimed at promoting self-regulatory skills of pregnant women at high risk for postpartum depression focusing on self-compassion. The program utilizes videos involving different types of exercises with guided instructions sequentially provided after completion of a previous module. The 6-week program lasts 10 hours with guided instructions: 36 episodes each lasting about 15 minutes	Not available	Largely based on mindfulness CBT; understanding and applying self-compassion, skills to manage difficult emotions rather than solving specific problems, exercises with guided instructions. Users were encouraged to practice the skills during the day and provided with an online diary book for reflection.
Unguided			
Barrera et al [47], United States	The Mothers and Babies Internet (e-MB) is aimed at Spanish- and English-speaking pregnant women to reduce the risk of postpartum depression. The e-MB consists of fully automated lessons and is sequential in nature, whereby each session needed to be completed first before proceeding to the next lesson. Following completion of each session, participants may access the lesson and worksheets infinitely for review. The e-MB consisted of 8 flexible sessions of fully automated self-help.	Not available	Information pages, audio, video, images, and worksheets based on the cognitive behavior framework, social learning theory, reality management training, attachment theory, and diverse sociocultural issues
Duffecy et al [48], United States	The Sunnyside website group intervention consisted of 10–15-minute didactic lessons using text and video material and included several interactive features in the form of (1) an activity feed, which was a constantly updating feed that displayed each of the women's activity on the site, whereby other participants can like and comment or provide feedback to other women's posts, (2) discussion questions posted by study staff after each session to encourage interaction, (3) individual garden plot and community garden linked to individual's profiles and providing gamification and interactive features individually and between other users, (4) contact moderator tool to report any issues with the site or with group members. After each session, participants are prompted with a "call to action" encouraging them to apply the skills learned during the sessions. The intervention consisted of an 8-week unguided online program.	Your mood and your pregnancy, worries about me and my baby, mood management, challenging your thinking, positive activity during pregnancy, physical activity during pregnancy, partner communication and support, body image and sex during pregnancy and postpartum, relationships with your mother and mother-in-law, challenges in relationships with friends and others, monitoring kick counts and other pregnancy anxiety, anxiety and parenthood, relaxation, employment issues, during and after the birth, moving forward, and conclusions	Psychoeducation, mood management, thought challenging, positive and physical activities, relationship with partner and others in the social circle, anxiety during pregnancy and parenthood, relaxation, employment issues and managing resources during and after labor; 5 interactive CBT tools: thought restructuring (think), mood tracking (feel), activity scheduling and monitoring (do), relaxation (relax), and goal setting (achieve)

Author(s) and country	Brief synopsis	Themes	CBT elements
Haga et al [51], Norway	Mamma Mia is a free universal preventive intervention for perinatal depression. The intervention is delivered by email and interactive websites, combining text, pictures, prerecorded audio files, and user input. User receives an email with a hyperlink for each session that lasts around 10 minutes each. The hyperlink directs the user to the Mamma Mia web page, and the intervention content proceeds sequentially to the next web pages (tunnel information architecture) to ensure continuity of the program narrative. The intervention consists of 3 fully automated phases with 44 sessions over 11.5 months: phase 1 (during pregnancy); phase 2 (infant is 2-3 weeks old, for 6 weeks); and final phase (10 sessions over an 18-week period)	Knowledge, expectancies and attitudes, attachment, emotion regulation, and help-seeking, relationship satisfaction, and communication skills	Assessment of depressive symptoms, metacognitive therapy, positive psychology, couples' therapy, breastfeeding, and psychoeducation; the metacognitive element emphasized the process of inflexible and recurrent thinking style due to negative thoughts, feelings, or beliefs. Acceptance commitment therapy and mindfulness elements were also incorporated.
Loughnan et al [52], Australia	The MUMentum Pregnancy transdiagnostic intervention targets anxiety and depression symptoms and is delivered via the online Virtual Clinic system. The program emphasized a short, illustrated story centered around 2 fictional characters experiencing depression and anxiety during pregnancy. The characters learn to manage their symptoms by applying CBT skills in the context of the character experiences, challenges, and symptoms common during pregnancy. The system employs a 7-day lockout period implemented between lessons to ensure participants spend time revising and implementing the lesson material before moving onto the next lesson. Of this, participants are also notified via email and SMS reminders regarding new lessons and to stay on schedule. The 4-week program consists of 3 brief unguided self-help lessons with only technical support.	About anxiety and depression, identifying symptoms, cognitive behavioral model, prioritizing self-care, physical symptoms, partners and supporters, controlled breathing, progressive muscle relaxation, about thoughts, identifying unhelpful thoughts, shifting unhelpful thoughts, accepting uncertainty, thought challenging, coping cards, structured problem-solving, unhelpful behaviors (low activity; avoidance), facing your fears, activity planning and monitoring, graded exposure, assertive communication, relapse prevention	Transdiagnostic intervention for depression and anxiety during pregnancy; involved psychoeducation, cognitive restructuring, problem-solving, behavioral activation, and relapse prevention; each lesson illustrated the characters' stories: introduction to core CBT skills, summary, and action plan to implement the skills and several supplementary resources.
Sun et al [53], China	The Spirits Healing (in Chinese) app is a mindfulness training program for use during pregnancy for perinatal depression and other mental health problems. It was available for Android and iOS operating systems in mainland China. The app provides reading materials, recordings for guided practice, videos, and a mindfulness journal that can be accessed anytime and utilized at users' own pace. Weekly reminder messages were sent via WeChat for users to complete the training. Participants were awarded 2 yuan (US $0.30) for completion of each week of training or each completion of assessment. The 8-week mindfulness CBT training automatically updated every day, and participants practiced according to their own schedules.	Understand mindfulness, be in the present, be mindful of negative emotions, accept difficulties, thoughts are just thoughts, enjoy daily happiness, mindful pregnancy and childbirth, continued mindfulness practice	Following psychoeducation information via the app, formal mindfulness training techniques were introduced. Users are encouraged to continue to practice, and they are supplemented with recordings and a mindfulness journal. Formal training included body scan, mindful breathing, mindful stretching, and mindful meditation. Informal training included encouragement to practice every day, pausing in the midst of daily life, mindful eating, mindful walking, and 3-minute breathing practices.

[a]iCBT: internet-based CBT.

Assessment of Risk of Bias

Figure 3 and Figure 4 display the risk of bias assessment results for each study. Six studies had a high overall risk of bias, as a high risk of bias was recorded in at least one domain, while 1 study recorded some concern for overall risk of bias. Self-reported measures are commonly used to evaluate psychological outcomes, but there were at least some concerns about the risk of bias that these provided in 7 studies, based on the ROB2 guideline [43]. The missing outcome data domain was of some concern, given nearly half (3/7, 43%) of the studies did not provide sufficient information about the reasons for dropout between groups or analyses to address these missing data. In addition, the way that the reported results were selected was of high concern. These were particularly related to the fact that 5 of the study protocols were not registered or there were inconsistencies, without justification, between the registered protocols and the published papers. These inconsistencies included the absence of follow-up results in the published paper or differences between these and the intended analysis plan in the published protocol.

Figure 3. Percentage of risk of bias based on the 5 Revised Cochrane risk-of-bias tool for randomized trials (ROB2) domains.

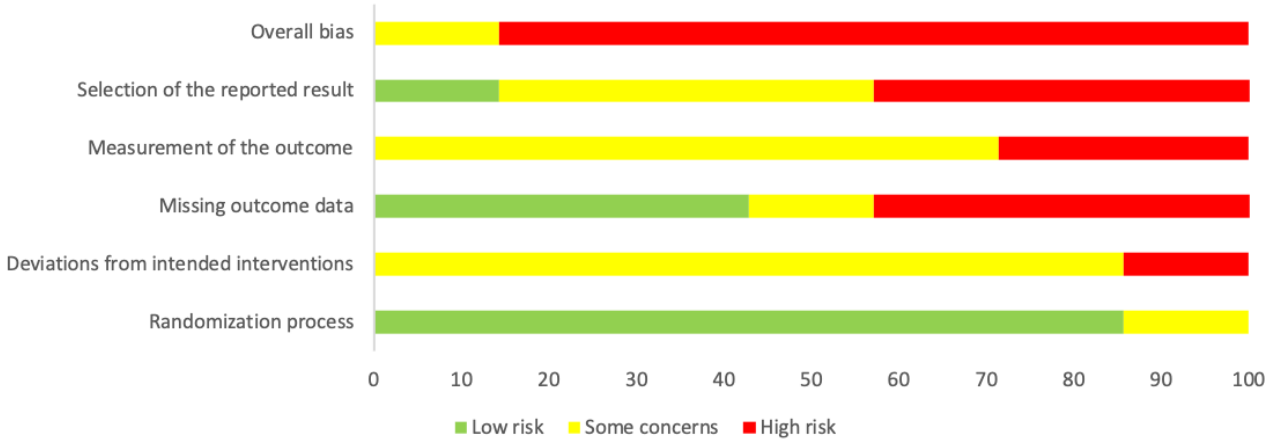

Figure 4. Risk of bias for depression outcomes, based on the individual studies.

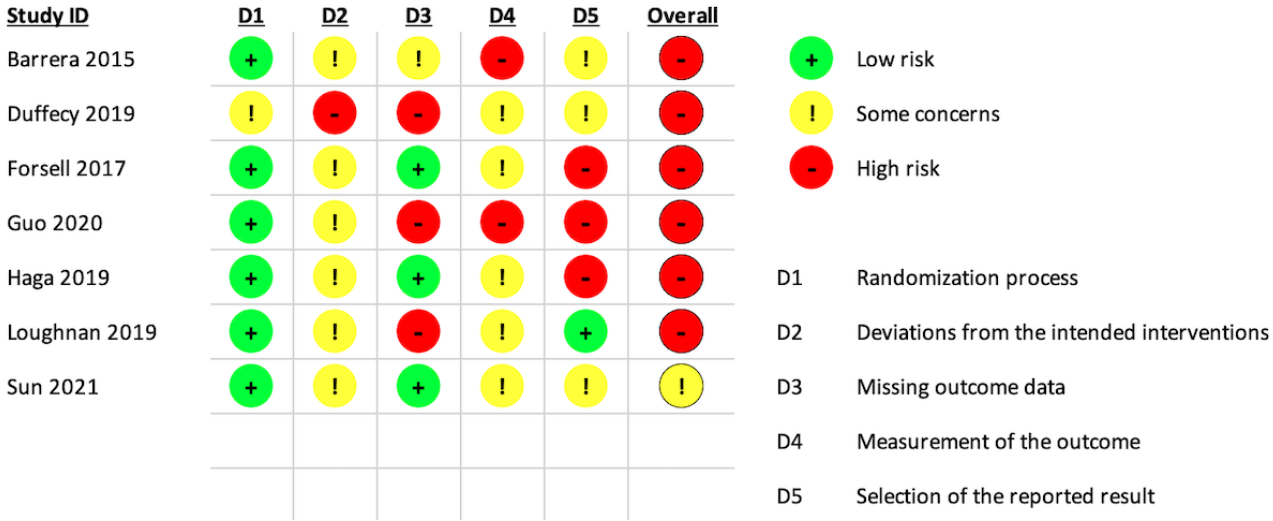
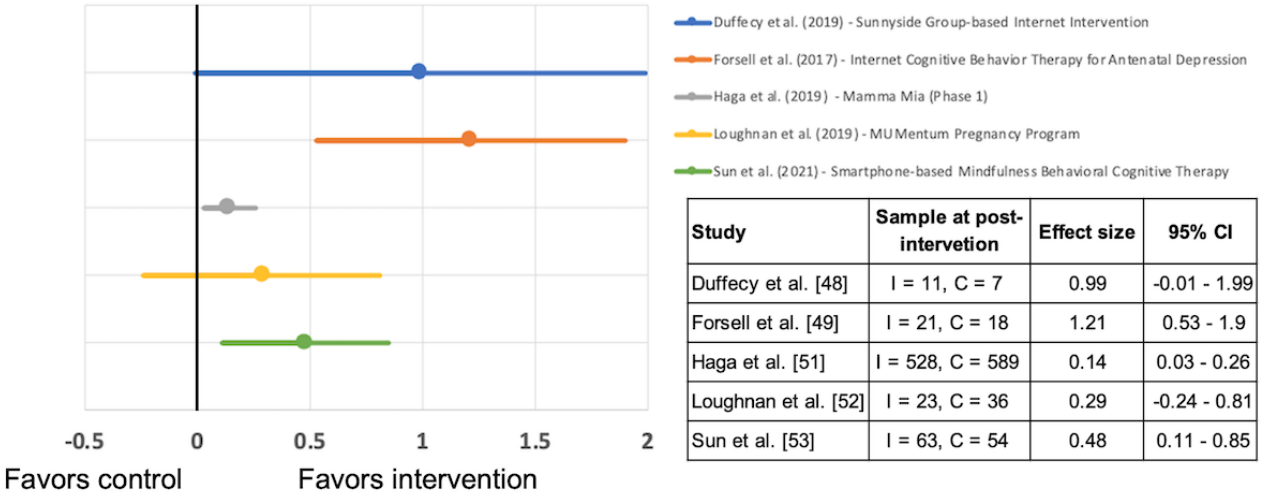


Efficacy of Digitalized CBT Interventions for Depression Symptoms During Pregnancy

In view of the overall high risk of bias in all except one of the studies, the efficacy of the interventions needs to be interpreted with caution. Five studies provided sufficient data for effect size calculations. Figure 5 summarizes the Hedges g effect size for the 5 studies [48,49,51-53]. In general, the more positive results for the intervention than for the control groups showed promising evidence for the efficacy of digitalized CBT interventions for pregnant women. It was notable that there were differences in efficacy between the guided and unguided interventions. The highest postintervention effect size was recorded for the Swedish Internet Cognitive Behavior Therapy for Antenatal Depression program, which focused on pregnant women who were judged to have no or a low risk of suicide when screened for symptoms of depression [49]. The remaining 4 interventions were all unguided and recorded large [48], moderate [53], or small [51,52] effect sizes.

Figure 5. Hedges g effect sizes (95% CIs) for depression after programs in the intervention (I) and control (C) groups.



Study	Sample at post-intervetion	Effect size	95% CI
Duffecy et al. [48]	I = 11, C = 7	0.99	-0.01 - 1.99
Forsell et al. [49]	I = 21, C = 18	1.21	0.53 - 1.9
Haga et al. [51]	I = 528, C = 589	0.14	0.03 - 0.26
Loughnan et al. [52]	I = 23, C = 36	0.29	-0.24 - 0.81
Sun et al. [53]	I = 63, C = 54	0.48	0.11 - 0.85

Acceptability of Digitalized CBT Interventions

Table 4 compares the acceptability assessments conducted by individual studies based on 3 time points: before, during, and after the intervention was delivered. Overall, most of the participants were satisfied with the interventions they received, but high attrition rates were recorded for the 4 unguided interventions (22.1%-46.5%). The way that intervention acceptability was measured varied significantly between the studies, especially the scales that were chosen. All the studies obtained feedback after the interventions had finished. Five studies assessed acceptability during the interventions [48,49,51-53], while only 2 studies assessed acceptability before they were used [48,51]. The highest attrition rates for the unguided interventions were for the unguided MUMentum Pregnancy transdiagnostic intervention [52]. In contrast, the guided intervention recorded a very low attrition rate of 4.5% for the Swedish Internet Cognitive Behavior Therapy for Antenatal Depression program [49].

Table 4. Acceptability before, during, and after the interventions.

Author(s) and country	Acceptability before	Acceptability during	Acceptability after	Attrition
Guided				
Forsell et al [49], Sweden	N/A[a]	Treatment Credibility Scale of the Credibility/Expectancy questionnaire: good treatment credibility	Client Satisfaction Questionnaire 8: good satisfaction level; treatment adherence and utilization described	4.5%
Guo et al [50], China	N/A	N/A	Brief dropout reasons provided; attendance rate=91.8%	N/A
Unguided				
Barrera et al [47], United States	N/A	N/A	3 open-ended questions: intervention helpfulness and usefulness rated favorably; content easy to understand	N/A
Duffecy et al [48], United States	Intervention development process involved target participants; topics, site motif (visual themes and look and feel of the internet site), and usability of potential application	Use of interactive features assessed	Usability, satisfaction, and ease of use: intervention usefulness, ease of use, ease of learning, satisfaction rated favorably	38.9%
Haga et al [51], Norway	Intervention development process published in Drozd et al [64]	Dropout reasons not described in paper; other acceptability and feasibility details in paper [65]	More than half completed >80% of intervention; other acceptability and feasibility details in the paper [51]	22.1%
Loughnan et al [52], Australia	N/A	Detailed dropout reasons provided; intervention content evaluated during each session	Treatment Satisfaction Questionnaire: high satisfaction; Credibility and Expectancy Questionnaire: intervention quality rated as excellent; Intervention utilization and implementation data provided	46.5%
Sun et al [53], China	N/A	Logs of practice on formal mindfulness training	Completion rates for all 8 sessions=8.3%; completion rates for 4 sessions=52.4%	25%

[a]N/A: not available.

Discussion

Principal Findings

Our review identified 7 RCTs of digitalized CBT interventions for depression symptoms during pregnancy that were promisingly efficacious and had good acceptability. RCTs using digital CBT for depression during pregnancy have been scarce in contrast to the number of studies on digitalized CBT interventions for depression overall. We judged 6 of the 7 studies to have a high risk of bias. The high risk of bias was mainly due to missing outcome data and selection of reported results domains. These point to the need to provide accessible trial registration information with sufficient information prior to commencement of controlled trials. Although missing data in psychological intervention studies are common, a detailed description of how these missing data were addressed and reasons for dropouts in the intervention and control group need to be clarified and compared in each study. Therefore, the findings on efficacy should be considered with caution, and more high-quality studies are needed. Despite these limitations, this review produced 3 main findings. First, technology can be used to deliver CBT programs that target depression during pregnancy. Second, digitalized CBT during pregnancy showed promising evidence of efficacy and positive outcomes for depression (Hedges g for guided interventions=1.21; Hedges g for unguided interventions=0.14-0.99). Third, the digitalized CBT interventions were well-received by pregnant women, especially interventions that were guided, which had lower attrition rates than the unguided interventions (4.5% versus 22.1%-46.5%).

CBT interventions have traditionally been delivered face-to-face, but technological advances have revolutionized the way they are being adapted to various platforms. The COVID-19 pandemic has also led to an urgent increase in the need for digital care delivery. For the past 20 years, the progress in digitalized interventions has been rapid, and various evidence-based digitalized interventions have been developed and disseminated [66], especially for depression [67]. However, little is known about digitalized CBT interventions for depression during pregnancy. All 7 interventions identified in this review used the internet and website or smartphone app platforms to deliver core elements of CBT, such as psychoeducation, cognitive restructuring, problem-solving, and behavioral activation. The central themes of these were managing challenges and expectations during pregnancy by using CBT skills. These platforms contained a combination of text, images, and videos to make the interventions attractive and engaging. Other additional interactive features were unique to some interventions. For example, the American-based Sunnyside Group-based Internet Intervention included an activity feed that displayed each participant's activity on the site. This meant that other participants could like, comment, or provide feedback on other women's public posts. It also had an individual garden plot and community garden that were linked to individual profiles. The intervention provided individual and group games, where garden gnomes or flowers could be collected by completing various tasks [48]. Likewise, the Swedish Internet Cognitive Behavior Therapy for Antenatal Depression program provided an online discussion group, in which participants could interact with each other anonymously [49]. These unique interactive features allowed participants to share their lived experiences during pregnancy, as well as provided a platform for emotional peer support. These are both considered to be key functions of traditional online pregnancy forums [68].

The limited evidence and high risk of bias in 6 out of the 7 papers we reviewed prevented us from coming to firm conclusions on the efficacy of digitalized CBT for depression during pregnancy. However, our review does provide promising evidence on the efficacy and positive impact of digitalized CBT for pregnant women. Previous research has reported that the prevalence of postnatal depression symptoms can be predicted by depression symptoms during pregnancy [3]. Interventions during pregnancy allow participants to acquire and apply coping skills at an early stage, potentially before their depressive symptoms worsen. It should also be noted that 5 of the included studies used standard care, an active control, or another intervention as control groups, which may partly explain the modest effect sizes in most of the studies. The Swedish intervention [49] had an exceptionally high effect size. Unsurprisingly, that intervention used a guided and indicated approach. The intervention was delivered via an online internet platform comprised of about 75,000 words of reading material, assessments, homework, case stories, and worksheets. The therapists provided regular individual feedback, encouragement, and support in written messages, with replies within 48 hours on weekdays. Interestingly, the therapeutic guidance was provided by CBT-trained therapists who were not mental health professionals. Compelling evidence from systematic reviews and meta-analyses of iCBT research for depression has highlighted the importance of providing support from a therapist or human guidance for effective interventions [69-72].

Six out of 7 studies we reviewed also assessed other self-reported maternal outcomes: anxiety, psychological distress, alcohol and drug use, mindfulness attention awareness, general health, stress, self-compassion, well-being, quality of life and work and social adjustment, positive and negative affect, sleep-related problems, fatigue, prospective memory, retrospective memory, and fear of childbirth. Only one study assessed infant outcomes, using the Infant Behavior Questionnaire, and another study assessed mother-child attachment or bonding using the Maternal Antenatal Attachment Scale. This was somewhat surprising, as there is compelling evidence that prenatal depression has been associated with various infant-related issues, including temperament, bonding, emotional and behavioral problems, cognitive impairment, and psychopathology [73-79]. The fact that there was so little research on infant-related or mother-infant attachment outcomes by the studies we reviewed limits any insightful discussion and highlights the need for further evaluation.

All the studies we reviewed reported diverse acceptability outcomes for at least 1 of the 3 time points: before, during, and after the intervention was delivered. All the interventions recorded good acceptability, especially after the intervention had been completed, as the participants were satisfied with the interventions and felt that they were useful. Acceptability data

before and during intervention delivery are still lacking, and more acceptability components can be explored further. The Theoretical Framework of Acceptability outlines 7 components of acceptability that could be explored in intervention studies at these 3 time points: affective attitude, burden, perceived effectiveness, ethicality, intervention coherence, opportunity costs, and self-efficacy [46]. Including all the acceptability data in a single paper may be challenging due to word count limits or information overload. To deal with this issue, authors could provide acceptability evaluations in separate papers. For example, the Mamma Mia intervention included in our review was the focus of 3 separate papers on intervention development [64], acceptability and feasibility [65], and efficacy [51].

The attrition rates for the unguided interventions were high (22.1%-46.5%), and this finding was consistent with previous meta-analyses on digitalized CBT interventions for depression [70,72]. The terms "universal" and "indicated" were based on the Institute of Medicine's spectrum of mental health interventions based on the risk for the target population: prevention (universal, selective, indicated), treatment (case identification, standard treatment for known disorders), and maintenance (compliance with long-term treatment, aftercare) [22]. Our review identified 2 "universal" interventions (developed for pregnant women with any risk level for diagnosable clinical depression) and 5 "indicated" interventions (developed for pregnant women already at risk for diagnosable clinical depression [eg, those that exceed a cut-off screening score]). These classifications (ie, universal, indicated) have also been used in other perinatal distress, depression, and anxiety research [80].

Guided versus unguided and universal versus indicated approaches may have their own merits when it comes to impact. For instance, the study on the unguided and universal Mamma Mia intervention recruited the highest number of participants, 1342, with 678 in the intervention group and 664 receiving standard care. Although this study showed small effect sizes, partly due to its universal approach, more than one-half (345/678, 50.9%) of the total participants in the intervention group completed 80% or more of the year-long program, with the first phase during pregnancy and the second and third phases during the postnatal period. Any approach requires consideration based on the readiness of pregnant women to change their health behavior, particularly with reference to the Capability, Opportunity, Motivation, Behavior (COM-B) framework [81]. In general, pregnancy has been called a "teachable moment," which is described by Phelan [82] as naturally occurring life transitions or health events that are thought to motivate individuals to spontaneously adopt risk-reducing health behaviors. Although pregnancy is a time when women may benefit from increased motivation for behavioral change, based on the COM-B framework, such changes can be difficult to realize if their capabilities and opportunities are neglected [83,84]. As discussed, earlier digitalized CBT may provide the opportunity for pregnant women to access digitalized interventions. However, their lack of capacity, namely reduced energy, may prevent the women from continuously engaging with the program. That is why it is crucial for those who develop interventions to consider the 3 elements of capacity, opportunity, and motivation together, in order to minimize attrition.

Pregnancy is a relatively short period, and shorter interventions could attract pregnant women to engage. CBT is problem focused and based on the way that people think and behave, and technology can make its delivery much more cost-effective. This was proven by the Australian MUMentum Pregnancy Program included in our review [52]. The transdiagnostic intervention targeted both depression and anxiety, by using a story that centered around 2 fictional characters experiencing depression and anxiety during pregnancy. The characters learned to use CBT skills to manage their symptoms, based on their experiences and challenges during pregnancy. The program received highly positive feedback from participants, in terms of satisfaction, quality, and how they became immersed in the storyline. The small effect size recorded by this unguided intervention should not mask its potential benefits. It should be emphasized that, during the study period, participants in the treatment-as-usual control group continued to receive existing health care services. This might have had a confounding impact on their symptom levels, compared with the MUMentum Pregnancy Program intervention group [52]. Virtually all pregnant women have regular contact with health care professionals, regardless of their psychosocial well-being, and that may also have a positive effect on any depressive symptoms. This is consistent with findings of a recent individual network meta-analysis that the effectiveness of guided iCBT interventions were higher for individuals with moderate to severe depression, but unguided iCBT showed similar effectiveness for individuals with mild or subthreshold depression [72].

Limitations

Although this review was conducted with high scientific rigor and we carried out a full quality appraisal of the included studies, there are several limitations that need to be taken into account when interpreting the findings. We only included papers published in English, and this may have meant that some potential studies in other languages or grey literature from other databases were not included. All except one of the included studies had a high risk of bias. They also used participant-reported measures for most of the outcomes, which can be influenced by knowledge of the intervention being received. Using the ROB2, this resulted in at least some concern of a risk of bias for all the studies. As only 1 study reported an infant-related outcome, namely infant temperament, and only 1 study assessed mother-infant attachment, meaningful discussions about infant outcomes and maternal attachment are not possible. In addition, our review only focused on CBT and did not include interpersonal psychotherapy, although both psychotherapies were included in the US Preventive Services Task Force treatment guideline for perinatal depression that was issued in 2019 [11]. A recent review found that interpersonal psychotherapy interventions for psychological distress in perinatal populations were limited to those delivered face-to-face or by telephone [85]. The nonstandardized description of interventions in our review also made it difficult to compare them. This calls for more standardized descriptions of interventions, such as using the Template for Intervention

Description and Replication checklist [86]. Future studies could also explore various acceptability outcomes before, during, and after interventions are delivered. This could be done by using the 7 components of the Theoretical Framework of Acceptability: affective attitude, burden, perceived effectiveness, ethicality, intervention coherence, opportunity costs, and self-efficacy [46].

Conclusion

This systematic review suggests promising evidence for the potential efficacy, acceptability, and integration of digitalized CBT interventions that start during pregnancy. However, all except one of the studies included in this review recorded a high overall risk of bias. In future, we need high-quality studies with larger population-based samples to comprehensively analyze the efficacy of the interventions and explore the mechanisms of change. Digital interventions may have significant global implications when planning effective, nonstigmatizing, and cost-effective mental health treatment to prevent the long-term consequences of psychosocial problems in pregnancy. These could also have other wide-ranging clinical applications. Furthermore, there is an urgent need to study digital and remote interventions, as mental health services struggle to deal with the considerable increase in demand due to the COVID-19 pandemic.

Abstract

Background: Sepsis is a significant cause of morbidity and mortality worldwide. Early detection of sepsis followed promptly by treatment initiation improves patient outcomes and saves lives. Hospitals are increasingly using computerized clinical decision support (CCDS) systems for the rapid identification of adult patients with sepsis.

Objective: This scoping review aims to systematically describe studies reporting on the use and evaluation of CCDS systems for the early detection of adult inpatients with sepsis.

Methods: The protocol for this scoping review was previously published. A total of 10 electronic databases (MEDLINE, Embase, CINAHL, the Cochrane database, LILACS [Latin American and Caribbean Health Sciences Literature], Scopus, Web of Science, OpenGrey, ClinicalTrials.gov, and PQDT [ProQuest Dissertations and Theses]) were comprehensively searched using terms for sepsis, CCDS, and detection to identify relevant studies. Title, abstract, and full-text screening were performed by 2 independent reviewers using predefined eligibility criteria. Data charting was performed by 1 reviewer with a second reviewer checking a random sample of studies. Any disagreements were discussed with input from a third reviewer. In this review, we present the results for adult inpatients, including studies that do not specify patient age.

Results: A search of the electronic databases retrieved 12,139 studies following duplicate removal. We identified 124 studies for inclusion after title, abstract, full-text screening, and hand searching were complete. Nearly all studies (121/124, 97.6%) were published after 2009. Half of the studies were journal articles (65/124, 52.4%), and the remainder were conference abstracts (54/124, 43.5%) and theses (5/124, 4%). Most studies used a single cohort (54/124, 43.5%) or before-after (42/124, 33.9%) approach. Across all 124 included studies, patient outcomes were the most frequently reported outcomes (107/124, 86.3%), followed by sepsis treatment and management (75/124, 60.5%), CCDS usability (14/124, 11.3%), and cost outcomes (9/124, 7.3%). For sepsis identification, the systemic inflammatory response syndrome criteria were the most commonly used, alone (50/124, 40.3%), combined with organ dysfunction (28/124, 22.6%), or combined with other criteria (23/124, 18.5%). Over half of the CCDS systems (68/124, 54.8%) were implemented alongside other sepsis-related interventions.

Conclusions: The current body of literature investigating the implementation of CCDS systems for the early detection of adult inpatients with sepsis is extremely diverse. There is substantial variability in study design, CCDS criteria and characteristics, and outcomes measured across the identified literature. Future research on CCDS system usability, cost, and impact on sepsis morbidity is needed.

sepsis; early detection of disease; clinical decision support systems; patient safety; electronic health records; sepsis care pathway

Introduction

Sepsis and Early Detection

Sepsis, defined in 2016 as "life-threatening organ dysfunction caused by a dysregulated host response to infection," is a leading cause of death worldwide [1]. A recent study by Rudd et al [2] estimated that 48.9 million cases of sepsis were reported in 2017, with 11 million sepsis-related deaths, representing 1 in 5 of all deaths globally [2]. Furthermore, survivors of sepsis often have a decreased quality of life, including higher rates of mortality, physical disabilities, chronic illnesses, mental health issues, and cognitive impairments [3-9].

Prompt administration of sepsis therapies, such as intravenous antimicrobials and fluid resuscitation, is associated with better patient outcomes and lower health care–related costs [10,11]. Therefore, it is critical to detect sepsis as early as possible to ensure rapid initiation of treatment [12-14]. Unfortunately, sepsis has no diagnostic gold standard and extremely heterogenous signs and symptoms, making it difficult for clinicians to distinguish it from other acute conditions [15]. The use of sepsis identification tools, such as the Quick Sepsis-Related Organ Failure Assessment, the National Early Warning Score, and the Adult Sepsis Pathway, helps facilitate early sepsis recognition [16-18]. However, these tools typically rely on manual input of vital sign information and score calculation by clinicians. Thus, timely sepsis identification hinges on vigilant and regular patient monitoring [19]. These difficulties often result in delayed sepsis diagnosis and treatment in hospitals [19,20].

Computerized Clinical Decision Support Systems

The extensive implementation of data-rich electronic health records in health institutions has brought the opportunity for widespread integration of digital health care support systems [21]. In particular, the incorporation of computerized clinical decision support (CCDS) into hospital systems has the potential to assist accurate and timely early sepsis detection. CCDS systems can be designed with integrated sepsis-risk warning tools that alert clinicians to patients at risk of sepsis [13,22], reducing the physical and mental workload associated with manual patient monitoring [21].

Over the past 10 years, CCDS technology has rapidly expanded, with two distinct approaches emerging: knowledge-based CCDS systems programmed with predefined rules derived from established clinical knowledge and adaptive CCDS systems using artificial intelligence and machine learning techniques [21,23,24]. In this scoping review, we focused on the use of knowledge-based CCDS systems in sepsis detection.

Research Questions and Aims

The use and implementation of sepsis CCDS systems in real-world clinical settings is a novel, rapidly expanding, and highly complex field [21,25]. In this scoping review, we systematically mapped the literature available on sepsis CCDS systems with the intention of identifying knowledge gaps and informing future research. The research question directing this review is *What is the evidence base for the use of knowledge-based clinical decision support systems in hospitals for early sepsis detection and how have they been evaluated?*

More specifically, through this scoping review, we aim to (1) scope the study contexts, designs, and research methods used; (2) summarize the study outcomes investigated; and (3) map the range of CCDS system designs and implementation features, such as sepsis clinical criteria.

Methods

Overview

The detailed methodology for conducting this scoping review was published previously in a protocol [26]. In brief, the review was guided by the Joanna Briggs Institute Reviewer's Manual [27], the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [28], and the 5-stage scoping review framework proposed by Arksey and O'Malley [29]. A search for current reviews and protocols on this topic was undertaken and confirmed the absence of scoping reviews. A completed PRISMA-ScR checklist is attached in Multimedia Appendix 1 [28].

Study Selection

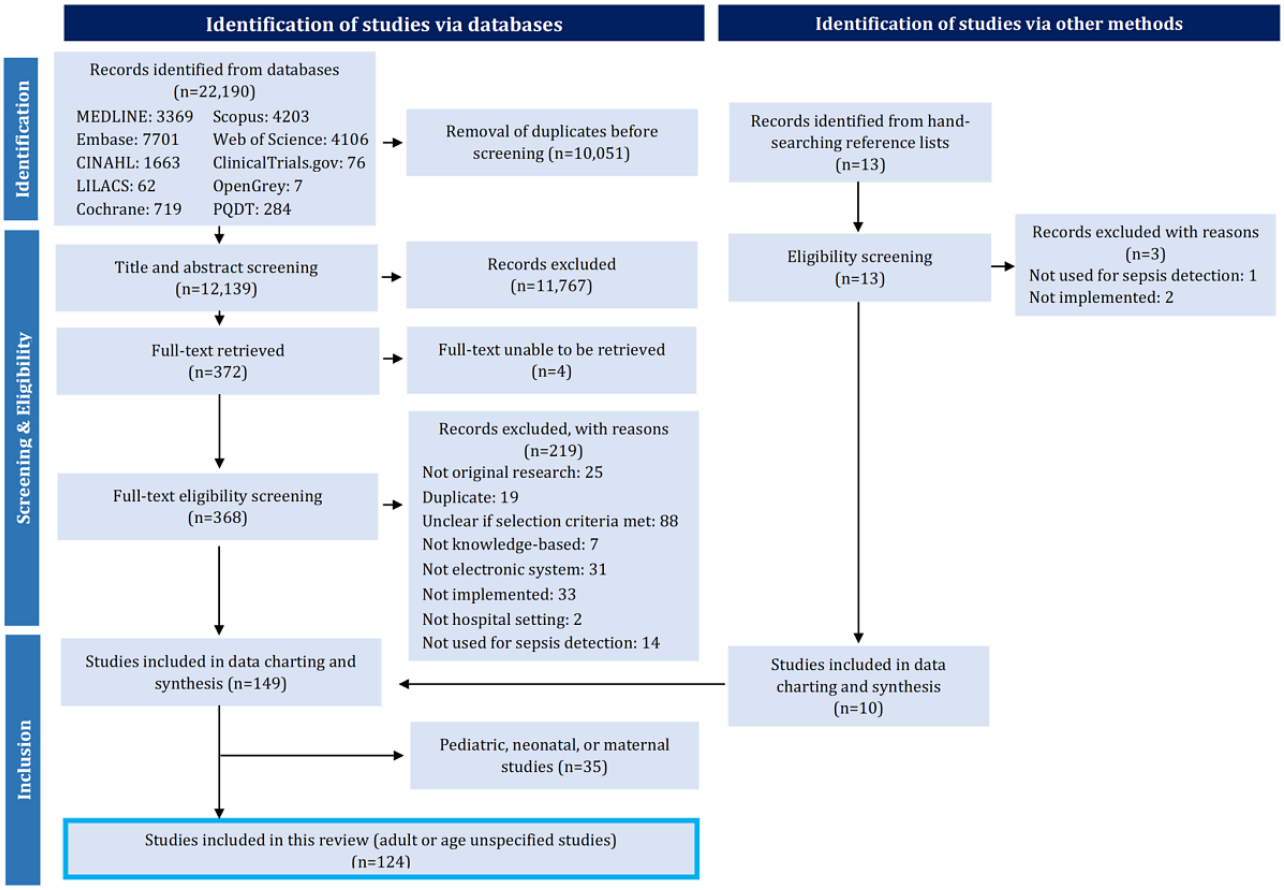
We used a broad 3-step search strategy, as outlined in our protocol [26]. An experienced librarian was consulted to help construct and refine the search. The final search strategy combined terms relating to sepsis with CCDS and detection, while excluding artificial intelligence, and was used to search MEDLINE, Embase, CINAHL, the Cochrane database, LILACS (Latin American and Caribbean Health Sciences Literature), Scopus, Web of Science, OpenGrey, ClinicalTrials.gov, and PQDT (ProQuest Dissertations and Theses Global). We restricted the search to human studies in the English language. An example of the final strategy adapted for MEDLINE can be seen in Multimedia Appendix 2. The database search was undertaken in September 2020, with no date limits applied. The reference lists of relevant systematic reviews were hand-searched to identify additional studies. Any studies identified via hand searching up until the end of data extraction (early 2021) were included. We included both peer-reviewed journal articles and gray literature (ie, conference abstracts and theses).

Following the search, duplicates were removed as was gray literature that had been published as a peer-reviewed journal article. However, we kept studies if they reported the same methods and study cohort but examined different outcomes. Using the eligibility criteria as reported in our protocol [26], 2 reviewers (KA and JB) independently performed title, abstract, and full-text screening, with any disagreements resolved through discussion or review by a third researcher (LL). Title and abstract screening was piloted with a random selection of 25 studies by both reviewers (KA and JB). Similarly, full-text

screening was piloted with a random selection of 10 studies. The 2 reviewers (KA and JB) had 100% agreement during the title and abstract screen pilot, 97.6% agreement for the full title and abstract screen, 60% agreement for the full-text screen pilot, and 77.4% agreement for the full-text screen. Hand searching was completed by 1 reviewer (KA) with identified studies confirmed by a second (JB). A PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram visually illustrating this process is shown in Figure 1.

Following screening, it was determined that the results of this review would be split over 2 papers, one investigating adult or unspecified populations and another investigating pediatric, neonatal, and maternal populations. Pediatric, neonatal, and maternal populations have remarkably different sepsis presentations and physiology compared with the general adult population [30-32]. The separation of results will allow for a more meaningful analysis. Included studies with unspecified age were assumed to likely include all patients in a general hospital setting and were grouped with adult populations. This paper reports the results of all studies investigating CCDS systems studied in adults or populations with an unspecified age.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart demonstrating the study selection process. LILACS: Latin American and Caribbean Health Science Literature; PQDT: ProQuest Dissertations and Theses Global.



Data Abstraction

The data charting form used was iteratively designed based on the study aims. The form was piloted by a single reviewer (KA) and double-checked by a second (JB). Changes to the form were made following discussion between 3 reviewers (KA, JB, and LL). Data charting was performed by 1 reviewer (KA) with ongoing consultation with the review team.

The final data charting form included the components listed in our protocol [26], with minor adjustments as reported in Multimedia Appendix 3 [33-39]. Notably, an additional category *clarity of outcome reporting* was added to the form to account for the variability in outcome reporting transparency. Studies were categorized as having *good* clarity of outcome reporting if they specified the primary outcomes, the outcome analysis method, and the outcome measure definitions and *poor* clarity if the outcomes were not clearly described or there was a substantial reporting discrepancy between the methods and the results. Studies were categorized as having *average* clarity if they fulfilled some criteria of both good and poor.

We accepted any definition of charted data items as specified by the studies. For example, we accepted any definition of systemic inflammatory response syndrome (SIRS), any definition of sepsis, or any cost outcomes specified for the CCDS system. We defined the usability outcome category to follow the ISO definition of usability from ISO 9241-11:2018, section 3.1.1: “extent to which a system, product or service can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specific context of use” [33]. We required usability outcomes to be specifically investigated from the perspective of end point users (ie, clinicians). To match this definition change, usability outcomes

were retrospectively categorized into the effectiveness, efficiency, or satisfaction of the CCDS system from the user's perspective.

Analyzing and Reporting the Results

The results were analyzed through both a narrative review and quantitative descriptive analysis. A narrative summary of the data is presented, organized by our 3 aims. The data charted for each aim are summarized into tables using frequency counts and percentages. Graphical figures were also produced, where appropriate.

Owing to the extensive scope of the data charted, several subgroups were collapsed into larger groups to avoid issues of small cell size and to allow for a more meaningful summary. A complete list of the smaller subgroups condensed into the larger groups, organized by table and figure, can be found in Multimedia Appendix 4. Of note, nurses were frequently reported as CCDS system responding personnel and so were grouped separately from other clinicians to better highlight this.

Ethics

Ethical approval or consent to participate was not required for the scoping review. The data were charted from published studies, and no individual information was included.

Results

Study Characteristics

Our initial search identified 22,190 studies, with 12,139 remaining after duplicate removal. Following title, abstract, and full-text screening, 149 studies met our inclusion criteria (Figure 1). Hand searching identified 10 additional studies, resulting in a total of 159 included studies. Of these 159 studies, 124 investigated adult or unspecified populations and were included in this manuscript (Figure 1). A table detailing the main study characteristics for all 124 included studies can be found in Multimedia Appendix 5 [40-163]. In total, 52.4% (65/124) of the studies were categorized as journal articles, 43.5% (54/124) as conference abstracts, and 4% (5/124) as theses (Multimedia Appendices 4 and 5).

Aim 1: Study Context and Design

The context and design characteristics of the studies included in this review are presented in Table 1. Of the 124 included studies, 111 (89.5%) used purely quantitative methods to evaluate CCDS systems (Table 1). Most studies (96/124, 77.4%) used either single cohort (54/124, 43.5%) or before-after (42/124, 33.9%) study designs (Table 1). Very few studies used more robust study designs, such as randomized controlled trials (5/124, 4%), controlled studies (7/124, 5.6%), or interrupted time series (4/124, 3.2%; Table 1). None of the studies reported the use of reporting guidelines. An approximately even distribution of studies was observed across different hospital settings, such as hospital-wide, and specific settings (eg, intensive care unit [ICU], emergency department, and inpatient wards; Table 1).

All studies but 1 (123/124, 99.2%) were published from 2009 onwards, and of the journal articles, 85% (55/65) were published in 2014 or later (Figure 2). Overall, the number of journal articles published steadily increased over time. Of the 65 journal articles, 46 (71%) reported studies conducted in the United States; 2 (3%) each in Germany, Saudi Arabia, and the United Kingdom; 1 (2%) each in Australia, Brazil, Israel, and South Korea; and 9 (14%) did not report which country they were conducted in (Multimedia Appendix 6).

Just over half (66/124, 53.2%) of the studies specified the age of the population as adult. Within these studies, there was a reasonable variation in the actual age range provided. Almost half (29/66, 44%) reported an adult population aged ≥18 years, whereas 30% (20/66) of the studies did not specify an age range further than *adult*. The remaining studies reported populations using thresholds such as aged >14 (1/66, 2%), ≥14 (3/66, 5%), >16 (2/66, 3%), ≥16 (3/66, 5%), ≥19 (6/66, 9%), and ≥70 (1/66, 2%) years, with 2% (1/66) of the studies inconsistently listing multiple thresholds.

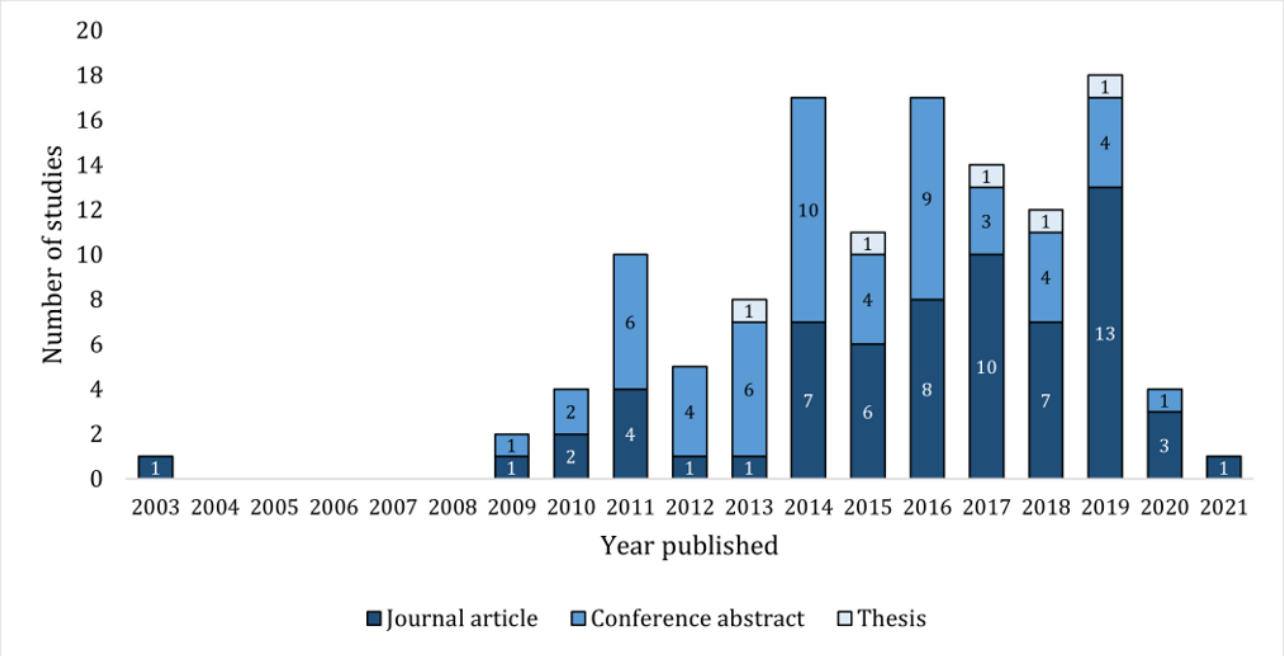
[a]If the study setting was not explicitly stated, it was assumed to be hospital-wide.

Figure 2. Number of studies by publication type and year published. Studies published in 2020 include those until September 2020. Studies published in 2021 were found through hand searching.



Aim 2: Study Outcomes

The outcomes investigated by the included journal articles and the conference abstracts and theses are presented in Table 2 and Multimedia Appendix 7, respectively. Of the 4 predefined outcome categories, patient outcomes were reported in the highest number of studies (107/124, 86.3%; Figure 3). Sepsis treatment and management outcomes were reported in 60.5% (75/124) of the studies, CCDS system usability outcomes in 11.3% (14/124), and cost outcomes in 7.3% (9/124; Figure 3).

Overall, only 31.5% (39/124) of the studies had good clarity in outcome reporting (Figure 4). Generally, studies had average (62/124, 50%) or poor clarity (23/124, 18.5%). Unsurprisingly, journal articles had better clarity of outcome reporting, with 40% (26/65) of the articles having good clarity, compared with 22% (13/59) of the conference abstracts or theses (Figure 4).

In the 65 journal articles, mortality was the most frequently reported patient outcome (39/65, 60%). Overall, 35 different types of mortality measures were reported 55 times across 39 studies (Multimedia Appendix 8). Of these, in-hospital mortality was the most frequently reported (13/55, 24%; Multimedia Appendix 8). Sepsis identification, length of stay, and *other* patient outcomes were also frequently reported, appearing in 38% (25/65), 34% (22/65), and 35% (23/65) of the articles, respectively (Table 2; see Multimedia Appendix 4 for the expanded list of included outcomes). ICU admission was the least reported patient outcome (12/65, 18%). In the sepsis treatment and management outcome category, antibiotic-related and *other* were the most frequently reported outcomes in journal articles (27/65, 42% and 31/65, 48%, respectively), followed by lactate-, fluids-, and blood culture–related outcomes (17/65, 26%; 14/65, 22%; and 14/65, 22%, respectively; Table 2; see Multimedia Appendix 4 for expanded list of included outcomes). Overall, sepsis bundle or protocol compliance was the least reported outcome in journal articles (12/65, 18%).

