Abstract

Background: Tinnitus is a symptom that can be very distressing owing to hearing sounds not related to any external sound source. Managing tinnitus is notoriously difficult, and access to evidence-based care is limited. Cognitive behavioral therapy (CBT) is a tinnitus management strategy with the most evidence of effectiveness but is rarely offered to those distressed by tinnitus. The provision of internet-based CBT for tinnitus overcomes accessibility barriers; however, it is not currently readily available in the United States.

Objective: The aim of this study is to investigate the efficacy of internet-based CBT compared with that of weekly monitoring for the management of tinnitus in reducing tinnitus distress; reducing tinnitus-related comorbidities, including tinnitus cognitions, insomnia, anxiety, and depression; and assessing the stability of the intervention effects 2 months after the intervention.

Methods: A 2-arm randomized clinical trial comparing audiologist-guided internet-based CBT (n=79) to a weekly monitoring group (n=79) with a 2-month follow-up assessed the efficacy of internet-based CBT. Eligible participants included adults seeking help for tinnitus. Recruitment was conducted on the web using an open-access website. Participants were randomized via 1:1 allocation, but blinding was not possible. The study was undertaken by English or Spanish speakers on the web. The primary outcome was a change in tinnitus distress as measured using the Tinnitus Functional Index. Secondary outcome measures included anxiety, depression, insomnia, tinnitus cognition, hearing-related difficulties, and quality of life.

Results: Internet-based CBT led to a greater reduction in tinnitus distress (mean 36.57, SD 22) compared with that in weekly monitoring (mean 46.31, SD 20.63; effect size: Cohen *d*=0.46, 95% CI 0.14-0.77) using an intention-to-treat analysis. For the secondary outcomes, there was a greater reduction in negative tinnitus cognition and insomnia. The results remained stable over the 2-month follow-up period. No important adverse events were observed. Further, 16% (10/158) of participants withdrew, with low overall compliance rates for questionnaire completion of 72.3% (107/148) at T1, 61% (91/148) at T2, and 42% (62/148) at T3.

Conclusions: This study is the first to evaluate and indicate the efficacy of audiologist-delivered internet-based CBT in reducing tinnitus distress in a US population. It was also the first study to offer internet-based CBT in Spanish to accommodate the large Hispanic population in the United States. The results have been encouraging, and further work is indicated in view of making such an intervention applicable to a wider population. Further work is required to improve compliance and attract more Spanish speakers.

Introduction

Background

Tinnitus is a condition characterized by the perception of sound in the absence of an external stimulus. It is highly prevalent, with at least 10% of Americans experiencing some form of tinnitus, of which a proportion have chronic burdensome or debilitating tinnitus [1]. Bothersome tinnitus causes various functional impairments in sleep, concentration, cognitive performance, and thought processing [2,3]. It is also associated with an increased risk of psychological difficulties, such as anxiety, depression, and reduced quality of life [4,5]. This may result in participant restrictions and activity limitations [6,7]. Owing to the negative impact of tinnitus, those distressed by their tinnitus require interventions to help them cope with the condition.

Managing tinnitus is notoriously challenging because it is often not a curable medical cause [8]. When comorbid problems such as hearing loss accompany tinnitus, hearing aids and sound therapy may reduce the severity of tinnitus [8]. Although these interventions may reduce tinnitus perception, they do not always alter negative reactions to tinnitus. Psychological interventions that change reactions to tinnitus have effectively helped reduce tinnitus distress [9]. The intervention with the strongest research evidence according to the American Academy of Otolaryngology–Head and Neck Surgery tinnitus practice guidelines [10-12] and several systematic reviews [9,13] is cognitive behavioral therapy (CBT) for tinnitus. CBT is a psychological intervention that addresses unhelpful thought patterns and emotional reactions caused by tinnitus [14]. Despite the evidence base, accessibility to CBT for tinnitus is limited owing to a dearth of health care providers with the knowledge and expertise to provide CBT to this population [15,16].

Previous Work

To overcome this barrier, an internet-based CBT for tinnitus [17] has been developed. This intervention was originally developed in Swedish [18] and was later translated into German [19] and English [20] and was provided with psychological guidance. To further increase accessibility, internet-based CBT for tinnitus has been adapted to be delivered by audiologists [21] with some training to handle the CBT elements without compromising outcomes [22-27]. The efficacy of internet-based CBT has been indicated in 9 clinical trials across mainland Europe and the United Kingdom (for a review, see the study by Beukes et al [28]). However, no clinical trials determined the effects of internet-based CBT in the United States. An evidence-based, standardized approach, such as internet-based CBT, is desirable, as tinnitus provision varies substantially across clinics and providers [16].

Study Rationale

To address this need, internet-based CBT was adapted for the US population to improve cultural and linguistic suitability [29]. It was further translated into Spanish to serve the large Spanish-speaking population in the United States, and functionality and acceptability testing was undertaken [30]. Internet-based CBT for tinnitus in the United States was evaluated within a clinical trial framework to evaluate complex interventions [31]. A small (N=28) phase I trial was undertaken in the United States [32], indicating feasibility. However, a larger randomized controlled trial (RCT) is needed to determine its efficacy in the US population. Efficacy cannot be assumed owing to many differences in health care provision in the United States and Europe. In the United States, tinnitus interventions include Tinnitus Retraining Therapy [33] and Progressive Tinnitus Management [34] with limited provision of CBT for tinnitus. It is also not known if a psychological approach will be acceptable because of the large emphasis of most tinnitus management programs on sound therapy and the fitting of devices [35]. The fee structure for health care in the United States is also very different to largely free of charge health care in the United Kingdom, as it is generally paid out of pocket, and clinicians have great difficulty receiving payment for nondiagnostic appointments such as tinnitus counseling. Before the COVID-19 pandemic, health care was also generally provided face to face. Hence, the uptake for a remote intervention is uncertain but has now become a more urgent matter. These factors may be potential barriers to or facilitators of internet-based CBT in the United States.

This RCT aims to explore the effects of internet-based CBT in the United States with the following:

1. To evaluate the efficacy of audiologist-delivered internet-based CBT in reducing tinnitus distress compared with that in weekly monitoring of tinnitus.
2. To ascertain the efficacy of internet-based CBT in reducing comorbidities associated with tinnitus.
3. To assess the stability of internet-based CBT intervention effects 2 months after the intervention.

The hypothesis was that patients with tinnitus would experience greater reduction of tinnitus distress and comorbidities after receiving internet-based CBT compared with patients receiving weekly monitoring.

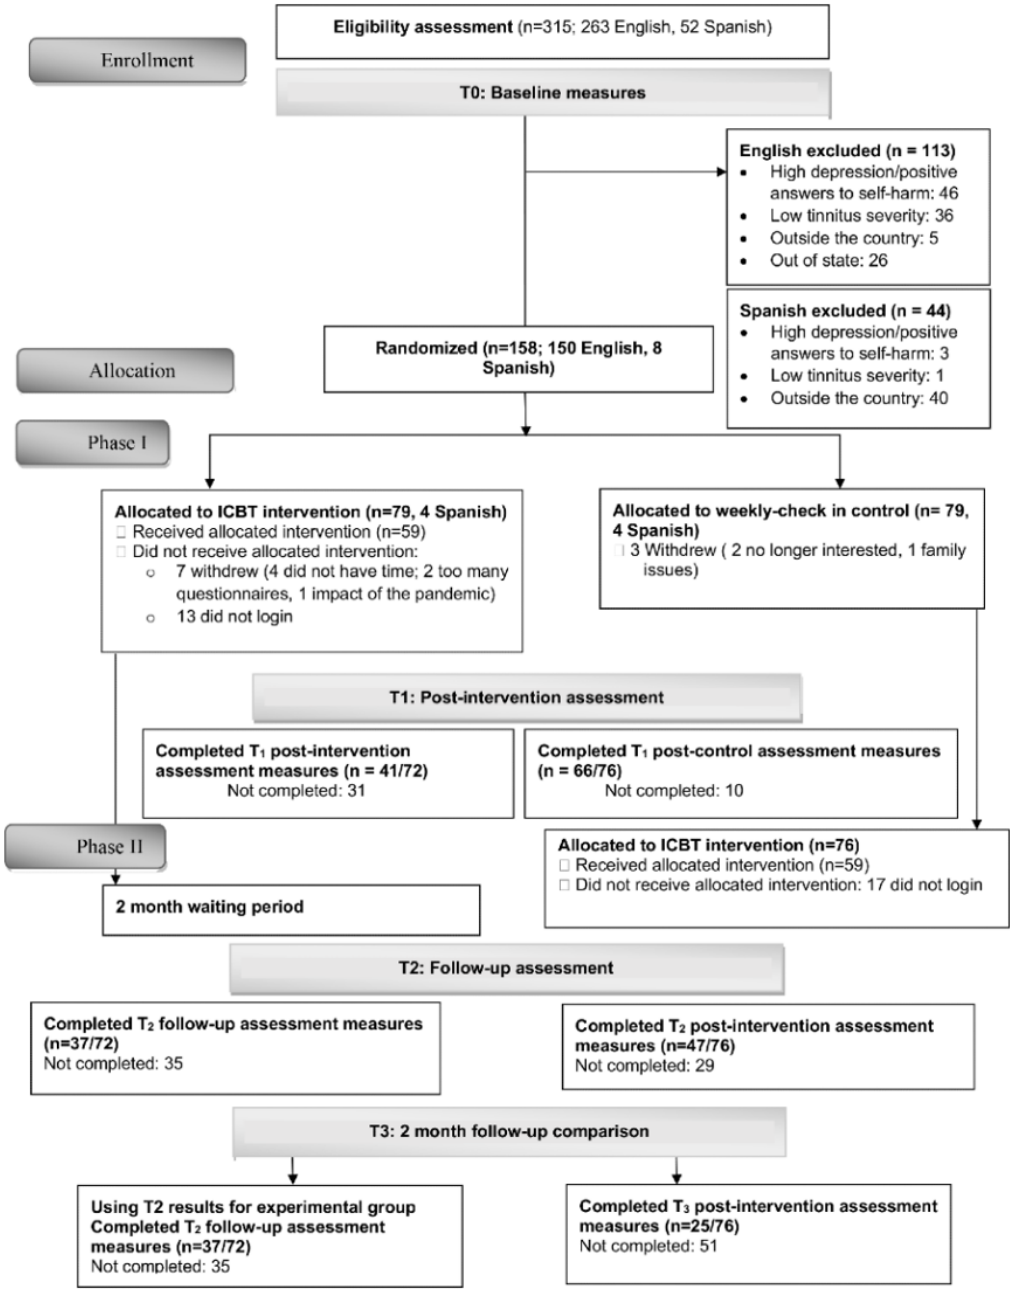
Methods

Trial Design

Overview

A prospective 2-arm delayed intervention efficacy trial with a 2-month follow-up was conducted. As an efficacy trial, an active comparator was not included. Participants were randomized with a 1:1 allocation ratio to the experimental group to receive the internet-based CBT intervention for 8 weeks or the control group whose participants were monitored weekly during the 8-week period. During the first phase, the experimental group completed the intervention. Following the experimental group completing the interventions, both groups completed the same outcome measure (T1, post intervention). During the second phase, the control group underwent the same internet-based CBT intervention, after which both groups were invited to complete the T2 outcomes, which were completed after the control group finished the intervention and 2-months postintervention for the experimental group (T2). This study design, therefore, provided the opportunity to evaluate the intervention effects in 2 independent groups at 3 time points as shown in Figure 1.

Figure 1. The CONSORT (Consolidated Standards of Reporting Trials) flow diagram. ICBT: internet-based cognitive behavioral therapy.



Ethics and Preregistration

This RCT and protocol were preregistered at ClinicalTrials.gov (trial number: NCT04004260) on July 2, 2019. Ethical approval was obtained from the Institutional Review Board at Lamar University, Beaumont, Texas, United States (IRB-FY17-209). The study was conducted and reported according to the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) guidelines [36] (Multimedia Appendix 1). An independent data-monitoring committee monitored the trial. There were no changes in the methods or trial outcomes used after the trial commenced. The participants were closely monitored for any harm. No harm or unintended effects have been reported.

Participants

The study was undertaken on the web and no clinical visits were required. The study eligibility criteria are presented in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Adults, aged ≥18 years, living in Texas, United States
- The ability to read and type in English or Spanish
- Having access to a computer and the internet and able to email
- Experiencing tinnitus for a minimum period of 3 months
- A tinnitus severity score of ≥25 on the Tinnitus Functional Index indicates the need for an intervention

Exclusion criteria

- Indications of significant depression (≥15) on the Patient Health Questionnaire-9
- Indications of self-harm thoughts or intent, answer affirming question 10 of the Patient Health Questionnaire-9
- Reporting any medical or psychiatric conditions that could interfere with the treatment
- Reporting pulsatile, objective, or unilateral tinnitus, which has not been investigated medically or tinnitus still under medical investigation
- Undergoing any tinnitus therapy concurrent with participation in this study

Eligibility was determined by a 2-stage process as follows:

1. A web-based screening questionnaire, which included demographic information, health- and mental health–related questions, and standardized outcome measures are shown in Table 1.
2. A telephone interview during which the researcher rechecked eligibility and provided the opportunity for potential participants to ask any questions related to the study. The study procedures were explained, and motivational interviewing was conducted to encourage participants to commit and engage in the intervention.
3. Participants who did not meet the inclusion criteria were participants with a score of ≥15 on the Patient Health Questionnaire-9 or indicated self-harm on question 10 received a phone consultation from a clinical psychologist on the research team. This call ensured that they were under care elsewhere, or necessary resources or referrals were provided.

Table 1. Study outcome measures used before and after the intervention and at the 2-month follow-up period.

Dimension	Outcome measures	Internal consistency	Scores (range)	Levels of significance	Time frame measured
Primary outcome measure					
Tinnitus distress	Tinnitus Functional Index: 42	0.97	0-100; a reduction in scores indicates improvement	>25 indicates a mild condition (no need for an intervention), 26-50 indicates a significant condition (possible need for an intervention), and ≥50 indicates a severe condition (need for a more intense intervention)	T0[a], T1[b], T2[c], and T3[d] (control only)
Secondary outcome measures					
Generalized anxiety	Generalized Anxiety Disorder-7: 44	0.89	0-21; a reduction in scores indicates improvement	0-4 indicates minimal anxiety, 5-9 indicates mild anxiety, 10-14 indicates moderate anxiety, and 5-21 indicates severe anxiety	T0, T1, T2, and T3 (control only)
Depression	Patient Health Questionnaire-9: 45	0.83	0-27; a reduction in scores indicates improvement	5-9 indicates mild depression, 10-14 indicates moderate depression, 15-19 indicates moderately severe depression, and 18-20 indicates severe depression	T0, T1, T2, and T3 (control only)
Insomnia	Insomnia Severity Index: 46	0.74	0-28; a reduction in scores indicates improvement		T0, T1, T2, and T3 (control only)
Tinnitus cognitions	Tinnitus Cognitions Questionnaire: 47	0.91	0-104; a reduction in scores indicates improvement	Higher scores indicate a greater tendency to engage in negative cognitions in response to tinnitus	T0, T1, T2, and T3 (control only)
Health-related quality of life	EQ-5D-5L[e]: 48	0.7-0.85	0-15; a reduction in scores indicates improvement	Measures 5 dimensions: mobility, self-care, usual activities, pain, discomfort, anxiety and depression	T0, T1, T2, and T3 (control only)
Health-related quality of life	EQ-5D-5L visual analog scale: 48	0.7-0.85	0-100; higher scores indicate improved health	Visual analog scale for overall health	T0, T1, T2, and T3 (control only)
Short measure for tinnitus, hearing disability, and hyperacusis	Tinnitus and Hearing Survey: 49	0.86-0.94	Subscale for tinnitus: 0-16; subscale for hearing: 0-16; subscale for sound tolerance: 0-8	—[f]	T0, T1, T2, and T3 (control only)
Weekly monitoring					
Screening of tinnitus severity	Tinnitus Handicap Inventory–Screening [37]	0.93	0-40; a reduction in scores indicates improvement	>6 indicates tinnitus handicap	Weekly, while undertaking the 8-week intervention

Dimension	Outcome measures	Internal consistency	Scores (range)	Levels of significance	Time frame measured
Tinnitus perception	Tinnitus Qualities Questionnaire [21]	Not assessed	0-100; a reduction in scores indicates improvement	Designed to determine whether tinnitus qualities such as loudness, pitch, the number of tones heard, and so forth improves while undertaking an intervention. Higher scores indicate that more bothersome aspects of tinnitus are present.	Weekly, while undertaking the 8-week intervention

[a]T0: before intervention.

[b]T1: 8 weeks after the experimental group started the intervention (before the control group started the intervention).

[c]T2: 8 weeks after the control group completed the intervention (2 months after the experimental group completed the intervention).

[d]T3: 2 months after the control group completed the intervention.

[e]EQ-5D-5L: European Quality of Life Five Dimension.

[f]Higher scores indicate more problematic tinnitus, hearing disability, and hyperacusis.

Recruitment Strategy

In line with the US government's health promotion initiative to make health care linguistically and culturally accessible [38], all the study materials were available in both English and Spanish and were also written at or below the sixth-grade English reading level [29,39]. The participants were mostly recruited from the general public using a range of strategies including a television broadcast, promoting the study via tinnitus support groups in Texas and the American Tinnitus Association, and contracting the company TrialFacts to boost recruitment. Further recruitment strategies included the use of social media (eg, Facebook and Twitter), flyers, and posters, which were distributed to local communities and put up in clinic waiting rooms. Professionals such as audiologists and otolaryngologists in Texas were also notified about the study and provided with leaflets to distribute to suitable patients. Recruitment was conducted on the web from an open access website between February 17, 2020, and March 30, 2020. Those interested were directed to the study website, which had detailed information about the study and the study team and registered their interest in study participation. Informed consent was provided on the web, confirming the understanding of how data would be used, to be randomized, the length of the trial, the commitment expected, and being contacted for follow-up data collection. Following registration, they were invited to complete the web-based screening, demographic, and outcome questionnaire. They were informed of their right to withdraw without penalty at any stage of the process.

Sample Size, Power, and Attrition

Sample size estimation was calculated using G*Power (version 3.1.6) [40] and based on achieving a 13-point clinically meaningful change between the baseline and postintervention measurements using the primary assessment measure, the Tinnitus Functional Index (TFI). Pilot data [32] indicated 26 participants per group with a 1:1 allocation to achieve 80% power to detect a between-group mean standardized difference effect size of Cohen d=0.50 (a moderate effect size). As this was fewer than the 58 participants suggested using data from an internet-based CBT RCT from the United Kingdom [23], we selected 58 participants per group. In addition, the sample size was inflated to account for missing data, estimated to be 20% of the US phase I trial data [32]. Thus, 146 participants were recruited, with 73 in each arm (calculated as 58/0.8).

Randomization

Participants meeting the inclusion criteria were randomly assigned in a 1:1 ratio and enrolled in either the experimental or control group using a computer-generated randomization schedule by an independent research assistant in blocks of varying sizes after participants were prestratified for language (English and Spanish). Participants and investigators could not be blinded to the group allocation owing to the nature of the intervention. Participants were informed immediately after randomization when the intervention commenced by the principal investigator, but not explicitly to which group they were assigned.

Patient-Public Partnership

A patient-public partnership was established to include 2 individuals with tinnitus who had piloted the internet-based CBT intervention, 2 audiologists, and 2 researchers. The meetings were held via videoconferencing. The aim of the patient-public partnership was to guide the study processes and provide inputs to the research strategy to boost recruitment and other elements of the study to ensure high compliance and engagement

Intervention

The internet-based CBT intervention content was based on a CBT self-help program originally developed in Swedish [18] and later adapted and translated into English [20]. The intervention was subsequently transformed into an 8-week interactive e-learning version suitable for the UK population [41] and then adapted linguistically and culturally to ensure suitability for the US population [29]. These adaptions prioritized accessibility of the intervention, such as lowering the readability to below the recommended sixth-grade level, as more than half of the US adult population has low literacy skills [42]. The intervention was augmented by a mindfulness module and more videos. The internet-based CBT platform (version 1)

in the US application consisted of 22 modules with worksheets and quizzes (see [21,29] for more details). Participants required an internet connection to access the materials and email correspondence regarding the intervention.

The intervention platform was transferred from Sweden and housed in the United States (Lamar University) to comply with the required US data protection regulations. Before this feasibility trial, the acceptability and functionality of this intervention for the US population were first ensured [30].

Both groups received the same intervention, and only the timing of receiving the intervention varied. The control group received the experimental intervention 8 weeks after the experimental group commenced the program. The intervention was 8 weeks long. Participants were asked to read the modules weekly and ideally spent 10 minutes each day practicing the suggested strategies.

Audiology Guidance

Guidance was provided to support the participants while undertaking the intervention. This included monitoring progress, monitoring weekly scores, providing feedback on worksheets completed, outlining the content of new modules, and answering questions. Participants who did not engage were contacted to support their participation and to discuss possible barriers. An encrypted 2-way messaging system was used to communicate with a minimum guidance time of 10 minutes per participant. Although psychologists have traditionally provided CBT interventions, audiologists generally deliver tinnitus management [16]. Thus, audiologists provided guidance to participants in a manner consistent with previous English trials [22-24] using this intervention to ensure standardization of the intervention approach. Support to the Spanish participants was provided by a Doctor of Audiology student with clinical experience whose first language was Spanish, using a handbook that was developed by the lead English-speaking audiologist.

Outcome Measures

Primary Outcome Measure

The primary outcome measure was tinnitus severity as measured by the TFI [43]. A meaningful change was defined to occur when scores were reduced by ≥13 points [43]. The TFI has been translated into >15 languages and has been validated for several populations, including the Chinese, Dutch, Swedish, and German [44]. It was selected over other tinnitus questionnaires as it was specifically developed to measure tinnitus severity and assess responsiveness to treatment and for comparison with previous trials [22-25].

Secondary Outcome Measures

Secondary outcome measures assessed anxiety [45], depression [46], insomnia [47], tinnitus cognitions [48], general health-related quality of life [49], and a short measure of hearing-related difficulties [50] as shown in Table 1. All questionnaires were used with the required permissions, and agreements were set up for those that were not freely available to use. For Spanish speakers, validated Spanish-translated versions were used. Where these were unavailable, validated translations were undertaken [39].

Weekly Monitoring of Tinnitus During the Active Intervention Period

Throughout the program, tinnitus in participants was monitored weekly using the Tinnitus Handicap Inventory–Screening (THI-S) version. The THI-S consists of a 10-item questionnaire, and scores are comparable (r=0.90) with the full version of the Tinnitus Handicap Inventory (THI) [37]. Weekly scores were also used to detect possible adverse effects. If scores increased by more than 10 points between 2 consecutive weeks, this was noted as an adverse effect. Those indicating adverse effects were contacted to address the identified problems. Participants were also monitored using a newly developed Tinnitus Qualities Questionnaire (TQQ) [21]. The TQQ measures tinnitus qualities such as pitch, loudness, and the number of tones heard. The TQQ scores can range from 0 to 100, with higher scores indicating more problematic tinnitus.

Intervention Variables

Intervention compliance was assessed by determining the retention rates and compliance in completing the outcome questionnaires. Intervention engagement was assessed by the number of log-ins, the number of modules read, and the number of messages sent during the intervention. Adverse effects were monitored by (1) direct questioning in the outcome questionnaire regarding the presence of adverse effects, (2) adverse effects written in messages or worksheets, and (3) an increase of 10 points or more during weekly monitoring using the THI-S questionnaire.

Questionnaire Administration

Web-based questionnaires were used throughout the study for both groups. Although not all measures were validated for web-based use, the results were to be comparable, as equivalent psychometric properties have been reported [51]. All the measures were completed at baseline (T0), T1 (after the intervention for experimental group), T2 (after the intervention for the control group) and at the 2-month follow-up for the experimental group). To measure the control group 2 months after the intervention, participants from the control group completed further outcome measures at T3 (adjusted). For data analysis, the T3 results for the control group and those at T2 for the experimental group were compared to assess the invention effect at the same experimental time point for both groups (ie, 2 months after the intervention). To maximize retention, 3 electronic reminders were sent to participants who had not completed questionnaires on 3 consecutive days after the release of the questionnaire. A further reminder was sent via email and text messages. If questionnaires were not completed, participants were telephoned to encourage completion of the questionnaire. Participants were also telephoned after completing the intervention to discuss the progress they had made and share their questionnaire results.

Statistical Analysis Plan

Statistical analyses were performed using the SPSS (version 26.0). All statistical tests were 2-tailed with an α set to .05. To account for missing data from participants not completing the postintervention or follow-up intervention analysis, an imputation analysis was undertaken. As the data were missing

at random, missing data were handled through multiple imputation using the Markov Chain Monte Carlo approach owing to its ability to reduce bias even when the proportion of missing data was large [52,53]. For comparison, a complete case analysis was also performed by analyzing only the completed questionnaire data without imputing missing data. As there were substantial differences, statistical analysis using the imputed data is reported in the results section as a more accurate unbiased account of the findings.

The primary study outcome was a change in the TFI score among the groups at after the intervention (T1). A difference in scores between T1 and T2 for the experimental group was used to assess the stability of the intervention effects. Effect sizes, linear mixed effects models, and a reliable change index were used to assess the primary and secondary outcomes. Changes in baseline to postintervention scores were compared within and among the groups using the pre- and posttest effect sizes (Cohen *d*) for all primary and secondary outcomes using the observed data. Effect sizes of Cohen d=0.20 represent small effect sizes, those of Cohen d=0.50 represent medium effect sizes, and those Cohen $d \geq 0.80$ represent large effect sizes [54].

A linear mixed model, which provided unbiased results in the presence of missing data (using all available data), was applied to analyze the intervention effect over time for each outcome measure. An unstructured repeated effects and identify-random effects covariance structure provided the best model fit based on the Akaike Information Criterion. Time was treated as a repeated and fixed effect. A restricted maximum-likelihood estimation was applied. The Type III *F* test sums of squares from the linear mixed model were calculated. As a sensitivity analysis, baseline tinnitus severity was initially added as a covariate, but as it had no significant effect on the results, it was removed from the model.

Another model was run to test the differences during the course of the 8-week intervention for weekly tinnitus outcome measures. Posthoc time comparisons were carried out in the case of significant group differences to assess at which time points these differences occurred. In addition to statistical significance, clinical significance has also been reported. A 13-point difference is recommended by the original developers of the TFI [43] to indicate a meaningful change in scores. To handle study variability, the reliable change index [55] is recommended as a means of calculating clinical significance for the TFI as the primary outcome. This was calculated using the mean pretest–posttest score difference, the pretreatment SD (17.49), and a test–retest reliability coefficient of 0.78 as reported in the validation study.

Sample Characteristics

Descriptive statistics including gender, age, ethnicity, race, tinnitus duration, hearing aid use, professional consultations, ease of computer use, veteran status, education, and employment status were used to describe the sample. The means and SDs were reported for each outcome measure at each time point. Descriptive statistics, including the number of log-ins and modules read, were also used to describe the sample and intervention engagement. A chi-square test of independence was used to identify group differences in engagement and compliance rates.

Results

Participant Characteristics

A total of 158 (50.2%) adults of the 315 participants screened met the eligibility criteria and were randomly assigned to the experimental (n=79) and control groups (n=79) as shown in Figure 1. In all, 8 (5.1%; 4 in each group) of the 158 participants were Spanish speakers who completed the Spanish version of the internet-based CBT program. Of the total sample (N=158), 80 participants (50.6%) were women and 78 participants (49.4%) were men with a mean age of 57 (SD 12) years for the full sample. The groups were well matched, and there were no clinically meaningful differences as seen in Table 2. Most participants (144/158, 91.1%) indicated that they were frequent users of computers and the internet. There were no functional failures related to the intervention during the trial. This trial commenced at the end of March 2020. This timing was unfortunate, as it coincided with the peak of the COVID-19 pandemic. Some participants reported becoming ill, struggling to adjust emotionally, or finding the required lifestyle changes difficult.

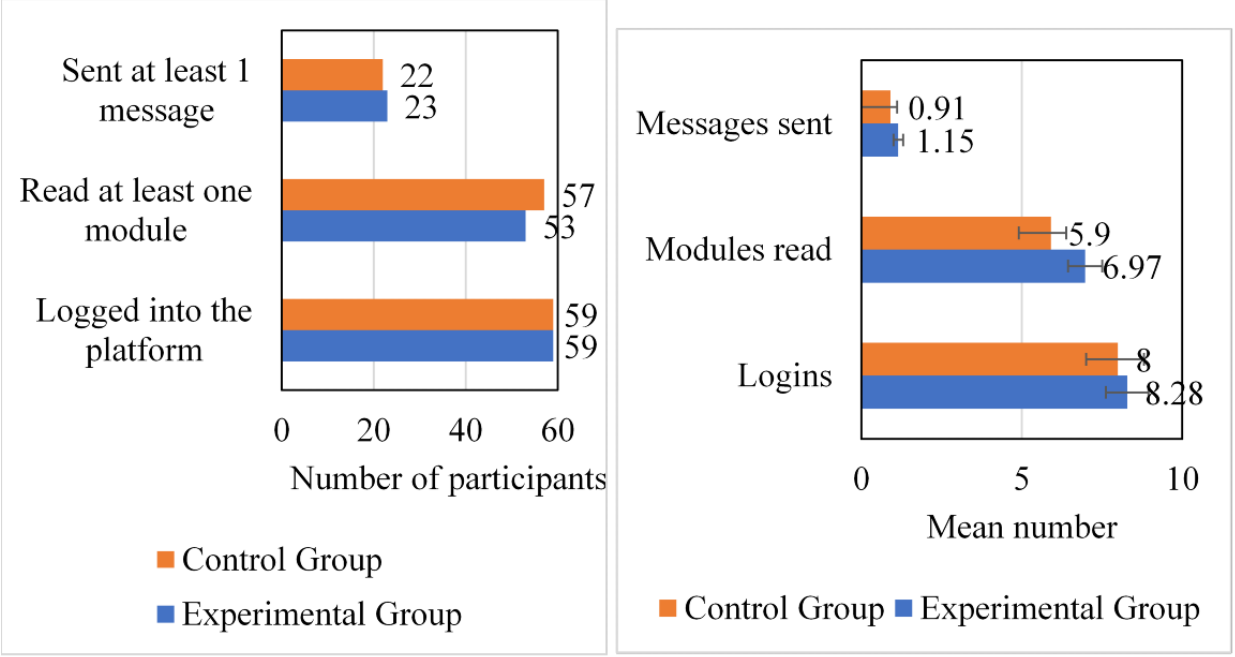
Table 2. Demographical characteristics of the participants.

Category and description	Experimental group (n=79)	Control group (n=79)	Overall (N=158)
Gender, n (%)			
Male	40 (50.6)	38 (48.1)	78 (49.3)
Female	39 (49.4)	41 (51.9)	80 (50.6)
Age (years), mean (SD; range)	56 (13; 19-76)	58 (11; 29-84)	57 (12; 19-84)
Tinnitus duration (years), mean (SD; range)	15 (16; 4 months to 70 years)	12 (12; 3 months to 58 years)	14 (14; 3 months to 70 years)
Ethnicity, n (%)			
Hispanic or Latino	9 (11.4)	11 (13.9)	20 (12.7)
Not Hispanic or Latino	70 (88.6)	68 (86.1)	138 (87.3)
Race, n (%)			
American Indian or Alaska native	0 (0)	0 (0)	0 (0)
Asian	1 (1.3)	0 (0)	1 (0.5)
Native Hawaiian or Pacific Islanders	0 (0)	0 (0)	0 (0)
Black or African American	2 (2.5)	2 (2.5)	4 (2.5)
White	74 (93.7)	74 (93.7)	148 (93.7)
More than 1 race	2 (2.5)	3 (3.5)	5 (3.1)
Highest educational level, n (%)			
High school	11 (13.9)	10 (12.7)	21 (13.2)
College or vocational training	22 (27.8)	31 (39.2)	53 (33.5)
University degree	46 (58.2)	38 (48.1)	84 (53.2)
Employment, n (%)			
Skilled or professional	55 (69.6)	41 (51.9)	96 (60.7)
Retired	22 (27.8)	30 (38)	52 (32.9)
Not working	2 (2.5)	8 (10.1)	10 (6.3)
All professionals seen, n (%)			
Primary care physician	41 (51.9)	44 (55.7)	85 (53.7)
Ear, nose, and throat physician	33 (41.8)	36 (45.6)	69 (43.7)
Audiologist	36 (45.6)	39 (49.4)	75 (47.5)
Veterans			
Veterans, n (%)	8 (10.1)	11 (13.9)	19 (12)
Duration in the military service, mean (SD; range)	8 (3; 2-10)	8 (6; 2-23)	8 (5; 2-23)
Ease of using a computer, n (%)			
Basic skills	7 (8.9)	7 (8.9)	14 (8.9)
Frequent user	72 (91.1)	72 (91.1)	144 (91.1)

Retention, Compliance, Engagement, and Adverse Effects

Overall compliance for completing the outcome measures was low, with 57% (41 participants) and 51% (37 participants) completion rates at T1 and T2, respectively, for the experimental group (Figure 1). Although compliance was greater in the control group with 87% (66 participants) and 62% (47 participants) completion at T1 and T2, there was only 33% (25 participants) completion for the control group at T3, resulting in a significant difference between the group completion rates (χ^2_3=7.98; N=411; *P*=.046) at T3 with lower completion by the control group as shown in Figure 2.

Figure 2. Intervention engagement.



Adverse effects have been reported to be low. During the intervention period, only 1 (0.6%) participant had an increase of more than 10 points in the THI-S questionnaire. On finding out more, this was related to a particularly stressful deadline for work under difficult circumstances during the COVID-19 pandemic. Only 1 (0.6%) participant reported an adverse effect on the outcome questionnaire, explaining that initially their tinnitus was more bothersome because of the focus on tinnitus at the start of the intervention. There were no serious adverse events, such as privacy breaches or major technical problems.

Intervention engagement was low but varied considerably among the participants. To identify if group allocation contributed, engagement among groups was compared, whereas each group was actively involved with the intervention. However, no significant group differences were identified (χ^2_1=0.13; N=273; *P*=.93) as shown in Figure 2. On average, 82% (59/72 participants) of the experimental group and 77% (59/76 participants) of the control group logged into the platform; 74% (53/72 participants) from the experimental group and 79% (57/72 participants) of the control group read at least one module, and 32% (23/72 participants) from the experimental group and 30% (23/76 participants) from the control group sent at least one message.

Efficacy of Internet-Based CBT in Reducing Tinnitus Distress Compared With Weekly Monitoring

The tinnitus severity among the treatment arms was not constant over time (Figure 3 and Multimedia Appendix 2). The mean difference indicated a significant difference for the internet-based CBT group with an effect size of Cohen *d*=0.46 at T1. The test of fixed effects (Table 3) indicated that the intercept, slope, and group by time interaction had significant effects on the changes in tinnitus severity. There was no estimated difference in baseline tinnitus severity among the groups (*P*=.92). The posttreatment effect was significantly lower in the control group. After the experimental group underwent treatment (T1), they had an estimated 10-point decrease in tinnitus severity (CI 3-16; $t_{156.00}$=−2.88; *P*=.004). After the control group also underwent treatment (T2), there was a nonsignificant estimated difference of 5 points (CI −2 to 11; $t_{156.00}$=−1.48; *P*=.14). This may have been because of the initial large reduction (mean 7.62, SD 18.21 points) in scores during weekly monitoring despite not having the intervention.

Figure 3. Change in tinnitus severity among groups over time. T1: only the experimental group had the intervention; T2: after the intervention for the control group and 2-month follow-up for the experimental group; T3: the comparison of the 2-month follow-up for both groups.

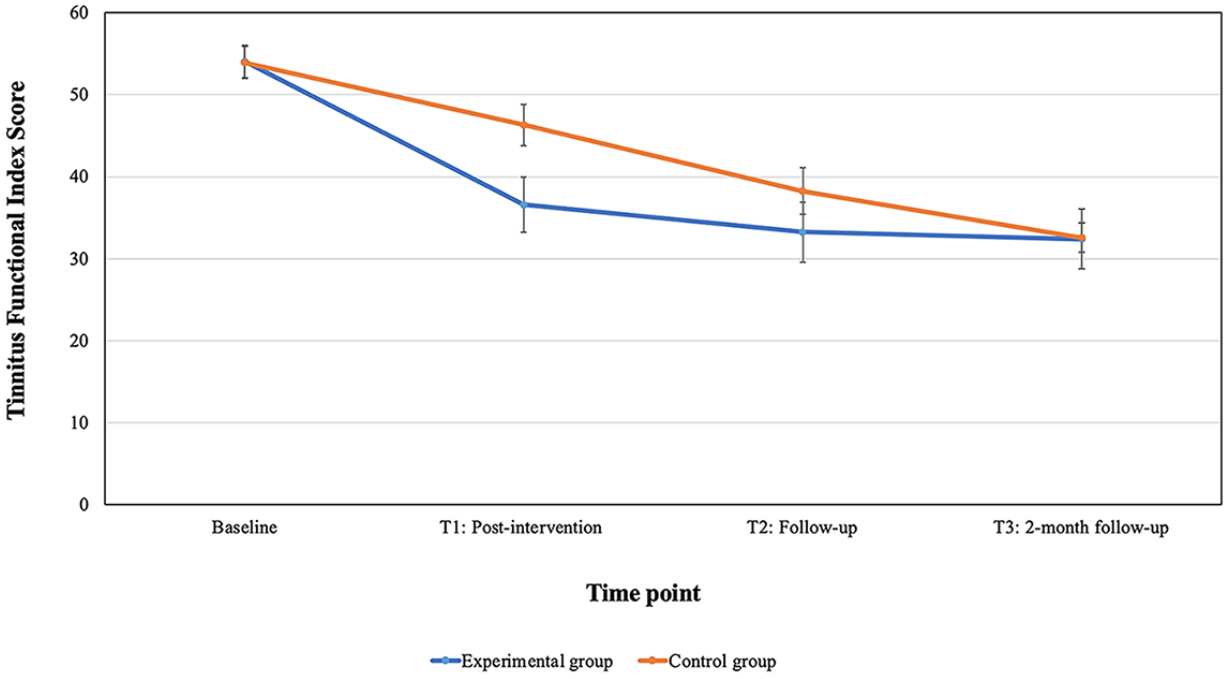


Table 3. Random intercept mixed model results using results from the imputation data.

Outcome predictor	Intercept		Time		Group		Time × group	
	F test (*df*)	*P* value	*F* test (*df*)	*P* value	*F* test (*df*)	*P* value	*F* test (*df*)	*P* value

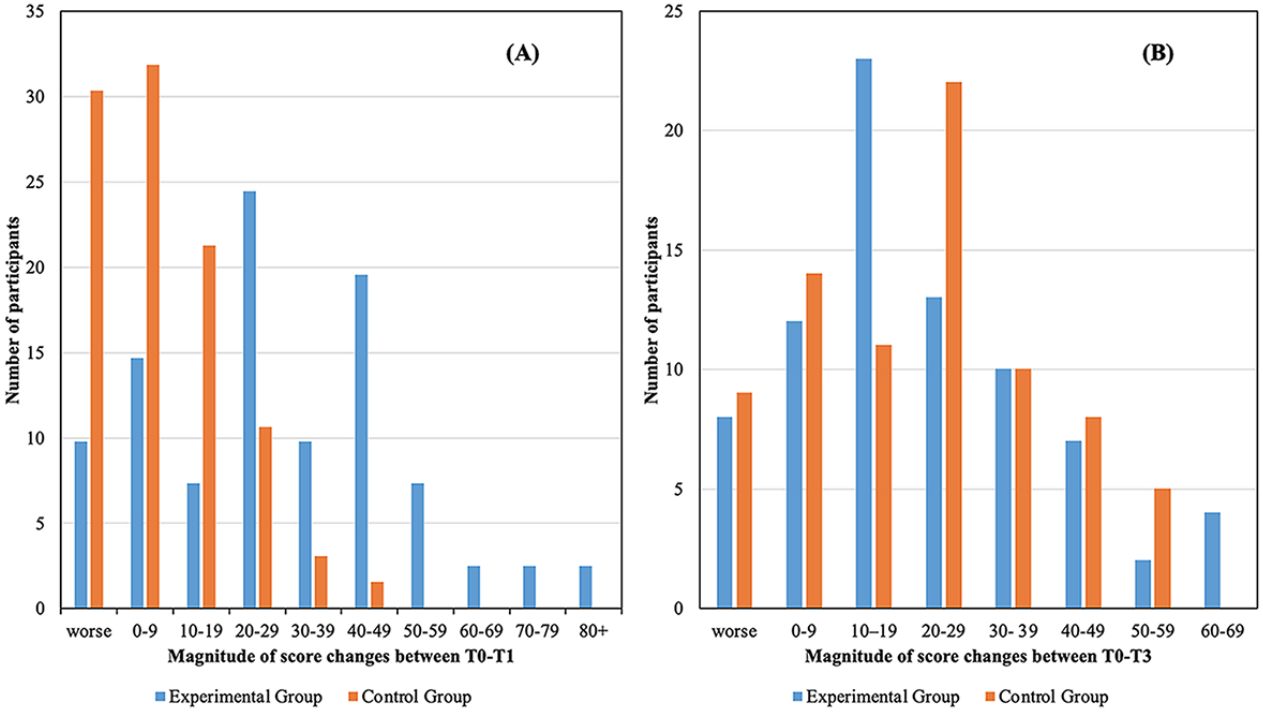
[a]EQ-5D-5L: European Quality of Life Five Dimension.

The model indicated an estimated baseline to 2-month follow-up mean difference of 22 points (CI 18-25) after undertaking the intervention with an estimated TFI score of 32 (baseline score was 54) at follow-up (CI 30-34).

A comparison of the margin of score reduction between T0 and T1 is shown in Figure 4. This indicates that the experimental group had a greater score reduction (between 20 and 50 points) owing to the intervention with a maximum reduction of 88 points, compared with a maximum reduction of 44 points in the control group (with the majority between 0 and 9 points) who were only monitored weekly during this period.

Figure 4. (A) Magnitude of Tinnitus Functional Index score changes between T0 and T1 after the experimental group underwent internet-based cognitive behavioral therapy. The control group was monitored weekly. (B) The magnitude of these changes between T0 and T3 at the 2-month follow-up after both groups completed the full intervention.



The clinical significance was calculated using a reliable change index. The reliable change criterion was calculated to be 22.74 in TFI score. Using this value, clinical significance was achieved by 45 (57%) participants in the experimental group and 12 (15%) participants from the control group at T1 (after the intervention was performed in the experimental group). A clinically significant change was found in 40 (51%) participants of the experimental group at T2 (2 months after the intervention) and 30 (38%) participants of the control group (after the control group completed the intervention) and 40 (48%) participants of the control group at the 2-month follow-up.

Efficacy of Internet-Based CBT in Reducing Tinnitus Comorbidities Compared With Weekly Monitoring

Results from the secondary assessment measures among the treatment arms were not constant over time, except for hyperacusis and the European Quality of Life Five Dimension visual analog scale scores for health-related quality of life, which did not have significant time effects (Table 3). After the intervention (T1), the experimental group had a significantly greater reduction in tinnitus cognition scores, indicating a medium effect (rounded off to Cohen *d*=0.50). The intercept, slope, and time by group interaction revealed significant effects on the changes in tinnitus cognition. Baseline tinnitus cognition was not significantly different among the groups (*P*=.58). After completing the intervention (T1), the experimental group had an estimated 8-point decrease in tinnitus cognition (CI 3-13; t_{156}=−3.13; *P*=.002). After both groups undertook the intervention (T2), there was no significant estimated difference among the groups (*P*=.08). For tinnitus cognitions, the model indicated an estimated baseline to 2-month follow-up mean difference of 7 points (CI 3-11) after undertaking the intervention with an estimated score of 32 at follow-up (CI 31-32).

The experimental group had a significantly greater reduction in insomnia scores after the intervention (T1) and at follow-up (T2), although there was only a small effect (Cohen *d*=0.30) at T1 and medium effect (rounded off Cohen *d*=0.50) at T2. There was no significant group by time interaction indicated by the test of fixed effects owing to later improvements by the control group. Likewise, although the experimental group had a significantly greater reduction in hearing disability at T1, this was only a small effect (Cohen *d*=0.3) without a significant group by time interaction owing to later improvements by the control group.

Confirming the results of the primary outcome, the Tinnitus and Hearing Survey secondary measure indicated that the experimental group had a significantly greater reduction in tinnitus (Cohen *d*=0.60) with no significant difference at baseline or after the control group completed the intervention. The test of fixed effects results indicated that there was no significant time by group interaction for anxiety, depression, health-related quality of life, or hyperacusis outcome measures, and no significant effect was seen.

Stability of Internet-Based CBT Intervention Effects 2 Months After the Intervention

At the 2-month follow-up, the experimental group indicated further reduction in tinnitus severity and all other outcomes. There were no significant differences in scores between T1 and T2 for the experimental group, indicating that intervention effects were maintained 2 months after the intervention.

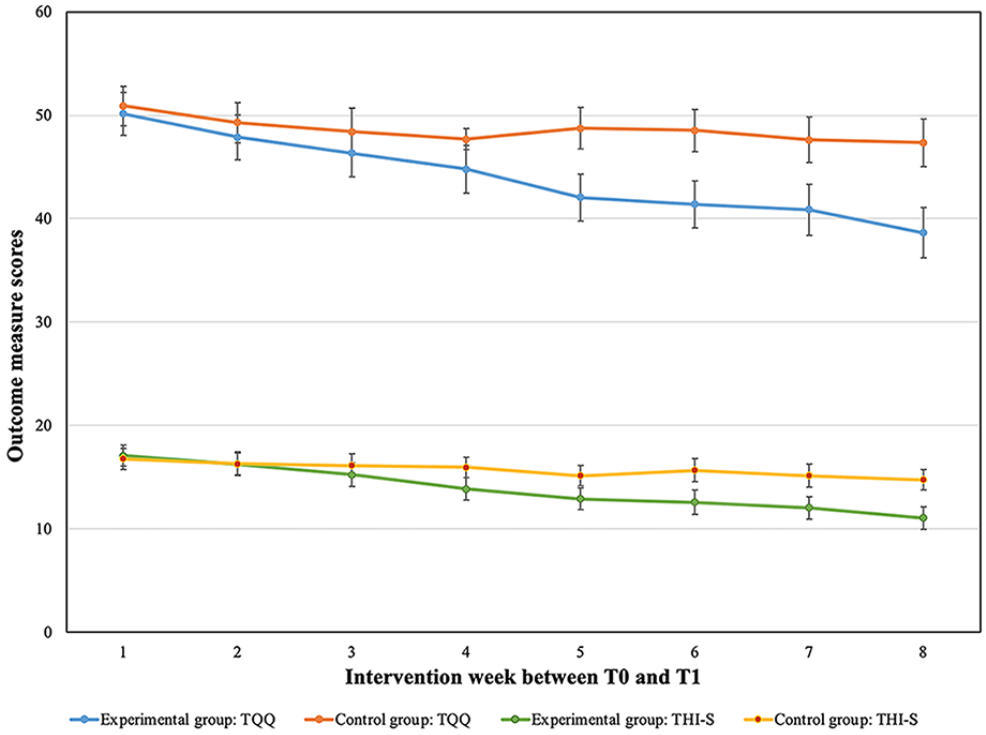
At the 2-month follow-up, most of the secondary outcome measure scores were stable. However, there was an increase in

anxiety scores for both groups, an increase in negative tinnitus cognitions for the experimental group, and a decrease in health-related quality of life for the control group, although these differences were not statistically significant.

Comparison of Weekly Tinnitus Severity During the Active Intervention Period

Differences among the intervention arms were not constant across the eight time points between T0 and T1 for both the THI-S and TQQ outcome measure scores. The experimental group had a greater weekly reduction in tinnitus distress as evidenced by the significant group by time interaction for both the THI ($F_{7,136.000}$=4.02; P=.04) and TQQ ($F_{7,136.000}$=2.55; P=.02), as well as a significant intercept and slope. Pairwise comparisons indicated significant differences among groups from week 5 for the TQQ and week 6 for the THIs, as the experimental group's (receiving internet-based CBT) tinnitus distress was rated significantly lower than that of the control group (not undergoing internet-based CBT). The maximum between-group mean difference in scores was at week 8, with the experimental group having a THI-S score of 3.5 (SE 1.1) points lower and TQQ score of 8.72 (SE 2.30) lower than that of the control group, as seen in Figure 5.

Figure 5. Weekly monitoring between the experimental and control group between T0 and T1. THI-S: Tinnitus Handicap Inventory–Screening; TQQ: Tinnitus Qualities Questionnaire.



Discussion

Overview

This study is the first to evaluate the efficacy of an audiologist-delivered internet-based CBT in reducing tinnitus distress in a US population. It was also the first study to offer internet-based CBT in Spanish to accommodate the Hispanic population in the United States. The study objectives were to evaluate the efficacy of the audiologist-delivered internet-based CBT in reducing tinnitus distress and the comorbidities associated with tinnitus compared with that of weekly monitoring of tinnitus. Furthermore, the stability of the intervention effects was assessed 2 months after the intervention.

Principal Findings

Participating in the internet-based CBT intervention led to significantly greater improvements in tinnitus distress and a medium effect size compared with that of weekly monitoring. This adds to the evidence base regarding the feasibility of audiologist-guided internet-based CBT as indicated in clinical trials in the United Kingdom using audiologist guidance [22-25]. These results are also in line with earlier internet-based CBT trials for tinnitus, indicating a pooled medium effect size (Cohen d=0.59) (for a review see the study by Beukes et al [28]) with those from Europe using psychologist guidance.

Most participants had a reduction of between 20 and 50 points in their TFI scores, although a range of outcomes was observed. Improvements were found in the control group after weekly monitoring, which has also been previously mentioned [56]. This may also be the effect of the control group knowing that they will be receiving an intervention, and this expectation may have helped them manage better before receiving the actual intervention. This initial improvement did seem to affect the postintervention results, which were lower in the control group than in the experimental group. When comparing the participants in each group on a weekly basis, it was observed that the experimental group had a greater reduction in tinnitus distress over the 8-week period. Significant differences were present from week 5 for TQQ and week 6 for THI. This was slightly later in the intervention than was found in the United Kingdom

trial when comparing differences for the THI by week 4 [23]. After the control group undertook the intervention, they made similar significant improvements as those demonstrated by the experimental group, and no significant differences were found among the groups. These results were maintained at the 2-month follow-up for both groups, although the magnitude of reduction was more variable, with the most participants from the experimental group indicating a 10- to 19-point reduction and those from the control group, a 20- to 29-point reduction in TFI scores. Further studies are required to assess whether they are maintained long-term (eg, 1 year) as has been found by previous internet-based CBT for tinnitus trials [17,25,57,58].

More participants from the experimental group had a clinically significant difference (57%; 45 participants) after their treatment compared with 38% (30 participants) of the control group following their treatment. At the 2-month follow-up, 51% (40 participants) and 48% (40 participants) from each group achieved a clinically significant change in tinnitus distress. This was lower than for the pilot study [32] owing to the reliable change criterion required being higher for this study because of a larger baseline SD. As the reliable change criterion was similar to internet-based CBT efficacy trial in the United Kingdom [23], comparable proportions of participants reached clinical significance in this study.

Secondary Results

Experiencing tinnitus is accompanied by various comorbidities that may exacerbate distress and negative emotional responses to perception. An important aspect of tinnitus intervention is the ability to address these challenging comorbidities. Undergoing internet-based CBT resulted in a significantly greater reduction in negative tinnitus cognitions (Cohen *d*=0.46) and insomnia (small effect). This finding is in line with the pooled results from previous internet-based CBT studies, also indicating a small effect (Cohen *d*=0.42). This was the first internet-based CBT for tinnitus study that included the tinnitus cognition questionnaire. The finding that this CBT intervention is able to reduce negative thought patterns associated with tinnitus is a positive finding and continued use of the tinnitus cognition questionnaire is important as recommended by Handscomb et al [59]. From the pooled results of internet-based CBT studies, there was no effect on quality of life [28], similar to this study, but there was a greater reduction in anxiety and depression, which was not found in this study. The reason may be related to the exclusion of individuals with severe mental health conditions, possibly reducing the opportunity to observe an intervention effect owing to the low baseline scores. Broader inclusion criteria are necessary to ensure internet-based CBT is provided to all affected individuals, including those with mental health conditions, as they seem to benefit from this as shown in previous studies [17,19,21-25,57,58]. The pilot study also indicated an effect for hearing disability and hyperacusis [32], which was not observed in this study. The content addressed in the modules providing hearing tactic strategies and advice on reducing sound sensitivity were in the optional modules, which were not read by many participants, and this may have contributed to these results. Interestingly, changes were noted in the TQQ, suggesting that the internet-based CBT may result in a change in tinnitus perception (eg, tinnitus pitch, loudness, and number of sounds heard) in addition to a reduction in tinnitus distress. However, these observations should be replicated in future studies, in addition to possible biomarkers.

Comparison With Previous Work

The study participants' characteristics were similar to those found in previous internet-based CBT trials; however, the mean age was slightly higher at 57 years than at a mean age of 51 years [28]. Despite extensive recruitment strategies and campaigns, following suggestions to support Hispanic and Latino research participants [60], only 8 participants selected to participate in the intervention in Spanish. Further efforts will be required to build trust within Hispanic communities before recruiting for subsequent trials [61].

Although the study administration mimicked that that would be provided in a routine application, the overall completion rate of the posttreatment questionnaires was low across time points and groups, compared with that of previous internet-based CBT for tinnitus studies [28]. Although only 10 participants (6%) withdrew, many enrolled participants never logged into the intervention website. Moreover, not all the modules were read, and very few messages were sent, indicating low intervention engagement. Numerous factors contribute to this finding. One may be the timing of this study during the COVID-19 pandemic. Participants explained that they were on their computers all day attending meetings on Zoom as they had to stay at home. This may be an additional computer work, making this intervention difficult, because of them wanting to take a break from their computers. Some participants mentioned having contracted the COVID-19 virus, and even after recovering, they remained fatigued, making intervention engagement difficult. Others found the lifestyle changes of working from home and juggling childcare difficult, and some were affected emotionally. However, the COVID-19 pandemic is unlikely to be the only reason for poor engagement. Differences in compliance among groups were also observed. After receiving the intervention, compliance was lower in the experimental group and lower in the control group at the 2-month follow-up. This may have reflected the trial design that the control group had an additional assessment time point and having already completed assessments after the control and intervention, decided not to complete another assessment at the 2-month follow-up. During the pilot study [32], lower engagement than noted in earlier studies was observed. Cultural differences may not be accounted for. In contrast to the United Kingdom and many parts of mainland Europe, many people pay for health care via third-party reimbursements in the United States. The internet-based CBT intervention was offered free of charge. It may be that people undervalued this treatment as a free treatment that may be perceived as less effective than one requiring payment. In addition, this study recruited participants only from Texas, United States, thus representing a very small population of the United States and may not represent the wider US population. Subsequent trials should be performed with a wider US population. Process evaluation may be helpful in identifying the factors contributing to the retention and engagement rates and identifying what may improve theses [26]. Continued public involvement in planning and implementing subsequent research

trials will be vital to gain insights into the factors important to participants [62,63].

Limitations

This study represents participants living in Texas, United States, who do not present with severe mental health conditions, often associated with tinnitus. This may not present the typical tinnitus population, and thus, the findings cannot be generalized to other populations. Despite recruitment efforts, only 8 Spanish participants were recruited; similarly, the participant groups also contained low numbers of ethnic and racial minorities when compared with the general population from this region. The study was furthermore conducted during the peak of the COVID-19 pandemic, a time when day-to-day living was disrupted for most people. The results may also have been different if a large proportion of participants were engaged and completed the outcome assessments.

Conclusions

Compounding the potentially debilitating nature of severe tinnitus, accessible, evidence-based interventions are still lacking. There is an urgent need to improve the availability of such interventions. Furthermore, the COVID-19 pandemic has highlighted the need for evidence-based eHealth approaches to overcome the limited in-person contact and support available for individuals with tinnitus [63]. These results further support the role of audiologists in guiding such forms of tinnitus management. The results have been encouraging, and further work is indicated in view of making such an intervention applicable to a wider population. Future work should consider enrolling heterogeneous tinnitus populations to examine who are more suitable (or not) for the internet-based CBT program. In addition, a stepped approach (eg, a brief intervention offered to all participants and a comprehensive intervention for more suitable patients following the brief intervention) should be examined to improve compliance and engagement.

Acknowledgments

We would like to thank webmasters George Vlaescu and Shrinivas Varadaraj for their help in installing the intervention platform and for providing technical assistance. We extend our thanks to all the participants who participated in this study; our public-patient advisory group; and the organizations, including the American Tinnitus Association, that helped with recruitment. We also thank Professor Stacia DeSantis for the statistical assistance provided.

This work was funded by the National Institute on Deafness and Other Communication Disorders of the National Institute of Health under award number R21DC017214. The funding body was not involved in the design of the study, data collection, data analysis, interpretation of data, or writing of the manuscript.

Authors' Contributions

VM obtained the funding and licenses. GA provided the software. All authors contributed to the research design. Data collection, analysis, and interpretation were performed by EB. EB drafted the manuscript. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The effectiveness of psychosocial interventions on quality of life (QOL) among people living with HIV has been validated, including mobile health (mHealth) interventions. However, it is unclear which components of such interventions account for these effects.

Objective: This study aims to examine positive coping as a potential mediator of the effects of an mHealth intervention on QOL among people living with HIV.

Methods: For this secondary analysis, we used data from an mHealth-based randomized controlled trial, Run4Love, which was conducted to improve QOL and mental health outcomes of people living with HIV. A total of 300 participants were randomly assigned to the intervention group to receive the adapted cognitive-behavioral stress management courses and regular physical activity promotion or the waitlist control group in a 1:1 ratio. Our analysis focused on positive coping and QOL, which were repeatedly measured at baseline and at 3-, 6-, and 9-month follow-ups. Latent growth curve models were constructed to explore the mediating role of positive coping in the effects of the mHealth intervention on QOL.

Results: Positive coping served as a mediator in the effect of the mHealth intervention on QOL for up to 9 months. The mHealth intervention had a significant and positive indirect effect on the slope of QOL via the slope of positive coping (b=2.592×1.620=4.198, 95% CI 1.189-7.207, P=.006). The direct effect of the intervention was not significant (b=0.552, 95% CI −2.154 to 3.258, P=.69) when controlling for the mediator.

Conclusions: The longitudinal findings suggest that positive coping could be a crucial mediator of the mHealth intervention in enhancing QOL among people living with HIV. These findings underscore the importance of improving positive coping skills in mHealth interventions to improve QOL among people living with HIV.

Introduction

Background

Substantial improvements to and increased coverage in antiretroviral therapy have resulted in extended life expectancy of people living with HIV, leading to over 1.25 million HIV seropositive survivors in China [1,2]. With improved survival, quality of life (QOL) during treatment has become increasingly important for people living with HIV [3]. Owing to HIV disease progression and treatment side effects, the QOL of people living with HIV continues to be lower than that of people living with other chronic diseases, as well as the general population [4,5]. Poor QOL is not only related to suboptimal adherence to antiretroviral therapy, leading to inferior therapeutic effects [6], but is also associated with elevated HIV risk behavior, leading to increased risk of HIV transmission in the community [7]. Therefore, effective interventions to improve QOL in people living with HIV are warranted, especially those that can reach a large number of the targeted population, such as mobile health (mHealth) programs.

The literature suggests that psychosocial interventions such as cognitive-behavioral stress management (CBSM) programs can improve QOL in a variety of populations with chronic diseases, including people living with HIV [8-12]. Evidence also shows that mHealth-based psychosocial interventions produce similar benefits in comparison with face-to-face interventions, and they have additional advantages because of the easy accessibility and cost-effectiveness [13,14]. Nevertheless, the potential mechanism by which these mHealth interventions improve QOL among people living with HIV remains unclear. There might be various factors that affect the outcomes of the intervention. Mediation constitutes a mechanism through which the independent variable affects the dependent variable of interest [15]. Exploration of mediators will help understand the effective components of an intervention, which is crucial for future optimization of the program design [16].

A considerable amount of research has focused on exploring factors associated with QOL, with positive coping being one factor that has received substantial attention [17-21]. Positive coping is defined as individuals' active cognitive response (eg, trying to see the positive side) and adaptive behavioral response (eg, talking with family or friends) when managing stressful situations [22]. A substantial body of cross-sectional studies have shown that higher positive coping is related to higher QOL [18-20]. Some randomized controlled trials (RCTs) have indicated that positive coping might be a key determinant of the effectiveness of psychosocial interventions in improving QOL among people living with HIV [23,24]. For example, Hansen et al [24] found that HIV-positive participants reported significant postintervention improvement in both QOL and positive coping in the cognitive-behavioral support group, as well as in the control group providing mental health sessions and psychiatric services upon individual request. Using mixed models, the study also found that positive coping was directly associated with improved QOL in multiple time points across the intervention [24]. Similarly, another study revealed that a CBSM intervention was effective in improving positive coping in HIV-seropositive men who have sex with men, and positive coping might be an important predictor of QOL improvement [23].

Previous studies exploring the mediators of the effects of interventions on improving QOL have mostly been conducted in face-to-face settings [23,25,26]. It is unclear whether the factor mediating the effects of an intervention on QOL in face-to-face settings remains effective in mHealth settings. Furthermore, existing studies on mediation analysis mostly use pre- and postintervention data, whereas interventions in repeated measure design are lacking [11,23,25]. As 2–time point data contain limited information on individual changes, longitudinal data tracking over multiple time points (≥3) may allow further investigation on the changes of both the mediator and the outcome, as well as the trajectory of the time-varying relationships between them over time [27].

Objective

To bridge the gaps in the existing literature, we used longitudinal data from the Run4Love study to examine the mediating role of positive coping on QOL in an mHealth intervention. The Run4Love study was a WeChat (Tencent)-based RCT to examine the intervention effects of an adapted CBSM course with physical activity promotion compared with usual care in people living with HIV. In this study, we hypothesized that the mHealth intervention would enhance the use of positive coping strategies in people living with HIV, which in turn was related to the significant improvement in QOL over time.

Methods

Research Setting and Ethical Considerations

The study used data from an mHealth-based RCT, Run4Love (ChiCTR-IPR-17012606) [28]. The Run4Love intervention was designed to improve mental health outcomes of people living with HIV, including, but not limited to, the reduction in depressive symptoms and improvement in QOL [28,29]. It was conducted from September 2017 to October 2018 in Guangzhou, the third-largest city of China [30]. A total of 300 participants were randomly assigned to either the intervention group to receive a 3-month WeChat-based mHealth program or the waitlist control group to receive usual care in a 1:1 ratio. The study design, recruitment procedures, and process of randomization were detailed in the study protocol, which was approved by the Institutional Review Board of Sun Yat-sen University [28].

Participants Enrollment

The trained research staff recruited participants from the infectious disease outpatient department of the only hospital

designated for HIV care and treatment in Guangzhou. Patients who showed interest in the study were invited to participate in a consultation session to receive further information about the program and complete a screening questionnaire. Patients were eligible to participate if they met all of the following inclusion criteria: (1) aged ≥18 years, (2) HIV seropositive, (3) having elevated depressive symptoms (Center for Epidemiologic Studies-Depression score ≥16), and (4) using WeChat, the most popular instant messaging mobile program in China, with more than 1 billion active users worldwide [31]. Patients were excluded if they met any of the following exclusion criteria: (1) currently on psychotherapy or taking psychiatric drugs, (2) unable to complete the questionnaires, (3) unable to read or listen to the intervention materials, and (4) unable to engage in physical activities for medical reasons.

Participants who met the aforementioned eligibility criteria and provided written informed consent were enrolled in the study. Under the guidance of the research staff, participants were asked to complete electronic questionnaires in the outpatient department at baseline and 3-, 6-, and 9-month follow-ups. Participants would receive 50 RMB (ie, approximately US $8) or gifts of equivalent value (eg, a yoga mat) as an incentive for completing each assessment.

The Run4Love Intervention

Participants in the intervention group received a 3-month WeChat-based intervention, which consisted of the adapted CBSM course and physical activity promotion [28]. CBSM is a therapeutic approach to teaching people living with HIV to manage their stress by focusing on how individuals' thoughts affect their emotions and behaviors and to influencing participants' irrational thoughts and changing their thought patterns and behaviors [32]. The adapted CBSM course mainly included coping and stress reduction skills such as meditation, muscle relaxation, and abdominal respiration training. The physical activity promotion program mainly included guidance on exercise, benefits of exercise, and a healthy diet. The content of these 2 intervention components was provided through 65 intervention materials in multiple formats, including short articles, motivational posters, and audio clips. These materials were delivered to participants on a near-daily basis (5-6 times a week) via an enhanced WeChat platform, the Run4Love platform. On average, each of the short articles had around 1300 words, which required about 5 minutes to read; each poster with motivational messages required about half a minute to read; each audio recording required 5 to 10 minutes to listen to [33].

Participants in the control group received a brochure on nutrition and healthy living style. They would be offered the Run4Love program as soon as the study was completed (ie, 9 months after their enrollment).

Measurement

QOL Assessment

QOL was measured using the 31-item World Health Organization Quality of Life HIV short version (WHOQOL-HIV BREF) at baseline and 3, 6, and 9 months. The WHOQOL-HIV BREF has been widely used among people living with HIV with proven reliability and validity [34,35]. The 31-item scale measures QOL across six domains (ie, physical, psychological, level of independence, social relationships, environment, and spirituality) over the last 2 weeks. Each item was rated on a 5-point Likert scale ranging from 1 (not at all) to 5 (extremely), altogether providing a 4-20 score in each domain and a 24-120 score for the whole scale after the transformation, with higher scores indicating better QOL [34]. An example of these items assessing QOL was "How much do you enjoy life?" Good reliability of the WHOQOL-HIV BREF was shown in the study, and Cronbach α ranged from .727 to .838 across the 4 assessment points.

Positive Coping

Positive coping was measured using the 12-item subscale of the Simplified Ways of Coping Questionnaire with good reliability and validity in the Chinese populations [36-38]. The subscale consists of 12 items such as "Try to look on the bright side of things" and "Find out several different methods to solve the problem" to assess the frequency of positive attitudes and skills of coping that a participant adopted in daily life. Each item was rated on a 4-point Likert scale ranging from 0 (not use at all) to 3 (use frequently), providing a 0-36 score, with higher scores indicating higher levels of positive coping. Cronbach α ranged from .848 to .925 across the 4 assessment points in this study.

Demographic Characteristics

Demographic characteristics included age, gender, marital status, educational level, sexual orientation, employment status, family monthly income, and duration of HIV infection (years).

Statistics Analysis

The intention-to-treat principle was applied to all analyses in this study. Descriptive analyses of demographic characteristics, QOL, and positive coping were performed. Differences in outcome measures and baseline characteristics between the intervention and control groups were evaluated using the 2-tailed *t* test or Wilcoxon rank-sum test for continuous variables and the chi-square test for categorical variables. Latent growth curve models (LGCMs) were constructed to examine the mediating role of positive coping in the effects of the mHealth intervention on QOL among people living with HIV. All statistical hypothesis tests were 2-sided, and a *P* value <.05 was considered statistically significant. Descriptive analyses and group comparisons of the key variables were conducted using R (version 3.5), and LGCMs were constructed using Mplus (version 7; Muthén & Muthén). Missing data in all LGCMs were managed using the robust maximum likelihood estimation procedure.

The analyses of the mediation effect were conducted in 3 steps [39]. First, 2 unconditional LGCMs were constructed separately to estimate the growth trajectories of the outcome measure (QOL) and potential mediator variable (positive coping). The latent variables of intercept and slope (ie, the initial status and rate of change) were estimated from the repeated measures at 4 time points. For the intercept factor, the loadings across the 4 assessment points were fixed to 1. For the slope factor, the first loading was fixed to 0, the second to 1, and the other loadings were freely estimated [40]. Instead of assuming a linear

trajectory by setting the loadings onto the slope factor to 0, 1, 2, and 3, it was more reasonable to explore the potentially nonlinear trajectories by setting the third and fourth loadings free when the assumption of linear LGCM was unconfirmed [40].

Second, 2 conditional LGCMs were specified to separately examine the impact of the intervention on QOL and positive coping. The conditional models were extensions of the unconditional models to incorporate the variable of intervention group assignment (ie, intervention group=1 and control group=0) as a covariate.

Third, a parallel-process LGCM was constructed to evaluate whether the intervention was effective in improving QOL via the mediator variable of positive coping. The parallel-process model was a combination of the aforementioned 2 conditional LGCMs, which simultaneously estimated the trajectories of QOL and positive coping, and incorporated intervention group assignment as a covariate. The mediation effect was tested based on bias-corrected 95% bootstrapped CIs with a resampling of 5000 [41,42].

Model fit was evaluated using chi-square test statistics and other indexes, including the Tucker-Lewis index (TLI), the comparative fit index (CFI), the root mean square error of approximation (RMSEA), and the standardized root mean square residual (SRMR). An LGCM with adequate model fit should meet the following criteria: TLI>0.90, CFI>0.90, RMSEA<0.08, and SRMR<0.08 [43-45].

Results

Baseline Characteristics

Descriptive statistics for baseline characteristics are shown in Table 1. The baseline characteristics of the participants were balanced between the intervention and control groups, except for the fact that a slightly higher proportion of heterosexual participants were allocated to the control group. The median age of the participants was 27.5 years, and the median duration of HIV infection was 1.7 years. The majority were male (277/300, 92.3%), well-educated (182/300, 60.7% with at least some college education), unmarried (262/300, 87.3%), and employed (251/300, 83.7%) and had a moderate level of income (176/300, 58.7% with family monthly income <7000 yuan [US $1100]). Up to 81.7% (245/300) of the participants were homosexual, bisexual, or uncertain of their sexuality.

Table 1. Baseline Characteristics of the participants in the Run4Love randomized controlled trial (N=300).

Variables	Total (N=300)	Intervention (n=150)	Control (n=150)	*P* value
Age (years), median (IQR)	27.5 (24.5-31.3)	27.4 (24.3-31.1)	27.8 (24.6-32.2)	.29
Gender, n (%)				.13
Male	277 (92.3)	142 (94.7)	135 (90)	
Female	23 (7.7)	8 (5.3)	15 (10)	
Educational level, n (%)				.10
>High school	182 (60.7)	98 (65.3)	84 (65)

Duration of HIV infection (years), median (IQR)	1.7 (0.6-3.7)	1.7 (0.6-4.0)	1.8 (0.6-3.9)	.62
Positive coping, mean (SD)	18.4 (5.8)	18.4 (5.5)	18.3 (6.2)	.92
Quality of life, mean (SD)	77.0 (9.2)	77.4 (9)	76.6 (9.4)	.44

Changes in Repeated Measures

Repeated measures of the outcome variable (ie, QOL) and potential mediator (ie, positive coping) at the 4 assessment points are presented in Table 2. The sample mean and 95% CIs of QOL and positive coping over 9 months for both the intervention and control groups are presented in Figure 1. Participants in the intervention group had significantly higher levels of QOL and positive coping than those in the control group at the 3-, 6-, and 9-month follow-ups, indicating significant effects of the Run4Love mHealth intervention on improving QOL and positive coping over time. Specifically, in comparison with those in the control group, participants in the intervention group also had significantly higher mean scores in all 6 domains of QOL at the 3-, 6-, and 9-month follow-ups (Figure 2; Table 3).

Table 2. Repeated measures of quality of life and positive coping of the participants in the Run4Love randomized controlled trial.

Variables	Quality of life, mean (SD)			Positive coping, mean (SD)		
	Intervention[a]	Control[b]	*P* value	Intervention[a]	Control[b]	*P* value
Baseline	77.43 (9.03)	76.59 (9.42)	.44	18.39 (5.46)	18.32 (6.15)	.92
3 months	82.54 (12.03)	76.63 (11.08)	<.001	20.79 (7.33)	17.70 (5.88)	<.001

[a]For variables in the intervention group, the sample sizes were 150, 139, 132, and 133 at baseline and 3-, 6-, and 9-month follow-ups, respectively.

[b]For variables in the control group, the sample sizes were 150, 135, 133, and 127 at baseline and 3-, 6-, and 9-month follow-ups, respectively.

The dropout rates were 8.7% (26/300; 11/150, 7.3% in the intervention group; 15/150, 10.0% in the control group), 11.7% (35/300; 18/150, 12.0% in the intervention group; 17/150, 11.3% in the control group), and 13.3% (40/300; 17/150, 11.3% in the intervention group; 23/150, 15.3% in the control group) at 3-, 6-, and 9-month follow-ups, respectively. The average completion rate of the 3-month Run4Love program among people in the intervention group was 50.8% (33/65) [33].

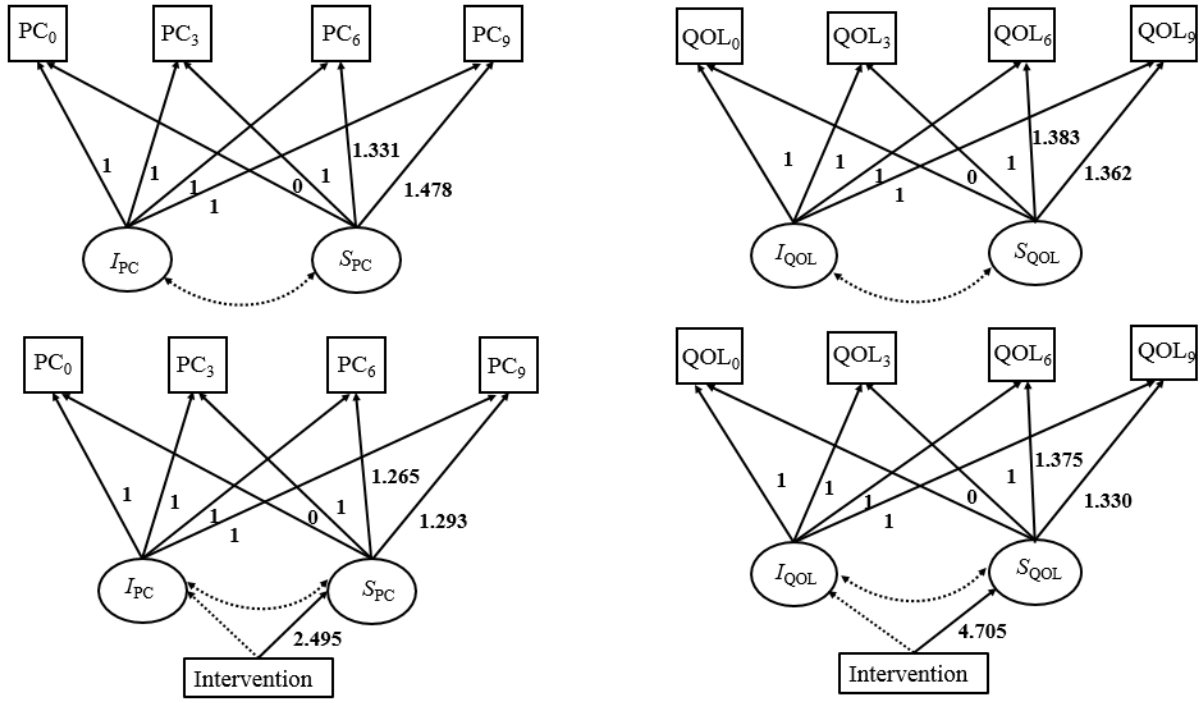
Results of LGCMs

The results of the unconditional LGCMs indicated that both QOL and positive coping improved across the course of the study, and the largest improvement occurred at the 3-month follow-up. The path diagrams of these 2 unconditional LGCMs are presented in Figure 3. The unconditional LGCM for QOL had a good model fit: χ^2_3=2.7 (*P*=.26), CFI=0.999, TLI=0.996, SRMR=0.044, and RMSEA=0.034 (Figure 3). The mean intercept was 77.032 (*P*<.001, SE 0.527), indicating a mean QOL score of 77.032 at baseline. The mean slope was 2.241 (*P*<.001, SE 0.503), and the factor loadings on the slope were 0, 1, 1.383, and 1.362 at baseline and 3, 6, and 9 months, respectively. These results reflected a nonlinear pattern of improvement in QOL: a rapid increase in QOL scores (2.241 points) occurred at 3 months, and then the magnitude of improvement flattened out. The variances of the intercept and

the slope of QOL were 92.509 (*P*=.001) and 54.013 (*P*=.04), respectively, which indicated significant individual differences in the initial levels and rates of change in QOL over time. The covariance between the intercept and the slope of QOL was −16.029 (*P*=.48), implying that the rate of change in QOL was not associated with its initial levels. The unconditional LGCM for positive coping also had a good model fit: χ^2_3=1.6 (*P*=.66), CFI=1.000, TLI=1.000, SRMR=0.025, and RMSEA<0.001 (Figure 3). The mean positive coping score was 18.373 (*P*<.001, SE=0.340) at baseline, and the mean slope was 0.699 (*P*=.04, SE=0.336). Similarly, the results of the slope factor also reflected a nonlinear pattern of improvement in positive coping: a rapid increase in positive coping scores (0.699 points) occurred at 3 months, and then the magnitude of improvement flattened out. The variances of the intercept and the slope in positive coping were 21.571 (*P*=.01) and 10.194 (*P*=.21), respectively, indicating significant individual differences in the initial levels of positive coping but not in its rates of change. The rate of change in positive coping was also unrelated to its initial levels, with a covariance between the intercept and the slope of −2.664 (*P*=.70).

The results of the conditional LGCMs indicated that the mHealth intervention had significantly positive effects on both QOL and positive coping across the course of the study. The path diagrams of these 2 conditional LGCMs are also presented in Figure 3. The conditional model for QOL fitted the data well: χ^2_5=3.3 (*P*=.50), CFI=1.000, TLI=1.000, SRMR=0.041, and RMSEA<0.001 (Figure 3). The intervention had a significant impact on the slope factor (*b*=4.705, SE=0.911, *P*<.001), indicating an improvement in QOL in the intervention group compared with the control group over time. Similarly, the conditional model for positive coping fitted the data well: χ^2_5=5.7 (*P*=.34), CFI=0.997, TLI=0.995, SRMR=0.030, and RMSEA=0.022 (Figure 3). There was a higher rate of change in positive coping in the intervention group (*b*=2.495, SE=0.826, *P*=.003), indicating a larger improvement in positive coping in the intervention group.

Figure 3. Path diagrams of the unconditional latent growth curve models (LGCMs) for quality of life (QOL) and positive coping and the conditional LGCMs with intervention groups as a covariate. Observed variables are denoted by boxes. Latent variables are denoted by ovals. Unidirectional arrows indicate the effects of 1 variable on the other. Bidirectional arrows indicate the correlations. The nonsignificant paths are shown as dotted lines. Intervention is either the Run4Love intervention group or the waitlist control group. I: intercept; PC: positive coping; S: slope; 0: baseline; 3: 3-month follow-up; 6: 6-month follow-up; 9: 9-month follow-up.



The results of the parallel process LGCM indicated that the mHealth intervention was effective in improving QOL via the mediation effect of positive coping. The path diagram of the parallel process LGCM is presented in Figure 4, and the estimates of the main coefficients are shown in Table 4. The results showed a good model fit for the parallel process LGCM: χ^2_{24}=64.1 (*P*<.001), CFI=0.971, TLI=0.957, SRMR=0.065, and RMSEA=0.075 (Figure 4). The intervention had a significantly positive impact on the slope of positive coping (*b*=2.592, *P*<.001), which in turn had a significantly positive impact on the slope of QOL (*b*=1.620, SE=0.321, *P*<.001). The indirect effect of the intervention on the slope of QOL via the slope of positive coping was significant (*b*=2.592×1.620=4.198, *P*=.006). These results indicated a mediation effect of positive coping on patients' QOL, where the exposure to the mHealth intervention significantly improved participants' positive coping over time, which in turn led to a positive change in QOL. The intervention no longer had direct effects on the slope of QOL (*b*=0.552, *P*=.69), indicating that the effects of the intervention on QOL might be explained by the mediation effect of positive coping. There were no significant differences as a function of intervention in the initial status of either repeated measures,

indicating no group differences in the starting point for either positive coping or QOL. The covariance between the 2 intercepts was 21.571 (*P*=.01), indicating that initial levels of positive coping were positively related to initial status with respect to QOL. In other words, participants who reported higher levels of positive coping at baseline tended to report higher levels of QOL at the same time. However, neither the covariance between the intercept of positive coping and the slope of QOL (2.941, *P*=.26) nor the covariance between the intercept of QOL and the slope of positive coping (−3.900, *P*=.16) was statistically significant. These results indicated that the initial level of positive coping was not significantly associated with the rate of change in QOL, nor was the initial level of QOL and the rate of change in positive coping.

Figure 4. Path diagram of a parallel process latent growth curve model for quality of life (QOL) and positive coping with intervention groups as a covariate. Observed variables are denoted by boxes. Latent variables are denoted by ovals. Unidirectional arrows indicate the effects of 1 variable on the other. Bidirectional arrows indicate the correlations. The nonsignificant paths are shown as dotted lines. Intervention is either the Run4Love intervention group or the waitlist control group. I: intercept; PC: positive coping; S: slope; 0: baseline; 3: 3-month follow-up; 6: 6-month follow-up; 9: 9-month follow-up.

[a]QOL: quality of life.

Discussion

Principal Findings

To the best of our knowledge, our secondary analysis of data from the Run4Love study is among the first efforts to examine the mediating role of positive coping in patients' QOL in an mHealth-based RCT among people living with HIV. The results of LGCMs demonstrated that the Run4Love trial significantly improved positive coping among people living with HIV over 9 months, and the enhancement of positive coping led to significant improvement in QOL across the study. There was full mediation between positive coping and QOL in the Run4Love trial. Thus, our study revealed one of the potential mechanisms of improvement in QOL in mHealth-based CBSM interventions. To better design and implement effective interventions for people living with HIV, more studies are needed to investigate and identify the processes and/or mechanisms by which interventions lead to significant improvements in health outcomes, especially in emerging mHealth interventions [27].

Although several cross-sectional studies and 1 cohort study have examined the mediating role of positive coping on QOL [19-21], such designs are not sufficient for a robust conclusion because their findings are based on passive observational data.

An experimental design in which the proper intervention is used to improve an individual's positive coping and QOL would greatly reduce confounding effects and enhance the strength of causal inferences. However, few RCTs have explored this relationship, especially in mHealth interventions. Only 1 face-to-face RCT showed that improvement in positive coping significantly mediated the effects of psychosocial intervention on QOL using pre- and postintervention assessments [25]. A comprehensive literature review suggested that mediation analysis could only be properly examined in well-designed RCTs with repeated measurements and sufficient power [27]. Thus, our study is well suited to investigate such a relationship and has confirmed the mediating role of positive coping on QOL, which may expand the literature on mechanisms of mHealth-based interventions.

In addition to the RCT design, the time point repeated measures and corresponding methodology of LGCM used in this study allow more conclusive findings and more abundant information for the mediation analysis or other research. Unlike cross-sectional data or pre- and postintervention data adopted in the previous literature, LGCMs that use longitudinal data allow the trajectory estimation of changes in outcome measures over time [39,40]. For example, the results of the LGCMs in our study suggested that both positive coping and QOL had increasing and nonlinear trajectories with a slower rate of increase over time, and there were statistically significant individual differences in the initial levels and rates of change of positive coping and QOL over time. In addition, the parallel process LGCM allowed for the examination of intercept-intercept, intercept-slope, and slope-slope relationships of the trajectories, which might extend our understanding of the relationships between the factors investigated [46]. In our study, we found a significant slope-slope relationship between positive coping and QOL, which indicated a mediation effect of positive coping on QOL in the mHealth intervention. Therefore, the LGCMs could not only estimate the growth curve of each outcome measure over time but also simultaneously examine the mediation relationship between 2 outcomes (eg, positive coping and QOL) in an intervention by controlling for their growth trajectories [39].

Given the critical role of positive coping in improving QOL, it is important to develop positive coping skills in mHealth interventions to improve participants' QOL. Previous psychosocial interventions for people living with HIV found that training in active cognitive and adaptive behavioral coping strategies was effective in improving positive coping [23,47,48]. In the Run4Love trial, we adapted the evidence-based CBSM intervention with important components of training in various types of coping skills, such as active cognitive coping (eg, mindfulness and problem- or emotion-oriented coping) and adaptive behavioral coping (eg, regular exercise) [28]. In addition, we adapted the CBSM courses originally designed for people living with HIV in the United States by removing some parts of the courses that were not suitable in the Chinese context, such as religion-related materials. Therefore, we had 9 sessions out of the original 10 sessions of the CBSM courses. Furthermore, as Chinese people living with HIV visit the hospital for antiretroviral drugs and regular clinical follow-ups every 3 months, we matched the patients' hospital visits and adapted the length of the intervention to 3 months by adding 3 review sessions and having weekly delivery of the total 12 sessions of the CBSM courses [28]. In addition, our CBSM intervention delivered in the mHealth platform allowed and encouraged participants' repeat visits to the training items, which might result in enhanced and sustained intervention effects over 9 months by repeatedly accessing the CBSM courses and practicing the coping skills, thus producing improved and sustained effects on patient outcomes such as QOL. To our knowledge, there is limited evidence about the long-term effects of mHealth interventions; few studies have reported intervention effects for over 6 months [49,50]. Few studies have been conducted on the potential mechanisms of the persistent intervention effects in mHealth interventions. The investigation in this study may provide important information and evidence on intervention mechanisms for long-term sustained effects in mHealth interventions.

Limitations

This study had several limitations. First, the self-reported data on positive coping and QOL in our study might have resulted in recall and social desirability biases. More objective measures, such as biomarkers, could be incorporated in future studies. Second, although participants were recruited from a large hospital for HIV treatment in Guangzhou with over 10,000 patients who were HIV seropositive, the sample was mostly from an urban setting and was predominantly male, particularly young men who have sex with men. Therefore, the generalizability of our findings should be treated with caution. Third, as all the 6 dimensions of QOL were improved in the intervention group at 3, 6, and 9 months, and the improvement was not limited to the mental health dimension, it is possible that the improvement in QOL was also related to other factors besides positive coping, such as reduced depressive symptoms, stress, and/or HIV-related stigma and increased social support [51-53]. Although it is beyond the scope of this study to incorporate other factors, one of our previous studies found mediating roles of perceived stress and depressive symptoms for suicide reduction [53], whereas another study found positive coping and HIV-related stigma as intervention mediators on depressive symptoms [52]. Therefore, other potential mediators should be further explored to clarify the mechanisms of intervention effects and processes of how mHealth interventions improve health outcomes for better designing and implementing effective mHealth interventions.

Conclusions

In conclusion, this study found a full mediation effect of positive coping on QOL among people living with HIV in an mHealth intervention using 4 time point repeated measures and LGCMs. Future research and policies aimed at QOL improvement among people living with HIV should be designed with specific features that enhance the use of positive coping strategies.

Acknowledgments

This study was supported by the National Natural Science Foundation of China (grant 71573290) and China Medical Board open competition funding (grant 17-271). The funding sources had no role in the study design, data collection, statistical analyses, or writing of the manuscript.

Authors' Contributions

YG and YZ had full access to all the data in the study and take responsibility for the integrity of the data and the accuracy of the data analysis. They contributed to the conceptualization and design of the study. YZ, MZ, CZ, YL, JQ, and HZ were responsible for the acquisition, analysis, or interpretation of data. YZ drafted the manuscript. YG, RH, AMW, and YZ conducted critical revision of the manuscript for important intellectual content. LL, WC, and CL provided administrative, technical, or material support. YG supervised the study.

Abstract

Background: Nonadherence to medication in tuberculosis (TB) hampers optimal treatment outcomes. Digital health technology (DHT) seems to be a promising approach to managing problems of nonadherence to medication and improving treatment outcomes.

Objective: This paper systematically reviews the effect of DHT in improving medication adherence and treatment outcomes in patients with TB.

Methods: A literature search in PubMed and Cochrane databases was conducted. Randomized controlled trials (RCTs) that analyzed the effect of DHT interventions on medication adherence outcomes (treatment completion, treatment adherence, missed doses, and noncompleted rate) and treatment outcomes (cure rate and smear conversion) were included. Adult patients with either active or latent TB infection were included. The Jadad score was used for evaluating the study quality. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guideline was followed to report study findings.

Results: In all, 16 RCTs were selected from 552 studies found, and 6 types of DHT interventions for TB were identified: 3 RCTs examined video directly observed therapy (VDOT), 1 examined video-observed therapy (VOT), 1 examined an ingestible sensor, 1 examined phone call reminders, 2 examined medication monitor boxes, and 8 examined SMS text message reminders. The outcomes used were treatment adherence, including treatment completion, treatment adherence, missed dose, and noncompleted rate, as well as clinical outcomes, including cure rate and smear conversion. In treatment completion, 4 RCTs (VDOT, VOT, ingestible sensor, SMS reminder) found significant effects, with odds ratios and relative risks (RRs) ranging from 1.10 to 7.69. Treatment adherence was increased in 1 study by SMS reminders (RR 1.05; 95% CI 1.04-1.06), and missed dose was reduced in 1 study by a medication monitor box (mean ratio 0.58; 95% CI 0.42-0.79). In contrast, 3 RCTs of VDOT and 3 RCTs of SMS

reminders did not find significant effects for treatment completion. Moreover, no improvement was found in treatment adherence in 1 RCT of VDOT, missed dose in 1 RCT of SMS reminder, and noncompleted rate in 1 RCT of a monitor box, and 2 RCTs of SMS reminders. For clinical outcomes such as cure rate, 2 RCTs reported that phone calls (RR 1.30; 95% CI 1.07-1.59) and SMS reminders (OR 2.47; 95% CI 1.13-5.43) significantly affected cure rates. However, 3 RCTs found that SMS reminders did not have a significant impact on cure rate or smear conversion.

Conclusions: It was found that DHT interventions can be a promising approach. However, the interventions exhibited variable effects regarding effect direction and the extent of improving TB medication adherence and clinical outcomes. Developing DHT interventions with personalized feedback is required to have a consistent and beneficial effect on medication adherence and outcomes among patients with TB.

tuberculosis; intervention; eHealth; medication adherence technology; nonadherence; digital health; systematic review; treatment outcomes

Introduction

Tuberculosis (TB), an infectious disease caused by *Mycobacterium tuberculosis* (M. tb), is one of the top 10 most deadly infectious diseases worldwide [1]. The M. tb pathogen can easily spread through air transmission by coughing or sneezing [1]. In 2019, it was estimated that 10 million people globally were infected with TB [1]. Therefore, long-term antibiotic treatment is needed to control TB infection and avoid disease spread.

Treatment for active drug-susceptible TB usually takes at least 6 months, while latent tuberculosis infection (LTBI) can be between 1 and 6 months [2]. The duration of treatment can be longer if the pathogen is resistant to either the first- or second-line of anti-TB medication [3]. Although effective TB medication is available, treatment is prone to nonadherence, resulting in treatment failure [2]. Numerous factors affect medication adherence, such as poor communication between patient and health care provider, socioeconomic status, health care system factors, patients' mental condition, therapy features, and other patient factors [4,5]. Moreover, a high risk of nonadherence to the medication has been reported in patients with LTBI because they do not feel any signs or symptoms of the disease but do experience the side effects of the medication[2].

Previous studies have indicated that nonadherence to TB medication impacts clinical and economic TB outcomes [6]. Notably, the consequences of nonadherence include worsening of the disease [6,7] but also the development and spread of drug-resistant TB [7]. Although poor medication adherence is a widely significant problem in TB treatment, it cannot be managed easily due to the heterogeneity of the underlying factors [5].

Different digital health technologies (DHT) help manage patients with TB by monitoring and supporting their medication adherence [8]. Among them, SMS text message reminders and video directly observed therapy (VDOT) stand out [8]. On the one hand, past evidence indicates that their effect concerning supporting medication adherence among patients with TB is questionable [9,10]. On the other hand, the field of DHTs is evolving rapidly, and some more recent developments may provide more promising approaches in the management of medication adherence. An updated, comprehensive analysis is needed to analyze the effect and potential development of DHTs for managing medication adherence in patients with TB. Therefore, this study systematically reviewed the effect and potential development of various DHTs in improving medication adherence and treatment outcomes in patients with TB.

Methods

Study Design

Randomized controlled studies (RCTs) indexed in the PubMed and Cochrane databases were systematically reviewed following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) guidelines [11,12] (Multimedia Appendix 1).

Data Sources

As a reputable databases in the medical field, PubMed was selected to effectively obtain qualified RCTs. Additionally, the Cochrane Database was included since it provides published and unpublished interventional studies.

Inclusion and Exclusion Criteria

RCTs published in English between March 2002 and January 2020 focusing on interventions using DHT for improving treatment outcomes and medication adherence in patients with TB were included in this review. The time restriction was defined using the leading World Health Organization (WHO) report from 2003 on interventional strategies for improving medication adherence as the starting point [4]. Studies that did not measure the effect of the intervention, had no comparison, applied a different study design, were not original studies (eg, study protocol, review), or were reported as an abstract only were excluded. The population, intervention, comparison, and outcome were predefined to collect articles according to the study's objective.

Population

The study population comprised patients aged 15 years or older with all types of TB (active TB, LTBI, pulmonary TB, extrapulmonary TB, drug-sensitive TB, or drug-resistant TB). TB status needed to be confirmed using laboratory or clinical

testing, such as Mantoux, TB symptoms, chest radiography, interferon gamma release assays, and smear or sputum test; or other examinations, such as polymerase chain reaction or phenotypic drug susceptibility testing.

Interventions and Comparisons

We included studies evaluating the effect of DHTs, such as smartphone apps, video observation, phone reminders, ingestible sensors, SMS reminders, and other digital health interventions, that aimed to improve medication adherence and TB treatment outcomes. All selected studies had a comparison group with patients receiving usual care (mainly traditional directly observed therapy [DOT]) to measure the incremental effect of the intervention.

Outcome Measures

The primary outcome was medication adherence (ie, treatment completion, adherence rate, and missed doses), while the secondary outcome included clinical outcomes (ie, cure rate and smear sputum conversion rate).

Medication adherence could be measured using self-report on the device directly (VDOT) and indirectly (VOT), responding to phone calls and SMS text messages, detecting drug taking through a monitor box, or pill counting. Notably, medication adherence to (respiratory) medicines consists of 3 phases: initiation, implementation, and persistence [13] according to the global TB definition [14] and the ESPACOMP Medication Adherence Reporting Guideline (EMERGE) [15]. In this study, the adherence rate was defined as the rate of anti-TB medication taken by a patient with TB with treatment completion. Following the WHO definition, completion treatment was defined as a patient with TB who completed treatment without evidence of failure (no record of sputum smear or culture test results in the last month of treatment). Hence, the adherence rate was operationally defined as the implementation phase in this study. Moreover, the persistence phase was defined as completion treatment, and noncompletion treatment was deemed to be similar to nonpersistence. Noncompletion treatment was defined as a patient with TB who discontinued the medication before the last defined dose [16,17]. Missed doses were included in the implementation phase and were defined as the percentage of monthly TB medicines missed as measured according to pill count and failure to open the medication box, where the minimum percentage of missed doses was 20% [18].

The clinical outcomes included cure rate, with cure being defined as M. tb culture–positive results at the beginning and negative results in the last month of treatment and on at least 1 previous occasion. The other clinical outcome was sputum conversion, which was defined as the conversion of positive to negative M. tb culture during the treatment [14].

Search Strategies

Specific key terms related to the study population, intervention, comparison, outcome, and design were developed for the specific databases used. The search strategies for the PubMed and Cochrane databases are described in the following sections.

PubMed Database

The search strategy for PubMed was as follows: (“technology”[tw] OR “digital adherence”[tw] OR “mHealth”[tw] OR “mobile health”[tw] OR “mobile app”[tw] OR “mobile apps”[tw] OR “mobile application”[tw]) AND (“medication adherence” [Mesh] OR “adherence”[tw] OR “concordance”[tw] OR “compliance”[tw] OR “nonadherence”[tw] OR “noncompliance”[tw] OR “nonconcordance”[tw]) AND (“tuberculosis/drug therapy”[Mesh] OR “tuberculosis infection”[tw] OR “tb”[tw] OR “active tuberculosis”[tw] OR “latent tuberculosis”[tw] OR “pulmonary tuberculosis”[tw] OR “extrapulmonary tuberculosis”[tw]).

Cochrane Database

The search strategy for Cochrane Database was as follows: (“technology” OR “digital adherence” OR “mHealth” OR “mobile health” OR “mobile app” OR “mobile apps” OR “mobile application”) AND (“medication adherence” [Mesh] OR “adherence” OR “concordance” OR “compliance” OR “nonadherence” OR “noncompliance” OR “nonconcordance”) AND (“tuberculosis/drug therapy” [Mesh] OR “tuberculosis infection” OR “tb” OR “active tuberculosis” OR “latent tuberculosis” OR “pulmonary tuberculosis” OR “extrapulmonary tuberculosis”).

Data Selection, Collection, and Extraction

AR conducted eligibility evaluation based on the title and abstract. The full texts of potentially eligible articles were retrieved and assessed by AR. ISP and SDA conducted further independent verification of the abstract and full-text screening. Any disagreements among the reviewers (AR, ISP, and SDA) were resolved by discussion. Data from the selected articles were extracted by AR and then verified by ISP for relevant information, such as publication year, type of DHT intervention, setting, population, study outcome, and comparison groups.

Summary Measures and Synthesis of Results

In the case of comparable homogenous studies being retrieved, quantitative data synthesis was considered. However, a qualitative narrative review was used in case the data were heterogenous in terms of the population, intervention, comparisons, or outcomes. Several point estimates were considered for the data analysis, such as the mean ratio for continuous outcome data and the relative risk (RR) and odds ratio (OR) for dichotomous outcome data with a 95% CI.

Quality Assessment of the Included Articles

As all included articles were RCTs, the Jadad score was used to assess the individual articles [19]. The Jadad score has 3 assessment domains: randomization, blinding method, and participant withdrawal with a minimum score of 1 (poor quality) and a maximum score of 5 (good quality).

Results

Study Selection

Our literature search initially identified 552 articles. After removal of duplicates, the screening of titles and abstracts

yielded 20 relevant articles. The full-text screening process resulted in a final study sample of 16 articles. Variations in the study population, comparisons, and outcomes across the included studies were identified; therefore, quantitative analysis could not be conducted in this study considering the heterogeneity. The flow diagram and the screening process are provided in Figure 1.

The 16 included studies were conducted in different countries: England [20], USA [21-23], Taiwan [24], China [17,25], Pakistan [26,27], South Africa [9], Cameroon [28], Canada [10], Argentina [29], Sudan [17], Thailand [30], and Haiti [31].

The median sample size of the source population was 259 participants, ranging from 37 participants [29] to 1110 participants [24]. Most studies targeted either patients alone (n=12) or patients and health care professionals (n=4). Several study designs were used in the included articles: 11 RCTs with a 2-arm design [10,17,21-24,26,27,29-31], 4 with a 2-arm cluster design [9,20,25,28], and 1 with a 4-arm cluster design [17].

Across the studies, multiple various interventions were assessed, including 3 assessing VDOT [21,22,24], 1 VOT [20], 1 phone call reminders [30], 2 medication monitor boxes [18,31], 1 ingestible sensors [23], and 8 SMS reminders [9,10,17,25-29]. The characteristics of all included articles are indicated in Table 1.

Figure 1. Flow diagram of the article selection process.

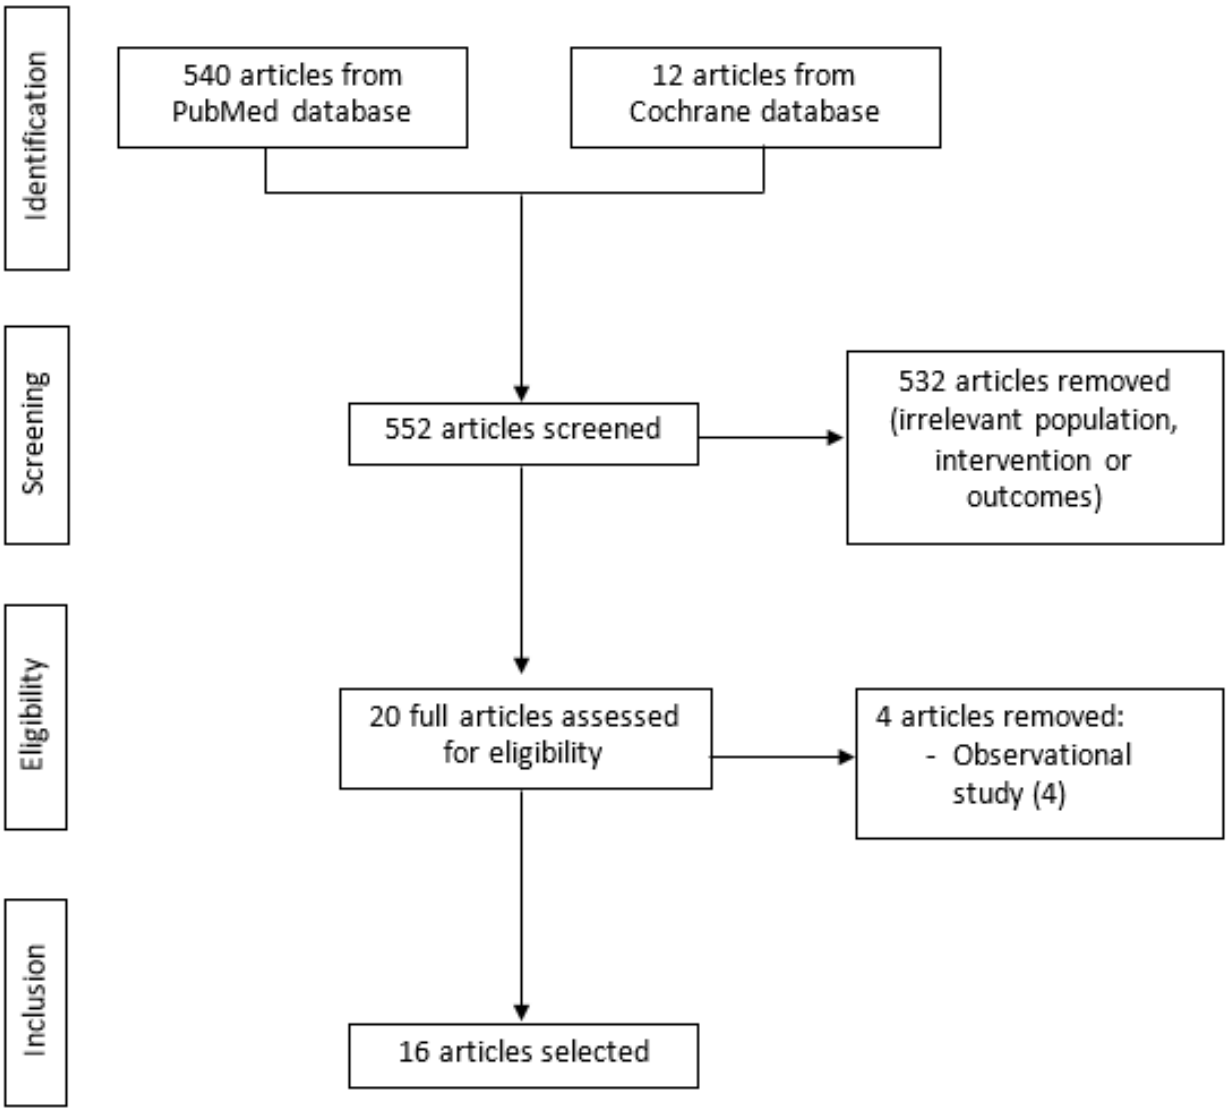

Table 1. Characteristics of the included articles.

No.	Authors, publication year	Target	Study period	Setting	Intervention	Participants in the intervention and comparison group, n	Study outcomes	Outcome measurements
1	Story et al, 2019 [20]	Patients	Sept 2014 to Oct 2016	22 clinics in England (UK)	VOT[a] intervention in which patients record and send videos of every dose ingested and adverse medicine events using the smart app[b]	112 and 114	Treatment completion	Scheduled treatment observation
2	Chuck et al, 2016 [21]	Patients	Sept 2013 to Sept 2014	TB[c] clinics in New York City, USA	Patients swallowing a pill in front of a camera on their schedule on VDOT[d] calls[b]	49 and 267	Treatment completion	Scheduled VDOT[d] session
3	Lam et al, 2018 [22]	Patients	Feb to Oct 2015	4 New York City health department TB clinics, New York City, USA	Patients taking medicine observed by a VDOT worker[b]	50 and 302	Treatment completion	Scheduled VDOT session
4	Chen et al, 2020 [24]	Patients and HCP[e]	Jan 2014 to Dec 2017	Health facilities in Taipei, Taiwan	Patients taking medicine under 2-way video calls[b]	80 and 160	Treatment adherence	Scheduled VDOT session
5	Kunawararak et al, 2011 [30]	Patients	Apr 2008 to Dec 2009	Public hospitals in 7 provinces of Northern Thailand	Patients receiving phone call reminders to take their medication[b]	30 and 30	Cure rate	Negative culture result at the end of treatment
6	Liu et al, 2015 [18]	Patients	June 2011 to Mar 2012	36 districts within the province of Heilongjiang, Jiangsu, Hunan, and Chongqing, China	Patients receiving a reminder via SMS, medication monitor box, or their medication[b]	3069 and 1104	Missed doses	Pill count and failure to open the medication monitor box
7	Moulding & Caymittes, 2002 [31]	Patients	July 1983 to Nov 1985	Clinic at Port-Au-Prince, Haiti	Medication monitor and counseling in which the medication monitor is based on moving a minute piece of uranium along a strip of photographic film to record the interval between the removal of each tablet of medication[f]	64 and 127	Noncompleted rate	Counting the number of dots on the film strip
8	Browne et al, 2019 [23]	Patients	Oct 2013 to Jan2017	San Diego and Orange County divisions of TB Control and Refugee Health, USA	Patients given the WOT[g] IS-Rifamate (ingestible sensor)[i]	41 and 20	Treatment completion	The number of doses confirmed
9	Fang et al, 2017 [25]	Patients	Dec 2014 to Dec 2015	6 districts from Anhui province, China	An SMS reminder sent once per day to remind patients for taking the medicine, reexamining the physical condition, and improving knowledge[b]	160 and 190	Treatment completion and missed doses	Pill counting
10	Mohammed et al, 2016 [26]	Patients and HCP[e]	Mar 2011 to Feb 2014	Public and private sector tuberculosis clinics in Karachi, Pakistan	Daily SMS reminders sent to participants who are asked to respond through SMS or missed calls after taking their medication[b]	1110 and 1097	Treatment completion and smear conversion	Pill counting and smear conversion at the end of treatment

Outcomes

The medication adherence-related outcomes reported across the 16 RCTs were treatment completion in 10 (63%) studies [9,10,20-23,25,26,28,29], treatment adherence in 2 (13%) [24,29], missed doses in 2 (13%) [18,25], and noncompleted rate in 3 (19%) [17,27,31]. Note that some RCTs reported more than 1 adherence outcome. Clinical outcomes included cure rate in 4 RCTs (25%) [17,27,28,30] and smear conversion in 1 RCT [26] (6%).

Adherence Outcomes: Positive Findings

Four RCTs showed that treatment completion was significantly and positively impacted by a DHT intervention, with effect sizes varying by type of intervention. Notably, VDOT or VOT was found to be more effective compared to DOT in 2 studies from the UK and USA (UK: OR 2.52; 95% CI 1.17-5.54 [20]; USA: RR 1.36; 95% CI 1.19-1.55 [22]). Furthermore, studies on ingestible sensors (OR 7.69; 95% CI 4.51-14.48) [23] and 1 of the SMS reminder intervention studies (RR 1.1; 95% CI 1.04–1.18) [25] reported positive effects on treatment completion.

The outcome of treatment adherence was increased in 1 study that evaluated SMS reminders (RR 1.05; 95% CI 1.04-1.06) [29], and missed doses was reduced in 1 study that used a medication monitor box (mean ratio 0.58; 95% CI 0.42-0.79) [18] in patients with TB.

Adherence Outcomes: Negative Findings

Beyond the trials that reported the positive impact of DHT interventions on adherence outcomes, several studies that did not report any significant effect on medication adherence outcomes were also identified. Three RCTs did not find any significant effect on treatment completion from VDOT (RR 0.99, 95% CI 0.93-1.05 [21]; RR 1.00, 95% CI 0.79-1.26 [26]; RR 0.87, 95% CI 0.81-0.94 [9]), and another 3 indicated a lack of evidence for a positive effect of SMS reminders (OR 1.45, 95% CI 0.81-2.56 [28]; RR 0.97, 95% CI 0.88-1.07 [10]; RR 0.99, 95% CI 0.93-1.05 [29]).

Additionally, treatment adherence was not impacted by VDOT in 1 RCT (RR 1.08; 95% CI 0.89-1.32 [24]), and neither were missed doses by SMS reminders (RR 0.40; 95% CI 0.11-1.50 [25]), or the noncompleted rate by a monitor box (RR 0.55; 95% CI 0.21-1.42 [31]), or SMS reminders (OR 1.67, 95% CI 0.52-5.37 [17]; RR 0.76, 95% CI 0.18-3.28 [27]).

Clinical Outcomes: Positive Findings

In 2 studies, the clinical outcome of cure rate was positively affected by DHT [17,30]. It was observed that cure rate was increased through SMS reminders (OR 2.47, 95% CI 1.13-5.43 [17]) and phone call reminders (RR 1.30, 95% CI 1.07-1.59 [30]) in patients with TB.

Clinical Outcomes: Negative Findings

Three studies did not find there to be a significant effect of DHT on clinical outcomes, with 2 RCTs indicating no effects of SMS reminders on cure rate (OR 1.06;,95% CI 0.65-1.73 [28]; RR 1.05, 95% CI 0.62-1.76 [27]) and 1 study indicating no effect of SMS reminders on smear conversion (RR 1.00, 95% CI 0.90-1.12) [26]. The effects of interventions are summarized in Table 2.

Quality Assessment of the Included Articles

None of the included studies had the maximum Jadad score (5 points). Eleven studies (69%) had a relatively high score (3 points) since they appropriately described the randomization method and clearly illustrated the withdrawals of participants [9,10,18,20,23,25-29,31]. Furthermore, 5 of the 16 studies (31%) had lower Jadad scores (2 points) due to the absence of a description of the randomization procedure [17,21,22,24,30].

The risk of bias assessment is indicated in (Multimedia Appendix 2).

Data Synthesis

As shown in Table 1, considerable variations in the study population, comparisons, and outcomes across the included studies were identified. Therefore, the quantitative analysis could not be conducted considering the heterogeneity observed.

Discussion

Main Findings

This systematic review indicated that DHT interventions, including VOT, VDOT, medication monitor boxes, ingestible sensors, and SMS reminders, could effectively improve medication adherence in patients with TB. However, half of the 4 V(D)OT and over half of the 8 SMS reminder studies showed no significant effect on adherence outcomes, resulting in inconclusive evidence regarding their effectiveness with respect to the extent of improving medication adherence. Regarding reported clinical outcomes, 1 study with phone call reminders and 1 of the 3 studies with SMS reminders showed positive effects on TB cure rates, and no DHT exhibited effects on sputum conversion rates.

Among the primary DHT interventions, VDOT and VOT are the interventions with the potential for improving TB medication adherence. With video-observed treatment, medication adherence can be directly recorded (VDOT) or indirectly (VOT) while a patient takes the medication. Hence, the health care provider can monitor the medication intake process remotely. However, this technology needs adequate smartphone specifications (eg, picture resolution, memory), good connectivity, and user ability. Smartphones with good connectivity are required because each video should be sent in an adequate video resolution and fairly large file size for proper drug monitoring. The benefit of video treatment is that patients' and health care workers' travel time can be significantly decreased compared to traditional DOT [22]. As an intervention, VDOT or VOT is preferred by patients with TB because it is easier to accept, cheaper, and more effective than is standard DOT [20]. Moreover, the implementation of VDOT or VOT has been associated with treatment completion [20-22] and treatment adherence [24] in patients with TB. Our review found that 2 VDOT studies significantly enhanced treatment completion compared to DOT [20,22], while 2 other studies demonstrated no difference between VDOT and standards of care [21,24]. The challenges concerning its implementation are the availability of (smart) phones and the network-related interruption of audio-video connections during VDOT sessions. However, the widespread use of smartphones will encourage providers to improve network quality. Therefore, VDOT or VOT can be a promising approach to overcoming medication adherence problems [32], especially in countries with high smartphone use [33,34]. The average availability of smartphones in the top-30 high-burden TB countries is 93.98 per 100 people, ranging from 14.9 in North Korea to 185.69 in Montenegro [35]. The data highlighted the potential use of DHT interventions based on smartphone intervention.

Beyond VDOT, SMS reminders were one of the most frequently studied DHT interventions. Phone call reminders are used to remind patients directly to take their medicine. The technology used in this approach is simpler than that of VDOT or VOT because the phone call reminder does not need high device specifications and patient ability; thus, patients can easily use it. One study in Thailand that evaluated 2 models for TB control, single DOT and DOT with phone call reminders, showed that phone call reminders can increase the cure rate [29]. The reminders supported the patients during their treatment because they did not feel alone or socially isolated. Another type of reminder-based intervention is the medication monitor box. This device can also record the history of medicine usage and can be used for adherence monitoring by health care providers at a distance [18]. The medication reminder feature can overcome forgetfulness in patients with TB. A study conducted in 36 districts in China using a medication monitor box with a reminder exhibited a lower missed-dose rate than did a medication monitor box without a reminder [17]. Another RCT conducted in Haiti reported that the medication monitor box without reminders did not effectively reduce the noncompleted rate among patients with TB [31]. The study highlighted that the reminder feature attached in the medication box could affect the completion rate.

Another DHT is the ingestible sensor. The sensor is attached to the medicine and sends a signal to the operator when the medicine is ingested. If the patient is not taking the medication, the system will automatically send a reminder urging them to take medicine immediately. With this ingestible sensor, the potential adverse effects should be considered since the sensor is attached to the patient. An RCT conducted in the USA on patients with advanced-phase TB indicated that ingestible sensors could increase treatment completion with an accuracy of 99.3%. However, rash and pruritus were reported as side effects in up to 10% of the participants [23]. It would be worthwhile to conduct a cost-effectiveness analysis to assess the increased treatment completion at the additional cost of the ingestible sensors and the side effects.

SMS reminders can be considered and combined with other interventions to improve medication adherence in patients with TB. SMS reminders are sent periodically to encourage patients to take their medicine. This feature does not require high smartphone specifications. Indeed, 3 of the 8 RCT studies conducted in 6 countries indicated that the SMS reminder could increase treatment completion [25], treatment adherence [29], and cure rate [29]. The SMS reminder can be applied widely because of its ease of access, low cost, and ready acceptance by patients. Like the medication monitor box, the SMS reminder plays an essential role in improving patients' medication schedules [25]. However, 5 studies found no benefit compared to the standard of care [9,10,17,26,28]. This implies that careful consideration should be made before implementing this intervention. Implementation under operational research conditions would be ideal as data would become available to evaluate the benefit of the SMS reminder service.

Some studies have indicated that DHT interventions could improve treatment outcomes and patient adherence. However, some studies exhibited no difference compared to the standard

of care [9,10,17,21,24,26,28,31]. The variable effects of DHT interventions can be explained using the heterogeneity of the population, comparison, and outcome definitions used across the included studies. For instance, although the same type of intervention and outcome was applied, the use of various comparisons (DOT and standard care without DOT) [10,25] makes it challenging to aggregate results. Notably, the features of the population should be taken into consideration when interpreting the intervention effect on adherence. As nonadherence can be explained using multiple factors (eg, social, economic, and behavioral factors) [4], it is essential to characterize the individual problem of nonadherence when conducting the intervention. Hence, a one-size-fits-all intervention to resolve nonadherence is unlikely to be successful. Therefore, a tailored and targeted intervention for improving medication adherence is essential to resolving nonadherence.

Implications and Future Directions

Given the contradicting study outcomes, more research and developments regarding the role of DHTs in medication adherence management for patients with TB are needed. These developments should focus on the (technical) drug monitoring aspects and the intervention(s) that can effectively improve medication adherence and treatment outcome. Considering the multiple factors underlying medication nonadherence in patients with TB (eg, social, economic, geographic, facility, and behavioral factors) [4], a tailored and targeted intervention for improving medication adherence is essential. Therefore, a DHT with screening and monitoring for nonadherent patients can be further enhanced by considering the individual problems patients encounter. Subsequently, these data can further support health care providers in effectively delivering personalized interventions for improving medication adherence in patients with TB. This may also require further training of health care providers in effective communication strategies.

Most DHT-based interventions in this study were assessed under trial conditions that may not represent the real-world condition for implementation. Numerous factors may drive the effect of a DHT's intervention in the real world: population density, facilities, transportation, smartphone network coverage, health care systems, human resources, costs, individual characteristics, and integration of the intervention with the national TB program [36]. This underlines the fact that implementing a particular intervention will have very different meanings depending on the local context. Therefore, understanding the local context is critical for successful DHT intervention implementation in real-world settings. Additionally, governmental policy and proper reimbursement are needed to support and regulate DHTs for successful implementation. Further implementation studies are needed to evaluate the maturity of interventions in the real world to scale up DHT interventions beyond trial settings.

Strengths and Limitations

This study's strength is that a comprehensive and up-to-date overview of existing DHTs, ranging from their use, device specifications, and efficacy that can be used to improve the problem of medication adherence and treatment outcome among patients with TB, was provided. However, although all efforts were made to provide a robust analysis, several limitations should be acknowledged: although unpublished RCT studies were covered in the Cochrane Database, potential publication bias may exist in this study due to limited inclusion of gray literature, non–English language studies, and studies indexed in other databases; a meta-analytical analysis could not be conducted due to the heterogeneity across the included studies; as the focus was on RCT studies—known as the gold standard in analyzing the effects of interventions—well-designed pre-and postintervention studies were excluded in this study.

Conclusions

It was found that DHT can be a promising approach in improving medication adherence and treatment outcomes among patients with TB despite the variable intervention effects that were discovered. Considering individual factors of nonadherence to medication among patients with TB, developing DHT interventions with personalized feedback is required to have a consistent and beneficial effect on medication adherence and treatment outcomes among patients with TB. Further implementation studies are needed to evaluate the maturity and scale-up of the interventions in the real world.

Acknowledgments

The authors wish to thank Prof. Federico Gago, University of Alcala, Madrid, Spain, for his support on this study and suggestions on preparing the manuscript. This study was funded by the Ministry of Education, Culture, Research and Technology of the Republic of Indonesia, under the Southeast Asia–Europe Joint Funding for Research and Innovation 2019 (grant #9/AMD/E1/KP.PTNBH/2020) and the Scientific and Technological Research Council of Turkey ARDEB International (JFS2017; grant #119N553).

Abstract

Background: Patient education, home-based exercise therapy, and advice on returning to normal activities are established physiotherapeutic treatment options for patients with nonspecific low back pain (LBP). However, the effectiveness of physiotherapy interventions on health-related outcomes largely depends on patient self-management and adherence to exercise and physical activity recommendations. e-Exercise LBP is a recently developed stratified blended care intervention comprising a smartphone app integrated with face-to-face physiotherapy treatment. Following the promising effects of web-based applications on patients' self-management skills and adherence to exercise and physical activity recommendations, it is hypothesized that e-Exercise LBP will improve patients' physical functioning.

Objective: This study aims to investigate the short-term (3 months) effectiveness of stratified blended physiotherapy (e-Exercise LBP) on physical functioning in comparison with face-to-face physiotherapy in patients with nonspecific LBP.

Methods: The study design was a multicenter cluster randomized controlled trial with intention-to-treat analysis. Patients with nonspecific LBP aged ≥18 years were asked to participate in the study. The patients were treated with either stratified blended physiotherapy or face-to-face physiotherapy. Both interventions were conducted according to the Dutch physiotherapy guidelines for nonspecific LBP. Blended physiotherapy was stratified according to the patients' risk of developing persistent LBP using the Keele STarT Back Screening Tool. The primary outcome was physical functioning (Oswestry Disability Index, range 0-100). Secondary outcomes included pain intensity, fear-avoidance beliefs, and self-reported adherence. Measurements were taken at baseline and at the 3-month follow-up.

Results: Both the stratified blended physiotherapy group (104/208, 50%) and the face-to-face physiotherapy group (104/208, 50%) had improved clinically relevant and statistically significant physical functioning; however, there was no statistically significant or clinically relevant between-group difference (mean difference −1.96, 95% CI −4.47 to 0.55). For the secondary outcomes, stratified blended physiotherapy showed statistically significant between-group differences in fear-avoidance beliefs

and self-reported adherence. In patients with a high risk of developing persistent LBP (13/208, 6.3%), stratified blended physiotherapy showed statistically significant between-group differences in physical functioning (mean difference −16.39, 95% CI −27.98 to −4.79) and several secondary outcomes.

Conclusions: The stratified blended physiotherapy intervention e-Exercise LBP is not more effective than face-to-face physiotherapy in patients with nonspecific LBP in improving physical functioning in the short term. For both stratified blended physiotherapy and face-to-face physiotherapy, within-group improvements were clinically relevant. To be able to decide whether e-Exercise LBP should be implemented in daily physiotherapy practice, future research should focus on the long-term cost-effectiveness and determine which patients benefit most from stratified blended physiotherapy.

eHealth; nonspecific low back pain; physiotherapy; blended care; mobile phone

Introduction

Low back pain (LBP)–related disability and the related socioeconomic burden remain high despite the many treatment options and health care resources available for LBP [1]. LBP can be caused by a specific pathology or trauma; however, in >90% of cases, an underlying disease is absent [2]. The clinical course of this so-called *nonspecific LBP* varies and, as expected, is often less favorable; some patients recover within a couple of days or weeks, and other patients experience persistent disabling symptoms leading to chronic LBP. Up to 65% of primary care patients with LBP still experience pain 1 year after onset [3,4].

Clinical practice guidelines recommend a patient-centered approach for the management of LBP [5,6]. This approach identifies patients with an increased likelihood of delayed recovery at an early stage and stratifies the treatment accordingly [6-8]. An example of a tool for identifying individuals at risk of delayed recovery is the Keele STarT Back Screening Tool [9,10]. In general, in patients who have a *low risk* for delayed recovery, early management comprises advice, reassurance, and education about the nonspecific nature of their LBP and encouragement to stay active. For individuals at *medium risk* for developing persistent LBP, personalized and supervised exercise therapy should be considered. For the *high-risk* group, this exercise therapy can be supported by a graded activity approach or cognitive behavioral components [8,11]. In addition to a patient-centered and stratified approach, patients' adherence to prescribed (home-based) exercises and recommended physical activity behavior is crucial for the effectiveness of care [12]. Earlier research showed that 45% to 70% of patients do not adhere to prescribed exercises and physical activity recommendations, whereas adherent patients with LBP have a reduced risk of recurrent LBP [13,14].

Within the treatment of patients with LBP, *blended care* is a promising new and understudied field [15]. Blended care refers to the integration of web-based and offline components within the treatment process and requires that both components contribute equally to the treatment process [16,17]. The integration of web-based components, such as websites and apps, provides new solutions to monitor and coach patients' individual health behaviors and support the optimization of face-to-face care tailored to the patients' individual needs [18-20]. Thereafter, web-based components can be an effective means of stimulating adherence to prescribed exercises at home between face-to-face sessions and possibly increase self-management of LBP [21,22]. Until now, evidence on patient-centered and stratified care has not been integrated into blended care. Therefore, we recently developed e-Exercise LBP, a stratified blended intervention in which a smartphone app is integrated within face-to-face physiotherapy treatment, and established its feasibility and proof of concept for the treatment of functional disability and pain [23]. e-Exercise LBP is an adapted version of previously developed and evaluated blended physiotherapy programs [24,25]. Following the promising effects of web-based applications for patients' self-management skills and adherence to exercise and physical activity recommendations, it is hypothesized that e-Exercise LBP will improve patients' physical functioning. However, the effectiveness of e-Exercise LBP in comparison with primary care physiotherapy still needs to be determined. The primary aim of this study is to investigate the short-term (3 months) effectiveness of stratified blended physiotherapy (e-Exercise LBP) on physical functioning in comparison with face-to-face physiotherapy in patients with nonspecific LBP.

Methods

Design and Ethical Considerations

The e-Exercise LBP study was a prospective multicenter cluster randomized controlled trial. The study protocol was approved by the medical research ethics committee of the University Medical Center Utrecht, the Netherlands (18-085/D), and registered at the onset of patient enrollment (ISRCTN 94074203). From January 2018 to June 2018, 122 physiotherapists working in 58 primary care physiotherapy practices were recruited and randomized to either stratified blended physiotherapy (e-Exercise LBP) or face-to-face physiotherapy. Details of the design and methods of the study have been published previously [26]. This study is reported according to the CONSORT (Consolidated Standards of Reporting Trials) statement for cluster randomized trials (Multimedia Appendix 1).

Recruitment

Setting and Randomization

Physiotherapists were recruited by an invitational letter sent to the professional network of the authors and physiotherapists who participated in a previous e-Exercise study [24]. In addition, an advertisement was placed in the web-based newsletter of the Royal Dutch Society for Physiotherapy. Physiotherapy practices could participate with ≥1 physiotherapist, regardless of professional experience and education or specialization (eg, manual therapy). Physiotherapists were cluster randomized at the level of practice to avoid contamination. Treatment allocation was concealed and performed by an independent researcher using a computer-generated, a priori created, random sequence table and in a 1:1 allocation ratio. Physiotherapists and patients were not blinded to the group allocation.

The physiotherapists in the stratified blended physiotherapy group received two 4-hour training sessions on e-Exercise LBP and the study procedures. In the face-to-face physiotherapy group, physiotherapists received a 4-hour training session in current best practices according to the LBP guidelines of the Royal Dutch Society for Physiotherapy [11] and the study procedures.

Patients

Patients with LBP who contacted a participating physiotherapy practice were orally informed about the study and invited to participate. Interested patients received a patient information letter by email and an informative phone call by one of the researchers (TK or RMA) before the first appointment. When a patient was willing to participate after the phone call, a face-to-face appointment was scheduled (by TK or RMA) to obtain written informed consent and verify eligibility. The eligibility criteria were as follows: (1) being a patient requesting physiotherapy treatment for nonspecific LBP, defined as pain in the lumbosacral region (sometimes associated with radiating pain to the buttock or leg) [11]; (2) aged ≥18 years; (3) possessing a smartphone or tablet (iOS or Android operating system) with access to the internet; and (4) mastery of the Dutch language. The exclusion criteria were as follows: (1) a specific cause of LBP determined through medical imaging or a medical physician, (2) serious comorbidities (eg, malignancy or stroke), and (3) current pregnancy because of the prevalence of pelvic girdle pain as a specific form of LBP.

Intervention

Experimental: Stratified Blended Physiotherapy (e-Exercise LBP)

Patients allocated to the stratified blended physiotherapy group received blended physiotherapy, comprising a smartphone app integrated within face-to-face physiotherapy treatment [23,26]. Both the contents of the smartphone app and the face-to-face physiotherapy treatment are based on the recommendations of the LBP guidelines of the Royal Dutch Society for Physiotherapy [11]. The duration and content of the stratified blended physiotherapy intervention were based on the patients' risk for developing persistent LBP (*low*, *medium*, or *high*) using the Keele STarT Back Screening Tool [9,10]. The smartphone app contains video-supported self-management information, video-supported exercises, and a goal-oriented physical activity module. Both the contents of face-to-face care and the smartphone app were tailored by the physiotherapists to the patients' individual needs and progress (Table 1). Although physiotherapists were recommended to treat according to the stratified blended physiotherapy protocol, they were free to deviate from the protocol with respect to their clinical competence. Print screens of the smartphone app are provided in Multimedia Appendix 2.

Table 1. Overview of the stratified blended physiotherapy intervention (e-Exercise low back pain [LBP]).

Mode of delivery	Low-risk profile	Medium-risk profile	High-risk profile
Smartphone app			
Duration	3 weeks	12 weeks	12 weeks
Information module	Knowledge-based platform with several LBP self-management information themes (directly available)	12 weekly self-management themes, including assignments	12 weekly self-management themes, including assignments, pain education, and psychosocial risk factors
Exercise module	3 to 4 home-based exercises tailored to the patient's specific functional limitations	3 to 4 home-based exercises tailored to the patient's specific functional limitations	3 to 4 home-based exercises tailored to the patient's specific functional limitations
Physical activity module	Physical activity recommendations in accordance with the LBP guidelines of the Royal Dutch Association for Physiotherapy	A 3-day baseline test to determine the current level of physical activity; an 11-week, 3-times per week, goal-oriented training program to maintain or improve the level of physical activity; in patients avoiding physical activity because of LBP, a graded activity functionality can be activated	A 3-day baseline test to determine the current level of physical activity; an 11-week, 3-times per week, goal-oriented training program to maintain or improve the level of physical activity using a graded activity approach
Face-to-face care			
Sessions	2 sessions	Maximum of 8 sessions	Maximum of 12 sessions
Content	Reassurance, information about LBP, instruction on self-management options, and the importance of adequate physical activity behavior	Content similar to low risk, and in addition, the physiotherapist can consider providing evidence-based interventions (eg, passive or active joint mobilization) as recommended by guideline LBP of the Royal Dutch Association for Physiotherapy	Content similar to medium risk, and in addition, the physiotherapist will address the patient's specific psychosocial risk factors using a cognitive behavioral approach, and pain education will be given
Integration of face-to-face care and smartphone app			
First session	Provide information about LBP and instructions on home-based exercises addressing patient's specific functional limitations using the smartphone app	Provide information about LBP, instructions on home-based exercises addressing patient's specific functional limitations, and instructions on 3-day baseline test using the smartphone app	Provide information about LBP, instructions on home-based exercises addressing patient's specific functional limitations, and instructions on 3-day baseline test using the smartphone app
Middle sessions	N/A[a]	Evaluation of progress with the smartphone app and optimizing face-to-face care	Evaluation of progress with the smartphone app and optimizing face-to-face care
Final session	Evaluate the progress with the smartphone app and give recommendations to prevent recurrent episodes of LBP and maintain or improve the physical activity level	Evaluate the progress with the smartphone app and give recommendations to prevent recurrent episodes of LBP and maintain or improve the physical activity level	Evaluate the progress with the smartphone app and give recommendations to prevent recurrent episodes of LBP and maintain or improve the physical activity level

[a]N/A: not applicable.

Control: Face-to-face Physiotherapy

Patients in the face-to-face physiotherapy group received only face-to-face care following the recommendations of the LBP guidelines of the Royal Dutch Society for Physiotherapy [11]. The guideline distinguishes between three different patient profiles based on the clinical course of recovery (ie, normal recovery, abnormal recovery without predominant psychosocial factors, and abnormal recovery with predominant psychosocial factors) but does not use a specific tool to stratify care a priori. The content of face-to-face physiotherapy was the same as the stratified blended care intervention (ie, information, exercises, and recommendations regarding physical activity). However, no recommendations or restrictions were provided with regard to the number of face-to-face sessions. Although web-based applications, such as websites and apps, are not recommended in the guidelines, physiotherapists were instructed to treat people without using any web-based applications to assure contrast between both groups. Practical content considerations were made by the physiotherapists themselves with respect to their clinical expertise.

Measurements

Patients received a web-based questionnaire and an accelerometer at baseline and after 3 months of follow-up. Baseline measurements were conducted face to face and follow-up measurements through web-based communication (eg, FaceTime) or face to face when requested. No financial incentives were offered to complete the measurements. In the

case of an unfilled questionnaire, patients were reminded after 7 and 14 days.

Outcome Measures

Primary Outcome

Physical functioning because of pain was assessed using the Oswestry Disability Index (ODI; version 2.1a) [27,28]. The ODI was derived from the internationally accepted core outcome set for research into patients with nonspecific LBP [28]. A higher score (0-100) indicates increased functional disability.

Secondary Outcomes

Pain intensity was measured using an 11-point numeric rating scale for the average LBP intensity in the last week (0=no pain and 10=worst possible pain) [28,29].

Physical activity was objectively measured using Activ8 (2M Engineering) [30]. Patients were instructed to wear the Activ8 for 5 consecutive weeks starting at baseline and 8 consecutive days at the 3-month follow-up, except during sleeping, showering, bathing, or swimming. For the purpose of this study, only the first 7 days at both the baseline and 3-month follow-up were used. Accelerometer data were eligible if patients had worn the meter for at least 3 days for ≥10 hours a day [31]. For each patient, the mean time spent in moderate to vigorous physical activity (all activities >3.0 metabolic equivalents [32]) in minutes per day was computed by summation and divided by the number of eligible wearing days.

Fear-avoidance beliefs about physical activity and work were measured using the Fear-Avoidance Beliefs Questionnaire [33]. A higher score (range 0-96) indicates stronger fear and avoidance beliefs about how physical activity and work negatively affect LBP.

Pain catastrophizing was measured using the Pain Catastrophizing Scale [34]. A higher score (range 0-55) indicates a higher level of catastrophizing.

Self-efficacy was measured using the General Self-Efficacy Scale [35,36]. A higher score (range 10-40) indicates greater or stronger perceived self-efficacy.

Self-management ability was assessed using the Dutch version of the short form Patient Activation Measure [37]. A higher score (range 0-100) indicates a higher level of self-management.

Health-related quality of life was measured using the EuroQol-5D-5L [38]. A higher score (range 0-100) indicates a higher health-related quality of life.

Patient self-reported adherence to prescribed home exercises was measured using the Exercise Adherence Rating Scale [39]. A higher score (range 0-24) indicates better adherence.

Other Measures

Physiotherapists were asked to complete a registration form about the number of face-to-face sessions and report the applied treatment modalities per session. Patient characteristics and relevant clinical variables were assessed as part of the baseline questionnaire.

Data Analysis

Overview

Descriptive statistics were used to explore baseline comparability and describe patients' general characteristics, the number of face-to-face physiotherapy sessions, and the treatment modalities. To investigate selective attrition, general characteristics and primary baseline variables of dropouts and nondropouts were compared. All analyses were performed according to the *intention-to-treat* principle. Missing value analyses were performed by assuming the missing at random assumption. Multiple imputation was applied using multivariate imputation by chained equations with predictive mean matching for missing data in all outcomes. A total of 36 imputed data sets were generated, corresponding to the highest missing value percentage [40]. For all analyses, a 2-tailed significance level of $P<.05$ was considered statistically significant.

Analyses of Effectiveness

Linear mixed models (LMMs) with random effects to control for correlation within patients and physiotherapy practices [41] were used to determine the short-term effectiveness of stratified blended physiotherapy compared with face-to-face physiotherapy on primary and secondary outcome measures. Regression coefficients with 95% CIs signifying the differences between stratified blended physiotherapy and face-to-face physiotherapy were estimated. Analyses were adjusted for predefined confounders (eg, age, gender, and duration of pain [42-44]) that changed the between-group estimate by ≥10%. In addition, analyses were also adjusted for variables with a substantial difference at baseline that changed the regression coefficient for the between-group estimate by ≥10%. Potential interaction terms were explored. In the case of a statistically significant interaction term, stratified LMM analyses, controlling for the same variables as the primary analysis, were performed for the effect modifier.

Sample Size

The power calculation was based on the recommendations of Campbell et al [45] for cluster randomized trials and performed for the physical functioning primary outcome at the primary end point of the e-Exercise LBP study (ie, 12-month follow-up). In addition, repeated measures of the primary outcome during follow-up were taken into account [46]. An intraclass correlation coefficient of 0.05 was assumed. In addition, to detect a clinically relevant difference between groups at the 12-month follow-up, a difference of >6 points in physical functioning (ODI) [47,48], and an SD of 14.5 [49] were used in the sample size calculation. For the repeated measures of physical functioning, a correlation of 0.5 was estimated between baseline and follow-up measurements until the 12-month follow-up [46]. On the basis of these assumptions (power 80%; $\alpha=.05$) and an average cluster size of 5, a total of 165 patients were needed. With an expected dropout rate of 20%, a total of 208 participating patients (n=104 per arm) were needed.

Results

Flow of Participants, Therapists, and Centers Through the Study

From June 2018 to December 2019, 434 eligible patients with LBP were asked to participate in 58 physiotherapy practices. In 22 physiotherapy practices allocated to stratified blended physiotherapy and 20 practices allocated to face-to-face physiotherapy, 47.9% (208/434) patients were included (Figure 1).

Baseline characteristics of the patients are presented in Table 2. The stratified blended physiotherapy group comprised more men, more patients with a low level of education, and more patients with a duration of LBP >12 months. No other relevant differences in characteristics were seen between groups. At baseline, complete data on outcome measures were available from 97.1% (101/104) of the patients in the stratified blended physiotherapy group and 99% (103/104) of the patients in the face-to-face physiotherapy group, and eligible accelerometer data were available from 84.6% (88/104) and 83.7% (87/104), respectively. Of the 208 patients, 4 (1.9%) ineligible patients (n=2, 50% in the stratified blended physiotherapy group and 2, 50% in the face-to-face physiotherapy group) were unjustified included, did not receive the allocated intervention and were therefore excluded from all analyses.

At the 3-month follow-up, complete data on outcome measures were available from 86.5% (90/104) of the patients in the stratified blended physiotherapy group and 93.3% (97/104) of the patients in the face-to-face physiotherapy group, and eligible accelerometer data were available from 74% (77/104) and 76% (79/104) of these patients, respectively.

Figure 1. Flow diagram of the e-Exercise low back pain study.

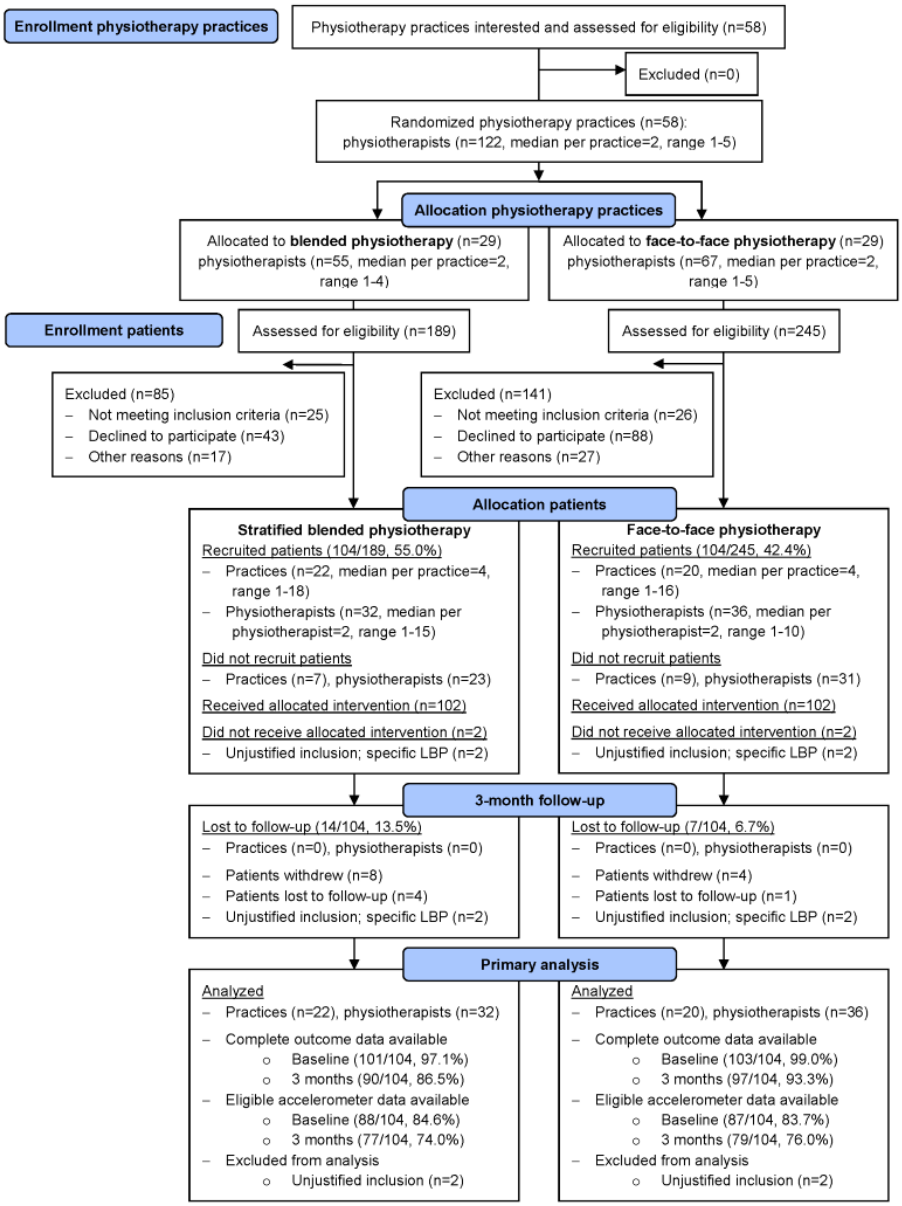

Table 2. Baseline demographic and clinical characteristics for patients from the stratified blended physiotherapy group and face-to-face physiotherapy group (N=208).

Characteristics	Baseline	
	Stratified blended physiotherapy (n=104)	Face-to-face physiotherapy (n=104)
Gender (female), n (%)	45 (43.3)	57 (54.8)
Age (years), mean (SD)	48.10 (15.08)	47.26 (13.58)
BMI (kg/m^2), mean (SD)	25.78 (3.79)	26.31 (5.11)

Number and Treatment Modalities of Physiotherapy Sessions

In total, 189 physiotherapist registration forms were returned (n=95, 50.3% stratified blended physiotherapy and n=94, 49.7% in face-to-face physiotherapy). Table 3 shows the number and treatment modalities of the face-to-face physiotherapy sessions. Patients in the stratified blended physiotherapy group received an average of 4.81 (SD 2.94) face-to-face sessions. For the low-, medium-, and high-risk groups, the average number of sessions was 3.77 (SD 2.54), 5.65 (SD 2.65), and 7.67 (SD 3.54), respectively. Patients in the face-to-face physiotherapy group received an average of 4.94 (SD 2.26) face-to-face sessions. The average number of sessions for the *low-*, *medium-*, and *high-risk* groups was 4.88 (SD 2.02), 5.09 (SD 2.51), and 4.33 (SD 4.16), respectively.