CCDS system usability outcomes were reported in similar numbers of journal articles, with 12% (8/65) of the journal articles reporting on the efficiency of the system, 11% (7/65) on system effectiveness, and 11% (7/65) reporting on users' satisfaction with the system (Table 2). Among the CCDS system-related cost outcomes, cost was reported in the greatest number of journal articles (5/65, 8%), whereas cost-effectiveness or savings were reported in only 5% (3/65) of the articles (Table 2).

Table 2. Main outcomes and outcome categories in journal articles.

Outcome categories	Outcome classification[a], n (%[b])			Total, (n=65), n (%)[c]
	Primary	Secondary	Not specified[d]	
Patient outcomes

[a]Some studies reported both primary, secondary, or nonspecified outcomes within the same outcome group. To avoid double-counting these studies, secondary outcomes were not counted in favor of counting primary outcomes. Similarly, nonspecified outcomes were not counted in favor of primary or secondary outcomes. For example, a study may have the primary outcome mortality (30-day) and the secondary outcome mortality (7-day), which would both fall into the mortality outcome group. In this example the study would be counted as having mortality as the primary outcome.

[b]These percentages were calculated as row percentages, that is, using the number in the "Total" column in each row as the denominator.

[c]The percentages were calculated from the number of journal articles (n=65), not the number of total outcomes. As many journal articles reported multiple outcomes, there were more than 65 outcomes in each category, and therefore, the percentages will add up to more than 100%.

[d]The study did not specify whether the outcome was primary or secondary.

Figure 3. Proportion of studies reporting each outcome category.

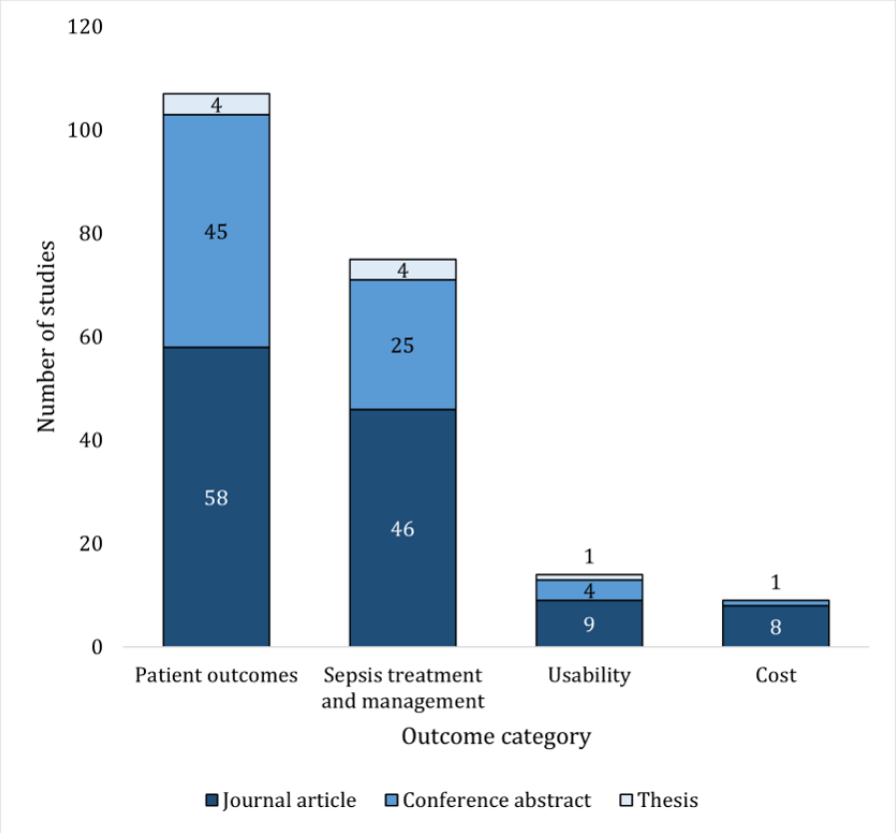

Figure 4. Clarity of outcome reporting in the studies.

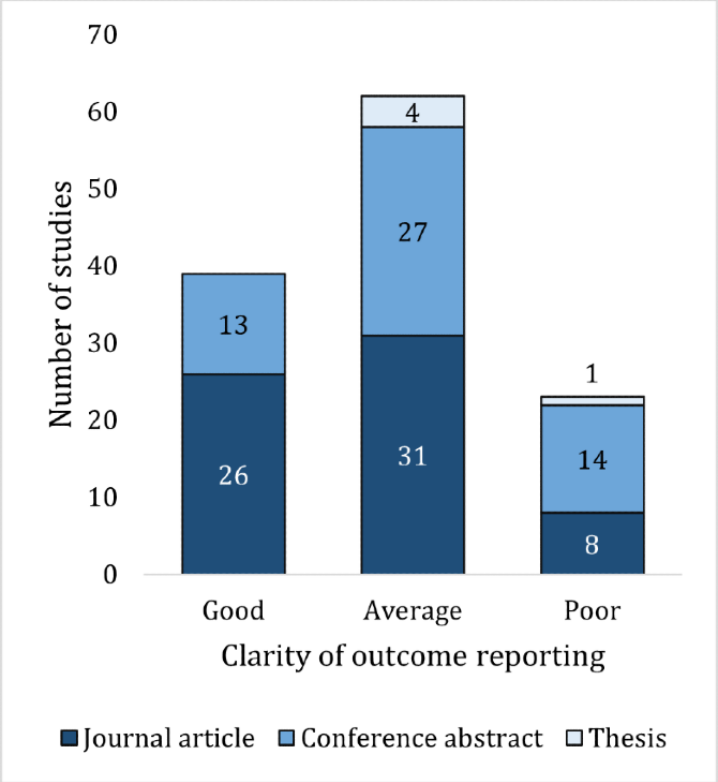

Aim 3: CCDS Characteristics

The characteristics of the CCDS systems reported in the included studies are presented in Table 3. Half (64/124, 51.6%) of the studies, most of which were journal articles (44/64, 69%), implemented homegrown CCDS systems. Of the 124 studies, only 13 (10.5%), including 10 (77%) journal articles, implemented commercial CCDS systems, of which 69% (9/13) were the St John's Sepsis Surveillance Agent (Cerner Corporation, Kansas City, Missouri, United States; Table 3).

Most included studies (95/124, 76.6%) evaluated *live* CCDS systems only, where the CCDS was implemented and actively sending alerts. Silent CCDS, where the system would run in real time but not send clinical alerts, were implemented by 7.3% (9/124) of studies, and 11.3% (14/124) of studies implemented both silent and live CCDS, either sequentially or concurrently.

SIRS alone was the most frequently used CCDS clinical criteria for sepsis identification (50/124, 40.3%), followed by SIRS combined with organ dysfunction (28/124, 22.6%), and SIRS combined with other criteria (23/124, 18.5%; Table 3). In addition, a diverse range of other criteria were used by 32.3% (40/124) of studies (Multimedia Appendix 4), while 7.3% (9/124) did not specify the clinical criteria used (Table 3)

Over half of the studies reported the implementation of CCDS systems alongside numerous other related interventions (68/124, 54.8%), such as staff education programs and antibiotic order sets (Table 3). The most common type of concurrent intervention used was clinical protocols in 41.9% (52/124) of the studies (Table 3).

Most commonly, studies reported nurses (51/124, 41.1%) or other clinicians (37/124, 29.8%) as the main CCDS alert responding personnel (Table 3). Some studies reported on CCDS with response teams (12/124, 9.7%), study coordinators (8/124, 6.5%), or other personnel (11/124, 8.9%) responding to the alerts. Of the 124 studies, 33 (26.6%) reported the use of the electronic health record to distribute CCDS alerts, 26 (21%) the use of pagers, 15 (12.1%) the use of a patient dashboard or work list, and 8 (6.5%) the use of another form of alert delivery (Table 3).

Unspecified	42 (77.8)	19 (29.2)	2 (40)	63 (50.8)

[a]As some studies reported multiple characteristics within each category, there were more than the total number of studies, and therefore, the percentages may add up to more than 100%.

[b]SIRS: systemic inflammatory response syndrome.

[c]As nurses are frequently reported as CCDS system responding personnel, they were grouped separately from other clinicians.

Discussion

Principal Findings

This review canvassed 124 studies in total, representing a comprehensive overview of current research, including an extensive body of gray literature. Over half of the included studies were journal articles (65/124, 52.4%), and nearly all studies were published in the last decade, indicating the considerable volume of recent research investigating the use of CCDS systems for early detection of adult inpatients with sepsis. Our findings demonstrate the substantial diversity of studies across all three aims: (1) the context and design of the study, (2) the type and measurement of outcomes investigated, and (3) the design and implementation of the CCDS system evaluated. We identified little research into the effects of CCDS on patient morbidity or CCDS usability and cost outcomes, highlighting key knowledge gaps in the literature. Our review also underlines the need for robust study designs, as well as improved generalizability and reporting in future studies.

Variability Across Studies

There is extensive heterogeneity in the current literature investigating the implementation and evaluation of CCDS systems for early sepsis detection in adult hospital patients. In particular, there was considerable diversity displayed in the chosen clinical criteria for sepsis identification across the studies included in our review. Although many studies used the SIRS criteria, alone or with adjuncts, there was a substantial range of other criteria used (Multimedia Appendix 4). This can be attributed to the extremely diverse presentations of patients with sepsis, which has led to the development of numerous different clinical scores for sepsis detection [15-18,164]. In addition, our findings demonstrated variability in the method of alert delivery, personnel who respond to alerts, and concurrent implementation of related interventions. Studies were conducted across a range of different hospital settings, including hospital-wide or specific sites, such as the emergency department or ICU (Table 1). The chosen threshold for what age participants were included in the study was also quite variable, with studies defining their *adult* population using cutoff points ranging from 14 to 19 years and older. Finally, our review illuminated the expansive number of outcomes used to evaluate and investigate sepsis CCDS systems. Previous systematic reviews have similarly highlighted this diversity [13,21,22,165,166]. This heterogeneity across settings, participants, CCDS system characteristics, and outcomes makes it difficult to compare studies and to make general statements regarding sepsis CCDS systems.

This diversity can be partially attributed to the novel nature of sepsis CCDS systems and the recent emergence of the field. Our findings show a vast expansion of the literature, with three-quarters of studies published since 2014 (Figure 2). Owing to this recent rapid development of the field and the simultaneous evolution of information and communication technology in health care [21,167], there is no well-established research strategy or dogma for this specific area. Consequently, different authors have designed and executed their studies using a diverse range of variables and study design methodologies.

This variability can also be attributed to the complexity involved in the implementation of health care interventions [168,169]. To characterize this complexity, Greenhalgh et al [170] have designed the NASSS (nonadoption, abandonment, scale-up, spread, and sustainability) framework. In the case of CCDS systems for early sepsis detection in hospitals, the 7 NASSS framework domains can be identified as follows: sepsis (the condition); the CCDS system (the technology); the commercial and health-associated value of CCDS systems (value proposition and value chain); the responding personnel (the adopters); the hospital setting (the organization); the local, state, or national health system (the wider system); and software plasticity (embedding and adaptation over time). Our findings demonstrate that these domains are extremely diverse across the included studies, presenting many variables and variable combinations, consequentially expanding the complexity involved in sepsis CCDS system implementation. As the complexity of a system has been associated with its capacity for successful and sustainable implementation [25], this heterogeneity could detrimentally impact the performance of sepsis CCDS systems. To counter this issue, Greenhalgh et al [25] highlights the importance of system usability and adaptability, suggesting that a user-centered and iterative approach is needed, centralizing the involvement of relevant providers in the implementation plan. Unfortunately, our findings indicate that few of the included studies investigated the usability of sepsis CCDS systems.

Knowledge Gaps for Future Research

Patient Outcomes

Although patient outcomes were the most commonly reported outcome (Figure 3), none of the included studies directly measured the effect of CCDS systems on sepsis morbidity. Surviving sepsis is associated with cognitive impairment, higher mortality rates across the life span, physical disability, and mental health issues [3,4,6,7,9]. This not only substantially reduces the quality of life of survivors of sepsis but also presents an enormous financial burden on both patients and health care

systems [5,8,171,172]. Reducing sepsis morbidity rates through CCDS use would be extremely valuable for patient health and quality of life and in mitigating personal and health care–related costs. Consequently, it is highlighted as a clear gap in the evidence base.

Usability and Cost Outcomes

We identified inadequate investigation of CCDS-related usability and cost outcomes, with most included studies focusing on clinical outcomes. The ability of a user to successfully operate a clinical information system is critical to the success of a system [25,173-175]. This is accentuated in the busy hospital environment, where medical providers are often time poor and carry enormous mental burdens [21,42]. Of particular concern in sepsis CCDS systems is the occurrence of alert fatigue [176,177]. Alert fatigue refers to when clinicians become desensitized to clinical alerts and consequently ignore or turn off alarm systems, potentially missing real sepsis cases [176,177]. This can have serious implications for patient outcomes. Strategies to ensure good CCDS system usability include incorporating human factor design elements, integrating CCDS system sepsis workflows into current medical emergency clinical pathways, and linking CCDS systems with existing clinical deterioration policies [42,178-180]. Only 11.3% (14/124) of the studies we investigated included usability outcomes, with only 14% (2/14) of these studies [70,93] evaluating alert fatigue. This represents a clear gap in the current literature for further research to support the successful implementation of appropriate, usable, and effective CCDS systems for early sepsis detection in hospitals.

In addition, very few studies investigated cost outcomes of CCDS system implementation. Sepsis is an extremely expensive condition to treat [171]. It has been reported to cost more than US $20 billion annually and is listed as the most financially costly condition in US hospitals [172]. Sepsis-related costs can range from extensive hospital costs during acute treatment to high long-term treatment and rehabilitation costs in survivors of sepsis [3,171,181]. Determining the cost-effectiveness of sepsis CCDS systems would assist in establishing the financial feasibility of implementation in hospitals and support widespread implementation.

Study Design and Generalizability

Few studies applied robust study designs such as randomized controlled trials, interrupted time series, stepped wedge clusters, and controlled trials. Future research in this area should attempt to use more rigorous methodology to present stronger evidence.

Approximately three-quarters of the included journal articles were conducted in the United States (Multimedia Appendix 6), limiting generalizability to other settings. A recent study demonstrated that the bulk of the sepsis burden is in countries with a low, low-middle, or middle sociodemographic index [2]. Future studies investigating the use of CCDS systems for adult sepsis inpatient identification should be encouraged to examine trends in countries outside the United States. In particular, CCDS systems should be evaluated in low- to middle-income countries when possible, given the limited availability of electronic health care technology in such regions.

Reporting and Transparency

A large proportion of studies did not specify important study design, CCDS system, and main outcome details (Tables 1-3). An unexpectedly high number of journal articles did not report these details nor did most conference abstracts; however, this is more understandable given word limit constraints. Of particular concern is that almost two-thirds of the included journal articles were found to have an average or poor clarity of outcome reporting (Figure 4). None of the studies included in this review published the use of reporting guidelines, likely because of many journals not specifically requiring it. Overall, we found that the quality of reporting is low and identified a need for improved reporting and transparency throughout the literature.

Strengths and Limitations

This scoping review comprehensively canvassed the literature investigating knowledge-based implemented CCDS systems for early sepsis detection in adult hospital patients. Its strength lies in this breadth of coverage and the wide range of study elements examined. The review followed the PRISMA-ScR expansion [28] guidelines, the Joanna Briggs Institute Reviewer's Manual [27], and the framework presented by Arksey and O'Malley [29].

A limitation of this scoping review is that it only included studies written in English or had English translations readily available. Furthermore, only a sample of the charted data was double-checked by a second reviewer, potentially resulting in a higher error margin. However, the data charting forms were well structured, and any issues occurring during charting were fully discussed among the research team to reach consensus.

Conclusions

This review highlights the extensive variability in the design, outcomes, and system characteristics in studies investigating the use of CCDS for the early detection of sepsis in adult inpatients. This heterogeneity can be largely attributed to the considerable complexity of sepsis, CCDS software, and the hospital environment. Our findings have identified clear gaps in the current literature, with few studies investigating CCDS system usability, cost, or the effects on patient morbidity. There are limited studies conducted outside the United States or with robust study designs. Our findings have illustrated frequent poor reporting of CCDS system information and study outcomes. It is critically important for future research to close these knowledge gaps, ensuring comprehensive evaluation of these rapidly emerging sepsis CCDS systems.

Acknowledgments

The authors would like to thank Mr Jeremy Cullis, an experienced clinical librarian, for his advice and expertise in designing the final search strategy and translating it to other databases.

The authors received no financial support or funding for this study.

Abstract

The decision to accept or reject new digital health technologies remains an ongoing challenge among health care patients, providers, technology companies, and policymakers. Over the past few decades, interest in understanding the choice to adopt technology has led to the development of numerous theories and models. In 1979, however, psychologists Kahneman and Tversky published their seminal research article that has pioneered the field of behavioral economics. They named their model the prospect theory and used it to explain decision-making behaviors under conditions of risk and uncertainty as well as to provide an understanding of why individuals may make irrational or inconsistent choices. Although the prospect theory has been used to explain decision-making in economics, law, political science, and clinically, at the individual level, its application to understanding choice in the adoption of digital health technology has not been explored. Herein, we discuss how the main components of the prospect theory's editing phase (framing effect) and evaluation phase (value function and weighting function) can provide valuable insight on why health care patients, providers, technology companies, and policymakers may decide to accept or reject digital health technologies.

decision-making; digital health technology adoption; prospect theory

The Challenge to Accept or Reject a Digital Health Technology

Digital health technology includes a broad spectrum of categories, such as mobile health, clinical information systems, wearable devices, telehealth, and personalized medicine. From mobile fitness applications to machine learning technologies used to improve disease diagnosis, clinical decision-making, and health care delivery, digital health is revolutionizing the field of medicine [1]. Nevertheless, the decision to accept or reject new digital health technologies remains an ongoing challenge among health care patients, providers, technology companies, and policymakers. Over the past few decades, interest in understanding the choice to adopt technology has led to the development of numerous theories and models.

The Technology Acceptance Model

The Technology Acceptance Model (TAM), proposed by Fred Davis in 1989, is one of the most prominent theories developed to explain the behavioral intention to use a technological innovation [2]. Applying concepts from the theory of reasoned action and theory of planned behavior, the TAM suggests that the intended use of technology is determined by its "perceived ease of use" and "perceived usefulness." Both factors are connected with one's behavioral intention, which is linked to actual behavior and system characteristics (external variables) [2,3]. Although the TAM's simplified rationale has made it

popular among researchers, academics, and within the technology industry, it is also one of its main criticisms [4]. In many studies, it is reduced to concepts that make outcomes such as intended use the primary finding, which lowers the TAM's explanatory capability and provides little insight on the actual use of the technology studied [4].

The Prospect Theory

In 1979, however, psychologists Kahneman and Tversky published their seminal research article that has pioneered the field of behavioral economics by providing a novel understanding of decision-making. They named their model the prospect theory and used it to explain decision-making behaviors under conditions of risk and uncertainty [5]. This theory also provides an understanding of why individuals may make irrational or inconsistent decisions [5]. Although the prospect theory has been used to explain decision-making in economics, law, political science, and clinically, from the physician's perspective, its application to understanding choice in the adoption of digital health technology has not been explored [6]. Notably, this can provide valuable insight on why health care patients, providers, technology companies, and policymakers may decide to accept or reject digital health technologies under conditions of risk or uncertainty as well as provide an explanation for the perceived irrational or inconsistent decisions concerning the adoption of digital health technology in medicine [7].

The Editing Phase of the Prospect Theory

The prospect theory consists of two main phases, an editing phase and an evaluation phase. In the editing phase, individuals perform a preliminary analysis of choices or prospects they are provided. This allows one to organize and edit the choices available with the aim of simplifying the decision-making process [5]. It is also during this phase that reference points, often referred to as framing effects, are made to help guide one's decision. However, framing effects can be influenced by the order, method, or wording in which they are presented [5].

Regarding the adoption of digital health technology, a framing effect can occur when a patient is offered a choice concerning their management of care. For example, individuals with a high risk of experiencing an acute cardiac event can be offered the choice to continue their current level of care (eg, routine clinic visits) or adopt a novel wearable digital health device, such as a smart watch that monitors their vital signs dynamically and advises them when to modify their lifestyle behaviors or seek medical attention.

Similar to Tversky and Kahneman's framing effect experiments involving hypothetical infectious disease management scenarios, the adoption of wearable digital health devices can be framed in various manners. For instance, the use of a wearable digital health device can be described as providing a 100% likelihood of improving one-third of users' quality of life when compared with the current standard of care. Conversely, the same device can be described as offering a 100% probability that two-thirds of users will not experience any quality-of-life improvement when compared with the current standard of care. In the first scenario, the choice is framed as an opportunity to achieve a gain of improved quality of life. Conversely, choosing the digital health device in the second example is framed as a loss as there is a greater likelihood of no benefit, but wasted time. In reality, the outcomes of both choices are the same. However, Kahneman and Tversky discovered that people make different decisions among the same choices with certainty in gains (100% likelihood of improving one-third of users' quality of life) being more desirable than certainty in loses (100% probability that two-thirds of users do not experience an improvement in their quality of life) [5].

The Evaluation Phase of the Prospect Theory

Once a choice is simplified and framed for a decision, the evaluation phase of the prospect theory begins. There are two key components in this phase, the value function and weighting function. The value function refers to the original reference point or choice, which is often the individual's current status. This baseline reference point is then compared with an operative reference point, often a future goal. An important characteristic of the value function is that the worth of each choice is dependent on how the individual perceives the change between their current and future states [5]. For example, when compared with the current standard of care (routine clinic visits), the value function for patients with cardiovascular disease using a digital health smart watch can be described as providing continuous medical feedback that fosters patient autonomy, education, and personalized preventative care while reducing health care costs.

Another important aspect of the value function is that individuals are more risk averse in the context of making gains. For example, many telehealth companies are reporting significant increases in revenue as their digital platform usage grows due to the United States' COVID-19 government policies promoting social distancing, equal reimbursement for virtual and physical visits, and the permission granted to physicians to use these tools to practice care across state lines, as well as without requiring additional state medical licenses. If these companies choose to save the additional profits or gains made during the COVID-19 pandemic instead of using them to upgrade or develop new products, they are demonstrating the value function's risk aversion approach. Conversely, Kahneman and Tversky found that individuals are more likely to take risks in the context of experiencing losses [5]. This would mean that if telehealth companies experienced substantial revenue losses during the COVID-19 pandemic, they would likely take greater financial risks to return to a favorable position [5].

The final concept of the value function is known as loss aversion, which states losses are more painful than equal gains are pleasing. In a hypothetical scenario, health care policymakers are presented with a choice to adopt a novel electronic health record (EHR) system that aims to reduce hospital costs and inefficiencies by improving resource management. However, the risk in adopting this system is a loss of $100 million of taxpayers' money if it fails. Conversely, if it succeeds, $100 million of taxpayers' money will be saved. In their research,

Kahneman and Tversky found that when individuals are presented with a similar loss or equal gains choice, they must be offered at least twice as much in gains as compared with losses to take the risk [8]. Concerning the EHR example above, this means health care policymakers would be more likely to adopt the system if the net gain or money saved is $200 million or more when compared with the risk of losing $100 million if it failed.

Regarding the evaluation phase's weighting function, Kahneman and Tversky showed that people give higher value to outcomes that are less likely to develop, while giving less importance to outcomes with a medium to high probability of occurring. Moreover, individuals are more likely to take a sure loss against a small possibility of a larger loss. This is often seen with the purchase of warranties or insurance, a sure loss, on digital health devices such as smart watches that monitor vital signs or EHR systems. In this situation, the cost of repairing the device if it breaks is higher (a small possibility of a larger loss) when compared with the minimal loss of insuring the product (a sure loss).

Conclusion

The prospect theory, as illustrated by the examples given, provides valuable insight on why health care patients, providers, technology companies, and policymakers may decide to accept or reject digital health technologies. Given the rapid growth of this industry, the medical field and its stakeholders have more choice than ever regarding the adoption of digital health tools. Nevertheless, by understanding why choices are made, we can make better informed decisions when selecting our next digital health technology prospect.

Abstract

Background: Psychiatry has long needed a better and more scalable way to capture the dynamics of behavior and its disturbances, quantitatively across multiple data channels, at high temporal resolution in real time. By combining 24/7 data—on location, movement, email and text communications, and social media—with brain scans, genetics, genomics, neuropsychological batteries, and clinical interviews, researchers will have an unprecedented amount of objective, individual-level data. Analyzing these data with ever-evolving artificial intelligence could one day include bringing interventions to patients where they are in the real world in a convenient, efficient, effective, and timely way. Yet, the road to this innovative future is fraught with ethical dilemmas as well as ethical, legal, and social implications (ELSI).

Objective: The goal of the Ethics Checklist is to promote careful design and execution of research. It is not meant to mandate particular research designs; indeed, at this early stage and without consensus guidance, there are a range of reasonable choices researchers may make. However, the checklist is meant to make those ethical choices explicit, and to require researchers to give reasons for their decisions related to ELSI issues. The Ethics Checklist is primarily focused on procedural safeguards, such as consulting with experts outside the research group and documenting standard operating procedures for clearly actionable data (eg, expressed suicidality) within written research protocols.

Methods: We explored the ELSI of digital health research in psychiatry, with a particular focus on what we label "deep phenotyping" psychiatric research, which combines the potential for virtually boundless data collection and increasingly sophisticated techniques to analyze those data. We convened an interdisciplinary expert stakeholder workshop in May 2020, and this checklist emerges out of that dialogue.

Results: Consistent with recent ELSI analyses, we find that existing ethical guidance and legal regulations are not sufficient for deep phenotyping research in psychiatry. At present, there are regulatory gaps, inconsistencies across research teams in ethics protocols, and a lack of consensus among institutional review boards on when and how deep phenotyping research should proceed. We thus developed a new instrument, an Ethics Checklist for Digital Health Research in Psychiatry ("the Ethics Checklist"). The Ethics Checklist is composed of 20 key questions, subdivided into 6 interrelated domains: (1) informed consent; (2) equity, diversity, and access; (3) privacy and partnerships; (4) regulation and law; (5) return of results; and (6) duty to warn and duty to report.

Conclusions: Deep phenotyping research offers a vision for vastly more effective care for people with, or at risk for, psychiatric disease. The potential perils en route to realizing this vision are significant; however, and researchers must be willing to address the questions in the Ethics Checklist before embarking on each leg of the journey.

Introduction

"The deeper you go, the more you know." This headline captures the tantalizing promise of deeply probing digital health research in psychiatry [1].

Psychiatry has long needed a better and more scalable way to capture the dynamics of behavior and its disturbances, quantitatively across multiple data channels, at high temporal resolution in real time. By combining 24/7 data—on location, movement, email and text communications, and social media—with brain scans, genetics, genomics, neuropsychological batteries, and clinical interviews, researchers will have an unprecedented amount of objective, individual-level data [2,3]. Analyzing these data with ever-evolving artificial intelligence offers the possibility of intervening early with precision and could even prevent the most critical sentinel events [4]. Ideally, this could one day include bringing interventions to patients where they are in the real world, in a convenient, efficient, effective, and timely way [5,6].

Yet, the road to this innovative future is fraught with ethical dilemmas [7-10], and ethical, legal, and social implications (ELSI) on issues such as informed consent and return of results must be reexamined in light of research employing previously unavailable deep and computational characterization of humans based on: (1) real time and cross-sectional behavioral measures; (2) imaging, interviews, and other phenotypic data; (3) genotypic data; and (4) epigenetic and environmental data. The potentially boundless data collection across these streams gives rise to what might be described as "deep biobehavioral typing" or "deep geno/phenotyping." Given these multiple streams, ethical frameworks for deep biobehavioral typing must integrate the overlapping ethics of genetics, genomics, ethics of brain imaging, ethics of real time digital monitoring, and so forth to critically reexamine well-known ELSI issues. For example, when considering return of results, although it is true that the deeper you go, the more you know, it is unclear when a researcher knows enough to justify sharing data with a clinician, alerting appropriate individuals about potential self-harm, and returning individual research results [11].

Supported by a National Institutes of Health (NIH) Bioethics Administrative Supplement award (NIH 1U01MH116925-01), we have been exploring the ELSI of digital health research in psychiatry, with a particular focus on what we label "deep phenotyping" psychiatric research, which combines the potential for virtually boundless data collection and increasingly sophisticated techniques to analyze that data. We convened an interdisciplinary expert stakeholder workshop in May 2020, and this checklist emerges out of that dialogue. As we use it in this article, the phrase "deep phenotyping" in psychiatric research is meant to describe research that—even if it does not encompass a large number of research subjects—goes deep into the lives of those subjects by collecting many digital and biological data streams (eg, digital data such as text messages, phone screen shots, and GPS location; health data such as heart rate and blood pressure; and clinical evaluations and biological data such as genetics and brain scans).

Consistent with recent ELSI analyses [8,9], the bottom line of our bioethics analysis is that existing ethical guidance and legal regulation are not sufficient for deep phenotyping research in psychiatry. At present, there are regulatory gaps and inconsistencies across research teams in ethics protocols. There is also a lack of consensus among institutional review boards (IRBs) on when and how deep phenotyping research should proceed [12,13]. Efforts are underway to fill these gaps, notably those led by the Connected and Open Research Ethics initiative at the University of California San Diego [9].

Until the field develops more robust consensus guidelines, however, the onus clearly falls on individual research teams to take the lead in shaping the applied ethics of digital health research in psychiatry.

To guide these ethics considerations, we developed a new instrument, an Ethics Checklist for Digital Health Research in Psychiatry ("the Ethics Checklist"). The Ethics Checklist is composed of 20 key questions, subdivided into six interrelated domains: (1) informed consent; (2) equity, diversity, and access; (3) privacy and partnerships; (4) regulation and law; (5) return of results; and (6) duty to warn and duty to report. The questions included in the checklist are presented in Table 1, and Multimedia Appendix 1 provides the Ethics Checklist as a user-friendly instrument for research teams.

The goal of the Ethics Checklist is to promote the careful design and execution of research. It is not meant to mandate particular research designs; indeed, at this early stage of digital phenotyping research and without consensus guidance, there are a range of reasonable choices researchers may make. But the checklist is meant to make those ethical choices explicit, and to require researchers to give reasons for their decisions related to ELSI issues. The Ethics Checklist is primarily focused on procedural safeguards, such as consulting with experts outside the research group and documenting standard operating procedures for clearly actionable data (eg, expressed suicidality) within written research protocols.

Table 1. Ethics checklist for digital health research.

Category	Category description	Checklist items
Informed consent	How can we meaningfully communicate and be transparent about research methods that involve deep, complex, often passive and continuous data collection, machine learning analysis, and interpretation?	1. Have we appropriately adapted our informed consent procedures to our specific study population, including possible use of surrogate consent?
		2. Will we provide background education on relevant technologies, such as explaining what social media companies may already be doing with the participant's data?
		3. Have we determined what a reasonable person would want to know, and explained in our institutional review board proposal the evidence on which we reached that determination?
Equity, diversity, and access	How will we address concerns that our research might replicate existing, or generate new, biased results or contribute to health inequities in access based on race, ethnicity, gender, sexual orientation, age, or another legally protected class?	4. Starting at the early conceptualization and research design stages, have we sought input from a diverse community of stakeholders to identify and address potential equity concerns and opportunities to advance justice with our proposed research?
		5. Has our research plan addressed potential inequities in access, for instance varying levels of access to mobile technology and to health care services?
		6. Has every member of the research team completed our institution's recommended trainings around diversity, inclusion, equity, and access?
Privacy and partnerships	How can we design our research to balance an interest in robust data collection, with a potentially competing interest in protecting participant privacy?	7. Have we consulted with information security experts about exactly where the data will flow, from start to finish?
		8. Do we have a written policy on data deidentification and participant privacy that is consistent with best practices in psychiatry and neuroscience?
		9. Have we determined which, if any, third-party vendors will be required to be HIPAA[a] compliant and sign a Business Associate Agreement?
Regulation and law	Which state, federal, and international law and regulatory guidance must be adhered to in our research?	10. Have we examined the terms of service, end user license agreements, privacy statements, and HIPAA notices for each of the vendors and software applications involved in our research?
		11. Have we determined how laws in applicable jurisdictions will treat the data we collect, for instance considering the data to be "sensitive," "special category," or "personal health information"?
		12. Have we ensured compliance with state, federal and international laws governing our research, HIPAA privacy requirements, state data privacy laws, and applicable international privacy laws?
Return of results	By which criteria will we determine if our data analytic models are sufficiently valid and reliable for us to share the individual research results and data with the research participant and the participant's clinicians?	13. Have we considered whether our study will generate any "actionable" results, based on established guidelines and how we have defined actionability?
		14. Have we established with what frequency results will be returned? (eg, should participants have daily, weekly, and monthly access to some subset of their data?)
		15. Have we clarified the protocols and mechanisms for returning different types of information, (eg, raw data, interpreted data, etc)?
		16. Do we have a protocol in place for contacting a participant's clinicians and nonclinical caregivers?

Category	Category description	Checklist items
Duty to warn and duty to report	When might our research trigger a legal or ethical duty to report the potential for participant self-harm or harm to others, and what are our protocols for determining whether in individual instances we have such a duty?	17. Has everyone in our research lab received sufficient training to know when to flag data or results as requiring follow-up review by a supervisor? 18. Will our analytic methods allow us to identify the precursors to dangerous or illegal behavior, to oneself or to others, and if so, at which point will we intervene to protect the research participant or a third party? 19. Have we updated our lab's suicidality standard operating procedure to be consistent with the novel data acquisition and analysis techniques we are using in our study? 20. Do we have a protocol for responding to legally mandated reporting if our data uncover child pornography, restraining order violations, and so on?

[a]HIPAA: Health Insurance Portability and Accountability Act.

The Ethics Checklist in Action

Each of the 20 ethics checklist questions are phrased so that they can be answered with a "Yes," "No," or "Pending" response. In our view, deep phenotyping research in psychiatry should not proceed until a research team answers "Yes" or "Pending" to each checklist question. To arrive at "Yes" or "Pending" for each question will require research labs to carefully consider a complex interplay of ethical and legal considerations.

It is beyond the scope of this short paper to address all of these complexities, but we offer here several illustrative examples, from each of the 6 key domains, of how the checklist might be applied in practice.

Informed Consent

The revised Common Rule requires researchers to present participants with information that is "most likely to assist … in understanding the reasons why one might or might not want to participate in the research," and that is what "a reasonable person would want to have …" (Title 45 of the Code of Federal Regulations, part 46, effective July 2018) [14]. The Ethics Checklist thus requires researchers to address the question: "Have we determined what a reasonable person would want to know, and explained in our IRB proposal the evidence on which we reached that determination?" There are presently no empirical data or standard protocols for determining what information a reasonable person would want to have before agreeing to participate in deep phenotyping research. Privacy scholars and ethicists are increasingly concerned that the rights of "notice, access, and consent regarding the collection, use, and disclosure of personal data" are no longer adequate because "many privacy harms are the result of an aggregation of pieces of data over a period of time by different entities" [15]. Thus, researchers must consider a broad range of possible information to communicate.

We offer here several of these many possibilities. One decision is whether to provide research participants a list of clear, concrete examples of the inferences that can likely be made from participants' data. For example, the informed consent material could explicitly say, "You should know that, although we will not reveal this information outside the research team, we may be able to identify when you are going to the bathroom or having sex." Another decision, especially for researchers who are collecting data on participants' GPS data and social media content, is whether to provide basic background education to make participants more informed on the data collection and data sharing practices already being utilized by the mobile technology and apps they already use regularly. Third, ethics research has identified a need to make informed consent processes more meaningful and valid by improving communication [16,17]. Research teams may consider innovative strategies such as video-based multimedia as part of the consent procedure [18-20]. They may also consider staged informed consent [21,22], dynamic consent to facilitate 2-way communication between researchers and participants [23], or a systemic oversight approach for big data research that provides flexibility for addressing uncertainty in how data will be used [24].

In addition, researchers in psychiatry must address a further question that has long been challenging for the field, "how to ensure meaningful and valid informed consent with participants who have a mental illness?" [25,26]. The question of decisional capacity in psychiatric research has been well researched, with multiple instruments now available [27], but the field will need to revisit the effectiveness of these instruments in the new context of deep biobehavioral research.

Equity, Diversity, Inclusion, and Access

It is well established that biomedical research generally [28] and psychiatric research specifically struggle to enroll racially and ethnically diverse participants [29]. In the United States, for example, there is a reluctance of African Americans to participate in research given a long history of racism and exploitation [30,31].

The Ethics Checklist proposes that researchers answer the following question: Starting at the early conceptualization and research design stages, have we sought input from a diverse community of stakeholders to identify and address potential equity concerns and opportunities to advance justice with our proposed research? The question emphasizes that equity concerns extend beyond simply developing proportional samples, and that from the start, "[r]esearch relationships must

become balanced, reciprocal, and community informed, without centering researcher and institutional priorities" [32]. Community advisory boards, which can be comprised of community and family stakeholders, can be a useful vehicle for facilitating such engagement [33]. Operationalizing "diverse community of stakeholders" will depend on the nature and scope of the research, institutional context, and affected communities. The stakeholder group will necessarily be comprised differently; for instance, whether the focus is on a single disease versus basic research, or the research involves multiple international sites versus a single community partner.

In defining the stakeholders, the checklist encourages researchers to go beyond their own research team to seek guidance and build trust, even at the conceptual and research design stage. We agree with Wilkins [34], who suggests that enhancing trust "must build on the principles of community engagement including balancing power dynamics, equitable distribution of resources, effective bidirectional communication, shared decision-making, and valuing of different resources and assets (such as the lived experience and knowledge of group norms and perspectives)." Researchers might, for instance, consult with their institution's leadership on diversity and inclusion to see if the institution already has mechanisms in place for community engagement. Additional options include reviewing the best practices in community-based participatory research and community-engaged research [35] and consulting expertise in other disciplines, including law [36] and the humanities [37].

Privacy and Partnerships

In an analysis of smartphone digital phenotyping, Onnela and Rauch [38] write that "[p]atient and participant privacy is always of utmost importance in clinical and research settings." The literature on ethics of deep phenotyping has similarly identified privacy as foundational [39,40]. Deep phenotyping research requires that data flow across multiple platforms and vendors; thus, to safeguard data privacy, researchers must be aware of where the data go, what happens to the data at each stop, and where security vulnerabilities may exist [10]. The Ethics Checklist thus includes the question, "Have we consulted with information security experts about exactly where the data will flow, from start to finish?" Such consultation could potentially lead to modifications in data collection and data analysis techniques to improve privacy safeguards. For instance, security experts may be aware of the vulnerabilities of particular apps or new technical advances recently developed.

Regulation and Law

The regulation of mobile health apps is currently undergoing transformation [41,42], as is the regulation of artificial intelligence and machine learning data analysis [43]. At the same time, state privacy laws are emerging [44], as are international law innovations such as the European Union's General Data Protection Regulation [45]. These legal developments have implications for the deep phenotyping research we describe in this article [7].

For instance, the data collection may require interfacing with multiple third-party vendors, and it is the responsibility of the research team to examine the terms of service, end user license agreements, privacy statements, and Health Insurance Portability and Accountability Act (HIPAA) notices for each of these vendors and associated software applications (Checklist question 10). This may not be an easy task, as research on mobile health apps suggests that many vendors do not have a privacy policy publicly available [46]. It will also be challenging to determine how applicable laws will treat the data being collected (Checklist question 11). Different laws define categories differently. For example, what is considered "sensitive" data under the California Consumer Privacy Act and California Privacy Rights Act might be different from what is considered "special category" data under the European Union's General Data Protection Regulation or considered "personal health information" under HIPAA [47]. In setting up the research design, the research team may need to enlist institutional or external expertise to help understand and comply with these statutes.

In addition, when data collection follows the individual across state or international boundaries, and when data flow across those boundaries, the research will be exposed to multiple legal jurisdictions, including emerging state laws governing privacy and research [48]. For example, if data is collected continuously while a research participant living in Boston visits a relative in Chicago, then goes to a meeting in Baltimore, both the Illinois Biometric Privacy Act and the Maryland Confidentiality of Medical Records Act may apply. This may place different requirements on the research team. Similarly, if data gathered from a research participant in Detroit are transferred to a vendor operating in nearby Windsor, Canada's data privacy laws may now be relevant in a way they would not be for traditional research with subjects and data firmly rooted in the United States. Given this potential for movement of research subjects, researchers should answer the question, "Have we ensured compliance with state, federal and international laws governing our research, HIPAA privacy requirements, state data privacy laws, and applicable international privacy laws?" Reviewing HIPAA compliance is foundational, and the details of such review are beyond the scope of our commentary; however, we emphasize here that, given the geographic mobility of the subjects, HIPAA is not the only applicable privacy regime. Thus, addressing legal and regulatory concerns may likely require consultation with legal experts in the researcher's institution. This review of privacy law can be integrated with the Ethics Checklist question 10 concerning vendors' policies and question 11 concerning the designation of sensitive information.

Return of Results

The return of individual research results has garnered significant attention in the ethics literature [49-51]. In the context of deep phenotyping research, the return of results is challenging because there are potentially so much data to return and because some of that data fluctuate over time and could be returned hourly, daily, weekly, monthly, and so on. In a virtual workshop we hosted in May 2020, a group of 25 stakeholders from science, medicine, law, and ethics gathered to explore the issues of return of results in deep phenotyping research. The discussion in that workshop made clear that, at present, there is considerable

uncertainty over what constitutes "actionable" information in this space as well as divergent practices among research teams in which information participants can access. The Ethics Checklist includes 4 different questions on return of results, including, "Have we considered whether our study will generate any 'actionable' results, based on established guidelines, and how have we defined actionability?" The concept of actionability is debated across multiple fields [50,52], and in the context of deep phenotyping it is not clear where the bounds of actionability are.

For instance, if a research team is measuring step count data and a participant's step count drops below average in a given week, alerting that participant of the data is actionable in the sense that the participant—informed by these data—may choose to walk substantially more steps next week. But what about more complex results, such as a machine learning algorithm that predicts that the participant has a 72% higher likelihood of experiencing a manic episode in the following year? When has the scientific knowledge base accumulated sufficiently to make such a prediction "actionable"? An even more fundamental question is implicated: for any measurement or prediction, what is the confidence in the measurement, sensitivity, or specificity of the interpretation or prediction, and how should that be shared? The effects of researcher mobile health interventions on participants within research studies are only now being studied [53], and the field is still formulating practices for clinical interventions based on phenotyping data [54].

The potential ethical responsibility and legal duty for reanalysis of data is also of concern. For instance, in genomics research, many genetic variations are classified as "variant of uncertain significance (VUS)," but as knowledge increases, those variations may be reclassified [55]. An ethical and legal question is whether researchers should (or must) revisit previously collected data to determine whether reclassification is warranted, and if so, when and how should they contact those participants from the earlier study [56]. This issue will likely emerge in deep geno/phenotyping research, and it should be proactively anticipated with a policy put into place.

Duty to Warn and Duty to Report

The duty to warn and the duty to report are well known to psychiatric researchers, but the advanced data collection and data analysis methods of deep phenotyping introduce unique concerns [57]. At present, the field has only begun to develop protocols and thresholds for when the data should trigger a legal or ethical duty to report the potential for participants' self-harm or harm to others, and further work is needed to address the possibility of false positives, false negatives, and reliable signal detection. For instance, among the 4 questions included in the Ethics Checklist under this heading, we require that researchers address the question, "Have we updated our lab's suicidality standard operating procedure (SOP) to be consistent with the novel data acquisition and analysis techniques we are using in our study?" Traditionally, suicidality SOPs have relied almost exclusively on the clinical judgment of the psychiatrist or psychologist reviewing individual records and conducting interviews with the participant. The goal of deep phenotyping research, however, is to reduce reliance on this single stream of data, and instead to incorporate many additional real-world data points. The suicidality SOP may need to be modified in recognition of this new paradigm of psychiatric assessment. For instance, if GPS data show that the participant has spent 3 hours at a local bar, then is located on a bridge at 2 AM in the morning, and has sent 20 text messages in the past 5 minutes, is there a way for the research team to have such behavior flagged in real time and should there be a real time intervention in the protocol? The Ethics Checklist requires that researchers consider such situations.

The Urgent Need for Consensus Guidance

Deep phenotyping research offers a vision for vastly more effective care for people with or at risk of psychiatric disease. The potential perils en route to realizing this vision are significant; however, researchers must be willing to address the questions in the Ethics Checklist before embarking on each leg of the journey.

The illustrative examples discussed above make clear that deep phenotyping researchers have few guideposts and little empirical data with which to address many pressing ethical and legal questions critical for their research. This lack of clarity regarding best practices is understandable for a field that has emerged rapidly, mainly in the past 5 years. But as the field continues to expand, there is a need to fill this gap by developing consensus guidance, informed by quantitative and qualitative bioethics research, as well as community and patient advocate input. This paper has raised more questions than answers, and it did not reach many other avenues of inquiry including considerations for international research and research with children.

To make progress toward consensus guidance, we identify 2 immediate action items. First, ethics should be integrated into the practice of deep phenotyping research (as is already being carried out at centers such as the McLean Institute for Technology in Psychiatry and the Connected and Open Research Ethics initiative at the University of California San Diego Research Center for Optimal Digital Ethics in Health).

Second, professional organizations such as the American Psychiatric Association and the Digital Medicine Society, along with institutions such as the NIH and National Academies, are well positioned to convene an interdisciplinary team to conduct in-depth analysis and produce foundational reports to guide the field.

The deeper you go in deep phenotyping research, the deeper the ethical and legal challenges. But with timely, concerted action, the research community can promote ethically sound and legally compliant digital health research in psychiatry.

Acknowledgments

We thank our student research assistant Lois Yoo. We also thank the participants in a virtual workshop hosted by the McLean Institute for Technology in Psychiatry on May 8, 2020, to explore the ethical, legal, and social implications of return of results in deep phenotyping research. Research reported in this publication was supported by a Bioethics Supplement from the National Institute of Mental Health (NIMH) of the National Institutes of Health (NIH) under Award Number 1U01MH116925-01. The content is solely the responsibility of the authors and does not necessarily represent the official views of NIMH or NIH.

Authors' Contributions

FXS, BCS, and JTB conceived and designed the work. FS and BS substantially conducted the ethics research and drafted the manuscript. SLR and JTB substantially edited and critically revised the manuscript. PM and SK significantly contributed to the ethics research and revised the manuscript. All the authors gave final approval of the completed manuscript version and are accountable for all aspects of the work.

Conflicts of Interest

SLR is employed by McLean Hospital/Mass General Brigham, serves as the secretary of Society of Biological Psychiatry, and on the Boards of McLean Hospital, National Network of Depression Centers, National Association of Behavioral Healthcare, and Community Psychiatry/Mindpath Health. He receives royalties from Oxford University Press and APPI. None of these are known to represent conflicts of interest with this work. JTB has received consulting fees from Verily Life Sciences, as well as consulting fees and equity from Mindstrong Health, Inc, unrelated to the present work.

Abstract

The need to support innovation in health care delivery was prompted by payment reforms and access to digital tools and has been accelerated by the shift to virtual care as part of the COVID-19 pandemic response. Prior to the pandemic, a growing number of health systems set up innovation centers to focus on creating new services and exploring new business models relevant to value-based care. This is distinct from process improvement or implementation science, and often needs a different set of incentives to succeed within a large organization. We used a national survey to identify a diverse sample of innovation centers, and interviewed leaders to describe their aims, organizational structures, and activities. They all aim to improve patient outcomes and experience while reducing costs, but their strategic focus may differ. The centers also vary in their reporting structure, how they build internal capacity, and how they measure success. We highlight the range of strategies through examples of projects that improve quality, reduce costs, and generate new revenue. While the optimal forms and impact of innovation centers are still emerging, the fiscal pressures and the rapid uptake of digital technologies present opportunities for the redesign of health services in the postpandemic era. The experiences of these centers illustrate a set of approaches to increase any organization's capacity for innovation.

Introduction

While improvement and innovation are ubiquitous terms, the COVID-19 pandemic response has made innovation more of a core requirement than a marketing tool in health care. Both aim to solve problems, improve outcomes, and reduce costs, but there are key distinctions. Improvement is an iterative and incremental process. It involves testing and measuring the effects of small changes to optimize the reliability of services [1]. Fundamentally, improvement enhances a system by removing perceived defects and evaluating the consequences.

Innovation, by contrast, takes a less incremental approach. Innovation is about creating or adapting novel ideas that may disrupt the status quo or solve a specific problem. It is particularly useful when the end goal is vaguely defined, a new service of unclear value is developed, or the environment and underlying needs are changing rapidly [2]. Health systems face growing challenges in controlling costs while providing patient-centered care. The current model of care is being

overwhelmed by an aging population with increasingly complex and chronic diseases. Productivity in the US health care system dropped by 0.8% per year between 1990 and 2007 [3]. Even before the COVID-19 pandemic, these conditions created an environment ripe for disruption, and innovation has become an indispensable approach to solving health care's most daunting challenges.