In general, education was the main treatment modality during the face-to-face sessions in both treatment groups. No remarkable differences in treatment modalities were found between the 2 groups or between the different risk groups of developing persistent LBP.

Table 3. Number and treatment modalities of face-to-face physiotherapy sessions for patients from the stratified blended physiotherapy group and face-to-face physiotherapy group.

Is Stratified Blended Physiotherapy Effective Compared With Face-to-face Physiotherapy?

In the mixed model analyses, log likelihood ratios of naive models and models that included a random intercept for both physiotherapy practice and physiotherapist were similar. Therefore, physiotherapy practice or physiotherapist was not included as a level in the LMM analyses. At 3 months, LMM analyses showed no clinically relevant or statistically significant between-group difference in the primary outcome of physical functioning (mean difference [MD] −1.96, 95% CI −4.47 to 0.55). For the secondary outcomes, a statistically significant between-group difference was found in favor of stratified blended physiotherapy for fear-avoidance beliefs (MD −4.29, 95% CI −7.22 to −1.37) and patients' self-reported adherence to prescribed home exercises (MD 0.73, 95% CI 0.06-1.39). Within-group analyses showed clinically relevant and statistically significant improvements in physical functioning (MD −11.48, 95% CI −15.06 to −7.91), average pain intensity (MD −2.38, 95% CI −3.00 to −1.76), and fear-avoidance beliefs (MD −5.14, 95% CI −9.22 to −1.06) in the stratified blended physiotherapy group. In the face-to-face physiotherapy group, clinically relevant and statistically significant improvements in physical functioning (MD −11.22, 95% CI −14.64 to −7.80) and average pain intensity (MD −2.51, 95% CI −3.11 to −1.90) were found (Table 4).

As indicated by a statistically significant interaction term, the patients' risk of developing persistent LBP was an effect modifier of the between-group differences on the primary outcome of physical functioning. In patients with a high risk of developing persistent LBP, the stratified analysis showed a statistically significant between-group difference in favor of stratified blended physiotherapy on physical functioning (MD –16.39, 95% CI –27.98 to –4.79), average pain intensity (MD –3.43, 95% CI –6.55 to –0.31), and fear-avoidance beliefs (MD –14.51, 95% CI –28.21 to –0.81). In patients with a medium risk of developing persistent LBP, a statistically significant between-group difference was found in favor of stratified blended physiotherapy on fear-avoidance beliefs (MD –5.93, 95% CI –11.45 to –0.40). In patients with a low risk of developing persistent LBP, no statistically significant between-group differences were found (Table 5).

Discussion

Principal Findings

This study evaluated the short-term (3 months) effectiveness of the stratified blended physiotherapy intervention e-Exercise LBP on physical functioning in comparison with face-to-face physiotherapy in patients with nonspecific LBP. In contrast to our expectations, the study results showed no statistically significant between-group difference in physical functioning and most of the secondary outcome measures. Only fear-avoidance beliefs and patient self-reported adherence to prescribed home exercises improved significantly in patients who were allocated to stratified blended physiotherapy. When looking at the different prognostic risk groups in patients with a high risk of developing persistent LBP, a statistically significant between-group difference in favor of stratified blended physiotherapy on physical functioning, average pain intensity, and fear-avoidance beliefs was found; however, these results come with some uncertainty.

Interpretation of the Findings

The results of this study complement the findings from previous systematic reviews of randomized controlled trials that showed that in the short term, web-based applications could reduce LBP-related pain and disability; however, when compared with other interventions, the results are inconclusive [15,22,50]. A possible explanation for these inconclusive findings is the considerable heterogeneity in the studied characteristics and comparators, which hampers a clear comparison. For example, in our study, we integrated a web-based application within face-to-face guidance and compared it with face-to-face physiotherapy. Previous studies in this research area have focused predominantly on web-based applications as a stand-alone intervention without the face-to-face guidance of a health care professional [15,22,50]. Only a few studies have investigated web-based applications as an adjunct to face-to-face guidance, and the results regarding the added value of these combined interventions have been inconclusive [15,51]. Similar to our study, Sandal et al [51] investigated a smartphone app as an adjunct to face-to-face guidance. The app was tailored using artificial intelligence and did not influence face-to-face guidance. In this study, the reported between-group difference was statistically significant in favor of the combined intervention when compared with face-to-face guidance alone; however, the difference was small and of uncertain clinical significance.

Another example of heterogeneity in research on web-based applications is the large variation in delivery modes and duration. Similar to e-Exercise LBP, most web-based applications tailored the content of the intervention using patient characteristics and focused on self-management support,

home-based exercise, and physical activity prescription [15,22,50]. However, the e-Exercise LBP app provided this content in weekly information modules and daily reminders to exercise and physical activity recommendations during a 3- or 12-week duration [26]; the duration in other studies ranged from 3 weeks to 1 year. In addition, the delivery modes showed large variation; that is, from no specific recommendations to multiple web- or telephone-based coaching sessions [15,22,50].

Thus, looking at the different characteristics of web-based applications, such as the role of the health care professional within the intervention and the delivery mode and duration, future research needs to focus on the comparison of web-based applications with different characteristics to obtain a better understanding of which elements work the best.

In our study, the short-term within-group improvements in physical functioning and average pain intensity of stratified blended physiotherapy were comparable with face-to-face physiotherapy, both of which were statistically significant and clinically meaningful. Patients in the stratified blended physiotherapy group improved on average 11.48 (95% CI −15.06 to −7.91) points (59.5%) in physical functioning, and patients in the face-to-face physiotherapy group improved by an average of 11.22 (95% CI −14.64 to −7.80) points (56%). For average pain intensity, these improvements were 2.38 (95% CI −3.00 to −1.76) points (42.8%) and 2.51 (95% CI −3.11 to −1.90) points (46.9%), respectively. As physical functioning and average pain intensity decreased by >30%, the improvements in both groups were considered clinically meaningful [52]. At the moment, e-Exercise LBP cannot be considered an alternative to face-to-face physiotherapy as this study was conducted as a superiority trial. To be able to value the true potential of e-Exercise LBP, the meaningful within-group improvements must be considered from the perspective of the additional effort and costs needed to implement such an intervention in daily physiotherapy practice. Future cost-effectiveness analyses will provide more insight into the long-term economic benefits of stratified blended physiotherapy. On the other hand, given the additional effort and costs, the potential of e-Exercise LBP needs to be considered from the perspective of future health care. It is expected that technology will be increasingly integrated into care for patients who are suitable to use it. Future studies need to determine which patients benefit most from a stratified blended physiotherapy approach.

The e-Exercise LBP intervention significantly increased patients' self-reported adherence to prescribed home exercises, as hypothesized. In addition, it resulted in a significant reduction of fear-avoidance beliefs when compared with face-to-face physiotherapy. The between-group difference in patients' self-reported adherence to prescribed home exercises was 3.3% points in favor of the e-Exercise LBP intervention. For fear-avoidance beliefs, the between-group difference was −4.6% points in favor of the e-Exercise LBP intervention. Although there are no established cutoffs for the minimum clinically important between-group differences in these outcomes, we consider the between-group differences as small. The difference in adherence might be explained by the benefits of integrating a smartphone app. The 24/7 availability of the app and functionality to remind the patient to perform scheduled exercises might have stimulated the patients to adhere to their prescribed home exercises in a better way than in the face-to-face physiotherapy group [18,53]. Further research on the long-term clinical relevance of adherence to home exercises as prescribed in e-Exercise LBP is ongoing.

The reduction of fear-avoidance beliefs complements evidence from a systematic review and meta-analysis that concluded that patient education provides reassurance for patients with acute or subacute LBP [54]. In our study, this reduction in the stratified blended physiotherapy group might be explained by the information module of the smartphone app. As the information module provides the patient with self-management information about LBP, the patient can reread the advice and reassurance given in the face-to-face sessions by the physiotherapist about their LBP at all times. As a result, the harmless and nonspecific nature of LBP is possibly remembered in a better way [55]. Long-term results should indicate whether this reduction in fear-avoidance beliefs also influences physical functioning, the handling of recurrent complaints, and costs a patient incurs because of LBP.

Several explanations are possible to clarify why the additional benefits of stratified blended physiotherapy were not found. A first explanation is that the added value of a stratified approach in itself must be critically evaluated. Although clinical practice guidelines have adopted and advocated a stratified care approach for several years to improve patient outcomes, the added value of this approach is, at present, unclear. On the basis of previous recommendations, we decided to use the Keele STarT Back Screening Tool to create a matched web-based application [10]. Our results show that, after specific training, treatment intensity (ie, the number of face-to-face sessions) in the e-Exercise LBP group was in line with the patient's risk profile, which was not the case in our control group. However, this difference in treatment intensity did not lead to relevant between-group differences. This seems to be in line with more recent studies evaluating the stratified approach according to the Keele STarT Back Screening Tool. The results from these studies are not convincing regarding the added value of such a stratified approach [56,57]. Future research should focus on determining whether this concerns the added value of the tool itself or the added value of a stratified care approach in general.

In addition, stratified blended physiotherapy might not be suitable for every patient. Earlier research has shown that it is difficult to determine what works best for each individual patient [22,50]. In our study, we did not take into account the patient's suitability for blended care to determine the optimal personalized blended treatment [58]. As a result, patients might have received stratified blended physiotherapy without being suitable for it; for example, a lack of motivation or digital literacy skills. Consequently, this could have resulted in the suboptimal effectiveness of our stratified blended physiotherapy intervention when compared with face-to-face physiotherapy. For future studies on blended care, it is recommended to use patients' suitability for blended care as inclusion criteria or criteria to match treatment. The Dutch Blended Physiotherapy Checklist [58] could be a useful aid in this process.

A third explanation might be the relatively high proportion of patients with a low risk of developing persistent LBP in this study. For this group, earlier research has shown that providing advice as a single intervention is likely to reassure the patient with LBP but does not result in different management of pain and disability in the short term [54,59]. In addition, for this group, a stratified approach is beneficial from an economic perspective rather than in terms of clinical outcomes, as many of these patients recover completely within 2 to 3 weeks but nevertheless receive unnecessary treatment [57,60,61].

A final explanation is the timing of our follow-up measurement at 3 months only. Given the favorable course of LBP [62] and the rationale that stratified blended physiotherapy will stimulate patients' self-management and adherence [21,22], patients in the stratified blended physiotherapy group might recover faster, which is not captured by a single follow-up measurement at 3 months. Therefore, for future studies that aim to investigate postintervention effectiveness, it is recommended to measure the clinical outcomes immediately after the intervention is completed and to monitor the time to recovery.

Strengths and Limitations

This study had several important strengths. It is the next step in a multiphase development and implementation process based on the Center for eHealth Research Roadmap [63]. After developing a prototype and testing its feasibility in a pilot study [23], this study determined the short-term effectiveness of the final stratified blended physiotherapy protocol and showed its potential compared with face-to-face physiotherapy. The pragmatic, multicenter, cluster randomized controlled trial design allowed for the evaluation of stratified, blended physiotherapy in comparison with face-to-face physiotherapy in a real-world situation. The baseline characteristics of both treatment groups and the distribution of the different prognostic risk groups of developing persistent LBP reflect the characteristics of patients with LBP normally being treated in primary care physiotherapy [60], which enhances the generalizability of our results. The use of measurement instruments recommended in the core outcome set for research into patients with nonspecific LBP [28] and a low dropout rate (10.1%) guaranteed the internal validity of the results.

Nevertheless, this study also had a few limitations. First, the results seem to suggest that patients' risk of developing persistent LBP could be an effect modifier of the between-group differences on the primary outcome. Especially in the highest risk group, consistent between-group differences were seen in both the primary and secondary outcomes, supporting the rationale for stratified blended physiotherapy. As it was not the primary aim of this study, the sample size calculation did not take interaction into account, the numbers were small, and therefore, the results should be interpreted with caution. Second, as we conducted a pragmatic study, the experiences of physiotherapists in either using web-based applications or treating patients with nonspecific LBP were not considered inclusion criteria for physiotherapy practices. However, given both the complexity of blended care [17] and the complexity of treating patients with nonspecific LBP [4], it can be expected that more experienced physiotherapists are able to deliver better treatment than less experienced physiotherapists. Therefore, experience might have influenced our analysis. Finally, 4 included patients were excluded from the analysis after being diagnosed with specific LBP. As this number is low and occurred equally in both treatment groups (2 in each group), we expect that this has not influenced the results [64].

Conclusions

The stratified blended physiotherapy intervention e-Exercise LBP is not more effective than face-to-face physiotherapy in patients with nonspecific LBP in improving physical functioning in the short term. For both stratified blended physiotherapy and face-to-face physiotherapy, within-group improvements were clinically relevant. To be able to decide whether e-Exercise LBP should be implemented in daily physiotherapy practice, future research should focus on the long-term cost-effectiveness and determine which patients benefit most from stratified blended physiotherapy.

Acknowledgments

This study was cofunded by the Taskforce for Applied Research SIA (RAAK.PRO02.063), part of the Dutch Research Council. The funder had no role in the study design, data collection and analysis, decision to publish, or preparation of the manuscript. The authors are grateful for the invaluable help provided by Loes Kolenberg in the analysis of the physical activity data.

Authors' Contributions

TK participated in the development of the design of the study, conducted the study, performed the statistical analyses, and drafted and revised the manuscript. MFP was the principal investigator, developed the design of the study, and participated in the writing and revision of the manuscript. CJJK participated in the development of the design of the study and participated in the writing and revision of the manuscript. RMA participated in the design of the study, conducted the study, and participated in revising the manuscript. RWJGO supervised the project, advised the design of the study and statistical analysis, and participated in revising the manuscript. CV supervised the project, advised the design of the study and statistical analysis, and participated in revising the manuscript. All authors read and approved the final manuscript.

Abstract

Background: Multicomponent mobile health approaches can improve lifestyle intervention results, although little is known about their long-term effectiveness.

Objective: This study aims to evaluate the long-term effectiveness (12 months) of a multicomponent mobile health intervention—combining a smartphone app, an activity tracker wristband, and brief counseling, compared with a brief counseling group only—on weight loss and improving body composition, physical activity, and caloric intake in Spanish sedentary adults with overweight or obesity.

Methods: We conducted a randomized controlled, multicenter clinical trial (Evident 3). A total of 650 participants were recruited from 5 primary care centers, with 318 participants in the intervention group (IG) and 332 in the control group (CG). All participants were briefly counseled about a healthy diet and physical activity at the baseline visit. For the 3-month intervention period, the IG received training to use the app to promote healthy lifestyles and the smart band (Mi Band 2, Xiaomi). All measurements were performed at baseline and at 3 and 12 months. Physical activity was measured using the International Physical Activity

Questionnaire–Short Form. Nutritional habits were assessed using the Food Frequency Questionnaire and Adherence to Mediterranean diet questionnaire.

Results: Of the 650 participants included, 563 (86.6%) completed the 3-month visit and 443 (68.2%) completed the 12-month visit. After 12 months, the IG showed net differences in weight (−0.26, 95% CI −1.21 to 0.70 kg; *P*=.02), BMI (−0.06, 95% CI −0.41 to 0.28 points; *P*=.01), waist-height ratio (−0.25, 95% CI −0.94 to 0.44; *P*=.03), body adiposity index (−0.33, 95% CI −0.77 to 0.11; *P*=.03), waist circumference (−0.48, 95% CI −1.62 to 0.66 cm, *P*=.04) and hip circumference (−0.69, 95% CI –1.62 to 0.25 cm; *P*=.03). Both groups lowered daily caloric intake and increased adherence to the Mediterranean diet, with no differences between the groups. The IG increased light physical activity time (32.6, 95% CI −30.3 to 95.04 min/week; *P*=.02) compared with the CG. Analyses by subgroup showed changes in body composition variables in women, people aged >50 years, and married people.

Conclusions: The low-intensity intervention of the Evident 3 study showed, in the IG, benefits in weight loss, some body composition variables, and time spent in light physical activity compared with the CG at 3 months, but once the devices were collected, the downward trend was not maintained at the 12-month follow-up. No differences in nutritional outcomes were observed between the groups.

Introduction

Background

The combination of excess body weight and physical inactivity contributes to global mortality [1,2] and to a shorter healthy life expectancy [3]. Moreover, both are associated with a major risk for serious chronic diseases, including type 2 diabetes and cardiovascular diseases, as well as increasing cardiovascular risk factors [4]. Such conditions may impact individual quality of life and well-being while increasing the burden on the health system [5]. Several strategies have been implemented to tackle obesity, mainly focusing on changing lifestyles. In general, weight loss interventions aim to increase physical activity, reduce daily energy intake, improve diet or nutritional habits, and achieve psychological changes [6]. Owing to the complex nature of obesity, multicomponent interventions, capable of addressing various aspects related to its causes, are shown to be more effective in reducing cardiovascular risk factors [7] and body weight [8]. However, finding accessible and cost-effective multicomponent strategies that promote healthy lifestyles over time is challenging.

Mobile Health

Mobile health (mHealth) approaches, which are defined as the use of mobile wireless technologies for health [9], could optimize these efforts as portable and flexible tools, as well as improve the follow-up and feedback by registering health information [10] and provide efficient health management assistance for patients [11]. Specifically, some reviews suggested that mHealth could be more effective in losing weight than traditional approaches [12,13]. Among mHealth tools, smartphones are positioned as the most effective approach to achieve weight management [14], showing the most beneficial effects in the short term [15] (≤6 months). However, mobile phone intervention reports modest improvements in other lifestyles such as physical activity [16] or changes in biomarkers [13], highlighting the need to complement the intervention with other tools. Along these lines, wearable devices have garnered attention in improving physical activity and reducing sedentary lifestyle. Pedometer-based interventions have been widely explored [17], but the constant evolution of these tools requires the inclusion of emerging electronic devices [18]. Activity tracker wristbands, also called “smart bands,” have shown their validity and reliability in measuring physical activity outcomes [19] (eg, steps, kilometer walked, and intensity). Furthermore, a recent systematic review found that these device-based interventions are effective for increasing physical activity among chronic disease populations [20], making activity tracker wristbands a good option for inclusion in lifestyle interventions, as wearable activity trackers have the potential to increase physical activity participation [21]. However, wearable activity trackers alone may not be sufficient to achieve the expected lifestyle changes [22], so their inclusion in mHealth multicomponent obesity interventions, which appears to be more effective than app interventions alone [23], could be a beneficial strategy to obtain positive results in diet, physical activity, or other health variables [24,25]. In addition, self-monitoring in digital health interventions is associated with greater weight loss [26], so the use of both approaches could produce better weight outcomes.

Despite these promising results, the evidence for long-term efficacy is still limited, revealing that more evidence of effectiveness over long follow-up periods is required [27]. A systematic review showed that wearable devices might improve long-term physical activity and weight loss outcomes, although a comparison with traditional methods did not show clear benefits [28]. A similar situation exists with regard to multicomponent interventions with wearables, which may provide a strategy to improve long-term weight loss [29] despite the limited data on its effectiveness.

Objectives

Previously, the Evident 2 study evaluated the effect of adding an app (Evident 2) to a standardized intervention designed to improve adherence to the Mediterranean diet and increase physical activity in the general population [30]. The Evident 3 study aimed to evaluate the long-term effectiveness (12 months) of a multicomponent mHealth intervention—combining a later version of the smartphone app (Evident 3) and a smart band, compared with a brief counseling–only group—on body weight loss, improving body composition, increasing time spent in physical activity, and decreasing caloric intake in Spanish sedentary adults with overweight and obesity. The short-term study results (3 months) related to body composition have already been published [31].

Methods

Design and Setting

A multicenter, randomized controlled clinical trial with 2 parallel groups was conducted in a primary care setting (Evident 3 study). The Primary Care Research Unit of Salamanca (APISAL) at the Biomedical Research Institute of Salamanca (IBSAL) coordinated the project in 5 health centers located in Spain from the Network for Preventive Activity and Health Promotion (REDIAPP; Salamanca, Valladolid, Cuenca, Palma de Mallorca, and Zaragoza). The main aim of the study was to evaluate the effect of the intervention on weight loss in participants with overweight and obesity [32] (ClinicalTrials.gov NCT03175614). Between June 2017 and June 2020, evaluations were made at baseline and after the completion of 3 and 12 months. The results presented in this paper correspond to the long-term effect (12 months) of the 3-month mHealth intervention on the primary outcome (weight loss) and secondary outcomes related to physical activity and diet.

Study Population

The participants were selected by random sampling among patients who attended a consultation with their primary care provider in each participating center. The inclusion criteria were age between 20 and 65 years, a BMI between 27.5 kg/m^2 and 40 kg/m^2, classified as sedentary (20 minutes of vigorous-intensity activity ≤3 times per week; 30 minutes of moderate-intensity activity ≤5 times per week; or any combination of moderate and vigorous activity ≤5 times per week [33]), agreement to participate in the study, and signing the informed consent document. A detailed description of the exclusion criteria can be found elsewhere [32].

Sample Size

The sample size calculation was performed for the primary study endpoint of weight loss at 12 months. Accepting an α risk of .05 and a β risk of .20, with an SD of 12 kg, estimated in participants from the Evident 2 study [30], 592 participants would be needed (296 per group) to detect a decrease in weight of ≥3 kg [34] in the intervention group (IG) versus the control group (CG), considering a 15% loss to follow-up. This effect size represents a 3% to 5% difference between groups, which should produce clinically relevant health benefits [35].

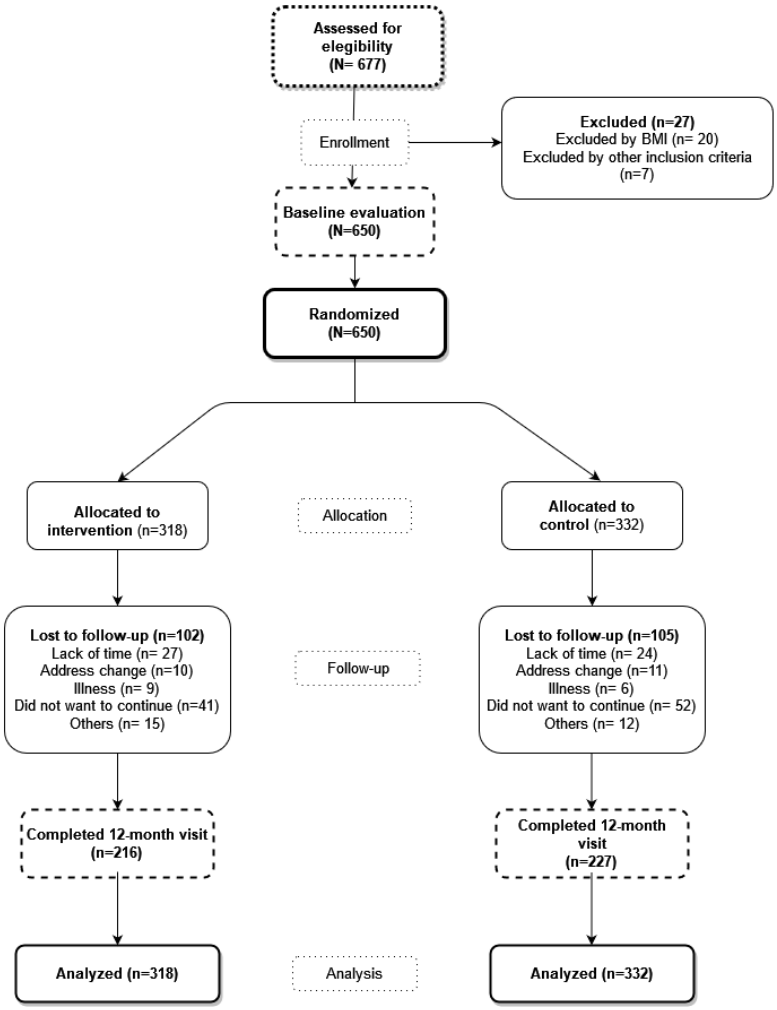
Randomization

Participants were randomly assigned to either the IG or the CG after the baseline visit and provided informed consent. The allocation sequence was generated in a 1:1 ratio using the Epidat (version 4.2; Xunta de Galicia) software package [36] by an independent researcher and concealed until the group was assigned. Owing to the nature of the study, the intervention could not be blinded to the participants.

Procedures

Each participant completed an initial visit and 2 follow-up visits at 3 and 12 months after randomization (Figure 1). They did not receive any compensation for the study or visit completion. Data from the visits were collected by a research nurse on a paper-based Case Report Form and recorded after the visit on the study website. The IG completed an additional appointment 7 days from the baseline visit to explain the use of the smartphone app and set it with the participant's data. The researcher who carried out the additional appointment was different from the researcher who collected the data of the visits.

Figure 1. Flowchart of the Evident 3 study.



Primary and Secondary Outcomes

Overview

The primary outcome was weight loss (kg). The secondary outcomes included changes in physical activity (min/week), caloric intake (kcal/day), adherence to the Mediterranean diet (points), and changes in body composition (anthropometric indexes). All outcomes were measured at baseline and at 3 and 12 months after randomization.

Weight Loss

Body weight was measured twice to the nearest 0.1 kg, with the participant barefoot and wearing light clothing, using a homologated electronic balance (Scale 7830; Soehnle Professional GmbH & Co). Height was measured with the participant barefoot in the standing position using a portable system (Seca 222; Medical scale and measurement system). BMI was calculated by dividing weight (kg) by height squared (m^2). Waist circumference was measured twice on bare skin, using a flexible tape parallel to the floor, at the level of the upper border of the iliac crest, with the participant standing and after inspiration, following the recommendations of the Spanish Society for the Study of Obesity [37]. Hip circumference was similarly measured at the level of the trochanters over the underwear.

In addition, anthropometric indices were estimated to evaluate body composition changes:

Waist–height ratio =

$$WC / Height \quad \textbf{(1)}$$

Body adiposity index =

$$[HC / (Height^{1.5})] - 18 \quad \textbf{(2)}$$

Waist–hip ratio =

$$WC / HC \quad \textbf{(3)}$$

Body shape index [38] =

$$WC / [(BMI^{0.666}) \times (Height^{0.5})] \quad \textbf{(4)}$$

Body roundness index [39] =

$$364.2 - 365.5 \times \sqrt{\{1 - [WC / (2 \times 3.1416)]^2 / (0.5 \times Height)^2\}} \quad \textbf{(5)}$$

Physical Activity

Physical activity was assessed using the short version of the International Physical Activity Questionnaire–Short Form (IPAQ-SF) [40]. The IPAQ-SF is a self-reported questionnaire that evaluates sitting and active time in the last 7 days through 7 questions. The categories consisted of walking, moderate-intensity activity, and vigorous-intensity activity, according to the energy expenditure estimated for each of them:

3.3, 4.0, and 8.0 metabolic equivalents (METs), respectively; 1 MET being the amount of oxygen consumed while sitting at rest [41]. Thus, the IPAQ-SF enables METs-minutes per week to be calculated, and participants were stratified into 3 activity levels (low, intermediate, and high).

Nutritional Habits

Caloric intake (kcal/day) and dietary habits of participants were evaluated using a semiquantitative Food Frequency Questionnaire previously validated in the Spanish population [42]. The frequency options are divided into 9 intake categories, ranging from never to >6 servings per day. Food Frequency Questionnaire data were used to estimate the daily intake of macro- and micronutrients and the mean kcal/day.

Adherence to the Mediterranean diet was assessed using the validated 14-point Mediterranean Diet Adherence Screener [43] developed by the prevention with Mediterranean diet study group, which comprises 12 questions on food consumption frequency and 2 questions on food intake habits. Each question was scored as 0 or 1, and the total score ranged from 0 to 14. A total score of 9 points or higher indicated adequate adherence.

Adherence to Self-monitoring on the Smartphone App

Adherence to self-monitoring on the smartphone app was assessed by the number of days that the participants logged into the app and recorded any dish or food. Records were classified into 4 categories: 0 days, 1 to 30 days, 31 to 60 days, and >60 days. Participants who used the app for >60 days during the 3 months that they had the app were classified as sufficiently adherent, whereas ≤60 days of use was classified as having low adherence.

Other Variables

Sociodemographic Variables

Data on age, sex, marital status, educational level, and occupation were collected at the time of inclusion in the study.

Peripheral Blood Pressure

Three measurements of systolic and diastolic blood pressure were performed using the average of the last 2 measurements with a validated Omron M10-IT model sphygmomanometer (Omron Healthcare). The measurements were made on both arms, with the participant seated, after at least 5 minutes of rest with an appropriately sized cuff, following the recommendations of the European Society of Hypertension [44].

Smoking Status

This was assessed through a questionnaire of 4 standard questions adapted from the World Health Organization monitoring of trends and determinants in cardiovascular disease study [45]. Study participants were classified as current smokers, former smokers (>1 year without smoking), or nonsmokers.

Intervention

A detailed description of brief counseling and specific intervention has been published in the study protocol [32]. All the intervention materials were provided in Spanish.

Standard Counseling (CG and IG)

A trained nurse at each primary health center, who was not involved in other aspects of the study, gave 5 minutes of lifestyle counseling to both groups (CG and IG) before randomization, focusing on physical activity and diet in compliance with the international recommendations for the general population. The health benefits of physical activity were explained as well as the recommendation to complete at least 30 minutes of moderate activity 5 days a week, or 20 minutes of vigorous activity 3 days a week. Counseling on food was in compliance with the plate method [46], in which a plate is divided into 4 parts: half the plate for salad or vegetables, one-quarter for proteins (white meat preferred over red meat), and the final quarter for carbohydrates. In addition, a medium-sized piece of fruit and a skimmed dairy product should be consumed for dessert. This advice enhanced the intake of healthy food, according to the Mediterranean diet pattern, and daily caloric intake goals were not included. No reinforcement of counseling was offered at any other study visit or between the 3- and 12-month visits.

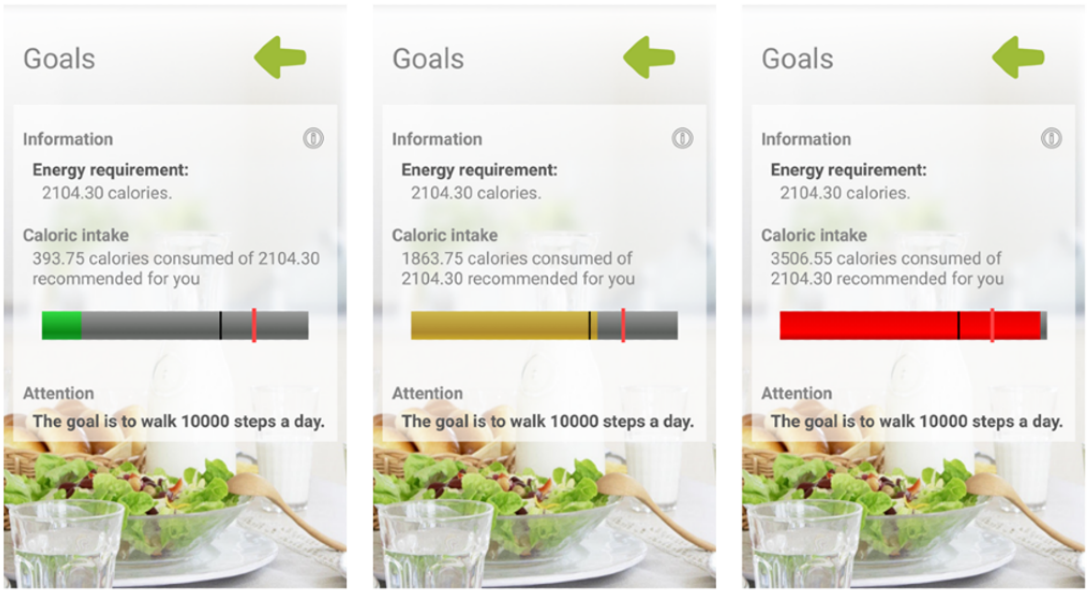
Specific Intervention (IG)

The IG received a low-intensity intervention consisting of a smartphone with the EVIDENT 3 app (Samsung Galaxy J3) and a smart band (Xiaomi Mi Band 2) for 3 months, corresponding to the length of the intervention, without any additional reinforcement or counseling by the investigators throughout the study. Participants were trained at another 15-minute visit scheduled 7 days after the baseline visit in the use of the app (EVIDENT 3 app [record entry no. 00/2017/2438]) specifically designed for the study by CGB Computer Company and APISAL, as well as the use of the smart band, instructing them to use both tools daily.

During this visit, the app was configured with each participant's data (sex, age, weight, and height). It was designed to allow full daily self-monitoring of food intake (Figure 2) and automatically record physical activity through the smart band, which was configured to synchronize with the app. Participants entered their food intake daily by selecting dishes and foods from the app menu and indicating the portion size. Food composition data were collected from the Spanish Food Composition Database [47], developed by Spanish Food Composition Database Network and Spanish Agency for Food Safety and Nutrition. Once all the daily information is collected, the app integrates the data to create personalized healthy food recommendations based on the Mediterranean diet pattern and specific targets for daily calorie intake that would lead to weight loss. The app displays the amount of calories recorded (Figure 2) and a bar that changes color (green, yellow, or red) according to the level set. It was configured to achieve a hypocaloric diet, calculating the upper limit (the red line) by adding, according to age and sex, the basal metabolic rate, diet-induced thermogenesis, and estimated energy expenditure for sedentary activities. The lower limit (the black line) was 85% of the calories calculated, and below this, the bar appeared in green; between the red and black lines, it appeared in yellow; and above the red line, it appeared in red. The participant was able to consult the app for these recommendations as well as information about caloric intake changes and macronutrient

distribution (carbohydrates, proteins, and unsaturated and saturated fats). The smart band was set to congratulate the user when reaching 10,000 steps/day, and the app displayed this step recommendation in the goals section. Behavioral strategies were included in the mHealth intervention to enhance self-efficacy using self-monitoring, goal-setting, and positive reinforcement. At the 3-month visit, participants returned the intervention tools to the researchers. Thereafter, participants did not have access to the intervention devices and were advised not to use other digital tools for weight loss until the end of the study. All the information generated by the app was duly analyzed and entered into the database. In addition, once the tools were returned, monthly mean daily steps and activity minutes were collected for the last 2 of the 3 months of the intervention from the Mi Fit app (Xiaomi) to assess whether the smart band was worn.

Figure 2. Evident 3 app screenshots.



Blinding Strategy

The researcher who carried out the specific intervention was different from the person responsible for the assessment and the standard counseling; both were kept blinded throughout the study, as was the investigator who conducted the data analysis. Owing to the nature of the study, the participants could not be blinded. To prevent contamination between groups, in the follow-up visits (3 and 12 months), only the study variables were evaluated, but no advice or reinforcement was provided. In addition, the app was not available for download on the internet or anywhere until the end of the study, so the CG was not able to make use of it in any way. During the follow-up visits, participants were instructed not to use other digital health technologies.

Statistical Analysis

Baseline characteristics of the study population were expressed as mean and SD for quantitative variables and as frequency distributions for categorical variables. Student *t* test (2-tailed), chi-square test, and Fisher exact test were used to determine differences in baseline characteristics between the IG and CG. Analyses of the results were performed on an intention-to-treat basis. Paired Student *t* test or McNemar test was applied to assess changes within the same group. To analyze the effect of the intervention, in the follow-up for primary and secondary endpoints, we performed several multivariate analyses of the variance of repeated measures using the general linear model, comparing the changes observed between the IG and CG in the analyzed variables, first unadjusted and then adjusted for age and sex.

We performed a subanalysis by multivariate analysis of the variance of repeated measures of the intervention effect in primary and secondary outcomes stratified by sex (men and women), age (<50 years and ≥50 years), and marital status (married, single, or others).

The contrast in the hypotheses established an α value of .05. The data were analyzed using SPSS Statistics software (version 26.0; IBM Corporation).

Ethical Considerations

The study was approved by the clinical research ethics committee of the Health Area of Salamanca in April 2016. In addition, the study was approved by the ethics committees of the 4 collaborating centers: Aragón, Castilla-la Mancha, Baleares, and Valladolid Oeste. All procedures were performed in accordance with the ethical standards of the institutional research committee and the 2013 Declaration of Helsinki [48]. All participants signed written informed consent documents before participation in the study. The trial was registered at ClinicalTrials.gov with identifier NCT03175614 on May 31, 2017.

Results

Baseline Characteristics of the Participants and Follow-up

Of the 650 participants who completed the baseline visit, 563 (86.6%) completed the 3-month visit and 443 (68.2%) completed the 12-month visit. There were 207 (207/650, 31.8%) participants who dropped out of the study, 32.1% (102/318) in the IG and 31.6% (105/332) in the CG. Participants assigned to each group and the reasons for withdrawal from the trial may be consulted in Figure 1.

The clinical and sociodemographic baseline characteristics of the 650 participants are presented in Table 1. The mean age of the entire sample was 48.31 (SD 9.67) years, with a mean BMI of 33.0 (SD 3.48) kg/m^2. In addition, 68.5% (445/650) of participants were women, 68.3% (444/650) were married, and 46.8% (304/650) were aged ≥50 years. No differences were observed between the study groups at baseline.

The comparison between the baseline characteristics of the 207 participants who dropped out and those who completed the study are shown in Multimedia Appendix 1. It should be noted that those who dropped out were younger (46.3 vs 49.2 years) and had a higher weight (93.3 vs 90.2 kg) and BMI (33.6 vs 32.7 kg/m^2), with no difference in the rest of the variables analyzed.

Adherence to Self-monitoring on the Smartphone App

Adherence to self-monitoring on the smartphone app was calculated from the app output data by an independent researcher. The median app use was 64.5 days out of the 90 days of the intervention (71.67%). Of the 318 participants assigned to the IG, 150 (47.2%) adhered sufficiently by recording data in the app between 61 and 90 days. In total, 3 participants did not register any food, and there were 36 data files from which no information was available for technical reasons (Multimedia Appendix 2). Multimedia Appendix 3 displays the median days of app use out of the 90 days in percentage to show adherence to self-monitoring on the app, grouped by sex, marital status, and age.

Changes in Weight and Anthropometric Variables During the Study Period

Table 2 shows the decrease in body weight at 3 and 12 months in both groups. Comparing groups, the IG achieved a net weight loss difference of 0.76 (95% CI −1.33 to −0.19) kg at 3 months and 0.26 (95% CI −1.21 to 0.70; *P*=.02) kg at 12 months, more than the CG. The overall weight reduction of the IG was 2.05% at 3 months and 1.58% at 12 months, while the CG showed 1.1% and 1.26% reductions in body weight at 3 and 12 months, respectively. Only 18.2% (52/285) of the IG participants achieved a clinically significant weight loss of ≥5% at the 3 months visit and 19.4% (42/216) of them achieved that percentage at 12 months. In the CG, 12.9% (35/271) achieved a weight loss of 5% at 3 months and 18.5% (42/227) reached that loss at the 12-month visit. Regarding adherence to self-monitoring on the app, both in number of days used and median percentage of days, a positive correlation was found at 3 months with weight loss (*r*=0.239; *P*<.001) and BMI (*r*=0.203; *P*<.001) but not at 12 months or with weight (*r*=0.015; *P*=.83) and BMI (*r*=0.021; *P*=.77).

In addition, the IG showed changes in waist circumference (−0.76, 95% CI −1.47 to −0.05 cm) and hip circumference (−1.02, 95% CI −1.68 to −0.34 cm) compared with the CG at 3 months. Similar results were found at 12 months, with net decreases in waist circumference (−0.48, 95% CI −1.62 to 0.66 cm) and hip circumference (−0.69, 95% CI −1.62 to 0.25 cm; *P*=.04 and *P*=.03, respectively) between groups. Regarding body composition parameters, BMI decreased at 3 months (−0.30, 95% CI −0.52 to −0.09 points) and slightly changed at 12 months (−0.06, 95% CI −0.41 to 0.28 points; *P*=.01), comparing the study groups. Similar results were found for waist–height ratio at 3 months (−0.48, 95% CI −0.92 to −0.04) and 12 months (−0.25, 95% CI −0.94 to 0.44; *P*=.03) and body adiposity index at 3 months (−0.50, 95% CI −0.81 to −0.18) and 12-month follow-up (−0.33, 95% CI −0.77 to 0.11; *P*=.03) between groups. Although the IG tended to show decreases in the rest of the indexes analyzed (waist–hip ratio, body shape index, and body roundness index) at both follow-up visits, no significant differences were observed between groups.

Figure 3 shows the evolution of the main anthropometric parameters analyzed over time, with a decrease at 3 months in both groups, especially in the IG. However, the downward trend was not maintained in the IG at 12 months, while the CG continued to decrease.

Table 2. Effect of the mobile health intervention on body weight and other anthropometric parameters.

Parameters	Intervention group (n=318)		Control group (n=332)		Net difference

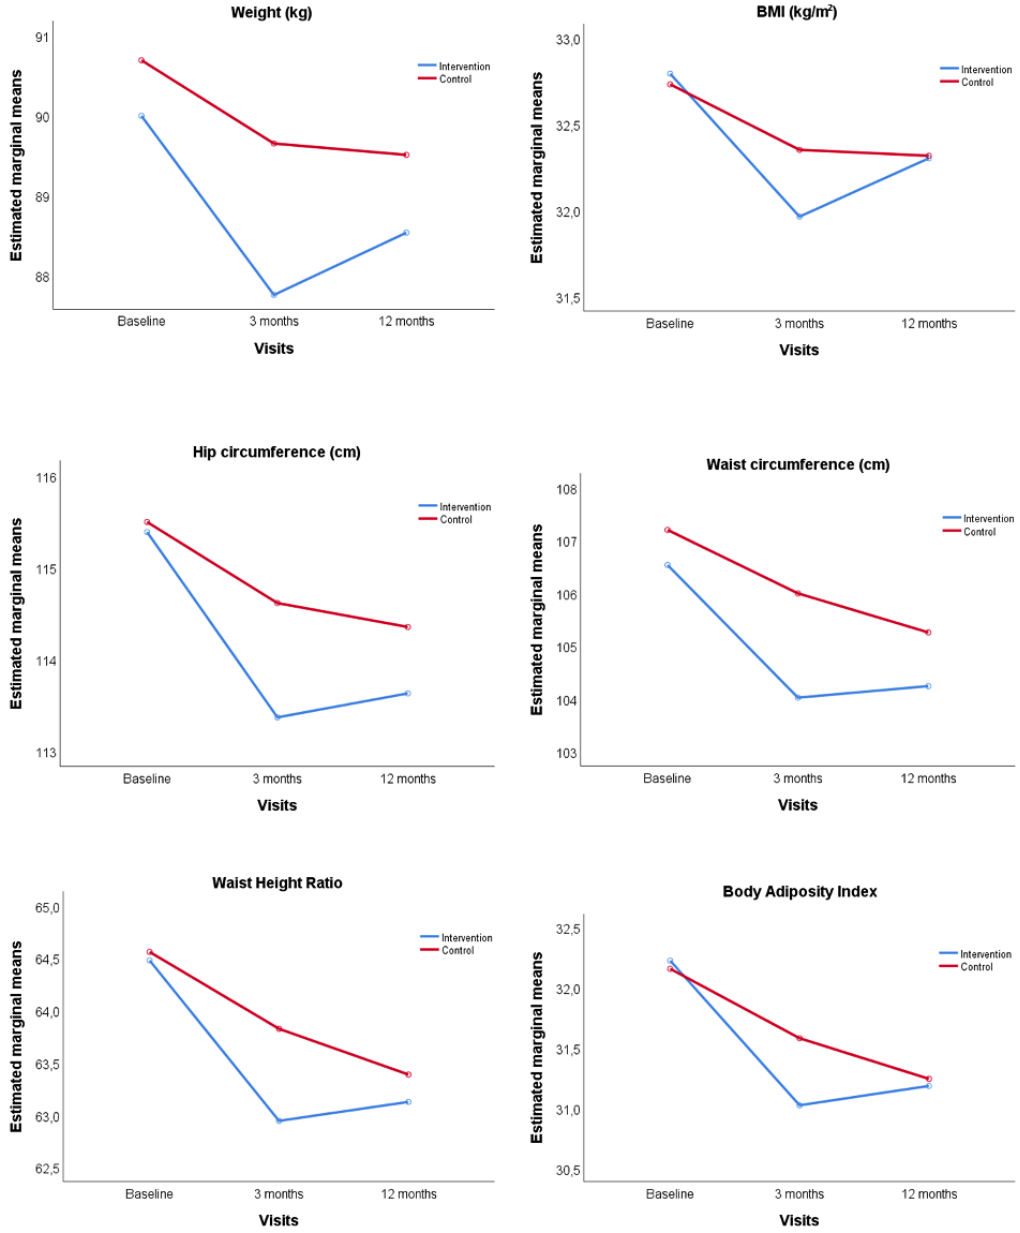
Figure 3. Evolution of weight, BMI, and other anthropometrics parameters from baseline to 3 and 12 months comparing the intervention and control group. *P* value between groups was adjusted by age and sex: weight, *P*=.02; waist circumference, *P*=.04; hip circumference, *P*=.03; BMI, *P*=.01; waist–height ratio, *P*=.03; and body adiposity index, *P*=.03.



Changes in Diet and Physical Activity

In terms of diet, daily caloric intake was lower in both groups (IG: −295, 95% CI −391.63 to −198.93 kcal/day; CG: −222, 95% CI −310.62 to −135.14 kcal/day) at 12 months, with no significant differences between groups (Table 3). The Mediterranean diet adherence increased in both groups at 3 and 12 months, but the differences were not statistically significant. The IG experienced a trend toward increased adherence to the Mediterranean diet at 3 months, but decreased at 12 months, while adherence was maintained in the CG.

Physical activity time in all intensities (light, moderate, and vigorous) assessed by the IPAQ-SF increased in both groups at 3 and 12 months, whereas the time of sedentarism decreased. Although the IG tended to show greater increases in light activity, vigorous activity, and total activity time, only light physical activity (LPA) time showed a net increase of 81.2 (95% CI 31.93-130.58) minutes per week at 3 months and 32.6 (95% CI −30.31 to 95.04) minutes per week at 12 months (*P*=.02) compared with the CG. Regarding the smart band, Multimedia Appendix 4 shows the correlation between the IPAQ-SF data (METs per week and min/week for each activity level) at 3 months in the IG and the information collected from the smart band after 3 months of the intervention (daily average of steps and activity minutes), with a low correlation between variables, which was higher in women than in men.

Table 3. Effect of the mobile health intervention on diet and physical activity variables.

[c]MD: Mediterranean diet.

Analyses of the Effect Stratified by Baseline Characteristics

Only women experienced decreases in weight, waist, and other anthropometric parameters analyzed, except for waist–hip ratio, body shape index, and body roundness index, with a net weight loss of 0.50 (95% CI −1.53 to 0.54; *P*=.002) kg at 12 months. With regard to age, those aged <50 years showed a decrease in hip circumference, while people aged >50 years showed a reduction in weight and BMI. Finally, analysis by marital status showed that only married people showed decreases in weight (−0.90, 95% CI −2.0 to 0.2 kg; *P*=.02), BMI (−0.3, 95% CI −0.7 to 0.1 points; *P*=.01), and other anthropometric parameters at 12 months. These analyses are presented in Multimedia Appendix 5.

Discussion

Principal Findings

Overview

The Evident 3 study evaluated the intervention effect and its maintenance over time at 3 and 12 months after the baseline visit. The main findings of the use of a smartphone app in combination with an activity tracker wristband for 3 months and brief counseling showed a greater weight loss compared with the CG, but once these devices were collected, the trend was not maintained at 12 months. Although both groups had reduced weight, BMI, and other anthropometric variables, the IG showed a greater trend to reduce weight, BMI, waist and hip circumference, waist–height ratio, and body adiposity index at the 3-month follow-up and did not maintain a downward trend at the 12-month visit. Regarding diet, both groups decreased their caloric intake (kcal) and improved their Mediterranean diet adherence, but no differences between groups were found. A similar result was observed in physical activity, where physical activity time increased in both groups, but the IG showed an increase in weekly LPA time at 12 months. Analyses stratified by baseline characteristics showed patterns toward greater changes in body composition variables in women, people aged >50 years, and married people.

Weight

Findings from meta-analyses have shown that mHealth weight loss interventions were effective in comparison with minimal intervention or control in the short term but with inconclusive long-term results [15,16]. The Evident 3 study provides insights into the long-term effects of weight loss, BMI, and other anthropometric variables at 3 months, but this trend was not maintained in the period when they no longer had access to the devices up to the 12-month visit. In addition, overall weight reduction in the IG was 2.05% at 3 months, so clinically relevant weight loss was not achieved (>5%).

Despite the heterogeneity found in these types of interventions, some systematic reviews [23,49] suggest that the combination of mHealth tools could be useful for changing lifestyles to healthier ones, but its effect on weight loss remains unclear. Along these lines, the Innovative Approaches to Diet, Exercise and Activity study, which provided a wearable technology combined with a website to the enhanced IG, found no significant difference in weight or physical activity between groups [29] across the 24-month intervention in young adults. Moreover, another study that evaluated the effect of a web-based weight loss program with and without an activity tracking device found that its addition to the intervention did not produce higher changes in weight loss at the 12-month follow-up [50] than those in the CG. In contrast, the Quant study, whose intervention included 3 feedback devices (Bioelectrical Impedance Analysis scale, blood pressure, and step counter) found a positive effect on fat loss at the 12-month follow-up [51]. These results are consistent with those found in our study, where there were differences between groups in weight, body composition variables, and physical activity but without reaching clinically relevant results.

Notwithstanding the effectiveness of self-monitoring behaviors in weight management [52], the challenge lies in finding a way to keep the users using the app, because the frequency of logging into the app is highly related to weight loss success in web-based interventions [53] and mHealth apps [52], as the user adopts new behaviors over time that is supported by the tools. In this regard, the rate of users who adhered sufficiently to the study app (150/318, 47.2%) may be insufficient to show better results in the main outcomes at 12 months. It should also be noted that

between the period in which mHealth tools were collected at the 3-month follow-up and the 12-month visit, there was no reinforcement or any contact with the participants by the researchers. Therefore, despite not obtaining clinically relevant weight loss, the results suggest that the intervention should be modified (longer intervention period, improved adherence strategies, some professional support, etc), as the trend of weight reduction was not maintained over time when tools were removed. Moreover, the CG also reported weight loss but lower than that of the IG, which is commonly reported in weight loss interventions [25], especially if the CG received usual care [54].

Physical Activity and Diet

The study intervention, which included an activity tracker wristband, was shown to increase weekly LPA time measured by the IPAQ-SF. Increasing LPA may improve important health outcomes, such as markers of lipid and glucose metabolism and mortality in the general population [55]. Although the general physical activity recommendations are based on promoting moderate to vigorous physical activity, increasing LPA in the sedentary population may be a good starting point for decreasing inactivity in people with overweight and obesity [56]. Previous studies have reported beneficial changes in physical activity variables, observing a small increase in moderate to vigorous physical activity in women [57] and people with overweight and obesity [22] or in steps per day [20] in people with chronic diseases. Specifically, a recent study reported increased resistance training and reduced energy intake at 6 months using a multicomponent mHealth intervention [25], showing the potential of these tools in physical activity promotion by allowing a more tailored intervention and greater feedback.

Furthermore, energy intake was reduced, and adherence to the Mediterranean diet increased in both groups. However, the app intervention did not achieve better results than the CG. Potential explanations for this include that the brief diet counseling using the plate method was explained at the end of the baseline visit, which could lead to an improvement in the entire sample. Moreover, Solbrig et al [58] suggested that there is a mismatch between people's need for help and what weight management apps provide, as people dislike counting calories, the basis of most self-management apps, and need more tailored support and motivational elements. Along these lines, a recent study found that a digital app that provides personalized nutritional recommendations appeared to be successful in reducing weight in users with obesity [59]. Future research will focus on the inclusion of new adaptive features in health apps to achieve greater results in health outcomes and higher rates of intervention adherence.

Analyses of the Effect Stratified by Baseline Characteristics

These analyses showed that the intervention was more effective in specific groups than in the general IG. Women showed greater weight loss, BMI changes, and other anthropometric variables, whereas men did not show differences. This could be explained by the higher rate of participation by women in this study (445/650, 68.5%), following the trend of weight management studies [60] and by the lower number of men included (n=205), which may have resulted in an underpowered analysis to find differences in the male group. In addition, women are more likely to participate in weight loss interventions [61] and use health apps [62], so the sex factor has to be considered. Regarding age, people aged >50 years obtained differences in more outcomes than younger people, and they were more adherent to the self-monitoring on the app. A systematic review found that middle-aged adults are more willing to adhere to such interventions with activity trackers [63] than younger people, so it is feasible that differences are found between age groups, as in the study results. In terms of marital status, married people seem to benefit more from the intervention. However, the unequal size of the groups could explain why single people, who obtained higher median adherence days than married people, did not show positive results. The influence of sociodemographic factors on the digital intervention effect, or adherence, has to be explored in-depth, but a study among users of eHealth approaches suggested that married people, among other characteristics, generally used more mHealth apps [64], which might lead to more positive results. Although more research is needed to determine which personal factors could influence mHealth effectiveness, these analyses highlight the need to develop more tailored interventions, adapting them according to certain characteristics of the user to enhance the effect of these digital approaches.

Finally, the average dropout rate was higher than expected (207/650, 31.8%) but balanced between study groups (IG: 102/318, 32.1% vs CG: 105/332, 31.6%). As a group, the participants who dropped out of the study were younger, with greater mean weight, BMI >30 kg/m^2, and a higher proportion of smokers, in line with the dropout predictors found by a systematic review [65]. The participant attrition rate from digital interventions often exceeds 20% [66], and it is common to find large dropouts in weight management mobile phone apps [67] and multicomponent interventions [51]. Potential explanations could be participants' higher weight loss expectations [65] and experiencing difficulty in maintaining self-monitoring.

Strengths and Limitations

This study had several strengths. The study included a large sample with a multisite design with a wide range of ages and educational background, which offers robustness to the results obtained. Both the intervention and the statistical analysis were conducted by blinding researchers to the assignment groups. The 3- and 12-month visits allowed evaluation of the short-term and long-term effects of this type of technology on weight loss in the absence of additional face-to-face intervention. Moreover, the adherence rate to the self-monitoring diet on the app was acceptable (median percentage of days 71.7%).

In addition, some limitations of this study should be noted. Although participants were instructed not to use any other mHealth tool that could interfere with the study, there are no guarantees to ensure this occurred. The data collected from the smart band did not allow for the assessment of daily use and adherence to this device. In addition, the nature of the intervention precludes blinding of the participants, although recent findings suggest that blinding is less important than often believed [68]. The exposure time to the intervention (3 months) might not be sufficient to identify more positive results in

changing lifestyles and weight loss. The number of participants in each baseline characteristics (sex, age, and marital status) group could be insufficient to show more relevant effects in the stratified analysis. Finally, the dropout rate of 31.8% (207/650) may have biased the final sample study composition and underpowered the study with regard to detecting a significant effect in the results between groups. However, random allocation and a balanced dropout between arms show that the group characteristics differ little from the initial sample, making the comparison between groups possible [69].

Conclusions

The low-intensity intervention of the Evident 3 study showed in the IG, benefits on weight loss, some body composition variables, and time spent in LPA compared with the CG at 3 months, but once the devices were collected, the downward trend was not maintained at the 12-month follow-up. No differences in nutritional outcomes were observed between the groups. Analyses stratified by baseline characteristics revealed that the intervention was more effective in women, people aged ≥50 years, and married participants. Further research is needed to determine the optimum intervention period to achieve greater results, as well as the inclusion of more tailored strategies in health apps and weight management interventions that improve intervention adherence and retention rates.

Centro de Salud Sta Ponça de Palma de Mallorca (Health Service of Balear Islands): José I Ramírez-Manent, José L Ferrer-Perelló, José E Romero-Palmer, Manuel Sarmiento-Cruz, Guillermo Artigues, Jitka Mudrychova, María Albaladejo-Blanco, Margarita I Moyá-Seguí, Cristina Vidal-Ribas, Patricia Lorente-Montalvo, Isabel Torrens-Darder, María M Torrens-Darder, and Lucía Pascual Calleja.

Centro de Salud San Pablo de Valladolid (Health Service of Castilla y León): María J Álvarez-Miguel, María D de Arriba-Gómez, María A Rodríguez-Fernández, Isabel Arranz-Hernando, Silvia Ramos-de la Torre, Amparo Arqueaga-Luengo, María E Moreno-Moreno, Agustina Marcos-García, Nora Manrique-Vinagre, Nieves Palomo-Blázquez, José L Montalvillo-Montalvillo, María E Fernández-Rodríguez, Alejandro González-Moro, Marta, Santiago-Pastor, María I Pérez-Concejo, and Aurora Rubio-Fernández.

Centro de Salud Casa del Barco de Valladolid (Health Service of Castilla y León): Amparo Gómez-Arranz, Carmen Fernández-Alonso, Daniel Rodríguez-Dominguez, Irene Repiso-Gento, Aventina de la Cal-de la Fuente, Rosa, Aragón-García, Miguel A Díez-Garcia, Elisa Ibañes-Jalón, Ines Castrillo-Sanz, Ana M Corcho-Castaño, Esther Jiménez-López, Daniel Correa-González, Lucía Barruso-Villafaina, Isabel Peña-García, Dolores Escudero-Terrón, Pilar Mena-Martín, Rosario Fraile-Gómez, Alberto Alonso-Gómez, Pilar Urueña, Francisca Martínez-Bermejo, Concepción Hernández-San José, Manuela Nuñez-Gómez, Patricia Sanz-Capdepont, Ana I Pazos-Revuelta, Sofía Pérez-Niño, and María E Junquera-del Pozo.

The CGB Computer Company in Salamanca, Spain, contributed to the technical development of the EVIDENT 3 app.

Authors' Contributions

LGO, MAGM, and JIRR contributed to the conception and design of the study. LGO had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of data analysis. CLS, LGO, and MAGM contributed to the drafting of the paper, and CLS had the primary responsibility for the final content. LGO and MAGM contributed as senior authors to the manuscript. LGO, ERS, and MAGM contributed to the analysis and interpretation of the data. CLS, MAGM, ERS, JIRR, and LGO contributed to the critical review of the paper for important intellectual content. CLS, JIRR, CAC, IRG, EGA, MASC, and JIRM were responsible for the collection and assembly of data. All authors have read and approved the final manuscript.

Conflicts of Interest

None declared.

Multimedia Appendix 1
Baseline characteristics comparison between participants who completed the study and those who dropped out.
[PDF File (Adobe PDF File), 91 KB - jmir_v24i2e30416_app1.pdf]

Multimedia Appendix 2
Adherence to the smartphone app (number of days with a record in the app).
[PDF File (Adobe PDF File), 62 KB - jmir_v24i2e30416_app2.pdf]

Multimedia Appendix 3
Adherence to self-monitoring on the app analyzed by the median percentage out of the 90 days of the intervention grouped by sex, marital status and age.
[PDF File (Adobe PDF File), 68 KB - jmir_v24i2e30416_app3.pdf]

Multimedia Appendix 4
Correlations between International Physical Activity Questionnaire-Short Form and the Smart band at the 3-month visit in the intervention group.
[PDF File (Adobe PDF File), 96 KB - jmir_v24i2e30416_app4.pdf]

Multimedia Appendix 5
Analysis of the mobile health intervention effect on weight and body composition variables grouped by baseline characteristics.
[PDF File (Adobe PDF File), 117 KB - jmir_v24i2e30416_app5.pdf]

Multimedia Appendix 6
CONSORT eHEALTH Checklist (V 1.6.1).
[PDF File (Adobe PDF File), 335 KB - jmir_v24i2e30416_app6.pdf]

Abstract

Background: Remote data capture for blood glucose (BG) or blood pressure (BP) monitoring and the use of a supportive digital app are becoming the model in diabetes and hypertension chronic care. One of the goals in chronic condition management is to increase awareness and generate behavioral change in order to improve outcomes in diabetes and related comorbidities, such as hypertension. In addition, there is a lack of understanding of the association between BG and BP levels when using digital health tools.

Objective: By applying a rigorous study framework to digital health data, this study investigated the relationship between BP monitoring and BG and BP levels, as well as a lagged association between BP and BG. We hypothesized that during the first 6 months of BP monitoring, BG and BP levels would decrease. Finally, we suggested a positive association between BP levels and the following month's BG levels.

Methods: In this retrospective, real-world case-control study, we extracted the data of 269 people with type 2 diabetes (T2D) who tracked their BG levels using the Dario digital platform for a chronic condition. We analyzed the digital data of the users who, in addition to BG, monitored their BP using the same app (BP-monitoring [BPM] group, n=137) 6 months before and after starting their BP monitoring. Propensity score matching established a control group, no blood pressure monitoring (NBPM, n=132), matched on demographic and baseline clinical measures to the BPM group. A piecewise mixed model was used for analyzing the time trajectories of BG, BP, and their lagged association.

Results: Analysis revealed a significant difference in BG time trajectories associated with BP monitoring in BPM and NBPM groups (t=–2.12, P=.03). The BPM group demonstrated BG reduction improvement in the monthly average BG levels during the first 6 months (t=–3.57, P<.001), while BG did not change for the NBPM group (t=0.39, P=.70). Both groups showed similarly stable BG time trajectories (B=0.98, t=1.16, P=.25) before starting the use of the BP-monitoring system. In addition, the BPM group showed a significant reduction in systolic (t=–6.42, P<.001) and diastolic (t=–4.80, P<.001) BP during the first 6 months of BP monitoring. Finally, BG levels were positively associated with systolic (B=0.24, t=2.77, P=.001) and diastolic (B=0.30, t=2.41, P=.02) BP.

Conclusions: The results of this study shed light on the association between BG and BP levels and on the role of BP self-monitoring in diabetes management. Our findings also underscore the need and provide a basis for a comprehensive approach to understanding the mechanism of BP regulation associated with BG.

Introduction

Major goals for the treatment of diabetes are to prevent or delay complications and optimize the quality of life [1]. People with type 2 diabetes (T2D) face challenging self-management regimens to improve glycemia and decrease morbidity and mortality, while often dealing with high costs of care [2]. Hypertension is the most common chronic illness in the United States, and the standard model of office-based care delivery continues to yield suboptimal outcomes, with approximately 50% of affected patients not achieving blood pressure (BP) control [3]. Elevated BP values are a common finding in people with T2D. In fact, hypertension is reported in over two-thirds of patients with T2D [4], and its development coincides with the development of hyperglycemia [5]. Furthermore, a large proportion of persons with diabetes exhibit poorly controlled hypertension, which may reflect not only delayed recognition of the presence of hypertension, clinical inaction, and poor adherence to the prescribed regimen but also uncertainty regarding the treatment targets and pathogenic correlation [6].

The pathogenic relationship between T2D and hypertension is assumed to be bidirectional [7]. Elevated BP levels are supposed to reflect at least partially the impact of the underlying insulin resistance on the vasculature and kidneys, while there is clinical evidence suggesting that disturbances in carbohydrate metabolism are more common in individuals with hypertension [4]. In persons with diabetes, hypertension confers an enhanced risk of cardiovascular disorder, having a similar risk for people with hypertension but without diabetes [5]. Hypertension and diabetes are major risk factors for cardiac diseases, stroke, and kidney disorders [8-10]; however, hypertension is the leading cardiovascular disease–related cause of morbidity and mortality among persons with T2D [11,12].

Previous studies have shown the beneficial effect of BP-lowering treatment on end-stage renal disorders in T2D [13]. Moreover, a significant improvement was demonstrated in all diabetes-related outcomes resulting from long-term tight BP control in patients with T2D and hypertension [14,15].

Among normotensive individuals, T2D at baseline was shown as a significant predictor of incident hypertension (independent of age, body mass index [BMI], and family history of diabetes) [6]. Furthermore, most of the care for the patient with hypertension typically relies on the primary care physician, whose time for face-to-face patient care has become progressively limited [3]. Approximately half of the persons treated for T2D do not have adequate BP or glycemic control [16]. It is clear that management of a chronic condition requires a change in strategy to meet the real-time needs of the population.

Ideal management of chronic conditions, such as T2D and hypertension, often includes monitoring lifestyle changes and pharmacological interventions to improve metabolic health [17]. Home BP measurement has been recommended by many hypertension guidelines and addresses several limitations of traditional office-based care, including reducing misclassification because of white-coat or masked hypertension and an ability to take a more suitable action and a course of corrective therapy [18].

Self-monitoring has been shown in previous studies as 1 of the key elements for successful chronic condition management. One of the examples of successful chronic condition management was shown with self-monitoring behaviors involving weight measurements, which demonstrated self-monitoring as a significant predictor of weight loss during 6 months [19]. Of note, there is evidence showing that patients' willingness to self-monitor is associated with disease controllability, and persons with diabetes, asthma, and hypertension are most willing to self-monitor [20]. Home glucose self-monitoring has been associated with improved glycemic control and reduced long-term complications [21]. Current meta-analysis supports the claim that self-monitoring can significantly reduce BP [22,23].

Treatment optimization through digital health could enhance users' alertness to their health conditions through real-time monitoring, leading to effective treatments. Timely communication and feedback also can play a key role in efforts toward achieving hypertension and diabetes control. Technology-driven solutions can help persons with diabetes build awareness of their daily health-related behaviors and promote increased engagement with those behaviors [24-26]. Communication of test results also has been shown to be highly desired among people with hypertension [27], and lifestyle-focused educational messages providing advice, motivational reminders, and support also were shown to be effective in improving hypertension and other chronic conditions [28]. Real-time digital communication can additionally include progress reports focusing on achieving BP and blood glucose (BG) goals and displaying insights as well as guidelines promoting lifestyle change. Using a mobile app for self-management purposes could make it easier for people with chronic conditions to obtain insight into and control of their BG and BP levels.

On the one hand, mobile apps have been shown to improve diabetes outcomes via education and support for adhering to evidence-based recommendations [29-32]. On the other hand, there are mobile apps focused solely on hypertension management. These are designed primarily for health management functions and have proved an effective solution in improving medication adherence and systolic and diastolic BP levels [33-35]. Although mobile apps have the potential to be beneficial for people with hypertension or diabetes, little is known about their efficacy targeting several chronic conditions at 1 time or monitoring both BP and BG levels on 1 mobile app [36]. Further research is necessary for investigating the effectiveness of mobile health for hypertension self-management over time [35]. Moreover, the current literature is missing rigorous real-life studies to test the role of BP self-monitoring and diabetes management and to better understand the direct association between BP monitoring and glycemic outcomes. Further, in glucose-lowering trials, it is not clear whether different ongoing BP levels are associated with different BG-lowering outcome effects [37,38].

This study used a retrospective analysis of a home-use diabetes BG meter and BP-monitoring system with full data capture using a supportive mobile app among people with T2D and poorly controlled BP levels. This study can illuminate the dynamic of the relative contribution of BP self-monitoring to successful diabetes and hypertension self-management using real-life data. We analyzed users' data for 6 months before and 6 months after using the BP-monitoring system and compared them with a matched control group that never used the BP-monitoring system (NBPM). We hypothesized that BP monitoring will be associated with reduction in systolic and diastolic BP, as well as with BG levels. We additionally hypothesized a linkage between BP levels and following BG levels.

Methods

Platform

This study used the Dario digital therapeutics solution (DarioHealth) for chronic conditions to support self-management of diabetes and high BP levels. The Dario BP-monitoring system combines an innovative meter with a phone app that is available for both Android and iOS devices. The glucose meter consists of a small, pocket-size holder for strips, a lancet, and the meter. The BG meter is removed from the holder and plugged directly into a smart mobile device, effectively converting the smart mobile device into a display screen for the meter. The BP-monitoring system measures the systolic and diastolic BP and pulse rate by using a noninvasive technique in which an inflatable cuff is wrapped on the upper arm. The BP-monitoring system provides Bluetooth transmission. The BP cuff is paired with the mobile app, and the data are transmitted to the smart mobile device via Bluetooth. The BP reading is displayed on the mobile app screen.

First, connecting the BG meter directly and pairing the BP cuff to the phone ensures 100% data capture during glucose readings. Second, users open the mobile app with their BG or BP measurement. The measurements are taken independently. This makes contextually tagging a measurement easy at the time of taking the measurement. More specifically, the measurement is shown on the mobile phone in a decision support system view. After the measurement is shown, the user is transferred to a data entry screen where additional information (measurement time [fasting/premeal/postmeal/bedtime]; carbohydrate intake (g); meal, mood, and location settings; and physical activity [kcal]) can be added to the BG measurement. All information is stored in the users' logbook in the app, attached to the specific BG or BP reading. Data are uploaded to the cloud for backup and further analysis. Mobile app functions include interface design elements as well as specific educational content, wording, or digital interventions that affect the users' choices in the digital environment that provides personal health information and prompt feedback.

Measures

The outcome metrics were the monthly average BP level (systolic and diastolic BP), defined as the mean of all the user's BP measurements taken over a 30-day interval, and the monthly average BG level, defined as the mean of all the user's BG measurements taken over a 30-day interval.

The relationships of interest potentially could be investigated on different scales emphasizing daily, weekly, or monthly fluctuations. In this real-world data analysis, the timescale was designed to reflect the monthly aggregated interval change over a 6-month period because of the difficulty in tracking daily changes in digital monitoring.

The mobile app collected the following medical and sociodemographic information (by self-report) for each user: gender, age, BMI, physical activity, stress level, and comorbidities, such as high lipids, chronic kidney disease, cardiovascular disease, sleep disorder, cancer, or stress and depression. Socioeconomic status was matched by applying zip code data to census.gov. All data were transferred and stored in compliance with Health Insurance Portability and Accountability Act (HIPAA) requirements, using Amazon AWS database services. All data were anonymized before extraction for this study.

Users

In total, 269 users with T2D who used the Dario BP-monitoring system between 2019 and 2020 were included in this analysis. The sample included 172 (63.9%) men, 45 (16.7%) having comorbidities. Their average age was 62.0 (SD 11.9) years, average BMI was 31.7 (SD 6.4), and median household income was US $29,100 (SD 3150).

Study Design

The BPM group included persons with diabetes who measured their BG and BP levels (BPM group, n=137, 50.9%). Inclusion criteria were as follows for the BPM group: measured BP levels in the first and fourth months, with at least 5 BP measurements per month; the first-month average BP level was in the elevated category (systolic BP 120-129 mmHg; diastolic BP less than 80 mmHg) [18] or above; and measured BG levels in the first and fourth months after starting to use the Dario BP-monitoring system, with at least 5 BG measurements per month.

We applied a quasi-experimental case-control study design to improve the methodological rigor and validity of the findings and take advantage of the users' digital follow-up. We used the existing Dario database to extract the background population to match a control group, NBPM, that did not use BP monitoring. The BG measurement inclusion criterion for the NBPM group was the same as for the BPM group (measured BG levels in the first and fourth months, with at least 5 BG measurements per month) to find the best match for the cohort of 137 (49.1%) users who started using BP monitoring. Matching is used in the context of estimating the causal effect of a binary condition of interested in or exposed to on an outcome, while controlling for potential confounding variables or variables prognostic of the outcome [39]. The goal of matching was to produce a covariate balance, seeking for approximately equal distributions of covariates in the 2 groups, as they would be in a randomized experiment. The covariate balance results in increased robustness to the choice of model used to estimate the treatment effect. The match was based on sociodemographic and clinical parameters: gender, age, BMI,

physical activity level, stress level, and self-reported comorbidities (hypertension, high lipids, chronic kidney disease, cardiovascular disease, sleep disorder, cancer, mental condition), socioeconomic status, number of BG measurements, and average BG. We applied the nearest-neighbor propensity score matching without replacement, with the propensity score estimated using logistic regression of the treatment on the covariates [40,41]. This approach resulted in an adequate balance using the data of 132 users who did not measure BP.

No significant differences were found between BPM and NBPM conditions by age (B=–0.007, Z=–0.22, *P*=.83), gender (B=0.53, Z=0.59, *P*=.56), BMI (B=0.03, Z=0.34, *P*=.73), physical activity level (0=not active, 10=very active; B=–0.28, Z=–1.55, *P*=.12), stress level (0=not stressed, 10 =very stressed; B=0.002, Z=0.01, *P*=.99), median household income (B=–0.28, Z=–1.55, *P*=.12), number of BG measurements (B=–0.01, Z=–0.60, *P*=.55), insulin treatment (B=–0.98, Z=–0.90, *P*=.37), comorbidities (B=–0.66, Z=–0.65, *P*=.52), and digital engagement (tagging meal type, physical activity in the context of measurement [26]; B=0.02, Z=0.97, *P*=.33).

Ethical & Independent Review Services [33], a professional review board, issued the institutional review board exemption for this study (#18032-04).

Analytic Approach

A classical linear longitudinal model assumes a single-slope growth pattern for changes in an outcome variable across time. Sometimes, such a simple model does not fit the empirical data. In contrast, piecewise-based mixed-effects models allow flexibility in the modeling of trajectories across time [42]. Here, a mixed piecewise model assessed differences in the monthly average BG level in 2 segments: before and after BP-monitoring system usage. The piecewise model allowed the data to exhibit different linear trends over their different regions. This statistical approach provided an opportunity to model curvilinear changes in the monthly average BG level as a single process and to test complex effects.

Users' data were centered around the beginning of the BP measurements and 6 months before and after that point were included in the analysis. For the NBPM (control) group, that had never started BP measurements, we included users with at least 18 months of monitoring, choosing a random cutoff point and including in the analysis only the data collected during 6 months before and after the simulated cutoff point.

A piecewise-based mixed - effects model was fit to the data, modeling temporal changes of the monthly average BG level for the 2 groups (BPM vs NBPM). The piecewise cutoff point for the model was set to the beginning of BG monitoring, assuming a change in the time-related monthly average BG trajectory between the groups by the included interaction terms between time trajectories and group. The model included a person-based random intercept and random slope for the time trajectory after the piecewise cutoff.

Next, we used mixed-model analysis to access the time trajectory of systolic and diastolic BP for the initial 6 months of BP monitoring. The models included a random intercept and random slope of the time trajectory. We reported unstandardized regression weights (B), test statistics (*t*), and associated significance (*P*).

To better understand the dynamic of BP and BG association, we conducted a lagged analysis, predicting the following month's BG level based on the BP level.

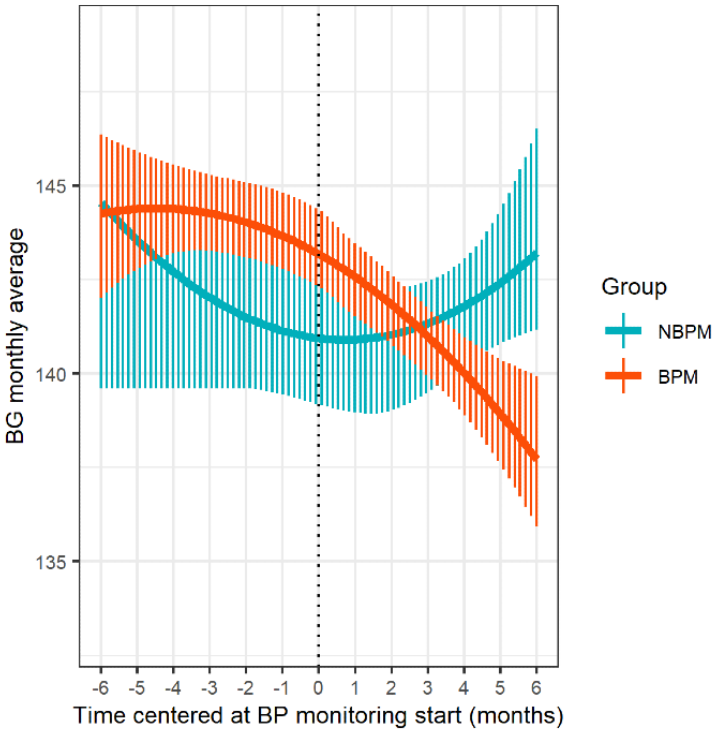
Results

BP Monitoring Is Associated With BG Levels

Piecewise mixed-model analysis revealed a significant interaction between the time after starting BP monitoring and group (B=−1.50, *t*=–2.12, *P*=.03) on BG levels. The BPM group showed a significant reduction in BG (B=−1.16, *t*=–3.57, *P*<.001), while the NBPM group did not show a significant time trend (B=0.24, *t*=0.39, *P*=.70); see Figure 1. Before BP monitoring, group difference was observed in BG time trends (B=0.98, *t*=1.16, *P*=.25), both BPM (B=−0.13, *t*=–0.43, *P*=.67) and NBPM (B=−1.16, *t*=–1.49, *P*=.14) groups showed no BG trend. Extended information is provided in Multimedia Appendix 1.

We reran the analysis including all the potential confounders into the models. In the new analysis, the pattern of the findings remained the same. Users with hypertension (B=25.27, *t*=2.57, *P*=.02) and insulin treatment (B=18.17, *t*=3.02, *P*=.003) showed increased monthly average BG levels. In addition, stress level (B=4.26, *t*=2.38, *P*=.02) and median household income (B=0.006, *t*=4.88, *P*<.001) were associated with increased monthly average BG levels. Age, gender, BMI, physical activity, alcohol consumption, and comorbidities were not related to the monthly average BG (all *P*>.09).

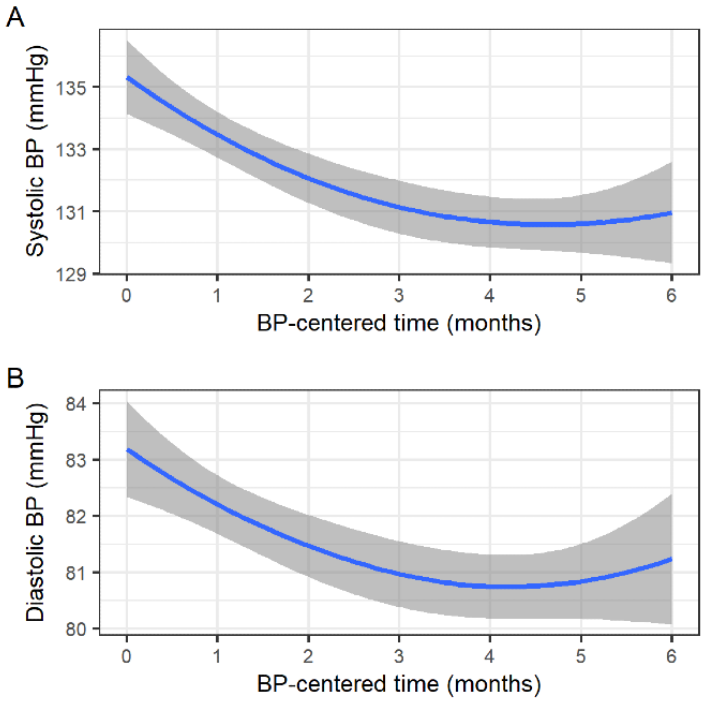
Figure 1. BG monthly average fluctuation for the BPM group and the NBPM group. Zero in the x-axis means the start of BP monitoring. Vertical lines represent a 95% CI over time. BG: blood glucose; BPM: blood pressure monitoring; NBPM: no blood pressure monitoring.



BP Monitoring and the Link to BG

We analyzed the recorded monthly averaged BP during the first 6 months of monitoring. Systolic (B=−0.82, *t*=–6.42, *P*<.001, 135.4-130.8 mmHg) and diastolic (B=−0.41, *t*=–4.80, *P*<.001, 83.3-81.7 mmHg) BP showed significant reductions during that period (Figure 2), and 37 (27%) of 137 users achieved systolic BP reduction of >10 mmHg (*P*<.001). In addition, results from the lagged analysis, predicting the following month's BG based on BP levels, showed that following month's elevated BG is associated with higher systolic (B=0.24, *t*=2.77, *P*=.001) and diastolic (B=0.30, *t*=2.41, *P*=.02) BP.

Figure 2. Monthly average BP fluctuation over the first 6 months of monitoring for (A) systolic and (B) diastolic BP. The x-axis presents the centered time, with 0 indicating the start of BP monitoring. The gray area represents a 95% CI over time. BP: blood pressure.



Discussion

Principal Results

This study showed that using a piecewise mixed-model statistical framework appears to be an appropriate base model to describe nonlinear fluctuations in BG levels comparing different user cohorts over time. In our study, the model indicated that before the BP adoption phase, both groups evidenced flat trajectories. However, after starting the use of the BP monitoring system connected to the same mobile app, the BPM group experienced a significant decrease in BG levels, while the NBPM group's BG levels remained flat. In addition, we ran a lagged analysis demonstrating that monthly systolic and diastolic BP can predict the following month's average BG. This finding suggests the hypothesis that BP reduction may serve as a mechanism of BG reduction; further studies would be needed to confirm this and to analyze the mechanism by which BP reduction has an effect on BG levels.

This real-world analysis presents data analyzing associations between BP monitoring and reduction in BG levels in people with T2D and elevated BP for those who start using the mobile app for diabetes and hypertension management. More specifically, results indicate an association between BG reduction and BP monitoring. This effect was not observed among the users who did not use BP monitoring, although both groups showed statistically equivalent BG trends before BP monitoring and had similar demographic and clinical characteristics. In addition, analysis of the monthly average BP during the first 6 months of monitoring showed a significant decrease in systolic and diastolic BP during this period. Moreover, monthly averaged BG was associated with systolic and diastolic BP levels.

Consistent with the literature, we found that the BPM group, which monitored their BP and improved their levels over time, experienced a change in their BG levels, while the NBPM group's levels remained flat over the same time. Moreover, based on the lagged analysis, we observed that higher systolic and diastolic BP is associated with elevated BG in the following month. Previous studies have shown a significant improvement in all diabetes-related outcomes resulting from long-term tight BP control in patients with T2D and hypertension [14,15]. There is substantial overlap between T2D and hypertension in etiology and illness mechanisms. Hypertension and diabetes substantially share common pathways, such as obesity, inflammation, oxidative stress, insulin resistance, and mental stress [43,44]. Patients with diabetes experience increased peripheral artery resistance caused by vascular remodeling and increased body fluid volume associated with insulin resistance–induced hyperinsulinemia and hyperglycemia. Both these mechanisms elevate systemic BP [7].

The constellation of metabolically related abnormalities, such as obesity, glucose intolerance, and hypertension, are evident in metabolic syndrome [45]. Successful management should address all the factors involved. The goal in a clinical setting is to improve the ability to identify and intervene with factors contributing to metabolic syndrome, including lifestyle modification, weight management, diet, and physical activity changes. One critical view on the individualization of target goals for patients at risk is that this has not always been well adapted for people with low education levels or other sociocultural factors that could distract from finding the time and motivation for improving their individual lifestyles [46]. Our participants showed elevated BP, BG, and BMI. Such a clinical profile resonates with previous diabetes studies [47]. Due to the nature of metabolic disease, factors such as high BP, diabetes, and obesity are shown to be the most suitable therapy areas to address via digital health. This approach may provide information suitable for the user's clinical condition and may improve self-management efficiency and the clinical course through personalized intervention [48]. Lifestyle changes, such as dietary habits and following exercise recommendations, are crucial for persons with diabetes and hypertension, even when pharmacological treatment is required [43,49]. Further, guidance on lifestyle changes must be provided for people with diabetes and hypertension.

BP management presents a possible course to control BG and improve the patient's well-being. Reducing BP is more helpful for people with than without diabetes in terms of absolute cardiovascular risk [43]. Previous studies have revealed the beneficial effect of BP treatment in people with high-risk diabetes: attaining standard glycemic control resulted in a decreased risk of cardiovascular events, including heart failure [50].

Cardiovascular disease is the most significant health threat to adults with T2D, and it is clear that efforts aimed at controlling BP and cholesterol will have much greater effects on health outcomes than those focused only on glycemic control [51]. For reducing cardiovascular risk, treatment should focus on specific goals: reductions in systolic and diastolic BP, BG, and plasma low-density lipoprotein (LDL) cholesterol [45].

Our results also revealed a synergistic effect in that the management of BG and the management of BP became evident with the start of controlling BP levels, while this association was not present in the NBPM group, which did not use the BP-monitoring system. Moreover, we demonstrated that the diabetes clinical outcome (ie, monthly averaged BG) is positively lagged with the hypertension clinical outcome (ie, systolic and diastolic BP levels).

It was previously shown how distinct features of a digital therapeutic app have the potential to deliver equitable person-centric care and how digital engagement can play a key role in enhancing a person's chronic condition self-management [16,52-54]. Previously, we demonstrated that digital engagement may improve diabetes management [26]. Importantly, in this study, the BPM and NBPM groups were not different in their digital engagement. In addition, the tracking tool can be disseminated via a simple-to-use, accessible, and low-cost device. Further, the median household distribution of the users in both groups was equal and revealed that the digital diabetes management solution is desired and affordable among lower-, middle-, and high-income levels to improve glycemic outcomes.

From a psychological perspective, it is assumed that individuals using a digital platform may develop more active roles in managing their health [55]. Previous studies have identified

psychosocial factors that could be targeted by interventions to improve diabetes self-management and treatment outcomes [51]. National survey data from the United States highlight basic knowledge gaps among many adults with diabetes and note that less than 50% know their level of glycemic control and only 63% know their BP level [56]. For people with hypertension, evidence for digital interventions has mostly come from small trials with relatively short follow-up and substantial heterogeneity of results [57]. Thus, more studies are needed with larger samples and longer periods of follow-up. Digital interventions (eg, apps, programs, or health software) have the potential to support people in self-management and to facilitate lifestyle change [57].

Our finding on the significant decrease in systolic and diastolic BP occurring within the first 6 months of using the device and mobile app suggests that even the short-term use of our digital monitoring device may be an effective means to increase users' knowledge base and self-care behavioral awareness in the context of everyday life. The mobile app provided the users with numeracy skills, including the ability to interpret and respond to hypertension numerical feedback and to focus greater attention on the self-management of more than 1 chronic condition. The intervention is designed to influence user behavior by using a person-based approach. Users were advised with personalized reminders to take BP readings, with specific messages driven by their BP levels, calculated averages, displayed BP measurements levels by color scale, and other lifestyle activities (smoking, caffeine, activity). Health behavior change theory posits that new health behaviors emerge when people gain both knowledge and self-efficacy to implement said knowledge [58-60].

The logbook screen inside the mobile app presenting measurements and data records possibly can be shared with the health care provider for further support. The digitalization of health care has the potential to save time and money and enable better physician-patient relationships and personalized treatments based on the specific characteristics of patients, especially patients with hypertension [61,62]. Important components may play a role in regulation of BP and BG and other self-measured values by health care providers.

Finally, our findings indicated that monitoring several chronic conditions may have the potential to offer a greater means for helping person with diabetes and hypertension effectively modulate their glycemia and BP than managing each of the conditions separately. We expect that the analytical approach applied in this study will be useful for examining other chronic conditions and metabolic syndrome outcomes (eg, lipid profile and weight loss). Moreover, this type of analysis may provide valuable information for optimizing patients' planning and strategies for chronic condition management.

Limitations

We noted several limitations in this study. First, as in all studies involving retrospective real-world data, groups were not randomly assigned, and treatment protocols were not prescribed. Both limitations created challenges for drawing casual effects. It is possible that users who chose to manage both diabetes and hypertension were those who were motivated to change. However, our inclusion criteria were designed to ensure that both BPM and NBPM groups showed evidence of being engaged with their diabetes management. There were no significant differences between the groups in terms of the number of BG measurements and digital engagement (behavioral tagging). This would suggest that motivation may not be the primary difference between BPM and NBPM. That said, the statistical modeling covers the pitfalls of the comparison between the 2 groups, allowing a quasi-causal inference. However, there might be variables that were not collected that may impact the group imbalance.

In this real-world data analysis, the timescale was designed to reflect the monthly interval change over the 6-month period before and the 6-month period after starting the use of the BP-monitoring system. However, the relationship of interest in this study could be potentially investigated on different scales emphasizing daily, weekly, or monthly fluctuations. Owing to the difficulty in tracking daily changes in real-world studies, most studies focus on monthly fluctuations.

Another challenge regarding our data was that available demographic data were limited. Although there were no differences between groups by age, gender, or median household income, there is always the possibility that uncontrolled demographic bias was present from other demographic factors. In addition, available medical and physical data were limited. No differences existed between groups in terms of physical activity, stress level, insulin treatment, and other comorbidities. However, there is always the possibility that an uncontrolled parameter bias was present from other medical record factors.

Conclusion

Our findings show a significant association between BP measurement and improved glycemic control. The association is consistent with the hypothesis that there is a physiologic link between BP and glucose control. An alternative explanation is that persons who measure both parameters are more likely to be involved and motivated in their health care. Focusing on BP self-monitoring and lifestyle activities may lead to better glycemic outcomes. The clinical impact was observed in users who measured their BG in the first 6-month period of BP monitoring. We also observed real-time linkage between a reduction in BP levels and a reduction in BG levels. From the behavioral science perspective, this is not surprising. Simultaneously, directing effort onto actionable areas for improvement of BP is likely to increase the thought and action needed for improvement of BG. Moreover, the process of BP self-monitoring in lowering systolic and diastolic BP levels was demonstrated. Future work should focus on investigating the mechanisms underlying the comorbidity of diabetes and hypertension and their management, identifying and applying mediation models and behavioral interventions that go beyond actionable multiple chronic conditions that drive prohealth behavioral change. Furthermore, similar studies examining the impact of gradual trajectories on other behavior changes, including health coaching, gamification, and behavioral economics, are essential. These investigations would help move the field beyond the claim of "what is the impact of the digital tools on managing chronic conditions such as diabetes or

hypertension" to a deeper understanding of how digital solutions drive clinical outcomes and how to integrate multiple digital solutions and under what clinical situations. Finally, qualitative research is needed for understanding users' real-world experiences and as a tool for sensitivity analysis and validation of complex computational models in order to enhance personalized medical approaches.

Conflicts of Interest

YFH, DB, and OM are employees of DarioHealth. MDR and DLH serve as DarioHealth scientific advisory board members, and PG has received a consulting fee to assist with analyses but otherwise has no conflict of interest.

Multimedia Appendix 1
Piecewise mixed-model analysis of BP monitoring affecting monthly BG. BG: blood glucose; BP: blood pressure.

Abstract

Background: Web-based mental health interventions offer a novel, accessible, and self-paced approach to care delivery to family carers (ie, relatives and close friends who support a loved one with psychosis). We coproduced COPe-support (Carers fOr People with Psychosis e-support), a psychoeducational intervention delivered via an enriched web-based learning environment with network support from professionals and peers. In addition to the rigorous investigation of the effectiveness of COPe-support on the well-being of carers and mental health outcomes, it is imperative to understand the experiences of using the web-based intervention by carers and its associated web-based implementation and facilitation strategies.

Objective: This study aims to explore the experiences of carers and perceived acceptability of COPe-support and its different components, how carers found engagement with COPe-support affected their own well-being and caregiving, and the ideas of carers for improving COPe-support and its delivery to inform any future wider implementation.

Methods: We conducted a qualitative study, individually interviewing 35 carers, following their use of COPe-support for 8 months through a web-based, randomized controlled trial across England. A semistructured guide with open-ended questions was used to explore the experiences of carers and perceived acceptability of the intervention and their ideas to improve the provision. All interviews were conducted remotely through mobile phones or internet communication media, audio recorded and transcribed verbatim. We used a thematic analysis framework to analyze the data.

Results: Three key themes were identified: remote, flexible, and personalized support; impacts on well-being and outlook on caregiving; and future implementation and integration with existing services. Overall, carers found COPe-support a flexible source of knowledge and support from professionals and peers that they could personalize to suit their own needs and convenience. Participants described gaining self-confidence, hope, and a sense of connectivity with others in a similar situation, which helped ameliorate isolation and perceived stigma. Most importantly, COPe-support promoted self-care among the carers themselves. Participants' experiences, use, and activity on COPe-support varied greatly and differed among carers of various ages and levels of computer literacy.

Conclusions: Nearly all participants had a positive experience with COPe-support and supported its wider implementation as a beneficial adjunctive support resource for carers in the future. Any future scale-up of such an intervention needs to consider feedback from carers and suggestions for further improvement. These included having more graphics and audiovisual content materials, improving the navigation, and building in more interactional and customization options to suit various user styles, such as emoji reactions, live web-based chat, opting in and out of updates, and choosing the frequency of reminders. To ensure successful implementation, we should also consider factors pertinent to reaching more carers and integrating the web-based resources with other conventional services.

Introduction

Background

Family members or close friends supporting a loved one affected by psychosis (ie, family or informal carers) play a crucial role in promoting better prognosis and well-being of individuals [1-3]. However, the demands and responsibility of caregiving can make carers vulnerable to physical and mental ill-health [4,5]. Carers need access to psychosocial treatment for knowledge and support to care for their loved ones and to sustain their own well-being [6]. In recent years, with the increasing popularity of digital health interventions targeting a wide range of common mental health symptoms among the general population [7], a few clinical trials investigating such provision for carers of people with psychosis have emerged [8-11]. These web-based interventions tend to be complex multicomponent encompassing psychoeducation (ie, information focused on the health condition and its management) and web-based forums where carers can share emotional support with peers in a *closed* group, for example, COPe-support (Carers fOr People with Psychosis e-support) [12] and Relatives Education And Coping Toolkit [13]. Indeed, psychoeducation on psychosis and related care giving and problem-solving strategies, especially when integrated with peer support among carers, have been identified in systematic reviews as the most desirable ingredients for carer-focused interventions, delivered via the internet or in person [1,14,15]. In previous trials of web-based interventions targeting carers of people with psychosis, psychoeducation was the most common therapeutic approach used. The web-based medium enriched information environment allows carers to self-pick information and advice to suit their own needs and go through them at their own pace [8,11,12]. Psychoeducation and peer support can also target difficulties commonly reported among carers, including isolation, stigma, and uncertainty [16].

Web-based interventions allow for flexible access by carers, minimizing accessibility barriers, such as geographic constraints from needing to be in a particular location and time constraints from juggling multiple roles and responsibilities [17,18]. The web-based medium of delivery also facilitates autonomous use of an individually tailored package of support (ie, carers can choose how and when to use the content at their own convenience) [14,19]. Paradoxically, web-based interventions typically report much lower adherence and completion rates compared with face-to-face interventions, limiting the evidence about their effects [7,14]. Internet support groups and web-based peer forums are often highlighted as desirable features of web-based interventions for promoting social connections and mutual support in mental illness [7,20]. However, their effects, on their own or as part of a complex multimodal intervention, are inconclusive [21-23]. Although users have often identified a peer forum as an engaging element of web-based health interventions [24,25], user characteristics and their use of such forums vary widely [21,26]. Recently, Geramita et al [20] explored the applicability of the 1% rule in a computerized cognitive behavioral therapy platform, which included a patient support group. The 1% rule originated from the web-based marketing literature, suggesting that 1% of participants in web-based communities generate approximately 90% of new content [27]. A computerized cognitive behavioral therapy study [20], among other web-based health intervention trials [24,26], identified that a small number of users (approximately 10%) post most of the content in peer forums, and the remainder mainly observe activity. When considering the use of web-based health tools and services by an individual and subsequent health behavior uptake in general, Powell and Deetjen [26] proposed a new typology. In their study, they identified 6 types of web-based health users (learners, pragmatists, skeptics, worriers, delegators, and adigitals), prompting consideration of the motivation of individuals and orientations behind health-related internet use [26]. Limited evidence to date suggests that high engagement levels with peer forums or discrete elements of complex web-based interventions (eg, information and forums) are associated with better health outcomes or subjective satisfaction or acceptability [7,14,20,28-30]. At the same time, these issues highlight the challenge of implementing complex web-based health interventions that include a peer support forum element with diverse participant profiles and experiences.

Although web-based interventions present a promising opportunity to address a long-standing lack of treatment and support for carers of individuals with psychosis, they can only affect meaningful changes in their users by optimizing their engagement and facilitation strategies to ensure they get the intended benefits. Considering other challenges inherent in developing and evaluating web-based interventions (eg, safety,

personalization, trust, reach, and uptake) [29], it is imperative to embed qualitative process evaluation within web-based intervention trials. While randomized controlled trials (RCTs) are the gold standard study design to establish the clinical effectiveness of an intervention, process evaluation to evaluate the experience of participants and perceived acceptability of the intervention and associated facilitation strategies can identify essential contextual factors in outcomes. For web-based interventions, the contextual factors in question are multiplied, as these interventions are designed to be used autonomously by users in their own homes. Hence, the Medical Research Council complex intervention framework advocates that a thorough process evaluation is needed to understand both the intervention and its implementation process, as experienced by the participants, and to clarify variations in outcomes under contextual influences [31].

Objectives

This qualitative study explores carers' experiences and perceived acceptability of COPe-support and its different components as part of the process evaluation of the COPe-support trial [9,32]. We aim to understand from the carers if and how using COPe-support affected their own well-being and the way they provided care for their loved one. With their experience of using COPe-support, the ideas of carers for improving COPe-support and its delivery were also invited to inform any future wider implementation.

Methods

Research Design and Setting

This study used in-depth individual interviews conducted between February 2019 and October 2020, with participants who had been randomly allocated to use the intervention, after the final follow-up data collection (ie, 8 months after the allocation), as described in the trial protocol [9].

For the RCT of COPe-support, a total of 407 family members or close friends who provided at least weekly support for a loved one affected by psychosis across England were recruited [32]. Over the duration of 2 years (ie, March 2018 to February 2020), 6 cohorts each starting 4 months apart and lasting 8 months were scheduled; when participants consented to participate in the trial, they were allocated to the next cohort scheduled to start [9]. This approach allowed us to group an optimal number of participants (ie, 40-120 participants) established from our earlier systematic reviews into each cohort, which was closed [1,14]. We believe these strategies facilitate peer-group building, thus enhancing the web-based elements of the intervention. Half of the participants were randomly allocated to the intervention arm, that is, access to COPe-support for 8 months, which included being able to post on the peer and expert forums for the initial 4 months (termed the active intervention use period), in addition to usual care. The remaining participants were randomized to receive a web-based noninteractive information bank as an attention-matched control, also with usual care [9].

The Intervention

The web-based intervention COPe-support was coproduced using participatory research methodology as described elsewhere [12]. COPe-support was delivered through a web-based, enriched environment platform that carers could access through a web browser using a computer or a laptop or through an app on smartphones or tablets [9,12]. COPe-support comprises multiple components, including psychoeducation on psychosis and related caring issues, guidance on well-being promotion information and exercises, a *Resource for carers* section signposting to a wide range of external resources weblinks; and 2 web-based forums (one called *Ask the Experts*, where participants could post questions for advice from a panel of experts and the other called *Peer to Peer* for participants to exchange views with one another; see Figures 1-3 for screenshots of COPe-support components). Throughout the study period, a web-based facilitator (an experienced mental health nurse, JS) monitored and moderated all the interactive functions of COPe-support. A weekly email update was sent through the COPe-support platform to all participants for the first 4 months of the study period, which was regarded as the active use period. For security and confidentiality considerations, participants were required to follow a set of ground rules, including using a self-chosen pseudonym and observing confidentiality principles by not sharing any identifying information about themselves and their cared-for person on the COPe-support platform. The web-based intervention platform had an inbuilt use data recording system for log-ins, time spent, and the number of posts made by each participant.

Figure 1. COPe-support (Carers fOr People with Psychosis e-support) home page.

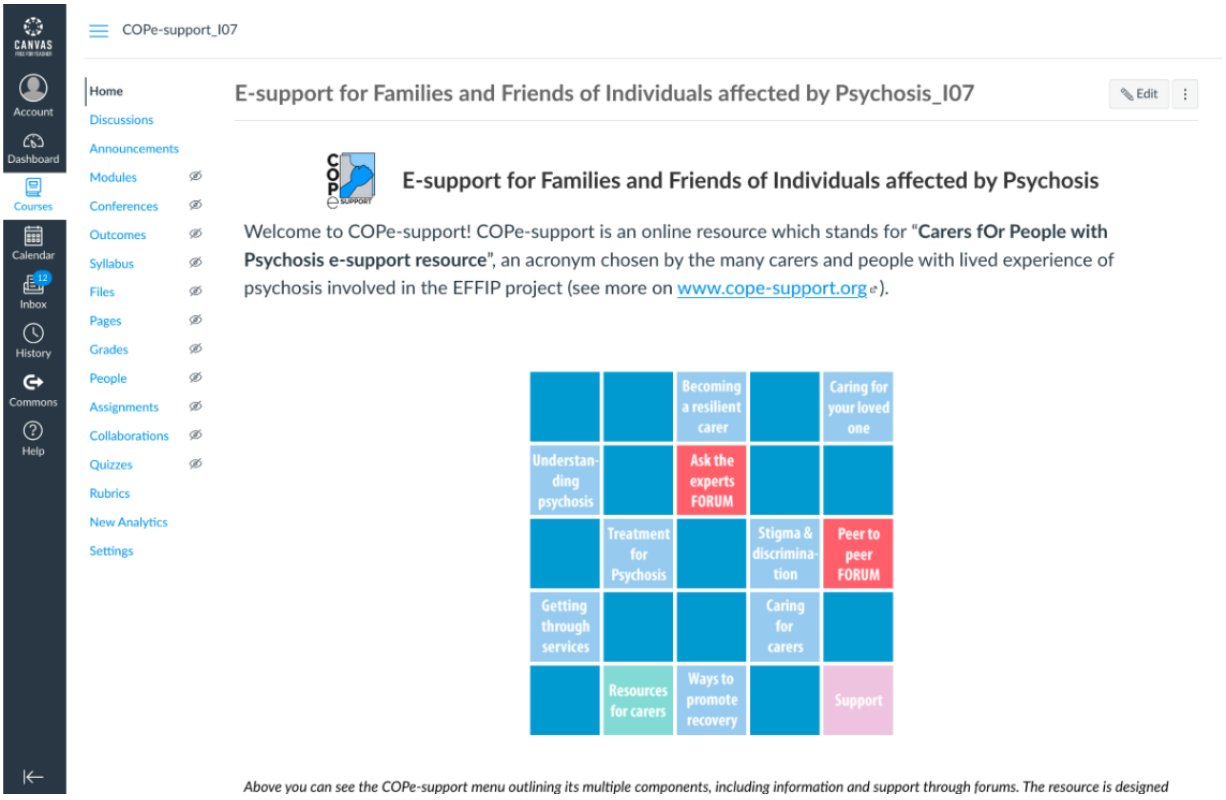

Figure 2. Ask the Experts forum webpage.

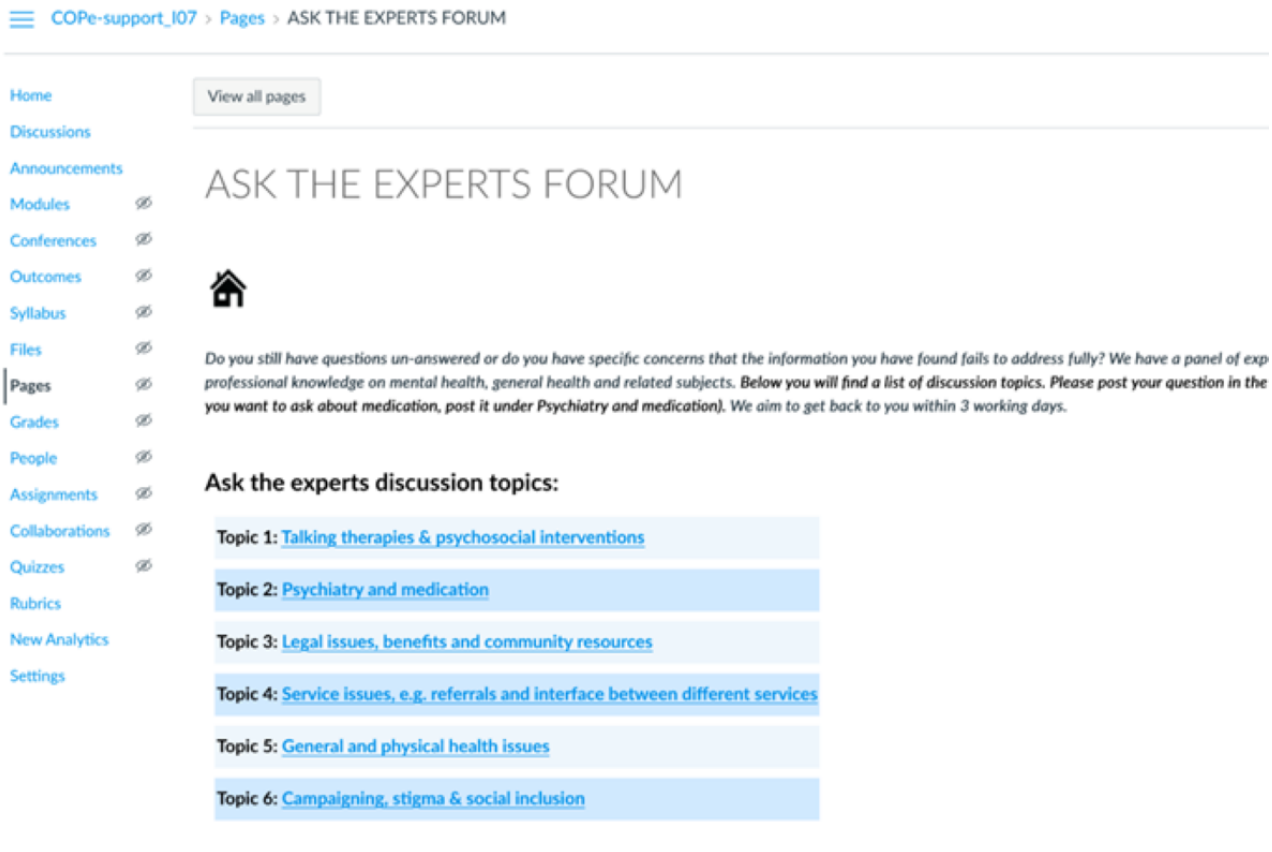

Figure 3. Information on psychosis on COPe-support (Carers fOr People with Psychosis e-support).

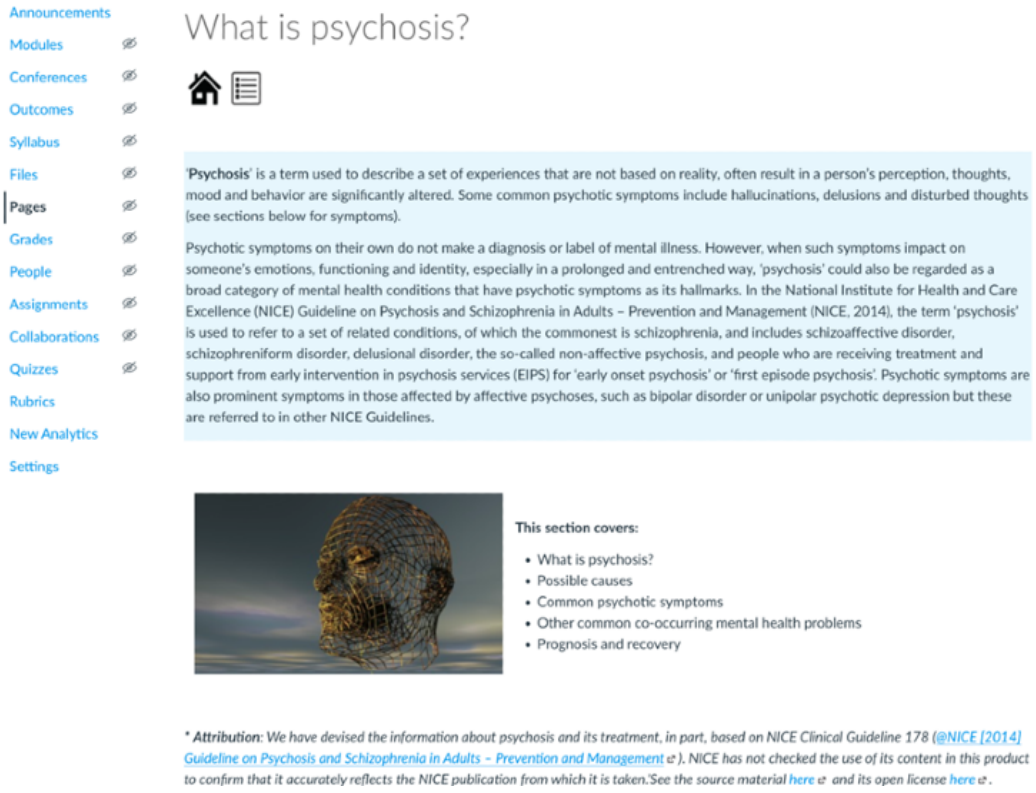

Participants

The inclusion criteria for the RCT specified family members, relatives, and close friends who were aged ≥18 years, had at least weekly contact with the cared-for person (in any form ranging from face-to-face to social medical communications), living in England, able to communicate in English in usual web-based communications, and had daily access to the internet, including emails [9]. The inclusion criteria for this qualitative study specified that participants had (1) been randomized to the intervention arm and (2) completed the final RCT follow-up (8 months). Furthermore, purposive sampling was used to identify about 20% of participants in each cohort intervention group from across the *2*-year study period to ensure representation of those with different demographic factors and different levels of use of COPe-support. As previous literature shows that female and White individuals tend to form most of the participants in intervention trials targeting carers for a loved one with psychosis in Western countries [1,3,6,14], we prioritized male carers and those from ethnic minority backgrounds in approaching potential participants. To examine use, we followed the approach by Valentine et al [33] in categorizing participants into levels of use based on the overall number of log-ins by participants to the COPe-support platform over the 4-month active intervention use period. We categorized participants into three use groups as follows: (1) noncompliers, participants who had not activated their log-in or only logged in once; (2) moderate users, those who had logged in between ≥2 and ≤10 times; and (3) high users, those who had logged in >10 times. Within the use categories, we also considered whether participants had forum posts. Thus, participants in the three use groups were further categorized into the following: (1) passive users, participants who did not post, and (2) active users, participants who made at least one forum post, in accordance with previous web-based forum research [34,35]. Participants representing the various demographic considerations and use levels were then contacted via email and invited to participate in an individual interview. A total of 43 participants were invited; 81% (n=35) of the participants agreed, whereas 19% (n=8) of the participants did not respond to the invitation with *2* reminders (their reasons for not responding were not provided).

A total of 35 participants were interviewed and included in the study. The mean age of the participants was 56 years (SD 13 years, range 23-73 years). Most of the participants interviewed were White (29/35, 82%, White British and 2/35, 6%, other White), whereas 6% (2/35) of the participants each described themselves as Asian and Black. Approximately 63% (22/35) of the participants were women, and most (23/35, 66%) cared for a male person. Parents comprised most of the participants (23/35, 66%), followed by partners (7/35, 20%), whereas siblings (2/35, 6%) or close friends (3/35, 8%) formed the remainder. According to the data on their caregiving roles and activities provided by the participants, the mean age of the cared-for persons was 35 years (SD 14 years, range 17-66 years). Just over half (18/35, 51%) of the participants reported that their cared-for persons first became unwell with psychosis <5 years ago, whereas 11% (4/35) of the participants described their loved ones had their first psychotic onset over 20 years previously, and the remainder (13/35, 37%) had been caring for between 5 and just under 20 years. Approximately half (17/35, 49%) of the participants lived with their cared-for person, and 40% (14/35) of carers reported spending over 20 hours per week in caregiving activities. Table 1 provides a summary of the participants' demographic, caregiving, and use data.

Table 1. Summary of participant use and demographic information categorized by use groups.

Users and pseudonym	Cohort (start time)	Sex of carers	Age of carers (years)	Relationship with CfP[a]	Sex of CfP	Age (years) of CfP	Overall weekly log-ins[b]	Overall page-views[c]	Posts made

[a]CfP: cared-for person.

[b]Number of weeks with log-ins across the 4-month active intervention use period.

[c]Total page-views across the 4-month active intervention use period.

[d]Has not activated the log-in.

Multiple participants from each of the different use groups across cohorts were interviewed. All participants were interviewed shortly after their access to the intervention platform ceased (ie, at the 8-month follow-up), although their last access to the platform varied widely. Of the 35 participants, 17% (n=6) participants were classified as noncompliers. All noncompliers were passive users (passive noncompliers). Many participants (19/35, 54%) were classified as moderate users, 53% (10/19) of whom were passive (passive-moderate users) and 47% (9/19) were active (active-moderate users). High users comprised the remaining 28% (10/35) of participants, all of whom were active within the COPe-support forums (active-high users).

Data Collection

All interviews were conducted remotely, suiting the preferences of participants for either phone or internet-facilitated interviews (using Skype [Microsoft] or Microsoft Teams). No face-to-face interviews were used, as all participants had joined the web-based trial of a web-based intervention, with no requirement for in-person contact. Author JS conducted all interviews. Informed written consent was obtained from each participant through the web-based study platform before the interview. At the beginning of each interview, we asked the participants to confirm their consent orally, including for the interview to be audio recorded. All interviews were audio recorded, apart from 3% (1/35) of the participants who opted for their interview recorded by written notes instead.

The interviews followed a topic guide that was devised by the Project Reference Group members, including individuals with lived experiences of psychosis or caring for a loved one with psychosis, who had been involved in developing the intervention [12]. In line with the objectives of this interview study, the interviewer asked open-ended questions to explore the experiences of participants and their views of COPe-support, any specific features of the intervention that they liked or disliked, and the barriers to and facilitators of their access and use of COPe-support, including the facilitation strategies used. The interviewer asked the participants to reflect on their subjective evaluation of the impact of using COPe-support on both themselves and their caregiving experiences. Finally, the interviewer asked the participants for their views and ideas for a plausible wider implementation of COPe-support in the future. The topic guide, which includes the semistructured interview questions and prompts, is presented in Multimedia Appendix 1. Interview times ranged from 14 to 49 minutes and a total of 1117 minutes of data were transcribed.

Data Analysis

The audio recordings were transcribed verbatim. Only transcribed anonymized textual materials were used for the analysis. The data were analyzed in 4 phases using thematic framework analysis [36], with the software NVivo 12 (QSR International) [37]. In accordance with the thematic framework analysis, we commenced the data analysis once the first qualitative interview had been completed and transcribed. To ensure the analysis was grounded in the data and the exploration of the experiences of participants was driven by the emerging results, the interviews and analysis were performed in parallel so that the identified themes and framework of analysis could be tested and validated in latter data.

In the first analysis phase, the authors (JS, S Gulshan, HS, and RB) familiarized themselves with the data by rereading the transcripts and noting interesting aspects. In the second phase, 2 authors (S Gulshan and HS) coded all the data, and a third author (RB) coded 20% of the data independently. The data coded by the third author was selected based on user type and demographics, to ensure that all groups across the full sample were represented. Open (unrestricted) descriptive codes summarizing text segments were applied across the data set. The codes were discussed and reviewed by the authors through several iterations. In the third phase, initial themes and subthemes reflecting broad units of common ideas were formed by grouping relevant codes. These were compared by reviewing the entire data set as well as within individual cases. In the fourth and final phase, the authors (RB, S Gulshan, HS, EW, and JS, all women) cross-referenced, discussed, and clearly defined the themes and subthemes and their interrelated links over several meetings. We used a combined inductive and deductive approach to coding and selecting themes throughout the analysis process [38]. Initially, we used inductive coding, driven by the data (ie, the experience of participants or the way they assigned meaning to their perception of using COPe-support). Nonetheless, as the study aimed to explore the participants' perception of specific elements, functions, and facilitation strategies related to the web-based intervention, we also coded the data deductively with reference to previously reported findings as reported in the literature on wider web-based health interventions and those targeting carers for individuals with a mental illness. These concerned web-based content, forums, facilitation, and perceived safety and security and were explored by questions within our interview topic guide [8,14,24]. Suggested improvements specific to COPe-support were coded deductively using the ideas generated from the views expressed by the participants. Iterative analysis of the transcript

showed that saturation of data was achieved as the final 2 interview transcripts produced no new themes or subthemes [39].

Ethics Approval and Consent to Participate

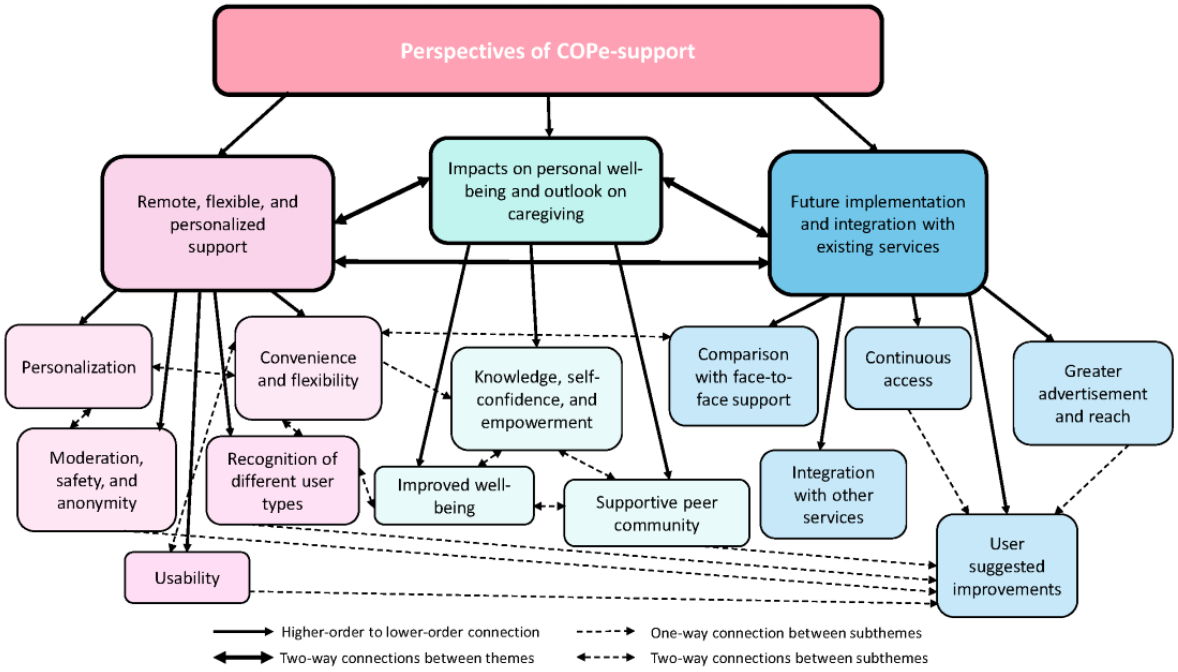
This study, as part of the overall RCT, was reviewed and approved by the South Central—Oxford C Research Ethics Committee (reference: 18/SC/0104) and the Health Research Authority (reference: IRAS 240005). Before study participation, all participants were required to view and give consent on the web to the information provided in the participant information sheet.

Results

Overview

In total, 3 main themes were identified, with each theme divided into subthemes to comprehensively capture the phenomenon explored. The three main themes were as follows: (1) remote, flexible, and personalized support; (2) impacts on well-being and outlook on caregiving; and (3) future implementation and integration with existing services (Figure 4). A brief summary of each theme and subtheme is provided in Multimedia Appendix 2.

Figure 4. Coding tree summarizing the interrelated themes and subthemes. COPe-support: Carers fOr People with Psychosis e-support.



Remote, Flexible, and Personalized Support

This theme covered the experiences and perspectives of carers using COPe-support, with particular regard to navigation, safety, and usability. This theme incorporated 5 subthemes as follows.

Personalization

Carers mostly appreciated that they could choose and focus on specific content on COPe-support, suiting their own circumstances and needs. Several carers also valued the ability to choose their own pseudonyms. Although sharing a common caregiving role, carers recognized that they each have specific interests and needs based on their cared-for person's presentation, treatment, and a range of caregiving factors. For instance, for some carers, information and advice on getting through the benefits system could be a priority at the time, whereas others were after a summary of research evidence of a new treatment:

> *Whereas the stuff from the website was quite helpful and we could tailor it to our own sort of thing. Yes, it was just nice.* [Aaron; male, partner, passive noncomplier]

Some carers discussed a preference for having a greater sense of independence and choice regarding communication in the forums. This included being able to opt in and out of updates and chose the frequency of reminders.

Convenience and Flexibility

Many carers appreciated the convenience of having the information and resources they needed in one place and being able to revisit information and access information at any time and place in day-to-day life. Carers particularly valued the flexibility of their use of COPe-support. This included having autonomy over their use and posting without having to adhere to engagement targets, as well as being able to pick out relevant information at their own pace. Several carers found revisiting and downloading the information for future reference particularly useful:

> *Yes, I mean anything that was easier to download and keep for reference, I mean it's always good to have reference material.* [Ben_2; male, parent, active-moderate user]

Carers particularly appreciated having access to a range of professionals and found it fascinating to receive different perspectives from experts with various experiences and

knowledge. Most carers also appreciated the convenience of expert knowledge on COPe-support. Several considered this novel and felt it addressed the lack of access to experts in existing services for loved ones. Carers valued the opportunity to ask specific questions at any time and received prompt and thought-out answers. A couple of carers noted that this was in contrast to their experiences of feeling rushed within appointments with professionals:

> *I think looking back to seeing the doctors and the psychiatrists you feel a bit rushed and they haven't got time to think about it much but if it's sent as a question you feel someone has taken time to give you an in-depth answer.* [Abby; female, partner, active-high user]

Moderation, Safety, and Anonymity

Being anonymous helped many carers feel more comfortable interacting on forums. Most carers felt that anonymity helped to protect the privacy of their loved one with psychosis and did not affect the community feel on COPe-support:

> *Anonymization probably is quite important because if you are posing questions or comments about your experience as a carer, you inevitably have to talk about that person and they might not like you doing that.* [Maryam; female, parent, active-high user]

Carers particularly appreciated the ground rules (eg, being respectful and not mentioning identifying information) and forum moderation (eg, checking and approving content), providing reassurance that the forums comprised a safe environment. Some carers expressed appreciation and preference for professionals (as used in the trial) over hypothetical carer moderation, providing the professional understood the needs of carers, to help increase the accuracy of information, dispel potentially misguided beliefs, and manage disagreements.

Weekly emails tended to have a positive impact: carers felt they not only served as a reminder for the intervention but also that someone cared. Some carers described themselves as looking forward to or smiling at the emails. Overall, the carers shared a sense that COPe-support was safe and trustworthy, as reflected in the following:

> *It's having a trusted site to look at and knowing that if you put anything on it it's a safe place.* [Abbie; female, parent, active-moderate user]

Usability

Mixed experiences were shared regarding the usability of the COPe-support. Some carers felt confident owing to good computer literacy or previous experience with similar platforms, whereas others described barriers, such as age and poor computer literacy. Carers appreciated accessing COPe-support on different devices (eg, computers, laptops, or mobile phones), with some finding devices with larger screens easier to navigate. Most carers described an adjustment period during which they initially struggled with navigating the interventions but adjusted and grew in confidence over time:

> *I did start to get a bit more used to [navigating] after a while but to begin with I did find it complicated.* [Summer_1; female, parent, active-high user]

Recognition of Different User Types

Many carers expressed awareness of different user types on COPe-support. Carers tended to distinguish between enthusiastic (active) users whose names frequently appeared within forums and other (passive) users who tended to observe. Some active users reported focusing on the peer and expert forums and felt these aspects in themselves made COPe-support *powerful* (Eleanor; female, friend, active-high user and Alexandra_3; female, parent, active-moderate user). A couple of active users were unaware of being particularly active and felt unsure of how many people read their posts. Most passive users were aware that they had not posted and found reading what others had to say useful and knowing the forums were there if needed comforting in itself:

> *I guess there are some people who are going to be very active on there and discuss things a lot and then there are going to be people who are very quiet on there...It doesn't mean to say that they're not taking it all in and getting something from it...I also regret slightly now that I wasn't a bit more active at the same time.* [Summer_2; female, parent, passive-moderate user]

Impacts on Well-being and Outlook on Caregiving

Three subthemes represented the impacts on well-being and outlook on caregiving experienced from participating in COPe-support.

Knowledge, Self-confidence, and Empowerment

Many caregivers felt that COPe-support provided comprehensive, relevant, and helpful information across various important topics. New carers found the information especially suitable for their first time learning about psychosis. For others with existing knowledge, the information supplemented the resources they had previously accessed. Although some felt COPe-support had enhanced their knowledge and skills enough to not require further support, others appreciated the signposting to other sources and local and national services to further support their loved ones:

> *I've got 99% certain I will either get signposted in the right direction or find what I want rather than Googling and going through different websites and trying to find the same information.* [Faye; female, parent, passive-moderate user]

Some carers felt that the information was quite generic, outdated, and repetitive. Moreover, some newer carers initially found the amount of information overwhelming, although they reported adjusting and learning over time:

> *It's also a strength is the fact that once you are in the program you realize just how comprehensive and detailed it actually is and that this could be a bit daunting initially for people signing up.* [Eleanor; female, friend, active-high user]

Most carers felt that the tone of the experts was just right: not pressurizing or patronizing, yet empathetic, respectful, and comforting. Understandable language (eg, no acronyms, abbreviations, and technical terms) was also used to explain complex information in an understandable way. However, several carers felt that the answers were sometimes generic or vague, although they appreciated that the experts were not aware of the full situation of their loved ones and still found the suggestions helpful. The information provided and knowledge gained subsequently empowered them to seek further conversations with mental health professionals caring for loved ones, as expressed by a participant:

> *They've not been able to provide really specific answers sometimes because obviously they don't know our situation but the fact of it is they've been able to signpost or suggest something that you maybe hadn't thought of.* [Alexandra_3; female, parent, active-moderate user]

Some carers discussed the lack of preparation for caring roles and the ongoing self-doubt surrounding doing the right thing or supporting their loved one in a helpful way. These carers felt by gaining information, resources, and knowledge on COPe-support had better equipped them and also improved their self-confidence in their ability as carers:

> *I'm sure it's given me more confidence as a carer because I've got more information and that also becomes a part of how I care for my daughter and talk to the family and others as well.* [Maryam; female, parent, active-high user]

Supportive Peer Community

One significant benefit identified was a sense of belonging to a supportive peer community, without ever seeing or knowing one another. Many carers discussed feelings of loneliness and isolation experienced by them. Reading the resources and forums showed carers that others were experiencing similar and relatable difficulties, helping them feel less alienated, isolated, and detached:

> *Sometimes when you are a carer you think you are alone. When you go to these groups or you do these things, you realise you are not. It makes a difference.* [Anna; female, parent, passive noncomplier]

Carers also reported feeling more connected and having a sense of solidarity and unity with others to proceed on the caring journey. Carers valued having a sense of community, group alliance, and connection, which naturally arose from sharing similar experiences and challenges and feeling mutually understood, something they often lacked in their own lives. This was made explicit by the following:

> *Being able to see that people are getting some support and that it normalizes the issues that we don't talk about.* [Abbie; female, parent, active-moderate user]

Most carers valued being linked with other carers, especially new carers who felt shell-shocked and craved speaking to others in a nonjudgmental environment. Many carers appreciated the opportunity to learn from peers, including practical tips, advice, and awareness of differing carer experiences. Some also valued the opportunity to help other carers and the positive feelings that came with that:

> *But in the main I found the whole thing quite helpful especially for the first month or so when I could see or read about everyone else's problems and some were similar to mine and some of the advice they gave if you know what I mean.* [Ben_1; male, parent, active-high user]

In addition to creating a community and reducing loneliness, many carers noted that reading posts from other carers also helped normalize and validate their feelings and experiences. The intervention content and forums also helped to normalize concerns, fears, and often stigmatized psychosis-related topics that carers often found difficult to talk to people in their personal lives about. Such normalization and validation subsequently helped carers feel less overwhelmed:

> *Yes, I think I found it really helpful as well because some of the ways that it was designed with the different subjects helped as well to make me think oh yes well this experience I'm having is normal, which is like there was, how it was set up the program it had stigma.* [Eleanor; female, friend, active-high user]

Some carers felt that the expert and peer support forums provided hope, particularly in instances where carers were able to provide lived accounts and reassurance of particular aspects and situations improving over time. Some carers especially valued reminders that their loved one is still their loved one and reflected that kind words provided *light*, led to a feeling of hope:

> *In some respects, it made me feel a bit better because other people are going through not completely the same as me but very similar as me and they've managed to get through it, etc.* [John; male, partner, passive-moderate user]

Improved Well-being

Carers recognized that the COPe-support was specifically designed for them. Some carers discussed how COPe-support not only provided support for the well-being of their loved ones but also their own. This included recognizing the importance of supporting their own needs, focusing on self-care, and fostering healthier routines, such as improving their diet, fitness, and sleep hygiene:

> *It was just really, really helpful to learn how I can manage my well-being in terms of trying to support myself in terms of trying to help the person I'm caring for...like I said it has made a really big difference to my well-being and my partner's well-being and it has been a lifeline.* [Edward; male, partner, passive moderate user]

> *I have actually changed my eating this last few months as a direct result of the site, so that's quite something.* [Alexandra_3; female, parent, active-moderate user]

Even the concept that COPe-support had been designed specifically for carers helped carers recognize their support needs were valid and acknowledged, reducing guilt associated

with personal help-seeking. Some carers described how COPe-support had provided personal space and time to reflect on their personal journey as carers, get more in touch with their emotions, and listen to the reflections of others:

> *Even just using the questionnaires at times were good for me because it made me sit and focus a little bit on where things were at...and actually think about how I was feeling.* [Alexandra_1; female, parent, passive noncomplier]

Future Implementation and Integration With Existing Services

The following subthemes reflect the perspectives of carers surrounding the future implementation of COPe-support and integration with existing services. This includes suggested improvements for COPe-support.

Comparison With Face-to-face Support

Compared with face-to-face support for carers, the perspectives of COPe-support were mixed. Although some expressed a preference for traditional means of delivery, others preferred web-based platforms and ideally a blended approach. Barriers to face-to-face support, including geographic factors, family life, funding and time constraints, and the benefits of web-based delivery in minimizing these barriers were discussed by some carers. Other carers considered barriers to web-based interventions, including age and a desire to personally meet carers and be able to sit with others going through similar situations. This is expressed as follows:

> *And I think that e-support is definitely a very, very useful, well it's a very good use of technology for people who have computers or phones and have the confidence to access stuff. You can't beat that one-to-one when you need it, you can't beat that.* [Faye; female, parent, passive-moderate user]

Integration With Other Services

Several carers commented that, given the funding restrictions on existing services, implementing COPe-support could *only be a benefit*. Some carers highlighted that participating in COPe-support addressed their concerns surrounding interventions for carers and motivated use of other services, such as face-to-face groups and courses for carers. Although some felt the support they had received through COPe-support was sufficient for their needs, others emphasized that COPe-support should serve as an adjunct to existing services rather than a replacement:

> *It also encouraged me to join a carers and coping course...I think it's made me question why I would find it so hard...to sit in a group with other people and hear about what's been happening to them, so yes I'm definitely looking forward to going to a six-week course at the end of this month.* [Summer_2; female, parent, passive-moderate user]

Continuous Access

Perspectives on the length of time to access COPe-support were mixed. Some felt they had received access for just the right amount of time to remain engaged and gain optimal benefits as a carer. However, some desired a longer use time. Several carers highlighted that as caring can be a long and complex journey, it would be reassuring to be able to revisit information and know they would be able to use it and have instant access to support in the future if new challenges arise (ie, dip in and out):

> *People have different periods of crisis. You would not want to have the sense of support suddenly be taken away.* [Martin; male, parent, passive-moderate user]

To allow for continuous access to carers' needs, some suggested being able to self-refer back into the intervention if necessary or have continual access and be able to opt out when they felt they had used it enough:

> *It was very good, too good; hence I asked if I can enroll again...it was a lifeline for me...COPe-support came along and gave me all the help and support I've ever wanted.* [Summer_1; female, parent, active-moderate user]

Greater Advertisement and Reach

Some carers reflected on coming across COPe-support *by chance* and emphasized a need for greater advertisement to reach more carers if it was to be rolled out widely in the future. Several advertising and promotion routes have been suggested, including local authorities and social services, charities, general physician surgeries, existing services for carers and trust websites, noticeboards, and newsletters. Awareness among health and social care professionals was also noted as important, with potential screening for the well-being of carers and onward signposting to COPe-support recommended. Suggestions for ways to reach carers include the following:

> *When you roll it out into various Trusts and it goes further that's where it needs to be as well. There are a number of options there.* [Mark; male, parent, passive noncomplier]

> *They always ask at the GP surgery when you register or every so often they'll say are you caring for anyone and it could be quite helpful to maybe signpost it at that point.* [Aaron; male, partner, passive noncomplier]

User Suggested Improvements

Many carers have proposed improvements for COPe-support. Some were about the way information was presented, which some found, at times, overwhelming and off-putting (ie, *too much on the screen sometimes*). To reduce confusion, fewer chunks of text and more graphics and visual aids or *see more* dropdown options were recommended:

> *I suppose what I'm trying to say is even a little, you need to have something...if you want to do mindfulness it needs to have a little picture, it needs to be more visually stimulating.* [Molly; female, parent, active-moderate user]

With regard to forum communications, although some described freely writing open posts as cathartic, several carers reflected on an emotional burden arising from posts. At times, carers found posts distressing to read and that they could generate

worries. Thus, providing a general warning of content causing potential distress and content warnings for particular comments was recommended:

> *There were things where...you know, there were things that triggered me to think about things and thought this maybe something worth sharing.* [Matthew; male, partner, active-high user]

Moreover, some caregivers desired more ongoing conversations. Thus, suggestions for a chatroom or befriender element were made by a few carers to help build stronger connections. Some carers reported it was hard to relate to others given different life circumstances (eg, having several children to care for too). Hence, a couple of carers recommended brief profiles with basic, yet nonidentifying, information (eg, sex, caring responsibilities, relationship, or living situation) to provide advice and support, as well as seeking relatable content. However, when certain forum topics received a good number of posts, one common problem that arose was having to go forward and backward among pages and scrolling excessively to see forum comments. This was described by an active user as follows:

> *I remember the format of the message threads when you had five or six interactions or replies on the same thread it becomes almost impossible to read on the phone because you have to scroll down and the indentation starts going to the right.* [Tony; male, partner, active-high user]

Hence, for navigating the forums and the COPe-support content overall, *frequently viewed* and *recently viewed* buttons were recommended by some carers. Some would also like to be able to choose which posts on the forum to expand. Most found the instructions for navigating COPe-support clear, although some would have appreciated an opt-in for 1:1 guidance.

Finally, to encourage engagement, some carers noted that they would have appreciated some additional prompting after periods of inactivity. Several passive users regretted not using the forums more and reported barriers to posting, including their busyness, mental state, difficulties expressing their feelings, worries surrounding sharing with unknown people, and experiencing hesitation and self-doubt. Some carers suggested having rolling discussion topics and implementing alternative options (eg, emoji reactions) to facilitate forum engagement:

> *If that [thumbs up or other emojis for acknowledgement] feature had been available and I'd seen a couple of thumbs up to the things I'd posted I think that would have been great...And maybe that's a stepping stone as well they start by just a few reactions, emoji reactions and then it's small steps. They can do that the first time and then maybe the next time they will write a few words.* [Felix; male, stepparent, active-moderate user]

Discussion

Principal Findings

This study aimed to explore the following: (1) carers' experiences and perceived acceptability of COpe-support and its different components; (2) how they found engagement with COPe-support affected their own well-being and caregiving; and (3) ideas of carers for improving COPe-support and its delivery to inform any future wider implementation. Notably, this qualitative study is one of the first to explore the experiences of carers of individuals with psychosis by using an entirely web-based psychoeducation and peer support intervention, coproduced by carers and people with experiential expertise. Experiences of participants were predominantly positive with COPe-support, and carers identified a range of benefits from using the intervention. Nonetheless, the carers highlighted some key areas of improvement. Overall, three themes were identified, each addressing one of the objectives of the study as follows: (1) remote, flexible, and personalized support; (2) impacts on well-being and outlook on caregiving; and (3) future implementation and integration with existing services.

Overall, the subjective experiences of COPe-support among carers were positive. In addition to the web-based gains provided by COPe-support, such as improved accessibility, flexibility, and anonymity, participants also reported that the intervention was beneficial in providing access to a rich repertoire of credible information [8,11,12] and fostering personal development by enhancing their self-confidence and understanding. Our results indicate that COPe-support was perceived as a crucial resource to reinforce feelings of empowerment in carers while reducing their sense of isolation. COPe-support also prompted carers to prioritize their own well-being. These impacts motivated some carers to access further support and engage more with professionals, indicating additional long-term benefits [1,3,6,14,15].

Notably, our themes and subthemes should be recognized as a set of interconnected and interacting constructs to be considered in the overall design (eg, content) and facilitation (eg, moderation) of web-based interventions, such as COPe-support [8]. For instance, carers would only enjoy interacting on the web-based forums, provided they felt safe and supported through specific implementation strategies. Carers would be less likely to see the essential intervention contents should access and navigation be less than facilitative.

Moreover, similar to earlier studies on web-based interventions with a forum component [20-23,33], we found that the use by carers in terms of numbers of posts and log-ins does not always align with their perceived acceptability and usefulness of the intervention. Although the carers who actively initiated posts themselves were eager to see more exchanges on the forums, many others found benefits in being passive observers. Some carers identified that anonymous participation on web-based forums allowed them not to feel pressurized to participate in a certain fashion as in a face-to-face group setting. Many carers described finding resonance, connections, and solidarity from the peer and expert forums without making a post themselves, although some identified that they would have made posts if given more time or if a specific question came up.

Future Directions

The experience of participants seemed partly dependent on factors, such as their own demographic profile (eg, length of time as a carer and age) and preferences for particular delivery

formats and computer literacy as highlighted in previous studies [14,26,40,41]. It is imperative to incorporate these perspectives in considering how best to further refine COPe-support and its facilitation. Upon future implementation, several advertisement routes were recommended to increase the reach of COPe-support, as well as a need for greater awareness among professionals who have contact with carers. In line with previous research [41], the need for more proactive approaches from professionals and services to identify and refer carers were highlighted, such as potential screening for the well-being of carers and signposting to COPe-support [32].

In any future rollout of COPe-support, it is imperative to consider the revision and refinement of the content as much as the facilitation of the minimally guided web-based intervention holistically to keep the participants engaged, to induce the anticipated impact [7]. Further scaling-up implementation of COPe-support and similar interventions also needs to carefully consider what constitutes the optimal group size and setup for a multicomponent web-based object, including closed forums catering for numerous users with varying use and participation profiles and a more flexible time frame to suit the ongoing needs of carers. Some participants also highlighted a desire for blended services—that is, COPe-support being adjunctive to, rather than a replacement of, in-person support. Indeed, a blended approach could foster the discussed benefits of both web-based and face-to-face support, as well as provide carers with options to cater for their needs and preferences.

Strengths and Limitations

We considered the sample of 35 carers interviewed for this study as a strength, as this contributed to a wide variation in user experience and use from carers with different relationships with individuals with psychosis and in different caregiving situations. Having multiple researchers to independently code and analyze the rich data led to unanimous results and increased the rigor and reflexivity of the study [36,42]. The study results allow us to understand how carers engaged with COPe-support, what helped or hindered their engagement, and how using it affected themselves. Through these results, we underscored that carers' experiences of COPe-support were shaped by a range of demographic and web-based health literacy factors, in addition to the intervention design and delivery itself. To ensure that users obtain the intended benefits of the COPe-support in the future rollout, it is imperative to consider how best to engage a wide variety of users to use all its essential ingredients [7,14].

This study had several limitations. Although we aimed to interview carers after completion of outcome data collection at 8 months, some carers had stopped using COPe-support earlier than the study duration and hence found it difficult to recall their experience with the intervention in detail. Although we strived to invite participants with low use and those from ethnic minority backgrounds for the interviews, such populations remained underrepresented (in the overall trial and this study) [43,44]. Our interviewees may have been positively biased in their views surrounding the intervention and study. It could be valuable to extend future work to explore reasons for nonenrollment among potential participants within services where the intervention was advertised, yet they chose not to take part.

Conclusions

Overall, this qualitative interview study captured the experiences of carers of using the web-based intervention COPe-support. The variation in responses among active and passive users captured the carer's perception of COPe-support. Notably, support and engagement with peers and experts were appreciated for meeting and validating the needs of carers, and the importance of usability ease, personalization, convenience, and safety were discussed. Further work is required to develop COPe-support based on these suggestions and explore the steps for optimal implementation.

Acknowledgments

The authors thank all the carers who participated in the study. The authors thank all the input and contributions from the members of the Project Reference Group, which provided an overview of the research program. The members include Ellen Harris; Jacqueline Marks; Angela Ryan; Storm Ryan; Lana Samuels; Clive Travis, PhD; Leigh Wallbank; and EW.

We thank all the members who helped to run the Ask the Experts forum. They include Ana Maria Corredor Collazos; David Coughlin; Dr Ranjita Dhital; Sian Evans; Dr Ban Haider; Julia Heathcote; Dr Claire Henderson; Dr Sarah Mansfield; Dr Aileen O'Brien; Mona Qassim; Juliet Sserunkuma; Clive Travis, PhD; and EW.

To recruit participants into the study, the project team acknowledges the support of the National Institute for Health Research through the Clinical Research Network (Division 4).

This trial, as part of a larger research program entitled E-support for Families and Friends of Individuals Affected by Psychosis, is funded by the National Institute for Health Research under its Postdoctoral Research Fellowship (awarded to JS, reference: PDF-2015-08-035). The study was peer reviewed by the funding bodies.

The views expressed in this publication are those of the authors and not necessarily those of the National Health Service, the National Institute for Health Research, or the Department of Health and Social Care. The funder National Institute for Health Research had no involvement in the study design; collection, analysis, or interpretation of data; writing of the manuscript; or decision to submit the manuscript for publication.

Authors' Contributions

JS conceived the study and initiated the study design with supervision from CH and S Gillard. RB, JS, CH, S Gillard, LAW, S Gulshan, and HS further developed the study design and its implementation. RB, S Gulshan, HS, EW, and JS analyzed and interpreted the results. RB and JS drafted the paper, and S Gulshan, HS, and EW supported its further revision. All authors read and approved the final manuscript. JS is the grant holder.