The health care sector proved its resilience and flexibility by adapting to novel and rapidly evolving conditions as the pandemic unfolded [4]. However, as we enter the postpandemic era, health care organizations must enhance their capacity for innovation to meet pressing medical, social, and fiscal demands [4].

The Rise of Innovation Centers

Within the last 10 years, a growing number of health systems have set up innovation centers [5], with at least 110 in the United States [6,7]. Motivated by payment reforms, the potential for new revenue streams, changing patient expectations, and the prospect of losing out to competitors, health system leaders are betting that innovation centers will enable them to offer more patient-centered, affordable care. Their focus is often on creating new services that may be unrelated to current care processes. This is distinct from classic quality improvement [8] and broader than delivery science [9] since it also involves exploring new business models [10]. Business model innovation can include the design of new services, but it also considers modifying internal cost structures or revenue sources, as well as partnerships and delivery channels [11]. Since they focus on generating and eliminating novel options, and some strategies may undermine the dominant business model, innovation centers require a different set of skills and incentives to succeed within a large organization [12]. While the idea of concentrating innovation efforts in one center has been challenged [13], this model is becoming more common and is likely a feasible starting point [14]. Looking to innovation methods that have galvanized change in other industries like user-centered design, agile development, and novel digital tools, they aim to create new scalable health services [12]. Value-based payment reforms by the US federal government and other payers are creating incentives to experiment with ways to deliver care that are independent of current processes.

Innovation centers are new enough that health system leaders are still learning how to build and manage them [15]. This novelty is yielding a variety of approaches as shown by a prior Commonwealth Fund survey of innovation centers and by several case studies [6,16,17]. We examined the responses from 33 innovation centers to identify centers that appeared to have developed and spread an innovative model of care at the time, and found 10, to which we added another 3 through snowball sampling. This paper enriches the existing literature by further elucidating the link between the goals of various innovation centers and the structures built by organizations to fulfill those goals. While the internal capabilities of health systems in the discipline of service design and business model innovation are where quality improvement was two decades ago, we feel that these skills are essential to the development of sustainable, person-centered health systems.

The Aims and Organization of Innovation Centers

Nearly all centers share the aim of improving patient health status and patient experience while reducing costs. However, in practice, their strategic focus differs. Centers may focus on quality improvement, streamlining back-end processes, internal cost reduction, or revenue generation. These areas of focus suggest different structures, with examples of centers reporting to leaders in clinical quality, information technology (IT), or finance. Some emphasize improving clinical quality and operations within the organization, while others seek to create scalable models of care or new technologies with the hope of generating revenue externally. For example, the Virginia Mason Institute (hereafter referred to as Virginia Mason) focuses almost entirely on improving clinical quality within the organization (based on an adaptation of the Toyota Production System). The center is based within their quality improvement department, and the center's leadership reports to the senior vice president of quality and safety. NewYork-Presbyterian Innovation Center also focuses on internal operations, but its innovation center is distinct because it is based within the IT department and its staff report to the chief information officer. A team of IT experts and managers support system-wide implementation of mature mobile technologies to improve access to care and reduce costs. In 2019, the Hauser Institute for Health Innovation was launched to focus specifically on advancing telemedicine capabilities.

The University of Pittsburgh Medical Center (UPMC) Enterprises emphasizes the objectives of reducing costs and increasing revenue and is co-led by the treasurer of the health system. It includes a venture fund that seeds investments in start-up companies with products or services that can both support UPMC's internal operations and generate revenue from returns on investments. Northwell Ventures is primarily focused on venture investing to generate revenue. It is a distinct division within the health system that consists of an investment fund and a team of finance and management experts that work with internal and external partners to develop new technologies or models of care, but scale them up internally only if they identify interested outside investors, signaling an external market and a higher likelihood of financial return. While all of these examples aim to fulfill the broad goal of improving quality through innovation, their strategies can be delineated in practice according to their focus, structures, and key performance indicators.

Staffing and Expertise to Support an Innovation Center

Modern approaches to innovation seek a deep understanding of the user experience along with rapid prototyping and iterative testing [5]. Health systems have not traditionally employed individuals with expertise in user-centered design or entrepreneurial management methods such as lean startup. Health systems must choose between training current staff,

hiring staff with new skills, or partnering with external groups. Efforts to build internal capacity include engaging current staff through internal grants, crowdsourcing for new ideas, asking employees to vote on potential strategies to adopt, and training staff in new methods. In some cases, innovation centers create new leadership positions, such as chief innovation officer, and hire new types of staff, such as designers, developers, entrepreneurs, or finance experts. Some build facilities for rapid prototyping, offsite clinics that serve as test environments, and some have tried to build new information systems infrastructure that connects data from health systems, patients, and software and application developers [18]. Some centers hire new types of staff who work in separate divisions, while others are embedded within frontline care provision. For example, UPMC Enterprises employs engineers, designers, and clinicians who have dedicated time to develop new technologies and models of care. By contrast, Virginia Mason has employed staff to train clinical and administrative staff throughout the larger organization in methods like user-centered design while assisting them as they redesign clinical services while engaged in routine service delivery. Some groups partner externally to acquire new skills, like the Cedars-Sinai Accelerator, a collaboration between the Cedars Sinai-Medical Center and Techstars, which engaged health system leaders to identify priority areas and select start-ups to address them in cohorts with US $100,000 in financial support and mentoring to launch in a clinical environment. Others have engaged design firms and included them on advisory boards, such as the Mayo Clinic Center for Innovation engaging with the firm IDEO.

Strategic Decisions About Structuring Innovation Efforts

Many health systems displayed remarkable agility as they rapidly shifted in-person services to virtual platforms during the pandemic to reduce in-person care, but can they build this into a core capability postpandemic? There are several questions health system leaders should consider as they decide on the best structure and focus for their innovation efforts. First, is the primary goal to improve core business or develop new businesses and service lines? Second, what relevant expertise and competencies already exist in-house? These assets could include software developers, designers, technology transfer offices, or connections with early-stage entrepreneurial companies. What level of risk is the organization willing to tolerate? Those willing to tolerate higher risk may wish to go beyond improving current core activities to take on higher-risk, higher-reward options. Those with lower risk tolerance may wish to stay closer to improving core functions and focus on innovations that protect existing business from the changing landscape. What form should organizational investment in the innovation center take? Options range from smaller investments, such as partnerships and internal training of current staff, to larger investments in seed funding for a center that is expected to become financially independent, to ongoing core funding to build new facilities and hire new types of staff. Lastly, can these goals be achieved within an existing department, or do they require a new, dedicated center?

What Have Innovation Centers Achieved to Date?

There are few formal evaluations of the results of innovation center activities. As health care organizations are just beginning to learn what innovation centers can achieve, most have taken a flexible approach to evaluating them. For example, the Mayo Clinic Center for Innovation is often assigned strategy development projects, such as imagining the future of payment or quality improvement. These are tasks that other divisions are ill-equipped to pursue, and that may not have easily measurable short-term impacts. Nevertheless, there are successful examples of innovation centers improving quality, reducing costs, or generating revenue. On the quality improvement front, Virginia Mason developed and refined a clinical care protocol that reduced the time from onset of sepsis to start of treatment from 6 hours to 1 hour and refined the protocol to further reduce the time to 30 minutes, a success well beyond what other organizations have achieved. While this resembles quality improvement in approach (changes in the responsibilities of clinical staff), the magnitude of the improvement (12-fold reduction in time to treatment) is in line with what one expects from breakthrough innovations. This highlights the potential overlap between the outcomes of multiple small tests of change and radical new practices.

In the area of cost reduction, UPMC Enterprises provided seed funding to a start-up that refined natural language processing to improve coding accuracy, quadrupled coder productivity, and identified previously missed conditions to risk adjust patients for Medicare Advantage. In this instance, UPMC went from launching an untested technology developed by an external start-up to achieving system-level cost savings within one year. For revenue generation from new sources, UPMC Enterprises developed an internal consulting model for their transition to an accountable care organization. UPMC then turned the team and its protocol into an independent company called Evolent Health. From a US $38 million initial investment, the company had an initial public offering of over US $1 billion, and UPMC's stake grew to US $300 million [19,20]. While this illustrative example showed benefit in a short time frame, the centers took many years to build this capacity and have engaged in many projects before having successes like this.

How Have Innovation Centers Fared During the COVID-19 Pandemic?

Managing the response to the COVID-19 pandemic made innovation an organizational imperative, and innovation centers across the country responded in various ways. An overarching lesson from the COVID-19 response was that innovation rapidly became an organizational, rather than departmental, imperative. The task of innovating was no longer the realm of those in formal roles within innovation centers; innovation was on display as a core function for all health system leaders. Further, innovations largely focused on improving or maintaining access to services during a time of physical distancing (often through remote care), as opposed to focusing on improving quality.

UPMC Enterprises continued to invest heavily in health care innovations throughout the pandemic. UPMC Enterprises led the development of a digital patient portal for virtual appointment scheduling, expanded telemedicine capacity, and helped portfolio companies grow [21]. Butterfly Network, a medical imaging company in which UPMC Enterprises invested, went public through a US $1.5 billion acquisition deal [22]. Notably, the organization also announced a US $1 billion investment in the life sciences by 2024 [21].

Cedars-Sinai Medical Center continued to host its start-up accelerator program, albeit virtually [23]. Techstars ran a Global Startup Weekend, bringing together thousands of innovators globally to collaborate on creative solutions to the unique challenges posed by the COVID-19 pandemic [24]. The Hauser Center for Health Innovation continued to focus on innovations related to remote patient monitoring and increasing telemedicine capabilities more broadly [25].

Virginia Mason continued to improve internal quality and quickly adapted to shifting supply chain metrics and guidance from the US Centers for Disease Control and Prevention (CDC) [26]. The organization also accelerated its multiyear plan to increase telehealth capabilities [26].

Conclusion

Innovation is a set of approaches, not a destination. While the optimal forms, goals, and impact of innovation centers are still emerging, the fiscal pressures of new payment models and the potential for new digital health technologies to challenge current delivery models are real. Most health care organizations remain focused on regulatory compliance, using quality improvement to make relatively small improvements to existing processes. But this may not yield the changes needed to thrive in the future. The early experiences of innovation centers illustrate the variety of paths available to those seeking to grow their organization's capacity for innovation. As health systems adapt to the postpandemic era, it remains to be seen whether innovation centers will meet the growing medical, technological, and fiscal demands.

Abstract

There is a fundamental need to establish the most ethical and effective way of tracking disease in the postpandemic era. The ubiquity of mobile phones is generating large amounts of passive data (collected without active user participation) that can be used as a tool for tracking disease. Although discussions of pragmatism or economic issues tend to guide public health decisions, ethical issues are the foremost public concern. Thus, officials must look to history and current moral frameworks to avoid past mistakes and ethical pitfalls. Past pandemics demonstrate that the aftermath is the most effective time to make health policy decisions. However, an ethical discussion of passive data use for digital public health surveillance has yet to be attempted, and little has been done to determine the best method to do so. Therefore, we aim to highlight four potential areas of ethical opportunity and challenge: (1) informed consent, (2) privacy, (3) equity, and (4) ownership.

(J Med Internet Res 2022;24(2):e30524) doi:10.2196/30524

KEYWORDS

passive data; public health surveillance; digital public health surveillance; pandemic response; data privacy; digital phenotyping; smartphone; mobile phone; mHealth; digital health; informed consent; data equity; data ownership

Background

In the wake of the COVID-19 pandemic, a more effective and ethically sound system for tracking disease is necessary. In recent years, due to their ubiquity, mobile phones—and the data they collect—have become a potential tool for tracking disease on a broad scale. These devices generate massive amounts of passive data, or information collected without the active participation of the user [1]. However, the current utilization of these data for public health crises is limited; such data are predominantly used for basic contact tracing via Bluetooth or GPS [2]. Emerging technologies, such as digital phenotyping, defined as moment-by-moment quantification of the individual-level human phenotype in situ using data from personal digital devices, allow for continuous monitoring of individuals' health, which has previously been impossible [3]. Attempts to employ these data for digital public health surveillance, defined as "ongoing systematic collection, analysis, and interpretation of data [not generated with the primary goal of surveillance], integrated with the timely dissemination of these data to those who can undertake effective prevention and control activities," are currently being undertaken; public health

officials must look to history and current moral frameworks to avoid past mistakes and ethical pitfalls [4,5]. Thus, this viewpoint uses a scoping literature review and novel arguments to aid policy makers in critically analyzing how passive data might be used for digital public health surveillance ethically, with a particular focus on lessons to be learned from history.

A Historical Perspective on Surveillance: Proactive Versus Reactive Interventions

In 1854, John Snow laid the groundwork for modern epidemiology by disabling a cholera-contaminated water pump in Soho, London. By saving lives, Snow's experiment and subsequent health policy advances promoting hygiene demonstrated the fundamental need for proactive public health intervention in times of crisis [6]. Conversely, during the 1918 influenza pandemic, governments met the disease with deliberate ignorance [7]. Death tolls rose to 50 million worldwide, and citizens were forced to implement makeshift systems of social distancing, such as mask wearing and displaying anti-spitting signs [8,9]. The disjointed nature of the response is characteristic of the reactive approach; without unified guidelines, decided upon beforehand, citizens are left with little framework on which to base their decisions [10]. A juxtaposition can be found in the 2003 severe acute respiratory syndrome (SARS) epidemic. Although heavily affected countries developed protocols from which they have benefitted during the COVID-19 pandemic, the United States did not face the direct effects of SARS, resulting in very few steps being undertaken to prepare for future outbreaks [11-13]. Likewise, citizens in SARS-affected countries were more willing to adhere to interventions [13]. Operating with preordained protocols, these SARS-affected countries found far greater early success against COVID-19.

Pandemic response progress has fluctuated based on contemporary national politics, social norms, and the scientific understanding of diseases through history [14]. Generally, examples of health crises demonstrate that coordinated surveillance by officials and public adherence to guidelines are integral to limiting disease spread (Figure 1) [15-23]. This must be kept in mind when turning toward the future to maximize the impact of emerging technologies such as digital phenotyping for health surveillance systems. Now is the time to make policy decisions, as the choices made about passive data use for digital public health surveillance in the years following the COVID-19 pandemic have the potential to impact our lives profoundly. Although discussions of pragmatism or economic issues tend to guide digital public health surveillance decisions, ethical questions of informed consent, data privacy, data equity, and data ownership are the foremost public concerns; a consequence of not addressing these issues is eroding trust in governmental institutions and science [24]. Surveillance measures, therefore, must be functional and within ethical guidelines.

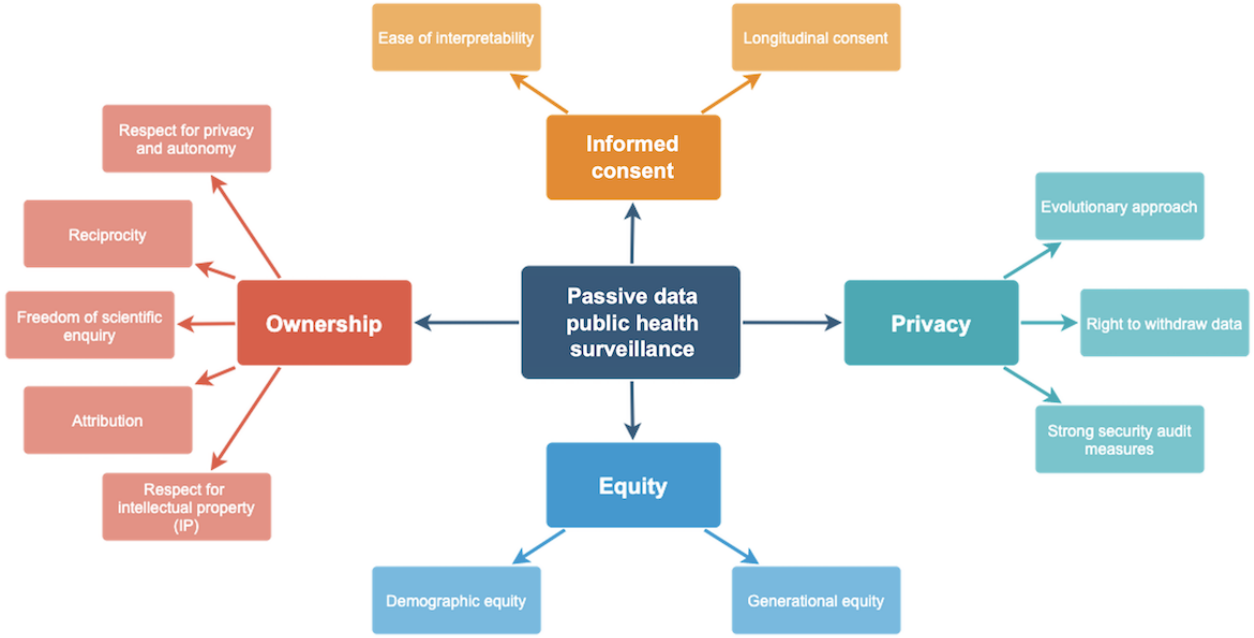
Passive Data: Pandemic Surveillance Pearls and Promises

The momentum of technological innovations has inspired a new age of digital solutions in public health. In 2014, the number of mobile phone subscriptions surpassed the number of people on the planet (~7.2 billion), illustrating a new parity between humans and devices on which policies could capitalize [3]. Early in the pandemic, governments and technology corporations deployed contact-tracing systems using Bluetooth interactions widely [2]. However, this type of solution is limited; it is reactive, only applicable after disease transmission has likely already occurred.

Recent innovations in using passive data, such as digital phenotyping, have the potential to measure a subject's physical and mental well-being and will allow for a far more accurate level of surveillance [3]. Passive data encompass various streams, including GPS, accelerometer, text, and call log data, and have been employed in a wide range of clinical settings, from monitoring spinal surgery patients' recoveries to tracking relapses in patients with schizophrenia [25-37]. The significant benefits of using passive data for digital public health surveillance include the data's objectivity, quantifiability, and continuous nature [1]. This contrasts with the use of active data, such as patient-reported outcome measures, which rely on subjective measurements that are harder to quantify accurately [1]. The sophisticated analysis of passive data for digital public health surveillance has yet to be attempted on a large scale, however, and there is no academic consensus on how best to do so [38-40]. Thus, this paper puts forth four challenges that must be addressed when considering the ethics of digital public health surveillance: (1) the level of transparency during the consent process (informed consent), (2) the anonymity and security measures taken to protect the data (privacy), (3) the equitable distribution of benefit from digital public health surveillance (equity), and (4) the determination of who has rights to the data (ownership; Figure 2) [24].

Figure 2. Goals for ethical passive data public health surveillance.



Informed Consent

Confirming that the public genuinely provides informed consent becomes challenging as information is increasingly digitized. The platform for medical surveillance has moved from controlled (eg, doctors' offices) to uncontrolled (eg, smartphones) environments. In examining the challenges of gaining patients' permission to use their data, two main pillars arise: (1) ease of interpretability and (2) longitudinal consent. Trust between officials and the public can be maintained as long as the information provided is understandable and interpretable. Levels of patient comprehension comparable to current consent procedures are attainable through mobile health consenting programs, assuming care is taken to design the interface intuitively [41]. Tools such as social annotations, live feedback, and visual aids have been suggested to help accomplish this goal [1,41,42]. However, there is little evidence to show that no current method of consenting patients achieves adequate patient comprehension [43]. Customizable, interactive, and educational consent forms to be evaluated on the patients' own time, rather than in person, would help to streamline the process and relieve stress on both sides [44,45]. Likewise, it would allow for greater regulation of bias on the part of the provider, which has been shown to play a role in patients' ability to give consent freely [46].

The perpetuity of consent has also come into question, as the technology used is inherently complex and often outside of patients' or providers' realms of expertise [47]. Therefore, the growth of digital public health surveillance could entail a move from the current practice of a "consent or anonymize" approach to one of "consent for governance" [1]. Under the former, the patient gives "broad consent" under the assumption that data will be implemented later using pseudonymization; this allows patients no long-term rights to their data. Conversely, the latter incorporates the context in which an entity hopes to use the data, making it conditional. Thus, gaining initial patient consent does not guarantee longitudinal ethical viability. A continued effort to maintain a reliable open source of information for patients is necessary.

Privacy

Experts note five distinct threats to data privacy under digital surveillance: the invisibility, inaccuracy, immortality, marketability, and identifiability of data [48]. Given this, we put forth three main pillars to be upheld in maintaining data

privacy: (1) an evolutionary approach, (2) the right to withdraw data, and (3) strong security audit measures. Authorities remark that if surveillance practices currently being conducted digitally were carried out in person (eg, a third party reading patients' text messages and following them from location to location), rather than invisibly, it would be unacceptable [48], yet this level of observation would be inherent to digital public health surveillance systems. Further, machines interpret data literally; therefore, the analysis of specific actions (eg, unknowingly dropping one's phone on the street) through passive data could lead to inaccurate conclusions (eg, a traumatic fall requiring emergency medical services) [48]. Third, researchers note that the immortality of data inevitably results in elevated risk, as even the lowest possible risk over an extended period translates to high overall risk [48]. The marketability of data is also a concern, as it is the entities that collect the data (institutions), not those that generate the data (patients) that are currently compensated, creating an incentive for unethical practices [48]. Finally, it has been demonstrated that anonymized patient data can be reidentified using machine learning [49]. Thus, the identifiability of the data could have wide-ranging consequences, from fostering attempts to shape political opinions based on one's health profile to allowing one's prognosis to have an impact on their ability to be hired [48].

Innovative multisectoral approaches will be needed going forward to prevent breaches and maintain requisite data privacy and security. The Health Insurance Portability and Accountability Act (HIPAA) in the United States and the new General Data Protection Regulation (GDPR) in the European Union were enacted to ensure legal repercussions for those who break data confidentiality. However, in the digital age, it has been posited that all data can be used as health data [48]. Likewise, as these regulations only apply to personal health information in its traditional form, they have become inadequate and outdated. Digital public health surveillance systems must continually be refined to incorporate the idiosyncrasies involved in in vivo health surveillance. Current efforts to accomplish this goal include innovations such as the cryptographic and differential privacy approach, which makes patient data less recognizable and reidentifiable, as well as federated learning, which promotes the idea of building systems without any data sharing [50]. Additionally, individuals must be allowed the right to request deletion of their health data at any time and for any reason to restrict data perpetuity. Strong privacy and security audit policies must become commonplace, as complacency with security measures could lead to areas of weakness to be exploited. Furthermore, continuous communication from the entities storing the data of its security and trustworthiness will be necessary, so as not to foster a "generalization of suspicion," where patients feel as though they are guilty until proven innocent [51].

Equity

In recent history, the unchecked or blind usage of innovative technologies has exacerbated existing health care inequalities, reflected in the form of biased data, such as the own-race bias phenomenon in facial recognition [52]. Passive data–driven solutions, then, should be thought of as tools that could reduce disparities by widening access to public health surveillance, but only if implemented mindfully, as it is unclear which subpopulations are truly at the greatest risk of these health inequities [1,53]. To ensure fairness in passive data use, a balance must be struck between two principles: (1) demographic equity and (2) generational equity. Low socioeconomic status populations and people of color are often marginalized and burdened by negative social determinants of health [54]. Passive data can potentially reduce health inequities for these populations, as conventional determinants such as lack of insurance and access to health care facilities could theoretically be circumvented [54-56]. In 2019, smartphone ownership was fairly consistent across races, with 82% of White people, 80% of Black people, and 79% of Hispanic people owning a smartphone, compared to more variable health care coverage status (92.2%, 90.4%, and 83.3%, respectively) [57,58]. Passive data use also has the potential to improve digital public health surveillance globally, as smartphone ownership in low- and middle-income countries (LMICs) continues to increase rapidly. In 2019, the median smartphone ownership was 45% in emerging economies, up from 37% in 2015 [59,60]. In LMICs, where access to adequate health care can be scarce, strengthening access to these technologies could be a viable supplement.

However, unrestrained use of technology in passive data collection and analysis could also introduce health inequities such as preventing those without technological access or with physical, age-related, disease-related, or mental impairments from receiving equitable care [61]. One population that might be left behind by increased digital public health surveillance is older adults. Although all US adults older than 65 years have access to health coverage through Medicare, only 55% owned a smartphone in 2019 [57,58]. Potential solutions to generational inequities include working with manufacturers to design digital public health surveillance technology and services keeping in mind how older populations specifically might perceive and use them, as well as implementing optimized plans and models to provide all people with affordable high-speed internet access. Overall, disparities in technological access both in the United States and globally must be tracked and actively combatted if digital public health surveillance systems are to provide equitable levels of care across demographics and generations.

Ownership

Though there is no current consensus on how best to address passive data storage and ownership issues, experts have put forth potential solutions. The majority of these involve policy interventions to restrict single institutions from monopolizing databases [39]. For example, some suggest public policy to create networks of patients with data sharing responsibility. In contrast, others promote policies that consider the rights to one's health data to be civil liberty [39,62,63]. Another possible solution that has gained traction is a paradigm shift in governing data access from ownership to custodianship [64]. This aligns with the theory that big data cannot be "owned" in a traditional sense, but instead should be guarded and overseen [64]. For this new structure to be viable, five principles must be upheld: (1) respect for privacy and autonomy, (2) reciprocity, (3) freedom

of scientific enquiry, (4) attribution, and (5) respect for intellectual property (IP) [64]. Under this system, a balance must be struck between confidentiality and accountability, as institutions (or custodians) of the data must keep the identities of the subjects (or donors) private while also remaining beholden to them. Likewise, custodians must also be forthcoming with their findings and metadata, just as donors are with the original passive health data. Health data should be used solely for the common good, as its value makes it a target to be bought and sold by bad actors [64]. Lastly, proper credit and respect for IP will reduce the restriction of access to databases by ensuring that the sacrifices made by both donor and custodian are appreciated. These data-sharing agreements are made fittingly [64]. Pioneering policy ideas such as these will be necessary if passive data is to be implemented into digital public health surveillance successfully.

Even under the assumption that future frameworks should widen access to these data, some researchers argue for a centralized database, while others support decentralization [39,58]. The latter group argues that patients have little idea of their data's actual value. Systems such as blockchain (ie, a digital record of transactions validated by a peer-to-peer network) could serve to decentralize and better quantify the worth of individuals' health data [39,65]. Each proposal has positives and negatives. For example, centralization would increase ease of access but could leave databases more susceptible to large-scale hacks. In addition, although decentralization would allow patients to earn tangible rewards for their data, this could lead to undue influences playing a role in the decision to share one's data [63,65]. Coming to a consensus on these issues is one of the most critical next steps for advancing passive data use for digital public health surveillance.

Conclusion: Planning Now for the Future

The time to plan and prepare for the next pandemic is now. This means coming to terms with the massive potential (for better or worse) of passive data derived from personal digital devices. The potential for success of digital public health surveillance relies on the ethical viability of its implementation. Before the next pandemic, officials must ensure that we are prepared by overhauling current consenting protocols. During the next pandemic, policies must be enacted to account for all possible inequities, while maintaining trust between citizens and institutions. In the wake of the next pandemic, the long-term security of health data must be guaranteed with an assurance that it will not be used for any undue gain. These preparations must be undertaken now, proactively, using the lessons fresh in citizens' collective consciousness. Passive data and methods such as digital phenotyping can serve as the foundation upon which this improved system can be built. However, if done without historical, ethical, and practical considerations, we will be left with even more challenges than we face today.

Abstract

Despite an ever-expanding number of analytics with the potential to impact clinical care, the field currently lacks point-of-care technological tools that allow clinicians to efficiently select disease-relevant data about their patients, algorithmically derive clinical indices (eg, risk scores), and view these data in straightforward graphical formats to inform real-time clinical decisions. Thus far, solutions to this problem have relied on either bottom-up approaches that are limited to a single clinic or generic top-down approaches that do not address clinical users' specific setting-relevant or disease-relevant needs. As a road map for developing similar platforms, we describe our experience with building a custom but institution-wide platform that enables economies of time, cost, and expertise. The BRIDGE platform was designed to be modular and scalable and was customized to data types relevant to given clinical contexts within a major university medical center. The development process occurred by using a series of human-centered design phases with extensive, consistent stakeholder input. This institution-wide approach yielded a unified, carefully regulated, cross-specialty clinical research platform that can be launched during a patient's electronic health record encounter. The platform pulls clinical data from the electronic health record (Epic; Epic Systems) as well as other clinical and research sources in real time; analyzes the combined data to derive clinical indices; and displays them in simple, clinician-designed visual formats specific to each disorder and clinic. By integrating an application into the clinical workflow and allowing clinicians to access data sources that would otherwise be cumbersome to assemble, view, and manipulate, institution-wide platforms represent an alternative approach to achieving the vision of true personalized medicine.

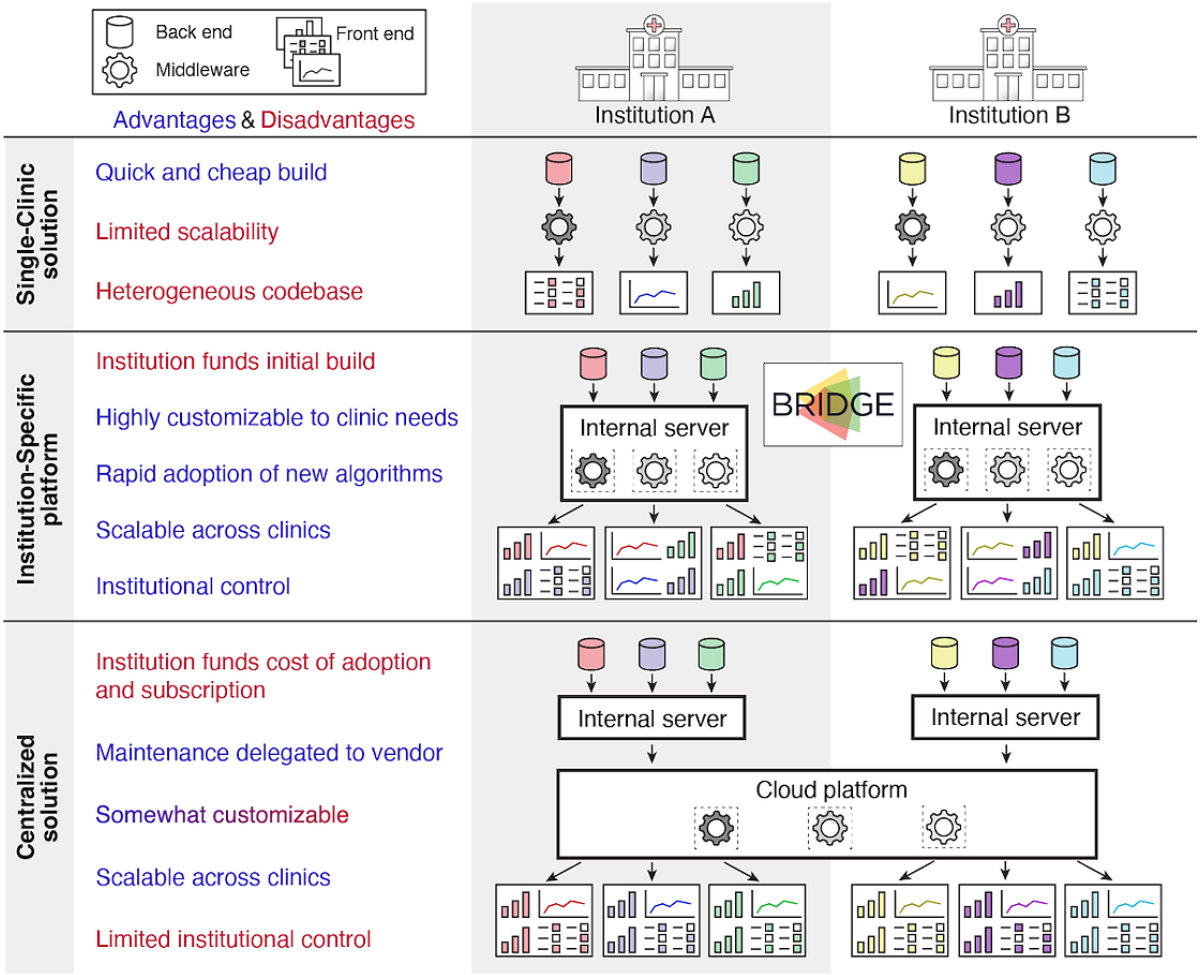
Introduction

Precision medicine holds the potential to revolutionize medicine [1-3], just as prior technological advances, such as microscopy, molecular diagnostics, and imaging, have done in the past. In the research realm, big data and artificial intelligence have yielded substantial advances that showcase the potential of precision medicine [4,5]. However, translating these advances into the clinical realm remains a challenge [6,7]. A patient is more likely to interact with complex algorithms informed by big data in the waiting room (ie, algorithms in the form of internet searches, travel directions, or tailored social media) than in the actual clinic. The medical field needs similarly intuitive interfaces that can collate the necessary patient-related data to highlight salient knowledge, pinpoint a patient's condition, predict optimal therapy, or estimate the risk of disease or death [3]. Much of the required physical infrastructure is already in place, with computers being available in most clinics and the majority of clinical data being stored in electronic health

records (EHRs). A small minority of wealthier clinics and health care systems have built custom, domain-specific interfaces into their EHRs to deliver the more complex precision medicine algorithms and visualizations that their physicians need; however, in the majority of health systems, only the most basic algorithms (eg, those for calculating BMI) are built into the EHR, while other, more sophisticated clinical indices (eg, atrial fibrillation stroke risk [8,9]) are calculated via manual entry into a public website [10].

The task of translating innovative precision medicine tools from research projects to clinical care is inhibited by a catch-22 problem. To justify the expense of building the costly computational infrastructure required to run complex algorithms on patient data, the algorithms or visualizations need to demonstrate real-world value. However, to evaluate and prove these algorithms' value, the needed infrastructure must already be in place. One solution to this conundrum is building boutique, single-clinic solutions consisting of carefully designed, specialized algorithms or data displays built within or alongside the EHR [11,12]. Although this bottom-up approach is limited in scope to a single clinical domain and thus can be comparatively quick and cost-effective to implement, scalability and rapid obsolescence are major concerns. To adapt data displays to other clinics, an institution has to maintain, secure, and update an ever-expanding heterogeneous code base across those clinics. Yet, the originating "owners" of these algorithms are often clinical researchers and physicians without the backing of an enterprise-level developer team that is equipped to manage the software as a service over several years of use (Figure 1). The opposite extreme is commercial vendors building generalized health care software suites that run on cloud-based infrastructures. Such centralized solutions address the scalability challenges of bottom-up approaches, but the emerging health system–wide products are typically far too generic to meet the medically heterogeneous and shifting requirements of individual clinics. Furthermore, adopting such solutions requires substantial institutional investment, and becoming locked into a single vendor in a rapidly evolving marketplace poses a risk.

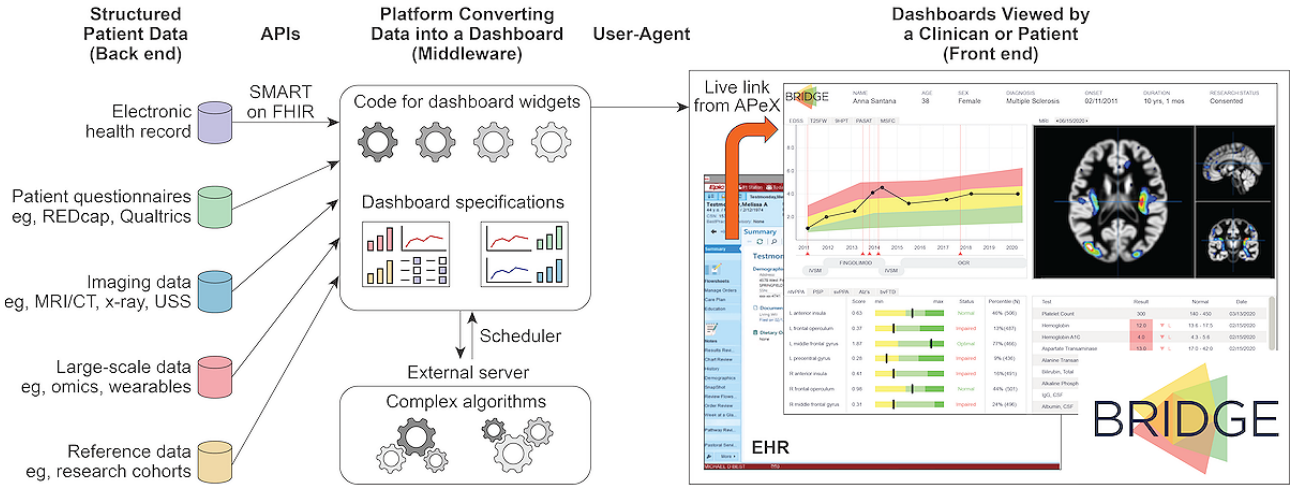
Figure 1. Approaches to delivering precision medicine results to the clinic. This figure compares the platform design elements across the following three main approaches to building clinical systems to support precision medicine: (1) single-clinic solutions, (2) institution-specific platforms like BRIDGE, and (3) centralized solutions purchased from external vendors. Key advantages (blue) and disadvantages (red) of each approach are listed.



Between these two extremes exists a third solution that solves many of the aforementioned problems. Institution-wide platforms permit rapid innovation in parallel across multiple clinics but are built on a single secure, stable, and cost-efficient

technological foundation. These platforms benefit from a common architecture built within an institutional firewall with real-time EHR access and application programming interfaces (APIs) to major (eg, REDCap [Research Electronic Data Capture; Vanderbilt University] and Radiology PACS [Picture Archiving and Communication System]) and custom data resources, which facilitate the integration of multimodal research data across all specialties. Yet, these platforms also incorporate clinic-specific visualization tools that allow clinicians to tailor the display of information. Therefore, specific research discoveries can be rapidly translated into clinical tools that fit each specialty (Figure 2). This approach strikes a balance between the fast development and flexibility of single-clinic solutions and the scalability and sustainability of centralized health care solutions while optimizing transparent institutional oversight.

Figure 2. Overview of technological components for the integrated delivery of precision medicine through an institution-specific platform like BRIDGE. The flow of information is depicted as it moves from back-end data sources, through the integrating middleware layer of light and heavy computational resources, and to the multiple, functionally distinct widgets shown in a user-facing front-end dashboard designed to reflect the needs of a single clinic. APeX: Advanced Patient-Centered Excellence; API: application programming interface; CT: computerized tomography; EHR: electronic health record; FHIR: Fast Healthcare Interoperability Resources; MRI: magnetic resonance imaging; REDCap: Research Electronic Data Capture; SMART: Substitutable Medical Applications and Reusable Technologies; USS: ultrasound sonography.



The BRIDGE platform at University of California, San Francisco (UCSF), is one example of this approach. Based on our experience with developing BRIDGE, we describe key considerations and practical steps for implementing institution-wide solutions in this rapidly progressing field to provide a road map for other health care systems considering a similar approach. We also consider future developments that will enable the medical community to quickly and comprehensively realize the potential of computational medicine to improve the lives of patients.

Consideration 1: Human-Centered Design

Overview of the Human-Centered Design of Precision Medicine Tools

For a precision medicine tool to be adopted in a clinic, it needs to provide pertinent, actionable information in a format that is appropriate to the user (either a clinician or a patient). Therefore, perhaps the most essential components of effective precision medicine tool deployment are the principles and phases of human-centered design (HCD) [13-15]. For tools targeted at medical professionals, clinician users, who are well informed, should be at the center of decisions about which technological format is the most appropriate for their workflow, which innovations in their specialty are scientifically ready for deployment at clinics, and how evaluations of tool effectiveness should be conducted to justify the continued use of such tools (Textbox 1). Many of these decisions reflect the dimensions of precision medicine, as articulated in a recent scoping review [7].

Textbox 1. Key decisions in designing a digital application for clinical research.

Key questions

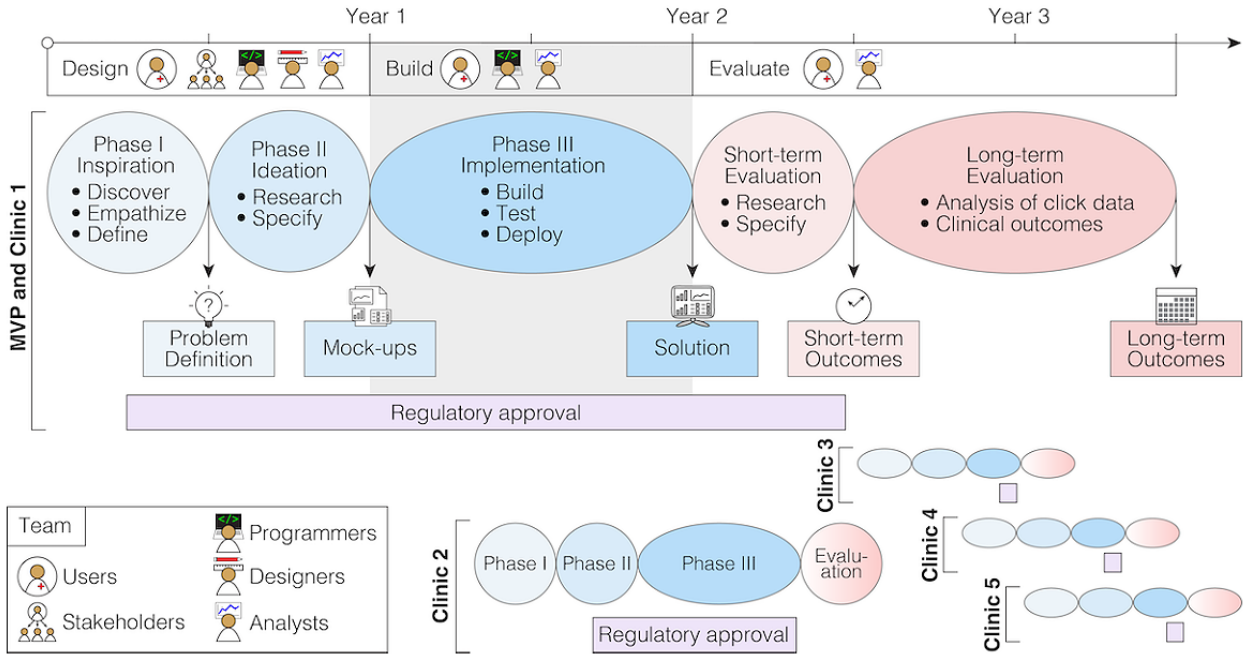
1. Who are the users (eg, clinicians, patients, and specialists)?
2. What do the users need (eg, novel data sources, novel algorithms, novel visualization, and data collation)?
3. How will it improve care (eg, patient experience, clinic efficiency, morbidity, and mortality)?
4. How does the user access the application (eg, individual log-in and authorization via an existing clinical system)?
5. Where is it hosted (eg, local server, cloud-based server, or external vendor)?
6. What is the maintenance schedule (eg, 9 AM to 5 PM on Monday to Friday or 24 hours per day year-round)?
7. What are the constraints of the system? For example, will it not write to the electronic health record? Are data behind an institutional firewall?

Practical Considerations From the BRIDGE Experience

From its inception, BRIDGE exemplified both the principles and phases of HCD [13,14]. It was conceptualized and designed according to the requirements of clinician scientists, including the project's principal investigators (manuscript authors RB, KPR, and SJS). Further, the key architectural decisions (Textbox 1) were made by applying HCD principles to engage clinician, patient, scientific, programming, design, industry, and institutional stakeholders.

The three HCD phases are also being deployed in the iterative process of adapting BRIDGE to each new clinic that is interested in a BRIDGE dashboard (Figure 3). In the "Inspiration" phase, the BRIDGE clinician scientists and programmers identify and meet with a small number of clinician champions to collaboratively define the problems to be solved to improve care in the clinician champions' clinic. They also generate ideal use cases based on that clinic's workflow, such as those for data types, data sources, and visualizations. In the "Ideation" phase, a design mock-up is shared with a broader set of intended stakeholders from that clinic to obtain their input, after which the final set of minimum viable product (MVP) specifications is derived for the dashboard, and programming begins for the jointly approved design mock-up. The finalized MVP is built in the "Implementation" phase, during which early testing is conducted by a small superuser group of clinicians who generate feedback about bugs and minor refinements. These clinic domain experts are the primary drivers for designing and conducting formal evaluations of their precision medicine tools, which include clinician users' feedback about dashboard ease, utility, and fidelity; patients' satisfaction with care; impacts on workflow, including automated click tracking; and longer-term analyses of the clinical impact, value, and cost-effectiveness of these tools. Clinical validation, technological or therapeutic innovation, or user demand may result in further cycles of design.

Figure 3. Example timelines and milestones of clinical application development. The design and development of an institution-specific platform for clinical applications, such as BRIDGE, is a multiyear undertaking (eg, 2 years for the MVP and clinic 1). Following the principles and phases of human-centered design ensures the development of a product that meets the needs of the users and the requirements of the institution. Obtaining institutional regulatory approval—a process that runs in parallel with the design and development processes—is critical and can risk becoming the rate-limiting step. The evaluation of the product initially focuses on user experience, followed by clinical outcomes such as morbidity, mortality, or efficiency. With the majority of the platform built, the design and build times are dramatically reduced for clinic 2, and they continue to fall as the process becomes refined (eg, under 6 months for clinics 3-5) and occurs in parallel. MVP: minimum viable product.



HCD: Future Directions

Since the back-end infrastructure of an institution-wide platform is unified, only 1 set of corresponding regulatory approvals is needed, and this approach reduces the cost and time required to develop a front-end tool and allows multiple tools to be developed in parallel (Figure 3). However, given the number of medical specialties, clinical scenarios, disorders, and algorithms across a health care system, engaging in this intensive HCD process with each new clinic will not be cost-effective in the long term. Instead, a library of existing data sources and graphical interfaces could be generated, and clinicians (or patients, ie, in the event of a patient-facing version) could customize this library to design their own dashboards, thereby freeing programmers to concentrate on developing new modular interfaces and data sources. Generating more universal standards for describing clinical dashboards and their connections to APIs and EHRs could ease the deployment of dashboards across a wide range of health care platforms. Containerization, the Substitutable Medical Applications and Reusable Technologies (SMART) on Fast Healthcare Interoperability Resources (FHIR) API, and the Epic App Orchard (Epic Systems) represent important steps in this direction, but substantial scope for further standardization remains. The adoption of this type of adaptable clinical dashboard at scale would provide sufficient data for iteratively testing and improving performance, resulting in a second data-driven evaluation phase that focuses on surveys and click data. As the scale of data grows, especially across institutions, a third design phase that is based on both clinical outcomes and user experience will become possible.

Consideration 2: Technological Design

Common Approaches to the Technological Design of Digital Health Tools

The architecture of most digital health tools involves a connection among the back-end databases, middleware software algorithms that convert the data into useful knowledge, and front-end displays for users (Figure 2). Both single-clinic and centralized solutions are often hard-coded to represent a specific data source and visualization type, which slows the development of novel iterations and results in higher overall costs. A more efficient solution is to build a framework of reusable APIs that connects a multiplying number of data sources, computational algorithms, and modular visualization schematics and is adaptable and scalable to diverse types of medical data and clinical specialties.

Practical Considerations From the BRIDGE Experience

Overview of Practical Considerations

The BRIDGE platform was designed as a proof-of-principle MVP scaffold that could be developed efficiently and quickly but later refined and scaled up depending on its success and the collaborative opportunities generated. The HCD process made clear the following four key technical requirements: (1) it had

to permit access to a variety of data sources (ie, beyond the EHR), which could then be either displayed directly or processed through computationally intense algorithms [7]; (2) it needed to enable the visualization of these data in an intuitive and actionable manner, and this process needed to be embedded in the clinical workflow, so that it was not cumbersome for clinicians to access or operate; (3) following logically from the second requirement, it required the ability to launch directly from the EHR; and (4) it had to be as modular as possible to make iterative clinic-by-clinic customizations easier and more efficient to program.

Data Sources

Many data types contribute to precision care. To build a data foundation for BRIDGE that would best meet the needs of a variety of clinical use cases, we opted to include real-time clinical data from the EHR, minimally processed data from widely available data platforms (REDCap and Qualtrics [Qualtrics International Inc]) [16], data from institutional tools (eg, TabCAT [Tablet-Based Cognitive Assessment Tool; UCSF]) [17] and research databases [18], and complex data that either cannot be currently hosted in the standard EHR or require processing by complex analytics processing pipelines (Figure 2). For example, images from the Radiology PACS can be obtained ahead of time based on scheduled appointments, thereby allowing time for computationally intensive image processing pipelines to run prior to a patient appointment. Further innovations requiring advanced data processing include accessing expansive knowledge networks to compute precise clinical risk and treatment predictions [19]. As it would represent the convergence of so many sensitive data streams, BRIDGE required robust front-end and back-end architectures that were unified around security and hosted within the UCSF firewall.