Abstract

Background: Mobile health (mHealth) platforms show promise in the management of mental health conditions such as anxiety and depression. This has resulted in an abundance of mHealth platforms available for research or commercial use.

Objective: The objective of this review is to characterize the current state of mHealth platforms designed for anxiety or depression that are available for research, commercial use, or both.

Methods: A systematic review was conducted using a two-pronged approach: searching relevant literature with prespecified search terms to identify platforms in published research and simultaneously searching 2 major app stores—Google Play Store and Apple App Store—to identify commercially available platforms. Key characteristics of the mHealth platforms were synthesized, such as platform name, targeted condition, targeted group, purpose, technology type, intervention type, commercial availability, and regulatory information.

Results: The literature and app store searches yielded 169 and 179 mHealth platforms, respectively. Most platforms developed for research purposes were designed for depression (116/169, 68.6%), whereas the app store search reported a higher number of platforms developed for anxiety (Android: 58/179, 32.4%; iOS: 27/179, 15.1%). The most common purpose of platforms in both searches was treatment (literature search: 122/169, 72.2%; app store search: 129/179, 72.1%). With regard to the types of intervention, cognitive behavioral therapy and referral to care or counseling emerged as the most popular options offered by the platforms identified in the literature and app store searches, respectively. Most platforms from both searches did not have a specific target age group. In addition, most platforms found in app stores lacked clinical and real-world evidence, and a small number of platforms found in the published research were available commercially.

Conclusions: A considerable number of mHealth platforms designed for anxiety or depression are available for research, commercial use, or both. The characteristics of these mHealth platforms greatly vary. Future efforts should focus on assessing the quality—utility, safety, and effectiveness—of the existing platforms and providing developers, from both commercial and research sectors, a reporting guideline for their platform description and a regulatory framework to facilitate the development, validation, and deployment of effective mHealth platforms.

KEYWORDS

mHealth; digital medicine; anxiety; depression; systematic review; mental health conditions; mobile phone

Introduction

Mobile health (mHealth) refers to medical, health care, and public health practices that use mobile computing or technologies such as mobile phones, wireless devices, patient monitoring devices, and web-based platforms [1-3]. With the overarching objective of improving health-related outcomes and awareness, mHealth platforms can either serve as standalone or complementary platforms and offer the potential to cater to the needs of many users, from health care professionals to patients and consumers. The existing infrastructure and technology of mobile devices, such as mobile apps and mobile sensors, make them ideal candidates for offering convenience while addressing clinical concerns and improving health-related outcomes. For example, mobile apps can be installed on a mobile device that allows for the measurement and collection of vital information such as location data and activities. These tracking data are invaluable as they may help inform users about their health status or provide necessary information to health care professionals during their decision-making process [4] to subsequently provide actionable feedback to their patients [5]. In addition, as most of the world's population already uses mobile devices, it is possible that mHealth interventions may allow greater access to care [6]. According to a digital global report published in October 2020, mobile phones and the internet had a penetration rate of 60% and 67% worldwide, respectively [7], both of which increased by a staggering 1% in just 3 months compared with July 2020 [8]. It is plausible that the COVID-19 pandemic that has driven most of the world into forceful isolation may have contributed to this increment. It is evident that mobile devices are increasingly becoming an indispensable part of our lives and will continue to be so [9]. As such, mHealth may offer a feasible approach for targeting a wide range of health conditions.

In recent years, there has been an increase in the use of mHealth platforms to intervene in the management of mental health conditions [10,11]. As a result, research is emerging on the implementation and clinical outcomes of mHealth platforms [10,11], and preliminary evidence on their efficacy is beginning to surface. Anxiety and depression, which have the highest prevalence among mental health conditions, are at the forefront of these targeted mHealth interventions [12,13]. The convenience facilitated by technology coupled with a higher quality of interventions—evidenced from randomized controlled trials (RCTs) and real-world evidence (RWE) delivered for those with anxiety or depression compared with those delivered for people with general health issues [10,11]—further propels mHealth as an increasingly appealing solution for the prevention and management of anxiety or depression. As a result, a plethora of mHealth platforms for anxiety or depression have been and continue to be developed.

This accelerated proliferation of anxiety or depression mHealth platforms that are readily available makes it difficult for stakeholders to determine not only those that may be useful but also those that may be potentially counterproductive. In addition, the resulting quantity of available platforms does not necessarily correlate with the scale of effectiveness validation. mHealth, as a whole, is still a relatively new field. Subsequently, regulatory policies and standards for the development of these platforms and the claims made by their developers have not been fully established [14,15], adding to the difficulty for stakeholders in identifying appropriate and safe mHealth apps. Accordingly, as the number of mHealth platforms for anxiety or depression continues to grow, it is important for relevant stakeholders, including users, clinicians, researchers, and developers, to understand what is currently available.

A recent review [16] has provided a comprehensive overview of commercially and academically available mental health apps offered in the Spanish language in the United States; however, a similar review of mental health mHealth apps available in the English language, to our knowledge, has not been conducted to date. Therefore, the aim of this review is to systematically identify and amalgamate the characteristics of the currently available English language mHealth platforms for anxiety or depression that have been developed for research, commercial use, or both. The outcome of this review may provide insights into considerations in the development, regulation, implementation, and adoption of future mHealth platforms for anxiety or depression.

Methods

Study Design

A cross-sectional study was performed to characterize mHealth platforms developed for depression or anxiety that were available for commercial, research, or both purposes. The mHealth platforms included apps, websites, and web-based software. A 2-pronged approach was used in this study. This included systematically searching relevant literature that described mHealth platforms as interventions developed for research and simultaneously searching 2 major app stores systematically to identify commercially available platforms. The protocol was registered on PROSPERO (International Prospective Register of Systematic Reviews; CRD42020193956) after preliminary searches were conducted. The piloting of inclusion and exclusion criteria and formal screening were conducted after the official PROSPERO registration.

Identifying Platforms Described in Research Literature

Search

The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines were used and adhered to for the literature search [17]. A systematic search of the databases PubMed, Embase, CINAHL, and PsycINFO was completed on June 23, 2020, from database inception dates. The search string was developed using the population, intervention, comparison, outcome strategy [18] using keywords and search terms combined with Boolean operators (Textbox 1). The search terms were carefully selected so that the homogeneous terms could be used in both the literature and app

store searches. The full search strings per database can be found in Multimedia Appendix 1. All searches were performed with no restriction on the publication period or year of release. There were no age or location restrictions on the target population.

Textbox 1. Keywords and search terms used for the formulation of the search string in the literature search.

Mental health condition

- *Mental health, mindfulness, anxiety, depression*

Platform

- *mHealth, mobile health, mobile device, mobile application, digital therapeutics, digital intervention, ehealth, smartphone, mobile phone, text message, web based, web application*

Selection

After duplicate articles were removed, 2 reviewers (SS and QYL) independently applied the eligibility criteria to titles and abstracts and subsequently to full-text articles using the Covidence software (Veritas Health Innovation) [19]. A third reviewer (AR) resolved any discrepancies. Articles were included if they were published in English, were full-text original journal articles or conference papers, and provided at least one characteristic of interest about an mHealth platform for anxiety or depression.

Articles were excluded if they were reviews (but reference lists were cross-checked for included studies), had no characteristic description of the mHealth platform, did not have the name of the mHealth platform, were not designed specifically for anxiety or depression, described mHealth platforms that targeted physical conditions only, or targeted secondary mental health problems related to a physical condition, health behaviors (eg, smoking cessation, risky drinking, obesity, and exercise), neurodegenerative disorders (eg, dementia), chronic pain, a specific phobia, posttraumatic stress disorder, addictions, subclinical symptoms, or a severe mental illness.

As the primary focus of the review was to characterize mHealth platforms, a formal assessment of the study quality and risk of bias was not performed.

Identifying Platforms Available Commercially

Search

Building on the methodologies by Bender et al [20] and Giunti et al [21], we systematically completed our search of all available platforms from 2 major app stores accessible from Singapore—Google Play Store and Apple App Store—on June 19, 2020. In-depth searches across the Apple App Store were included to identify platforms compatible with iOS or macOS devices. The search terms used were *anxiety*, *depression*, *mental health*, and *mindfulness* (Textbox 1), with no restriction on the app category.

Selection

Apps were initially included if the title or description of the app included the terms anxiety or depression. After the removal of duplicates, 2 reviewers (SS and QYL) independently assessed the eligibility of the app using the a priori determined criteria. Any discrepancies were addressed by a third independent reviewer (AR).

The included mHealth platforms comprised apps targeting mental health, specifically anxiety, depression, or both. Apps were excluded if they were no longer available, not available in English, or provided app descriptions that lacked the characteristics of interest.

Data Coding and Extraction

Data Coding

An mHealth platform characteristic coding scheme was developed based on an internally identified mHealth platform's characteristics of interest. If the mHealth platform characteristics were not clearly described or discrepancies were found during the classification of the mHealth platforms, discussions were held until consensus was reached. The final coding scheme and outcomes are detailed in Table 1.

Table 1. The mobile health (mHealth) characteristic coding scheme of the characteristics of interest from the respective searches and the description of each item.

Characteristic	Description	Literature search	App store search
Platform name	The name of the platform that was developed for research, available for commercial use, or both	✓	✓
Targeted condition	The condition the platform was designed for: anxiety, depression, or both	✓	✓
Targeted group	The intended users the platform was designed for	✓	✓
Commercial availability	The commercial availability of the platform in either the Apple App Store, Google Play Store, or both	✓	✓
Purpose of platform	The intended use that the platform was designed for. For example, diagnostics, monitoring, prevention, treatment, education, and support	✓	✓
Type of technology	The mobile modality and operating system in which the mHealth platform was rolled out	✓	✓
Type of intervention	Applicable only for platforms that offer treatment	✓	✓
App store categorization	App store category assigned to the platform by the development team that best describes its main function or subject matter		✓
Additional mHealth characteristics	Additional characteristics reported such as language, ratings, and cost of the platform	✓	✓
Clinical evidence and regulatory information	A secondary search was performed to obtain additional information of the identified platforms which included the availability of clinical evidence in the form of randomized control trials, real-world evidence, and regulatory approval	✓	✓
Other studies that reported the platform	Studies cited in the platform's article regarding the development, validation, or further evaluation of the platform	✓	
Cited literature	References to academic publications provided in the platform's app store description		✓

Data Extraction

The mHealth platforms and their characteristics of interest from both searches were extracted and recorded in a custom-developed Microsoft Excel template. The collected and assessed data included characteristic information of the mHealth platforms, which were based on the description in the app stores, provided by 2 reviewers (SS and QYL), and any discrepancies were resolved by a third reviewer (AR).

Statistical Analysis

Descriptive statistical analyses were performed for all the variables. The categorical variables were presented as absolutes and relative frequencies. Statistical analyses were performed using Microsoft Excel (version 16.43).

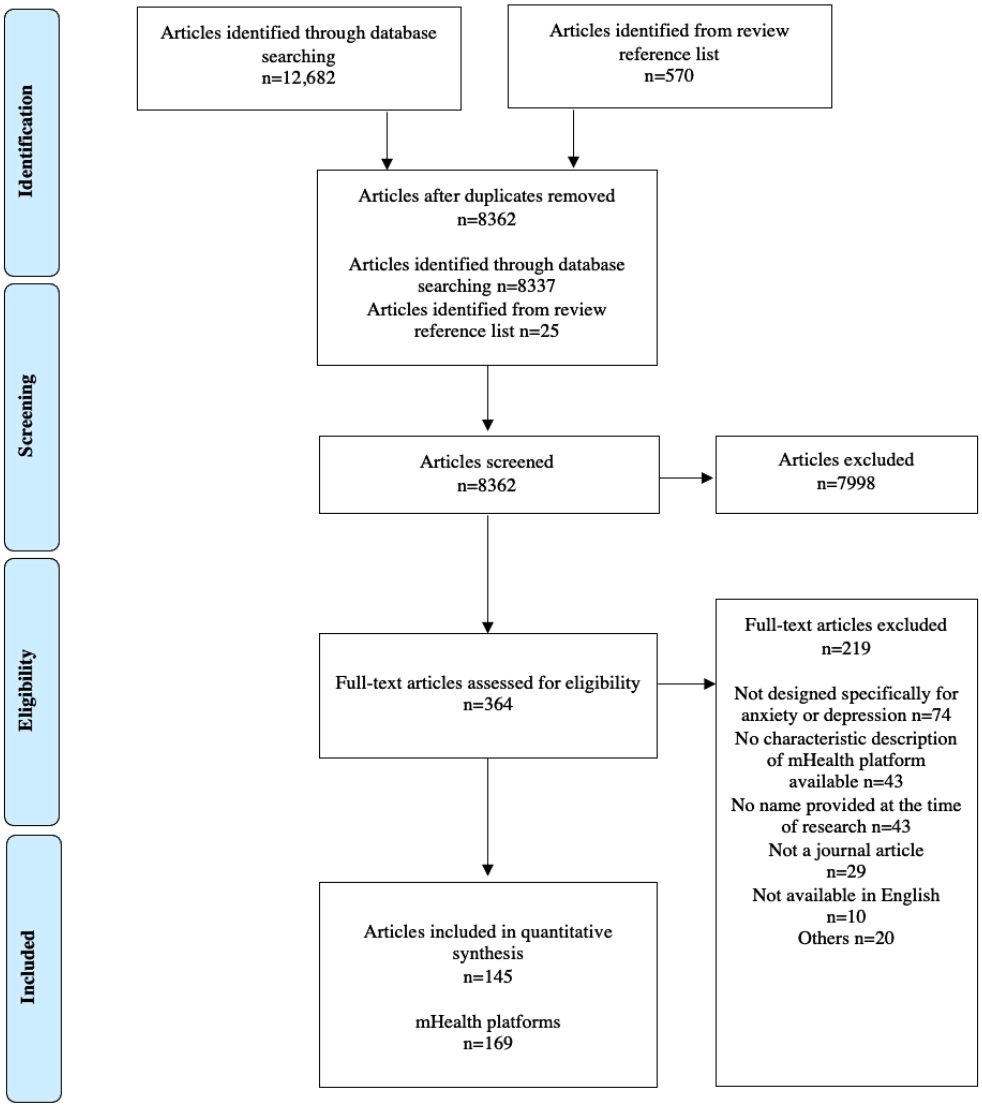
Results

Platforms Available in Literature Search

Selection

As depicted in Figure 1, after duplicate removal and review of reference list cross-checking, 8362 articles were initially screened. This resulted in the identification of 169 mHealth platforms described in 1.7% (145/8362) of articles (Multimedia Appendix 2 [22-166]). Some articles reported ≥1 platform, whereas some platforms were described in ≥1 article. Examples of platforms found across multiple studies were Deprexis (6/169, 3.6%), MoodGYM (6/169, 3.6%), Happy@Work (4/169, 2.4%), myCompass (4/169, 2.4%), and Partners in Parenting (4/169, 2.4%).

Figure 1. PRISMA (Preferred Reporting Item for Systematic Reviews and Meta-Analyses) flow diagram of search strategy and the finalized number of articles and resulting mHealth platforms included for this review. mHealth: mobile health.



Commercial Availability of Apps From the Literature Search

Of the 169 apps identified in the literature search, 8 (4.7%) were available in the app stores. All 8 apps were found in the Google Play Store, whereas a subset (6/8, 75%) was commercially available in the Apple App Store. No platform was reported as a medical device. However, of the 169 platforms, 2 (1.2%)—myStrength and HelpID—were reported as being used in health care settings. myStrength was used as a psychological intervention and had affiliations with health care providers, whereas HelpID was included in health care plans and insurance.

Targeted Condition

Of the 169 platforms reported in the articles, 116 (68.6%) targeted depression, 22 (13%) targeted anxiety, and 31 (18.3%) targeted both (Table 2). Approximately 1.8% (3/169) platforms—Situman, TeleCoach, and LifeRhythm—acted as complementary apps to other platforms targeting depression. The roles played by these apps varied, where Situman provided situational awareness to the Moodbuster platform, TeleCoach involved weekly calls to help with adherence to the MoodManager intervention, and LifeRhythm helped in data collection for the DepWatch system.

Table 2. Summary of the mobile health (mHealth) platforms characteristics from the literature search (N=169).

mHealth platform characteristics	Platforms, n (%)
Targeted condition	
Anxiety	22 (13)
Depression	116 (68.6)
Both	31 (18.3)
Target group	
Children	3 (1.8)
Young people	15 (8)
University students	3 (1.8)
Adults	8 (4.7)
Older adults	1 (0.6)
Employees	3 (1.8)
Migrants	1 (0.6)
Patient or clinician	2 (1.2)
Not specified	136 (79.9)
Purposes	
1 only	90 (53.3)
2	71 (42)
≥3	8 (4.7)
Number of languages	
1	2 (1.2)
2	5 (3)
≥3	4 (2.4)
Not specified	158 (93.5)

Targeted Group

Of the 169 platforms reported in the articles, 135 (79.9%) were not developed for a specific target group. The remaining 20.1% (34/169) targeted 8 different groups: children, young people, university students, adults, older adults, employees, migrants, and patient or clinician communication. Of the 169 apps, 2 (1.2%)—BiP Anxiety and Supporting Our Valued Adolescents—involved ≥1 target group and required the engagement of parents along with their children and adolescents, respectively.

Purpose

Approximately half of the platforms were designed with ≥1 purpose (Table 2). Treatment was the most common purpose, with 72.2% (122/169) of the platforms including it (Table 3).

Table 3. The primary purpose of mobile health platforms for anxiety or depression identified in the literature search (N=169).

Purpose	Description	Example	Platforms, n (%)
Education	• Provide mental health and medication information • Teach a variety of skills, including self-management and problem solving • Impart lessons through modules	Text-based information, audio or visual materials, and blogs	45 (26.6)
Diagnostic	• Identify depression and anxiety symptoms • Serve as a screening tool	Psychological questionnaires before use or over time	12 (7.1)
Monitoring	• Track self-reported symptoms and medical adherence • Collect relevant sensor data such as location and mobility information	Ecological momentary assessment through a mobile app, prompts to rate mood or complete short questionnaires, and data collection through wearable devices and mobile phones	38 (22.5)
Treatment	• Deliver psychological interventions through modules • Teach a variety of skills such as positive emotion skills, self-management skills, and guided meditation • Learn about coping strategies	Cognitive behavioral therapy, problem-solving therapy, gamification, lessons by topic, and homework	122 (72.2)
Prevention	• Similar to Treatment but targets individuals who are at risk of anxiety or depression	Text-based information and audio or visual, synchronous, or offline asynchronous activity	29 (16.2)
Support	• Offer a decision support system to clinicians • Manage care activities • Provide access to peer-to-peer support or health care professionals for support	Messaging service, discussion forum, web-based interaction in self-help groups, and web-based directory of bodies offering support	11 (6.5)

Type of Intervention

In platforms designed for treatment purposes, the incorporation of ≥2 intervention types was common (20/169, 11.8%). The most common types of intervention were cognitive behavioral therapy (CBT; 50/169, 29.6%), problem-solving therapy (11/169, 6.5%), and psychoeducation (9/169, 5.3%). An average of 8 (SD 5.04) modules was offered by 41.4% (70/169) of platforms that provided module-based sessions. The common frequency of intervention was weekly (32/169, 18.9%), followed by daily (8/169, 4.7%) on the (42/169, 24.9%) platforms that reported this characteristic. Of note, some (5/169, 3%) platforms incorporated some form of in-app human interaction, where the interaction personnel included medical physicians (1/5, 20%; Ascend), psychologists (1/5, 20%; HelpID), therapists (1/5, 20%; SmartCAT), trained health care professionals (1/5, 20%; PratenOnline), Master's degree–level students in clinical psychology (2/5, 40%; Happy@Work and Ascend), and occupational social workers (1/5, 20%; Happy@Work).

Type of Technology

Various types of technology have been deployed to fulfill the purposes of the mHealth platforms. Some (22/169, 13%) platforms used ≥1type of technology, with top choices including web-based interventions (90/169, 53.3%) and mobile apps (57/169, 33.7%; Table 4).

Table 4. Types of technology used by the platforms made for research purposes (N=169).

Technology type	Platforms, n (%)
Web-based platforms	90 (53.3)
Mobile apps	57 (33.7)
Text messaging	12 (7.1)
Others	6 (3.6)
Not specified	25 (14.8)

Additional mHealth Characteristics

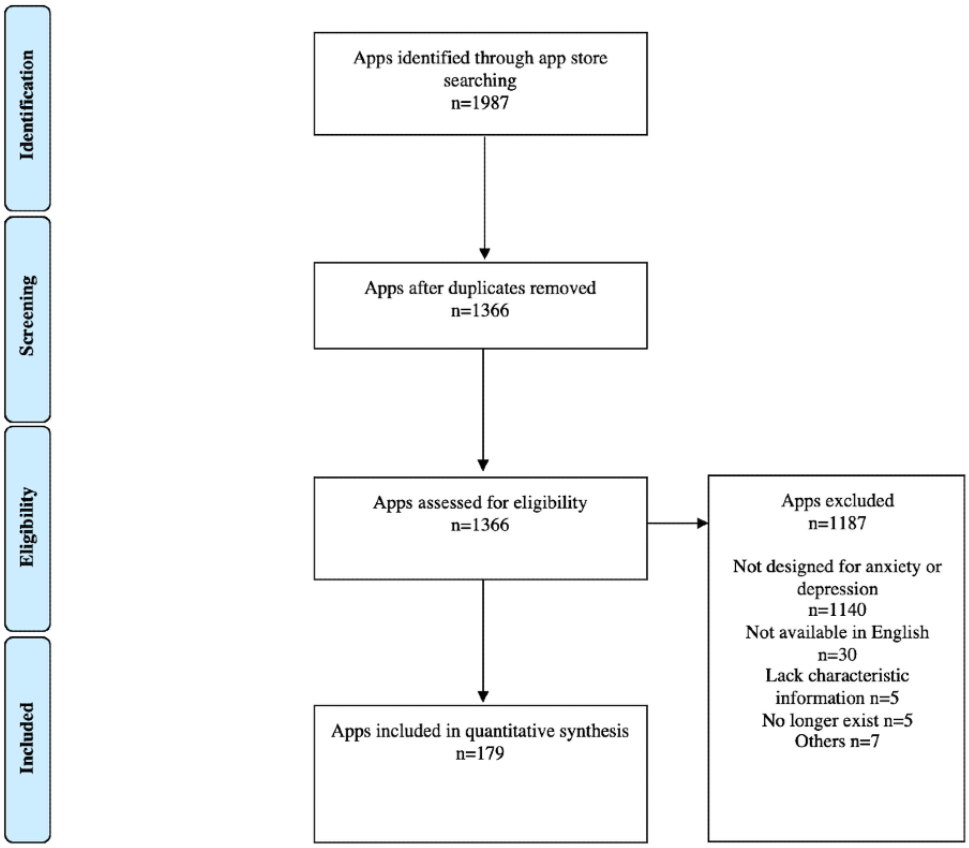
Of the 169 platforms, 9 (5.3%) were available in ≥2 languages (Table 2). Of these, the most common languages besides English were German (4/9, 44%) and Spanish (4/9, 44%).

App Store Search

Selection

The search terms yielded 179 mHealth platforms from the selection of apps in the Singapore region's Google Play Store and Apple App Store (Figure 2; Multimedia Appendix 3).

Figure 2. PRISMA (Preferred Reporting Item for Systematic Reviews and Meta-Analyses) flow diagram of search strategy and the finalized number of platforms included in the app store search for this review.



Commercial Availability

More apps were available in the Google Play Store (140/179, 78.2%) than in the Apple App Store (61/179, 34.1%; Table 5). Approximately 12.3% (22/179) apps were available in both app stores.

Table 5. Summary of characteristics of commercially available mHealth platforms (N=179).

Characteristics	Google Play Store (n=140), n (%)	Apple App Store (n=61), n (%)	Both[a] (n=22), n (%)	All, (n=179), n (%)
Targeted condition				
Anxiety	58 (41.4)	27 (44.3)	12 (54.6)	73 (40.8)
Depression	39 (27.9)	13 (21.3)	2 (9.1)	50 (27.9)
Both	43 (30.7)	21 (34.4)	8 (36.4)	56 (31.3)
Purposes				
1	77 (55)	32 (52.5)	7 (31.8)	102 (57)
2	45 (32.1)	16 (26.2)	7 (31.8)	54 (30.2)
≥3	18 (12.9)	13 (21.3)	8 (36.4)	23 (12.9)
Frequency of intervention				
Daily	4 (2.8)	3 (4.9)	0 (0)	7 (3.9)

[a]Both refer to platforms found in both Google Play Store and the Apple App Store.

[b]Ratings were rounded to the nearest integer.

Targeted Condition

The mHealth apps identified in both app stores were designed predominantly for anxiety (73/179, 40.8%). Approximately 30.7% (43/140) of the apps in the Google Play Store and 34% (21/61) of the apps in the Apple App Store claimed to address both anxiety and depression (Table 5).

Targeted Group

All platforms provided suitable age groups. One of the platforms, the Geriatric Depression Scale 2.0, detailed a specified target group, that is, older adults.

Purpose

Most apps found in both stores offered 1 purpose (Android devices: 77/179, 43%; iOS devices: 32/179, 17.9%; Table 5). Among the identified purposes available through the apps,

treatment was the most common purpose in both app stores, with 72.1% (129/179) of the apps including it (Table 6).

Table 6. The primary purpose mobile health platforms for anxiety or depression identified from the Google Play Store and Apple App Store (N=179).

Purpose	Description	Examples	Apps, n (%)
Education	• Provide information and communication of self-monitoring procedures • Dissemination of information by health care professionals	Text-based information, video materials, and SMS text messaging	50 (27.9)
Diagnostic	• Interpret symptoms • Identify possible mental health conditions	Self-administered questionnaires and psychological tests	34 (19)
Treatment	• Offer treatment tips, recommendations, and advice • Provide some form of intervention	SMS text messaging, real-time videoconferencing, and text-based treatment suggestions	129 (72.1)
Monitoring	• Tracking of symptoms • Prompts and reminders for tasks and appointments	In-app notifications, self-administered questionnaires, and journaling	26 (14.5)
Support	• Provide access to some form of support • Features option to call a friend, a family member, health care professionals, or a nearby help center directly from the platform	Forums, chatbots, and SMS text messages	34 (19)
Prevention	• Claim to prepare for and prevent anxiety-related or depressive episodes • Offer modules or activities that serve as preventive measures	Text-based information, audio, and activities	8 (4.5)

Type of Intervention

A total of 22 types of interventions were identified from the 72.1% (129/179) of apps that offered some form of treatment. Of these, referral to care or counseling (36/129, 27.9%), problem solving (27/129, 20.9%), and CBT (22/129, 17.1%) were the most common types of interventions available. Apart from encouraging to seek or directly offering specialist support, some apps provided support from the community, for example, access to forums with like-minded users (16/179, 8.9%). A subset of the apps that offered referral (14/179, 7.8%), counseling (4/179, 2.2%), or forum services (2/179, 1.1%) was subscription-based or required payment to gain access.

Type of Technology

Of the 179 platforms, all the platforms were available for mobile devices, except for 1 (0.6%; At Ease Anxiety and Worry Relief), which was accessible from both iOS and macOS devices. Of these 179 platforms, 140 (78.2%) were available on the Android operating system, 61 (34.1%) were available on iOS, and 22 (12.3%) were available on both operating systems. Other notable forms of technology that complemented or were incorporated in the platforms included wearable devices, such as headsets or smartwatches (1/179, 0.6%), and artificial intelligence–backed counseling sessions (3/179, 1.7%).

App Store Categorization

The app categorization and classification differed between the 2 stores. In Google Play Store, mHealth apps were categorized into 14 categories (Health and Fitness, Medical, Lifestyle, Books and Reference, Education, Trivia, Casual, Simulation, Adventure, Puzzle, Music and Audio, Social, Personalization, and Productivity), whereas Apple App Store mHealth apps were categorized into 5 categories (Health and Fitness, Medical, Lifestyle, Games, and Social Networking). The Health and Fitness category was the most common classification of mHealth platforms available on both the Google Play Store (81/179, 45.3%) and Apple App Store (39/179, 21.8%). The Medical category was the second most common classification available on both the Google Play Store (27/140, 19.3%) and Apple App Store (18/61, 29.5%).

Additional mHealth Characteristics

Of the 179 mHealth platforms, 100 (55.9%) were made freely available, with 56 (31.3%) providing both free and paid versions and 23 (12.8%) offering only paid versions. The costs of platforms that required payments ranged from SGD 1.21 (US $0.90) per installation to SGD 399.99 (US $296.20) for lifetime use.

Clinical Evidence and Regulatory Information for Literature and App Store mHealth Platforms

RCTs are clinical evidence and a prerequisite for regulatory approval. However, not all platforms had RCTs. Additional regulatory information—RWE and regulatory approval—was searched. In the secondary search mentioned in Table 1, a subset of apps had a credible source that offered some form of empirical evidence. In the app store searches, 3.4% (6/179) of the apps included scientific evidence claims, whereas 2.8% (5/179) of the apps were affiliated with health care experts and reputable institutions.

None of the apps in both literature and app store searches were reported as medical devices. In the literature search, 44.4% (75/169) and 45% (76/169) of articles presented evidence from

RCTs and RCT protocols (Table 7), respectively, whereas the remaining 10.7% (18/169) did not provide evidence from RCTs. Further analysis of the clinical and regulatory evidence—through the search for additional RCTs, RWE, and regulatory approvals—demonstrated that 41.4% (70/169) of platforms presented evidence from RCTs, 0.6% (1/169; Wysa) presented preliminary RWE, 1.2% (2/169; myStrength and Moodgym) presented evidence from RCTs and RWE, and 0.6% (1/169; Deprexis) presented evidence from RCTs and RWE and had obtained regulatory approval.

From the app store search, a subset of apps was pinpointed to be based on substantial validation studies to assess effectiveness. In particular, RWE can serve as a key gateway and vitally important indicator for supporting health care decisions, as well as impact and value toward patient care and the broader health care ecosystem. For example, 1.1% (2/179) of the apps provided evidence from each of the following sources: RCTs (Sanvello and Moodmission); RWE (Talkspace and Wysa); RCTs, RWE, and regulatory approval when applicable (Flow and Sooma).

Table 7. Availability of clinical-grade evidence and regulatory oversight in mobile health platforms for anxiety or depression identified from the literature and app store searches.

Evidence	Literature search (N=169), n (%)	App stores search (N=179), n (%)
RCTs[a] protocol	75 (44.4)	—[b]
RCTs	76 (45)	2 (1.1)
RWE[c]	—[b]	2 (1.1)
RCT+RWE	—[b]	0 (0)
RCT+RWE + regulatory approval	—[b]	2 (1.1)
None	18 (10.7)	173 (96.7)

[a]RCT: randomized controlled trial.

[b]No reported clinical evidence or additional regulatory information found.

[c]RWE: real-world evidence.

Discussion

Principal Findings

This review provides an in-depth analysis of the current mHealth platforms developed for anxiety or depression available for research and commercial purposes. Through a novel combined approach—a 2-pronged systematic search across the research literature and marketplace—we identified 169 and 179 mHealth platforms, respectively. Most platforms developed for research purposes were designed for depression (116/169, 68.6%), whereas the platforms made available in the app stores were mainly developed for anxiety (Android: 58/179, 32.4%; iOS: 27/179, 15.1%). We identified that mHealth characteristics such as platform name, aspects of mental health addressed, purpose, type of intervention, type of technology, and level of evidence varied largely across these platforms. In addition, we highlighted a significant lack of adoption of the regulatory framework and standards governing these mHealth platforms. An overview of the existing platforms for anxiety and depression available for research, commercial use, or both, as reported in this review, allowed us to identify gaps in the literature and marketplace and subsequently provide guidance for recommendations for future frameworks of mHealth development and regulations.

Targeted Group, Purpose, and Intervention Type of Available mHealth Platforms for Anxiety and Depression

Among the abundance of mHealth options currently available for anxiety or depression, relatively few have been developed for youths and emerging adults [167,168]. This is surprising, as these age groups are among the most prevalent users of mobile technologies as well as the groups that are most in need of mental health interventions. In particular, typical engagement with standard care for mental health has low appeal to young people and can be antagonistic to their developmental needs [168]. The low motivation inherent in emotional disorders; the need for agency, anonymity, and privacy; the greater sensitivity to stigma and discrimination associated with mental health; and the development of self-monitoring among young people can be addressed by mHealth approaches that provide personalized and timely treatment [169,170]. Future developers of mHealth platforms for anxiety or depression should consider developing them with this targeted group in mind.

The main purpose of most of the mHealth platforms for anxiety or depression identified in this review focused on treatment. The treatment used features such as module-based sessions and the teaching of coping and management strategies, which were based on the principles and guidelines of CBT, problem-solving therapy, and psychoeducation. Previous research has revealed 3 primary areas for enhancing the effectiveness of the treatment function of mHealth [167]. First, mHealth needs to be complemented by human interactions, especially with a medical physician or health care worker, to increase compliance, adherence, dropout [2,171,172], and efficacy in treatment [173-175]. However, findings from this review highlighted that few mHealth platforms included human interactions. To be effective, the digital framework for human interaction needs to consider individuals' desire for anonymity and privacy. Second, initial engagement and sustained use of mHealth platforms for young people require some form of social support from peers, schools, or mental health professionals. Although the role of social support and the associated outcomes are similar to that

found with the standard of care, the distinct feature of digital social support that mHealth platforms provide is anonymity and accessibility. The opportunity to share similar lived experiences of anxiety or depression with one's peers and being accountable to an authority (eg, health care professional) for the purpose of monitoring or assessment of their symptoms has the potential to increase their engagement and adherence to the mHealth platforms. Notwithstanding the support function of mHealth platforms, few platforms included this in their design feature. Finally, an mHealth platform needs to be easy to navigate, relatable, engaging, and esthetically appealing in providing education for mental health users—another common function of mHealth platforms. Previous studies have found that the boring and repetitive nature of modules and lessons presents a barrier to greater engagement with the education feature of an mHealth platform [10].

Type of Technology

mHealth can be deployed via one or a combination of mobile technologies. An increasing trend, which is also observed in health care, is to reach the individuals by communication technologies that are already in use for the seamless incorporation of the intervention into their daily life. Our literature search reported web-based platforms (90/169, 53.3%), mobile apps (57/169, 33.7%), and messaging (12/169, 7.1%) as the most common modalities deployed, which is consistent with findings in other studies [176]. In our literature search, 13% (22/169) of the platforms used ≥1 type of technology.

The app stores search identified discrepancies in the number of apps available in each app store. The higher number of apps in the Google Play Store (140/179, 78.2%) than in the Apple App Store (61/179, 34.1%) can be attributed to a preference for the Android operating system over iOS in Asia (82.7% vs 16.5%) and Singapore (65.2% vs 33.9%), as recorded in June 2020 [177]. Although the infrequent download count data from iOS disables the comparison in this category in our review, the literature suggests that in the United States, the iOS preference is reversed (41.7% vs 58.2% for Android and iOS, respectively) [177], and iOS apps show a higher number of downloads of behavioral health mobile apps [178]. Interestingly, a recent study collecting location data has shown that the platform type had a measurable effect on the retention of passive data collection because of the increased battery consumption of the app for the iOS system. In addition, the operating systems differ in their battery-saving modes and memory space–saving strategies, for example, app offloading to a cloud, which may have further implications. In the same study, no differences were detected in active data collection retention, suggesting that the operating system had no effect on active user interactions with the mHealth platform [179].

The deployment technology type and its specific technical considerations (eg, operating system) can *make or break* an mHealth platform. A digital intervention design should carefully consider the context of how each technology is already being used, as well as its technical and behavioral limitations. An mHealth platform can be deployed either via one technology type only or in a hybrid model to reap the benefits of each technology type to maximize usability with sustained functionality toward the highest efficiency of the intervention.

Commercial Versus Academic Motivation Considerations

Of note, only 4.7% (8/169) of the mobile apps identified in the literature search were available in app stores. This can be potentially related to the geographical constraints of the app store search compared with the unconstrained geography of the literature search. In addition, the literature searches covered articles from inception to 2020, whereas the app store search included only the apps present in the marketplace in June 2020. It is not unusual that after the gathering of evidence, the apps become unavailable in the marketplace [178,180,181]. The lack of commercial translation of research published in literature can be attributed to multiple factors: funding timelines (eg, relatively short grant duration and high staff rotation may not enable long term app management) and downstream research objectives (basic or fundamental research, tool development, and proof-of-concept to support potential future commercial and large-scale deployment) [182].

From the perspective of the marketplace, 1.7% (3/179) of apps in the app store search were described in a peer-reviewed article identified in our search. This can be potentially attributed to a business strategy that favors *quick-in* and *quick-out* rather than laborious and costly app evaluation without prevailing guidelines or incentives—monetary, regulatory, or otherwise—in doing so. Although consumers make the initial decision of which app to download based on easy-to-judge attributes such as graphics, price, and rating [178,183], it is the credibility and trustworthiness that drive engagement with mental health apps [184-186]. With this realization, it is important for commercial app developers to generate scientific evidence that validates their apps to substantiate the scientific descriptions, which will collectively enhance the app's appeal. In a study of the app descriptions of the top-ranked apps, it was previously found that apps use scientific jargon and are not supported by principles backed by peer review and validation studies, or they do not align with established findings in the scientific literature [187]. Instead of objectively informing about the evidence, the function of the app description is to appeal to consumers and drive the number of app downloads, independent of the platform's objective quality [187]. Accordingly, app user ratings do not indicate clinical utility or quality [188,189].

Regulatory Information: Scientific Evidence and Regulatory Status of mHealth Platforms for Research and Commercial Use

Clinical evidence, in the form of RCTs, reported in the publications found in the literature search (151/169, 89.4%) vastly exceeded that for apps found in the app store (2/179, 1.1%). Regulatory approvals (0.6% vs 1.1%) and RWE (0.6% vs 1.1%) were more balanced between platforms from the literature and app stores. The relatively high frequency of RCTs but low numbers in RWE and regulatory approvals for platforms featured in the literature search seem to indicate a pre-eminently investigative intent of those platforms. In addition, 33.7% (57/169) of the platforms were available as mobile apps, further hinting at treatment commercialization as a secondary

possibility. Maintenance and update of the website platforms were, in some cases, not frequent, indicating ad hoc use.

A large proportion of the mHealth platforms from the app store were unregulated, clinically untested, and unevaluated for real-world effectiveness (173/179, 96.7%), indicating a potential need for business models that support investment in robust clinical or real-world validation. Importantly, although 1.7% (3/179) of the apps found in the app store search in this review could claim to have scientific evidence or regulatory approval, 15.1% (27/179) and 10.1% (18/179) of the mHealth platforms for anxiety or depression extracted from the Google Play Store and Apple App Store, respectively, were included in the Medical category. Under this category (excluding telehealth), 8.4% (15/179) of the platforms affirmed that health professionals were involved in the design of the apps. From the app stores, 8.9% (16/179) of the platforms included a disclaimer notifying that the app was not intended to be a replacement for treatment or any sort of medical intervention. Another 12.3% (22/179) of the apps mentioned information sources used to design the app, such as validated tests (eg, Patient Health Questionnaire-9 for the assessment of depression and Generalized Anxiety Disorder-7 for the assessment of anxiety), international organization guidelines (eg, World Health Organization), validated therapies (eg, CBT), or peer-reviewed articles. These numbers reflect the need to develop more actionable and meaningful app store categorizations for medical apps. In addition, increased app store categorization oversight and strategies to enable or incentivize owners to implement changes, as well as clearer accountability guidelines pertaining to store content quality, may be needed. For example, oversight could be extended to app store owners to assist in enhancing specificity regarding the medical classification of apps. In addition, greater user education in the selection of apps may be a downstream consideration for health authorities. Consumers may need to be able to discern real-value apps by analyzing their claims, the involvement of health professionals, regulatory status, and scientific evidence. Apps that have not been supported by established validation guidelines adversely affect the field and users in multiple ways. For example, they may add a burden to already strained health care systems. In addition, they may create opportunity costs when the technological promise is not realized, resulting in mHealth fatigue of the clinicians, patients, and consumers, thus delaying the implementation of evidence-based, efficient mHealth platforms.

Overall, a need for enhanced regulation, especially in the Medical category of the stores, indicates that authorities may be able to positively affect the mHealth landscape toward requirements that include threshold validation and other applicable compliance guidelines. Several attempts have been made in that direction from various government organizations and professional societies. For example, the Institute of Electrical and Electronics Engineers—an engineering professional society—developed the Institute of Electrical and Electronics Engineers 1752 standards in 2017, which define specifications for standardized representations for mHealth data and metadata for cardiovascular, respiratory, and metabolic measures [190]. Health Level Seven International—an international mHealth professional workgroup—released the Consumer Mobile Health Application Functional Framework in 2018 with the primary goal of providing a standard whereby a mobile app's characteristics can be assessed [191]. In 2020, the American Psychiatric Association—a professional organization of psychiatrists—developed the American Psychiatric Association App Advisor, an initiative to identify an app evaluation model that was specific to mental health to be used by clinicians and their patients [192]. Most recently, in February 2021, a joint unit formed by the National Health Service England and the Department of Health and Social Care—released the Digital Technology Assessment Criteria with the aim to set the expectation of digital health technologies for potential developers [193]. In addition, other digital health and medicine professional societies, such as the Digital Medicine Society and Digital Therapeutics Alliance, also have initiatives to develop frameworks, standards, and resources for the different stakeholders of digital health interventions [194,195]. Furthermore, the International Organization for Standardization Technical Specification, in collaboration with the European Committee for Standardization, is currently developing a health app quality label *ISO/TS 82304-2 Health software–Part 2: Health and wellness apps–Quality and reliability* [196,197]. Although the continued development of these regulatory frameworks is critical, to have a real-world impact on the quality of mHealth platforms and apps, they must also be widely adopted by developers and requested by regulators, marketplace owners, and target populations alike. This will ultimately result in the development of high-quality mHealth platforms with stringent safety and security measures required in health care.

Methodological Limitations and Further Considerations

Although we took a novel approach of combining both a systematic literature search and app store search, some mHealth platforms may have been excluded. For example, although we had no geographical filters in our literature search, our commercially available app search was based on regional availability in Singapore's Google Play Store and Apple App Store. Although this may be a region-specific search, this review also provides new insight into the field as it serves as an early resource detailing available mHealth apps and platforms in South-East Asia. As Singapore is a globally recognized regional information communications technology hub with a well-established and efficient health care innovation ecosystem, this review provides the basis for a review of commercially available mHealth platforms available in surrounding countries and worldwide, alongside actionable recommendations. In addition, we restricted our inclusion criteria to mHealth platforms in English. It is possible that some apps may be published exclusively in other countries' stores (eg, United States, United Kingdom, or Canadian stores) and in other languages that were ultimately excluded from our search and this review. Furthermore, in the academic setting, the goal of the research team may be to assess the efficacy of the mHealth intervention they developed. After proven efficacious, commercialization may be the next step in the pipeline, in which case a name may be given to the platform. As such, this review does not include nameless mHealth platforms that were developed solely for research purposes. This decision was made

so that we could identify the app crossover between the 2 searches. In addition, we used exclusion criteria such as mHealth platforms developed for specific target populations (eg, comorbidities), secondary mental health problems related to a physical condition (eg, pregnancy), and platforms targeting health behaviors (eg, anxiety for smoking cessation) and severe mental illnesses. These criteria narrowed down the included platforms considerably. Overall, the possibility of mHealth platform exclusion may have introduced bias into our analysis. However, by including a comprehensive search of both the literature and multiple app stores, we aimed to minimize the possibility of mHealth platform exclusion in this review. Finally, as previously mentioned, we carefully selected search terms that could be used in both the literature and app store searches to ensure that these searches could be conducted as homogeneously as possible despite the different methodological requirements for each. As a result, some common key terms (eg, treatment and prevention) and phrases for the clinical conditions (eg, mood, sadness, affective disorder, phobias, and CBT) that would be included in a traditional literature database search were excluded. Therefore, it is plausible that some mHealth platforms described in the literature may have been excluded from this review. However, this review aimed to provide an overview of current mHealth platforms developed specifically for general nonspecific anxiety or depression; thus, we do not expect many potentially excluded platforms from this review. If more specific anxiety and depression conditions such as mood disorders or phobias are of interest, the keywords should be developed accordingly.

Furthermore, this review does not include a quality assessment of the mHealth platforms. We intended to use the Mobile App Rating Scale [198], as indicated in our PROSPERO registration (CRD42020193956). However, it was beyond the scope of this project to download all the included mHealth platforms, many of which required payment for installation or were not accessible (ie, from the literature). Therefore, we used the information detailed in the descriptions provided by the app stores or in the literature. As a result, some data were not available, and we could not avail of the Mobile App Rating Scale for the intended purpose. We attempted to use an alternative mHealth quality assessment tool; however, we did not find one that would be suitable for these purposes. Nouri et al [199] has previously identified substantial heterogeneity in the assessment criteria for mHealth apps in different studies. As valid and reliable frameworks to assess the quality of mHealth platforms are developed, future reviews, such as ours, should incorporate them.

Future Directions: Digital Therapeutics as the Next Step for mHealth Solutions for Anxiety and Depression

It is estimated that 264 million people have depression and 284 million people have anxiety worldwide [200]. The COVID-19 pandemic may exacerbate these numbers [201]. Although effective treatments exist, many health systems worldwide are underresourced and struggling to respond to the burden of anxiety, depression, and other mental health disorders effectively and efficiently [201]. As a result, mHealth platforms continue to gain popularity and are emerging as a feasible option for improving the quality of and overcoming access barriers to mental health support. However, the aforementioned concerns of lack of regulation and low levels of evidence are limiting factors for the current mHealth platforms developed for anxiety and depression to become successful solutions. A leap forward would involve venturing into digital therapeutics (DTx), which is widely regarded as the next step for mHealth. DTx offers effective, safe, highly personalized, objective, and cost-saving health care where barriers between information silos are overcome [202], all of which are ideal for addressing mental health conditions such as anxiety and depression. DTx require clinical and regulatory oversight and demonstrated RWE and are further differentiated by the delivery of a clinical-grade intervention (beyond tracking) to treat or manage a disease [198]. In other words, DTx interfere with the patient to modify their state, often through behavioral alteration. They can operate as a standalone treatment (eg, treating a mental disorder through gamification) or adjunct to other therapies to enhance them (eg, improving drug adherence). With the expectation to grow dramatically over the next few years, DTx can potentially affect users, organizations, and the health care industry in different ways: new treatment options, improved care pathways, incorporation of new standards of care, improved patient and population health outcomes, similar coverage to existing therapies, international product quality standards, and acceptance as an independent class of medicine, among others [203]. DTx is a favorable next step in mHealth solutions for anxiety and depression.

Conclusions

This study analyzed the characteristics of mHealth platforms for anxiety or depression that were available for research, commercial use, or both. A systematic search of the current literature and 2 popular app stores identified 169 and 179 mHealth platforms, respectively. mHealth platforms varied in their targeted condition, targeted group, purpose, intervention type, and technology type. In addition, most platforms from popular app stores lacked clinical and RWE, and a small number of platforms present in the literature were available commercially. Future efforts should focus on further accessing the quality—utility, safety, and effectiveness—of the existing platforms and ensuring the adoption by developers, from both commercial and academic sectors alike, of a reporting guideline for their platform description, as well as a regulatory framework to facilitate the development, validation, and deployment of mHealth platforms for anxiety or depression.

Abstract

Background: Being diagnosed with cancer during childhood or adolescence can disrupt important periods in an individual's physical, psychosocial, and spiritual development and potentially reduce the quality of life (QOL) after treatment. Research is urgently required to improve the QOL for child and adolescent cancer survivors, and it is necessary to analyze the trends in prior research reported in international academic journals to identify knowledge structures.

Objective: This study aims to identify the main keywords based on network centrality, subgroups (clusters) of keyword networks by using a cohesion analysis method, and the main theme of child and adolescent cancer survivor–related research abstracts through topic modeling. This study also aims to label the subgroups by comparing the results of the cohesion and topic modeling.

Methods: A text network analysis method and topic modeling were used to explore the main trends in child and adolescent cancer survivor research by structuring a network of keyword (semantic morphemes) co-occurrence in the abstracts of articles published in 5 major web-based databases from 2016 to 2020. A total of 1677 child and adolescent cancer survivor–related studies were used for data analyses. Data selection, processing, and analyses were also conducted.

Results: The top 5 keywords in terms of degree and eigenvector centrality were *risk*, *control interval*, *radiation*, *childhood cancer treatment*, and *diagnosis*. Of the 1677 studies used for data analyses, cluster 1 included 780 (46.51%) documents under *risk management*, cluster 2 contained 557 (33.21%) articles under *health-related QOL and supportive care*, and cluster 3 consisted of 340 (20.27%) studies under *cancer treatment* and *complications*.

Conclusions: This study is significant in that it confirms the knowledge structure based on the main keywords and cross-disciplinary trends in child and adolescent cancer survivor research published in the last 5 years worldwide. The primary goal of child and adolescent cancer survivor research is to prevent and manage the various aspects of the problems encountered during the transition to a normal life and to improve the overall QOL. To this end, it is necessary to further revitalize the study of the multidisciplinary team approach for the promotion of age-specific health behaviors and the development of intervention strategies with increased feasibility for child and adolescent cancer survivors.

KEYWORDS

text network analysis; topic modeling; cancer survivors; child; adolescent; research trends; knowledge structures

Introduction

Background

More than 300,000 children worldwide are diagnosed with cancer every year; every 3 minutes, a family somewhere in the world receives the unexpected and shattering news that their child has been diagnosed with cancer [1]. According to a 2017 survey of major causes of death across all races and sexes in the United States, malignant neoplasm was the leading cause of disease-related death in children and adolescents [2]. Approximately 137 million children are predicted to be diagnosed with cancer worldwide between 2020 and 2050 [3].

With significant advances in diagnosis and increase in multimodal treatment, childhood cancer survival rates have improved significantly in recent decades [4]. In the case of 5-year survivors of childhood cancer, the 30-year cumulative survival rate is 81.9% (95% CI 81.1-82.7) [5]. However, most child and adolescent cancer survivors experience additional problems and health effects after cancer treatment. More than 60% of survivors report with at least one chronic disease, and more than one-third report experiencing a reduced quality of life (QOL) with at least 2 complications [6,7].

Late complications experienced by child and adolescent cancer survivors may be psychosocial and behavioral, such as depression, anxiety, and risky health behaviors, or physical, such as cardiovascular disease, secondary cancer, and hormonal and immune deficiencies [8,9]. Even after full recovery, many child and adolescent cancer survivors have a high risk of death and morbidity resulting from secondary infections [10,11]. In other words, being diagnosed with cancer at this age can disrupt key periods of physical, social, and psychological development and potentially reduce QOL after treatment [12,13]. Therefore, significant effort is required to improve the QOL of child and adolescent cancer survivors.

More targeted research is needed to improve the QOL of child and adolescent cancer survivors; it is necessary to analyze previous research and organize the research results. A systematic literature review and meta-analysis, which are common methods used to intensively analyze intervention effects in the field of interest, are based on specific research questions and analyzed for a limited number of relevant papers [14]. Although it is possible to investigate the outcome of a topic of interest in this way, there is a limitation in that the overall knowledge structure of the context in which the major research concept and topic are studied or the type of connections between the main concepts cannot be known.

Exploiting a text network analysis to study research trends provides useful information with new ideas for future research [15,16]. These results can be used to form a body of knowledge by quantitatively analyzing a large number of papers and qualitatively interpreting the discovered knowledge structure to identify a certain pattern in the scattered data [17]. In addition, because numerous related papers are collected and used for analysis, this method has a significant quantitative scientific basis in terms of the research results and in identifying core research topics in academic fields and its relevance to various subtopics. In particular, it is possible to intuitively explore the knowledge structure by visualizing such research results [18,19].

Through text network analysis, it is possible to check the connectivity (links) between the words included in the documents (in our case, the words in the abstracts) and the connectivity group (community) of keywords based on their links. In addition, if a topic modeling analysis, which has the advantage of identifying topics representing the community based on the probability distribution of words included in the document, is applied simultaneously within a text network analysis, then trends based on the core topic of research in the field of interest can be clearly identified. Although the probability distribution of words in a document does not have any intuitive meaning, researchers can interpret the meaning of a specific topic, and thus, the extracted topic can be used as important information representing the document [20,21].

In the field of adult cancer and cancer survivor care, the number of studies applying a text network analysis to confirm the knowledge structure and overall research trends in the field of interest have increased over the past 10 years [16,22-25]. However, few studies that were published in 2017 applied a network analysis method to child and adolescent cancer survivors [15]. Because information technology has been undergoing rapid advancements, it is important that research on child and adolescent cancer survivors is shared all over the world.

To improve the QOL of child and adolescent cancer survivors based on the latest information, it is necessary to comprehensively identify research trends related to child and adolescent cancer survivors using text network analysis on studies published in internationally recognized academic databases. Therefore, in this study, using a text network analysis method and topic modeling, the main research concepts of previous studies on child and adolescent cancer survivors published in international academic journals in the last 5 years were reviewed, and research trends were identified.

Objectives

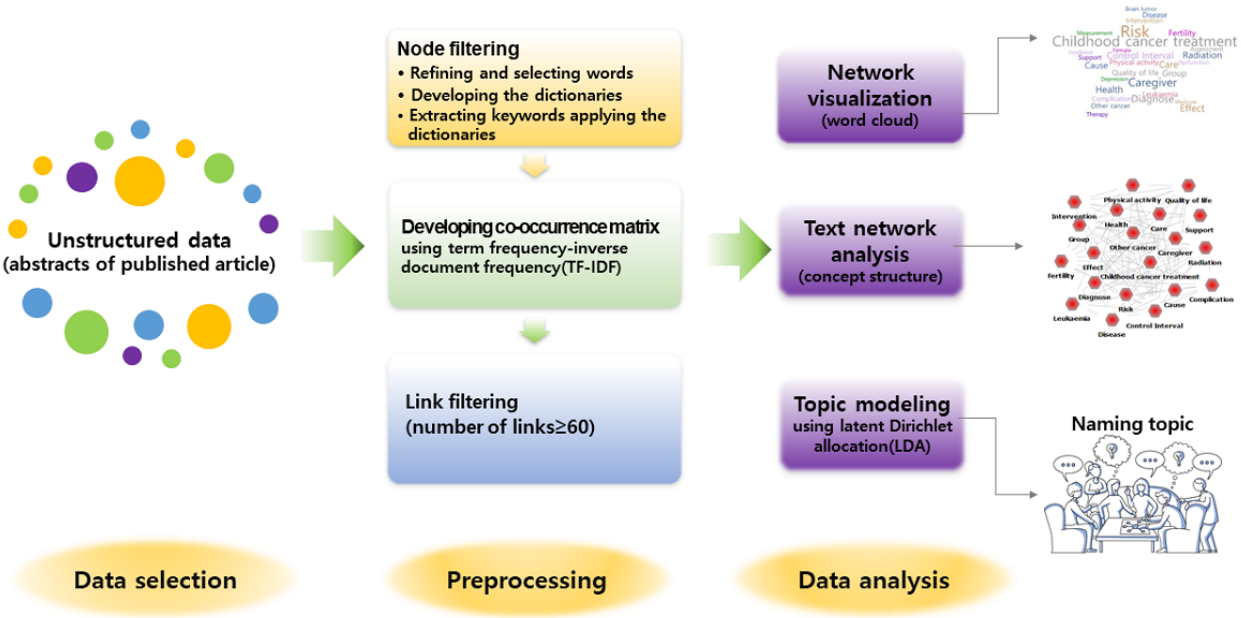
The specific goals of this study that analyze the abstracts of child and adolescent cancer survivor–related research papers are as follows: identifying the main keywords based on network centrality, finding the subgroups of a network of keywords using a cohesion analysis, clustering the main theme of child and adolescent cancer survivor–related research abstracts through topic modeling, and comparing and analyzing the results of cohesion and topic modeling.

Methods

Study Design

This study used text network analysis and topic modeling to explore the main research trends of child and adolescent cancer survivors by structuring a word co-occurrence network among the keywords (semantic morphemes) in the abstracts of articles published in 5 major web-based databases between 2016 and 2020. The process used is illustrated in Figure 1.

Figure 1. The process of this study.



Ethical Considerations

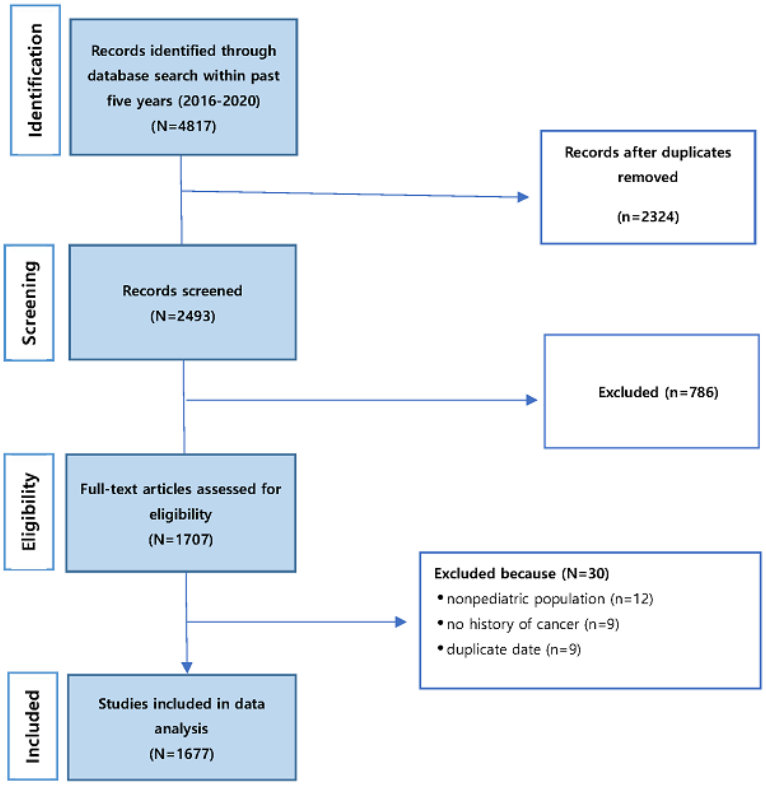
This study was approved by the Institutional Review Board of Sahmyook University (IRB No. 2020116HR). The data were collected from published articles in web-based databases, and no harm or risk was posed by the research to the participants. In addition, the collected data will not be used for any purpose other than for this study.

Data Selection

Keyword Selection

The first search to retrieve published articles from all time periods in 5 major databases (PubMed, CINAHL, Cochrane, Embase, and PsycInfo) was conducted in January 2021. The main keywords used included *Adolescent* [Mesh] OR *Child* [Mesh] OR *Pediatrics* [Mesh] and *Cancer Survivors* [Mesh] along with *Childhood cancer survivors*, *Adolescent cancer survivors*, and *Pediatric cancer survivors*. Only articles written in English during the 5-year period of 2016-2020 were selected. The article identification and selection process used the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram protocol (Figure 2) to retrieve 4817 articles during the initial search; 51.75% (2493/4817) articles were retained after eliminating duplicates (2324/4817, 48.25%). Each title was reviewed in accordance with this study's topic of interest, and 31.52% (786/2493) irrelevant studies were excluded. In all, 68.47% (1707/2493) of full-text articles were assessed for eligibility. Of the 1707 articles assessed, 30 (1.76%) that included a nonpediatric population (12/30, 40%), no history of cancer (9/30, 30%), and duplicate data (9/30, 30%) were excluded. Finally, 67.27% (1677/2493) abstracts were collected after reviewing their adequacy, and a network analysis was conducted on the data.

Figure 2. A PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.



Collection of Abstracts

A total of 2 researchers (HYK and KAK) of this study reviewed the titles of the retrieved data to identify the criteria for selection and exclusion. Moreover, 2 other researchers (SJH and JC) of this study repeated the former review process. A total of 1677 studies were selected for the final data analyses.

Preprocessing

Overview

The final selected abstracts were categorized to generate compatible unstructured data that could be accessed by NetMiner (Cyram) version 4.0. NetMiner is a validated program that conducts text network analysis by extracting a keyword from the abstracts and applying automatic filtration of the parts of speech (eg, nouns, verbs, and adjectives), generating a word co-occurrence matrix, and visualizing the analysis results [26].

First, to create compatible unstructured data, we categorized the retrieved studies based on publication year, author, title, abstract, and keywords using Microsoft Excel 2016. The raw data were then imported into NetMiner, and 10,786 words were identified as the main set of nodes.

Node Filtering

Word Refining and Selection

In all, 2 researchers of this study conducted a brief review of the first main node set of 10,786 words, regardless of the occurrence frequency. There is no scientific protocol available for the cut-off standard; however, it is widely accepted that words that only appear once can be excluded. During the review process, most of the words with a frequency of 1-4 showed inaccurate spellings or errors, irrelevance with respect to the main concept of the study, and general verbs or adjectives that were considered far removed from the actual content. Therefore, both researchers reached a consensus to exclude words with a frequency of <5, thus leaving 2755 words as a result.

Development of Dictionaries

For meaningful text network analysis, refining the semantic morphemes is important [17,26]. For the further filtering process, 4 researchers conducted a detailed review of each term and created a filtering dictionary. A total of 3 types of filtering dictionaries were created during this review. First, the thesaurus dictionary contained the identification of keywords that had the same definition but were listed in different ways (eg, *QOL*, *quality of life*, and *Quality of Life*). An exclusion dictionary was created to eliminate words that were not significantly related to the study content (eg, *apple*, *Netherlands*, and *cars*), and terms that were composed of multiple words representing a single definition (eg, *physical activity* as a single term, not *physical* and *activity* separately) were listed in the defined dictionary.

Keywords Extracted by Applying Dictionaries

The dictionaries were applied using the NetMiner software while importing unstructured data. With a network structure in which people in a social network analysis are nodes (points) and relationships among people are links (lines), a text network

analysis helps us understand the relationship among words comprehensively and intuitively by providing a sociogram in which words are applied as nodes, and co-occurrence relationships are applied as links [18]. This filtering process was repeated until the main node set of words was clearly noticeable without any errors (eg, uncapitalized terms, undefined terms, or unorganized synonyms). When the first filtering process was completed, 217 words remained in the main node set.

Development of Co-occurrence Matrix for Keywords (From 2-Mode to 1-Mode Network)

In this study, an abstract was considered a single document unit; each term represented a single node unit, and the initial word-document network was created (2-mode). Then, to process the comembership between terms, a co-occurrence word network (1-mode) was generated using the recoded weight value of term frequency-inverse document frequency (TF-IDF). The TF-IDF value reflects both the importance and frequency of a term occurring in a set of documents; therefore, it can be considered as an appropriate value for conducting a keyword network analysis [17,18,26]. An inner-product-proximity measure was adopted during the mode-conversion process.

Link Filtering

The generated 1-mode network consisted of 10,826 links. An excessive number of links in a network must be filtered to clearly view the results for network visualization. The cut-off standard for link reduction was determined by conducting a link-reduction simulation. A link frequency of ≥60 was chosen for the reduction, and 378 links were finally included in the data analysis.

Data Analysis

NetMiner version 4.0. was used for data analyses.

Network Visualization

Network visualization is the styling of nodes and links such that the connecting structure can be intuitively expressed [17,20]. A total of 3 simulations (with a link frequency of ≥55, ≥60, and ≥65) were conducted to visualize the map of the 1-mode network, and a consensus among the authors was reached to adopt a link frequency of ≥60, which best reflects the major trends in childhood cancer research. We applied a word cloud to visualize the network.

Text Network Analysis

Centrality is a useful index employed to determine the node (keyword) that lies at the center of the network, and the rank is determined based on its relativity rather than the absolute size. A node with a high centrality value can be considered as the core-acting node in a network [17,18,27]. This study adopted the following two approaches: degree and eigenvector centrality.

Degree centrality measures the number of connections carried by a single node, which indicates that a node with a higher degree centrality value and a higher number of connections within a network can be determined as a core keyword. The concept of eigenvector centrality is somewhat similar; however, rather than determining the direct connections of a node, it overviews the entire network to discover the most influential keyword by counting its surrounding neighbors. The standardized value of centrality lies between 0 and 1 and is used to determine the core-acting keywords in the theme of this study [17,26].

A cohesion analysis was conducted to identify the subtopic groups and the division of communities belonging to the co-occurrence word network [17,28]. In the first step, the giant component was extracted, and a community analysis was conducted. The largest modularity (best cut) is regarded as the most optimized value, with values of 1.25-2.75 indicating normal values and 2.75-3.5 indicating good values [17,28]. A higher modularity with a positive value means that the community is significantly divided; this link density within the group is high and between groups is low [17,18,28].

When visualizing the results of the network analysis, it is difficult to interpret the connections between many nodes and links because of their complexity. In this study, a pathfinder network, which is abbreviated such that only important links are left for each node, was used as a graph-drawing algorithm for centrality and cohesion analysis.

Topic Modeling

The topic modeling method, which is a technique used in text mining, assumes that a document is a set of words and that each document contains multiple topics with a specific probability distribution [19-21,27]. For topic modeling, this study applied latent Dirichlet allocation (LDA), a classic type of machine learning method, to discover topic keywords that best represented the core value in the collection of documents [19,21,26]. In this study, a topic modeling analysis applying LDA was used to validate and provide evidence for a cohesion analysis which was the categorization of themes concluded by the authors. LDA was conducted using NetMiner 4.0. The values of the parameter settings were α=.01 and β=.01, and the number of iterations was 1000. The adequate distribution of topics was set at 7, showing a clear distinction between all topics. Probable keywords for each topic were chained to refer to the categorization results of the cohesion analysis.

Results

Characteristics of Included Research

In the last 5 years, an average of 335.4 articles per year were published on child and adolescent cancer survivors (SD 65.24). The number of studies was 252 in 2020, 429 in 2019, 303 in 2018, 349 in 2017, and 344 in 2016. The year in which the most number of child and adolescent cancer survivor–related articles were published was 2019, whereas the most recent year, 2020, had the lowest number of publications.

Text Network Analysis

Degree Rank of 2-Mode (Word Documents), Degree, and Eigenvector Centrality of Keywords

Multimedia Appendix 1 presents the top 20–ranked keywords in the 2-mode network (word documents), degree centrality, and eigenvector centrality. Keywords that appeared most

frequently in the documents included childhood cancer treatment (degree=925), risk (degree=748), effect (degree=681), diagnosis (degree=652), and cause (degree=578). In contrast, the top 5 keywords in terms of degree centrality were *risk*, *control interval*, *childhood cancer treatment*, *diagnosis*, and *radiation*. The degree centrality index was 26.606%, with a mean of 0.018 (SD 0.04). The index of the centrality ranges from 0% to 100%, indicating that the links were fairly distributed within the network when the percentage is closer to 0% [20]. The top 5 keywords in the eigenvector centrality were *risk*, *control interval*, *radiation*, *childhood cancer treatment*, and *respiratory rate*. The mean was 0.025 (SD 0.064. The trends in the theme of the keywords, in both degree and eigenvector centrality rank, revealed their similarity because 75% (15/20) of the keywords overlapped with each other.

Cohesion With Network Visualization

For cohesion analysis, the giant component was extracted from the 1-mode network, which represented the relationship between a set of keywords (main node vs main node) and documents (abstracts). The component included 90 keywords from the network consisting of link frequencies >60 based on the TF-IDF recoded value. A component community analysis, using the Blondel processing method, divided the groups into 3 clusters with a maximum modularity value of 0.258. Textbox 1 lists the clusters divided according to their connection strengths. Cluster 1 contains 34 keywords, including *risk*, *control interval*, *female*, *condition*, and *cancer center*. Cluster 2 contains 31 keywords, including *caregiver*, *effect*, *care*, *health*, and *group*. Cluster 3 contains 25 keywords, including *childhood cancer treatment*, *diagnosis*, *radiation*, *cause*, and *leukemia*. Multimedia Appendix 2 shows the top 10 keywords of each cluster and map of the communities.

Textbox 1. Results of cohesion (clusters; maximum modularity=0.258) and included keywords.

Cluster 1 (n=34): risk management

- *Behavior, BMI, Cancer Center, cardiovascular Disease, Cohort, comorbidity, Comparison, Condition, Control Interval, Death, Deficiency, Diabetes, Engagement, Ethnicity, Exposure, Female, Gonadal, Hormone, Hospitalization, human papillomavirus, Insurance, Knowledge, Male, Malignancy, Mortality, Peer, Perception, Prognosis, Pulmonary, respiratory rate, Risk, Sex, Sibling, Surveillance.*

Cluster 2 (n=31): health-related quality of life and supportive care

- *Anxiety, Burden, Care, Caregiver, Central control station, Concern, Counseling, Depression, Education, Effect, Fatigue, Fertility, Group, Health, health care professional, Information, Intervention, Measurement, Nutrition, Physical activity, Physician, Posttraumatic growth, quality of life, Resilience, School, Stress, Support, Survivorship, Symptom, Transition, well-being.*

Cluster 3 (n=25): cancer treatment and complication

- *5 y, Assessment, BMD, Brain tumor, Cardiac, Cause, Central Nervous System, Chemotherapy, Childhood cancer treatment, Complication, Diagnose, Disease, Dysfunction, Experience, Incidence, leukemia, Lymphoma, magnetic resonance imaging, Medicine, Operation, Other cancer, Radiation, Regimen, Therapy, Transplant.*

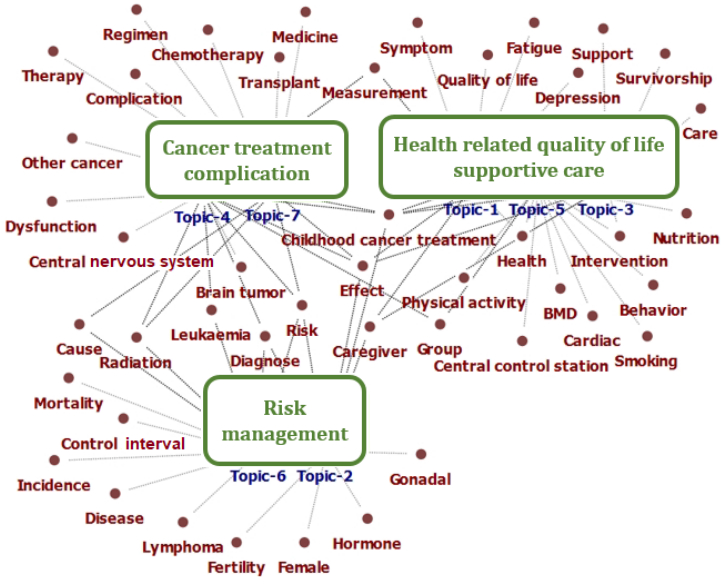
Topic Modeling

The keywords in the results of topic modeling, when applying LDA, feature the probability of being the best representation for the classified documents. In this study, 7 topics were determined to be appropriate matches in accordance with the results of the cohesion analysis. Multimedia Appendix 3 presents the keywords representing each topic based on a probability distribution with the number of documents included for each topic. Among the keywords representing the documents belonging to each topic, the first keyword has the highest probability of representing each topic, and the probability decreases with each keyword [28]. In this study, only the first and second keywords were considered for the analysis. Of the 1677 documents, topic 1 consisted of 265 (15.8%) documents, and the most probable keywords representing the documents belonging to this topic in order were *care* or *caregiver*. Topic 2 consisted of the lowest number of documents at 6.97% (117/1677), with *fertility* or *female* as representative keywords. Topic 3 had the largest number of documents at 21.36% (358/1677), with *care* or *caregiver* as the representative keyword. Topic 4 included 12.52% (210/1677) documents and was represented by the keywords *brain tumor* or *radiation*. Topic 5 consisted of 9.36% (157/1677) documents, with keywords including *physical activity* and *health*. Topic 6 consisted of 13.30% (223/1677) documents, with *risk* or *control interval* as representative keywords. Finally, Topic 7 contained the second largest number of documents at 20.69% (347/1677), with *complication* and *radiation* as representative keywords.

Comparison of Results of Cohesion With Topic Modeling and Topic Naming

On the basis of the keyword trends in each community, analyzed through cohesion, the authors reviewed the similarities among keywords, included in each cluster, in the results of the cohesion as well as each topic with representative keywords in the results of the topic modeling. As shown in Textbox 1 and Multimedia Appendix 3, comparing topics 2 and 6, we reached a consensus to name cluster 1 as *risk management*. Cluster 2 with topics 1, 3, and 5 was labeled *health-related QOL and supportive care*, and cluster 3 with topics 4 and 7 was labeled *cancer treatment and complication*. Figure 3 presents a clearer comparison of the keywords surrounding each categorized topic based on cohesion analysis and topic modeling.

Figure 3. Comparison map of results between cohesion analysis and topic modeling.



Discussion

Principal Findings

In this study, child and adolescent cancer survivor–related research trends over the past 5 years were analyzed by reviewing papers published in all academic fields.

The main findings of this study were that the top 5 keywords in terms of degree and eigenvector centrality are risk, control interval, radiation, childhood cancer treatment, and diagnosis. Of 1677 documents, cluster 1 included 780 (46.51%) documents under *risk management*, cluster 2 contained 557 (33.21%) articles under *health-related QOL and supportive care*, and cluster 3 consisted of 340 (20.27%) studies under *cancer treatment* and *complications*.

Among the documents included in the 3 subgroups, the knowledge structure and research trends were described by comparing the results of the meta-analysis that presented research results regarding the concerned topics. The giant component from the centrality analysis in this study showed 3 subgroups based on the cohesion analysis. To name the cluster of subgroups more accurately, we compared the results of the cohesion analysis and topic modeling. Cohesion analysis has the advantage of showing the degree of cohesion between keywords belonging to the relevant community [17,28]. However, there is a limitation in that it does not have guidelines based on mathematical calculations to name a given community. Recently, topic modeling, in which keywords that can represent documents belonging to each topic are presented based on probability values, has frequently been used to supplement the limitations of cohesion analysis [20,21]. On the basis of keyword trends in each community with cohesion analysis, the authors reviewed the similarity among keywords included in each cluster in the results of cohesion analysis and each topic with representative keywords in the results of topic modeling. In addition, keywords representing each topic should be mutually exclusive [26]. In the topic modeling results of this study, the first and second keywords representing each topic did not overlap and were mutually exclusive. Therefore, the cohesion analysis and topic modeling results indicate that the clusters of keywords representing recent research trends were reasonably named.

In cluster 1, labeled *risk management*, keywords related to periodic risk management and various risks that child and adolescent cancer survivors could experience while living as survivors after cancer treatment were included. A total of 10 meta-analysis studies corresponding to cluster 1 were identified. In all, 6 meta-papers [29-34] regarding long-term risk and management needs were published, and smoking, binge drinking, and drug use were reported as vulnerable issues for child and adolescent cancer survivors. In particular, the importance of periodic surveillance for late risk management such as cardiac toxicity was reported in a study related to surveillance guidelines among 4 meta-papers [35-38] related to survivorship in child and adolescent cancer survivors. On the basis of this analysis, it is necessary to conduct various studies related to education, information provisioning, health care–provider training, and social support and care system establishment related to periodic surveillance systems for potential risk management.

In cluster 2, labeled "health-related QOL and supportive care," keywords related to the various experiences of child and adolescent cancer survivors' care, and QOL required for survivorship were included. A total of 30 articles were identified in the meta-analysis studies corresponding to cluster 2. Most meta-studies on the development and effect of interventions related to physical health behaviors, such as exercise, nutrition, health promotion behavior, and obesity prevention, were found in 13 articles [39-51]. The results of this study related to keywords such as *effect*, *health*, *physical activity*, *intervention*, and *nutrition* were also confirmed. Specifically, studies proposed that future research should focus on providing evidence of the efficiency and feasibility of interventions that use web-based technologies (such as @TheTable e-cookbook) to facilitate

remote intervention delivery and peer support as the most effective means of promoting changes in health behavior [39-41,49,50,52]. We identified *anxiety*, *burden*, *depression*, *resilience*, *stress*, *counseling*, *measurement*, and *post-traumatic growth*. In 7 meta-analyses [53-59], child and adolescent cancer survivors were highly likely to experience mood or affective disorders [56], and brain tumor in child and adolescent cancer survivors was significantly associated with anxiety, depression, and health-related QOL, highlighting the importance of psychosocial screening. Furthermore, in 1 systematic review and meta-study [54], dealing with the keyword *post-traumatic growth* identified in this study, the need for targeted social support, clinical intervention, and education to facilitate posttraumatic growth was suggested through an analysis of 18 studies. Other keywords related to academics, school, and social adaptation were *education*, *group*, *school*, and *transition*, with 6 meta-studies [60-65] related to these keywords. In particular, the results of 26 studies were analyzed in a meta-study conducted by Saatci et al [65], and compared with controls there were significant differences in educational attainment among survivors according to country and culture. It has been reported that the support and participation of a cross-professional group, such as that of clinicians, teachers, and policymakers, is needed, and the problem of academic and school adjustment for child and adolescent cancer survivors involves an extremely critical developmental issue and an important global care problem that should not be overlooked. A total of 3 studies [66-68] addressed the fertility issues among child and adolescent cancer survivors. The most commonly reported barriers were a lack of patient educational materials regarding oncofertility psychosocial support and staff training [67], whereas another study attempted to realize a qualitative meta-synthesis [69] by synthesizing 51 research results into 5 themes (ie, experiencing difficulties related to cancer, fluctuating realities, coping strategies, new roles and responsibilities of the child, and practical resources to enable the managing of cancer). Compared with the keyword-analysis results confirmed for cluster 2 of this study, it is necessary to continuously conduct research on adaptation and improvement of QOL for children with cancer in terms of their physical, psychological, social, future occupational, and reproductive problems.

Cluster 3 of the cohesive analysis was labeled *cancer treatment and complication* because the main keywords were matched with topics 4 and 7 of the topic modeling results. Among the relevant papers, 11 meta-analysis studies [48,70-79] were identified, and the correlation with keywords included in cluster 3 of this study was confirmed. Keywords related to major carcinomas were *leukemia*, *brain tumor*, and *lymphoma*, and for other cancer types, *other cancer* were designated as representative words. Words related to *childhood cancer treatment* and *diagnosis* were the main keywords. Meta-studies were conducted on the subject of complications and therapeutic management of the endocrine system [78], nervous system [71,77,79], heart [48,72-74], tinnitus [75], and infection [76]. In particular, meta-analyses related to cardiac toxicity were predominant in 4 articles [48,72-74]. Most of the studies conducted in the medical field were identified as the main characteristics of the studies that fall into cluster 3, and the characteristics of interdisciplinary research topic keywords were confirmed.

Implications

The purpose of this study was to identify the knowledge structure based on major research trends and core research topics related to all child and adolescent cancer survivors. The 3 categories (*risk management, health-related QOL and supportive care*, and *cancer treatment* and *complications*) imply the current research trends. The results of this study are significant in that they can suggest practical research directions for the specific needs regarding QOL of child and adolescent cancer survivors in all academic fields.

In terms of the significance of the research methodology, this is the first study to use a text network analysis on child and adolescent cancer survivor–related topics and categorize interdisciplinary research trends. It has the advantage of increasing the validity of research trends as a quantitative method, based on a higher probability, by comparing a cohesion analysis with topic modeling.

Limitations

This study included data from only the last 5 years. The limitation is that the trends in child and adolescent cancer survivor–related research conducted based on the past 5- or 10-year periods cannot be compared or analyzed. The results of this study, focusing on the meta-analysis results included in each cluster, were analyzed and compared with 1677 studies in this research area. Therefore, potential limitations could exist, as some topics have been addressed infrequently in some studies; therefore, these might have been overlooked. Finally, studies in the genetic and biochemical fields were excluded.

Conclusions

This study is significant, in that it confirmed the knowledge structure based on the main keywords and cross-disciplinary research trends related to child and adolescent cancer survivors published in the last 5 years worldwide. To more accurately name the knowledge structure on a quantitative basis, the results of coherence analysis and topic modeling were compared and analyzed based on the giant component confirmed through a centrality analysis. In both cluster 1, *risk management*, and cluster 2, *health-related QOL and supportive care*, many research results for multidisciplinary teams have also been published.

Regarding cluster 3—*cancer treatment and complications*—papers published in the medical field prevailed, confirming the identity of interdisciplinary research topics. Improving QOL is the primary goal of child and adolescent cancer survivors, preventing and managing various aspects of problems encountered during the transition to normal life. To this end, it is necessary to further revitalize the studies through a multidisciplinary team approach to promote age-specific health behaviors and develop intervention strategies with increased feasibility and educational effects for child and adolescent cancer survivors.

Abstract

Background: In December 2019, the COVID-19 outbreak started in China and rapidly spread around the world. Many studies have been conducted to understand the clinical characteristics of COVID-19, and recently postinfection sequelae of this disease have begun to be investigated. However, there is little consensus on the longitudinal changes of lasting physical or psychological symptoms from prior COVID-19 infection.

Objective: This study aims to investigate and analyze public social media data from Reddit to understand the longitudinal impact of COVID-19 symptoms before and after recovery from COVID-19.

Methods: We collected 22,890 Reddit posts that were generated by 14,401 authors from March 14 to December 16, 2020. Using active learning and intensive manual inspection, 292 (2.03%) active authors, who were infected by COVID-19 and frequently reported disease progress on Reddit, along with their 2213 (9.67%) longitudinal posts, were identified. Machine learning tools to extract biomedical information were applied to identify COVID-19 symptoms mentioned in the Reddit posts. We then examined longitudinal changes in individual physiological and psychological characteristics before and after recovery from COVID-19 infection.

Results: In total, 58 physiological and 3 psychological symptoms were identified in social media before and after recovery from COVID-19 infection. From the analyses, we found that symptoms of patients with COVID-19 lasted 2.5 months. On average, symptoms appeared around a month before recovery and remained for 1.5 months after recovery. Well-known COVID-19 symptoms, such as fever, cough, and chest congestion, appeared relatively earlier in patient journeys and were frequently observed before recovery from COVID-19. Meanwhile, mental discomfort or distress, such as brain fog or stress, fatigue, and manifestations on toes or fingers, were frequently mentioned after recovery and remained as intermediate- and longer-term sequelae.

Conclusions: In this study, we showed the dynamic changes in COVID-19 symptoms during the infection and recovery phases of the disease. Our findings suggest the feasibility of using social media data for investigating disease states and understanding the evolution of the physiological and psychological characteristics of COVID-19 infection over time.

Introduction

COVID-19 is a pandemic viral infectious disease that has quickly spread worldwide. The clinical presentation of COVID-19 has been well defined from active clinical and basic scientific research. Risk factors and commonly observed symptoms at the diagnosis of COVID-19 and throughout the acute disease course have been well documented [1,2]. Several studies have tried to identify self-reported COVID-19 symptoms using social media data [3,4] and investigated the dynamics of symptoms that were observed prior to and throughout COVID-19 infection [5]. Our own analysis of social media and clinical literatures suggested less common or rarely observed

novel symptoms related to COVID-19. We also observed that different sets of clinical and demographic characteristics are associated with specific clinical outcomes, such as severity of disease progression, hospitalization, and intensive care unit admission [6]. These efforts have helped to understand the development of COVID-19 and identify appropriate medical treatment options and diagnostic methods.

Since early 2021, researchers have found emerging evidence of long-term sequelae in a considerable proportion of patients who have recovered from COVID-19. Several systematic reviews and cohort-based studies have suggested a set of symptoms from which COVID-19 survivors have partially recovered or those they have retained [7,8]. Most of these studies have focused on a set of symptoms that appeared at a static time point (eg, symptoms before, or at, the moment of confirmation of COVID-19; symptoms during recovery; or symptoms after recovery from COVID-19) and were based on retrospective data of hospitalized patients. When we considered that about 15% of patients with COVID-19 have been hospitalized [9], there was limited understanding of patients who experienced less severe symptoms and received home-based care. This created a huge knowledge gap to understand the symptom landscape and symptom durations in the general patient population (ie, 85% of patients with COVID-19). A comprehensive understanding of the full spectrum of symptoms and their dynamic changes throughout the patient journey (ie, disease course) was essential to obtain better information about acute and chronic/persistent COVID-19 symptoms in general patients and develop a complete understanding of the longitudinal impact of COVID-19 infection in the population.

To better understand the longitudinal changes in the physiological and psychological characteristics of the COVID-19 patient population throughout the patient journey, we systematically investigated Reddit public social media data from individuals who had previously been infected with COVID-19 and have recovered. Social media provides an efficient method of gathering large amounts of real-world data on the general public, which are scalable and convenient for users at any time of day, especially from remote or unattended regions. In addition, the development of sophisticated machine learning methods has been used to collect high-quality medical information from social media [10,11]. For this study, social media data were utilized to capture the disease course of general patients with COVID-19, including nonhospitalized patients with various levels of symptom severity. Machine learning methods were applied to select reliable patients with COVID-19 and their posts from social media data and to identify the full spectrum of symptoms of COVID-19 in a comprehensive manner.

Methods

Data

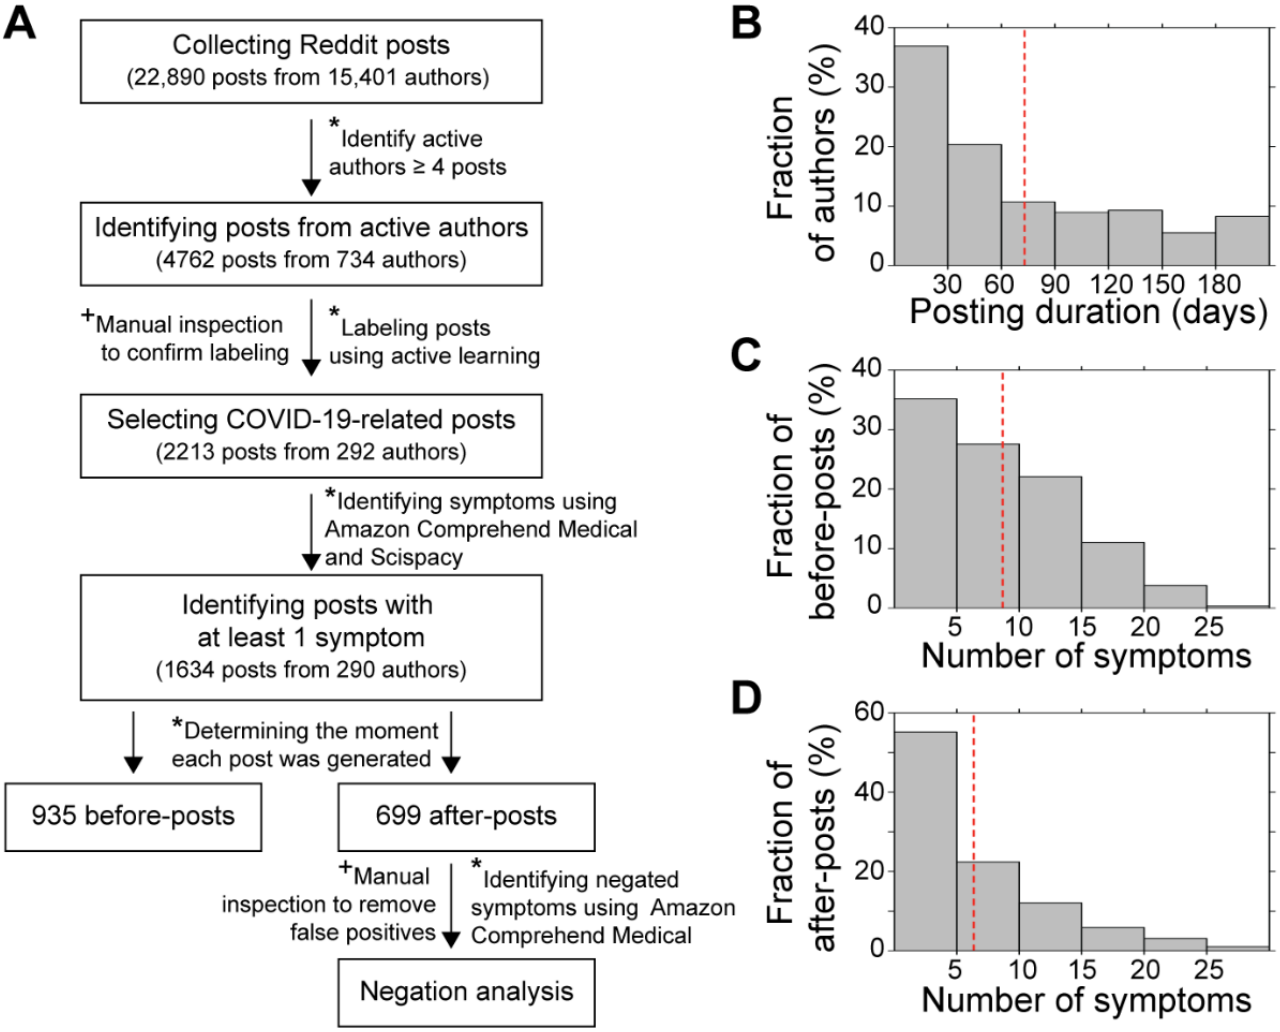
Reddit was used to collect social media posts of COVID-19 survivors. Reddit is a large user-generated content website and text-based social media platform (without the limitation of text length) enabling us to extract detailed information about a given topic. Reddit is also a community-based social media platform providing sections devoted to topic-specific discussions (subreddits). Authors express their opinions or concerns on subreddit forums. Subreddit defines its characteristics and eligible members. Therefore, people who are really interested in each topic can participate in a subreddit community. Furthermore, Reddit provides a publicly accessible Application Programming Interface (API) so that researchers can collect and analyze anonymized posts for their own purpose. Such clear definitions of topics and member eligibility, as well as anonymized data access through the API, made Reddit a reliable and effective social media platform to find the appropriate target audience for this study.

For this analysis, we collected posts that were generated from the moment the United States declared COVID-19 a national emergency (March 13, 2020; we collected posts from March 14, 2020) until the Food and Drug Administration (FDA) issued an emergency use authorization to both Pfizer-BioNTech's and Moderna's COVID-19 vaccines (December 17, 2020; we collected posts until December 16, 2020). After the World Health Organization (WHO) declared COVID-19 a pandemic and the United States declared COVID-19 a national emergency, it was logical to assume that the general population started to become aware of the presence of the COVID-19 virus and be interested in symptoms and their health conditions. In addition, they were exposed to the risk of COVID-19 contraction before the vaccine was available. During this period, people could actively discuss COVID-19-related issues and share their personal experience. We especially considered posts generated in "COVID-19Positive" and "CoronavirusSurvivors" subreddits. "COVID-19Positive" was self-described as "a place for people who came back positive for COVID-19 to share your stories, experiences, answer questions and vent!" "CoronavirusSurvivor" was self-described as a community for survivors of the coronavirus. At the time the conversations analyzed for this study were downloaded, the "COVID-19Positive" subreddit had about 81,000 members and the "CoronavirusSurvivors" subreddit had about 1000 members.

The procedure to process and analyze social media data is described in Figure 1A. In total, 22,890 posts from 15,401 authors were collected from Reddit. Of the 15,401 authors, 11,900 (77.27%) generated only 1 post, which was inappropriate to examine longitudinal changes in COVID-19 symptoms. We did not consider them for further analyses.

To identify active authors' authentic COVID-19-related posts, we performed active learning. After the automated active learning procedure, manual inspection was performed to examine the reliability of post labeling (Figure 1A). Details are described in the Acquiring Pertinent Labels for Reddit Posts section.

Figure 1. Overview of social media data related to COVID-19 patient journey. (A) Social media data collection and analysis procedure. In total, 1634 posts from 290 active authors who continuously posted their disease progress were identified and used for further analyses. * and + indicate automated steps and steps requiring manual inspections, respectively. (B) Fraction of active authors, depending on posting duration. Posting duration is the time difference between the first and last COVID-19 posts from the same active author. The red-dashed line indicates the average posting duration. (C) Fraction of before-posts, depending on number of symptoms. (D) Fraction of after-posts, depending on the number of symptoms. The red-dashed line indicates the average number of symptoms mentioned in a post.



Acquiring Pertinent Labels for Reddit Posts

We observed some authors asking questions about COVID-19 or posting about symptoms, or about a family member, rather than themselves. It was apparent after reading many posts that not all authors were COVID-19 positive. This observation necessitated distinguishing between true patients with COVID-19 and authors who had not tested positive for COVID-19. Furthermore, we wanted to identify those authors that had discussed recovery from COVID-19 in their posts. We were also interested to know how different physical and psychological symptoms were discussed within Reddit posts.

We first generated an unlabeled data set of 4762 posts that were written by 734 authors who had posted at least 4 times in our COVID-19-related subreddits (Figure 1A). We designated 4 classes (ie, label types) that we needed for our analysis. For each post in our data set, we needed to check whether the post had (1) evidence that the author is/was COVID-19 positive (label: “posi”), (2) evidence that the author has recovered from COVID-19 (label: “reco”), (3) evidence of physiological symptoms (label: “physio”), and (4) evidence of psychological symptoms (label: “psycho”). More details of labeling are described in Multimedia Appendix 1.

To do this, we implemented an active learning method [12] to capture the different labels for Reddit posts in an automated and expedited manner. Active learning is a popular method to find relevant materials from within documents and is widely used in the e-discovery domain (eg, labeling documents as relevant or nonrelevant from a collection of legal documents or research papers). It also has been applied to identify the literature that is relevant to infection prevention and control of COVID-19 from a large biomedical corpus [13] and used to build a diagnostic method for COVID-19 [14].

Using active learning, we built a classifier for each of the label classes; the classifier was periodically updated with new evidence, as saved by a human assessor (Multimedia Appendix 1). This way, the classifier can capture newly found text features with each training iteration. The goal for the classifier is to find the next best-candidate Reddit post that can contain a label evidence string. The human assessor, when presented with the candidate post, assesses the post as nonrelevant (providing a

true-negative label) or highlights and saves an evidence string (providing a true-positive label). After retraining with a set of new labels, the classifier "relearns" which features in the text are likely to be found relevant and it presents the next best candidate to the user for assessment. For the human assessor, the likelihood of finding true-positive labels increases early in the label-gathering process, which helps with expediting labeling efforts when we are looking for true-positive labels on a budget.

A labeling interface was built to capture labels using our active learning method (Multimedia Appendix 1). An assessor is presented with 1 Reddit post at a time for 1 label class. The assessor can mark the post as nonrelevant for the particular post for the particular class or save (copy/paste) an evidence string that is representative of the label class description. The classifier for the respective label type is then retrained with the new evidence string. Then, all remaining unlabeled posts are scored by the classifier. The top-ranked unlabeled post is then presented to the assessor for judgement. Thus, after each judgement cycle, the classifier learns which text features are relevant to the assessor, and the method then presents the most likely relevant candidate for assessment to the user next. This way, the most relevant posts are labeled quickly, with the added advantage that assessment budgets and available time are utilized more efficiently.

We recruited 13 well-trained assessors for the labeling task; the number of assessors varied across label classes. The goal for assessors was to find and label as many label-relevant posts as fast as possible. To do this, we provided 2 hours of training sessions so that accessors could find relevant posts generated by reliable patients with COVID-19. Labeled data completed by accessors were then manually inspected by the authors in this study to confirm that labeling was done correctly (Multimedia Appendix 1). The assessors made 2785 judgements and found 1072 evidence strings across all classes (Multimedia Appendix 1).

Identifying Active Authors

We selected active authors who were infected by COVID-19 and described their experiences and COVID-19 symptoms across the entire patient journey: from the confirmation of COVID-19 infection to after recovery from COVID-19. To do this, we examined the median time duration between the first post and the last post that a given user generated (Multimedia Appendix 1), and selected the optimal number of posts that could represent the patient journey.

We found that symptoms usually take 5-6 days to appear after COVID-19 exposure (incubation period of COVID-19) [15]. We also estimated the recovery time after onset of the symptoms. We calculated the average recovery time (duration between the posts with the label "posi" and the posts with the label "reco") for the subset of users who had mention of recovery in their posts. For this calculation, first we removed the outliers that were considered as cases with recovery time higher than 2×SD. We obtained 15.7(SD 10.4) days as the average recovery time after testing positive. Since our subset was small (n=38 users) and there was high variation in the data, we decided to use the commonly accepted recovery time from the literature. Although there were various studies reporting different durations [5], 14 days was the duration we most often found in our search [16-19]. Therefore, we utilized 14 days as the recovery period after having tested positive for COVID-19, and we assumed that 20 (6+14) days of posting period could represent a typical patient's journey. In addition, 4 posts were used as a cut-off to find active authors since they were generated for 22 days, which was the closest period to our adopted notion of COVID-19 duration (20 days).

Identifying Symptoms of COVID-19

To identify the physical or psychological symptoms that were mentioned in Reddit posts, we applied 2 automated symptom extraction methods. Using the Amazon Comprehend Medical tool (Amazon Web Services), we extracted medical entities. The Amazon Comprehend Medical tool uses machine learning to extract health-related information from text automatically. For this study, we considered medical entities "symptoms" and "signs" as COVID-19 symptoms. In addition to the Amazon Comprehend Medical tool, we also built a model to identify medical entities using Scispacy (v.0.4.0). Scispacy is a Python package for handling scientific documents and extracting medical and clinical terminology [20]. We considered the medical entity "disease" as COVID-19 symptoms. From the performance evaluation of medical entity extraction models, we found that the models identified over 80% of COVID-19 symptoms correctly and reliably (Multimedia Appendix 1). The model achieved 87% precision, 83% recall, and an F1 score of 0.85. In total, 58 physical and 3 psychological symptoms were identified (Multimedia Appendix 1). The 3 psychological symptoms were "confusion or fluster," "depression or anxiety," and "mental discomfort or distress" (eg, foggy head and loss of consciousness).

In total, 1634 posts generated by 290 active authors mentioned at least 1 COVID-19 symptom (Figure 1A). Next, we determined when each post was generated: before or after recovery from COVID-19. We divided the posts into 2 groups, before-posts and after-posts, based on their posting time. Before-posts were written before COVID-19 recovery, and after-posts were written after recovery. Posts that were generated before recovery posts (label: "reco") were defined as before-posts. When authors only had positive posts (label: "posi"), posts generated from the date of the first positive post to the next 14 days were considered as before-posts based on the study that patients with COVID-19 take about 14 days to recover from the disease [16]. Remaining posts were defined as after-posts. We assumed the date of the first before-post was the moment users realized COVID-19 symptoms or confirmed their infection by COVID-19.

Since the number of before- and after-posts was different, identified COVID-19 symptoms were observed with different frequencies. For a fair comparison of symptom frequency between before and after COVID-19 recovery, we normalized the frequency of each symptom to 100 posts (ie, of 100 posts, how many mentioned a given symptom). Depending on this frequency, acute and chronic symptoms were determined. Acute symptoms developed rapidly and were mentioned more frequently in before-posts. Chronic symptoms developed gradually and were slow to resolve, remaining as sequelae, and

were mentioned more frequently after recovery from COVID-19 (after-posts).

Identifying Symptoms Mentioned Together

To identify symptoms that commonly appear together, we performed association rule analysis [21]. We measured support, which is defined as the proportion of posts in which a certain set of symptoms come together. We adopted the Apriori algorithm and followed a bottom-up approach that starts from every single symptom, and then symptom subsets are extended 1 item at a time. At each step, the group of candidates is tested, and the ones that include infrequent items are pruned.

Negation Analysis

To understand how patients perceive and respond to COVID-19 symptoms, negation analysis was performed using the Amazon Comprehend Medical negation model [22] and manual inspection (Figure 1A). Negation analysis showed whether a given symptom was denied (eg, "I have gotten no fever" or "I don't cough anymore"). Therefore, in our study, negation indicated that a given symptom was relieved or disappeared after recovery from COVID-19. After automatic identification of negated symptoms, we removed false positives through manual inspection. False positives are symptoms that present after COVID-19 recovery, but negation analysis detected them due to the sentence structure (eg, "I still have no smell and taste after I received a negative polymerase chain reaction [PCR] test"; "no smell and taste" was not negation. This symptom was still presented after recovery). Of 699 after-posts, negation was detected from 240 (34.3%) posts.

Statistical Analysis

To compare the duration of symptoms before and after COVID-19, Spearman rank correlation coefficient measurement was performed using the programming language Python (v.3.8.1) and SciPy package (v.1.6.2). $P<.05$ was considered statistically significant. For the visualization of analyses, the BPG library (v.6.0.1) in R was used [23].

Results

Result 1: Overview of Reddit COVID-19 Posts

To understand longitudinal changes in physical and psychological characteristics during the COVID-19 patient journey, we decided to collect patients' self-generated posts from Reddit. Reddit is a community-based online forum where patients can share their clinical journey, symptoms, and experiences from diagnosis to postrecovery. We identified 292 active authors who continuously and voluntarily discussed their physiological and psychological symptoms from the beginning of COVID-19 contraction to the after-recovery stage of COVID-19 (see the Methods section and Multimedia Appendix 1 for details). From the active learning experiment, we found that active authors generated 2213 posts that described their positive COVID-19 infection and the symptoms they had before and after recovery from COVID-19. On average, active authors generated 8 posts in 73 days (difference between the first before-post and the last after-post; Figure 1B). It is suggested that COVID-19 symptoms remain after recovery and present for about 2.5 months from diagnosis.

Next, we fed all 2213 posts into the biomedical named entity recognition (Bio-NER) program to find COVID-19 symptoms in a comprehensive manner. In total, 1634 (73.84%) posts mentioned at least 1 COVID-19 symptom (Figure 1A). From those, 935 (57.22%) posts were written from diagnosis (eg, confirmation of a positive test or notification of COVID-19 symptoms) to before recovery from COVID-19 (eg, received a negative test after the positive test). These were defined as before-posts. In addition, 699 (42.78%) posts were written after recovery (after-posts; see the Methods section for details). On average, each active author mentioned 9 symptoms in the before-post (Figure 1C) period and 6 symptoms in the after-post (Figure 1D) period.

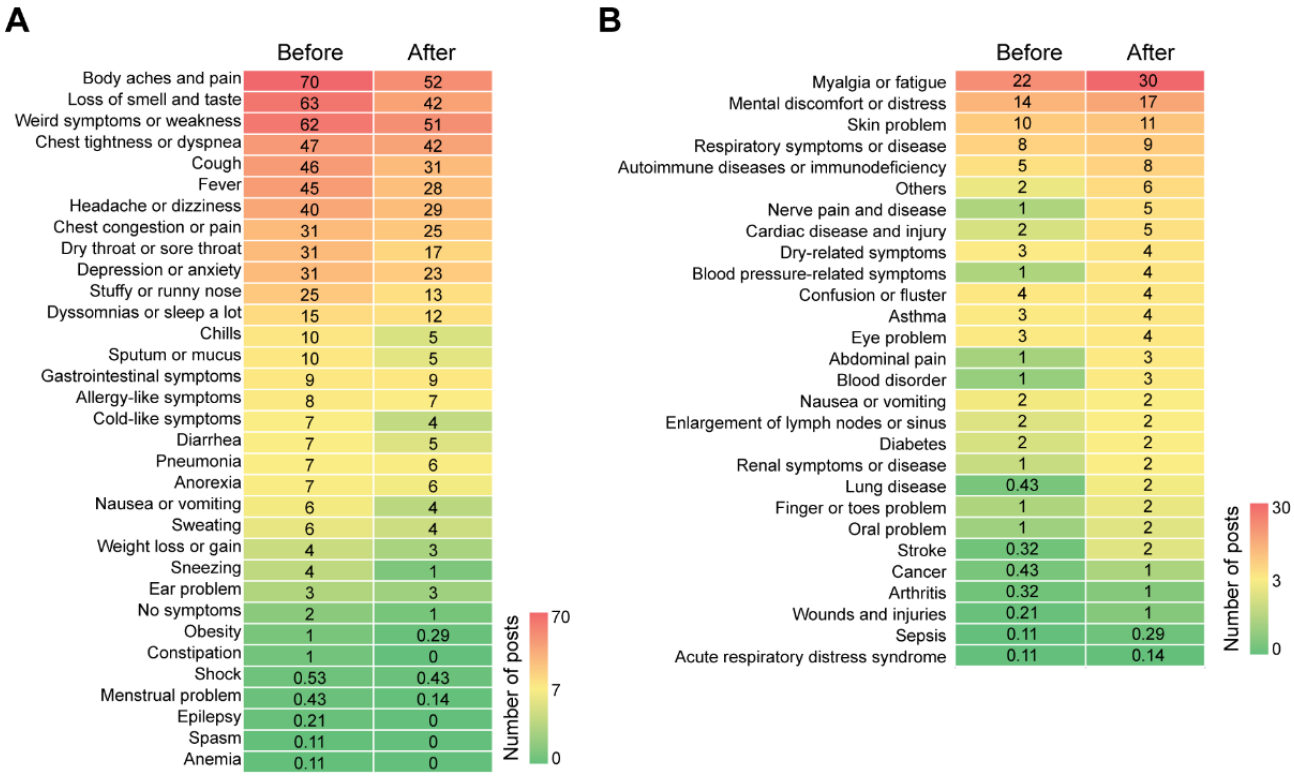
Result 2: COVID-19 Symptom Landscape in Social Media Data

To understand the dynamic development of physiological and psychological symptoms throughout the COVID-19 patient journey, we compared how often individual symptoms were mentioned in before- and after-posts. Of 61 symptoms, 33 (54%) were acute symptoms. They were mentioned more frequently before recovery from COVID-19 compared to after recovery. The most known COVID-19 symptoms, such as weakness, body aches, cough, fever, chest tightness, and loss of smell and taste, were mentioned frequently in before-posts. We observed that these symptoms were relieved or improved after recovery. For example, in 100 posts, loss of smell and taste was mentioned 63 times in before-posts. However, after recovery, it was 32.89% less frequently mentioned (42 times in after-posts). Fever, cough, and throat discomfort (dry or sore throat) were approximately 40% less frequently mentioned after recovery (Figure 2A). Chills (51.23% reduced), cold-like symptoms (42.38% reduced), nausea (40.04% reduced), and sputum (43.52% reduced) were also mentioned less after recovery. Negation analysis supported these findings. When negation was detected in a sentence that contained a symptom, we could assume that a symptom was relieved or disappeared. We performed negation analysis using after-posts and found that common symptoms, including fever, cough, or chest tightness, were denied (eg, "I have no fever or no cough") in after-posts. In addition, 5%-20% of after-posts clearly mentioned that these symptoms disappeared after recovery from COVID-19 infection (Multimedia Appendix 1). In addition, 4 (7%) extremely rare symptoms (epilepsy, spasm, constipation, and anemia; less than 1% of posts mentioned these symptoms) were only identified before the recovery period (Figure 2A).

Furthermore, 28 (46%) of 61 symptoms were mentioned more frequently after recovery from COVID-19 (chronic symptoms). We observed that patients with COVID-19 mainly complained of psychological symptoms during this time. Mental discomfort and distress, including brain fog, stress, and panic, were mentioned 18.27% more often, and confusion/fluster was mentioned 8.63% more after recovery. Constitutional symptoms, such as fatigue (25.96%), and physiological symptoms, including problems in toes or fingers (eg, tingly hands/feet and toe/finger rash, 41.26%), renal-related problems (eg, frequent

urination and kidney pain, 38.43%), and immunodeficiency (eg, autoimmune disease and immune system disorder, 37.94%), were also frequently mentioned after recovery (Figure 2B). These results suggested that well-known symptoms are likely to be acute symptoms and do not remain as postrecovery sequelae of COVID-19 infection. Rather, after recovery, patients experience mental discomfort and symptoms that are less common at or shortly following the time of diagnosis of infection and slow to resolve [6].

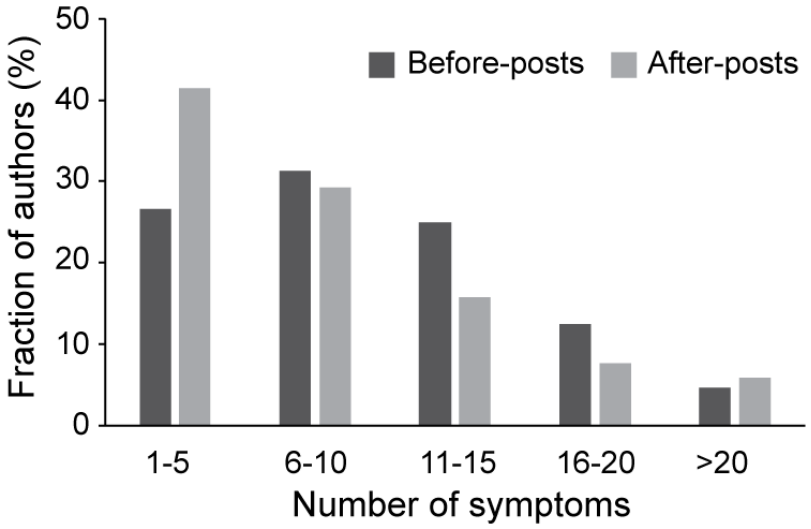
Figure 2. Symptom landscape in before- and after-posts. (A) There were 33 acute symptoms that were frequently mentioned before recovery from COVID-19. (B) There were 28 chronic symptoms that were frequently mentioned after recovery from COVID-19. The number indicates the incidence of a given symptom per 100 posts.



Result 3: Co-occurrence of COVID19 Symptoms Before and After Recovery

It has been shown that COVID-19 can cause multiple symptoms during early infection and progression [6]. To understand the dynamic co-occurrence of COVID-19 symptoms through the patient journey, we examined a set of symptoms that were mentioned together in a Reddit post. We found that each author mentioned more symptoms before recovery than after recovery (Figure 3). For example, of 256 authors who generated before-posts, 64 (25%) mentioned 11-15 symptoms, and this was 1.63 times higher compared to those who generated after-posts (n=222; 35 [15.8%] mentioned 11-15 symptoms). Meanwhile, 92 (41.4%) of 222 authors mentioned fewer symptoms (1-5 symptoms) in after-posts, which was 1.56 times higher (68/256, 26.6%) compared to before-posts. Next, we examined what symptom pairs were observed before and after recovery. In total, we identified 368 co-occurred symptom pairs. We observed that common and acute symptoms of COVID-19 were mentioned more frequently together before recovery. Chills with loss of smell and taste (2.51 times), cough (2.44 times), fever (2.39 times), chest tightness (2.39 times), or body aches (2.31 times) frequently co-occurred before recovery from COVID-19 compared to after. Meanwhile, 1 of the chronic symptoms, immunodeficiency (eg, autoimmune disease and immune system disorder), co-occurred with other chronic symptoms, such as mental discomfort/distress, myalgia/fatigue, and skin problems only after recovery from COVID-19 (Multimedia Appendix 1).

Figure 3. Number of COVID-19 symptoms in before- and after-posts. Dark- and light-gray bars indicate the fraction of authors who mentioned a given number of symptoms in before- and after-posts, respectively.



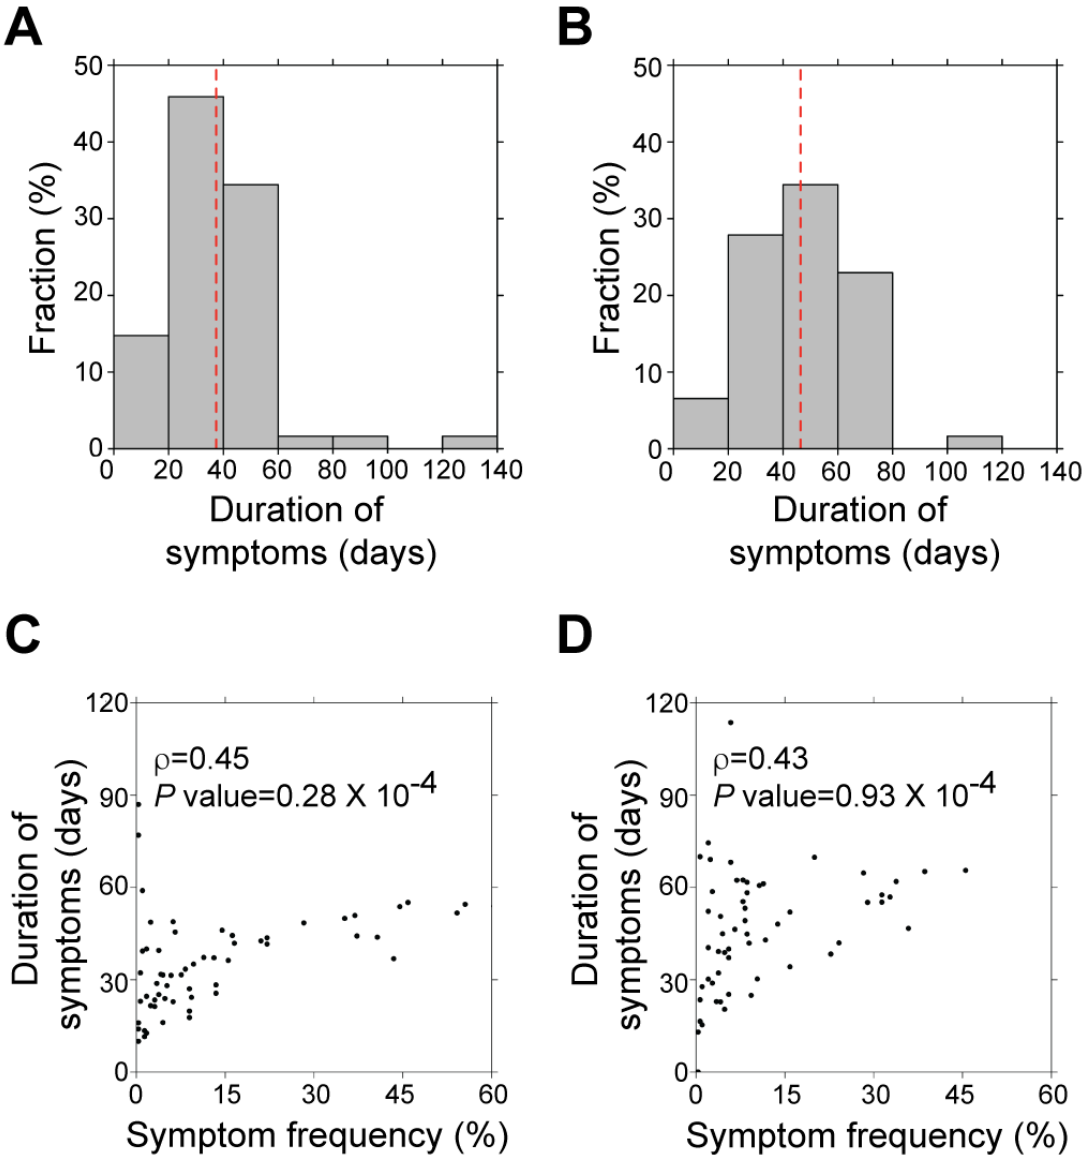
Result 4: Symptom Duration in Patients with COVID-19

Our data set was composed of posts that followed time courses, enabling us to perform temporal analyses to understand dynamic changes over time. We examined the duration of symptoms across the COVID-19 patient journey. On average, each symptom persisted for 83 days. On average, symptoms appeared 37 days before recovery (Figure 4A) and remained up to 46 days after recovery (Figure 4B). This implied that about a month was required to recover from the first COVID-19 symptom presentation and that symptoms remained for 1.5 months after recovery.

We found that there was a weak correlation between frequency of symptoms and symptom duration (ρ=0.45, P=.28×10^{-4}; Spearman correlation coefficient, Figure 4C). In before-posts, well-known acute COVID-19 symptoms (eg, weakness, body ache, cough, fever, dyspnea, and headache) were mentioned by at least 116 (40%) of 290 active authors. They appeared relatively early compared to other symptoms (appeared 54 days before recovery). Loss of smell and taste (37 days), nausea (37 days), and asthma (31 days) appeared about 1 month before recovery. Less common symptoms, including arthritis, epilepsy, and anemia (<1% of before-posts mentioned these) appeared around 10 days before recovery (Multimedia Appendix 1).

After recovery, we observed a similar trend. There was a weak but statistically significant positive correlation between frequency of symptoms and time of presentation (ρ=0.43, P=.93×10^{-4}; Spearman correlation coefficient, Figure 4D). Chronic symptoms (frequently observed after recovery), such as confusion, immunodeficiency, and fatigue, were slow to resolve. They remained for over 50 days after recovery. Mental discomfort/distress (38 days) also remained longer than other symptoms. Menstrual problems, shock, and acute respiratory distress–related symptoms (<1% of after-posts) remained about 15 days after recovery (Multimedia Appendix 1).

Figure 4. Duration of COVID-19 symptoms. (A) Duration of symptoms before recovery from COVID-19. (B) Duration of symptoms after recovery from COVID-19. The red-dashed line indicates the average symptom duration. The relationship between symptom duration and symptom occurrence (C) before and (D) after recovery from COVID-19.



Discussion

Principal Findings

Our longitudinal analysis based on social media data showed the dynamic evolution of symptoms through the COVID-19 patient journey. From this observational study, we identified acute and chronic symptoms that were frequently or specifically observed before and after recovery from COVID-19. Individual symptoms showed differing durations and recovery times. Social media data expanded our understanding of COVID-19 symptoms and their longitudinal changes through the patient journey.

From social media data, we observed that the most common COVID-19 symptoms (eg, fever, cough, and weakness) appeared earlier in patient journeys and were mentioned more frequently before recovery from COVID-19. These common COVID-19 symptoms were easily recognizable and evaluated by ordinary people without any screening tools. In addition, they were basic indicators used in clinical and medical research. Accumulated COVID-19 research defined them as well-characterized diagnostic indicators for COVID-19 [24]. Furthermore, at the beginning of the pandemic, national- or international-level awareness campaigns were conducted with a limited understanding of COVID-19 symptoms. We suggested that the public's basic awareness and easy recognition could disproportionate the prevalence of COVID-19 symptoms, increasing the reporting of common symptoms in social media before recovery from COVID-19.

Interestingly, common symptoms were relieved or disappeared after recovery from COVID-19 (acute symptoms) based on our analyses of symptom negation and the duration over this entire period. Fever was considered a beneficial response to infection. Increased temperature reduces pathogens' survival and increases mobilization of immune cells [25]. Cough is an intrinsic and protective reaction to many respiratory infections [26]. Skeletal muscle atrophy can be caused by an immune response, leading to weakness or body ache [27,28]. Taken together, we suspected that many common and acute symptoms are likely to be

associated with the initial immune response and are relieved as the initial immune response decreases over time after viral clearance.

Significance of Mining Social Media Data

Currently, there is limited information about nonhospitalized or initially asymptomatic patients with COVID-19 who have had persistent and chronic symptoms after their recovery. In addition, there is a lack of information about longitudinal changes in COVID-19 symptoms due to the limited methods or accessibility to identify COVID-19 survivors on a global level. Our study explored dynamic changes in COVID-19 symptoms throughout patient journeys using social media data. Although social media may lack some depth of patient information, it provides an effective method of collecting a wide breadth of data. Social media data can be easily gathered across the world 24 hours a day, without the need for a clinician visit, and is an extremely efficient method [29] for rapidly disseminating new knowledge related to COVID-19 [30]. Indeed, we observed more than 60 symptoms that were extracted from the Reddit posts, including all the symptoms of COVID-19 suggested by the Centers for Disease Control and Prevention (CDC) [31]. This number of symptoms observed in social media was about 2 times higher than the number of symptoms mentioned in the biomedical literature (34 symptoms), which was published by clinical institutes [6]. Furthermore, tracking COVID-19 symptoms in social media data over time gave us novel insights to understand the full clinical spectrum of symptoms and the patient journey. Social media has also been used to predict COVID-19 waves [32], forecast the number of cases [33], and develop crisis management strategies [34]. Taken together, social media data could be useful for understanding the symptoms and epidemiology of novel diseases, such as COVID-19. Accumulated knowledge and techniques that utilize social media data would be rapidly applied for future pandemic preparedness and response in an effective manner.

Limitations and Future Work

The presence and rapid diffusion of misinformation in online communities is a growing concern for patients and health care providers [35]. We suspected that similar experiences and common interests among patients would make strong emotional connections in online disease communities, enabling us to extract relatively reliable information compared to nondisease communities. It has been shown that online disease communities are mainly composed of patients, family members of patients, and caregivers who are in similar situations and want to obtain accurate information by posting their real experience-based inquiries online [36]. In addition, patients are more likely to express emotions and share aspects of their life in an online community that they would not share face-to-face [37]. Such similar experiences, common interests, emotional connections, and empathy could develop and operate patient empowerment by creating and disseminating relevant information that would help them to understand their health conditions and to receive psychological support. Furthermore, disease communities develop practices that improve the quality of the information that peers exchange [38]. Since disease communities deal with life-related matters, peer interactions in online disease communities have found low levels of inaccuracy [39], and most false or misleading statements are rapidly corrected by participants [40]. In addition to patients' honest voluntary participation, we adopted an active learning method by collecting manually labeled Reddit posts and performed second-round manual inspections of labeled posts to improve the authenticity of the social media data. We believe these efforts have greatly improved the reliability and authenticity of our study.

It could be possible that all the symptoms extracted from Reddit would not cover the entire literature of COVID-19 symptoms or would not necessarily be COVID-19 symptoms. Moreover, there is an inherent uncertainty in social media analysis about the accuracy of temporal directions and the potential delays that might occur between the actual event and the time of posting, which is challenging to detect. A closely related limitation is our assumption of a duration of 20 days for the COVID-19 patient journey, which is derived through the available data (Reddit posts).

Natural language processing (NLP) could assist in identifying the temporal mentions and adjusting the outcomes. We might be able to improve our recovery time estimates using NLP, helping to improve temporal accuracy. As we work beyond social media surveillance and integrate with other data sets in the future, we are likely to find better alignment regarding the patient journey and related timelines.

We believe that the integration of various social media data sets and the accumulation of data or systematic surveys of COVID-19 survivors as well as customized machine learning algorithms to capture COVID-19 symptoms would help to decide which symptoms are manifestations of COVID-19 infection and provide new and untapped insights into understanding the longitudinal evolution of symptoms throughout the entire COVID-19 patient journey. This also could be a novel means of assessing the fraction of COVID-19 survivors with persistent symptoms.

Conclusion

In this observational study, we demonstrated the extensive variability of physiological and psychological impacts of COVID-19 infection and their variability during the acute infection and recovery phases of illness. We also demonstrated the usefulness of gathering social media data as an effective and alternative way to understanding the patient journey from diagnosis through recovery. Our findings show the practicality and feasibility of employing social media data for investigating disease states and understanding the evolution of physiological and psychological characteristics of disease over time. These practices could be incorporated into routine procedures for COVID-19 patient care, providing appropriate treatment and long-term care after recovery from COVID-19.

Acknowledgments

We would like to thank all members of the Applied Sciences team at Klick Inc for their helpful advice and assistance. JJ and GB designed the study. JJ, GB, and YF collected the data. JJ and SS analyzed and interpreted the data. JJ wrote the manuscript. Especially, we thank Jana Foley, Tae Wook Kang, Kinzie Earle, Nicholas Terpstra, Gai Paupaw, Paul Bourke, Aida Cagula, Dallas Gao, Sean Brice, Louisana Baldoz, Vlada Ross, Dave Coley, and Gaurav Baruah for assessing posts and assigning labels. All authors in this study revised the manuscript and contributed to the final review and editing and have approved the final manuscript. This research was internally funded and received no specific grant from any funding agency in the public, commercial, or not-for-profit sector.

Conflicts of Interest

None declared.

Abstract

Background: The recent introduction of COVID-19 certificates in several countries, including the introduction of the European green pass, has been met with protests and concerns by a fraction of the population. In Italy, the green pass has been used as a nudging measure to incentivize vaccinations because a valid green pass is needed to enter restaurants, bars, museums, or stadiums. As of December 2021, a valid green pass can be obtained by being fully vaccinated with an approved vaccine, recovered from COVID-19, or tested. However, a green pass obtained with a test has a short validity (48 hours for the rapid test, 72 hours for the polymerase chain reaction test) and does not allow access to several indoor public places.

Objective: This study aims to understand and describe the concerns of individuals opposed to the green pass in Italy, the main arguments of their discussions, and their characterization.

Methods: We collected data from Telegram chats and analyzed the arguments and concerns that were raised by the users by using a mixed methods approach.

Results: Most individuals opposing the green pass share antivaccine views, but doubts and concerns about vaccines are generally not among the arguments raised to oppose the green pass. Instead, the discussion revolves around the legal aspects and the definition of personal freedom. We explain the differences and similarities between antivaccine and anti–green pass discourses, and we discuss the ethical ramifications of our research, focusing on the use of Telegram chats as a social listening tool for public health.

Conclusions: A large portion of individuals opposed to the green pass share antivaccine views. We suggest public health and political institutions to provide a legal explanation and a context for the use of the green pass, as well as to continue focusing on vaccine communication to inform vaccine-hesitant individuals. Further work is needed to define a consensual ethical framework for social listening for public health.

Introduction

Background

Since the beginning of large-scale vaccination campaigns against COVID-19, many countries have had to deal with the issue of vaccine hesitancy [1]. Already defined by the World Health Organization in 2019 as one of the major threats to global health [2], vaccine hesitancy has become even more relevant in the context of the COVID-19 pandemic [3]. In Israel, the first country that was able to ensure sufficient supplies of the Pfizer-BioNTech vaccine, the Ministry of Health swiftly started a vaccination campaign in late 2020. However, after covering health care staff, older adults, and vulnerable patients, the campaign reached a stagnation phase, as a relevant percentage of individuals were not willing to get vaccinated. After

considering other forms of incentives [4], the Israeli Ministry of Health developed a new ad hoc strategy to increase the vaccination rate. According to this plan, vaccinated people would receive a special document that would allow them access to social and cultural events, national and international mobility, and exemption from quarantine. The declared aim of this document or the "green passport" was to encourage citizens to receive COVID-19 vaccinations while allowing some reopening of the economy [5]. The proposal for the Israeli green passport was passed on December 14, 2020 [4]; on January 27, 2021, the eHealth network of the European Commission started to develop a set of guidelines in order to implement a "EU Digital COVID certificate" system in Europe. On June 1, 2021, the European Union Gateway, that is, the backbone interconnecting national green pass systems in the European Union, went live [6]. On July 23, 2021 the Italian government passed Decree-Law 105, regulating the use of the green pass [7], already recognized and defined on April 22, 2021 by Decree-Law 52, article 9 [8].

Compared to other nudging strategies to tackle vaccine hesitancy, the green pass looks like a promising concept, as it incentivizes people to get vaccinated without imposing a decision; however, already in its first implementation in Israel, it generated some debate as it can be considered as a tool for discrimination based on someone's vaccination status. Another argument often used by green pass critics regards privacy; when showing their green pass, people are de facto obliged to disclose health information—thus, their sensitive information—to third parties [5]. The adoption of the green pass strategy in Europe caused the very same debate and the very same arguments already seen in Israel. In many European countries, opposition movements started to form and grow, discussing the use of the green pass and organizing protests, sit-ins, and rallies [9]. In a time of physical distancing due to containment measures, many of these discussions were taking place online on social media and communication platforms. As popular social media platforms increasingly corrected their policies to decrease the flow of misinformation [10,11], people and organizations holding critical views about the green pass started to deplatform toward alternative social media channels, a phenomenon already seen and studied, mostly regarding the far-right and conservative world [12]. Notably, one of the most prominent destinations for deplatformed individuals and organizations has been Telegram.

Over the last few years, Telegram has become one of the most prominent instant messaging services. This success is due to a combination of 2 factors: on the one hand, end-to-end encryption [13] and an infrastructure distributed over several jurisdictions [14] makes it rather difficult to extract data from the system [15]. As stated on the official Telegram's frequently asked questions, to this day, Telegram has "disclosed 0 bytes of user data to third parties, including governments" [14]. On the other hand, Telegram's services go way beyond conventional instant messaging services: Telegram groups allow a maximum of 200,000 members and include advanced features such as unified history, instant search, replies, permissions, and moderation tools, making them outstanding tools for many-to-many discussions. In parallel, Telegram broadcast channels allow an unlimited number of followers, making them an appealing alternative to Twitter for one-to-many communication [14,16]. This combination of publicity, mobilization capabilities, and privacy provides a solution to the so-called "terrorists' dilemma," that is, the balancing security and outreach in choosing a web-based communication platform [17]. The use of Telegram among "no-green-pass groups" in Italy started to grow rapidly already in July 2021; as soon as the green pass was introduced, groups and individuals offering forged green passes for purchase started to exist [18] as well as groups organizing protests and rallies against the green pass [19].

Aims

This study has 2 aims: (1) to study the discourse revolving around the opposition to the green pass and its use in Telegram chats by no-green-pass groups in Italy, with a focus on groups used by university students; and (2) to detail a novel approach to online social listening by using a combination of quantitative and qualitative approaches and to question its ethical aspects.

Methods

Ethical and Legal Considerations

As this study did not fall under the scope of the Swiss Human Research Act [20], authorization from the Cantonal Ethics Committee was not required. The messages analyzed in this study were retrieved from public chats using the "download history" function of Telegram Desktop. This qualifies the data as publicly available. According to the General Data Protection Regulation (GDPR) [21] article 6.1, data processing without explicit consent of data subjects is possible when protecting the interest of the data subject and when "necessary for the performance of a task carried out in the public interest." Research falls in the category of public interest, but this criterion being very broad, it is important to weigh the public interest and benefits to the risk for the individuals, especially because the data set might contain special categories of personal data (ie, health, politics, or worldview-related data). Generally, the information detailed in article 14 of the GDPR should be provided to the data subjects individually, although this could be considered as a disproportionate effort, given the number of users involved in this study. However, one could argue that the necessary information could be provided in a general way through posting into those chats. Since either way this transparency might result in both a higher risk of reidentification and a serious impairment to the pursue of research, it could be argued that is against the public interest and should therefore be omitted. Articles 14.5 and 89 of the GDPR exempt from the provision of information to study participants where and insofar it would involve a disproportionate effort or render impossible or seriously impair the achievement of the objectives (ie, the research goals in the public interest). As specified in article 14.5.b, we took appropriate measures to protect the privacy of data subjects whose messages are included in our study: the JSON files retrieved from Telegram have been completely anonymized (removal of personal names and toponyms from the message text) and pseudonymized (replacement of the user ID with a pseudonym), the original data set has been destroyed, the analysis has been conducted on the anonymized version, the anonymized data set will be available upon request, and as

the search of segments of text in the original chat would allow reidentification, the links to the chats will not be disclosed.

Data Collection

Data were collected from 2 groups of chats. The first comprised no-green-pass groups of Italian universities (one in the north, one in the center, and one in the south) and generic no-green-pass groups. The second, our negative control, comprised groups discussing topics unrelated to COVID-19 or to the green pass, such as video games, parrot breeding, and other general topics. The selection of these control chats followed 3 criteria: the chats were active (at least 10 messages sent in the last week), they counted at least 200 users, and the main language used was Italian. We identified relevant chats and downloaded the message history as JSON files. We downloaded the JSON files containing the entire history of the said groups on September 9, 2021. The data collection is described in Multimedia Appendix 1.

Data were downloaded directly using the function "export chat history" of Telegram's official desktop client. For this study, we downloaded only textual data. We parsed the JSON files into Pandas data frames. To protect the privacy of the users while still maintaining the possibility to track conversations in qualitative analysis, we combined anonymization and pseudonymization. Anonymization was performed by removing metadata from messages and by removing personal names and replacing them with [name] [22]. Similarly, every toponym was replaced with [place] [23]. Direct mentions of users in the text (eg, @thisuser) were searched and replaced with [username]. Surnames were not removed from messages. Since the chats were in an informal context, people did not refer to other members of the chat or to themselves using surnames. However, surnames are often used to refer to public figures or sources of information and thus represent a valuable component for the analysis.

Analysis

For this project, first, we used a mixed methods approach, which involves the use of qualitative and quantitative data. Second, for the quantitative analysis, with a top-down approach, we defined a series of dictionaries relevant for the purpose of this study—each one containing regular expressions that belong to the same concept. Regex (Regular Expressions) allows the definition of fairly complex rules, able to reduce ambiguity, and capture precise concepts. As an example, the rule (tesser.\sverd.?|pass\sverd.?|certifica\w*\sverd.?) will fire on "tessera verde" (green pass) or "tessere verdi" (green passes) or "pass verde" (green pass) or "certificato verde" (green certificate) but not on "casa verde" (green house) or "verderame" (verdigris) or "tessera del cinema" (cinema card). The autocoding has a weight system: if only one rule from the dictionary fires, the autocode is assigned a weight of 1, if 2 rules fire, the weight will be 2 and so on. Autocodes can then be used to measure the prevalence of topics through the corpus to segment the quantitative analyses or as a starting point for the qualitative work. Third, we extracted the lemmas used in the corpus by using the Python package "spaCy" and its pretrained model for Italian [24]. This was performed on a large bag of words including every message in the corpus and by dividing messages by code. In the final step of the quantitative analysis, we performed a sentiment analysis [25], both on the entire corpus and on messages divided by code. The sentiment analysis was performed using the Python package "feel-it" [26], through which we calculated the probability of positive or negative sentiment for each message. We developed the analysis pipeline in Python; the code is structured in a JupyterLab notebook, available through Zenodo [27].

For the qualitative analysis, we generated a structured text file, annotated with pseudonymized speakers and codes resulting from the autocoding system. The file was then imported into MAXQDA for thematic analysis. The development of the regular expressions used for autocoding has been an iterative process. We ran the code several times, exploring the results, noting the gaps, and fine-tuning the regular expressions. The thematic analysis has been conducted by native Italian speakers on messages written in Italian; the text has been translated by the authors to be comprehensible to a wider audience but still as close as possible to the original. The original quotes in Italian and the categories/topics included in the analysis are provided as supplementary material (Multimedia Appendix 2 and Multimedia Appendix 3).

Results

Quantitative Results

Lemmas, Terms, and Rules: the No-Green-Pass Discourse Encompasses Legal Aspects, Actions, and Vaccine Skepticism

To understand the interests of individuals critical of the green pass, their arguments, and the opinions that shape their position in the debate, we quantified and analyzed the most frequently used lemmas in control chats (Multimedia Appendix 4)—discussing issues not related to green pass, vaccines, or COVID-19, and in chats focused on green pass opposition (Multimedia Appendix 5). As a positive control, we checked whether the lemmas "green" and "pass" were found to be among the most frequently used in green pass opposition chats when compared with control chats. As expected, "green" was the second most frequently used lemma in green pass opposition chats, and "pass" was the fourth most frequently used lemma (frequencies 9.2% and 7.5%, respectively). However, these lemmas were barely used in control chats (frequency of 0.02% for both lemmas). As expected, the average frequency of the 2 lemmas combined ("green" + "pass") in green pass opposition chats was significantly higher than that in control chats (Figure 1A). Among the 20 most used lemmas in either control or green pass opposition chats, we identified 2 relevant categories of terms: legal terms and action terms. Legal terms included law (*legge*) and article (*articolo*). These terms were highly overrepresented in green pass opposition chats when compared with those in control chats (Figure 1B). Action lemmas included can (*potere*), must (*dovere*), want (*volere*), know (*sapere*), ask (*chiedere*), do (*fare*), say (*dire*), speak (*parlare*), take (*prendere*), put (*mettere*), use (*utilizzare*), come and go (*andare* and *venire*), and write (*scrivere*). Among these, we identified 3 lemmas to be relevant and underrepresented in green pass opposition chats: take (*prendere*), put (*mettere*), and use (*utilizzare*).

Overrepresented lemmas were can (*potere*), ask (*chiedere*), and speak (*parlare*) (Figure 1C). Besides these lemmas, we were interested in understanding which rules were the most relevant in control chats, and, in addition to the rule "green pass," we focused on the rules "COVID-19" and "vaccine" and "freedom." With this analysis, we wanted to understand whether the legal lemmas that were overrepresented in green pass opposition chats were linked to a pronounced discussion about personal freedom, in connection with the discussion about the green pass and COVID-19 vaccines. All the abovementioned rules were represented with a higher frequency in green pass opposition chats when compared with those in control chats, and these differences were statistically significant (Figure 2). As expected, the rule for "green pass" fired very frequently in green pass opposition chats and more frequently than the rules "COVID-19" and "freedom." Surprisingly, however, the rule "vaccine" was the most frequently used in green pass opposition chats, more so than the rule "green pass," indicating that among green pass critics, even when the discussion revolves around legal aspects connected to personal freedom, skepticism toward vaccines likely remains as the predominant reason to oppose the green pass.

Figure 1. (A) Average lemma frequency (in percentage) in control versus green pass opposition chats. Average lemma frequency (in percentage) for green pass in control (grey bar) versus green pass opposition chats (black bar). (B) Average lemma frequency (in percentage) for legal terms in control chats (grey bars) when compared with green pass opposition chats (black bars), extracted from the 20 most frequently used words in the green pass opposition chats. (C) Average lemma frequency (in percentage) for action terms in control (grey bars) versus green pass opposition chats (black bars), extracted from the 20 most frequently used words in both control and green pass opposition chats. The green background highlights the most relevant action terms that are overrepresented in the green pass opposition chats, whereas the grey background highlights the most relevant action terms that are overrepresented in control chats. **P*<.05, *t* test. Error bars represent standard error of the mean.

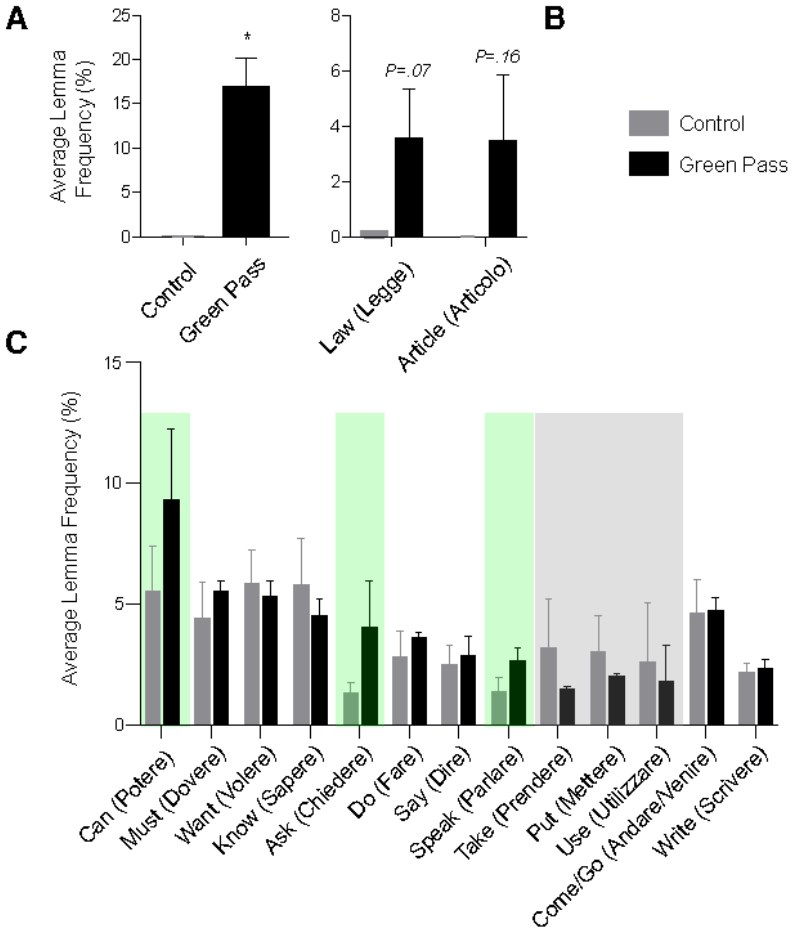

Figure 2. Average rule frequency (in percentage) in control versus green pass opposition chats. Average rule frequency for terms grouped under the rules “COVID-19,” “freedom,” “green pass,” and “vaccine” in control (grey bars) versus green pass opposition chats (black bars). *P<.05; ***P<.001, t test. Error bars represent standard error of the mean.

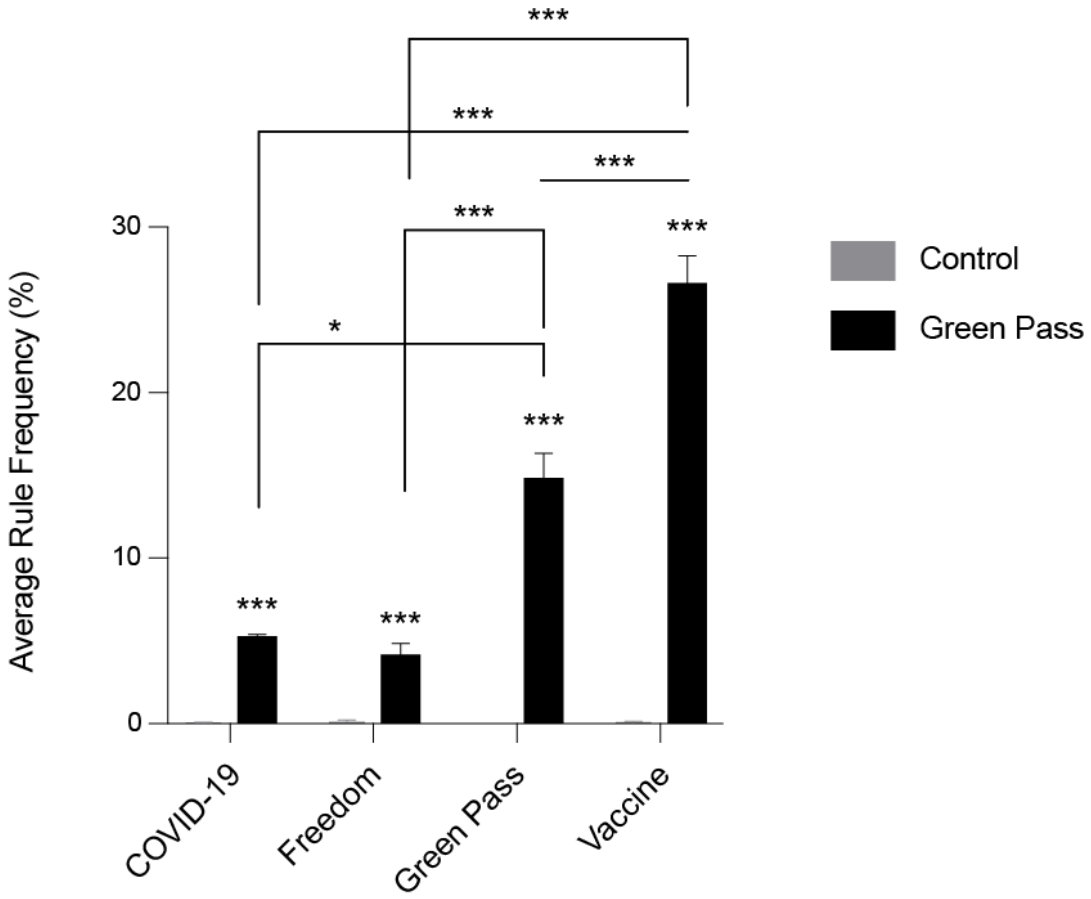
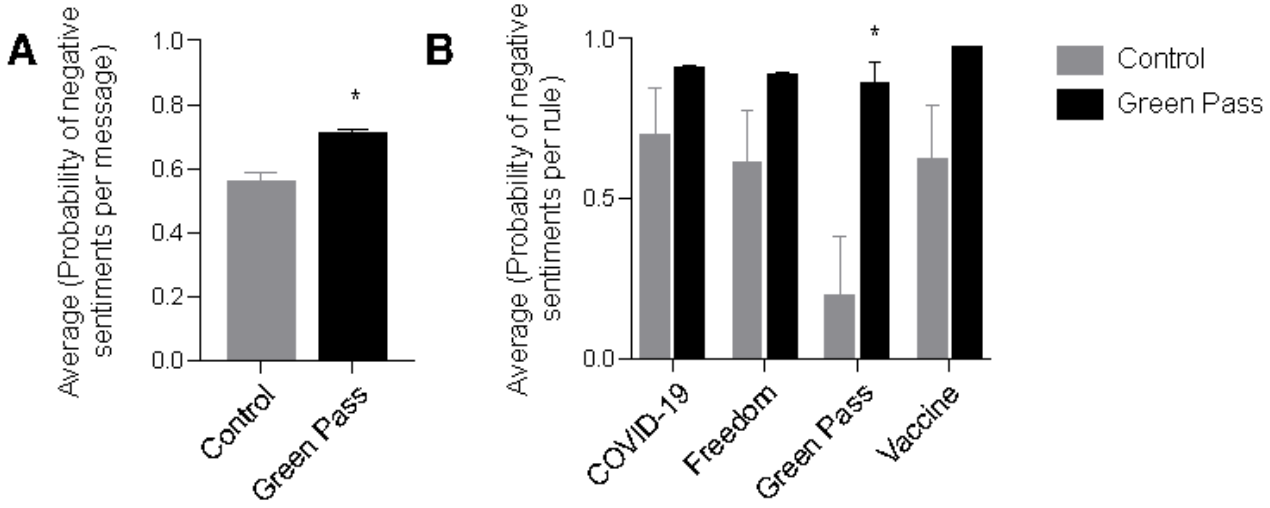


“No-Green-Pass” Individuals Have a Negative Sentiment Toward Green Pass and Vaccines

After having identified the predominant themes associated with anti–green pass discourse, we analyzed whether such a discourse is associated with a higher probability of negative sentiments. By defining the likelihood of negative sentiment for each message, we averaged the sentiment for each chat and finally across chats within the same category. As expected, the average likelihood of negative sentiment was significantly higher in green pass opposition chats when compared to that in control chats, with a probability of 0.70 and 0.55, respectively (Figure 3A). In addition, we calculated the average probability of negative sentiment associated with the rules “COVID-19,” “freedom,” “green pass,” “vaccine,” and determined that for all these rules, messages depicting negativity were overrepresented in green pass opposition chats when compared with those in control chats (Figure 3B). This effect was significant for the rule “green pass,” which can serve as a positive control, indicating that green pass critics are, in fact, assessing the issue with negative sentiment, when compared with people that do not necessarily oppose its introduction and use. Of particular interest, messages related to the rule "vaccine" had a 96.26% probability to depict negative sentiment, a particularly high probability also when compared with negativity for "COVID-19", "freedom", and "green pass" in green pass opposition chats (90%, 88%, and 85%, respectively), thus providing strength to the hypothesis that vaccine skepticism is the primary reason to oppose the green pass.

Figure 3. Sentiment analysis in control versus green pass opposition chats. Average probability of negative sentiment in messages published in control (grey bar) versus green pass opposition (black bar) chats. (A) Average probability of negative sentiment per rule in control (grey bars) versus green pass opposition chats (black bars). The following rules are taken into consideration: "COVID-19," "Freedom," "Green Pass," and "Vaccine" (B) 0 indicates the maximum likelihood for an average message to display positive sentiment, whereas 1 indicates the maximum likelihood for an average message to display negative sentiment. *P<.05, t test. Error bars represent standard error of the mean.



Rules and Lemma Frequency: Interplay Between Vaccines and Green Pass

To further understand the relationship among the topics "green pass," "vaccine," "freedom," and "COVID-19," we analyzed the most frequently used lemmas when the discussion was on one of such topics (as determined using the associated rules). For the rule "COVID-19," the lemmas "green," pass," and "vaccine" were among the most used (Figure S1A in Multimedia Appendix 6). For the rule "freedom," as expected, lemmas associated with legal terms were overrepresented as well as "green" and "pass" (Figure S1B in Multimedia Appendix 6). For the term "green pass," we could not identify "vaccine" among the most relevant and used lemmas, although we identified lemmas associated with legal terms, including "freedom," "law," "article," "can," and "must" (Figure S1C in Multimedia Appendix 6). Instead, for the rule "vaccine," we could identify "green" and "pass" among the most relevant and significant lemmas (Figure S1D in Multimedia Appendix 6). As our previous results indicate, although our analysis was focused on green pass opposition chats, vaccines constituted a widely discussed topic, which even dominated the discussion about the green pass. In line with our previous observations, here we show that green pass discussion takes place when vaccines are being discussed but not vice versa. This might suggest that green pass critics tend to share antivaccine views but do not wish their argumentations against the green pass to revolve around their antivaccine views. Rather, they prefer to support their position by discussing limitations to personal freedom and advancing legal considerations.

Qualitative Results

Green Pass and Vaccines

The qualitative analysis supports the findings described in our quantitative analysis. Although our analysis was focused on chats discussing the green pass, users often started debating about related topics, including the risk-benefit profile of COVID-19 vaccines, their efficacy, and their use. Of note, moderators often asked participants to stay on topic and avoid discussing these parallel issues. There were 2 main reasons: one was to avoid conflict, as a (small) fraction of individuals who positioned themselves as opposed to the green pass were for vaccinations; the other was to avoid floods of misinformation, which could discredit what the moderators perceived as a much needed debate. The quotes below are shown by the subcorpus (university group or generic group, and the position refers to the line in the subcorpus).

> *…On the other hand, it is a big mistake to take a stance on vaccines. Those who want to do so should do so. The point is only to be against this limitation of freedom and many vaccinated people are against the green pass. Do not introduce divisive or extremist elements that vote the initiative down.* [University, south, position 742]

Users themselves are very aware of how hard it is to discuss the green pass without discussing the reasons for which it is needed.

> *…how can one ignore the vaccine issue if it is literally the main option for getting a pass?* [University, north, position 6693]

As stated above and as noted in the quantitative analysis, these no-green-pass chats have de facto been a proxy to discuss vaccines. Users know the green pass was introduced as a nudging measure to avoid mandatory vaccination. Nevertheless, they do not perceive this strategy in a positive way. Even if there are other ways to receive a valid green pass (ie, recovery from COVID-19 or testing), vaccination is the most obvious and less burdensome one. Users perceive this as a cunning imposition, which possibly makes them even angrier than mandated vaccines.

> *…I am against the green pass because I see it as a coercive and hypocritical tool put in place by the government because if they saw the vaccine as a safe*

> *way, they should have the consistency to make it compulsory and instead they don't bother to do so.* [University, south, position 1807]

> *…the green pass is a way of circumventing compulsory vaccination. The green pass is an "incentive," said to be very soft, but in fact it is a compulsory requirement.* [University, center, position 14716-14718]

Even though, as discussed above, moderators would prefer to disentangle the discussion about the green pass from the topic of vaccinations, pointing out that even someone who is vaccinated could hold no-green-pass positions, most of the users shared common critical beliefs about vaccines.

> *…It is becoming increasingly clear from the scientific literature that (1) There are very effective treatments for COVID that indicate that vaccines are not at all essential. (2) Vaccines often have serious short-, medium- and long-term side effects, there is a well-founded fear that they could induce serious pathologies (tumors, autoimmune and degenerative diseases, sterility...) and they are still at the experimental stage. (3) Vaccines facilitate the development of variants, many of which are particularly virulent, and should not be carried out during epidemics, let alone pandemics. (4) Vaccines do not absolutely protect against COVID as they are said to do, ie, those vaccinated may become infected and may in turn infect others... so they should not have a Green pass unless they too are swabbed.* [University, center, position 3572-3579]

Users are especially afraid of the possible side effects. This narrative proposes that the vaccine is worse than the disease it is meant to prevent.

> *…who can guarantee that I will not have serious effects as a result of the vaccine, which could harm my future? Who will compensate me for any damage?* [University, north, position 25293-25294]

> *…Statistics show that the number of deaths due to COVID is the same as the number of deaths due to the vaccine, only that the number of deaths due to COVID is much overestimated (the number also includes deaths due to other causes but catalogued as COVID because they are positive to the test), while deaths due to the vaccine (not to mention cases of serious adverse effects) are much underestimated because only passive surveillance is done, and poorly.* [University, center, position 15682-15688]

Moreover, according to several users, there is no evidence that vaccines work. They do not prevent the spread of the disease and are less effective and more burdensome than alternative therapies to reduce the symptoms (the most quoted are hydroxychloroquine, cortisone, heparin, ivermectin, nonsteroidal anti-inflammatory drug, and hyperimmune plasma transfusions).

> *…We must rebel, this vaccine is a gene therapy with no guarantee that it will work. Vaccinated people are just as infectious as unvaccinated people, it is clear that this vaccine does not protect against COVID.* [University, north, position 2612]

> *…It is written in all official documents of the pharmaceutical companies and the WHO that there is no evidence that vaccination will stop the spread of the virus.* [University, north, position 3385]

Finally, some users suggested that vaccines could be part of a bigger scheme, again orchestrated by governments and covert powers, possibly aiming to reduce the world's population.

> *…Overpopulation, they have been saying this for years, and the Vax in my opinion serves to solve that problem, not COVID.* [University, south, position 2343]

> *…Their aim is to manipulate human beings by injecting them with a serum containing graphene, which can react with certain frequencies and modify the behavior of cells. By changing the behavior of cells, you can change the behavior of human beings.* [Generic, position 72471]

Beyond Vaccines: Green Pass, Legal Aspects, and Personal Freedom

Despite vaccines being the predominant topic in these chats, the majority of individuals did not make use of arguments related to vaccines, including conspiracy theories about vaccines, to justify their opposition to the green pass. Rather, they claimed the green pass was an illegal measure and it is discriminatory.

> *…it is clear that the green pass is an instrument of political discrimination that has no relation to the actual health status.* [University, center, position 3572-3579]

> *…The green pass is clearly unconstitutional and discriminatory in nature and is a purely political instrument as it has no scientific basis; the report linked before is very clear about it, then they do not make it mandatory by law otherwise they would be obliged to compensate those who died of the vaccine.* [University, center, position 7520-7522]

In some circumstances, users alluded to conspiracy theories according to which the green pass is an element of a bigger plan put in place either by governments or by covert powers to achieve other ends, usually the institution of a totalitarian regime.

> *…Do you still have to realize that even if the Regime decides to withdraw the COVID PASS, to let you go back to work, you have already become citizens of a totalitarian Regime? Citizens of a lousy Regime based on lies, on the progressive elimination of freedoms, on the violent suppression of dissent?* [Generic, position 2127]

Many users believed the green pass was a serious limitation of personal freedom. This argument was developed following 3 main threads in order of importance: jurisprudential, consequentialist, and deontological. On the jurisprudential side, users appeal mostly to the Italian constitution (articles 13 and

120), to law 196/2003 (personal data protection code), and to the Oviedo convention.

> *…the "green pass" cannot be checked because it is discriminatory, prejudicial to privacy and violates the following articles of law: - Art. 187 of the TULPS Regulation: a commercial operator is obliged to welcome in his business any person, without discrimination, under penalty of a fine up to €3000,00.- Privacy Law: no one can force us to provide information about our health conditions.- Art. 120 Italian Constitution: no one can limit the freedom of movement of the individual in the territory of the Italian republic. - Art. 13 Italian Constitution: no one may restrict personal freedom without a provision of the Judicial Authority on facts concerning the individual.* [Generic, position 3448]

> *…Add that we will respect all the anti-COVID security measures (social distancing, hygiene, mask). With regard to the reference to laws and treaties, don't we want to mention the convention on human rights, the Oviedo treaty and the Supreme Court ruling stating that the health of the individual cannot be sacrificed for the sake of collective health? don't we want to mention the principle of self-determination?* [University, center, position 395-397]

On the consequentialist side, users tend to fall into a slippery slope fallacy. In their view, the green pass system will necessarily lead to a system of capillary social control, repression of dissent, and loss of critical thinking capabilities—a system that is clearly undesirable and immoral; therefore, the green pass is undesirable and immoral as well.

> *…Look at the Chinese social score system to understand the crazy direction of these actions, typical of dictatorial systems and not of advanced democracies.* [University, south, position 3755]

> *…By now I think these people are lobotomized and probably don't even know the word FREEDOM.* [University, south, position 1255]

A minority of users tried to build a deontological argument, balancing values such as freedom and life. Their conclusion was that life and freedom have equal importance; hence, it is unjust to protect life by limiting freedom.

> *…If the answer to the question is that life is more important than liberty, then all the liberticidal laws made so far are justifiable and I would say almost fair, I can also understand why the green pass, a blatantly discriminatory law, is considered fair by many.*

> *…If the answer to the question is freedom, it is clear that everything that has been done so far is considered a mistake regardless of whether a particular law was made to save lives.*

> *…We come to the last answer, the most balanced one for me at least, that life and freedom are of equal importance. In view of this answer, it is clear that taking precautions to limit contagion and death is right and proper, so limitations will be inevitable (such as social distancing, masks indoors, limiting seating etc.), but at the same time it is important to preserve the freedoms of all citizens.* [University, center, position 14996-15012]

The 3 arguments converge on a single conclusion: the green pass and the system of control it creates are either seen as tools in the hands of dictators or as preparatory tools to gather power.

> *…What kind of disgusting nightmare do we want to bequeath to our children? A Health Regime? A Regime that brutalizes the minds and bodies of its citizens on a daily basis? Enough! Rebel!* [Generic, position 2127]

> *…We are living in a health dictatorship and political authoritarianism that must be opposed. I wonder if a general acting as a commissioner who comes out with absurd words about wanting to flush out the 'unvaccinated' house by house? These people must leave the government. We must demand to go to the polls again.* [University, center, position 5904-5906]

Action Plan

Leveraging on this understanding of freedom, users perceive a clear duty to react. The first and foremost action is understanding who the real enemy is, that is, not the virus, nor the people who get vaccinated or obey the regime. The real enemies are the political system and the political representatives who allowed this to happen.

> *…It is a political issue everywhere. If we understand this we know who we have to fight, and for sure it's not a virus.* [University, north, position 20112]

In the university groups, users discussed a lot about communication strategies that would allow them to be credible, also because they are aware that their groups might be studied. The most important points were regarding avoiding defusing topics (ie, conspiracy theories) and focusing on self-determination. Again, coherently with our quantitative findings, the main issue appeared to be the vaccine, for which the green pass was just a proxy.

> *…we have been able to ascertain the intense doxing activity also of Telegram groups. In short, now that membership is growing, we need a minimum of 'art of war' (or rather strategy, just to avoid accusations of terrorism).* [University, north, position 20233]

> *…no disquisitions that go beyond the topic to be defended, such as the existence or nonexistence of the virus, the no-pro vax diatribe, the Davis forum, depopulation, mass experimentation, variants, damage, etc. These are all topics on which one has burnt the candle at the stake. These are all topics on which the authoritativeness of many prominent figures has been burned, since they easily fall under the so to speak 'defusing' labels (conspiracist, degree obtained on Google, no Mask, no vax, no test, denialist).* [University, north, position 3607]

Lastly, many users considered protests as valid strategic options to make their voices heard. The options they considered ranged from flash mobs to general strikes, to occupations of the parliament.

> *…Shall we make a flash mob where all the unvaccinated all go in at the same time where they can't? Maybe running so that we are sweaty (so they are afraid to touch us) maybe with a hat that says "the Jew rebels"* [Generic, position 1007]

> *…You will sign in front of the incredulous eyes of your employer your declaration of nonviolent struggle. Your declaration of an all-out general strike. Full stop. Nothing else is needed. There will be 100,000 of us, and we will block Italy, offices, services, production. We will pull the plug of this infamous regime.* [Generic, position 2127]

Summary: Explaining Green Pass Opposition Without Involving Vaccines

Among those opposing the introduction of the green pass, especially among university students, only a few were in favor of vaccinations and those in favor of freedom of choice were typically hesitant about vaccines. The "being aware" antivaccine discourse has been typically dismissed by a large fraction of the Italian society and by the political class as conspiratorial in nature and not worth considering. Anti–green pass antivaccine supporters have oriented themselves toward different argumentations to defend their positions, revolving around legal aspects related to the concept of personal freedom. Our considerations are well summarized by the following message.

> *…The main argument must continue to be that one must be able to refuse an injection, whatever it may be. The body is mine and I decide. And if you were to be convinced that the serum prevents x% of the infection (as some try to suggest), would our whole battle fall apart? I certainly hope it's not the case.* [University, north, position 24367]

The battle is fought on grounds different from that of vaccines, but vaccines are what this battle is for.

Other Aspects

COVID-19

In the no-green-pass corpus, 2 main positions about COVID-19 emerged. According to the first, COVID-19 exists but is much less dangerous than what it is communicated by the mainstream media.

> *…In addition, in response to the pathetic provocation, I would like to point out that 99% of COVID deaths are of over-80s with multiple pathologies.* [University, center, position 2199-2202]

> *…COVID exists but you can't stop the world because of it. It's a fucking flu, especially for young people. Many more people have died of the flu and it has never been talked about.* [University, north, position 2864]

According to the second dominant position, COVID-19 does not exist and is yet another element of a bigger plan conceived to limit personal freedom and eradicate free thinking through fear.

> *…Do you realize that you're talking about a virus that nobody anywhere in the world can prove exists?* [University, north, position 1328]

> *…The virus has never been isolated or purified.* [University, north, position 6509]

At the junction of these 2 narratives, COVID-19 would be a strategy to pursue other means.

> *…the virus is just a means to achieve other goals that have nothing to do with health protection.* [University, center, position 8092-8095]

Expertise

If COVID-19 does not exist or is not particularly dangerous, then the need for measures such as the green pass would be unfounded. These beliefs are supported by a wide network of experts, which according to users are brave free thinkers who are not afraid of speaking their mind and standing against these covert powers.

> *…In addition, the most important doctor we have in Italy, Dr Remuzzi with H index 189, has long since drawn up an approved treatment protocol. Go to the website of the [name] Negri Institute and find out more. Dr Scoglio, candidate for the 2018 Nobel Prize, should also be considered.* [University, center, position 14640-14643]

> *…COVID can be treated at home, with medication. There is a group of volunteer doctors who do just that. "Terapie domiciliari COVID," a very popular Facebook group.* [University, south, position 1974]

> *…Listen also to Dr Citro, Dr [name] Montanari, Dr Bolgan, to what they say. [Authorities] forced people to get vaccinated with fear, and blackmailed young people with the green pass. There are many adverse reactions and they don't tell you that, so resist for your own good.* [University, center, position 4198-4200]

> *…The mask does not protect against viruses. Instead, it creates colonies of bacteria that you breathe in, as well as other filth that I won't tell you about, not to look like a conspiracy theorist. My colleague's comments on Dr Gatti are right. A great nanopathologist.* [University, north, position 742]

> *…According to Dr Delgado, it is not a virus that causes the disease. I will explain this when we meet.* [University, north, position 3485]

Preferred Measures

Among those who believe that COVID-19 is actually an issue to be contained, some try to delineate alternatives to the green pass. These include the use of masks, social distancing, tests, and dual teaching (both in presence and online).

> *…Exactly, you must respect all the rules to prevent contagion and therefore masks and distancing.* [University, south, position 1467]

> *…if we really want to be sure that the virus does not spread in the university, shouldn't the swab be used for everyone who enters the university, as it is the only instrument with a high percentage of detection of the virus?* [University, north, position 25297]

> *…However, I would like to see mixed teaching, both face-to-face and online, at least in the first semester so as not to increase the risk of infection and to allow everyone to get vaccinated. The situation in [place], with transport and everything, means that the risk of contagion is too high, even for those who are vaccinated and may be carriers. I don't feel like taking the responsibility of walking around in [place], even if I'm vaccinated, and putting other people's life at risk.* [University, center, position 2095-2102]

However, in the same groups, there is a strong critique of the dehumanization caused by online teaching, and tests are perceived as burdensome (economically and physically) and as unfair.

> *…In spite of the effort to reach the university, it is not real university what you do online. [The real one is] made of people, looks, REAL dialogues; it is precisely the effort and the time spent to go to the university that sanctions its founding and formative value. Distance learning is not an appropriate cultural medium.* [University, north, position 19204]

> *…the test becomes an economically limiting tool for the individual, since university students are not guaranteed free access to this service at all, which puts an economic burden on those who choose not to vaccinate.* [University, north, position 25298]

Antitest and Antimask Positions

Although more testing and systematic use of masks are sometimes suggested as a preferred protection strategy, many users have concerns about both. Some users think that tests and masks do not work; some think tests are dangerous as while collecting a mucus sample, it is possible to damage the brain; and some believe that masks are dangerous as they create bacterial colonies.

> *…I still don't understand... (it's rhetorical and sarcastic) why for the most contagious virus that spreads with a single droplet - with aerosol even, in the air... you have to pierce all the way to the encephalic barrier and up to the pineal gland? Maybe because otherwise you don't assimilate graphene oxide & who knows what else? Vets have long used nasal vaccination. Ps. There have been cases of rhinoliquorrhoea, ie, loss of cerebrospinal fluid, dizziness, abnormal migraines, etc, but of course, as with everything else, everything is covered up and minimized.* [University, north, position 11697-11698]

> *…The mask does not protect against viruses. Instead, it creates colonies of bacteria that you breathe in, as well as other filth that I won't tell you about, not to look like a conspiracy theorist. My colleague's comments on Dr Gatti are right. A great nanopathologist.* [University, north, position 742]

Reliance on Anecdotal Evidence

Users often bring information to support their claims. Sometimes, they provide links to blog posts but seldom to scientific studies or to statistical analyses. Sometimes, they engage with such information critically; sometimes they do not. Of note, stories based on anecdotes and personal narratives tend not to be questioned.

> *…My grandfather died with COVID. We followed what the doctors said about treatment at home for my grandmother. She survived. My grandfather wanted to follow the standard procedure instead. 2 weeks worsening. Intensive care and death.* [University, center, position 13863-13866]

> *…I spoke to a doctor from [place]. Do you know what they do to make it look like only the unvaccinated are in the ICU? When COVID patients come in, even those vaccinated with two doses, they have orders to move the vaccinated to other wards and leave the unvaccinated in the ICU.* [University, north, position 24524]

Discussion

Vaccine Skepticism and Public Health Recommendations

Our analysis clearly shows how the green pass has become a proxy and a catalyzer for vaccine skepticism. Especially during this time, people and politicians supportive of vaccines strongly oppose vaccine skepticism or denialism. The discussion about the dangers of vaccines as well as the conspiracy theories and the misinformation in general are not considered relevant and are silenced since these positions are not backed up by scientific evidence. Antivaccine supporters have come to learn that shifting their focus on the green pass allows them to bring new arguments, which are more likely to be heard, to indirectly bring arguments against the use of vaccines. In fact, questioning the validity of the green pass rather than that of vaccines is seen as less socially problematic, albeit it remains strictly connected to the discussion about vaccines. In practice, the green pass has become the fig leaf of the antivaccine movement. That said, it is also important to note that tensions and diverging narratives exist, even within the groups under analysis. As our results show, moderate positions (ie, COVID-19 is an issue, but the green pass is not an appropriate measure) coexist with conspiracy theories (ie, COVID-19 does not exist and COVID-19, vaccines, and the green pass are part of a bigger plan). De facto, opposition to the green pass is what glues together these opinions and attitudes. This opposition is often justified on the grounds of a naïve idea of freedom, conceptualized in a jurisprudential, consequentialist, or deontological form. Based on our findings, we believe that it is possible to trace some recommendations for public health

authorities and political institutions engaging with communication on these topics:

1. Acknowledge the doubts of individuals opposed to the green pass without dismissing their opinions and arguments as ramblings.
2. Disambiguate the purpose of the green pass: it should be made clear that it is a tool intended to incentivize vaccinations and thus to protect people—not only to people who cannot get vaccinated but also to protect everybody's personal freedom (ie, those who are not willing to risk to contract the virus but still desire to enjoy a meal in a restaurant, watch a theater play, or a football match in a stadium, etc). We see this discussion as a reminiscent of the long-standing debate about smoking in closed environments.
3. Since freedom is an important topic, counteract the models of freedom in which the opposition to the green pass is grounded, offering alternatives, for example, Rawls' "greatest equal liberty" principle [28], according to which each person should be given the most extensive basic freedoms that are compatible with another person's freedom.
4. Clarify the legal basis of the green pass, explaining how it is founded and regulated in existing jurisprudence, and how its scope and application is defined and limited by the contingency of the pandemic. It is necessary to explain why it has a specific "expiry date" and under which circumstances and for how long people should expect these measures to be in place.
5. Keep informing about vaccines, with a specific focus on transparency and risk-benefit balance. In this context, complement as much as possible narratives based on data and scientific evidence with personal narratives (still backed up by science), as they are easier to relate to and can be more effective [29].

Ethical Considerations and Recommendations

A Plea for Active Social Listening

Communication is a key component of human life. The ability to communicate privately with others can be understood as an expression of the right to privacy. Privacy, in turn, is not a luxury that can be easily overridden by other seemingly more urgent or more important needs. Rather, it is a fundamental human right recognized by the United Nations Declaration of Human Rights and many other international and national treaties. The COVID-19 pandemic has presented us with tricky dilemmas regarding the protection of both privacy and public health. Although there is no doubt about the need for the effective management of the pandemic, concerns have been voiced that "measures taken to control the spread of COVID-19 have negatively impacted the enjoyment of the right to privacy and other human rights" [30]. These concerns become even more acute when measures are coupled with artificial intelligence technology that can enhance not only analysis and forecasting but also the ability to effectively target the behavior of groups and individuals [31]. The key ethical question is therefore how effective communication and management during important public health crises such as pandemics is possible without undermining privacy as a human right.

Telegram grants end-to-end encryption, and encrypted communication might grant a sense of safety to users. In fact, owing to this perceived safety, often it is chosen for illegal activities as it happened for the sale of false green passes [18]. However, when a curious user acquires access to the group, either directly or with social engineering techniques, he has access to the entire history of the chat, no matter the encryption. It is worth noting that similar or related groups often cross-share messages; when a message is shared, it incorporates a link to the original chat where it was posted. Thus, by scraping chats for "t.me" links, it is rather simple to obtain access to related groups. Finally, it is important to mention that often these groups use bots offering more advanced moderation features, for example, silencing a user for a specified amount of time. As bots come to users as black boxes, it would not be difficult to load them with malicious features, for example, sending the links of the chats where they are used if specific rules fire. Even when users do not use their name and surname as their username, still there are many possible strategies for reidentification. Users might share emails, locations, and even pictures. Crossing this information and identifying a person is just a matter of amount of data, time, and commitment.

Having proven that the approach and the techniques detailed in this paper can provide useful and deep insight on critical topics debated in Telegram groups, we still tend to think that these techniques should not be applied broadly for social listening. We live in a time in which societies are already experiencing a progressive loss of trust, and techniques of passive social listening—intended as collecting information from digital communities without engaging with them—can only worsen the situation. Passive social listening, as detailed in this paper, is incredibly powerful, as it can extensively and rapidly map communities, measure their discussions, and potentially help predicting protests and violent actions. Active social listening—intended as actively asking people their opinion on delicate topics such as vaccine distribution strategies or safety measures—is slower and less comprehensive, as it depends on creating efficient bidirectional interfaces between the public and authorities. However, it has a big advantage: it can build trust rather than undermine it further. Engaging directly with communities by offering concerned people the possibility to voice their worries can create a sense of not only being listened to but also of being heard, recognized, and valued. A recent example of an active social listening tool is PubliCo [32], a web-based platform that collects data on public perception of the pandemic and its management. Following a participatory citizen science approach, it invites users not only to provide data but also to suggest new survey items or to research the database with queries of their particular interest [33].

Transparency and Recommendations

The software and the procedure we developed are subject to the dual-use problem. In nondemocratic regimes, they could be used not only to map and understand dissent but to eradicate it. Our decision to share it is motivated by 3 reasons: first, science should be open and transparent in its objectives, means, and

methods, not only in its findings. Second, as Steven Levy noted, "If you don't have access to the information you need to improve things, how can you fix them?" [34]. Pavel Durov, Telegram's founder, stated that "Telegram must continue to serve the world as an example of a tech company that strives for perfection and integrity" [35]. If Telegram wants to stay true to that claim, the company needs to know how a characteristic of their software can be exploited as a vulnerability compromising users' privacy. Third, if a nondemocratic regime would want to develop a similar system, it could do it anyways unless this vulnerability is fixed.

Limitations

As we collected our data from public Telegram groups, our sampling is not representative of the general anti–green pass population. We do not have any information about the magnitude of the phenomenon nor do we have demographic variables to stratify the analysis. However, the sample is relevant for the scope of this study and we can characterize why and how these groups oppose the green pass by drawing reliable conclusions and outlining possible approach strategies. Our approach to thematic analysis departs from standards: in thematic analysis, data should be disassembled and reassembled in a different shape to reveal its themes and patterns [36,37] with a bottom-up approach to coding. Codes should emerge during the analysis to capture emerging and unforeseen phenomena, which contrasts with the very notion of autocoding that we employed. To mitigate this, we adopted an iterative process with continuous testing, analysis, and expansion of the rules. Still, we believe autocoding is a good compromise to map the content of large volumes of data in reasonable time.

Conclusion

Through our social listening analysis on Telegram chats, we conclude that a large fraction of individuals opposed to the green pass share antivaccine views. We also show they generally do not argue their opposition to the green pass with antivaccine rhetoric but rather focus on the legal aspects and limitations of personal freedom. We suggest that public health and political institutions provide a legal explanation and a context for the use of the green pass as well as to continue focusing on vaccine communication to inform hesitant individuals. Finally, we point to the ethical ramifications of our research and propose ways to ensure that social listening analysis is transparent and ethically sound. Further work is needed to define a consensual ethical framework for social listening for public health.

Authors' Contributions

GS, FG, and NBA conceived the study design. GS wrote the software and collected the data. FG and GS performed the quantitative analysis. FG prepared the figures and GS performed the qualitative analysis. GS, FG, and NBA wrote and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Patients' participation is crucial to the success of randomized controlled trials (RCTs). However, recruiting and retaining patients in trials remain a challenge.

Objective: This study aims to describe patients' preferences for the organization of RCTs (visits on- site or remotely) and evaluate the potential impact of fulfilling preferences on their willingness to participate in a clinical trial.

Methods: This was a vignette-based survey. Vignettes were case scenarios of real clinical trials assessing pharmacological treatments. These RCTs evaluated 6 prevalent chronic diseases (ie, osteoporosis, osteoarthritis, asthma, cardiovascular diseases, diabetes, and endometriosis). Each vignette described (1) the RCT and characteristics of the treatment tested (ie, doses, administration routes) and (2) the trial procedures and different options (on-site or remotely) for how the trial was organized for informed consent, follow-up visits, and communication of results when the trial was completed. We recruited 628 participants from ComPaRe (www.compare.aphp.fr), a French e-cohort of patients with chronic diseases. The outcomes were the participants' preferences for the way the trial was organized (on-site or remotely) and their willingness to participate in the trial.

Results: Of the 628 participants who answered the vignettes, 491 (78.2%) were female (median age 55 years), with different chronic diseases ranging from endometriosis in 59 of 491 (12%) patients to asthma in 133 of 628 (21.2%) patients. In addition, 38 (6.1%) participants wanted to provide informed consent and all trial visits on-site, 176 (28%) wished to participate in the trial entirely remotely, and 414 (65.9%) wanted to combine remote-based and hospital-based visits. Considering the trial as a whole, when the trial was organized in a way that the patients preferred, the median (Q1-Q3) likelihood of participation in the trial was 90% (80-100) versus 60% (30-80) if the trial followed the patients' nonpreferred model. Furthermore, 256 (40.8%) patients responded to open-ended questions expressing their experience with trial participation and visits to the hospital and providing suggestions for improvement. The patients emphasized the need to personalize the way a trial is organized according to each patient's needs and conditions.

Conclusions: There was a significant diversity in the participants' preferences. Most participants preferred hybrid organization involving both on-site and remote visits. Participants were more likely to participate in a trial organized according to their preferences.

Introduction

Patients' participation is crucial to the success of randomized controlled trials (RCTs). However, recruiting and retaining patients in trials remain a challenge [1,2]. For example, less than a third of RCTs funded by the National Institute for Health Research (NIHR) in the United Kingdom achieved the target sample size, and about a third of RCTs in the United States recruited less than 75% of the planned sample size [1,3]. With the increasing complexity of trial procedures, patients' decisions to take part and remain in a trial depend not only on the potential benefits and risks of the interventions evaluated but also on the practical logistics of trials and how burdensome these are to patients [4,5]. Evidence shows that participating in RCTs can be burdensome for patients, particularly due to the ways informed consent is managed, follow-up visits organized, and trial results communicated [5,6]. Several efforts have tried to ease this burden by using technologies to allow patients to take part in a trial remotely using electronic informed consent, dispensing study drugs at patients' homes, performing entirely web-based data collection, and conducting virtual visits via video calls [7-9]. However, the model of remote trials has not significantly succeeded in improving trial recruitment and retention and might not be suitable to all patient groups [7,10].

Information about patients' preferences for the way a trial is organized could inform the trial planning to enhance the participation rate. However, the previous literature on patients' willingness to participate in clinical trials mainly focused on their attitudes toward the randomization, without considering other aspects of trial organization [11]. In this study, we developed a new approach, using an online vignette-based survey to involve a large number of patients to explore their preferences on trials visits (on-site or remotely) and to evaluate the impact of fulfilling their preferences on potential participation.

Methods

Study Design

We conducted a vignette-based survey asking patients a set of directed questions to elicit their preferences for different ways of organizing a trial. Vignettes have traditionally been used in a number of areas, including medical training to evaluate clinical practice, and are being increasingly used in research to address topics such as identifying the best trial designs for methodological questions [12-15]. In this study, vignettes were case scenarios of real clinical trials assessing pharmacological treatments. These vignettes explained to patients what a clinical trial is and what they are expected to do when participating in the clinical trial.

This study received ethical approval from the French National Institute of Health and Medical Research Ethic Committee (IRB00003888; reference 19-580). We reported our findings following the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) checklist for online surveys [16].

Vignette Development

The vignettes were developed from existing protocols of ongoing or recently completed RCTs either published or available on clinicaltrials.gov. Two patient representatives and a steering committee comprising trialists and methodologists contributed to the development of the vignettes.

Clinical Trial Protocol Search

We systematically searched clinicaltrials.gov and PubMed for protocols of ongoing or recently completed (2017 onward) phase 3 RCTs evaluating pharmacological treatments. We limited the search to 6 prevalent chronic diseases: osteoporosis, osteoarthritis, asthma, cardiovascular diseases, diabetes, and endometriosis (Multimedia Appendix 1). Trials were included if they had a parallel design, at least 1 year of follow-up, and a full protocol available. We excluded trials that were exclusively on patients less than 18 years old or that were conducted exclusively in Asia, Africa, and Latin America. We also excluded trials testing treatments for secondary conditions (eg, osteoporosis induced by glucocorticoids). In total, 93 RCTs were retrieved from the search, with 18 (19%) fulfilling the inclusion criteria. One protocol was chosen for each disease, with the goal of maximizing the diversity of funding and the type of administration route across the vignettes, leading to 6 protocols being chosen for vignette development (Multimedia Appendix 2).

Vignette Conception

Each vignette was structured in 2 parts. The first part described the RCT and the characteristics of the treatment tested (ie, doses, administration routes). The second part described the procedures of the trial and different options of how the trial was organized for each step: (1) informed consent, (2) follow-up visits, and (3) communication of results when the trial was completed. For informed consent, the participants were asked to choose 1 of the 3 ways: (1) The trial was explained to the patients, and they signed the informed consent form at the research center; (2) information was explained via a video, and the patients electronically provided signed informed consent; and (3) the trial was explained to the patients at the research center, and they then electronically signed the informed consent form at home after getting an opportunity to discuss with their family. For follow-up visits, we provided details of the number of visits and types of tests involved in each visit. The patients were asked to choose 1 of 3 options: (1) All follow-up visits happened at the research center; (2) all follow-up visits happened at the patients' homes, with a nurse visiting their home, and tests were conducted at a local hospital if they could not be performed at home; and (3) the patients were able to decide which visits happened at the research center and which at home. We described all logistics involved in each option (eg, contact with doctor, travel and waiting time). For communication of results,

the patients were asked to choose 1 of 4 options: (1) have a face-to-face meeting with investigators, (2) have a video call with investigators, (3) receive the results by email, and (4) receive the results by post. The description of each option for informed consent and communication of results were kept unchanged across the vignettes, while the number of visits and frequency of tests performed varied according to the protocols of the real RCTs. Textbox 1 presents an example of the choices for the informed consent process for the osteoarthritis RCT. Other vignettes are provided in Multimedia Appendix 3. The vignettes were then translated into French by a professional translator. A senior researcher (author IB) and a patient representative who was a native French speaker reviewed the translation to ensure its accuracy.

Textbox 1. Vignette for the randomized controlled trial (RCT) of osteoarthritis.

1. Informed consent

Before you participate in the clinical trial, the research team will explain to you the study, the new treatment, and the schedule of assessments. You will sign a consent form if you agree to participate.

Where do you want to have the information of the clinical trial explained to you and sign the consent form? Choose 1 of the 3 choices below:

At the university hospital

You will:

- Travel to the hospital and wait to see a study doctor.
- Meet the doctor who explains the trial to you.
- Ask your questions to the doctor.
- Sign the consent form if you agree to participate.
- Keep a copy of the consent form.

At home using the internet

You will:

- Stay at home.
- Watch a video online explaining the trial.
- Call the study doctor by telephone if you have questions when you want during working hours.
- Discuss with your family.
- Sign the consent form via a computer when you are ready.

A copy of the consent form will be sent to you by email or by post based on your choice.

At the university hospital and at home

You will:

- Travel to the hospital and wait to see a doctor.
- Meet the doctor who explains the trial to you.
- Ask your questions to the doctor.
- Return home and discuss with your family.
- Call the study doctor by telephone if you have questions when you want during working hours.
- Sign the consent form via a computer when you are ready.

A copy of the consent form will be sent to you by email or by post based on your choice.

Participants

We recruited patients from La communauté de patients pour la recherche (ComPaRe, an ongoing cohort of patients with chronic conditions in France) [17]. The patients were adults (>18 years old) who reported having at least 1 chronic condition (defined as a condition requiring health care for at least 6 months). They helped accelerating research on their conditions by completing patient-reported outcome questionnaires, suggesting ideas for new research or participating in the analysis of research projects [18-20]. By February 2020, there were 36,000 patients participating in ComPaRe. All patients provided electronic informed consent before participating in the e-cohort. By signing this electronic informed consent form to participate in ComPaRe, they agreed to receive invitations to participate in research provided via the platform.

We sent an invitation email to all patients who reported having asthma, diabetes, endometriosis, hypercholesterolemia, osteoarthritis, or osteoporosis via the ComPaRe platform. Two reminder messages were sent to nonrespondents. We then sent

the questionnaire including the vignette corresponding to the patients' chronic diseases to patients who replied yes to the invitation email via the secure ComPaRe platform. The patients were recruited from February 12 to April 23, 2020.

Outcomes

We evaluated the following outcomes:

- Participants' preferences for the way a trial is organized at each step: The patients were asked to indicate their preferred choices for the following questions: *Where would you like to receive the information about the trial and sign the informed consent? Where would you like to do the follow-up visits? How do you want to receive the results of the trial?*
- Participants' willingness to participate in the trial: The patients were asked the following questions: *If this step is performed at the hospital, how likely would you participate in the trial? If this step is performed at your home, how likely would you participate in the trial? If this step is performed at both the hospital and your home, how likely would you participate in the trial?* The patients answered each question on a scale from 0 to 100, with 0 being very unlikely and 100 being very likely.
- The patients were also invited to propose new ideas for organizing each step of the trial.

They were able to express their ideas in free text by responding to open-ended statements: *If you have an idea to improve your experience with receiving information about the trial and sign informed consent, please let us know* and *If you have an idea to improve your experience with follow-up visits, please let us know*.

Data Analysis

Descriptive analysis was used to describe the characteristics of the patients participating in the survey and their preferences for trial organization. The analysis was performed using R software (version 4.0.2).

Analysis of the patients' answers to open-ended questions about their ideas for how clinical trials should be organized were informed by thematic analysis. Data were imported into NVivo (QSR International) to facilitate the coding process. One researcher (author VN) performed open coding through an iterative process. A subset of responses to open-ended questions from 50 participants was coded line by line. The codes were then organized into themes to create a coding framework. This coding framework was then discussed with a senior researcher (author IB) and refined by considering the context of the data with the wider data set. The coding framework was used to analyze the remaining survey responses and refined throughout the process of analysis.

Data Sharing

De-identified data from this study are available on request to the academic researchers who have submitted a protocol to the scientific committee of ComPaRe and signed a data use agreement.

Patient and Public Involvement

Two patient representatives participated in the development of the vignettes.

Results

Study Population

We sent invitation emails to 2155 patients in the ComPaRe e-cohort, including 434 (20.14%) patients with asthma, 317 (14.71%) patients with diabetes, 480 (22.27%) patients with endometriosis, 114 (5.29%) patients with hypercholesterolemia, 276 (12.81%) patients with osteoarthritis, and 534 (24.78%) patients with osteoporosis. Of the 2155 patients, 834 (38.7%) initially responded positively to our invitations. We then sent this group the survey containing the vignettes of trials corresponding to their conditions. A total of 628 (75.3%) patients answered the vignette-based survey. Table 1 presents the demographic information of the respondents. The patients mainly lived in France (621/628, 98.9%), with age ranging from 21 to 84 years (median 55 years, IQR 44-64), and were mainly female (491, 78.2%). In addition, 427 of 628 (68%) patients lived in an urban area. Most of the patients had obtained at least a high school diploma, and 107 (17%) had experience of participating in an RCT before. Nearly 377 (60%) of the patients could reach a university hospital within 1 hour of driving from their place of residence. Multimedia Appendix 4 provides the demographic information of nonrespondents.

Table 1. Characteristics of patients.

Characteristic	Total (N=628)	Asthma (n=133)	Diabetes (n=83)	Endometriosis (n=59)	Hypercholesterolemia (n=76)	Osteoarthritis (n=125)	Osteoporosis (n=152)
Gender, n (%)							
Female	491 (78)	107 (80)	41 (49)	59 (100)	35 (46)	97 (78)	152 (100)

Patients' Preferences for the Way a Trial Is Organized

All patients answered the vignette of the trial testing treatment for their conditions. For the informed consent process, 311 (49.5%) patients indicated that they preferred to be given information about the trials and sign the consent form at home over the internet, while 239 (38.1%) patients preferred the 2-step approach: having information about the trial explained at the hospital and signing the consent form at home.

Regarding follow-up visits, 251 (39.9%) patients wished to have all follow-up visits at home and 254 (40.4%) patients preferred the combination of both on-site visits at research centers and home-based visits with the possibility to arrange the visits according to their choices. Only 122 (19.4%) patients chose to have all follow-up visits at the hospital.

Most of the respondents (276/628, 43.9%) wished to have an in-person meeting with research investigators when receiving the results of the trials, 192 (30.6%) chose to receive a summary of results by email, and 126 (20.1%) preferred a video call with research investigators (Table 2). Overall preferences were consistent across conditions. However, for the informed consent process, 33 of 59 (56%) patients with endometriosis preferred the trial to be explained to them at the hospital and to sign the informed consent form at home. Patients with hypercholesterolemia were the only group in which most patients chose to receive trial results by mail (33/76, 43%), while the other groups wished to meet a research investigator in person (Table 2).

Table 2. Patients' choices of trial organization.

Choice	Total (N=628)	Asthma (n=133)	Diabetes (n=83)	Endometriosis (n=59)	Hypercholesterolemia (n=76)	Osteoarthritis (n=125)	Osteoporosis (n=152)
Informed consent, n (%)							
At home	311 (49.5)	73 (54.9)	39 (47)	19 (32)	47 (62)	58 (46.4)	75 (49.3)
At hospital and at home	239 (38.1)	32 (24.1)	40 (48)	33 (56)	22 (29)	40 (32)	62 (40.8)
At hospital	78 (12.4)	18 (13.5)	4 (5)	7 (12)	7 (9)	27 (21.6)	15 (9.9)
Follow-up visits[a], n (%)							
By choices	254 (40.4)	51 (38.3)	29 (35)	28 (48)	23 (30)	61 (48.8)	62 (40.8)
At home	251 (39.9)	58 (43.6)	42 (51)	19 (32)	41 (54)	30 (24)	61 (40.1)
At hospital	122 (19.4)	23 (17.3)	12 (15)	12 (20)	12 (16)	34 (27.2)	29 (19.1)
Receive results, n (%)							
Meeting a doctor at the hospital	275 (43.8)	58 (43.6)	39 (47)	32 (54)	24 (32)	62 (49.6)	60 (39.5)

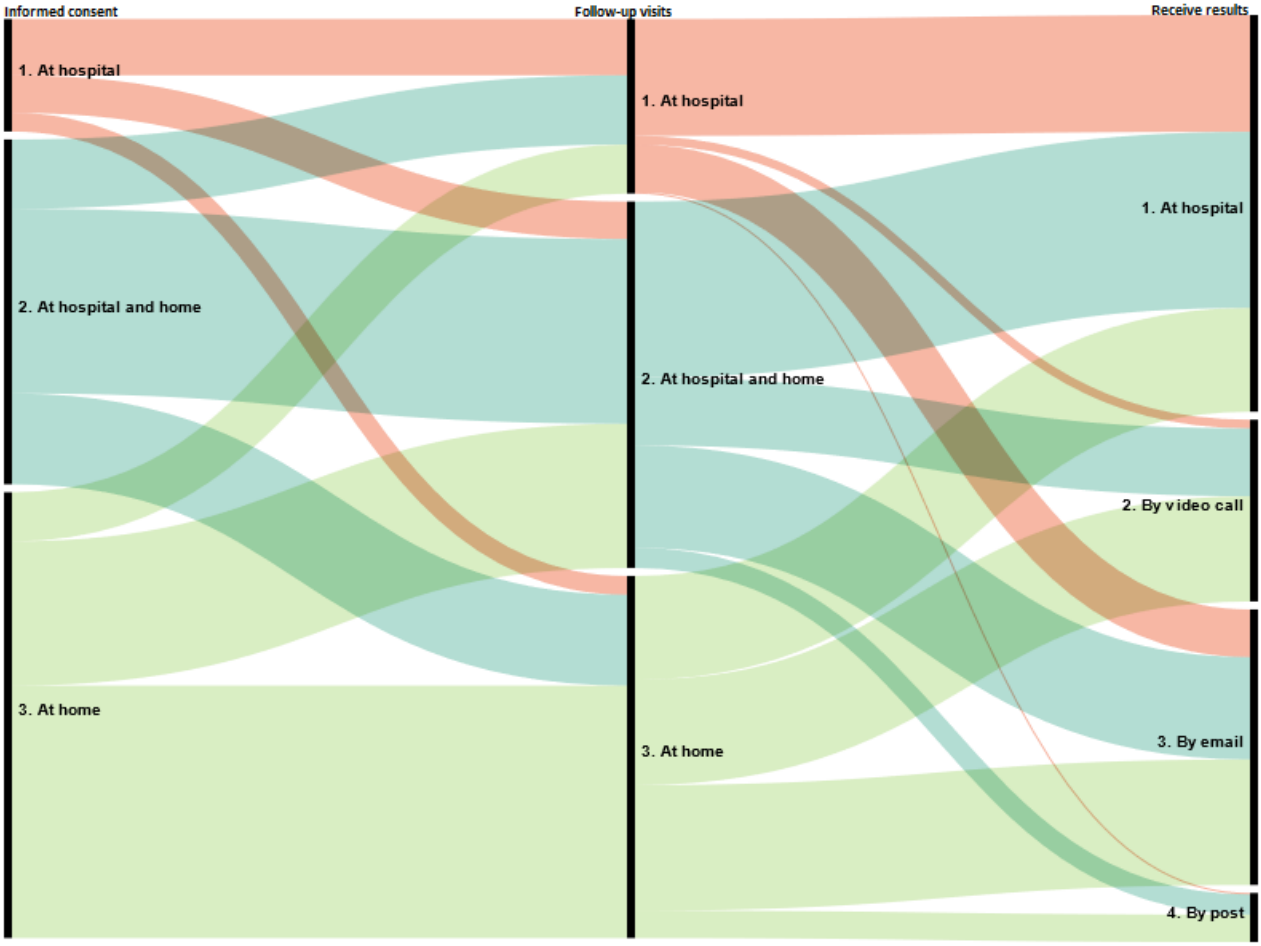
[a]One participant did not answer this question.

Figure 1 illustrates the diversity of the patients' preferences regarding trial participation as a whole. For example, of 311 (49.5%) patients who wished to have the informed consent process at home, more than half (175/311, 56.3%) chose to have all follow-up visits at home. Of these 175, 73 (41.7%) wished to receive trial results by mail, 55 (31.4%) wished to be informed about trial results via a video call, and 31 (17.7%) preferred to meet a research investigator in person.

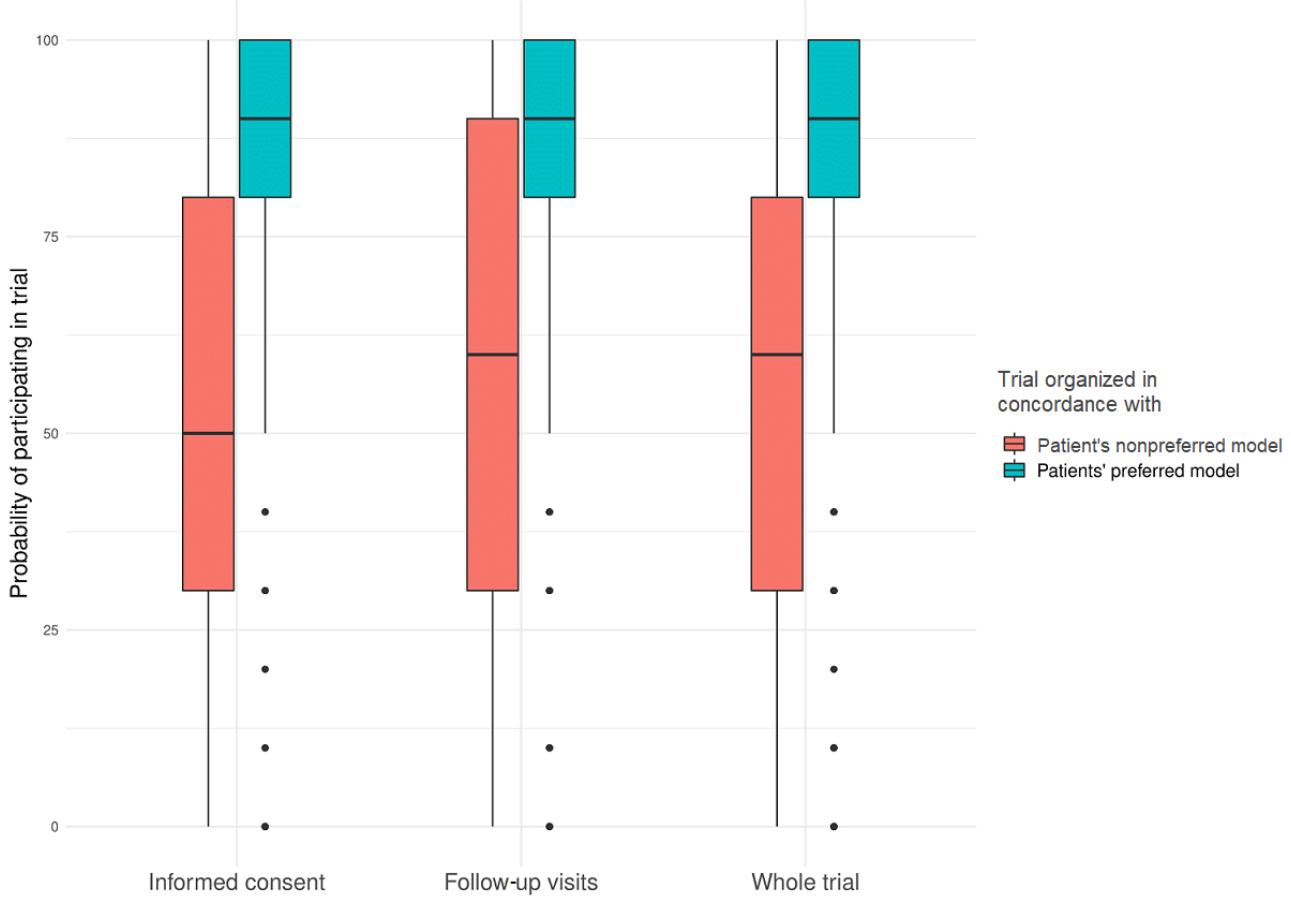
Figure 1. Diversity of patients' preferences for the way a trial is organized. This alluvial diagram presents patients' choices for each step of trial participation. The streams connecting the columns present the proportion of patients selecting each option in each column. For example, the red streams connecting "Informed consent" and "Follow-up" present the proportion of patients deciding to have follow-up visits at the hospital (n=39, 50%), at both the hospital and home (n=26, 33%), or at home (n=13, 17%) among all patients who decided to provide informed consent at the hospital (n=78). The red streams connecting "Follow-up" and "Results communication" present the proportion of patients deciding to receive the results at the hospital (n=81, 66.9%), by video call (n=6, 4.9%), by email (n=33, 27.3%), and by post (n=1, 0.8%) among all patients who decided to have all follow-up visits at the hospital (n=121).



Patients' Willingness to Participate in a Trial According to Their Preferences for Trial Organization

When the informed consent process was organized in a way that the patients preferred, the median likelihood to participate in the trial was 90% (IQR 80%-100%) versus 50% (IQR 30%-80%) if the informed consent process followed the patients' nonpreferred model. Similarly, the median likelihood to participate in a trial if follow-up visits followed the patients' preferred model was 90% (IQR 80%-100%) versus 60% (IQR 30%-90%) if trials were set up according to the patients' nonpreferred model. Considering the trial as a whole, when the trial was organized in a way that the patients preferred, the median likelihood of participation in the trial was 90% (IQR 80%-100%) versus 60% (IQR 30%-80%) if the trial followed the patients' nonpreferred model. See Figure 2.

Figure 2. Probability of participating when a trial is performed in accordance with patients' preferences.



Patients' Suggestions to Improve the Way a Trial Is Organized

Of 628 patients, 256 (40.8%) responded to at least 1 open-ended question, expressing their experience with trial participation and visits at the hospital and providing suggestions for improvement. Patients emphasized the need to personalize the way a trial is organized according to each patient's needs and conditions.

> *I think you cannot generalize, but for each clinical trial, the patient must be given a choice of how to participate. This depends mainly on the distance between home and hospital and of course whether the person has a professional activity or not. The way of participating could be proposed to the patient at the same time as the consent and the patient will then be in control of whether he or she can and wants to participate.* [Patient #125 with asthma]

Patients' Propositions to Improve Trial Visits at the Hospital

The patients suggested changes to the logistical organization of hospital visits to reduce waiting time and also suggested that flexible appointment times be offered to suit the individual situations of patients (Textbox 2).

Textbox 2. Patients' proposals to improve visits.

1. Keep appointment times and reduce waiting time.

> *Make sure that appointments with doctors or ECG radiography departments are on time.* [Patient #41 with osteoarthritis]
>
> *It all depends on the location of the hospital and how easy it is to get there by public transport (I don't drive). On the other hand, please respect the appointment times very strictly.* [Patient #5 with osteoporosis preferring home-based visits]

2. Arrange a reception dedicated to trial participants.

> *Make sure that appointments with doctors or ECG radiography departments are on time, without going through the general reception of the hospital . . . In order for me to participate in a study, the "logistics" must be as fluid as*

possible and outside the traditional care circuit in terms of administration and waiting time. [Patient #41 with osteoarthritis preferring combination of hospital and home-based visits]

3. Provide flexibility of appointment time.

Having the possibility to have intelligent appointments, to have all examination and tests in the morning or in the afternoon or from 10:00 to 15:00, for example . . . this allows fragile, sick, and tired people to take time and take care of their health, when they come from far away or when they have difficulty to move. It is important to be able to organize according to our conditions. [Patient #13 with diabetes preferring combination of hospital and home-based visits]

I would be willing to go to the hospital without any worries, but I do not want this to be done during my working hours as it should not be the concern of my employer. [Patient #65 with asthma preferring combination of hospital and home-based visits]

4. Combine follow-up visits with routine care visits.

Should we combine the visit with the examination and radiography for osteoarthritis? [Patient #97 with osteoarthritis preferring combination of hospital and home-based visits]

5. Reimburse transportation fees and provide free parking.

The fee of transportation and parking should be reimbursed for traveling to and parking at the research center. [Patient #35 with osteoarthritis preferring combination of hospital and home-based visits]

Patients' Proposals Regarding Remote Trial Visits

The patients highlighted the advantages of participating in a trial from home over the internet as a solution to reduce travel, save time, and avoid disruption of their work. They, nevertheless, indicated that human contact is important and an in-person conversation with research investigators would help reassure them when making decisions related to trial participation.

In the context of a clinical trial, a contact with a real human is important. The internet does not transmit the emotion. [. . .] It is reassuring [in] the hospital setting. They (doctors) can see my condition, and I also feel that I am a stakeholder and an actor of my own decisions when having a human in front of me. [Patient #73 with osteoarthritis preferring hospital-based visits]

One patient also explained that she wanted to keep her home as a private place for rest and recreation.

My home is a place of conviviality, rest, or recreation. I do not want my home to become a place of care. I already have auto-injections. I prefer to go to the doctor, in a center of care, even if that seems more constraining. [Patient #4 with asthma preferring combination of hospital and home-based visits]

Several patients suggested that researchers should foresee measurements to ensure the accuracy of tests and data collected outside the context of the hospital, which might influence the quality of research. Further, they also reminded researchers about the fact that not all patients would have access to equipment for video calls with doctors and that their internet connection might be unstable.

The patients also suggested that trial investigators could collaborate with local hospitals and laboratories to organize visits and examinations, which would reduce travel time, while maintaining the quality of data collected. The patients also spoke of the possibility to involve their primary care doctors in the trials, which would help them feel more reassured when participating in trials (Textbox 3).

Textbox 3. Patients' suggestions regarding remote trial visits.

1. Involve local hospitals and health care providers for follow-up visits.

I participated in a clinical trial. The appointments with the doctor took place at the hospital. The biological tests between appointments at the hospital were done at a laboratory near my home. I appreciated this organization. [Patient #56 with asthma preferring hospital-based visits]

To not wait too long at the hospital, and to be able to do the visits at a hospital nearby to reduce the travel time. [Patient #123 with asthma preferring combination of hospital and home-based visits]

2. Involve primary care doctors for informed consent and follow-up visits.

Another suggestion is to involve the primary care doctor as an intermediary to explain the study. [Patient #82 with osteoarthritis preferring hospital-based visits]

To involve the primary care doctor to avoid a part of the travel to the hospital. [Patient #51 with endometriosis preferring hospital-based visits]

Follow-up of the trial by primary care doctor and nurse for usual blood examination in close contact with the research team of the university hospital. [Patient #37 with hypercholesterolemia preferring home-based visits]

3. Ensure close contact with investigators.

Contact by video call rather than by telephone. [Patient #55 with diabetes preferring home-based visits]

It would be good to be able to exchange email with the doctor. [Patient #63 with diabetes preferring combination of hospital and home-based visits]

4. Provide equipment suitable to patients' conditions.

I have a computer with a large screen, but my osteoarthritis makes me suffer so much that I cannot sit upright for more than 5 minutes. I can use [the] telephone for a video call, and I can lie down, although it will be less effective for communication. [Patient #54 with osteoarthritis preferring hospital-based visits]

I would like to have home-based visits, but I am not sure to have a webcam with my computer. [Patient #6 with hypercholesterolemia preferring combination of hospital and home-based visits]

5. Apply technology to reduce the burden of data collection.

Plan (or use an existing one) an application with file sending via email for patients already doing PeakFlow follow-ups if this can replace or complement the certain spirometry (to avoid sending an IDE at home). [Patient #115 with asthma preferring home-based visits]

Discussion

Summary of Findings

In this study, we used a vignette-based survey to solicit patients' preferences for the way RCTs are organized from a large group of patients. We created 6 vignettes based on protocols of real clinical trials. In total, 628 patients with different chronic diseases, ranging from 59 (9.4%) patients with endometriosis to 133 (21.2%) patients with asthma, shared their preferences. Our results highlight the diversity of the preferences and show that if trials are planned according to patients' preferred choices, the likelihood of participating in trials could increase by 30%.

Implications

Our results showed the desire of patients to move from the one-size-fits-all approach of trial participation and tailor the way trials are organized to better suit each patient's condition, such as severity of their diseases, employment status, and distance to the hospital. By allowing flexibility in the way patients participate in a trial, patients who are underrepresented due to barriers, such as employment, income, and distance to hospitals, might be enabled to take part, thus increasing external validity [21,22]. The COVID-19 pandemic has created challenges for clinical trials but also created opportunities to significantly change how trials are conducted. Many clinical trials have adapted to recruit patients online and remotely perform trial visits [23]. For example, the Pragmatic Evaluation of Events And Benefits of Lipid-lowering in Older Adults (PREVENTABLE) trial shipped medications to patients' homes and cognitive assessment was performed at the patient's home by trained research staff [24]. A trial evaluating fluvoxamine to treat COVID-19 was conducted entirely remotely. Patients were recruited online and signed the e-consent form, and data were collected via mail or telephone [25]. These examples show the feasibility of remote trials as an alternative to overcome certain barriers to trial participation. Further research is needed to assess the validity of data collected in a setting outside the research center [26,27]. Nevertheless, other barriers, such as understanding of complex concepts related to clinical trial participation (eg, randomization) or concerns about adverse effects of tested treatments, might not be resolved by remote trials [24]. Thus, discussion to address the concerns of participants and identify the best approach for their participation in trials is necessary.

The patients in our sample also expressed the need to be informed about trial results, preferably during a discussion with a doctor, to get a chance to bring up questions and these being answered directly. This desire is in line with efforts to enhance transparency of trial results for which funders are striving. Further, informing patients about trial results helps them understand the significance of their contribution to science and could encourage them to participate again in future studies [28].

Our study also shows that vignette-based surveys are a useful and innovative design to incorporate perspectives of a large number of patients and public members in research. The vignette is an effective way to communicate the complex concept of clinical trials to patients. In the development of the vignettes for this study, we explained the process and practicalities of taking part in a trial, such as the distance of travel, types and number of examination tests, and the total amount of time for each visit. We cocreated the vignettes with patient representatives to ensure that the structure and language used were comprehensible to the patients. Vignette-based surveys allow patients to express their opinions and ideas without pressure from other stakeholders [29-32]. Vignette-based surveys could also be used to discover patients' perspectives on other aspects of trial design, such as their preferences for comparators, outcomes, and study design.

Limitations

Our study had some limitations. We recruited patients from a patient e-cohort; thus patients in our sample had more experience with the use of the internet and participating in research. In France, 77% of the population has smartphones and 72% of the population has access to the internet [33]. In our study, 427 of 628 (67.9%) patients lived in urban areas and 364 (57.9%) had access to a university hospital in less than 1 hour, which is similar to the French population, with 54.6% of the population

living in urban areas (ie, areas with more than 50,000 inhabitants) [34]. Additionally, the majority of patients (621/628, 98.9%) lived in France; thus their experience with clinical trial participation might be different from that of patients living in other countries in order to be able to generalize the study results. Nevertheless, this study could be adapted to other languages and disseminated to international patient communities. Lastly, due to the hypothetical nature of the vignettes, we cannot exclude the fact that patients might make a different decision in a real-life situation.

Conclusion

We used a vignette-based survey, a new approach, to solicit preferences and ideas to improve RCT organization from a large number of patients. The patients emphasized the need to transform the current one-size-fits-all approach of clinical trial participation.

Acknowledgments

The authors thank Daniel Schanté and Philip Collis for their inputs to the vignettes as patient representatives and their comments on the paper.

This project is part of a Methods in Research on Research (MiRoR) project that received funding from the European Union Horizon 2020 research and innovation program under the Marie Sklodowska-Curie grant (agreement no. 676207). The funders had no role in the study design, data collection, and analysis; in the decision to publish; or in the preparation of the manuscript.

Authors' Contributions

Study conception was by VTN, IB, PR, BY, and V-TT; data collection by VTN, V-TT, and IB; data analysis and interpretation by VTN, IB, PR, BY, V-TT, and DS; and writing by VTN, IB, BY, and PR. All authors read and provided feedback on the manuscript. IB is the guarantor. The corresponding author attests that all listed authors meet authorship criteria and that no others meeting the criteria have been omitted.

Transparency declaration: The lead author (IB) affirms that the manuscript is an honest, accurate, and transparent account of the study being reported, that no important aspects of the study have been omitted, and that any discrepancies from the study as planned (and, if relevant, registered) have been explained.

Abstract

Background: Autism spectrum disorder (ASD) is a widespread neurodevelopmental condition with a range of potential causes and symptoms. Standard diagnostic mechanisms for ASD, which involve lengthy parent questionnaires and clinical observation, often result in long waiting times for results. Recent advances in computer vision and mobile technology hold potential for speeding up the diagnostic process by enabling computational analysis of behavioral and social impairments from home videos. Such techniques can improve objectivity and contribute quantitatively to the diagnostic process.

Objective: In this work, we evaluate whether home videos collected from a game-based mobile app can be used to provide diagnostic insights into ASD. To the best of our knowledge, this is the first study attempting to identify potential social indicators of ASD from mobile phone videos without the use of eye-tracking hardware, manual annotations, and structured scenarios or clinical environments.

Methods: Here, we used a mobile health app to collect over 11 hours of video footage depicting 95 children engaged in gameplay in a natural home environment. We used automated data set annotations to analyze two social indicators that have previously been shown to differ between children with ASD and their neurotypical (NT) peers: (1) gaze fixation patterns, which represent regions of an individual's visual focus and (2) visual scanning methods, which refer to the ways in which individuals scan their surrounding environment. We compared the gaze fixation and visual scanning methods used by children during a 90-second gameplay video to identify statistically significant differences between the 2 cohorts; we then trained a long short-term memory (LSTM) neural network to determine if gaze indicators could be predictive of ASD.

Results: Our results show that gaze fixation patterns differ between the 2 cohorts; specifically, we could identify 1 statistically significant region of fixation (P<.001). In addition, we also demonstrate that there are unique visual scanning patterns that exist for individuals with ASD when compared to NT children (P<.001). A deep learning model trained on coarse gaze fixation annotations demonstrates mild predictive power in identifying ASD.

Conclusions: Ultimately, our study demonstrates that heterogeneous video data sets collected from mobile devices hold potential for quantifying visual patterns and providing insights into ASD. We show the importance of automated labeling techniques in generating large-scale data sets while simultaneously preserving the privacy of participants, and we demonstrate that specific social engagement indicators associated with ASD can be identified and characterized using such data.

Introduction

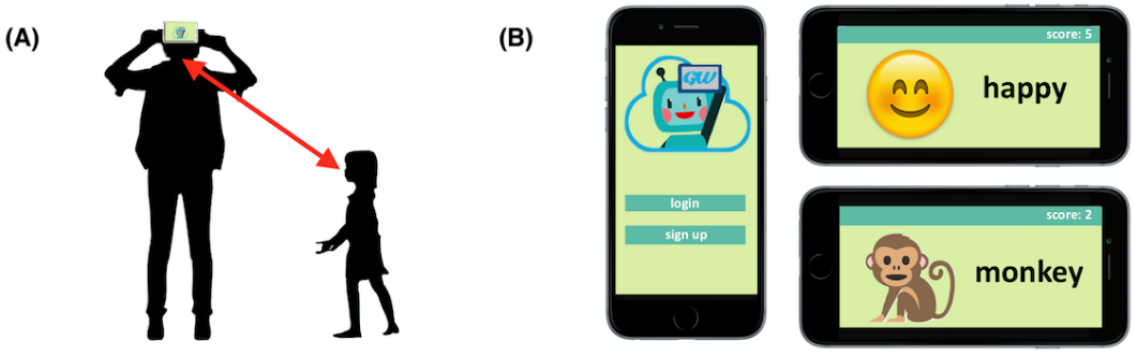
Background

Autism spectrum disorder (ASD) is a neurodevelopmental disorder characterized by social impairments, communication difficulties, and restricted and repetitive patterns of behavior. Currently, 1 in 44 children in the United States have been diagnosed with ASD, with males 4 times more likely to be affected than females [1,2]. ASD usually manifests in infants and children and presents a wide range of symptoms that vary in intensity from person to person. The heterogeneity of ASD presents a major diagnostic challenge, with clinicians typically employing a combination of lengthy parent questionnaires and clinical observation to evaluate children.

Standard diagnostic mechanisms for ASD are often accompanied by a range of issues that result in long waiting times for results [3-5]. However, in recent years, significant strides have been made in the fields of computer vision and mobile technology, giving rise to the possibility of using home videos of a child's natural behaviors to identify characteristics linked with ASD and enable a more accurate and timely diagnosis [6].

We previously created a mobile app called GuessWhat, which yields video data of children engaged in socially motivated gameplay with parents in a natural home environment [7-13]. The app presents a charades game, encouraging kids to act out a series of given prompts, such as emotions, sports, or chores. During a game, parents will open the GuessWhat app and place the smartphone on their foreheads, with the front-facing camera pointing at the child; the child then proceeds to act out the prompt displayed on the device while the parent attempts to predict the answer, as shown in Figure 1. The game ends when the 90-second time limit is exceeded. At this point, the parent can view the video recording of the child and is then given the option to share this data with our research team.

Figure 1. GuessWhat Mobile app. (A) The parent places the mobile phone in a fixed location, allowing the recording of a semistructured gameplay video. (B) The children are presented with a variety of charades prompts, such as emotions and animals.



The data collection pipeline employed by GuessWhat provides several benefits that make the obtained information amenable to computational analysis. First, although children are performing varied tasks in diverse environments, GuessWhat videos encourage inherent structure, with factors such as the position of the phone camera, location of the child relative to the camera, and game-based social interactions between the parent and child remaining generally consistent between videos. In addition, as children are in a home environment and are unencumbered by bulky hardware such as eye trackers or head mounts, they can interact with their parents and surroundings in a natural manner. As a result, we hypothesize that computer vision algorithms can be designed to monitor socially motivated facial engagement in children during gameplay, allowing effective identification of behaviors, eye contact events, and social interactions potentially correlated with the ASD phenotype.

In this work, we used computational techniques to analyze these videos and identify differences in social interactions between children with ASD and neurotypical (NT) children. We specifically analyzed 2 common social engagement signals that are included in standard clinical diagnostic instruments and can be identified through computer vision methodologies: (1) gaze fixation patterns, which represent the regions of an individual's visual focus and (2) visual scanning methods, which refer to the ways in which individuals scan their surrounding environment. We performed these tasks without sharing participant videos or private patient information with human annotators.

Ultimately, the development of this system can help improve diagnosis of ASD through automated detection of impaired social interactions, mitigating the problems associated with limited diagnostic resources for neurodevelopmental disorders, especially in regions where access to care is limited [14]. This work also demonstrates the usefulness of game-based approaches and automated labeling methods in preserving privacy, generating large diagnostic data sets, and improving human understanding of complex conditions.

Prior Work

Researchers have demonstrated the usefulness of video data in providing diagnostic insights into gaze and engagement behaviors associated with ASD. Prior work can generally be divided into three categories: (1) manual annotation methods, (2) eye-tracking systems, and (3) use of structured environments.

Manual Annotation Methods

Some studies have used human annotators to label social interaction and engagement information in video frames. Several prior works, such as those by Tariq et al and Leblanc et al, performed manual annotation of behavioral features in home videos, which enabled the creation of classifiers that could identify ASD with high accuracy [15-20]. Chorianopoulou et al collected structured home videos from participants and had expert annotators label the data set with the actions, emotions, gaze fixations, utterances, and overall level of engagement in each video; this information was then used to train a classifier to identify specific engagement features that could be correlated with ASD [21]. Rudovic et al trained a large and generalizable neural network to estimate engagement in children with ASD from different cultural backgrounds [22]. Engagement labels were manually annotated by trained individuals. Although these methods enable the creation of human-vetted, accurate data sets, such approaches require large numbers of trained annotators when implemented on a large scale, which is expensive and time-consuming. In addition, these techniques may compromise the privacy of participants by providing annotators with access to video footage, although some methods have been developed to address privacy concerns with crowdsourced annotations [23,24].

Eye-Tracking Systems

Several studies have used eye trackers to identify patterns in gaze and engagement behaviors that may be indicative of ASD or other developmental conditions [25-28]. Pusiol et al showed that deep learning models trained on data collected from a head-mounted eye tracker and camera could be used to classify idiopathic developmental disorder and fragile X syndrome with high precision [29]. Similarly, Riby et al used eye trackers to show that individuals with ASD had atypical gaze patterns when watching movies and cartoons [30]. To counteract artificial movements often associated with facial eye trackers, Noris et al developed a nonintrusive eye-tracking device mounted on a hat that recorded a child's interactions with an interviewer; the study concluded that children with ASD were more inclined to look downward during social interaction than their NT peers [31]. Despite the accuracy and quality of gaze data collected from such systems, eye trackers require custom hardware that can often be expensive and inaccessible, especially for individuals living in resource-limited regions. As a result, these approaches are unlikely to be accessible to the general population.

Use of Structured Environments

Hashemi et al explored the use of computer vision algorithms to identify behaviors associated with ASD [32]. A trained clinician administered a series of predefined, structured tasks involving toys and other visual stimuli, while a video camera captured footage of the child's response. A computer vision system that analyzed the child's body orientation and facial movement was able to evaluate the child's engagement with high accuracy. Similarly, Chang et al used the front-facing camera of a mobile device to capture gaze scanning patterns as children watched strategically designed short movies [33]. Automated computer vision techniques were then used to identify differences in gaze patterns between children with ASD and NT individuals. Egger et al also used mobile phones to collect videos of ASD and NT children engaging with short movies. Visual stimuli in movies were carefully designed based on neuroscience principles, and children's emotional and behavioral responses were computationally analyzed [34]. These works demonstrate effective methods for analyzing engagement patterns without the use of manual annotations or external eye-tracking hardware; however, these studies were conducted with highly structured tasks (eg, carefully selected movies and toys) and controlled environmental factors (eg, Hashemi et al and Chang et al controlled the room lighting and distance of the camera from the participant's face). As a result, the ability of these techniques to translate to natural nonclinical environments and unstructured tasks remains to be explored. In addition, these works do not evaluate engagement and behaviors in social situations.

Our Contributions

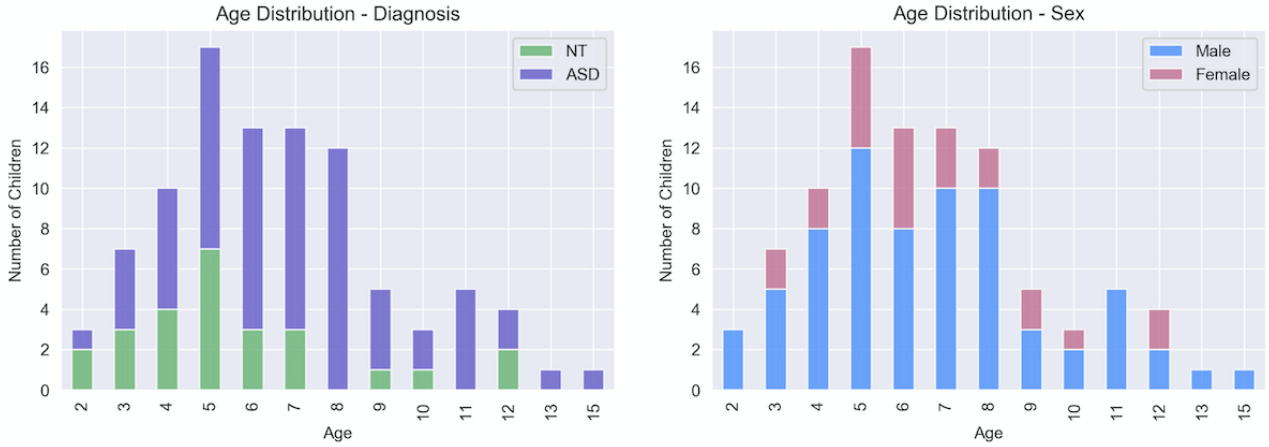
To the best of our knowledge, this is the first study that attempts to obtain diagnostic insights into ASD from social gameplay videos without the use of eye-tracking hardware, manual frame-level annotations, and structured scenarios or environments. We show that semistructured gameplay videos collected on mobile devices reveal specific regions of gaze fixation as well as visual scanning patterns that differ between individuals with ASD and NT children during social gameplay. With further research and development, our system can be deployed as a diagnostic tool in diverse settings on a large scale.

Methods

Data Collection

We used the GuessWhat mobile app to collect videos of children engaged in gameplay with a parent. Participants were recruited using social media advertisements and research email lists maintained by the study team. Approximately 1000 individuals proceeded to download the GuessWhat app, and we collected 449 videos from 95 children for this study. The participants ranged in age from 2 to 15 years and included 68 children (15 females, 53 males) diagnosed with ASD as well as 27 NT children (9 females, 18 males). Each child contributed a mean of 4.7 videos (SD 7.3), resulting in a total data set size of 1,084,267 individual frames and 11.1 hours of footage, presented in Figure 2. All parents consented to share their videos with our research team and completed a survey to provide the age, sex, and diagnostic status of their children.

Figure 2. Data set information. These graphs show the breakdown of our data set by age, diagnosis, and sex. In our data set, 1 NT male failed to provide his age, and this information has been excluded from this figure. ASD: autism spectrum disorder; NT: neurotypical.



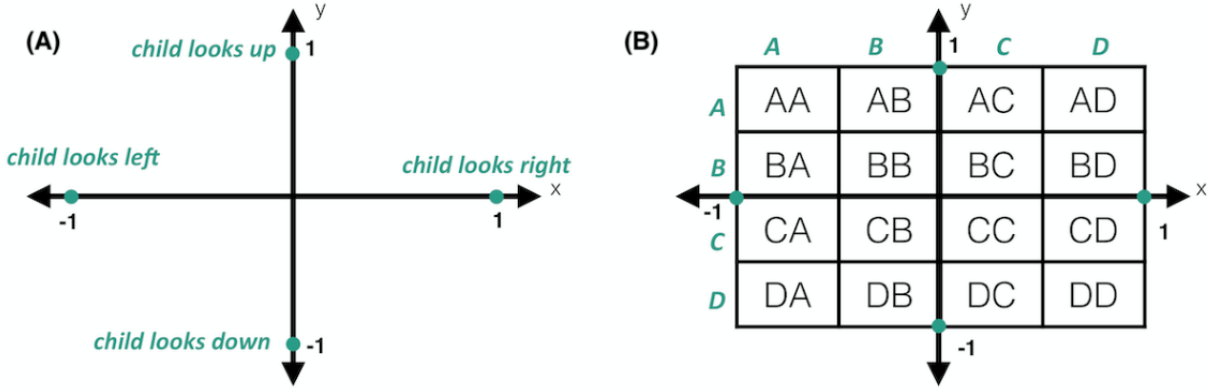
Data Preprocessing

Although the semistructured format of our video data set presents numerous advantages, home videos are naturally heterogeneous in quality; this results in several challenges that must be addressed prior to computational analysis. Specifically, excessive camera movement and poor lighting conditions rendered some frames in our data set too blurry for use. Moreover, other adults or siblings would often join in gameplay, resulting in multiple faces in the frame and making identification of the participating child challenging. Another major challenge arises from the lack of fine-grained annotations and ground truth labels; although the lack of eye-tracking hardware enables natural child motions and interactions, this also results in a lack of calibration information for obtaining accurate gaze locations.

We began our analysis with extensive quality control and data preprocessing. To preserve privacy, we annotated our data set solely using computational methods. We first used Amazon Rekognition, a powerful off-the-shelf computer vision platform developed by Amazon, to perform noisy labeling of key features in each still frame, including 30 facial landmarks and facial bounding boxes. Frames with 0 or greater than 2 faces were removed from the data set. We then used an open-source facial landmark annotation platform called OpenFace to obtain automated estimates of gaze directions [35,36]. Each frame with an identifiable face was assigned a coordinate pair (x,y) representing the direction of the individual's gaze. The value of x ranges from –1 (indicating a leftward gaze) to 1 (indicating a rightward gaze); similarly, the value of y ranges from –1 (indicating a downward gaze) to 1 (indicating an upward gaze), as shown in Figure 3. As these coordinates were assigned with respect to the smartphone camera, a frame in which an individual is gazing straight ahead into the camera is assigned a coordinate pair of (0,0). If the OpenFace model demonstrated low confidence in gaze estimation values (defined as confidence below 75%) because of occluded eyes or insufficient image quality, the frame was removed from the data set; as a result, we expected the final annotations to be of high quality, but the presence of some noise and incorrect labels was to be expected. This procedure resulted in a total of 619,620 annotated frames, representing 520,536 frames from children with ASD and 99,084 frames from NT children.

Finally, to discretize gaze annotation data, we divided the coordinate map into 16 distinct areas of interest (AOIs), as shown in Figure 3. All gaze coordinates that fell within the bounds of a particular AOI were grouped together. Such an approach allowed us to identify trends in an individual's gaze fixations and scanning patterns.

Figure 3. Gaze annotations. (A) Gaze coordinates range between –1 and 1 on the x- and y-axes. (B) To categorize gaze coordinates into discrete regions, we divided the gaze map into 16 buckets. Each area of interest is labeled with corresponding row and column letters.



Differential Pattern Analysis

Gaze Fixation Patterns

Gaze fixation, which occurs when one's gaze is held on a single target for an extended period, plays an important role in social interaction by signaling communicative intent and enabling interpersonal relationships. In a dyadic social interaction, individuals usually fixate their gaze on the target's eyes. However, individuals with ASD often face difficulty with maintaining eye contact and instead tend to focus their visual attention on other regions of the target's face. Several studies involving eye trackers and visual stimuli have shown that children with ASD tend to fixate on the mouth or other body parts; this has even been observed in children aged as young as 2 to 6 months who were later diagnosed with ASD [37-39]. Eye contact avoidance, which is explicitly examined in standard clinical diagnostic examinations, can result in decreased facial identification and social engagement.

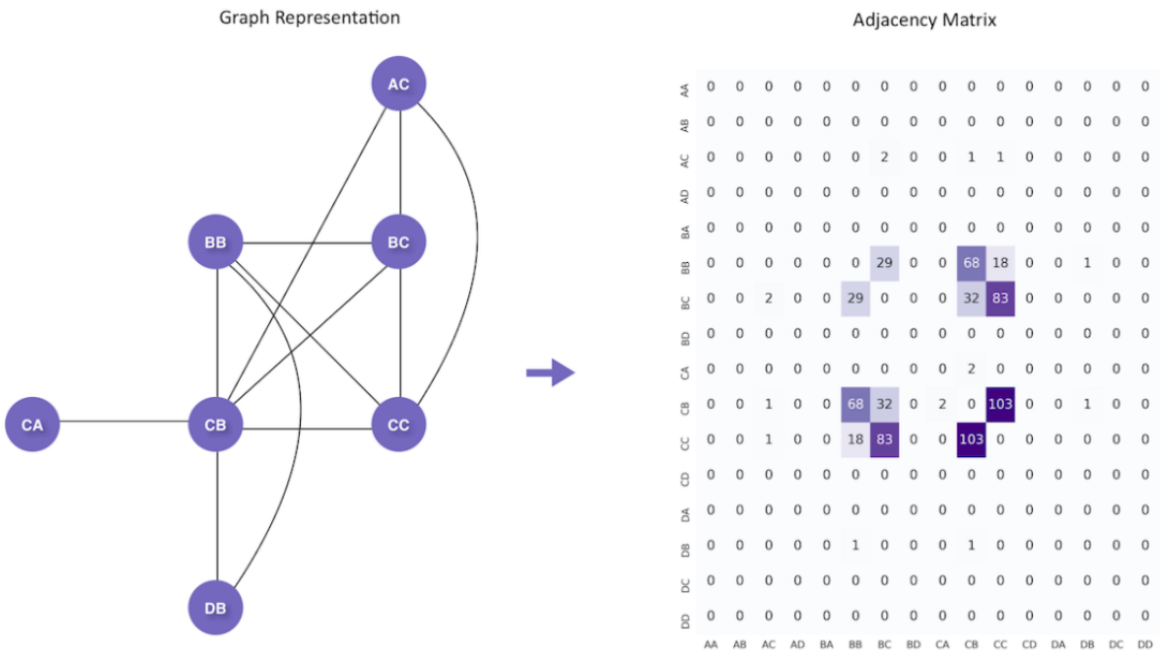
To determine the gaze fixation patterns of individuals during a single 90-second game, we used the coarse gaze annotations obtained from our preprocessed data set. For each video in our data set, we computed the percentage of time that the child fixated his or her gaze on each of the 16 predefined AOIs. A 2-sided permutation test was used at every AOI to identify statistically significant differences between the ASD and NT populations, with the null hypothesis that the fixation times for both populations followed an equivalent distribution; we calculated the difference in the mean fixation times for 100,000 rearrangements of the 2 groups. Bonferroni correction was applied to account for multiple hypothesis tests. It is important to note that because the AOIs are correlated, the Bonferroni correction is extremely stringent and will reduce the likelihood of Type 1 errors.

Visual Scanning Patterns

Humans tend to transition their gaze between various objects in their environments when encountering visual stimuli, a phenomenon called visual scanning. The patterns and frequencies with which humans scan their surroundings can provide insight into how individuals process the world around them. In the context of social interaction, prior research has shown that individuals with ASD vary in the way that they scan a target's facial landmarks during a social scenario, which may contribute to difficulty with interpreting emotional or nonverbal cues. This was shown by Pelphrey et al, who demonstrated that when presented with images of faces, NT individuals typically transitioned their gaze between core features, such as the eyes and nose, whereas individuals with ASD appeared to scan nonfeature areas of the face, such as the forehead and cheeks [40]. A similar study conducted by Chawarska and Shik on toddlers corroborated these findings, providing evidence of atypical scanning patterns in children with ASD when compared to their age-matched NT peers [41]. Understanding these patterns can reveal differences in the way that individuals with ASD process visual stimuli and interact in social situations.

Modeling gaze transition patterns as a graph problem can provide insight into the regions that children focus on while scanning their environments [42]. For each 90-second video of gameplay, we constructed a network consisting of 16 nodes n_{AA}, n_{AB}, …, n_{DC}, n_{DD}, with each node representing a predefined AOI. When a child shifts his or her gaze between locations on the 16-AOI gaze map, an undirected edge $e=(n_i, n_j)$ is drawn between the 2 corresponding nodes. Edges are weighted by the number of transitions that occur during the game. The graph can then be converted to a 16 × 16 adjacency matrix, as depicted in Figure 4.

Figure 4. Graph model of gaze transitions. We modeled the gaze transitions in each gameplay video as a graph, which was then used to generate a 16 × 16 adjacency matrix.



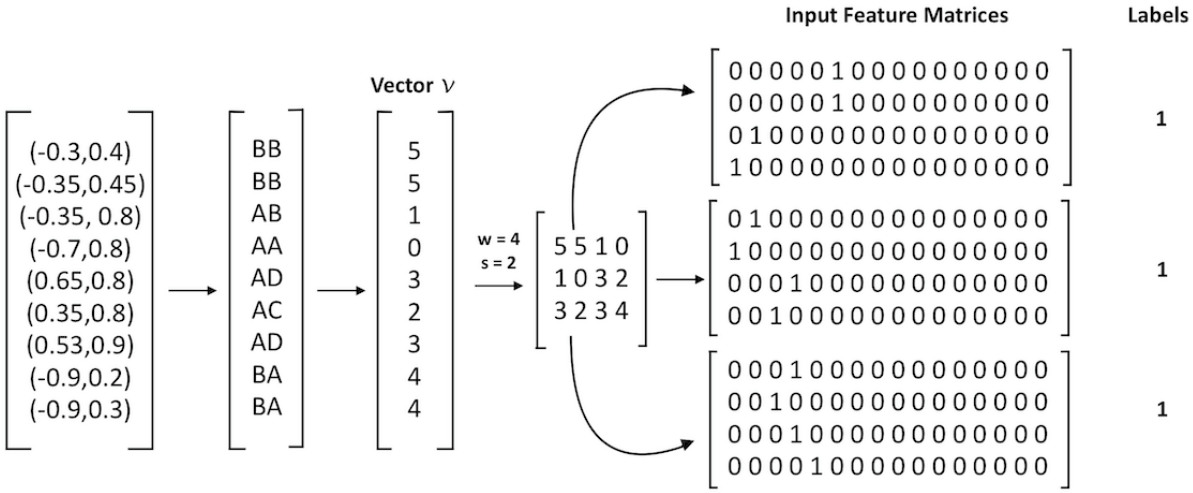
We computed adjacency matrices for all gameplay videos and normalized each matrix by dividing each entry by the total number of transitions. Then, we computed the average of all matrices associated with the NT individuals in our data set, resulting in a single 16 × 16 matrix depicting the mean percentage of transitions occurring between each pair of AOIs in a single game. This process was repeated for the gameplay videos associated with the ASD cohort. We conducted 2-sided permutation tests at each location in the transition matrix to determine if there were significant differences in the transition types between the 2 groups.

Deep Learning Model

Next, we used deep learning techniques to measure the predictive power of gaze fixation patterns. We began by converting fixation data points into feature matrices that could serve as the input to our classifiers. We first extracted the sequence of gaze coordinates from each video using the coarse annotation procedure described in the previous section. This resulted in a vector of n ordered pairs (x,y) for every video, where n represents the number of valid frames in the video, and x and y are the gaze fixation coordinates ranging from –1 to 1. We then matched each ordered pair with its associated AOI, as demonstrated in Figure 3. This yielded a vector of n AOIs, representing the regions of the gaze map that each individual fixated on during a game. Next, each of the 16 predefined AOIs was assigned a number from 0 to 15 in alphabetical order, with 0 representing AA and 15 representing DD; this formed a vector of n integers, which we will refer to as v.

We used a sliding window approach to divide v into separate vectors using 2 predefined parameters, namely window and shift. The window parameter w represents the number of frames included in a single feature vector; in our experiments, this value ranged from 50 to 500 frames, which roughly corresponds to 2 to 20 seconds of video content. The shift parameter s defines the number of elements by which the window slides between feature vectors, and we experimented with shift values between 10 and 100. These parameters allowed us to extract feature vectors from v consisting of w elements, with vectors separated by exactly s frames; note that if $s<w$, vectors will contain overlapping elements. Finally, we converted each w vector into a $w \times 16$ feature matrix, with each AOI integer encoded by a one-hot vector. A demonstrative example is shown in Figure 5.

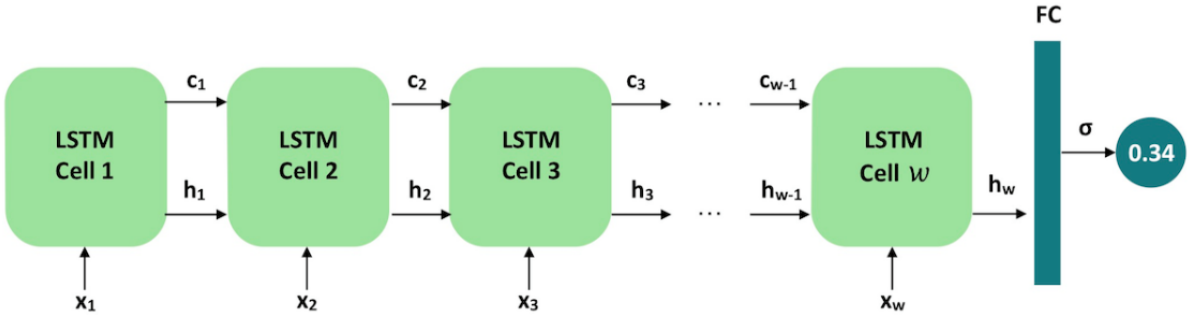
Figure 5. Gaze fixation feature representation. In this demonstrative example, we begin with a video consisting of 9 frames. Gaze coordinates are matched with corresponding area of interest (AOI) regions. Using a window of 4 and a shift value of 2 divides vector v into 3 feature vectors. Each feature vector is then one-hot encoded. All input feature matrices are assigned the same label.



We then used deep learning models to determine if gaze fixation patterns could be predictive of ASD. We assigned 324 videos (275 ASD, 49 NT) in our data set to the training set, 71 videos (62 ASD, 9 NT) to the validation set, and 54 videos (43 ASD, 11 NT) to the held-out test set, ensuring that all videos corresponding to a single child were assigned to the same set. Input feature matrices were constructed using the approach described above. A binary label $l \in \{0,1\}$ was assigned to each matrix to represent the diagnosis of the child in the associated video, with 1 representing the presence of ASD.

To exploit the temporal nature of our data set, we used long short-term memory (LSTM) networks, which are a type of recurrent neural network that can model long-term dependencies. A $w \times 16$ feature matrix served as the input to an LSTM model with w cells; each cell accepted a one-hot encoded 16-feature vector as the input. We used the Adam optimizer with a learning rate of 0.001, a batch size of 5, and a weighted binary cross-entropy loss function. The last cell of the LSTM network was connected to a fully connected layer with a single class output followed by a sigmoid nonlinearity; this resulted in a final value ranging between 0 and 1. This value was rounded to the closest integer to determine the final prediction, as observed in Figure 6.

Figure 6. Model architecture. The model consists of a long short-term memory network with w cells. Each cell accepts a one-hot vector of size 16, represented in the figure by x_i, and outputs a cell state c_i and a hidden state h_i. The final cell is connected to a fully connected layer, which generates a single class output. FC: fully connected layer; LSTM: long short-term memory.



Finally, to characterize model performance, we report four metrics: macroaveraged recall, macroaveraged precision, weighted-average recall, and weighted-average precision. As our data set exhibits class imbalance with cases outnumbering controls, these metrics provide the most accurate representation of model performance. Macroaveraged statistics compute the arithmetic mean of performance on each class, whereas weighted-average statistics compute the weighted mean. We performed all parameter experiments on our validation set and evaluated our final best-performing models on the held-out test set.

Ethics Approval

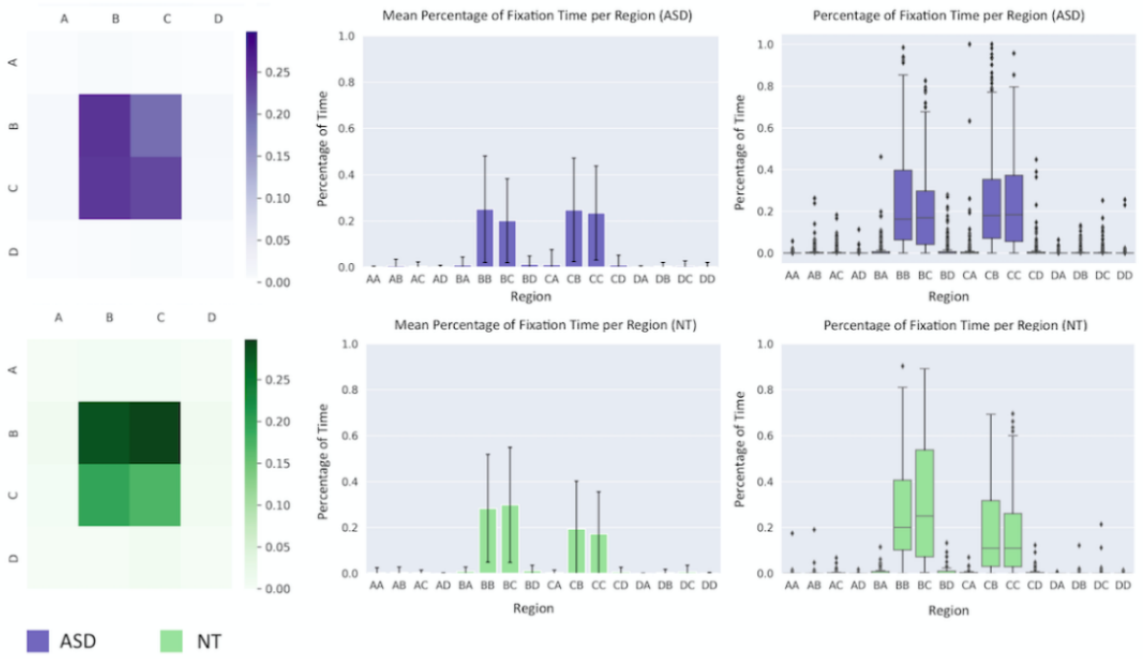
This study was approved by the Stanford Institutional Review Board (eProtocol number: 39562).

Results

Gaze Fixation Patterns Differ Between ASD and NT

We first analyzed gaze fixation patterns to determine if regions of focus differ between children with ASD and NT children during a single 90-second game. Coarse gaze annotations, which were obtained using the automated labeling procedure described in the Methods section, were grouped into 16 AOIs, and the percentage of time that the child fixated on each region was computed. Figure 7 shows the mean percentage of time that the ASD and NT cohorts fixated on each AOI during a game. As shown by the heat maps, children mostly fixated on the 4 central locations BB, BC, CB, and CC, which are located closest to the camera of the mobile phone. The distributions show that several differences exist between the 2 populations; children with ASD were most likely to fixate on locations BB and CB, whereas NT children spent much of the 90-second game focusing on locations BB and BC. We conducted a 2-sided permutation test at each AOI with 100,000 permutations of the data, setting a Bonferroni-corrected significance threshold of 0.0031 to account for the 16 hypothesis tests. A significant difference in fixation distributions between the 2 cohorts was observed at location BC (P<.001).

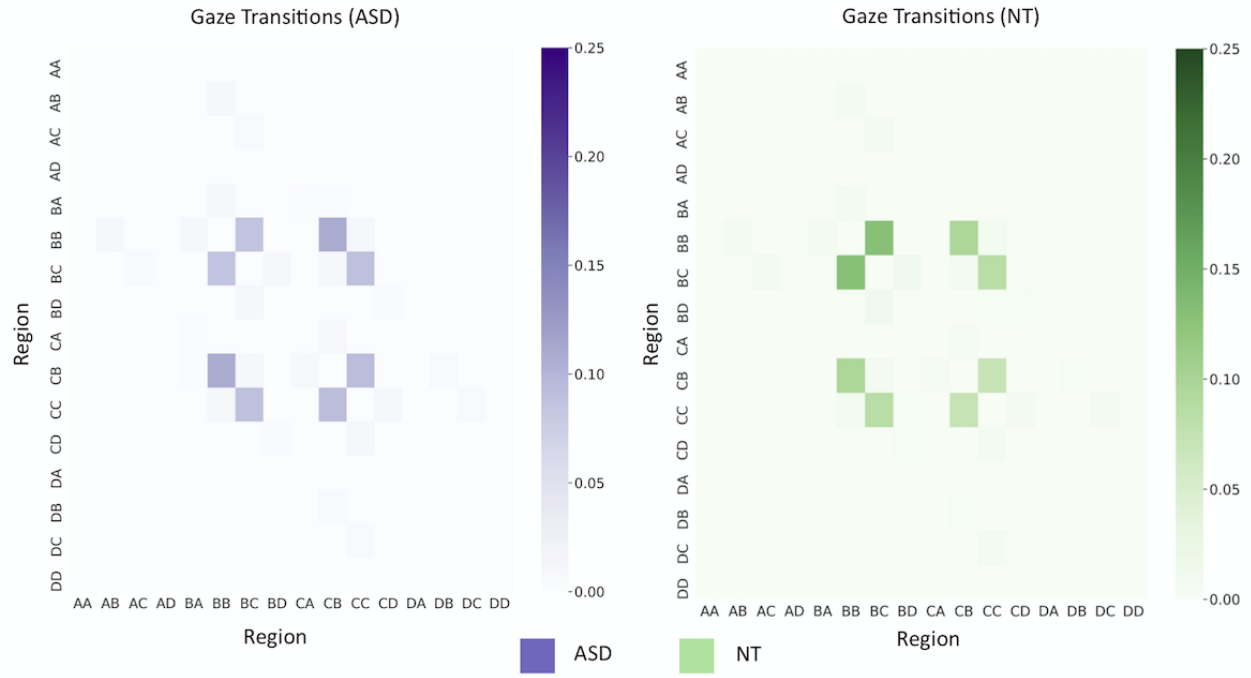
Figure 7. Gaze fixation results. The heat maps located at the upper left and lower left show the mean percentage of time that an individual fixated his or her gaze on each area of interest (AOI). The bar charts and the box and whisker plots show the distribution of fixation times across all videos. ASD: autism spectrum disorder; NT: neurotypical.



Visual Scanning Patterns Differ Between ASD and NT

Next, we used graph methods to analyze the ways in which participants scanned their environments during gameplay. We modeled the gaze transitions in each gameplay video as a network and computed the mean adjacency matrices for the ASD and NT populations, which are shown in Figure 8; a cell of the matrix in row *i* and column *j* represents the mean percentage of gaze transitions in a single 90-second game that occur between AOI *i* and AOI *j*. We conducted permutation tests with 100,000 permutations at each of the 61 nonzero, unique locations in the adjacency matrices; as the matrix is symmetric, the distributions for each distinct transition pair were tested for significance exactly once. We then used a Bonferroni-corrected significance threshold of 0.0008 to account for 61 hypothesis tests. Our results show that a significant difference exists in the percentage of gaze transitions between regions BB and BC (P<.001). As shown by the heat maps in Figure 8, 9.4% of the gaze transitions made by an individual with ASD occur between BB and BC; however, for NT children, 13% of the gaze transitions made during a 90-second game occur between BB and BC.

Figure 8. Gaze transition heat maps. These heat maps show the percentage of gaze transitions that occur between each pair of AOIs during a 90-second game. AOI: area of interest; ASD: autism spectrum disorder; NT: neurotypical.



Gaze Fixation Patterns Provide Mild Predictive Power

We measured the classification performance of models trained on gaze fixation patterns. Gaze fixation coordinates were encoded as one-hot vectors and passed as input to an LSTM network, which generated a single class output representing the likelihood of ASD. LSTM models were trained with a range of window and shift parameter values and evaluated on the validation set. Our results from the validation set allowed us to identify our top 3 models, which were trained with parameters (1) w=100, s=10; (2) w=200, s=10; and (3) w=500, s=10. These networks were then evaluated on the held-out test set. In Table 1, we provide precision and recall values for an LSTM model trained with those values of the window w and shift s that achieved the best performance on the validation set.

Table 1. Classifier performance on held-out test set with gaze fixation features.

Window (w)	Shift (s)	Macroaveraged recall	Macroaveraged precision	Weighted-average recall	Weighted-average precision
100	10	0.598	0.595	0.656	0.661
200	10	0.561	0.577	0.662	0.635
500	10	0.576	0.577	0.625	0.624

The model with parameters w=100 and s=10 demonstrated the best performance. Macroaveraged statistics are lower than weighted-average statistics, suggesting that the accuracy of prediction differs between the 2 classes. In summary, the results suggest that gaze fixation patterns can provide mild predictive power.

Discussion

In this study, we used computational techniques to analyze home videos and obtain diagnostic insights into ASD. We collected a large data set of semistructured videos featuring children engaged in gameplay with a parent, and we analyzed 2 key markers of social engagement that have been shown to differ

between children with ASD and their NT peers: (1) gaze fixation and (2) visual scanning. For each marker, we identified statistically significant differences between the 2 cohorts and demonstrated that this information could be useful in identifying the presence of ASD.

Our study demonstrates the potential that mobile tools hold for quantifying visual patterns and providing insights into ASD. Despite the presence of high heterogeneity and varying quality in our data set, the automated labeling techniques and deep learning classifiers used in this work were able to extract usable signals and identify differences in gaze fixation and visual scanning patterns between the 2 cohorts. These methods also enabled us to preserve participant privacy by avoiding the use of human annotators. Our findings support prior works that have identified social and visual engagement differences between individuals with ASD and NT individuals [37-41], and we demonstrate here that these variations can be identified using mobile tools. In contrast to previous video-based diagnostic approaches, we demonstrate that diagnostic insights can be obtained without the use of manual annotation methods, eye-tracking systems, or structured environments.

This work has some limitations. First, due to the class imbalance in our data set, the predictive accuracy of ASD differs from that of the control individuals; this is reflected in Table 1, which shows variations between macroaveraged statistics and weighted-average statistics. Additional data set augmentations will be necessary to correct this issue in future. In addition, due to camera motion and variation in the location of the smartphone relative to the parent's face, the gaze fixation maps are difficult to interpret qualitatively, and AOIs cannot be definitely matched to a parent's specific facial regions.

Future directions for this work include expanding the size of the experimental population; analyzing additional motion-based features in gameplay videos, such as limb movements and coordination; performing qualitative human-centered investigations or pragmatic randomized controlled trials to evaluate clinical usability; and evaluating the real-world diagnostic capabilities of our approach across diverse environmental settings [43-47].

Overall, this study demonstrates the usefulness of game-based mobile apps and heterogeneous video data sets in aiding in the diagnosis of ASD. With further research and development, the system described in this work can ultimately serve as a low-cost and accessible diagnostic tool for a global population.

Acknowledgments

This work was supported in part by funds to DPW from the National Institutes of Health (1R01EB025025-01, 1R01LM013364-01, 1R21HD091500-01, 1R01LM013083), the National Science Foundation (Award 2014232), The Hartwell Foundation, Bill and Melinda Gates Foundation, Coulter Foundation, Lucile Packard Foundation, Auxiliaries Endowment, the ISDB Transform Fund, the Weston Havens Foundation, and program grants from Stanford’s Human Centered Artificial Intelligence Program, Precision Health and Integrated Diagnostics Center, Beckman Center, Bio-X Center, Predictives and Diagnostics Accelerator, Spectrum, Spark Program in Translational Research, MediaX, and from the Wu Tsai Neurosciences Institute's Neuroscience: Translate Program. Abstract

Background: Health self-tracking is an evidence-based approach to optimize health and well-being for personal self-improvement through lifestyle changes. At the same time, user-generated health-related data can be of particular value for (health care) research. As longitudinal data, these data can provide evidence for developing better and new medications, diagnosing rare diseases faster, or treating chronic diseases.

Objective: This quantitative study aims to investigate the impact of digital forced-choice nudges on the willingness of German health self-trackers to donate self-tracked health-related data for research. This study contributes to the body of knowledge on the effectiveness of nonmonetary incentives. Our study enables a gender-specific statement on influencing factors on the voluntary donation of personal health data and, at the same time, on the effectiveness of digital forced-choice nudges within tracking apps.

Methods: We implemented a digital experiment using a web-based questionnaire by graphical manipulation of the Runtastic tracking app interface. We asked 5 groups independently to indicate their willingness to donate tracked data for research. We used a digital forced-choice nudge via a pop-up window, which framed the data donation request with 4 different counter values. We generated the counter values according to the specific target group needs identified from the research literature.

Results: A sample of 919 was generated, of which, 625 (68%) were women and 294 (32%) were men. By dividing the sample into male and female participants, we take into account research on gender differences in privacy tendencies on the web and offline, showing that female participants display higher privacy concerns than male participants. A statistical group comparison shows that with a small effect size (r=0.21), men are significantly more likely (P=.04) to donate their self-tracked data for research if the need to take on social responsibility is addressed (the prosocial counter value in this case—contributing to society) compared with the control group without counter value. Selfish or pseudoprosocial counter values had no significant effect on willingness to donate health data among male or female health self-trackers in Germany when presented as a forced-choice nudge within a tracking app.

Conclusions: Although surveys regularly reveal an 80% to 95% willingness to donate data on average in the population, our results show that only 41% (377/919) of the health self-trackers would donate their self-collected health data to research. Although selfish motives do not significantly influence willingness to donate, linking data donation to added societal value could significantly increase the likelihood of donating among male self-trackers by 15.5%. Thus, addressing the need to contribute to society promotes the willingness to donate data among male health self-trackers. The implementation of forced-choice framing nudges within tracking apps presented in a pop-up window can add to the accessibility of user-generated health-related data for research.

Introduction

Self-tracked Health Data for Research

As of April 2020, more than half a million enthusiastic health self-trackers donated collected data to the federal government research institute responsible for disease control and prevention in Germany, via fitness wristbands or smartwatches [1]. As of February 2021, data records donated have exceeded 170 million sets, including pulse, blood pressure, weight, temperature, physical activity, and information on sleep cycles. Regarding the COVID-19 pandemic, heart rate measurement and physical activity are of particular interest because an accelerated pulse while decreasing activity is a likely fever indicator—a typical COVID-19 symptom. At best, this fever monitor will serve as an early warning system and predict the spread of coronavirus in Germany even before case numbers from public health authorities are available [2].

The approach described is only one instance of how user-generated health-related data could add value to research and support public health measures [3]. Moreover, this kind of real-world data can support the development of pharmaceutical innovation, accelerate rare disease diagnosis, and improve chronic disease treatment [4-10]. For the self-tracked data to be available for research, users have to share, more precisely, donate their data actively to research institutions [11,12]. In addition to observing regulatory, ethical, and privacy issues, it is crucial to know, understand, and evaluate the motives of a specific target group for data donation [13,14]. Research on data donation typically uses a population cross-section sample. Surveys indicate that 4 of 5 Germans are willing to donate their digital health data anonymously and free of charge for medical research [15]. As many as 95% of German and US social media users would specifically donate their data to scientists at universities and public research institutions [15,16]. The results can potentially be highly biased, as individuals may hypothetically signal their willingness to donate data and perhaps not even engage in health self-tracking at all. Thus, on the one hand, research lacks information on the willingness to donate self-tracked health-related data among those who actually engage in health self-tracking for personal reasons and with individual goals. On the other hand, we need to determine whether there are nonmonetary benefits for that target group that can possibly influence the willingness to donate data positively.

Research Question and Objectives

We argue that digital forced-choice nudging in general is an appropriate tool to introduce behavioral change toward donating personal health-related data among health self-trackers because health self-trackers are very likely to share their self-tracked data with third parties and primarily have other intentions for tracking. Thus, data donation for research might be perceived as rather unimportant and therefore present an appropriate field for effective nudging.

This quantitative study aims to investigate whether a digital forced-choice nudge can influence the willingness of German health self-trackers to donate self-tracked health-related data for research. We want to contribute to the body of knowledge on the effectiveness of nonmonetary incentives derived from the known needs of the target population. For this, we also consider research on gender differences in privacy tendencies on the web and offline. This shows that women display higher privacy concerns than men. This is in line with both evolutionary and social role theories. Therefore, we analyzed male and female health self-trackers separately [17,18]. Our study thus enables a gender-specific statement on influencing factors on the voluntary donation of personal health data and, at the same time, on the effectiveness of digital nudges for health self-trackers in Germany.

Background and Theory

Nudging

When discussing the active decision to donate self-collected health data and possible contributing factors, we already know that various psychological effects influence individuals, consciously or unconsciously, during their decision-making process [19,20]. People often act impulsively, emotionally, or simply out of habit [21]; they are not always able to calculate the expected consequences of given options and therefore choose the seemingly best available one [22].

In this context, nudges are tools for influencing behavior in decision-making processes without resorting to prohibition, commandments, or economic incentives [19,23,24]. Thus, a nudge is a nonregulatory approach that attempts to motivate individual behavior change through subtle alterations in the choice environments that people face [19,25], whereas a suggested benefit is embedded in the decision-making process [26]. Thus, Karlsen and Andersen [27] define nudging as a term for influencing decisions and behavior using suggestions, positive reinforcement, and other noncoercive means. Löfgren and Nordblom [28] show that the likelihood of a nudge having an effect is higher for choices that the individual perceives as rather unimportant and at a moment in time with limited attention. In summary, the behavior of our study group, health self-trackers in Germany, can potentially be influenced by a nudge that promises a benefit based on existing target group needs and is implemented at a point of limited attention.

Nudges in Health Systems

Nudges are widely applied in health systems, with the ultimate goal of a healthy population. According to Holland et al [29], most nudging measures aim at a healthier diet, more exercise, and the reduction of alcohol and tobacco consumption and are thus frequently applied in preventive interventions. Especially in the nutrition field, we find a body of evidence for the effectiveness of nudging interventions: the use of nudges such as food traffic lights, the prominent placement of healthy food alternatives, or the transparent display of calories increases the choice of the healthier option by an average of 16.3% in test participants [30]. Okeke et al [31] investigated the impact of haptic (digital detox) nudging (phone vibration) to reduce the time spent on the web to improve users' well-being, successfully reducing daily screen time by over 20%. The growing body of evidence on nudging is also increasingly attracting the attention of health care insurance providers. They can potentially realize considerable savings by encouraging their insureds toward

targeted (healthier) behavior changes while offering the prospect of bonuses in return.

Digital Nudges

With the extensive use of digital devices, decision-making in digital choice environments (so-called digital nudging) has emerged, especially in the field of e-commerce [27,32]. Digital nudges affect value cocreation by (1) widening resource accessibility, (2) extending engagement, or (3) augmenting human actors' agency [33]. Similar to offline nudges, ethical considerations for digital nudges are already discussed in the literature, focusing on topics such as preserving individuals' freedom of choice or autonomy, transparent disclosure of nudges, and individual (proself) and societal (prosocial) goal-oriented justification of nudging [34]. Mirsch et al [32] pointed out that digital nudging in general is a promising research area with great potential for improvement and opportunities, especially regarding user interface, user experience, and digital service design questions. The future potential is supported by findings from the study by Hummel and Maedche [35], who discovered that today, only 62% of digital nudging treatments are statistically significant. Regarding the effect size of digital nudges, a quantitative review showed no difference (median effect size of 21% depending on category and context) compared with offline settings while offering new perspectives of individualization [35]. However, research on smart digital nudges in the health care or data donation field is limited. Meske et al [36], for example, conclude that digital nudging in hospitals can positively influence the use of technology, new value creation, changes in structures, and consequently financial dimensions of digital transformation, supporting caregivers as well as caretakers [36]. Regarding charity program participation, forced-choice nudges are found to be the most efficient ones [37,38]; a review reveals that overall default nudges are most effective, and precommitment strategies are least effective [35].

Hypotheses Development

Overview

To test the effectiveness of digital forced-choice nudges for data donation among health self-trackers in Germany, we need to identify the needs of our test group to use the right triggers for behavior change—in our experiment, donate tracked data. The prospect of need satisfaction could be a potentially attractive reward, which might encourage self-trackers to donate their data in return. To this end, we will derive potentially attractive counter values (benefits) for framing in a digital forced-choice nudge based on the known prevailing motives and needs of our target group and for data donation in general.

Need of Achievement and Power by Self-expertization

People with a diagnosed disease predominantly track vital signs or biological parameters [39-42]. Intrinsic motivation to improve disease management by advancing personal disease knowledge and controlling health indicators (such as glucose or blood pressure levels) is key for tracking [39-42]. Goals are controlling symptoms and preventing or delaying disease progression.

People with self-perceived disease risk factors mainly track their dietary and physical activities. Motives include potential and subjectively perceived risk prevention (such as obesity) or the desire to learn and promote a healthier lifestyle [43,44]. People without a diagnosed or self-perceived disease or prevalence primarily track their nutrition and exercise parameters. Self-design by performance optimization and monitoring performance progress improvement is the motivation behind [45-47]. A less relevant motive is self-entertainment, which includes natural curiosity, a basic interest, and fun in data collection and visualization [46,48,49].

Health self-trackers thus collectively possess a desire to use digital technologies to optimize health and well-being via self-monitoring [50,51]. Self-motivation, self-discipline, or the desire for performance enhancement are motives found in every user group [52,53] and can be labeled as self-expertization [54]. According to McClelland, these motives arise from the need for achievement and power (over a disease or one's own body) [55-59]. As self-expertise is key in every subpopulation with no regard to personal medical conditions, our first hypothesis is as follows:

- H1A: The prospect of receiving individualized tips to improve one's health has a positive influence on female health self-trackers' willingness to donate personal self-collected health-related data for research.
- H1B: The prospect of receiving individualized tips to improve one's health has a positive influence on male health self-trackers' willingness to donate personal self-collected health-related data for research.

Need of Self-actualization by Contributing to Society

Research on the motives to donate personal data, for example, to charity, is consistent with findings on motives supporting prosocial behavior, such as blood donation [60-63]. Donations can positively impact self-image and sense of self, as the donor receives appreciation and care in return [64]. Thus, individual needs as well as the need for self-actualization are also satisfied in this context [65]. Kalkman et al [14] pointed out that although participants recognized the actual or potential benefits of data donation for research, they expressed concerns about confidentiality and data abuse [14]. Nonetheless, 2 positive influences on the willingness to donate personal data exist: social responsibility or sense of duty is the first and most influential factor [66]. It refers to indirect reciprocity: giving back to the community and expecting the same treatment in return [67,68]. This altruistic motive is predominantly based on perceived empathy—the willingness to help out of compassion [69].

Second, an individual's perception of the significance of their own contributions to the community is crucial. Nudging intervention can realize this by emphasizing benefits, such as potentially accelerating the cure of disease by valid research findings and improved therapeutic interventions [16,70].

Derived from identified positive influences on data donation in general and underlying needs, our second hypothesis is as follows:

- H2A: The prospect of contributing to the community has a positive influence on female health self-trackers' willingness to donate personal self-collected health-related data for research.
- H2B: The prospect of contributing to the community has a positive influence on male health self-trackers' willingness to donate personal self-collected health-related data for research.

Need of Recognition and Social Belonging

According to Gimpel et al [46], motives for sharing self-tracked data, such as diet- and exercise-related or vital and biological parameters, can be referred to as self-association. Cost-benefit trade-offs regarding sharing tracked data are strongly linked to situationally perceived experience [71]. On the basis of the social exchange theory by Homan, users unconsciously or consciously weigh the costs or disadvantages of disclosure against personally perceived advantages [72]. Prospects of satisfying feelings of belonging (to a community) and identification with personalized and individual data outweigh possible disadvantages, for example, receiving personalized advertisements or privacy concerns [46]. Self-association can be traced back to social and individual needs satisfaction according to Maslow and Kruntorad [65], as individuals feel an urge for recognition and belonging and, based on this, possess a desire for esteem and prestige. We derive hypotheses 3 and 4 according to the identified motives for personal health-related data sharing as follows:

- H3A: The prospect of recognition by the peer group (classification of personal tracking results) has a positive influence on female health self-trackers' willingness to donate personal self-collected health-related data for research.
- H3B: The prospect of recognition by the peer group (classification of personal tracking results) has a positive influence on male health self-trackers' willingness to donate personal self-collected health-related data for research.
- H4A: The prospect of belonging to a peer group (via personal donation activity) has a positive influence on female health self-trackers' willingness to donate personal self-collected health-related data for research.
- H4B: The prospect of belonging to a peer group (via personal donation activity) has a positive influence on male health self-trackers' willingness to donate personal self-collected health-related data for research.

Methods

Study and Questionnaire Design

To test hypotheses 1 to 4 using digital forced-choice nudges, we set up a web-based experiment with the questionnaire tool LimeSurvey for health self-trackers in Germany. We generated 5 different mock-ups of the tracking app, Runtastic. We chose the app for its continued popularity, familiarity across all age groups, and duration in the market (since 2009—one of the first apps for health self-tracking) [73-75]. These mock-ups depicted the following situation:

the user has just tracked a run of 5.2 km with Runtastic. This screen in particular is a characteristic of a frequently shared status update on Facebook or Twitter [76]. It represents the sharing of personal physical activity by predominantly recreational athletes via social networks [76]. At this point in the user journey within the app, users only want to see their personal stats (and share them).

On completion, a pop-up window with call to action appeared. The pop-up is a new built-in hurdle before reaching the desired results. The person is in a state of physical exertion, having just completed an intense sports session. Attention and interest in pop-up content could be considered lower at this point [28].

Each pop-up window had a recommendation to the user—donating the tracked data to research, followed by information that motivates and helps him choose the suggested behavior—1 of 4 different nudges (N1 to N4) [27]. Presented nudges refer to hypotheses H1A to H4B. N1 is a framing nudge with egoistic benefits, promising individual tips for data donation based on the need for achievement and power through self-experimentation. N2 promises a contribution to society and is thus our prosocial (framing) nudge based on the need for self-actualization by contributing to society. N3 promises the comparison of one's own results with other users (social norm framing), as the second egoistic nudge, built on the identified need for recognition. N4 promises joining the data-for-science community, indicated by a badge within the app, and is thus a pseudoprosocial nudge that also uses social norm framing (belonging to a community). The counter value is based on the identified needs of social belonging and the desire for prestige. Finally, N0 is the control group, with no offered counter value.

Willingness to donate was queried by assessing the likelihood of donating on an 11-point scale, ranging from 0% to 100% (How likely are you to click *Donate Now*?). Only one of the pop-up windows was randomly included in each questionnaire. In addition to three sociodemographic parameters, *gender*, *age*, and *education*, we added 2 items as inclusion criteria to the questionnaire. We started by querying *devices used for tracking health-related data* (*smartphone*, *smartwatch*, *fitness tracker*, or *none*), allowing multiple answers as well as the *frequency of accessing the tracked data* (*daily*, *weekly*, *monthly*, *fever*, or *never)*.

Recruitment

The recruitment strategy included digital social media channels, such as Facebook, Instagram, LinkedIn, Xing, and Twitter. Facebook groups dedicated to fitness and nutrition topics as well as Instagram stories of female fitness microinfluencers represented key channels. To question active health self-trackers in Germany that engage with their tracked data, the defined exclusion criteria were (1) if participants never used a tracking device and (2) if participants never actively or consciously tracked any health-related data.

Data Processing and Statistical Analysis

After collection, the data preparation included cleaning and organizing the raw data set in Excel (Microsoft Inc). We diligently checked for errors to eliminate incomplete questionnaires. Data processing involved encoding text format

data into numeric indicator variables. Ultimately, our sample included exclusively ordinal-scaled variables suitable for statistical analysis in SPSS. We divided the sample into female and male participants to examine gender-specific differences.

To perform appropriate statistical analysis for the experimental evaluation, we checked the data distribution. In addition, we checked for variance homogeneity within the 5 different test groups for each gender. To validate experimental hypotheses H1 to H4, we compared our 5 groups with each other for men and women separately. Regarding the data set characteristics, we applied the Kruskal-Wallis and Mann-Whitney *U* tests as nonparametric tests to compare independent samples with homogeneous variances. The Kruskal-Wallis test can evaluate whether there is an actual effect of group affiliation in the first step. With a subsequent post hoc test, we checked which of the groups differed significantly. We used the Dunn-Bonferroni test.

Results

Sample

We collected 1091 questionnaires in January and February 2021. Following our defined exclusion criteria, we excluded 5.04% (55/1091) of observations because of participants not using a tracking device and 0.73% (8/1091) of observations because they did not track any health-related data actively or consciously. Furthermore, we removed 9.99% (109/1091) of incomplete questionnaires. The final sample consisted of 919 participants.

Our data set was not normally distributed but left-sided (skewness=0.087) and compressed (kurtosis=−1.431; Table 1).

The sample included 68% (625/919) women and 32% (294/919) men. Overall, 45.1% (414/919) of the participants were aged between 18 and 34 years, 46% (423/919) of the participants were aged between 35 and 54 years, and 8.9% (82/919) of the participants were aged >55 years. Overall, only 0.2% (2/919) of participants did not finish high school. Overall, 4.5% (41/919) of the participants were still in school or high school graduates with no additional formal education. In addition, 43.5% (400/919) of the participants were attending or had graduated from college, and 51.8% (476/919) of the participants were going to or had graduated from a university. In terms of tracking frequency, 85.4% (785/919) of the participants reported daily tracking, 10.8% (99/919) of the participants tracked weekly, 1.4% (13/919) of the participants tracked monthly, and 2.4% (22/919) of the participants tracked less than once per month.

We found that 60.3% (554/919) of our sample used a smartwatch for health self-tracking. Overall, 43.2% (397/919) of the participants used a smartphone, and 33% (303/919) of the participants used a fitness tracker (multiple answers were possible).

The sample (N=919) was divided into 5 test groups with N0 as 186 (20.2%; control group without nudge) and 4 different nudge groups (N1=183, 19.9%; N2=163, 17.7%; N3=199, 21.7%; and N4=188, 20.5%; women and men combined).

Taking gender differences in privacy concerns into account, we split the sample into female (Table 2) and male (Table 3) participants for further analysis.

Table 1. Data distribution.

Probability to donate (men + women)	Values
Participants, n (%)	
Valid	919 (100)
Missing	0 (0)
Value, skewness (SE)	0.087 (0.081)
Value, kurtosis (SE)	−1.431 (0.161)

Table 2. Description of the female sample—divided into the 5 test groups (n=625).[a]

Nudge	Participants, n (%)	Value, mean (SD; SE; range; 95% CI)
0	127 (20.3)	41.18 (36.113; 3.205; 0-100; 34.84-47.52)
1	115 (18.4)	43.91 (31.336; 2.922; 0-100; 38.12-49.70)
2	118 (18.9)	47.97 (34.901; 3.213; 0-100; 41.60-54.33)
3	149 (23.8)	45.30 (34.574; 2.832; 0-100; 39.70-50.90)
4	116 (18.6)	34.83 (36.295; 3.370; 0-100; 28.15-41.50)

[a]Total: mean 42.77, SD 34.879; SE 1.395; range 0-100; 95% CI 40.03-45.51.

Table 3. Description of the male sample—divided into the 5 test groups (n=294).[a]

Nudge	Participants, n (%)	Value, mean (SD; SE; range; 95% CI)
0	59 (20.1)	47.80 (36.863; 4.799; 0-100; 38.19-57.40)
1	68 (23.1)	48.24 (36.608; 4.439; 0-100; 39.37-57.10)
2	45 (15.3)	63.33 (33.439; 4.985; 0-100; 53.29-73.38)
3	50 (17)	56.20 (34.279; 4.848; 0-100; 46.46-65.94)
4	72 (26.3)	41.25 (35.759; 4.214; 0-100; 32.85-49.65)

[a]Total: mean 50.10, SD 36.112; SE 2.106; range 0-100; 95% CI 45.96-54.25.

Outcomes of Web-Based Experiment: Nudging Female Health Self-trackers

The female sample contained 625 questionnaires. Regardless of the nudge applied, 77% (481/625) of women surveyed were willing to donate their tracked data for research (with a probability between 10% and 100%).

The Levene test indicates homogeneous variances for female health self-trackers (Table 4).

Using the Kruskal-Wallis test, we examined whether the probability of data donation is the same across the 5 sample groups. As a result, we had to reject the nil hypothesis because significant differences (P=.03) exist across at least 2 groups.

As a post hoc test, we applied the Dunn–Bonferroni test for pairwise group comparison to identify the groups with significant differences. Ultimately, we found no significant difference in the likelihood of donating data between the control group 0 and the 4 test groups. Accordingly, we had to reject the hypotheses H1A, H2A, H3A, and H4A for female health self-trackers, as none of the nudges exerted a significant positive influence on the willingness to donate data. However, there was a significant difference between group 2, the social nudge, and group 4, the prosocial nudge (P=.03; Figure 1; Table 5).

Table 4. Levene test of homogeneity of variances (women; N=625).

Parameters	Levene statistic (df)	Significance (P value)
Probability to donate (women)		
On the basis of the mean	2.007 (4,620)	.09
On the basis of the median	1.323 (4,620)	.26
On the basis of the median and with adjusted df	1.323 (4,548.352)	.26
On the basis of the trimmed mean	1.864 (4,620)	.12

Figure 1. Boxplots for willingness to donate among the 5 test groups (women).

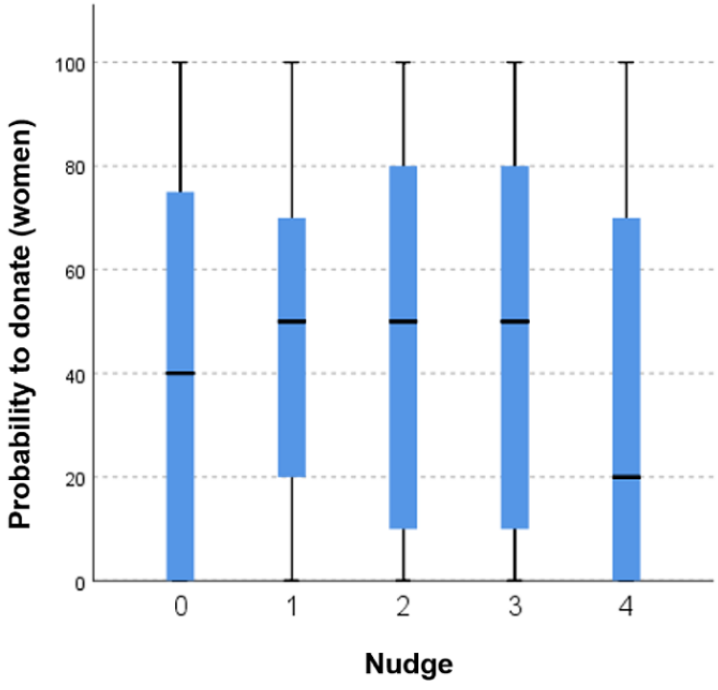

Table 5. Pairwise comparison of nudges (women; N=625).

Sample 1-sample 2[a]	Participants, n (%)	Test statistic (SE)	Standard test statistic	Significance (*P* value)	Adjusted significance[b] (*P* value)
4-0	243 (38.9)	33.037 (22.986)	1.437	.15	.99
4-1	231 (36.9)	52.646 (23.552)	2.235	.03	.25
4-3	265 (42.4)	57.423 (22.161)	2.591	.01	.09
4-2	234 (37.4)	69.431 (23.401)	2.967	.003	.03
0-1	242 (38.7)	−19.609 (23.038)	−.851	.40	.99
0-3	276 (44.2)	−24.386 (21.615)	−1.128	.26	.99
0-2	245 (39.2)	−36.394 (22.884)	−1.590	.11	.99
1-3	264 (42.2)	−4.777 (22.215)	−.215	.83	.99
1-2	233 (37.3)	−16.785 (23.452)	−.716	.47	.99
3-2	267 (42.7)	12.008 (22.055)	.544	.59	.99

[a]Each row tests the null hypothesis that the sample 1 and sample 2 distributions are the same. Asymptotic significances (2-sided tests) are displayed. The significance level is *P*=.05.

[b]Significance values have been adjusted by the Bonferroni correction for multiple tests.

The post hoc test results and plot visualization suggest a potential significant difference between groups 1 and 4 and between groups 3 and 2. We further applied a median-based pairwise group comparison using the Mann–Whitney *U* test. The results indicate significant differences between groups 1 and 4 (N=231; *P*=.01) and between groups 3 and 4 (N=265; *P*=.01).

In summary, for female health self-trackers, no offered counter value, based on egoistic, social, or prosocial motives or needs, has a significant positive or negative influence on the willingness to donate tracked data for research. However, the prospect of showing one's donation behavior to other users has a negative effect on willingness to donate data in direct comparison with groups that receive a prosocial or a self-serving return for their data donation.

Outcomes of Web-Based Experiment: Nudging Male Health Self-trackers

Overall, 79.9% (235/294) of the male respondents would donate their data (with a probability between 10% and 100%), regardless of the nudge queried (3% more than female respondents).

The Levene test indicates homogeneous variances for male health self-trackers (Table 6).

Testing for differences among groups in terms of donation probability also revealed a significant difference among male participants (*P*=.02) using the Kruskal-Wallis test.

A pairwise group comparison also revealed a significant difference between groups 2 (social nudge) and 4 (prosocial nudge; *P*=.02; Figure 2; Table 7).

The Mann-Whitney *U* test revealed significant differences between groups 1 and 2 (*P*=.04), between groups 0 and 2 (*P*=.04), and between groups 3 and 4 (*P*=.02).

As with female health self-trackers, we had to reject hypotheses H1B, H3B, and H4B for men as well. Thus, the prospect of a self-serving benefit or displaying data donation activity, named pseudoprosocial in our experiment, has no significant positive or negative influence on willingness to donate.

On the other hand, the prospect of making a prosocial contribution significantly influences the likelihood of donating self-tracked (health) data with a small effect size (*r*=0.21; *Z*=−2.087; N=104). Accordingly, we could not reject hypothesis H2B. Comparing means, nudging male health self-trackers in their donating decision-making process with a prosocial nudge would increase the willingness to donate data by 15.5%. At the same time, for male health self-trackers, we found evidence that open data donation significantly reduces the probability of donation compared with a *secret donation* (nudge 2), as well as compared with test groups 1 and 3, receiving a personal benefit. In addition, a group comparison of participants receiving personal tips and participants merely making a prosocial contribution reveals again that prosocial reasons are superior to selfish ones and increase the likelihood of donating data in direct comparisons.

By dividing the sample into male and female participants, we considered gender differences because of the known privacy concern differences between men and women. We also split the sample into different groups regarding age, education, devices used for tracking health-related data, and tracking frequency during analysis. The results show that there are no significant increases or decreases in the willingness to donate self-tracked health-related data when the sample is divided into the stated groups. A correlation analysis did not show any significant positive or negative correlations with the willingness to donate any other variable but gender (*P*=.001).

Table 6. Levene test of homogeneity of variances (men; N=294).

Parameters	Levene statistic (df)	Significance (*P* value)
Probability to donate (men)		
On the basis of the mean	0.873 (4,289)	.48
On the basis of the median	1.127 (4,289)	.34
On the basis of the median and with adjusted df	1.127 (4,275.393)	.34
On the basis of the trimmed mean	0.975 (4,289)	.42

[a]Each row tests the null hypothesis that the sample 1 and sample 2 distributions are the same. Asymptotic significances (2-sided tests) are displayed. The significance level is *P*=.05.

[b]Significance values have been adjusted by the Bonferroni correction for multiple tests.

Discussion

Principal Findings and Comparison With Previous Work

As apps represent digital environments in which users have to make decisions on an ongoing basis, a neutral choice presentation is impossible from a behavioral economics point of view. User interface design is crucial and influences users' app interactions. Developers need to know and understand user decisions and motives, as well as the inferable effects of design on user decision-making, to support desired actions. Our results show that digital nudges addressing the right user needs seem to be an action-triggering operation. Specifically, a digital forced-choice prosocial framing nudge, presented in a pop-up window, can increase the willingness to donate data among male health self-trackers by 15.5%. The results are in line with research on the effectiveness of digital nudging in general (20%) as well as on the effectiveness of offline nudges in health care (16%) [30,35]. We need to further examine how the nudge itself (framing), the presentation (pop-up window vs no pop-up window), and timing of the digital nudge impact nudge effectiveness. In general, however, developers and researchers should consider digital nudges addressing the need for social responsibility when asking for data donation within this specific user group.

The experimental results confirm the findings of previous research on the motives to donate personal data for the health area. Specifically, for health self-trackers, our study confirms the results of Skatova and Goulding [66] and Mujcic and Leibbrandt [68], who found social responsibility or duty to be the strongest predictor of willingness to donate personal data. Our experiment demonstrated that the prospect of doing something good for society positively influences willingness to donate personal health data. Arguably, the act of donating has a positive impact on self-image and sense of self. Unlike blood donation, which provides immediate reciprocal value to the donor in the form of appreciation and caring (during donation; Schiefer [64]) by those present, our results suggest the opposite for health data donation. The public donation of data and its visibility to third parties, especially peers, can potentially discourage health self-trackers from making this donation—they prefer to do so confidentially. Belonging to an ever more similar group within the group of self-trackers, in this case, people who donate their health data have no positive influence on willingness to donate data and more of a negative influence. Showing *charity*, therefore, negatively influences willingness to donate data. This finding should be taken into account when framing a data donation plea, for example, by explicitly referring to donor anonymity.

Compared with polls regarding willingness to donate data, our results show a significantly lower willingness among active health self-trackers. In contrast to population surveys, which put a willingness to donate data at 80% or social media users' willingness at 95% [15,16], only 41% (377/919) of surveyed health self-trackers would be willing to donate their tracked data to research with a probability above 50% and only 10% (92/919) with 100% probability. This discrepancy suggests that individuals who actively collect health-related data for a particular purpose value it more. It is important to keep this in mind when designing approaches to access health-related, self-tracked data. Research surveying a population cross-section disregards the hypothetical character of questions and answers, and thus, results can be biased and lead to ineffective measures.

Our results also show that women, who are evolutionarily more concerned about protecting their privacy, do not respond to any of the nudges presented adding to the findings by Tifferet [17] and Farinosi and Taipale [18], who found these gender differences, especially in social media users. Regarding the existing gender gap in clinical trials, addressed by Karp and Reavey [77], research needs to investigate which motives, needs, and nudges can increase access to women's health data equally.

Limitations

The findings have a number of limitations. Owing to recruiting primarily via social media and fitness influencers, the sample includes a disproportionately large number of younger and higher educated people as well as mostly female compared with male health self-trackers (2/3 to 1/3), which can bias our results.

Thus, the sample may not represent all German health self-trackers. Furthermore, people engaging in social media and following a call to action from influencers on Instagram and from peers in fitness Facebook groups (participating in the experiment in this case) have fewer privacy concerns and are more likely to share their health-related information with others. We did not perform ex ante power calculations to determine the sample size. Future research may therefore repeat the survey with a larger sample via additional recruitment channels to assess the reliability of our findings. In addition, the chosen geographic focus (Germany) might have biased the results because of cultural differences in terms of relevance and general attitudes toward privacy [78]. Further studies could consider international cross-cultural comparisons to verify the validity of our findings for a global app market.

Participants' nonreproducible or untruthful answers can also limit the results. The reasons could be the chosen and not clearly comprehensible scale levels or phrasing of the individual benefit. Future experiments could also imbed nudges in a different environment (a different app) and use an even more realistic situation with clickable mock-ups. Our hypothetical request for web-based health data donation may not represent reality. Future experiments could implement a real data donation tool within a popular health self-tracking app to verify our results.

Conclusions

The growing trend toward digital health and increasing acceptance as well as the use of health apps such as fitness trackers, digital check-ups, and nutrition apps will contribute to a significant increase in nudging measures. This study could aid access to health data for research and long-term care improvement.

Although selfish motives do not significantly influence willingness to donate, linking data donation to added societal value could significantly increase the likelihood of donating among male self-trackers by 15.5%. Thus, addressing the need

to contribute to society promotes willingness to donate data among male health self-trackers and should be emphasized when designing campaigns to donate health data. The implementation of forced-choice framing nudges within tracking apps presented in a pop-up window can add to the accessibility of user-generated health-related data for research.

Acknowledgments

The study was conducted as part of the ATLAS project, which is funded by the Ministry of Economic Affairs, Innovation, Digitalization, and Energy of North Rhine-Westphalia (funding code: ITG-1-1).

Authors' Contributions

KP conducted the literature research, conducted the quantitative study, and analyzed and discussed the data. SB-J provided content support for the process and reviewed the results. All authors have read and agreed to the published version of the manuscript.

Abstract

Background: Commercially available wearable (ambulatory) pulse oximeters have been recommended as a method for managing patients at risk of physiological deterioration, such as active patients with COVID-19 disease receiving care in hospital isolation rooms; however, their reliability in usual hospital settings is not known.

Objective: We report the performance of wearable pulse oximeters in a simulated clinical setting when challenged by motion and low levels of arterial blood oxygen saturation (SaO_2).

Methods: The performance of 1 wrist-worn (Wavelet) and 3 finger-worn (CheckMe O2+, AP-20, and WristOx2 3150) wearable, wireless transmission–mode pulse oximeters was evaluated. For this, 7 motion tasks were performed: at rest, sit-to-stand, tapping, rubbing, drinking, turning pages, and using a tablet. Hypoxia exposure followed, in which inspired gases were adjusted to achieve decreasing SaO_2 levels at 100%, 95%, 90%, 87%, 85%, 83%, and 80%. Peripheral oxygen saturation (SpO_2) estimates were compared with simultaneous SaO_2 samples to calculate the root-mean-square error (RMSE). The area under the receiver operating characteristic curve was used to analyze the detection of hypoxemia (ie, SaO_2<90%).

Results: SpO_2 estimates matching 215 SaO_2 samples in both study phases, from 33 participants, were analyzed. Tapping, rubbing, turning pages, and using a tablet degraded SpO_2 estimation (RMSE>4% for at least 1 device). All finger-worn pulse oximeters detected hypoxemia, with an overall sensitivity of ≥0.87 and specificity of ≥0.80, comparable to that of the Philips MX450 pulse oximeter.

Conclusions: The SpO_2 accuracy of wearable finger-worn pulse oximeters was within that required by the International Organization for Standardization guidelines. Performance was degraded by motion, but all pulse oximeters could detect hypoxemia. Our findings support the use of wearable, wireless transmission–mode pulse oximeters to detect the onset of clinical deterioration in hospital settings.