Workflow Fit and EHR Integration

As a fundamental requirement for BRIDGE, to give clinicians actionable information during patient encounters, it had to launch directly from patients' records in the EHR (ie, Epic; Epic Systems) and pull their clinical data in real time (Figure 2). This resulted in a central technical decision to design BRIDGE as a SMART on FHIR application. Launching from the EHR resulted in additional clinical workflow benefits; discrete data could be collected at the point of care by using clinic-specific EHR Flowsheets and SmartForms (sharable across institutions), and data could then be pulled into clinical notes. Direct flowsheet data entry also allows BRIDGE to call and visualize discrete research data during clinic visits more efficiently. Enabling this launch functionality required interactions with the EHR development group and resources for funding their modifications to the EHR.

Modular Design

BRIDGE was designed to capitalize on a common language of clinical information flow through the creation of core widgets, or visualization modules, that can be adapted to an expanding array of clinical scenarios (Figure 2). At the time of BRIDGE MVP deployment, we had programmed the following four reusable core widgets: (1) longitudinal clinical course in the context of treatment, (2) cross-sectional metrics, (3) specialty-focused laboratory data, and (4) quantitative neuroimaging. Both the cross-sectional and longitudinal widgets allow patients' scores and metrics to be contextualized against a larger reference cohort that indicates both normal and abnormal values as well as percentile calculations, thus allowing a patient's clinical status to be interpreted by a clinician at a glance (Figure 2). We were able to convert existing precision medicine tools, such as the UCSF Multiple Sclerosis BioScreen longitudinal viewer [12] and the UCSF Brainsight magnetic resonance image processing and visualization tool [20] into these initial BRIDGE widgets. The configuration data for all viewers are stored by BRIDGE, which queries these data in real time and then renders the specified widgets and data sources for the clinician. Updates to the configuration can be made quickly when existing dashboards need to be adapted, thus enabling both ongoing user engagement and rapid deployment to meet the evolving needs of specific clinics. As we expand to other clinics, new widgets (eg, geolocation and genomics) that can be retroactively made available to existing clinics are being developed.

Technological Design: Future Directions

Two architectural changes can be made. The first is integration with a middleware platform. BRIDGE is currently connected to multiple data sources through direct API integrations, and connecting to additional APIs necessitates the modification of the codebase. Making use of a platform that aggregates APIs would reduce maintenance efforts and promote more stable platforms. Examples of such platforms already exist (eg, Human API [21]) and include EHR data. The second architectural change is creating a graphical user interface (GUI) that clinicians can use to create their own dashboards. Currently, dashboard configuration is done by the BRIDGE development team. Building a GUI that allows clinicians to configure and customize their dashboards would accelerate progress and allow clinicians without programming experience to access relevant data sources. Such an endeavor will likely require the integration of institution-wide platforms and centralized platforms, and such an integration will benefit both types of platforms. The resulting unified platforms would probably combine generic, cloud-based back-end and middleware components but be able to deliver the customized, clinic-specific, front-end dashboards designed by clinicians through the GUI. Overall, BRIDGE aims to augment—not supplant—the EHR; should an institution's visualization show clinical value, the institution could choose to maintain it in BRIDGE or integrate it into their EHR more permanently.

Innovations are also needed to improve data quality in the EHR, including tools that systematically flag likely data entry errors, simplify the correction of the EHR by a clinician, and ensure that corrections are distributed to all clinical tools. Finally, to demonstrate that these tools comply with the Health Insurance Portability and Accountability Act (HIPAA) or equivalent guidelines, a cross-institutional body that is responsible for testing and validating these solutions could be created. It might accelerate progress substantially by, for example, supporting cloud-based, HIPAA-compliant, off-the-shelf solutions to ease this data quality burden.

Consideration 3: Regulation and Policy

Launching a clinical application with real-time access to identified patient health data requires close institutional oversight and multiple stages of regulatory approval, especially in cases where clear institutional road maps or leadership structures are lacking due to the innovative nature of such applications.

Practical Considerations From the BRIDGE Experience

With regard to developing the BRIDGE MVP, the Epic EHR, and the SMART on FHIR application, technological capabilities were already available within our institution, but multiple security, privacy, technological, and compliance concerns had to be addressed. Specifically, authorizing an expandable, cross-specialty, modular platform rather than a domain- and clinic-specific tool was entirely novel. This necessitated parallel revisions to the approval process itself. Early in the design process, we set clear functional constraints that would reduce the barriers to institutional approval. Foremost among these were (1) conceptualizing BRIDGE as a clinical research tool that is custom designed with clinical specialists rather than as an institution-wide, enterprise-level clinical solution; (2) not requesting write access to the EHR (real-time read access was enabled); and (3) ensuring that data do not leave the institutional firewall. With an approved clinical research platform in place, the bar for institutional approval is substantially reduced for subsequent clinical dashboards that iterate on the initial design, reducing this multi-month process to a simple, clinic-specific sign-off (Figure 3). Further approval is required for applications that add novel functionalities or revisit one of the major systems constraints (eg, sending data to an external server).

Regulation and Policy: Future Directions

BRIDGE provides a mechanism for rapidly deploying and evaluating novel precision medicine algorithms and visualizations developed by clinical researchers [22-24] to evaluate their clinical benefit [25]. As the system expands and more clinical visualizations become the standard of care, medical centers may eventually choose to move the fundamental infrastructure of their institution-wide platforms from an MVP clinical research entity, such as BRIDGE, to a full, enterprise-level clinical system that delivers the same capabilities at a higher level of reliability [26,27]. This shift will be precipitated by a number of considerations, including the need for professional-level version control and releases; automated testing and quality control; the capacity for multilevel monitoring, logging, and auditing; and the ability to handle high user volumes without concurrency issues. The institution will also need to ensure that there is adequate personnel infrastructure behind the system to permit sustainable 24-hour user support and timely design and adaptation for new clinics. In the end, all stakeholders must be able to trust the reliability and clinical value of the final platform and the sustainability of the system supporting it [28]. For many such algorithms, moving along the continuum from clinical research to enterprise clinical care may well necessitate regulatory approval from the Food and Drug Administration Center for Devices and Radiological Health [29], as spelled out in their Digital Health Innovation Action Plan, and alignment with the international Software as a Medical Device guidelines through the International Medical Device Regulators Forum.

Consideration 4: Evaluation and Impact

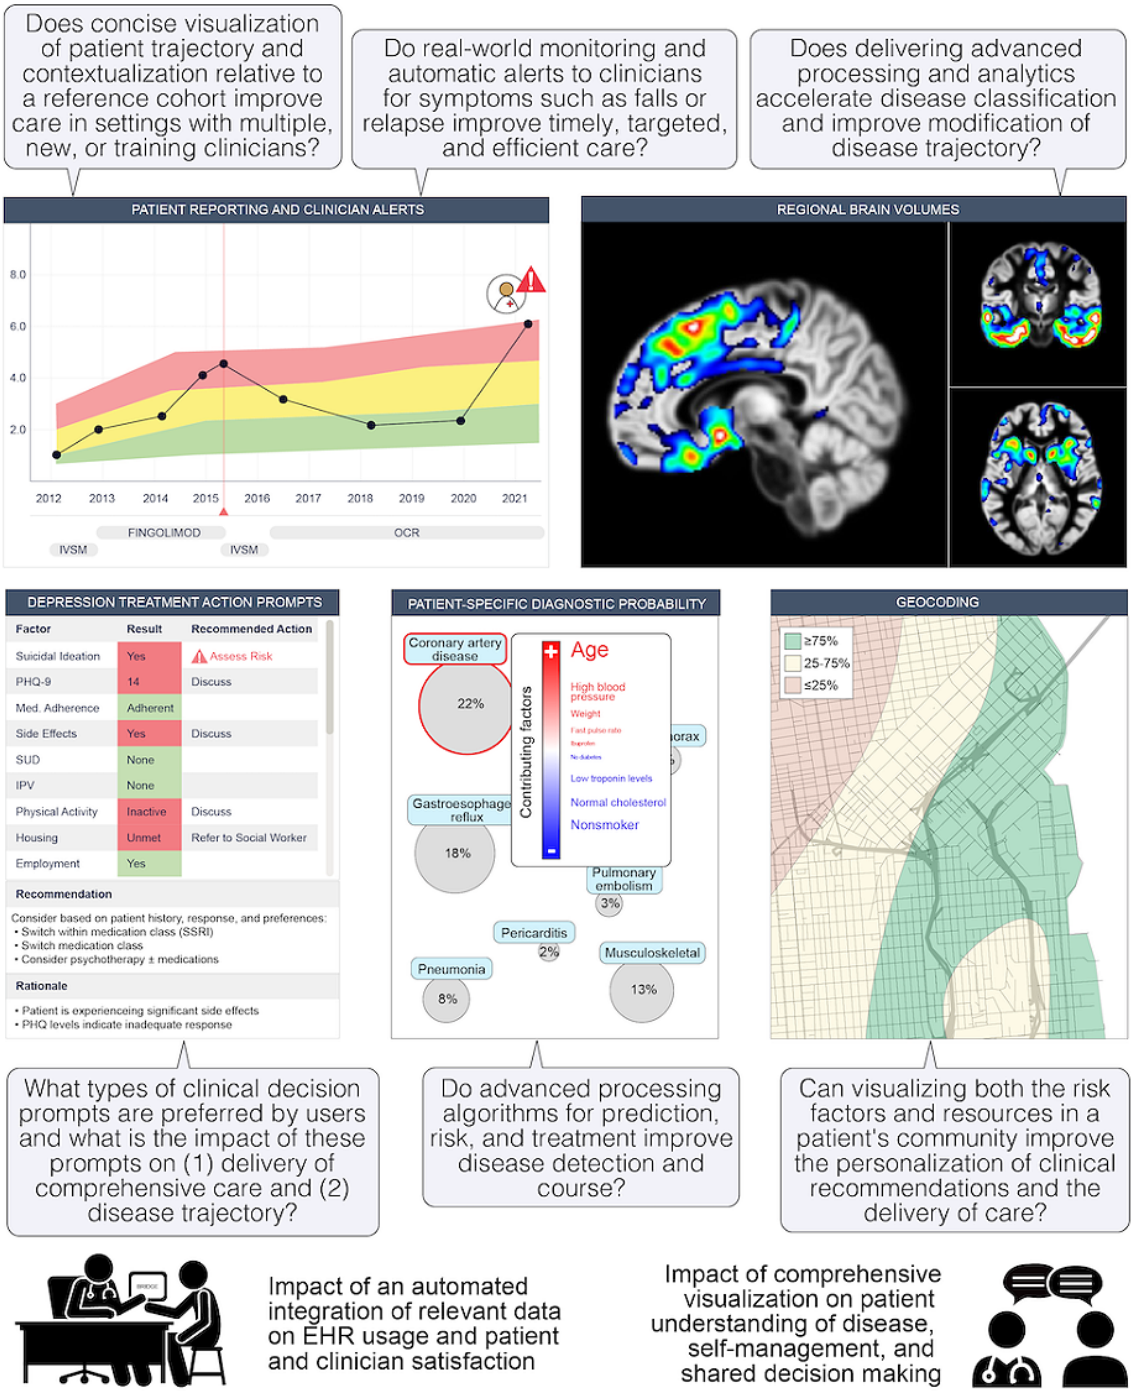
Pathway to Evaluation

Technological innovations in health care will ultimately be evaluated in terms of their impacts on patients, clinicians, data, and payors. In the near term, this requires the evaluation of a tool's interpretability and fidelity, that is, whether clinicians and patients like, understand, and use the tool and whether the use of the tool improves patients' experiences within the health system [15,28,30]. Making even the most complex algorithms visually digestible and actionable will be a key evaluation criterion [3]. To this end, for each BRIDGE dashboard, prior to measuring its clinical impact, we ensure that it meets key drivers of clinical adoption. We use the Health Information Technology Usability Evaluation Model [31] to evaluate at least 15 patients' and 8 clinicians' perceptions on the usefulness [32,33], ease of use [32,33], actionability [31], and likability [34] of each clinical dashboard. Low-scoring items (ie, <80% of respondents state "agree" for any given metric) engender another round of iterative development.

Evaluation and Impact: Future Directions

The impact of a dashboard like BRIDGE on clinical research and, eventually, care can be evaluated through in silico trials for answering a variety of clinical questions, as depicted in Figure 4. A near-term goal may be to compare users' preference for 2 types of symptom displays or to evaluate the impact of BRIDGE on workflow efficiency (eg, determining whether the use of the tool reduces the overall time spent on "clicking" through a patient's chart). Medium-term goals may be to refine a series of treatment action prompts that could yield a clinical decision support tool or to compare the effects of 2 different prediction algorithms on the risk of rehospitalization after a cardiac event. Long-term, altering clinical outcomes [2,25,27] that have obvious implications for health economics, such as reductions in the time to accurate diagnosis, rehospitalization, disability progression, morbidity, or death, will be directly relevant to an institution's assessment of a tool's utility.

Figure 4. Prototypes of clinical research enabled by BRIDGE. Clinical research applications include impacts on patient-doctor interactions and clinical workflows; the impact of monitoring patient-generated data, such as patient-reported outcomes and activity monitoring data; and the impact of delivering more advanced image processing and clinical algorithms (including prediction, prevention, and treatment algorithms) into the hands of clinicians. EHR: electronic health record; IPV: intimate partner violence; IVSM: intravenous solumedrol; MVP: minimum viable product; OCR: ocrelizumab; PHQ: Patient Health Questionnaire; PHQ-9: Patient Health Questionnaire-9; SSRI: selective serotonin reuptake inhibitor; SUD: substance use disorder.



Discussion

Determining whether big data analytics will truly disrupt clinical care depends on providing clinicians with access to the results of these analytics. In this paper, we describe one approach to overcoming the technical hurdle of making algorithms clinically available: the development of BRIDGE, an example of an institution-wide platform that allows for substantial clinic-specific customization. From the outset, BRIDGE was designed by intended users who worked closely with stakeholders, through an HCD process, to develop a structured and modular solution (Figure 2) that could be scaled and customized to specific clinic use cases in a cost- and time-efficient manner (Figure 3). The resulting platform addresses clinicians' requests to reduce data overload and more

precisely tailor the data that they use during clinical encounters. The lessons learned from building an institution-wide digital medicine platform include not only the importance of using HCD but also the importance of engaging with institutional partners and leadership early to collaboratively and transparently navigate through the long and arduous process of obtaining regulatory and security approval.

Based on our experiences, we propose that the development of similar platforms at other institutions is an efficient way to accelerate the testing of digital health algorithms in clinics. To reduce the burden of this undertaking, other academic clinical centers could use all or part of the BRIDGE platform code to create their own instances, especially if these centers used Epic, even though there would still be regulatory approval and software integration steps for making BRIDGE available within their EHRs. Additional developments could simplify this further, including sharing aspects of BRIDGE through centralized application stores, such as the Epic App Orchard, as well as creating centralized security audits and certifications that allow software to be vetted thoroughly once rather than vetting software at each new institution. Such centralization could be achieved by a federal initiative, a nationwide nonprofit society, or commercial vendors. For example, commercial vendors could provide institutions with centralized platforms that provide cloud-based computational resources, data access, security, and certification while clinicians and scientists develop dashboards and algorithms that run on these centralized platforms. BRIDGE provides a way to immediately develop and test these dashboards and algorithms in preparation for this future.

The potential of precision medicine will only be realized when the utility of the algorithms developed in this field can be evaluated at the point of care with real patients. Performing this testing requires substantial infrastructure development, which is hard to justify in the evaluation phase. Modular, scalable, institution-wide platforms, such as BRIDGE, represent one approach to resolving this catch-22 problem by providing an efficient mechanism for rapidly and cost-effectively deploying and evaluating new algorithms in clinics. Such a mechanism effectively serves as a bridge for translating research innovations into clinical tools.

Acknowledgments

The authors thank the funders (UCSF Weill Institute for Neurosciences), Dr Matthew State (for leadership of BRIDGE deployment in Psychiatry), Drs Ida Sim and Jason Satterfield (for iteration of a clinical action prompt tool), as well as Michael Schaffer (early BRIDGE architecture consultation) and Cosmo Mielke (w-map viewer in the UCSF Brainsight app).

Conflicts of Interest

RB receives research support from National Institutes of Health (NIH), California Initiative to Advance Precision Medicine, National Multiple Sclerosis Society (Harry Weaver Award), Hilton Foundation, and Sherak Foundation as well as Biogen, Novartis, and Roche Genentech. RB also receives scientific advisory board and consulting fees from Alexion, Biogen, EMD Serono, Genzyme Sanofi, Novartis, and Roche Genentech. BLM receives royalties from Guilford Press, Cambridge University Press, Johns Hopkins Press, and Oxford University Press and grant support from NIH and the Bluefield Project to Cure Frontotemporal Dementia. SLH serves on the scientific advisory boards of Accure, Alector, Annexon, and Molecular Stethoscope and the board of directors for Neurona. SLH has received travel reimbursement and writing support from Roche and Novartis for CD20-related meetings and presentations. KPR receives research funding from NIH, Quest Diagnostics, the Marcus Family Foundation, and the Rainwater Charitable Foundation. ES, PS, MG, SML, AB, and SJS have no conflicts of interest to declare.

Abstract

Social media provides an effective tool to reach, engage, and connect smokers in cessation efforts. Our team developed a Facebook group, CAN Quit (Connecting Alaska Native People to Quit smoking), to promote use of evidence-based smoking cessation resources for Alaska Native people living in Alaska, which are underused despite their effectiveness. Often separated by geography and climate, Alaska Native people prefer group-based approaches for tobacco cessation that support their culture and values. Such preferences make Alaska Native people candidates for social media–based interventions that promote connection. This viewpoint discusses the steps involved and lessons learned in building and beta-testing our Facebook group prototype, which will then be evaluated in a pilot randomized controlled trial. We describe the process of training moderators to facilitate group engagement and foster community, and we describe how we developed and tested our intervention prototype and Facebook group. All parts of the prototype were designed to facilitate use of evidence-based cessation treatments. We include recommendations for best practices with the hope that lessons learned from the CAN Quit prototype could provide a model for others to create similar platforms that benefit Alaska Native and American Indian people in the context of smoking cessation.

Introduction

Background

Social media is a powerful tool for reaching, engaging, and connecting smokers in cessation efforts. This could be especially true for Alaska Native people, who have the highest smoking prevalence in any US racial or ethnic subgroup [1]. Furthermore, Alaska Native residents of Alaska have a smoking prevalence more than double than that of Alaskan White residents (42% vs 17%), [2,3] but are difficult to reach with traditional face-to-face interventions because of their remote geography [4]. More than half of Alaska Native people live in more than 200 small communities (populations averaging 500-1000 total residents). Most of these communities are located off the road system and are accessible year-round only by a small plane, making them both geographically and socially remote.

Research indicates that internet (web)-based interventions are effective for smoking cessation and overcoming barriers related to travel; however, they are also associated with low use [5,6]. Conversely, social media has been shown to promote access and engagement among underserved, diverse populations with evidence-based content and peer support [7-9]. In contrast to individual-based treatments, social media platforms could lead to greater adoption and sustainability by encouraging collaborative efforts across adult generations that resonate with the Alaska Native cultural value of interdependence, defined as relationship oriented and collaborative in decision-making and lifestyle changes [10-12]. It is also important to note that traditional Alaska Native lifestyles, cultures, and holistic worldviews are intertwined and extend beyond mere social collectivism to include the interconnectedness of people with nature, the environment, and all elements of the universe [13,14]. Furthermore, Facebook is the dominant social networking platform used by 68% of US adults, more than double the proportion on Twitter (21%), Instagram (28%), Pinterest (26%), and LinkedIn (25%). Of Facebook users, 75% engage with the site daily. Facebook use indicates similarly high rates of engagement by sex (75% of females and 83% of males use Facebook), income (84% engagement among those earning <US $30,000/year vs 77% for those reporting >US $74,000/year), and age groups (88%, 18-29 years; 84%, 30-49 years; and 72%, 50-74 years), except for slightly less use (62%) among those aged ≥65 years. Of Alaskans, 91% reported having mobile broadband internet access [15-19], and surveys showed that the Alaska Native people in both rural and urban areas of Alaska use their smartphones to access social media, specifically Facebook [17,18,20].

On the basis of the above reasons, Alaska Native people, who value connection and community and represent an underserved health disparities group with significant barriers to receiving cessation treatment [21], may be optimal candidates for a social media platform where they can learn about evidence-based cessation resources in a group setting with other Alaska Native people also interested in quitting smoking. Furthermore, a Facebook intervention represents a potential platform for study recruitment, as Facebook is a primary source for social networking [17,18].

Objective

The overall purpose of the CAN Quit (Connecting Alaska Native People to Quit Smoking) intervention study is to promote use of evidence-based smoking cessation resources available to Alaska Native people state-wide using social media. In the first 2 phases, we evaluated content for inclusion in the study using qualitative and quantitative methods [22,23]. In this third phase, our goal is to develop and beta-test the intervention prototype. The purpose of this paper is to highlight the results of the beta-testing phase of this 4-phase study and share lessons learned that could be applied by others interested in similar health behavior interventions [22].

What Is the CAN Quit Study?

CAN Quit [22] is an ongoing 4-phase study to iteratively develop and pilot-test a culturally tailored social media–delivered intervention (via a secret Facebook group) to promote evidence-based smoking treatment uptake and cessation among Alaska Native people who smoke. The need for CAN Quit arose from a long-term collaboration between the Alaska Native Tribal Health Consortium (ANTHC) and Mayo Clinic. The goal of CAN Quit was to use peer support via social media to develop a scalable and sustainable intervention that could enhance use and reach of existing and effective cessation services offered to Alaska Native people through ANTHC, other Tribal cessation resources, and resources available through the Alaska State Quitline. If effective, we anticipate that ANTHC could manage and sustain CAN Quit as part of its tobacco cessation program and be moderated by its tobacco cessation counselors.

CAN Quit uses a culturally based digital storytelling approach [24-27], with content adapted from the effective Centers for Disease Control and Prevention (CDC) Tips from Former Smokers campaign [27] and from the ANTHC library of digital stories. Digital stories previously created by Alaska Native people contained their voices, pictures, and stories about tobacco cessation. We incorporated cultural variance and surface or deep structure frameworks [28] to address the influence of culture in designing health messages. The Mayo Clinic and Alaska Area institutional review boards and ANTHC Board of Directors' Health Research Review Committee reviewed and approved all study phases.

In the first 2 study phases (described in the studies by Sinicrope at al [22] and Merculieff et al [23]), we gathered feedback first qualitatively and then quantitatively from Alaska Native people who smoke recruited state-wide primarily through targeted paid Facebook ads. We asked about the suitability of content, including digital stories and photos with text provided by CDC Tips and ANTHC. Similar to Tips, taglines to all content included a call to action for tobacco treatment by providing the (1) State of Alaska toll-free Quitline number, (2) URL to regional Tribal tobacco cessation program websites, and (3) URL to the smokefree.gov quit smoking resources website. In phases 1 and 2, through analysis of qualitative interviews with Alaska Native people who smoke and stakeholders (Alaska Native tobacco counselors) who viewed existing text, image, and video content, we found that participants preferred content that included Alaska Native people engaged in Alaska Native

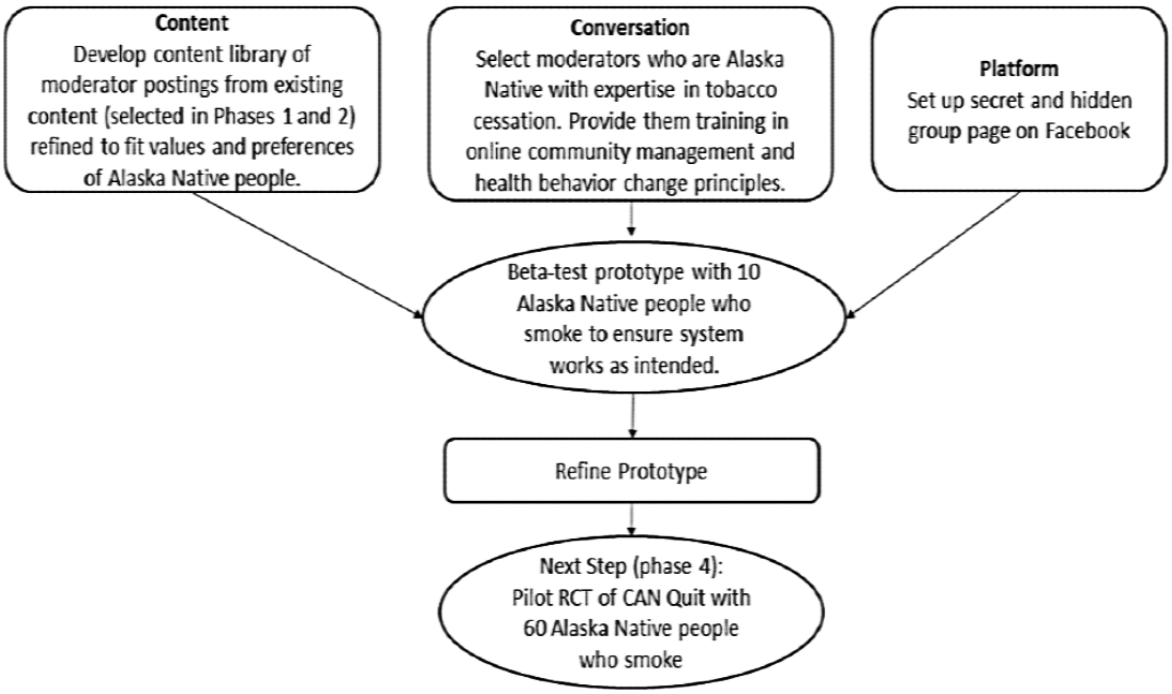
activities and were motivated to change smoking behavior when presented with images reflecting Alaska Native values of family, children, and community. Participants also preferred direct and honest storytelling styles told by other Alaska Native people without "sugar-coating" [23].

Prototype Components

Overview

Through this formative work, we developed an intervention prototype (phase 3) that included the following: (1) a Facebook group interface populated with culturally appropriate images and text outlining the purpose of the group, (2) a content library of images with text and digital stories (video) selected with sample moderator postings, and (3) a training plan for 2 Alaska Native study coordinators to moderate the Facebook group. Guidelines from Pagoto et al [29] informed the development of the components of our prototype and the training plan. Figure 1 provides an overview of the intervention prototype.

Figure 1. Overview of the CAN Quit (Connecting Alaska Native People to Quit Smoking) intervention prototype. CAN Quit is a 4-phase study. This figure highlights how phase 3 fits into the overall study design. RCT: randomized controlled trial.



Facebook Group Interface

We created community guidelines specific to CAN Quit to establish and maintain a supportive, inclusive, and respectful community. These were built on standard group conduct guidelines provided by Facebook when creating a group on the platform. The study team reviewed the standard group conduct guidelines together and elaborated on them to be specific to the CAN Quit group. For example, the group elements were as follows: (1) a name and cover photo for the group; (2) a description of the group's purpose, including contact information and a link to evidence-based quitting resources; and (3) an *about* section describing the group, its purpose, and five basic guidelines: be respectful and courteous, no hate speech or bullying, protect yourself and the group's privacy, no commercial posts or promotions and spam, and be careful about giving out medical advice. Privacy settings were established as *closed* (ie, only members could see who was in the group and what they post) and *secret* (ie, only members could find this group). Similar to CDC Tips content, prominent links to evidence-based quit smoking resources were located on all content and on the cover page.

Content Library

The team developed a content library organized similar to a conventional treatment manual, available only to the moderators; however, once posted, Facebook stored the content on the page history and in the photo library. We organized pivotal discussion points by content, taglines, and sample text so that moderators could initiate discussions to promote quitting. The final 64-page library (digital and written) included the following: (1) welcome posts, group description, guidelines, and contact information; (2) options for Facebook cover photos; (3) 64 posts (images and text or video that included a tag line to call the Quitline or use Tribal quitting resources, similar to the CDC Tips campaign); (4) guidelines for handling inappropriate or misinformation (eg, deleting unrelated or false posts and removing or blocking participants breaking group guidelines); and (5) a list of quitting resources, including the State of Alaska Quitline and regional Tribal resources.

We organized posts by subject (ie, quitting reasons and sources of quitting support), and all content included sample text the moderators can modify to fit with or be responsive to current group conversations. Figure 2 includes 2 images, one is the original CDC post that features Rebecca, a 57-year-old White

woman sitting on the sofa in her living room with the tag line "Quitting isn't about what you give up. It's about what you get back." The second adapted image includes the same tag line, but the image is that of an Alaska Native grandfather holding a baby, which resonates with the Alaska Native value of family and its importance as a motivator for smoking cessation. Sample text in the form of the question, "What are you hoping to gain from becoming smoke-free?" accompanied the post in which the moderator could add in to generate a discussion.

Figure 2. Example of Centers for Disease Control and Prevention Tips post and how it was refined for CAN Quit (Connecting Alaska Native People to Quit Smoking).

Moderators

The success of an online community is heavily dependent on the skills of moderators. Embedded in this skill is their familiarity with the topic (tobacco cessation), library content, understanding of and appreciation for Alaska Native cultural values, and ability to facilitate communication in a Facebook group. Recognizing this, we stressed hands-on scenario-based training and working directly with participants in each phase of the study so that moderators could continually develop their skills and become comfortable with working in the online community. Both Facebook moderators are trained tobacco specialists (TTSs) and Alaska Native employees of the ANTHC Tobacco Cessation Program in Anchorage, Alaska. Each received TTS training in motivational interviewing (MI) and additional training (as described in the section *Training Plan* below) to moderate CAN Quit. Moderators posted content every 2 to 3 days to prompt and reinforce participant posts and discussions (eg, sharing stories of tobacco use and quitting). Although content was prepared in advance in anticipation of discussions that would emerge, moderators also posted when relevant to guide and direct conversation and to provide timely content in response to member directions and needs.

Training Plan

Overview

A platform such as Facebook provides space for creating groups, but building a successful online community where members actively participate, engage with one another, and develop relationships requires an enabler (ie, a moderator) with organized strategic community management skills [30-33]. In addition, creating an online [30] community that serves Alaska Native people also requires that community managers and content developers pay attention to cultural norms and ways of interacting [31]. Therefore, the research team prioritized a moderator training using a scenario-based approach [34], providing moderators with skills to promote engagement, communication, and health behavior change (ie, use of evidenced-based quitting resources), whereas moderators provided feedback on how scenarios could be consistent with Alaska Native culture. The overall goal was to optimize and tailor the training specific to the needs of the CAN Quit study using *hands-on* instruction with real-life situations or scenarios relevant to learners [35]. In this instance, we created a CAN Quit practice Facebook group with posts and mock situations for moderators to practice crafting responses.

Two phases of training for moderators covered essential elements of online community management and moderator practices in part 1 and MI, tailoring, and cultural adaptation in part 2. The moderators actively participated in developing the training, providing their expertise and background as Alaska Native TTSs working with Alaska Native people.

Online Community Management and Moderator Practices Training

Over the course of 12 training hours, moderators acquired skills in strategic community management and applicable moderator practices required to build and maintain a thriving online health community (presented by CY). The training included the

following: (1) a pretraining questionnaire; (2) a 90-minute web-based introduction to online community management (see the section *Online Training*); (3) a 2-day in-person workshop (10.5 hours) with hands-on practice moderating and time for feedback and cultural tailoring; and (4) ongoing coaching through observing moderation practices in situ.

Pretraining Questionnaire

The pretraining questionnaire asked moderators four questions: (1) What do you hope the CAN Quit Facebook group will achieve? (2) As a moderator, what do you anticipate will be your single biggest challenge? (3) As a moderator, what type of interaction in the community would make you feel rewarded? and (4) What does success look like? Answers to these questions helped tailor the initial web-based training session.

Online Training

This 90-minute training was divided into 2 sessions. Session 1 introduced the fundamentals of community management, such as defining online community and understanding why people join patient support networks and what motivates them to return. The session addressed the interplay among the three ingredients for success: growth, activity, and sense of community. It also explored strategies and tactics supporting these items throughout the life cycle of an online community. The session examined strategic approaches for program inception: (1) welcoming new members and integrating them into the community; (2) ensuring every post receives a response; (3) connecting members; (4) keeping people talking; (5) asking questions that encourage self-disclosure and build trust; and (6) discovering members' knowledge, capacity, and strengths.

During the subsequent session, trainees posed questions to the community management expert or trainer in *Ask Me Anything* style. In this session, questions frequently include the following: (1) How do you engage inactive members? (2) How do you encourage meaningful interactions? (3) What do you do about members who do not follow community guidelines? Although these questions were addressed in brief during the *Ask Me Anything*, we also addressed them in the in-person workshop.

In-Person Workshop

A strategic community management plan ensures that the achievements of the online community and its members align with the overarching goal of sponsoring institutions. In this 2-day workshop, moderators and trainers developed a strategic community management plan (Figure 3), followed by hands-on practice applying strategies consistent with situational learning strategies [34]. The trainer (CY) relies on the best practices by Millington [30] adapted to a health setting in this study and in similar work with the online community Mayo Clinic Connect [32,36,37].

Figure 3. CAN Quit (Connecting Alaska Native People to Quit Smoking) strategic community plan.

Goal	Decrease smoking rates among Alaska Native people				
Objectives	**Convert** first recruits from passive to active participating members.			**Connect** members and get them to respond to other members, encourage them, and share their experiences.	
Strategies	Make members feel comfortable sharing their situation openly and asking questions	Make members feel proud as they set goals, show progress and achieve goals.	Make members feel accepted to come back to the community if they have a set back.	Make members feel joy in helping and being there for other members.	Make members feel confident they have useful experience and expertise to share. Make them feel comfortable asking questions of others.
Tactics	Ask questions to get more info about the member and to discover their knowledge.	Get members to share a target or goal. Celebrate milestones.	Find the positive in the setback to set a new goal.	Foster and reinforce positive connecting behavior.	Tag members and tell them why you did.

Strategic Planning Framework

The first day of the workshop focused on how to establish a framework for building an online community that includes the building blocks (goal, objectives, strategy, and tactics). The goal was defined as the direct value the organization gets from the community. Objectives are what members need to do to get this value. Strategy involves the emotion moderators amplify to get members to perform this behavior. Tactics are the things moderators do to amplify this emotion [30].

Importantly, the workshop emphasized that each action moderators take in the online community should be meaningful: (1) give new members confidence to make a first post, get help, and return to help others; (2) demonstrate the value of the CAN Quit group, a community where no question goes unanswered and people are supportive; and (3) amplify a sense of personal progress, success, and growing confidence in each member as they reach milestones and goals, or return for encouragement and support if a setback is experienced. Trainees were asked to reflect on the following questions: (1) What do you want members of the CAN Quit group to do? and (2) What do you have to do to make that happen? In the inception stage of this limited enrollment group, tactics were focused on moderator actions promoting activity and a sense of community objectives.

The remainder of the 2-day workshop concentrated on specific moderator approaches to support the above tactics. Although the moderator approaches remained platform agnostic, specific Facebook tools and their optimization were also discussed and a hidden *Practice CAN Quit* group was created to practice skills. Trainees learned and practiced the following: (1) *Setting up the group*: What do you want members to see when they visit the group? What 1 action do you want them to take? (2) *Getting*

the conversations started: How do you create conversations members want to participate in? (3) *Managing the tough stuff:* How do you deal with members who do not follow the community guidelines? (4) *Effectively using private messaging:* When should you use and not use private messaging? and (5) *Managing the group when it becomes active:* When should a moderator stay out of the way? How do you transition from micro to macro interactions? The team spent additional time discussing ways to monitor or track posts, strategy, and tactics to determine which may need adjustment.

The training wrapped up with a reminder of the importance of self-care. From the experience of the trainer (CY), reading all posts, responding with empathy, and helping members succeed can be emotionally taxing. The group addressed good self-care practices, including recognizing when to unplug from the group and taking time off and reaching out to fellow moderators and the research team for difficult situations or decisions.

Ongoing Coaching Through Observing Moderation Practices In Situ

Following the training, trainer CY provided moderators feedback biweekly, as they put the newly acquired skills into practice. They were given tips on how posts and interactions could be tweaked and recognizing opportunities to take action to promote further engagement. Moderators also reached out to other members of the research team with questions and concerns.

Effective Communication Strategies and Cultural Adaptation Training

In this training, moderators received approximately 10 hours of web-based training, divided across 2 days, approximately 5 months apart (July and December 2019). The trainer (KR) addressed the following: (1) theories of behavior change and tailored communications, (2) application of MI techniques for social media interventions, and (3) cultural adaptation of smoking cessation messages.

Theory of Behavior Change and Tailored Communications

The group discussed several behavior change conceptual models, including self-determination theory [38] and cognitive behavioral therapy [39,40]. The author KR also presented principles of cultural and psychosocial tailoring of health communications [28,41], at both the individual and group levels. He then applied theoretical models to cases directly addressing smoking cessation behavior in an Alaska Native population.

MI Techniques in a Social Media Intervention

MI is a client-centered counseling approach that has been tested in hundreds of studies, including numerous studies on smoking cessation [42]. This aspect of the training emphasized how to use key MI principles (eg, autonomy support) and strategies (rolling with resistance and eliciting change talk) of MI in the context of this social media intervention. The group discussed and practiced strategies for writing effective questions and reflective responses and for acknowledging and eliciting change talk, such as the following:

- "Sounds like you are moving toward giving up smoking."
- "Your post indicates you have lots of good reasons to quit, such as your kids, your community, and your health."
- "You are proud of yourself for staying quit for more than two weeks."
- "Although you are not quite ready to quit yet, it sounds like you are moving in that direction. You are getting close."

Cultural Adaptation of Smoking Cessation Messages

Moderators received training on incorporating the Alaska Native cultural content into their Facebook posts and responses. This included a review of Alaska Native core values and the practice of generating messages that linked smoking cessation to these values. For example, the team brainstormed ways that respect for nature, community, humility, and mindfulness could be linked to cessation messages. The team also explored ways to post polls on the Facebook page that queried users' core values, which they could then use to generate tailored messages about how their values might drive their efforts to reduce their tobacco use.

Training applied web-based exercises and actual or simulated Facebook posts in a scenario-based learning approach to enable moderators to master concepts and build messaging skills [34]. When given posts, the moderators generated responses in real time using the principles and strategies presented. For example, moderators received the following participant post:

> *I know quitting is going to be hard but I want to show my kids that I'm strong and I want to be around for them when they're older and have their own kids. I want to be there for my family.*

For this case, the response included the strategy of rolling with resistance around the perceived difficulty of quitting and use of a reflective statement capturing the meaning of quitting for this participant; that is, change talk about her desire to be there for her family, such as using a reflective state, for example, "on one hand you are scared that quitting will be challenging," as well as reflecting the meaning of quitting back to the participant that is her change talk, for example, "but quitting would send them a message that you care about them and are willing to do what's needed to be there for them."

Beta Test

Overview, Sample, and Methods

Upon completion of all training and 2 weeks of practice, we beta-tested the intervention prototype with our 2 moderators and a sample of 10 Alaska Native adults living in Alaska who smoke cigarettes. As in our prior study phases described previously [22], Alaska Native people who smoke were recruited state-wide primarily via targeted paid Facebook ads that included an image and short text consistent with Facebook's advertising guidelines based on the following criteria: aged >19 years, self-reported Alaska Native race or ethnicity, and keywords related to tobacco use. To be eligible to participate, participants had to be living in Alaska, aged ≥19 years, have smoked >1 cigarette per day over the past 7 days with cigarettes as the main tobacco product used, and be considering or willing to make a quit attempt. They also had to have access to broadband (high-speed) internet on a mobile phone, at home,

work, or other locations, and a Facebook account or be willing to set one up. Finally, they could not have been enrolled in a cessation program or using pharmacotherapy to stop smoking during the last 3 months. Prior work suggested 10 people as the minimum for optimal engagement in social media [43,44].

The purpose of this phase was to provide participants 30 days of exposure to the CAN Quit Facebook group and obtain their feedback to (1) ensure the system worked as intended, (2) identify technical issues, and (3) facilitate program refinements in preparation for the pilot randomized controlled trial (RCT). We administered a web-based survey at baseline to collect demographic, smoking behavior, and readiness to quit information. At completion of the 1-month beta test, we assessed readiness to quit, quit attempts, and use of cessation resources. In addition, we also assessed the acceptability of the CAN Quit group platform via the social media usability scale, which measures perceived ease of use and usefulness (3 items each), ease of learning (1 item), and satisfaction (6 items), rated on a 5-point scale (1—strongly disagree, 5—strongly agree) [45]. We also asked open-ended questions to provide feedback on modifications to the prototype. Participants received a US $25 gift card for their time after each assessment.

Analyses

We summarized the sample characteristics and usability measures using descriptive statistics (means, SDs, percentages, and frequencies). We analyzed the responses to open-ended questions using content analysis [46].

Results

Baseline

Of the 10 Alaska Native adults (mean age 35, SD 8.18; range 23-52 years; 9/10, 90% female; 7/10, 70% living in a rural area; 6/10, 60% employed for pay; and all had a high school degree or higher), the average number of cigarettes smoked per day was 10.2 (SD 7.5; range 2-25) at baseline. Furthermore, 60% (6/10) reported a high level of readiness to quit cigarettes (mean 7.2, SD 2.7; range 2-10), and 50% (5/10) reported readiness to use smoking cessation treatment (mean 7.1, SD 2.6; range 0-10) (data not shown).

One-Month Follow-Up

Among the 10 participants, 6 reported at least one quit attempt and 2 quit smoking (both called the Quitline). Feedback on the Facebook group revealed an overall social media usability score of 4.1 (SD 0.58; range 3.1-5.0) for the 13 items reported. Mean categorical scores were as follows: for usefulness (3 items), 3.7 (SD 0.66; range 3.0-5.0); for ease of use (3 items), 4.5 (SD 0.61; range 3.0-5.0); for ease of learning (1 item), 4.7 (SD 0.67; range 3.0-5.0); and for satisfaction (6 items), 4.0 (SD 0.71; range 3.1-5.0).

Facebook Page Activity Summary

We conducted a beta test in the fall of 2019. Moderators posted 19 unique posts from the content library, 1 participant created a post with a photo of their children as a reason for quitting, and the cover page was posted. Participants posted a total of 35 reactions (eg, all *likes* and *loves*), and 130 comments were generated across the posts, with 57.7% (75/130) of comments coming from moderators and 42.3% (55/130) from users. Of the 10 pilot testers, 9 posted 54 comments in all. The number of comments per person ranged from 1 to 24 (median 5). For the 2 people who reported quitting smoking, 1 posted 15 comments and the other posted 2. There was only 1 instance where a participant shared content outside the group on a personal Facebook page. When this occurred, the moderator sent the participant a private message, redirecting the participant to the group rules. There were no other boundary violation incidents (data not shown).

Participant Feedback on Group

Participants and moderators were asked to provide feedback on how to improve moderator posts as well as the Facebook group overall (Table 1). Four areas of response emerged: (1) providing incentives for participation, (2) clarifying the group purpose, (3) making posts more interactive and specific to rural Alaska Native people, and (4) encouraging group members to post more frequently. Moderators expressed that they felt prepared to use the skills from their training. They expressed challenges associated with working with the Facebook platform to ensure they did not miss comments because Facebook does not organize posts in chronological order in groups. They also expressed challenges associated with keeping track of multiple users across posts and found that maintaining a spreadsheet of group members and their stories helped to ensure that they responded appropriately to posts. One of the biggest challenges was responding to participants who shared traumatic or personal information. However, they expressed that training in MI principles of communication and self-care was especially helpful in this regard (Table 1 and Table 2).

Table 1. Moderator feedback on CAN Quit (Connecting Alaska Native People to Quit Smoking) beta test.

Question and moderator feedback	Changes made
What were the most challenging parts of moderating the CAN Quit group?	
Maintaining communication among participants on multiple threads at one time. It can be easy to miss someone's response if you are not diligent.	Study team monitors group and notifies moderators if they miss a post
There were participants who shared personal experiences (eg, death of a child and struggles with other substances) with the group, and it was challenging to figure out how to best respond to these comments. There was also a participant who used our post to sell items on a personal FB[a] page.	• Consultation with the trainer (CY) before crafting a response • Determine as a group the best way to handle more sensitive topics • Added an additional refresher training in MI[b] principles (KR) and practices before RCT[c]
Tracking each participant's responses so you can easily reference prior conversations. This is important when building rapport with the participant.	Moderators maintain a spreadsheet tracking all members with notes to help them remember details and respond accordingly
Connecting one person to another based on their personal experiences and actually getting a response or any dialogue between the two.	Feedback or reinforcement from the trainer (CY) on different tactics for connecting participants (ie, tagging, private messaging, and asking questions specific to interests or strengths of participants).
What advice would you give to someone who was about to moderate a group like CAN Quit?	
Keep a log of your communication with each participant from when the group starts. This way you can easily reference this spreadsheet to see what topics have been discussed with this participant. This can be especially helpful in groups with more than one moderator.	N/A[d]
Be thoughtful in your responses; sometimes it can be difficult to not sound robotic over the computer. I think this is important in developing a connection with each participant and building trust. The MI tips we learned were very helpful in making sure we are professional but personable when moderating.	N/A
What did you think you did best and what do you think you need to work on?	
We did a good job of posting new content with an interesting prompt every few days which helped the group stay active.	N/A
We did a good job of refining our responses to each participant and knowing when to refer the Quitline. We do not want to refer the Quitline so often that we sound robotic but we want to encourage participants to use evidence-based smoking cessation programs.	Use MI skills training and created additional posts that discuss the Quitline and Tribal quitting resources
We are working on generating quicker responses	Moderators share the responsibility of monitoring the Quitline

[a]FB: Facebook.

[b]MI: motivational interviewing.

[c]RCT: randomized controlled trial.

[d]N/A: not applicable.

Table 2. Beta tester feedback on CAN Quit (Connecting Alaska Native People to Quit Smoking) beta test.

Improvement areas (themes)	Representative quotes	Solutions implemented by team
Clarify group purpose	• "Have mental or behavioral health programs ready" • "I felt unsure if I was supposed to use the site to access the quit helpline through FB[a], because my region doesn't use the Quitline for assistance in quitting anymore"	• Additional welcome posts created that clarify group purpose as well as the Quitline and Tribal Quitting resources • Moderators incorporated feedback to reinforce FB page purpose and the quitting resources
Provide incentives or games	• "It would be great to get the rural communities involved and offer some sort of Photo, Video or Art contest that included a drawing, a photo or video that helps people quit smoking or talk about the negative effects of smoking. It would draw more people in and get people to participate in the efforts toward Tobacco Prevention and keep them busy toward something positive. If we could include a prize for 1st, 2nd and 3rd also!" • "Maybe some fun trivia games to get people wanting to look at the page." • "Do more instead of just post posters. I mean we all can brainstorm in a different way and play along as we go?"	• Team implemented "polls" where participants could vote on what values are important to them and write in additional values • Will add incentives for future groups
How to improve posts	• "Could use less medical type photos. More of our own pictures to help support each other" • "I think more should be put into it. More involvements" • "More videos that include rural areas would be a great idea" • "Posts being more clear about regional resources would be nice" • "Make more posts"	• More rural posts will be used in the randomized controlled trial • More posts relating to Alaska Native values were created using Alaska Native imagery (eg, people, families, communities, and activities) • New post and discussion prompt posted to the group every 2 days • Combined posts and video links to increase participant engagement • Creation of interactive posts like the FB poll • Developed a moderator spreadsheet to track posts to ensure full variety of topics and types of posts (eg, urban, rural, photo or text, and video) will be addressed
Moderators make group more interactive	• "Maybe encourage more people to post more often to gain connection." • "Find ways to make it more interactive."	• Moderators will tag participants to increase participation on individual posts • Moderators individually welcome all new members on the welcome post and encourage them to interact. • Prompted new members to introduce themselves and their reasons for wanting to quit. • Moderators connect members to interact who express similar experiences or concerns • Provided additional training to moderators that focused on health communication and ways of increasing interaction • Developed follow-up questions that may be asked on the original post to encourage discussion

[a]FB: Facebook.

Conclusions, Discussion, and Overall Recommendations

This paper shares the processes involved with developing and beta-testing a social media group as an intervention to promote use of evidence-based resources for quitting smoking using peer support. We share specific approaches, strategies, and methods for stimulating participant engagement in the Facebook group and emphasize the importance of moderator training and creating a content library. During training, trainers and moderators shared expertise to help build cultural competency and web-based communication skills that would build community and promote behavior change. Cultural tailoring is a critical component of the prototype. The research team used content linked to core Alaska Native values and/or Alaska Native imagery when possible, and Alaska Native moderators used their personal experience to incorporate cultural values and content into their written posts and responses. The purpose of these phases was to adapt the intervention and prepare moderators to deliver the intervention for the subsequent phase, which was a pilot RCT.