Introduction

Failure to recognize and act on physiological indicators of worsening acute illness in hospital wards is a prevalent problem first recognized over 20 years ago [1-3]. Current practice involves intermittent measurements of vital signs and use of early warning scores [4], which are limited by the intermittent nature of the measurements and the associated time burden for staff [5]. Monitoring vital signs continuously with wearable (ambulatory) devices may overcome these limitations and improve detection of deterioration [6-8]. However, recent pilot and observational studies of wearable monitoring devices have shown mixed results, and no large clinical trials of ambulatory monitoring systems (AMSs) have demonstrated improved patient outcomes [6,9,10]. For example, in pulse oximetry, it is well known that patient motion and low perfusion in extremities can generate artifacts that reduce the accuracy of peripheral oxygen saturation (SpO_2) readings [11]. This represents a major barrier to the deployment of these wearable devices for in-hospital patient monitoring [12]. Data averaging, alarm delay, and data holding are some of the strategies developed by pulse oximeter manufacturers to reduce the effect of motion artifacts and avoid false alerts [13], but there is still a need for studies of diagnostic accuracy and motion artifacts to support development of reliable wearable devices [3,7,14,15]. This need has become acute as health care systems have recommended the incorporation of ambulatory pulse oximeters in the home management of COVID-19 [16-18].

This study is part of a phased mixed-methods research project aiming to develop and refine an AMS using wearable devices to aid in the detection of deterioration and improve patient outcomes. The primary objective of this study was to determine the specificity and sensitivity of currently available ambulatory vital sign–monitoring equipment for the detection of hypoxemia. The secondary objective was to determine the effect of motion on data acquisition by the same devices.

Methods

Ethics

This research publication follows the Standards for Reporting Diagnostic Accuracy Studies reporting guidelines [19] and reports the results of the study protocol of Areia et al [20]. This study received ethics approval from the East of Scotland Research Ethics Service REC 2 (19/ES/0008) and was registered in June 2019 (no. ISRCTN61535692).

Study Design

This was a prospective, observational study in which SpO_2 estimates from the study devices were compared with the gold-standard arterial blood oxygen saturation (SaO_2) samples and clinical-standard SpO_2 estimates collected from arterial blood gas (ABG) samples and a nonambulatory Philips MX450 (Philips, Amsterdam, the Netherlands) pulse oximeter, respectively. The device's pulse rate estimation accuracy is reported in Multimedia Appendix 1.

Participants

Healthy adults (18 years or older) able to give informed consent for participation in the study were recruited consecutively from the Oxford area (United Kingdom) between June 18 and August 8, 2019. The exclusion criteria are described in detail in the study protocol [20], including clinical conditions that might bias the estimation of SpO_2 by oximetry (eg, anemia) or increase risk to the participants' health (eg, clotting disorders).

Test Methods

Study Sessions

The study sessions took place at the Cardiovascular Clinical Research Facility, John Radcliffe Hospital, Oxford, UK. An arterial line was first inserted, under local anesthesia, preferentially into the nondominant radial artery of participants placed in the semirecumbent position (30^o head up). Where it was not possible to cannulate the nondominant arm, the dominant arm was cannulated. Participants wore 1 wrist-only device (Wavelet; WaveletHealth, Mountain View, USA) and 3 wrist-worn pulse oximeters with a finger probe: CheckMe O2+ (Viatom Technology Co Ltd, Shenzhen, China), AP-20 (Shenzhen Creative Industry Co Ltd, Shenzhen, China), and WristOx2 3150 with Bluetooth Low Energy (BLE; Nonin Medical Inc, Plymouth, USA) on the same arm. These devices are among the few that make both numeric and waveform data available to other systems. This is a requirement in our research [20] as we plan to notify clinical staff about the signal quality of the waveforms from which the numeric estimates are derived. A nonambulatory Philips MX450 pulse oximeter was also worn. CheckMe O2+ was always placed on the first finger as per the manufacturer's recommendation. The position of the other 3 finger probes on the second, third, and fourth fingers was randomized using software from Haahr [21], per study visit day, ensuring an even distribution of placement. The participants also wore a 3-lead electrocardiogram (ECG) and an end-tidal carbon dioxide monitor connected to the Philips MX450 monitor, and an adhesive chest patch, for monitoring and acquisition of the heart rate and breathing rate. Results obtained with the chest patch are not reported here.

Stage 1: Movement Phase

An at-rest window was assigned to the period before the first ABG measurement, taken after fitting all the devices. The

participants then moved to a chair and were asked to complete a series of consecutive motion tasks: 20 times sit-to-stand (STS), 2-minute tapping at 2 Hz, 2-minute rubbing at 2 Hz, 20 times drinking from a plastic cup, 50 times turning pages, and a set of predefined tablet activity tasks [20]. ABG measurements were made at the end of each motion task in order to analyze the mean bias of the SpO_2 estimates for each task. For a sample of 15 participants, an additional ABG measurement was made in the middle of the STS motion to assess differences in the SaO_2 during and after that activity.

Stage 2: Hypoxia Exposure Phase

Participants moved to a semirecumbent, supine position and wore a tight-fitting silicone facemask connected to a device that reduces the inspired fraction of oxygen, the hypoxicator unit (Everest Summit Hypoxic Generator, Altitude Centre, London, UK). During this phase, oxygen saturation from the clinical-standard Philips MX450 monitor guided the titration of the hypoxicator by a senior anesthetist from the research team, with appropriate resuscitation facilities nearby. In addition, 7% oxygen in nitrogen was used to further lower the fraction of inspired oxygen (FiO_2), if required [22]. FiO_2 was also monitored via an in-line gas analyzer. ABGs were sampled when the participants reached stable prespecified target peripheral oxygen saturation levels: 95%, 90%, 87%, 85%, 83%, and 80%. A senior anesthetist decided when a stable oxygen level was achieved in order to take the ABG based on the clinical values shown by the standard SpO_2 monitor.

Data Collection

Demographic data, including age, sex, height, weight, skin type (Fitzpatrick scale [23]), baseline heart rate (Philips MX450 3-lead ECG), and SaO_2 (from the initial ABG), were collected for each participant at the start of their session. All data collection devices and software were synchronized to the same timestamp, at the start of each study session. SpO_2 data (1 Hz) from CheckMe O2+ and WristOx2 3150 were sent via BLE to and timestamped in different Android tablets (application developed in-house). The AP-20 SpO_2 data (1 Hz) were captured in the device and then downloaded via Oximeter Data Manager version 5.6 software (Shenzhen Creative Industry Co. Ltd., China). The Wavelet device first uploaded the photoplethysmography data to its web platform via an iOS app "On-site." The platform then retrospectively estimated SpO_2 (1 Hz), and these data were shared with the research team. The Phillips MX450 SpO_2 data were collected using ixTrend version 2.1 software. The start and stop times of each motion task and the ABG measurement timings were recorded in case report forms. Functional SaO_2 values were determined immediately after each ABG sample was taken, by multiwavelength oximetry, using a calibrated blood gas electrolyte analyzer, Radiometer ABL90 Flex (Radiometer, Copenhagen, Denmark).

Statistical Analysis

Sample Size

The sample size calculation was based on the International Organization for Standardization (ISO) 80601-2-61:2019 guideline for testing the accuracy of pulse oximeters, which requires at least 200 data points balanced across the SaO_2 range of 70%-100% from at least 10 subjects. We aimed to collect approximately 30 full data sets (with 7 ABGs being used in both the movement and hypoxia exposure phases, yielding a total of 420 readings, ie, 210 for each phase) to achieve a sufficient number of data points for the primary and secondary outcomes, and to recruit participants varying in their physical characteristics to the greatest extent possible. We excluded participants if incomplete data were collected for any 1 device during testing or if hypoxia was not achieved.

Accuracy, Bias, and Precision Metrics

Demographics and baseline vital sign descriptors were summarized using the mean, the median, and the first and third quartiles for continuous variables and proportions for categorical variables. In accordance with the ISO guideline, the accuracy of the SpO_2 estimates for each device was determined using the root-mean-square error (RMSE) between the measured values (SpO_{2i}) and the reference values (SaO_{2i}):

The RMSE 95% CI was determined using bootstrapping (random sampling with replacement) with 10,000 repetitions. The ISO guideline requires that valid oximeters present an RMSE below or equal to 4% (and below or equal to 8% when considering the CI). To interpret potential sources of the SpO_2 estimation error, the mean bias B and precision S were also calculated as

and

respectively. The latter is also known as the SD of the residuals, which determines the spread of the test SpO_2 data around the linear regression model, SpO_{2fit}, which predicts the SpO_2 estimates that best fit the reference SaO_2 values. The agreement between the test devices and the gold standard was also assessed via Bland-Altman plots. Finally, the mean absolute bias was also analyzed.

Movement Phase

The metrics were computed using the median SpO_{2i} from the 40-second window immediately before the stop time from each motion task and the SaO_2 value from the ABG taken immediately after the same motion task.

Hypoxia Exposure Phase

The metrics were computed using the median SpO_{2i} from a 40-second window, including 35 seconds before and 5 seconds after the i-th reference SaO_2 value (note that SaO_2 readings were taken for the 80%, 83%, 85%, 87%, 90%, 95%, and 100% target values, with the corresponding output of the blood gas analyzer then taken as the reference value). These metrics were also computed for 3 SaO_2 subgroups: severe hypoxia, SaO_2 lower

than 85%; mild hypoxia, SaO_2 from 85% to 89%; and normoxia, SaO_2 equal to or greater than 90%.

Statistical Tests

For both phases, one-way ANOVA followed by the Tukey-Kramer test [24] was used to evaluate differences in the mean bias and the mean absolute bias between groups. The Levene test [25] was used to evaluate differences in the precision between groups. In the movement phase, the distributions between the 15 additional SaO_2 values taken at the middle of the STS motion and those taken at the end were compared via the Wilcoxon test. Significance was considered at $P<.05$.

Sensitivity and Specificity in Detecting Hypoxemia

To evaluate each device's diagnostic accuracy in detecting hypoxemia, we determined the sensitivity, specificity, positive and negative predictive values (PPV and NPV), and accuracy (computed from the error matrix) for identifying values of SaO_2 below 90%. To consider whether device performance would be more reliable if recalibrated, we calculated the area under the receiver operating characteristic (AUROC) curve for each pulse oximeter and computed the same metrics at the optimal operating value. In addition, 95% CIs for all metrics were determined using bootstrapping.

Due to SpO_2 estimation performance issues, Wavelet analysis was removed. Its results can be found in Multimedia Appendix 2.

Results

Participants

Prescreening interviews were performed on 51 volunteers (Consolidated Standards of Reporting Trials [CONSORT] flow diagram in Figure 1). Of these, 1 (2%) volunteer was excluded due to a history of anemia, and 8 (16%) were not able to attend the study session. The remaining 42 (82%) participants attended a study session: 4 (10%) participants presented clinical conditions, evaluated at the start of their session, that were part of the exclusion criteria and would bias the SpO_2 estimations if included (3 [75%] additional anemia cases, evaluated from the first ABG, and 1 [25%] sickle cell trait); for 1 (2%) subject, it was not possible to induce hypoxia; for 2 (5%) subjects, it was not possible to insert an arterial line (in either arm); finally, 2 (5%) subjects had incomplete SpO_2 data for the WristOx2 3150 device. Complete data were therefore obtained from 33 (79%) healthy adults, 18 (55%) women and 15 (45%) men, spread across Fitzpatrick skin types 1-4, with a median age of 29 (SD 24-36) years. The baseline vital sign mean values, measured at the start of each session, were 71 beats per minute (bpm), 15 respirations per minute (rpm), 100% SaO_2, 130/75 mmHg, and a derived BMI of 23.7 kg/m^2 (demographics available in Table 1). Figure 2 shows an exemplar SpO_2 trend for each device for 1 study session. In general, poor estimation performance could be seen during the motion tasks (identified by the brown periods at the top), and all devices (expect Wavelet, whose analysis can be reviewed in Multimedia Appendix 2) followed the SaO_2 desaturation trend (red stars) during the hypoxia phase (from 9:58 AM to 10:14 AM). We discuss their accuracy next.

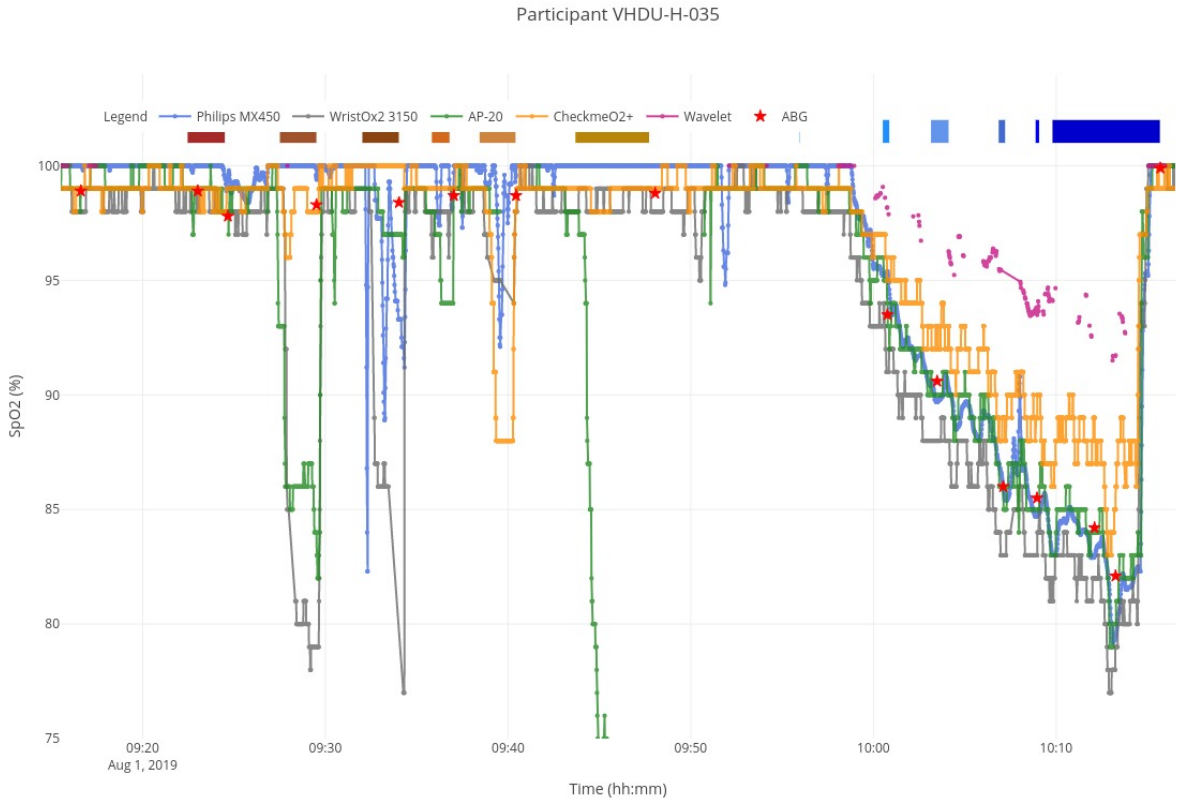
Figure 2. SpO_2 trend for each device during the movement (9:20 AM-9:50 AM) and hypoxia exposure (9:58 AM-10:14 AM) phases of 1 study session. The gold-standard SaO_2, derived from ABG samples, are shown as red stars. The different motion tasks and target desaturation intervals are illustrated by brown and blue rectangles at the top, respectively. Wavelet SpO_2 data are shown for comparison (results can be reviewed in Multimedia Appendix 2). ABG: arterial blood gas; SaO_2: arterial blood oxygen saturation; SpO_2: peripheral oxygen saturation.



SpO_2 Estimation in the Movement Phase

The results of SpO_2 estimation performance metrics for each device are shown in Table 2. The mean bias and precision are further illustrated for each motion task in Figure 3. The number of dropout values was comparable between the finger-worn devices. The RMSE values were below 4% when at rest and for the STS and drinking tasks for all devices. For all other tasks, they were above 4% for at least 1 device.

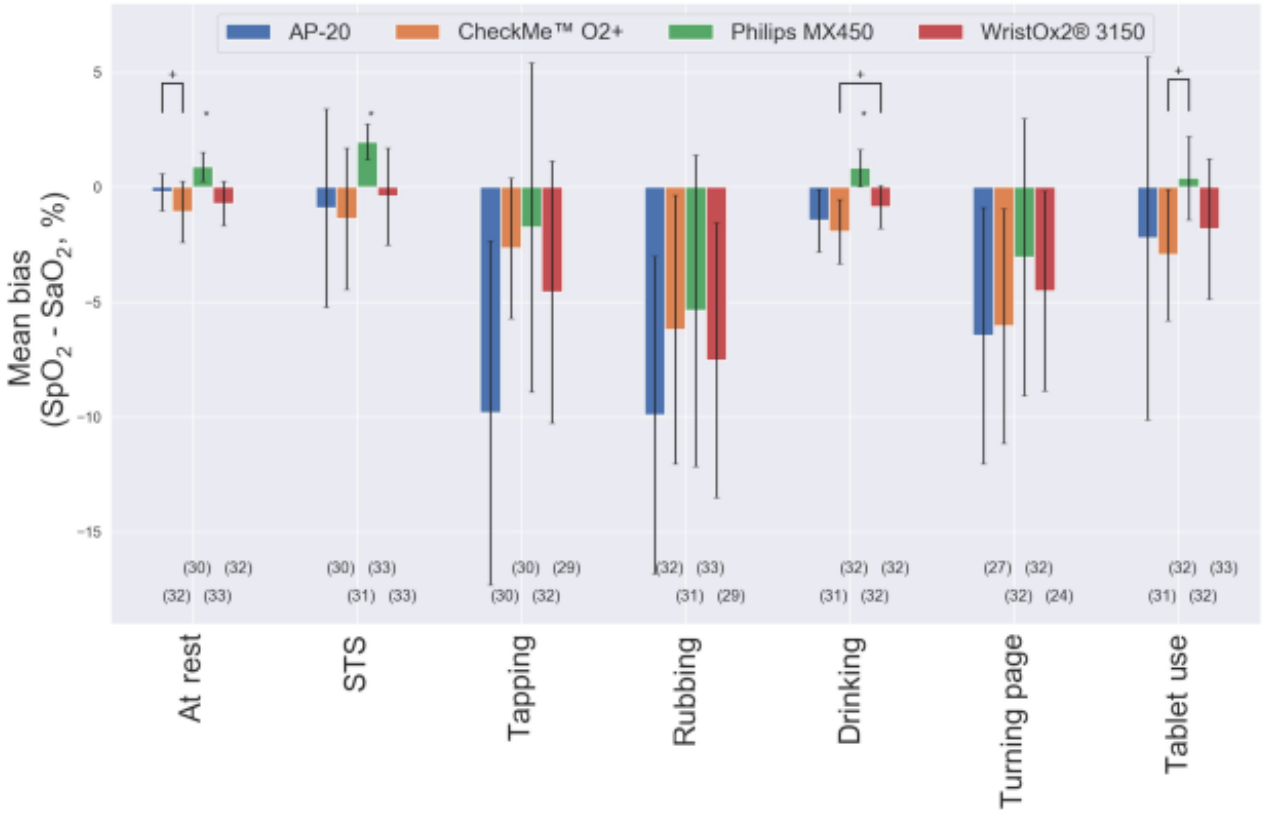
For each task, one-way ANOVA followed by the Tukey test was used to evaluate differences in the mean bias between devices. *Different from other values. +Different from each other. SaO_2: arterial blood oxygen saturation; SpO_2: peripheral oxygen saturation; STS: sit-to-stand.



SpO_2 Estimation in the Hypoxia Exposure Phase

Table 3 compares the SpO_2 estimation performance of the devices across the range of SaO_2 targets of the hypoxia exposure phase, and their Bland-Altman plots (with the mean bias and limits of agreement) can be reviewed in Figure 4. The WristOx2 3150 device underestimated SpO_2 in comparison with SaO_2 by almost 2%. The WristOx2 3150 and CheckMe O2+ devices had the numerically greatest mean absolute bias. However, SaO_2 subgroup analysis (see Figure 5 and Table 4) showed that the WristOx2 3150 device consistently underestimated SpO_2 across the measured range (with an overall mean bias of –1.92% [SD 2.73%]; Table 3), whereas the CheckMe O2+ device overestimated in the severe-hypoxia range and underestimated in the mild-hypoxia and normoxia ranges (Figure 5). However, WristOx2 3150, CheckMe O2+, AP-20, and Philips MX450 showed an overall RMSE below 4% (and below 8% when considering the 95% CI; Table 3), meeting the ISO 80601-2-61:2019 requirement.

Table 3. Comparison of accuracy (RMSE[a]) and mean bias of SpO_2[b] estimation between devices during the hypoxia exposure phase. There were 215 SaO_2 target windows in this phase.

Sensitivity and Specificity

Table 5 shows the performance metrics of the pulse oximeters in detecting hypoxemia (SaO_2<90%; AUROC curves available in Figure 6). A total of 128 SaO_2 targets were in the hypoxemia range versus 74 in the normoxia range. At a 90% cut-off, WristOx2 3150 showed significantly better sensitivity (0.97, 95% CI 0.93-0.99) than Philips MX450 (0.86, 95% CI 0.80-0.92). The values for the other metrics were comparable between all devices. All finger-worn devices achieved a good and comparable AUROC curve (≥0.92). Recalibration of the SpO_2 threshold to the optimal operating value resulted in AP-20 achieving significantly higher sensitivity than CheckMe O2+ (0.95 [95% CI 0.91-0.98] vs 0.78 [95% CI 0.71-0.85]). The remaining sensitivity and specificity values were comparable.

Table 5. Performance metrics of each pulse oximeter for detecting hypoxemia (SaO_2[a]<90%). The metrics are shown at a 90% SpO_2[b] cut-off and for the determined optimal SpO_2 cut-off.

Device	Cut-off, %	AUROC[c], mean (95% CI)	Sensitivity, mean (95% CI)	Specificity, mean (95% CI)	PPV[d], mean (95% CI)	NPV[e], mean (95% CI)	Accuracy[f], mean (95% CI)
90% SpO_2 (%) cut-off							
Philips MX 450	90.0	N/A[g]	0.86 (0.80-0.92)	0.93 (0.87-0.99)	0.96 (0.92-0.99)	0.79 (0.71-0.88)	0.89 (0.84-0.93)

Discussion

Principal Findings

Several studies have been published on both the usefulness and the potential issues of pulse oximetry in the clinical setting using nonambulatory devices. In this study, we compared the performance of wearable pulse oximeters and 1 nonambulatory pulse oximeter using gold-standard arterial blood samples drawn from healthy adult participants. Availability of waveform data was a requirement that limited the selection of devices. Our provision of waveform data will allow clinical staff to assess the reliability of the signal. However, a risk with all continuous-monitoring systems is that they increase the burden on clinical teams by providing excess data. Further work is required to determine the usefulness of these systems in clinical practice and how continuous-monitoring data should be summarized in the electronic patient record.

In tests of finger-based devices, WristOx2 3150 significantly underestimated SaO_2 (mean bias –1.92% [SD 2.73%]; Table 3) when compared with the other wearables. Nevertheless, all finger-based probes showed a similar mean absolute bias (about 2%) and RMSE (about 3%). Overall, all finger-worn wearable pulse oximeters achieved good sensitivity (≥0.87) and specificity (≥0.80), comparable to the standard nonambulatory device, in detecting hypoxemia (Table 5). Given that WristOx2 3150 underestimates SaO_2, it presented higher sensitivity (0.97, 95% CI 0.93-0.99) at the cost of a lower specificity value (0.80, 95% CI 0.70-0.89). This underestimation explains why recalibration by 2% achieves the optimal operating point. The remaining devices only required a change in the threshold by 1% at their optimal operating point.

From the 7 motion tasks, tapping, rubbing, turning book pages, and using a tablet challenged the finger-based wearable devices the most (the first 2 are also analyzed by Louie et al [11] and Barker and Shah [26]), resulting in an RMSE above 4% in at least 1 device. The mean bias at rest, STS, and drinking motions was comparable (<4%; Table 2).

Limitations

The sample size calculation for our study was based on the ISO 80601-2-61:2019 guidelines to evaluate the accuracy of pulse oximeters in detecting changes in SpO_2, not to identify differences in performance between pulse oximeters and between activities. The study was not designed to generalize results to the wider population, for example, for patients with darker skin types or with acute illness.

We chose to sample ABGs at the end of each task to avoid accidental removal of the cannula. However, it became clear during our study that the ABGs could have been sampled while the motion task was occurring, perhaps better representing that interval reference SaO_2. Preliminary analysis of the difference between ABGs taken immediately after the STS motion task and those taken at the midpoint of that motion, for 15 patients, showed that the SaO_2 dropped by an average of 1.87% (SD 0.87%, $P<.001$ between the 2 SaO_2 sample sets), indicating that the SpO_2 value might change between the time used to compute the SpO_2 estimates and that of the ABG samples taken after the exercise. Our hypothesis was that the STS task would be the motion task with the greatest effect on the participants' SaO_2. However, the error in the SpO_2 estimates from the wearable devices during motion was much larger, so this correction would not have changed our findings.

Conclusion

The accuracy of SpO_2 estimation by finger-worn pulse oximeters was within that required by the ISO 80601-2-61:2019 guideline (≤4%). The accuracy was degraded by motion but not more than that with usual-care bedside monitors. All finger-worn pulse oximeters were capable of detecting hypoxemia, their performance being comparable to that used in nonambulatory standard care.

Our findings support the use of wearable, finger-based, wireless transmission–mode pulse oximeters to detect the onset of clinical deterioration in the hospital, possibly earlier than intermittent vital-sign measurements. The continuous assessment of SpO_2, especially values below 90%, may be helpful to manage the care of ambulatory in-hospital patients who have been infected with the SARS-CoV-2 virus [27]. Further work is required to assess the impact of AMSs on patient outcomes, both during the COVID-19 pandemic and beyond.

Abstract

Background: Gay, bisexual, and other men who have sex with men (GBMSM) face the highest burden of HIV in the United States, and there is a paucity of efficacious mobile health (mHealth) HIV prevention and care interventions tailored specifically for GBMSM. We tested a mobile app combining prevention messages and access to core prevention services for GBMSM.

Objective: This study aims to measure the efficacy of the Mobile Messaging for Men (M-cubed) app and related services to increase HIV prevention and care behaviors in diverse US GBMSM.

Methods: We conducted a randomized open-label study with a waitlist control group among GBMSM in 3 groups (low-risk HIV-negative group, high-risk HIV-negative group, and living-with-HIV [LWH] group) recruited online and in venues in Atlanta, Detroit, and New York City. Participants were randomly assigned to receive access to the app immediately or at 9 months after randomization. The app provided prevention messages in 6 domains of sexual health and offered ordering of at-home HIV and sexually transmitted infection test kits, receiving preexposure prophylaxis (PrEP) evaluations and navigation, and service locators. Serostatus- and risk-specific prevention outcomes were evaluated at baseline, at the end of the intervention period, and at 3, 6, and 9 months after the intervention period.

Results: In total, 1226 GBMSM were enrolled and randomized; of these 611 (49.84%) were assigned to the intervention group and 608 (99.51%) were analyzed, while 615 (50.16%) were assigned to the control group and 612 (99.51%) were analyzed. For high-risk GBMSM, allocation to the intervention arm was associated with higher odds of HIV testing during the intervention period (adjusted odds ratio [aOR] 2.02, 95% CI 1.11-3.66) and with higher odds of using PrEP in the 3 months after the intervention period (aOR 2.41, 95% CI 1.00-5.76, *P*<.05). No changes in HIV prevention or care were associated with allocation to the intervention arm for the low-risk HIV-negative and LWH groups.

Conclusions: Access to the M-cubed app was associated with increased HIV testing and PrEP use among high-risk HIV-negative GBMSM in 3 US cities. The app could be made available through funded HIV prevention providers; additional efforts are needed to understand optimal strategies to implement the app outside of the research setting.

Introduction

The ambitious goal of the US Ending the HIV Epidemic Initiative to reduce new HIV diagnoses by 90% by 2030 [1] will not be reached without reducing new HIV infections in gay, bisexual, and other men who have sex with men (GBMSM). GBMSM comprised 54% of annual new HIV diagnoses in 2019 in the United States [2] and face the highest burden of HIV in the United States [3]. However, there are few efficacious or promising mobile health (mHealth) HIV prevention and care interventions tailored for subgroups of GBMSM [4,5]. New HIV prevention tools should address the needs of GBMSM, young GBMSM aged 15-24 years (YGBMSM) [6], and YGBMSM of color, for whom HIV incidence is the highest [7-9]. Currently, HIV prevention services are underused by GBMSM: in 2018, just over half (56%) reported being tested in the past 12 months, high proportions (76% of HIV-positive and 66% of HIV-negative GBMSM) reported recent condomless receptive anal intercourse, and few (<20%) reported preexposure prophylaxis (PrEP) use [10,11]. Statistical models demonstrate that high levels of coverage of prevention services will be required to substantially reduce HIV incidence among GBMSM [12,13] and increased use of routine prevention services (eg, HIV testing) might increase uptake of biomedical interventions, such as PrEP [14]. A package of HIV prevention interventions is needed to maximally reduce the risks of infection, and uptake of multiple prevention services by a substantial proportion of the GBMSM population is needed to reduce HIV incidence among GBMSM.

A growing body of research has suggested that mobile phone apps are a promising environment to offer tailored and on-demand prevention services for GBMSM [5,6,15-19]. GBMSM are open to receiving prevention information and resources via mobile apps [20]. Communicating prevention messages through mobile apps (mobile messaging) might enhance intervention uptake, because it allows messaging to a wide audience of GBMSM, including rural GBMSM, who use sexual health services and PrEP at lower rates than GBMSM in urban areas [10,11,21]. Younger GBMSM might be especially interested in using mobile technology to receive health information [22].

HIV prevention and care interventions for GBMSM have most often been provided through in-person sessions with behavior change interventions, are often focused on specific subgroups of GBMSM (eg, high-risk HIV-negative episodic substance-using GBMSM, Black GBMSM with HIV-negative or unknown HIV serostatus, HIV-positive clinic patients) [23] and often target only 1 element of comprehensive prevention—for example, condom use, medication adherence, or PrEP uptake [4]. In a serostatus-neutral framework [24], we must evaluate interventions that address multiple prevention behaviors (eg, HIV testing, sexually transmitted infection [STI] testing, condom use, PrEP uptake, and medication adherence), many of which are relevant to GBMSM with HIV and those at risk for HIV infection.

To address these needs, we adapted an existing HIV prevention app designed for GBMSM, HealthMindr, to add and evaluate tailored prevention messaging [25-27]. The methods for the app content development specific to this study have been described elsewhere [28]. We aimed to develop a mobile app that can address multiple prevention and care needs for GBMSM, both those with HIV and those at risk for HIV acquisition (ie, HIV negative). We developed messaging for HIV-negative GBMSM that would be relevant for both high- and low-risk MSM. Messages were drawn from existing mHealth interventions [29,30] and adapted through a theory-driven approach with stakeholder input, as previously described [28]. Messages were provided through in-app content and videos. We used the core HealthMindr app [25,26] to offer a suite of prevention services, including self-screening for HIV and STI risk; a scheduling and reminder system for routine HIV and STI testing; a PrEP eligibility screener; a nonoccupational postexposure prophylaxis (nPEP) risk assessment tool; an ordering platform for delivery of at-home HIV- and STI-screening kits and of condoms and lubricants; and service locators for HIV and STI testing, PrEP, nPEP, and HIV treatment and care. The app included branding associating the app with Emory University. Content was frozen during the trial. Participants accessed the app from Apple App

Store or Google Play Store and received a study-specific activation code.

We aimed to evaluate the use and efficacy of the combined prevention messaging and app service components as a public health intervention strategy to reduce risks of HIV acquisition and improve HIV care outcomes among GBMSM. We hypothesized that exposure to the message delivery platform within a comprehensive HIV prevention app would result in improvements in participants' self-reported sexual health, prevention, and care behaviors, compared to GBMSM without access to the app.

Methods

Study Design

Data were collected from January 24, 2018, to October 31, 2019. The methods for the study have been previously described [28] and are summarized here. Eligibility criteria are summarized in Table 1. Men were classified as (1) HIV seropositive, (2) HIV seronegative at high risk (any anal sex not protected by condoms or not taking PrEP, as prescribed, in the past 3 months), and (3) HIV seronegative at low risk (anal sex protected by condoms in the past 3 months or taking PrEP, as prescribed, in the past 3 months, ie, adherent PrEP users). Owning a cell phone was also required, and smartphone literacy was thus a de facto eligibility criterion. This research was reviewed and approved by the Emory University institutional review board (protocol IRB00087684) on June 13, 2016. We collected individual informed consent in person at the study enrollment visit. Consenting participants were randomly assigned to either the immediate intervention group or the waitlist control group in a 1:1 ratio within 36 strata based on the 3 serostatus/risk groups, 3 cities, race/ethnicity (non-Hispanic White vs other race/ethnicity), and phone type (Android vs iOS) [31]. Participants in the intervention group received one 2-sentence message every other day and a 1-minute video weekly, in addition to access to HIV and STI kit ordering and informational resources.

At in-person baseline visits, participants assigned to the intervention group downloaded and received orientation to the study app and received access to the mobile app and prevention messages based on their risk profiles. Participant contact and retention activities were supported through the Emory Study Management and Retention Tool (SMART). The intervention was provided over 3 months, after which the app was deactivated. Waitlist control participants were not provided access to the intervention app at the baseline visit but continued to receive quarterly surveys. An overview of the study timeline and complete survey instruments have been published and are available online [28].

There were multiple prevention outcomes, which varied among the 3 risk groups, as previously reported [28]. The specific outcomes and measures used are summarized in Table 2.

Table 1. Eligibility criteria for a randomized controlled trial of the Mobile Messaging for Men intervention in Atlanta, Detroit, and New York City (2018-2019).

Criterion	Eligible level
Age (years)	• ≥18
Sex at birth	• Assigned as male
Current gender identity	• Male
Sexual risk behaviors	• Reports anal intercourse with a male partner in the past 12 months
City of residence	• Resident of Atlanta, Detroit, or New York City
Other eligibility criteria	• Plans to stay in the city area for the next 9 months • Owns and uses an Android or iOS smartphone • Is able to read and understand English without assistance

Table 2. Outcomes and measures used in the evaluation of Mobile Messaging for Men, a mobile health intervention to promote HIV prevention and care behaviors among GBMSM[a] in Atlanta, Detroit, and New York City (2018-2019).

Behavior	Group assessed	Definition
STI[b] testing	• All GBMSM	STI test[c] in the 3 months before the survey
HIV testing	• Low-risk HIV-negative GBMSM • High-risk HIV-negative GBMSM	Self-reported[d] HIV test in the 3 months before the survey
Current PrEP[e] use	• Low-risk HIV-negative GBMSM • High-risk HIV-negative GBMSM	Self-reported[d] being on PrEP as of the day of the survey
PrEP adherence	• All low- and high-risk HIV-negative GBMSM reporting PrEP use	Self-reported[d] taking at least 25/30 daily pills in the prior 30 days
Current ART[f] use	• All LWH[g] GBMSM	Self-reported[d] being on ART as of the day of the survey
ART adherence	• All LWH GBMSM on ART	Self-reported[d] taking ART, as prescribed, on ≥25 of the past 30 days
Anal sex not protected by PrEP or condoms	• Low-risk HIV-negative GBMSM • High-risk HIV-negative GBMSM	Self-reported anal sex with a main or casual partner when the participant was not on PrEP AND the insertive partner did not use a condom from start to finish[d]
Anal sex not protected by PrEP or condoms	• LWH GBMSM	Self-reported anal sex with a main or casual partner when the insertive partner did not use a condom from start to finish[d]

[a]GBMSM: gay, bisexual, and other men who have sex with men.

[b]STI: sexually transmitted infection.

[c]Includes Mobile Messaging for Men care kit orders with results.

[d]Self-report measures were previously validated as part of the American Men's Internet Survey [32].

[e]PrEP: preexposure prophylaxis.

[f]ART: antiretroviral therapy.

[g]LWH: living with HIV.

Data Analysis

Analyses were stratified by the baseline HIV status/risk group: high-risk HIV-negative, low-risk HIV-negative, and living with HIV (LWH) groups. Counts and relative frequencies were used to describe sociodemographics and sexual history at baseline by intervention status (intervention group vs control group) and HIV status/risk group, and chi-square tests assessed for differences in these characteristics by intervention status (Table 3). To account for within-person repeated measures and randomization strata, separate mixed-effect logistic models assessed for association over time of the intervention with each outcome.

A post hoc analysis was conducted to compare control participants with intervention participants who had at least 30 minutes of intervention use in order to assess the potentially mediating effect of the time spent on the app; 30 minutes was the estimated time required to read and rate all written messages and view the video messages. A second post hoc analysis was conducted because not all participants who ordered and received at-home STI test kits returned them. In this second analysis, we defined the intention to test for STIs as either ordering an STI test kit through the mobile app or reporting having taken an STI test. Result reporting was prepared in accordance with Consolidated Standards of Reporting Trials (CONSORT) guidelines [33].

Table 3. Sociodemographic and baseline behavioral characteristics of MSM[a] in the Mobile Messaging for Men study sample (2018-2019).

Characteristic	Overall (N=1220)	High-risk[b] HIV-negative (n=427)		Low-risk[c] HIV-negative (n=410)		HIV-positive (n=383)

[a]MSM: men who have sex with men.

[b]High risk (condomless/PrEP-less anal sex, past 3 months).

[c]Low risk (no condomless/PrEP-less anal sex, past 3 months).

[d]*P* value for chi-square testing (difference between intervention and control arms).

[e]One HIV-positive participant did not report race/ethnicity.

[f]Not applicable.

[g]Two high-risk HIV-negative and one HIV-positive participants did not report education level.

[h]STI: sexually transmitted infection.

[i]PrEP: preexposure prophylaxis.

[j]Among current users.

[k]ART: antiretroviral therapy.

[l]Condomless and PrEP-less anal sex for HIV-negative and condomless/detectable viral load for HIV-positive users.

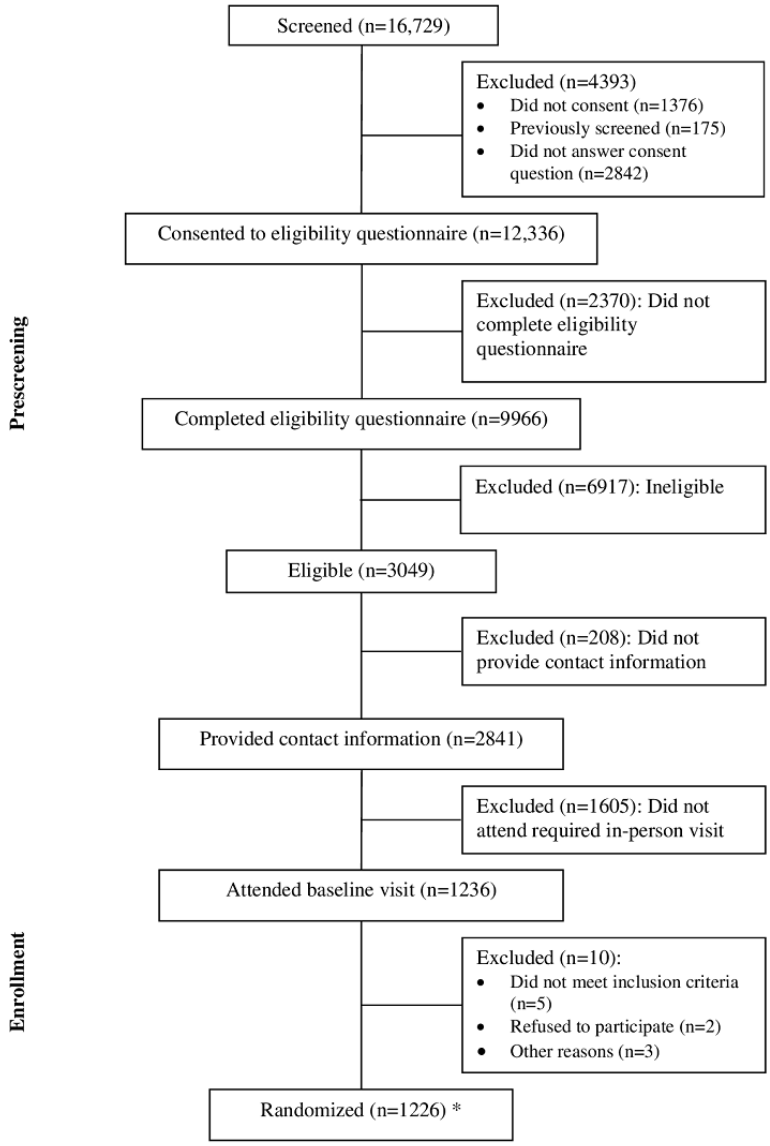
[m]Engagement in PrEP or ART care.

Results

Recruitment and Randomization

From January 24, 2018, to November 2, 2018, a total of 9966 GBMSM were assessed for eligibility for the randomized controlled trial; reasons for lack of eligibility are shown in Figure 1. Specifically, 2841 (28.51%) of 9966 GBMSM screened were eligible and provided contact information, of which 1236 (43.51%) attended a baseline study visit, 1226 (99.19%) consented and were randomized to intervention (n=611, 49.84%) and control (n=615, 50.16%) arms (Figure 1).

Figure 1. CONSORT diagram for the M-cubed randomized controlled trial among GBMSM (screening through randomization). CONSORT: Consolidated Standards of Reporting Trials; GBMSM: gay, bisexual, and other men who have sex with men; M-cubed: Mobile Messaging for Men.



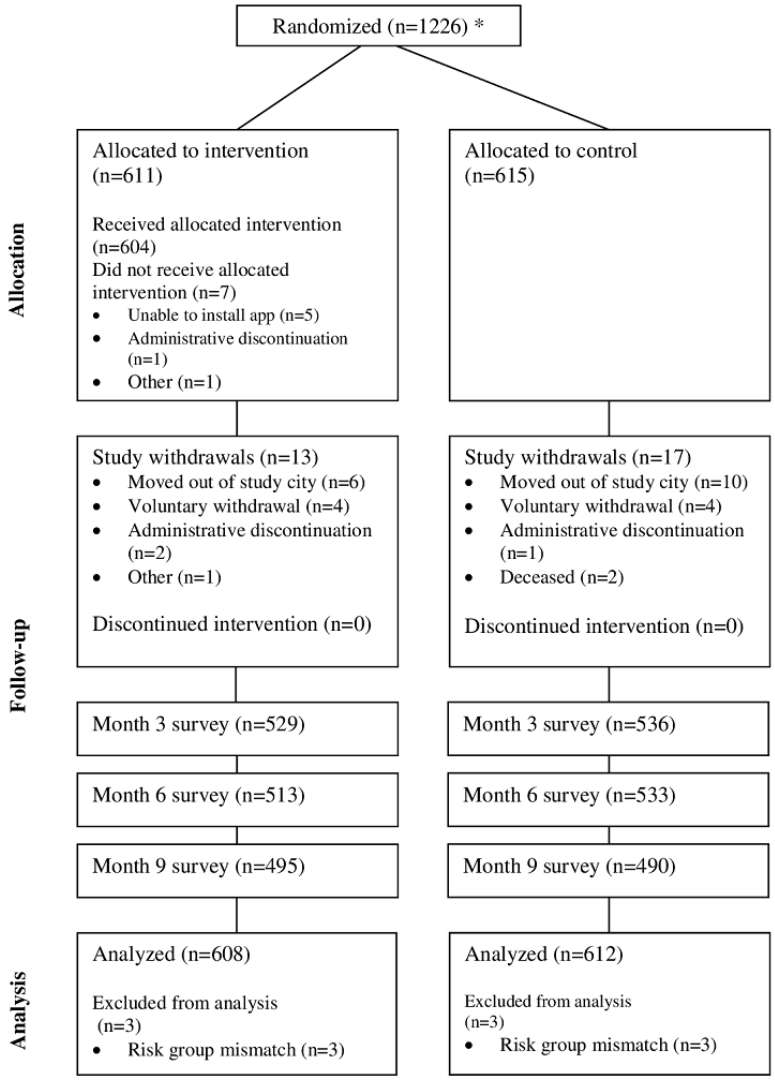
* Includes 388 in HIV-positive group, 410 in low-risk HIV-negative group, 428 in high-risk HIV-negative group

Sample Characteristics

The analytic sample comprised 1220 GBMSM enrolled in the study, including 608 (49.84%) randomized to the intervention arm and 612 (50.16%) randomized to the control arm (Figure 2). There was no failure of randomization within the 3 risk groups, except for unprotected anal intercourse among LWH GBMSM (Table 2). Most participants were GBMSM of color (n=378 [30.98%] Black/African American, n=183 [15%] Hispanic/Latino, n=148 [12.13%] other/mixed), were aged ≥30 years (772/1220 [63.28%]), and had at least a 4-year college education (654/1220 [53.61%]). Other indicators of risk and prevention services did not differ between control and intervention arms (data not shown). Self-reported levels of use of prevention and care services were often less than recommended by the Centers for Disease Control and Prevention

(CDC). High-risk HIV-negative GBMSM reported moderate levels of STI (165/427, 38.6%) and HIV (162/427, 37.9%) testing in the 3 months before baseline; only 22 of 427 (5.1%) reported using PrEP, and adherence to PrEP was low (11/22, 50%, reported ≥25/30 pills in the prior 30 days). A high proportion (392/427, 91.8%) reported sex not protected by PrEP or condoms in the past 3 months. Among low-risk HIV-negative GBMSM, baseline use of STI (254/410, 61.9%) and HIV (259/410, 63.2%) testing was higher; in addition, 222 of 410 (54.1%) reported being on PrEP, with high (212/222, 95.5%) adherence. Many HIV-negative GBMSM were designated as low risk because they were on PrEP; routine PrEP care includes HIV and STI testing. Among LWH GBMSM, most (271/383, 70.8%) reported recent STI testing, being on antiretroviral therapy (ART; 368/383, 96.1%) and high ART adherence (335/368, 91%). About 1 in 4 reported anal sex not protected by condoms in the past 3 months (98/383, 25.6%), and most (251/383, 65.5%) reported engaging in HIV care during the prior quarter.

Figure 2. CONSORT diagram for a randomized controlled trial of the M-cubed intervention for GBMSM (randomization through analysis). CONSORT: Consolidated Standards of Reporting Trials; GBMSM: gay, bisexual, and other men who have sex with men; M-cubed: Mobile Messaging for Men.



* Includes 388 in HIV-positive group, 410 in low-risk HIV-negative group, 428 in high-risk HIV-negative group

Retention was 1065 of 1226 (86.87%) at 3 months, 1046 of 1226 (85.32%) at 6 months, and 985 of 1226 (80.34%) at 9 months. Factors associated with retention were consistent across time points: retention was higher among participants who were White non-Hispanic, had more education, were employed full-time, and were not homeless. At the 9-month follow-up, higher retention was also associated with gay/homosexual identity (vs bisexual or other identities) and online recruitment (vs venue-based recruitment).

Intervention Efficacy

Intervention efficacy was analyzed by HIV status/risk group (Table 4). Among high-risk HIV-negative GBMSM, the odds of HIV testing (Figure 3) were higher at the immediate postintervention time point and the odds of current PrEP use

(Figure 4) were higher at the 3-month postintervention time point, but not at 6 or 9 months postintervention (Table 4). Of the high-risk GBMSM in the intervention arm who tested for HIV in the immediate postintervention period (n=126), 16 (12.7%) used an at-home HIV self-test kit provided through the app. As shown in Figure 4, although the initial prevalence of PrEP use was nonsignificantly lower in the intervention group at baseline, PrEP use rose from 3% at baseline to 15% by the 3-month follow-up assessment and remained at 15% through the 6-month follow-up assessment. Although odds ratio (OR) estimates comparing intervention to control for PrEP adherence were >1.0 at all postintervention time points for high-risk GBMSM, they were not statistically significant, given the small number of high-risk HIV-negative GBMSM taking PrEP.

For low-risk HIV-negative GBMSM, there were no changes in study outcomes associated with assignment to the intervention. For LWH GBMSM, STI testing was significantly lower in the immediate posttest period in the intervention group compared to the control group.

Table 4. Modeled behavioral measures at baseline, immediate posttest, and 3- and 6-month postintervention follow-up assessments for intervention efficacy of the Mobile Messaging for Men mobile app among MSM[a] by HIV status/risk group (N=1220).

[g]PrEP: preexposure prophylaxis.

[h]ART: antiretroviral therapy.

[i]Condomless/PrEP-less anal sex for HIV-negative MSM and condomless/detectable viral load for HIV-positive MSM.

Figure 3. HIV testing of high-risk GBMSM, reported by study time point and randomized allocation, in Atlanta, Detroit, and New York City (2018-2019). GBMSM: gay, bisexual, and other men who have sex with men.

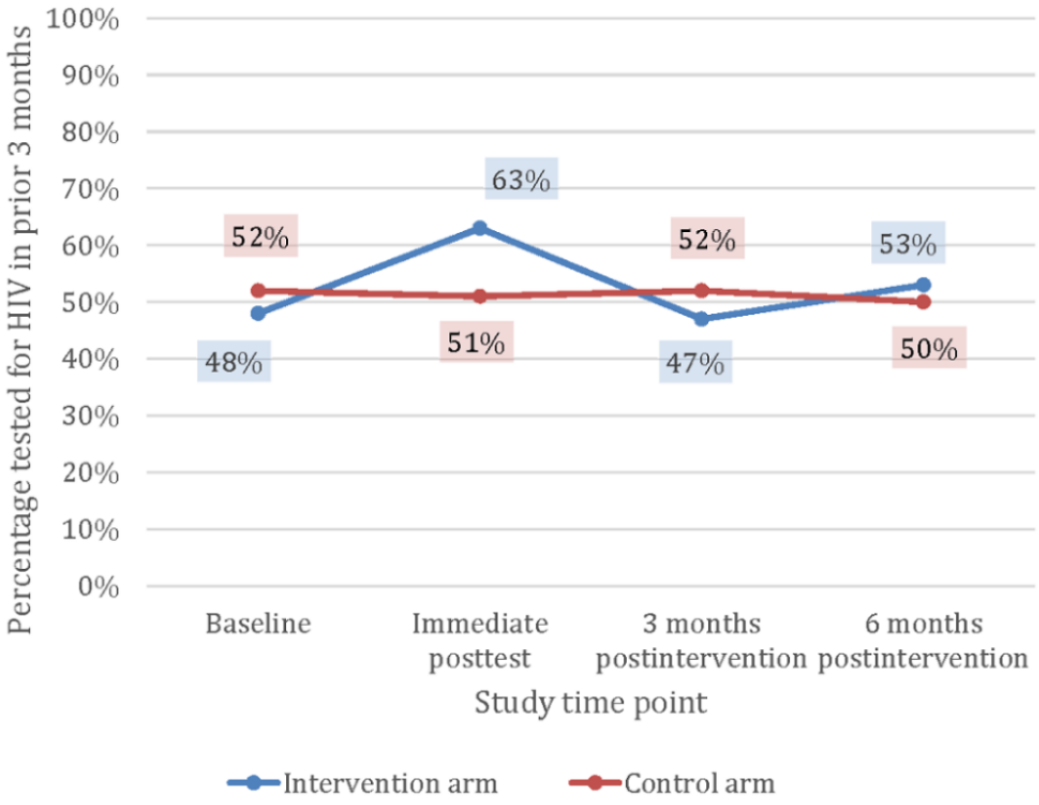

Figure 4. PrEP use among GBMSM who reported anal intercourse not protected by condoms or PrEP at baseline, reported by study time point and randomized allocation, in Atlanta, Detroit, and New York City (2018-2019). GBMSM: gay, bisexual, and other men who have sex with men; PrEP: preexposure prophylaxis.

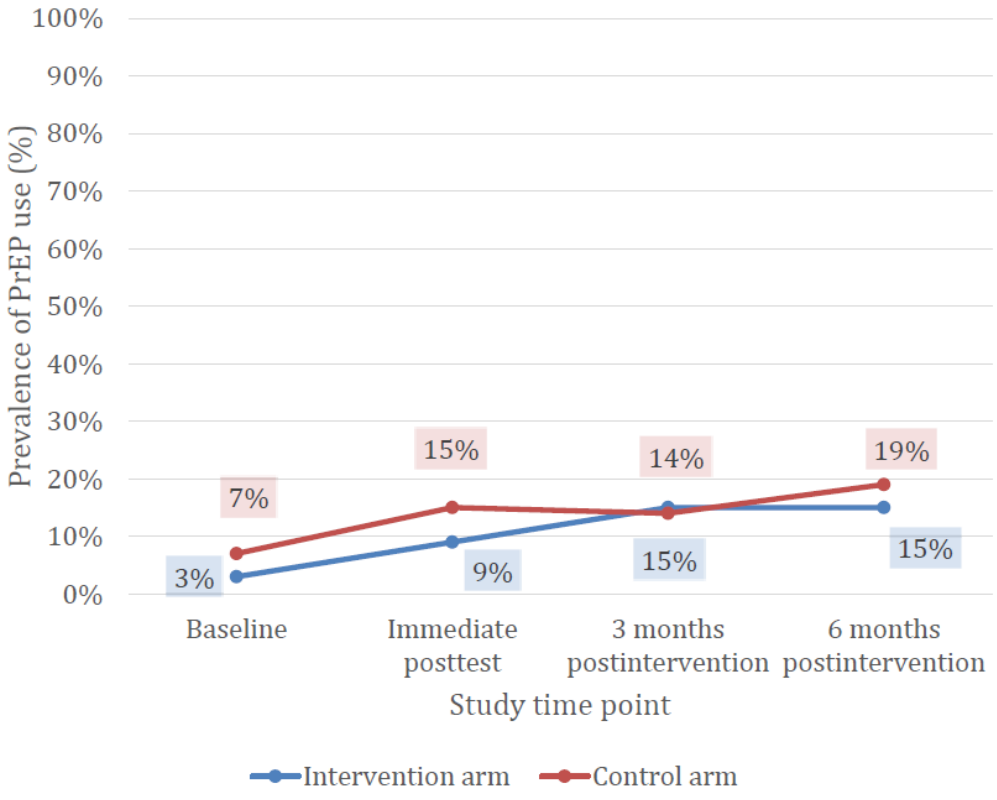

Posthoc Analyses of Intervention Effects by Key Demographic Variables and Time Spent on App and STI Testing

Given the potential importance of race/ethnicity, age group, and education level as potential moderators of intervention effects, we conducted stratified analyses of the outcome variables for each of the 3 HIV status/risk groups for the following subgroups: non-Hispanic White versus others; age 18-29 versus ≥30 years; and <4-year college degree versus 4-year degree or more. No meaningful difference in outcomes was identified among stratum-specific estimates. Further, a sensitivity analysis assessed the time spent on the mobile app over the 3-month intervention (control vs ≥30 minutes of intervention use) for the 3 HIV status/risk groups. No meaningful or significant difference in outcomes was identified.

In a posthoc analysis, the intention to test for STIs (ie, ordering an STI test kit or reporting having had an STI test) was higher in all HIV-negative participants (low-risk HIV-negative: aOR 3.1, 95% CI 1.7-5.6; high-risk HIV-negative: aOR 3.5, 95% CI 2.0-6.2; all HIV-negative regardless of risk group: aOR 3.4, 95% CI 2.3-5.1).

Discussion

Principal Results

We tested an app-based intervention to provide messages to promote HIV prevention and care and provide access to core HIV and STI prevention services to GBMSM. The results showed significant increases in HIV screening during the period of app use among high-risk HIV-negative GBMSM. The results also indicated increased prevalence of PrEP use among high-risk HIV-negative GBMSM in the 3-month period after app use. We identified no protective changes in study outcomes for low-risk HIV-negative GBMSM or LWH GBMSM. Given the high baseline PrEP use and adherence among low-risk HIV-negative GBMSM who did not report recent anal sex not protected by condoms and high levels of ART use and the high baseline adherence among LWH GBMSM, there was little room for improvement statistically among these groups on key outcome variables. We recognize, however, that the vulnerability of GBMSM may change over time (ie, seasons of risk [34]), so the utility of the app and its messaging might change over time for individual men.

We developed our intervention in light of 3 principles. First, we worked from the paradigm of integrated HIV prevention and care continua. Although the HIV status was determined at the beginning of the trial, when the app is used in practice, HIV testing will be the starting point for both continua. Thus, the intervention could serve GBMSM who do not know their HIV status [35]. Second, we sought to develop an intervention that could be offered to all GBMSM rather than to demographic or risk subsets of men. Third, we sought to develop an intervention that could be scaled to provide intervention content to large numbers of men without the need for a large staff of interventionists. A free, downloadable app that disseminates one 2-sentence message every other day and a 1-minute video weekly might be easily incorporated into a user's life without requiring the time and travel often required of more traditional, in-person interventions. Further, mobile app interventions are a potentially low-cost strategy from the perspective of health departments and community-based organizations (CBOs) that may choose to implement them in their jurisdictions.

We view our mixed efficacy outcomes from several perspectives. The fact that exposure to the app was associated with a doubling of HIV-testing behaviors and of prevalence of PrEP use among high-risk HIV-negative GBMSM suggests that the messages and app services could be a scalable, effective resource for GBMSM who engage in anal intercourse that is not protected by condoms or PrEP. Large national surveys of GBMSM suggest that 47%-53% of HIV-negative GBMSM would fall into this category [36,37]; considering the number of high-risk HIV-negative GBMSM in the United States [38], the potential user base for these services is about 1,800,000-2,000,000 US GBMSM.

The effect sizes for uptake of HIV screening and PrEP use were both about 2. However, the baseline levels of HIV screening and PrEP use were quite different. For high-risk GBMSM, the CDC recommends HIV testing at least annually, and in the intervention arm, nearly two-thirds reported HIV testing in the immediate posttest assessment period (tested in the prior 3 months). However, despite the same relative increase in PrEP use, only 1 in 6 (17%) high-risk GBMSM was taking PrEP at the 3-month postintervention time point. This suggests that additional and more intensive intervention services will likely be required for high-risk PrEP-eligible men who do not initiate PrEP within 6 months of starting the use of the Mobile Messaging for Men (M-cubed) app.

We also recognize that increases in PrEP usage and HIV testing associated with allocation to the app were short lived. The timing of the effects makes sense: the support for HIV testing provided during the period of app use included ordering at-home kits and navigating to testing locations; the significant increase in testing was observed during the period when men had access to the app, and about 1 in 7 high-risk men who tested for HIV used a mailed-out HIV self-test kit provided through the study. For PrEP, after the decision to start PrEP, there is a long process of making an appointment, undergoing lab tests, filling a prescription, and starting the medication; this outcome was higher in the 3 months after the period of app use. In practice, exposure to the app would not be limited to 3 months, and it is a separate question as to whether changes in behavior would be sustained over time with ongoing exposure to the app. Such a question could be answered in an implementation study.

Our approach was developed with an eye toward being able to reach large numbers of GBMSM with a basic package of prevention services. Given that there was efficacy for some outcomes, there are important questions about how the intervention might be made available to GBMSM who would be likely to benefit from it [39]. Most HIV prevention services are currently provided and funded through CBOs and health departments. Although some CBOs and health departments might have the technical capacity to support app-based prevention services, this capacity is likely quite limited. A currently underway randomized study of an efficacious eHealth

intervention (Keep It Up [40]) will examine the outcomes of centralized versus decentralized implementation approaches, and the results of the study may inform how the M-cubed intervention could be most effectively implemented [41].

Limitations

Our study was subject to several limitations. Although we used recruitment quotas to guide recruitment and achieved a balanced sample with respect to the 3 HIV status/risk groups, race/ethnicity, and recruitment venues, our sample was skewed to men with higher education. These selection biases threaten the external generalizability of the study; it is possible that the intervention might have had salutary effects for low-risk HIV-negative GBMSM or LWH GBMSM with lower education. However, although not powered for secondary comparisons, our post hoc stratified analyses did not suggest differential effects by educational attainment. Second, PrEP use in our sample was high at baseline (about 29% among all HIV-negative GBMSM), which is unique in large samples of GBMSM to date. For example, current PrEP use was reported by less than 20% of respondents to the American Men's Internet Survey (a large, national sample of US GBMSM) in 2017 [10] and by 25% of GBMSM who participated in 23 cities in the 2017 National HIV Behavioral Surveillance study [37]. Over half of GBMSM in our study who were not on PrEP reported HIV testing in the 3 months before enrollment; this is similar to the proportion who tested for HIV in the 12 months before interviews in the 2016 AMIS survey [11]. Third, outcomes were self-reported and so might be subject to misclassification because of social desirability bias [42]. Fourth, our sample was restricted to GBMSM recruited online; this might introduce selection bias, in that men recruited through physical venues, such as sex venues, might have higher or lower levels of risk. Lastly, our sample was limited to GBMSM in 3 urban areas of the United States who reported sex with a man in the past year; patterns of risk behaviors and use of prevention services are known to be different in other urban areas or among rural GBMSM [11,21]. The level of ART use in our LWH MSM was high, offering limited opportunity for improvement. Future studies of the app could condition enrollment on the need for support for ART initiation or maintenance for LWH MSM.

The next steps for the study include secondary analysis of extensive app usage data or *paradata* [43] in terms of understanding the ratings of each message and the time spent using various optional aspects of the app descriptively [44]. We will also conduct further assessments of the potential mediation of outcome effects by app usage to help direct future prevention research and program implementation of mobile apps. Based on our data, the app offered benefits to GBMSM who reported recent anal sex not protected by condoms or PrEP but not to HIV-negative men who did not report sex not protected by condoms of PrEP or LWH men. Therefore, we will consider how the app can be updated and implemented [39,45] for GBMSM engaging in sex not protected by condoms or PrEP and for LWH MSM. Because we found that the app is a successful way to increase the intention to test for STIs and to distribute at-home STI self-test kits, the kits were often not returned and additional research is needed to understand the barriers to returning STI specimen collection kits. If this barrier can be overcome, the M-cubed app might also effectively support increased STI testing for some groups of GBMSM.

Conclusion

We sought to produce and evaluate a mobile app with prevention messaging and services to support comprehensive HIV prevention and care with low levels of prevention staff interaction for all GBMSM, regardless of HIV status or current risk behaviors. Such a serostatus-neutral approach, if implemented successfully, would offer advantages in terms of cost efficiency and minimization of segmentation of GBMSM by serostatus. Future work with the M-cubed app should focus on implementing the app for GBMSM who are likely to benefit from it based on their current behaviors and evaluating methods of implementation of the app through public or publicly supported prevention providers [39].

Acknowledgments

This study was funded through the US Centers for Disease Control and Prevention (CDC) to Emory University (cooperative agreement no. U01PS004977) and the US National Institutes of Health (P30AI050409).

Abstract

Background: The World Wide Web has become an essential source of health information. Nevertheless, the amount and quality of information provided may lead to information overload. Therefore, people need certain skills to search for, identify, and evaluate information from the internet. In the context of health information, these competencies are summarized as the construct of eHealth literacy. Previous research has highlighted the relevance of eHealth literacy in terms of health-related outcomes. However, the existing instrument assessing eHealth literacy in the German language reveals methodological limitations regarding test development and validation. The development and validation of a revised scale for this important construct is highly relevant.

Objective: The objective of this study was the development and validation of a revised German eHealth literacy scale. In particular, this study aimed to focus on high methodological and psychometric standards to provide a valid and reliable instrument for measuring eHealth literacy in the German language.

Methods: Two internationally validated instruments were merged to cover a wide scope of the construct of eHealth literacy and create a revised eHealth literacy scale. Translation into the German language followed scientific guidelines and recommendations to ensure content validity. Data from German-speaking people (n=470) were collected in a convenience sample from October to November 2020. Validation was performed by factor analyses. Further, correlations were performed to examine convergent, discriminant, and criterion validity. Additionally, analyses of measurement invariance of gender, age, and educational level were conducted.

Results: Analyses revealed a 2-factorial model of eHealth literacy. By item-reduction, the 2 factors information seeking and information appraisal were measured with 8 items reaching acceptable-to-good model fits (comparative fit index [CFI]: 0.942, Tucker Lewis index [TLI]: 0.915, root mean square error of approximation [RMSEA]: 0.127, and standardized root mean square residual [SRMR]: 0.055). Convergent validity was comprehensively confirmed by significant correlations of information seeking and information appraisal with health literacy, internet confidence, and internet anxiety. Discriminant and criterion validity were examined by correlation analyses with various scales and could partly be confirmed. Scalar level of measurement invariance for gender (CFI: 0.932, TLI: 0.923, RMSEA: 0.122, and SRMR: 0.068) and educational level (CFI: 0.937, TLI: 0.934, RMSEA: 0.112, and SRMR: 0.063) were confirmed. Measurement invariance of age was rejected.

Conclusions: Following scientific guidelines for translation and test validation, we developed a revised German eHealth Literacy Scale (GR-eHEALS). Our factor analyses confirmed an acceptable-to-good model fit. Construct validation in terms of convergent, discriminant, and criterion validity could mainly be confirmed. Our findings provide evidence for measurement invariance of the instrument regarding gender and educational level. The newly revised GR-eHEALS questionnaire represents a valid instrument to measure the important health-related construct eHealth literacy.

Introduction

Background

The concept of health literacy emerged in the 1990s as a competence to gather health information and use it to address health questions and problems [1]. Nutbeam [2] defined health literacy as "cognitive and social skills which determine the motivation and ability of individuals to gain access to, understand, and use information in ways which promote and maintain good health." In the following years, health literacy has turned out to be an important predictor for various health outcomes (eg, behavior of patients with diabetes mellitus or heart failure) [3,4]. The World Health Organization has declared health literacy as a key determinant of health and defined it as a Sustainable Development Goal [5].

With the rise of the internet as a source of information, the gathering of health information was no longer limited to professional or face-to-face health sources but was available from many different health topic websites [6]. With the increasing availability of health information on the internet, the number of people using this source for seeking health information rose as well [7,8]. However, sources on the internet contain inconsistent information as contributions are not by professionals only [9]. As a result, the amount and differences in quality of information provided on the internet may lead to health information overload [10]. For example, in 2020, COVID-19 became a global pandemic, and disease-related information, especially from the internet, grew exponentially, leading to an "infodemic" [11,12]. Not only is a large amount of information available, but a significant amount of it must be considered misinformation because the sources of the information must be classified questionable [13,14].

For the context of information from the internet, Norman and Skinner [15] applied the concept of health literacy to electronic health literacy (eHealth literacy). With the development of the eHealth Literacy Scale (eHEALS) questionnaire [16], the concept of eHealth literacy became measurable and emerged as a growing interest in psychological and medical health sciences. Systematic reviews have shown that eHEALS is associated with different health-related outcomes, but findings could not be consistently confirmed [17,18]. Associations of eHealth literacy with different health outcomes have been found, such as health intentions [19], acquiring health knowledge [20-23], and health prevention behavior [21,24,25]. Furthermore, research showed associations between eHealth literacy and healthy behaviors like exercise behavior, balanced nutrition, and regular breakfast [26,27]. In the context of COVID-19, associations of eHealth literacy and lower psychological symptoms [28] and higher prevention behaviors [29] could be confirmed. To sum up, research indicates that eHealth literacy is associated with prevention behaviors, the acquisition of knowledge, and people's ability to cope with diseases, which confirms eHealth literacy as an important construct in examining people's health behavior.

To cope with information overload and use the information from the internet, Norman and Skinner [15] proposed a set of different competencies: skills to read, identify, and understand different information to distinguish helpful from less helpful or even false or harmful information. These competencies represent a sequential process of handling available information. In the first step, basic cognitive skills are needed to search for information regarding a certain topic. In a subsequent cognitive process, information available must be distinguished as helpful or less helpful in order to answer specific questions. These steps represent an elaborated cognitive information process rather than a heuristic one. The distinction of cognitive processes was formerly described within dual-process theories in psychological literature and confirmed in multiple studies [30-32]. Dual-process theories distinguish between fast cognitive processes, which describe heuristic and holistic approaches representing intuitive, implicit cognitions, and slow cognitive processes, which are analytic and rule-based and focus on explicit learning [33]. Slow cognitive processes run serially and require cognitive capacity to answer or address specific questions. In the context of eHealth literacy, the handling of health information from the internet clearly represents a serial process of subsequent cognitions that require different competencies building on each other.

eHEALS: Translations of the Original eHEALS Questionnaire and its Limitations

Since its publication, the original eHEALS questionnaire has been translated into many languages, including Italian [34,35], Spanish [36], Dutch [37], Chinese [38], Serbian [39], Korean [40], Indonesian [41] and German [42]. However, some of these studies could not confirm the 1-factorial model as assumed by Norman and Skinner [16]. Looking at many different validation studies of the eHEALS questionnaire, a consistent factorial structure has not been verified; 1-factorial [16,37,43], 2-factorial [42,44,45], and 3-factorial models [46-48] have been identified in different validation studies and languages. These results indicate that the eHEALS questionnaire lacks consistent factorial structure.

The German version of the questionnaire validated by Soellner and colleagues [42] especially lacks methodological and content-related accuracy. They developed an initial instrument for assessing eHealth literacy for the German-speaking community (G-eHEALS). However, Soellner and colleagues [42] did not meet scientific criteria substantially; first, they did not meet the criteria scientifically recommended for translation of instruments. Second, in their 2-factorial model content validity was questionable because some items reflected the subdimension of information appraisal rather than the assigned subdimension of information seeking ("I know how to use the health information I find on the internet to help me" or "I feel

confident in using information from the internet to make health decisions"). In addition, Soellner and colleagues [42] collected their data on a limited sample of 327 students aged 16 to 21 years at only one type of school (gymnasium: a German school type preparing for university attendance), and people of older age were not considered for validation. However, as people of older age may be less familiar using the internet [49-51] and eHealth literacy especially depicts a particular digital literacy, the model proposed by Soellner and colleagues [42] is possibly not valid for assessing eHealth literacy in older people. Moreover, the educational level of the participants could not be considered within their biased study sample. Juvalta and colleagues [52], who used the G-eHEALS, have also collected their data on a limited sample of young parents (88.5% female). In another German-speaking study, Reder and colleagues [53] have shown a 3-factorial structure for the G-eHEALS. However, only women participated in this study, which is a limited sample for examining the validity of the G-eHEALS. Inconsistent findings and methodological limitations of these studies indicate an unclear factorial structure of the G-eHEALS.

Another limitation of the original eHEALS questionnaire refers to insufficient representation of an elaborated cognitive information process. The original scale does not reflect the above-mentioned complexity of an information process in its entirety. Petrič and colleagues [54] focused on this limitation and developed an extended eHealth literacy scale (eHEALS-E). Creating a 20-item questionnaire, they found a 6-factorial structure. Despite this extension and other concepts and questionnaires [55-57], eHEALS is still the instrument most used for measuring eHealth literacy.

Aims of This Study

In summary, the G-eHEALS validated by Soellner and colleagues [42] was a valuable first approach to the important topic of eHealth literacy, but it underlies significant methodological limitations and lacks in psychometric quality. Nevertheless, as eHealth literacy could be confirmed as an important construct of health-related outcomes, the possibility of assessing eHealth literacy is crucial for health care practitioners and researchers in understanding health competence in German-speaking people. In response to the practical and scientific demands and described limitations, we developed a new instrument for measuring eHealth literacy with 4 objectives:

- Extension of the existing questionnaire of Norman and Skinner [16] by 8 nonoverlapping items proposed by Petrič and colleagues [54]. By combining the questionnaires, a better representation of the construct of eHealth literacy regarding the cognitive processes of seeking, identifying, and evaluating health information should be achieved.
- German translation of the items according to common scientific recommendations [58,59] to ensure content validity.
- Validation of the revised GR-eHEALS at a convenience sample in terms of construct and criterion validity. We decided to collect data in a convenience sample to reach participants with varied socioeconomic backgrounds. Furthermore, our goal was not to limit the sample in order to develop a measurement model that is as generic as possible.
- To our knowledge, there is no study examining measurement invariance of eHealth literacy between gender, age, or educational level in a German sample. Nevertheless, the interpretation of statistical differences between different groups of people requires measurement invariance between these groups [60]. As eHealth literacy represents competencies that are important for people regardless of their sociodemographic status, its measurement should obviously be independent of these influencing variables.

All in all, we are pursuing the study goals to develop a revised and validated instrument for measuring eHealth literacy. Further, we sought to examine the measurement invariance of the instrument regarding relevant sociodemographic variables.

Methods

Development of the New Instrument

The revised eHealth Literacy Scale (GR-eHEALS) is based on the original items from the eHEALS [16] extended by adding items from the eHEALS-E questionnaire from Petrič and colleagues [54]. The translation was conducted following the guidelines proposed by Beaton and colleagues [58] and Guillemin and colleagues [59] for translation of academic literature to ensure content validity. Accordingly, in a first step, 2 of the authors translated the items into German and merged these translations into a first translation proposal. In the second step, this proposal was discussed within a systematic expert panel consisting of the 2 translators and 2 psychologists who are experts in the context of health care and eHealth. The resulting second proposal was translated back into English in the third step to confirm that the essential meaning of the items is consistent with the original items. In the fourth step, cognitive interviews were conducted to make sure that all items are easy to understand, do not include offensive speech, and do not discriminate for age or gender. Interviewees were aged 23 to 72 years and had different educational backgrounds. The resulting final version of the translated and extended version consisted of 16 items. The original items and the translated items are displayed in Multimedia Appendix 1. Items 1 to 8 are translated from the original eHEALS questionnaire from Norman & Skinner [16], and items 9 to 16 are translated from the questionnaire (eHEALS-E) from Petrič and colleagues [54]. All subsequent nominations of item numbers refer to the item numbers mentioned in Multimedia Appendix 1. To validate the GR-eHEALS, we performed a prestudy in which we aimed to check for any complications in answering the translated items and to conduct an item analysis The results of this analysis are displayed in Multimedia Appendix 2. As the prestudy showed solid item characteristics, the developed instrument was considered good fitting for the purpose of the main study.

Study Design and Participants

The cross-sectional study was conducted via Unipark (Tivian XI GmbH), an online survey tool, between October and November 2020. The ethics committee of the Faculty of Medicine of the University of Duisburg–Essen reviewed and approved this study (20-9592-BO).

All data were collected anonymously. Participants for this study were recruited via personal and occupational networks and online social networks (Xing, Facebook, LinkedIn). In our analyses, only complete data sets were considered. From a total of 1634 participants, 524 have completed our questionnaire in full, which represents a completion rate of 32.1% and can be considered typical for an online survey [61]. We excluded cases in which participants took less than 5:34 minutes (5% percentile) or more than 25:45 minutes (95% percentile) to complete the survey. Furthermore, we excluded 1 participant for being under 18 years old. As only 1 person indicated gender as diverse, we excluded this case in order to perform the analysis of measurement invariance of gender. The resulting sample consisted of 470 respondents. The sample size is in accordance with recommendations for validation studies [62,63]. Answering the questionnaire took 11:32 (SD 4:24) minutes on average. All data supporting the conclusion of the study are included in Multimedia Appendix 3.

In the main study, it was our objective to validate the GR-eHEALS in a convenience sample to verify its convergent, discriminant, and criterion validity and test for measurement invariance.

We verified convergent validity by assuming a positive correlation between eHealth literacy and health literacy, which measures a similar construct but does not take the source of information into account. Furthermore, we assumed eHealth literacy to be positively interrelated with internet confidence and negatively associated with internet anxiety as eHealth literacy particularly focuses on the gathering of information from the internet.

To verify discriminant validity, we captured impulsivity and common personality traits assuming no significant interrelations. As eHealth literacy reflects competencies in dealing with health-related information [15] rather than a personality trait, there should be no content-related overlaps between eHealth literacy and personality traits.

Additionally, we considered the possible outcome variables mental and physical health status and life satisfaction to examine criterion validity. Criterion validity of an instrument describes the ability to prove relationships between the construct itself and possible outcomes [64]. Thus, we expected eHealth literacy to be associated with above mentioned health-related variables.

The survey included the following questionnaires (sample items presented below are translations). Most scales were assessed on 5-point Likert scales from 1=strongly disagree to 5=strongly agree. Exceptions are separately explained below. Scales contained inverted items that were recoded prior to statistical analyses.

Measurements

Health Literacy

Participants rated their health literacy on 16 items from the Health Literacy Questionnaire from Röthlin and colleagues [65]. A sample item is “How easy/difficult is it to find information about therapies for diseases that affect you?” Health literacy was measured on a 2-point scale (easy/hard). Therefore, it is used as a sum-score indicating the extent of health literacy between 0 and 16 (mean 12.63 [SD 2.99]). Cronbach alpha of this scale was .79.

Impulsivity

We used the 8-item Impulsive Behavior–8 Scale from Kovaleva and colleagues [66] to measure impulsivity (eg, “Sometimes I spontaneously do things that I should not have done”). Cronbach alpha of this scale was .72 (mean 2.78 [SD 0.59]).

Personality Traits

Personality traits (extraversion, neuroticism, openness, conscientiousness, and agreeableness) were each assessed by 2 items from Rammstedt and colleagues [67]. A sample item for neuroticism is “I get nervous and insecure easily.” Extraversion (mean 3.30 [SD 1.04]), neuroticism (mean 3.08 [SD 0.97]), openness (mean 3.61 [SD 0.99]), conscientiousness (mean 3.59 [SD 0.75]), and agreeableness (mean 3.15 [SD 0.76]) had Cronbach alphas of .79, .66, .62, .38, and .19, respectively. Due to low reliabilities, conscientiousness and agreeableness were excluded from the following analyses.

Further Constructs

In addition, we asked for internet confidence (3 items; mean 3.74 [SD 0.72], Cronbach alpha .89), internet anxiety (3 items; mean 1.81 [SD 0.82], Cronbach alpha .81) and single items to measure physical (mean 7.37 [SD 1.58]) and mental health (mean 7.27 [SD 1.90]) on 11-point Likert scales from 0=very bad health to 10=very good health (all self-formulated), and life satisfaction at a 5-point Likert scale from 1=not satisfied at all to 5=totally satisfied (mean 3.76 [SD 0.83]) from Beierlein and colleagues [68].

Furthermore, sociodemographic variables (age, gender, marital status, educational level, financial situation, internet availability, and community size) were considered to make sure that the sample represents the population.

Statistical Analysis

All data analyses were conducted using R (R Foundation for Statistical Computing), RStudio, and several packages.

Prior to conducting confirmatory factor analysis (CFA), we performed an exploratory factor analysis (EFA) to evaluate whether data were suitable for factor analysis. We used the Kaiser-Meyer-Olkin (KMO) and Bartlett test of sphericity for evaluation. Factor extraction was conducted using maximum likelihood estimation with Promax oblique rotation and number of factors were identified by scree plot inspection and Kaiser criterion (eigenvalue >1). Factor loadings ≥0.4 were considered as significant [69].

Subsequently, we performed consecutive CFA and compared fit indices and factor loadings to confirm the best-fitting model by considering the recommendations of Hu and Bentler [70] who assume to achieve a comparative fit index (CFI) and Tucker Lewis index (TLI) about 0.95 and root mean square error of approximation (RMSEA) and standardized root mean square residual (SRMR) about 0.06 and 0.08, respectively. We used the robust maximum likelihood estimator as our prestudy showed that items were slightly negative skewed, and a robust

estimator is more likely to produce less biased model statistics than maximum likelihood estimator [71].

Two-tailed Pearson correlations were conducted considering a significance level of 5% to examine convergent, discriminant, and criterion validity.

We performed tests of measurement invariance on our final model to examine whether the measurement is reliable for both genders as well as 2 age groups and 3 groups of educational level. For this purpose, we performed consecutive multigroup CFA with progressively stricter model assumptions by fixing an increasing number of model parameters for each of 3 measurement invariance models.

Measurement invariance—as a prerequisite for the interpretation of mean differences—is verified by 3 consecutive steps with increasingly strict model assumptions for (1) the number of factors and the pattern of factor-indicator relationships (configural invariance), (2) factor loadings (metric invariance), and (3) intercepts of indicators (scalar invariance) [72]. These 3 steps assume that there are no differences between observed groups regarding these parameters, and interpretation of mean differences is valid when scalar invariance is confirmed [73]. Differences between groups should only be interpreted when measurement invariance is confirmed since otherwise differences between groups may occur due to the fact that an instrument does not measure equally between different groups [60,73,74].

We applied a cutoff criterion of a difference of CFI (ΔCFI) of 0.01 as it is proposed as appropriate to assume invariance between two models [75,76]. Thus, for evaluation of measurement invariance we considered the model fit indices and difference of CFI between compared models.

Results

Sample Characteristics

Mean age of participants was 37.16 (SD 13.4, min 18, max 82, median 33) years. Sample characteristics of all other sociodemographic variables are shown in Table 1.

Table 1. Summary of sample characteristics (n=470).

Characteristics	Values, n (%)
Gender	
Female	332 (70.6)
Male	138 (29.4)
Marital status	
Married	161 (34.3)
Not married, in partnership	183 (38.9)
Single	115 (24.5)
Other	11 (2.3)
Educational level	
Lower secondary school	5 (1.1)
Upper secondary school	24 (5.1)
University entrance qualification	77 (16.4)
Vocational training	91 (19.4)
University degree	273 (58.1)
Financial situation	
Very good	9 (1.9)
Good	47 (10.0)
Middling	114 (24.3)
Bad	220 (46.8)
Very bad	80 (17.0)
Internet availability	
Always available	288 (61.3)
Mostly available	177 (37.7)
Occasionally available	5 (1.1)
Not available	0 (0.0)
Community size	
Big city (>100,000 inhabitants)	244 (51.9)
Medium city (>20,000 inhabitants)	88 (18.7)
Small city (>5000 inhabitants)	76 (16.2)
Rural village (<5000 inhabitants)	62 (13.2)

Exploratory Factor Analysis

KMO revealed a value of 0.92 and Bartlett test of sphericity was highly significant (P<.001), indicating that data were suitable for factor analysis. Empirical Kaiser criterion and scree plot implied a 2-factor model. Table 2 shows factor loadings of the 2 factors.

As item 14 did not significantly load on any of the 2 factors it was excluded from the following analysis. The remaining 15 items were considered in the CFA.

Table 2. Results of exploratory factor analysis.

Item no	Factor 1	Factor 2
1	0.88	–0.06
2	0.80	0.03
3	0.84	0.00
4	0.97	–0.06
5	0.49	0.37
6	0.10	0.62
7	0.03	0.70

Confirmatory Factor Analysis

In model 1, 15 items were assigned on the 2 factors identified by the EFA. Based on the content meanings of the underlying items, factor 1 represents information seeking and factor 2 represents information appraisal. However, items 13, 5, and 15 did not fit the factor proposed by the EFA in terms of their content. Therefore, item 13 was reassigned to information seeking whereas items 5 and 15 were reassigned to information appraisal in model 2. For model 3, we removed 6 items due to low factor loadings (<0.65). Moreover, we excluded 1 more item to develop a parsimonious model resulting in a 2-factorial model with 4 items on each of the 2 factors. Table 3 shows the model fits of the 3 models.

CFI, TLI, and SRMR practically meet the criteria of a good model fit. RMSEA is slightly above the recommendations of Hu and Bentler [70]. Considering the recommendations, model 3 shows an acceptable-to-good model fit.

Figure 1 depicts the structure of the 2-factorial model with its factor loadings. All item factor loadings were greater than λ=0.71.

Information seeking and information appraisal achieved satisfactory Cronbach alphas of .92 and .83, respectively. Table 4 shows the statistics of the final items. Based on mean and standard deviation, lower levels of information seeking and information appraisal are below a mean score of 2.99 and 3.20, respectively. Higher levels can be assumed above mean scores of 4.71 and 4.69, respectively.

Table 4. Descriptive statistics of the revised German eHealth Literacy Scale (GR-eHEALS) items.

Item	Mean (SD)	Median	Skew
Information seeking	3.85 (0.86)	4.00	–0.78
1. Ich weiß, wie ich Internetseiten mit hilfreichen Gesundheitsinformationen finden kann.	3.93 (0.95)	4.00	–0.93
2. Ich weiß, wie ich das Internet nutzen kann, um Antworten auf meine Gesundheitsfragen zu erhalten.	4.04 (0.87)	4.00	–1.01
3. Ich weiß, welche Seiten mit Gesundheitsinformationen im Internet verfügbar sind.	3.63 (1.00)	4.00	–0.60
4. Ich weiß, wo ich im Internet hilfreiche Gesundheitsinformationen finden kann.	3.81 (1.01)	4.00	–0.89
Information appraisal	3.95 (0.74)	4.00	–0.77
5. Ich weiß Gesundheitsinformationen aus dem Internet so zu nutzen, dass sie mir weiterhelfen.	3.91 (0.88)	4.00	–0.77
6. Ich bin in der Lage, Internetseiten mit Gesundheitsinformationen kritisch zu bewerten.	4.18 (0.87)	4.00	–1.24
7. Ich kann zwischen vertrauenswürdigen und fragwürdigen Internetseiten mit Gesundheitsinformationen unterscheiden.	4.07 (0.84)	4.00	–0.93
8. Ich fühle mich sicher darin, Informationen aus dem Internet zu nutzen, um Entscheidungen in Bezug auf meine Gesundheit zu treffen.	3.62 (1.03)	4.00	–0.57

Validation of the GR-eHEALS

To examine convergent, discriminant, and criterion validity of the GR-eHEALS, we performed correlation analyses with the 2 factors (information seeking and information appraisal). Moreover, correlations of the 2 factors with demographic variables were calculated. Results are shown in Table 5. Both factors were strongly positively correlated with health literacy and internet confidence and strongly negatively correlated with internet anxiety. None of the 2 scales correlated significantly with impulsivity or extraversion. Information appraisal was interrelated with neuroticism while information seeking was associated with openness. Information appraisal was correlated with mental and physical health and life satisfaction, which was not true for information seeking. Furthermore, information seeking was significantly associated with age.

Table 5. Pearson correlation coefficients of the eHealth literacy factors.

Scales	Information seeking (*P* value)	Information appraisal (*P* value)
Convergent validity		
Health literacy	0.43 (<.001)	0.53 (<.001)
Internet confidence	0.17 (<.001)	0.17 (<.001)
Internet anxiety	–0.21 (<.001)	–0.23 (<.001)
Discriminant validity		
Impulsivity	–0.06 (.16)	–0.05 (.28)
Extraversion	–0.03 (.58)	0.03 (.56)
Neuroticism	–0.08 (.09)	–0.14 (.001)
Openness	0.10 (.03)	0.07 (.12)
Criterion validity		
Mental health	0.06 (.20)	0.19 (<.001)
Physical health	0.06 (.21)	0.12 (.01)
Life satisfaction	–0.01 (.83)	0.12 (.01)
Sociodemographic variables		
Age	0.10 (.02)	0.06 (.16)
Gender	–0.03 (.55)	0.01 (.78)
Marital status	–0.02 (.71)	–0.07 (.15)

Financial situation	–0.05 (.27)	0.04 (.45)
Internet availability	0.01 (.76)	0.02 (.71)
Community size	0.02 (.60)	–0.04 (.41)

Test of Measurement Invariance

Measurement invariance of the GR-eHEALS was performed to test whether the scale is a suitable measurement independently of gender, age, and educational level. Prior to these analyses, a median split was performed to separate participants into 2 groups according to age. Median age was 33 years. Also, to divide the study sample into 3 groups of educational levels, we separated participants into people who held a university degree, people who completed a vocational training, and people who had any school certificate. Results of the analyses are shown in Table 6.

Besides chi-square and fit indices, Table 6 shows the differences of CFI between models. Regarding measurement invariance of gender and education, all changes in CFI are below 0.01, indicating that model fits did not substantially decrease between more constraint models. Measurement invariance regarding age must be rejected as configural invariance could not be confirmed.

Table 6. Results of measurement invariance for gender, age, and education using multigroup confirmatory factor analysis.

Model	Chi-square	df	CFI[a]	TLI[b]	RMSEA[c]	SRMR[d]	ΔCFI[e]

Discussion

Principal Findings

The results of our factor analyses show that eHealth literacy consists of 2 factors, information seeking and information appraisal. Our first study aim was to examine whether the measurement of eHealth literacy could be improved by adding nonoverlapping items from the eHEALS-E [54] to the original eHEALS [16]. We performed an EFA and several CFAs to examine the factorial structure of our instrument. Our analyses show that the measurement of eHealth literacy could not be improved by adding additional items to the well-established eHEALS questionnaire.

However, our study significantly contributes to the existing measurement of eHealth literacy. By strongly following scientific recommendations regarding academic translations, we developed the GR-eHEALS with high content validity. By taking statistical and content-related consideration into account when conducting factor analyses, we developed a measurement model of eHealth literacy with high content validity and acceptable-to-good model fit. Cronbach alpha was satisfactory for the 2 factors indicating good internal consistency and confirming reliability of the instrument.

Our findings on the examination of convergent, discriminant, and criterion validity of our instrument were not completely consistent with our expectations and require critical discussion. As expected, the 2 factors showed significant correlations with the convergent constructs of health literacy, internet confidence, and internet anxiety. By contrast, while impulsivity and extraversion consistently showed, as expected, no significant correlations with the 2 factors, neuroticism and openness indicated more inconsistent interrelations. Neuroticism was strongly negatively correlated with information appraisal, but not with information seeking. On the other hand, openness was only correlated with information seeking but not with information appraisal. To understand these unexpected correlational patterns, we examined findings of studies discovering the associations of personality traits and health-related constructs. Other studies showed that neuroticism is associated with lower health behavior self-efficacy and health behaviors [77] and lower internet use for learning and education [78]. These findings could indicate that neuroticism distorts cognitive processes of higher elaboration that are required for information appraisal but not necessarily for information seeking. Regarding the personality trait of openness, Bogg and Vo [79] have shown that people with higher openness more often search the internet regarding health-related topics. One could think that openness promotes people to search for new information in a sense of curiosity. However, the subsequent and cognitively demanding process of information appraisal may not be promoted by people's openness.

Referring to the examination of criterion validity, positive correlations with the possible outcome variable mental health,

physical health, and life satisfaction were expected, although only information appraisal was significantly related to these constructs. These results could be potentially explained by the idea that information seeking is a process that requires cognitive efforts but may not be sufficient to promote satisfaction and health status on its own but needs a high competency in information appraisal as a mandatory precondition. However, the search of information is a necessary process to perform the subsequent process of information appraisal.

To sum up, convergent validity of our instrument can be comprehensively confirmed. Examination of discriminant validity and criterion validity reveal unexpected findings that should be subjects of further studies. Despite our results not completely meeting our expectations, findings indicate that the 2 factors represent different cognitive processes in line with dual-process theories of analytic and rule-based processes: information seeking as a first of 2 consecutive competencies exclusively focuses on the process of searching information on the internet but not on a deeper application of the information found. Within a second consecutive competency built on information seeking, information appraisal describes a cognitive process of interpretation of information and its application on personal health-related questions.

Furthermore, we investigated the measurement invariance for gender, age, and educational level. The results of our study suggest that measurement invariance of the GR-eHEALS can be assumed for gender and educational level at a scalar level of invariance but not for age. Our study is the first to examine measurement invariance for these sociodemographic variables. Particularly regarding sample limitations of previous studies investigating eHealth literacy, the GR-eHEALS is the first instrument that can be deployed and interpreted regardless of gender and educational level. Therefore, future researchers are able to interpret statistical differences of these sociodemographic variables on eHealth literacy by using the GR-eHEALS. This is highly important as one could think of differential levels of eHealth literacy due to gender, which was confirmed for the construct of health literacy [80]. Regarding educational level, studies suggest that education also plays a role in the context of eHealth literacy [81,82], but, to our knowledge, neither used instruments confirmed to be measurement invariant.

Concerning the finding of inequality of our instrument with respect to age, one potential explanation could be that older people are less familiar with using the internet than younger people in terms of a digital divide [49] and have a different understanding of information seeking and information appraisal than younger people. Chesser and colleagues [83] suggest that age is a relevant variable in the context of eHealth literacy. Further, in our data we found significant interrelations of age and information seeking but not of age and information appraisal. This should be examined further in upcoming research.

In summary, prior research indicates that the investigation of differences of eHealth literacy of different groups of people is of high scientific interest. Nonetheless, previous studies were lacking considering statistical differences should not be interpreted unless measurement invariance is confirmed. With the GR-eHEALS, we close this gap and contribute substantially to the understanding of the concept of eHealth literacy and the interpretation of mean differences for gender and educational level.

Due to its high validity, the GR-eHEALS provides researchers and practitioners with a measurement for the increasingly important construct of eHealth literacy. As eHealth literacy is linked with many health-related outcomes and behaviors [19,26,27], the GR-eHEALS could provide a basis for educational programs to improve eHealth literacy by focusing on the main cognitive processes important for interpreting health information from the internet. Also, there is evidence that students lack in competencies regarding eHealth literacy [84]. Hence, the assessment and development of eHealth literacy should be a part of students' curriculum to provide young people with the competencies needed to maintain or improve one's health status. Consequently, the GR-eHEALS could be part of educational psychologists' diagnostic repertoire as well as a foundation for specialist training programs in schools and universities. We propose that the results of the GR-eHEALS should be interpreted based on the 2 competencies for diagnostic and interventions of eHealth literacy considering the described mean scores for higher and lower levels of information seeking and information appraisal.

Strengths and Limitations

The main strengths of this study are the high methodological and psychometric standards applied to develop GR-eHEALS and confirm its content, construct, and criterion validity. Furthermore, confirmation of measurement invariance is a state-of-the-art approach with strong practical implications regarding the interpretations of group differences.

One limitation of our study was that we measured eHealth literacy by self-assessment only. Since this construct is intended to measure skills and competencies, eHealth literacy should either be compared with actual behaviors or assessed using behavior-based measurement. Furthermore, our data were collected in a cross-sectional study. Therefore, correlational directions show relationships but are not interpretable causally. Future research should explore if our 2 factors show different effects on health-related outcomes. Additionally, as we used an online survey, participation by people familiar with the internet was more likely than by people who rarely use the internet. Thus, the possibility of selection bias should be considered. In our sample, a high proportion of people holding a university degree limits the representativeness regarding the education level. As in Germany about 19% of the population hold a university degree [85], our sample with a proportion of 58% holding a university degree clearly overrepresents academic persons. Even though it was our goal to collect data on a convenience sample, our study sample consisted of 71% female participants and cannot be considered as population-representative. Therefore, future studies should replicate our findings using a population-representative sample.

Conclusion

eHealth literacy reflects the important competence of people in maintaining and improving their health status. This competence

will become more and more important since the internet provides a rapidly increasing amount of health information with considerable bandwidth of quality and trustworthiness. The GR-eHEALS, with its 8 items on 2 factors, is a validated instrument to capture eHealth literacy in the German language. The GR-eHEALS contributes to the measurement of eHealth literacy in 3 ways: (1) instrument has high content validity because of a translation following scientific recommendations, (2) instrument has an acceptable-to-good model fit and confirms measurement invariance for gender and educational level, and (3) instrument revises the existing G-eHEALS and fills an important gap in measuring eHealth literacy to provide researchers and practitioners an accurate and valid assessment.

Abstract

Background: The lifetime risk of breast and ovarian cancer is significantly higher among women with genetic susceptibility or a strong family history. However, current risk assessment tools and clinical practices may identify only 10% of asymptomatic carriers of susceptibility genes. Bright Pink developed the Assess Your Risk (AYR) tool to estimate breast and ovarian cancer risk through a user-friendly, informative web-based quiz for risk assessment at the population level.

Objective: This study aims to present the AYR tool, describe AYR users, and present evidence that AYR works as expected by comparing classification using the AYR tool with gold standard genetic testing guidelines.

Methods: The AYR is a recently developed population-level risk assessment tool that includes 26 questions based on the National Comprehensive Cancer Network (NCCN) guidelines and factors from other commonly used risk assessment tools. We included all women who completed the AYR between November 2018 and January 2019, with the exception of self-reported cancer or no knowledge of family history. We compared AYR classifications with those that were independently created using NCCN criteria using measures of validity and the McNemar test.

Results: There were 143,657 AYR completions, and most participants were either at increased or average risk for breast cancer or ovarian cancer (137,315/143,657, 95.59%). Using our estimates of *increased* and *average* risk as the gold standard, based on the NCCN guidelines, we estimated the sensitivity and specificity for the AYR algorithm–generated risk categories as 100% and 89.9%, respectively (P<.001). The specificity improved when we considered the additional questions asked by the AYR to define *increased* risk, which were not examined by the NCCN criteria. By race, ethnicity, and age group; we found that the lowest observed specificity was for the Asian race (85.9%) and the 30 to 39 years age group (87.6%) for the AYR-generated categories compared with the NCCN criteria.

Conclusions: These results demonstrate that Bright Pink's AYR is an accurate tool for use by the general population to identify women at increased risk of breast and ovarian cancer. We plan to validate the tool longitudinally in future studies, including the impact of race, ethnicity, and age on breast and ovarian cancer risk assessment.

KEYWORDS

breast cancer; ovarian cancer; risk assessment; genetic testing

Introduction

In the United States, there are nearly 250,000 cases of breast cancer and 25,000 cases of ovarian cancer diagnosed annually [1,2]. Breast cancer is the leading cause of cancer-related deaths and the most commonly occurring cancer among women globally [3-5]. In contrast, ovarian cancer is only the 10th most common cancer but the fifth leading cause of cancer-related death among women [1,6] and the leading cause of death from gynecological cancer [7]. Studies have estimated that 5% to 10% of breast cancer and 10% to 18% of ovarian cancer are due to hereditary susceptibility, in particular from breast cancer gene (*BRCA*) mutations or a strong family history [8-10]. Among *BRCA1* carriers, specifically, estimates suggest a 40% to 87% cumulative breast cancer risk by age 70 years, whereas for ovarian cancer risk, estimates range from 16% to 68% [11]. However, studies have also demonstrated that current risk assessment and clinical practices only identify a small proportion of the at-risk population.

A central component of breast and ovarian cancer prevention programs is education on personal risk, as determined by factors such as family history, genetic susceptibility, hormonal risk factors, and modifiable health behaviors [12-14]. However, studies have estimated that current practices identify at most 10% of asymptomatic BRCA 1/2 carriers [8,10,15-17]. Moreover, among those with a strong family history of breast or ovarian cancer, but who have not received genetic testing, an estimated 20% to 30% have a pathogenic mutation in a breast cancer susceptibility gene [10]. Bright Pink is a nonprofit organization devoted to improving breast and ovarian cancer prevention through the belief that empowering educated patients leads to (1) lower distress associated with cancer risk assessment and (2) improved cancer prevention outcomes [18,19].

To achieve these goals, Bright Pink developed the Assess Your Risk (AYR) tool that provides a user-friendly, web-based survey to determine lifetime breast and ovarian cancer risk at the population level. Bright Pink was developed in collaboration with genetic counselors, public health practitioners, and clinicians to ensure alignment with standards of breast and ovarian cancer risk assessment but with a modern, consumer-facing interface that would be accessible to the general population. Since 2014, the Bright Pink AYR has been used by more than 1.2 million women to assess breast and ovarian cancer risk. The AYR tool offers a streamlined, educational, and actionable user experience with the goal of substantially increasing the number of women nationwide, as well as internationally, learning about breast and ovarian cancer risk.

However, the AYR tool has not yet been compared with the gold standard clinical guidelines for identifying women at increased risk for breast and ovarian cancer who are eligible for consultation with a genetic counselor. The aims of this study are to (1) describe the AYR tool and its content, (2) describe the AYR tool user population, and (3) compare the AYR tool classification against the National Comprehensive Cancer Network (NCCN) guidelines for genetic and family high-risk assessment in breast and ovarian cancer [2,17]. Moreover, improving health equity and early identification of young adult women at increased risk are the primary goals of Bright Pink and public health. Thus, this analysis is also the first to examine AYR classification compared with the NCCN criteria by race, ethnicity, and age group. Demonstration that Bright Pink AYR is an accurate tool for risk assessment at the population level is a critical step in ensuring that the general population, as well as patients and providers, have a reliable tool for the identification and education of women at risk for breast and ovarian cancer.

Methods

Study Population

Bright Pink, a national nonprofit organization based in Chicago, Illinois, was started in 2007 with the mission of empowering women to know their breast and ovarian cancer risk to manage their health proactively. For this study, eligible participants included Bright Pink AYR 3.0 users from October 2018 to March 2019, who were women aged ≥18 years. We included women of White non-Hispanic or Latinx, African American, Asian, or Hispanic or Latina race and ethnicity and all age groups. We excluded participants with a personal history of breast or ovarian cancer (excluding nonmelanoma skin cancer) or no knowledge of family history from calculations of agreement between the NCCN and the AYR. The goal of the NCCN criteria is to identify individuals who may be eligible for genetic testing and counseling for breast or ovarian cancer; therefore, we included women at increased risk for either breast or ovarian cancer.

Ethics Approval

This study was approved by the Northwestern University Human Subjects Protection Program (review number STU00207333).

Bright Pink AYR: History

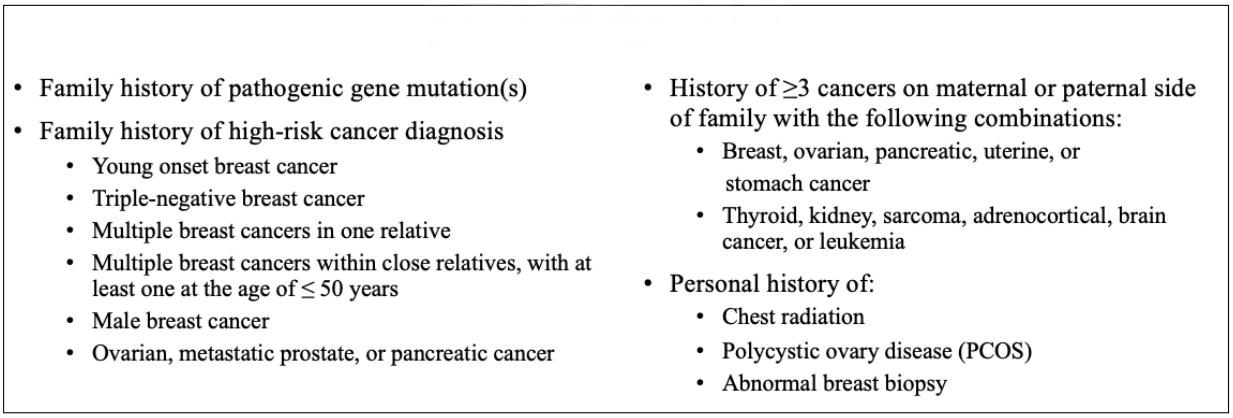
Bright Pink developed the original AYR tool in 2014 to support the goals of modernizing and increasing access to risk assessment for breast and ovarian cancer at the population level. The AYR tool estimates breast and ovarian cancer risk through a user-friendly, informative web-based quiz with superior-rated readability [20]. In late 2018, Bright Pink introduced a new version of AYR with an updated user experience and the goal of significantly increasing the number of women in the general population learning about breast and ovarian cancer risk. Specifically, the new version of the AYR tool includes a user-friendly quiz experience and updated mobile-first design features based on feedback gathered from surveys and focus groups of key target demographics, including African American women. Bright Pink also updated the educational content throughout the AYR tool to improve the user's understanding of how their responses affect risk calculations and understand personalized risk management recommendations. The National Society of Genetic Counselors has reviewed and approved the AYR tool. The AYR tool not only provides accessible risk assessment to the general population but also links women to additional resources, including Bright Pink's Explore Your Genetics website, breast health mobile messaging program, and an online peer support forum.

Bright Pink AYR: Design and Content

The AYR 3.0 tool includes 26 questions (Figure 1) based on the NCCN criteria for *Genetic/Familial High-Risk Assessment: Breast and Ovarian* [2,17]. However, the AYR tool is unique compared with other existing risk assessment tools designed primarily for use in clinical settings. The NCCN criteria that trigger consideration of genetic testing among asymptomatic individuals include (1) a family history of *BRCA1/2* or other gene variants, (2) a family history of high-risk cancers such as triple-negative or male breast cancer, or (3) a family history of more than 3 cases of cancers on either side.

On the basis of these NCCN criteria, Bright Pink's AYR tool categorizes women into the *high* category when they report already having a mutation in a breast cancer susceptibility gene identified through genetic testing. Specifically, AYR high risk is triggered by a personal history of positive genetic testing for genes associated with hereditary breast and ovarian cancer syndrome (*BRCA1* and *BRCA2*), Lynch syndrome (*MSH2*, *MLH1*, or *EPCAM*), or Peutz-Jeghers Syndrome (*STK11*) [2]. In contrast, *increased* risk is triggered by a personal history of positive genetic testing for other moderate to lower penetrance mutations (eg, *BRIP1*, *RAD51C*, *RAD51D*, *PMS2*, *and MSH6*) or a relative with a positive gene mutation test combined with no personal history of genetic testing. Moreover, a strong family history of high-risk breast or ovarian cancer, as well as a history of three or more cancers within the family, will trigger an increased risk in the AYR tool. Finally, AYR also uses components from the Gail and Tyrer-Cusick models, including a personal history of childhood radiation to the chest, abnormal breast biopsy, or polycystic ovary syndrome (PCOS) [21-24]. Women with no family history of these genes, and none of the other criteria listed in Figure 1, are categorized as *average* risk and provided with educational messaging focused on appropriate clinical screening guidelines and current evidence related to the impact of health behaviors on cancer prevention.

Figure 1. Description of the 3.0 criteria used by the Bright Pink Assess Your Risk (AYR) for breast and ovarian cancer risk assessment among asymptomatic women.



Statistical Methods

The primary goal of the AYR is to estimate the lifetime risk of breast and ovarian cancer among women with no history of breast or ovarian cancer. We thus excluded women reporting a previous history of breast or ovarian cancer from the analysis because the focus of AYR is on cancer prevention and early detection. In this subset, we calculated descriptive statistics for the AYR participants overall then by average, increased, and high AYR breast and ovarian categories. We then examined measures of agreement between the NCCN and AYR criteria.

We used the AYR quiz questions to create our own *average* and *increased* categories based on the NCCN criteria for breast and ovarian cancer genetic testing. We then compared these with the categories assigned by the AYR algorithm when the quiz was taken. We assessed measures including sensitivity and specificity to estimate the ability of AYR to distinguish between women who are eligible for genetic testing (AYR increased risk) versus those who are at average risk and thus not eligible for genetic testing, considering our NCCN criteria variables as the *gold standard*. We also examined the positive predictive value (PPV) and negative predictive value (NPV) to determine whether the AYR tool correctly identifies eligible or ineligible women based on NCCN criteria among those in the AYR increased or average categories, respectively. A *true positive* was when AYR risk category matched with the independently created NCCN categories. We calculated McNemar test of agreement, with an α of .05.

Results

AYR User Population

There were 143,657 AYR completions between October 2018 and March 2019, with complete data on health behaviors and family history. We examined the results for both breast (Table 1) and ovarian (Multimedia Appendix Table S1) cancer AYR risk categories. Overall, most AYR participants reported White race, and the mean age was 30.0 years (SD 10.7), with over half of participants in the 18-29 years age group. The mean BMI was 28.2 (SD 7.6) kg/m^2, and most women reported that they limit alcohol intake to less than 2 drinks per day and did not smoke. However, 60.54% (86,969/143,657) of women reported that they did not meet the physical activity guidelines for 150 minutes of moderate-intensity activity per week.

Table 1. Characteristics of the Bright Pink Assess Your Risk population for breast cancer risk.

Characteristics	Overall (N=143,657)	Average (n=62,760)	Increased (n=74,555)	High (n=6342)
Age (years), mean (SD)	29.66 (10.71)	29.8 (10.76)	30.2 (10.49)	29.0 (12.46)
Age group (years), n (%)				
18-29	84,506 (58.82)	37,689 (60.05)	42,533 (57.05)	4284 (67.55)
30-39	32,408 (22.56)	13,558 (21.60)	17,937 (24.06)	913 (14.40)
40-49	17,450 (12.15)	7369 (11.74)	9529 (12.78)	552 (8.70)
50-64	8152 (5.67)	3647 (5.86)	4050 (5.43)	455 (7.17)
≥65	1141 (0.79)	497 (0.79)	506 (0.68)	138 (2.18)
Race and ethnicity, n (%)				
White	97,227 (67.68)	38,984 (62.12)	53,694 (72.02)	4549 (71.73)
African American	5001 (3.48)	2620 (4.17)	2224 (2.98)	157 (2.48)
Asian	4469 (3.11)	2924 (4.66)	1398 (1.88)	147 (2.32)
Other or multiple	22,411 (15.60)	10,238 (16.31)	11,200 (15.02)	973 (15.34)
Ashkenazi Jewish ethnicity	716 (0.50)	249 (0.40)	400 (0.54)	67 (1.06)
Hispanic or Latina ethnicity	13,833 (9.62)	7745 (12.34)	5639 (7.56)	449 (7.08)
BMI, mean (SD)	28.22 (7.63)	28.00 (7.52)	28.51 (7.75)	27.12 (6.99)
Alcohol intake; ≥2 drinks per day, n (%)	16,171 (11.26)	6820 (10.87)	8498 (11.4)0	853 (13.45)
Exercise; <150 min/week, n (%)	86,969 (60.54)	37,481 (59.72)	45,879 (61.45)	3609 (56.91)
Current smoker, n (%)	21,801 (15.18)	8618 (13.73)	12,102 (16.23)	1081 (17.05)
Personal history of breast cancer only, n (%)	4599 (3.20)	0 (0)	0 (0)	4599 (72.52)
Personal history of ovarian cancer only, n (%)	1275 (0.89)	316 (0.50)	948 (1.27)	11 (0.17)
Personal history of breast and ovarian cancer, n (%)	1182 (0.82)	0 (0)	0 (0)	1182 (18.64)
Dense breasts, n (%)	24,347 (16.95)	8448 (13.46)	14,321 (19.21)	1578 (24.88)
History of breastfeeding, n (%)	24,720 (41.50)	10,554 (41.93)	13,304 (41.07)	862 (42.86)
Polycystic ovary syndrome, n (%)	13,825 (9.62)	5116 (8.15)	7881 (10.57)	828 (13.06)
Abnormal biopsy, n (%)	3521 (2.45)	0 (0)	2550 (3.42)	971 (15.31)
Chest radiation, n (%)	1541 (1.07)	0 (0)	1283 (1.72)	258 (4.07)
Family history early-onset breast cancer, n (%)	26,080 (18.15)	0 (0)	23,450 (31.45)	2630 (41.47)
Family history triple-negative breast cancer, n (%)	5851 (4.07)	0 (0)	5267 (7.06)	584 (9.21)
Family history multiple breast cancers in same relative, n (%)	16,453 (11.45)	0 (0)	14,888 (19.97)	1565 (24.68)
Family history of multiple breast cancers with at least one ≤50 years, n (%)	13,721 (9.55)	0 (0)	12,322 (16.53)	1399 (22.06)
Family history of male breast cancer, n (%)	1002 (0.70)	0 (0)	874 (1.17)	128 (2.02)
Family history of ovarian cancer, n (%)	16,711 (11.63)	0 (0)	15,704 (21.06)	1007 (15.88)
Family history of metastatic prostate cancer, n (%)	7813 (5.44)	0 (0)	7481 (10.03)	332 (5.23)
Family history of pancreatic cancer, n (%)	11,732 (8.17)	0 (0)	11,158 (14.97)	574 (9.05)
Personal genetic testing history, n (%)	5290 (3.68)	845 (1.35)	3064 (4.11)	1381 (21.78)
Family member genetic testing history, n (%)	20,553 (24.13)	2103 (6.46)	16,690 (34.26)	1750 (45.44)

We also examined participant characteristics by the risk category assigned by the AYR algorithm, which is shown for breast (Table 1) and ovarian (Multimedia Appendix 1, Table S1) cancers. Most participants were classified as average or increased risk for breast cancer, with only 4.41% (6342/143,657) reporting high risk. White race was the most commonly reported (97,227/143,657, 67.67%) compared with 3.48% (5001/143,657) for African American, 3.11% (4469/143,657) for Asian, and 9.62% (13,833/143,657) for Hispanic or Latina ethnicity. After stratifying for the AYR-assigned risk category, a greater

proportion of high-risk women tended to be aged >50 years and reported Ashkenazi Jewish ethnicity. For health behaviors, we observed a trend of higher alcohol intake and current smoking among women with increased and high breast cancer risk AYR categories. However, women in the high-risk category were least likely to report that they did not meet the physical activity guidelines (378/683, 55.3%) compared with 61.89% (49,566/80,091) and 58.53% (36,358/62,122) for increased and average risk, respectively) and reported the lowest mean BMI of 27.1 kg/m^2. High-risk women were also more likely to have a personal history of dense breast, PCOS, or abnormal breast biopsy as well as a family history of high-risk cancers. For ovarian cancer (Multimedia Appendix 1, Table S1), we observed similar trends overall and by risk category. This is supported by Table S2 in Multimedia Appendix 1, which demonstrates that most participants matched in the AYR risk category for breast and ovarian cancer.

Agreement Between AYR-Defined Categories Versus Independently Assessed NCCN Risk Categories

In examining the agreement between the AYR tool classifications and our classification based on NCCN criteria for breast and ovarian cancer risk, we calculated the sensitivity, specificity, PPV, and NPV. As shown in Table 2, the sensitivity and NPV were 100% for AYR compared with NCCN for all categories. However, overall, the specificity of the AYR tool was 89.9%, whereas the PPV was 94%. We also examined variation in measures of validity between the AYR and NCCN criteria by race, ethnicity, and age group (Table 3). We found the lowest estimates of specificity and PPV for Asian race, followed by Ashkenazi Jewish ancestry. Overall, specificity ranged from 85.9% for the Asian race to 91.3% for the African American race. For age group, there was also some variation in specificity, and the values ranged from 87.6% for the 30-39 years age group to 93.7% for those aged ≥65 years.

To explore the reasons for the observed variation in specificity and sensitivity, we also examined the frequency of the additional characteristics evaluated by the AYR tool, including personal history of chest radiation, PCOS, or abnormal breast biopsy by race, ethnicity, and age group (Multimedia Appendix 1, Table S3). Women with Ashkenazi Jewish ethnicity reported the highest frequency of previous chest radiation, PCOS, and abnormal breast biopsy. However, Asian women and women reporting for other races also reported 14.88% (638/4288) and 13.93% (2434/17,474) relatively high frequency, respectively, of a history of PCOS. Older women were more likely to report a history of chest radiation, whereas younger women were more likely to report PCOS. We also observed a trend of higher frequency of abnormal breast biopsy for the over 40-49, 50-64, and ≥65 years age groups (905/18,671, 4.85%; 644/7997, 8.05%; and 109/1151, 9.47%, respectively) compared with younger age groups.

Discussion

Principal Findings

We present the AYR tool as a valuable, new risk assessment tool with great potential to impact breast and ovarian cancer prevention in the general population. Overall, the AYR tool is highly accurate in identifying women at increased risk for breast and ovarian cancer in comparison with the gold standard NCCN criteria. We also identified differences by race, ethnicity, and age group that highlight opportunities for improving the reach of the AYR tool to additional populations as well as objective for future studies to validate the AYR tool among diverse populations. Overall, the Bright Pink AYR tool provides reliable, evidence-based risk assessment to the general as well as clinical populations for the identification of women at increased risk for breast and ovarian cancer.

Existing Risk Assessment Tools Compared With Bright Pink AYR

Bright Pink AYR is unique compared with other web-based risk assessment tools for breast and ovarian cancer, primarily because of its nature as a participant or patient-facing web-based tool designed for use by the general population. This includes, but is not limited to, clinical risk assessment tools such as the Breast Cancer Risk Assessment Tool (BCRAT; also known as the Gail model), the International Breast Cancer Intervention Study (IBIS), the Breast and Ovarian Analysis of Disease Incidence and Carrier Estimation Algorithm (BOADICEA) model, and BCRAPRO [25-29]. There is much overlap between these validated, clinically oriented tools with AYR but also important differences. For example, the BCRAT model uses 7 questions including age, race, ethnicity, health history (age at menarche and history of abnormal breast biopsy), and family history of breast cancer to estimate the 5-year risk and lifetime risk of invasive breast cancer based on the probability of cancer incidence during a defined age range [21,22]. The BCRAT model, however, does not include the risk of genetic mutations but instead refers participants to alternative tools for testing [21,22]. In contrast, although software such as IBIS using the Tyrer-Cuzick model also estimates 5-year and lifetime risk, the model incorporates genetic mutations and breast density into the most recent versions [23,24]. Moreover, both IBIS and BOADICEA were recently updated to include polygenetic risk scores, which is a limitation that other models such as the AYR should examine in future iterations. BRCAPRO is a similar model that relies primarily on basic demographics, family history, and genetic testing results, if available [30]. However, one major difference between AYR and these other tools is that, other than BOADICEA, none include lifestyle or health behavior

risk factors in the models [27]. Overall, although there are many similarities between AYR and existing breast and ovarian cancer clinical risk assessment tools, the major difference is that AYR was designed as a resource for the general population.

Opportunities for Improving Risk Assessment Through Bright Pink AYR

Bright Pink built the AYR for the general population as a tool to help inform women of their risk and to provide education on cancer prevention activities appropriate to their risk level. We believe that the patient-oriented interface, developed with the help of marketing experts, makes AYR a particularly user-friendly risk assessment tool with the potential to reach populations that existing clinical tools may not reach because of issues such as health care access. The Bright Pink AYR tool represents an advance in the field of population-level cancer prevention as a screening tool with the potential to improve the reach and use of web-based breast and ovarian risk assessment among diverse populations.

The Bright Pink AYR tool has also demonstrated a strong reach to potentially underserved populations. Epidemiological data from the Surveillance, Epidemiology, and End Results Program demonstrate disparities in breast and ovarian cancer incidence and mortality by race [31-33]. However, studies show that much of the differences in breast and ovarian cancer incidence and mortality rates by race and ethnicity are driven by factors such as access to recommended screening and treatment [34,35]. To improve early cancer detection among high-risk groups and younger women not yet eligible for cancer screening, it is critical to increase access to and use of risk assessment tools in the general population. The Bright Pink AYR was designed to bridge these gaps. However, studies have demonstrated that other current methods for breast and ovarian cancer risk assessment may not currently be acceptable to diverse populations. Studies by Cragun [36] and Sheppard et al [37] demonstrated the disparities by race in the acceptability and use of breast and ovarian cancer risk assessment. The results demonstrate that breast and ovarian cancer risk assessment in a clinical setting is less likely to be acceptable or used by African American and Hispanic or Latina women compared with White women [36,37]. The observed disparities by race and ethnicity in breast and ovarian cancer risk as well as use of risk assessment tools justify the need to modernize risk assessment to make it more broadly accessible to the general population. We have demonstrated that the Bright Pink AYR reaches these diverse populations in the general population and provides accurate risk assessment; however, the educational follow-up emails also make AYR unique.

The AYR tool is also unique compared with other tools in that health behaviors are collected and used to tailor email messages to promote cancer prevention behaviors. Previous studies have demonstrated the impact of education on health behaviors among high-risk populations. For example, Quach et al [38] examined baseline and 6-month reporting of health behaviors among Ashkenazi Jewish individuals (n=120) who underwent genetic testing for *BRCA1/2*. The study found that women and those with higher education were more likely to report a healthy diet. The results showed no change in diet, vitamin use, or physical activity over time. However, there was no education component for health behaviors incorporated into the genetic counseling sessions. Another study examined health behaviors among participants of self-reported genetic testing (n=3016; with n=136 reporting genetic testing) using data from the Health Information National Trends Survey 4 [39]. The results demonstrated that lifestyle factors were not statistically significantly different between those who reported genetic testing and those who did not. However, the sample size was relatively small, and the study did not examine multivariate models. The AYR tool collects data on health behaviors, unlike many other clinician-oriented risk assessment tools. However, the AYR educational component has a strong potential to impact population-level participation in cancer prevention activities.

Studies have examined the impact of risk assessment programs for breast or ovarian cancer on adherence to cancer prevention guidelines or recommendations for lifestyle risk factors, and most have identified opportunities for improvement [38-43]. For women with a strong family history, Price et al [44] reported that among 748 women in a breast cancer family registry, between baseline and 3-year surveys, 16% were underscreened for mammography and 55% were underscreened for clinical breast examinations. Moreover, a study by Loescher et al [45] examined cancer surveillance behaviors among 107 women aged ≥18 years who presented for genetic risk assessment for breast and ovarian cancer. The results showed that 60% engaged in the minimal level of recommended breast cancer prevention activities, but 70% reported behaviors below optimal guidelines for cancer prevention. The study also found that a lack of physician recommendation was the most commonly reported reason for not engaging in breast or cancer prevention activities [45]. Similarly, Botkin et al [46] studied the impact of *BRCA1* genetic testing on preventative cancer screening behavior over 2 years (n=408). Among women aged ≥40 years, 82% of mutation carriers followed guidelines for screening mammography in the first year and 67% in the second year, which was significantly increased from baseline and greater than the levels observed among noncarriers [46]. These studies provide evidence that knowledge of risk for breast and ovarian cancer may not only impact participation in cancer prevention activities but also that reported levels are not optimal and expanded adoption of combined risk assessment and educational modalities such as the AYR tool may improve cancer prevention in the general population.

There are strengths and limitations of the current analysis. The strengths include the very large sample size of the completions of the AYR tool in a short period and a diverse population. However, although the population was diverse, the frequency by race and ethnicity was lower than expected for some populations. This reflects the opportunity to improve access and use of the AYR tool in diverse populations. Moreover, the questions asked by the Bright Pink AYR tool are categorical and often binomial, such as health or family history and physical activity questions. This limits the level of detailed data collected on high-risk cancers and the ability to evaluate factors such as age at cancer diagnosis and pathology or subtype of breast cancer. Finally, these data were cross-sectional. Longitudinal studies will be necessary to validate the accuracy of AYR risk

assessment in breast and ovarian cancer risk prevention. However, overall, the results demonstrate that AYR accurately classifies women according to breast and ovarian cancer risk using existing gold standard criteria.

These results demonstrate that Bright Pink's AYR accurately classifies women at an increased risk of breast or ovarian cancer. The variation observed by race, ethnicity, and age group demonstrates the need to improve access and use of risk assessment tools in diverse populations. Overall, Bright Pink AYR is a valuable tool for use by the general population as well as patients and clinical providers for early detection and education, which will improve the prevention of breast and ovarian cancer.

Abstract

Background: The rapid aging of the world's population requires systems that support health facilities' provision of integrated care at multiple levels of the health care system. The use of health information systems (HISs) at the point of care has shown positive effects on clinical processes and patient health in several settings of care.

Objective: We sought to describe HISs for older persons (OPs) in select government tertiary hospitals and health centers in the Philippines. Specifically, we aimed to review the existing policies and guidelines related to HISs for OPs in the country, determine the proportion of select government hospitals and health centers with existing health information specific for OPs, and describe the challenges related to HISs in select health facilities.

Methods: We utilized the data derived from the findings of the Focused Interventions for Frail Older Adults Research and Development Project (FITforFrail), a cross-sectional and ethics committee–approved study. A facility-based listing of services and human resources specific to geriatric patients was conducted in purposively sampled 27 tertiary government hospitals identified as geriatric centers and 16 health centers across all regions in the Philippines. We also reviewed the existing policies and guidelines related to HISs for OPs in the country.

Results: Based on the existing guidelines, multiple agencies were involved in the provision of services for OPs, with several records containing health information of OPs. However, there is no existing HIS specific for OPs in the country. Only 14 (52%) of the 27 hospitals and 4 (25%) of the 16 health centers conduct comprehensive geriatric assessment (CGA). All tertiary hospitals and health centers are able to maintain medical records of their patients, and almost all (26/27, 96%) hospitals and all (16/16, 100%) health centers have data on top causes of morbidity and mortality. Meanwhile, the presence of specific disease registries varied per hospitals and health centers. Challenges to HISs include the inability to update databases due to inadequately trained personnel, use of an offline facility–based HIS, an unstable internet connection, and technical issues and nonuniform reporting of categories for age group classification.

Conclusions: Current HISs for OPs are characterized by fragmentation, multiple sources, and inaccessibility. Barriers to achieving appropriate HISs for OPs include the inability to update HISs in hospitals and health centers and a lack of standardization by age group and disease classification. Thus, we recommend a 1-person, 1-record electronic medical record system for OPs and the disaggregation and analysis across demographic and socioeconomic parameters to inform policies and programs that address

the complex needs of OPs. CGA as a required routine procedure for all OPs and its integration with the existing HISs in the country are also recommended.

(J Med Internet Res 2022;24(2):e29541) doi:10.2196/29541

Introduction

The world's population is rapidly aging, from the 12% estimate in 2015 to the 22% total global population in 2050 [1]. In the Philippines, 7.5 million, or 7.5%, of the total country population in 2015 were senior citizens (aged 60 years and above) [2]. Recognizing their complex health needs and considering that sound and reliable information is the foundation of decision making across all health systems, the World Health Organization (WHO) developed the Global Strategy and Action Plan on Aging and Health (GSAP 2016-2020), which includes adapting information systems to collect, analyze, and report data on intrinsic trends in the capacity of the aging population [3].

Comprehensive geriatric assessment (CGA) is a form of collecting, analyzing, and reporting data on the intrinsic capacity of an older person (OP). It is a multidimensional, multidisciplinary diagnostic and treatment process conducted by a team of health professionals through a systematic evaluation that identifies a variety of treatable health problems and leads to better health outcomes [4]. It is currently being utilized in different settings, government and private facilities, outpatient and inpatient care, primary care, and research. It contains multiple data points and essential health information about OPs that must be considered in providing holistic and integrated care. Based on findings of meta-analyses [5-10], CGA leads to improved detection and documentation of geriatric problems as well as improvement of health outcomes, such as improvement of functional status, prevention of hospitalization, and reduction in readmission rates or mortality, depending on the specific model and setting in which it is implemented [4]. Furthermore, recent evidence on the cost and effects of CGA showed a reduction in the need for hospital care days in a high-risk population of older adults, which could be of great importance in managing the increasing prevalence of frailty and multimorbidity [11]. This information is also crucial for program and policy development.

One of the main challenges of today's health system in the country is access to real-time information for decision making [12]. The 2018 Philippine's health system review highlighted that integrating and harmonizing all existing health-related information systems and data sources, and the inadequacy of a governance structure on information and communication technologies (ICT) are critical challenges [13]. Moreover, the privacy of heath information was also identified as a challenge in policy and practice [14].

The rapid aging of the population requires systems that support health facilities' provision of integrated care at multiple levels of the health care system. A health information system (HIS) that maintains "1 person, 1 record" facilitates efficient provision of services for OPs. Furthermore, the use of HISs at the point of care has shown positive impacts on clinical processes and patient health in multiple settings of care [15]. The adoption of health information exchange (HIE) programs has proven to lessen utilization of health care services, such as ambulatory care and hospital readmissions, and allow smooth transition from inpatient to outpatient care [16,17].

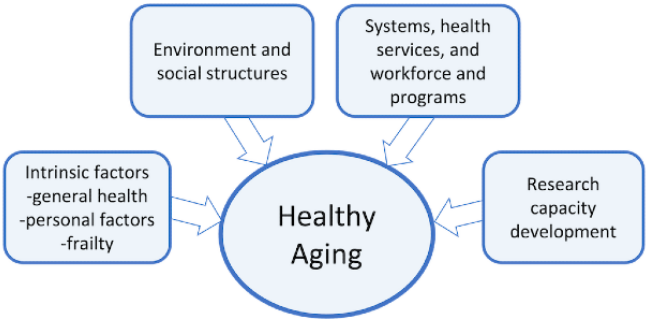
In recognition of the need for Filipino senior citizens to receive appropriate geriatric health care services, the Department of Health (DOH) provided funding for upgrading the 27 DOH-retained hospitals across regions where geriatric centers will be established [18]. CGA will be conducted in these centers and in primary care settings through Guidelines on the Adoption of Baseline Primary Health Care Guarantees for All Filipinos (DOH Administrative Order [AO] no. 2017-002) [19].

Given the rapid aging population, complex needs of OPs, importance of health information in the delivery of services, and challenges to health information in general, identifying the current status of HISs for OPs is significant in aligning the health system in the country to achieve healthy aging. This is especially true for government tertiary hospitals and health centers where OPs usually access health care.

Figure 1 shows the Focused Interventions for Frail Older Adults Research and Development Project (FITforFrail) framework adapted from the WHO Healthy Aging Framework, which defines healthy aging as the process of developing and maintaining the functional ability that enables well-being in older age [20]. The systems, health services, workforce and programs, intrinsic factors, environment and social structures, and research capacity development are essential parts of the whole-of-system approach that supports healthy aging.

Since healthy aging is the main focus of the GSAP, wherein 1 of the key strategies is aligning health systems to the needs of OPs [3], FITforFrail Study 1 concentrated on the analysis of current health systems for aging in the Philippines. The systems, health services, and workforce and programs, as well as aspects of the environment and social structures, were covered by Study 1, where mixed methods of data collection were utilized.

Figure 1. FITforFrail healthy aging framework. FITforFrail: Focused Interventions for Frail Older Adults Research and Development Project.



According to WHO, health systems need to be transformed and realigned to ensure access to evidence-based health interventions responsive to the needs of OPs [3]. A HIS is one of the building blocks of the health system. It provides the underpinnings for decision making where data generation, compilation, analysis and synthesis, and communication and use are its key functions [21]. With the advent of technology, eHealth or the use of ICT for health can maximize its potential toward integrated care of OPs.

The HIS is particularly under the systems, health services, and workforce and programs wherein review of policies related to OPs and listing of services and workforce specific for geriatric patients are conducted.

The data on HISs in general and even among specific population groups in the Philippines are limited. Thus, this paper sought to describe the existing HISs specific for OPs, especially among government tertiary hospitals and health centers across regions in the country. Specifically, it aimed to review the existing policies and guidelines related to HISs for OPs in the Philippines; determine the proportion of select government hospitals and health centers with existing health information specific for OPs, such as CGA, medical records, analysis of top causes of morbidity and mortality, and registry of specific diseases, and electronic medical records (EMRs); and describe the challenges related to HISs in select tertiary hospitals and health centers.

Methods

FITForFrail

FITforFrail is a research and development project funded by the DOH through the Philippine Council for Health Research and Development (PCHRD) under the Advancing Health through Evidence-Assisted Decisions with Health Policy Systems Research (AHEAD-HPSR) program. Using the WHO Healthy Aging Framework, the project aims to identify the current health system for the aging population and describe the health status of OPs in select communities. FITforFrail Study 1 analyzed the health system, and FITforFrail Study 2 evaluated the health status of OPs, with a focus on frailty.

Study Design

A cross-sectional research study design using mixed methods of data collection was utilized. Mixed methods and community participation were hallmarks of this research. For this specific paper, a review of policies and papers related to OPs and a facility-based listing of health services and workforce specific for OPs were conducted to collect the data on HISs.

Sampling

Purposive sampling was used in selecting study sites. The inclusion criteria for the hospitals were (1) Ministry of Health–/DOH-retained government tertiary hospitals and (2) geriatric centers identified through the Philippine Health Development Plan 2017-2022. For health centers, they had to be within the catchment area of the identified hospital in the region. All the 27 hospitals identified as geriatric centers and 17 health centers within the catchment area across all regions were included in the study.

Study Setting and Participants

The researchers conducted a listing of health services and workforce specific for OPs in the 27 hospitals identified as geriatric centers and the 17 health centers within their catchment area. An advance copy of the listing tool along with the letter addressed to the heads of the institutions was sent prior to actual data collection. The heads of the institutions assigned and identified focal or point persons to be interviewed to provide their facility data. These identified point persons served as key informants. They were mostly in charge of the geriatric program in their institutions. The research team scheduled separate meetings with the informants to explain the study and obtain consent prior to actual data collection. Policies and the existing literature on HISs were also reviewed.

Ethics Clearance

FITforFrail obtained a total of 6 ethics approvals from the University of the Philippines Manila Research Ethics Board (UPMREB), the Single Joint Research Ethics Board (SJREB), and 4 institutional review boards of hospitals (Multimedia Appendix 1). The UPMREB oversight applies to UP Manila researchers and non-UP Manila researchers doing research in non-UP Manila sites with no local ethics review committee (as mandated by the Philippine Health Research Ethics Board [PHREB]), while the SJREB is a joint review mechanism among the PHREB–duly accredited research ethics committees (RECs) of DOH hospitals. The rest of the reviews and approvals were from the DOH hospitals that required separate institutional review.

Data Collection

Desk Review

Policies were collected through consultation, online search or bibliographic databases visits, and manual search or onsite library visits. For bibliographic databases and online search, the following search terms were used covering the period of 1980 to July 2020: “aging,” “senior citizens,” “older persons,” “Philippines,” “Republic Act,” “memorandum,” “circulars,” “policy,” “administrative order,” “health information system,” “information systems,” and “programs.”

Listing of Services and Workforce

A facility-based listing of services and workforce specific for OPs was conducted. The DOH hospitals identified as geriatric centers were selected as study sites. For primary care units, health centers within the catchment area of the identified regional hospitals were purposely selected across 17 regions in the country. A total of 27 DOH-retained hospitals identified as geriatric centers and 17 health centers were visited for the facility-based listing of services and workforce, with particular attention to HISs for OPs.

A checklist or facility-based listing form was used (Multimedia Appendix 2). The listing form was developed by trained research assistants through policy review and series of consultation meetings with the project and study leaders. The sections of the listing form are as follows: facility demographics, human resources, competencies and training, health services, health financing, information system, and health policies and programs. The specific section on HISs contains questions on patient medical records, disease registries, online databases, and reasons for not having such registries and databases. Moreover, the question on CGA was included under the Health Services section.

Data Management and Analysis

The collected data from the listing were entered in a password-protected EpiInfo data entry program. Data verification and cleaning were conducted using Microsoft Excel through the help of a statistical assistant and under the supervision of a statistician. Cleaned data sets were endorsed to the statistician for analysis. Descriptive statistics (means, SDs, and frequency distribution) were calculated for all continuous and categorical variables measured using Stata (StataCorp).

Results

Policies and Guidelines on Health Information Systems for Older Persons

Republic Act No. 11223 or the Universal Health Care (UHC) Act of 2019 state that all health facilities are required to maintain a HIS consistent with DOH standards, which will be electronically uploaded on a regular basis through interoperable systems [22]. The DOH and PhilHealth will fund and manage the development, quality assurance, and maintenance of the information systems. Under the implementation of the UHC Act is the establishment of a HIS in every health facility, which requires multiple key players for the provision of population- and individual-based health services, including the services for OPs. The DOH, PhilHealth, and the Department of Interior and Local Government (DILG) will integrate all local health systems into a province-wide health system. The private sector will also be encouraged to participate in the integrated local health system through a contractual arrangement.

Prior to the UHC Act, the DOH issued standard policies, procedures, and guidelines governing all ICT-related work in 2005 [13]. It also established the Knowledge Management and Information Technology Service (KMITS); developed the Department of Health Enterprise Architecture (DOH EA) for HISs, which is national in scope; implemented information systems using client-server technology; and established an eHealth framework [23]. A part of the eHealth framework is the Philippine Health Information Exchange (PHIE) through the Joint DOH-DOST-PhilHealth AO no. 2016-001. It aims to achieve integrated health care services and delivery that are also seamlessly responsive, efficient, cost effective, and in real time [24].

The Joint AO no. 2016-003 of DOH and PhilHealth gave way to the adoption of PHIE Lite, which aims to institutionalize the implementation of a harmonized approach and system in developing applications and information systems [25]. OPs were included in the initial priorities of PHIE Lite interoperability as they are included as expanded primary benefit care (ePCB)-entitled sponsored members.

The National Health Data Dictionary (NHDD) and the Unified Health Management Information System (UHMIS), and interoperability standards were also developed and implemented through DOH AO nos. 2013-025 and 2015-037 [26,27]. Unfortunately, the latest version of the NHDD (version 2.0) [28] do not include standard age group classification (young, middle, and oldest old) and relevant diseases, such as geriatric syndromes (ie, dementia, frailty, malnutrition, polypharmacy, and incontinence).

A program dedicated to OPs, the National Health and Wellness Program for Senior Citizens (NHWPSC) through the DOH AO no. 2015-009, was established. One of its objectives is to establish and maintain a database management system and conduct research in the development of evidence-based policies for senior citizens [29]. To date, there is no database management system specific for OPs.

To summarize, multiple agencies are involved in the provision of services for OPs, with several records containing health information about OPs. Moreover, there is no system to integrate or enable interoperability of data systems of OPs at primary, secondary, or tertiary levels of care. Hence, a provider for an OP would be unable to access medical, social, or insurance information in a single record.

Health Information Specific for Older Persons

Table 1 summarizes the health information for OPs in visited government tertiary hospitals and health centers across all regions in the country.

Table 1. Health information for OPs[a] in government tertiary hospitals and health centers, 2019-2020.

Health information	Hospitals (N=27), n (%)	Health centers (N=16), n (%)
Facilities	27 (100)	16 (100)
CGA[b]	14 (52)	4 (25)
Medical records of patients	27 (100)	16 (100)
Data on top causes of mortality and morbidity	26 (96)	16 (100)
Registry of diseases of OPs	20 (74)	13 (81)
Diseases in the registry		
Hypertension	18 (67)	13 (81)
Diabetes mellitus	18 (67)	13 (81)
CVD[c]	18 (67)	10 (62)
Stroke or cerebrovascular attack	18 (67)	10 (62)
Heart attack/myocardial infarction	17 (63)	10 (62)
Respiratory tract diseases	20 (74)	13 (81)
Cancer	20 (74)	5 (31)
Mental disorders	7 (26)	3 (19)
Disability	9 (33)	7 (44)
Online web-based database		
Patient records	23 (85)	10 (62)
iHoMIS[d]	15 (56)	0
UDRS[e]	10 (37)	1 (6)
iClinicSys[f]	0	10 (62)
Others (Bizbox, MedSys, Medix, CHITS[g])	8 (30)[h]	1 (6)[i]
Not updated regularly	4 (15)	6 (37)
Reasons[j]		
No trained/not enough personnel	4 (15)	2 (12)

[g]CHITS: Community Health Information Tracking System.

[h]Values for Bizbox, MedSys, and Medix.

[i]Value for CHITS.

[j]Multiple responses possible.

Comprehensive Geriatric Assessment

A total of 27 DOH tertiary hospitals and 17 health centers were visited. Of the 17 health centers, only 16 (94%) have facility-based listing data. There was no information obtained from a health center in Region IV-B, a cluster of islands in southern Luzon, Philippines [30]. The specific question on CGA was in the Health Service Delivery section of the checklist.

The study revealed that only 14 (52%) of the 27 hospitals identified as geriatric centers conduct CGA for their geriatric patients (Table 1). Of these, only 5 (18%) hospitals use CGA to screen for all their geriatric patients; the rest have specific

conditions or guidelines regarding to whom they can administer CGA. Most hospitals would only utilize CGA in specific age brackets; other hospitals would only do so through referrals, when the patient is admitted, or when they think the patient is frail or at risk. Commonly reported reasons for not administering CGA to all OPs in hospitals include the lack of manpower, inadequate trained personnel, and the length of the assessment. However, of the 16 health centers, only 4 (25%) conduct CGA for their geriatric patients.

Medical Records and Registries for OPs in Hospitals and Health Centers

All 27 hospitals and 16 health centers maintain medical records of their patients. The data on the top causes of mortality are available in almost all (26/27, 96%) visited hospitals and all (16/16, 100%) health centers. When asked whether the facilities have a registry of diseases of OPs, there are more health centers than hospitals that have these (13/16 [81%] vs 20/27 [74%]), as summarized in Table 1.

In terms of specific registries (Table 1), hospitals have better registries on cardiovascular disease (CVD; 18/27 [67%] vs 10/16 [62%]), stroke (18/27 [67%] vs 10/16 [62%]), heart attack (17/27 [63%] vs 10/16 [62%]), cancer (20/27 [74%] vs 5/16 [31%]), and mental disorders (7/27 [26%] vs 3/16 [19%]). However, health centers have better registries on hypertension (13/16 [81%] vs 18/27 [67%]), diabetes (13/16 [81%] vs 18/27 [67%]), respiratory tract diseases (13/16 [81%] vs 20/27 [74%]), and disability (7/16 [44%] vs 9/27 [33%]). Whether these registries are or are not CGA based is not known, as this was not covered by the study and was considered 1 of its limitations.

There are more hospitals that utilize online web-based database of patients records than health centers (23/27 [85%] vs 10/16 [62%]). More than half (15/27, 56%) of the hospitals utilize the Integrated Hospital Operations and Management Information (iHOMIS), and more than a quarter (10/27, 37%) utilize the Unified Disease Registry System (UDRS). iHOMIS is a Windows-based computerized hospital information system for government hospitals, while the UDRS is a unified registry that contains an injury surveillance system, an integrated noncommunicable diseases registry, a violence against children and women registry, and a persons with disabilities registry [31].

Other third-party providers, such as BizBox, MedSys, and Medix, were also reported. Bizbox is a PhilHealth-accredited health information technology provider that passed the eClaims certification on the case rate system [32]. The MedSys EMR is a web-based application developed for physicians and staff within a health care institution to ensure accuracy, privacy, and service efficiency [33]. Lastly, Medix is a cloud-based clinic management software that helps practitioners improve their clinic operations [34]. Some of these are also being utilized by government hospitals despite the availability of DOH-maintained iHOMIS.

For the health centers, more than half (10/16, 62%) utilize an online web-based database for patient records through the Integrated Clinic Information System (iClinicSys), while only 1 (6%) uses the Community Health Information Tracking System (CHITS), as shown in Table 1. iClinicSys is a system owned by the DOH that efficiently and effectively monitors patient cases in rural health units (RHUs) [31], while CHITS is an EMR system for government primary care health centers in the Philippines [35].

Challenges Related to HISs in Select Tertiary Hospitals and Health Centers

In terms of management of HISs, the most common reasons for not regularly updating the web-based database are a lack of or inadequate trained personnel to maintain and manage the information systems (in 4/27 [15%] of hospitals and 2/16 [12%] of health centers), an unstable internet connection (2/16 [12%] of health centers), the use of an offline system (1/16 [6%] of health centers), and technical issues (2/16 [12%] of health centers), as shown in Table 1.

Discussion

Principal Findings

This study described HISs specific for OPs, especially among government tertiary hospitals and health centers across regions in the Philippines. It reviewed the existing policies and guidelines and determined the proportion of select government hospitals and health centers with existing health information specific for OPs, such as CGA, medical records, top causes of morbidity and mortality, registries of specific diseases, and EMRs. Furthermore, challenges related to HISs in select health facilities were described.

There are various HISs in the country. For primary care benefit providers, the following are the DOH-accredited EMR systems: iClinicSys, CHITS, Segworks Tecknologies (Seg-RHIS), the eHatid local government unit (LGU), Secure Health Information Network and Exchange (SHINE OS+), and Wireless Access for Health (WAH) [36]. Furthermore, the DOH maintains 10 information systems and databases. These include the Electronic Drug Price Monitoring System (EDPMS), iClinicSys, the Integrated Chronic Non-Communicable Disease Registry System (ICNCDRS), the Integrated Drug Test Operations Management Information System (IDTOMIS), iHOMIS, the Integrated TB Information System (ITIS), the Online National Electronic Injury Surveillance System (ONEISS), the Philippine Registry for Persons with Disabilities (PRPWD), the National Rabies Information System (NaRIS), and the Violence Against Women and Children Registry System (VAWCRS) [31]. In addition, there are other private or third-party providers of HISs in the country, such as BizBox, MedSys, and Medix.

Among the existing HISs maintained by the DOH, there is no specific one for OPs. The data on OPs can be distributed in almost all existing HISs (ie, PRPWD; ICNCDRS; online reporting of cancer, diabetes, chronic obstructive pulmonary disease, stroke, blindness, mental, coronary artery disease, and renal data from health facilities; ITIS; ONEISS; and other HISs). All these systems require log-in credentials; thus, only authorized personnel have access.

Based on the policies and literature review, there are policies and guidelines that support the establishment and integration

of HISs for OPs. However, there is no current database management system specific for OPs to date, and the data from the existing HISs maintained by the DOH are not readily accessible. Geriatric syndromes, including frailty, malnutrition, dementia, incontinence, and polypharmacy, are not in the NHDD.

There are multiple information systems and agencies involved in the provision of services and sources of health information about OPs, which leads to fragmented health information about OPs in the country. Given the limited accessibility and fragmentation, coming up with evidence for program and policy development that will address the needs of OPs is a major challenge.

More than half of the hospitals identified as geriatric centers and only a quarter of the health centers conduct CGA for their geriatric patients. According to the DOH AO no. 2017-001, "All older patients with a positive risk screen should have a Comprehensive Interdisciplinary Geriatric Assessment for individual special complex needs" and the "Comprehensive Geriatric Assessment should be updated prior to discharge in chronic care facilities and made available to accepting facilities or carers and vice versa" [37].

This study found a limitation in the conduct of CGA, especially in the primary care setting. Not all visited DOH hospitals, although being identified as geriatric centers, conduct CGA. The commonly reported reasons for not administering CGA to all OPs in hospitals include the lack of personnel, inadequate trained personnel, and the length of the assessment.

All visited hospitals and health centers maintain medical records of their patients. The data on the top causes of mortality are available in all health centers and almost all visited hospitals. There are more hospitals that utilize online web-based databases of patients records than health centers. More than half of the hospitals utilize iHOMIS, and more than a quarter utilize the UDRS. In addition, there are third-party providers, such as BizBox, MedSys, and Medix.

There are more health centers than hospitals that have a specific registry of diseases. Hospitals have better registries on CVD, stroke, heart attack, cancer, and mental disorders. However, health centers have better registries on hypertension, diabetes, respiratory tract diseases, and disability. More than half of the health centers visited utilize an online web-based database for patient records through iClinicSys, while only 1 uses another information system, specifically CHITS.

Most of the information systems utilized by the hospitals and health centers are for all patients in general wherein data on OPs can only be extracted. However, the extraction of data on OPs is complicated due to the nonuniform age group categories. In some facilities, the data on patients aged 60-64 years could not be properly retrieved, as these are incorporated into the 45-64-year age group. Age group classification is not standardized across facilities. Having multiple platforms for managing health information deteriorates interoperability between different health facilities, which, in effect, reduces the ease of service delivery.

Limitations

The study was able to cover facilities representing each region across the country; however, these are limited to the selected hospitals identified as geriatric centers and the health centers within their catchment area. Private health facilities were not covered by the study. Thus, the status of HISs in this study was limited only to public health facilities. Moreover, the status of the Philippines' HISs in general was not within the scope the study and thus warrants further investigation.

Comparison With Prior Work

In 1990, the BLACKBOX was the management information system for public health programs, vital statistics, mortality, and notifiable diseases. It handled and retrieved all data that were being routinely collected by public health workers all over the Philippines. It was developed toward a need-responsive and cost-effective health and management information system (HAMIS) [38]. Decades later, with the advancement of eHealth, there are various HISs in the country. For primary care benefit providers, there are 6 DOH-accredited EMR systems [36]. Furthermore, the DOH maintains 10 information systems and databases, which are being implemented in various health care settings through the UHMIS [31]. In addition, there are other private or third-party providers of HISs in the country. These are harmonized through the interoperability standards and guidelines issued by the DOH. However, based on the results of this study, there is no current database management and HIS specific for OPs to date.

The National Objectives for Health 2005-2010 and 2011-2016 prioritized the use of ICT in various reforms areas, critical health programs, and specific areas in health administration [39,40]. The Philippine eHealth Strategic Framework and Plan 2014-2020 was also developed [23]. The current and overall status of the PHIE warrants further investigation.

In terms of management of HISs, the most common reasons for not regularly updating the web-based database are a lack of or inadequate trained personnel to maintain and manage the information system, an unstable internet connection, the use of an offline system, and technical issues. These barriers are also consistent with the findings of other studies, such as a lack of standards, the use of different information systems, infrastructure issues for electricity and connectivity [35], a lack of human expertise [41], the need for training and support for human resources [41,42], and technical complexity [43,44]. In Malaysia, several issues have influenced overall HIS implementation in public hospitals, such as limited financial sources, maintenance by different departments, HIS implementation orders by the Malaysian Ministry of Health, addition of new systems, confidentiality issues, low acceptance levels, low satisfaction levels, different vendors, infrastructure issues, system breakdown, duplication of data, and different systems [45].

In developing countries, the establishment of well-coordinated information collection systems at various levels of the health care system using appropriate staff could contribute greatly to improvements in health care delivery [46]. Furthermore, ICT need to be seen as part of wider approaches involving

technological, social, and institutional innovation; health workers need to be educated more broadly on the use of HISs for action [46,47]; health institutions need to adapt in many ways toward local accountability and patient and health worker empowerment; and software development for HISs needs to integrate computerized systems with work practices to make work more effective [47]. In decentralized and democratic governments similar to the Philippines, HISs can play a crucial role in supporting and sustaining processes by serving as a repository for generated and analyzed information at the local level so that primary health care can address the dynamic and unpredictable elements of health care planning in developing countries [48].

Routine HIS interventions in the European region were identified to be promising; however, different areas of improvement, such as technical, organizational, and behavioral elements, were identified [49]. In Japan, the areas of improvement in health care information technology include the necessity for leadership and IT knowledge in medical communities, provider incentives, legislation regarding accountability, security, privacy and confidentiality, inclusion of stakeholders in solution development, and creation of sustainable business models [50].

In terms of sustainability of HISs, many challenges are faced, and these could be addressed through the systems' technical design, stakeholder coordination, and the building of organizational capacity to maintain and enhance such systems [51]. Furthermore, effective collaboration between major actors (donors, developers, and the Ministry of Health) is fundamental to sustain HISs [52].

Conclusion and Recommendations

The review of existing policies and guidelines provided a background on the status of HISs for OPs in the Philippines. The facility-based listing revealed the proportion of select facilities that conduct CGA and the status and challenges related to the HIS in select tertiary hospitals and health centers in the country.

Current HISs for OPs are characterized by fragmentation, multiple sources of health information, and inaccessibility. Barriers to achieving appropriate HISs for OPs include inability to update HISs in hospitals and health centers and a lack of age group and disease standardization.

A comprehensive assessment and care plan shared with all providers is one of the important elements of integrated care for OPs. In line with the universal health coverage and Sustainable Development Goal of "*Ensuring healthy lives and promote wellbeing for all at all ages*," an emerging landscape of innovation and development on integrated care of OPs is essential in order to address the multidimensional needs of the aging population.

A 1-person, 1-record EMR system for OPs is recommended in order to address their complex needs, as well as extract data to inform policies and programs. Furthermore, the data on OPs should be disaggregated and analyzed across geographic and social parameters in order to identify gaps in programs and provision of services.

Specifically, we recommend the following:

- Integration of data of OPs in the existing HISs in the country, wherein data can be derived and disaggregated across all health care facilities
  - Standardizing the definition of age groups (young, middle, and oldest old) and geriatric syndromes (ie, frailty, malnutrition, falls, dementia, delirium, incontinence, polypharmacy, deconditioning) and inclusion in the latest version of the NHDD (KMITS-DOH)
  - Funding and creating a dashboard for OPs (DOH, PhilHealth)
  - Conducting a CGA of all OPs as a clinical record to be shared across health care providers in all health settings, which will be integrated in the existing HIS
- Alignment of the integration of HISs for OPs with the existing mandates of the NHWPSC and health care provider networks (NHWPSC-DOH, centers for health development [CHDs], LGUs)
- Hiring and capacity building of personnel for management and maintenance of facility-based HISs (Health Human Resource Development Bureau [HHRDB]-DOH, regional hospitals, LGUs)
- Research, evaluation, and monitoring of the integrated HIS (National Commission of Senior Citizens [NCSC], National Privacy Commission [NPC], Health Policy Development and Planning Bureau [HPDPB]-DOH, academia, research institutions)

Acknowledgments

The authors thank the Advancing Health Through Evidence-Assisted Decisions (AHEAD) program of the Department of Health (DOH; specifically Dr Beverly Ho, Mr Pio Asuncion, and Ms Barbara Michelle de Guzman) and the Philippine Council for Health Research and Development, Department of Science and Technology (specifically Dr Jaime Montoya, Dr Paul Ernest De Leon, Ms Guiditta Galera, Ms Clarissa Reyes, and Mr Jay Vee Bartolome) for funding and fund management.

We also thank the National Institutes of Health, University of the Philippines Manila, for housing the implementing agency, which is the Institute on Aging, as well as the University of the Philippines (UP) for providing administrative assistance through the UP Manila channels and the Research Grants and Administration Office.

The Study 1 advisory board members and consultants were Dr Minerva Vinluan, Mr Roderick Napulan, Teresa Cleofe, Arlene Ruiz, Dennis Destacamento, Dr Orville Solon, Dr Nicamil Sanchez, Dr Harvy Joy Liwanag, and Atty. Maryann Lorraine Legaspi.

The authors also thank the hospital administrators of private hospitals, medical center chiefs and focal persons of the DOH regional hospitals, and mayors and city/municipal health officers and staff of health units that the team visited for their hospitality and active participation; policy makers, hospital administrators, and primary care implementers and older persons (OPs) and health care provider participants, barangay captains, and heads of the senior citizen organizations for their participation and kind assistance in the project implementation; and statisticians and project assistants (Leo Angelo Ocampo, Sarah Jane Fabito, Joy Marie Gillera, Maverick Tyrone Jacalan, Celia Abbago, Francis Michael Torreblanca [physical therapist registered in the Philippines (PTRP)], Lance Frederick Dusaban [registered pharmacist (RPh)], Xyzra Kyte Bober, Basil John Fitzgerald Zano, and Alyssa Mae Bernasol) and local field enumerators for their valuable assistance in data collection.

Finally, most of all, we thank the OPs for serving as the team's inspiration in this endeavor.

Authors' Contributions

APG performed protocol development, data collection, analysis, manuscript writing, and review and approval of the paper; SFDLV performed protocol development, data collection, manuscript writing, and review and approval of the paper; and SPM performed data collection, analysis, manuscript writing, and review and approval of the paper.

Abstract

Background: Prior literature suggests that alert dismissal could be linked to physicians' habits and automaticity. The evidence for this perspective has been mainly observational data. This study uses log data from an electronic medical records system to empirically validate this perspective.

Objective: We seek to quantify the association between habit and alert dismissal in physicians.

Methods: We conducted a retrospective analysis using the log data comprising 66,049 alerts generated from hospitalized patients in a hospital from March 2017 to December 2018. We analyzed 1152 physicians exposed to a specific clinical support alert triggered in a hospital's electronic medical record system to estimate the extent to which the physicians' habit strength, which had been developed from habitual learning, impacted their propensity toward alert dismissal. We further examined the association between a physician's habit strength and their subsequent incidences of alert dismissal. Additionally, we recorded the time taken by the physician to respond to the alert and collected data on other clinical and environmental factors related to the alerts as covariates for the analysis.

Results: We found that a physician's prior dismissal of alerts leads to their increased habit strength to dismiss alerts. Furthermore, a physician's habit strength to dismiss alerts was found to be positively associated with incidences of subsequent alert dismissals after their initial alert dismissal. Alert dismissal due to habitual learning was also found to be pervasive across all physician ranks, from junior interns to senior attending specialists. Further, the dismissal of alerts had been observed to typically occur after a very short processing time. Our study found that 72.5% of alerts were dismissed in under 3 seconds after the alert appeared, and 13.2% of all alerts were dismissed in under 1 second after the alert appeared. We found empirical support that habitual dismissal is one of the key factors associated with alert dismissal. We also found that habitual dismissal of alerts is self-reinforcing, which suggests significant challenges in disrupting or changing alert dismissal habits once they are formed.

Conclusions: Habitual tendencies are associated with the dismissal of alerts. This relationship is pervasive across all levels of physician rank and experience, and the effect is self-reinforcing.

KEYWORDS

alert systems; habits; electronic medical record; health personnel alert fatigue

Introduction

Background and Significance

Electronic medical records (EMR) systems have many embedded clinical support alerts to help warn or remind clinicians about patient-related issues [1]. However, the ubiquitous use of such alerts has led to a significant number of alert dismissals [2-8]. Some of these alerts were wrongly dismissed, leading to significant health consequences [1,9]. For example, Slight et al [10] estimated that in the United States alone about 57.6 million adverse drug event alerts were dismissed in 2014, and of those, about 5.5 million were inappropriately overridden, resulting in approximately 196,600 adverse drug events.

Prior literature suggests at least 3 interrelated reasons for the excessive dismissal of alerts. The first reason is the relevance or effectiveness of the alerts [11,12]. Physicians are more likely to dismiss less relevant alerts when they are repeatedly exposed to them. As such, studies have examined how the tiering of alerts based on their medical significance [13] could improve a physician's alert compliance. Irrelevant alerts are also linked to the second reason—alert fatigue. Alert fatigue is a result of alert overload that causes clinicians to become desensitized to subsequent alerts [14,15]. The third reason, as suggested by Baysari et al [16], alerts are excessively dismissed is because of physicians' habitual dismissal of alerts. Using field observations and physician interview data, the authors found that physicians had developed the habit of dismissing alerts over time, which resulted in an excessive number of alerts being dismissed without significant cognitive considerations. As such, Baysari et al [16] called for more empirical studies to examine the role that habit plays in influencing alerts dismissal and establish the prevalence of such incidences of habitual dismissal. In particular, they suggested studying the association between the number of alerts clinicians experience and their alert dismissal rates and how the rate of alert exposure impacts the formation of alert dismissal habits.

Put together, if physicians under high workload environments rely on habituated responses as a way to cope with alert overload and not critically process these alerts as a result [16], then it would have significant implications on the efficacy of alerts in situations that matter most. Therefore, we concur with Baysari et al [16] that it is important to establish the prevalence of such habitual behaviors among physicians and understand how such habits are formed and their impacts on patient care.

Habits are driven by an environmental stimulus that leads to consistent follow-up action in response to that stimulus. Quantifying habitual behavior using empirical observations is challenging; however, this area of research has received increased attention in recent years with the development of quantitative models to measure habit strength [17,18]. These models permit researchers to empirically quantify habitual actions to answer the call for empirically investigating the effects of habits on alert dismissal [16].

Objective

The objective of this study is to empirically quantify the prevalence of alert dismissal associated with physician habit (habitual dismissal) as well as the association between a physician's habitual dismissal and their subsequent tendency for alert dismissal.

Methods

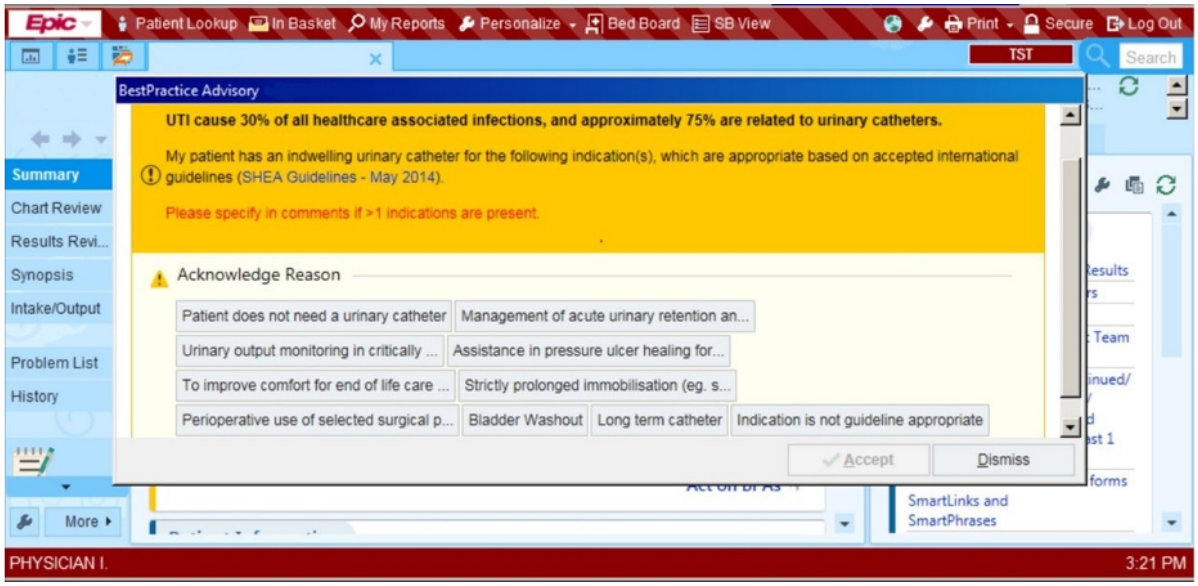
Research Context

The study is a retrospective analysis of log data from 66,049 alerts generated from hospitalized patients captured by the Epic EMR system (Epic Systems Corp) over a 20-month period from March 2017 to December 2018.

Settings and Data Context

The study was situated at Jurong Health Campus, which consists of the integrated 700-bed Ng Teng Fong General Hospital and the 400-bed Jurong Community Hospital. An alert was set up in the EMR system to check if a patient had an indwelling catheter (IDC) for an extended period and was at risk of urinary tract infection. The IDC alert was activated each time the physician accessed the patient's medical record, and it would have informed the physician of the following clinical guideline: "Urinary tract infection causes 30% of all health care–associated infections, and approximately 75% are related to urinary catheters." A screenshot of the alert can be seen in Figure 1. The alert would have reminded the physician to assess the patient and indicate the reasons as to whether the patient should or should not continue to use the catheter. If the physician indicated that the catheter should be removed, they could enter the order in the Epic system. If the patient required continued use of the catheter, the physician could acknowledge this and indicate the reasons in the alert pop-up. In order to not obstruct the physician's workflow, the alert also allowed the physician to ignore the alert by clicking on the dismiss button. Alerts that were acted upon by physicians (eg, alerts that were acknowledged with reasons for nonremoval or ordered for removal) would no longer appear. Alerts dismissed without acknowledgment continued to appear each time the physician accessed the patient's medical record.

Figure 1. Indwelling catheter alert interface screenshot (modified to remove patient identifiers).



Between March 2017 and December 2018, we captured the actions of 1152 physicians who interacted with the IDC alert. This IDC alert was implemented in March 2017, after which we began the data capture. Physicians were not exposed to this alert prior to March 2017 as the IDC alert was custom-built and implemented only in this hospital campus. The IDC alert's interface was also different from other clinical alerts in the EMR system as it is a customized alert. Our data consist of a total of 66,049 alerts from 1874 patients; each patient triggered an average of more than 30 alerts during their hospitalization. A total of 91.2% (60,236/66,049) of all alerts were dismissed by physicians.

Outcome: Alert Dismissal

The unit of analysis for this study is each alert instance, and the main dependent variable is alert dismissal (*dismiss*), represented by a binary measure to indicate if the physician dismisses the alert. As a robustness check, we have also included 3 other possible dependent variables: dismissal performed in under 1, 2, or 3 seconds after the alert's appearance (*dismiss1*, *dismiss2*, and *dismiss3*). We have included time limits for these alerts as a robustness check because habits are often associated with actions that are performed automatically with little cognitive effort and awareness.

Automaticity [16,19] is a trait of habits and an efficient way of handling familiar situations where the individual can execute actions with limited mental effort. Automaticity during a habitual action means that an individual is less likely to search for new information while ignoring additional situational information and will follow up with the usual habitual responses in a short amount of time [20]. Prior literature suggests that habitual dismissal occurs when physicians dismiss an alert without reading the content of the alert [16,21]. Given the clinical information included in the IDC alert, dismissal of alerts in under 1 second after they appeared were likely to be acts of automaticity and it was unlikely the physician had assessed the content of the alert. As a robustness check, other timing cutoffs were also used (ie, alerts dismissed in under 2 seconds [*dismiss2*] and 3 seconds [*dismiss3*]) with statistically similar findings.

Primary Predictors: Habit Strength From Habitual Learning

To quantify habitual behavior, we represent habitual learning as a mathematical form of Hebbian learning as proposed in prior studies [17,22-26].

$$H_{t+1} = H_t + \alpha_H (\alpha_t - H_t) \quad \textbf{(1)}$$

H represents the physician's habit strength at different points in time denoted by t. α_t corresponds to the action taken on time t. An action that corresponded to the response observed in the habitual behavior (ie, dismissal of alert) was coded as 1; it was coded as 0 if the action was otherwise. α_H is a parameter that quantifies the rate of learning after each habitual action. Larger α_H values suggest a faster habit learning rate, and it typically takes on small values (ie, less than 1) [17]. For robustness and comparative purposes, this study used 3 values of α_H to compute the physician's habit strength—0.01 ($H_{0.01}$), 0.05 ($H_{0.05}$), and 0.1 ($H_{0.1}$). Given that the alert system is custom-built and that we captured all alert responses from the start of the alert's implementation, we set the initial habit strength, H_t, at 0 since no physicians had prior exposure to this particular alert before the implementation of the alert.

Covariates

We divided the covariates used in this study into 5 categories: context of the alert, physician's historical exposure to alerts, physician's characteristics, patient's characteristics, and timing effects. The names of the covariates are in brackets and italicized.

- Context of the alert: captured if the alert appeared during ward rounds (ward).
- Physician's historical exposure to alerts were controlled for in 5 ways. First, given that many physicians can consult 1 patient and a physician can have many patients, we first computed the patient-physician (P_C) dyads. This dyad allowed us to precisely measure each physician's alert exposure for a particular patient. We computed P_Ctotal,

the total number of alerts a particular physician received for a particular patient. Second, we computed P_Cward, the total number of alerts received during ward rounds for the patient-physician pair. Third, to control for prior exposure to alerts unrelated to a particular patient, we computed the total number of alerts a particular physician received within the hospital from the beginning of the IDC alert program's implementation (Ctotal). Physicians have heterogeneous experience and exposure to these alerts as they consult a large number of patients; the Ctotal variable controls for a physician's familiarity with the system. Fourth, we controlled for the number of unique patients with indwelling catheters the particular physician encountered in a particular workday (CPatNum) to account for the physician's exposure to patients with similar ailments. Finally, we controlled for the number of days since the physician,C, received the first alert for the patient, P.

- Physician characteristics: the variable C_rank (ie, seniority of the physician—intern, resident, fellow, or attending) was a proxy for the level of physician experience. We also captured the main medical specialty (specialty) in charge of the patient (eg, cardiology). Finally, we captured the type of ward the patient was in (dept).
- Patient characteristics: the patient's age, gender, and race; the total length of stay (los) and number of diagnoses based on International Classification of Diseases, Tenth Revision classification (Diagnosis_count) were used as proxies for the severity of the patient's condition.
- Timing effects: controlled for by recording the day of the week to account for the change in shift duty and the month of the year to account for seasonality.

The complete list of covariates and their detailed descriptions can be seen in Table S1 in Multimedia Appendix 1.

Statistical Analysis

We computed the descriptive statistics to explore the distribution of how long it took each alert to be processed across different physician types and alert outcomes. We computed the point biserial correlations between the outcome variables and primary predictors, as well as Pearson correlations among the rest of the primary predictors. Calculating the point biserial correlation was required for instances where one of the variables was a binary variable.

To test the independent association of the physician's habit strength on dismissal, we estimated 3 fixed effects, logistic regressions with the variable dismiss as the outcome variable, and each of the 3 measures of habit strength ($H_{0.05}$, $H_{0.01}$, and $H_{0.1}$) as predictor variables. Fixed effects regression—grouped at the physician level—was required as the same physician's dismissal behavior is likely to be correlated across alert instances, and controlling for physician-level effects allowed us to isolate the association between habit strength and dismissal outcomes beyond the physician's idiosyncratic characteristics. As a robustness test, we estimated 3 more sets of fixed effects: logistic regression models using alternative, dependent variable measurements of dismissal (ie, *dismiss1*, *dismiss2*, and *dismiss3*). Likewise, the 3 primary predictors of habitual learning were regressed on each of these 3 alternative dependent variables, resulting in an additional (3 × 3) 9 regressions. As a further robustness check, we replicated the 12 regression models described above using regular logistic estimators and random effects logistic estimators for comparative purposes. These additional 24 models are reported in Multimedia Appendix 1.

All regressions used the covariates described above as controls during estimation, and we performed our analyses using Stata (version 14.2, StataCorp LLC).

Ethics Approval

Ethics approval for this study was received by the Domain Specific Review Board (Ref: 2018/01306) in the National Healthcare Group, Singapore.

Results

Descriptive Statistics

Table 1 presents the summary statistics of our sample. We observed that physicians, on average, dismissed 91.2% (60,236/66,049) of all IDC alerts they encountered. Further, 13.3% (8750/66,049) of all alerts they encountered were dismissed in under 1 second, 56.9% (37,546/66,049) of alerts were dismissed in under 2 seconds, and 72.5% (47,890/66,049) of alerts were dismissed in under 3 seconds. A total of 45.6% (30,132/66,049) of all alerts appeared during the physician's ward rounds (*ward*). Physicians, on average, were exposed to 84.9 alerts during this period in the hospital (C_{total}). For any specific patient, a physician received, on average, about 3.9 alerts within the ward (P_C_{ward}) and 8.2 alerts during the patient's stay (P_C_{total}). On any particular day, a physician would encounter an average of 1.3 patients (C_{PatNum}) when the IDC alert was triggered.

Figure 2 presents the distribution of processing time for the alerts before they were dismissed. We observed that, on average, 79.5% (47,890/60,236) of all dismissed alerts were dismissed in under 3 seconds, and 14.5% (8750/60,236) of all dismissed alerts were dismissed in under 1 second.

We also observed changes in physicians' response times over time (Figure 3). The average time for a physician to process an alert dropped from 5.90 seconds (95% CI 5.46-6.34) in the first alert exposure to 2.43 seconds (95% CI 1.75-3.10) during the 60th exposure.

We further explored the distribution of dismissal times across different physician experience levels (Figure 4) and observed similar patterns in dismissal times across medical interns, residents, fellows, and attending physicians. These results suggest that habitual tendencies in dismissing alerts apply to all levels of medical experience.

To visualize how a physician's habit strength ($H_{0.01}$, $H_{0.05}$, and $H_{0.10}$) changed relative to their increasing exposure to the alerts, see the relationship plotted for a typical physician in Figure 5.

Table 1. Summary statistics of the variables[a].

Variable	Mean (SD)	Minimum	Maximum

[a]All variables listed above were described earlier in the text. Refer to Table S1 in Multimedia Appendix 2 for a list of detailed definitions of the variables.

Figure 2. Distribution of processing time of all dismissed alerts.

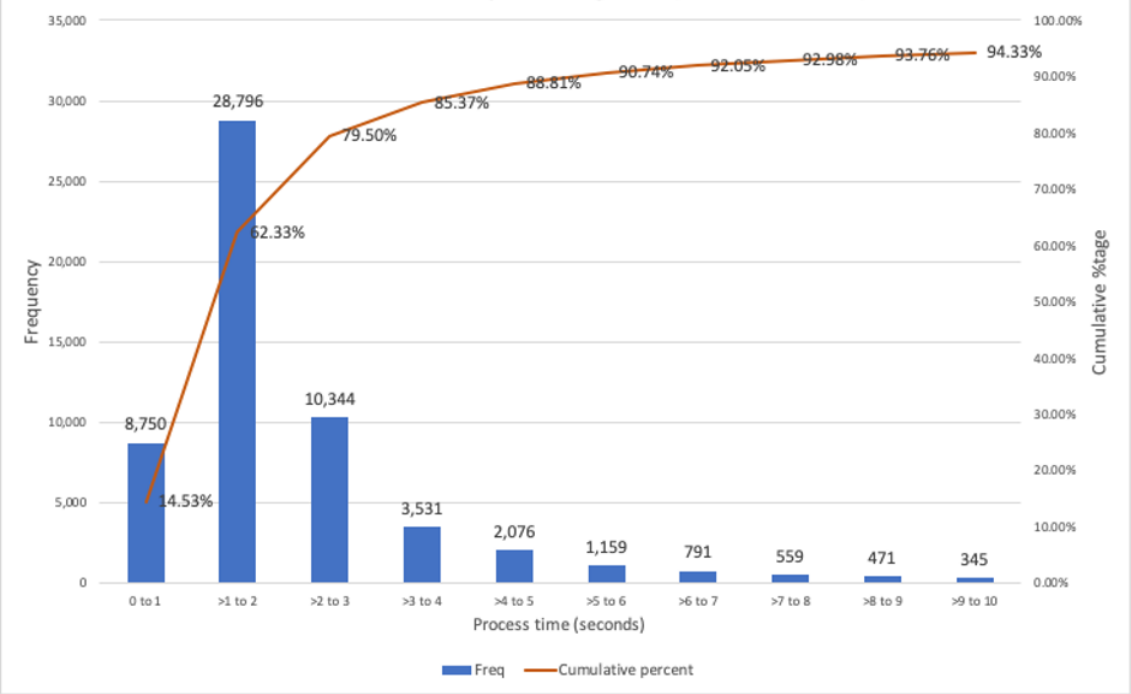

Figure 3. Physicians' average alert processing times across number of alert exposures.

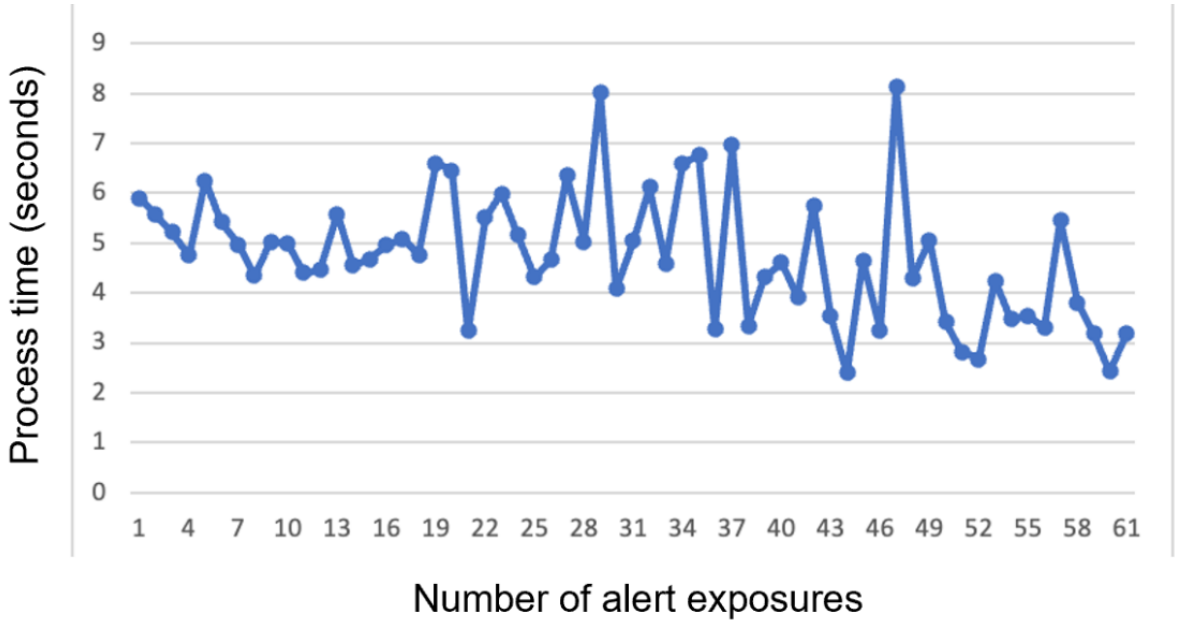

Figure 4. Distribution of response time by physician's rank (level of experience).

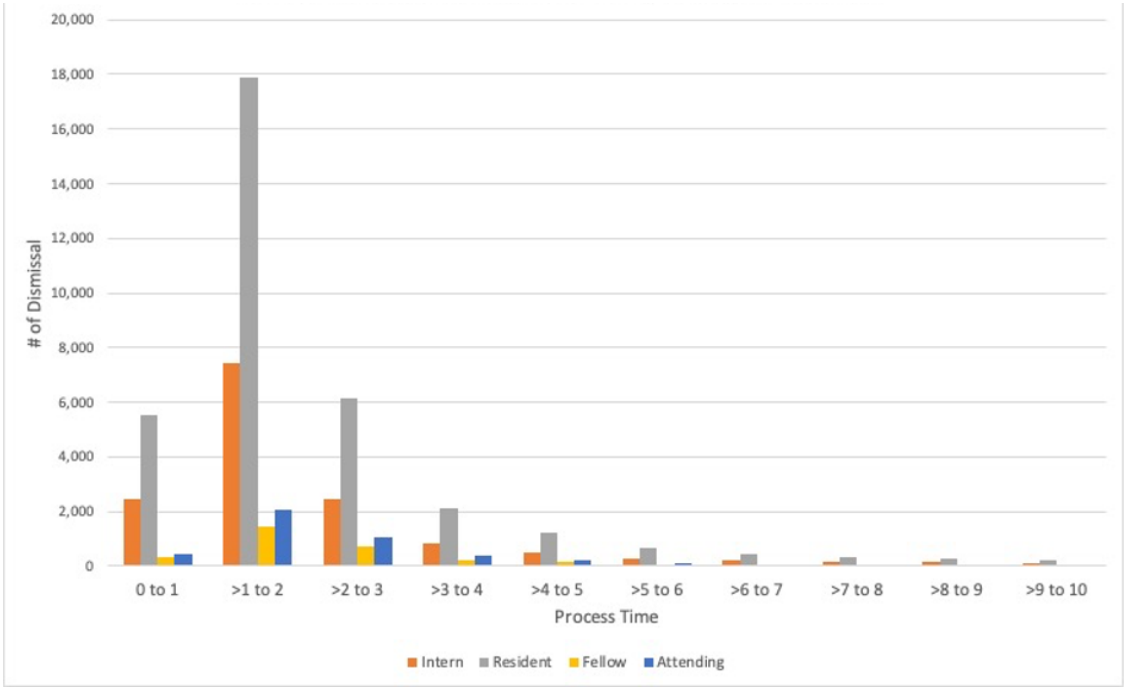

Figure 5. Variation of habit strength across number of alert exposures. Note: P-C (Total) represents the number of alert exposures a physician experiences.

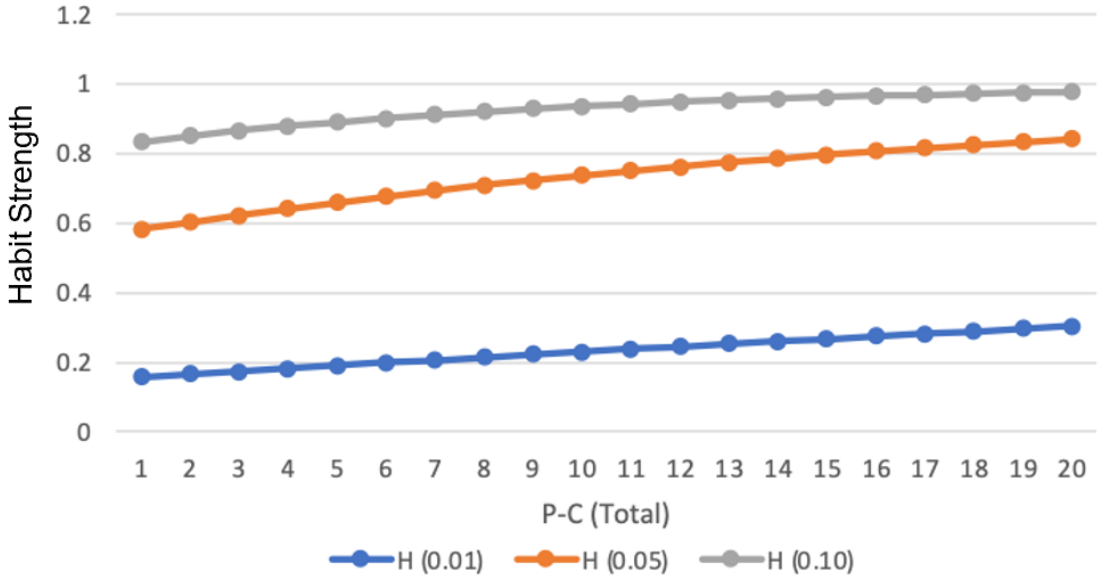

The pair-wise correlations between the outcome variable and primary predictors can be found in Table 2. Alert dismissal was found to positively correlate with all primary predictors (habit strength) in this study, with correlations ranging from 0.227 to 0.421 (P<.001). Further, all dismissals under 1, 2, and 3 seconds (*dismiss#*) were found to positively correlate with the physicians' habit strengths. The point biserial correlation values ranged from 0.024 (P<.001) to 0.270 (P<.001). The correlations were found to be higher for dismissals under 2 seconds (the correlation values ranged from 0.106 to 0.220; P<.001) than dismissals under 1 second (the correlation values ranged from 0.024 to 0.082; P<.001). Dismissals under 3 seconds had the highest correlations between the physician's habit strength and alert dismissal (correlations ranged from 0.136 to 0.270; P<.001). We observed stronger positive correlations for a higher rate of habitual learning with dismissal outcomes, indicating that physicians with stronger habitual tendencies were more likely to dismiss alerts within a short period of time.

Table 2. Correlations[a] among outcome variables and key predictors.

	dismiss (P value)	*dismiss1* (P value)	*dismiss2* (P value)	*dismiss3* (P value)	$H_{0.01}$ (P value)	$H_{0.05}$ (P value)	$H_{0.1}$ (P value)
dismiss	.99	—[b]	—	—	—	—	—
dismiss1	0.121 (<.001)	.99	—	—	—	—	—
dismiss2	0.357 (<.001)	0.341 (<.001)	.99	—	—	—	—
dismiss3	0.505 (<.001)	0.241 (<.001)	0.707 (<.001)	.99	—	—	—
$H_{0.01}$	0.227 (<.001)	0.024 (<.001)	0.106 (<.001)	0.136 (<.001)	.99	—	—
$H_{0.05}$	0.347 (<.001)	0.065 (<.001)	0.183 (<.001)	0.223 (<.001)	0.845 (<.001)	.99	—
$H_{0.01}$	0.421 (<.001)	0.082 (.002)	0.220 (<.001)	0.270 (<.001)	0.703 (<.001)	0.956 (<.001)	.99

[a]Variables *dismiss*, *dismiss1*, *dismiss2*, and *dismiss3* are binary, so we perform a point biserial correlation for their relationships with other predictors. All other correlations are Pearson correlations.

[b]Not applicable.

Regression Results

The regression results in Multimedia Appendix 2 show the association between physicians' current habit strength of alert dismissal ($H_{0.01}$, $H_{0.05}$, $H_{0.1}$) and the probability of their dismissal of the current alert (*dismiss*). The results show that all 3 ways of quantifying habit strengths were positively associated with an increased likelihood of dismissing alerts received in the present time. A 1 standard deviation increase in habit strength was associated with an increase in odds of a physician's dismissal of an alert they received in the present time by 0.642 to 0.810 times.

The results for the other 9 models with alternative measures of dismissals performed within 1, 2, and 3 seconds of appearance (*dismiss1*, *dismiss2*, and *dismiss3*) were also consistent with the main findings. Physicians with higher habit strength were found to more likely dismiss the next alert in under 1 to 3 seconds. Specifically, every 1 standard deviation increase in habit strength was associated with an increase in odds ratio by 0.362 to 0.510 times for the dismissal of the next alert within 1 second of the

alert's appearance. The effect was similar for dismissals that occur in under 3 seconds of the alert's appearance—a 1 standard deviation increase in a physician's habit strength was associated with an increase in odds ratio of 0.350 to 0.503 times for dismissing the subsequent alert. We further computed a random-effects estimator to derive the intraclass correlation coefficient for this model and found that physician characteristics account for 0.716 of the total unexplained variance in dismissal.

Extant studies have found mixed results on how physicians of different ranks (ie, level of experience) would respond to alerts differently. For example, Baysari et al [27] found that only 17% of alerts presented to senior doctors were read compared to junior doctors reading 78% of patient alerts they received. However, Straichman et al [28] and Tamblyn et al [29] found that a physician's seniority had no impact on their alert overriding behavior. To explore if habits had a different influence on physicians of different ranks (levels of experience), we divided the alert instances into 4 subsamples based on the physician's rank (intern, resident, fellow, or attending). For each subsample, we observed that an increase in habit strength was positively associated with dismissals, with dismissals below 1 to 3 seconds of alert exposure across all physician ranks (Table 3).

Table 3. Fixed effects logistic regression results for different physician ranks.

Physician rank and habit strength	*dismiss*		*dismiss1*		*dismiss2*		*dismiss3*	
	β[a] (95% CI)	*P* value	β (95% CI)	*P* value	β (95% CI)	*P* value	β (95% CI)	*P* value
Intern (first year post-medical school)								
$H_{0.05}$	3.235 (2.785-3.685)	.23	1.656 (1.368-1.944)	.15	1.476 (1.288-1.664)	.10	1.560 (1.364-1.756)	.10
Resident (2 to 6 years of work experience)								
$H_{0.05}$	2.604 (2.374-2.835)	.12	1.354 (1.174-1.535)	.10	1.496 (1.374-1.618)	.06	1.486 (1.357-1.614)	.07
Fellow (completed residency and in specialist training)								
$H_{0.05}$	1.591 (0.372-2.811)	.62	2.285 (1.397-3.173)	.45	1.831 (1.333-2.329)	.25	1.584 (1.010-2.157)	.29
Attending physician (specialists)								
$H_{0.05}$	1.830 (1.008-2.651)	.42	1.934 (1.272-2.596)	.34	2.077 (1.641-2.512)	.22	1.652 (1.184-2.121)	.24

[a]Coefficients are exponentiated and represent odds ratios. Each cell represents the coefficient of a single fixed effects logistics regression. Full regression results are available in Multimedia Appendix 1. All multivariate models are adjusted for the context of the alert, physician's historical exposure to alerts, physician characteristics, patient characteristics, and timing effects.

Finally, we computed the relationship between habit strength and physician processing time in an alternative analysis with fixed effects, random effects, and ordinary least square estimators. Here, we observed that processing time of alert is significant and negatively associated with habit strength after controlling for contextual factors, providing further evidence for the association between habit and automaticity ($\beta_{fixed\_effects}$=–1.161, P<.10; $\beta_{random\_effects}$=–1.305, P<.05; β_{OLS}=–2.402, P<.05). We further computed a random-effects estimator to derive the intraclass correlation coefficient for this model and found that physician characteristics account for 0.164 of the total unexplained variance in processing time.

Discussion

Principal Findings

Physicians in clinical settings often experience high workload, significant time pressure, and information overload. The use of clinical support alerts supposedly ensures that, amid these challenging work conditions, physicians can quickly attend to patients potentially at risk of adverse events. The irony, however, is that the very same challenging conditions are also the conditions that may result in the formation of habits in physician responses to the alerts [16,20]. Under such conditions of high workload and information overload, individuals are more likely to rely on automaticity in their responses. Further, as physicians experience more alerts, as argued by Baysari et al [16], they may form habits that are biased toward more habitual dismissal. We empirically show that this is true in our study's clinical context.

Our study contributes to the area of habit research by operationalizing an empirical measure of habitual actions. Traditionally, habitual actions are observed and understood from the perspective of the physician performing the action. However, it is inherently difficult to determine the cognitive state of the physician as they perform different actions [19]. As such, it is challenging to conduct a large-scale empirical study to quantify physician habits. Our study provides a different approach to address this challenge by using a theoretically based alternative that tracks repeated actions as an empirical proxy to quantify habitual actions [18]. We tested the habit strength measure's relationship with the physician's subsequent alert dismissal and found significant positive relationships between them. Our additional analyses also showed that habit strength

measures yielded consistent and similar results with models that used simpler measurements of habit such as physicians' past dismissal rates. Our empirical method of quantifying the habitual response of alerts provides a way for future empirical research that studies the role of habits in physician actions in general.

Our study also answers the call for more systematic empirical research to examine the role of habits in high alert dismissal. Our findings, where we observed a large proportion of alerts dismissed in under 3 seconds, provide empirical evidence of physicians relying on automaticity while dismissing alerts. Our findings support the view that habits play a significant role in influencing alert response.

Specifically, our findings provide 3 key insights into the relationship between habits and alerts. First, we found that the association between habit strength and alert dismissal is pervasive in the sample of alert responses we studied. Second, we showed that habitual alert dismissal occurs in physicians across all levels of experience; senior and junior physicians alike all have the tendency to habitually dismiss alerts. Together, these insights suggest that health informatics professionals and designers of clinical support alerts need to take into account the effect of habits on physicians when designing, implementing, and interpreting the impact of clinical alerts. Research on alert relevance that uses dismissal rates as a measure of relevance (ie, lower dismissal rates suggest a higher relevance of the alert) need to take into account how fast alerts are dismissed. Our study found that there is more to alert dismissal than simply a physician's judgment of the alert's relevance. This is especially true for alerts dismissed within time durations that are too brief to support any meaningful assessment of the alert. Third, we found that habits are self-perpetuating, self-reinforcing, and, as a result, hard to mitigate once they are formed. Physicians who have a history of dismissing alerts are more likely to dismiss subsequent alerts and tend to dismiss them more hastily without much consideration. The self-reinforcing nature of habitual dismissal is a cause of concern as it may significantly reduce the effectiveness of the focal alert and possibly impact the physicians' responses to other clinical support alerts implemented in a clinical setting.

However, given our understanding of the role of a physician's habit formation in the context of alert dismissal and the prevalence of habitual dismissal in health care settings, we propose that future research should draw on our understanding to examine how work conditions and alerts could be designed to mitigate the formation of habitual behavior. Extant literature informs us that habits are shaped by associating an external cue with a repeated, stable response, which, in turn, produces a set of consistent consequences [30]. Habits form when individuals experience a stable context that triggers a habitual action performed frequently, and the habitual action leads to an affirmative outcome that reinforces the behavior. These 3 antecedents are necessary for habit formation, and prior studies on strategies to reduce habitual responses have suggested disrupting or removing these antecedents to reduce habitual behaviors [31,32]. One example to mitigate habit formation is to disrupt the stable environment and triggers that lead to habitual responses. Although these studies are not situated in the medical context, the strategy of removing the individual's familiar environment and triggers of habitual response is an approach that could be explored in the clinical alert context. For example, designers of clinical support alerts could consider varying the format and form of the alerts based on the risk levels or types of clinical conditions involved. Rare alerts associated with higher risks could be designed with a different alert interface, which could disrupt the stable environment (similar presentation mode) that triggers the habitual response. Furthermore, the alert interface could be programmed to be refreshed periodically to remove the stable environment required for habit formation and thereby reduce the incidence of habitual responses.

Limitations

One limitation of this study is that it examined habitual dismissal for only one type of clinical alert: the removal of IDCs. Although we examined all the alerts that appeared during the sample time frame, future research could include different types of alerts as part of the study to understand if our findings are generalizable beyond a specific alert. However, studies involving different alerts will require these additional alert systems to be custom-built to accurately analyze physician responses from the start of the alert's implementation to quantify physician habit strength. Studies that use existing alert systems may not yield accurate findings, as physicians would have had prior exposure to these alerts. Although we attempted to control for physicians' alert fatigue by including, as a covariate, the number of unique patients with the IDC alert the physician consulted on that day, this may not completely control for alert fatigue that might result from other types of medical alerts. Again, future research may attempt to include the impact of other alerts as a control in the study.

Finally, like most retrospective cohort studies, our study does not seek to establish causal evidence or a causal relationship between a physician's habits and the subsequent dismissal of alerts. Here, we use a computational model of habit to show the association between habit formation and a physician's dismissal of alerts within a real-world clinical context. Without further studies that examine the intentions, less feasible in a real-world clinical context, the ability to isolate habit as the sole cause of dismissal is challenging and calls for further research.

Conclusion

This study shows that the strength of a physician's habit for dismissing medical alerts is positively associated with their tendency for subsequent incidences of alert dismissal. Additionally, it was found that most (72.5%) dismissed alerts occurred in under 3 seconds of the physician's exposure to the alert. This empirical finding is in line with prior health informatics literature, suggesting the role of habit in EMR alert dismissal. We contribute to this stream of work by showing that habitual dismissal occurs across all levels of physician experience and that this is a self-reinforcing phenomenon. As physicians habitually dismiss alerts, the likelihood of them hastily dismissing subsequent alerts increases significantly. This phenomenon presents challenges to removing such inclinations toward habitual dismissal among physicians.

Abstract

Background: COVID-19 caused by SARS-CoV-2 has infected 219 million individuals at the time of writing of this paper. A large volume of research findings from observational studies about disease interactions with COVID-19 is being produced almost daily, making it difficult for physicians to keep track of the latest information on COVID-19's effect on patients with certain pre-existing conditions.

Objective: In this paper, we describe the creation of a clinical decision support tool, the SMART COVID Navigator, a web application to assist clinicians in treating patients with COVID-19. Our application allows clinicians to access a patient's electronic health records and identify disease interactions from a large set of observational research studies that affect the severity and fatality due to COVID-19.

Methods: The SMART COVID Navigator takes a 2-pronged approach to clinical decision support. The first part is a connection to electronic health record servers, allowing the application to access a patient's medical conditions. The second is accessing data sets with information from various observational studies to determine the latest research findings about COVID-19 outcomes for patients with certain medical conditions. By connecting these 2 data sources, users can see how a patient's medical history will affect their COVID-19 outcomes.

Results: The SMART COVID Navigator aggregates patient health information from multiple Fast Healthcare Interoperability Resources–enabled electronic health record systems. This allows physicians to see a comprehensive view of patient health records. The application accesses 2 data sets of over 1100 research studies to provide information on the fatality and severity of COVID-19 for several pre-existing conditions. We also analyzed the results of the collected studies to determine which medical conditions result in an increased chance of severity and fatality of COVID-19 progression. We found that certain conditions result in a higher likelihood of severity and fatality probabilities. We also analyze various cancer tissues and find that the probabilities for fatality vary greatly depending on the tissue being examined.

Conclusions: The SMART COVID Navigator allows physicians to predict the fatality and severity of COVID-19 progression given a particular patient's medical conditions. This can allow physicians to determine how aggressively to treat patients infected with COVID-19 and to prioritize different patients for treatment considering their prior medical conditions.

Introduction

Precision medicine, as defined by the National Institutes of Health's Precision Medicine Initiative, is "an emerging approach to disease treatment and prevention that takes into account individual variability in genes, environment, and lifestyle for each person" [1]. Recent increases in the availability of electronic patient data have facilitated the development of precision medicine. For instance, electronic health records (EHRs) store all information collected in hospitals, such as blood tests, radiographs, diagnostic tests, and any biographical information about a patient, such as their age, weight, or height [2]. This approach to medical treatment could prove to be useful in dealing with the COVID-19 caused by SARS-CoV-2, which has been ravaging the United States and the world [3,4]. Currently, a vast amount of research is being conducted to understand how a patient's underlying health conditions interact with the progression of the virus infection. For example, certain conditions such as diabetes and heart disease have been found to raise the severity and fatality rates of patients who have become infected with the virus [5]. Applying the tools of precision medicine can help doctors customize treatment for patients affected by COVID-19 based on the patient's underlying conditions. Attempts at clinical decision support systems for COVID-19 have been made using information on risk factors and biomarker measurements [6,7].

With the rapid spread of COVID-19 and the scarcity of physician resources and time, there is an immediate need for a clinical decision support system that provides patient and disease interaction information to clinicians to allow them to practice precision medicine. In this paper, we describe the creation of the SMART COVID Navigator, a web-based application designed to assist clinicians to relate patient risk factors to the growing amount of research that identifies how various underlying patient conditions affect the progression of COVID-19. This application identifies patient risk factors based on integrating comprehensive data available through multiple EHRs. The application then allows clinicians to quickly access a large set of research studies based on their patient's medical history in an easy-to-access format, helping promote updated information on COVID-19 and its risks for a diverse community. This tool will simplify a clinician's search for relevant research and findings and support clinical treatment.

The SMART COVID Navigator connects patient information from multiple EHR servers to 2 databases of COVID-19 research studies. This will allow clinicians to access data-driven research based on a particular patient's risk factors. The SMART COVID Navigator builds on the framework developed by the SMART Cancer Navigator, which offers clinical decision support by connecting patient EHR information to cancerous gene variants [8,9]. The Navigator is a further step for creating Fast Healthcare Interoperability Resources (FHIR) protocol–based tools to support personalized medicine [10]. This web-based application was built by researchers at the Biomedical Cybernetics Laboratory in Harvard Medical School. It was created using an Angular and Bootstrap front-end framework. The code is available at [11].

Methods

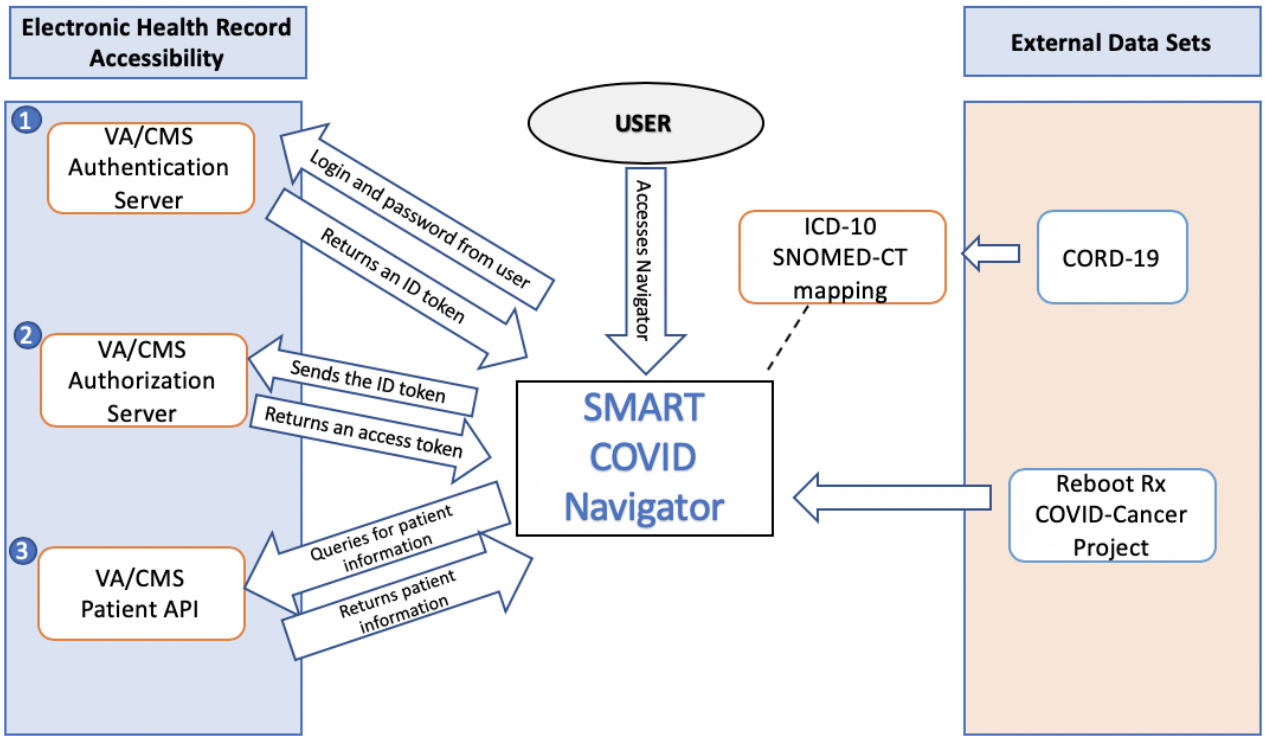
Accessing Multiple FHIR Servers

The SMART COVID Navigator allows the user to log into 2 EHRs: the Veterans Affairs (VA) and the Center for Medicare and Medicaid Services (CMS). There are significant advantages to the application being able to log into multiple EHR servers [12]. Doctors viewing their patient's medical information through the application have the ability to discern any discrepancies between the data sources. Similarly, doctors and patients can be sure that they are receiving the most up-to-date information regarding their health records, as any information not captured in one of the EHRs would most likely be shown in the other. The VA and CMS servers follow the FHIR standard [13]. The FHIR platform allows for the interoperability of the navigator with other EHRs that follow the FHIR protocol. The application is registered with the relevant EHRs. The system can be expanded to access additional health records, provided their application programming interfaces (APIs) follow the FHIR standard. The EHRs provide the application with a client ID and a client secret, which is used for authentication purposes. The following section describes the login process.

To log into the 2 API-enabled EHR systems, the application implements the OAuth2 [14] and OpenID Connect [15] standards to achieve secure authentication and authorization. The authentication process involves a user entering their login credentials, while the authorization process requires a request to the EHR's server to obtain an access token. Upon receiving the access token, the application is authorized to retrieve relevant patient information. The left side of Figure 1 depicts the system architecture for the EHR access process. The login process begins when the user clicks one of the login buttons. The user is redirected to the login portal for the EHR of their choice to enter their login credentials. The OAuth2 process redirects the user back to the application with an ID token in the URL (step 1 in Figure 1). With this ID token, the application then requests an access token from the relevant API to obtain access to the patient's medical information. The application accomplishes this second step by sending the ID token along with additional information such as the application's client ID and client secret back to the EHR server through an HTML POST request. The

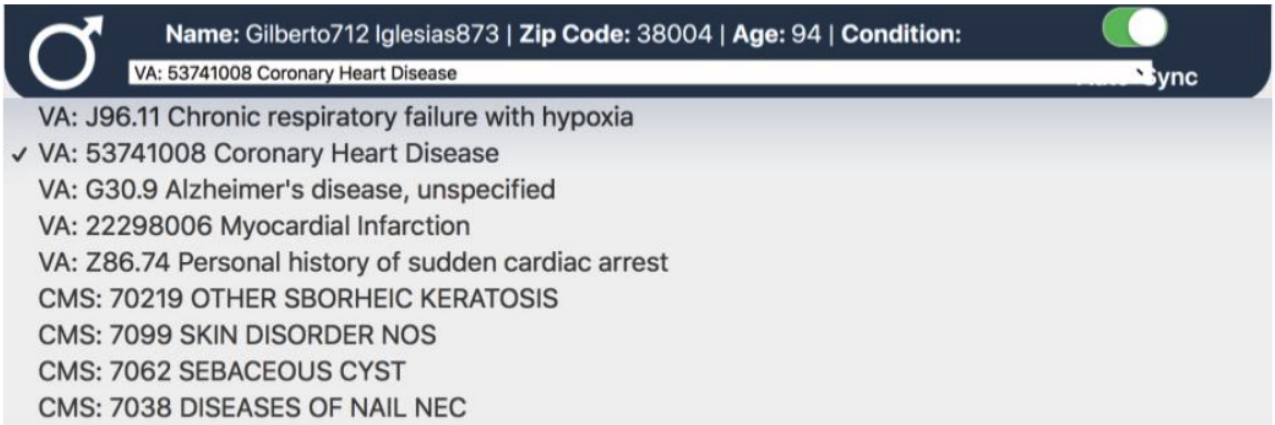
server then returns an access token, which the application can use to gain access to any part of the patient's profile (step 2 in Figure 1). The access token is saved to the local storage of the app; thus, if the user refreshes the application or attempts to log into another EHR, they will still retain access to the first EHR. This 2-step process ensures better security of sensitive medical data. From the EHRs, the following information is retrieved: (1) the patient's name, (2) their location zip code, (3) their date of birth (which is used to calculate their age), and (4) a list of medical conditions associated with the patient along with a numerical code presenting the condition (step 3 in Figure 1).

Figure 1. Architecture diagram of the SMART COVID Navigator. API: application programming interface; CMS: Center for Medicare and Medicaid Services; CORD-19: COVID-19 Open Research Dataset; ICD-10: International Classification of Diseases-tenth version; SNOMED-CT: SNOMED Clinical Terms; VA: Veterans Affairs.



The EHR server results are visually displayed at the top of the screen. This menu appears when a user logs into either one of the servers. It displays demographic information such as the patient's name, age, and current zip code. It also shows a list of medical conditions retrieved from the patient's profile with the list of conditions appearing in a dropdown menu (Figure 2). If the user is logged into both the VA and CMS servers, then the application retrieves demographic information from the VA server, while the condition list is a combined list from both EHRs. Please note that the patient information displayed in Figure 2 and in other figures below are based on information taken from VA- and CMS-simulated patient data; since these data are not from a real patient, there are no Health Insurance Portability and Accountability Act concerns. With these patient conditions now available in the Navigator, the next step is to connect these conditions to risk factors shown to affect COVID-19 progression.

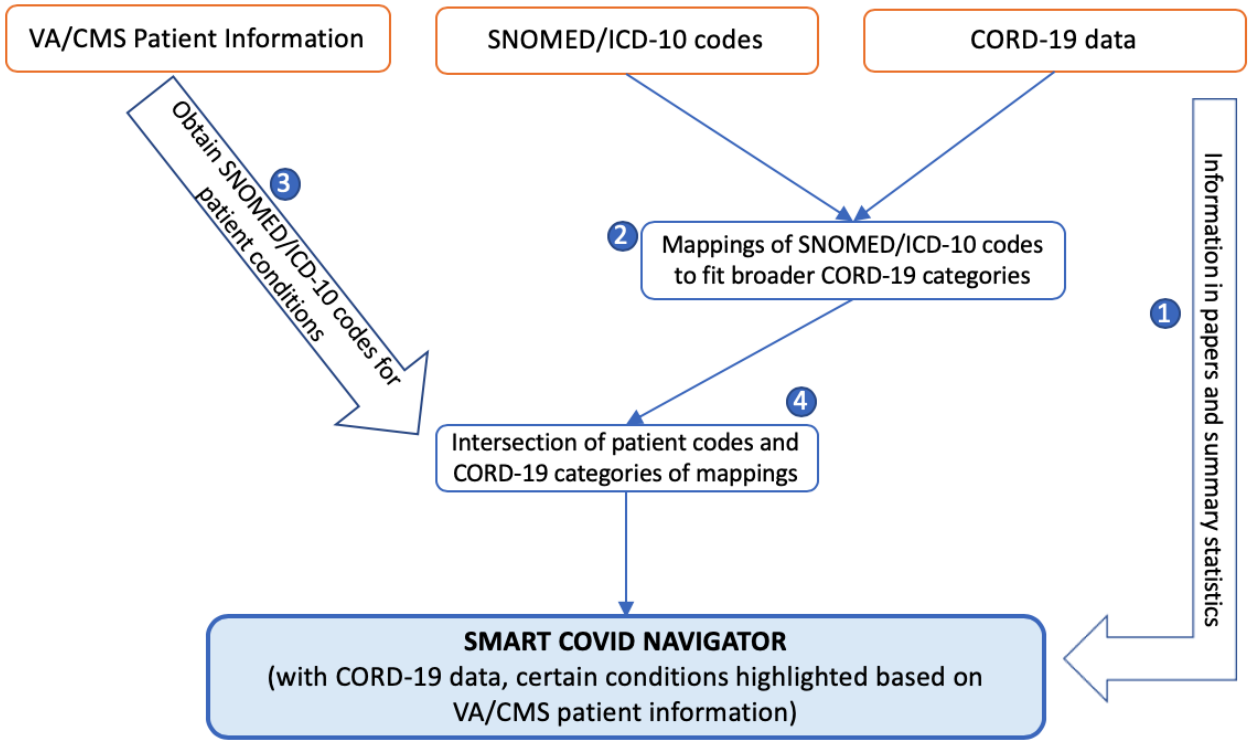
Figure 2. The disease condition list for a Veterans Affairs test patient. This dropdown appears from the patient header.



Accessing Artificial Intelligence–Powered Knowledge Base From the COVID-19 Open Research Dataset

The SMART COVID Navigator collects risk factor information from 2 external data sets, as shown on the right side of Figure 1 and relates it to patient medical conditions. The first data set is the COVID-19 Open Research Dataset (CORD-19), created by the White House and a set of leading research groups such as the Georgetown University's Center for Security and Emerging Technology and the National Library of Medicine, National Institutes of Health [16]. This resource currently contains over 200,000 scholarly papers related to COVID-19. Researchers apply artificial intelligence techniques to create this knowledge base. CORD-19 sources papers from the World Health Organization, PubMed Central, bioRxiv, and medRxiv. These can be in the form of physical printouts, PDF files, or XML files. The papers and preprints are then collected by Semantic Scholar [17], and the resulting metadata are harmonized and deduplicated. The full text of the papers is then extracted [18]. This knowledge base is stored on Kaggle, a web-based community of data scientists and machine learning practitioners [19]. The Navigator utilizes the "risk factors" section of CORD-19 to support clinical assessment of how a patient's medical conditions affect their chances of having a severe or fatal COVID-19 infection (step 1 in Figure 3).

Figure 3. Architecture diagram of the interactions between the Veterans Affairs and Center for Medicare and Medicaid Services electronic health record systems, SNOMED/International Classification of Diseases-tenth version codes, and the COVID-19 Open Research Dataset. CMS: Center for Medicare and Medicaid Services; CORD-19: COVID-19 Open Research Dataset; ICD-10: International Classification of Diseases-tenth version; SNOMED-CT: SNOMED Clinical Terms; VA: Veterans Affairs.



The CORD-19 data are publicly available and are stored in CSV files. Each file tracks studies relating to a specific condition (eg, hypertension, heart disease) that is being tracked. Each row in the CSV file represents a study. The study name, link, date, and significance of the severity and fatality of the patients are all provided. Textbox 1 provides a list of the risk factors provided in CORD-19. As shown in Textbox 1, the CORD-19 data set consists of 28 risk factors—22 of which are disease conditions, while the other 6 are patient biographical characteristics. The comprehensive clinical terminology coding systems, SNOMED Clinical Terms used by the VA [20] and the International Classification of Diseases-tenth version (ICD-10) used by CMS [21], consist of thousands of more specific disease identifiers than the broader disease categories tracked by CORD-19. We mapped the identifiers in the SNOMED Clinical Terms and ICD-10 code sets to the CORD-19 risk factors to be able to match patient conditions to disease categories tracked by CORD-19 (step 2 in Figure 3). This mapping was accomplished through word matching. For each of the 28 risk factors present in CORD-19, the name of the risk factor or a part of the name was matched with every instance of that name occurring in the SNOMED Clinical Terms and ICD-10 code sets by using a Python script created by the authors. For instance, the risk factor "diabetes" links to any disease classification in the code sets that has the word "diabetes" or variations such as "diabetic." Because the disease identifiers in the code sets are more specific than the broad risk factors tracked by CORD-19, many risk factors align with hundreds of more specific disease names from the code sets. Since the mapping involved matching words or parts of words using Python code (and was not done manually), we believe there is unlikely to be incorrect mapping. For example, we searched for the string "diabet," which would capture both "diabetes" and "diabetic." Nevertheless, it is possible that some conditions in the 2 code sets might not have been captured despite our attempts at careful mapping.

Textbox 1. Risk factors tracked by the COVID-19 Open Research Dataset.

Risk factors

- Age
- Endocrine diseases
- Asthma
- Ethnicity: Hispanic versus non-Hispanic
- Autoimmune disorders
- Heart disease
- Chronic obstructive pulmonary disease
- Heart failure
- Cancer
- Hypertension
- Cardiovascular and cerebrovascular disease
- Immune system disorders
- Cerebrovascular disease
- Male gender
- Chronic digestive disorders
- Neurological disorders
- Chronic kidney disease
- Overweight or obese
- Chronic liver disease
- Race: Asian versus White
- Chronic respiratory diseases
- Race: Black versus White
- Dementia
- Race: Other versus White
- Diabetes
- Respiratory system diseases
- Drinking
- Smoking status

Visually in the Navigator, the information from CORD-19 regarding studies related to COVID-19 risk factors appears as a menu of conditions (Figure 4). When the user clicks a particular condition, a pop-up screen is displayed, providing all the information collected about studies relevant to that condition (Figure 5). This will allow a user to view the studies and use the findings for clinical decision support. The study name (with a hyperlink to the full study), date, and the significance of the severity and fatality statistics are shown for each study. At the top of the pop-up, an overview of the studies associated with the chosen condition is displayed. The information included are the total number of studies for that condition, the percentage of studies that found the selected condition to cause a significant change in the severity of COVID-19 progression (out of the studies that measure for severity), and the percentage of studies that found a significant change in fatality due to COVID-19. We alert the user if the proportion of papers finding a significant result is greater than 50%. If a particular risk factor is found to be associated with the severity or fatality due to COVID-19 infection in a high proportion of observational studies, then physicians should pay more attention to patients with that risk factor. However, individual physicians should make their own decisions based on the information in the SMART COVID Navigator and the severity of their patients' health conditions.

Figure 4. A view of the application logged into a test Veterans Affairs profile. A button appears for each condition that is being tracked. Based on the conditions in the patient's profile, certain risk factors on the screen are highlighted in orange.

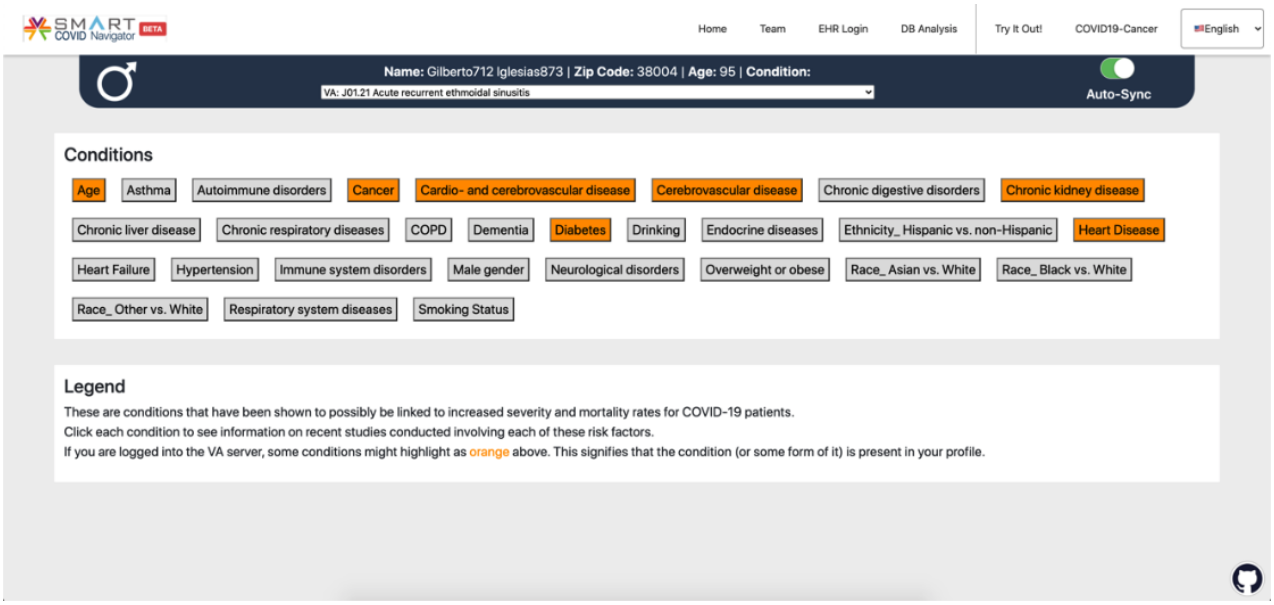


Figure 5. Presentation of information from the COVID-19 Open Research Dataset relating to a particular risk factor (in this case, the example is for the "age" risk factor).

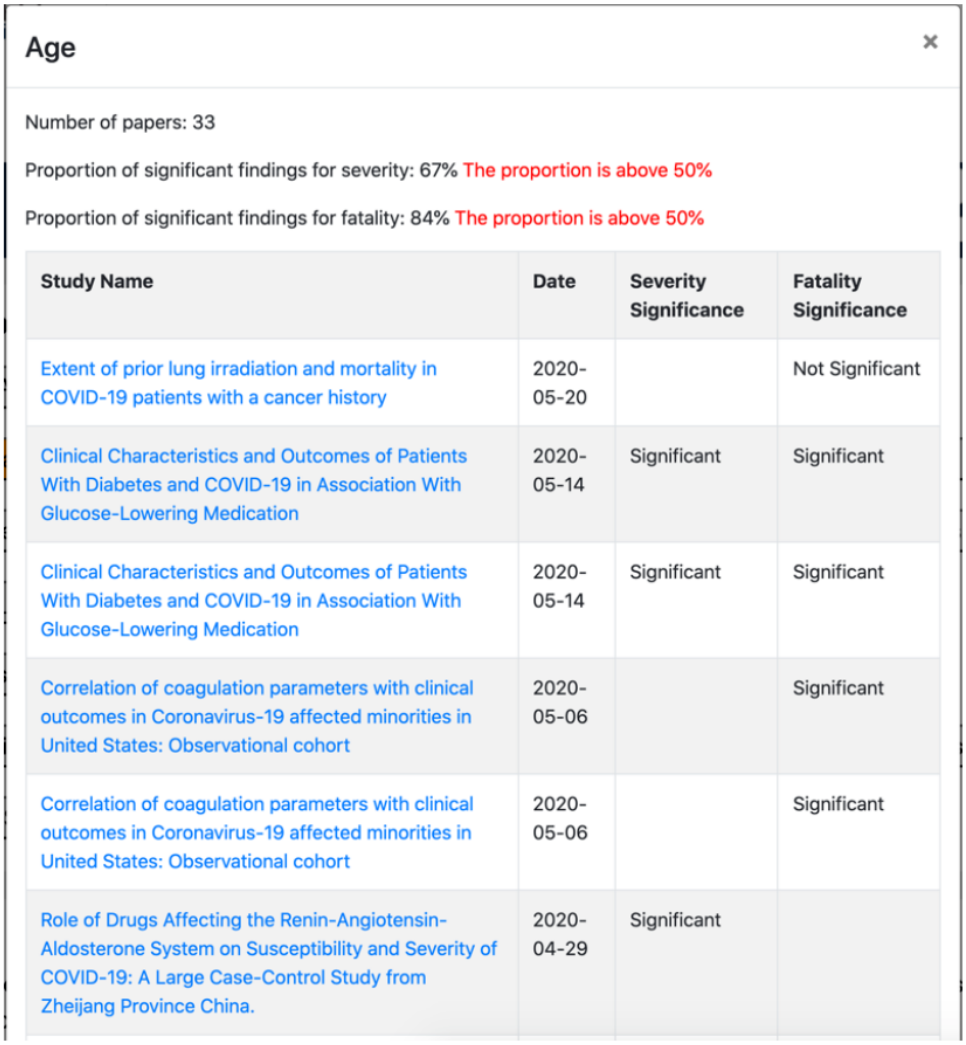

Age

Number of papers: 33

Proportion of significant findings for severity: 67% The proportion is above 50%

Proportion of significant findings for fatality: 84% The proportion is above 50%

Study Name	Date	Severity Significance	Fatality Significance
Extent of prior lung irradiation and mortality in COVID-19 patients with a cancer history	2020-05-20		Not Significant
Clinical Characteristics and Outcomes of Patients With Diabetes and COVID-19 in Association With Glucose-Lowering Medication	2020-05-14	Significant	Significant
Clinical Characteristics and Outcomes of Patients With Diabetes and COVID-19 in Association With Glucose-Lowering Medication	2020-05-14	Significant	Significant
Correlation of coagulation parameters with clinical outcomes in Coronavirus-19 affected minorities in United States: Observational cohort	2020-05-06		Significant
Correlation of coagulation parameters with clinical outcomes in Coronavirus-19 affected minorities in United States: Observational cohort	2020-05-06		Significant
Role of Drugs Affecting the Renin-Angiotensin-Aldosterone System on Susceptibility and Severity of COVID-19: A Large Case-Control Study from Zhejiang Province China.	2020-04-29	Significant	

The patient's biographical and health information retrieved from the EHRs can be used to better guide clinicians on the health conditions they should be concerned about in relation to COVID-19. The Navigator uses the previously described mappings from SNOMED Clinical Terms and ICD-10 identifiers to the CORD-19 risk factors; wherever there is a match between the code in a patient's EHR condition list (step 3 of Figure 3) and those associated with each CORD-19 risk factor, the condition highlights orange (step 4 of Figure 3), thereby alerting the user to presence of the condition of concern (Figure 4). If the patient is older than 60 years, then the "age" condition is highlighted as well. The clinician should click on any highlighted conditions to access further information from the CORD-19 database, as this information is likely to be relevant for the patient in question.

COVID-19 in Patients With Cancer

Cancer has been shown to be a risk factor for COVID-19, and the different types of cancers affect COVID-19 progression differently [22]; therefore, it is important for physicians to understand disease progression if patients with cancer become infected with COVID-19. To help with this, the SMART COVID Navigator accesses Reboot Rx's Reboot: COVID-Cancer Project data sets in order to display information regarding the impact of COVID-19 and its treatment on patients with cancer [23]. The Reboot: COVID-Cancer Project identifies relevant published clinical studies and extracts and aggregates the data from those studies into 2 data sets. The first data set examines COVID-19 disease progression for patients with cancer. The second data set examines what effect drugs currently being tested for COVID-19 treatment could have on cancer (independent of their effect on COVID-19). The data sets are publicly available on the Reboot: COVID-Cancer Project website via interaction dashboards and can be requested in the form of Excel files. This feature gives an organized tool for clinicians to better understand COVID-19 outcomes for different types of cancer. Textbox 2 shows each of the tissue types that are examined in the Reboot: COVID-Cancer Project data sets (the numbers in parentheses indicate which data sets the tissue type is in). As shown in Textbox 2, the data sets consist of 30 tissue types. Tissue types were chosen to distinguish the cancers instead of cancer types, as the number of tissue types was more manageable and therefore would be easier to access for the user of the application.

When a user navigates to the "COVID19-Cancer" tab of the SMART COVID Navigator, they will see a menu of tissue types, similar to how the CORD-19 risk factors are displayed, as well as another button that displays the summary information for all of the tissues in 1 pop-up, colored blue to distinguish it from the other buttons representing tissue types (Figure 6). When one of the buttons is clicked, a pop-up appears with 2 tabs. The first tab displays information retrieved from data set 1 regarding patient outcomes, and the second tab displays information from data set 2 about COVID-19 drugs that could be useful for cancer treatment (Figure 7). When the summary tab is clicked, information retrieved from data set 1 about all tissue types in that data set is displayed, so that clinicians can easily see all the patient outcome statistics on 1 central page (Figure 8). Please note that the use of data set 1 in the SMART COVID Navigator is to display patient outcomes for the treatment of COVID-19 in patients with cancer. This use is similar to how we used the CORD-19 data set. The display of data set 2 is for a different purpose—to inform physicians treating cancer that how drugs that are being used for COVID-19 treatment have an application in cancer treatment.

Textbox 2. Tissue types tracked by the Reboot: COVID-Cancer Project data sets. The numbers in parentheses indicate which data sets the tissue type is in.

Tissue types

- Bladder/unitary tract (1,2)
- Head and neck (1,2)
- Pancreas (2)
- Bone and soft tissue (1)
- Hematologic not specified (1)
- Pleura (1)
- Bowel (1,2)
- Kidney (1,2)
- Prostate (1,2)
- Bowel, esophagus/stomach (2)
- Liver (1,2)

Data Governance

There are 2 sources of data used in the application. The first is patient data from the VA and CMS, which are accessed when a patient logs into their accounts in these EHRs. The SMART COVID Navigator does not store any patient data. These data are accessed by the patient or physician under authorization by the patient. These data are used to identify patient risk factors when the physicians/patients are using the application. When they are done using the application and log out, the patient data are deleted from the local machine, which is being used to access the app. At no point is patient data stored in the main server running the application. The second source of data is from the publicly available CORD-19 and Reboot: COVID-Cancer Project data sets for use in the application. Given these are publicly available repositories of research papers, we do not implement any specific data governance with respect to this information.

Results

Knowledge Base Analysis

In addition to the development of the SMART COVID Navigator, we performed analyses on the research studies in the CORD-19 and the Reboot: COVID-Cancer Project knowledge bases. Given the large number of studies both in the CORD-19 knowledge base and the COVID-Cancer data sets, it would be difficult for a clinician to quickly assess if a particular patient's disease condition or cancer type interacts significantly with COVID-19. For the CORD-19 knowledge base, we explored whether on average, the studies found significant results for each of the 28 conditions examined, and for the Reboot: COVID-Cancer Project data sets, we explored the likelihood of mortality for a particular cancer type based on the aggregate data collected from the data sets.

CORD-19 Knowledge Base Analysis

First, we discuss the results from the CORD-19 knowledge base relating to risk factors. We found that out of the 816 studies examined in the risk factors section, 355 studies (43.5%) studied only how a particular disease condition affected the severity of COVID-19 progression, 328 studies (40.2%) examined only how the disease condition affected fatality, 89 studies (10.9%) examined both severity and fatality, and 44 studies (5.4%) had no entry for severity nor fatality. We examined each of the 28 individual risk conditions to identify which of them have been found more frequently to be a significant factor in COVID-19 severity and fatality rates. These data are displayed in Tables 1 and 2. Table 1 presents the data for each condition regarding severity, and Table 2 presents the data regarding fatality.

Table 1. Severity statistics for all risk factors.

Risk factor	Total papers (N)	Studies on COVID-19 severity (n)	Studies showing significant severity, n (%)[a]
Age	33	15	10 (67)
Asthma	6	3	0 (0)
Autoimmune disorders	3	1	0 (0)
Cancer	26	16	8 (50)
Cardiovascular and cerebrovascular disease	10	7	4 (57)

Race: Other versus White	9	9	3 (33)
Respiratory system diseases	7	2	2 (100)
Smoking status	56	26	5 (19)

[a]The proportion of studies showing significant fatality was calculated from the number of studies showing fatality of COVID-19 in people with the particular risk factor.

[b]N/A: not applicable.

Table 1 documents severity statistics; specifically, the number and proportion of studies that find if a given condition results in a statistically significant change in the likelihood of a patient having a severe COVID-19 infection. For example, out of the 98 studies on heart disease, 54 of them study severity and 42 (78%) found a significant result for severity. However, chronic liver disease seems to not have a significant impact on COVID-19 severity, as out of the 12 papers that study this condition, 6 study severity and only 1 study (17%) found a significant correlation. This application alerts users if more than 50% of papers report a significant finding.

Table 2 is similar to Table 1, except that instead of documenting findings about COVID-19 severity, it documents statistics regarding fatality. We can again look at some examples of medical conditions. As in the case of severity of COVID-19 progression, heart disease is a useful predictor of COVID-19 fatality; out of the 51 papers that measure fatality statistics for the condition, 43 of them (84%) found a significant correlation. Being a smoker, however, does not seem to have the same high degree of correlation; only 5 (19%) out of the 26 papers that measure fatality statistics for smoking status found a significant result. Similarly to that for severity, the application alerts users if more than 50% of papers report a significant finding for fatality.

There are conditions for which the papers tracked by CORD-19 do not offer a definitive answer. Cancer is one of these conditions; 50% (8/16) of studies found a significant finding for severity, while 46% (6/13) found a significant finding for

fatality. A possible explanation for this inconclusive result is the existence of various types of cancers in different tissues of the body, resulting in a mixed result when grouping various cancer types together. For such cases, clinicians will need to access additional information from other papers. As discussed before, we display the severity and fatality percentage summary statistics in the application for each condition so that clinicians can obtain a quick overview of the significance of that condition without having to review each study in detail. However, we caution that clinicians might want to review the studies in greater detail depending on the medical condition of the concerned patient.

Reboot: COVID-Cancer Project Knowledge Base Analysis

In addition to the CORD-19 analysis, we conducted an analysis based on the papers in the Reboot: COVID-Cancer Project data set relating to patient outcomes. This data set stores the number of patients with a specific type of cancer and with COVID-19, the number of those patients who died, and the percentage fatality found. The Navigator aggregates these data to offer the user summary statistics for each of the tissue types. Table 3 documents the aggregate patient outcomes for each cancerous tissue, compiled by adding the number of patients with COVID-19 and number of deaths reported in all the papers relating to the given tissue type. Some cancer tissue types in the table can be seen to be associated with a relatively high fatality rate. For instance, out of the 200 patients with thoracic cancer, 66 died (33%) due to COVID-19. Similarly, 152 out of the 504 patients with lymphoid cancer died (30.1%) and 67 of the 225 patients with lung cancer died (29.7%), indicating that cancers of these tissue types generally result in a higher fatality rate for COVID-19. However, only 5 out of the 91 patients with breast cancer died (6%), indicating that breast cancer is associated to a lesser degree with COVID-19 fatality than some other cancer tissue types.

For some tissue types, the data available through the Reboot: COVID-Cancer Project do not contain an adequate number of patients to support clinical decisions. For instance, based on the fatality rate of 33% (3/9), it would seem that bone and soft tissue cancer is associated with a high risk of COVID-19 fatality. However, the data contain only 9 patients with bone and soft tissue cancer; therefore, more information is needed to make clinical decisions for patients with COVID-19 and bone and soft tissue cancer. Clinicians can access additional information from the full text of papers from the Navigator to make better decisions about patient treatment.

Table 3. Outcome statistics for all tissue types.

Tissue type with cancer	Patients (n)	Deaths due to COVID-19 (% fatality), n (%)
Bladder/urinary tract	1	0 (0)
Bone and soft tissue	9	3 (33)
Bowel	5	0 (0)
Brain/central nervous system	2	0 (0)
Breast	91	5 (6)
Cervix	1	0 (0)
Genitourinary	4	0 (0)
Gynecological	180	20 (11)
Head and neck	8	0 (0)
Hematologic not specified	1893	492 (26)
Kidney	18	2 (11)
Liver	5	1 (20)
Lung	225	67 (30)
Lymphoid	504	152 (30)
Myeloid	29	5 (17)
Not specified	13265	2632 (20)
Ovary/fallopian tube	2	0 (0)
Pleura	1	0(0)
Prostate	124	28 (23)
Skin	3	0 (0)
Thoracic	200	66 (33)
Thymus	1	0 (0)

Discussion

Views From Clinician Users

We surveyed clinicians who tested the SMART COVID Navigator to elicit their assessment. Their feedback highlighted the following uses of the application in patient care and as an educational resource. The clinicians noted that the application allows for a real-time assessment of comorbidities that any given patient may have that could impact severity and fatality risk from COVID-19 and that it allows for the assessment of patients in which multiple factors may be at play. The clinicians also noted that the application could be used at the point of care, and this application filled an unmet clinical need. They stated that the application made it easier to narrow down the literature and find out the relevant patient management–related answers quickly. They also pointed out that the fatality and severity rates displayed by the CORD-19 data could help them in triaging and stratifying patients in limited resource conditions, allowing them to decide whether aggressive treatment was warranted immediately or not. This would also help them involve palliative care early enough if needed. Finally, they commented that the application would help them in shared decision-making with patients.

Apart from patient care, the clinicians felt that the SMART COVID Navigator could serve as an educational resource for teaching medical students, residents, journal clubs, and perhaps, even in continuing medical education for physicians. Some also felt that the application can help in making institutional guidelines. The clinicians made suggestions for future work related to the SMART COVID Navigator. Real-time use of the application would be enhanced by creating a smartphone interface in addition to the current desktop-based web interface, considering that physicians often perform literature reviews on smartphones. Although the application currently links to the VA and CMS, some clinicians felt that the application would benefit from being linked to other EHRs such as Epic. In fact, the same type of user interface and back-end API (SMART-on-FHIR) can be leveraged and is supported by these as well. Another suggestion was to link the application to a patient's COVID-19 vaccination records to further improve the physician's ability to treat the patient.

Additional Comments and Extensions

SMART COVID Navigator was created in response to a growing need for precision medicine tools to assist doctors dealing with COVID-19–infected patients with risk factors shown to affect COVID-19 progression. The Navigator achieves this by connecting patient medical information—in the form of EHRs—with data sets giving comprehensive information about patient outcomes. We show in this paper how to create a clinical decision support system for physicians to understand how a new disease (COVID-19) interacts with a broad set of patient risk factors through the use of the CORD-19 data set. In addition, we expand 1 existing patient condition, namely, cancer, and provide physicians information on how various types of cancers interact with COVID-19. This can be extended to other conditions such as heart disease since certain chronic conditions appear with a large number of variations in patients.

This application benefits from the creation of research study data sets such as CORD-19 and the Reboot: COVID-Cancer Project, thereby showing the value of such collaborative efforts to collect current research findings in one place. Currently, these data sets do not provide API access; therefore, we have to periodically download these data sets for use in the app. In the future, we recommend that such data sets provide API access to enable real-time updating. We note that in the CORD-19 data set, some disease categories are examined by a limited number of papers; thus, the results may not be meaningful for our understanding of COVID-19's impact on patients with that risk factor. Similarly, certain cancer tissue types are not well represented in the Reboot: COVID-Cancer Project data set. We expect that as research into COVID-19 progresses further, there will be better representation across disease categories and tissue types. The ability for users to log into 2 FHIR-supported EHR systems is a useful feature of the application. In addition to providing physicians the latest information about patient's health records, it can also alert users to discrepancies between different databases, giving them an opportunity to correct their health records. This application is not limited to just the 2 EHR databases currently used (VA and CMS); more EHRs can be added to the application as long as they follow the FHIR format, allowing for even more expansion of patient record access.

A possible next step for the SMART COVID Navigator could be to better consolidate the research available in CORD-19 and the Reboot: COVID-Cancer Project by using meta-analysis of the various studies to provide more information to the clinician [24]. For instance, more sophisticated weighting of the results in different papers could be implemented. Another extension would be to provide treatment information through the Navigator platform depending upon the patient's health profile. In addition, advancements in artificial intelligence and machine learning technologies could play an important role in the improvement of the Navigator platform, as well as precision medicine as a whole, by offering predictions about disease progression based on past patient health information, thereby tailoring treatment for the individual and allowing for increased efficiency in treatment [25]. This could take the form of creating patient risk scores generated based on data from EHRs.

Conclusion

Precision medicine has long been hailed as the next step in advancing patient care, with institutions such as the White House creating initiatives to further precision medicine technology advancement [26]. The SMART COVID Navigator is a clinical decision support tool designed to allow physicians to provide precision medicine in the context of COVID-19. Using the app, clinicians can identify patient risk factors from multiple EHRs and connect them to databases of COVID-19 research. Without a clinical decision support system supporting COVID-19 precision medicine, a clinician would need to examine multiple studies in order to fully understand disease progression and fatality outcomes, given a particular disease that their patient has, which is costly in terms of time and effort. The number of studies examining particular disease conditions and their relationship to COVID-19 is growing at a rapid pace. This application simplifies this by providing summary statistics on the risk factors' effect on COVID-19 severity and fatality.

Although this application currently focuses on COVID-19, it can be a readily available platform for quickly expanding into any potential new diseases that emerge.

Abstract

Background: As people increasingly turn to web-based sources for medical information, we offer some insight into what website traits influence patients' credibility assessment. Specifically, we control for brand and content length, while manipulating three website traits: authorship, format, and tone. Furthermore, we focus on medical skepticism to understand how patients with high levels of medical skepticism may react to web-based medical information differently. Medical skepticism is related to a patient's doubts about the value of conventional medical care; therefore, skeptics may have different practices and criteria when conducting their own web-based medical searches.

Objective: The aim of this study is to evaluate how website traits affect the likelihood that patients follow web-based medical advice and how this varies among patients with differing levels of medical skepticism.

Methods: This web-based experiment presented participants with a hypothetical medical situation about leg cramps and offered a website with treatment advice. We varied the websites the participants observed across three traits: authorship (patient or physician), format (article or discussion forum), and tone (objective or experience-based). The 2305 participants were randomly assigned to 1 of 8 possible conditions and then asked the extent to which they would follow the advice. Health care patterns and coverage, demographics, and the participants' level of medical skepticism were captured.

Results: Our participants were selected to be demographically representative of the population of internet users in the United States. The 2305 complete responses were analyzed with ordinary least squares regression. Our analysis reveals that people are more likely to accept web-based medical advice authored by a physician (P<.001) and presented with an objective tone (P=.006), but these preferences erode as the levels of medical skepticism increase. Medical skepticism was measured by means of a previously established index on a 0 to 4 scale, and the average score was 2.26 (SD 0.84). Individuals with higher levels of medical skepticism were more likely to follow web-based medical advice in our experiment (P<.001). Individuals with low levels of medical skepticism found the discussion forum format more credible, whereas those with high levels of medical skepticism preferred the article format (P=.03). We discuss the interactions between medical skepticism and all 3 website traits manipulated in the experiment.

Conclusions: Our findings suggest that, generally, physician authorship and an objective tone create more persuasive web-based medical advice. However, there are differences in how patients with high levels of medical skepticism react to web-based medical resources. Medical skeptics are less discerning regarding the author's credentials and the presentation tone of the information. Furthermore, patients with higher levels of medical skepticism prefer article format presentations, whereas those with lower levels of medical skepticism prefer discussion forum–style formatting.

Introduction

Background

Skepticism toward medical care and treatment has been a long-standing issue in health care [1], ranging from the development of antivaccination beliefs [2,3] and affecting how smokers perceive health-risk information [4] to affecting which treatments people with arthritis decide to use [5]. Medical skepticism, specifically, is related to a patient's doubts about the value of medical care and is defined as "global doubts regarding the ability of conventional medical care to appreciably alter health status" and has been shown to correlate with higher rates in mortality at follow-up [6]. However, other studies have noted the potential benefits of medical skepticism, such as medically skeptical older adults reporting higher levels of self-rated overall health [7]. Previous work has focused on which demographics are more inclined to be skeptical of health care, generally concluding that it is highest among young White people with less education and often lacking health insurance [8,9]. Even so, medical skepticism is widespread, and the trend may be rooted in a consumerist movement where patients are encouraged to be more involved in their health care, making it of particular interest to understand how their decision-making process regarding medical care unfolds [10].

The internet is an obvious tool for patients to find alternative medical information [11,12]. All patients, regardless of their medical skepticism, increasingly use web-based resources to seek health information [13,14]. A Pew Research Center report found that 80% of US internet users (>93 million people) have searched for health-related topics on the web, and most of the health-related searches are related to specific medical problems they are experiencing [15]. In 1 survey, 80% of the physicians confirmed experiences of patients presenting internet-sourced medical information [16]; and in another survey, 41% of the patients stated that they had used a medical professional to confirm their own internet diagnoses [15]. However, this growing interest in web-based medical information has been answered by an explosion of available health content, ranging from predatory websites that spread misinformation and nonprofit institutions creating web-based article repositories to patients using interaction-enabled web-based formats to discuss medical information in a question-and-answer format [17-19]. As gathering health information on the web has been established as a norm, it is important that we understand what causes a patient to follow or ignore medical advice they read on the web [20-24]. Logically, medically skeptical patients may also have different web search behaviors and react to website traits differently. Therefore, we consider what web-based content traits drive people's willingness to follow the advice, as well as the role medical skepticism plays in the web-based credibility assessment process.

Previous research has looked at the use of patient portals as a web-based form of communication between patients and physicians [25-27], but portals provide a web-based communication mechanism that supplements a previously established relationship between a physician and a patient. Prior research has also considered how active participation in web-based health care communities may influence patient outcomes and provide emotional support [28-31]; yet, this assumes that a patient has joined, and is actively participating in, a community, usually sharing their own details and questions. In contrast, our study aims to better understand how patients decide whether to follow web-based medical advice in more casual web research scenarios, specifically those that do not necessarily require the intervention of a physician or long-term emotional support. To that end, we focus on three potential traits that shape web content and may affect credibility assessment: authorship, format, and tone of presentation.

The objectives of this study are to (1) determine what website traits affect a patient's likelihood to follow the presented medical advice and (2) determine whether patients with higher levels of medical skepticism exhibit different patterns of website traits influencing their likelihood to follow medical advice found on the web. Our findings increase our understanding of how patients decide whether to follow web-based medical advice and may inform the design of health care websites. Furthermore, we extend our knowledge about medical skepticism by finding evidence that it alters the credibility assessment that patients undertake when considering web-based medical advice.

Website Traits

Overview

There has been an explosion in medical websites in the last several decades that individuals may turn to for obtaining advice, sharing experiences, voicing concerns, and informing decisions [32-34]. In any context, web users must look for cues signaling that the content is credible and trustworthy [35,36]. We identify three specific website traits that vary across common health information websites: authorship, format, and presentation tone.

Authorship

The authorship of content is a major factor in how people assess the credibility of information [37]. A meta-analysis of studies looking at the effects of health care expertise on the credibility of health information suggests that authorship of web-based content is important and experts are favored [38]. However, the research is not consistent, and in some situations, patients prefer nonexpert advice [39] or perceive a source as credible because of positive judgments about the trustworthiness of the author instead of professional credentials [21]. For simplicity, we focused on two major categories of authors who often provide web-based health care information: physicians and other patients. Physicians represent the easy-to-recognize role of a health care professional who has formal training and expertise, whereas other patients are peers who may have faced similar medical situations.

Format

The increasing prevalence of user-generated content is one of the strongest trends of the past decade [40,41]. This has created new types of web-based content fundamentally different from the more traditional static webpage format, especially regarding navigation design and connectedness [42]. For example, a medical article is usually presented as a static page and is read-only. The owner of a static webpage is also the controller of the information presented. For brevity, we refer to this static, read-only delivery as article format. In contrast, web forums or blogs invite users to also create and share content (eg, ask questions or respond to previous posts) in a dynamic and participative manner [41]. This cocreation process means that the webpage owner is not solely responsible for generation of the content that is visible. We refer to this dynamically cocreated content as discussion forum format. The article format presents a single point of view in a controlled environment, whereas the discussion forum format often presents a cocreated set of advice.

Tone of Presentation

Medical information can be presented on the web as objective or experiential [9]. Objective information is content presented as fact, devoid of any personal attachment or interpretation by the person conveying the information. Experiential information is presented as derived from the actual experiences and insights of the person conveying the information. Some previous research makes the assumption that information provided by health care professionals is objective and information provided by other patients is experiential [28]; however, we believe that the 2 should not be conflated but instead considered separately. Health care professionals can offer advice because of their experiences with other patients, and other patients can convey information as objective fact. Broadly speaking, people tend to appreciate experiential information in decision-making contexts because it signals familiarity with the content [21]; yet, traditionally, an objective presentation signals that the information is well established and broadly accepted [43].

Methods

Sampling and Data Collection

We conducted a web-based experiment through a web-based survey. Qualtrics software was used to recruit participants, and after excluding those with missing or incomplete data, we obtained a sample of 2305 participants. Panelists were recruited to be demographically representative of the population of internet users in the United States, which is a strength of Qualtrics panels [44]. We excluded participants who worked in a medical profession and those who had previous experience with leg cramps (the focus of our experimental manipulation) to remove participants with previous expertise in the study's context. We captured demographics (sex, race, education level, income, age, and geography: whether they lived in a rural, suburban, or urban area), health care situation (number of recent health care visits, current method of receiving primary care, and health insurance status), and the respondent's level of medical skepticism.

Each participant was presented with the same hypothetical medical situation to begin the experiment: "Your friend has recently been battling leg cramps. They ask you to help them research the condition online, and you find the following resource. Please read the web page presented and then answer the questions related to your experience with the online resource."

This situation was chosen such that there would be a nontrivial treatment recommendation that could nonetheless be administered without formally seeking professional medical intervention. Next, 1 of 8 different webpages containing health information regarding leg cramps was presented to the participant. The set of 8 webpages used in the experiment (2×2×2 experimental design) represents each possible permutation of the three website traits of interest: authorship (physician or patient), format (article or discussion forum), and tone (objective or experiential). Each prompt provides identical treatment advice regarding leg cramps, regardless of the website traits shown in the experimental manipulation to which they were assigned.

A positive perception of a specific brand or the reputation of a website increases the likelihood that people will follow the presented advice [42,45-47]. Opinions of friends and acquaintances about a particular website source might also influence patients because they build brand recognition [48,49]. In addition, the length of the text and other formatting features that affect the ease of skimming (eg, bullet points vs long blocks of text) are known to affect the likelihood that people will read the advice and then follow that advice [50-52]. To avoid confounding effects rooted in brand recognition, text length, or readability, our experimental design eliminates these factors by removing branding and standardizing the text length and grammatical presentation of the content shown to participants across all 8 website prompts (including order of information and sentence structure to the extent possible). Example prompts are presented in Figures 1 and 2; all 8 are available upon request.

Individuals were randomly assigned to each experimental condition, and there were between 269 and 301 individuals in each of the 8 possible website version groups. After viewing the prompt, participants were asked to indicate the likelihood that they would recommend the presented advice to their friend with leg cramps.

Figure 1. Experimental website prompt displaying physician authorship, article format, and experiential presentation tone.

How to Stop Leg Muscle Cramps

M Weatherspoon, M.D.
July 6, 2018

What's going on?

We experience muscle cramps when a muscle involuntarily contracts on its own. I had a patient last week describe her muscle cramp as a hard lump at the point of pain — that's the contracted muscle. Cramps usually occur for a reason. My patient hadn't strained a muscle, so her cramping was probably because of muscle fatigue or overuse. Her body may have been dehydrated, or she wasn't getting enough electrolytes, such as potassium or magnesium. Those minerals help our muscles work more smoothly, and fluids help our body process the minerals.

Most cases of muscle cramps do not indicate a worrisome underlying condition. Cramps might be related to alcoholism, hypothyroidism, or diabetes. If the frequency of your cramps bothers you, tell your doctor.

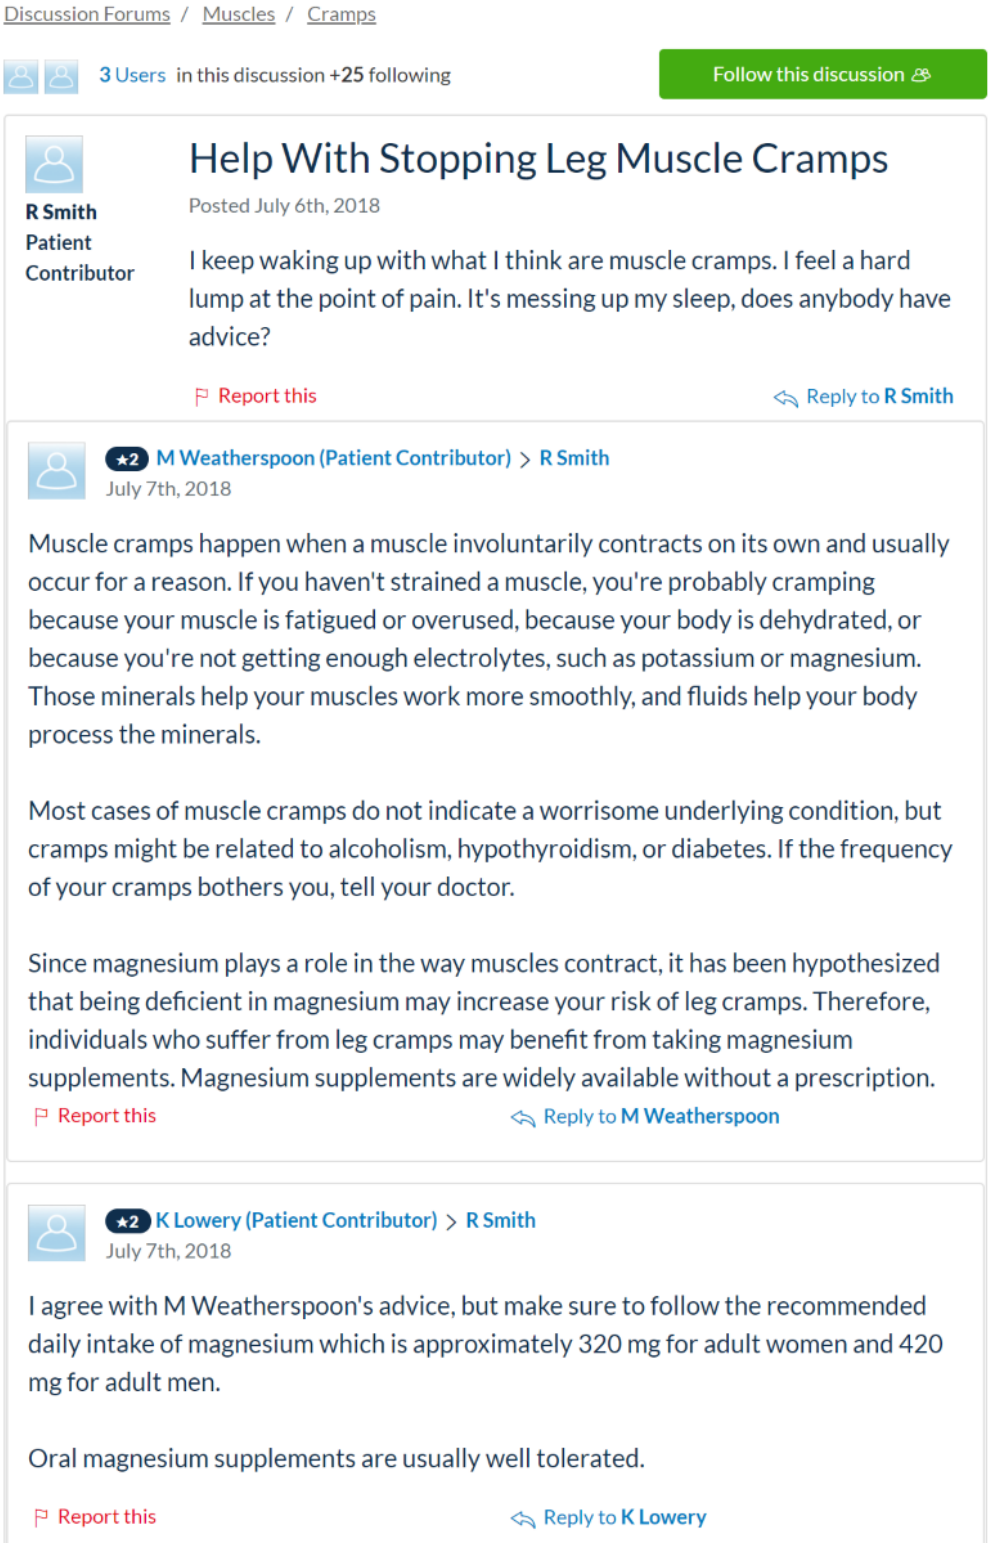
Magnesium Supplements

Since magnesium plays a role in the way muscles contract, it has been hypothesized that being deficient in magnesium may increase your risk of leg cramps. Therefore, I advised my patient that taking magnesium supplements may be beneficial. Magnesium supplements are widely available without a prescription.

Additional Considerations

I recommend taking the daily intake of magnesium which is approximately 320 mg for adult women and 420 mg for adult men. Oral magnesium supplements are usually well tolerated by my patients.

Figure 2. Experimental website prompt displaying patient authorship, discussion forum format, and objective presentation tone.



Outcomes and Measures

Follow Web-Based Medical Advice

Our dependent variable was a continuous variable, ranging from 0 to 4, where lower numbers indicated that individuals were less likely to follow web-based medical advice and higher numbers indicated that individuals were more likely to follow web-based medical advice. This variable was an index composed of four ordinal measures indicating the extent to which individuals agreed with the following: (1) recommending that their friends try magnesium supplements, (2) the extent to which individuals believe that trying magnesium supplements is good advice, (3) if an individual had leg cramps, the extent to which they agree that they would try magnesium supplements, and (4) the webpage convinced them that they should try magnesium supplements to reduce leg cramps.

Individuals reported the extent to which they agreed with each of these statements by responding to a Likert scale that ranged

from *strongly disagree* to *strongly agree*. We averaged these measures to form a continuous index for following web-based medical advice (Cronbach α=.94).

Independent Variables

Experimental Conditions

We included three independent variables to account for each of the aforementioned experimental conditions: the author (physician or patient), the format (article or discussion forum), and the tone (objective or experiential).

Medical Skepticism

We used an index to measure medical skepticism, and this index was based on 3 characteristics that captured an individual's skepticism toward medicine. Medical skepticism was measured by means of a previously validated scale [8,53]. Respondents were asked the extent to which they agreed (on a scale of 0-4) with the following questions: (1) I can overcome most illness without help from a medical professional, (2) home remedies are better than medicines prescribed by doctors, and (3) I understand my health better than most physicians do (Cronbach α=.62). Although the reliability score is below the recommended threshold of Cronbach α=.70, it is an established scale [8,53] and similar to the reliability score reported in previous studies (eg, Cronbach α=.69 in the study by Fiscella et al [6] and Cronbach α=.63 in the study by Jensen et al [10]).

Health Care Situations

We used several independent variables to account for individuals' health care situations. These were important aspects to capture for both our research objectives. A patient's medical care situation and exposure may influence how they interpret web-based health care information [54,55], in general, and previous work has noted that medical skeptics may seek out in-person health care differently [8]. To accurately measure and control for these variations, we first included the approximate number of health care visits that respondents had made in the last 2 years because of illness or injury. Health care visits included visits that respondents have made for themselves or as a companion to a friend or family member because either visit would expose the individual to conversations with individual health care providers. Second, we used a measure that indicated the location where respondents sought primary medical care. This was a dichotomous measure that showed whether a respondent used emergency or urgent care as their primary care or whether they used a clinic, primary care physician, or other health care facility or whether the respondent did not seek any medical care. Finally, we included a variable that measured whether the respondent had health insurance. We compared those who did not have health insurance with individuals who had any type of health insurance (ie, Medicaid, Medicare, employer-provided, military or veteran, self-funded).

Control Variables

We included geographical setting and demographic data in our models, including sex, race, age, income, and educational attainment (Table 1).

Table 1. Descriptive statistics (N=2305).

Variable	Description	Value
Dependent variable: follow web-based medical advice, mean (SD)	This is a continuous variable, ranging from 0 to 4, indicating the likelihood that the respondent will follow the web-based medical advice provided at the end of the prompt (Cronbach α=.94)	2.97 (0.90)
Experimental conditions: 2 × 2 × 2 design involving the following three factors, n (%)		
Physician	Dichotomous variable indicating that the experimental prompt was written by a physician (as opposed to a patient)	1170 (50.76)
Article	Dichotomous variable indicating that the experimental prompt was written in article format (as opposed to a discussion forum format)	1171 (50.8)
Objective	Dichotomous variable indicating that the experimental prompt was written in an objective manner (as opposed to experiential manner)	1158 (50.24)
Medical skepticism, mean (SD)	This is a continuous variable, ranging from 0 to 4, indicating the extent to which the respondent is skeptical toward medicine (Cronbach α=.62)	2.26 (0.84)
Health care situation		
Number of health visits, mean (SD)	The approximate number of health care visits in the last 2 years (as a patient or accompanying a friend or family member)	4.40 (3.47)
Primary care is emergency or urgent, n (%)	Dichotomous variable indicating that the respondent uses emergency or urgent care as their primary or usual care option (as opposed to other sources such as primary care physician or a community clinic)	477 (20.69)
No insurance, n (%)	Dichotomous variable indicating that the respondent has health insurance (as opposed to being without insurance)	344 (14.92)
Home geographical category, n (%)		
Rural	Respondent lives in a rural setting	558 (24.21)
Suburban	Respondent lives in a suburban setting	1046 (45.38)
Urban	Respondent lives in an urban setting. This is the reference category	701 (30.41)
Demographics		
Female, n (%)	Respondent is female (the reference category is male)	1352 (58.66)
Asian or Pacific Islander, n (%)	Respondent identifies as Asian or Pacific Islander	158 (6.85)
Black, n (%)	Respondent identifies as Black	511 (22.17)
Hispanic or Latino, n (%)	Respondent identifies as Hispanic or Latino	210 (9.11)
Other race, n (%)	Respondent identifies as other race	88 (3.82)
White, n (%)	Respondent identifies as White. This is the reference category	1338 (58.05)
Bachelor's degree, n (%)	Dichotomous variable indicating that the respondent has at least a bachelor's degree (reference category is less than a bachelor's degree)	689 (29.89)
Income, mean (SD)	An ordinal variable, ranging from 0 to 11, entered into the model as a continuous predictor because of its underlying interval–ratio nature. The answer 4 (the average) indicates a salary of approximately US $30,000 to US $39,999	4.01 (3.16)
Young, n (%)	Respondent is young: aged 18-34 years	728 (31.58)
Middle-aged, n (%)	Respondent is middle-aged: aged 35-64 years	1223 (53.06)
Older, n (%)	Respondent is older: aged 65 to ≥85. This is the reference category	354 (15.36)

Data Analysis

We used an ordinary least squares (OLS) regression model to analyze how factors such as the experimental condition, medical skepticism, and demographic characteristics contributed to the extent to which individuals were willing to follow the advice offered for a leg cramp medical condition. Our dependent variable was continuous in nature, thus making OLS regression the most appropriate analytical model.

Ethics Approval

This study was approved by the University of Virginia's Institutional Review Board for Social and Behavioral Science (Project Review 2018-0398-00).

Results

Participant Characteristics

Of the 2305 participants in our study, 1352 (58.66%) were women. Our sample was racially diverse, with 58.05% (1338/2305) of the participants identifying as White, 22.17% (511/2305) as Black, 9.11% (210/2305) as Hispanic or Latino, 6.85% (158/2305) as Asian or Pacific Islander, and 3.82% (88/2305) as a different race. Of the 2305 participants, 1223 (53.06%) were aged 35-64 years and 728 (31.58%) were aged 18-34 years, whereas 354 (15.36%) were aged >65 years.

On average, the respondents reported approximately 4.40 (SD 3.47) health care visits in the last 2 years (to accompany a friend or family member or as patients themselves), and 20.69% (477/2305) of the respondents indicated that their primary care occurred in an emergency room or urgent care clinic. Most of our respondents carried some sort of insurance (eg, Medicare, Medicaid, and private insurance), but 14.92% (344/2305) reported having no insurance provider. Our respondents included those who lived in suburban (1046/2035, 45.38%), urban (701/2305, 30.41%), and rural (558/2305, 24.21%) areas. Of the 2305 respondents, 689 (29.89%) had a bachelor's degree or higher, and the average respondent reported an income generally consistent with that of the middle class [56] (Table 1).

Following Web-Based Medical Advice

At the end of each prompt, the respondents were provided with the same treatment advice regarding leg cramps, regardless of the website traits shown in the experimental manipulation. We present OLS regression results (Table 2) that assess how experimental conditions and medical skepticism contribute to the likelihood that respondents will follow this advice. In model 1 (Table 2), we focus on the direct relationships between our independent variables of interest and the likelihood that respondents follow web-based medical advice. Our findings suggest that website traits do affect whether individuals are likely to follow medical advice. When presented with an example written by a physician, the respondents were significantly more likely to follow advice (P<.001). Similarly, an objective writing style, as opposed to a tone reflecting personal experience, was positively associated with following web-based medical advice (P=.006).

[a]Not included in base model.

[b]N/A: not applicable.

As medical skepticism increased, individuals were more likely to follow web-based medical advice (*P*<.001). This may be because these individuals are more receptive to self-service sources of information as a substitute for the advice of health care providers, whom they distrust. Individuals who reported more frequent health care visits in the last 2 years were also positively associated with following web-based medical advice (*P*<.001). When individuals used the emergency room or urgent care as their primary source of health care, they were more likely to follow the presented advice (*P*=.04). The sex, race, and income of our respondents were not significantly related to whether they followed web-based medical advice, but education and age were significant predictors. Compared with those without higher education, individuals who had attained at least a bachelor’s degree were significantly less likely to follow web-based medical advice (*P*<.001). In general, younger individuals were less likely to follow web-based medical advice (*P*<.001 for young adults and *P*=.03 for middle-aged adults), which is consistent with previous research that found that younger patients were less likely to believe that providers listened to them [57] and less likely to seek medical care [58].

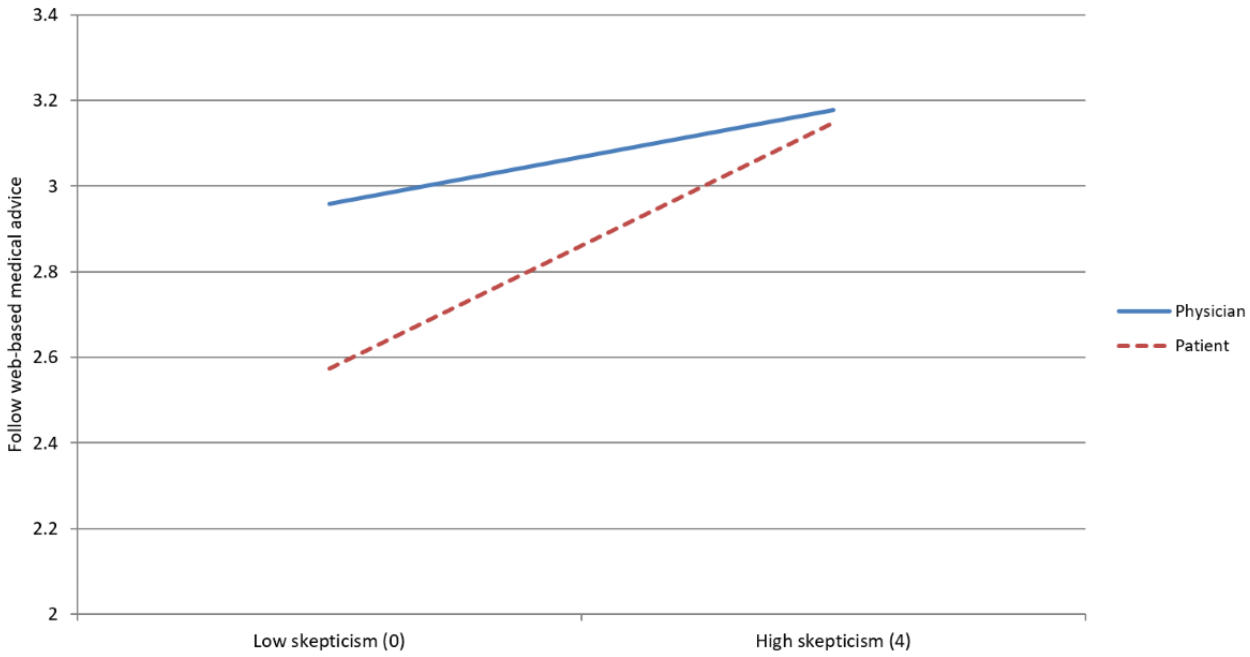
Interaction Between Medical Skepticism and Website Trait Influence

In model 2 (Table 2), we additionally examine moderation effects that capture the complex relationship between experimental conditions and medical skepticism. Model 1 demonstrates that individuals reporting higher levels of skepticism were more likely to follow web-based medical advice, regardless of the experimental condition. However, the significant coefficients for our 3 interaction terms indicate that the association between experimental condition and following web-based medical advice does vary by the degree of medical skepticism.

Physician Authorship × Medical Skepticism

Model 1 shows that physician advice (as opposed to patient advice) was more likely to be followed. However, as model 2 and Figure 3 show, this effect was moderated by medical skepticism such that the physician advantage was much smaller among respondents with higher skepticism compared with those with lower skepticism (*P*=.04). Follow-up regression models indicated that the physician authorship advantage was nonsignificant among respondents in the highest tertile of skepticism, but it was relatively large and statistically significant among those in the lowest tertile of skepticism (b=0.202; *P*=.05). Despite this erosion of physician authorship advantage among more skeptical users, individuals across all skepticism levels favored physician-authored web-based material—in no case were respondents more likely to follow web-based medical advice in the experiment after reading a webpage with a patient author.

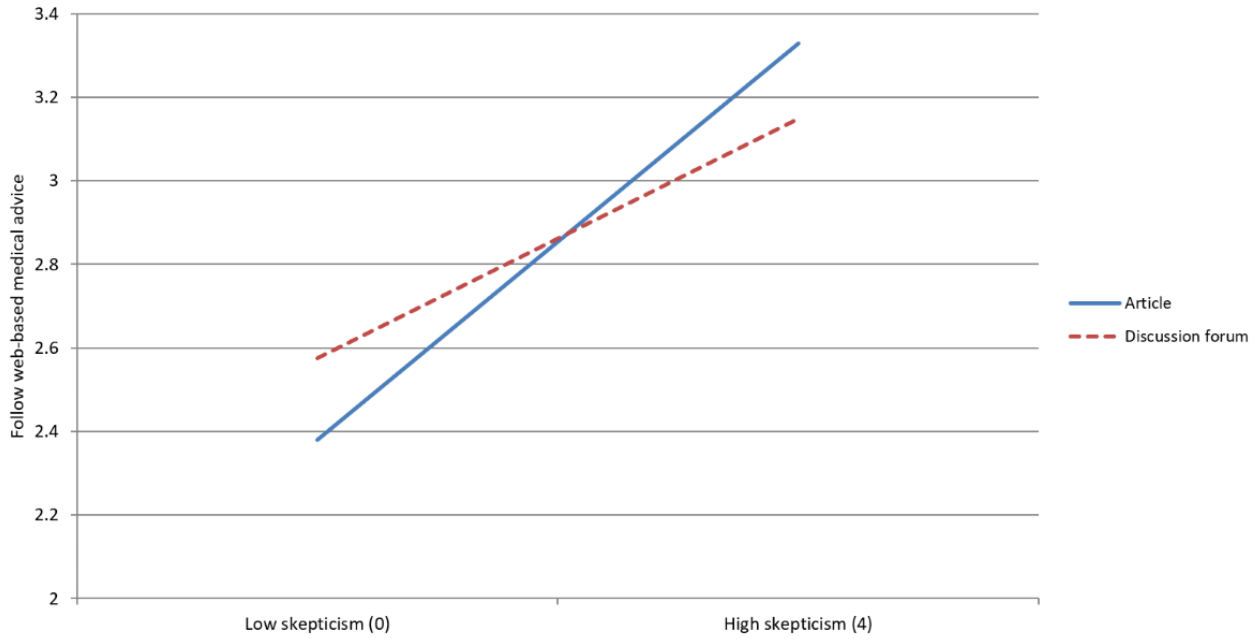
Figure 3. Interaction between medical skepticism and authorship.



Webpage Format × Medical Skepticism

In model 1, the format of the webpage (article vs discussion forum) was not significantly related to whether individuals followed web-based medical advice. However, model 2 and Figure 4 demonstrate that the effect of a webpage format was moderated by medical skepticism (*P*=.03). Those with lower levels of skepticism were more likely to follow web-based medical advice when presented with a discussion forum format. Follow-up regression models indicated a statistically significant discussion forum (vs article) advantage for respondents in the lowest tertile of medical skepticism (b=–0.270; *P*=.008), whereas those in the highest tertile of skepticism significantly preferred an article format (b=0.270; *P*=.008). This suggests that individuals with high levels of medical skepticism are swayed by an article format, but those with low levels of medical skepticism show a preference for a discussion forum format.

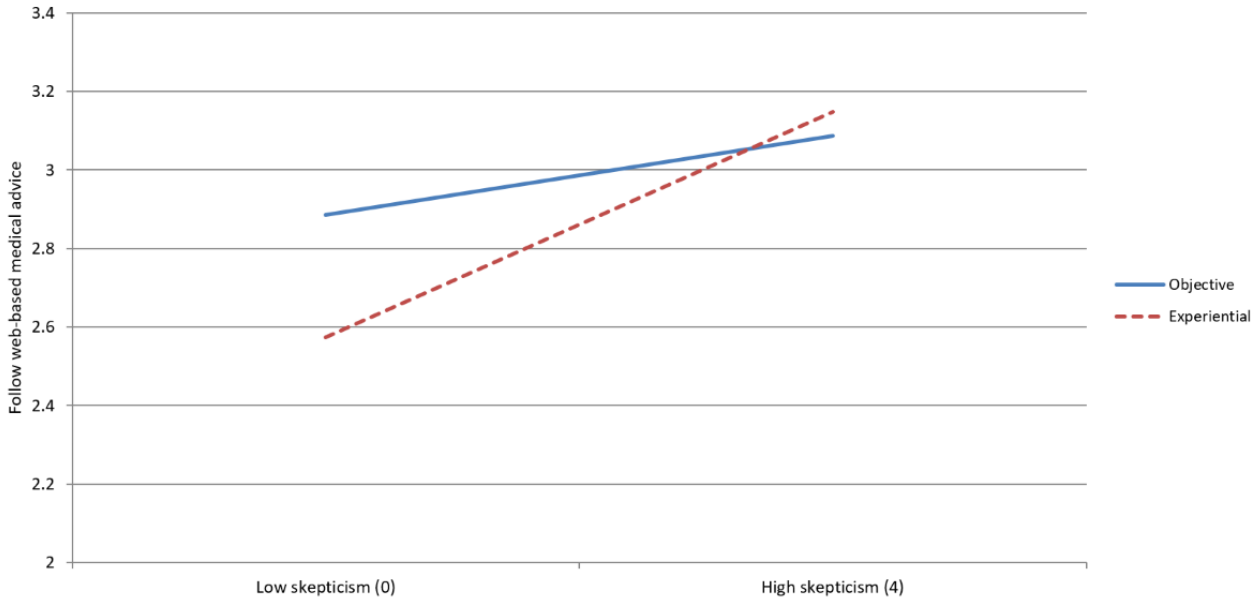
Figure 4. Interaction between medical skepticism and format.



Content Tone × Medical Skepticism

Our final interaction term illustrates how individuals with the highest level of medical skepticism have diminished content tone preferences. Model 2 and Figure 5 show how the effect of the content tone was moderated by medical skepticism (*P*=.03). Follow-up regression models demonstrate that the objective tone advantage was statistically significant among respondents in the lowest tertile of skepticism (b=0.240; *P*=.02). On average, people are more likely to follow objectively written advice, but that advantage disappears among those with higher skepticism.

Figure 5. Interaction between medical skepticism and writing style.



Discussion

Principal Findings

Our results demonstrate that, within our experimental condition of leg cramp advice, website presentation traits of medical information on the web do matter. Generally, patients are more receptive to medical information authored by a physician and presented in an objective tone, with this advantage diminishing among those with higher skepticism. The website format trait (article format vs discussion forum format) is more complex. Although our findings in model 1 suggest this trait is not a significant influencer when considering all participants on average, Figure 4 helps explain that this is due to different preferences depending on the level of medical skepticism, with low-skepticism participants preferring the discussion forum format and high-skepticism participants preferring the article format. This distinction implies that different website formats may be better suited for audiences of different levels of medical skepticism.

Medical skepticism has been previously identified as an important trait to consider when trying to understand patient behavior [5,6,8,9,59]. Learning about medical conditions and taking a more active role in health decisions may manifest in higher medical self-efficacy and simultaneously make patients more skeptical about physician advice [59]. For example, high levels of medical skepticism were associated with the use of complementary and alternative medical treatments in patients with arthritis [5]. We extend our understanding of medical skepticism and show evidence that it is also important in how people consume web-based medical information. We find that people consume and judge web-based medical advice credibility differently, depending on their level of medical skepticism. Patients with a greater degree of medical skepticism are more likely to follow web-based medical advice, regardless of the website traits. This insight makes sense because they are likely more familiar with getting medical advice or ideas from web-based sources because they conduct their own research instead of seeking out and listening to medical professionals in person. This underscores the ever-deepening power of web-based medical advice on patient behaviors, often at the expense of seeking in-person medical diagnoses.

Furthermore, the preferences of physician authorship over patient authorship and an objective writing tone over an experiential writing tone diminish as medical skepticism increases. This implies that medical skeptics may be more open to a wider variety of web-based medical advice. They are receptive to patient and physician accounts as well as experiential recounts, in addition to objective information. However, patients with a greater degree of medical skepticism find the article format more credible than the discussion forum format, which is opposite of the preferences of those with lower degrees of medical skepticism. This is an interesting finding, and may be due to a sense of legitimacy conveyed in an article format to a population more interested in researching and making their own medical decisions.

This research suggests that medical organizations should consider website traits when designing solutions to communicate medical advice. Physician-authored information written in objective tones in a discussion forum format seems to be a potentially effective combination for individuals with low medical skepticism. We do not formally survey web-based information sources to determine the relative frequency of presentation formats, but this combination seems to be rare, presenting a potentially significant opportunity. Our findings may also be useful to health care professionals because they interact with patients who are likely bringing their own ideas and information gathered from web sources into consultations. Those with higher levels of medical skepticism tend to be less discriminating about website traits, although they find web-based articles more persuasive.

Limitations and Future Research Directions

The hypothetical situation of a leg cramp scenario might have influenced participants in certain ways that limit the broader generalizability of our insights. The strength of an experiment is the ability to control factors in the participant's situation, but the experimental scenario may not accurately predict how real-world scenarios unfold [60]. Care was taken to select a medical scenario that (1) was plausible to research independently (ie, not so severe as to need immediate medical attention) and (2) could involve medical treatment advice that was not trivial but did not necessitate physician oversight. We also screened out participants who had previous experience with leg cramps in an attempt to recruit unbiased participants without existing opinions about leg cramp treatments.

Patients read internet content on a variety of devices, including desktop computers, laptops, tablets, and smartphones [61]. Our data reflect this variety, with 54.49% (1259/2305) of the participants accessing the study from mobile devices. Therefore, we believe that our findings are generalizable to a variety of consumer devices used by patients. However, future work would benefit from studying user device preferences more directly to see whether they alter patient acceptance of web-based medical advice.

Our website format distinction was between an article format (static website that the owner controls) and a discussion forum format (dynamic cocreation among multiple users). It is worth noting that there is a plethora of discussion forum styles and blogs, with their own different sets of features and uses. Our design incorporated a simple discussion forum layout, but future research could extend this research question to determine which set of traits and functions in a discussion forum layout distinctly affect patients' willingness to follow web-based medical advice.

Our study focused on nonchronic ailments for which patients may seek web-based medical advice. Patients who have chronic ailments may exhibit different behaviors regarding their assessment and adherence to web-based medical advice. For example, previous work has examined the importance of web-based communities for patients with chronic diseases [62-64]. Another extension of this research would be to consider a broader decision-making process of the patient. Our experimental design focused only on the participant's initial assessment of a single isolated webpage. In reality, patients may look at multiple webpages to form opinions.

Conclusions

Although already prevalent, the number of patients conducting their own web-based medical research increases every year [13,15]; yet, not enough is known about what makes a medical website persuasive to the average patient. Our research identifies three website traits (authorship, format, and tone) relevant to patient credibility assessments and provides evidence about how these traits influence patients. Furthermore, we extend the conversation about medical skepticism and show how patients with high levels of medical skepticism may interpret website traits to assess medical advice credibility differently.

Abstract

Background: SIMPLe is an internet - delivered self - management mobile app for bipolar disorder (BD) designed to combine technology with evidence-based interventions and facilitate access to psychoeducational content. The SIMPLe app was launched to the real world to make it available worldwide within the context of BD treatment.

Objective: The main aims of this study are as follows: to describe app use, engagement, and retention rates based on server data; to identify patterns of user retention over the first 6-month follow-up of use; and to explore potential factors contributing to discontinuation of app use.

Methods: This was an observational ecological study in which we pooled available data from a real-world implementation of the SIMPLe app. Participation was open on the project website, and the data-collection sources were a web-based questionnaire on clinical data and treatment history administered at inclusion and at 6 months, subjective data gathered through continuous app use, and the use patterns captured by the app server. Characteristics and engagement of regular users, occasional users, and no users were compared using 2-tailed *t* tests or analysis of variance or their nonparametric equivalent. Survival analysis and risk functions were applied to regular users' data to examine and compare use and user retention. In addition, a user evaluation analysis was performed based on satisfaction, perceived usefulness, and reasons to discontinue app use.

Results: We included 503 participants with data collected between 2016 and 2018, of whom 77.5% (n=390) used the app. Among the app users, 44.4% (173/390) completed the follow-up assessment, and data from these participants were used in our analyses. Engagement declined gradually over the first 6 months of use. The probability of retention of the regular users after 1 month of app use was 67.4% (263/390; 95% CI 62.7%-72.4%). Age (*P*=.002), time passed since illness onset (*P*<.001), and years since diagnosis of BD (*P*=.048) correlate with retention duration. In addition, participants who had been diagnosed with BD for longer used the app on more days (mean 97.73, SD 69.15 days; *P*=.002) than those who had had a more recent onset (mean 66.49, SD 66.18 days; *P*=.002) or those who had been diagnosed more recently (mean 73.45, SD 66 days; *P*=.01).

Conclusions: The user retention rate of the app decreased rapidly after each month until reaching only one-third of the users at 6 months. There exists a strong association between age and app engagement of individuals with BD. Other variables such as years lived with BD, diagnosis of an anxiety disorder, and taking antipsychotics seem relevant as well. Understanding these associations can help in the definition of the most suitable user profiles for predicting trends of engagement, optimization of app prescription, and management.

bipolar disorder; psychoeducation; smartphone; app; SIMPLe; Intervention; mobile phone

Introduction

Background

Globally, an estimated 46 million people have been diagnosed with bipolar disorder (BD) [1]. Besides behavioral changes occurring during mood episodes, BD has a serious impact on psychosocial functioning, cognition, quality of life, and survival rate of individuals with this condition [2,3]. Although ranges vary dramatically because of methodological differences among studies, there is agreement that people with BD are between 9 and 30 times more likely to die from suicide than someone without this condition [4,5].

Although the fundamental treatment for BD relies basically on psychopharmacology, some adjuvant psychological interventions have been shown to improve the long-term outcomes of this disease [6]. Among psychological interventions, psychoeducation programs have proven to be a cost-effective approach to prevent episodes by helping patients to improve adherence, embrace healthy habits, and learn to recognize the prodromes and symptoms of upcoming episodes. It is obvious that efficacious treatments only work for patients who can receive them [7]; yet, these psychological interventions are scarce and difficult to access for most patients [8].

e-Mental health—the delivery of mental health–related tools through the internet and related technologies [9]—is one of the most promising strategies to address this access gap, relieving overburdened mental health services and increasing the services' cost-efficiency while maintaining its quality. Although internet-based interventions for mental health are still relatively new, the number of solutions such as web-based platforms, smartphone apps, and wearables is rapidly growing globally [10], with their actual acceptability by patients tending to be increasingly higher [11].

However, the strong desire to proliferate e-mental health solutions has not been translated into a transformation in the delivery of mental health care because there is little available evidence of uptake of mental health apps [12]. Moreover, despite the increasing number of e-mental health apps available in app stores, few are properly validated in a scientific process; this lack of validation could jeopardize the safety and health of potential users [13,14]. In addition, the quality of the content of the apps for BD in the app stores does not live up to expectations because most of them do not rely on the available best practice clinical guidelines [15]. Thus, it remains a challenge to implement platforms developed within evidence-based–practice frames that, simultaneously, have been subjected to efficacy tests [16,17].

Within this framework, the SIMPLe project was designed to leverage the potential of combining technology with evidence-based interventions by developing and evaluating an internet - delivered self - management mobile app (SIMPLe 1.5) for BD in addition to standard treatment. The SIMPLe 1.5 app collects information about potential symptoms, with the advantage of providing users with personalized psychoeducational messages and alerts that are tailored to specific needs. The app is based on group psychoeducation, a well-established and evidence-based care-focused psychological intervention that addresses relevant issues of self-management for BD, such as identification and management of early warning signs, lifestyle, and treatment adherence [18,19].

Up until now, the SIMPLe app has proved acceptable to users and has shown interesting and optimistic results: a high retention rate was attained in a 3-month feasibility study and positive outcomes regarding satisfaction were found in a naturalistic implementation feasibility study [20-22]. In addition, some potential improvements in terms of biological rhythms and medication adherence were suggested by post hoc analyses [23]. It is worth mentioning that pharmacological treatment adherence is a particularly complex issue in BD because more than 50% of the patients are estimated to be nonadherent fully to the prescribed doses of medication [24].

Considering that the ultimate aim of the SIMPLe project is to extend and facilitate access to psychoeducational content through the SIMPLe app to all potential users, wide and free access to the SIMPLe 1.5 app around the Spanish-speaking world was offered. This way, we had the opportunity to routinely collect implementation data on use in a real-world setting and naturalistic condition.

A previous report on the OpenSIMPLe study presented partial data demonstrating the high dropout rates when a psychoeducation smartphone-based intervention for individuals with BD is offered openly [22]. We hereby present the results of the whole sample of SIMPLe users throughout the study. This research differs from our previous partial sample in terms of both sample size and follow-up time frame. Statistical analyses of the previous partial sample only included descriptive, pre–post, and logistic regression tests without considering the temporal retention period as we did in this paper.

In this paper, we focus on exploratory analyses that aim to investigate in depth the relationships among variables that may predict overall engagement as well as retention rates mainly by

means of survival analyses. More specifically, we intend to shed some light on the ways in which the SIMPLe app engagement and user retention patterns are influenced by individual variables, including sociodemographic and clinical data.

This study is based on an ecological experimental implementation of an e-mental health resource. Thus, the reader may miss the usual randomized controlled studies' constraints such as the lack of sample size calculation (which, by definition, would be *the bigger the better*) or some control measures. However, this study reflects the real day-to-day problems faced by a mental health app when launched to the app stores to be used by the target population.

Objectives

The main aims of this study are to (1) describe app use, engagement, and retention rates based on server data; (2) identify patterns of user retention over the first 6-month follow-up of use; and (3) explore potential factors contributing to the risk of discontinuing app use.

The expectations are that these exploratory analyses will help to confirm preliminary use data of the SIMPLe app and understand user retention rates as well as the ways in which users self-manage BD in a real-world setting. In addition, we hope that the results will provide our research colleagues with relevant insights into the interplay, dynamics, and predictive factors of user engagement with mental health apps at the time of their implementation in real-world conditions.

Methods

Procedure and Participants

Participation availability was open on the project website [25] to anyone with BD who was fluent in Spanish. Specific app characteristics and functionality offered for the SIMPLe app have been published elsewhere [20,21]. In brief, the app consisted of a daily graphic 5-item screening test (mood, energy, sleep time, medication adherence, and irritability) and a weekly, more comprehensive Yes or No test, considering all Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, criteria for manic and depressive episodes. The resulting mood assessments were displayed in a chart on the home screen. On the basis of the information collected, a daily pop-up notification prompted the user to read a short psychoeducational message providing brief information or advice about how to deal with specific situations to avoid relapses. Each message was extracted from a library of more than 500 messages categorized according to different clinical situations based on a published psychoeducation manual and lay-language books on BD written by 2 of the authors (FC and EV). Additional optional modules available in the app were personalized medication reminders, prodromal symptoms, and mood-chart sharing.

Following a real-world naturalistic approach, no active recruitment strategy or advertisement was used. Potential participants approached the study voluntarily through the website [25] (more detailed information can be found elsewhere [22]). Potential participants needed to meet the following inclusion criteria: (1) aged ≥18 years; (2) having a psychiatrist-confirmed diagnosis of BD before entry; (3) pharmacological treatment for BD provided by a psychiatrist; (4) owning and using daily an Android or iOS smartphone; (5) fluency in Spanish; (6) an active email account; and (7) standard cutoff score of 7, co-occurrence of at least two symptoms, and moderate or severe impairment on a modified version of the Mood Disorder Questionnaire (MDQ) [26,27]. The participants' answers were reviewed by a psychiatrist to assess consistency, after which they were informed whether they were eligible for the study.

To prevent duplicate use and potential misuse, the possibility of completing the questionnaire multiple times from the same IP address was blocked. Web-based technical support was provided to the app users, if needed, through email.

Data from the sample were drawn from 503 SIMPLe users who had provided informed consent and completed the app's onboarding questionnaire between May 2016 and June 2018. Of the 503 participants, 390 (77.5%) used the app, and data from these participants were used in the analyses.

All procedures contributing to this work complied with the ethical standards of national and international guidelines and the basic principles of protection of dignity and human rights, as stated in the Declaration of Helsinki (64th General Assembly, Fortaleza, Brazil, October 2013), and were conducted according to current regulations. The ethical committees from both Hospital Clínic of Barcelona (HCB/2016/0403) and the Hospital del Mar Medical Research Institute (2016/6764/I) approved the protocol.

Assessments

In all, two sources of data were used: (1) a web-based form administered at program inclusion and at 6 months and (2) subjective data gathered through continuous app use and the use patterns captured by the app server.

Psychometric External Assessments

Sociodemographic data as well as illness and treatment history were collected at program inclusion through a web-based form from participants who had provided informed consent. The number of hospitalizations and suicide attempts as well as treatment history during the past 6 months were also collected 6 months after inclusion.

The Spanish validated version of the 5-item World Health Organization Well-being Index [28] was used to assess mental well-being at baseline and 6 months later at the final follow-up.