The results of the beta test were encouraging with participants expressing a high degree of usability of the CAN Quit Facebook group based on the Social Media Usability Measure, and there was a signal of potential effectiveness, with 2 out of 10 participants using the Quitline and reporting quitting smoking.

Qualitative feedback was helpful in directing the research team to specific improvements needed to make the Facebook group more successful or usable; for example, providing additional training to moderators to promote interactions among participants, support conversations that may contain emotional content, and add more welcome posts to the group page to better clarify the group's purpose: use of evidence-based quitting resources. Given that the group is on Facebook, which is popular in Alaska Native communities [16], most users were not new to the technology, which made it easier to avoid technical challenges in participating. We noticed that no video content was posted by moderators and some other content was posted repeatedly, whereas other content was not used. The selection of content was based on the activity of their group members at the discretion of the moderators. However, based on this observation, we determined that it would be helpful to the moderators as they select content, to develop a spreadsheet to track posts already used from the content library.

Strategies to promote engagement between participants rather than between participants and the moderator are the primary areas for improvement. Strategies suggested by our community management expert (CY) included tagging, private messaging, pinning posts so they show up at the top of the group feed, and drafting new follow-up questions to add to posts to further stimulate discussion. Several strengths were noted during the beta-testing phase. Moderators were able to model empathy and support, which included their adept use of reflective listening skills and personal experiences as tobacco counselors. Both moderators had received TTS training and were of Alaska Native heritage, which made it easier for them to quickly connect to participants through a mutual appreciation of core Alaska Native values and their TTS background.

Our approach has several strengths. The development of our training and content library was iterative and theory based. We used social media and health communication experts to conduct training grounded in situational learning. We used a combination of face-to-face and web-based formats and provided a scenario-based approach for moderators to practice their skills. All participants (moderators and trainers) in the training sessions served as experts to each other such that all participants were able to acquire new skills. We gathered feedback from the research team and our beta testers on how to improve the CAN Quit prototype. This feedback resulted in practical solutions that will be embedded in the RCT, which is beneficial for developing an intervention in phases (iteratively), as recommended by the National Institutes of Health and CDC guidelines [47,48]. Most importantly, our approach was created based on the need to improve use of evidence-based tobacco cessation resources specifically for Alaska Native people, a high-risk group for tobacco-related morbidity and mortality. This approach provided a systematic process to tailor or adapt content and training to appeal specifically to Alaska Native people living in Alaska.

Our approach also has some limitations. Implementing the prototype on Facebook results in a lack of control on some aspects of the intervention design, such as the order in which posts were introduced, which required moderator flexibility in responding to changes accordingly. Despite this limitation, given that Facebook is commonly used and familiar, less on-boarding of participants is required to participate in the intervention. In addition, a sample size of 10 was the minimum recommended for a group social media intervention; it is likely that engagement would be easier to achieve with a larger group size, as will be used for the RCT. Stimulating group interaction during the beta-testing phase presented a challenge to the moderators given the small number of participants and the short amount of time they participated. However, this challenge resulted in stronger engagement skills among moderators, which will aid in the RCT phase. Meanwhile, consistent with and building on the work of Pagoto et al [29], we came up with ten recommendations of lessons learned that could help guide others interested in developing similar social media intervention prototypes: (1) select moderators who can relate to your group; (2) build on existing skills of your moderators; (3) build community engagement; (4) use existing resources for content; (5) adapt content for cultural fit; (6) design content that highlights your goals; (7) include a wide variety of content and organize it into an easily searched library; (8) balance content with conversation; (9) support moderators to handle emotional communication; and (10) groom group participants as moderators. Table 3 outlines these recommendations in detail.

In summary, providing practical information on how we developed and evaluated our intervention prototype demonstrates how a beta-testing phase is essential in identifying how the platform, content, and moderation can be improved before rolling out a large-scale intervention. We learned that a social media group intervention is most likely to succeed if it balances well-developed culturally congruent content with strategies to engage Alaska Native participants in social media conversations facilitated by moderators. Moderators need to be provided with the necessary skills and methods for promoting web-based community engagement with and among group members and in encouraging behavior change. In our case, having Alaska Native moderators who were themselves Alaska Native and already experienced the challenges associated with smoking cessation was extremely helpful in both developing the training plan and promoting engagement. Future studies could explore using former intervention participants transitioning to a moderator role to enhance sustainability, growth, and feasibility of the intervention. Our next step will be to evaluate the prototype via a pilot RCT.

Table 3. Recommendations for creating a successful social media group to promote use of evidence-based smoking cessation resources for Alaska Native people.

Recommendation	Description
Select moderators who can relate to your group	We chose moderators with expertise in smoking cessation (TTS[a]) who also shared similar Alaska Native ancestry and cultural values. This approach is effective with building rapport among group participants and moderators.
Build upon existing skills of your moderators	Beyond training as TTS, our moderators received 20 additional hours of training in strategic web-based community management and health behavior change. We recommend training be scenario-based, experiential, and use actual posts for moderating practice.
Build community engagement	Our moderators shared that getting to know group participants made it easier to respond to their posts, reinforce quitting messages, and provide support. Train moderators to react, tag, and instant message participants to respond when they post. They should acknowledge active participants while also checking in with inactive participants, inviting them back to the group.
Use existing resources for content	We evaluated and adapted existing, evidence-based content already created by the CDC[b] and ANTHC[c], with their permission. This was both cost and time effective. We recommend using or refining existing high-quality content whenever possible, seeking necessary permissions.
Adapt content for cultural fit	We used an iterative theory-based process of qualitative and quantitative feedback from both participants and stakeholders to adapt our content and be responsive to the evolution of the participants and the group. We recommend using a conceptual framework with community and stakeholder input.
Design content that highlights your goals	Our goal was to promote use of evidence-based resources. We found it important to include links to the Alaska Quitline or Tribal cessation resources on all content. We suggest including a call to action with each post.
Include a wide variety of content and organize it into an easily searched library	It is difficult to predict how participants will communicate and what will motivate them to engage in the group. Having an organized library with a variety of content allows moderators flexibility to select content that is responsive to an ongoing conversation or that meets the needs or interests of group participants to maintain engagement.
Balance content with conversation	We used content that fit concerns and conversations happening within the group. We believe the key to success lies in fostering group engagement through conversation with moderators and with each other. It is necessary to create a community of talkers, not readers.
Support moderators to handle emotional communication	We provided 20 hours of MI[d] and web-based community management training to prepare moderators to support group participants who share sensitive information. We recommend training also include a plan for moderators to seek additional support.
Groom group participants to be moderators	Once our group was underway, we saw some participants were very engaged, not only with moderators but also with other group participants. Consider inviting and training former group participants to volunteer as peer mentors or moderators.

Acknowledgments

Authors thank the Alaska Native Tribal Health Consortium Research Consultation Committee for providing guidance on the development and implementation of this study. They also appreciate the contributions of Selma Oskolkoff-Simon, Fiona Brosnan, Michael Doyle, and Alaska Native Tribal Health Consortium Marketing and Communication. The authors are grateful for the technical assistance provided by the Health Communications Branch of the Centers for Disease Control and Prevention. In addition, the authors would like to acknowledge the Mayo Clinic Survey Research Center for their assistance with the survey design and data collection. They also thank Michelle Pearson and Kimberly Kinnoin for their assistance with the manuscript.

This research was supported by the National Institute on Drug Abuse of the National Institutes of Health under award number R34DA046008 (Patten). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

We thank the staff at the Office of Smoking and Health at the Centers for Disease Control and Prevention, who arranged access to the image used in this study.

Conflicts of Interest

Unrelated to this project, JJP has provided consultation to pharmaceutical and technology companies that make medications and other treatments for quitting smoking and has received funding from Facebook for planning evaluation of a mobile health intervention. JJP has also served as an expert witness in lawsuits against tobacco companies. All other authors declare no conflicts of interest.

Abstract

Although the Office of The National Coordinator for Health Information Technology's (ONC) Information Blocking Provision in the Cures Act Final Rule is an important step forward in providing patients free and unfettered access to their electronic health information (EHI), in the contexts of multiuser electronic health record (EHR) access and proxy access, concerns on the potential for harm in adolescent care contexts exist. We describe how the provision could erode patients' (both adolescent and older patients alike) trust and willingness to seek care. The rule's preventing harm exception does not apply to situations where the patient is a minor and the health care provider wishes to restrict a parent's or guardian's access to the minor's EHI to avoid violating the minor's confidentiality and potentially harming patient-clinician trust. This may violate previously developed government principles in the design and implementation of EHRs for pediatric care. Creating legally acceptable workarounds by means such as duplicate "shadow charting" will be burdensome (and prohibitive) for health care providers. Under the privacy exception, patients have the opportunity to request information to not be shared; however, depending on institutional practices, providers and patients may have limited awareness of this exception. Notably, the privacy exception states that providers cannot "improperly encourage or induce a patient's request to block information." Fearing being found in violation of the information blocking provisions, providers may feel that they are unable to guide patients navigating the release of their EHI in the multiuser or proxy access setting. ONC should provide more detailed guidance on their website and targeted outreach to providers and their specialty organizations that care for adolescents and other individuals affected by the Cures Act, and researchers should carefully monitor charting habits in these multiuser or proxy access situations.

Introduction

"*Primum non nocere*" ("*First, do no harm*") or nonmaleficence is a fundamental principle taught to every health care provider. It suggests that before applying any medical intervention, one needs to consider the potential negative effects on the patient. In this piece, we examine the potential for patient harm by the Office of The National Coordinator for Health Information Technology's (ONC) Information Blocking Provision in the Cures Act Final Rule and the additional burden that health care providers, those who provide patient care and provide documentation in the electronic health record, will now face when documenting sensitive information.

On December 13, 2016, the 21st Century Cures Act (hereinafter referred to as the "Cures Act") was signed into law with the intent to "accelerate the discovery, development, and delivery of 21st century cures, and for other purposes" [1]. The Act defined electronic health record (EHR) interoperability, addressed health information technology certification requirements, and prohibited information blocking—the practice that prevents or interferes with those with permission to access electronic health information (EHI) [2]. As the federal entity coordinating efforts to implement health information technology and exchange EHI, ONC, a division within the US Department of Health and Human Services (HHS) [3], developed the Cures Act Final Rule to direct the implementation of the Cures Act legislation [4].

The ONC Cures Act Final Rule

The stated goal of the ONC Cures Act Final Rule is to empower patients to interact "with their health record in a modern health IT economy" [4]. ONC postulated that "putting patients in charge of their health record is a key piece of patient control in healthcare and patient control is at the center of HHS's work towards a value-based healthcare system." The Cures Act Final Rule also encourages innovations in health care technology and hopes to deliver the following:

- Transparency on cost and outcomes of care
- Competitive options in obtaining medical care
- Convenient access to medical records using smartphone apps
- Innovation and choice for patients, physicians, hospitals, payers, and employers through an app-based economy [4]

The Cures Act Final Rule promotes interoperability across EHR vendors through the adoption of data exchange standards and calls upon the health care information technology (IT) industry to adopt standardized application programming interfaces through specified Conditions of Certification. Additionally, ONC aims to increase patients' access to their EHI through minimizing measures that block patient access to information [5-7].

The Information Blocking Provision

The Information Blocking Provision of the Cures Act Final Rule mandates that patients have unfettered, free access to their EHI, and provides clear requirements for compliance by health care providers, institutions, health information exchanges, and EHR vendors [8].

The spirit of the Information Blocking Provision is similar to that of the OpenNotes movement, which over the past decade has been adopted by several health care institutions across the United States, Canada, and Sweden and provides patients with near immediate and full access to their EHI [9,10]. The Information Blocking Provision requires that patients have access to parts of their EHI defined by the United States Core Data for Interoperability (Figure 1) by April 5, 2021, with eventual expansion to all EHI by October 6, 2022 [11-13]. Of note, patients have had the right to access their medical record since the implementation of the Health Insurance Portability and Accountability Act (HIPAA). The Cures Act final rule does not increase the type of health information that patients and families can access, it only facilitates automatic release via patient portals and easier access electronically.

The Information Blocking Provision includes a means to report violations and enforcement options. ONC encourages anyone who experiences or observes information blocking by any health care provider, health IT developer, certified health IT, health information network, or information exchange to share their concerns through an information blocking portal on ONC's website [11]. Health IT developers, health information networks, and health information exchanges can be subject to civil monetary penalties of up to US $1,000,000 per violation [14]. Health care providers found to have committed information blocking will also be subjected to penalties that are to be determined [14].

Figure 1. Elements of the United States Core Data for Interoperability [11].

Exceptions to the Information Blocking Provision

The Information Blocking Provision defines eight exceptions that do not constitute information blocking [15]. The preventing harm exception and the privacy exception are applicable to the documenting health care provider.

The preventing harm exception stipulates that provided certain conditions are met, a health care provider can prevent the access to a patient's EHI if it is "reasonable and necessary to prevent harm to a patient or another person" [15]. Key conditions include that the health care provider must reasonably believe that preventing access to a patient's EHI will significantly reduce a risk of substantial harm, and that the interference is no broader than necessary. The patient has the right to request a review of an individualized determination of risk of harm [16].

According to ONC's guidance in the "Information Blocking Frequently Asked Questions," the "Preventing Harm" exception does not apply to situations where the patient is a minor and the health care provider wishes to restrict a parent or legal representative's access to the minor's EHI to avoid violating the minor's confidentiality and destroying the trust between the youth and the health care provider [12]. This lack of applicability in the case of adolescent confidentiality stands in tension with principles outlined by experts in the design and implementation of EHRs [17], endorsed by the American Academy of Pediatrics and Society of Adolescent Health And Medicine [18,19]. The concern over the implication of the Cures Act on adolescent confidentiality has been noted in the literature [20]. The premise underlying confidential care encourages adolescents to communicate with health care providers about sensitive topics such as sexual and reproductive health and substance abuse without the fear that their parents or guardians will have access to this information. Confidentiality on certain health care problems facilitates obtaining medical care that adolescents might forgo if information were shared with others. In the context of providing confidential care, the Cures Act's broad focus on patient EHI access may cause a trade-off with patient–provider relationships, trust, and nonphysical types of harm. The text of the Final Rule specifically states that the desire to maintain confidentiality and to protect patient–provider relationships is insufficient to prevent the release of sensitive information. In certain multiuser access cases, this may erode the patient's control over his/her information instead of increasing control. It is worth noting that HIPAA and the Cures act defer to the state laws that grant adolescents the ability to consent for certain conditions. While it is challenging to keep track of each state's individual and varied confidentiality laws that result in 56 (one for each state and territory) different legal requirements for users of pediatric EHRs, these laws do provide clear legal backing to protect adolescent confidentiality.

The other exception to the Cures Act Final Rule's patient access provision immediately relevant to health care providers is the privacy exception. Under this exception, interfering with access to EHI is deemed not to be information blocking when the intent is to protect the patient's privacy. These exceptions, listed in Textbox 1, are included by ONC to comply with HIPAA and other state privacy regulations and allow patients the opportunity to request information not be shared. Depending upon institutional practices, providers and patients may have limited awareness of this exception. Notably, the privacy exception states that providers cannot "improperly encourage or induce a patient's request to block information" [21]. This stipulation affects a provider's ability to guide patients for fear of being found in violation of the Information Blocking Provision and fined. Institutional policies and procedures will affect the implementation and management of this exception. Providers may not be aware of the procedure for patients to request their information not be shared during an encounter. Depending upon when the patient places the request (eg, before, during, or after an encounter), the institution may not be able to fulfill the request in a timely manner relative to the immediacy of information being released. Additionally, the privacy exception does not clearly describe if and how a patient can block individual pieces of data (data segmentation) instead of all data. The exception only describes how patients can request to block access and can request to regain access. The interpretation and implementation of this exception is left to the institution and provider and, given the complex nature of the exception, necessitates deference to informatics expertise and legal resources with experience in state and federal privacy laws and statutes for interpretation and use.

Textbox 1. Privacy exceptions to information blocking.

Exceptions:

- More stringent state or federal preconditions to exchange is not met
- Information technology developer is not covered by the Health Insurance Portability and Accountability Act Privacy Rule
- Inability to validate a requester's right to access
- The individual requests the information not to be shared

Limitations to the Information Blocking Provision: Multiuser or Proxy Access

Overview

The OpenNotes initiative has been shown to potentially increase patient activation, engagement, satisfaction, trust, and safety, and to improve the patient–physician relationship [22-25]. However, concern exists that the Information Blocking Provision will result in damaging breaches of confidentiality for cohorts of patients when parents or legal representatives are provided multiuser or proxy access to EHI [26,27]. In circumstances where EHI is made available within a web-based portal with multiuser or proxy access, the information could compromise the confidentiality of the patient, parent, or legal representatives and damage the relationship between the health care provider, patient, parent, or legal representative. The breach of confidentiality may occur bidirectionally as a caregiver may share information with a provider, which could be shared back with the patient. One recent study highlighted another area of concern: when guardians access an adolescent patient's portal account. The study revealed that the estimated prevalence of guardian access could be as high as 76% of adolescent accounts and also showed a relatively low rate of proxy account creation [28]. When adolescents had their own portal account, proxy accounts for adolescent patients were created in only 0.3%-10% of cases [28]. The reality that many portal accounts are used and managed by guardians must be taken into consideration for adolescent patients who, in the context of their care setting, may lack the autonomy to prevent their guardians from accessing their personal patient portals.

Pediatric and Adolescent Patients

Prior to the Information Blocking Provision, pediatric institutions participating in the OpenNotes movement had addressed the concern for violating confidentiality and damaging relationships by blocking all clinical notes from several clinics including adolescent, gynecology, psychiatry, substance abuse, and the child protection team [29]. Although the Cures Act Final Rule explicitly states that maintaining confidentiality and protecting relationships is not sufficient to prevent the release of sensitive information, the effects of releasing this information on patients, their parents or legal representatives, and the patient–provider relationship cannot be underestimated and are concerning to adolescent medicine providers and other health care providers who care for youth [30].

The Adolescent–Health Care Provider Relationship

There are many situations that do not fit the "Preventing Harm" exception where adolescent patients may be adversely affected when their private information is accessed by others (Table 1). For example, an adolescent female with concerns for a sexually transmitted infection (STI) such as *Neisseria gonorrhoeae* or *Chlamydia trachomatis* may avoid seeking medical care to avoid repercussions or stigma if she knew her parents would have access to this information. This untreated STI could progress to pelvic inflammatory disease, a more serious infection, which may require hospitalization and intravenous antibiotic administration and could affect future fertility. Prior research has shown that 59% of surveyed females younger than 18 years would "stop using all sexual healthcare services, delay testing or treatment for HIV or other STDs, or discontinue use of specific (but not all) sexual healthcare services if their parents were informed they were seeking prescribed contraceptives" [31]. The concern for loss of confidentiality extends to other sensitive topics including mental health, substance use, gender identity, and sexual orientation and may conflict with federal and state laws.

Table 1. Hypothetical scenarios for potential harm related to either lack of clarity of the laws, technical limitations regarding the release of electronic health information, or a combination of both.

At risk for harm	Third party receiving information	Domain	Mode of disclosure	Consequence
Patient	Parents or guardian	Mental health	Patient portal	Avoiding care or deterioration
Patient	Parents or guardian	Substance use	Patient portal	Avoiding care, overdose, or continued addiction
Patient	Parents or guardian	Sexual history or reproductive health	Patient portal	Avoiding care, complications from sexually transmitted infection, or infertility
Patient	Parents or guardian	Gender management or identity	Patient portal	Avoiding care, delay in gender reassignment, or psychological impact
Patient	Parents, guardian, or abuser	Violence or abuse (physical or sexual)	Patient portal	Avoiding care, continued abuse, complications, or death
Patient	Parents or guardian	Complex social situations	Patient portal	Avoiding care or delayed care
Patient	Parents or guardian	Neglect	Patient portal	Avoiding care, delayed care. or continued neglect
Child/Adolescent	Parents or guardian	Foster or custody issues	Patient portal	Avoiding care, delayed care, or family strife
Child/Adolescent	Parents or guardian	Misattributed paternity	Patient portal	Avoiding care, delayed care, or family strife
Parent/Care Giver / Legal Guardian	Patient, other parent, or other care giver	Perinatally acquired sexually transmitted infection	Patient portal	Avoiding care, delayed care, or family strife
Parent/Care Giver / Legal Guardian	Patient, other parent, or other care giver	Substance abuse	Patient portal	Avoiding care, delayed care, or family strife
Parent/Care Giver / Legal Guardian	Patient, other parent, or other care giver	Parent or caregiver's mental health	Patient portal	Avoiding care, delayed care, or family strife
Parent/Care Giver / Legal Guardian	Patient, other parent, or other care giver	Violence, abuse, or legal problems	Patient portal	Avoiding care, delayed care, or family strife
Parent/Care Giver / Legal Guardian	Patient, other parent, or other care giver	Misattributed paternity	Patient portal	Avoiding care, delayed care, or family strife
Parent/Care Giver / Legal Guardian	Patient, other parent, or other care giver	Stress associated with chronic care	Patient portal	Family strife or mistrust
Provider	Patient, other parent, or other care giver	Patient or family disagreement with provider	Patient portal	Delayed or missing documentation
Provider	Patient, other parent, or other care giver	Neglect or abuse	Patient portal	Lawsuit or unsafe environment for the provider

Inadvertent Disclosure of Medically Relevant Information Obtained From Proxies

There may be situations in which health care providers may document pertinent information that they receive from parents, relatives, and legal representatives, which may adversely affect the patient, parent, or legal representative or damage relationships when disclosed (Table 1). For example, parents may disclose their difficulty in coping with an adolescent's chronic illness to a provider who documents it in the adolescent's chart. This information could then be seen by the adolescent in their patient portal and affect the parent–child relationship. Another example is if a parent discloses information about a drug use during pregnancy or perinatally acquired STI to the pediatrician caring for the newborn. This information would be accessible through the infant's electronic record by other users, such as the other parent. In both situations, disclosing medically relevant information may be disincentivized for fear of its discovery by another person having access to the medical record.

Health Care Provider–Patient Relationship in Difficult Diagnostic Dilemmas

Disclosure of information can adversely affect health care provider–patient relationships, especially when there is disagreement between the health care provider and the parents or patient (Table 1). In functional disorders where the medical work up does not demonstrate an organic etiology for the complaint, the parents or patient may believe otherwise. For example, when the defined Rome's Criteria of Functional Abdominal Pain fits a patient's symptoms, parents or the patient may disagree with this diagnosis. In similar cases where the relationship among the patient, family, and health care provider is critical to helping the patient improve, documenting this information could further damage a fraught or tenuous relationship with the health care provider. Although providers should hold themselves to high standards for documenting information in the EHR, providers should not feel pressured to augment their documentation for fear of their medical opinion offending patients or proxies. This can be the case when child abuse is in a differential diagnosis, and documentation of this in the child's record may adversely affect the relationship between parent and health care provider if the parent feels unfairly accused or judged. There are situations where abuse is in a differential diagnosis, albeit with a very low index of suspicion, or where a provider may want to document that they have thought of but ruled out abuse or neglect. In these cases, it is unlikely the information will be compiled in "reasonable anticipation of, or for use in, a civil, criminal, or administrative action or proceeding" [32], which is clearly protected and eligible for legal blocking by HIPAA, and the remainder of the documented information may be of interest to the patient or proxy. The limited capabilities of data segmenting technology create an awkward or burdensome situation for providers.

Older Adult Patients

Overview

The complexity of care and the large number of comorbidities and treatments associated with aging make the electronic patient portal an attractive tool for persons with multiple health conditions. However, many older adults feel uncomfortable or ill-equipped using technology and rely on their caregivers for their health care–related tasks, necessitating proxy portal access. Less than 20% of US hospitals that allow caregiver proxy access also allow patients to filter or partially block the EHI passed on to their proxies [33]. Therefore, older adults are faced with many of the same challenges and potential harms that adolescents may experience.

The Older Adult Patient–Caregiver Relationship

Despite an increase in STIs among adults over the age of 65 years, many older adults are reluctant to share a recent sexual encounter [34] with their health care provider, knowing that this information will be available to caregivers. Syphilis, which is a treatable condition, can mimic dementia and neurocognitive disorders in late stages of the disease if the diagnosis is missed. Similarly, older patients may withhold health information regarding mental health (including depression) and elder abuse (physical, sexual, emotional, neglect, abandonment, financial, and self-neglect) from their health care providers for fear of their proxy finding out (Table 1). Again, the emphasis on broad access may paradoxically erode the patient's control over who can access their data. One potential solution may be allowing patients to block all information related to a specific topic from all users of the patient portal, including themselves, and unblock it again when they become sole users of the portal.

Inadvertent Disclosure of Medically Relevant Information Obtained From Caregivers

Caregivers may disclose emotional, physical, or mental exhaustion leading to burnout. If this information is documented and shared with the older adult patient, unintended consequences are feelings of guilt, overburdening, and depression (Table 1).

Of note, there is a clause in the HIPAA Privacy Rule that specifically addresses keeping third-party information confidential. According to this clause [35]:

> *Any information disclosed to the provider by another person who is not a healthcare provider that was given under a promise of confidentiality (such as that shared by a concerned family member), may be withheld from the patient if the disclosure would be reasonably likely to reveal the source of the information.*

Since the Cures Act defers to the HIPAA, this clause should be applicable under the Cures Act; however, this is likely not well-known or understood across institutions.

In some cultures, it is common practice for caregivers to withhold negative information such as the diagnosis of a cancer or a terminal illness. Caregivers are also frequently surrogate decision-makers and may for many reasons ask a health care provider to withhold a diagnosis [36]. Although we consider

disclosure to the patient as the ethically preferable choice, we acknowledge that the inability to block information may not align with the cultural norms of certain patient groups [37]. The patient may also desire information blocking, such as when an older patient is afraid that disclosure of a new diagnosis of cancer or recurrence may burden their caregiver or lead to caregiver burnout.

Health Care Provider–Patient Relationship in Difficult Diagnostic Dilemmas

Maintaining a good relationship with patients is critical for health care providers taking care of older adults, as dynamic shifts in health often require changing or transitioning goals of care. Even neutral personal descriptors such as "elderly" in a note can make patients feel judged and perceived themes of disrespect, errors, and surprises can lead to straining of a patient–provider relationship [38]. For example, the term palliative is often misinterpreted for end-of-life care when in fact the goal is symptom and quality of life improvement for any serious illness (even curative ones), irrespective of prognosis. Further, the National Center for Educational Statistics reports that 21% of adults in the United States (~43 million) are illiterate or functionally illiterate [39]. Misinterpreting documentation may prevent older adults from seeking care to relieve symptoms and stress and align treatment options with their goals. One unintended, but positive, consequence of the information blocking rules might be that it encourages providers to be more vigilant in their documentation to achieve language that is both medically accurate and affirming of the patient's dignity.

Where Information Blocking Went Too Far

Although the potential adverse outcomes previously discussed do not meet the Cures Act Final Rule definition of harm, in some cases, releasing this information may violate the foundational principles of a trusting provider–patient relationship.

Information Blocking in the Multiuser EHR

While the Cures Act final has made it easier to access information electronically, this increase in access is not accompanied with the requisite technical advances to block access to data in appropriate circumstances. In the situations when information blocking can be legally used, strategies are limited in number and capability, especially in the context of a multiuser or proxy access. Information blocking is technically and logistically challenging, and the burden is placed upon the documenting health care providers to determine what EHI is and is not appropriate to block and to whom. For some health care providers, such as those practicing in adolescent medicine, family medicine, general pediatrics, pediatric subspecialties, internal medicine, and geriatrics, navigating information blocking may be a routine experience depending on patient needs.

At the institutional level, the hospital system can deactivate proxy access; however, this may be burdensome and can be delayed depending upon institutional implementation (eg, a health care provider clicking a button in the EHR versus contacting health information management and placing a ticket for a request to be completed). The ONC exceptions emphasize that information blocking should be no broader than necessary. It will be an infrequent occurrence that a patient or proxy is completely blocked from accessing all EHI and more common that the blocking will occur on a data-element-by-data-element (clinical documentation, laboratory tests, imaging, etc) basis. This may create a substantial burden for the health care institutions and be prone to user errors. Additionally, the absence of information may be conspicuous when a patient or proxy who usually receives information does not. There is an evolving standard called "Data Segmentation for Privacy" (DS4P) where a health care provider could mark portions of a note to be blocked from access; however, the adoption of this standard is minimal [40,41].

Beyond institutional policies and EHR technical capabilities, the health care provider can adopt new documentation workflows when information blocking is legally acceptable. For example, the health care provider could create one note that is appropriate to share with all users and another that includes the information which is then blocked (ie, shadow charting); however, this solution is time-consuming and burdensome and unlikely to be adopted as clinical documentation has already been shown to be a significant contributor to burnout among health care providers [42-46]. Further, duplicate documentation would also be error-prone, jeopardizing safety and creating additional work and confusion for other health care providers on the treatment team relying on documentation to support patient care. Health care providers may choose to avoid caring for patients who are more prone to these complicated situations.

Where information blocking is not acceptable, the health care provider, not wanting to damage a relationship or breach confidentiality, may decide to stop documenting certain information. This is a potentially dangerous practice that could affect medical care, reduce accurate billing, and result in incomplete communication about the patient's medical history with other health care providers.

Conclusions and Recommendations

The Cures Act Final Rule is undoubtedly necessary to facilitate significant improvements in patient care and innovation; however, in some cases of a multiuser or proxy access situation, the Information Blocking Provision conflicts with the standard that health care providers hold themselves to in the United States. Additionally, applying these exceptions to the Information Blocking Provision in legally acceptable cases will be burdensome and could lead to increased burnout among health care providers. Paradoxically, providing patients more control over their data may actually jeopardize their control and privacy in some scenarios. Although breaching confidentiality and damaging the patient–provider relationship will not necessarily cause substantial harm as defined by the text of the Final Rule, it may cause unnecessary anguish, limit the quality of care, or cause a patient to forgo or delay care, and lead to increased morbidity. Additionally, the privacy exception may be underutilized as it necessitates patients and providers be

educated on the application of this rule and an institution's policies and procedures. In light of these concerns, we recommend that ONC provide more detailed guidance both on their website and targeted outreach to health care providers caring for patients in the adolescent health setting and other multiuser or proxy access situations. As clause 171.202 (b) of the Cures Act allows institutions to develop policies around information blocking, we encourage ONC to develop and publish sample policies that institutions may use or modify. Such guidance should outline the exact processes by which a patient can opt out of their health data being shared with a proxy user using the privacy exception and detail how providers can best guide patients through decision-making without the fear of being in violation of the information blocking rules. Where data segmentation for privacy is not feasible, we recommend that ONC considers carving out an option for providers to return to traditional sharing options to prevent breaches of privacy. We also urge ONC to interpret the privacy exception broadly and not penalize hospitals or providers for information blocking when proxy access is the reason for the information blocking. We suggest that ONC and researchers carefully monitor charting habits in these multiuser or proxy access situations by studying how often patients use the privacy exception compared with single-user EHR access scenarios, how much time is spent documenting for these scenarios, and how much shadow-charting is taking place. We also suggest researchers carefully monitor the effect of information blocking on patient, provider, and proxy relationships. Additionally, we recommend limited penalties on health care providers in multiuser or proxy access situations during the implementation process of the Cures Act Final Rule until technological capabilities advance to better segment notes and block them from certain users.

Conflicts of Interest

ML has been compensated for presentations for the Texas Pediatric Society, for consulting on modules to educate providers for Texas Health Steps, for time working with the Texas Essential Knowledge and Skills Proclamation 2022 Review Adoption Review Panel, and as a consultant for the Texas Child Psychiatry Access Network. She was also awarded support funds through the Technology and Adolescent Mental Well Being (TAM) youth Advisory Board (funding to start in January 2022), received a grant from Texas Pediatric Society Foundation, and is a Nexplanon trainer for Organon. CUL owns shares in Celanese and Markel. The remaining authors have no conflicts to declare.

Abstract

Big data is poised to revolutionize health care, and performance dashboards can be an important tool to manage big data innovations. Dashboards show the progress being made and provide critical management information about effectiveness and efficiency. However, performance dashboards are more than just a clear and straightforward representation of performance in the health care context. Instead, the development and maintenance of informative dashboards can be more productively viewed as an interactive and iterative process involving all stakeholders. We refer to this process as *dashboarding* and reflect on our learnings within a large European Union–funded project. Within this project, multiple big data applications in health care are being developed, piloted, and scaled up. In this paper, we discuss the ways in which we cope with the inherent sensitivities and tensions surrounding dashboarding in such a dynamic environment.

dashboarding; big data; balanced scorecard; performance measurement; key performance indicators; digital health; dashboards; knowledge translation; health information; stakeholders; health care

Introduction

Big data innovations in health care are on the rise, with benefits that include providing clinical intelligence about a patient's risk of future adverse health events [1], empowering patients through big data–driven eHealth applications [2], increasing interest in clinical prediction tools [3], and reducing costs by leveraging big data to detect fraud, abuse, waste, and errors in health insurance claims [4]. Recently, China has used big data technology in its attempts to prevent and control the spread of COVID-19 [5]. All in all, big data innovations in health care promise to address the rising demand for high-quality health care services and to reduce the accompanying costs of care. This makes big data appealing for governments and funding agencies, who are increasingly investing in large-scale, interdisciplinary projects and consortia that seek to develop big data innovations, implement them in the health care field, and ideally demonstrate their desired impact. Such projects usually involve a multitude of stakeholders who, in addition to the project goal, have their own objectives, such as creating social or economic impact, publishing research, or commercializing the innovation. These large investments and diverse goals and objectives call for close monitoring of the overall progress and performance of projects. Such performance monitoring is frequently done utilizing dashboards containing key performance indicators (KPIs).

Dashboards provide a visual overview of the information needed for performance management, and by doing so, facilitate decision-making and project management. In the health care field, the use of dashboards is manifold. Types of dashboard include unit-specific nursing performance dashboards [6], hospital-wide or disease-specific quality and safety diagnostics dashboards [7,8], and population-level maternal and newborn dashboards [9]. Management literature has emphasized the use

of performance dashboards to provide an overview of relevant KPIs and to enable performance management in hospitals [7,10,11]. As such, dashboards are often preferred as managerial instruments to gain insights about progress and performance.

Despite their appeal and aura of rationality, performance dashboards are not simply a clear and straightforward representation of health care performance. Indeed, this point has gained traction within recent accounting literature [12]. Building on the insights from accounting literature, critical management studies, and science and technology studies, we argue that one cannot simply design a dashboard to capture the productivity or efficiency of something as inherently complex and multifaceted as the performance of big data innovations in health care [12]. At the same time, dashboards continue to have enormous appeal, both for funders of research and implementation projects (who perceive them as providing tangible outcomes to account for investments made) and for health care managers (who view them as instruments that can provide valuable information). Therefore, such tools cannot simply be dismissed because of the inherent challenges mentioned above.

In this paper, we introduce our perspective on the development of systems for monitoring big data innovation projects in health care through performance dashboards and discuss caveats concerning these systems. Our perspective focuses on the social dimension of this interactive process, that is, we do not delve into the technical dimensions, such as techniques for data analytics and visualization [13]. Importantly, we view the performance dashboards as the *means* to monitor big data innovation projects. In our paper, they are not the *results* of big data innovations.

We argue that the development of such dashboards does not match the prevalent rationalist narrative usually assumed. Far from being a series of rational decisions, this development can be better understood as a process of collective sensemaking. While the idea of sensemaking has strong roots in organizational psychology, in which the notion is used to study the microfoundations of organizing, we use the notion here to point toward a more general focus on interpretive forms of research that address how meanings are negotiated and constructed [14]. Nevertheless, although we do not build on the full theoretical framework associated with sensemaking, our use also shares affinities with organizational research that describes sensemaking as being "not about truth and getting it right," but instead "about continued redrafting of an emerging story so that it becomes more comprehensive, incorporates more of the observed data, and is more resilient in the face of criticism" [15]. Therefore, we suggest a more pragmatic approach toward the development and use of performance dashboards. In this process, for which we propose the term *dashboarding*, many decisions need to be made jointly with the most important stakeholders. Anything but a linear sequence of decisions, this is a necessarily iterative, recursive process of moving back and forth to find out which indicators are feasible, acceptable, measurable, and informative.

Our viewpoint is based on both our familiarity with the literature regarding the goals, drivers, and problematic aspects of using dashboards as instruments for performance measurement, and on our experiences as researchers and dashboard developers in a large-scale, 3-year European project aimed at developing big data applications in health care, titled "Big Data for Medical Analytics," shortened to "BigMedilytics" (this project was approved by the ethics board of the Erasmus Medical Centre [MEC-2018-056] and the ethics review board of Erasmus University [EA18-01]). Drawing on our experiences in the development, tailoring, and further modification of performance dashboards for 12 pilot projects to develop big data innovations in health care in 8 European countries, our aim is to increase awareness of tensions and to develop sensitivities among academics, clinicians, and practitioners involved in performance measurement of health care innovations, especially those involving big data. We draw on the numerous discussions we have had with the research team and pilot partners, our experiences in organizing various pilot project–specific workshops discussing dashboard designs at various stages, and the many emails, phone calls, and various other interactions we have had with pilot project teams over the last years.

The BigMedilytics Project

Our empirical setting is the 3-year BigMedilytics project, funded by the European Union. This project aims to "enhance patient outcomes and increase productivity in the health sector by applying big data technologies to complex datasets while ensuring security and privacy of personal data" [16]. The entire consortium consists of 35 different entities, ranging from health care providers, technology companies, and insurers to research institutes and universities. At the core of the consortium are 12 pilot projects that develop big data innovations in health care in 8 European countries, divided into 3 areas: population health and chronic disease management, oncology, and health care services industrialization, as described in the underlying protocol paper [13]. The big data technologies include systems to derive predictive models, clinical decision support systems, and real-time asset location systems.

The Inherent Complexities of Dashboarding

While performance dashboards can provide useful insights into the effectiveness and quality improvement potential of big data innovations, rational, straightforward design and implementation of these dashboards is problematic for several reasons. Building on literature in accounting, critical management studies and science and technology studies, we identify 4 important insights that deeply problematize the idea that dashboards simply "capture" performance. First, performance is an inherently debated and complex concept [17,18]. At the core of health care systems are health care organizations that seek to fulfill multiple, sometimes even conflicting aims. As such, tensions are likely to arise between what counts as "performance" in different contexts. This makes performance monitoring and performance management inherently complex. Second, there is always a trade-off between validity and feasibility. The search for exhaustive validation of a dashboard comes at the cost of practical feasibility; when measurement aims to provide a flawless map of the organization's landscape, this often hinders practical utility and enhances strategic behavior [19,20]. Third,

there is some tension between using performance dashboards internally for learning purposes and using dashboards externally as bases for monitoring and accountability [21]. In order to learn from performance dashboards, it is vital to stimulate discussions based on the performance scores. Using performance measurement as an accountability tool is an "external" use of the dashboard, in which those who monitor the project use the dashboard to steer and direct. Using performance measurement as an accountability and control tool is likely to corrode and corrupt the performance indicators, undermining the conditions required for quality improvement [21]. Fourth, performance monitoring is never simply a representation of reality, but also shapes and structures the reality to be acted upon in a process of coconstitution [22,23]. Dashboards never only represent performance or particular aspects of performance; they are also social facts that generate actions and reactions, for example, by defining managerial priorities and by reconfiguring work routines and relationships between actors [24,25]. They are thus "performative" [24,25] in the sense that they do not only represent aspects of organizational performance but also help shape and define the very aspects of performance that come to matter—an aspect that is also recognized within the accounting literature [26].

Three Persistent Tensions

Based on our experiences in the BigMedilytics project, we will describe 3 persistent tensions that we and other actors in the consortium experienced while working toward performance dashboards that met the dual requirements of being useful to pilot partners while allowing for some form of assessment regarding goals and achievements. After this description, we will outline the main implications, reiterate our suggestion that a more pragmatic perspective on dashboarding should be developed, and discuss the implications of this perspective for academics, clinicians, and practitioners involved in the performance measurement of health care innovations.

Tension 1: Navigating Between Divergent Stakeholder Views and Expectations

The consortium that we were a part of included the developers of a range of big data innovation projects, which involved, like many similar projects, various stakeholder groups from academia, government, and industry. At the core of the consortium were 12 big data pilot projects to develop and implement big data innovations in 8 European countries: Austria, France, Germany, Ireland, the Netherlands, Spain, Sweden, and the United Kingdom. These pilot projects were divided into 3 themes: population health and chronic disease management (n=5), oncology (n=3), and health care services industrialization (n=4). Each of the 12 pilot project teams included several members, introducing a multitude of experiences and expertise.

Consortia necessarily bring together a range of stakeholders, who each have their own specific ideas about the goals of the project. Many innovation projects, not just those organized as consortia, involve internal or external funding. In order to apply for funding, stakeholders need to align goals with each other. An inherent feature of the application and alignment process is time constraint, which hampers the ability to acquire all the information needed in order to make a fully informed decision. Consequently, one must settle on a goal that is deemed acceptable for all groups given the information available at the time. This necessitates broadly defined goals that require further specification over time. In our case, the BigMedilytics consortium aligned on the broad and ambitious aim to improve health care in Europe through big data and "demonstrate an increase in healthcare productivity between 20% and 63%" [27].

But as time unfolded, it became evident that people attributed different meanings to the term *productivity*, which affected the way they conceptualized and operationalized it. One prominent definition of productivity considers it to be the ratio of input to output and to thereby express how efficiently resources are used [28,29]. Defining the overall project goal in such strong economic and engineering language, however, did not match the perception of how individual pilot projects could contribute to achieving productivity gains by deploying big data. With the big data innovations organized in 12 very different pilot projects, various idiosyncratic features needed to somehow be reflected in how the productivity of the projects was measured. A one-size-fits-all approach was considered inappropriate and a certain degree of divergence was deemed inevitable. One might raise the argument that this divergence was a consequence of the heterogeneity of the pilot projects, and consider that homogeneous pilot projects would not face this tension. While this argument has some appeal, we know from the literature that even in similar settings, different opinions prevail on what constitutes productivity [30], performance [31], and quality of care [32]. Consequently, some divergence is inevitable if one is to maintain stakeholders' support and engagement. Stakeholders need to see their pilot project–specific contribution to the overall goal adequately reflected.

This divergence needs to be managed. The more pilot project–specific idiosyncrasies are considered, the better pilot project–specific developments can be monitored and the more precisely we can formulate a pilot project–specific conclusion. By the same token, the more pilot project–specific idiosyncrasies are considered, and the more pilot projects diverge, the more challenging it becomes to converge again and draw conclusions across pilot projects. This indicates a tension: if divergence amongst pilot projects is too high, goal congruence might be compromised. On the other hand, not allowing any divergence would amount to the one-size-fits-all approach that was already considered inappropriate. Managing this tension thus calls for a compromise that allows for some divergence but at the same time enables alignment between stakeholders and convergence toward the overall project goal.

Striving for convergence but simultaneously allowing for necessary divergence resulted in the following approach: we applied a broader angle and considered performance along multiple dimensions. While the multi-dimensionality of the performance framework thus increased the likelihood that stakeholders considered the framework acceptable, it initiated a discussion on what type of performance dimension adequately captured the objectives and intentions of the big data innovations. This called for a compromise: we decided to align on dimensions broad enough that they applied to multiple pilot projects (in step 1), but also recognized that we needed to give pilot projects the possibility to define KPIs within these

dimensions that adequately captured their unique qualities (in step 2). We used a balanced scorecard (BSC) [33] to monitor multiple performance dimensions and tailored its design by determining pilot project–specific KPIs. The BSC [33,34] is a widely applied framework, primarily in for-profit business organizations, and consists of a set of KPIs that gives top managers a fast but comprehensive view of the organization. The set of KPIs includes financial performance measures that show the results of actions already taken. The BSC complements the financial measures with operational, process, and quality measures of various performance dimensions that are the drivers of future financial performance.

Although popularized in for-profit business organizations, the application and study of BSCs in the health care industry is not new. In the health care industry, most prominent descriptions of BSCs refer to monitoring quality aspects of performance. For example, Chong et al [35] found that "measuring the quality of a hospital is an important but exceedingly difficult task. Different methods of capturing quality have been devised, including composite scores of compliance with various quality indicators to the adoption of BSC techniques from the business world." Also, Fernando et al [36] support this idea by claiming that scorecards are used by institutions "for the purposes of monitoring clinical performance and driving quality improvement."

Tension 2: Navigating Between Timely and Meaningful Data Collection

For each of the performance dimensions of the BSC (ie, patient satisfaction, patient outcomes, process outcomes, and financial outcomes), we determined pilot project–specific KPIs in close collaboration with the pilot project stakeholders via an iterative procedure. For example, pilot projects that related to population health, chronic disease, and oncology often included long-term financial measures (eg, the projected cost of care over 10 years) next to short-term measures, such as the average cost per patient. In most pilot projects, patients were expected to be directly impacted by the big data innovation. In these cases, patient satisfaction surveys and patient-reported measures were relevant to measure the dimension "patient satisfaction." Mortality was a typical measure for the dimension "patient outcomes." In contrast, the pilot projects related to industrialization did not measure KPIs for the "patient satisfaction" dimension, as patients were not directly impacted by the big data innovations, but instead focused on process outcomes (such as completion time for diagnoses).

Through this collaboration we aimed to ensure the relevance of the selected KPIs to the pilot projects, as well as increase commitment of the pilot project teams to the dashboard. This commitment was key as the pilot project teams were supposed to report on these KPIs every 6 months. The suggestion from the project consortium was to rely on standardized lists of KPIs. These KPIs were often already available in the reporting and management systems used in the pilot projects or the organizational bodies (eg, hospitals) to which the pilot projects belonged. Such availability would make reliable data collection very efficient. However, efficient data collection of readily available KPIs is not the same thing as valid and meaningful data collection of KPIs that capture the actual performance and progress of pilot projects.

Therefore, we engaged in a discussion with the pilot project teams about the strategic aims of the pilot projects to make an initial assessment of priorities and feasibility. First, we organized a series of workshops where we presented the 4 dimensions to pilot project stakeholders and let the stakeholders openly brainstorm potential KPIs for each of these dimensions. Then, we compared the KPIs across pilot projects to identify similarities and differences and inquired whether KPIs that were suggested in other pilot projects might also be relevant for the pilot project in question. As a final step in the development of the KPI dashboard, the researchers and the pilot project stakeholders agreed on a set of pilot project–specific KPIs that were deemed relevant to the pilot project in question and for which reliable data were expected to be periodically collected.

After a baseline measurement of the KPIs, which provided a crucial anchor point for benchmarking the pilot project's subsequent performance, the KPIs were supposed to be updated periodically using the same operating procedures and definitions. Receiving periodic updates has, however, frequently been challenging. Reasons for this were manifold: updating the KPIs was not deemed meaningful at that point in time; pilot projects were partially dependent on other entities to deliver the data, which prevented timely data submission; databases were not updated as frequently as intended; information technology systems were changing over time, which required modifying the operating procedures to gather the KPI data; and some KPIs turned out to be unreliable and needed to be revised whereas other KPIs—despite all good intentions—simply could not yet be measured due to a lack of data. Consequently, the set of KPIs changed over time, altering the design of the dashboard and reducing the reliability of the measurement over time.

In contrast to the idea that KPIs can capture performance and progress over time, this project made clear that a set of KPIs—even if tailored to a specific context—cannot be considered to be static, but must rather be thought of as dynamic, evolving, and changing. This holds true specifically for big data innovations in which more and more learnings are generated as time passes and new data become available. The trade-off between validity, reliability, and feasibility becomes apparent: KPIs that have initially been considered a valid indicator of performance might be more reliable due to the amount of data available, but they may also no longer be considered to be valid because they fail to capture state-of-the-art performance. Again, this tension points toward the need to understand KPI dashboards in process terms: as a dynamic process of "dashboarding" that requires adaptations over time in order to remain informative given the state of the art.

Tension 3: Navigating Between Different Dashboarding Needs and Purposes

Through collaboration with each individual pilot project team, we wanted to develop dashboards that would do justice to the idiosyncratic nature of the pilot projects and would be loaded with relevant and timely datapoints for an informative performance analysis. Performance analyses can be informative for the members of each pilot project team, enabling them to

learn and improve, and for those monitoring progress across pilot projects. Serving both these needs, however, turned out to be difficult. Monitoring progress across pilot projects required comparability that could only be achieved by choosing a set of KPIs that was a compromise; they did not fit individual projects perfectly, making them a suboptimal choice. Learning and improving within a pilot project, however, requires selecting KPIs that are as closely related to the innovation as possible. Since big data innovations themselves do not improve health care directly, but rather contribute to improvements by changing the information used in decision-making, the way the innovation is embedded needs to be reflected in the KPIs. For example, the BigMedilytics "asset management" pilot project deployed a track-and-trace interface that professional caregivers used to locate medical equipment. As such, the interface was directly involved in a caregiver's search process and could thereby directly influence the health care process. There were also pilot projects, however, where such direct embedding was not the case. The purpose of the "stroke workflow" pilot project was to use big data to identify bottlenecks in the workflow. As such, big data was used as a diagnostic tool to identify problematic areas in the health care process. This identification step revealed changes in the health care process that needed to be made, yet the big data innovation itself was not directly involved in health care delivery. Similar arguments pertain to other BigMedilytics pilot projects, showing that the way in which the innovation is used and how it affects the health care process differ in specific situations.

With pilot project members closely involved in the KPI selection process, one would expect the dashboards to be used for learning and improvement purposes. However, we did not observe strong indications of this. In our experience over the years, the dashboards were more often perceived as a managerial necessity for which KPI data needed to be provided for monitoring purposes. Ironically, we also did not observe strong indications of dashboards being used to oversee progress across pilot projects, which seems to indicate that the overall purpose of the dashboard remained unclear and that its potential to facilitate learning and monitor progress was insufficiently realized.

Implications

Based on our experience with developing performance dashboards for 12 big data innovation pilots, we have argued for the need to develop a more pragmatic, process-based perspective on performance dashboards. We describe this as the notion of "dashboarding." This perspective recognizes that despite its rationalistic aura, developing, tailoring, and modifying performance dashboards is in essence an unpredictable, messy, and iterative process that (1) involves a wide range of stakeholders with often diverging goals and expectations, (2) calls for situation-specific assessments of the balance between efficient and meaningful data collection, and (3) comes with struggles with hard-to-reconcile demands, such as the need to monitor achievements across pilot projects to account for investments made versus the need to provide tailored insights to help specific pilot project teams evaluate and improve their performance.

What are the implications of this perspective for academics, clinicians, and practitioners involved in the performance measurement of health care innovations? The first implication is that those involved in the process of dashboarding need to develop the political sensitivity to acknowledge and manage differences in interests and objectives among various stakeholders that are directly involved in and indirectly affected by the dashboard. Importantly, this goes beyond the idea of cocreation with stakeholders. While incorporating stakeholders early on is an important condition for generating support, it is by no means a panacea [37]. With an increasing number of stakeholders involved, the diversity in interests and expectations is likely to increase as well. Obviously, this may cause tensions if interests and expectations are diverging or even conflicting. In line with related literature [7,37], we therefore suggest involving stakeholders in co-designing dashboards, but we also stress that this requires careful expectation management, sensitivity toward different needs and requirements, and persistence in navigating between different perspectives and interests. Collaborative design brings together specialists and generalists from various backgrounds who share knowledge of the design process as well as the design content in order to create shared understanding of both aspects [38]. Such principles of collaborative design can be combined with principles of participatory design, which refers to the participation of prospective users, who become true participants and not just informants in the design process [39]. We involved future dashboard users from different disciplines (including data scientists and medical professionals) to some extent but would recommend more extensive and more explicit use of collaborative and participatory design principles in the dashboarding process.

The second implication of the pragmatic perspective we propose relates to the iterative nature of dashboarding. Developing dashboards iteratively through multiple stages of refinement does not align well with the logic of "projectification" that often underlies large-scale programs like the BigMedilytics program [40,41]. The notion of projectification refers to a mode of science governance that sets the concept of the "project" as its basic organizing principle [42]. As such, it highlights not only the ubiquity of the project format, but also points to underlying instrumental reasoning and a rationalistic attitude toward predictability (eg, an emphasis on activities leading to "milestones" and "deliverables") that is often considered to be in tension with other values of research and innovations (such as academic freedom and creativity) [40,43]. This attitude is at odds with the dynamic and continuously evolving environment organizations find themselves in. Far from a controlled, experimental setting, pilot projects exist among a swirl of other projects, initiatives, developments, and changes. In the BigMedilytics program, for instance, all pilot projects were confronted with two major changes: the introduction of the General Data Protection Regulation and the COVID-19 pandemic. The main implication of this is that researchers and dashboard developers would benefit from building in more leeway for interim changes. Thinking through the implications of this to the fullest extent would also require funders and other policy makers to think about innovative ways of funding

research and technology development that do not take the logic of projectification as a pre-eminent reality.

The third implication relates to the need for flexibility in dashboarding. Dashboards are used for different purposes that range from providing external accountability and internal benchmarking to enabling improvement initiatives [7]. Dashboards are also frequently considered to be informational tools that stimulate discussion and critical reflection [6]. As such, dashboards need to be flexible enough to cater to multiple purposes and different stakeholder needs [7]. This flexibility requires a specific view on progress monitoring via performance dashboards. Instead of striving for comparability across dashboards in a volatile environment (which is particularly relevant for big data as well as health care), progress monitoring can also be achieved with a focus on continuous improvement. If each project team develops its own set of KPIs (with some steering, as described above), a dashboard will emerge that will be deemed informative by the project team. Project teams should also regularly reflect on whether the set of KPIs is still informative and whether adaptations are necessary. The reasons for incorporating a new KPI or dropping an old one reveal important insights about the progress that can even go beyond the indications derived from comparing KPI scores across project teams or time.

Future research might investigate which specific approaches, tools, techniques, programming languages, and design environments are most effective for such a collaborative, iterative and flexible dashboarding process. Successful cases of dashboard development, including details on the technologies used, are available in the literature [7,44-46], but there remains a need for a systematic comparison of dashboarding approaches.

Conclusion

Dashboarding is a dynamic process that features various tensions. Instead of neglecting these tensions, we plead for reflection upon them and navigation through them. Our recommendations therefore do not come in the form of a magic bullet and do not offer clear-cut solutions but are rather a description of 3 sensitivities that performance dashboard designers should develop to handle the tensions involved in the process of dashboarding. Capitalizing on these sensitivities will lead to dashboarding that is iterative, integrative, and informative.

Abstract

The COVID-19 pandemic accelerated the uptake of digital health worldwide and highlighted many benefits of these innovations. However, it also stressed the magnitude of inequalities regarding accessing digital health. Using a scoping review, this article explores the potential benefits of digital technologies for the global population, with particular reference to people living with disabilities, using the autism community as a case study. We ultimately explore policies in Sweden, Australia, Canada, Estonia, the United Kingdom, and the United States to learn how policies can lay an inclusive foundation for digital health systems. We conclude that digital health ecosystems should be designed with health equity at the forefront to avoid deepening existing health inequalities. We call for a more sophisticated understanding of digital health literacy to better assess the readiness to adopt digital health innovations. Finally, people living with disabilities should be positioned at the center of digital health policy and innovations to ensure they are not left behind.

The Digital Paradox as a Modern Wicked Problem

As foundational parts of society continue to digitalize [1], the risk of existing inequalities worsening cannot be overstated. Digital divides constitute a wicked challenge in European countries [2], especially considering how digital literacy and access to digital infrastructure differ across age, sex, socioeconomic and educational strata, place of residence, and disability status [2,3]. The COVID-19 pandemic has highlighted the benefit of advances in digital health technologies [4], which could be deployed at a large scale to reach population groups that are otherwise difficult to reach. This reflects the paradox of digital health that we are currently facing: the potential that digital health innovations hold can be transformational for delivering care to underserved population groups, but these groups are most likely to be excluded from the digital world through their sociodemographic characteristics [5].

One example of such groups is the autism community. Recent research suggests that autistic individuals have comparatively shorter life spans [6,7] and are more likely to experience nearly any chronic physical and mental health condition [8-10]. Despite greater health care utilization and expenditure [10-12], autistic individuals report lower quality health care, worse health care access, and poorer patient-provider communication [11,13-17]. In qualitative interviews, autistic adults expressed difficulties evaluating or describing their health, sensory sensitivities, executive function, body awareness, slow processing speed, stigmatization, and systemic barriers [13-16]. As a result, the autism community can be considered highly vulnerable to digital exclusion, not only because of the aforementioned challenges but also due to the poorer educational and employment outcomes associated with autism [18].

The European Commission recognizes in the Union of Equality: Strategy for the Rights of Persons with Disabilities 2021-2030 that accelerated digital transformation offers opportunities to remotely deliver high-quality care to people living with disabilities that is tailored to their needs [19]. However, the precise actions needed to develop an inclusive digital health system that benefits people living with disabilities instead of excluding them, as well as best practices, are undefined.

It is important to note that this article takes a holistic approach to digital health. In other words, digital health as a concept can refer to a technology, user experience, service, product, process, infrastructure of its own, or part of the ecological system of health services [20-24]. It is important to be mindful of all these potential framings of digital health to encourage a systems thinking approach to how digital health may be incorporated in the status quo of health care. While there is great potential in the deployment of digital health services, the digital paradox makes it painfully clear that the utility of digital health is proportional to how well it meets the health care needs of the person interacting with it.

In this article, we explore the ways in which digitalization affects the health sector, specifically looking at the distribution of information, social determinants of health, and access to digital infrastructure. We then highlight how these digital developments may affect people living with disabilities, using the autism community as a case study. Afterward, we showcase existing policy perspectives from Sweden, Australia, Canada, Estonia, the United Kingdom, the United States, Singapore, Japan, and South Korea that either facilitate or obstruct the creation of digital health systems accessible for people living with disabilities. Finally, we identify principles of digital health that can underpin and facilitate the safe and inclusive development of a digital health ecosystem. We believe this article may be of particular interest to policy makers, health practitioners, patient groups, health funders, social workers, and other stakeholders in the field of health care. Details on the methodology and the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) flowchart can be found in Multimedia Appendix 1.

Impact of Digital Technologies on the Distribution of Information

While the relationship between digital technologies and health is nonlinear and multifaceted, digital technologies can facilitate the distribution and dissemination of public health information and action (eg, widespread broadcasts by the World Health Organization throughout the COVID-19 pandemic). Digital health can also enhance clinical and laboratory work by supporting administrative tasks, leaving more time for health care workers to spend with their patients [1,23]. This, however, requires a careful balance between increasing efficiencies through digital means and reducing the cognitive burden of frontline staff (explored later in this paper). Telemedicine can improve access to life-saving medical care. Soon, digital technology will augment clinical diagnostic processes, improve data collection and analysis, and provide targeted support in the form of precision medicine and precision public health [1,22,23,25].

On the other hand, health disinformation and misinformation can easily and rapidly be spread in a digital society through social media, contributing to the continued existence and strengthening of factually incorrect health beliefs [26]. A recent notable example of health misinformation has been the tremendous decline in vaccine confidence [27]. Machingaidze and Wiysonge [27] explain how digital technologies can be excellent tools for self-education, a key component of vaccination decision-making. However, they also present various challenges of using digital technologies at scale, many of which are present in high-income countries, including misinformation, incomplete information, and conflicting and complicated scientific information that may be difficult to understand [27].

Digital Technologies and Social Determinants of Health

Digital technology can also further entrench established social determinants of health [24]. For example, wearable technologies hold great potential to equip the general public with the ability to proactively monitor and manage their health care, fitness, and aging [28,29], although this comes at a financial cost.

Presently, this expense is borne by consumers with the ability to pay. This creates inequities in access to personalized health data, placing it at the fingertips of wealthier individuals and further widening health divides between socioeconomic groups. As such, when advocating for the widespread uptake of digital health among vulnerable groups, we must avoid constructing or fueling the paradigm of digital health as a pinnacle of health consumerism, as this would only expand the existing digital paradox [21]. A recent study in the United Kingdom highlights that access to free or affordable health care and individual behaviors and choices dominate the public perception of what impacts an individual's health and that 24% of the UK population believes health is entirely the responsibility of the individual [30]. As a result, the belief that healthier choices are available to more resourceful population groups is commonly propagated, disregarding the potential and complex effects of social determinants of health.

Furthermore, economies of scale achieved through increased use will drive down the price of wearable technology [31]. A case study in rural India demonstrated the benefits of wearables for chronically underserved rural and remote populations, showing improved health outcomes, including decreased readmission and mortality rates, by monitoring health data and improving preventive care [32]. Furthermore, wearables reduced the need for costly transport and frequent doctor visits as a patient's health could be observed at home and transmitted to their doctor in another locality [32]. This remote monitoring approach could prove hugely beneficial for people living with disabilities, as wearables are able to address various dimensions of disability, including physical, sensory, emotional, and intellectual conditions [33]. This approach could provide people living with disabilities with greater autonomy, augment their ability to live independently, and improve educational and employment outcomes [34].

Wearables have been shown to enable people to become informed about their health status and conditions, give patients a sense of agency over their health metrics, and improve health literacy [29,35]. Moreover, health care providers and governments can harness digital technology's aggregated information and insights to improve the quality of diagnosis and broader population health [29,36]. As such, digital divides threaten the equitable access of health care and public health services and fundamentally disadvantage the strata of the population that cannot pilot digital technologies [3,22,24]. Therefore, measuring digital health literacy is critical as it will help evaluate the readiness of a health system to implement digital health innovations, design targeted educational tools before implementation, and avoid costly attempts that were certain to fail from the start [37].

Differences in Access to Digital Technologies and Infrastructure

Considerable work has been done to measure the world population's ability to access digital services in terms of available infrastructure and digital literacy [3,22,38]. Nevertheless, these efforts are often limited to a binary measure of internet access and an overly simplified set of digital skills [3,38]. As such, they fall short by failing to acknowledge complex or domain-specific skills required to maximize the benefits of digital medical services. Simultaneously, while digital technologies are frequently designed to be used at the individual level, a system-level approach is required to fully understand the breadth and depth of how digital technologies can shift or augment a (public) health system [23].

A crucial part of this system-level approach is the ability of frontline health care workers to engage with and effectively use digital (health) technologies and platforms to streamline their workflows. With digital health technologies, the technology must be user-friendly to relieve the cognitive burden of health workers so they can focus on providing medical care [39]. Fractured communication and different systems across facilities and departments are often significant reasons for increased cognitive load [39]. As such, by optimally managing and communicating information through standardized systems, the potentials of digital health could be maximized to achieve the most significant benefit for health professionals [39].

Nurses are well placed to drive the digital health literacy agenda and upskill their colleagues. Moreover, as nurses often act as the primary care providers for rural or vulnerable populations, they would benefit from developing the knowledge and skills to implement and use telehealth technologies [40]. Strengthening their ability to use digital health technologies should therefore be an integral part of education for nurses and other health professions. A multimodal training approach (ie, didactics, patient simulations, practice immersions, and project work) has enabled students to develop the skills required to embrace telehealth and be comfortable using it [40]. Simultaneously, medical training continues to focus heavily on the quantitative side while underserving the arts and humanities of medicine [41], inherently limiting the extent to which medical professionals can advocate for the influence of various social determinants on health. However, it is the social determinants that often play a multifaceted role in whether a patient is able to access digital health services. In order for digital health care to become a mainstream mode of health care, medical education needs to be rebalanced with adequate coverage of arts and humanities of medicine and social medicine to train future health professionals when it is appropriate to deploy digital services, especially as long as the digital divide remains as extensive as it is currently. Additionally, social prescribing (ie, referring people to a range of local, nonclinical services) is increasingly becoming a core role of clinicians [42]. This could be further ameliorated with specialized training programs to ensure they have the right tools and referral pathways on hand to deploy it effectively.

Virtual medicine has significantly changed the way health care professionals deliver care. The COVID-19 pandemic has accelerated the development of telehealth services to the point where they have become a viable pathway for remotely delivering accessible, cost-effective, and quality care to patients [40,43]. Although videoconferencing is increasingly regarded as an adequate substitute for face-to-face consultations, network coverage shortages and lack of digital access or literacy among doctors and patients have meant that a proportion of remote primary care still takes place via telephone [44,45]. This change

in the modality of care provision is also expected to persist after the pandemic as users appreciate the convenience and accessibility afforded by telehealth services [40,46,47], especially in remote areas or for vulnerable populations who prefer or require access to health care closer to home. Digital health must, in turn, become more accessible, as must the incorporation of features that enable its acceptance and the reimbursement of this modality [46]. This is particularly important in resource-limited settings and low- and middle-income countries, where accessible pathways must be established. This will maximize the potential of telehealth to transform health care delivery for the wider global population [48].

Digital Technologies, Health, and Disability

While people living with disabilities cannot be taken as a monolith, they are on average older, poorer, and less likely to have a regular health care provider (and thus less likely to seek health care regularly) [49]. They are also more likely to experience multiple co-occurring conditions [49]. These factors pose additional challenges for developing and integrating the infrastructure of telemedicine into the lives of people living with disabilities [50]. However, digital health platforms offer an opportunity for improved engagement with populations with complex health needs who may receive poorer quality health care services, including those on the neurodiversity spectrum.

Telemedicine appointments allow patients to interact with health care providers at home [40,48,51], limiting exposure to overwhelming and unknown sensory environments while also accommodating alternative forms of communication (eg, audio-based or chat-based), which may be preferred by autistic adults [11]. Telemedicine and digital health may provide an online record of health care appointments (past and future), diagnoses, and prescriptions that patients can view at any time [51], which may afford greater autonomy for autistic patients or caregivers in managing their health care. Finally, online access to health care records for patients—particularly those with complex care needs—can provide reminders for essential tasks (eg, attending future follow-up appointments, collecting prescriptions) and offer opportunities for health care records to be corrected in the event of miscommunication between patients and providers.

Systematic reviews of pediatric and adult populations found that services delivered via telehealth were equally effective or superior means of providing health care to people living with disabilities, including those on the autism spectrum [52-54]. Furthermore, other forms of digital health like wearable technologies may provide novel opportunities for remote monitoring of people living with disabilities in distress situations or promote healthy lifestyle choices (eg, diet, exercise, and sleep) [29,51]. These tend to be significantly worse among autistic adults relative to neurotypical people and are associated with excess risk of chronic cardiovascular conditions [55]. Although we have explored the potential advantages of integrating telemedicine into health care systems for autistic adults, these benefits may also apply to those with other disabilities and the general population. Thus, telemedicine may be an efficient and cost-effective means of beginning to close the gaps in equitable access to high-quality health care for all.

Policy Perspectives and Practices

This section shows an overview of guidelines established in 3 countries to help facilitate the (digital) inclusion of people living with disabilities. Each set of principles shown in Textboxes 1, 2, and 3 [56-59] lays a foundation for a collaborative environment where all stakeholders are involved and empowered in the development and implementation of digital health, allowing for different vulnerable groups to be included during the development process to ensure their needs are met by the end product.

Sweden's digital health initiatives have been ongoing for 15 years at the time of writing with its current Vision for eHealth 2025 being adopted in 2016 (Textbox 1) [56]. The Vision acknowledges the opportunities that digital health brings for improving the welfare and well-being of vulnerable communities. It states that for these opportunities to be actualized digital health should be nondiscriminatory and respond to the needs of different groups. This is possible given the inherent characteristic of digital health to be deployed at an individual level.

Textbox 1. Strategy for implementing Vision for eHealth 2025 in Sweden [57].

Objectives:

- Involve the individual as cocreator
- Ensure that all relevant information is easily available when needed
- Guarantee that personal information is processed safely and securely
- Acknowledge that development and digital transformations go hand-in-hand

Fundamental principles:

- Regulations should (1) safeguard individual rights such as privacy, equality, patient safety, and accessibility; (2) enable the most optimal use of digital health innovations; and (3) stand the test of time and be specific enough to be applied
- Terminology and semantics should be used consistently across administrative systems to ensure and improve interoperability
- Acknowledging that a lot of standardization occurs at the European Union level, common and cross-sectoral standards (ie, procedures of application and development) are promoted to prevent national or sector-specific unique solutions

Textbox 2. National Disability Strategy–United Kingdom [58].

The governmental approach to disability is guided by 5 principles:

- Ensuring equity and fairness: people living with disabilities will be empowered by advocating for fairness and equality in opportunities, experiences, and outcomes
- Considering disability from the start: inclusive and accessible approaches will be embedded in government functioning to mitigate the creation of excluding experiences for people living with disabilities
- Supporting independent living: initiatives that support all people living with disabilities to have choice, control, and autonomy in their life will be actively encouraged
- Increasing participation: a diverse group of people living with disabilities will be included in the design, development, and delivery of products, services, and policies
- Delivering joined-up responses: work will occur across organizational boundaries to improve data and evidence gathering to better understand the complex issues that affect people living with disabilities

Textbox 3. Accessible Canada Act [59].

The purpose of this legislation is to benefit all persons, especially people living with disabilities, by removing existing barriers and preventing new barriers within Canada on or before January 1, 2040. It sets out 7 principles to guide the transformation process:

- Every person must be treated with dignity regardless of their disabilities
- Every person must have the same opportunity to make for themselves the lives that they are able and wish to have regardless of their disabilities
- Every person must have barrier-free access to full and equal participation in society, regardless of their disabilities
- Every person must have meaningful options and be free to make their own choices, with support if they desire, regardless of their disabilities
- Laws, policies, programs, services, and structures must take into account the disabilities of persons, the different ways that persons interact with their environments, and the multiple and intersecting forms of marginalization and discrimination faced by persons
- People living with disabilities must be involved in the development and design of laws, policies, programs, services, and structures
- The development and revision of accessibility standards and the making of regulations must be done with the objective of achieving the highest level of accessibility for people living with disabilities

This sentiment also arose from the United Kingdom Disability Survey 2021, which indicates that "44% of [people living with disabilities] who received [online] formal care said it made them feel more in control or much more in control of their lives" [58]. For this transformation to occur sustainably, strong principles are required to guide and facilitate the transformation process.

In terms of operationalizing the fundamental principles in Textboxes 1, 2, and 3, Australia and Canada showcase good policy practices. Australia adopted the Digital Transformation Strategy 2018-2025 in 2018, which is geared toward the digital transition of government services [60]. The strategy includes the Digital Service Standard criteria, which extensively outlines how developers and innovators can ensure that their services are usable by every person who needs them [61]. The guidelines distinguish 4 phases of progress (discovery, alpha, beta, and live), each containing between 4 and 15 requirements that need to be met before the next phase can begin. During the first 3 phases, innovators must prove that people from different backgrounds and people living with disabilities were involved in the development process and that the innovation is accessible for these groups. While the guidelines were designed for innovation in government services, the criteria are good practice guidelines for inclusive digital innovation in every sector, including health care. These guidelines can be further augmented by making funding contingent on adherence to such guidelines. The Accessible Technology Program in Canada is an example of this. Even though the program description does not offer extensive guidelines like the ones set out in Australia, its overarching aim is similar: "to develop innovative assistive and adaptive digital devices and technologies for persons with disabilities" [62].

Alternatively, the United Kingdom provides an extensive list of organizations that give support, advice, or information for each stage of the development life cycle for digital health and care products [63].

When considering active citizen engagement, we must consider what meaningful or equitable engagement looks like in health research. Literature on various frameworks for patient or citizen engagement is rich [64-67], although there is a common consensus among these studies that the frameworks themselves are lackluster and no specific research on the involvement of people living with disabilities or vulnerable groups has been carried out. As such, we are not in the position to establish concrete guidelines for meaningfully including people living with disabilities in the co-design process. That said, there is a consensus that meaningful engagement adheres to a number of principles (eg, the INVVOLVE principles: Invest in co-design; Needs assessment; Vision roles, responsibilities, and rewards; Validate participants; Organize interaction carefully; Lead the engagement; Value patient time and input; Evaluate and report [67]). When determining a method for meaningful engagement of people living with disabilities, it is good practice to consider the ability and preferences of the participants [68]. For instance,

workshops can be a meaningful way to invite and interact with a representative group of people living with disabilities throughout the design process [69] but may only attract certain clusters that can handle the sensory or cognitive input paired with attending workshops. Ratwani and colleagues [70] further elaborate on some good and bad practices regarding user-centered design processes in the development of electronic health records that can be particularly relevant for informing co-design methods for people living with disabilities.

Estonia is currently regarded as the frontier of how an integrated digital health system can function [71,72]. Estonia offers citizens the ability to access diagnostic services, consultations, prescription refills, and referrals online. The digital health system is built on the basis of an information society, which was initiated in 1992. Having regained independence from the Soviet Union in 1990, Estonia was able to rebuild and develop a society pointed toward the Digital Age without the remnants of past times. In contrast, most Western countries are run by long-established governments and sometimes even longer established ideologies, which may constrain the adoption of transformational innovations that significantly challenge the status quo [73].

For example, health care coverage and insurance, including telemedicine access, remains disjointed and variable for people living with disabilities in the United States. In 1990, the Americans With Disabilities Act (ADA) was passed to protect people living with disabilities against discrimination, specifically requiring that health care entities provide full and equal access for people living with disabilities. However, until the passage of the Affordable Care Act (colloquially known as Obamacare) in 2010, insurers could discriminate against people living with disabilities by charging higher premiums or denying health care coverage by capitalizing on an exemption in the ADA [74]. As the United States does not offer universal health care or health insurance schemes, service access for people living with disabilities presently depends on insurance type: Medicaid (37.7%), Medicare (27.1%), private insurance (36.1%), military benefits (6.0%), and uninsured (8.5%) [75], in turn providing patchwork telemedicine coverage. This is particularly true for Medicaid (the largest single provider of health insurance coverage for people living with disabilities), as each state runs their Medicaid system independently, individually interpreting federal mandates (like the ADA) and definitions of telemedicine. As of 2021, both Medicare and Medicaid universally offer some access to telemedicine services [76]; however, these programs are limited based on location, plan type, service type, provider type, and provider licensing state, and prescriptions may not be allowed via telemedicine. Further, only 10 state-run Medicaid programs offer all 3 major types of telemedicine to enrollees: live conferencing, remote patient monitoring, and store-and-forward electronic health records [76]. As it stands, this system (or lack thereof) leaves people living with disabilities either unable to access a wide range of telemedicine services or forced to reckon with significant system-level barriers, including deciphering individual insurer policies (and sometimes individual state insurance policies) to determine which types of telemedicine coverage can be reimbursed, much less whether their specific provider will be covered. Finally, it cannot be overstated how access issues compound when dealing with intersectional populations (including those experiencing poverty, homelessness, racism, and sexism along with disabilities), in turn providing greater disparities in health care coverage as well as greater opportunities for closing the gap via telemedicine.

Policy searches were also performed for South Korea, Japan, and Singapore. However, it appeared that digital transformation strategies were not yet developed in these countries, which is not only a contrast to the Western world but also to the fact that these countries are perceived as leaders in the field of digital transformation [77].

Limitations

Before accurate recommendations for policy and practice can be established, the circumstances under which this article was written need to be considered. The findings of this article should be interpreted as scoping and are not definitive due to the unsystematic nature of data collection. Our aim is to inspire more thorough research and initial/preliminary action in the discussed topics. Additionally, the quality of included sources has not been assessed, which reinforces the need to interpret the results carefully.

Moreover, the author team consists almost exclusively of young professionals who grew up during a period when digital technologies flourished and had access to digital technologies during their formative years. The author team also exclusively consists of people with a Western background (European/North American). Consequently, the values, interpretations, opinions, and recommendations in this piece—while rooted in scientific evidence—may be considered progressive and transformational when presented to population groups that have different relationships with digital technologies. That said, the demographic makeup of the author team can also be considered a strength of the article, as youth and young professionals have a strong stake in the future development of the health system.

Principles for Policy, Research, and Practice

The policy perspectives above point toward a strong need to work collaboratively across sectors. Technological, social, organizational, and political innovations that fundamentally reimagine health care delivery must be embraced with the aim to establish a new social contract that is fit for purpose for delivering high-quality digital health care to people living with disabilities [78,79]. At the same time, these policy perspectives highlight how digital health is currently framed in policy as a technology or a service more so than anything else. It is framed to be used by a consumer or a patient rather than be delivered by a health professional.

For effective implementation of digital (health) technologies, legal challenges, security breaches, regulatory concerns, and industry barriers must be addressed. Existing legislation, regulations, and policies have largely been written for face-to-face health care delivery, and security regulations vary widely across (and even within) territories [43,44]. When

considering the developmental trajectory of Estonia in the field of digital health, it becomes evident that a collaboration of public and private stakeholders, including national governments, patient groups, international governmental and nongovernmental organizations, citizen representatives, health care representatives, and social sectors, must convene to consider whether the values underpinning existing health care structure are still fit for purpose. Subsequently, this coalition should move to develop a high-level consensus on definitions, boundaries, protocols, monitoring, evaluation, and data privacy that is needed to meet the rapid advancement of digital health [47]. Specifically, they should focus on reimbursement of digital health care, privacy/cybersecurity, liability, licensure, and technology access, while ensuring that all countries participating in this coalition meet an internationally recognized minimum standard [80]. International and national policy makers need to amend the existing policy framework to support and enable new ways of working driven by digital health [57,60]. In the interim, given that many professional liability policies currently exclude digital health from coverage, health care practitioners are advised to acquire additional coverage to ensure protection from liability issues [43].

Designing an ecosystem of digital health technologies with health equity in mind is imperative to avoid deepening health inequalities [81]. In other words, the burden of implementing digital health innovations should not fall on citizens by focusing solely on upskilling after digital health tools are developed. This applies doubly when aiming to reach people living with disabilities and other groups that are frequently digitally excluded and may garner unique benefits from these services. Following the Swedish and Australian examples, policy makers can draft policies that include vulnerable groups as integral parts of the co-design process. Additionally, funding agencies can follow the Canadian example and require that people from different backgrounds, including people living with disabilities, are included at every stage to get funding for a project.

Future research should work toward adopting a broader and more sophisticated understanding of digital health literacy (for instance, the transactional model of eHealth literacy [82]). Subsequently, digital health research should meaningfully engage with vulnerable population groups to ensure that new digital tools meet their individual needs [57,60,62,83]. Specifically, a new relationship between qualitative and quantitative research fields needs to be established that considers qualitative and quantitative research complementary to each other [84]. Related to this is the need for software developers to partner with user experience and user interface experts in designing digital health technologies accessible to everyone [85] and reduce rather than add to the workload of health care professionals. The relationship between qualitative and quantitative research may also need to be reconsidered as new data streams become available through digital health innovations.

In summary, there is a role for national governments, actors from private sectors (eg, telecommunication, technology), international/global governing bodies (eg, World Health Organization, Organisation for Economic Co-operation and Development), and other stakeholders to collaboratively create a regulatory framework that ensures a high level of quality in digital health care through independent evaluation and certification [20]. The task of quality assurance should not fall to the individual. In other words, a systems thinking approach involving as many stakeholders as possible is paramount to safely and sustainably implementing digital transformations of this magnitude. This approach should be complemented by novel forms of collaborative governance and leadership that are goal-oriented, embrace risk-taking, and derive value from improved patient and societal outcomes rather than monetary gain [78]. The good practices and recommendations in this article have been condensed into domain-specific principles shown in Textbox 4. These principles are designed to facilitate the initial stages of development of a digital health ecosystem that is accessible to all.

Textbox 4. Principles focused on policy, practice, governance, and education for the sustainable integration of digital health innovations.

Health policy:

- Digital health is framed as a multidimensional concept that can refer to a technology, user experience, service, product, process, infrastructure of its own, or part of the ecological system of health services
- Digital health care services are a viable way to deliver health care to underserved populations that is comparable in quality to analog health care
- Health data, a major driver of digital health care, is stored safely and securely with the patient having autonomy over with whom the information is shared
- People living with disabilities and vulnerable groups are core subjects upon which digital health-related policy is built

Health care design and delivery:

- The design and development of digital health services are in close collaboration with people living with disabilities and other vulnerable population groups
- The involvement of people living with disabilities and other vulnerable groups in co-designing digital health services is systematic, purposeful, and equitable
- Clear agreements regarding expectations, input, and reward are made before the design process starts
- Digital health services are released and monitored collaboratively with people living with disabilities and other vulnerable groups

Governance:

- Governance approaches within health care embrace risk-taking, learn to function based on incomplete information, and assess value by outcome measures instead of monetary costs
- Collaborative governance is a central tenet in the governing process of health care that drives the other fields of policy making, health care design and delivery, and education

Education:

- A baseline course on the social determinants of health and their relevance to individual health is included in educational curricula of primary or secondary education
- A more in-depth course on the social determinants of health or social medicine is included in the educational curricula of all health professions
- Digital health literacy is a skill that needs to be maintained and updated intermittently to consistently engage with digital health services over time

Conclusions

Digital technology is fundamentally reshaping the way health care is delivered. The current scope of its use is not fully living up to its potential. The COVID-19 pandemic saw digital health catapulted into widespread use as virtual delivery became a priority for many health services worldwide. However, the pandemic also emphasized that digital health in its current form exacerbates health inequalities. At greatest risk of digital exclusion are older people, people in rural and remote areas, and people living with disabilities.

While the futuristic use of digital technologies is auspicious, we must allow both the policy landscapes and global digital health literacy levels to catch up with the rapid advances in technology [86]. We must ensure that digital technologies are used equitably and do not become an exclusive domain of high-income countries or populations. People living with disabilities and other vulnerable groups must be put at the center of digital health development on a global scale. Ultimately, achieving equitable access to digital health will significantly benefit the health and well-being of the wider population, especially vulnerable groups, and go a long way in reaching the Agenda for Sustainable Development 2030.

Acknowledgments

EO'N participated in this research independently of her role at Deloitte, where she is employed. Furthermore, Deloitte did not provide funding or other support for this research. EW received funding from the Corbin Charitable Trust, Autism Research Trust, Rosetrees Trust, and the Collaboration for Leadership in Applied Health Research and Care East of England at Cambridgeshire and Peterborough National Health Service (NHS) Foundation Trust. SBC received grant 214322\Z\18\Z from the Wellcome Trust. For the purpose of Open Access, the author has applied a CC-BY public copyright license to any author accepted manuscript version arising from this submission. In addition, SBC received grant 777394 from Innovative Medicines Initiative 2 Joint Undertaking (the funders had no role in the design of the study; in the collection, analyses, or interpretation of data; in the writing of the manuscript; or in the decision to publish the results. Any views expressed are those of the authors and not necessarily those of the funders). The Innovative Medicines Initiative 2 Joint Undertaking receives support from the European Union's Horizon

2020 research and innovation program, the European Federation of Pharmaceutical Industries and Associations, AUTISM SPEAKS, Autistica, and the Simons Foundation Autism Research Initiative (SFARI). SBC also received funding from the Autism Research Trust, SFARI, the Templeton World Charitable Fund, the Medical Research Council, and the National Institute for Health Research (NIHR) Cambridge Biomedical Research Centre. The research was supported by the NIHR Collaboration for Leadership in Applied Health Research and Care East of England at Cambridgeshire and Peterborough National Health Service Foundation Trust. The views expressed are those of the authors and not necessarily those of the NHS, NIHR, or Department of Health and Social Care. The funding agencies did not play a role at any stage in the development of this article.

Authors' Contributions

RVK, EM, and RH were in charge of conceptualization. RVK, RH, EO'N, EW, and BLHW were responsible for data collection, writing, reviewing, and editing the manuscript. MA, SBC, and EM were involved in the reviewing and editing of the manuscript. RVK supervised the project. RH, EO'N, and EW contributed equally to this manuscript and retain the right to list themselves as the second author for the purpose of their CV and grant applications.

Conflicts of Interest

None declared.

Abstract

Background: Internet-based treatment programs present a solution for providing access to pain management for those unable to access clinic-based multidisciplinary pain programs. Attrition from internet interventions is a common issue. Clinician-supported guidance can be an important feature in web-based interventions; however, the optimal level of therapist guidance and expertise required to improve adherence remains unclear.

Objective: The aim of this study is to evaluate whether augmenting the existing Reboot Online program with telephone support by a clinician improves program adherence and effectiveness compared with the web-based program alone.

Methods: A 2-armed, CONSORT (Consolidated Standards of Reporting Trials)–compliant, registered randomized controlled trial with one-to-one group allocation was conducted. It compared a web-based multidisciplinary pain management program, Reboot Online, combined with telephone support (n=44) with Reboot Online alone (n=45) as the control group. Participants were recruited through web-based social media and the This Way Up service provider network. The primary outcome for this study was adherence to the Reboot Online program. Adherence was quantified through three metrics: completion of the program, the number of participants who enrolled into the program, and the number of participants who commenced the program. Data on adherence were collected automatically through the This Way Up platform. Secondary measures of clinical effectiveness were also collected.

Results: Reboot Online combined with telephone support had a positive effect on enrollment and commencement of the program compared with Reboot Online without telephone support. Significantly more participants from the Reboot Online plus telephone support group enrolled (41/44, 93%) into the course than those from the control group (35/45, 78%; χ^2_1=4.2; *P*=.04). Furthermore, more participants from the intervention group commenced the course than those from the control group (40/44, 91% vs 27/45, 60%, respectively; χ^2_1=11.4; *P*=.001). Of the participants enrolled in the intervention group, 43% (19/44) completed the course, and of those in the control group, 31% (14/45) completed the course. When considering the subgroup of those who commenced the program, there was no significant difference between the proportions of people who completed all 8 lessons in the intervention (19/40, 48%) and control groups (14/27, 52%; χ^2_1=1.3; *P*=.24). The treatment efficacy on clinical outcome measures did not differ between the intervention and control groups.

Conclusions: Telephone support improves participants' registration, program commencement, and engagement in the early phase of the internet intervention; however, it did not seem to have an impact on overall course completion or efficacy.

KEYWORDS

chronic pain; online pain management; telephone support; clinician guidance; adherence; digital health; eHealth; internet interventions; multidisciplinary

Introduction

Background

The global prevalence of chronic pain is estimated to be 10% to 33% [1-3], and pain conditions continue to be a leading cause of worldwide disability [4]. The accepted best practice for managing chronic pain is a multidisciplinary pain program that involves attending a group program—typically convened face to face at a hospital or clinical site—facilitated by members of a multidisciplinary team [5].

A main challenge to the management of chronic pain is the lack of services available within existing health care systems. Access to multidisciplinary pain management groups can be compromised for people living in rural areas, those with family or work commitments, and those with mental health issues that limit their ability to engage and be involved in a social group environment [6]. Furthermore, because of the COVID-19 global pandemic, increased social isolation and reduced accessibility of face-to-face clinical interactions have further compromised access to required pain management services for many people [7]. Web-based treatment programs present a solution for providing access to pain management for those unable to access clinic-based multidisciplinary pain programs [6,7] and for delivering care at reduced personnel costs [7-9].

The evidence to date suggests that internet-based health interventions that provide a combination of information and some form of user support—such as decision management support, behavior change support, or social support—lead to improvements in knowledge as well as behavioral and clinical outcomes [8,10-13]. Generally, internet-based pain programs focus on unimodal interventions that offer a single discipline of therapy, most commonly psychological therapies such as internet-delivered cognitive behavioral therapy (CBT) [14]. These programs typically show small to moderate effects on pain-related disability and interference as well as pain catastrophizing and are a cost-effective alternative to face-to-face therapy [13,14].

Reboot Online was one of the first internet-based pain management programs that offered a multidisciplinary model. The program has been shown to significantly improve pain self-efficacy and reduce pain-related disability, kinesiophobia, and psychological distress compared with usual care [15,16]. These studies were carried out within a strict clinical trial paradigm. Although highly effective for those participants who completed the program, adherence rates were moderate, with only 61% of the trial participants completing all the lessons. Adherence (completion of all 8 lessons of the program) and effectiveness (significant changes in clinical outcome measures) of the program in real-world conditions were subsequently evaluated [17]. Without the regulated framework and rigor embedded within a clinical trial design, the adherence to the Reboot Online program reduced to 41% when used under routine care conditions.

Attrition, or dropout of study participants, is a common problem for internet-based treatments [18,19]. In a systematic review of internet interventions for chronic pain [19], the range in attrition levels across published trials was considerable, from 4% to 54%. Different methods have been used to prevent dropout, such as telephone support, personalized reminders and feedback, and financial incentives [19]. However, it remains unclear how helpful these methods are [19].

Clinician-supported guidance can be an important feature in web-based interventions for mental health disorders; however, the optimal level and pattern of therapist guidance required to improve adherence remains unclear [20]. Having human social support, whether it be peer-led or specialized clinician–led, has been suggested to help support healthy behavior change [21,22] and has been shown to have small effects on improving adherence compared with unguided interventions for individuals with chronic pain [22-25]. The addition of clinician-supported guidance has not yet been tested in routine care using the Reboot Online program.

Objectives

We aim to evaluate whether augmenting the existing Reboot Online program with telephone support by a clinician improves program adherence and effectiveness compared with the web-based program alone. We hypothesized that the Reboot Online plus telephone support group would have better adherence (defined as higher number of enrollments, higher number of commencements, and higher completion rates) to the program than the control group who received the Reboot Online program only.

Methods

Study Design

The study was a 2-armed, CONSORT (Consolidated Standards of Reporting Trials)–compliant, registered randomized controlled trial with one-to-one group allocation. It compared a web-based multidisciplinary pain management program, *Reboot Online*, combined with telephone support with *Reboot Online* alone as the control group.

The study was approved by the human research ethics committee of St Vincent's Hospital, Sydney, Australia (2019/ETH08682). The trial was prospectively registered on the Australian New

Zealand Clinical Trials Registry (ACTRN12619001076167), and the protocol was followed as per the registry.

Participants

Participants were recruited between September 2019 and April 2020 through social media advertisements (eg, Facebook and Twitter) and through the This Way Up service provider network. To replicate real-world conditions, the trial was run through the established web-based platform through which the Reboot Online program is available: *This Way Up* [26]. Applicants completed a 2-step screening process. All applicants first completed web-based screening questionnaires about their chronic pain symptoms and demographic details, followed by a telephone interview to confirm their chronic pain diagnosis and study eligibility. The Mini International Neuropsychiatric Interview (version 5.0.0) [27] for major depressive disorder (MDD) and risk assessment modules were also administered during the telephone interview as a screening and diagnostic tool for depression. MDD helps us to compare the sample characteristics with our previous trials and establish the number of individuals who had comorbid depression, which also assists in clinical support. MDD plus risk assessment modules help establish how the clinician will prioritize and triage calls as well as monitor and ensure that participants who are at risk are appropriately supported throughout the program.

Applicants were eligible for inclusion if they (1) had experienced pain for >3 months, (2) were aged ≥18 years, (3) were a resident of Australia, (4) had their pain assessed by a physician in the past 3 months, (5) were prepared to provide contact details of their general practitioner, (6) had access to the internet and computer or tablet and deemed themselves to have basic computer literacy, and (7) were fluent in written and spoken English. Applicants were excluded if they had psychosis, bipolar disorder, were actively suicidal (eg, demonstrated intent or a plan or had a recent suicide attempt). These exclusion criteria were included to be consistent with other trial exclusion criteria and to be able to adequately evaluate participants' needs and assist their access to more intensive clinical support if required. Participants were also excluded if they had participated in a group-based pain management program within the last 6 months so that their prior treatment or learning would not confound the results. Participants were also ineligible for the study if they had surgical procedures scheduled in the 6 months after their application; had commenced or made significant changes to their psychotropic medication in the previous 2 months before intake assessment; or had commenced face-to-face CBT within 4 weeks of the intake assessment. These exclusion criteria were included because of their potential confounds. We wanted to explore the effects of clinician support on program adherence and outcomes and minimize the confounding effects of these features.

Participants provided electronic informed consent before being enrolled in the study; they also provided permission for their pain physician (or general practitioner) to be notified by the study team detailing their involvement in the trial. Measures of psychological distress (Kessler-10 Psychological Distress Scale [28,29]) were monitored throughout the program for any risk of harm.

Randomization

The eligible participants were randomly assigned to either the intervention or control group in a 1:1 allocation based on a random number sequence generated [30]. An individual web-based link for baseline data questionnaires through REDCap (Research Electronic Data Capture [31]) was sent to the eligible participants to complete. Once the initial baseline questionnaires were completed, an individual registration link to Reboot Online through the usual *This Way Up* process was sent to the participants, which gave them access to register for the course, complete pretreatment questionnaires, and commence the first lesson. Telephone screening interviewers at baseline remained blinded to the participants' group allocation. Study staff members conducting the telephone support intervention could not be blinded to group allocation. Group allocation was indicated to the participant by whether they received telephone support after registration into the program.

Intervention

Reboot Online Program (Control)

Participants received free access to the standard Reboot Online program [32]. Details of the content and design of the program have been previously outlined [16]. In brief, Reboot Online consists of 8 lessons delivered over 16 weeks. Participants follow an illustrated story of a fictional character who learns to self-manage her chronic pain using a multidisciplinary approach. The content delivers psychoeducation on the socio-psycho-biomedical nature of chronic pain within a multidisciplinary framework. The core lessons are combined with a *movement station* section: a graded, patient-led exercise program focusing on activity and exercise reactivation. This is combined with pacing: an activity-management technique aimed to maximize a person's activity by developing a structured, slow, and gradual planned increase in activity levels over a period of time. The level of activity is dependent on the planned quantity rather than pain intensity experienced by the patient. The program also incorporates SMART (specific, measurable, achievable, relevant, and timely) goal-setting principles, whereby the patient leads the process of identifying issues or problems that matter most to them, sets the goal that they want to accomplish, and develops strategies and goals that are specific, measurable, achievable, relevant, and within a time frame. This is coupled with evidence-based CBT skills activities, including thought challenging, activity planning, problem solving, effective communication, and flare-up management. Participants also have access to expert educational videos as well as tai chi and relaxation audio guides. See Table 1 for details of the lesson content of the program. All participants received automatic email communication to notify them when a lesson was available and to encourage lesson completion as well as engaging in activity.

Table 1. Reboot Online lesson content.

Lesson title	Lesson content	Homework activities	Lesson resources (PDF or video)
Lesson 1: What Is Chronic Pain and What Is the Best Way to Manage It?	• Chronic pain explained • The Brick Wall of Chronic Pain • Medication overview • The movement station	• Review of acute vs chronic pain • Complete own Brick Wall of Chronic Pain • Instructions for the movement station	• Welcome (video) • Medication management (video)
Lesson 2: Goal-Setting and Moving Toward Acceptance	• Scans, test results, and pain • The cycle of chronic pain • Moving toward acceptance • SMART[a] goals	• Reviewing the cycle of pain • Identifying acceptance, change, and goals • Setting short- and long-term SMART goals	• Medical imaging (video) • Making life changes (PDF)
Lesson 3: Movement, Pacing, and Daily Activity Scheduling	• Exploring the relationship between pain and activity • Learning about the "Boom Bust" pattern • Fear avoidance beliefs • Importance of pacing • Introduction to daily activity scheduling	• Identifying healthy vs unhealthy coping skills • Pacing activity • Keeping a movement diary	• Daily activity scheduling (PDF)
Lesson 4: Monitoring Thoughts and Recognizing Unhelpful Thinking Patterns	• Revision of chronic pain cycle and the link among thoughts, feelings, and behaviors • Recognizing unhelpful thinking patterns • Monitoring thoughts and learning to think more helpful thoughts	• Ways to recognize own unhelpful thinking patterns • Complete thought record • Continue to monitor and track thoughts	—[b]
Lesson 5: Mood and Pain, Thought Challenging, and Managing Arousal	• Challenging unhelpful thinking • Activity planning in practice • Emotions and pain • Strategies to manage anxiety • Mood	• Thought-challenging situations • Activity planning and monitoring • Managing anger: looking out for triggers and learning strategies • Practicing relaxation	• My Thought Challenging Worksheet (PDF)
Lesson 6: Stress Management and Getting Better Sleep	• What is stress? • How to manage stress better • Using problem solving • Barriers to good sleep with chronic pain and ways to get better sleep	• Recognizing sources of stress and own signs and symptoms • Structured problem-solving task • Sleep diary to improve habits	• Good sleep guide (PDF) • Better sleep for chronic pain (video)
Lesson 7: Communication and Relationships	• What is good communication? • Communication styles • Relationships with others • Ways to improve those relationships	• Communication skills practice • Task: select a relationship and explore how you would like that relationship to be different • Revisiting thought-challenging exercise	• Conversation skills tips (PDF) • Chronic pain and information for family and friends (PDF)
Lesson 8: Managing Flare-ups and Continuing Management of Chronic Pain	• Exploring flare-ups, relapse, and the need for a flare-up plan • Continuing chronic pain management • How to get further help	• Ten things to help during a relapse • Flare-up prevention plan • Summary	• What is a pain clinic? (video) • Congratulations (video)

[a]SMART: specific, measurable, achievable, relevant, and timely.

[b]Not available.