App-Derived Assessments

Subjective Information

The subjective information assessed was as follows:

1. Self-reported mood, sleep, medication adherence, and energy: The app prompts users to answer 5 daily slider screening tests on mood, energy, sleep time, irritability, and drug-treatment adherence. The daily scores appearing in the chart are the results of an algorithm, which was previously tested during the development phase [20]. In addition, a more comprehensive test, considering Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition,

criteria for manic and depressive episodes, including suicide thoughts, was prompted weekly.

2. Self-reported usability: The app was evaluated by users who made it through to complete follow-up assessment. The users' perception of the usability of the app was measured through the System Usability Scale (SUS) [29], a 10-item questionnaire with 5 response options (from strongly agree to strongly disagree) that allows evaluation of products and services. Interpretation of the raw scores was achieved by converting them into percentile ranks [30] and associating them with adjectives [31].
3. Satisfaction and perceived helpfulness: Satisfaction and perceived helpfulness of each subcomponent of the app were assessed in the follow-up questionnaire through Likert scales after 6 months of program initiation. Suggestions and comments regarding the app were also registered.

Mobile Terminal–Mined Information

User retention, app use, and engagement data were constantly recorded at the servers over the study duration, reflecting continuously and in detail app use and engagement. User retention was defined as the proportion of participants who used the app for the entire duration of the study and completed the 6-month follow-up assessment. The SIMPLe app has multiple components, three of which we consider the core active ingredients: the daily and weekly tests and the psychoeducational messages. To determine retention, we considered the user to be active if we registered data in the servers from these 3 interactions, and we considered the user to have discontinued participation if there was a lack of data from these variables in the server for >1 month.

Engagement with mobile apps is considered a multidimensional construct, and different definitions can be used or combined to measure it. In this study, engagement was understood as the ability of an app to engage users and sustain user interactions and it was assessed through indicators such as usability, acceptability, and feasibility [32]. In this case, engagement was calculated based on the weekly percentage of completed tasks (ie, answering daily and weekly tests and reading the daily psychoeducational messages).

Design

This is an observational ecological study in which we pooled available data from a real-world implementation of the SIMPLe app.

The rationale for the OpenSIMPLe study and detailed methods have been published elsewhere [22]; the methods are briefly outlined here.

Statistical Analysis

Smartphone app data (ie, participants' mood ratings, manic or hypomanic and depressive symptoms, and details of their use of the app) were downloaded directly from the servers. Likewise, the users' baseline and follow-up responses at both baseline and follow-up web-based questionnaires were retrieved from the servers. All analyses were run using SPSS software (version 26.0; IBM Corp) and R statistical package for Windows (version 4.0.2; The R Foundation for Statistical Computing).

Initially, basic descriptive statistics of sociodemographic and clinical variables were run, including age, sex, marital status, family psychiatric history, follow-up time, number of episodes, substance abuse, and comorbid medical and psychiatric diagnoses. Continuous variables have been described based on the mean and SD; the median and the 25th and 75th percentiles have also been used in comparative analyses of the time spent using the SIMPLe 1.5 app. We defined categorical variables in terms of the number and percentage of users per response category. In addition, statistical techniques were used to confirm assumptions of the statistical tests before carrying out parametric tests to compare means and proportions. When the assumptions of parametric tests were violated, nonparametric tests were used.

We performed a comparative analysis of the variables among groups using a 2-tailed *t* test or analysis of variance on continuous variables or their nonparametric equivalent; the Wilcoxon test or the Kruskal–Wallis test was performed depending on the inherent characteristics of the variables analyzed; the Mann–Whitney U test was carried out when dependent variables were ordinal; and the chi-square test was performed when analyzing categorical variables.

The Spearman correlation coefficient (ρ) was used to examine correlations between SIMPLe 1.5 app time use and the different continuous variables.

A subsample of users with *engagement* ≥12% was selected for the analysis of the use time of the SIMPLe 1.5 app to determine a minimum frequency of use and avoid overestimating the use time. A homogeneity analysis was performed between the selected subsample and the rest of the participants using the chi-square test for categorical variables and the Kolmogorov–Smirnov Z test for continuous variables.

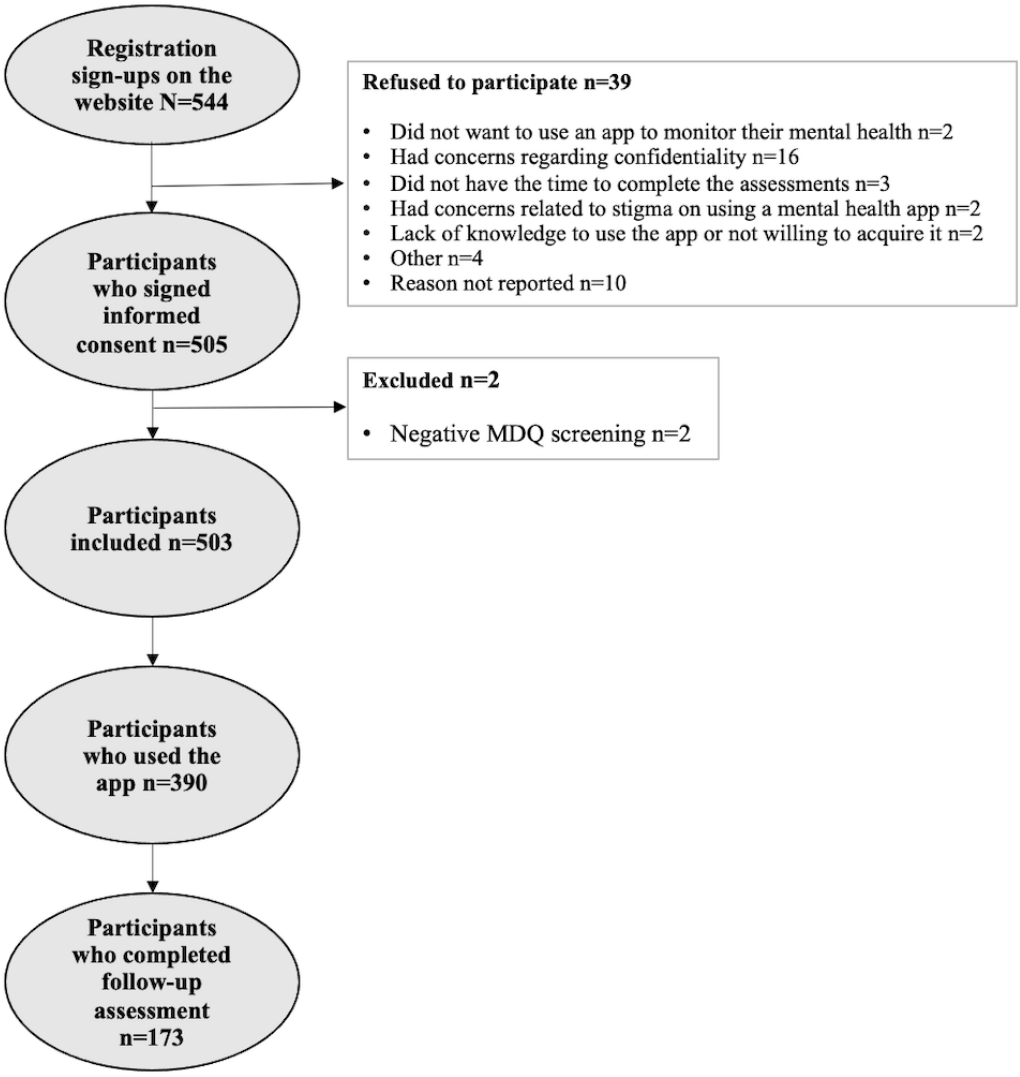
Survival analysis was used on the selected subsample to examine the time spent using the SIMPLe 1.5 app because the length of the follow-up period was variable and there were participants who did not experience the event *quit using the app* during the 6-month follow-up. Estimates of survival and risk functions of the time use of the app were calculated by applying the Kaplan–Meier method. We used the log-rank test to compare various survival distributions and the Cox proportional-hazards model validated by Schoenfeld residual analysis to assess risks related to the survival of the app users. A sensitivity analysis was performed by repeating the survival analysis with all users to evaluate the effect of the selection of the subsample in the study of the use time. Results were considered significant with 2-sided *P* values <.05.

Results

Descriptive Analysis

Figure 1 depicts the number of participants registered on the OpenSIMPLe website who were initially interested in using the app alongside those included in the statistical analysis. The reasons reported by users who did not want to participate in the study are also listed. Finally, potential participants who were excluded are described, as well as the number of participants who actually used the app and those who responded to the 6-month follow-up assessment.

Figure 1. Flowchart of participants included in the statistical analysis. MDQ: Mood Disorder Questionnaire.



Sociodemographic and Clinical Characteristics

The mean age of users was 34.74 (SD 10.48) years, and most (264/390, 67.7%) of them were women. The most frequent ethnicity was Latin American (266/390, 68.2%), with high education levels (241/390, 61.8%). A high percentage of the sample was employed at the time of study entry (156/390, 40%), whereas only 17.7% (69/390) were either on temporary or permanent disability leave. Regarding housing conditions, 33.8% (132/390) of the participants lived in the parental household and more than half of the sample reported living independently, either owning (117/390, 30%) or renting their current house or flat (90/390, 23.1%). Sociodemographic variables of the SIMPLe app users are described in Table 1.

Regarding the clinical variables, a mean disorder duration of 13.23 (SD 9.97) years was identified; 49.7% (194/390) of the users stated that they had experienced ≥10 depressive episodes; and 33.3% (130/390) reported ≥10 manic or hypomanic episodes. Most of the participants who used the app were receiving treatment with at least one mood stabilizer (353/390, 90.5%) and at least one antipsychotic (252/390, 64.6%), whereas almost half (193/390, 49.5%) of the participants were receiving at least one antidepressant. Furthermore, 71.5% (279/390) of the participants were receiving some kind of psychological treatment. The clinical variables collected at baseline are described in Table 2.

Engagement

The 503 participants included in the study can be divided into three broad categories based on their app use: no users (never used the app), occasional users (engagement <12%), and regular users (engagement ≥12%). Of the 503 participants, 113 (22.5%) were no users, 357 (70.9%) were regular users, and 33 (6.6%) were occasional users. In addition, among the participants who used the app, 44.4% (173/390) completed the follow-up assessment too.

We analyzed the number of days containing any kind of record in the app from users over the 6-month follow-up period. Monthly progress of regular users' engagement declined gradually over the first 6 months. The highest engagement was observed in the first month (mean 0.74, SD 0.20); in the second month, it dropped sharply. At 6 months, the users had a mean engagement of 0.39 (SD 0.34).

Occasional users used the app a mean of 139.06 (SD 56.80) days, with a use frequency of 2.05 (SD 0.87) days per month, whereas regular users used the app 83.98 (SD 69.95) days, with a use frequency of 19.42 (SD 7.76) days per month. The group of occasional users rarely used the app over long periods of time, which could overestimate use time rates, for example, a participant who used the app at the 3-month follow-up for the last time but only used the app 4 times overall. The estimate that this participant used the app for 3 months may lead us to a use bias. As the SIMPLe app was developed for daily use, we could consider that the interaction of this kind of user with the app is low enough to overestimate the time of use in the statistical analysis. To avoid this bias, we used the variable overall engagement—the percentage of tasks completed compared with those expected to be completed during the time in which they used the app—to identify users who may make us enhance the time-of-use overestimation. Occasional users were ruled out in the survival analysis.

Sensitivity and homogeneity analyses show homogeneous baseline variables across subsets of participants defined by retention duration, with the exception of the *cocaine use* variable, which was significantly greater among the group of no users than among the occasional and regular users. In addition, we performed survival analysis again with all users to assess the effect of the selection of regular users in the estimations of retention duration. The results showed a 7-day increase in the median survival time when we included occasional users in the analysis, whereas the probability of survival only increased by a score of 0.027 (SD 0.007) on average. Therefore, we are confident that selection bias did not occur and that the subsets were representative of the data of the sample.

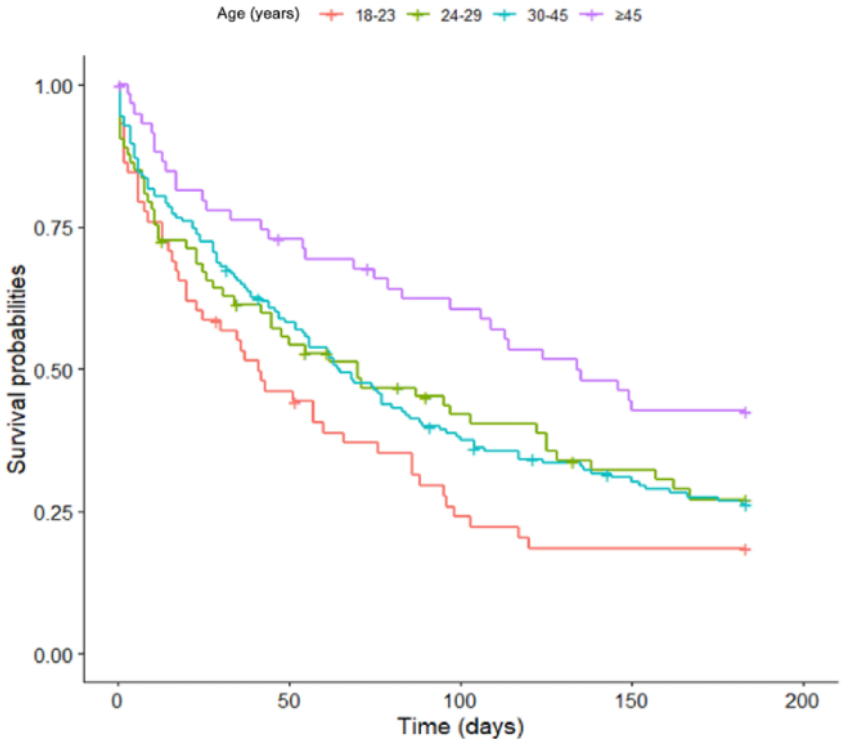
Use and Retention Duration

We analyzed the number of days with records in the app from users over the 6-month follow-up period. It turned out that only 13.8% (54/390) of the users used the SIMPLe app for >100 days. The mean survival time of regular app users was 87.95 (SD 72.08; 95% CI 80.48-95.43) days.

The probability of survival for the 357 participants under consideration for these analyses after 1 month of app use was 67.4% (95% CI 62.7%-72.4%); at 3 months, the probability of survival was 43% (95% CI 38.1%-48.5%); and at the 6-month follow-up assessment, the probability of survival was 28% (95% CI 23.6%-33.2%). The risk of discontinuing app use increased as the days passed: at 3 months, the cumulative risk of discontinuing app use was 83.7%; however, at 6 months, this rose to a cumulative risk of 126.3%.

The correlations between retention duration and the sociodemographic and clinical variables of users at baseline were analyzed. A direct correlation between age and engagement was observed (ρ=0.168; *P*=.002); older users (aged ≥46 years) had higher total app use (mean 109.78, SD 71.42; *P*=.005) than younger users (aged 18-23 years; mean 63.12, SD 63.94; *P*=.005; Figure 2).

Figure 2. Plot of Kaplan–Meier age estimates of survival of participants using the SIMPLe app. The horizontal axis represents the survival time (in days) with records in the app (6 months maximum).



Time passed since illness onset was strongly associated with time of use (ρ=0.194; *P*<.001) and years since diagnosis of BD (ρ=0.106; *P*=.048). In addition, participants who had been diagnosed with BD for longer (>17 years) used the app for more days (mean 97.73, SD 69.15; *P*=.002) than those who had had a more recent onset (mean 66.49, SD 66.18; *P*=.002) or those who had been diagnosed <6.5 years ago (mean 73.45, SD 66; *P*=.01).

We performed log-rank (Mantel–Cox) test analysis to compare survival curves and detect potential factors contributing to the risk of discontinuing app use (Table 3). Variables with a significant contribution were years since onset (χ^2_2=11.7; *P*=.003), years with BD diagnosis (χ^2_1=8.9; *P*=.003), opiate use (χ^2_1=7.9; *P*=.005), age (χ^2_3=12.3; *P*=.006), housing status (χ^2_4=12.3; *P*=.006), employment status (χ^2_5=13.5; *P*=.02), and antipsychotic use (χ^2_1=4.9; *P*=.03).

Survival-curve plots for the variables of interest were produced over the 6-month-long follow-up period and are described in the following paragraphs (Table 4).

Table 3. Log-rank test for overall survival[a].

Employment status		
Unemployed	72.87 (7.74; 57.69-88.05)	55.00 (12.96; 29.58-80.41)
Student	75.02 (7.85; 59.62-90.42)	57.00 (14.14; 29.28-84.71)
Employed	97.40 (6.09; 85.45-109.36)	80.00 (12.27; 55.9-104.06)
Retired	109.40 (24.72; 60.93-157.86)	84.00[b]
Temporary disability leave	101.96 (13.21; 76.06-127.86)	104.00 (61.23; 0.00-224.01)
Permanent disability leave	85.14 (14.47; 56.77-113.52)	69.00 (24.71; 20.55-117.44)
Diagnostic time (years)		
0-6.5	81.14 (4.79; 71.74-90.54)	61.00 (7.45; 46.38-75.61)
>6.5	98.15 (6.36; 85.67-110.63)	94.00 (15.98; 62.67-125.32)
Anxiety disorder		
No	95.07 (4.91; 85.43-104.71)	83.00 (9.17; 65.01-100.98)
Yes	78.19 (5.93; 66.56-89.83)	46.00 (7.96; 30.39-61.61)

[a]Users with engagement ≥12%.

[b]SE and 95% CI are not available.

The app use survivorship of the oldest participants (aged ≥46 years) seems greater than that of the youngest group of users (aged 18-23 years) because the estimated mean was 114.83 (95% CI 96.85-132.80) days for users in the former age range, whereas the use mean was 65.72 (95% CI 48.85-82.58) days for users in the latter group. At 60 days, the probability of survival of the youngest users was 38.9% (95% CI 28%-53.9%); this likelihood increased to 69.4% for the oldest group of participants, with a cumulative risk of 0.923 and 0.36, respectively.

Regarding housing status, we observed that the mean estimation of app use survival of people sharing a house or flat was 62.65 (95% CI 43.21-82.08) days, that is, between 15 and 37 days fewer than users with other housing statuses, suggesting a survival disadvantage. At 60 days, the cumulative incidence risk estimates among users who shared a house were 0.880, whereas they were 0.435 for individuals who lived in residences, 0.488 for tenants, 0.509 for homeowners, and 0.734 for those who lived in the parental home.

Being unemployed seemed to worsen app use survivorship pretty much at all time points because the survival likelihood mean estimation of unemployed participants was 72.87 (95% CI 57.69-88.05) days, that is, lower than any other employment status. At 60 days, the highest survival cumulative risk was that of unemployed participants (0.737), followed by students (0.734), individuals on permanent (0.596) and temporary disability leave (0.573), employers (0.523), and retired people (0.336).

In addition, app use declined faster among participants who had been recently diagnosed (<6.5 years) compared with users who had been diagnosed for a longer period of time; at 60 days, the cumulative risk of app use discontinuation among people who had a recent diagnosis was 0.681, whereas this risk was lower for those who had been diagnosed earlier (0.518). The mean app use estimation of individuals with a more recent diagnosis of BD was 8.14 (95% CI 71.74-90.54) days, whereas it increased to 98.15 (95% CI 85.67-110.63) days for people with an earlier diagnosis.

The survival time of patients with comorbid anxiety disorder diverged from those who did not have symptoms of it over time, with a cumulative risk of use discontinuation of 0.789 and 0.500 at 60 days, respectively. Relatively few patients continued to use the app after the very first month overall, but among those who were still using it, participants with anxiety disorder continued to show a survival disadvantage over those who did not experience it. The mean estimation of app use of the latter group was 95.07 (95% CI 85.43-104.71) days, whereas that of participants with an anxiety disorder was 78.19 (95% CI 66.56-89.83) days; therefore, having an anxiety disorder significantly influenced app use. Nevertheless, anxiety disorder was self-reported based on what users consider anxiety; hence, we tried to see if there was homogeneity between self-reports and treatment prescriptions at study initiation. Analysis showed that there is a statistically significant relationship between anxiolytics use and self-reported anxiety disorder (P<.001), and 59.6% (99/166) of the users who reported having an anxiety disorder did use them, whereas anxiolytics use decreased to 37.5% (84/224) among the participants who did not report an anxiety disorder. As antidepressant drugs can also be used to treat a number of other conditions, including anxiety disorders, we also analyzed association of self-reported anxiety disorder with anxiolytics, along with the most widely prescribed antidepressants for anxiety. It turned out that 74.7% (124/166) of the users who reported having an anxiety disorder did use these medications, despite the guideline recommendations to avoid antidepressants in BD.

Furthermore, we performed a Cox (proportional hazards) regression analysis to estimate the hazard of discontinuing app use for regular users, given their prognostic variables. The results of the Cox model analysis are presented in Table 5.

Table 5. Cox regression model analysis of user survival using the SIMPLe app 1.5[a].

Characteristics	Coefficient	Exp (coefficient; 95% CI)	*P* value	Concordance, mean (SE)
Age	–0.016	0.984 (0.971-0.998)	.02	0.589 (–0.019)
Country				N/A[b]
Spain	—[c]	—	—	
Chile	–0.143	0.867 (0.588-1.278)	.47	
Argentina	0.091	1.096 (0.748-1.605)	.63	
Mexico	–0.121	0.886 (0.495-1.585)	.68	
Colombia	0.318	1.375 (0.797-2.37)	.25	
Other	0.141	1.152 (0.779-1.703)	.47	
Anxiety disorder	Yes	0.233	1.262 (0.975-1.634)	.07
Antipsychotic	Yes	0.334	1.396 (1.058-1.843)	.02

[a]Schoenfeld residuals to check the proportional-hazards assumption: age (χ^2_1=0.006; P=.94), anxiety disorder (χ^2_1=2.7; P=.10), and antipsychotic (χ^2_1=0.1; P=.72).

[b]N/A: not applicable.

[c]Our Cox model analyzed the risk of discontinuing the app use that participants from different nationalities had in comparison with Spanish participants. This row was maintained in the table to make clear that Spain was not included in the category *Other*.

The variables age, anxiety disorder, antipsychotic, and country were explored (Table 5). In this model, age is suggested as a protective factor for app use discontinuation, that is, the older the individual, the lower the risk of discontinuing app use. The regression coefficient for age was –0.016 (P=.02), which would imply a better engagement for older individuals. We calculated the percentage change in hazard rate for years' increase in age using the formula $100 \times (e^{(-0.016 \times 10)} - 1) = -14.8$, which allows us to estimate that a user older by 10 years would have a 14.8% reduction in their hazard compared with a user younger by 10 years.

We did not observe statistically significant differences among countries. Participants from the countries analyzed did not have a significantly different risk of discontinuing app use compared with Spanish users.

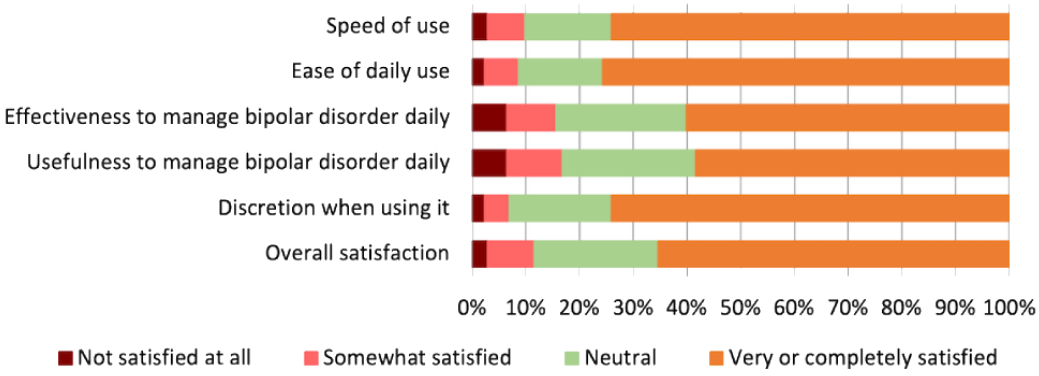
The regression coefficient for taking antipsychotics is statistically significant (coefficient=0.334, 95% CI 1.058-1.843; P=.02), which suggests that this variable is a risk factor and that users who take antipsychotics have a 33% hazard for discontinuing app use.

Usability, Satisfaction, and Perceived Usefulness

The analysis of user evaluation of the SIMPLe app contained in this section was exclusively performed with data of the 173 participants who used the app and completed the follow-up assessment too.

The mean raw SUS score was 77.05 (SD 17.21), which is above average at the 75th percentile. As shown in Figure 3, 74% (128/173) of the users were highly or completely satisfied with the speed and discretion of the app and 75.7% (131/173) of the users were satisfied with the ease of daily use. A high or complete level of overall satisfaction was rated by 65.3% (113/173) of the users.

Figure 3. Satisfaction with the SIMPLe app. The bars denote the percentage of satisfaction of users who responded to the follow-up questionnaire (n=173) after having experienced using the app.



With regard to usefulness, most users found somewhat useful or very useful the following features and functions: daily test (125/173, 72.3%), mood chart (127/173, 73.4%), personalized psychoeducational messages (117/173, 67.6%), weekly test (117/173, 67.6%), stressful events record (108/173, 62.4%), emergency alert notifications (103/173, 59.6%), the enabled option to share the mood chart (94/173, 54.3%), and the prodromes module (87/173, 50.3%).

Among the users who registered the reason for discontinuing using the app (91/173, 52.6%) by answering a multiple-choice question, 28.6% (26/91) found it very repetitive, 23.1% (21/91) had technical issues, 17.6% (16/91) did not find it useful, 16.5% (15/91) stated that it was an undesired daily reminder of their condition, 14.3% (13/91) stated that it affected smartphone performance, 13.2% (12/91) gave other reasons, 7.7% (7/91) were concerned about the stigma attached to having it installed on their smartphone, 4.4% (4/91) relapsed, and 3.3% (3/91) found it difficult to use.

Users suggested app improvements by responding to a multiple-choice question. The improvements more frequently suggested were enabling a personalized plan to follow when potential relapse symptoms appear (122/173, 70.5%), personalization of stressful events (103/173, 59.5%), and a wider variety of psychoeducational messages (99/173, 57.2%).

Discussion

After proving positive outcomes regarding satisfaction, usability, and helpfulness in previous research, the SIMPLe app was launched to the real world to make it available worldwide within the context of BD treatment.

Principal Findings

The outcomes of this real-world study represent the first attempt to evaluate, by means of survival analysis, use, retention patterns, and engagement of a large-scale wide-reaching app-based intervention providing psychoeducational content to patients with BD.

One of the most important advantages of the data collected through smartphone apps in clinical studies is the continuous and granular characteristics of the data registered at servers. Using detailed log and use data to examine predictive factors allows an understanding of the engagement and its underlying mechanisms. It will also aid optimization of smartphone-based interventions and improvement in the real-world uptake of self-management apps for BD, as well as in clinical benefits and associated outcomes [33].

Comparison With Prior Work

Survival analysis is not a new idea in statistics, and it is frequently used in several medical fields; in fact, it was considered the main outcome measure in the seminal works by Colom [34], who first showed the efficacy of group psychoeducation of patients in participants with BD. However, this method is a novel approach to quantify user retention and engagement of mobile apps that few studies have previously applied in nonpsychiatric populations [35,36]. Interestingly, Chien et al [37] used machine learning techniques to identify heterogeneity in patient engagement with internet-based cognitive behavioral therapy (CBT) for symptoms of depression and anxiety and found that patterns of patient behavior may reveal different modalities of engagement.

The aforementioned results are in line with one of the largest data sets on engagement in remote digital health compiled to date [38] (there is significant attrition in remote research). In addition, Pratap et al [38] observed indicators of retention in remote digital health studies through survival analysis, which revealed the factors associated with an increase in participant retention time, including older age (an increase of 4 days). In contrast, our study revealed that years since onset and years since diagnosis of BD (2 variables highly related to age) had a significant impact on app use; mobile app median use of participants with earlier disease onset and diagnosis increased by 32 days and 29 days compared with individuals with a more recent onset and more recent diagnosis, respectively. Similarly, when comparing potential predictors of traditional group psychoeducation in BD in a digital format, Reinares et al [39] identified that receiving an early diagnosis of BD may indicate a better response to face-to-face group psychoeducation. Other factors with a significant contribution to the risk of discontinuing app use (that are also highly associated with age) were housing and employment status. Retention duration of unemployed participants and those who shared a house was lower than that of users with other housing statuses. It is obvious that having a recent onset and diagnosis, sharing a house, and unemployment are more common in younger populations, suggesting a disadvantage regarding app use.

Our findings are consistent with previously collected preliminary use data on the SIMPLe app [22]. We previously observed that older age was a predictor significantly associated with higher odds of retention. In addition, the attrition rate of the program was still high, but this time our research focused on retention factors. Furthermore, overall satisfaction of the participants was quite positive because 65.3% (113/173) were highly or completely satisfied with SIMPLe in the context of low retention. The satisfaction, usability, and helpfulness outcomes are in line with our previous results deriving from an implementation feasibility study of SIMPLe. In terms of usefulness, the best-rated features and functions of the app were daily and weekly tests, mood charts, and personalized psychoeducational messages. The last-named is a unique and differentiating feature that other mobile-based platforms for BD do not offer [40]. On the basis of the information collected through screening tests on mood, energy, sleep time, medication adherence, and irritability, the SIMPLe app pushes daily pop-up notifications with a short psychoeducational message containing brief information (usually fewer than 50 words) on how to deal with specific situations to avoid relapses. Psychoeducational short messages carefully provided to cover detected specific user needs are the closest way to feature the *human touch*, and they fulfill quite convincingly our initial intention to partly replicate the successful Barcelona Bipolar Psychoeducation model [18] in an app so that it could de-escalate treatment costs and make combined therapy (psychoeducation and psychopharmacology) available to the greatest number of affected individuals.

In contrast, Faurholt-Jepsen et al [41] investigated the effect of smartphone-based patient-reported and objective monitoring, including a mood prediction system. The collected objective smartphone data included phone use, social activity, and mobility. Patients with BD were randomized to the Monsenso monitoring system (Monsenso A/S) or to standard treatment. Clinical feedback was established for patients in the intervention group in the case of signs of impairment (eg, lack of self-monitoring data). Overall, there was no effect of smartphone-based monitoring on symptoms compared with the control group. The intervention group adhered to the daily self-monitoring 72.6% (196/270) of the days over the 9-month study period.

Yet another project [42] evaluated 2 mobile phone–augmented interventions: an in-person session of CBT combined with automated thought-challenging and adaptive behavior delivered through mobile devices and an in-person session of psychoeducation with mobile interaction involving self-monitoring of symptoms. The retention rates were 77% for the self-monitoring group and 91% for the CBT condition at 6 months. Follow-up in both active conditions consisted of telephone calls by the study therapist to remind participants of assessment appointments and encourage adherence. However, these outcomes are difficult to extrapolate and compare because the cited Californian study included patients with schizophrenia as well as patients with BD. Previously, Depp et al [43] had explored a similar approach integrating a mobile device–delivered intervention linking patient-reported mood states with self-management strategies, preceded by face-to-face brief psychoeducation in BD. At 12 weeks, the retention reported was 93%; however, it was only operationalized based on the percentage of participants who returned the borrowed mobile devices of the study.

At odds with the aforementioned studies, the SIMPLe app was designed as an independent self-management method targeting relapse prevention. For research purposes, the study team helped (remotely) participants to install the app and log into the system, as well as provided a brief explanation. Users were provided with a telephone number to contact the research team for further assistance in case they experienced technical issues. The retention rate of the original SIMPLe study was 74% (36/51) after 3 months of app use [21].

The OpenSIMPLe study differs from the others in that it is the only modality that does not involve some contact with a person providing support or human interaction. It is reasonable to assume that the lower retention rates of the OpenSIMPLe study may have been influenced by the absence of human support in comparison with the other studies assessing smartphone-based platforms; the latter were more demanding in terms of time and staff resources. Besides the notifications systems recalling adherence in the aforementioned studies, the fact that participants established an alliance with clinical study staff and received previous face-to-face intervention or continuous telephone-delivered psychoeducation has influenced retention for certain [44].

It has been suggested that a positive relationship between app engagement and improvements in therapeutic outcomes in mental health and well-being may indicate the effectiveness of internet-based interventions [45]. Moreover, the type of engagement in terms of intervention use has demonstrated different relationships with outcomes [46]. However, there is a general tendency among mental health apps toward low retention and engagement rates [32,47]. At the same time, detailed engagement and retention rates are rarely reported in smartphone-based clinical trials but are of crucial importance to understand the underpinning of their effects. Those studies reporting and analyzing them frequently do so with heterogeneous and nonstandardized methodologies.

It is worth mentioning that we are comparing our retention, app use, and engagement data with other studies that used different parameters to measure these indicators for mental health apps and even used different criteria to assess them. Results from a systematic review conducted by Ng et al [32] indicated high variability across studies regarding the operationalization of the indicators of engagement, as well as highlighted the need to using objective criteria when assessing them. To date, the lack of clear consensus on the definition and standardization of these parameters represents a big obstacle to understanding feasibility and comparing results in the field of mobile-based apps and digital therapeutics. The real effectiveness of every intervention can be hardly estimated without quantifying the exact *dosage* of intervention that individuals receive, and engagement is not usually considered or it is evaluated erratically through effect size estimation in randomized controlled trials.

Limitations

Some limitations of this study should be noted, and caution should be exercised in generalizing results. First, our analyses relied on a rather heterogeneous sample, where participants differed in terms of sociodemographic, clinical, and psychological characteristics. This can be explained by the fact that we opened the platform to a real-world setting without considering inclusion and exclusion criteria that were too restrictive. However, the participants were a good representation of an unselected real-world population.

All measures were administered using exclusively self-reported web-based methods that did not allow us to get back in touch with participants who dropped out to collect feedback on the reasons for attrition. In addition, we did not have access to either medical records or passive data to validate the accuracy and reliability of the information provided, which may have influenced our sample and outcomes. As shown in Figure 1, there were only 2 participants excluded by the MDQ at screening. The MDQ is a popular, simple, and sensible screening instrument for the detection of BD. However, this tool is far from perfect [48]; it has low specificity, and it is likely that it did not discriminate among participants with a range of disorders such as borderline personality disorder. This is a common disadvantage in studies that screen participants through web-based methods exclusively.

A weakness of this study is that we limited use and retention analysis to the regular users of the SIMPLe 1.5 app and did not analyze other data from the occasional users, who did not use the app consistently. However, the aim of limiting these analyses to data provided by regular users was to avoid overestimation of use time and retention. In addition, sensitivity and homogeneity analysis confirmed that the data were coherent when we repeated the survival analysis with the whole sample of users; this showed that the selection of regular users in the study of app use prevented an overestimation of it, whereas the effect of the selection on survival probability is small.

Furthermore, only 44.4% (173/390) of the users completed the follow-up assessment, which implies some bias in the data collected regarding evaluation of the app because the variables measured at follow-up (including SUS, perceived usefulness, and satisfaction) were exclusively assessed by these users. An example that indicates this bias is that we found differences in the time range of app use between patients who used the SIMPLe app (n=390) and those who used it and completed the follow-up assessment (n=173); the former group used it a mean of 88.64 (SD 70.56) days, whereas this mean increased to 119.64 (SD 69.9) days in the latter group. However, the former group used the app slightly more every day on average (mean 0.92, SD 0.73) than the latter group (mean 0.83, SD 0.51). Therefore, these differences in terms of app use between the groups suggest that the users may have different profiles.

As this work was an exploratory study (ie, a flexible rather than structured approach to data collection was considered useful), there was no control group or alternative intervention for comparison of effects because the study was not designed to test the efficacy of the SIMPLe app. For the same reason and to avoid unlimited assessments that would probably result in the attrition rate soaring to unacceptable levels, we decided to keep control and covariate data to a minimum, which obviously represents at the same time something gained and something lost.

All the participants included came from Latin American or Spanish populations. The cultural characteristics of these origins may be difficult to generalize, but little is known about app adherence (or even drug or psychotherapy adherence) across cultures. This may become an exciting topic awaiting proper exploration.

Finally, it should be considered that the outcomes of this study deal with a high level of missing data derived from highly variable retention rates and lack of adherence after a few weeks of use among users of mental health apps, which is a common hindrance in internet-based research [12,49] that we tried to handle in an honest and rigorous manner.

Conclusions

The user retention rate of the app decreased at a rapid rate after each month until reaching only one-third of the users at 6 months. There exists a strong association between age and app engagement of individuals with BD. Other variables such as years lived with BD, diagnosis of an anxiety disorder, and taking antipsychotics seem to play a relevant role as well. We believe that an understanding of these associations will help clinicians in the definition of the most suitable user profiles for predicting trends of engagement, optimization of app prescription, and management.

Acknowledgments

The authors of this manuscript were indirectly supported by research grants from the Spanish Ministry of Economy and Competitiveness PI15/00588 and PI19/00009 (to FC) and FI20/00008 (to AGE); Instituto de Salud Carlos III, Subdirección General de Evaluación y Fomento de la Investigación; and Fondo Europeo de Desarrollo Regional, Unión Europea, *Una manera de hacer Europa*. GA is supported by a Pons Bartran 2020 grant (PI046549). EV's research is supported by the Spanish Ministry of Science and Innovation integrated into the Plan Nacional de I+D+I and cofinanced by the Instituto de Salud Carlos III (Subdirección General de Evaluación) and the Fondo Europeo de Desarrollo Regional; the ISCIII; CIBER Mental Health; the Secretaria d'Universitats i Recerca del Departament d'Economia i Coneixement (2017 SGR 1365), the Centres de Recerca de Catalunya program, and the Departament de Salut de la Generalitat de Catalunya. The funding sources did not have any involvement in study design, collection, analysis,

interpretation of data, or the writing of this manuscript. The authors are very grateful to all the users of the SIMPLe app for their collaboration in this project. The technical development of the app software was commissioned to Sodep SA (Asunción, Paraguay).

Authors' Contributions

This study was conceived by FC, DH, and EV. DH and FC developed and maintained the project's website. FC, DH, and AGE were responsible for the methodology. JC assisted with data cleaning, statistical analysis, and interpretation of the results. Regarding the manuscript, the original draft was prepared by AGE, GA, and DH; review and editing were carried out by NAO, GA, EMM, FC, and VP; and supervision was by FC. EV and FC were responsible for funding acquisition. All authors have read and approved the final version of the manuscript.

Conflicts of Interest

DH, EV, and FC designed the SIMPLe smartphone app mentioned in this study. The authors do not have any economic interests in the SIMPLe app, its use, or copyrights. EV has received grants and served as consultant, advisor or CME speaker for the following entities (unrelated to the present work): AB-Biotics, Abbott, Abbvie, Aimentia, Angelini, Biogen, Boehringer -Ingelheim, Casen-Recordati, Celon, Dainippon Sumitomo Pharma, Ferrer, Gedeon Richter, GH Research, Glaxo Smith-Kline, Janssen, Lundbeck, Organon, Otsuka, Sage, Sanofi-Aventis, Sunovion, Takeda, and Viatris. GA has received CME-related honoraria, or consulting fees from Janssen-Cilag, Lundbeck, and Angelini with no financial or other relationship relevant to the subject of this article.

Abstract

Background: Electronic communication (e-communication), referring to communication through electronic platforms such as the web, patient portal, or mobile phone, has become increasingly important, as it extends traditional in-person communication with fewer limitations of timing and locations. However, little is known about the current status of patients' use of e-communication with clinicians and whether the use is related to the better patient-perceived quality of care at the population level.

Objective: The aim of this study was to explore the prevalence of and the factors associated with e-communication use and the association of e-communication use with patient-perceived quality of care by using the nationally representative sample of the 2019 Health Information National Trends Survey 5 (HINTS 5)-Cycle 3.

Methods: Data from 5438 adult responders (mean age 49.04 years, range 18-98 years) were included in this analysis. Multiple logistic and linear regressions were conducted to explore responders' personal characteristics related to their use of e-communication with clinicians in the past 12 months and how their use was related to perceived quality of care. Descriptive analyses for e-communication use according to age groups were also performed. All analyses considered the complex survey design using the jackknife replication method.

Results: The overall prevalence of e-communication use was 60.3%, with a significantly lower prevalence in older adults (16.6%) than that in <45-year-old adults (41%) and 45-65-year-old adults (42.4%). All percentages are weighted; therefore, absolute values are not shown. American adults who used e-communication were more likely to be high school graduates (odds ratio [OR] 1.95, 95% CI 1.14-3.34; *P*=.02), some college degree holders (OR 3.34, 95% CI 1.84-6.05; *P*<.001), and college graduates or more (OR 4.89, 95% CI 2.67-8.95; *P*<.001). Further, people who were females (OR 1.47, 95% CI 1.18-1.82; *P*=.001), with a household income ≥US $50,000 (OR 1.63, 95% CI 1.23-2.16; *P*=.001), with more comorbidities (OR 1.22, 95% CI 1.07-1.40; *P*=.004), or having a regular health care provider (OR 2.62, 95% CI 1.98-3.47; *P*<.001), were more likely to use e-communication. In contrast, those who resided in rural areas (OR 0.61, 95% CI 0.43-0.88; *P*=.009) were less likely to use e-communication. After controlling for the sociodemographics, the number of comorbidities, and relationship factors (ie, having a regular provider and trusting a doctor), e-communication use was found to be significantly associated with better perceived quality of care (β=.12, 95% CI 0.02-0.22; *P*=.02).

Conclusions: This study confirmed the positive association between e-communication use and patient-perceived quality of care and suggested that policy-level attention should be raised to engage the socially disadvantaged (ie, those with lower levels of education and income, without a regular health care provider, and living in rural areas) to maximize e-communication use and to support better patient-perceived quality of care among American adults.

KEYWORDS

electronic communication; quality of care; person-related characteristics; patient preference; HINTS

Introduction

Effective patient-clinician communication is a critical component of high-quality patient-centered care. With the rapid diffusion of advanced technology, the use of electronic services such as email, text messaging, and patient portals as a platform of communication (ie, electronic communication [e-communication]) between patients and clinicians has become increasingly popular [1]. Evidence shows that patients are enthusiastic about e-communication with clinicians regarding a wide variety of clinical contexts such as chronic condition self-management and follow-up examinations [2-4]. e-Communication has become a valuable supplement to traditional in-person communication through office visits [5,6]. It has fundamentally improved patients' interactions with the health care system and their engagement in shared decision-making with clinicians [7,8].

Despite the increasing popularity and potential impacts of e-communication on health care services, the actual use of e-communication among various patient populations still remains relatively low [9-12]. A review of patient portals for adults with diabetes found that 29%-46% of adults registered an account, but only 27%-76% of them actually accessed the portal [12]. A study of an encrypted message system in a pediatric clinic showed that only 4.3% of parents of chronically ill children made use of the system [11]. Similarly, a study of Health Information National Trends Survey 5 (HINTS 5)-Cycle 3 data in 2003-2005 indicated that only 10% of adult internet users communicated with the clinicians through web-based communication services [9]. Age can be a potential factor affecting the use of e-communication [13,14]. Clarke et al's [14] study showed that young adults preferred text messaging, middle-aged adults preferred phone calls, and older adults preferred paper-based and in-person interactions with clinicians. These findings imply that the prevalence of e-communication use might be lower among older adults as compared to that among young and middle-aged adults. Considering older adults' needs for technology-enabled health care support can help them become the major users of e-communication. In recent years, older adults' adoption of information and communication technology has been increasing, and they are likely to increasingly incorporate digital technology into their daily life [15]. Given the ever evolving technology and various populations' needs for support, it is important to understand how e-communication use varies across different age groups. Another commonly reported factor associated with patients' use of e-communication is patient-clinician relationships [16-20], for example, how much one trusts information from a doctor can influence the person's decision-making for using e-communication [19].

All these barriers can presumably affect both patients' use of e-communication [20] and their perceptions of quality of care [21]. However, there lacks empirical evidence to quantify the association between e-communication use and patient-perceived quality of care [22,23]. Patient-perceived quality of care refers to patients' perception of health care services received based on their experiences of what actually happened during the care process [24]. As one of the essential indicators of care quality, patients' perception of quality of care is an important driver of patient satisfaction, reflecting their desire for individualized high-quality care, which is also the main goal for those providing the care [25]. Factors that affect patient-perceived quality of care mainly include person-related conditions such as the patients' age, sex, education level, and self-reported health status, and external objective care conditions such as the organizational structure of care, competence of health care personnel, the size of the hospital, inpatient stay and occupancy, and comfortable environment [26]. Patient-clinician communication has been reported as one of the major factors driving patient perception of quality care in addition to hospital staff responsiveness, the care transition process, and hospital environment [27]. In the era of digital health, particularly with the increased popularity of e-communication between patients and clinicians and extended health care efficiency, the use of e-communication may increase the patient-perceived quality of care as opposed to no use of any e-communication [21]. However, the lack of empirical evidence to quantify the effectiveness of e-communication on patient-perceived quality of care may delay the promotion of e-communication adoption and the development of new models of patient-clinician interaction to satisfy patients' needs for high-quality health care services [21].

The purposes of this study were to examine the prevalence of patients' use of e-communication with clinicians and the potential factors (in particular, person-related factors such as age) associated with their use of e-communication and to explore the potential association between e-communication use and patient-perceived quality of care. Based on previous literature reports [21,24,25,27], we hypothesized that patients' use of e-communication was related to better patient-perceived quality of care.

Methods

Data Source

Data used in this study were from the HINTS 5-Cycle 3 [28]. HINTS is a nationally representative survey designed to understand American adults' knowledge of, attitudes toward, and use of cancer- and health-related information [29]. HINTS 5-Cycle 3 used a single-mode mail survey, with a 2-stage sample design, including a stratified sample of addresses and a selected adult within each sampled household [28]. The data were collected from 5438 respondents from January to May 2019 (English version only), with an overall 30.3% response rate [28]. Comprehensive reports on the sampling design for the HINTS survey have been published elsewhere [28-30]. The

survey data were deidentified and are publicly available; institutional review board approval was not applicable.

Variables

Perceived Quality of Care

The outcome variable patient-perceived quality of care was assessed via self-report on a single question asking "*overall, how would you rate the quality of health care you received in the past 12 months?*" with a 5-point Likert scale from 1=poor to 5=excellent, with a high score indicating better perceived quality of care (see Table 1).

Table 1. Variables and survey measurements.

Variable	Survey measurement
Patient-perceived quality of care	Overall, how would you rate the quality of health care you received in the past 12 months? (1=poor to 5=excellent)
Use of electronic communication	
1	In the past 12 months, have you used a computer, smartphone, or other electronic means to communicate with a doctor or a doctor's office? (1=yes, 0=no)
2	Have you sent a text message to or received a text message from a doctor or other health care professional within the last 12 months? (1=yes, 0=no)
3	In the past 12 months, have you used your online medical record to securely message health care provider and staff (eg, email)? (1=yes, 0=no)
4	In the past 12 months, have you used your online medical record to add health information to share with your health care provider, such as health concerns, symptoms, and side effects? (1=yes, 0=no)
5	Have you shared health information from either an electronic monitoring device or smartphone with a health professional within the last 12 months? (1=yes, 0=no)
6	Have you electronically sent your medical information to another health care clinician? (1=yes, 0=no).
Sociodemographics	
1	Age (young: ≥18 and <45 years, middle-aged: ≥45 and <65 years, and older adults ≥65 years)
2	Sex (0=male, 1=female)
3	Education level (0=less than high school, 1=high school graduate, 2=some college, 3=college graduate or more)
4	Marital status (0=not married, 1=married or partnered)
5	Race/ethnicity (0=White, 1=African American, 2=Hispanic, 3=other)
6	Household income (0=<US $50,000; 1=≥US $50,000)
7	Living status (0=living with others, 1=living alone)
8	Residency (0=nonrural, 1=rural)
Comorbidities	The number of comorbidities: Has a doctor or other health professional ever told you that you had any of the following medical conditions? Choices for this question included cancer, hypertension, diabetes, heart condition, chronic lung disease, and depression, and a sum score was used.
Patient-clinician relationship	
1	Having a regular health care provider: Not including psychiatrists and other mental health professionals, is there a particular doctor, nurse, or other health professional that you see most often? (0=no, 1=yes)
2	Trusting a doctor: In general, how much would you trust information about health or medical topics from a doctor? (1=not at all to 4=a lot)

Use of e-Communication

Patients' use of e-communication with clinicians in the past 12 months, such as using the computer, smartphone, text messaging, web-based messaging, web-based medical records, or any other electronic means to share medical information, were assessed through 6 survey questions (see Table 1). Survey responders who answered "yes" to either of the 6 questions were considered having e-communication with their clinicians, defined as users, while responders who answered "no" to all 6 questions were considered as nonusers.

Sociodemographics and Comorbidities

Age was measured as a continuous variable in the HINTS 5-Cycle 3 and was categorized into 3 groups: young adults (≥18 and <45 years of age, 38.4%), middle-aged adults (≥45 and <65 years of age, 39.7%), and older adults (≥65 years of age, 19.7%). All percentages are weighted; therefore, absolute values are not shown. Other sociodemographic covariates included sex, education level, marital status, race/ethnicity, household income, living status, and residency. The number of comorbidities was a sum score of 6 doctor-diagnosed chronic conditions, namely,

cancer, diabetes, hypertension, heart disease, lung disease, and depression (see Table 1).

Patient-Clinician Relationship

Patient-clinician relationship variables included (1) having a regular health care provider (yes/no) and (2) trusting a doctor (rating from 1=not at all to 4=a lot) (see Table 1).

Statistical Analysis

All analyses considered the complex survey design of the HINTS 5-Cycle 3 sample by using the HINTS-supplied final weights to estimate population estimates and 50 replicate weights to compute the standard errors with the jackknife replication approach [29]. Specifically, descriptive statistics were used to describe the prevalence and the characteristics of e-communication users and nonusers. Multiple logistic regression analyses were used to assess the association of sociodemographics and comorbidities (Model 1) and sociodemographics, comorbidities, plus patient-clinician relationship factors (Model 2) with e-communication use. Multiple linear regression analyses were used to examine the association between e-communication use and patient-perceived quality of care with the control of sociodemographics and comorbidities (Model 3) and the control of sociodemographics, comorbidities, plus patient-clinician relationship factors (Model 4). Missing data pattern analysis indicated that most variables had missing data <5% (see Table S1 in Multimedia Appendix 1). Multiple imputation was performed, and the pooled results of model 3 and model 4 were based on 50 imputed data sets using multiple imputation by chained equations. All analyses were conducted using Stata software (version 14; StataCorp). Results were reported as weighted point estimates and 95% CIs. The level of significance was .05.

Results

Prevalence and Characteristics of e-Communication Users

The overall prevalence of the use of e-communication was 60.3%. Most American adults who used e-communication with clinicians in the past 12 months were younger than 65 years, as older adults only accounted for 16.6% of e-communication users but 25.7% of nonusers (see Table 2). Table 2 also displays that most e-communication users were females (53.9%), had at least some college (41.7%), and 36.4% college graduates or more, were White people (65%), currently married (59.9%), with a household income ≥US $50,000 (63.9%), and did not live alone (85%) or in rural areas (89.5%). e-Communication users and nonusers were significantly different in all person-related characteristics. In addition, significantly more e-communication users had a regular health care provider than e-communication nonusers (72.9% vs 51.4%, respectively; P<.001) (see Table 2). All percentages are weighted; therefore, absolute values are not shown.

Factors Associated With e-Communication

Table 3 presents the results of multiple logistic regression analyses on the sociodemographics, comorbidities, and patient-clinician relationship factors for e-communication use. In model 1, where only sociodemographic factors and comorbidities were considered, age (odds ratio [OR] 0.87, 95% CI 0.66-1.14), female (OR 1.44, 95% CI 1.17-1.77), education level (eg, for college graduates or more, OR 4.78, 95% CI 2.63-8.68), household income (OR 1.77, 95% CI 1.34-2.34), rural residency (OR 0.62, 95% CI 0.44-0.87), and number of comorbidities (OR 1.33, 95% CI 1.16-1.52) were associated with e-communication use (see Table 3). In model 2, after adding the relationship factors to the model, people who were females (OR 1.47, 95% CI 1.18-1.82), high school graduates (OR 1.95, 95% CI 1.14-3.34), having some college (OR 3.34, 95% CI 1.84-6.05), and college graduates or more (OR 4.89, 95% CI 2.67-8.95), with a household income at or greater than US $50,000 (OR 1.63, 95% CI 1.23-2.16), with more comorbidities (OR 1.22, 95% CI 1.07-1.40), or having a regular health care provider (OR 2.62, 95% CI 1.98-3.47) were more likely to use e-communication, whereas those who were older adults (OR 0.42, 95% CI 0.31-0.57) or rural residents (OR 0.61, 95% CI 0.43-0.88) were less likely to use e-communication.

Associations Between e-Communication Use and Patient-Perceived Quality of Care

Table 4 displays the results of the association between e-communication use and patient-perceived quality of care among American adults. After controlling for sociodemographic factors (age, gender, education, income), comorbidities, and patient-clinician relationship factors (having a regular health care provider, trust a doctor), the use of e-communication was statistically associated with better quality of care (β=.12, 95% CI 0.02-0.22; see Model 4 in Table 4).

Discussion

Principal Findings

This study examined the prevalence of and factors associated with e-communication use and the potential association between e-communication use and patient-perceived quality of care in a nationally representative sample of American adults. To the best of our knowledge, this study is the first to explore the association of e-communication use with patient-perceived quality of care at the population level. Several important findings emerged in this study.

First, the majority of American adults (60.3%) used some forms of e-communication with clinicians throughout 2019, which was significantly higher than the reported 7% in 2003, 10% in 2005 [9], and 31.5% in 2014 from the previous HINTS [31]. This finding indicates that e-communication use has become increasingly popular for adults to interact with their clinicians. The increased prevalence rate can be attributed to the increased availability and popularity of electronic health devices [32,33] and supportive policies (eg, promoting patient access to their electronic medical records) [34]. Although our data showed an overall growing trend in the use of e-communication, it is important to note that older adults' use of e-communication still remained relatively low, and this rate was not much improved from that in 2003 and 2005 [12]. Literature indicates that older adults usually prefer direct in-person interactions with their clinicians [12], while there are increasing reports about older adults' positive attitude toward e-communication and their preference for email and messaging communication with clinicians that is similar to that for younger adults [35,36]. Our

finding suggests that there is still a gap in the actual use of e-communication between older adults and young adults [31,37,38]. More studies are needed to explore the practical challenges that older adults may encounter in the use of e-communication. Older adults are potentially the major users of e-communication, considering their high level of health care needs. It is important to develop appropriate e-communication support for this population for their better health outcomes.

In addition to age, we also found that the use of e-communication varied by gender, education, income, and residency, indicating that individuals who are females, with higher education, higher income, and more comorbidities, or who reside in nonrural areas were more like to use e-communication with their clinicians. This finding is congruent with reports of the general adoption of eHealth in literature [39-42]. Consistent with our finding, the positive association between education and e-communication usage was reported in previous studies [31,39], which can be interpreted as individuals who have higher education might have more eHealth literacy skills and technological capabilities [43] to help them better use electronic forms of information [31,39]. However, Senft and Everson's recent study [44] reported that individuals who had lower levels of education and had negative care coordination experiences are more likely to use eHealth activities to communicate with clinicians [44], indicating that personal health care experiences can possibly interplay with education and thus influence the use of e-communication. However, it is unclear whether the limited use of e-communication among rural residents is related to lack of internet connectivity or awareness of e-communication services [45]. Additional studies can be conducted for further exploration.

Compared to those who did not use e-communication in the past year, in this study, e-communication users were more likely to have a regular health care provider and reported better trust in information from a doctor. However, trusting a doctor was not an independent predictor of e-communication use when having a regular health care provider was controlled for in the model. A previous qualitative study has indicated that a trusting relationship between patient-clinician is a significant contributor to better online patient-clinician interactions [20,46]. Even those who tend to frequently seek web-based health information are more willing to use the information provided by their trusted clinicians for their health decision-making [17,47]. Our findings suggested that patients with a regular health care provider had the greatest association with their use of e-communication. It is possible that patients who have a regular health care provider have already built a trusting relationship with their clinicians. Given the importance of trust in a provider in the patient-centered care process, future research directly examining possible confounding of this factor using longitudinal data is recommended.

Finally, it is not surprising that this study found that the use of e-communication was an independent predictor of patient-perceived quality of care. In 2001, the Institute of Medicine suggested that e-communication could improve the quality of care [48]. The previous literature review demonstrates that e-communication provides a convenient way of patient-clinician interaction, has a positive impact on patient satisfaction while saving time for patients and clinicians, and has the potential to extend health care efficiency [21,49]. The benefits and challenges of e-communication have been well addressed in the literature, while its benefits for the quality of care may not have been clearly quantified previously. The measures of quality of care can vary by the dimensions of care and care processes [50]. However, this study focused on the measure of the patient-perceived quality of care, which solely reflected patients' perceptions of health care services received based on their experiences of care [24]. It did not mean to measure any technical clinical quality, for example, cholesterol screening [51]. There is increasing interest in patient-reported measures, as experiences with care are more easily understood by patients. In addition, previous literature demonstrated that the measure of patient experiences of care was related to measures of the technical quality of care, which can serve as valid summary measures of hospital quality [52]. These study findings were based on the analysis of nationally representative survey data, which should be generalizable to all American adults. The positive association between the use of e-communication and perceived quality of care confirms that e-communication can serve as an important tool to improve patient satisfaction and their perceptions of quality of care. This finding is particularly significant and applicable in the current COVID-19 pandemic when traditional in-person communication is less feasible. It is expected that e-communication will continuously replace an adequate portion of traditional face-to-face encounters and has the potential to transform the health care system [21]. Future research can be conducted to explore the sustainable long-term effects of e-communication on patient-centered care outcomes.

Limitations

This study has a few limitations. First, data were mainly based on self-reports, which might have introduced recall bias. Second, the survey questions regarding the use of e-communication did not specify the frequency of use; therefore, they did not accurately reflect responders' experiences of using e-communication and might affect their perceptions of quality of care. Third, a binary measure of e-communication use (yes/no) was used, which might result in the loss of information or power. However, considering the conceptual overlaps across 6 questions about e-communication behaviors in the survey, a combined continuous assessment for the number of e-communication behaviors would be conceptually inaccurate. Fourth, the e-communication was between patients and clinicians. However, the survey only focused on the patient side and thus, it was not possible to know clinicians' perceptions of e-communication use. Finally, the results could be underestimated by potential reverse causality owing to the nature of the study design. The prevalence of e-communication use was higher in our study than that that reported in previous studies. The difference may also be due to varying measurement methods across studies. In our study, we used 6 questions to measure e-communication, which are more than that used in other studies. Different measures might affect comparisons of the prevalence of e-communication use across studies.

Conclusions

American adults' use of e-communication with clinicians has been significantly increased in the past decade, which may be due to increased patient needs and advanced support from technologies and policies. As a convenient way of patient-clinician interaction, the use of e-communication is significantly associated with patient-perceived quality of care. The findings of multiple factors associated with e-communication use and the positive association between e-communication use and patient-perceived quality of care suggest that policy-level attention is needed to engage the socially disadvantaged (ie, those with lower levels of education and income, without a regular health care provider, and living in rural areas) to maximize the use of e-communication and to support better patient-perceived quality of care among American adults.

Abstract

Background: The care of pediatric trauma patients is delivered by multidisciplinary care teams with high fluidity that may vary in composition and organization depending on the time of day.

Objective: This study aims to identify and describe diurnal variations in multidisciplinary care teams taking care of pediatric trauma patients using social network analysis on electronic health record (EHR) data.

Methods: Metadata of clinical activities were extracted from the EHR and processed into an event log, which was divided into 6 different event logs based on shift (day or night) and location (emergency department, pediatric intensive care unit, and floor). Social networks were constructed from each event log by creating an edge among the functional roles captured within a similar time interval during a shift. Overlapping communities were identified from the social networks. Day and night network structures for each care location were compared and validated via comparison with secondary analysis of qualitatively derived care team data, obtained through semistructured interviews; and member-checking interviews with clinicians.

Results: There were 413 encounters in the 1-year study period, with 65.9% (272/413) and 34.1% (141/413) beginning during day and night shifts, respectively. A single community was identified at all locations during the day and in the pediatric intensive care unit at night, whereas multiple communities corresponding to individual specialty services were identified in the emergency department and on the floor at night. Members of the trauma service belonged to all communities, suggesting that they were responsible for care coordination. Health care professionals found the networks to be largely accurate representations of the composition of the care teams and the interactions among them.

Conclusions: Social network analysis was successfully used on EHR data to identify and describe diurnal differences in the composition and organization of multidisciplinary care teams at a pediatric trauma center.

Introduction

Background

Multidisciplinary care teams in health care are increasingly being seen as a multi-team system (MTS) [1,2], where 2 or more teams communicate and coordinate to achieve overarching goals [3], such as providing optimal care. MTSs are different from traditional teams in that MTS constituent teams are interdependent, work across boundaries, share accountability, and function through a hierarchy of goals that determine how lower goals are accomplished to realize higher goals [3]. MTSs have three attributes as follows: (1) compositional attributes (eg, number of teams, size of teams, and changes in team composition), (2) linkage attributes (eg, interdependence, hierarchical structure, and communication structure), and (3) developmental attributes (eg, changes in team membership over time) [4], which support the specialization and flexibility that allow constituent teams to pursue lower goals while trying to achieve higher goals [5].

MTS are often seen in environments where tasks are ambiguous, multifaceted, dynamic, and urgent [5]. In health care, trauma teams that take care of patients with trauma are examples of MTS. The care of patients with trauma is complex, multidimensional, and time sensitive, requiring multidisciplinary collaboration among a variety of health care professionals (HCPs) with complementary expertise, [6] with high fluidity of team membership (ie, members join and others leave based on the needs of patients) [7]. In addition, staffing levels at trauma centers vary with the time of day and the day of week, such that services of HCPs deemed nonessential may not be available during *off hours* (nights and weekends) [8-11], necessitating changes and adaptation in MTS structures.

Assessment of MTS, as they perform their work in actual settings, is important to gain a better understanding of work as done (as opposed to work as imagined) [12] and to identify how to improve their performance given the *realities and variations of work* [1]. Social network analysis can enable the understanding and assessment of MTS at the compositional (ie, membership) and organizational (eg, subteam) levels [1,13]. Typically, such assessment is done through observation, which can be highly resource intensive and may not be practical to capture all the cognitive work of team members involved in the trauma. Moreover, a self-reported surveys [5], which relies exclusively on perceptions of care professionals may also be limited in its ability to provide rich details [3]. The ability to exploit *digital traces* [14], which may provide opportunities over survey data [15,16] or observational data, is desirable. Electronic health record (EHR) systems offer the opportunity to study the composition and organization of care teams working as part of an MTS [17]. EHRs capture many clinical activities that are performed by HCPs in the process of care delivery [17,18], and previous studies have shown the feasibility of obtaining plausible information about care teams from EHR data [17].

Objective

This study aims to identify MTS and demonstrate the dynamic nature of the compositional and organizational structures of the MTS by describing diurnal differences at various locations in a pediatric trauma center using EHR data.

Methods

Research Setting

This study was conducted as part of a larger research project (AHRQ R01HS023837) [19-21] aimed at redesigning pediatric trauma work systems based on health information to improve care transitions and patient safety. This study builds on a core methodology that has been previously described and validated [22,23]. The core methodology is reproduced here from data set subsection to “generation of master event log” subsection with necessary modifications for this paper.

Study Setting

This study was conducted at a large academic children’s medical hospital with a level I pediatric trauma center in the Eastern United States, which receives approximately 1000 pediatric patients with trauma per year. The participating hospital triages incoming patients into one of four trauma activation levels as follows: alpha (level I or highest severity), bravo (level II), critical trauma transfers (includes interfacility, but patients who are stable but critically injured, and is also known as a consult) and emergency department (ED) response, that are ordered by decreasing acuity and need for multidisciplinary care with ED response activations exclusively handled by the ED staff.

Trauma activation levels determine the composition of the trauma team, as specified by state [24] and institutional policy. The trauma team is derived from the ED staff, the general pediatric surgery service, pediatric intensive care unit (PICU), and the ancillary support staff (eg, child life specialists, chaplains, and social workers). Following resuscitation, if inpatient admission is required, patients with single-system injuries are admitted under the appropriate specialty service, whereas patients with multisystem injuries are admitted under the general pediatric surgery service, which is responsible for coordinating care among managing specialty services (eg, neurosurgery or orthopedic surgery).

The Johns Hopkins Medicine Institutional Review Board approved the study (IRB00076900).

Data Set

Data were extracted from the pediatric trauma registry and the EHR data warehouse (ie, the Clarity database of Epic). We limited EHR data to encounters with trauma activation levels of alpha, bravo, and critical trauma transfers that were managed between January 1 and December 31, 2017. Demographic and encounter data including age, sex, origin of patient, trauma activation level, injury severity score, and Glasgow Coma Scale score were collected from the registry. Admission, discharge, and transfer (ADT) data and metadata of 5 clinical activities (ie, notes, procedure orders, medication orders, flow sheet entries, and medication administration entries) captured in the EHR were collected from the EHR data warehouse. For each EHR activity type, we obtained the encounter ID (visit ID), activity timestamp, unique ID, and generic clinical roles (eg, attending or resident) of the HCP that performed the activity.

The note metadata included the service of the authors, whereas the procedure orders, medication orders, and medication administration entries included the care location (eg, ED or PICU) where the activity was performed.

Data Preparation

Each encounter was assigned a randomly generated, unique study ID. Timestamps of EHR metadata were normalized by replacing them with time (in minutes) from ED arrival, which ensured that the temporal sequence of events was maintained for each encounter. Activities without a full complement of data were excluded. Activities that were initiated by the EHR system and initiated by student roles (eg, nursing and medical students) were also excluded as they bore no accountability for patient care. As notes were typically signed off much later from when they were started, we considered the note creation time as the note completion time. As flow sheet and note data lacked care location data, we inferred the care location for each activity from the ADT data as follows: First, a location timeline was generated from the ADT data (ie, sequence of admissions to various hospital locations from ED arrival to hospital discharge). The normalized timestamps of each activity in the flow sheet and note metadata were then subsequently related to the location timeline, and the corresponding care location was taken as the care location where the flow sheet and note activities were performed.

Identification of Functional Roles

We considered collaboration at the level of functional roles (eg, ED nurse, neurosurgery resident, PICU fellow, and surgery attending) rather than individuals, as past studies have shown that mirrors the reality of clinical practice [25]. To determine functional roles, we identified the service (eg, orthopedic or ophthalmology service) to which each identified HCP belonged and prefixed it to their generic role (eg, resident or attending). This service could be a service that is bound to a care location (eg, ED, PICU, or general care floor) or a service that operates across care locations (eg, general pediatric surgery service or physical therapy).

We assumed that the services of certain functional roles (eg, attending, fellows, physician assistants, and nurse practitioners working on specialty services) were fixed as determined from their notes. Chart reviews and directory lookups were conducted to identify the services of individuals whose services could not be determined from the extracted metadata. The services of medical residents, which frequently change as they rotate through various services for their training, were determined on an encounter basis derived from the service of the attending that cosigned the notes. The services of registered nurses, unit-based nurse practitioners, and allied HCPs (excluding radiology technicians) were determined by taking the mode of the frequency distribution of the location of the activities they performed. The services of radiology technicians were determined on an encounter basis similar to that of residents.

Activities by individuals whose services could not be determined were excluded. Since the location of flow sheet and note activities were inferred, the records were excluded if the inferred location did not correspond to the base unit of HCPs.

Methodologic Approach

We used a process mining approach, which is a field of data science that *aims to discover, monitor, and improve real processes by extracting knowledge from event logs* [26]. The starting point for process mining is an event log, which contains a collection of events. Each event represents a discrete activity (eg, note writing) in a given process (eg, clinical care), performed by an actor (eg, ED resident), and relates to a case (eg, patient encounter). Each event is time-stamped (eg, order placed on January 22, 2000, at 10:45 AM), allowing all events for a patient encounter to be ordered chronologically [27]. By applying a *metric* described below, social network interactions and collaboration between different functional roles were obtained [28].

Working together is a commonly used metric for representing collaboration in unstructured processes with frequent ad hoc behavior such as in health care [29]. The working together metric counts how frequently 2 actors work together on same cases [28]. In its regular form, the working together metric does not accommodate for temporal distance between actors, which is important in health care where different HCPs are involved in patient care at different stages of care. Consequently, we defined a variant of the working together metric, referred to as *working closely together*, to account for temporal distance among actors. The working closely together metric counts the number of times 2 actors worked closely together with respect to time for a given patient relative to the number of times the 2 actors had the opportunity to work together. To operationalize this metric, we considered the shift rotation as the unit of clinical work and collaboration, and assumed that functional roles that were involved in the care of a patient during a shift had the opportunity to work together, whereas functional roles that were captured in the EHR within a similar time interval were *working closely together*. Therefore, this metric translates to functional roles that are jointly involved in completing the same tasks or completing disparate tasks within the same time interval.

Generation of Master Event Log

EHR metadata were processed into an event log consisting of the study ID, normalized time, EHR activity type, unique ID, and functional role of the HCP, and care location. Multiple *same-time events* were generated from notes, procedures, and medication orders that involved multiple HCPs. The encounter timeline was divided into shift rotations (day: 7 AM-6:59 PM and night: 7 PM-6:59 AM) numbered 0 to N, and each event in the event log was labeled with the corresponding shift number and shift type (day or night). Events within each shift were partitioned into segments based on *natural breaks* in the continuity of events. We assumed a natural break to be a minimum of 30 minutes between adjacent events in the event log to accommodate the lag between the occurrence of activities in real life and registration in the EHR. The Jenks Natural Break Optimization algorithm [30] was used to determine the optimal break interval between 30 and 120 minutes in 5-minute increments.

Generation of Sublogs

The master event log was divided based on shift type (day or night) and care location (ED, floor, or PICU) to obtain six individual event logs: ED morning, ED night, floor morning, floor night, PICU morning, and PICU night.

Network Representation

For each individual sublog, an undirected edge (ie, the relationship among nodes) was created for all pairwise combinations of identified functional roles within each event segment. Unique edges across all segments across all shifts across all encounters were obtained as the collaboration network. The weight of the edges was obtained by dividing the number of shifts an edge was present between 2 functional roles by the number of shifts in which both functional roles were involved, which effectively normalized the weights and accommodated for variation in care team composition across encounters.

Threshold Selection

To prevent the capture of spurious edges (ie, edges that do not really exist or edges with spurious weights) in network analysis, a threshold number of shared encounters among nodes (ie, functional roles) is usually applied to constructed networks. The eventual network structure is sensitive to the selected threshold. Various approaches that have been used to determine this threshold are subjective [31], including arbitrary selection [32], clinician informed [33], and retaining only a fixed top percentage of the strongest edges [34]. In this study, we attempted to take a more objective approach to threshold determination by introducing a heuristic method akin to the elbow method [35], which is used to determine the optimal number of clusters in k-means clustering. For each event log, we obtained and plotted the rate of change of the total number of edges removed as the threshold value (ie, representing the number of shared shifts) was incrementally increased from 2 to 20 and obtained a LOWESS (Locally Weighted Scatterplot Smoothing)-smoothed curve of the plot. The elbow point—the smallest threshold value at which the rate of change becomes insignificant or constant, was taken as the optimal threshold. The underlying assumption of this method is that as the threshold of the shared number of encounters is increased, trivial and spurious edges are removed, and the network structure changes up to a point where further increases in threshold value result in minimal removal of edges with little or no change in the network structure. At this threshold point, we assume that the network structure is relatively stable and only significant edges and nodes remain.

Network Visualization and Analysis

We used the igraph 1.1.1 package [36] in R (version 3.4.0; R Foundation for Statistical Computing) [37] to create and visualize the networks. From each network, we obtained the node count (ie, number of functional roles) and edge count (ie, number of relationships among functional roles). We used the linkcomm package 1.0.11 [38] to identify the overlapping communities in the networks. A community is a subnetwork that contains a high density of edges among members but fewer edges with members of the larger network, thus represents a tightly knit subgroup [39]. The linkcomm package is an R implementation of the algorithm by Ahn et al [40] that, as opposed to other community detection algorithms that cluster nodes—clusters edges assuming a node can belong to multiple communities, thus enabling the discovery of overlapping and nested communities. The algorithm by Ahn et al [40] is the most commonly used overlapping community detection algorithm and tends to produce superior performance if multiple ad hoc behaviors result in a high degree of overlap in derived networks, as is commonly seen in health care settings [41,42]. The algorithm uses a hierarchical clustering method to produce a dendrogram that, in the default setting, is cut at a level that maximizes the partition density [40]. The linkcomm package offers a unique visualization that uses different colors to depict edges and nodes that belong to different communities. Nodes are sized to reflect the number of communities the node belongs to, with larger nodes belonging to more communities. Nodes belonging to more than one community are also presented as pies with the pies divided and colored based on the proportion of the edges for that node in various communities that the node belongs. We parameterized the algorithm with the McQuitty hierarchical clustering method, also known as the Weighted Pair Group Method with Arithmetic Mean [43], so that edge weights can be considered in community determination. We subsequently obtained community-depicted networks produced at maximum modularity that were visualized with easily understandable network layout algorithms.

Statistical Analysis

We obtained and compared descriptive statistics of demographic, injury, and outcome characteristics of day and night shift encounters. We also compared composition of days and night shift event logs for each care location. Differences among interval and categorical variables were examined using Wilcoxon rank-sum and Pearson chi-square tests, respectively. Differences were considered statistically significant at an $\alpha<.05$. The analysis was performed using Stata 13 [44].

Validation

Two forms of validation were conducted. In the first validation step, we compared the results of this study with the secondary analysis of data from and results of a previous study [45] in which we developed a *role-location matrix*, which is a 2×2 table of functional roles and the inpatient locations in which they typically worked via semistructured interviews with clinicians (n=21) and subject matter experts (n=22), and a review of the institutional and trauma registry protocol. We compared the functional roles and the locations in which the functional roles were found in this study to the role-location matrix. In the second validation step, we validated the collaboration patterns of pediatric trauma MTS via member-checking interviews (n=6) with care professionals (ie, pediatric trauma program director, PICU attending, and pediatric trauma nurses) that were involved in pediatric trauma care. The interviews were conducted by AD, KW, and GSD and APG as a group. During each session, the collaboration patterns of care teams were individually presented to the HCP, who were asked to comment on (1) the accuracy and completeness of the roles that were captured by location and shift; (2) whether the collaborative patterns mirrored reality or not; and (3) whether the differences between day and night

patterns for a given care location (ie, ED, PICU, or floor) were suggestive of reality.

Results

Overview

There were 413 encounters in the cohort, of which 65.9% (272/413) and 34.1% (141/413) began during day and night shifts, respectively. Compared with patients who arrived during day shifts, those who arrived during night shifts were significantly older (median age 7 vs 10 years; *P*=.04), had a higher proportion of critical trauma transfers (8.8% vs 26.2%; *P*<.001), and had a higher proportion of penetrating injuries (5/272, 1.8% vs 11/141, 7.8%; *P*<.001; Table 1). There were no significant differences in sex, injury severity score, Glasgow Coma Scale, operating room and PICU admissions, ED, PICU, hospital length of stay, and mortality.

Table 1. Comparison of demographic and encounter characteristics by shift type[a].

Variables	Day (n=272)	Night (n=141)	*P* value
Age (years), median (IQR)	7 (3-11)	10 (3-13)	.04
Male sex, n (%)	184 (67.7)	83 (58.9)	.08
Trauma activation, n (%)			<.001
Alpha	26 (9.6)	5 (3.6)	
Bravo	222 (81.6)	99 (70.2)	
Critical trauma transfer	24 (8.8)	37 (26.2)	
Origin, n (%)			<.001
Scene of injury	245 (90.1)	102 (72.3)	
Transfer	2 (0.7)	38 (27)	
Others	2 (0.7)	1 (0.7)	
Injury type, n (%)			.01

OR[f] admission, n (%)	41 (15.1)	22 (15.6)	.89
PICU[g] admission, n (%)	43 (15.8)	27 (19.2)	.39
PICU LOS (days), median (IQR)	1 (1-3)	1 (1-2)	.48
Hospital LOS (hours), median (IQR)	7 (4-32)	14 (4-41)	.21
Mortality, n (%)	7 (2.6)	2 (1.4)	.72

[a]Day shift is defined as 7 AM to 6:59 PM, whereas night shift is defined as 7 PM to 6:59 AM.

[b]ISS: injury severity score.

[c]GCS: Glasgow Coma Scale.

[d]ED: emergency department.

[e]LOS: length of stay.

[f]OR: operating room.

[g]PICU: pediatric intensive care unit.

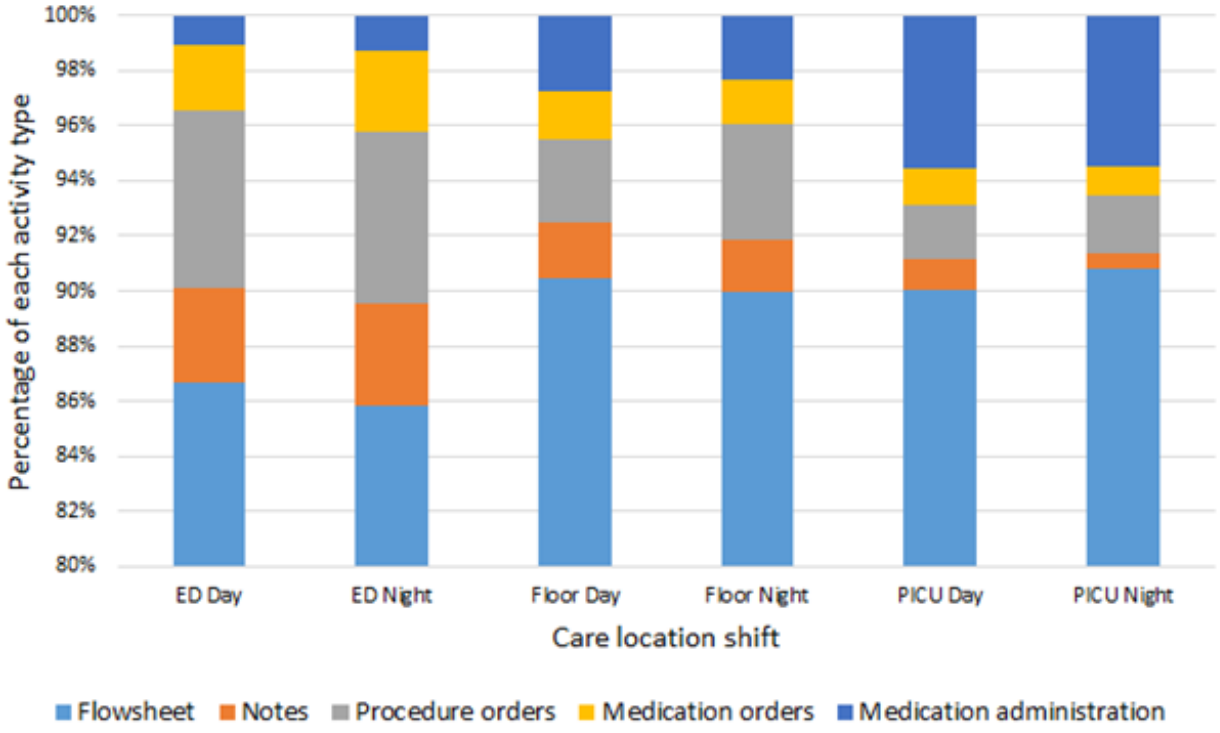
Master Event Log Characteristics

There were 837,318 events in the initial event log, respectively. Only 0.19% (1564/837,318) of the events were excluded owing to the inability to resolve the functional role of the actor. Consequently, 835,754 events remained in the master event log. Flow sheet entries accounted for 89.45% (749,000/837,318) of all events in the log. A total of 1647 unique HCPs occupying 110 functional roles were identified, of which 58 functional roles were recorded in at least 4.8% (20/413) of encounters. The ED registered nurses were recorded in all 413 encounters, whereas the ED attending, ED resident, and ED radiology technician were recorded in 98.5% (407/413), 93.2% (385/413), and 80.6% (333/413) encounters, respectively.

Comparison of Sublogs Obtained Based on Shift Type and Care Location

Figure 1 depicts the composition of the individual sublogs for each care location and shift duty. The proportions of various activities in the day and night logs for each care location were similar, with some notable differences. The ED night log contained more medication administration orders than the ED day log, which contained more flow sheet events. The floor day log contained more medication administration than the floor night, which contained more procedure-order events. The PICU day contained more notes events that the PICU night, which contained more flow sheet events.

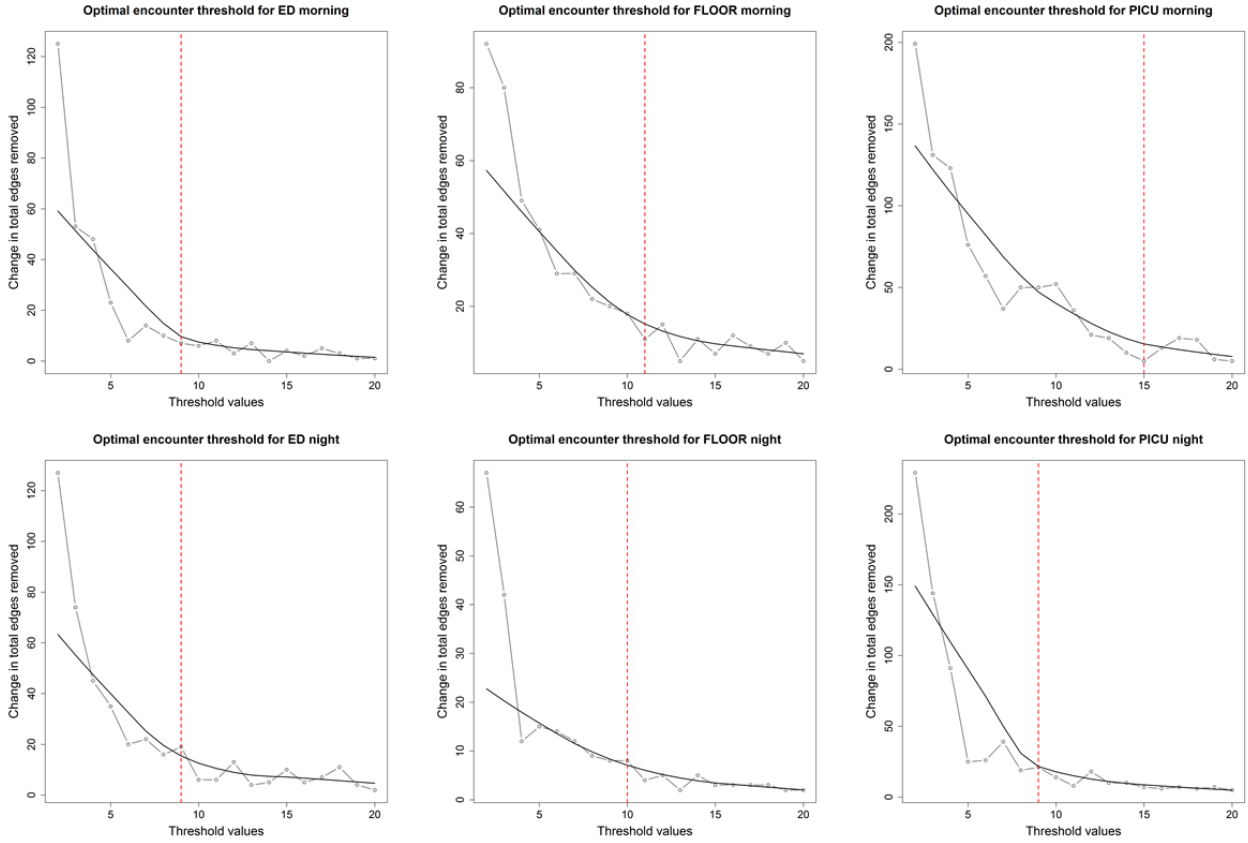
Figure 1. Comparison of the composition of various activity types by care location and shift type. ED: emergency department; PICU: pediatric intensive care unit.



Threshold Selection

Figure 2 shows the plots of the rate of change of total edges removed against increasing threshold values. The gray line and point plot show the difference in edges removed as the threshold is increased, whereas the smooth black line is the LOWESS curve. Some LOWESS curves, such as the ED morning and PICU night, have sharply defined elbows, whereas others have subtle elbows. The red vertical lines indicate the selected threshold number of shared encounters by HCPs for each event log. For both ED day and night, the threshold was determined to be 9. For the floor, 11 and 10 were selected as the thresholds for day and night, respectively, whereas for the PICU, 15 and 9 were selected as the day and night thresholds, respectively.

Figure 2. Determination of encounter threshold for each event log. ED: emergency department; PICU: pediatric intensive care unit.



Collaborative Care Teams in the Pediatric ED

Figure 3 shows the collaborative care team pattern in the ED during the day and at night visualized using the Kamada Kawai layout algorithm [46], which is a force-directed algorithm. Table 2 contains the meaning of the abbreviations used in Figure 3 and in all other network diagrams in this paper. The day pattern contained 18 nodes and 87 edges, whereas the night pattern contained 28 nodes and 160 edges. The night pattern was distinctively star-shaped and had 5 overlapping communities with the ED attending, residents, nurses, radiology technicians, and the general pediatric surgery attending and resident forming the core and belonging to all 5 communities. The day pattern had a less distinctively defined star pattern and had only 1 community. Attending-resident pairs from neurosurgery and orthopedic surgery services, and allied HCPs, including social workers, chaplains, and child life specialists, were at the periphery in both patterns. Attending-resident pairs from otolaryngology and plastic surgery were seen only in the night pattern and belonged to separate communities, whereas only the resident from the ophthalmology service was seen in the night pattern. The PICU nurse, resident, and the imaging data coordinator (IDC) were also seen in the night pattern.

Figure 3. Collaborative care team patterns in the emergency department. Left: day shift; right: night shift.

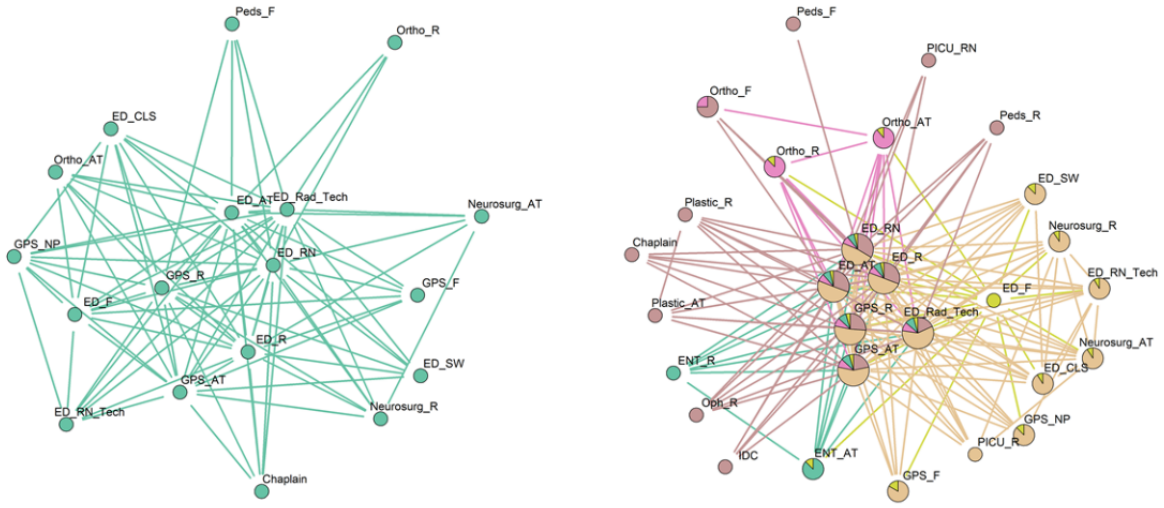


Table 2. Abbreviations used in the network diagrams.

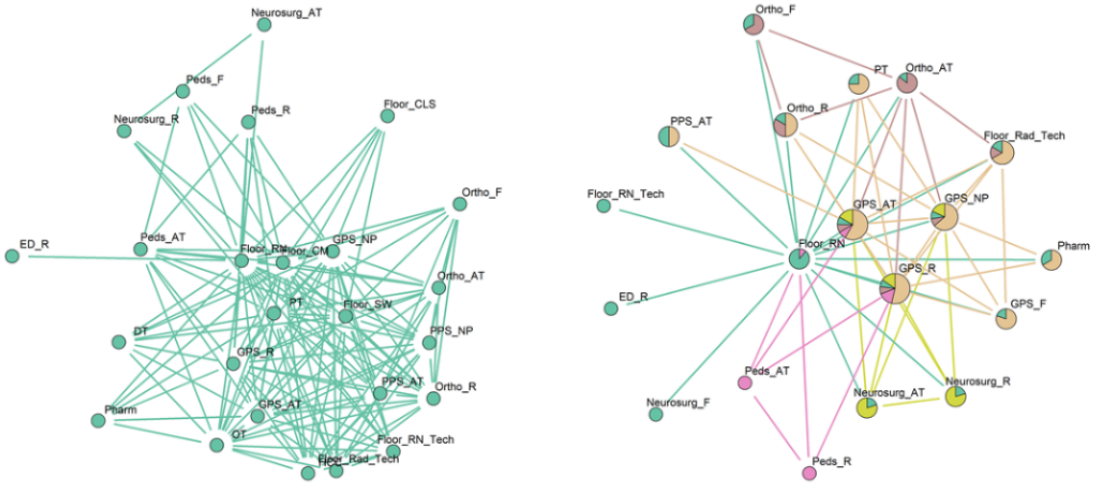
Abbreviation	Meaning
Anes	Anesthesia
AT	Attending
CLS	Child life specialist
CM	Case manager
DT	Dietitian
ED	Emergency department
F	Fellow
GPS	General pediatric surgery
HCC	Home care coordinator
IDC	Imaging data coordinator
Neuro	Neurology
Neurosurg	Neurosurgery
NP	Nurse Practitioner
Oph	Ophthalmology
Ortho	Orthopedic surgery
OT	Occupational therapy
PA	Physician assistant
Peds	Pediatrics
Pharm	Pharmacist
PICU	Pediatric intensive care unit
PMR	Physical medicine and rehabilitation
PPS	Pediatric pain service
PT	Physical therapist
R	Resident
Rad_Tech	Radiology technician
RN	Registered nurse
RN_Tech	Nurse technician
SW	Social work

Collaboration Patterns of Care Teams in the Floor

Figure 4 shows the collaboration pattern on the floor during the day and at night visualized using the large graph layout [47]. The day pattern contained 24 nodes and 135 edges, whereas the night pattern contained 19 nodes and 55 edges. The bedside nurse was at the center of both patterns. Functional roles present in the day pattern but absent in the night pattern were home care coordinators, case managers, social workers, child life specialists, occupational therapy, and dietitians. The ED resident was present in the night pattern but not in the day pattern. One community was identified in the day pattern, whereas 5 overlapping communities were identified in the night pattern with the neurosurgery, orthopedic surgery, and pediatric services having separate communities and the general pediatric surgery-resident and general pediatric surgery attending belonging to all 5 communities.

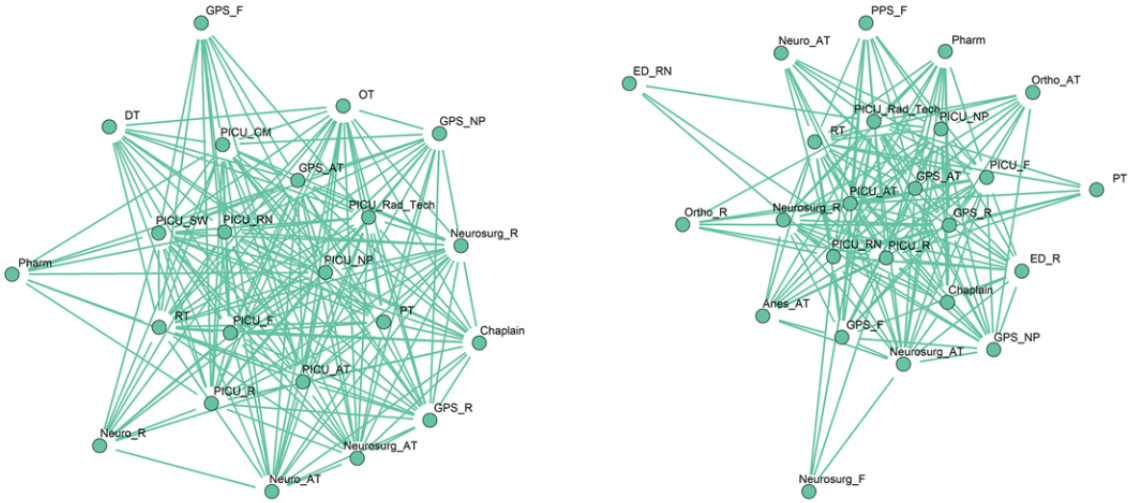
Figure 4. Collaborative care team pattern on the floor. Left: day; right: night. Only one community was identified in the day pattern while 5 communities (different colors) were identified in the night pattern.



Collaboration Patterns of Care Teams in the PICU

Figure 5 shows the day and night collaborative care team pattern in the PICU visualized using the Frutchterman–Reingold layout algorithm [48]. The day pattern contained 30 nodes and 283 edges, whereas the night pattern contained 24 nodes and 175 edges. Both collaboration patterns had a large spherical core made up of functional roles from the PICU, general pediatric surgery, neurosurgery, and neurology services (day pattern only), and few *appendages* that include functional roles from the orthopedic surgery, ophthalmology and pediatric pain service. One community was identified in both the patterns. Functional roles present in the day pattern but absent in the night pattern were unit case managers, social workers, occupational therapists, and dietitians. Functional roles present in the night pattern but absent in the day pattern include the ED resident, ED nurse, orthopedic surgery team, and anesthesiology attending.

Figure 5. Collaborative care team patterns in the pediatric intensive care unit. Left: day; right: night.



Validation

In a previous study that used semistructured interviews with care professionals [45], we identified 56 roles involved in pediatric trauma care across all care locations. In this study, we identified a total of 110 functional roles and 58 frequent functional roles across all locations. Eight functional roles were identified in a previous study but not in this study. These roles were ED documenting nurses, charge nurses, emergency medical services personnel, security, family or caregiver, pediatric trauma manager, perfusionist, and in-hospital transport team. A total of 54 functional roles were identified in this study but not in a previous study. Most of these roles belonged to specialty service roles that were not frequently involved in patient care. Of the 58 frequent roles identified in this study, 15 (26%) were not identified in the prior study. These roles included dietitians, IDCs, home care coordinators, ophthalmology service, otolaryngology service, neurology service, pediatric pain service, and plastic surgery services.

A comparison between this study and the prior study showed that the locations of the functional roles they had in common mostly matched. For example, both studies confirmed that ED nurses, ED residents, and PICU nurses go to the floor, usually during patient transport. However, few differences exist. For example, in a previous study, it was revealed that the PICU attending, PICU fellow, and respiratory therapist responded to

alpha traumas in the ED both during the day and at night, but this was not captured in this study.

The 6 HCPs who were interviewed for this study found the composition of the derived care teams to be largely accurate. However, they pointed out that some functional roles were not accurately captured. For example, PICU attendance, PICU fellows, and respiratory therapists were not identified in the ED collaborative care teams (Figure 3). This was attributed to the fact that PICU team members who responded to traumas rarely did any documentation while in the ED. They also pointed out that the team pattern for the PICU night did not capture the ED social worker who usually covers the PICU at night, and the floor care team patterns were missing functional roles from anesthesiology.

Regarding interactions among roles and communities that were identified, clinicians confirmed the general pediatric surgery coordinated care among specialist services and understood why they belonged to multiple communities. Clinicians explained why only 1 community was identified in the PICU, as concerted efforts have been made to improve coordination of care between the PICU and surgical services, and the PICU characteristically performed multidisciplinary rounds with other nonsurgical services and allied HCPs. However, clinicians acknowledged that collaboration with the orthopedic service, particularly in the PICU, can be further improved. Clinicians confirmed that the neurosurgery service was well integrated into the trauma team in the ED.

Discussion

Principal Findings

We compared diurnal differences in the composition and organization of collaborative care teams at 3 care locations in a level I pediatric trauma center using EHR data. Our study is unique in several ways. First, we introduced a heuristic for determining the threshold number of shared patient encounters for interaction between HCPs. The heuristic method allows a more objective approach to threshold selection. In 67% (4/6) of the scenarios, we obtained distinct elbow points, whereas in the other 33% (2/6) of the scenarios, we easily identified the appropriate threshold on closer examination. Second, we used an overlapping community detection algorithm that allowed a functional role to be part of multiple communities to reflect ad hoc clinical collaborations that clinicians form to address the unique needs of patients. In 33% (2/6; ED night and floor night) of the scenarios, we identified multiple overlapping communities suggestive of MTS, whereas in the other 67% (4/6), only a single community was identified. Third, we confirmed the presence of MTS using the EHR data. We also showed that the EHR data complemented interview data for identifying functional roles. Although interview data were especially helpful in identifying team members or roles who rarely document in the EHR, the EHR data enabled a more comprehensive and systematic analysis and identification of functional roles (56 functional roles identified with interviews vs 110 with EHR data).

There were 3 significant differences among patients who arrived during night shift compared with those who arrived during the day time. The patients who arrive at night tend to be older (median age 10 vs 7 years) and have penetrating injuries (11/141, 7.8% vs 5/272, 1.8%). This is likely related to prevailing epidemiological conditions and is consistent with what has been reported in the literature [49,50]. These patients also tended to arrive as transfers from other facilities (38/141, 27% vs 2/272, 0.7%). A higher percentage of transfers received at night reflects operational circumstances. Our pediatric trauma center is a level I trauma center that serves as a referral center for a large area. The decision to transfer patients is made by the originating facility, but several factors determine when patients physically arrive at our facility. First, the patients must be stabilized (to some extent) at the originating facility to ensure that they will survive transportation before departing the originating facility. Second, the level of staffing at the originating facility may influence transfer decisions such that patients who would be unsafe to manage at night when staffing is low are transferred to us after stabilization. Third, the distance of the originating facility and logistics of transportation can influence when transfer patients physically arrive at our facility.

There were some notable differences in the composition of event logs at various locations. The lower proportion of flow sheet activities in the ED is likely because of the relatively short time (usually <60 minutes) spent in the ED as compared with the entire hospital stay (usually days). The higher proportion of flow sheets and medication activities in the PICU compared with the ED and the floor reflects the intensive care provided in the PICU. The higher proportion of procedure orders in the ED compared with both the floor and PICU suggests the initiation and delivery of immediately necessary and likely lifesaving interventions.

Important differences were observed between the collaborative care teams in the ED during the day and at night. Compared with the day pattern, the night pattern had a better-defined core team made up of ED and general pediatric surgery personnel and involved more specialty services, which was reflective of the nature and severity of injury of patients presenting at night [8,51,52]. In addition, the neurosurgery team was part of both day and night patterns. However, in the night pattern, the neurosurgery team was part of the main community that included the core team and allied HCPs. This suggests that the neurosurgery team has a close relationship with the trauma team in the ED, which was confirmed by the interviewed clinicians. In addition, the collaborative care team in the ED at night included roles that did not exist in the day pattern. These roles include the IDC, a role that is responsible for uploading imaging data from transferring hospitals that do not use an interoperable EHR (which can be explained by the significantly higher number of trauma transfers arriving at night), and the PICU resident and PICU nurse, which suggested greater involvement at night, possibly to facilitate faster admission to the PICU). The orthopedic surgery attending and resident, and the ED resident and ED nurse were captured by the night pattern in the PICU but not during the day, which suggested greater involvement in PICU-related activities of trauma patients at night.

Compared with the day pattern, multi-team structures were more pronounced at night. Constituent specialty teams usually consisted of attending-resident pairs, except for the

ophthalmology service, which consisted only of residents. Validation with clinicians confirmed that ophthalmology attending physicians do not take in-house night duty calls, given the seldom emergent nature of many ophthalmologic problems. Conspicuous multi-team structures reflected the presence of fewer ancillary support services that often serve as coordinators of care. In the ED, as ancillary support services were present at night, this may be reflective of the greater need of the patients received at night and the difficulty in coordination of care among the various services. On the floor, where ancillary support services are not present at night, this suggests that ancillary support staff play important roles in coordinating care and ensuring that various teams function as a unit. However, this was not the case in the PICU, where the night collaboration pattern was essentially similar to the day pattern despite the absence of ancillary support staff at night.

There are a number of reasons for the observed variations between day and night networks. As described, the level of staffing during the day was higher than that at night. During the day, more functional roles and support staff (care coordination, social work, etc) are present, and they participate in collaboration between teams. At night, some functional roles and nonessential staff are not available, which changes the dynamics of work and collaboration. In addition, more care activities (patient rounds, elective procedures, discharge planning, etc) occur during the day as opposed to nighttime. These activities create the need and opportunity for close collaboration compared with nighttime. Finally, there are likely differences in the manner of collaboration, for example, the use of non-EHR–based communications such as telephone and paging is more common during the night when team members tend to be more geographically dispersed, as opposed to during the day when they are geographically closer or physically working together.

In addition to organizational factors, methodological issues may also account for the variations. Only a single community was identified at all locations during the day. Although it is probable that the specialty teams actually do work very closely together during the day, it is likely that they do in a multi-team setup, which we did not identify by overlapping community detection. This may be owing to several reasons. The data may lack adequate *power* to detect overlapping communities during daytime. Certainly, smaller teams could be identified using cliques, which are unique subnetworks containing at least three nodes that are all connected to one another by edges. However, given the number of nodes involved, hundreds of overlapping cliques would be identified, which would be difficult to interpret. Another factor could be threshold selection. It is possible that by selecting different thresholds for day networks, we could identify overlapping communities. However, because the weights of the edges are considered by the community detection algorithm, such a sensitivity analysis was not required. Nevertheless, a narrow sensitivity analysis of the day networks using +/−1 the selected threshold did not show any major difference in terms of communities (Multimedia Appendices 1-3).

This study has several implications: the methodology can be adapted and used in other settings to identify and study MTS structures in an efficient manner. The methodology can also be adapted to study how MTS evolves over the care timeline of patients and identify areas in need of improvement. In-depth analysis of MTS across time, location, and team members using EHR metadata can provide insights to support management and operational decisions. For example, it can be used to derive insights into how HCPs and care teams organize themselves given the realities of *actual work*, rather than how they are supposed to organize according to protocols. Such insights can be used to inform staffing and team composition decisions, team training and development efforts, and complement efforts to improve collaboration and coordination to improve team-based health care delivery. In addition, the ability to compare temporal patterns in MTS dynamics based on EHR metadata enables assessment and evaluation of the impact of any quality improvement and intervention efforts aimed at improving MTS performance.

This study had several notable limitations. First, by only EHR data, we did not capture other important teamwork-related activities such as face-to-face and telephone conversations, which are a major part of clinical activities [53]. Second, we were less likely to capture functional roles that documented infrequently in the EHR. For example, we were unable to capture the PICU attending and PICU fellows in the ED patterns for both day and night, as these 2 roles rarely used the EHR for documentation while in the ED. We were also unable to capture several other HCPs, such as emergency medical services personnel, security, family and/or caregiver, pediatric trauma manager, perfusionist, and in-hospital transport team who rarely or never use the EHR for a trauma case, but are an integral part of the care team, as revealed by interview data. Other methods, such as in-depth interviews or direct observations, can be used to overcome these limitations. Third, our method for determining the functional roles was based on heuristics. Consequently, it is possible that not all possible roles were identified, and that some of the assigned functional roles were inaccurate. Nevertheless, as demonstrated, the methodology performs quite well; future EHR systems should be designed to support functional roles, which are the appropriate unit of clinical collaboration, rather than individuals; for example, clinical documentation could be primarily based on functional roles, but signed as individuals. Such systems have the potential to optimize collaborative work to deliver improved care and enable robust research using EHR data.

Conclusions

We identified and described diurnal variations in MTS and collaborative care teams at various locations and stages of care, as well as various shift types in a pediatric trauma center using EHR data. We validated our results using qualitative data and showed that the derived structures can accurately represent reality. The methodology described can be adapted to study how MTSs evolve over time and across locations, and the insights can be used to support management and operational decisions.

Multimedia Appendix 1
Sensitivity analysis of the collaborative care team patterns for the emergency department day shift using +/−1 the selected threshold. At a lower threshold of 8, a minor overlapping community that included the orthopedic resident (Ortho_R) and imaging data coordinator (IDC) as additional members was identified.
[PNG File , 772 KB - jmir_v24i2e30351_app1.png]

Multimedia Appendix 2
Sensitivity analysis of the collaborative care team patterns for the floor day shift using +/−1 the selected threshold. At a threshold of 10, functional roles with single connection to the floor nurse were identified. However, these functional roles were removed as the threshold is increased with no functional role having a single connection at a threshold of 12.
[PNG File , 712 KB - jmir_v24i2e30351_app2.png]

Multimedia Appendix 3
Sensitivity analysis of the collaborative care team patterns for the pediatric intensive care unit day shift using +/−1 the selected threshold. At a higher threshold of 16, a minor community including the neurology resident as the only additional member was identified.

Abstract

Background: Alcohol moderation (AM) interventions may contribute to better treatment outcomes and the general well-being of cancer survivors.

Objective: This study evaluates the effectiveness, cost-effectiveness, and cost-utility of MyCourse, a digital AM intervention, compared with a noninteractive digital information brochure for cancer survivors.

Methods: A health economic evaluation alongside a pragmatic 2-arm parallel-group randomized controlled trial was conducted with follow-ups at 3, 6, and 12 months after randomization. The study was conducted on the web in the Netherlands from 2016 to 2019. Participants were adult 10-year cancer survivors drinking over the Dutch-recommended drinking guidelines (≤7 standard units [10 g of alcohol] per week) with the intention to moderate or quit drinking. Overall, 103 participants were randomized and analyzed: 53 (51.5%) in the MyCourse group and 50 (48.5%) in the control group. In the MyCourse group, participants had access to a newly developed, digital, minimally guided AM intervention, *MyCourse–Moderate Drinking*. The primary outcome was the self-reported number of standard drinks (10 g of ethanol) consumed in the past 7 days at the 6-month follow-up. The secondary outcome measures were alcohol-related problems as measured by the Alcohol Use Disorders Identification Test (AUDIT) and treatment satisfaction. For the health economic evaluation, health care costs, costs because of productivity losses, and intervention costs were assessed over a 12-month horizon.

Results: Alcohol use at the 6-month follow-up decreased by 38% in the MyCourse group and by 33% in the control group. No difference in 7-day alcohol use was found between the groups (*B*=2.1, 95% CI −7.6 to 3.1; *P*=.22) at any of the follow-ups. AUDIT scores for alcohol-related problems decreased over time in both groups, showing no significant difference between the groups (Cohen *d*=0.3, 95% CI −0.1 to 0.6; *P*=.21). Intervention costs per participant were estimated at US $279 for the MyCourse group and US $74 for the control group. The mean societal costs were US $18,092 (SD 25,662) and US $23,496 (SD 34,327), respectively. The MyCourse group led to fewer gained quality-adjusted life years at lower societal costs in the cost-utility analysis. In the cost-effectiveness analysis, the MyCourse group led to a larger reduction in drinking units over time at lower societal costs (incremental cost-effectiveness ratio per reduced drink: US $ −1158, 95% CI −1609 to −781).

Conclusions: At 6 months, alcohol use was reduced by approximately one-third in both groups, with no significant differences between the digital intervention MyCourse and a noninteractive web-based brochure. At 12 months, cost-effectiveness analyses showed that MyCourse led to a larger reduction in drinking units over time, at lower societal costs. The MyCourse group led to marginally fewer gained quality-adjusted life years, also at lower societal costs.

KEYWORDS

alcohol; brief interventions; cancer survivors; effectiveness; cost-effectiveness; eHealth; mobile phone

Introduction

Alcohol use is one of the main lifestyle factors influencing cancer development, and there is also evidence that it negatively affects the development of new malignancies [1], cancer treatment success [2], and mortality rates [3]. Therefore, it is recommended that cancer survivors quit or minimize alcohol use [4]. Currently, drinking rates among cancer survivors are comparable with drinking rates among the general population, with estimates that 5.1% of cancer survivors are heavy drinkers (>2 drinks per day for men; >1 drink per day for women) versus 6% of the general population [5].

Studies evaluating alcohol moderation (AM) interventions in cancer survivors are scarce. AM interventions offer support in reducing or quitting alcohol use and can range from brief face-to-face interventions by health care providers to smartphone app–based interventions. A 2018 review on smoking and alcohol cessation interventions in patients with head and neck cancer and oral dysplasia [6] found no randomized controlled trials (RCTs) evaluating AM interventions for head and neck cancer survivors, and neither did a recent meta-analysis on AM distance–based interventions for cancer survivors of all cancer types [7]. The latter review identified a few studies that incorporated AM as a module in a broader lifestyle program and found insufficient evidence of the interventions' effectiveness on AM. A qualitative study assessed patients' experiences with a face-to-face alcohol cessation program in bladder cancer survivors undergoing surgery; results indicated that major bladder surgery was a useful cue for motivating patients with cancer to reconsider the consequences of risky drinking, and the alcohol intervention was seen as a relevant offer around the time of surgery [8]. Facilitating access to AM interventions for cancer survivors via distance-based interventions, particularly digital ones, might be an effective and highly accessible means to provide the growing population of cancer survivors with AM support [9].

Studies among the general population have shown that brief face-to-face and digital interventions can be effective in reducing alcohol consumption. An individual patient data meta-analysis comparing guided and unguided low‐intensity internet interventions for AM found that participants in both types of interventions used on average 50 g less ethanol per week than the controls (5.02 standard units of 10 g of ethanol, 95% CI −7.57 to −2.48) [10]. A conventional meta-analysis evaluating brief AM interventions delivered in a primary care setting found that participants used on average 20 g (95% CI −28 to −12) less ethanol per week than the controls [11]. A meta-analysis of personalized digital interventions found similar results when comparing the interventions to nonintervention control groups (23 g less ethanol per week in participants receiving a digital intervention compared with no or minimal interventions, 95% CI 15-30 based on 41 studies) and found no difference in reduction of alcohol consumption in personalized digital interventions compared with face-to-face interventions, based on 5 studies [12].

Brief alcohol interventions in primary care settings have been found to be cost-effective for the general population [13]. Referral to a digital AM intervention was a cost-effective strategy in 3 European countries [14]. A game with tailored feedback on alcohol awareness was found to be cost-effective from the societal perspective in reducing the number of drinks in subgroups (older age and lower educational level) of adolescents [15]. We found no studies on the cost-effectiveness of digital AM interventions for cancer survivors, but cost-effectiveness is a key element in the knowledge base needed for policy decisions regarding implementation and financing of digital interventions [16,17]. It is unknown what results in effectiveness and cost-effectiveness are to be obtained from a digital AM intervention that is tailored to cancer survivors, as cancer survivors have increased feelings of distress and symptoms of anxiety and depression [18,19], and they could have additional benefits of AM (eg, in terms of treatment outcomes) [2].

Therefore, it was deemed necessary to evaluate both the effectiveness and cost-effectiveness of a minimally-guided digital intervention aimed at supporting cancer survivors to moderate their alcohol use: *MyCourse–Moderate Drinking* (in Dutch: *MijnKoers–Minderen met Drinken*). The development process and a detailed intervention description are provided elsewhere [20]. In this study, we aim to answer the following research questions: (1) Is the digital, minimally guided AM intervention *MyCourse–Moderate Drinking* more effective than a digital AM brochure to moderate alcohol use? (2) From a societal perspective, is the digital, minimally-guided AM intervention *MyCourse–Moderate Drinking* more cost-effective than a web-based AM brochure in terms of incremental costs per reduced weekly drink and incremental costs per quality-adjusted life year (QALY) gained?

We expect the MyCourse intervention to be both more effective and more cost-effective than a web-based brochure on AM.

Methods

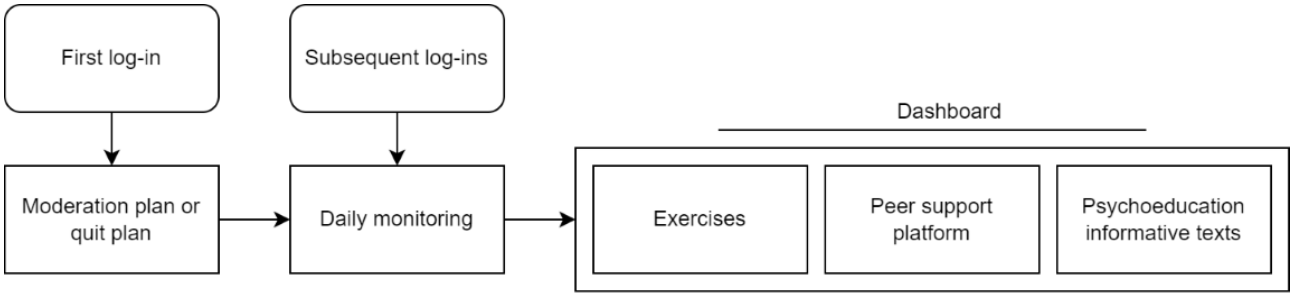
Design

In a 2-arm, individually randomized RCT conducted in the Netherlands between 2016 and 2019, the effectiveness and cost-effectiveness of the *MyCourse–Moderate Drinking* intervention for cancer survivors was evaluated. The first inclusion was on November 28, 2016, and the last inclusion was on September 3, 2018. The last follow-up measurement was collected on September 30, 2019. The study was prospectively registered in the Netherlands Trial Register (NTR6010). The planned inclusion period was extended by several months to recruit as many participants as possible. An extensive description of the study protocol has been provided in the study by Mujcic et al [20]. This study was part of a set of 2 separate RCTs on digital interventions for AM and smoking cessation in cancer survivors. The results of the RCT on the smoking cessation intervention (*MyCourse–Quit Smoking*) will be published separately. Ethical approval was obtained from an accredited medical research and ethics committee in the Netherlands (Toetsingscommissie Wetenschappelijk Onderzoek Rotterdam NL55921.101.16).

Participants and Recruitment

Participants could find out about the study and apply for participation via a web-based screening questionnaire on a dedicated website that was created for the study. Participants were eligible if they were aged ≥18 years, had been diagnosed with any form of cancer in the past 10 years, had a PC or laptop and internet connection at home, had the ability and intention to participate in the study for 12 months, used alcohol more than recommended by Dutch guidelines (operationalized as drinking >7 European standard units of alcohol [70 g of ethanol] per week), and had the intention to reduce their alcohol use. The exclusion criteria were insufficient mastery of the Dutch language, pregnancy or self-reported suicidal ideation, acute psychosis, severe alcohol dependence, dementia, or severe depression at the time of screening. The same screening questionnaire procedure was used for both this trial and the similar parallel trial evaluating a smoking cessation intervention [20]. Some people were eligible for both trials; if so, they were allowed to participate in only one of the trials, based on their own choice (Figure 1 [20]).

Figure 1. Intervention flowchart (adapted from Mujcic et al [20]).



Both web-based and offline strategies were used for the recruitment of participants. Targeted web-based advertisements on social and other media, and on search engines referred those interested to the website and the web-based screening questionnaire. Patient organizations, oncology departments in hospitals, and meeting centers for cancer survivors were contacted and offered promotional material (flyers and posters) to help refer cancer survivors to the website.

Procedure

After filling out the screening questionnaire on the study website, applicants were informed by a computer-generated email about their eligibility for study participation. Those eligible were sent an invitation email containing all relevant patient information, the informed consent form, and a link to register. Eligible cancer survivors had up to 30 days to decide about their participation, and during this period, they could contact the research team or an independent physician with questions. After they had digitally signed the informed consent form, they were sent the baseline questionnaire. Immediately after completion of the baseline measurement, participants were automatically allocated to either the MyCourse or the control group arm in a 1:1 ratio through adaptive randomization (minimization of baseline imbalances with regard to age, sex, and education level) through a server-sided hypertext preprocessor script using a Mersenne twister random number generator. Participants received an email confirming their allocation and containing their username and instructions on how to log on. They were not blinded to study condition allocation (the participants were not explicitly informed about their allocation, but recruitment material included a video showing interactive elements of MyCourse, making it plausible that the participants knew they were not allocated to the

experimental condition. Thus, we cannot consider the participants blinded). At 3, 6, and 12 months after randomization, the participants received a link to the web-based questionnaire via email. The nonresponders received up to 3 reminder emails, and in case of continued nonresponse they were contacted by telephone. For each completed follow-up assessment, they were reimbursed with €25 (approximately US $30). As this was a pragmatic RCT, patients in both groups were not asked to refrain from using additional support if they wanted to.

MyCourse Group

MyCourse–Moderate Drinking is a newly developed, minimally-guided, digital intervention aimed at supporting AM in cancer survivors. It is based on well-established therapeutic approaches: motivational interviewing, cognitive behavioral therapy, and acceptance and commitment therapy, as well as a Dutch digital AM intervention previously found to be effective in the general population [21]. Throughout the development process, cancer survivors and professional experts in eHealth, oncology, and substance use disorders were involved through a series of interviews and focus groups. The intervention was accessible through PC, tablet, and smartphone. At first log-in, the participants were guided by website prompts in either setting up a quit plan or a moderation plan, including a quit date or moderation date, after which they would gain access to several exercises, a web-based diary for self-monitoring of alcohol use and contextual cues, and a peer support platform (See Figure 1 adapted from Mujcic et al [20] and Multimedia Appendix 1 [22]). MyCourse could be used by the participants whenever they chose to, but they were encouraged to log in daily for at least 4 weeks. The intervention and its development process have been extensively described elsewhere [20].

Control Group

The control group consisted of a noninteractive web-based static information brochure on the risks of (increased) alcohol use and tips on how to moderate or quit drinking. It was accessible to the participants at any time by logging into the website. The brochure contained both general information on AM and information specifically relevant to cancer survivors. However, no interactive elements of the MyCourse condition were present, and the participants did not receive reminders.

Additional Support

Both groups were provided with the contact details of the national AM information line (in Dutch: *Alcoholinfo-lijn*), which could help refer participants to additional support if they deemed the received intervention to be insufficient. At the end of the study, at 12 months after randomization, the participants in the control group received access to the digital intervention, *MyCourse–Moderate Drinking*, which was offered to the MyCourse group.

Measures

Baseline

At baseline, we assessed the sociodemographic characteristics and type of cancer. Alcohol use was assessed using Timeline Followback (TLFB) self-reports [23] (number of standard drinks consumed in the past 7 days, ie, 7-day alcohol use). Problematic alcohol use was assessed using the 10-item Alcohol Use Disorders Identification Test (AUDIT) questionnaire. In participants reporting smoking, we assessed tobacco use with TLFB self-reports and nicotine dependence using the 6-item Fagerstrom Nicotine Dependence Test questionnaire [24]. Socially desirable answering tendencies, which may have affected the reliability of the self-reported questionnaire data, were assessed using the Marlowe-Crowne Social Desirability Scale (MCSDS) [25]. We used the 5-level EuroQol 5 Dimension (EQ-5D-5L) [26] measure to assess QALYs. The Medical Outcomes Study Short Form [27] was used to calculate the Short Form 6-dimension (SF-6D) quality of life measure using the Brazier algorithm [28].

Follow-up Measurements

At all follow-up measurements, we assessed alcohol use with TLFB self-reports, quality of life using the EQ-5D-5L and the Medical Outcomes Study Short Form, productivity and health care costs, and use of other AM support. Intervention use variables (eg, number of log-ins and use of major content elements) were collected automatically. The AUDIT questionnaire was administered at the 6- and 12-month follow-ups. At the 3-month follow-up, treatment satisfaction was assessed using a Dutch translation of the German adapted Client Satisfaction Questionnaire (Fragebogen zur Messung der Patientenzufriedenheit; Patient Satisfaction Questionnaire [ZUF-8]) [29]. The use of additional support for AM was retrospectively assessed at follow-up.

Primary and Secondary Outcome Measures

The primary outcome measure was 7-day alcohol use (number of standard drinks; 1 standard drink=10 g of ethanol) at the 6-month follow-up measured by TLFB self-reports. The 6-month assessment was the primary end point, as the studies that formed the basis of our power analysis were based on outcomes at the 6-month follow-up and it is a common end point in alcohol trials [30]. Those who reported no drinking at all in the past 7 days were considered abstinent (score: 0/1). Secondary outcome measures were AUDIT problematic alcohol use (score: 0-40), ZUF-8 treatment satisfaction (score: 8-32), EQ-5D-5L quality of life (score: 0-1), health care costs, and productivity loss.

Costs

Costs were calculated from a societal perspective for the index year 2019. Intervention costs included intervention depreciation costs, costs for hosting the website, technical support, and recruitment costs (which consisted of both advertising costs in web-based and offline media as well as printing costs of promotional material). Recruitment costs were included as they were considered an essential part of the MyCourse and control groups. Health care costs were calculated by multiplying the number of reported contacts with a health care professional with the standard unit cost prices for the Netherlands [31]. Health service costs stemmed from contacts with specialized somatic and mental health care, plus the patients' out-of-pocket costs for home care, but travel costs were not included because, in both groups, the interventions were delivered over the internet. Other health care costs included appointments for physiotherapy,

alternative medicine, and social work. Medication costs were calculated by multiplying the reported dose of a drug with its unit cost price [32].

Productivity loss included costs from absenteeism and presenteeism, calculated according to the friction cost method, meaning productivity losses were limited to a maximum of 85 days, after which production losses cease to exist because the sick employee has been replaced by another and calculated using an elasticity factor of 0.8 as there is not a strict 1:1 relation between days not worked and productivity losses. Cost data related to health care use and productivity loss were assessed using the Trimbos/Institute for Medical Technology Assessment questionnaire for costs associated with psychiatric illness [33] at all follow-up assessments. Cumulative societal costs over the entire follow-up period of 12 months were calculated from the sum of health care costs and productivity losses. Costs were converted from euros to US dollars using purchasing power parities for the reference year 2019. No discount rate was applied as the follow-up period was 12 months.

Sample Size

The sample size was based on conventional levels of statistical significance ($\alpha \leq .05$). On the basis of the average of 2 previous RCTs on very similar self-help interventions in the Netherlands versus a control group [21,30,34], a Cohen *d* effect size of 0.40 was expected. Using the power calculation package pwr for R 3.0.1 (R Foundation for Statistical Computing) [35], we calculated that a sample size of 2 × 57 participants in the case of 1-sided testing led to a power of 0.77 or a power of 0.66 in the case of 2-sided testing. The choice for 1-sided testing was discussed in the previously published protocol paper [20].

Statistical Analyses

Imputation of Missing Data

Except for the ZUF-8 (treatment satisfaction) questionnaire, all primary and secondary outcome measures were analyzed in accordance with the intention-to-treat principle. To that end, missing data for primary and secondary outcome measures, and costs, were multiple-imputed using the predictive mean matching method from the mice package in R [36]. For each missing observation, 50 imputations were created. The responses to the ZUF-8 questionnaire were not imputed.

Effect Evaluation

Alcohol use in the past 7 days (count data 0, 1...,N) was analyzed using robust estimation of generalized linear mixed models from the robustlmm package in R [37], as the data did not fit well into any of the commonly supported distributions. Imputation of missing values before running a generalized linear mixed model allowed us to consider all variables that could have affected the dropout. Covariates in the model were the minimized variables (gender, age, and education) and the MCSDS (to statistically account for any social desirability of responses). Model estimates, Cohen *d*, 95% CIs, and *P* values were reported. Differences over time and between the groups on AUDIT problematic alcohol use and ZUF-8 patient satisfaction scores were analyzed using a linear mixed model in the lme4 package in R [38]. We used 1-sided testing and an α of .05 as described in the study protocol [20].

Cost-effectiveness Analyses

An economic evaluation was conducted alongside the RCT in concordance with the Consolidated Health Economic Evaluation Reporting Standards Statement [39] and following the approach by Drummond et al [40]. QALYs over the entire follow-up period were computed using the Dutch tariff (utility weights) [41] and the area under the curve method. The incremental cost-effectiveness ratio (ICER) was calculated as follows:

$$ICER = (C_1 - C_0) / (E_1 - E_0) \quad \textbf{(1)}$$

where C refers to costs, E refers to effects, and the subscripts 0 and 1 refer to the MyCourse and control arms, respectively. We generated 2500 nonparametric bootstrapped samples and plotted the corresponding incremental costs and incremental effects on a cost-effectiveness plane. Both ICER per QALY and ICER per reduced weekly drink were calculated from the following 4 perspectives: societal, health care, productivity loss, and intervention cost only. Cost-effectiveness acceptability curves (CEACs) were also drawn to assess the likelihood that the experimental intervention will be deemed cost-effective given a series of willingness-to-pay ceilings.

Sensitivity Analyses

The robust regression on the mice-imputed data was the main analysis. We conducted several sensitivity analyses to assess effectiveness and cost-effectiveness using QALYs based on the SF-6D (instead of the EQ-5D-5L), imputation using the Amelia II package instead of the mice package, Winsorization of costs, and different statistical models (Multimedia Appendix 1).

Results

Sample Characteristics

The participant flow and retention rates are shown in Figure 2. Of the 2346 ineligible people, 1684 (71.78%) had had no diagnosis of cancer in the past 10 years. A total of 321 cancer survivors were eligible for participation in the study, of whom 206 (64.2%) declined to participate, and 34 (10.6%) participated in the study on smoking cessation instead. Of 115, 10 (8.7%) cancer survivors did not complete the baseline questionnaire and were therefore not randomized, and 2 (1.7%) cancer survivors withdrew during the course of the study. This resulted in a study sample of 103 participants; of whom, 53 (51.5%) were randomized into the experimental MyCourse group and 50 (48.5%) were randomized into the control group. Table 1 presents the sociodemographic and other characteristics of the sample. In summary, the mean age of the participants was 54.6 (SD 11) years, 16.5% (17/103) were men, most were married or living with a significant other (70/103, 68%), and 31.3% (32/103) had a middle or low educational level. Breast cancer was the most frequently reported type of cancer (65/103, 63.1%). Problematic alcohol use as measured by the AUDIT was significantly higher in the MyCourse group than in the control group as calculated using the Welch 2-sample *t* test (2-tailed) for continuous variables ($t_{100.9}$=2.03; *P*=.02). No difference was found in the proportion of missing data between the groups

(χ^2_1=2.5 *P*=.11; see Multimedia Appendix 2 for details). Data were missing because of loss to follow-up (participants who did not respond after several reminders by email and telephone).

[a]Percentages may not add up to 100 because of rounding.

[b]AUDIT: Alcohol Use Disorders Identification Test.

Treatment Uptake and Satisfaction

Overall, patients were most satisfied in the MyCourse group (Cohen d=0.81; $t_{61.5}$=3.42; P<.001; see Multimedia Appendix 2 for the mean scores). Most participants logged in at least once (46/53, 87%). The average number of times the participants logged in was 31.4 (SD 50.5), with a median of 8 (range 0-254). For those who logged in at least once, the period between the first and last log-in was on average 105.6 (SD 125.6) days with a median of 45 days. There was little use of AM support besides MyCourse; no support was reported most often (control group: 26/50, 52%; MyCourse group: 26/53, 49%) and some connected with others who were also moderating their drinking (control group: 4/50, 8%; MyCourse group: 5/53, 9%). Of 103 participants, only 1 (0.9%) reported having had contact with a health care professional about AM.

Incremental Effects

Primary Outcome

Despite the randomization, there was an apparent, although nonsignificant, difference between the groups in baseline alcohol use (Table 1). The number of drinks consumed in the past week at the 6-month follow-up decreased by 38% in the MyCourse group and by 33% in the control group and even more at the 12-month follow-up—by 48% in the MyCourse group and 38% in the control group (Table 2). No difference in 7-day alcohol use was found between the groups (unstandardized regression coefficient, B=−2.1, 95% CI −7.6 to 3.1; P=.22; Table 3) at 6 months—or at any of the other follow-up assessments—when controlling for MCSDS score, baseline alcohol use, gender, age, and education.

Table 2. Drinking behavior outcomes at the 3-, 6-, and 12-month follow-ups (N=103)[a].

Variable	MyCourse (n=53)	Control (n=50)
Number of drinks in past 7 days, mean (SD)[b]		
Baseline	26.8 (19.0)	20.7 (14.7)
3-month follow-up	17.3 (15.8)	15.1 (11.9)
6-month follow-up	16.6 (15.2)	13.8 (11.4)
12-month follow-up	13.9 (11.0)	12.9 (10.7)
Change in number of drinks in past 7 days, mean (SD)[c]		
3-month follow-up	−8.5 (12.0)	−5.2 (13.5)
6-month follow-up	−9.4 (15.0)	−6.4 (16.4)
12-month follow-up	−12.1 (16.3)	−7.4 (13.3)
AUDIT[d], mean (SD)		
Baseline	14.5 (6.0)	12.2 (5.4)
6-month follow-up	11.3 (6.2)	9.9 (5.1)
12-month follow-up	10.0 (6.0)	9.3 (5.1)
Abstinence, n (%)		
3-month follow-up	6 (11)	7 (14)
6-month follow-up	6 (11)	8 (16)
12-month follow-up	5 (10)	7 (14)

[a]Missing data were imputed.

[b]The number of drinks per day was maximized at 11 units in the follow-up measurements for the imputation of missing data, meaning that 77 was the maximum number of drinks in the past 7 days.

[c]Mean number of drinks at follow-up minus the mean number of drinks at baseline.

[d]AUDIT: Alcohol Use Disorders Identification Test.

Table 3. Treatment effects on drinking behavior at the 3-, 6-, and 12-month follow-ups[a].

Outcome measure	Treatment effect		
	$B_{adjusted}$ (SE; 95% CI)	*P* value	Cohen *d* (95% CI)
Number of drinks in past 7 days[b]			
3-month follow-up	−3.2 (2.6; −8.5 to 1.9)	.11	N/A[c]
6-month follow-up	−2.1 (2.7; −7.6 to 3.1)	.22	N/A
12-month follow-up	−3.7 (2.7; −8.9 to 1.6)	.09	N/A
AUDIT[d]			
6-month follow-up	−0.9 (1.0)[e]	.21	0.3 (−0.1 to 0.6)
12-month follow-up	−1.6 (1.0)[e]	.06	0.1 (−0.2 to 0.5)

[a]Missing data were imputed.

[b]Adjusted coefficients are based on a robust regression mixed model with random intercept and fixed slope in which the outcome measure at follow-up is regressed upon baseline number of drinks, covariates, and group.

[c]N/A: not applicable.

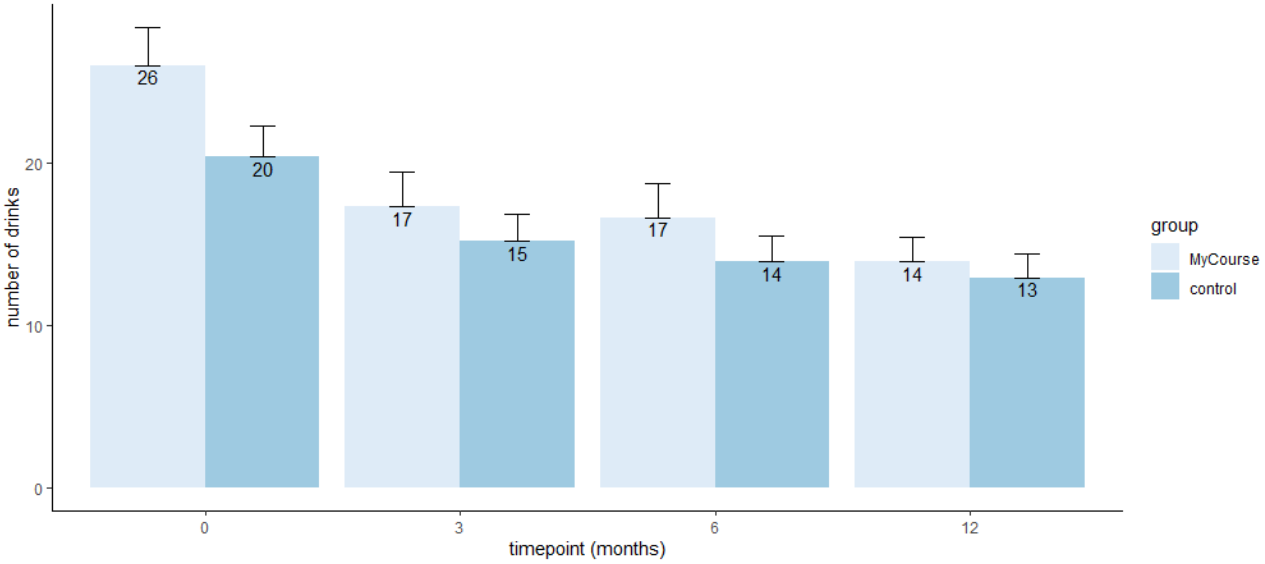
[d]AUDIT: Alcohol Use Disorders Identification Test (adjusted coefficients are based on a linear mixed model with random intercept and fixed slope in which the outcome measure at follow-up is regressed upon baseline number of drinks, covariates, and group).

[e]95% CI value is not available.

Secondary Outcomes

AUDIT scores decreased over time in both groups (Table 2 and Figure 3), but there was no difference between the groups (Cohen *d*=0.3, 95% CI −0.1 to 0.6; *P*=.21; Table 3) at 6 months. The mean EQ-5D-5L QALYs score in the MyCourse group was 0.82 (SD 0.12) and in the control group 0.84 (SD 0.10). There was no significant effect of the treatment on the quality of life based on EQ-5D-5L scores ($B_{adjusted}$=0.003, SE 0.01; *P*=.39).

Figure 3. Mean number of drinks in the past 7 days in both groups at baseline and during the course of the study, including SEs.



Incremental Costs

Table 4 presents the costs per group and the incremental costs (cost difference between the MyCourse and control groups) per cost item. The intervention was costed at US $279 per participant in the MyCourse group and US $74 per participant in the control group. The average health care costs accumulated over the full 12-month follow-up time were US $7840 (SD 11,767) per participant in the MyCourse group and US $8233 (SD 15,077) per participant in the control group, and the incremental health care costs were US $−393. Costs owing to productivity losses were mainly driven by absenteeism: US $9532 (SD 19,389) per participant in the MyCourse group and US $14,799 (SD 23,364) per participant in the control group, with high within-group variance. Incremental productivity costs per participant were on average US $−5217 (SD 26,378). The average cumulative societal costs were US $5404 (SD 42,859) lower in the MyCourse group compared with the control group.

Table 4. Mean cumulative costs (in US $) by group and incremental costs (N=103).

Cost item	MyCourse (n=53), mean (SD)	Control (n=50), mean (SD)	Incremental costs[a] (n=53), mean (SD)
Health care costs	7840 (11,767)	8233 (15,077)	−393 (19,125)
Specialized somatic	3819 (5772)	3627 (6463)	192 (8665)
Specialized psychiatric	1209 (3878)	688 (1906)	521 (4321)
Patient and family costs	953 (5517)	178 (1811)	775 (5807)
Other	907 (1142)	1126 (1434)	−219 (1833)
Medication	953 (5479)	2613 (10,521)	−1660 (11,862)
Productivity loss	9972 (1934)	15,189 (26,307)	−5217 (26,378)
Presenteeism	153 (319)	210 (408)	−57 (518)
Absenteeism	9532 (19,389)	14,799 (26,364)	−5267 (32,726)
Unpaid work	452 (1049)	474 (1007)	−22 (1454)
Intervention costs	279 (0)	74 (0)	205 (0)
Total societal costs	18,092 (25,662)	23,496 (34,327)	−5404 (42,859)

[a]Costs in the MyCourse group minus costs in the control group.

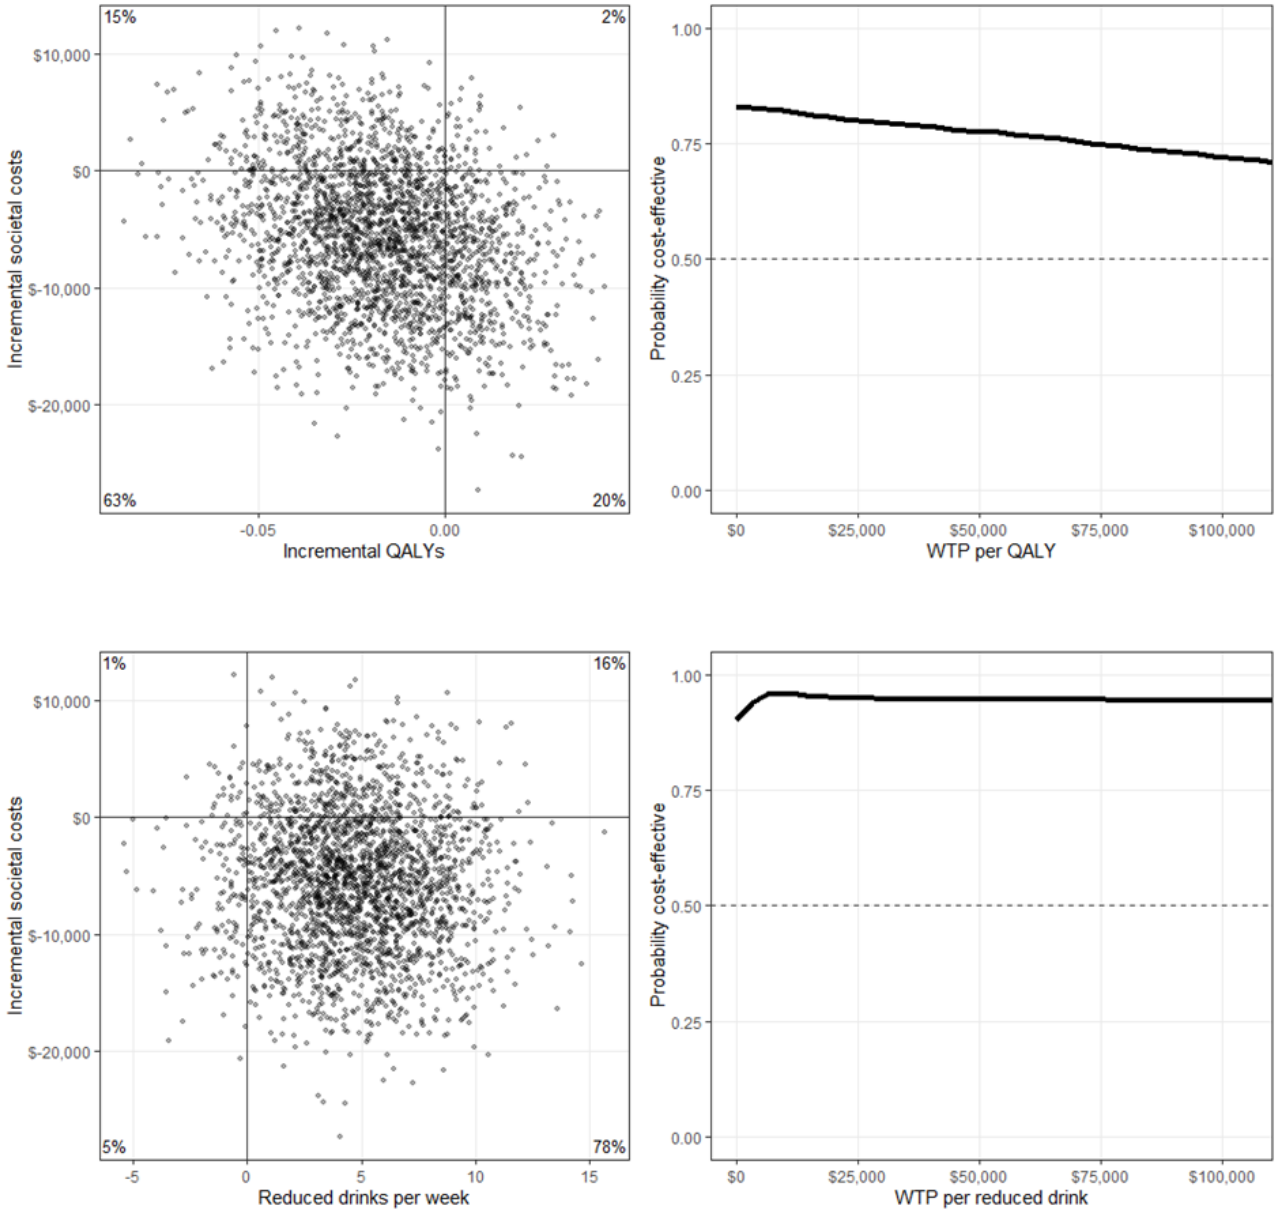
Cost-Utility

With QALY as the outcome, the ICER was US $314,606 (95% CI 186,201-553,552). The cost-effectiveness plane (Figure 4) shows that there is a 63% chance that the MyCourse intervention will lead to fewer QALYs gained at lower societal costs and a 15% chance that it will lead to more QALYs gained at lower societal costs. The relatively high ICERs are mostly a result of

a difference in productivity costs (Table 4) and a very small differential effect on QALYs.

Assuming an intervention-cost-only perspective, the ICER per QALY gained became negative (US $−11,930; 95% CI −18,440 to −8912), indicating that intervention costs were higher and the QALY gains were lower in the MyCourse group compared with the control group.

Figure 4. Cost-effectiveness planes and cost-effectiveness acceptability curves in US $. QALY: quality-adjusted life year; WTP: willingness to pay.



Cost-effectiveness

The MyCourse group reduced their number of weekly drinks more on average (mean 12.1, SD 16.3 drinks) than the control group (mean 7.4, SD 13.3 drinks) over a 12-month period and at lower societal costs. ICER per reduced drink was calculated at US $−1158 (95% CI −1609 to −781), indicating that compared with the control group each additional reduced drink in the MyCourse group was associated with a societal cost reduction. There is a 78% chance that the MyCourse intervention will lead to more weekly reduced drinks at lower societal costs and a 16% chance that it will lead to more weekly reduced drinks at higher costs (Figure 4). MyCourse will be preferred over the control group at any willingness-to-pay level (see Figure 4 for the CEAC curve). Assuming an intervention-cost-only perspective, a reduction of 1 additional weekly drink would cost an additional US $44 (95% CI 38-53) in the MyCourse group compared with the control group. Table 5 shows a breakdown by perspective.