Reboot Online Program With Telephone Support (Intervention)

Participants received free access to the standard Reboot Online program, as outlined in the control intervention, in conjunction with telephone support. They received a phone call every fortnight for the duration of the program (maximum of 8 phone calls). There was a set maximum of 3 attempts if contact by phone was unsuccessful. The phone call was conducted by a single clinician (senior allied health clinician) experienced in the management of chronic pain. To replicate what may occur

in routine clinical care, we sought a flexible approach whereby the duration of the phone call was led by the needs of the patient. During the call, the participants were advised that the call was to check in and to see how their program was going. They were asked to report on their progress and encouraged to continue engaging with the program. The participants were also given the opportunity to discuss any challenges or hurdles they were experiencing, to problem-solve possible strategies to overcome them, and to receive feedback on their progress.

For both treatment groups, a senior clinician (senior pain physiotherapist TG and pain psychologist JW) experienced in chronic pain management monitored questionnaire responses, and if any responses indicated deterioration in well-being, phone contact was made with the participant and further clinical intervention was advised if indicated.

Outcome Measures

Participants were assessed using a suite of outcome measures, collected at three time points: baseline (immediately before commencing treatment), after treatment (weeks 16-17) and follow-up (3 months after completing posttreatment questionnaires).

The primary outcome for this study was adherence to the Reboot Online program. Adherence was quantified through three metrics: (1) completion of the program assessed through the number of participants who completed all 8 lessons of the intervention and who were classified as *completers*, whereas those who did not complete all 8 lessons were classified as *noncompleters*; (2) the number of participants who enrolled to undertake the program; and (3) the number of participants who commenced at least one lesson of the program. The rate of overall program completion was the primary outcome measure for adherence. These adherence measures were chosen to capture three key potential points where patients may drop out: (1) enrolling after being prescribed the course, (2) after completing baseline questionnaires and commencing the course, and (3) once engaged in the program after each lesson. Data on adherence were collected automatically through the This Way Up platform.

The secondary outcomes were as follows:

1. Pain Self-Efficacy Questionnaire [33] to assess participants' confidence to perform activities while in pain, with higher scores indicating greater confidence in functional capacity. A minimally clinically important difference (MCID) was considered to be 5.5 [34].
2. Tampa Scale for Kinesiophobia [35] to measure fear and avoidance of movement. An MCID was considered to be 6 [36].
3. Brief Pain Inventory [37] to assess pain severity and its impact on function through its 2 subscales for severity and pain interference. An MCID was considered to be 2 [38].
4. Pain Disability Index [39] to assess the degree to which chronic pain interferes with participants' daily activities and essential life activities. An MCID was considered to be between 8.5 and 9.5 [28].
5. International Physical Activity Questionnaire [29,40] to measure self-reported physical activity in the previous 7 days. Metabolic equivalents and level of physical activity were calculated using a preformed Microsoft Excel program [41]. This program calculated metabolic equivalents and levels of physical activity as low, moderate, and high according to International Physical Activity Questionnaire short form categorical scoring.
6. Kessler-10 Psychological Distress Scale [42,43] to measure psychological distress.

Self-reported data on clinical outcome measures were collected through the This Way Up platform as well as the REDCap tool hosted at St Vincent's Hospital, Sydney [44,45]. REDCap is a secure, web-based software platform designed to support data capture for research studies, providing (1) an intuitive interface for validated data capture, (2) audit trails for tracking data manipulation and export procedures, (3) automated export procedures for seamless data downloads to common statistical packages, and (4) procedures for data integration and interoperability with external sources.

Telephone Support Time and Satisfaction

Descriptive data pertaining to the amount of clinician contact and time spent conducting the telephone support calls were collected for all participants in the intervention group. Descriptive data on treatment satisfaction and perceived usefulness of the intervention were collected from all participants (both groups) during the posttreatment assessments. Additional user feedback was collected from the intervention group regarding how helpful and motivating they found the telephone support calls received as part of the intervention. Data on subjective participant feedback were quantitative in nature (collected on a rating scale from 1 to 10) and were analyzed descriptively through median values and IQRs (because of nonparametric data distribution).

Statistical Methods

Before commencement of the study, a power calculation was conducted to determine the minimum sample size required to detect a difference in the proportion of participants adhering to the course between the intervention and control groups. This was based on previous investigations [16], where 60% of the participants were observed to have adhered to the complete program under *control* conditions and an increase of 25% in adherence was predicted for the telephone support intervention group. Assuming a power of 80% and a Cronbach α set at .05, a minimum sample size of 39 participants in each group was needed to detect a 25% difference in the proportion of completers. To account for an anticipated approximate 10% dropout rate, a total of 44 participants were required in each study arm.

Descriptive statistics were used to characterize the demographic and clinical features of the study groups at baseline. Data on the time taken to deliver the telephone support and subjective participant feedback on the telephone support and web-based aspects of the Reboot Online program were also analyzed descriptively.

Cross-tabulations were used to examine between-group differences in the primary outcome of adherence. Chi-square analyses were performed with binary factors of group

(intervention and control) and adherence (yes or no) for each of the identified adherence metrics (enrollment, course commencement, and course completion). A Mann–Whitney *U* test was used to compare the median number of lessons completed by the intervention and control groups.

To examine treatment efficacy, intention-to-treat linear mixed models were implemented separately for each of the secondary outcome measures. This form of analysis can robustly account for the unbalanced nature of repeated measures data, including missing data because of participant dropout. Each model included group, time, and a group-by-time interaction as fixed factors. A random effect of participant was also included in each model, with an identity covariance structure used to model the covariance structure of the random intercept. Model fit indices supported the selection of an unstructured covariance matrix for each of the outcome measures. Significant treatment effects were followed with pair-wise comparisons of their estimated marginal means. For each outcome, the estimated marginal means derived from the model were used to calculate within-group effect sizes (Hedges g, adjusted for the correlation among time points). Pre- to posttreatment effect sizes (Hedges g, adjusted for the correlation among time points) were calculated, corresponding to the changes between pre- and posttreatment values and between posttreatment and follow-up values. Between-group effect sizes (Hedges g, adjusted for the correlation among time points) for each outcome after treatment and at follow-up were also calculated. Effect sizes of <0.49, 0.50-0.79, and >0.80 were considered to be small, moderate, and large, respectively [46].

Statistical analyses were conducted using SPSS software (version 25; IBM Corp), and results were considered significant where $P<.05$.

Results

Baseline Sample Characteristics

Baseline and sample characteristics are outlined in Table 2. Demographic data were available for all participants (N=89) who met the inclusion criteria. The participants had a mean age of 49.3 years (SD 16.1; range 21-86 years), and most of them were women (59/89, 66%). At baseline, 42% (37/89) of the participants reported taking simple analgesia for pain (nonopioid analgesics such as paracetamol and nonsteroidal anti-inflammatory drugs), 27% (24/89) took gabanoids, 43% (38/89) took antidepressant medication, and 44% (39/89) took opioid analgesia. Approximately 1 in 3 participants (28/89, 32%) met the criteria for MDD at the time of study enrollment.

Table 2. Baseline demographics (N=89).

Characteristics	Total sample (N=89)	Intervention (n=44)	Control (n=45)	Between-group comparison	
				Values	*P* value

[a]Italicized results are significant at $P<.05$.

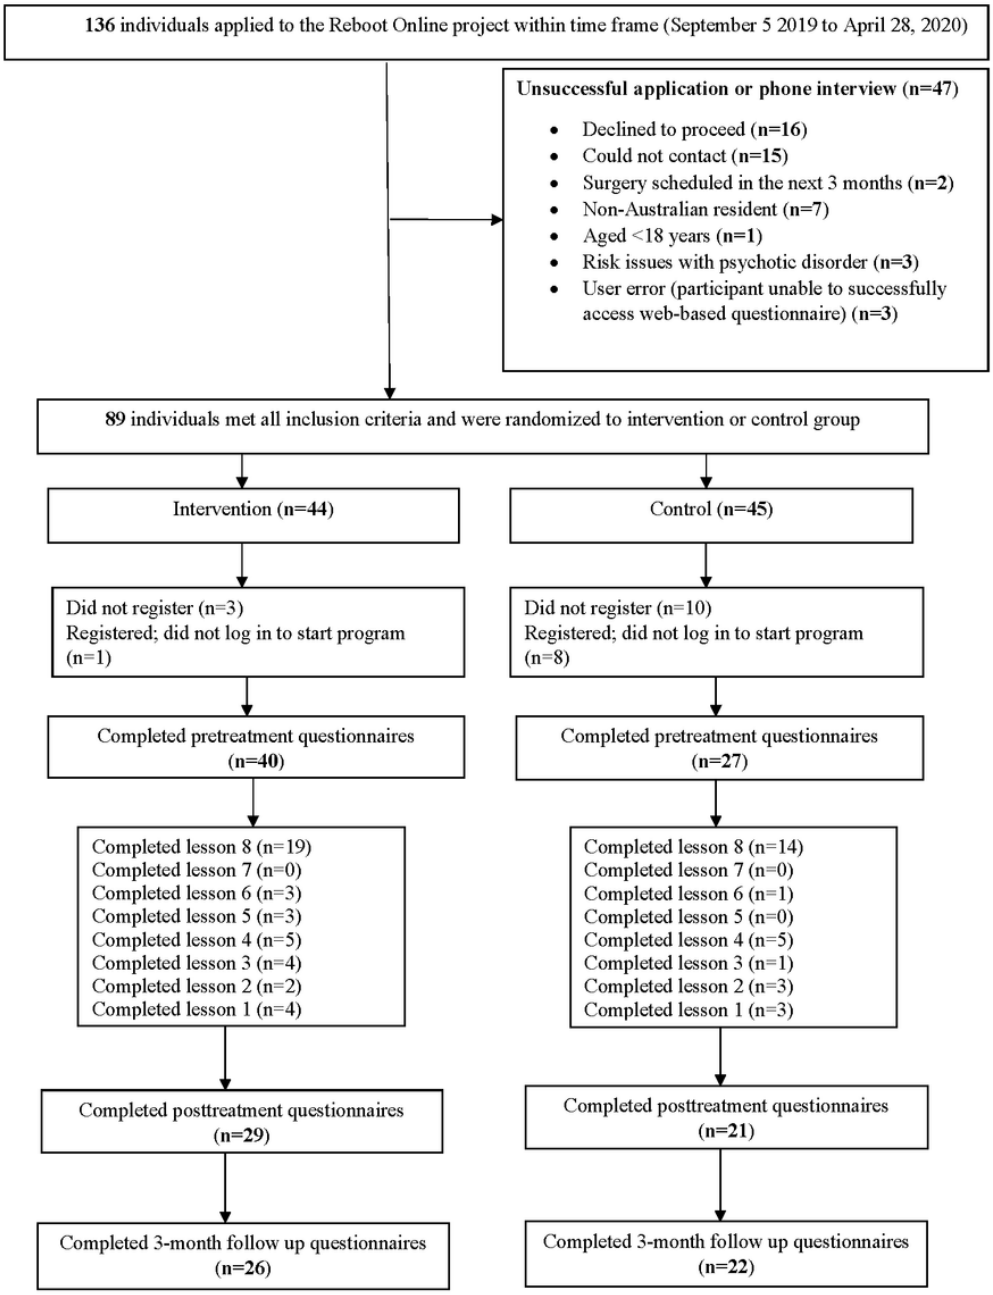
Adherence

Participant flow through the trial is illustrated in Figure 1. Reboot Online combined with telephone support had a positive effect on enrollment and commencement of the program compared with Reboot Online without telephone support. Significantly more participants from the Reboot Online plus telephone support group enrolled (41/44, 93%) into the course than those from the control group (35/45, 78%; χ^2_1=4.2; P=.04). Furthermore, more participants from the intervention group

commenced the course than those from the control group (40/44, 91% vs 27/45, 60%, respectively; χ^2_1=11.4; *P*=.001).

The median number of lessons completed by those in the intervention versus control groups was significantly different; the intervention group completed a median of 6 (IQR 3-8) lessons compared with a median of 2 (IQR 0-8) lessons in the control group (Mann–Whitney *U*=682; *P*=.009). More participants from the intervention group completed at least half the course (≥4 lessons; χ^2_1=5.0; *P*=.03) than those from the control group. The overall completion rate for both groups was 37% (33/89). Of the participants enrolled in the intervention group, 43% (19/44) completed the course, and of those in the control group, 31% (14/45) completed the course. When considering the subgroup of those who commenced the program, the overall course completion was 49% (33/67) from both groups; however, there was no significant difference between the proportions of people who completed all 8 lessons in the intervention (19/40, 48%) versus control groups (14/27, 52%; χ^2_1=1.4; *P*=.24).

Figure 1. Participant flowchart.



Effectiveness in Clinical Outcomes

Estimated marginal means at pretreatment, posttreatment, and 3-month follow-up as well as within- and between-group effect sizes for all outcome measures, are shown in Table 3. Significant main effects of time showing improvements from before to after treatment were observed for measures of pain self-efficacy ($F_{2,48}$=16.4; *P*<.001), kinesiophobia ($F_{2,52}$=10.3; *P*<.001), pain

interference ($F_{2,53}$=12.4; P<.001), pain disability ($F_{2,50}$=10.8; P<.001), and psychological distress ($F_{2,46}$=9.6; P<.001). There was no significant main effect of time with measures of pain severity ($F_{2,53}$=2.0; P=.15) or physical activity ($F_{2,55}$=1.8; P=.19). Within each group, posttreatment improvements were maintained at 3-month follow-up assessment, with no significant changes in outcomes between posttreatment and follow-up values.

There was no significant group-by-time interaction observed for any outcome measure, indicating that treatment efficacy on these outcome measures did not differ between the intervention and control groups.

Table 3. Estimated marginal means (EMMs) before and after treatment and at follow-up and within- and between-group effect sizes.

Outcome	Before treatment, EMM (SD)	After treatment, EMM (SD)	Follow-up, EMM (SD)	Pre- to posttreatment within-group comparison		Posttreatment to follow-up within-group comparison		Posttreatment between-group comparison, between-group effect size, Hedges g (95% CI)	Follow-up, between-group comparison, between-group effect size, Hedges g (95% CI)

Telephone Support Sessions

Over the course of the study, all participants in the telephone support group (n=44) had at least one telephone support session and 30% (13/44) had 8 support sessions, with a mean number of 5.7 (SD 2.4) sessions for each participant. The total cumulative telephone time for the intervention group was 3240 minutes, which comprised multiple attempts to make telephone contact as well as successful telephone support sessions, and the overall active telephone time in which the clinician was engaged with the participant was 1780 (54.94%) minutes. This equated to a mean total of 73.6 (SD 31.8) minutes of clinician time per participant over the entire program, of which 40.5 (SD 26.8) minutes was active time spent engaging with the participant. The mean clinician time at each active session was 7.9 (SD 5.5) minutes. No additional time was spent with any participants in either group for follow-up because of acute deterioration in well-being.

Treatment Satisfaction

When asked to rate their satisfaction with the treatment received in this study on a scale from 0 to 10, the participants provided a median rating of 7 (IQR 5-8). Furthermore, when asked to rate how helpful they found the study intervention for managing their chronic pain, the participants responded with a median rating of 8 (IQR 5-9) out of 10. There was no significant difference between the groups for scores of either satisfaction or how helpful they found the Reboot Online program. Of the 44 participants in the intervention group, 35 (79%) reported that the telephone support made it easier for them to participate in or complete the Reboot Online program. When asked how motivating or encouraging they found the telephone support aspect of their treatment specifically (rated out of 10), the median score of the participants was 7 (IQR 5-9).

Discussion

Principal Findings

This study aimed to investigate whether additional clinician guidance, in the form of telephone support, would significantly enhance adherence to the Reboot Online program for chronic pain and improve clinical outcomes. We found that Reboot Online combined with telephone coaching resulted in improved rates of enrollment and commencement (onboarding) of the program compared with the usual Reboot Online program. The overall completion rate from both groups was 37% (33/89; intervention 19/44, 43%, and control 14/45, 31%). The overall completion rate for those who commenced the program from both groups was 49% (33/67); however, there was no significant difference in overall completion rate between the groups (intervention 19/40, 48%; control 14/27, 52%) once the program was commenced. These completion rates are consistent with our real-world adherence outcome of 41% [17] and reflect published attrition rates: 4% to 54% [20]. Furthermore, there was no significant group difference in treatment efficacy on a variety of outcome measures.

The most effective way to provide clinician guidance adjunct to other interventions remains unclear. Little is known as to whether providing guidance evenly timed over the entire course of an intervention is most effective or whether initial support gradually tapered to self-management would be more effective [18]. Our results showed a significant difference between the groups in the rates of enrollment and commencement of the program—the *onboarding phase*. Once participants commenced the program, there was no significant difference in completion rates between the groups, regardless of phone support. This would suggest that telephone support is most effective in improving the onboarding of persons with chronic pain undertaking web-based treatments. The average amount of time involved for each telephone session (including time spent calling to contact participants together with time of consult) was 9.2 (SD 6.0) minutes, with a mean active consult time of 7.9 (SD 5.5) minutes. Thus, the telephone support intervention did not seem onerous and therefore could be easily incorporated into a clinical caseload. When considering where to best use clinical resources, clinician time may be best used in the early phase of onboarding to maximize adherence.

The telephone support provided in this study was delivered by experienced allied health clinicians with specialized training in pain management. The content of the telephone support calls was basic and consisted mainly of reaffirmation of the course material as well as feedback on progress and suggestions to address any barriers that the participants were experiencing. There was no specialized psychological treatment or intervention to address mood or cognition delivered through the calls themselves; nor was there detailed clinical education or advice on movement and physical activity. As the support did not provide specialized intervention, in future it could be provided by a trained peer or junior clinician to streamline the provision of clinical resources, which may be adequate for patients who are not clinically complex. Other studies have shown little difference between clinician and peer-led coaching.

It has been suggested that telephone support provides the possibility to make a diagnosis, tailor the intervention, and actively assist patients to access other needed services [47]. A triage system could also be used to identify persons with more complex issues who need to be referred to specialist clinician intervention. This may be relevant for those with chronic pain who are particularly afraid of movement because of fear of pain because it has been shown that high kinesiophobia negatively

effects adherence rates [17]. Research investigating the level of telephone support stratified according to kinesiophobia scores may be worthwhile, with this study being underpowered to investigate this aspect.

The act of individually tailoring a web-based intervention has been suggested to help with adherence and outcomes [47]. Standardized and nontailored internet treatments may leave little room for patient and clinician preferences [48] regarding course content, format, and learning styles. Chien et al [49] identified 5 engagement subtypes in patients enrolled in an internet-delivered CBT program. Their study suggests that by identifying subtypes of patient engagement, programs can be targeted to what is most meaningful to different patients by providing different levels of support or additional treatment modules. The inclusion of telephone support may enable the clinician to assess patient preferences early in the program and adapt the course content to better suit their needs. Others have suggested that allowing the patient to choose the level of support they require would allow efficient allocation of clinician resources to where greater support is wanted, without affecting outcomes or adherence rates [50].

An important consideration related to patient adherence is the logical assumption that adherent patients will have better treatment outcomes than nonadherent patients, although the evidence has not always supported this assumption [51,52]. This study would suggest that additional telephone support does not have an effect on clinical outcomes; however, it did improve onboarding rates, thus increasing the number of participants who commenced the program. Web-based adherence is difficult to monitor because key therapy components are delivered on the web and practiced without the physical presence of a clinician [51]. For instance, a patient may practice the skills outlined in a program without logging in to the internet module. A more relevant way to measure adherence may be to look at intended use, defined as "the extent to which individuals *should* experience the content (of the intervention) to derive maximum benefit from the intervention, as defined or implied by its creators" [52]. This may explain why the patients who did not complete all modules in our study still showed significant improvements in their outcome measures. Further evaluation of the minimum amount of engagement with the program required to induce improvement may provide valuable insight. However, inherent difficulties lie in conducting such an analysis because those who stop engaging with treatments are also more likely to be lost to follow-up assessment.

As internet-delivered interventions evolve, the importance of various technical features in programs and their influence on adherence and outcomes need to be better understood. The mode of guidance, whether by email, text, phone, telehealth, program content, web design, multimedia format, web-based design features, or a hybrid of these features, may play a part in successful engagement of the individual [52]. Qualitative data would support this, with real-world Reboot Online service users anecdotally reporting a desire for more multimedia capability and web-based features. Program developers will need to consider these aspects of design that have an impact on usability and user experience during the development and ongoing evaluation of internet-delivered programs. Further evidence is needed to elucidate what effect each of these design components may have on user engagement and adherence and, in turn, whether design optimization strategies could be successfully used to improve treatment adherence and outcomes [20].

Studies investigating web-based CBT courses for pain conditions [24] report mixed results on whether adjunct guidance improves measures of pain catastrophizing, self-efficacy, and pain interference more than unguided internet interventions alone. Although our study showed significant improvements in measures of pain self-efficacy, kinesiophobia, pain interference, pain disability, and psychological distress over time, there was no significant difference in outcome measures between Reboot Online combined with telephone support and the usual Reboot Online intervention. This may indicate that adding telephone support may not add to the effect of the core Reboot Online program on clinical outcome measures.

The results presented here need to be considered within the context of a number of study limitations. Blinding of participants and the telephone support coach was not possible, introducing a possible risk of bias. Responder bias is another limitation noted because participants self-selected to participate in the trial and outcome data were lost from those participants who dropped out of the course. The power calculation was performed with reference to our primary outcome measure, which was adherence. The study was not powered formally for effectiveness on secondary outcomes and did not correct for multiple comparisons. Loss of follow-up data after treatment and at 3 months resulted in a smaller sample than estimated, which may have led to biased estimates or overestimates of treatment effects. Intention-to-treat analyses were conducted to enable inclusion of participants with suboptimal compliance into the data analysis, and linear mixed model analyses were selected, given that they remain robust in the presence of considerable missing data. Most of the baseline data were collected through patient-reported surveys, and thus the reliability of data are limited by the accuracy of participant recall and self-report. The subjective physical activity questionnaire may have been subject to notable reporting bias; an objective measure of physical activity (such as an activity-monitoring device) is needed in future evaluations' estimate of physical activity. Although outside the scope of this study, collection of more detailed data on direct intervention costs and opiate use could have facilitated more comprehensive evaluation of the benefits of the Reboot Online program. The study used 2 therapists (TG and JW) to conduct the telephone support, both senior clinicians in chronic pain and trained in the telephone coaching protocol. Although this allowed for consistent intervention during the study, it is unknown whether our findings would generalize to broader clinical settings or multiple clinicians. Finally, the study was conducted between September 2019 and November 2020. During this time period, there were significant and unprecedented local (drought and bushfires in Australia) and global events (COVID-19) that may have had an impact on the ability of participants to adhere and commit to the study as well as on measures of their well-being and mental and physical health.

Conclusions

Reboot Online offers an effective web-based intervention for chronic pain. Telephone support improves participants' registration, program commencement, and engagement in the early phase of the internet intervention; however, it did not seem to have an impact on overall course completion or efficacy. To maximize adherence to web-based interventions, clinician resources may be best used in the early phase of onboarding. Further research is warranted to gain better understanding of optimal guidance levels and models as well as program design components that will most effectively improve adherence to web-based interventions.

Abstract

Background: The treatment of insomnia with sleep medication causes problems such as long-term use, dependence, and significant economic losses, including medical expenses. Evidence-based lifestyle guidance is required to improve insomnia symptoms not only in person but also in easy-to-use web-based formats.

Objective: This study aims to clarify whether unguided internet-based cognitive behavioral therapy (ICBT) or the Three Good Things (TGT) exercise, both administered as self-help internet interventions without email support, could improve insomnia symptoms compared with a waiting list control (WLC) group.

Methods: A 4-week program was implemented, and participants were randomly allocated to 1 of the 3 groups. The primary outcome measure was the Pittsburgh Sleep Questionnaire (PSQI) score at 4 weeks compared with baseline.

Results: Of the 21,394 individuals invited to participate, 312 (1.46%) met the eligibility criteria and were randomly assigned to 1 of the 3 groups. Of these 312 individuals, 270 (86.5%; ICBT 79/270, 29.3%; TGT 88/270, 32.6%; and WLC 103/270, 38.1%) completed a postintervention survey at 4 and 8 weeks. The adjusted mean changes of the primary outcome measure (PSQI) in the ICBT (−1.56, 95% CI −2.52 to −0.59; P<.001) and TGT (−1.15, 95% CI −2.08 to −0.23; P=.002) groups at 4 weeks from baseline showed a significant improvement compared with the WLC group. The adjusted mean changes in the secondary outcome measures of sleep onset latency, total sleep time, Athens Insomnia Scale score, and Patient Health Questionnaire-9 score at 4 weeks from baseline, as well as in the PSQI at 8 weeks from baseline, showed significant improvement for ICBT. Moreover, total sleep time, Athens Insomnia Scale, and Patient Health Questionnaire-9 scores at 4 weeks from baseline showed a significant improvement in the TGT group compared with the WLC group.

Conclusions: A total of 4 weeks of unguided ICBT and TGT exercises improved insomnia.

Introduction

Background

Insomnia describes the inability to sleep, including difficulty falling asleep, difficulty staying asleep, difficulty sleeping, and early waking, despite an attempt to sleep at the right time and in the right environment. This condition reduces an individual's quality of life by causing various daytime dysfunctions, including sleepiness during the day [1]. Insomnia can be caused by a variety of factors, including changes in social life such as decreased interpersonal interaction and socializing, as well as mental and physical illnesses, decreased physical function, and physiological changes in the brain. Insomnia impairs daytime activity and triggers additional illnesses such as depression, lifestyle-related diseases, and cancer. Insomnia is a common complaint in adults, with 13.5% to 20.6% of the general population experiencing daytime sleepiness >3 times per week [2]. It has been reported that 14.9% of people in Japan have profound daytime sleepiness [3]. Another study found that 1 in 5 Japanese adults had sleep problems [4]. In Japan, the economic losses caused by sleep deprivation and insomnia have been estimated to be 15 trillion yen (US $8.67 billion) [5,6].

From the perspective of optimizing medical costs associated with lifestyle-related diseases, such as diabetes, hypertension, and hyperlipidemia, lifestyle guidance is increasingly being introduced as a complement to the use of medication. However, the evidence base to support the introduction of lifestyle guidance is lacking. The provision of face-to-face advice paired with an insomnia improvement program delivered as easy-to-use internet-based life guidance will likely reduce medical expenses.

Insomnia practice guidelines in the United States and Australia recommend cognitive behavioral therapy (CBT) as the first choice for the treatment of insomnia. In Japan, there are very few medical institutions that can provide CBT, and there are no barriers to prescribing psychotropic drugs outside of psychiatry and psychosomatic medicine. However, pharmacotherapy is associated with side effects such as dependence, tolerance, anterograde amnesia, muscle relaxant effects, carryover effects, and rebound insomnia. Furthermore, it increases the risk of double prescription and overdose and requires long-term treatment. However, the success of pharmacotherapy is limited. According to the Japanese Society of Sleep Studies guidelines, it is preferable to prioritize CBT over pharmacotherapy for insomnia.

CBT for insomnia is a treatment that focuses on anxiety and biased thinking about sleep and improves insomnia by reviewing an individual's lifestyle, existing anxiety and tension, and any thinking related to the maintenance of insomnia. Sleep hygiene instructions can provide important knowledge about sleep, including how to adjust living conditions so that good-quality sleep can be obtained, and practice measures for maintaining good-quality sleep throughout life. This study used internet-based CBT (ICBT) without email support to provide sleep hygiene guidance as a trial treatment. ICBT was paired with a self-help intervention as a form of noninvasive self-medication.

Positive psychology focuses on positive psychological traits such as happiness, optimism, and satisfaction with life and was developed by Seligman et al [7] of the University of Pennsylvania based on the reflection that traditional psychology was excessively focused on normalizing negative traits such as mental illness. Positive psychology is based on the idea of nurturing [7]. A typical method of positive psychology comprises the exercise of writing 3 good things every day before going to bed every night [7]. It is a simple diary-like exercise that involves listing 3 good things that happened that day and providing a written explanation of why those things happened. In this study, this exercise was called the Three Good Things (TGT) exercise.

ICBT has gained increasing attention as a possible treatment for improving insomnia, and many studies on ICBT have been conducted. ICBT provides web-based CBT and sleep hygiene guidance, simulating an ordinary CBT session (counseling) that is typically conducted by the patient and therapist face-to-face. With the approval of the Chiba University School of Medicine Hospital clinical trials ethics review board (approval number G27040), the combination of guided ICBT for insomnia and routine care (ie, usual care [UC]) has been shown to significantly reduce the Pittsburgh Sleep Quality Index (PSQI) score [8,9]. In a randomized controlled trial (RCT) of 23 patients with insomnia whose symptoms persisted even after taking sleep medications such as benzodiazepines, the adjusted mean change in total PSQI score from baseline to 6 weeks was −6.11 in the ICBT+UC group (n=11), which was significantly better than the 0.40 change seen in those who underwent UC alone (n=12; $P<.001$). In addition, a significant improvement was seen for the adjusted mean changes in PSQI score; sleep onset latency (SOL); sleep efficiency (SE); number of awakenings; and mean change in depression at 3, 6, and 12 weeks from baseline in the ICBT+UC group. No adverse events were reported.

Seligman et al [7] previously evaluated the effects of the TGT exercise in a RCT. According to that study, the group that performed this exercise daily for 1 week not only increased self-reported levels of happiness but also reported decreased depression compared with the control group, and the effect persisted after 6 months. To the best of our knowledge, no studies have examined whether the TGT exercise can reduce insomnia. However, recent reviews have shown that there is a correlation between positive emotions and sleep [10]. TGT may improve sleep by improving positive emotions.

Objectives

This study aims to determine the effectiveness of an unguided, web-based self-help intervention in reducing insomnia. Using an RCT design, a nonclinical population of adults with insomnia

was allocated to one of three groups: (1) the ICBT group, (2) the TGT group, and (3) the waitlist group. It is hypothesized that unguided ICBT and TGT would result in higher quality sleep in the treatment groups than in the waitlist group.

Methods

Trial Design

We report this RCT trial in accordance with the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) version 1.6 checklist (Multimedia Appendix 1).

This study comprised an exploratory, parallel-group (3 groups), randomized, open-label, controlled study, incorporating a nonintervention group (waiting list control [WLC]). The registration of the participants was started in February 2019.

Participants and Recruitment

An email was sent to the registered monitors owned by the internet research company that commissioned the research, and a preliminary survey was conducted on the internet in relation to the inclusion and exclusion criteria given in the following sections, after which informed consent was obtained.

Potential participants were required to meet all the following inclusion criteria at the time of the preliminary survey: (1) aged 20 to 70 years (regardless of sex); (2) patients with mild or severe sleep disorders, who scored ≥6 on the Athens Insomnia Scale (AIS) and ≥6 on the PSQI; (3) sleep disorder occurring at least three nights per week and lasting for at least 3 months; (4) access to internet use with PCs, smartphones, and tablets; and (5) understood the explanations in Japanese and freely provided web-based consent.

Exclusion criteria of the study included (1) those with moderate or severe anxiety symptoms, scoring ≥10 on the Generalized Anxiety Disorder-7 (GAD-7) questionnaire; (2) those with moderate or severe depression symptoms, scoring ≥10 points on the Patient Health Questionnaire-9 (PHQ-9); (3) the confirmed presence of alcohol or drug dependence, diagnosed by a medical institution within the past year, excluding tobacco smokers; (4) suicidal thoughts, with a score of ≥2 in the Q9 part of the PHQ-9; (5) the confirmed diagnosis of cerebral organic diseases such as sleep apnea syndrome, restless leg syndrome, epilepsy, dementia, or cerebrovascular disease; (6) the confirmed diagnosis of a severe progressive physical illness, such as cancer or heart failure; (7) the use of pharmacotherapy for mental disorders, including insomnia symptoms; and (8) night shift work between 8 PM and 2 AM.

Individuals who met the above conditions and provided consent were enrolled as study participants. This study excluded patients commonly treated with pharmacotherapy for insomnia.

Case Registration and Allocation Methods

Case registration was performed via the trial website. Among the registered members (candidate participants) of monitors owned by the internet research company, those who met the conditions were automatically assigned participant identification codes when they accessed the servers. Members voluntarily underwent a preliminary survey after explanation and agreement, following the distribution of the recruitment materials. In the first preliminary survey, AIS, PSQI, GAD-7, and PHQ-9 were administered to select and screen participants for inclusion. Only those who met the inclusion criteria and did not meet any of the exclusion criteria were able to proceed to the next preliminary survey. The second preliminary survey was conducted 2 weeks after the first preliminary survey and contained the same content as the first survey. Only those who met the inclusion criteria and did not meet any of the exclusion criteria proceeded to take part in the study. Responses from the second preliminary survey were used in the analysis as baseline values before the intervention. After the participants were randomly assigned, the method of accessing the intervention program assigned to each participant was provided by email.

Randomization

Allocation modifiers included baseline PSQI scores (≥12 and ≤11) and gender (male and female).

Intervention

Intervention Schedule and Methods

Participants were randomly assigned to 1 of the 3 groups. The study period was 4 weeks; thus, the ICBT group underwent an unguided ICBT program for 4 weeks, the TGT group underwent a TGT exercise program for 4 weeks, and the nonintervention group (WLC) waited for 4 weeks without an intervention. They then received access to their assigned unguided ICBT program and the TGT exercise program for 4 weeks, 7 times a week for 15 to 20 minutes each time.

The intervention programs comprised the following two types: unguided ICBT program and TGT program.

Unguided ICBT Program

We encouraged participants to take part in the unguided ICBT program for 4 weeks. Participants accessed the ICBT site and performed the following tasks autonomously:

1. Week 1 session: keeping a sleep diary (understanding the significance of the sleep diary and how to write it)
2. Week 2 session: changing behavior (improving behavioral habits that maintain insomnia, using stimulus control)
3. Week 3 session: capturing thoughts (reconstructing cognition related to sleep using the column method)
4. Week 4 session: changing sleep time (adjusting sleep schedule using the sleep restriction method)

TGT Program

Participants were encouraged to participate in the TGT exercise for 4 weeks. The participants who accessed the site received the prompt by email and autonomously filled out the 3 good things on that day. An explanation of the methods of the TGT exercise is provided elsewhere by Seligman et al [7] and Seligman [11].

Measures

Evaluation Items

The primary outcome was the change in PSQI scores from baseline to the postintervention survey at 4 weeks. The

secondary outcome was the change in PSQI scores from baseline to the postintervention survey at 8 weeks and changes in SOL, total sleep time (TST), SE, AIS, GAD-7, PHQ-9, and Center for Epidemiologic Studies–Depression Scale (CES-D) positive items only from baseline to the first and second postintervention surveys at 4 and 8 weeks. Web-based assessments were also administered.

PSQI Evaluation

The PSQI is a self-administered questionnaire for evaluating sleep and sleep quality [12]. Eighteen questions evaluated seven factors: sleep quality, sleep onset time, sleep time, SE, difficulty sleeping, use of sleep medication, and drowsiness during the day that hinders daily life. A total of 7 factors (0-3 points) were summed to calculate the total score (0-21 points). The higher the score, the greater the sleep impairment. A Japanese version has also been developed, with the cutoff set at 6 points [13].

AIS Evaluation

The AIS is a self-administered questionnaire for assessing the severity of insomnia [14]. It comprises eight items: sleep, midnight awakening, early morning awakening, TST, overall sleep quality, daytime satisfaction, physical and mental daytime activity, and daytime sleepiness. A total of 8 items (0-3 points) were summed to calculate the total score (0-24 points). A Japanese version has also been developed, with the cutoff set at 6 points [15].

GAD-7 Evaluation

The GAD-7 is a self-administered questionnaire for evaluating generalized anxiety disorders [16]. It comprises 7 items, and covers the 2 weeks immediately before the administration of the test. The scoring system is as follows: *No at all: 0 points*, *Several days: 1 point*, *More than half: 2 points*, and *Almost every day: 3 points*. The total score is calculated from 0 to 21 points. A Japanese version has also been developed, with 0 to 4 points suggesting no generalized anxiety disorder, 5 to 9 points representing mild generalized anxiety disorder, 10 to 14 representing moderate generalized anxiety disorder, and 15 to 21 indicating severe generalized anxiety disorder [17].

PHQ-9 Evaluation

The PHQ-9 is a self-administered questionnaire for evaluating major depressive disorder [18]. It comprises 9 items and covers 2 weeks immediately before administration of the test. The scoring system is as follows: *No at all: 0 points*, *Several days: 1 point*, *Half or more: 2 points*, and *Almost every day: 3 points*. The total score is calculated from 0 to 27 points. A Japanese version has also been developed, with 0 to 4 points suggesting that the individual is not depressed, 5 to 9 points suggesting mild depression, 10 to 14 points suggesting moderate depression, 15 to 19 points suggesting moderate to severe depression, and 20 to 27 points suggesting severe depression [19].

CES-D Evaluation

The CES-D is a self-administered questionnaire for assessing depression [20]. It comprises 20 items about mood and physical condition covering the past week using a 4-point scale ranging from 0 (not at all) to 3 (over 5 days). In this study, 16 negative items were not used, and only positive items were used. The positive items comprised four statements: “I think I have the same ability as other people,” “I can think positively about the future,” “I can enjoy my life without complaints,” and “I enjoy every day.” The total score is calculated from 0 to 12 points. A Japanese version has also been developed, with a higher total score indicating a higher degree of positive emotions [21].

Statistical Analysis

Overview

All participants who enrolled in this study, responded to the intervention program at least once after randomization, and had efficacy data were the most significant population for full analysis set (FAS). However, participants for whom baseline data could not be obtained and those who violated the dominant protocol (eg, violating the inclusion criteria or exclusion criteria and incorrect assignment to the intervention program) were excluded.

Participants selected from the FAS and those meeting the following criteria were selected as the target population per-protocol set (PPS) that complied with the study protocol: (1) completed at least 75% of the intervention program, (2) had available measurements of critical variables, and (3) had no major test plan violation such as selection criteria violation, exclusion criteria violation, or incorrect assignment to an intervention program.

The sample size was based on a previous study by van Straten et al [22], which indicated that the estimated difference in changes of PSQI scores from baseline was approximately 3.5. Assuming a group difference of 3.5 (SD 10.0) points, 66 participants per group provided 80% power to detect a difference in PSQI scores among the WLC, ICBT, and TGT groups at a 5% significance level.

Analysis of Participant Background

The distribution of participant background data and summary statistics for each analysis population were calculated for each group. For nominal variables, the frequency and proportion of categories have been shown for each group. For continuous variables, summary statistics (number of cases, mean, SD, minimum, median, and maximum) were calculated for each group. Pearson chi-square test was used for nominal variables, except when ≥20% of the cells had an expected frequency <5 (when Fisher exact test was used). 2-tailed Student *t* test, or Wilcoxon rank-sum test, were also used. The significance level was set at 5% for both sides.

Analysis of Effectiveness

The primary outcome of the efficacy of the interventions was the PSQI score, an index for improving insomnia. The primary purpose of this study was to examine the superiority of the ICBT and TGT groups in improving the insomnia status of nonclinical cases of insomnia compared with the WLC group. We estimated the difference in PSQI score change between the test and control groups and the 95% 2-sided CI. To test the null hypothesis that the changes in PSQI scores in both groups were equal in the primary analysis, covariance analysis was performed using the assignment adjustment factor as a covariate. The allocation adjustment factors were the PSQI score at the time of

registration and gender. The significance level of the test was set at 5% (2-sided). Adjustment of multiplicity was performed using the Dunnett method, as a pairwise comparison of the 2 groups was performed for the control group.

The secondary evaluation items of effectiveness were analyzed to supplement the primary analysis results. No adjustment for multiplicity was made in the analysis of the secondary efficacy outcomes. The significance level of the hypothesis test was set at 5% (2-sided), and the two-sided 95% CI was calculated.

Statement of Ethics

This study was approved by the clinical trials ethics review board of the Chiba University Hospital (registration number G30022) and was registered as a clinical trial (UMIN000034927). A document explaining consent was presented to the participants on a webpage, accompanied by a verbal explanation as part of a video animation by the principal investigator. After viewing these materials, individuals who freely agreed to participate were recruited into the study.

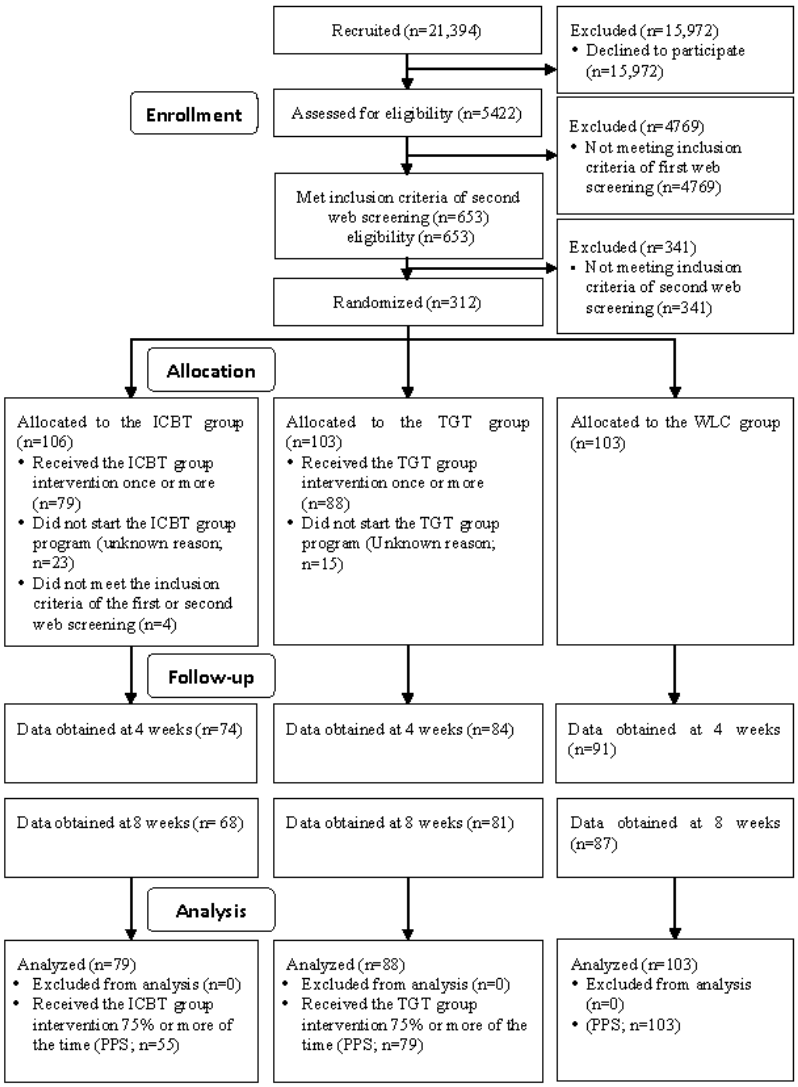
The authors assert that all procedures contributing to this work comply with the ethical standards of the relevant national and institutional committees on human experimentation and with the Helsinki Declaration of 1975, as revised in 2008.

Results

Trial Flow

Figure 1 shows the research flow based on the CONSORT (Consolidated Standards of Reporting Trials) guidelines. Of the 21,394 individuals contacted through the internet research company, consent to participate in the study was obtained from 312 (1.46%) individuals who met the eligibility criteria and were randomly assigned to the ICBT, TGT, or WLC group. Of the 106 people assigned to ICBT, 23 (21.7%) did not start the ICBT program at least once, and 4 (3.8%) who performed the ICBT program at least once were classified as trial deviations, leaving 79 (74.5%) individuals with a FAS.

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) diagram of participant flow throughout the study. ICBT: internet-based cognitive behavioral therapy; PPS: per-protocol set; TGT: Three Good Things; WLC: waiting list control.



For details of the deviation related to PSQI, there was an error in the formula set by the internet survey company that conducted the web questionnaire, and the correct score was ≤5; however, it was judged to be ≥6 by incorrect calculation. Therefore, of

the 312 individuals, 4 (1.3%) individuals who had initially been selected as participants and who should not have been selected underwent the ICBT program; these individuals were reported as deviations to the Chiba University Hospital clinical trials ethics review committee and accepted as such.

Separately, there was an error in the formula used by the internet survey company that conducted the web questionnaire. In the error, the correct PSQI total score was ≥6; however, it was judged incorrectly to be ≤5. The correct PHQ-9 total score should have been calculated from the 1st to 9th items (the 10th item should have been excluded); however, the internet survey company that conducted the web questionnaire mistakenly calculated from the 1st to the 10th item. In addition, the correct GAD-7 total score should have been calculated from the first to seventh items (the eighth item was not added); however, the internet survey company that conducted the web questionnaire mistakenly calculated from the first to eighth items. For these reasons, of the 21,394 individuals, 83 (0.39%) were not selected in the first screening, and 25 (0.12%) were not selected in the second screening.

Of the 106 participants assigned to the ICBT group, 74 (69.8%) provided data at 4 weeks, 68 (64.2%) provided data at 8 weeks, and 55 (51.9%) had an attendance of ≥75% during the ICBT program; thus, the PPS was 55. Of the 103 participants assigned to the TGT group, 15 (14.6%) were excluded who did not start the TGT program at least once; thus, the FAS was 88. In the TGT group, of the 103 participants, 84 (79.2%) provided data at 4 weeks, and 81 (78.6%) provided data at 8 weeks. Approximately 76.7% (79/103) of participants had an attendance of ≥75% during the TGT program; thus, the PPS was 79.

Of the 312 participants, 103 (33%) were assigned to the WLC group; thus, the FAS score for this group was 103. Data were obtained successfully for 88.3% (91/103) of these participants at 4 weeks and for 84.5% (87/103) of participants at 8 weeks; thus, the PPS was 103. The registration of participants started in February 2019, and the follow-up ended in May 2019.

There were no adverse events. When adverse events occurred for participants, we asked them to report the adverse events by email. However, there were no reports.

Participant Characteristics

Table 1 shows the characteristics of the participants at baseline. Female participants comprised 41.5% (112/270; ICBT group 32/79, 41%; TGT group 39/88, 44%; and WLC group 41/103, 39.8%) of the study population, with a mean age of 50.4 (SD 10.8; ICBT group: 49.8, SD 11.1; TGT group: 50.5, SD 11.0; and WLC group: 51.0, SD 10.4) years. There were no significant differences in sex, age, marital status, educational history, or employment status among the 3 groups.

Table 2 presents the baseline data for the primary and secondary outcome measures. There were no significant differences among the 3 groups for the PSQI, AIS, GAD-7, or PHQ-9 scores.

Table 1. Participant characteristics (N=270).

Characteristics	ICBT[a] group (n=79)	TGT[b] group (n=88)	WLC[c] group (n=103)	*P* value
Sex , n (%)				.81
Female	32 (40.5)	39 (44.3)	41 (39.8)	
Male	47 (59.5)	49 (55.7)	62 (60.2)	
Age (years), mean (SD)	49.8 (11.1)	50.5 (11.0)	51.0 (10.4)	.78
Marriage, n (%)				.26

Intervention Effects

Primary Outcome

Figure 2 and Table 3 show the changes in the primary outcome score (PSQI) in each group, and Table 4 shows the comparison of the changes in the primary outcome PSQI between the intervention and control groups. At week 4, the adjusted mean change from baseline in the ICBT group compared with the WLC group was −1.56 (95% CI −2.52 to −0.59; *P*<.001), and the adjusted mean change from baseline in the TGT group compared with the WLC group was −1.15 (95% CI −2.08 to −0.23; *P*=.002), indicating that both the ICBT and TGT groups had a significant reduction in their PSQI scores compared with the WLC group.

Figure 2. Means and SDs (raw data) for the primary outcome and improvement in the Pittsburgh Sleep Quality Index (PSQI) score. ICBT: internet-based cognitive behavioral therapy; TGT: Three Good Things; WLC: waiting list control.

[a]Dunnett–Hsu.

[b]PSQI: Pittsburgh Sleep Quality Index.

[c]ICBT: internet-based cognitive behavioral therapy.

[d]WLC: waiting list control.

[e]TGT: Three Good Things.

[f]SOL: sleep onset latency.

[g]TST: total sleep time.

[h]AIS: Athens Insomnia Scale.

[i]GAD-7: Generalized Anxiety Disorder-7.

[j]PHQ-9: Patient Health Questionnaire-9.

[k]CES-D: Center for Epidemiologic Studies–Depression Scale.

At 4 weeks, the adjusted mean change from baseline in the ICBT group compared with the WLC group was −11.73 for SOL (95% CI −20.36 to −3.10; *P*=.003), 17.50 for TST (95% CI 15.17-50.98; *P*<.001), −1.62 for AIS (95% CI −2.85 to −0.39; *P*=.004), and −1.70 for PHQ-9 (95% CI −2.90 to −0.51; *P*=.002). There was a significant improvement in the ICBT group compared with the WLC group in SOL, TST, AIS, and PHQ-9 scores at 4 weeks.

At 4 weeks, the adjusted mean change from baseline in the TGT group compared with the WLC group was 20.70 for TST (95% CI 3.51-37.89; *P*=.01), −2.27 for AIS (95% CI −3.46 to −1.08; *P*<.001), and −1.78 for PHQ-9 (95% CI −2.94 to −0.63; *P*=.001). A significant improvement in the TGT group compared with the WLC group in TST, AIS, and PHQ-9 scores was observed at 4 weeks.

At 8 weeks, the adjusted mean change from baseline in the ICBT group compared with the WLC group was −1.09 for PSQI (95% CI −2.07 to −0.12; *P*=.02). There was a significant improvement in the ICBT group compared with the WLC group in PSQI at 8 weeks.

At 8 weeks, the adjusted mean change from baseline in the TGT group compared with the WLC group did not show a significant difference.

Effectiveness of the Intervention

Table 6 shows the standardized change from baseline to the postintervention survey (at 4 and 8 weeks). Immediately after the intervention, at 4 weeks, the primary outcome effect size (Hedge g) for the PSQI was 0.81 in the ICBT group (95% CI 6.90-8.20) and 0.76 in the TGT group (95% CI 7.06-8.20).

Table 6. Standardized changes of baseline to postintervention outcomes.

[a]Hedges *g* (effect size; 95% CI lower limit to upper limit of each outcome).

[b]Effect size values for baseline were not applicable; hence, only 95% CI values have been reported.

[c]ICBT: internet-based cognitive behavioral therapy.

[d]TGT: Three Good Things.

[e]WLC: waiting list control.

[f]PSQI: Pittsburgh Sleep Quality Index.

[g]SOL: sleep onset latency.

[h]TST: total sleep time.

[i]AIS: Athens Insomnia Scale.

[j]GAD-7: Generalized Anxiety Disorder-7.

[k]PHQ-9: Patient Health Questionnaire-9.

[l]CES-D: Center for Epidemiologic Studies–Depression Scale.

The secondary outcome effect sizes (Hedge g) were as follows: 0.72 for SOL in the ICBT group (95% CI 18.18-28.63), 0.68 for TST in the ICBT group (95% CI of 346.87-374.80), 0.51 for SE in the ICBT group (95% CI 86.26-91.87) and 0.53 in the TGT group (95% CI 88.73-92.64), and 0.67 for AIS in the ICBT group (95% CI 7.40-8.87) and 0.84 in the TGT group (95% CI 6.49-8.08).

After the follow-up period, at 8 weeks, the secondary outcome effect sizes (Hedges *g*) were as follows: 0.70 for PSQI in the ICBT group (95% CI 6.96-8.48) and 0.52 in the TGT group (95% CI 7.59-8.75), 0.51 for SOL in the ICBT group (95% CI 21.50-34.30), 0.59 for TST in the ICBT group (95% CI 340.71-371.09), 0.60 for SE in the ICBT group (95% CI 87.52-92.07), and 0.50 for AIS in the ICBT group (95% CI 7.53-9.41).

Discussion

Principal Findings

The results of this study suggest that a self-help internet intervention without email support is effective as a noninvasive self-medication for adults with insomnia. The ICBT group showed a significant change of −6.11 in the PSQI score. The participant characteristics of this study differed significantly from those of similar previous studies. A previous study by van Straten et al [22] showed the efficacy of guided ICBT using an RCT design, in which 1500 patients with insomnia were invited by email, and 118 patients were assigned to the ICBT group (n=59) and a WLC group (n=59). However, the reported baseline mean PSQI score in the ICBT group in that study was relatively severe (12.4, SD 2.1). The mean change in PSQI scores in the ICBT group was −3.5, and in the WLC group it was −0.1. Our previous study of ICBT guided by email support reported a severe baseline PSQI mean score of 13.5 (SD 2.7); furthermore, participants had persistent symptoms despite taking sleep medications such as benzodiazepines [9].

In this study, the unguided ICBT group showed a change of −2.19, the TGT group showed a change of −1.79, and the WLC group showed a change of −0.64; the mean change in PSQI scores was smaller than those reported by van Straten et al [22] and Sato et al [9]. This could be because of the baseline average score of PSQI being 9.8, which indicates relatively mild insomnia. In addition, given that the ICBT was unguided, participant motivation to continue in this study may not have been well-supported.

The TGT group showed a significant decrease in PSQI scores compared with the WLC group only at the end of the program, that is, at the 4-week time point. To the best of our knowledge, no previous studies have examined the effects of TGT on insomnia through an RCT. However, as no significant improvement in positive emotions (indicated by the actual items on the CES-D) was observed in the TGT group, this casts doubt on the existence of a mechanism for the improvement of insomnia through the improvement of positive emotions. Contrary to previous studies, the TGT exercise did not lead to the improvement of positive emotions, and thus, it is unclear whether TGT really contributes to the improvement of happiness.

In this study, comparing the ICBT group and the TGT group was not the original purpose; however, the number of participants who received >75% of the intervention in the ICBT group was 70% (55/79) of participants compared with 90% (79/88) of participants who received >75% of the intervention in the TGT group. This could have been because of difficulties with regular participation in the ICBT program.

At the 4- and 8-week follow-ups, the ICBT group showed a significant improvement in PSQI scores over the WLC group, whereas the TGT group did not show a significant improvement over the WLC group. Therefore, ICBT could have longer-term effectiveness. If further research shows that ICBT results in sustained effects on insomnia, and TGT is easier to participate in more regularly, it may be necessary to consider an unguided intervention that combines both ICBT and TGT to achieve optimal outcomes.

Limitations

In this study, there were errors in the calculation set by the internet research company that conducted the web questionnaire for PSQI, PHQ-9, and GAD-7 scores, which may have affected the eligible participants. In future studies, the distribution of inclusion and exclusion criteria should be carefully monitored to avoid similar mistakes.

Some participants in the ICBT and TGT groups did not participate more than once. However, in the WLC group, all participants were included in the final analysis. To ensure consistency with the ICBT and TGT groups in future research, it will be necessary to select those who have participated at least once in the WLC group for inclusion in the final analysis, or alternatively a placebo sham program could be implemented.

Conclusions

In conclusion, this RCT provided evidence that 4 weeks of unguided ICBT and TGT exercise for adults with insomnia, both administered as self-help internet interventions without email support, may improve insomnia symptoms compared with the WLC group. The findings also suggest that the effects of ICBT may last longer than TGT, whereas TGT may be easier to participate in more regularly. However, this study experienced errors during the selection process. Further research is warranted to examine the effectiveness of a combined intervention of ICBT and TGT for insomnia.

Acknowledgments

The authors thank all the participants for their valuable contributions to this study. This study was funded by the Research Institute of Economy, Trade, and Industry (RIETI), Japan, and supported, in part, by the Grant-in-Aid for Scientific Research (B) from the Japan Society for the Promotion of Science (grant KAKENHI 17H04091 to ES), the Grant-in-Aid for Scientific Research (C) from Japan Society for the Promotion of Science (grant KAKENHI 18K10716 to DS), and grants from the Chiba Foundation for Health Promotion and Disease Prevention. The RIETI was involved in the conduct of the study through its contact with the market research company. The RIETI had no role in the study design, data analysis, decision to publish, or preparation of the manuscript.

Authors' Contributions

DS, YS, CS, YH, SO, MH, and ES contributed to the design of the study. RT performed statistical analysis. DS, YS, and ES interpreted the data and drafted the manuscript. All authors have approved the manuscript.

Conflicts of Interest

SD and ES have developed the web-based treatment but have no commercial interests.

Abstract

Background: Cognitive impairments are features of many psychiatric disorders and affect functioning. A barrier to cognitive research on psychiatric disorders is the lack of large cross-disorder data sets. However, the collection of cognitive data can be logistically challenging and expensive. Web-based collection may be an alternative; however, little is known about who does and does not complete web-based cognitive assessments for psychiatric research.

Objective: The aims of this study are to develop a web-based cognitive battery for use in psychiatric research, validate the battery against the Measurement and Treatment Research to Improve Cognition in Schizophrenia (MATRICS) Consensus Cognitive Battery, and compare the characteristics of the participants who chose to take part with those of the individuals who did not participate.

Methods: Tasks were developed by The Many Brains Project and selected to measure the domains specified by the MATRICS initiative. We undertook a cross-validation study of 65 participants with schizophrenia, bipolar disorder, depression, or no history of psychiatric disorders to compare the web-based tasks with the MATRICS Consensus Cognitive Battery. Following validation, we invited participants from 2 large ongoing genetic studies, which recruited participants with psychiatric disorders to complete the battery and evaluated the demographic and clinical characteristics of those who took part.

Results: Correlations between web-based and MATRICS tasks ranged between 0.26 and 0.73. Of the 961 participants, 887 (92.3%) completed at least one web-based task, and 644 (67%) completed all tasks, indicating adequate completion rates. Predictors of web-based participation included being female (odds ratio [OR] 1.3, 95% CI 1.07-1.58), ethnicity other than White European (OR 0.66, 95% CI 0.46-0.96), higher levels of education (OR 1.19, 95% CI 1.11-1.29), diagnosis of an eating disorder (OR 2.17, 95% CI 1.17-4) or depression and anxiety (OR 5.12, 95% CI 3.38-7.83), and absence of a diagnosis of schizophrenia (OR 0.59, 95% CI 0.35-0.94). Lower performance on the battery was associated with poorer functioning (B=−1.76, SE 0.26; P<.001).

Conclusions: Our findings offer valuable insights into the advantages and disadvantages of testing cognitive function remotely for mental health research.

Introduction

Background

Cognitive impairments are core features of many psychiatric disorders [1-3], persist during remission [2,3], are not alleviated by current treatments [4-6], and are associated with poor functional outcomes [7,8]. Existing cognitive research on psychiatric disorders is limited by relatively small sample sizes, as collecting cognitive data can be labor intensive, and the use of existing cognitive batteries can be expensive given licensing restrictions. A potential solution to this is to use web-based data

collection methods, which may be an effective way of acquiring large amounts of cognitive data using minimal resources. Data can be collected remotely using specially designed tasks that are administered via the internet and accessed using the participants' own devices and web browsers in an unsupervised setting, such as the participants' homes. The advantages of web-based methods include (1) relatively inexpensive costs per participant [9,10], (2) automatic data entry that limits errors [10], (3) ability to recruit from locations that would normally be out of reach [11], and (4) promotion of research to the public [11].

To date, studies comparing web-based and laboratory-based cognitive tasks have reported high correlations, few systematic differences between the assessments, and good internal reliability of web-based tasks [9,12-15]. One such study is the global citizen science project, *TestMyBrain*, which has collected cognitive data via the internet on >2 million volunteers around the world. Analysis of the data collected from the website compared with data collected using the same tasks under supervision in a research laboratory showed few differences in mean performance, variance, and internal reliability between the 2 sets of tasks [12]. A recent study of UK Biobank (UKB) participants demonstrated adequate concurrent validity between 11 cognitive assessments administered without supervision and 11 previously validated tests from the published literature (correlations between 0.22 and 0.83) [16]. The highest correlation (r=0.83) was observed between versions of the same task—the National Institutes of Health Toolbox Picture Vocabulary Test—whereas the lowest correlations were observed between tasks with differing methodologies (UKB Pairs Matching test and Wechsler Memory Scale-IV Designs Total; r=−0.33) or tasks with low levels of performance variance (UKB Prospective Memory test and Rivermead Behavioral Memory Test Appointments; r=0.22). Similar results were reported in a study comparing the Amsterdam Cognition Scan with a traditional test battery (correlations ranged between 0.36 and 0.78), where lower correlations were observed in tasks that had differing designs [15]. Another study compared identical Cambridge Neuropsychological Test Automated Battery tasks administered unsupervised via the internet and administered in person at a research facility (r=0.39-0.73) [14]. Correlations were similar to previously reported test–retest reliabilities for the tasks, although it was noted that tasks with a reaction time component were less comparable across the different administration settings.

To date, studies have evaluated the use of web-based cognitive assessments in healthy population samples. Therefore, questions remain about whether web-based tasks conducted in an unsupervised setting without a researcher present are suitable for research on individuals with psychiatric disorders. This is a particularly important question, given that these individuals are more likely to have moderate to severe cognitive impairments. An issue is participation bias, as web-based studies may exclude individuals who are less computer literate or who do not have internet access, such as older adults, those with lower incomes or education levels, or those with more severe psychiatric disorders. For example, a study that used Facebook to recruit participants for a mental health survey found that the participants were younger, more likely to be female, more educated, and more likely to be English speakers compared with the national averages taken from census data and a population study [17].

Objectives

This study has 2 aims. Our first aim is to develop and validate a web-based cognitive battery for use in psychiatric research. Our second aim is to determine whether web-based cognitive testing is a suitable method for large-scale mental health research. By offering participation in a web-based cognitive study to those who had already been recruited into a cohort of individuals with mental health conditions, we will be able to identify the characteristics of those who chose to take part and compare them with those who did not. This study is presented in two parts: (1) validation of the web-based battery and (2) expansion of the web-based battery via recruitment of a large cross-disorder sample.

Methods

Participants

Participants from 2 studies conducted within the Medical Research Council Centre for Neuropsychiatric Genetics and Genomics at Cardiff University were invited to take part: (1) the National Centre for Mental Health (NCMH) cohort study [18] and (2) the Cognition in Mood, Psychosis, and Schizophrenia Study (CoMPaSS) [19]. Diagnoses were ascertained through either self-report in the NCMH or through a clinical interview in the CoMPaSS (Schedule for Clinical Assessment in Neuropsychiatry [20]). In the NCMH, participants were asked the following question: "Has a doctor or health professional ever told you that you have any of the following diagnoses?" Participants were given a list of diagnoses and asked to indicate all diagnoses that applied, the diagnosis they considered to be their primary diagnosis, and whether their clinical team would agree. Both studies included confirmation of consent from participants to be approached for other research within the Centre and consent for medical records to be accessed to obtain information regarding diagnosis and other clinical details. The full details of these studies can be found in Multimedia Appendix 1 [12,19-39]. All stages of the web-based study received ethical approval from the School of Medicine research ethics committee at Cardiff University (reference number 15/64), and each parent study had National Health Service ethical approval (NCMH reference number: 16/WA/0323; CoMPaSS reference number: 07/WSE03/110). The participants indicated their consent on the web by ticking a box at the bottom of the information page. We did not collect any identifiable information about the participants during the assessments; the participants' data were pseudonymized and linked with an ID number. The assessment websites complied with current UK data security best practice guidelines in consultation with the Information Technology Systems Security Team and Research Governance Officers at Cardiff University.

Neuropsychological Assessments

Web-Based Battery

All tasks were selected from and hosted on The Many Brains Project's web-based cognitive testing platform, TestMyBrain [12,40]. We selected the tasks to assess, as closely as possible, the domains outlined by the National Institute of Mental Health–Measurement and Treatment Research to Improve Cognition in Schizophrenia (MATRICS) initiative [41]. We were able to include a formally equivalent web-based version of digit symbol coding. However, it was not possible to select formally equivalent tasks for the remaining domains because of a lack of availability of web-based versions. In addition to these domains, we included a measure of crystallized intelligence and a measure of risk-taking propensity. The final battery included 9 tasks (see Table 1 for domains, tasks, and equivalent MATRICS Consensus Cognitive Battery [MCCB] tasks). Full descriptions of the tasks can be found in Multimedia Appendix 1. The total administration time was approximately 45 to 50 minutes.

The tests were designed to run on desktop and laptop computers, touchscreen tablet computers, and smartphones. The Many Brains Project developed the cognitive tasks and hosted them on their secure TestMyBrain server, which could be accessed using a study-specific website link. The assessments were loaded in the participant's internet browser, and the data were stored locally during each task. At the end of each task, the data were encrypted and uploaded to a secure server.

Table 1. Web-based and Measurement and Treatment Research to Improve Cognition in Schizophrenia Consensus Cognitive Battery (MCCB) tasks[a].

Domain	MCCB task	Web-based task
Speed of processing	BACS[b]: digit symbol coding	Digit symbol coding
Social cognition	MSCEIT[c]: Managing Emotions	Morphed emotion identification
Verbal learning	Hopkins Verbal Learning Test–Revised	Verbal paired associates
Working memory	Letter–number sequencing	Backward digit span
Visual learning	Brief Visuospatial Memory Test–Revised	Hartshorne visual working memory
Reasoning and problem solving	NAB[d]: Mazes	Matrix Reasoning Test
Strategic risk taking[e]	N/A[f]	Balloon Analogue Risk Task
Attention	Continuous Performance Test–Identical Pairs	Multiple object tracking
Premorbid IQ[g]	National Adult Reading Test–Revised	Vocabulary

[a]Web-based tasks are shown in order of administration.

[b]BACS: Brief Assessment of Cognition in Schizophrenia.

[c]MSCEIT: Mayer–Salovey–Caruso Emotional Intelligence Test.

[d]NAB: Neuropsychological Assessment Battery.

[e]No equivalent offline measure was included.

[f]N/A: not applicable.

[g]No equivalent MCCB task; thus, the National Adult Reading Test was included for comparison.

Reference Battery

The MCCB was administered to participants as the reference battery in part 1 of the study to validate the web-based battery. The MCCB was created through the MATRICS initiative with the explicit aim of developing a consensus cognitive battery that could be used in schizophrenia research. The selection of tasks for the MCCB was driven by expert panels; consultations with scientists; evaluations of factor-analytic studies to identify relevant domains; and assessments of the psychometric properties, practicality, and tolerability of existing cognitive tasks [41,42]. The final MCCB comprises 10 tasks assessing 7 domains of cognition. In addition to the MCCB, the National Adult Reading Test (NART) was administered as a measure of premorbid IQ [21]. The NART is a measure of vocabulary that comprises 50 irregularly spelled words that the participant must read aloud, and it was included as a reference test for the web-based vocabulary test.

Clinical and Demographic Variables

In addition to the cognitive assessment, participants answered questions about current diagnosis, medication, education, occupation, and current mood. The 12-item self-report version of the World Health Organization Disability Assessment Schedule Version 2 (WHODAS 2.0) was included as a measure of functioning [43]. The web-based questionnaire also included the Hospital Anxiety and Depression Scale [44] and the Altman Self-Rating Mania Scale [45]. Data on lifetime diagnosis, age of onset, and hospital admissions were obtained from the parent studies, CoMPaSS and NCMH (Multimedia Appendix 1).

Part 1: Validation Study

Participants

Participants with major depressive disorder (15/65, 23%), bipolar disorder (type 1: 11/65, 17%; type 2: 5/65, 8%), or schizophrenia (15/65, 23%), as well as healthy controls (19/65, 29%) were recruited for the validation study. We selected these 3 diagnostic groups based on extensive research establishing

the characteristics of cognitive performance of participants with each of these disorders using offline, traditional cognitive testing. For this study, we decided upon a conservative definition of depression that required a reported diagnosis and previous treatment with at least one antidepressant medication. This definition has been used in a study using self-reported measures of depression in the UKB [46]. Informed consent was obtained at both stages, in writing before administration of the MCCB and on the web before completing the web-based cognitive battery, and the participants were reimbursed for their participation.

Study Design

The participants were asked to complete two cognitive batteries on consecutive days: (1) the MCCB and the NART [21] and (2) the web-based battery (Table 1). A trained researcher administered the MCCB in a supervised setting on the first day, and then the participants were asked to complete the web-based battery unsupervised on the second day. The order of completion was not counterbalanced for practical reasons. First, some participants from the NCMH were recruited prospectively by completing the MCCB with a researcher immediately after completing the NCMH assessment; therefore, we could not randomly assign the order of completion. Second, it would have been difficult to ensure that the participants assigned to complete the web-based part first did so before their appointment as they were not supervised. The participants were asked to return a feedback questionnaire on completion of the study. They rated the overall web-based battery on enjoyment, duration, and difficulty and rated the clarity of the given instructions and information. They named the tasks that they liked the most and the least. They were also asked to provide information on any technical difficulties they experienced.

Data Analysis

All statistical analyses were conducted using R (version 3.3.0; R Foundation for Statistical Computing). Convergent validity was examined by conducting correlations between the MCCB and web-based tasks that assessed equivalent cognitive domains (Table 1). Correlations were conducted across the entire sample and for cases only. Pearson correlations were used when task performance was normally distributed, whereas Spearman correlations were used for tasks that were not normally distributed. A correlation matrix of all web-based tasks and the MCCB-equivalent tasks was also generated. Partial correlations were used to adjust for the time between completion of the batteries, age, and *g* (excluding domain of interest). Finally, correlation analyses were repeated after stratification by input device type (keyboard or touchscreen). Although previous studies do not appear to have corrected for multiple testing as the correlation coefficients are more important for validation [14-16], we calculated the corrected *P* values using the false discovery rate method.

Part 2: Feasibility of Web-Based Cognitive Testing

Participants

Following completion of the validation study, participants from the NCMH and CoMPaSS were sent invitation letters or emails with instructions on how to participate in the study and their unique website link. A reminder was sent to participants who did not respond to our initial invitation. Response rates can be found in Multimedia Appendix 1. The collected data were combined with the validation data set. Participants were excluded from the analyses if they reported a neurological condition likely to affect cognitive function or if they did not complete any of the cognitive tasks. Diagnostic groups with >20 participants were included in the analyses. Healthy controls were excluded from the analyses if they reported a history of psychiatric diagnosis or medication or first-degree family history of schizophrenia, bipolar disorder, autism, or intellectual disability. Therefore, the final sample for analysis (N=887) included 21.1% (187/887) of controls, 16.5% (146/887) of participants with bipolar spectrum disorders, 4.8% (43/887) of participants with schizophrenia, 29.4% (261/887) of participants with unipolar depression, 7.6% (67/887) of participants with anxiety disorders, 5.4% (48/887) of participants with posttraumatic stress disorder, 2.4% (21/887) of participants with an eating disorder, and 12.9% (114/887) of participants who reported comorbid depression and anxiety disorders. The flow diagram in Multimedia Appendix 1 shows a breakdown of the number of participants excluded according to our criteria.

Data Analysis

Preparation of Cognitive Data

For each task, z scores were derived using the mean and SD of the controls (187/887, 21.1%). General cognitive performance *g* was derived using multidimensional scaling (MDS) for participants who had completed at least five tasks, as we have done in a previous study [47]. MDS is an analogous approach to principal component analysis; however, an advantage of this approach is that it can accommodate missing data [48,49]. General cognitive performance *g* was calculated as the first dimension produced by the MDS analysis. Measures of *g* derived from MDS and principal component analysis were highly correlated (r=0.996). All statistical analyses were conducted using R (version 3.3.0).

Sample Characteristics

We compared those who participated in part 2 of the web-based study (n=1152) with those who were invited but did not take part (nonresponders; n=5768) to assess whether there was recruitment bias in the web-based sample. These comparisons were conducted separately for cases and controls and were further separated by original study (NCMH or CoMPaSS). Logistic regressions were conducted with participation in the study as the outcome and the following predictors: age; sex; education; lifetime occupation; ethnicity; time since recruitment into parent study; and, among cases only, diagnosis, age of illness onset, and ever admitted to a psychiatric hospital.

Cognitive Performance and Functioning

We performed linear regressions with cognitive score as the predictor, total score on the WHODAS 2.0 as the outcome, and age and sex as covariates to test the association between cognitive performance and functioning. We repeated this regression by covarying for diagnosis. We ran separate linear regressions for each cognitive task and *g*. *P* values were corrected using the false discovery rate method.

Comparing Cognition Between Diagnostic Groups

We compared cognitive performance between healthy controls (187/887, 21.1%), major depressive disorder (295/887, 33.3%), bipolar disorder (116/887, 13.1%), and schizophrenia (38/887, 4.3%) using analysis of covariance with age and sex as covariates. Owing to the self-report nature of diagnoses in the NCMH, more conservative inclusion criteria were used to define depression, bipolar disorder, and schizophrenia in these analyses by considering medication use (see Multimedia Appendix 1 for details). Analyses of covariance were followed up with the honestly significant difference test by Tukey for pairwise comparisons. Hedge *g* effect sizes were calculated by dividing the mean group difference by the pooled SD [50].

Statement of Ethical Approval

All participants in part 1 (validation study) provided written informed consent. All participants in part 2 (web-based only) were required to indicate their informed consent by selecting *yes* in response to the statement "I agree to take part in this study and know that I am free to leave the study at any point," located on the information page of the study website. All stages of the web-based study titled *Cognition in Mood, Psychosis and Schizophrenia Study (CoMPaSS Web)* received ethical approval from the School of Medicine research ethics committee at Cardiff University (reference number: 15/64). The NCMH received a favorable ethical opinion from Wales research ethics committee 2 (reference: 16/WA/0323). CoMPaSS received a favorable ethical opinion from the South-East Wales research ethics committee panel (reference: 07/WSE03/110). All experiment protocols were conducted in accordance with the ethical standards of the Cardiff University School of Medicine research ethics committee and with the Declaration of Helsinki.

Data Availability

The data sets generated and analyzed during this study are available at the Medical Research Council Centre for Neuropsychiatric Genetics and Genomics Walters Group Data Repository [51].

Results

Part 1: Validation Study

Data Completion and Sample Characteristics

Approximately 89% (58/65) of participants completed all the web-based tasks, and the same number completed all the MCCB tasks and NART (see Table 2 for individual domains). The sample had a wide age range (22 to 78, mean 47, SD 14.8 years) and a higher percentage of women (38/65, 58%) than men. More than one-third of the sample had an undergraduate degree (26/65, 40%; see Multimedia Appendix 1).

[b]Correlations significant after correction for multiple testing.

[c]Spearman rank correlation ρ shown instead because of nonnormal distribution for these tests.

[d]N/A: not applicable.

Convergent Validity

The results of correlations between tasks measuring equivalent domains are shown in Table 2 (performance on the MCCB and web-based battery can be found in Multimedia Appendix 1). The measures of *g* derived from the MCCB and web-based batteries were correlated (r=0.78). Scores from 88% (7/8) of the web-based tasks were correlated with scores from the MCCB equivalents (r=0.26-0.73). These results did not change when the time between completion of the batteries was added as a covariate, although correlation coefficients were attenuated after adjustment for age and *g*. When analyses were restricted to cases with a psychiatric diagnosis, scores from 75% (6/8) of the web-based tasks were correlated with scores from the MCCB equivalents (r=0.33-0.69). Similar correlations were observed when analyses were stratified by input device type (keyboard users: 47/65, 72%, r=0.17-0.75; touchscreen users: 17/65, 26%, r=−0.01 to 0.75); however, fewer correlations were significant because of reduced power. Scores on the Balloon Analogue Risk Task (BART) showed low correlations with the MCCB tasks (r=0.07-0.25; Figure 1).

Figure 1. Pearson correlations between web-based and Measurement and Treatment Research to Improve Cognition in Schizophrenia Consensus Cognitive Battery (MCCB) tasks. Red squares indicate tasks assessing the same domain. Only tasks from the MCCB with an equivalent web-based task are shown (the Trail Making Test-A, Animal Naming Test, and Wechsler Memory Scale-III: Spatial Span were excluded). BVMT-R: Brief Visuospatial Memory Test–Revised; CPT-IP: Continuous Performance Test–Identical Pairs; HVLT-R: Hopkins Verbal Learning Test–Revised; MSCEIT-ME: Mayer–Salovey–Caruso Emotional Intelligence Test–Managing Emotions; NAB: Neuropsychological Assessment Battery; NART: National Adult Reading Test.

Tolerability

Feedback questionnaires were received from 63% (41/65) of participants. Of those who responded, all participants agreed that the instructions given at the start of the study were clear and rated the clinical questionnaire positively. Overall, the cognitive tasks were rated as enjoyable by 100% (41/41) of the participants who responded and as being of reasonable duration and difficulty by 95%. Approximately 3% (2/65) of participants rated the duration and difficulty of the battery as *poor*. The most popular task was multiple object tracking, and the least popular was verbal paired associates. Of the 40 participants who responded to the question, 34 (85%) reported that they would be *more likely* to take part in future web-based studies after taking part in this study, whereas 5 (13%) responded *don't know*, and 1 (3%) responded that they were *less likely*. Of the 40 participants, 6 (15%) reported technical difficulties and, of these 6 participants, 5 (83%) were able to complete all the tasks; thus, this did not affect the availability of data for these participants.

Part 2: Feasibility of Web-Based Cognitive Testing

Sample Characteristics

We compared the demographic and clinical characteristics of all participants recruited during part 2 of the study (n=1152) and nonresponders (n=5768; see Table 3 for cases and Table 4 for controls) to evaluate whether recruitment bias was present in the web-based sample. In CoMPaSS, web-based participants were more highly educated than nonresponders (odds ratio [OR] 1.49, 95% CI 1.15-1.98; P=.004). Among NCMH cases, the

significant predictors for web-based participation were diagnosis of eating disorder (OR 2.17, 95% CI 1.17-4; *P*=.01), diagnosis of comorbid depression and anxiety (OR 5.12, 95% CI 3.38-7.83; *P*<.001), absence of diagnosis of schizophrenia (OR 0.59, 95% CI 0.35-0.94; *P*=.03), older age (OR 1.01, 95% CI 1-1.02; *P*=.003), being female (OR 1.3, 95% CI 1.07-1.58; *P*=.009), ethnicity other than White European (OR 0.66, 95% CI 0.46-0.96; *P*=.03), younger age of onset (OR 0.99, 95% CI 0.98-0.99; *P*=.001), higher level of education (OR 1.19, 95% CI 1.11-1.29; *P*<.001), and shorter time since recruitment into the NCMH (OR 0.98, 95% CI 0.97-0.98; *P*<.001). Among the controls, older age (OR 1.03, 95% CI 1.01-1.04; *P*<.001), higher levels of education (OR 1.5, 95% CI 1.19-1.83; *P*<.001), and shorter time since recruitment into the NCMH (OR 0.95, 95% CI 0.93-0.96; *P*<.001) were associated with web-based participation.

Completion Rates

Of the 961 participants who met the inclusion criteria, 887 (92.3%) completed at least one web-based cognitive task, and 644 (67%) completed all the tasks in the web-based battery. A breakdown of completion rates for each task and by diagnostic group can be found in Multimedia Appendix 1.

Cognitive Performance and Functioning

Linear regression indicated that lower cognitive performance (*g*) was associated with higher WHODAS 2.0 scores, indicating poorer functioning (B=−1.76, SE 0.26; *P*<.001). This association remained significant after covarying for diagnosis (B=−1.64, SE 0.26; *P*<.001). Higher scores on all tasks were associated with better functioning (Table 5).

Table 5. Association between cognitive performance and functioning (N=961).

Variable	Participants, n (%)	B[a] (SE)	*P* value
General cognitive performance (*g*)	561 (58.4)	−1.76 (0.26)	<.001
General cognitive performance (*g*) after covarying for diagnosis	561 (58.4)	−1.64 (0.26)	<.001
Individual tasks			
Digit symbol coding	645 (67.1)	−3.08 (0.47)	<.001
Verbal paired associates	557 (58)	−1.72 (0.50)	<.001
Backward digit span	528 (54.9)	−2.03 (0.51)	<.001
Hartshorne visual working memory test	499 (51.9)	−1.73 (0.51)	.008
Morphed emotion identification	565 (58.8)	−1.78 (0.53)	<.001
Matrix Reasoning Test	489 (50.9)	−1.54 (0.43)	<.001
Balloon Analogue Risk Task	487 (50.7)	−1.29 (0.39)	<.001
Multiple object tracking	459 (47.8)	−1.92 (0.43)	<.001
Vocabulary	470 (48.9)	−1.51 (0.51)	.003

[a]Regression coefficient.

Comparing Cognition Between Diagnostic Groups

There was a significant main effect of diagnosis for *g* ($F_{3,511}$=21.89; *P*<.001). Participants with depression had a lower performance than the controls (Hedges *g*=0.32; *P*=.01). The bipolar disorder group had lower performance than the controls (Hedges *g*=0.65; *P*<.001) and the depression group (Hedges *g*=0.33; *P*=.03). Participants with schizophrenia had the lowest performance relative to the controls (Hedges *g*=1.36; *P*<.001) and had lower performance than participants with depression (Hedges *g*=1.04; *P*<.001) and bipolar disorder (Hedges *g*=0.71; *P*=.002). Domain-specific effect sizes for pairwise comparisons are shown in Multimedia Appendix 1.

Discussion

Principal Findings

We developed a web-based cognitive battery for use in psychiatric research. The battery was designed to test the domains specified by the National Institute of Mental Health's MATRICS initiative. The aims of this study were to validate the web-based battery against the MCCB and evaluate whether web-based cognitive testing is suitable for research on psychiatric disorders. Our principal findings for each part of the study are outlined in the sections below.

Validation of the Web-Based Battery

We assessed convergent validity by conducting correlations between tasks that measured equivalent domains. Approximately 88% (7/8) of web-based tasks were correlated with the MCCB equivalent (*r*=0.26-0.73). This is comparable with the correlation coefficients reported in the validation of the UKB tasks (*r*=0.22-0.83) [16], web-based Cambridge Neuropsychological Test Automated Battery (*r*=0.39-0.73) [14], Amsterdam Cognition Scan (*r*=0.36-0.78) [15], and NutriCog Battery (*r*=0.42-0.73) [52]. However, only digit symbol coding, matrix reasoning, and vocabulary were most highly correlated with their equivalent offline tasks, and even these tasks were correlated with other MCCB tasks. The correlations between equivalent domains were also attenuated and, in some domains, close to 0 after correction for *g*. These findings suggest that at least some of the correlations between the web-based tasks and the MCCB were nonspecific and may reflect the tendency of cognitive tasks to be at least moderately correlated with a large proportion of the variance in performance accounted for by a higher-order factor (*g*) [53]. Overall, the battery may be better suited as a measure of general cognitive function *g* rather than a measure of specific cognitive domains.

There are two key differences between the web-based battery and the MCCB: (1) website versus offline administration and (2) use of different tasks to measure the same domain. Both differences are likely to affect the magnitude of the correlations between the tasks. Examining the correlation for speed of processing provides some insight into the extent to which the correlations are affected by these differences as the speed of processing domain was measured using offline and web-based versions of the same task, digit symbol coding. These tasks were the most highly correlated (*r*=0.73), suggesting that differences in web-based and traditional administration may not have had such a large impact on the magnitude of the correlations as differences arising from different tasks being used. This is consistent with the findings from the UKB and the Amsterdam Cognition Scan, showing that tasks with differing methodologies had lower correlations than those with similar methodologies [15,16]. A further consideration is the delay between administering the first and second batteries, as some participants did not complete the web-based battery on the second day as instructed. The correlations between the MCCB and the web-based battery did not change after controlling for the delay between the completion of the batteries, suggesting that the delay had little influence on the relationship between the tasks.

We observed the lowest nonspecific correlations between tasks that used different methodologies. For example, the morphed emotion identification task had a low correlation with the measure of social cognition in the MCCB, the Mayer–Salovey–Caruso Emotional Intelligence Test–Managing Emotions (MSCEIT-ME; *r*=0.26), but higher correlations with all other MCCB measures (*r*=0.33-0.56). Morphed emotion identification and MSCEIT-ME are designed to tap different aspects of social cognition. Morphed emotion identification is designed to measure a participant's ability to recognize emotional facial expressions [22], whereas the MSCEIT-ME was developed to measure emotion self-regulation [54]. We did not select a formally equivalent web-based task for the MSCEIT-ME for 2 reasons. First, although previous research has identified impaired performance on the MSCEIT-ME in participants with schizophrenia [19,55], studies have not identified impairments in this task for participants with bipolar disorder [19,56,57]. Therefore, we did not consider it a suitable measure for this web-based battery, which was designed to measure cognitive function in participants with a range of psychiatric disorders. Second, in our experience of administering the MSCEIT-ME to >1000 participants with psychosis, we found that participants frequently required guidance and explanations of the scenarios, which would not be practical for a web-based, unsupervised measure. Studies have identified impairments in emotion recognition in participants with bipolar disorder [58,59], depression [60], autism [61], and posttraumatic stress disorder [62]. Therefore, we considered this a more suitable measure for cross-disorder research. However, we did not find evidence of impairments in this task for participants with depression or bipolar disorder in this study as effect sizes were small (*d*=0.17 for depression; *d*=0.28 for bipolar disorder) and nonsignificant (see Multimedia Appendix 1).

The Hartshorne visual working memory task was not correlated with its selected equivalent in the MCCB, the Brief Visuospatial Memory Test–Revised (BVMT-R). The BVMT-R is an immediate visual recall task in which participants are presented with shapes for 10 seconds and asked to draw these shapes from memory [63]. Drawings are rated based on the accuracy of recall and memory of the location of the shapes. It was not possible to select a task that would entirely replicate the BVMT-R because of the difficulties in automating the study administration and scoring on the web and the possibility that participants may cheat in an unsupervised setting by copying the shapes while they are being displayed onscreen. Therefore, the Hartshorne

visual working memory task was chosen as an alternative as performance on this task also relies on short-term memory of both shapes and locations. However, the Hartshorne visual working memory task is more complex as, in addition to memorizing shapes and locations, the participant must identify whether a new target shape is the same or different from the shape that previously occupied that position [23]. As such, the task incorporates aspects of working memory and problem solving. Our results suggest that these tasks are not comparable and that the Hartshorne visual working memory task is not a suitable alternative measure of immediate visual recall.

The BART was not correlated with any of the MCCB tasks. This was not surprising, given that the BART is a behavioral measure rather than a neurocognitive task, and the MCCB is primarily made up of neurocognitive measures. Nevertheless, the BART may be a useful measure of risk-taking behavior that does not rely on self-report, as it has been shown to be correlated with measures of sensation seeking, impulsivity, behavior constraint, and actual risk-taking behaviors [24].

Feasibility of Web-Based Cognitive Testing

We demonstrated that web-based cognitive testing is an effective method of collecting data from a large sample of participants with psychiatric disorders. To date, we have obtained cognitive data from >1000 participants diagnosed with a range of psychiatric disorders. A key concern with web-based testing in psychiatric research is whether the sample is representative, particularly given evidence that there is a digital divide between patients with psychiatric disorders and the wider UK population [64]. Across all samples (CoMPaSS and NCMH cases and controls), a higher level of education was associated with web-based participation. This finding suggests that earlier concerns about education bias in web-based samples may be correct and is a clear limitation of web-based testing. This issue is not exclusive to web-based cognitive testing, as similar recruitment biases have been identified in mental health studies using web-based questionnaires [17], and response rates to research invitations have been shown to be positively associated with educational attainment more generally [65]. The web-based control group was older and had been recruited more recently into the NCMH than nonresponders. Finally, participants with psychiatric disorders recruited from the NCMH were older, more likely to be female, less likely to be White European, and had been recruited more recently than nonresponders. The OR for age was close to 1, which does not support early preconceptions that internet samples would be overrepresented by younger people [11]. Our web-based sample was drawn from 2 existing clinical studies, and it should be noted that these original studies also have recruitment bias, although there is some evidence that the CoMPaSS sample is representative of the wider population of patients with psychosis in Wales based on the linkage of these data with routinely collected records [66]. Nevertheless, we were unable to assess whether the participants in our web-based study were representative of the wider population of patients with psychiatric disorders. However, our results do indicate that web-based samples may have recruitment bias beyond that seen in traditional clinical studies of psychiatric disorders.

In terms of clinical differences between participants and nonresponders, we did not find evidence of differences in hospital admissions. The difference in age of onset was significant; however, the OR was close to 1, indicating that the difference was very small. There were differences in the proportion of diagnoses, as individuals with schizophrenia were less likely to participate, and individuals with an eating disorder or comorbid depression and anxiety were more likely to participate. The response rates for individuals with other psychotic disorders were also low. These response rates may reflect the severity of illness. We did not find differences in hospital admissions as a binary measure but were unable to examine the number of admissions, length of hospitalizations, or whether admissions were under the Mental Health Act (as data were only available for a small proportion of the sample), which would have provided more detailed information on the severity of illness. Although this is another limitation of web-based testing in a mental health sample, an advantage of web-based testing is that the tests can be administered anywhere with internet access, supervised or unsupervised. Sample representativeness may be improved by providing opportunities for participants to take part in a supervised setting, such as a psychiatric clinic or research facility, if they lack the skills or resources to access the internet unsupervised. A combination of approaches (supervised and unsupervised and clinical or home settings) may reduce the financial and logistical burden of assessing cognitive function in large cohorts associated with traditional studies while limiting the recruitment bias associated with purely web-based studies. Studies using web-based methods for data collection should consider providing additional support to individuals with more severe mental illnesses, such as psychosis.

The completion rates give an indication of the tolerability of the cognitive battery. Of the 961 eligible participants who consented to the study, 887 (92.3%) completed at least one task, which is similar to the 87% reported by another web-based cognitive study [67]. Most participants completed all 9 tasks in the cognitive battery (644/961, 67% of eligible participants or 644/887, 72.6% of participants who started the tasks). This figure is comparable with the completion rates reported by the Twins Early Development Study for their web-based battery of 8 tasks (65%), although the study assessed children [9]. This figure is lower than those reported in face-to-face cognitive studies of participants with psychiatric disorders [68,69]. A lower completion rate was expected, given that the participants were unsupervised and would not have the support of a researcher to complete the study. However, this should be considered a potential limitation of web-based testing in psychiatric research, and more work is needed to understand who is likely to drop out; the reasons for dropout; and whether any measures can be taken to mitigate dropout; for example, by reducing the overall length of the battery. Overall, the completion rates were adequate, suggesting that the tasks were well-tolerated by most participants. All participants who did not complete the tasks were followed up by email or phone, and technical issues were recorded and resolved where possible. The number of technical issues reported by participants was small (part 1: 6 issues reported; part 2: 9 issues reported). In total, 19 participants reported technical problems, of which 13

(68%) were able to complete the battery (part 1: 6, 32% reported [9% of validation sample] and 5, 26% completed; part 2: 13, 68% reported [1.5% of sample] and 8, 42% completed).

Lower cognitive performance was associated with poorer functioning. These results suggest that performance on the battery is an important indicator of overall functioning. The results are consistent with a prospective study that reported an association between cognitive performance and WHODAS 2.0 scores in a cross-disorder sample of participants with depression, bipolar disorder, and psychosis [70]. In this study, performance on digit symbol coding and backward digit span was most strongly associated with scores on the WHODAS 2.0. Both digit symbol coding and backward digit span have short administration times and thus may be particularly suited for brief assessments of cognition in a clinical setting. It should be noted that this study was cross-sectional; thus, it was not possible to examine whether changes in performance on the battery were associated with changes in functioning.

We compared cognitive performance in participants with major depressive disorder, bipolar disorder, and schizophrenia as these groups have been extensively assessed for research using traditional cognitive assessments. Our results demonstrated a pattern of decreasing cognitive scores from major depressive disorder to bipolar disorder to schizophrenia and are consistent with studies showing lower performance in schizophrenia compared with major depressive disorder and bipolar disorder [70,71]. This suggests that the performance of the battery can be used to discriminate cases and controls. However, this pattern was not consistent in the analyses of individual domains. Effect sizes for the depression group across domains (Hedges g=0.07-0.39) were also lower than those reported by previous meta-analyses (effect sizes ranged from 0.32 to 0.97 across domains [3,72,73]), which may be explained by recruitment bias or the self-report nature of the NCMH diagnoses.

Limitations

In addition to the limitations discussed above, several further limitations should be noted. Test–retest reliability of the web-based battery was not assessed in this study. In assessing validity, the correlation between a new task and the gold standard task cannot exceed √(reliability of reference task×reliability of new task) [10]. Therefore, the upper limits of the correlations between tasks were unknown. This is helpful for interpretation but does not change the magnitude or significance of the correlations. The order of completion of the batteries was not counterbalanced in the validation study for practical reasons, which may mean that performance on the web-based battery was subject to practice effects, particularly those tasks with similar methodologies. However, we would expect practice effects to be minimal as most web-based and MCCB tasks used different methodologies, and none of the tasks used the same stimuli. In the NCMH sample, diagnosis was based on self-report rather than structured interviews, which may result in incomplete or inaccurate diagnoses. However, participants were asked to report diagnoses that they had been given by a health professional, which is consistent with the approach taken by other large studies with self-report measures of diagnosis, such as the UKB [25,26]. There was a smaller schizophrenia group because of a lower response rate from participants with this disorder. A further limitation of web-based testing is the unsupervised environment in which the data are collected, which makes it difficult to minimize distractions or cheating. A study by Germine et al [12] using the same platform (TestMyBrain) found low levels of self-reported cheating, and their data were not consistent with widespread cheating. We selected tasks that would minimize the possibility of cheating where possible and also instructed participants to complete the tasks in a quiet environment. In addition, most participants completed both batteries at home to minimize the differences in the test settings.

Conclusions

The web-based battery has several strengths, including the use of tasks taken from published research, domains selected based on the MATRICS initiative, and compatibility with a range of devices, including touchscreen devices. The availability of demographic and clinical data on individuals who did not participate in the study was a unique strength that allowed us to assess potential recruitment bias.

In conclusion, we developed a new web-based cognitive battery and used it to collect data from a large sample of participants with a range of psychiatric disorders. There was some evidence of recruitment bias, and the levels of impairment found in the depression group were less severe than those reported by traditional face-to-face studies. However, the battery provided a reliable measure of g, completion rates were adequate, our findings were consistent with studies using traditional assessments, and feedback from participants was positive. Our findings offer valuable insights into the advantages and disadvantages of testing cognitive function remotely for mental health research, which is particularly important given the increasing number of psychiatric studies using digital methods of assessment. In the next stage of development, we intend to use these findings to reduce the size of the battery to a briefer version removing tasks with low correlations, rated poorly by participants, or those presenting technical issues. Given that the correlations between some web-based tasks and the MCCB were nonspecific, the battery will include the tasks that were best suited for measuring their domain and providing a measure of g. We will also redesign the battery with a user-friendly interface with input from patient representative groups.

Cognitive impairments are one of the causes of long-term disability among patients with psychiatric disorders, particularly schizophrenia [7,8]. In the United Kingdom, assessment of cognitive skills has been recommended in clinical settings for patients with psychosis [74]. However, there are barriers associated with accessing appropriate cognitive assessments, such as cost, licensing, and the lack of available assessments that provide clinically meaningful feedback on performance [75]. It has been suggested that web-based tools may be a cost-effective solution [75]. Our results indicate that this assessment is suitable for detecting impairments in individuals with schizophrenia. Therefore, it is our intention to explore the potential clinical utility of the battery in future work.

Acknowledgments

This work was supported by a Medical Research Council (MRC) PhD studentship to AJL and by the National Centre for Mental Health (NCMH). The NCMH is a collaboration between the Cardiff, Swansea, and Bangor Universities and is funded by the Welsh Government through Health and Care Research Wales. The NCMH provided resources and staff to assist with the development of the battery and recruitment of participants for both stages of the study. The further development of the battery was supported by 2 MRC grants, the MRC Mental Health Data Pathfinder award (MC_PC_17212) and the MRC Confidence in Concept award (MC_PC_17170). The MRC Pathfinder award (MC_PC_17212) funded AJL's postdoctoral position. The MRC Confidence in Concept award (MC_PC_17170) is a proof-of-concept grant, which funded the further development of the cognitive assessment, including creating a user-friendly interface and supporting public involvement. The work at Cardiff University was funded by the MRC Centre (MR/L010305/1) and program grant (G0500509). This research was conducted with the support of the web-based platform TestMyBrain, a resource maintained and supported by The Many Brains Project, Inc. The web-based tasks remain the intellectual property of The Many Brains Project, which retains the copyright for these tasks and the source code. The authors thank Dr Laura Germine for her support in developing this battery. The authors thank the Cognition in Mood, Psychosis, and Schizophrenia Study and NCMH study participants for their invaluable contribution to this project. The authors also thank the NCMH field team, Dr Catrin Lewis, Dr Lawrence Raisanen, and Karin Alderson, for their support in recruiting participants for this study.

Authors' Contributions

AJL is the lead author and was involved in all aspects of the study, including designing the assessment tools and study methodology, overseeing the recruitment of participants, conducting analysis and interpretation of the data, and drafting and redrafting the manuscript. JTRW is the senior author; the principal investigator of the Cognition in Mood, Psychosis, and Schizophrenia Study; deputy director of the National Centre for Mental Health; and was involved in all aspects of the paper. IRJ is the chief investigator and director of the National Centre for Mental Health and advised on the methodology and interpretation of the results. All authors critically revised the paper and approved the final version to be submitted.

Conflicts of Interest

IRJ and JTRW have received grant funding from Takeda Pharmaceuticals for research unrelated to this manuscript.

Multimedia Appendix 1