Table 5. Incremental cost-effectiveness ratios between baseline and the 12-month follow-up[a].

Perspective	Incremental costs per QALY[b] (US $)	Incremental costs per reduced drink (US $)
	Value, mean (95% CI)	Value, mean (95% CI)
Health care	22,859 (−18,584 to 78,705)	−84 (−242 to 74)
Productivity loss	303,677 (198,917 to 516,624)	−1118 (−1497 to −823)
Intervention cost only	−11,930 (−18,440 to −8912)	44 (38 to 53)
Societal	314,606 (186,201 to 553,552)	−1158 (−1609 to −781)

[a]The incremental cost-effectiveness ratios were calculated as follows: $(C_1–C_0) / (E_1–E_0)$, where C refers to costs, E refers to effects, and the subscripts 0 and 1 refer to the experimental and control arms, respectively.

[b]QALY: quality-adjusted life year (as measured by the 5-level EuroQol 5 Dimension).

Sensitivity Analyses

Sensitivity analyses of the Amelia II-imputed data ($B_{adjusted}$=2.1, SE 1.8; *P*=.12) and completers-only data ($B_{adjusted}$=1.7, SE 1.4; *P*=.12) as well as a negative binomial mixed model on the mice-imputed data (incidence rate ratio=1.05, 95% CI 0.79-1.4; *P*=.38) corroborated the main findings and showed no effect of treatment on the number of drinks in the past week. All sensitivity analyses showed a decrease in alcohol use in both groups. Because of the apparent, although nonsignificant difference, between the groups in baseline alcohol use, we also modeled the individual change scores in alcohol use in a robust regression. Although the average reduction in alcohol use at 6 and 12 months was larger in the MyCourse group, the difference was not statistically significant, yielding the same results ($B_{adjusted}$=−2.1, SE 1.8; *P*=.12; Table 2). When QALYs were based on SF-6D scores, results of the economic evaluation remained similar. When Winsorization of extreme costs was applied at the 95th percentile, the cost-effectiveness planes and CEAC curves remained similar (Multimedia Appendix 3); however, ICER per EQ-5D-5L QALY was US $118,287 (95% CI 51,324-235,817), and ICER per reduced drink became less extreme (US $−435, 95% CI −680 to −219). Overall, the sensitivity analyses attested to the robustness of the findings in the main analysis.

Discussion

Principal Findings

We evaluated the effectiveness and cost-effectiveness of *MyCourse–Moderate Drinking*, a digital AM intervention for cancer survivors versus a web-based noninteractive information brochure. At the 6-month follow-up, the number of drinks in the past 7 days was reduced by 38% in the MyCourse group (mean −9.4, SD 15.0 standard units) and by 33% in the control group (mean −6.4, SD 16.4 standard units) and even further at the 12-month follow-up (MyCourse group: mean −12.1, SD 16.3 standard units; control group: mean −7.4, SD 13.3 standard units). No significant difference in 7-day alcohol use was found between the groups at any of the follow-up points. AUDIT scores decreased over time in both groups, but there was no statistically significant difference between the MyCourse group and the control group. Importantly, the participants were more satisfied in the MyCourse group.

In the cost-effectiveness analyses, the MyCourse group led to fewer QALYs and more reduced drinks, both at lower societal costs. Thus, MyCourse has shown to be more effective and cost-saving for number of reduced drinks.

From a societal perspective, the MyCourse group gained fewer QALYs at lower societal costs. The MyCourse intervention itself was associated with higher intervention costs than the noninteractive information brochure. Both ICERs reflected only marginally higher QALY gains in the control group. This study did not find any effect of MyCourse on QALYs. It could be hypothesized that a longer follow-up period would have been necessary for improvements in quality of life to take place in a population of cancer survivors, as their quality of life may be more directly influenced by factors pertaining to the cancer diagnosis (eg, invasiveness of cancer treatment, disease stage, cancer-related physical symptoms, and comorbidities) [42]. Therefore, we conclude that the MyCourse intervention seems more economically sustainable from a societal perspective than the noninteractive information brochure in reducing the number of drinks over a 12-month time horizon, whereas, to find evidence of possible cost-utility of a digital AM intervention, a longer follow-up period might be needed.

The difference in baseline alcohol use might be a possible explanation for the seemingly different conclusions between the incremental effect analysis and the cost-effectiveness analysis on the greater reduction of 7-day alcohol use in the MyCourse group. Even though the participants were randomized, at baseline, the participants in the MyCourse group had higher AUDIT scores and consumed more drinks on average than the participants in the control group (although the difference between the groups was not significant). At the 3-, 6-, and 12-month follow-ups, there was no significant difference in the number of drinks consumed in the past week or the AUDIT scores between the 2 groups. Thus, the larger nominal reduction in the number of drinks in the MyCourse group does not reflect a difference in the number of drinks at any of the follow-up assessments but rather a difference at baseline. This baseline difference translates differently in the incremental effect analysis, assessing differences at discrete time points, compared with the cost-effectiveness analysis, assessing differences over a period (12 months). It is also possible that, because of insufficient power, no significant difference was found in the incremental effect analysis, whereas, in the cost-effectiveness analysis, this was of lesser influence.

Wider Context

Meta-analyses of brief AM interventions [11] and AM internet interventions [10] among the general population have found that alcohol use in the past 7 days in the intervention group was reduced by approximately 20-50 g more than in the control group. Although this study did not find a significant effect on the AM rates of the MyCourse intervention over the control condition, we did find considerable reductions of approximately 70 g of ethanol at the 12-month follow-up in the control group and 120 g in the MyCourse group. These increasing reductions at longer follow-up assessments were also found in a previous digital AM intervention study [43]. In line with limited previous studies on brief and digital AM interventions [13-15], this study showed that a digital AM intervention can be cost-effective among cancer survivors. Unfortunately, because of a lack of literature, no comparisons could be made to other dedicated AM interventions for cancer survivors. A study on a telephone-counseling, combined alcohol, smoking, and depression intervention for head and neck cancer survivors also found a decrease in AUDIT scores after 6 months in both groups and no differential effect between the experimental intervention and the control group receiving only the nurse-delivered, face-to-face, 45-minute assessment, including a handout with referrals for further care (which the experimental group received as well) [44].

The lack of difference in alcohol use in the past 7 days between the MyCourse group and the control group might be due to several study aspects. It is also possible that because of the inclusion criterion of having the intention to reduce one's alcohol use, participants in both groups were highly motivated to change their alcohol use and that this obscured any effect of the MyCourse group. In addition, during this study, great efforts were made to recruit participants. At the time of recruitment in 2016-2018, AM discussion and support for cancer survivors was not well-implemented in many oncology settings; therefore, the researchers invested in informing oncology department staff on the importance and benefits of addressing AM in cancer survivors. Recruitment efforts were not only aimed at professionals; a dedicated website and a social media campaign were also in place, aiming to inform cancer survivors about the short-term benefits of AM after a cancer diagnosis while emphasizing an accepting tone to reduce possible feelings of guilt and ultimately guiding survivors to participate in the study. These recruitment efforts alone might have served as an intervention by focusing attention on AM. For cancer survivors not yet considering AM, the first step would be to address the knowledge gap on the adverse health effects of alcohol [45,46].

Second, the assessment load in this study was substantial, and the participants received multiple reminder emails and telephone calls from the researchers to fill out the survey at the respective follow-up measurement waves. Although these calls were kept as short as possible, some participants might have experienced them as part of the intervention; thus, possibly contributing to an intervention effect and making participants think regularly about their drinking behavior and feel supported [47,48]. This minimal guidance could thus have increased the AM rates in the control group. Future research should evaluate whether addressing AM in an accepting manner and with multiple repeated short reminders can encourage AM in cancer survivors.

It is possible that a true effect was not found in this study because the sample size was smaller than intended (103 instead of 114 participants). It is unlikely that the use of additional support explains the reduction of alcohol use in the control group, as very few people used any additional support. Low use of additional support was also found in a previous Dutch study on digital AM support [49]. Although the control group was as effective as the MyCourse group in reducing alcohol use in the incremental effect analyses, considering the significantly higher satisfaction rates and better economic sustainability in the MyCourse group, it would be preferable to offer the MyCourse group.

Strengths and Limitations

An important strength of this study is that the evaluation was conducted in a real-world setting; recruitment was done through both offline and web-based channels, which could plausibly be used in case of future implementation. This study succeeded in recruiting cancer survivors from a range of cancer types. The median number of times participants logged into MyCourse was high (8 times). Several sensitivity analyses have attested to the robustness of the findings. The long-term follow-up of this study showed that AM is sustained over a long period. The results should be interpreted in light of the limitations of the study. Most of this study's sample were women (86/103, 83.4%); thus, cautioning the generalization of the results to men. The participants were not blinded to their intervention allocation. Not all participants complied with the advised daily use of MyCourse for 4 weeks, and this might have influenced effects in the MyCourse group. A follow-up period of >12 months might be needed to find evidence of possible cost-utility of a digital AM intervention in cancer survivors.

Conclusions

To the best of our knowledge, this is the first study on a digital AM intervention for cancer survivors, and it showed that alcohol use was reduced by one-third in both the MyCourse and control groups and that this effect was sustained over 12 months. No significant differential effect on alcohol use between the MyCourse group and the control group was observed at the follow-ups, although cancer survivors were more satisfied in the MyCourse group. From a societal perspective, the MyCourse group seems economically more sustainable for reducing the number of drinks, as a greater reduction in the number of drinks over time was observed against lower societal costs.

Acknowledgments

The authors would like to thank Diede Kesler for her assistance in the recruitment and follow-up assessments of the participants, Yvonne Borghans for her assistance in the follow-up assessments of the participants, and professor Dr Filip Smit for his guidance

in the economic evaluations. This study was supported by grant TBOS2014–7169 from the Dutch Cancer Society (KWF Kankerbestrijding). The sponsor had no role in the design, data collection, analysis and interpretation of the data, writing of the paper, or the decision to submit for publication.

Conflicts of Interest

The intervention described in this study was developed by the Trimbos Institute (the Netherlands Institute for Mental Health and Addiction). The authors declare that they have no other competing interests.

Abstract

Background: One in eight women is diagnosed with breast cancer in the course of their life. As systematic palliative treatment has only a limited effect on survival rates, the concept of health-related quality of life (HRQoL) was developed for measurement of patient-centered outcomes. Various studies have already demonstrated the reliability of paper-based patient-reported outcome (pPRO) and electronic patient-reported outcome (ePRO) surveys and that the 2 means of assessment are equally valid.

Objective: The aim of this study was to analyze the acceptance and evaluation of a tablet-based ePRO app for breast cancer patients and to examine its suitability, effort, and difficulty in the context of HRQoL and sociodemographic factors.

Methods: Overall, 106 women with adjuvant or advanced breast cancer were included in a 2-center study at 2 major university hospitals in Germany. Patients were asked to answer HRQoL and PRO questionnaires both on a tablet on-site using a specific eHealth assessment website and on paper. The suitability, effort, and difficulty of the app and self-reported technical skills were also assessed. Only the results of the electronically acquired data are presented here. The results of the reliability of the pPRO data have already been published elsewhere.

Results: Patients regarded the ePRO assessment as more suitable (80/106, 75.5%), less stressful (73/106, 68.9%), and less difficult (69/106, 65.1%) than pPRO. The majority of patients stated that ePRO assessment improves health care in hospitals (87/106, 82.1%). However, evaluation of ePROs depended on the level of education (P=.003) in the dimensions of effort and

difficulty (regression analysis). The app was rated highly in all categories. HRQoL data and therapy setting did not show significant correlations with the app's evaluation parameters.

Conclusions: The results indicate that ePRO surveys are feasible for measuring HRQoL in breast cancer patients and that those patients prefer ePRO assessment to pPRO assessment. It can also be seen that patients consider ePRO assessment to improve hospital health care. However, studies with larger numbers of patients are needed to develop apps that address the needs of patients with lower levels of education and technical skills.

Introduction

Breast Cancer: Epidemiological Relevance

With about 70,000 new cases each year, breast cancer is the most common cancer in Germany. One in eight women is diagnosed with breast cancer in the course of their life [1]. Due to great advances in cancer therapy options, the relative 5-year survival rate after initial diagnosis has increased to 88% [2]. While patients in adjuvant situations have an improved prognosis, patients with metastatic disease remain incurable and are hence treated with palliative care. Since currently systemic palliative treatment has a limited effect on survival rates, the concept of health-related quality of life (HRQoL) and measurement of patient-reported outcomes (PROs) are gaining increasing importance in the therapy of progressive diseases, such as breast cancer, especially in the metastatic setting [3-7]. Under this directive, the issue of how HRQoL data can be collected as efficiently and accurately as possible in real-world settings is gaining importance [8].

PROs as a Holistic Addition to Clinic-Reported Outcomes

Drug evaluation studies have focused on clinical endpoints (clinic-reported outcomes), such as overall survival and progression-free survival, for years. Yet, PROs are becoming increasingly important to verify and compare the efficacy of different chemotherapeutic interventions in drug evaluation studies, not least owing to legal regulations [9]. This fact is confirmed by the enormous increase in studies publishing PRO data over the last few decades [10]. A PRO is widely defined as "any report of the status of a patient's health condition that comes directly from the patient, without interpretation of the patient's response by a clinician or anyone else" [11]. The concept of PRO takes into account the patient's point of view concerning health status, therapy intervention, negative side effects, mental and functional components, satisfaction with care, drug adherence, and impact of progressive disease [9-14].

Potential of Electronic PROs

Strong willingness to use technology within the population and existing infrastructure represents the rationale for digitalization in many sectors, including health [15]. While PROs are still routinely captured via paper-based methods, technical progress is gradually allowing more PRO data to be collected in the form of electronic PROs (ePROs), that is, via tablet computers or smartphones [16]. To ensure that patients are able to deal with ePRO data capture, studies that prove reliability and acceptance are needed. Various studies have already demonstrated that both paper-based PRO (pPRO) and ePRO surveys are reliable and equally valid means of assessment [4,17-21]. Nevertheless, knowledge about the detailed evaluation of ePRO apps and information regarding patient acceptance, feasibility, and barriers are still limited [22], especially in relation to sociodemographic aspects, health status, and technical skills [7,23-26]. It also remains unclear how ePRO questionnaires are accepted and evaluated in breast cancer patients, in whom high patient satisfaction with use and usability are important implementation prerequisites for capturing real-world evidence in routine clinical care.

Aims and Objectives

The aim of this study was to analyze the acceptance and evaluation of a tablet-based ePRO app for breast cancer patients. More specifically, we investigated how suitable patients maintain an app that is used to collect HRQoL data, whether they find it diffuse or difficult to use, and how to evaluate individual aspects of the questionnaire. To determine whether the HRQoL survey app can be used in all breast cancer patients, we also examined whether the app's suitability, effort, and difficulty ratings were dependent on HRQoL and sociodemographic factors (age, educational status, and computer skills).

Methods

Study Design and Sample

The methodology has already been described in detail elsewhere [19,21]. Here, it was shown that HRQoL can be validly assessed by the related tool, since no significant differences in response behavior between pPROs and ePROs were found with regard to reliability in both the European Organization for the Research and Treatment of Cancer core quality of life questionnaire (EORTC QLQ-C30) and the Functional Assessment of Cancer Therapy-Breast Cancer (FACT-B) questionnaires. In this study, the feasibility and acceptability will be evaluated. For digital assessment, we used a web-based solution PiiA (patient interactively informs doctor), allowing patients to answer the HRQoL assessment on a tablet after receiving anonymized user credentials [19,21]. Patients were recruited as a part of the ePROCOM (electronic Patient-Reported Outcomes and Compliance Analysis) and the PEPPER (Patient Engagement Breast Cancer) study. While the ePROCOM study aims to evaluate general patient acceptance and practicability of a

web-based app for a PRO questionnaire for patients with adjuvant or metastatic breast cancer, the PEPPER study aims to evaluate the impact of web-based PROs and pPROs for health care services. The inclusion criteria were female gender, full legal age, proven diagnosis of breast cancer in an adjuvant or metastatic setting, sufficient language skills in German, and signed declaration of consent. The exclusion criterion was participation in other studies to minimize the burden of questionnaires. Patients were asked to complete the questionnaire during an outpatient visit at the hospital under the supervision of an attending physician. From July 2015 to May 2016, questionnaires were completed by a total of 106 female adjuvant and metastatic breast cancer patients treated consecutively at the Department of Women's Health in Tubingen, Germany, and the National Center for Tumor Diseases (NCT) in Heidelberg, Germany. The study was designed as a 2-center prospective trial (Tübingen and Heidelberg). Ethical approval was granted by the Ethics Committee of the University of Heidelberg (S-569/2015) and the Ethics Committee of the University of Tübingen (project number 089/2015B01).

Questionnaires

All patients were required to complete both the ePRO and pPRO versions of the EORTC QLQ-C30 and FACT-B HRQoL questionnaires. The reliability of a tablet-based ePRO app of both questionnaires has already been analyzed (the results of the reliability analysis have been published previously [19,21]). Furthermore, patients were questioned about pre-existing technical skills, their willingness to use ePROs, potential barriers in relation to their health status, and socioeconomic variables [7,26]. Thereafter, patients were asked to evaluate the app and its handling, which is reported in the current paper. The questionnaires for measuring socioeconomic status and evaluating the app were developed by our own research group. Regarding the evaluation of the app, patients assessed the ePRO questionnaires in terms of suitability, effort, and difficulty compared with the pPRO questionnaires. They also mentioned whether the introduction of ePROs was thought to have a positive impact on the quality of health care and how they considered the app in terms of usability, graphic design, and applicability. Patients were informed about the aims of the study and were asked for their consent ex ante.

Statistical Analyses

All statistical analyses were conducted using IBM SPSS Statistics (Version 24). First, a frequency analysis was performed to determine the descriptive sociodemographic characteristics of the patients. Subsequently, the mean values and dispersion parameters of the variable age were calculated, and then, the frequencies of the individual dimensions of the variable educational attainment were determined. Thereafter, HRQoL from the EORTC QLQ-C30 questionnaire [21] and computer skills of the patients were assessed before the evaluation sheets were analyzed descriptively. Thereby, stratification was done by treatment setting, using the Mann-Whitney *U* test to test the significance of the identified frequency differences. Subsequently, multivariable regression analyses were conducted on the 3 aforementioned target outcomes. The aim of regression analysis was to determine whether the regression models showed statistically significant relationships between the evaluation dimensions of suitability, effort, and difficulty and between socioeconomic variables (age and educational attainment), computer skills, the treatment regimen (metastatic vs adjuvant), and HRQoL. For each level of ordinal variables, dummy variables were created in multivariable regression analyses. In all analyses, *P* values <.05 (2-tailed) were considered indicative of statistically significant differences (α=.05).

Results

Sociodemographic Variables

Table 1 shows the sociodemographic characteristics of the study group stratified by therapy setting with 76 (72%) patients in adjuvant therapy and 30 (28%) with metastatic disease, as well as their HRQoL, their self-related computer skills, and their computer use experience in years. There were no significant differences between adjuvant and metastatic patients. The mean age was 49.4 years in the adjuvant group and 53.9 years in the metastatic group. Nearly half of the patients (adjuvant patients: 38/76, 50%; metastatic patients: 14/30, 47%) had a higher level of education (advanced technical graduation or high school diploma). The mean HRQoL score was approximately 60 points in both groups (where 0 represents the worst value and 100 the highest value). Among all patients, more than three-quarters rated their computer skills as advanced or professional (adjuvant patients: 54/76, 71%; metastatic patients: 20/30, 67%), while the mean time of computer use was more than 10 years in both groups.

Table 1. Sociodemographic characteristics of the patients.

Sociodemographic variables	Adjuvant therapy group (n=76, 72%)	Metastatic situation group (n=30, 28%)	*P* value

[a]HRQoL: health-related quality of life.

[b]EORTC QLQ-C30: European Organization for the Research and Treatment of Cancer core quality of life questionnaire.

Evaluation of Suitability, Effort, and Difficulty: Comparison Between ePRO and pPRO Surveys

Figure 1 shows how the patients evaluated the app in comparison to the paper version. We examined how the platform was rated in terms of suitability compared to the pPRO survey on a 5-point Likert scale. A rating of 3 was considered as comparable suitability between the 2 assessment strategies, whereas a rating of 1 or 2 was regarded as low suitability and a rating of 4 or 5 was regarded as high suitability. Three-quarters of the patients (80/106, 75.5%) reported that the ePRO survey on the EORTC QLQ-C30 and the FACT-B questionnaire was more appropriate than the pPRO survey.

Similar results were obtained in the dimensions effort and difficulty. One-quarter of the patients stated that completing the ePRO sheets was as stressful (27/106, 25.5%) and as difficult (29/106, 27.4%) as completing the HRQoL questionnaires on paper, whereas 68.9% (73/106) of the patients rated the ePRO survey as less stressful and 65.1% (69/106) as less difficult than the pPRO survey. The proportion of patients who rated the ePRO survey worse than the pPRO survey was negligible (Figure 2).

Overall, 82.1% (87/106) of patients said that the introduction of the ePRO survey improved health care in hospitals, 16.0% (17/106) of patients said that the introduction of the ePRO survey was associated with deterioration in health care, and 1.9% (2/106) of patients said that the introduction of the ePRO survey had no impact on health care in hospitals.

Figure 1. Suitability of the electronic patient-reported outcome survey in relation to the paper-based patient-reported outcome (pPRO) survey.

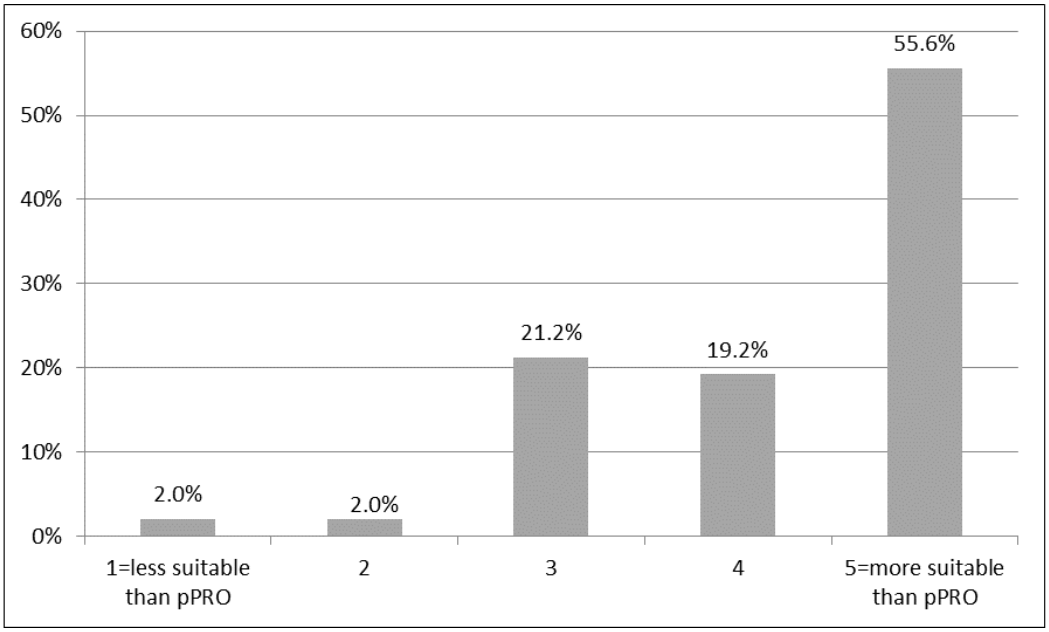

Figure 2. Effort and difficulty of the electronic patient-reported outcome survey in relation to the paper-based patient-reported outcome (pPRO) survey.

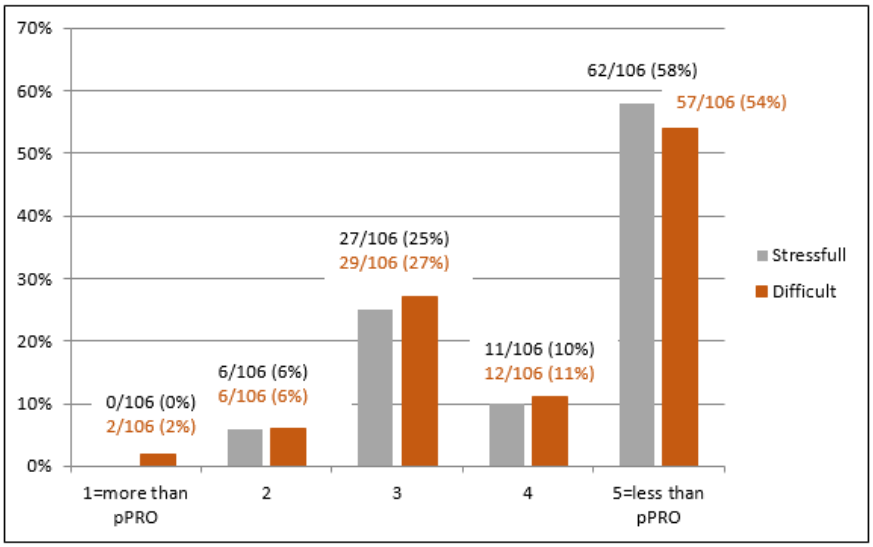

Influential Factors in ePRO Evaluation

For the suitability, effort, and difficulty of the ePRO survey, we examined whether the respective evaluation was influenced by socioeconomic factors, HRQoL, therapeutic setting, self-assessed computer knowledge, or experience in using computer technology. In the suitability dimension, no statistically significant correlations were found in the multivariable regression analysis. Statistically significant regression correlations were found between evaluation in the effort and difficulty dimensions and the educational level, as well as the time span of computer technology use. With higher levels of education and increasing time of using computer technology, completing the ePRO survey was more often reported as requiring less effort and being less difficult than completing paper questionnaires. By contrast, age, HRQoL, therapy setting (metastasized vs adjuvant therapy), and computer skills did not influence the response behavior in the evaluation. A total of 10.5% of the assessments could be attributed to the level of education in the effort dimension assessment, and a total of 14.5% in the dimension of difficulty, while time span of computer use only influenced the evaluation with 0.2% in both dimensions (Table 2).

Table 2. Multivariable regression analyses on suitability, effort, and difficulty of the electronic patient-reported outcome assessment app.

Variable	*R*	R^2	*P* value	95% CI
Dependent variable: Suitability of the ePRO[a] assessment

[a]ePRO: electronic patient-reported outcome.

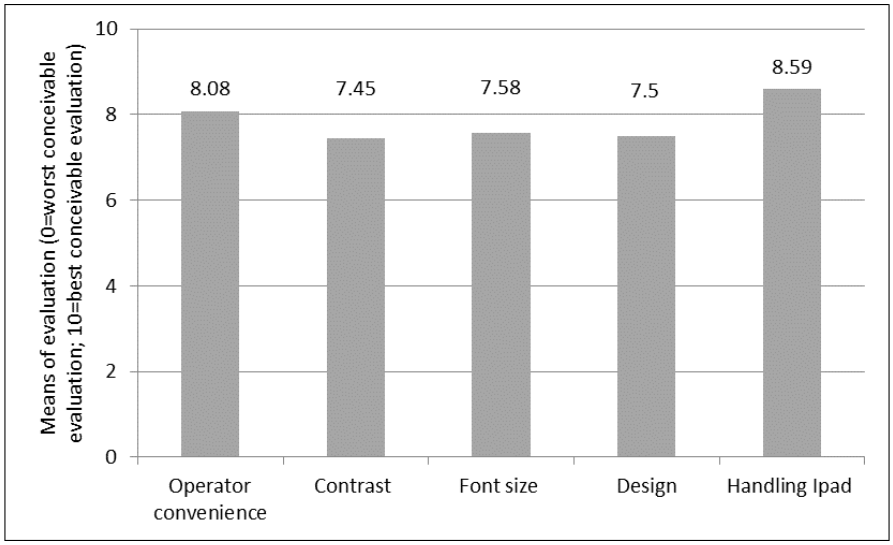
[b]HRQoL: health-related quality of life.

[c]Statistically significant difference.

Evaluation of the App's Usability

Figure 3 shows the mean values of the usability evaluation. All 5 dimensions had high to very high ratings. The dimensions operator convenience, contrast, font size, and design were scored between 7.4 and 8.1, while handling was scored at 8.6 on average.

Figure 3. Application usability in different aspects of user experience.



Discussion

Principal Findings

The results indicated that ePRO surveys are also applicable for measuring HRQoL in breast cancer patients with metastatic disease or under adjuvant therapy. The app was rated as more suitable, as requiring an equal or lesser degree of effort, and as being equally or less difficult than the pPRO survey. The evaluation of usability and applicability showed high to very high ratings. Thus, it could be shown that the ePRO survey can be used even in patients with a high burden of disease as well as in older patients, as HRQoL and age did not affect the evaluation. This is a significant finding, which extends the previous state of research, as it previously appeared unclear whether there were barriers to using ePROs in elderly and metastatic patients [7]. The influence of educational level on the evaluation was significant but rather small.

Comparison With Prior Work

Although ePRO apps are being adopted more frequently, paper-based surveys of PROs still predominate in clinical research because reliable electronically validated questionnaires are lacking. This is why knowledge about the detailed evaluation of ePRO apps and information regarding patient acceptance, feasibility, and barriers are still limited [22], although the potential of ePROs is high and the experience is very satisfactory so far [27]. The results of this study basically confirm the results of few existing studies [4,24,28,29]. Wintner et al likewise showed that cancer patients preferred ePRO questionnaires over pPRO questionnaires [28]. A high rating could also be found for electronic psycho-oncological screening instruments in breast cancer patients; here, the acceptance was greater than that of the paper-pencil screening [24]. However, only results from very small patient populations are available for breast cancer patients with metastatic disease or under adjuvant therapy. Both a Japanese and a German research group were able to demonstrate positive effects in this area. However, the number of patients included was less than 20 [4,29]. The current results therefore represent a unique characteristic, as we were able to demonstrate for the first time that ePRO surveys are also well received and better evaluated than paper-based surveys by patients with a high burden of disease in a larger collective. Other studies have not yet focused on the factors that influence app evaluation (and thus the response behavior of patients [22]). The fact that the level of education and the time span of using computer technology influence the evaluation of ePROs confirms the findings of our team, as the willingness to use such an app is also influenced by socioeconomic factors and computer skills [7,26].

Limitations

Despite positive results, some limitations of the study design and methodological implementation should be mentioned, which could possibly reduce the representativeness of the data. Patients were required to complete questionnaires during an outpatient hospital visit. The phenomenon of socially desirable response behavior might have influenced the evaluation results, such that the app might have been rated differently by patients in their home environment. It also needs to be noted that there might have been selection bias, as we did not examine whether the HRQoL was lower and the psychological distress was higher in those patients who could not be motivated to participate in the study. Only patients who were already technically inclined might have been willing to participate. Therefore, it remains unclear how acceptance differs from that in patients who only display a low level of use willingness [7,26].

Conclusions

Although digital assessment of HRQoL is constantly being adopted in clinical research and clinical routine, knowledge about the evaluation and acceptance of ePRO apps in breast cancer patients with a high burden of disease is insufficient. The results of this study indicate that breast cancer patients with metastatic disease and those under adjuvant therapy prefer ePRO surveys to pPRO surveys. However, the evaluation of ePROs depends on the level of education and the patient's computer skills and experience. Here, studies with larger collectives are needed to develop low-threshold offers that make ePRO surveys usable for all patient groups in both clinical and home settings and to better understand the needs of patients with a higher disease burden.

Abstract

Background: Type 2 diabetes mellitus (T2DM) is a leading cause of morbidity and mortality globally, with adverse health consequences largely related to hyperglycemia. Despite clinical practice guideline recommendations, effective pharmacotherapy, and interventions to support patients and providers, up to 60% of patients diagnosed with T2DM are estimated to have hemoglobin A_{1c} (HbA_{1c}) levels above the recommended targets owing to multilevel barriers hindering optimal glycemic control.

Objective: The aim of this study is to compare changes in HbA_{1c} levels among patients with suboptimally controlled T2DM who were offered the opportunity to use an intermittently viewed continuous glucose monitor and receive personalized low-carbohydrate nutrition counseling (<100 g/day) versus those who received usual care (UC).

Methods: This was a 12-month, pragmatic, randomized quality improvement program. All adult patients with T2DM who received primary care at a university-affiliated primary care clinic (N=1584) were randomized to either the UC or the enhanced care (EC) group. Within each program arm, we identified individuals with HbA_{1c} >7.5% (58 mmol/mol) who were medically eligible for tighter glycemic control, and we defined these subgroups as UC–high risk (UC-HR) or EC-HR. UC-HR participants (n=197) received routine primary care. EC-HR participants (n=185) were invited to use an intermittently viewed continuous glucose monitor and receive low-carbohydrate nutrition counseling. The primary outcome was mean change in HbA_{1c} levels from baseline to 12 months using an intention-to-treat difference-in-differences analysis comparing EC-HR with UC-HR groups. We conducted follow-up semistructured interviews to understand EC-HR participant experiences with the intervention.

Results: HbA_{1c} decreased by 0.41% (4.5 mmol/mol; *P*=.04) more from baseline to 12 months among participants in the EC-HR group than among those in UC-HR; however, only 61 (32.9%) of 185 EC-HR participants engaged in the program. Among the EC-HR participants who wore continuous glucose monitors (61/185, 32.9%), HbA_{1c} was 1.1% lower at 12 months compared with baseline (*P*<.001). Interviews revealed themes related to EC-HR participants' program engagement and continuous glucose monitor use.

Conclusions: Among patients with suboptimally controlled T2DM, a combined approach that includes continuous glucose monitoring and low-carbohydrate nutrition counseling can improve glycemic control compared with the standard of care.

type 2 diabetes mellitus; continuous glucose monitoring; low-carbohydrate counseling

Introduction

Background

Type 2 diabetes mellitus (T2DM) is a leading cause of morbidity and mortality globally, with adverse health consequences largely related to hyperglycemia [1]. Unfortunately, despite clinical practice guideline recommendations [2], effective pharmacotherapy [3], and interventions to support patients and providers [4-6], up to 60% of patients with diagnosed T2DM are estimated to have hemoglobin A_{1c} (HbA_{1c}) levels above recommended targets [2,7]. Multilevel barriers hinder optimal glycemic control, including those at the level of patients (eg, medication nonadherence [8]), providers (eg, clinical inertia [9,10]), and health systems (eg, lack of support resources [11]). Such barriers may be exacerbated by the high costs of many T2DM medications, including insulin [12].

Novel strategies that can be sustained and scaled in diverse clinical settings are needed to help more patients with T2DM to achieve the dual goals of glycemic control and reduced medication burden. Growing evidence suggests that these goals are achievable through dietary carbohydrate restriction. Very low–carbohydrate and low-carbohydrate diets (defined as <10% and 10%-26% of total daily energy from carbohydrates, respectively) have been successfully used in clinical trial settings to manage and reverse T2DM [13,14]. Accordingly, clinical practice guidelines for T2DM now support the use of carbohydrate-restricted meal plans among patients with T2DM who (1) are not meeting glycemic targets, (2) wish to reduce the use of antihyperglycemic agent, or (3) prefer such a dietary approach [15,16]. However, to date, few strategies exist to support the use of carbohydrate-restricted meal plans in general practice settings, as such diets often require intensive personalized instruction and close monitoring with medication adjustments to mitigate the risk of hypoglycemia among patients treated with agents other than metformin [17-19].

A promising strategy to effectively, efficiently, and safely support the use of carbohydrate-restricted meal plans among patients with suboptimally controlled T2DM may be through continuous glucose monitoring (CGM). CGM can support patients' self-education and self-management by providing real-time information on individuals' glycemic responses to specific foods. CGM technology—historically used in the management of type 1 diabetes mellitus—is now less expensive, user-friendly, and increasingly used to guide medication treatment decisions among patients with T2DM [20,21]. However, little is known about the potential role of CGM technology as a tool to help patients initiate and sustain behavior changes. In a previously published pilot study of 15 patients with prediabetes, we showed that CGM plus low-carbohydrate coaching is an acceptable and feasible approach to support dietary behavior change [22].

Objectives

We hypothesized that an intervention combining the use of CGM technology with dietitian-delivered education focused on dietary carbohydrate restriction would be effective in altering patients' eating behaviors and improving glycemic control among patients with suboptimally controlled T2DM. The primary objective of this pragmatic randomized quality improvement (QI) program is to compare mean change in HbA_{1c} levels among patients with suboptimally controlled T2DM (defined as HbA_{1c} ≥7.5%) who were offered the opportunity to use a CGM and receive nutritional counseling versus those who received usual care (UC).

Methods

Study Design

We conducted a 12-month, pragmatic, randomized controlled population level QI program evaluation. Although we could have conducted a more traditional, simple 2-arm randomized controlled trial, we wanted to be able to understand the potential reach of the QI program in a typical primary care office setting. Thus, rather than randomizing participants after obtaining consent as done in a usual research study, we first identified and randomized the entire population of adult patients with T2DM seen in the clinic to either a UC or an enhanced care (EC) arm. We then attempted to contact every patient who was randomized to the EC arm who had an HbA_{1c} level >7.5% (58 mmol/mol) and for whom tighter glycemic control was medically appropriate and invited them to engage in the program. This allowed us to estimate the potential reach of the program outside of a consented research setting. All patients who engaged in the study provided clinical consent, but only a subset of those who engaged consented to allow detailed data to be used for subsequent research or education. After 1 year, those who were eligible and randomized to the UC arm were also offered the opportunity to engage in the intervention, but the data presented here do not include the waitlist control results.

The evaluation was pragmatic in that the recruitment and intervention procedures were integrated into usual clinical workflows and were conducted by clinic staff rather than by research staff. We used the Pragmatic Explanatory Continuum Indicator Summary [23] to design the study and select strategies that were more pragmatic (rather than explanatory), thus increasing the likelihood that the program could be scaled and sustained in real-world clinical settings.

Owing to the complex evaluation design, the program was reviewed under 2 separate institutional review board (IRB)

applications by the University of Michigan's IRB. The QI program was deemed exempt and not regulated and was granted a waiver of informed consent for cohort identification and participant tracking (HUM00147295). This component included the quantitative evaluation of the primary outcomes assessed through deidentified cohort summary data. The second IRB application was applied only to the data repository subcohort. All individuals who engaged in the program were invited to participate in a data repository, which allowed study team members to review their complete electronic health record (EHR) for current and subsequent research and education. Participation in the data repository was voluntary and required written informed consent (HUM00148100). The program evaluation was conducted from November 2018 to November 2019.

Participants and Setting

This QI program took place at a university-affiliated family medicine clinic staffed by family medicine physicians, residents, and advanced practice providers. Although detailed patient-level sociodemographic data were limited owing to the QI nature of this program, most patients served by the clinic are White and have private insurance or Medicare.

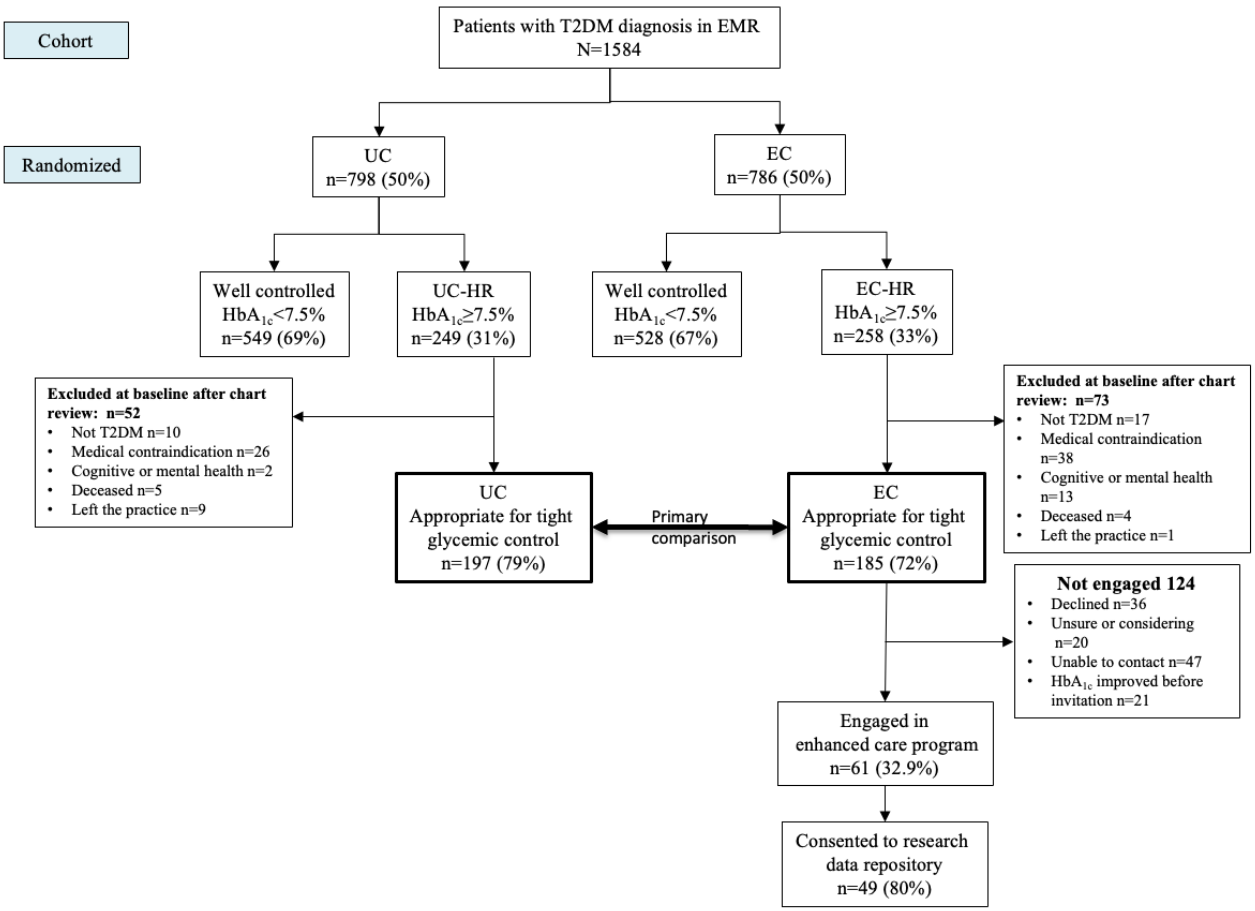
Using Data Direct [24]—the Michigan Medicine web-based tool for accessing data from >4 million patients within the health system—we identified patients aged ≥21 years with T2DM, as determined by EHR-based problem list diagnosis; with HbA_{1c} ≥6.5%; or active prescription for any antihyperglycemic medication other than metformin (N=1584).

Randomization

All individuals were randomized to one of the two program groups using 1:1 randomization with stratification based on age, gender, and BMI: UC or EC. The allocation sequence was generated using STATA 16.0 (StataCorp LLC).

As shown in Figure 1, individuals within each study group were classified as UC-high risk (UC-HR) or EC-HR if they had a baseline HbA_{1c} level ≥7.5% and were medically eligible for improved glycemic control as determined by clinical review of the patients' EHR data and discussion with a primary care physician (PCP), if necessary. Specifically, those individuals for whom tighter glycemic control (ie, HbA_{1c} <7.5%) was not recommended by the American Diabetes Association guidelines [25], older frail individuals at high risk of hypoglycemia and falls, those with a life expectancy of <6 months owing to a comorbid condition, or those with severe or untreated mental health conditions including eating disorders; women who were pregnant or breastfeeding; and those who had previous weight loss surgery were excluded from the high-risk cohorts.

Figure 1. Patients with type 2 diabetes mellitus diagnosis (T2DM) in the electronic medical record (EMR). EC: enhanced care; HbA_{1c}: hemoglobin A_{1c}; HR: high risk; UC: usual care.



Recruitment

Several recruitment strategies were used to engage EC-HR individuals in the program. These included invitation by postal letters, EHR-based electronic messages, and phone calls by a program team member. In addition, for patients who did not respond to this outreach, an attempt was made to engage them face-to-face when they visited the clinic with their PCP or another health care provider.

Program

UC Arm

Individuals within the UC arm received routine care during the 12-month study period. Routine care included PCP follow-up and the opportunity to receive nutrition counseling with a primary care–based dietitian who counseled patients to follow the standard calorie-restricted American Diabetes Association diet without a specific emphasis on dietary carbohydrate restriction [26].

EC Arm

All EC-HR individuals were invited to participate in the program (n=185). Of the 185 individuals, 61 (32.9%) of individuals engaged in the program and 80% (49/61) of individuals provided informed consent to participate in the data repository. Program participants used an intermittently viewed CGM (Abbott Freestyle Libre) and received personalized, low-carbohydrate dietary counseling from the program dietitian. In contrast to other CGM technologies including newer models of Freestyle Libre, the intermittently viewed CGM requires the user to scan the sensor to obtain results and does not have alarms for hypoglycemia or hyperglycemia. We use the term CGM rather than intermittently viewed CGM, as this is the overarching terminology used in consensus guidelines [1].

The sensor was placed by a dietitian and individuals had the opportunity to wear up to 7 CGMs during the 12-month program period. The program participants met one-on-one with the program dietitian. Although the dietitian was hired for program purposes, she did not have any advanced training that would preclude delivery of the intervention by dietitians in other primary care settings. During the first visit, the dietitian conducted a basic nutrition assessment (eg, diet recall) and instructed individuals on how to maintain an accurate food log that was used in conjunction with CGM data to facilitate nutrition coaching and tailored education.

After at least 10 days, the participants returned for a one-on-one visit with the dietitian who reviewed the CGM data and food logs and helped them understand how their dietary carbohydrate intake influenced their blood glucose levels. All the individuals were initially instructed to limit total daily dietary carbohydrate to ≤100 g per day, as this is a clinically relevant, pragmatic, and achievable target for many individuals [13,14]. The participants were subsequently advised to adjust their carbohydrate intake to optimize time in range, defined as blood glucose of 70-180 mg/dL (3.9-10 mmol/L). Specifically, the dietitian met with the patients to review the glucose monitoring data and food logs with the goal of discerning specific foods (eg, bread and bananas) that triggered glucose excursions. She then helped the participants to identify low-carbohydrate alternatives that met their dietary preferences and budget constraints and a lower carbohydrate target was specified (eg, a total of 50 carbohydrates per day) if the patients desired to count carbohydrates. When a lower carbohydrate goal was specified, the participants were instructed on how to count net carbohydrates (ie, total grams of carbohydrates–grams of fiber) to encourage intake of leafy greens and nonstarchy vegetables. In this way, nutrition counseling was tailored to the individual's needs and aimed to accommodate differences in the degree to which individuals may need to restrict dietary carbohydrates to achieve glycemic control.

Although the dietary recommendations were drawn from many publicly available resources, the guiding principles of the program were based on the *Always Hungry* diet developed by Ludwig [27]. The dietitian also educated the patients regarding the potential risks and side effects of carbohydrate restriction, including hypoglycemia; hypotension; and physical symptoms of headache, fatigue, nausea, and constipation. Moreover, the dietitian communicated via the EHR with primary care clinical pharmacists or medical providers to facilitate timely changes in participants' medications to avoid episodes of severe hypoglycemia and hypotension.

Multimedia Appendix 1 shows an example of the handouts used to teach the participants how to count carbohydrates. Multimedia Appendix 2 shows an example of the type of information reviewed during the visit with the dietitian.

Primary Outcome Measure

Baseline and follow-up HbA_{1c} levels were abstracted from the EHR. All the individuals had a baseline HbA_{1c} level obtained as part of routine clinical care before randomization. Follow-up HbA_{1c} data were obtained by the individuals' PCPs as part of routine clinical care. To facilitate complete data availability, the program's dietitian placed orders for HbA_{1c} levels for EC patients on PCPs' behalf; PCPs could approve or cancel, as clinically indicated. The change in HbA_{1c} level was calculated by subtracting participants' baseline HbA_{1c} level from the follow-up HbA_{1c} level.

Secondary Outcome Measure

Baseline and 12-month BMI were abstracted from the EHR. All the individuals had a baseline measurement of weight and height and calculated the BMI as part of routine clinical care before randomization. Follow-up BMI data were obtained by individuals' PCPs as part of routine clinical care; we abstracted the follow-up BMI nearest to the end of the 12-month study period. Change in BMI was calculated by subtracting participants' baseline BMI from follow-up values.

Exploratory and Process Outcomes

Program Engagement

We evaluated the rate of program engagement among the HR-EC cohort. We defined program engagement as the use of at least one CGM and having at least one meeting with the dietitian.

Change in Monthly Cost of Antihyperglycemic Medications

Change in the cost of antihyperglycemic medications was determined by subtracting the total cost of antihyperglycemic medications at baseline from the total cost of antihyperglycemic medications during follow-ups. Among the 61 individuals who engaged in the program, 49 (80%) consented to allow the study team members to review their complete EHR. Of the 49 participants, 1 (2%) participant left the practice, so 48 charts were reviewed for medication cost change data. A study team member reviewed the participants' EHRs and documented the prescribed antihyperglycemic medications and dosages at the start and end of the study period. The cost of individual antihyperglycemic medications was determined using 2017 data from a private insurance claims database, Clinformatics DataMart Database (OptumInsight). Clinformatics DataMart Database contains deidentified claims capturing health care encounters (ie, office visits, outpatient visits, and inpatient visits) for >80 million privately insured adults and children. All the cost data in Clinformatics DataMart Database are standardized to enable comparisons of costs across patients, data sources, and geographic areas in a consistent manner. We also examined the change in monthly cost of antihyperglycemic medications for the subset of patients who were on insulin at baseline.

Change in CGM Metrics

CGM sensor metrics automatically calculated in the CGM report included average blood glucose level, percentage of time above range, percentage of time in range, percentage of time below range, and the number of low glucose events. In the subset of 45 patients in the EC-HR group who engaged in the program, consented data repository participation, and wore at least two sensors during the 12-month program period, we compared CGM sensor metrics using simple bivariate linear regressions with each CGM metric as the dependent variable and a dichotomous time variable to indicate first or last sensor.

Participant Experiences in the EC-HR Group

We conducted semistructured interviews by phone with participants from the EC-HR arm to explore their experiences with participating in the intervention [1]. A semistructured interview guide was selected so that consistent questions were asked across interviews and interviewers, while still allowing each interviewer to ask follow-up questions that were specific to each participant [28]. Phone interviews were selected to enhance participation among individuals who may have difficulty attending in-person. Interviews were conducted by team members trained in semistructured interviewing techniques, with regular feedback from a qualitative methodologist.

Those who agreed to share their data (49/61, 80% of participants in the EC-HR arm) were contacted by phone by the research coordinator and invited to participate. All participants were given up to 2 phone calls for recruitment and voicemails were left when available. Recruitment ended when sufficient interviews were completed to reach thematic saturation. The participants provided verbal consent. The phone interview was audio-recorded and then professionally transcribed.

Statistical Analysis

Measures of central tendency (eg, proportions, means, and SDs) were used for all descriptive analyses. We compared changes in HbA_{1c} levels and BMI using an intention-to-treat difference-in-differences analytic approach using a linear mixed model. The difference-in-differences is the interaction term between a categorical variable denoting the period (eg, before vs after program period) and the study group (eg, UC-HR vs EC-HR). As a sensitivity analysis, we adjusted the models for age and gender. This had little effect on the parameter estimations for the difference-in-differences analysis. Therefore, we present only unadjusted results.

We estimated pre-post changes in HbA_{1c} levels and BMI among the 61 individuals who engaged in the program using a linear mixed model. We estimated pre-post changes in the cost of antihyperglycemic medications among the 79% (48/61) of individuals who consented to data repository participation. We calculated the mean pre-post costs and used paired *t* tests to determine the significance of difference. All analyses were conducted using STATA 16.0.

Qualitative Data Analysis

A total of 3 team members (MD, TN, and CB) trained in qualitative analysis conducted an inductive thematic analysis [29,30]. First, we reviewed and organized all the transcripts using MaxQDA software. MD, TN, and CB independently coded the same transcript and discussed emerging ideas. We created a list of descriptive codes to represent meaningful segments of text; descriptive codes were then applied to the next transcript. We discussed the application of the codes to ensure that codes were being consistently applied by all team members. At this time, additional codes were added, and other codes were revised as needed to clarify the definitions. This process was repeated for the first 3 transcripts. Next, TN and CB independently coded the remaining transcripts. Application of the codes, relationships between the codes, and their meanings were discussed during regular team meetings. After coding, related codes were grouped into themes and summarized using structured summaries, including a narrative description of the theme and all the quotes associated with the theme.

Results

Baseline Characteristics

Demographic characteristics of the complete population (N=1584) were assessed at baseline (Table 1). Slightly less than half of the cohort was female (740/1584, 46.71%), and the mean age was 63.3 (SD 13.1) years. The UC and EC groups were similar at baseline. Among 185 EC-HR participants, 61 (32.9%) were engaged in the program. As shown in Figure 1, among the 124 individuals who did not engage in the study, the most common reasons for nonengagement included inability to contact individuals (47/124, 37.9%) and decline to participate (36/124, 29%).

Table 1. Baseline characteristics of all patients stratified by study group assignment.

Characteristic	All patients	UC[a] group	EC[b] group	UC-HR[c] group	EC-HR[d] group	Engaged in program
Population, n	1584	798	786	197	185	61
Age (years), mean (SD)	63.3 (13.1)	62.9 (12.8)	63.7 (13.4)	60.2 (11)	60 (12.2)	59 (11.9)
Women, n (%)	740 (46.71)	370 (46.4)	370 (47.1)	75 (38.1)	70 (37.8)	28 (46)
Baseline HbA_{1c}[e] level (%), mean (SD)	7.2 (1.5)	7.2 (1.5)	7.2 (1.6)	8.9 (1.4)	9 (1.6)	9 (1.4)
Baseline HbA_{1c} level (mmol/mol), mean (SD)	55.2 (16.4)	55.2 (16.4)	55.2 (17.5)	73.8 (15.3)	74.9 (17.5)	74.9 (15.3)
Baseline BMI (kg/m^2), mean (SD)	34.6 (7.1)	34.8 (7.1)	34.3 (7.1)	35.5 (6.7)	35.8 (7.2)	37.3 (8.5)

[a]UC: usual care.

[b]EC: enhanced care.

[c]UC-HR: UC-high risk.

[d]EC-HR: EC-high risk.

[e]HbA_{1c}: hemoglobin A_{1c}.

Primary Outcome

Baseline data were collected from all the patients. Of the 61 patients, 50 (82%) patients underwent at least one additional HbA_{1c} evaluation as part of routine clinical care during the 12-month study period. The mean time to follow-up HbA_{1c} level was 262 (SD 83) days. The HbA_{1c} level decreased by 0.41% (4.5 mmol/mol; *P*=.04) more from baseline to 12 months among EC-HR participants than among UC-HR participants. Adjusting for age and gender had little impact on the difference. In the pre–post comparison among the EC-HR participants who wore CGMs (n=61), HbA_{1c} level was 1.1% (12 mmol/mol) lower at 12 months compared with baseline (*P*<.001). The pre–post change in BMI in these participants was not statistically significant (within-group difference −0.6, *P*=.06; Table 2).

Table 2. Pre-post analysis[a] for HbA_{1c}[b] and BMI of program participants at 12 months compared with baseline (N=61).

Characteristic	Baseline, mean (SEM[c])	12-month, mean (SEM)	Difference within group at 12 months	*P* value (2-tailed test)
HbA_{1c} (%)	9 (0.11)	7.9 (0.12)	−1.1	<.01
HbA_{1c} (mmol/mol)	74.9 (1.2)	62.8 (1.3)	−12.1	<.01
BMI	37.3 (0.5)	36.7 (0.51)	−0.6	.06

[a]Values predicted from the mixed model not adjusting for age or gender.

[b]HbA_{1c}: hemoglobin A_{1c}.

[c]SEM: SE of the mean.

Secondary Outcome

Baseline BMI was calculated for all the patients included in the cohort. Of the 61 patients, 53 (87%) patients had at least one additional BMI calculated as part of routine clinical care during the 12-month study period. The mean change in time to follow-up BMI was 287 (SD 81) days. There was no significant difference in BMI change from baseline to 12 months between the EC-HR and UC-HR participants (Table 3). Adjusting for age and gender had little impact on the difference. There was a trend toward modest weight loss among the EC-HR participants who wore CGMs (n=61) from baseline to 12 months, but this change was not statistically significant (−0.6 kg/m^2; *P*=.06).

Table 3. Difference-in-differences analysis[a] for HbA_{1c}[b] and BMI at 12 months compared with baseline [1].

Characteristic and group	Baseline, mean (SEM[c])	12-month, mean (SEM)	Difference within group at 12 months	*P* value (2-tailed test)	Difference-in-differences	*P* value
HbA_{1c} (%)					−0.41	.04
UC-HR[d]	8.9 (0.11)	8.43 (0.12)	−0.47	.001		
EC-HR[e]	9.01 (0.11)	8.12 (0.12)	−0.88	<.001		
HbA_{1c} (mmol/mol)					−4.5	.04
UC-HR	73.8 (1.2)	68.6 (1.3)	−5.2	.001		
EC-HR	75 (1.2)	65.2 (0.12)	−9.6	.001		
BMI					−0.11	.63
UC-HR	35.45 (0.49)	34.89 (0.49)	−0.56	.001		
EC-HR	35.84 (0.5)	35.17 (0.51)	−0.67	<.001		

[a]Values predicted from mixed model not adjusting for age or gender.

[b]HbA_{1c}: hemoglobin A_{1c}.

[c]SEM: SE of the mean.

[d]UC-HR: UC-high risk.

[e]EC-HR: EC-high risk.

Exploratory and Process Outcomes

Change in Monthly Cost of Antihyperglycemic Medication

The average change in cost of antihyperglycemic medications from baseline to 12 months was –US $107 (SE of the mean 129.7; *P*=.41) among the 79% (48/61) of individuals who wore sensors and consented to data repository participation. Among the 52% (25/48) of individuals who used insulin, the average change in monthly cost of antihyperglycemic medications from baseline to 12 months was −$363 (SE of the mean 227.1; *P*=.12).

Change in CGM Sensor Metrics

Participants in the EC-HR group who engaged in the program and consented to data repository participation wore an average of 4.3 (SD 1.8) sensors during the 12-month program period. Of the 48 individuals, 4 (8%) individuals wore only 1 sensor. Of the 94% (45/48) of participants who wore at least two sensors, the average glucose decreased (−29.1 mg/dL, SD 9.4 mg/dL; *P*=.003), the average percentage of time above range decreased (−19%, SD 5.8%; *P*=.002), and the average percentage of time in range increased (17.7%, SD 5.4%; *P*=.002). The average percentage of time below range (+0.3%, SD 1%; *P*=.86) and the average number of low glucose events (+0.2 events, SD 1 event; *P*=.84) did not change significantly.

Adverse Events

There were no major adverse events. Among the 61 participants, the most commonly reported events included skin irritation (6/61, 10%) or pain at the sensor site (3/61, 5%). Most endorsed transient symptoms did not preclude subsequent CGM use. Patients on oral anticoagulants noted bruising at the sensor site. Of the 61 participants, 1 (2%) patient reported an episode of sensor-detected hypoglycemia, which was determined to be owing to sensor error when she presented to the emergency department.

Qualitative Results

Overview

Of the 61 participants in the EC-HR arm, 21 (34%) participated in semistructured interviews. Thematic analysis resulted in three themes related to EC-HR participants' program engagement and CGM use: (1) ability to understand how specific foods impact blood glucose trends, (2) ease of following a low-carbohydrate diet, and (3) ease of blood glucose monitoring.

Ability to Understand How Specific Foods Impact Blood Glucose Trends

Participants in the EC-HR arm expressed that by using the CGM for blood glucose monitoring and reviewing their CGM data with the dietitian, they learned and better understood how different foods affected their blood glucose levels. Of the 21 participants, 1 (5%) participant explained:

> *The CGM was really good because it, it helped me just focus on, to see it in real time. I could watch my blood sugar rise, and then, see how high it rise, rose, after I ate somethin' like that. So, it was really cool, I liked it.* [Participant 010]

Participants could easily relate the fluctuations in their glucose levels by looking at the spikes and dips in the graphs generated by the CGM. Many participants observed their glucose levels after eating food to understand how certain food items affect their glucose levels in real time. For example:

> *I really reflected on portion control with that study, because, I noticed—and you know like the types of food I was eating, because, it would jack my sugar my sugar way up or down based on what I was eating. Like a protein shake, even though it was, said it was*

> *low carb and all that, my sugar levels would raise and stay up for quite a while. Versus eatin' like a boiled egg, you know, and a piece of toast. It would be more even. So, I learned like some foods are better for me than other foods are.* [Participant 021]

When reviewing the data independently and in collaboration with the dietitian, the participants could relate their mood, energy levels, concentration, and sleep cycles to the dietary choices they had made. Of the 21 participants, 1 (5%) participant summarized the helpful aspects of the intervention for them:

> *Workin' with [the dietitian], and I think knowing, being able to see the spikes and stuff with what I ate. Oatmeal, I love oatmeal, but it spiked it [glucose level].* [Participant 015]

Finally, owing to their observations, participants described making different dietary choices in anticipation of the impact on their blood glucose. For example, participants reported exchanging foods with higher carbohydrates for those with more protein when their blood glucose levels were high. As 1 (5%) of the 21 participants explained:

> *I mean if it was too high, I would change what I was planning to eat next. So, if I checked it on my way home, and I was gonna pick up dinner, I might change, you know. I was gonna get pizza, but my sugar's high, so instead I'm gonna get chicken.* [Participant 008]

When reviewing their CGM data in real time, the participants were able to respond and prevent subsequent spikes in their glucose levels.

Ease of Following a Low-Carbohydrate Diet

Most EC-HR participants reported that they were able to implement a low-carbohydrate diet as part of the study. They commented that they "do well on it," "no problem," or "it went pretty good." However, some participants reported challenges in implementing and maintaining the diet during the intervention period, including preferences for high-carbohydrate foods, dealing with cravings, and the convenience of highly processed foods. Of the 21 participants, 1 (5%) participant who was able to reduce the number of carbohydrates consumed during the intervention still described the challenges:

> *[The diet was] not a lot of fun. Everything I love happens to be a carbohydrate...* [Participant 013]

Another participant described how difficult it was to find and prepare low-carbohydrate foods when busy or away from home, for example, while traveling for work:

> *I travel for work, so...being able to consistently find something to eat when I'm...getting, when it's easier to go through fast food, than to find something lower carb, higher protein. Right. So that, you know, especially when my schedule's, it's halfway through my day and I end up being someplace I wasn't expecting to be.* [Participant 008]

Though an uncommon experience, 5% (1/21) of the participants noted that feeling "different" or high-maintenance was a barrier to the low-carbohydrate diet during the intervention. They explained:

> *I'm tryin' to hide [the diet]. You know there's, uh, I, I don't tell the whole family. My wife knows, my children know, my boys know, and...I basically don't just pass it around because everybody'll start treatin' you different..."Oh can you eat this though? Can you eat this though?" You know, all that...they'll make somethin' for me that nobody else will eat. So, you know, I'd really rather not be treated like that.* [Participant 002]

As participants continued with the low-carbohydrate diet, many of them reported improvements in mood, concentration, energy, and sleep, and fewer cravings for carbohydrates. Participants described having "more energy when I'm not eatin' carbs or drinkin' caffeinated pop and all that" (Participant 001). However, these improvements were not universal. Some reported difficulty in concentrating and less energy, particularly in the first few days after starting the diet.

When asked about their intentions to maintain the low-carbohydrate diet in the future, more than half of the participants indicated that they would stick to the diet, whereas another 29% (6/21) of participants described making slight modifications. These participants often indicated that they had experienced improvements in their health and well-being while participating in the intervention. For example:

> *I actually am on a low carb diet [still], and I feel more energy 'cause of the low carb diet.* [Participant 003]

Those who made modifications described being less strict with carbohydrate intake. Modifications included consuming more carbohydrates "in moderation" while still trying to "eat healthy" and "cut out junk."

In contrast, 14% (3/21) of the participants reported not continuing to eat a low-carbohydrate diet after experiencing difficulty during the intervention. For example, 5% (1/21) of the participants, who described not reducing carbohydrates intake during the intervention, explained that they found it very restrictive to reduce carbohydrates:

> *That was hard because everything on it is stuff that I eat. I'm not a big fish eater, um...so it was hard, 'cause I know with the carbs, you know, breads and pasta and...that's the kind a stuff I like to eat...[During the intervention] I really didn't change my diet out too much. I just ate less.* [Participant 004]

Ease of Blood Glucose Monitoring

The use of CGM influenced the lifestyle of the participants in many ways. First, participants described how using the CGM eliminated the need for a blood glucose monitor to check their blood glucose levels. For many participants, the CGM was more convenient:

> *It's good for anybody to use anywhere at any time.* [Participant 007]

Furthermore, participants overwhelmingly preferred using the CGM to "poking my fingers all the time." Participants were

frequently irritated with pricking their finger for blood glucose checks because it was not only inconvenient but also painful:

> *The pain with the sticks. And I have short little fat fingers, and it's really hard to grab those sticks and you know so much easier to put the monitor up there and...see my numbers.* [Participant 006]

Similarly, another participant commented that the CGM gives "instant results" instead of having to prick and squeeze the finger to measure the blood glucose.

Second, using the CGM resulted in more frequent blood glucose monitoring among EC-HR participants during the intervention. To illustrate, 5% (1/21) of the participants explained the frequency of their monitoring before the intervention:

> *I occasionally tested my blood sugar...It could go for...one every 3 months, to 2 months. Or was a hit and miss kind of a deal...* [Participant 003]

The participant went on to describe how this behavior changed during the intervention:

> *The changes that I noticed is that I checked my sugar more often. [Before the study] it could have been once every 3 months, once a week. So, there wasn't a scheduled time, just whenever I...thought maybe I should. I would track it. And with the monitor it was right there, handy...It didn't interfere with my life to check the blood sugars.* [Participant 003]

As described earlier, the convenience of the monitor made it easier for participants to incorporate blood glucose monitoring into their lifestyle. Another participant similarly described the laborious process when using the glucometer, rather than the "instant" and "handy" CGM system:

> *[With finger pricking] you got you know, the sensor, or the other thing you gotta, alcohol your finger, poke yourself, get the blood out of there. You know, check it. Alcohol your finger again, you know put everything away, throw away the strip. Uh, you know rather than just puttin' the phone up to your arm, boom it's done.* [Participant 020]

Third, using the CGM provided a more comprehensive picture of their blood glucose levels and blood glucose trends. For example, some participants described the benefit of being able to monitor trends in their blood glucose levels overnight and over time. Of the 21 participants, 1 (5%) participant explained how the additional knowledge about blood glucose trends influenced their diabetes management:

> *We found out also that the, uh...the blood glucose drops during the night, sometimes down in the 40s, which was [when I was] asleep. So, which is, you know, something you wouldn't normally pick up. You can track it more, as to what's been going on. It just gives lots more numbers.* [Participant 017]

Despite these benefits, several participants experienced barriers in using the CGM, including the challenges with the adhesive, skin infection, and the cost of CGM sensors postintervention. Most commonly, the adhesive on the CGM was insufficient, causing the sensor to fall off and then it has to be replaced during a subsequent visit. Although not a common experience, 5% (1/21) of the participants complained of skin infections at the site of the sensor insertion. Finally, some participants expressed that they would like to continue using the CGMs to monitor their blood glucose following the intervention, but were limited by the cost and their insurance:

> *Rather than poking my finger, I totally would go for that [the CGM] in place of the other [glucometer]. But my insurance won't cover it, so I can't continue on.* [Participant 004]

Discussion

Principal Findings

This 12-month pragmatic QI program evaluation examined whether CGM technology—in conjunction with low-carbohydrate nutrition counseling—could reduce HbA_{1c} among patients with suboptimally controlled T2DM. The results show a significantly greater reduction in HbA_{1c} (–0.41%; –4.5 mmol/mol; *P*=.04) among individuals randomized to EC (n=185) compared with individuals randomized to UC (n=197). The improvement in HbA_{1c} level was not accompanied by an increase in the cost of antihyperglycemic medications and was associated with improved CGM metrics. Qualitative results indicated that EC-HR participants positively viewed engagement with the intervention and use of the CGM; however, experiences with the low-carbohydrate diet were more variable.

A recent systematic review and meta-analysis revealed significant improvements in glycemic control at 3 and 6 months among low-carbohydrate diet group participants, but these improvements diminished by 12 months [1]. In contrast, other studies testing the effectiveness of very low-carbohydrate ketogenic diets demonstrate significant and durable improvements in HbA_{1c} levels up to 24 months [2,3]. In this study, although only 32.9% (61/185) of EC participants engaged in the program, we observed a significant reduction in HbA_{1c} at 12 months. Given that this program used low-intensity diet counseling, our results suggest that CGM technology may facilitate adherence to a low-carbohydrate diet.

CGM technology is rapidly advancing and is increasingly recognized as a novel tool to support personalized T2DM management [21]. However, to date, few strategies have examined the role of CGM technology in supporting T2DM management among patients in general practice settings [4]. Among existing interventions targeting individuals with suboptimal glycemic control, many aim to promote medication intensification and adherence to prescribed regimens [4,31]. In contrast to these existing strategies, CGM technology coupled with personalized nutrition counseling may facilitate improved glycemic control through behavior change without medication intensification. A small, nonrandomized study used CGM technology and personalized nutrition counseling to promote a low glycemic index breakfast and demonstrated a reduction in glycemic variability at 2-week follow-up [32]. In this study, we similarly observed improved glycemic control without an increase in antihyperglycemic medication use.

Previous studies have demonstrated the efficacy of low-carbohydrate diets for T2DM management [13,33]. However, few previous studies have demonstrated the effectiveness of low-carbohydrate diets among individuals in real-world settings [34,35]. A primary care–based intervention offered an in-person low-carbohydrate program to a nonrandomized group of patients and demonstrated significant improvements in weight and HbA_{1c} levels over the 13-month study period [34]. A web-based intervention available to the general public similarly demonstrated reductions in HbA_{1c} levels and body weight among a nonrandomized cohort of program completers [35]. We augment these previous findings by demonstrating a significant reduction in HbA_{1c} levels among a randomized cohort of patients using an intention-to-treat analytic approach. Our data suggest that personalized nutrition counseling focused on dietary carbohydrate restriction and guided by individuals' CGM data are more effective than routine PCP and dietitian follow-up among patients with suboptimally controlled T2DM. Intervention participants positively engaged in the intervention, noting the benefits of knowledge and support provided by the dietitian. Although not all participants maintained a low-carbohydrate diet after the intervention, they were able to successfully reduce carbohydrate intake during the intervention and noted improvements in their physical health and well-being.

Among the 185 EC-HR individuals eligible for tight glycemic control, 61 (32.9%) engaged in the program. This is considered a high rate of participation, given that individuals were randomized before the program invitation and all eligible individuals were included in the denominator. Among the 124 individuals who did not engage in the study, the most common reason for nonengagement was the inability to contact eligible individuals (47/124, 37.9%), whereas 29% (36/124) declined to participate in the program and 16.1% (20/124) were uncertain about participation and did not engage during the study period. We did not explore reasons why individuals declined to participate and this is something that could be investigated in future work. To our knowledge, few previous studies have explored barriers to and facilitators of CGM technology as a diabetes self-management tool among patients with T2DM [36,37]. Although CGM technology can empower and motivate patients with type 1 diabetes mellitus who are accustomed to routine self-monitoring of blood glucose to guide insulin dosing [36], CGM technology may enhance diabetes-related distress, which is a known barrier to T2DM self-management [38]. Moreover, carbohydrate-restricted diets may not appeal to some patients' preferred eating patterns, thus underscoring the need for additional personalized nutrition approaches [39,40].

Over the 12-month study period, we observed statistically significant within-group changes in HbA_{1c} levels and BMI among UC-HR and EC-HR individuals. This may reflect contemporaneous changes in clinical practice with a shift away from using obesogenic antihyperglycemic medications (eg, insulin and sulfonylureas) and toward newer agents that may facilitate weight loss and patient compliance (eg, sodium-glucose cotransporter-2 inhibitors and glucagon-like peptide 1 receptor agonists). Consistent with results of previous literature on primary care–based interventions to improve glycemic control among patients with suboptimally controlled T2DM [4], we did not observe a significant between-group change in BMI.

Limitations

First, we recruited individuals from a primary care clinic within a US academic medical center and the program content was delivered by a single dietician; therefore, our results may not be generalizable to other clinics or populations. Second, we did not evaluate outcomes beyond 12 months and were therefore unable to assess long-term changes in glycemic control. Third, as this was a pragmatic QI study that did not require consent for randomization, we used HbA_{1c} levels and BMI data that were obtained for clinical purposes. Therefore, there was variability in the time between the baseline and follow-up assessments. Moreover, we were limited in the type of data we could abstract from the EHR and we did not have the ability to review changes in antihyperglycemic medication use for the complete cohort. Among the EC-HR subset of individuals who provided written informed consent for EHR review, medication intensification did not drive between-group change in HbA_{1c} levels. Follow-up interviews were limited to the EC-HR data repository participants and the experiences of participants in the UC arm were not explored. Finally, we cannot discern the comparative effectiveness of dietary carbohydrate restriction plus CGM versus dietary carbohydrate restriction or CGM alone. However, our results suggest that CGM may facilitate the translation of low-carbohydrate diets into routine clinical practice. This contrasts with previous efficacy and effectiveness studies of dietary carbohydrate restriction, which are often intensive or require study-specific personnel, which may limit their generalizability to routine practice settings.

Conclusions

Many patients with T2DM do not achieve optimal glycemic control [7] despite clinical practice guideline recommendations [15,16] and interventions to support the intensification of patients' antihyperglycemic regimens [4]. There is now growing evidence to support the use of carbohydrate-restricted diets to help patients reduce blood glucose levels and medication use [16,18,41]. However, the degree to which individual patients need to restrict dietary carbohydrates to achieve benefits is unknown [19]. Our findings demonstrate that the use of CGM technology and personalized nutrition counseling focused on dietary carbohydrate restriction can help patients with suboptimally controlled T2DM to improve HbA_{1c} levels without increasing antihyperglycemic medication use. As CGM technology evolves [21] and carbohydrate restriction is increasingly accepted as a powerful tool to support T2DM self-management, this program may be a scalable and sustainable strategy to help and empower patients with T2DM to achieve glycemic control.

Abstract

Background: Digital health interventions may offer a scalable way to prevent type 2 diabetes (T2D) with minimal burden on health care systems by providing early support for healthy behaviors among adults at increased risk for T2D. However, ensuring continued engagement with digital solutions is a challenge impacting the expected effectiveness.

Objective: We aimed to investigate the longitudinal usage patterns of a digital healthy habit formation intervention, BitHabit, and the associations with changes in T2D risk factors.

Methods: This is a secondary analysis of the StopDia (Stop Diabetes) study, an unblinded parallel 1-year randomized controlled trial evaluating the effectiveness of the BitHabit app alone or together with face-to-face group coaching in comparison with routine care in Finland in 2017-2019 among community-dwelling adults (aged 18 to 74 years) at an increased risk of T2D. We used longitudinal data on usage from 1926 participants randomized to the digital intervention arms. Latent class growth models were applied to identify user engagement trajectories with the app during the study. Predictors for trajectory membership were examined with multinomial logistic regression models. Analysis of covariance was used to investigate the association between trajectories and 12-month changes in T2D risk factors.

Results: More than half (1022/1926, 53.1%) of the participants continued to use the app throughout the 12-month intervention. The following 4 user engagement trajectories were identified: terminated usage (904/1926, 46.9%), weekly usage (731/1926, 38.0%), twice weekly usage (208/1926, 10.8%), and daily usage (83/1926, 4.3%). Active app use during the first month, higher net promoter score after the first 1 to 2 months of use, older age, and better quality of diet at baseline increased the odds of

belonging to the continued usage trajectories. Compared with other trajectories, daily usage was associated with a higher increase in diet quality and a more pronounced decrease in BMI and waist circumference at 12 months.

Conclusions: Distinct long-term usage trajectories of the BitHabit app were identified, and individual predictors for belonging to different trajectory groups were found. These findings highlight the need for being able to identify individuals likely to disengage from interventions early on, and could be used to inform the development of future adaptive interventions.

KEYWORDS

type 2 diabetes; user engagement; digital behavior change intervention; trajectories; habit formation; mobile health

Introduction

Type 2 diabetes (T2D) is currently one of the most prevalent noncommunicable diseases burdening public health globally [1]. It is a progressing disease that compromises health-related quality of life [2,3], introduces severe comorbidities, and increases premature mortality [4,5]. It also has a significant economic impact on individuals, health systems, and societies [6]. However, research shows that T2D could be prevented efficiently by lifestyle improvement [7-9]. This highlights the need for early diabetes prevention. In addition, plausible effects of lifestyle changes are reported to sustain for several years [10,11]. Still, after 20 years of evidence of effectiveness, health care systems struggle to find and implement scalable individual-level lifestyle change support in routine practice.

Digital health interventions may offer a scalable way to prevent T2D by providing early support for healthy behavior improvement among individuals at increased risk of T2D with minimal burden to health systems. A recent review supported findings on the effectiveness of technology-driven T2D prevention interventions in producing short-term (≤6 months) and long-term (≥12 months) weight loss, with the number of behavior change techniques applied positively associated with effectiveness [12]. However, continuous user engagement in digital solutions remains a challenge [13-15], impacting the expected effectiveness. For this, finding out who will actively use and potentially benefit from digital solutions is essential for providing the right care to the right person at the right time, which, in turn, will potentially improve the personalization and optimization of the care.

The BitHabit app was developed in the Finnish Stop Diabetes (StopDia) project to provide adults at increased risk of T2D an easy way to form healthy lifestyle habits [16]. The applicability of the BitHabit app was further evaluated in the Finnish health care system in a 12-month randomized controlled trial (RCT) [16]. The aims of this study were to (1) identify long-term user engagement trajectories of the BitHabit app among the participants, (2) examine predictors of the trajectories, and (3) investigate associations between the trajectories and changes in T2D risk factors during the trial.

Methods

Study Design and Participants

This study is a secondary analysis of the StopDia trial, which was an unblinded parallel RCT (ClinicalTrials, NCT03156478). The participants of the trial were randomly allocated to a digital intervention group (DIGI; n=967), a group combining the digital intervention and face-to-face group coaching (DIGI+GROUP; n=971), or a control group (n=969). Randomization was done using a computerized randomization system with 1:1:1 allocation after baseline examinations. In this study, only data from the digital intervention arms (ie, DIGI and DIGI+GROUP) were used. The RCT study protocol, including the intervention lifestyle objectives and outcome measures, has been described in more detail in earlier work [16].

The participants were recruited from several communication channels, such as social media, newspapers, radio, television, websites, health care and social service units, and community pharmacies, by encouraging people to visit the website of the project to fill in the StopDia Digital Screening Tool [17]. The participants were adults aged 18 to 74 years living in 3 provinces of Finland and being at increased risk of T2D as identified with the StopDia Digital Screening Tool including the Finnish Diabetes Risk Score (FINDRISC) developed to estimate the 10-year risk of developing drug-treated T2D [18]. Adults at increased risk of T2D, who scored at least 12 points in the FINDRISC, had repeatedly measured impaired fasting glucose or glucose tolerance, or had a history of gestational diabetes, were invited to participate in the study. Other inclusion criteria were a possibility to use a computer, smartphone, or tablet with internet access; having a mobile phone number; and having adequate Finnish language skills. The exclusion criteria were current type 1 or 2 diabetes, current pregnancy or breastfeeding, having an active cancer, and being less than 6 months from active cancer treatment.

Intervention

Participants in the DIGI and DIGI+GROUP received access to the BitHabit app for the 1-year intervention period in 2017-2019. The BitHabit app was designed in the StopDia project based on principles derived from habit formation theories [19,20] and the Self-Determination Theory [21]. The BitHabit app has been described in more detail earlier [22]. Briefly, the main goal of the app was to help the participants form lifestyle habits that

would help prevent T2D. The app provided the user with a broad selection of behaviors in 13 different categories related to diet, physical activity, sleep, positive mood, stress management, smoking, and alcohol consumption. App use included browsing and selecting context-specific minimum-effort behaviors, reporting performances, and monitoring progress. Automatization of the behaviors into frequently repeated habits was facilitated by the nature of the behaviors (simple, with contextual triggers) as well as reminders for reporting performances.

In addition to using the BitHabit app, DIGI+GROUP members also participated in group coaching consisting of 6 meetings organized in local health care centers, as explained in detail previously [22].

Study Visits

At the first examination visit, after the participants had signed informed consent, clinical measurements, including body weight and height, and waist circumference, were taken by a study nurse in a local health care center. Thereafter, participants received a link to a StopDia Digital Questionnaire with standardized and validated questions in 3 sets to assess diet quality, eating behavior, physical activity, sedentary time, smoking, quality of life, stress, sleep, and several other factors related to T2D risk. The second examination consisted of laboratory measures, including blood glucose, taken in the local health care center. All baseline assessments were repeated at the 12-month follow-up.

After using the app for 1 to 2 months, the DIGI and DIGI+GROUP members were also asked to answer questions on app user experience. They were also asked if they would recommend the BitHabit app to their friends, with possible responses ranging from 0 (not at all likely to recommend) to 10 (very likely to recommend).

Assessments

Baseline Characteristics

At baseline, the participants reported on the following clinical factors: age (categorized as <50, 50-59, and ≥60 years), sex, BMI (kg/m^2), waist circumference (cm), glycated hemoglobin A_{1c} (HbA_{1c}; mmol/mol), FINDRISC, diet quality, and physical activity. Obesity was defined as BMI ≥30 kg/m^2, and abdominal obesity was defined as a waist circumference ≥88 cm for women and ≥102 cm for men [23]. Diet quality was assessed using the Healthy Diet Index that ranges between 0 and 100, and is calculated as the sum of scores for 7 main domains, including meal pattern (0-10 points), grains (0-20 points), fruits and vegetables (0-20 points), fats (0-15 points), fish and meat (0-10 points), dairy (0-10 points), and snacks and treats (0-15 points), with higher scores indicating a healthier diet [24]. Perceived self-efficacy related to nutrition was measured with the Nutrition Emotional Barriers Self-Efficacy Score, with higher scores indicating better emotional barrier self-efficacy [25]. Perceived stress was assessed with the Perceived Stress Scale consisting of 10 questions, with higher scores indicating a higher level of experienced stress [26]. Total physical activity (hours/week) was measured as the sum of leisure time total physical activity, combined total physical activity during work trips, and total conditioning and functional physical activity.

Socioeconomic factors considered were education (categorized as elementary school, high or vocational school, and college or academic degree), household size (categorized as single, and two or more members), and household gross income (categorized as <€25,000/year, €25,000-64,999/year, and ≥€65,000/year). A currency exchange rate of €1=US $1.14 is applicable.

Factors describing digital abilities were prior use of healthy lifestyle digital apps and internet use several times per day. The factor describing the intervention was the use of the BitHabit app together with face-to-face group coaching.

Early User Experience and Use Engagement

User experience was measured after using the app for 1 to 2 months as the rating of the likelihood to recommend the app to others (0-10), which was categorized according to the net promoter score definition [27] into detractors (0-6), passives (7-8), and promoters (9-10).

Furthermore, short-term user engagement was measured as the number of app usage days during the first month of use.

User Engagement

Automatically collected log files of BitHabit app use included time-stamped user interactions from which usage metrics, such as usage days, usage sessions and their durations, selected habits, and habit performances, were derived.

Outcomes

In this study, 12-month changes in selected T2D risk factors (ie, diet quality measured with the Healthy Diet Index, waist circumference, BMI, and HbA_{1c}) were used as outcome measures, which were measured as differences (in absolute scale or in percentage) between baseline and the end of the intervention at 12 months.

Statistical Analyses

Latent class growth models can be utilized to identify homogeneous subpopulations when studying developmental trajectories from a heterogeneous population [28-30]. This data-driven modeling technique was applied to cluster participants into distinct trajectories of app user engagement. App user engagement was measured as monthly usage days during 2 to 12 months after initiation of app use. This provided 11 repeated measurements on the number of app usage days within 1 month (0-31 days/month). First month usage days were not included in the trajectory analyses but were used as a predictor for trajectory membership in later analyses, as early use is a known predictor of sustained use [31-33]. The number of classes (ie, trajectories) is *a priori* unknown and must be estimated from the data by iteratively fitting alternative models. Models with 1 to 5 classes and varying shapes for the trajectories (linear, quadratic, and cubic) were fitted. Models were estimated with full-information maximum likelihood, and missing data were not imputed, but all available data were used. The method assumes no variation within the trajectories. Unadjusted analyses were conducted. To find the best model, we utilized information

from fit indices and the classification performance of the model, as well as clinical interpretation of the trajectories. The Bayesian information criterion was used as a measure of model adequacy, with a lower value indicating a better model with optimal balance between complexity and good fit. The Low-Mendel-Rubin likelihood ratio test with a *P* value <.05 was considered to indicate better fit for an *n*-class model than for an *n*−1 class model. Entropy was used to guide in the classification accuracy of the model, with higher values indicating better classification. Small classes with less than 4% of the total population were not accepted, and to ensure at least 70 participants per group, latent class growth modeling was performed using Mplus Version 8 [34].

Differences in baseline characteristics between the participant groups defined by the identified trajectories were examined with the chi-square test for categorical variables and the Kruskal-Wallis test for continuous variables. Thereafter, a multivariable multinomial logistic regression model was applied to examine the factors associated with the trajectory membership. In a sensitivity analysis, the model was also adjusted for belonging to the DIGI+GROUP. User experience was introduced in the main analysis by conducting a subgroup analysis among the participants who responded to the user experience questionnaire after the first 1 to 2 months of use. Finally, analysis of covariance was used to study associations between the trajectories and short-term changes in T2D risk factors. Models were adjusted for age, sex, and the baseline value of the specific T2D risk factor to account for possible differences in baseline values. Analyses were conducted with IBM SPSS Version 25.0 (IBM Corp) and R Version 4.0.4 (R Core Team). Statistical significance was set at *P*<.05.

Ethics Statement

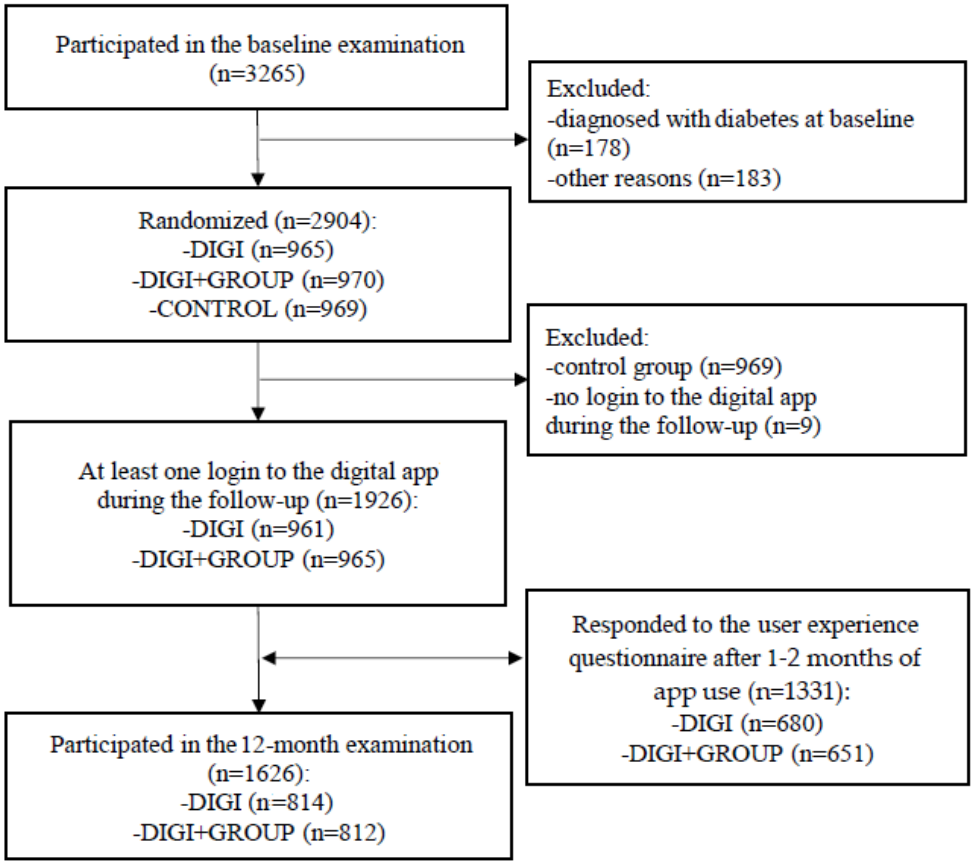
The StopDia study was approved by the Research Ethics Committee of the Hospital District of Northern Savo (number: 467/2016). Written informed consent for participation in the study and the use of data from national health care registers was obtained from all study participants.

Results

Population Characteristics

The study cohort included 1926 participants in the intervention arms with at least one login to the BitHabit app during the study period (Figure 1). Among them, the mean age was 55.2 (SD 10.0) years, and 79.7% (1535/1926) of the participants were women (Multimedia Appendix 1).

Figure 1. Flow chart of the study population. DIGI, digital intervention group; DIGI+GROUP, group combining the digital intervention and face-to-face group coaching.



User Engagement Trajectories

Based on the Low-Mendel-Rubin likelihood ratio test and the clinical interpretation, a 4-class cubic latent class growth model was identified as the best fitting model with good interpretability (Figure 2; Multimedia Appendix 2). Almost half of the participants (904/1926, 46.9%) had very few usage days in the first months of the study, and they dropped close to zero after 6 to 7 months. Another large group (731/1926, 38.0%) started

with approximately 6 usage days per month, which decreased gradually to 3 days per month by the 12th month. A further 10.8% (208/1926) of participants had approximately 14 usage days during the second month with a decrease to 8 days during the 12th month. The remaining 4.3% (83/1926) of participants had almost 23 days of use during the second month, and the usage was sustained with a gradual decrease to 18 days of use during the 12th month.

The identified trajectories were differentiated well when examined with other usage activity metrics (Table 1). Based on the trajectories and all usage metrics, the groups were named as (1) terminated usage, (2) weekly usage, (3) twice weekly usage, and (4) daily usage (Multimedia Appendix 1).

Predictors of User Engagement Trajectories

Active app use during the first month increased the odds of belonging to the more engaged trajectories (odds ratio [OR] 1.65, 95% CI 1.57-1.75 for daily usage; OR 1.45, 95% CI 1.40-1.51 for twice weekly usage; and OR 1.19, 95% CI 1.15-1.22 for weekly usage) than the terminated usage trajectory (Table 2). In addition, older age was associated with increased user engagement compared with the terminated usage category (OR 0.07, 95% CI 0.02-0.19 in those aged <50 years and OR 0.44, 95% CI 0.22-0.87 in those aged 50-59 years for daily usage; OR 0.19, 95% CI 0.11-0.33 in those aged <50 years and OR 0.40, 95% 0.26-0.64 in those aged 50-59 years for twice weekly usage; and OR 0.45, 95% CI 0.34-0.61 in those aged <50 years and OR 0.61, 95% CI 0.47-0.79 in those aged 50-59 years for weekly usage compared with those aged ≥60 years). Women were less likely to be daily users (OR 0.43, 95% CI 0.19-0.98) than terminated users. Better diet quality at baseline, measured with the Healthy Diet Index, increased the odds of belonging to the more engaged trajectories (OR 1.04, 95% CI 1.01-1.08 for daily usage and OR 1.03, 95% CI 1.01-1.05 for twice weekly usage) than the terminated usage trajectory. Prior internet use of several times per day (OR 0.41, 95% CI 0.21-0.79 for daily usage and OR 0.73, 95% CI 0.57-0.95 for weekly usage) decreased the odds of belonging to the more engaged trajectories than the terminated usage trajectory. According to the sensitivity analysis, face-to-face group coaching decreased the odds of belonging to the more engaged trajectories (OR 0.28, 95% CI 0.15-0.52 for daily usage; OR 0.49, 95% CI 0.34-0.73 for twice weekly usage; and OR 0.64, 95% CI 0.52-0.80 for weekly usage) than the terminated usage trajectory (Multimedia Appendix 3). However, there were no more differences between the sexes in trajectory membership.

In a subgroup analysis among 1314 participants who responded to the questionnaire after the first 1 to 2 months of use and had complete data on predictors, app usage days during the first month remained a predictor for trajectory membership (OR 1.56, 95% CI 1.47-1.66 for daily usage; OR 1.37, 95% CI 1.31-1.43 for twice weekly usage; and OR 1.13, 95% CI 1.10-1.17 for weekly usage compared with terminated usage; Multimedia Appendix 4). Furthermore, the detractors classified by the net promoter score had significantly lower odds of belonging to the more engaged trajectories than the terminated usage trajectory (OR 0.23, 95% CI 0.10-0.55 for daily usage; OR 0.19, 95% CI 0.11-0.35 for twice weekly usage; and OR 0.37, 95% CI 0.25-0.55 for weekly usage) compared with promoters of the app.

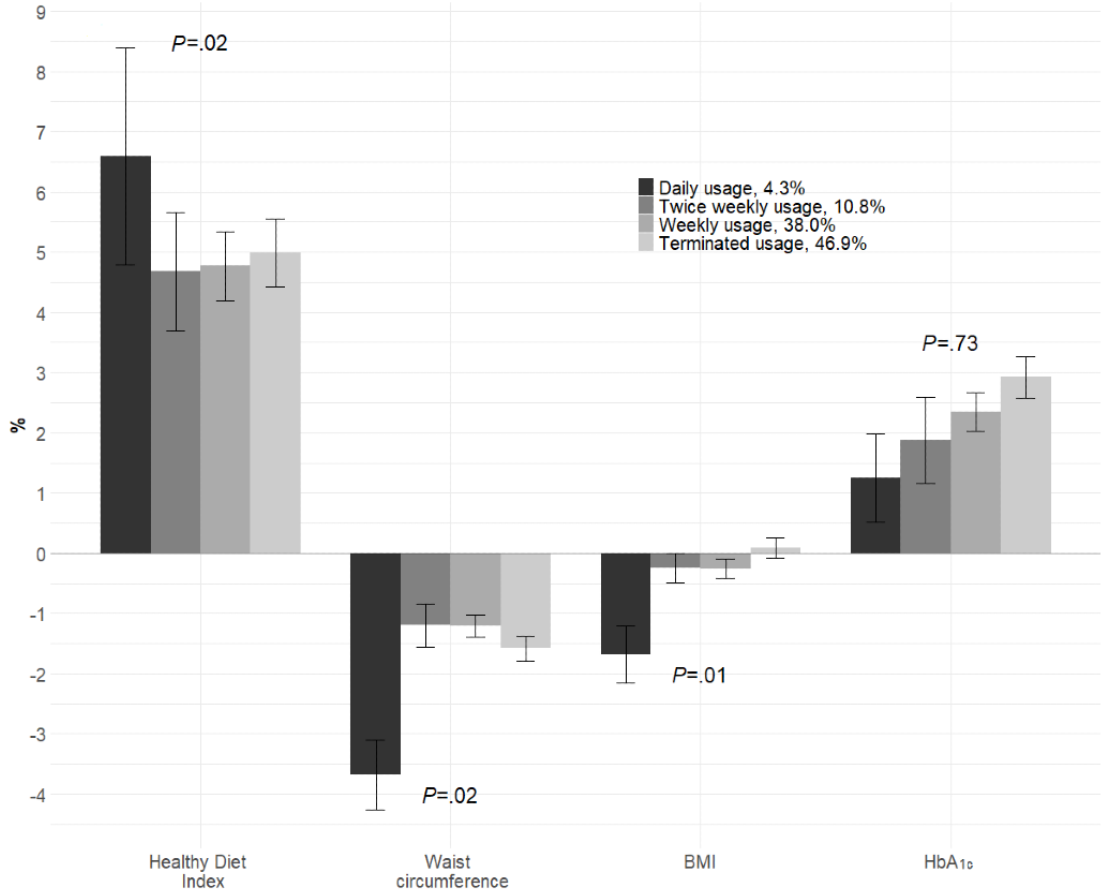
Trajectories and Changes in T2D Risk Factors Over 12 Months

High user engagement was associated with 12-month changes in T2D risk factor levels (Figure 3; Multimedia Appendix 5). Compared with the other trajectories, daily usage was associated with a higher increase in the Healthy Diet Index ($P=.02$) and a more pronounced decrease in BMI ($P=.01$) and waist circumference ($P=.02$) at 12 months.

Figure 3. Changes (%) in risk factor levels over 12 months by user engagement trajectories. The error bars represent 95% CIs for means. *P* values are obtained from the analysis of covariance for the main effect of the user engagement trajectory on the change score adjusted for age, sex, and baseline value. HbA_{1c}: glycated hemoglobin A_{1c}.



Discussion

Principal Findings

Four different trajectories of digital app use were identified with a data-driven technique. We observed that initial user engagement during the first month of the intervention, the net promoter score after the first 1 to 2 months of use, older age, and better diet quality at baseline predicted long-term user engagement. While those who had sustained use once to a couple of times per week showed small beneficial changes in risk factor levels in comparison to those who terminated use, those who used the app almost on a daily basis throughout the study showed the most beneficial changes.

Comparison With Prior Research

According to our previously reported results, 99% of participants who were allocated to use the BitHabit app logged into the app at least once and selected at least one habit, and 95% reported at least one habit performance during a 6-month follow-up [22]. No significant differences were observed in cumulative usage metrics between the DIGI and DIGI+GROUP, and more than 50% of the participants in both intervention groups continued to use the app at least on a weekly basis in the first 6 months [22]. This study showed that these active users continued to use the app for the entire 12-month intervention. However, according to the sensitivity analysis, receiving face-to-face group coaching in addition to the digital intervention slightly decreased engagement with the app. Participating in the face-to-face coaching may have decreased the need for later digital support. It should be noted that membership in the DIGI+GROUP arm may have mediated the effects in the sensitivity analysis, and therefore, it was omitted from the main analysis.

Overall, BitHabit app use remained remarkably high in comparison with the use of other digital health apps [22]. For example, Goh et al identified 3 short-term 8-week trajectories of weekly use activity for a caloric-monitoring mobile app among T2D patients [35]. A large proportion of the “minimal user” participants (79%) stopped use within the first 2 weeks. Although women seemed to be more active users, we found no gender differences in app use. Older participants were more likely to show frequent use. These background characteristics have been previously reported to be associated with more active use by others as well [36-38]. This result is promising as it demonstrates that digital interventions can be provided to people of all ages. One can only speculate on the reasons for this finding, but a plausible explanation is higher relevance of T2D prevention. Another explanation could be having less work- and family-related daily activities and hence more time for app use. Other than age and household income, no background factors were found to be associated with app use trajectories. However, prior internet use several times per day predicted

lower user engagement with the app. Intensive internet use has been associated with lower physical activity in adults [39], which may partly explain the observed association in this study.

App use during the first month and the net promoter score were predictors for user engagement trajectories. Previous studies have shown that short-term treatment adherence predicts future adherence outcomes better than baseline characteristics alone, for example, in the case of adherence to self-management for chronic diseases [31,32]. In a recent study, usage during the first 24 hours after login predicted long-term engagement with a weight loss app [33]. We tested the early adherence hypothesis with a 4-week period, considering it a sufficiently long window of opportunity for monitoring and supporting user engagement in real-world prevention programs.

Theoretically, terminating app use does not necessarily imply disengagement from using the behavior change techniques of the intervention [40]. For example, the habit formation approach in the BitHabit app could have led to termination of app use if participants felt that they had already formed sufficiently strong habits or had learnt to follow the habit formation process without the app. Based on the literature, habit formation takes 10 weeks on average, so even for forming multiple habits, 12 months is a rather long usage time [41]. However, our empirical findings suggest that this was not the case in our study, as those who terminated app use had selected less habits than the other user groups and showed no benefits of the intervention in terms of risk factor levels. Moreover, the benefits increased significantly when the frequency of use increased from weekly to daily. Our results are in line with the findings of previous studies reporting that the effectiveness of digital interventions is dependent on user engagement with the intervention [42-44]. Future studies are needed on whether plausible effects of lifestyle interventions sustain the longest among those with the most active engagement during the intervention or whether effective engagement should be determined through other metrics, such as the content of use (eg, type and quality of habits selected and tracked by the users).

The results indicated that only a minor proportion of the participants, belonging to the trajectory of most active users, achieved marked lifestyle changes. Furthermore, the most active users had better well-being at baseline (ie, better diet, more physical activity, and lower stress levels), which is consistent with previous studies [37,38]. Reaching and engaging those with the highest risks and needs are known challenges in most interventions. Adaptive interventions, that is, monitoring for the early indicators of nonresponse and adapting interventions (eg, augmenting or switching interventions), have been proposed as a solution [45]. This seems especially promising in digital interventions, which inherently enable real-time monitoring of user engagement and detection of waning usage as an early indicator of nonresponse. As this study showed, use activity and user experience after the first month of use predicted long-term user engagement. Thus, early use may be regarded as a window of opportunity where user engagement should be monitored and supported especially in real-world prevention programs. If strategies, such as personalized messages and reminders, fail to re-engage participants with the app, they should be offered alternative interventions, such as face-to-face interventions, or other types of digital solutions for weight management and lifestyle changes [46]. Especially in health care that faces cost containment pressures, this kind of approach would help in providing appropriate types of interventions to different individuals.

Strengths and Limitations

The strengths of our study include a real-life setting together with a larger sample size and a longer follow-up than in previous studies on the use of digital health apps in persons with prediabetes or T2D [31,43,47]. Additionally, the studied app could be accessed easily with any device as indicated by an almost 100% first login rate, which reduced selection bias and further strengthened our sample.

However, our study also has some limitations. Women were overrepresented in the sample. The proportion of participants who dropped out during the study and, therefore, the proportion of missing data in outcome variables differed between the identified trajectories. We utilized monthly usage days as a measure for user engagement. However, the sensitivity of this measure in detecting changes in risk factors compared with other user activity metrics remains unknown. The composition of selected habits may also be an important factor for risk factor changes and should be examined in future studies.

Conclusions

Data-driven analysis of digital app user activity is necessary because it reveals true usage patterns. In this study, short-term user engagement, defined as user activity during the first month after the initiation of app use, was found to predict long-term user engagement. Metrics of user experience, based on the net promoter score and measured after early use, was another predictor of long-term user engagement and is a measure that can be easily implemented. These findings could be used in further developments aimed at predicting responses to digital interventions, adapting digital interventions for persons at risk of disengagement, and identifying persons who would benefit the most from using the app.

Acknowledgments

We would like to thank the Strategic Research Council at the Academy of Finland for funding our "Stop Diabetes—from knowledge to solutions (StopDia)" project in 2016-2019 (diary number 303537), the Novo Nordisk Foundation for providing funding in 2018-2020 (diary numbers 33980 and 63753), the Finnish Diabetes Research foundation for providing funding, and the Academy of Finland for funding the project "T2D-DATA" in 2020-2023 (diary numbers 332464 and 332465). We would also like to acknowledge the valuable contributions of the research consortium, our national and international collaborators, the primary health care providers involved in the study, the citizens who participated in the feasibility testing, and the citizens who enrolled

in the study. The funders had no role in designing the study or collecting, managing, or analyzing the data; interpreting the results; writing the manuscript; or deciding to submit the manuscript for publication.

Conflicts of Interest

Abstract

Background: There is much public debate regarding the high cost of insulin. With 1-in-4 patients in the United States with type 1 diabetes reporting difficulties affording insulin, there is concern that some of these patients might look for cost savings on the internet, unaware that 96% of internet pharmacies are illegitimate. Patients who purchase insulin from illegitimate internet pharmacies remove themselves from traditional health care systems that ensure safe, quality-assured, and effective medication use.

Objective: This study aims to determine the accessibility of Humalog and NovoLog insulin from internet pharmacies and characterize how these sites approached patient safety, and priced as well as marketed their products.

Methods: From September to December 2019, we queried the phrases *buy insulin online*, *buy Humalog online*, and *buy NovoLog online* in common search engines. The first 100 search results from Google and Bing, and the first 50 search results from Yahoo! and DuckDuckGo were screened. Websites were included if they claimed to sell Humalog or NovoLog insulin, were active, free access, in the English language, and had a unique URL. The legitimacy of websites was classified using LegitScript. Safety and marketing characteristics were compared across the legitimacy of internet pharmacies. Internet pharmacy prices were compared with the prices offered through brick-and-mortar pharmacies using GoodRx.

Results: We found that 59% (n=29) of the 49 internet pharmacies in our analysis were illegitimate, whereas only 14% (n=7) were legitimate and 27% (n=13) were unclassified. Across illegitimate internet pharmacies, Humalog and NovoLog insulin were 2 to 5 times cheaper as compared with both legitimate internet pharmacies and brick-and-mortar stores. Risks associated with the use of illegitimate internet pharmacies by American consumers were evident: 57% (8/14) did not require a prescription, 43% (6/14) did not display medication information or warnings, and only 21% (3/14) offered access to purported pharmacists. This included 9 rogue internet pharmacies that sold Humalog and NovoLog insulin within the United States, where 11% (1/9) required a prescription, 11% (1/9) placed quantity limits per purchase, and none offered pharmacist services. Rogue internet pharmacies often offered bulk discounts (11/18, 61%), assured privacy (14/18, 78%), and promoted other products alongside insulin (13/18, 72%). The marketing language of illegitimate internet pharmacies appealed more to quality, safety, and customer service as compared with legitimate sites.

Conclusions: The ease of access to low-cost insulin through illegitimate internet pharmacies calls for urgent attention. Illegitimate internet pharmacies place patients at risk of poor-quality medications and subpar pharmacy services, resulting in adverse events

and poor diabetes control. A multifaceted approach is needed to close illegitimate internet pharmacies through legal and regulatory measures, develop better search engine filters, raise public awareness of the dangers of illegitimate internet pharmacies, and address the high costs of insulin.

Introduction

Access to Insulin

For patients with type 1 or type 2 advanced diabetes, insulin is the cornerstone of therapy. Furthermore, 1 in 10 Americans (around 34.2 million people) have diabetes, with nearly 1.6 million living with type 1 diabetes [1]. Patients with type 1 diabetes cannot produce endogenous insulin and thus require treatment with exogenous insulin. For patients living with type 2 diabetes, insulin is often required if adequate glycemic control is not maintained with lifestyle modifications and noninsulin medications. In patients who require insulin, regulation of blood glucose is tantamount to disease control; if uncontrolled, it can result in acute, life-threatening conditions of diabetic ketoacidosis or severe hypoglycemia, as well as chronic but still life-threatening complications such as cardiovascular disease, nephropathies, retinopathies, and neuropathies [2]. These complications can result in—among other outcomes—dialysis-dependence, blindness, amputations, serious quality-of-life reductions, and death [2].

Increasingly, rising costs unique to the US market have hindered access to insulin for patients [3]. Despite legislative initiatives to control prescription drug costs, high insulin costs in the United States persist, with list prices of insulin tripling between 2003 and 2013 [3]. Although insulin was first used as a medication in 1922, the insulin market remains dominated by branded products, with no actual generic drug approved. This is important as generic competition has been shown to decrease medicine prices by 60% on average, when 3 or more manufacturers that are generic are in the market [4]. High costs are associated with all insulin types, but rapid-acting insulin analogs such as Humalog (insulin lispro) and NovoLog (insulin aspart) are among the highest priced [3]. Humalog's list price, for example, continued to increase after 2014 from US $391 to nearly US $600 in 2017—a list price increase similar to that of its competitor NovoLog. It is worth noting that net prices remained relatively stable for Humalog and NovoLog during that time frame, meaning that an increase in costs was primarily offset by discounts made available [5]. Regardless, high list prices have a direct impact on patients; in 2019, 1 in 4 patients in the United States with type 1 diabetes reported difficulties affording their medication [6]. Patients such as these are often led to make difficult decisions. More than 1 in 4 patients in the United States with type 1 diabetes reported rationing their insulin in 2019 [7]. Patients who struggle to access insulin from traditional methods, namely brick-and-mortar pharmacies, might look for alternative, lower-cost methods, such as purchasing insulin from friends, across borders, or from illegitimate internet pharmacies [8,9].

Growth of Internet Pharmacies

Internet pharmacies are a popular destination for the purchase of prescription drugs, with 30,000 to 35,000 internet pharmacies accessible in 2016 [10]. Internet pharmacies are defined by whether they operate as legitimate pharmacies or whether they are illegitimate and in violation of US pharmacy laws and practice standards [11]. It has been reported that 96% of all accessible internet pharmacies are illegitimate [10]. According to the World Health Organization, more than 50% of medications acquired from internet pharmacies that do not advertise their physical location (a common characteristic of illegitimate internet pharmacies) are counterfeit or substandard [12]. The dangers associated with illegitimate internet pharmacies have led to the implementation of rules and regulations to ensure safe internet pharmacy use. For example, several states in the United States require internet pharmacies to be accredited with the National Association of Boards of Pharmacy (NABP) to receive licensure [13]. However, the enforcement of such rules and regulations is complicated by an intricate e-commerce environment composed of numerous, often international, stakeholders [11]. The complexity and anonymity of e-commerce allows illegitimate internet pharmacies to avoid detection, and even when detected, reopen operations under new web addresses [14]. Given the evasiveness and high prevalence of illegitimate internet pharmacies, there is concern that patients purchasing medications on the internet might be subject to low-quality products, which could result in the development of dangerous adverse effects, especially for high-risk medications such as insulin.

Beyond concerns related to medication quality, there is also concern regarding the lack of services offered by illegitimate internet pharmacies [15]. In choosing illegitimate internet pharmacies, patients opt out of medication counseling, monitoring, and drug-drug interactions checking that pharmacists and other health care professionals provide to ensure proper medication use [16]. The use of these resources is well documented to improve patient outcomes [17]. Insufficient safety measures could also be further exacerbated by marketing methods that illegitimate internet pharmacies use to attract consumers. Although it has been shown that patients using illegitimate internet pharmacies are at greater risk of developing adverse effects from treatment, there is a lack of current data on how illegitimate internet pharmacies approach patient safety and the marketing methods they use, particularly for high-risk medications [18].

Objective

The accessibility of rapid-acting insulins from illegitimate internet pharmacies could pose a threat to patient safety. We

investigated the availability of Humalog and NovoLog insulin from internet pharmacies through common search engines and documented the website's safety and marketing characteristics, as well as the costs of Humalog and NovoLog insulin.

Methods

Overview

Humalog and NovoLog were chosen for our analysis because of their relatively recent approval by the US Food and Drug Administration (FDA), high list prices, and their outsized role in the discussion of medication pricing in the United States [3]. Website screening was conducted from September to December 2019 using 4 search engines (Google, Bing, Yahoo!, and DuckDuckGo) with the phrases *buy insulin online*, *buy Humalog online*, and *buy NovoLog online*. For each search phrase, the first 100 results from Google and Bing and the first 50 of Yahoo! and DuckDuckGo were screened. Google, Bing, and Yahoo! were chosen for their widespread use in the United States. In addition, DuckDuckGo was searched because of its emphasis on user privacy. Websites were included if they claimed to sell Humalog or NovoLog insulin, were active, free access, in the English language, and had a unique URL. Websites selling Humalog or NovoLog insulin that were accessed from search engine results through a landing page were included. Screenshots were taken of each website for records.

The legitimacy of websites was assessed using LegitScript, which classifies pharmacies according to licensure or registration in affiliated jurisdictions, sale of controlled substances, previous discipline, requirement of valid prescription, protection of privacy, patient services offered, transparency, and domain name registration [19]. LegitScript was chosen to assess internet pharmacy legitimacy because of the breadth of internet pharmacies that it monitors (81,000+) and its partnerships with private (eg, Google, Amazon, Facebook) and governmental agencies (eg, FDA). The websites in this analysis were classified as (1) illegitimate, subclassified as (1a) rogue—*these merchants engage in illegal, unsafe, or misleading activities such as selling prescription drugs without a prescription* and (1b) unapproved—*there is some problem with regulatory compliance or risk, but it is typically less egregious than rogue* or (2) legitimate—*these merchants are registered with a LegitScript certification program and have passed LegitScript certification criteria* or (3) unclassified—no information was available from LegitScript.

The average monthly traffic to website domains defined as unique visits from any country was obtained from SimilarWeb [20]. This website aggregates information on website traffic from a variety of sources. We compared website traffic with the legitimacy of internet pharmacies. The IP addresses of internet pharmacies were examined using IP2location, which retrieves geographic information based on IP addresses [21]. IP address locations were compared with their listed locations.

Costs

Costs of Humalog and NovoLog 100 IU/mL insulin at the most frequently sold dosage forms (ie, 1×10-mL vials, 5×3-mL pens, 5×3-mL cartridges) were collected from a subset of internet pharmacies offering to ship within the United States. Prices per mL of 100 IU/mL Humalog and NovoLog insulin for vials, pens, and cartridges were calculated. The shipping costs and bulk discounts were not considered in the cost calculations. Internet pharmacy prices were compared with prices offered through GoodRx, a drug coupon website. GoodRx prices are representative of out-of-pocket prices that uninsured US patients might pay at brick-and-mortar stores. Average prices at brick-and-mortar stores were obtained from GoodRx on April 30, 2020. Costs were averaged by legitimacy of internet pharmacies among websites selling Humalog and NovoLog pens that offered US shipping.

Marketing

Marketing characteristics were selected based on previous literature, and the analysis focused on internet pharmacies classified by LegitScript [11,16,22,23]. Marketing characteristics were compared across the legitimacy of internet pharmacies. Cost-related marketing characteristics included whether internet pharmacies offered bulk discounts or promo codes. Promotional marketing characteristics included whether internet pharmacies displayed specific medication advertisements pertaining to any form of insulin, advertisements for other products on the page advertising Humalog or NovoLog insulin, or customer testimonies. Marketing characteristics appealing to customer service and general reputability included whether internet pharmacies displayed a phone number, offered the assistance of an associate, or claimed pharmacy registration in some form (eg, Canadian International Pharmacy Association, International Pharmacy Association of British Columbia, or PharmacyChecker [24]). Additional marketing characteristics included whether internet pharmacies offered privacy assurances (eg, discrete packaging or protection of health- or billing-related information) or offered shipping within the United States.

We qualitatively analyzed the website marketing language by collecting texts from the homepages of all included internet pharmacies. After initially reading through the texts to identify the most common marketing language, we selected and defined 6 characteristics. Texts were then screened to assess whether these six characteristics were discussed: (1) quality, (2) safety, (3) customer service, (4) reputability, (5) affordability, and (6) convenience. Quotes representative of each characteristic were collected by legitimacy of internet pharmacies.

Safety

Safety characteristics were selected based on previous literature and focused on internet pharmacies classified by LegitScript [11,16,22,23]. To allow a specific focus on US pharmacies, or those that should be compliant with US laws and regulations, safety characteristics were analyzed only for internet pharmacies that offered shipping within the United States. Safety characteristics were compared across the legitimacy of internet pharmacies. Basic pharmacy-related characteristics included the requirement of a prescription and controls on the amount of Humalog or NovoLog insulin that could be ordered (eg, restricting patients to a 90-day supply or the quantity listed on their prescription). Characteristics related to pharmacy services included whether there was an offer to speak with a pharmacist and whether medication information and drug-related warnings

and precautions were displayed on the product page. Characteristics related to location included whether the pharmacy listed a physical location and the website location listed matched the country of the IP address.

Results

Overview

We screened 300 websites and identified a total of 49 internet pharmacies that claimed to sell Humalog or NovoLog insulin. Of the internet pharmacies, LegitScript classified 59% (29/49) as illegitimate, including 37% (18/49) as rogue and 22% (11/49) as unapproved, whereas 14% (7/49) were legitimate and 27% (13/49) were unclassified. The listed locations of these internet pharmacies differed, with 41% (12/29, all rogue sites) of illegitimate internet pharmacies advertising no location. Of the 29 illegitimate internet pharmacies, 52% (15, 4 rogue and 11 unapproved sites) advertised a Canadian location. The remaining illegitimate internet pharmacies claimed to be located in Great Britain (1/29, 3%) or in Europe (1/29, 3%). No illegitimate internet pharmacies advertised a US location. For legitimate internet pharmacies, 43% (3/7) advertised locations in the United States, 29% (2/7) in Australia, 14% (1/7) in Canada, and 14% (1/7) in India. The majority (4/7, 57%) of legitimate internet pharmacies' physical locations listed on their websites matched those of their server locations. In contrast, physical and server locations matched only 27% (3/11) of the time among unapproved internet pharmacies. None of the physical and server locations matched among the 18 rogue internet pharmacies.

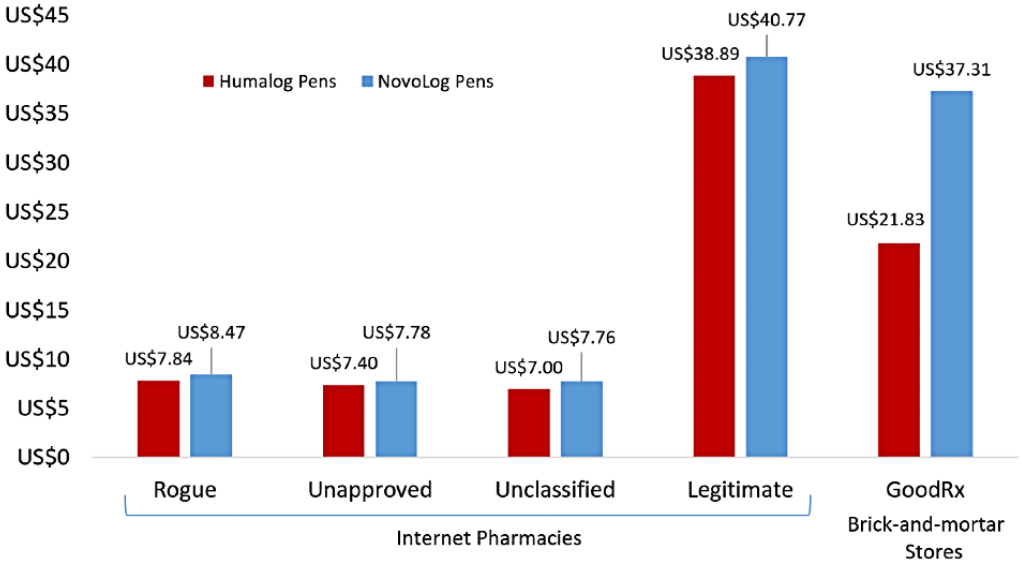
Traffic to internet pharmacies, as determined by SimilarWeb [20], differed depending on the legitimacy of internet pharmacies. Although illegitimate internet pharmacies were the most abundant in the search results, unique monthly visits to each site were comparatively lower for illegitimate internet pharmacies (0-250,000) than to legitimate internet pharmacies (5000-63.6 million). The 3 US-based legitimate internet pharmacies received the highest volumes of unique monthly traffic reported at 63.6 million (Costco), 40.35 million (CVS), and 1.17 million (Healthwarehouse) visits per month [25-27].

Costs

The costs of Humalog and NovoLog insulin vials, pens, and cartridges were recorded only for internet pharmacies shipping within the United States (n=22). The most commonly sold volume and strength of the insulin vials were 10 mL at 100 IU/mL. Humalog and NovoLog insulin 3 mL pens and 3 mL cartridges were most often sold in packages containing a quantity of 5, which is in alignment with product packaging available from brick-and-mortar pharmacies. The cost per mL of 100 IU/mL insulin varied depending on the legitimacy of the internet pharmacies. For rogue internet pharmacies, the average costs of insulin varied depending on dosage forms: Humalog vials cost US $11.30 (n=1), Humalog pens cost US $7.84 (n=4), and Humalog cartridges cost US $10.04 (n=4), whereas NovoLog vials cost US $5.90 (n=2), NovoLog pens cost US $8.47 (n=7), and NovoLog cartridges cost US $8.00 (n=3). Costs were similarly low in unapproved and unclassified internet pharmacies.

For legitimate internet pharmacies, the average costs of insulin (without insurance) were two- to five-fold higher: Humalog vials cost US $31.51 (n=2) and Humalog pens cost US $38.89 (n=2), whereas Humalog cartridges were not available; meanwhile NovoLog vials cost US $32.77 (n=2), NovoLog pens cost US $40.77 (n=2), and NovoLog cartridges cost US $38.47 (n=2). Compared with illegitimate pharmacies, GoodRx costs—representative of average costs at brick-and-mortar pharmacies—were also approximately 2 to 5 times more expensive. However, compared with the cost of legitimate internet pharmacies for uninsured patients excluding shipping costs, GoodRx prices were marginally cheaper: Humalog vials cost US $17.22, Humalog pens cost US $21.83, and Humalog cartridges cost US $34.13, whereas NovoLog vials cost US $29.38, NovoLog pens cost US $37.31, and NovoLog cartridges cost US $35.90. The difference in costs per mL of Humalog and NovoLog insulin pens (the most common dosage form in our analysis) depending on the source is depicted in Figure 1.

Figure 1. Costs of Humalog and NovoLog insulin pens available in the United States on the internet and at brick-and-mortar stores.



Marketing

The marketing characteristics of internet pharmacies selling Humalog and NovoLog insulin and classified by LegitScript (N=36) are described in Table 1. Rogue internet pharmacies differed from unapproved and legitimate internet pharmacies across several characteristics. More often, rogue internet pharmacies offered bulk discounts (11/18, 61%), assured privacy (14/18, 78%), and promoted other products on the Humalog or NovoLog insulin product pages (13/18, 72%). Although rogue internet pharmacies offered some form of contact through email or chat functions, most sites did not offer a phone number (11/18, 61%). Both legitimate (n=7) and unapproved (n=11) internet pharmacies shared similar characteristics, where few offered bulk discounts (2/7, 29% legitimate; 2/11, 18% unapproved), all displayed a phone number (18/18, 100%), and most touted registration or made accreditation claims (6/7, 86% legitimate; 10/11, 91% unapproved).

Table 1. Marketing characteristics of internet pharmacies selling Humalog or NovoLog[a].

Characteristics	Rogue (n=18), n (%)			Unapproved (n=11), n (%)			Legitimate (n=7), n (%)

[a]Illustrates marketing characteristics of 36 websites selling Humalog or NovoLog. This table does not include 13 internet pharmacies selling Humalog or NovoLog insulin that were not classified by LegitScript.

Marketing language from website homepages differed according to the legitimacy of internet pharmacies, particularly for quality, safety, and customer service. Although 83% (24/29) of illegitimate internet pharmacies appealed to quality, only 29% (2/7) of legitimate internet pharmacies used language that suggest the quality of medication or services. Marketing language appealing to safety (19/29, 66% illegitimate vs 1/7, 14% legitimate) and customer service (24/29, 83% vs 4/7, 57%) were also more common among illegitimate internet pharmacies. The frequency of use of marketing language was similar among reputability (16/29, 55% vs 4/7, 57%), affordability (24/29, 83% vs 5/7, 71%), and convenience (22/29, 76% vs 5/7, 71%).

Differences in marketing language are also demonstrated through the selection of quotes in Table 2. The marketing language of illegitimate internet pharmacies tended to communicate a sense of urgency to purchase products and strongly emphasized the merits of the pharmacy. For example, one quote from an illegitimate internet pharmacy appealed to reputation, affordability, and safety:

> *If you are looking to buy your prescription drugs in Canada, through a reputable international or online Canadian pharmacy, [our online pharmacy] provides you access to a trusted source of affordable and safe prescription drugs.* [Illegitimate pharmacy]

Table 2. Types of marketing language used on the home pages of internet pharmacies.

Characteristics	Description	Illegitimate (n=29)		Legitimate (n=7)	
		Values, n (%)	Selected quote[a]	Values, n (%)	Selected quote
Quality	Language suggesting quality of medication or services	24 (83)	"We guarantee that all [medications] for sale on this site are 100% genuine and extremely powerful."	2 (29)	"[We] offer you quality care..."
Safety	Language explicitly referring to the safety of medication products, internet ordering platform, or other services	19 (66)	"When it comes to your health, we know that safety is your number one concern. It's ours too."	1 (14)	"Besides delivering medicines at your doorstep, we...help people use their medicines effectively and safely."
Customer service	Language suggesting availability of staff to answer questions or remedy problems	24 (83)	"24/7 customer support (we are always at your disposal!)."	4 (57)	"Customer service: get answers to your questions."
Reputability	Language suggesting renown in selling or accreditation to sell prescription drugs	16 (55)	"[Our pharmacy] has a great reputation serving the community for 47 years and counting."	4 (57)	"Accredited and Certified in all 50 states."
Affordability	Language suggesting discounts or cheap prescription drugs	24 (83)	"[We] provide the same insulin that's available in the US except our prices are much lower, and we pass on the savings to you."	5 (71)	"At [our pharmacy], you can buy health products and medicines online at best discounts."
Convenience	Language suggesting ease of internet pharmacy use or prescription drug purchase; fast delivery or services that allow for time savings	22 (76)	"The process of payment through Bitcoin is simple. You need to go through only a few steps to quickly confirm and complete your order."	5 (71)	"You get the convenience of online shopping combined with the support and guidance of our dedicated team."

[a]Quotes were taken directly from internet pharmacy websites.

Safety

The safety characteristics of internet pharmacies selling Humalog and NovoLog insulin within the United States and classified by LegitScript (N=17) are described in Table 3. Overall, illegitimate internet pharmacies revealed poor patient safety records: 57% (8/14) did not require a prescription, 43% (6/14) did not display medication information or warnings, and only 21% (3/14) offered access to pharmacists. Rogue internet pharmacies differed from legitimate internet pharmacies more substantially than unapproved internet pharmacies in terms of patient safety. Rogue internet pharmacies seldom required a prescription (1/9, 11%) or placed quantity limits on the amount of medication that could be ordered (1/9, 11%), and none offered pharmacist services (0/9, 0%). Unapproved internet pharmacies uniformly claimed to require a prescription (5/5, 100%) and placed quantity limits (5/5, 100%), and some sites offered pharmacist services (3/5, 60%). Drug-related information and warnings were not uniformly displayed for both rogue and unapproved internet pharmacies.

Data were unavailable for one legitimate internet pharmacy regarding whether pharmacist services were offered (where member registration was required). Not all legitimate internet pharmacies were accredited through the NABP because of geography. However, legitimate internet pharmacies required or displayed characteristics consistent with best internet pharmacy communication practices, such as requiring pharmacists to offer individual, meaningful consultations [13].

Table 3. Safety characteristics of internet pharmacies selling Humalog or NovoLog insulin in the United States.

Safety characteristics	Rogue (n=9), n (%)			Unapproved (n=5), n (%)			Legitimate (n=3), n (%)		
	Yes	No	Not reported	Yes	No	Not reported	Yes	No	Not reported

[a]One legitimate pharmacy required an account to gain access to services. Overall, 5 internet pharmacies selling Humalog or NovoLog insulin in the United States were not classified using LegitScript.

Discussion

Principal Findings

Our analysis demonstrates that both Humalog and NovoLog insulin are readily available from internet pharmacies that engage in illegal sales of prescription drugs. Illegitimate internet pharmacies were found to be abundant using common search engines, outnumbering legitimate internet pharmacies. Of the internet pharmacies included in our analysis, nearly 60% (29/49) were illegitimate, whereas only 14% (7/49) were legitimate (with the remainder unclassified). The widespread availability of illegitimate internet pharmacies poses a threat to unsuspecting consumers and provides easy access to those seeking insulin without a prescription [9]. Incentives to purchase insulin from illegitimate internet pharmacies go beyond ease of access, as our analysis reveals that these internet pharmacies offer substantial price reductions as compared with brick-and-mortar stores and legitimate internet pharmacies.

Rising Insulin Costs

In the United States, rising list prices on rapid-acting insulin analogs such as Humalog and NovoLog insulin have resulted in a substantial cost burden for patients with diabetes. Legislative initiatives to curb insulin costs include, among others, setting out-of-pocket maximums and allowing personal drug importation. However, these reforms have only been trialed in some states, and the legality of the personal importation of insulin remains contentious [28,29]. In 2018, in the midst of public outcry at high insulin costs, the manufacturer Eli Lilly introduced Lispro, an authorized generic to Humalog, at a 50% discount on the Humalog list price [30]. Unfortunately, according to a Senate report, the uptake of Lispro has been meager at best, with 83% of 386 surveyed national pharmacies not having Lispro in stock and 69% unable to order the medication [31]. In 2020, the Trump Administration announced that Medicare would begin offering 1750 different insurance plans that capped out-of-pocket spending to US $35 for insulin [32]. However, this out-of-pocket maximum is limited only to Medicare beneficiaries. Given the relatively limited action from the federal government, manufacturers, and other key players in the United States pharmaceutical supply chain, high insulin list prices and out-of-pocket costs for many persist. Many patients continue to face insulin access problems, particularly those who are uninsured, which in 2018 accounted for 8.5% of the US population [3,33].

With financial pressure, some patients who need insulin to manage their diabetes have resorted to illegal activities such as borrowing insulin, importing insulin from lower-cost countries, or purchasing insulin from illegitimate internet pharmacies [8]. Our analysis, which focuses on the internet pharmacy marketplace, demonstrates that among pharmacies that ship within the United States, the per mL cost of Humalog and NovoLog insulin from illegitimate internet pharmacies was approximately 2 to 5 times cheaper than that offered by legitimate internet pharmacies or GoodRx. Such substantial price differences raise concerns that illegitimate internet pharmacies may appeal to patients priced out of traditional means of acquiring insulin. Beyond offering lower prices, rogue internet pharmacies do not require prescriptions and also use marketing methods that appeal to cost-conscious consumers, such as offering bulk discounts or coupons. In addition, illegitimate pharmacies appeal to affordability through language on their homepages.

Although costs are lower for Humalog and NovoLog insulin from illegitimate internet pharmacies, they remain illegal because of the serious risks associated with their use. Humalog and NovoLog insulin are high-risk medications that require both therapeutic monitoring to ensure optimal short- and long-term outcomes and sufficient counseling for the prevention of adverse events such as hypoglycemia. Between 2007 and 2009, nearly 20% of emergency hospitalizations for the treatment of emergent adverse events were because of insulin [34]. The costs of these visits are not trivial; in 2016, the total average cost per person per visit for hypoglycemia was US $1965 for an emergency department visit and US $11,632 for inpatient hospitalization in the United States [35]. The American Diabetes Association recommends that patients treated with insulin who are unaware of hypoglycemia should be counseled on signs and methods to treat it [36].

Threat of Illegitimate Internet Pharmacies

Our analysis demonstrates that illegitimate internet pharmacies, particularly rogue internet pharmacies, do not offer pharmacy services that are on-par with those offered through legitimate internet pharmacies. The majority (8/9, 89%) of rogue internet pharmacies allowed the purchase of Humalog or NovoLog insulin in the United States without a prescription, precluding the involvement of health care professionals in patient care. Further preventing communication with health care professionals, no rogue internet pharmacies made the offer to speak with pharmacists. On illegitimate internet pharmacy websites, patients were often left without medication information and drug-related warnings and precautions. Illegitimate internet pharmacies, with rogue internet pharmacies being the worst offenders, allow patients to access Humalog and NovoLog insulin with minimal information, predisposing these patients to poor diabetes control and potential development of adverse events.

There is also concern as to whether the quality of insulin obtained from illegitimate internet pharmacies is comparable with that obtained from legitimate internet pharmacies. Low costs offered through illegitimate internet pharmacies could suggest less stringent cold chain shipping methods or lower-quality medications. Although our analysis did not collect information on the quality of Humalog and NovoLog insulin obtained from illegitimate internet pharmacies, substandard and falsified medicines are globally prevalent [12,37]. Studies have suggested that poor medication quality from illegitimate pharmacies could further increase patient safety at risk [38]. Illegitimate internet pharmacies, as evinced in our analysis of marketing language, often make claims touting the quality of their products. Ironically, this could amplify the risk of consumers inadvertently purchasing low-quality medications. To address these risks, a multifaceted approach is needed to close illegitimate internet pharmacies, develop better search

engine filters, raise public awareness of the dangers of illegitimate internet pharmacies, and address high insulin costs.

National organizations are combating the proliferation of illegitimate internet pharmacies. The FDA's BeSafeRx campaign and the Alliance for Safe Online Pharmacies' *Buy Safe Rx* campaign help consumers identify illegitimate internet pharmacies and recognize their risks [39,40]. The NABP helps consumers identify legitimate internet pharmacies through their list of accredited digital pharmacies, as well as with a verification service through which legitimate internet pharmacies receive a *dot-pharmacy* domain [13]. The Center for Safe Internet Pharmacies also offers a verification service through its initiative *Verify Before You Buy* (powdered by LegitScript), wherein consumers can search the URL of an internet pharmacy to check its legitimacy [41]. In May 2020, North Carolina's Secretary of State announced a partnership with the Center for Safe Internet Pharmacies to raise consumer awareness [42].

Regulatory and legal actions are ongoing against illegitimate internet pharmacies. Operation Pangea, an effort led by Interpol in conjunction with the FDA and US Department of Justice, has resulted in the removal of thousands of illegitimate internet pharmacies [43]. LegitScript has also collaborated with the FDA to identify and close illegitimate internet pharmacies [44]. However, illegitimate internet pharmacies persist by closing and reopening under new web addresses, requiring continued vigilance by regulatory authorities.

Given that patients with diabetes are frequently counseled on the management of their disease, health care providers such as physicians and pharmacists are uniquely positioned to lead the charge in making consumers aware of the risks of acquiring insulin from illegitimate internet pharmacies.

Limitations

The limitations of our study include the small sample size and the cross-sectional design. However, our screening methods were consistent with what US consumers purchasing insulin on the internet might experience. An additional limitation is that we did not analyze the quality of products available from internet pharmacies, precluding conclusions pertaining to medication quality. We did not purchase medications from these websites because we questioned the ethical implications of financially supporting the operations of illegitimate internet pharmacies. Our analysis was conducted before the COVID-19 pandemic. We believe our results are even more relevant now as internet purchases have become commonplace in the United States [45]. Finally, we were unable to quantify the purchase volume of Humalog or NovoLog insulin from these internet pharmacies. The nonspecific, surrogate measure of unique monthly visits is representative of the overall traffic to these websites and is not necessarily indicative of interest in or purchases of Humalog or NovoLog insulin. Despite these limitations, we contend that our analysis reflects the internet pharmacy marketplace for insulin in the United States as accessed through common search engines.

Conclusions

The relatively low costs of Humalog and NovoLog insulin from easily accessible illegitimate internet pharmacies place patients at risk. Although the elimination of illegitimate internet pharmacies would be the gold standard way to reduce their risk to patients, illegitimate internet pharmacies are elusive. Governmental agencies should continue to pursue legal and regulatory measures with the intent of closing illegitimate internet pharmacies. Search engines should work to filter their results better, decreasing the visibility of illegitimate internet pharmacies. Finally, although public awareness campaigns and provider-to-patient efforts can bring attention to the dangers of illegitimate internet pharmacies, they do not address the reasons that patients may visit these sites. With patient safety in mind, US legislators and members of the pharmaceutical supply chain should work to lower the costs of insulin, thereby diminishing patients' incentive to purchase from illegitimate internet pharmacies.

Acknowledgments

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

The authors thank the directors and coordinators of the Research and Scholarship in Pharmacy (RASP) pathway at the UNC Eshelman School of Pharmacy for their guidance and support. The authors also thank Colleen Higgins on the Global Health Economics for Pharmacy (GHEP) team for her contributions.

Abstract

Background: The COVID-19 pandemic has increased online purchases and heightened interest in existing treatments. Dexamethasone, hydroxychloroquine, and lopinavir-ritonavir have been touted as potential COVID-19 treatments.

Objective: This study assessed the availability of 3 potential COVID-19 treatments online and evaluated the safety and marketing characteristics of websites selling these products during the pandemic.

Methods: A cross-sectional study was conducted in the months of June 2020 to August 2020, by searching the first 100 results on Google, Bing, and Yahoo! mimicking a US consumer. Unique websites were included if they sold targeted medicines, were in English, offered US shipping, and were free to access. Identified online pharmacies were categorized as rogue, unclassified, or legitimate based on LegitScript classifications. Patient safety characteristics, marketing techniques, price, legitimacy, IP addresses, and COVID-19 mentions were recorded.

Results: We found 117 websites: 30 selling dexamethasone (19/30, 63% rogue), 39 selling hydroxychloroquine (22/39, 56% rogue), and 48 selling lopinavir-ritonavir (33/48, 69% rogue). This included 89 unique online pharmacies: 70% were rogue (n=62), 22% were unapproved (n=20), and 8% were considered legitimate (n=7). Prescriptions were not required among 100% (19/19), 61% (20/33), and 50% (11/22) of rogue websites selling dexamethasone, lopinavir-ritonavir, and hydroxychloroquine, respectively. Overall, only 32% (24/74) of rogue websites required prescriptions to buy these medications compared with 94% (31/33) of unapproved and 100% (10/10) of legitimate websites (P<.001). Rogue sites rarely offered pharmacist counseling (1/33, 3% for lopinavir-ritonavir to 2/22, 9% for hydroxychloroquine). Drug warnings were unavailable in 86% (6/7) of unapproved dexamethasone sites. It was difficult to distinguish between rogue, unapproved, and legitimate online pharmacies solely based on website marketing characteristics. Illegitimate pharmacies were more likely to offer bulk discounts and claim price discounts, yet dexamethasone and hydroxychloroquine were more expensive online. An inexpensive generic version of lopinavir-ritonavir that is not authorized for use in the United States was available online offering US shipping. Some websites claimed hydroxychloroquine and lopinavir-ritonavir were effective COVID-19 treatments despite lack of scientific evidence. In comparing IP addresses to locations claimed on the websites, only 8.5% (7/82) matched their claimed locations.

Conclusions: The lack of safety measures by illegitimate online pharmacies endanger patients, facilitating access to medications without appropriate oversight by health care providers to monitor clinical response, drug interactions, and adverse effects. We demonstrated how easy it is to go online to buy medications that are touted to treat COVID-19 even when current clinical evidence does not support their use for self-treatment. We documented that illegitimate online pharmacies sidestep prescription requirements,

skirt pharmacist counseling, and make false claims regarding efficacy for COVID-19 treatment. Health care professionals must urgently educate the public of the dangers of purchasing drugs from illegitimate websites and highlight the importance of seeking treatment through authentic avenues of care.

KEYWORDS

COVID-19; medication; internet; online pharmacy; drug

Introduction

The coronavirus disease 2019 (COVID-19) pandemic has intensified the demand for effective medications and made online purchases commonplace. According to a recent global study of 5000 consumers, over one-third (36%) of consumers reported shopping online weekly since the pandemic, which is up from 28% pre-COVID-19 [1]. As online shopping becomes more common, the rate of online purchase of medications is also increasing [2]. Online pharmacies have grown from US $29.35 billion in 2014 to a projected global market size of US $128 billion by 2023 [3].

Yet, consumers may not be aware of how prevalent illicit pharmacies are online. In 2016, there were 30,000-35,000 online pharmacies accessible to US customers on the internet [4]. Of these pharmacies, 96% were found to be illegitimate and in violation of US pharmacy laws and practice standards [5]. Illegitimate online pharmacies pose a significant safety threat to consumers, as their products cannot be guaranteed; the manufacturing, storage, and shipping conditions of the drugs may not be regulated; and they bypass pharmacists who can ensure proper dosages and use of medications [6].

As the pandemic continues to claim many lives [7], there has been heightened interest in finding potential treatments for COVID-19 among existing medications. Several existing medications have been touted as potential treatments for COVID-19, including dexamethasone, hydroxychloroquine, and lopinavir-ritonavir [8]. Dexamethasone is a glucocorticoid agent used for several disease states for its anti-inflammatory and immunosuppressive properties. It has been trialed in patients with COVID-19 to see if it may reduce disease progression to respiratory failure and death [9]. A controlled, open-label trial among patients who were hospitalized with COVID-19 found that the use of dexamethasone resulted in lower 28-day mortality among those who were receiving either invasive mechanical ventilation or oxygen alone [9,10]. This trial, along with others, supports the idea that dexamethasone can prevent mortality in hospitalized patients with COVID-19 [11]. Such supportive evidence behind the effectiveness of dexamethasone has caused an increase in its use [12]. It is important to note though that corticosteroids such as dexamethasone are not benign drugs and should only be taken under the direct supervision of a medical provider. If misused, dexamethasone can cause side effects such as hypertension, endocrine abnormalities, vision problems, pancreatitis, and osteoporosis [13]. Monitoring the use of dexamethasone is therefore required to assess side effects and response to therapy.

Hydroxychloroquine has also been considered a potential COVID-19 treatment and prophylaxis [14]. Hydroxychloroquine is an aminoquinoline anti-infective agent indicated for the treatment of malaria. Despite promising mechanistic properties, several randomized clinical trials found that hydroxychloroquine did not prevent illness or confirmed infection when used as postexposure prophylaxis within 4 days after moderate or high-risk exposure to COVID-19 [14,15]. However, endorsement of the medication by high-profile figures including former US President Donald Trump during early phases of the pandemic drew public attention to the medication. It was reported that Google search volume for purchasing hydroxychloroquine increased by 14-fold in March 2020, when the clinical efficacy for the medication was still inconclusive [16]. The use of hydroxychloroquine for COVID-19 can be problematic especially without a health care prescription, putting patients at risk for insufficient laboratory monitoring and side effects such as nausea, low blood sugar, movement disorders, eye problems, and cardiac problems [10].

Another medication that has been touted for COVID-19 treatment is lopinavir-ritonavir. Lopinavir-ritonavir is an antiretroviral agent that is used for HIV infection suppression. Since lopinavir had in vitro inhibitory activity against the SARS-CoV virus in 2003 and the SARS-CoV-2 (COVID-19) virus is genetically similar, clinical trials were conducted in patients with COVID-19 [17]. However, a randomized, controlled, open-label trial involving hospitalized adult patients with severe COVID-19 found no benefit of lopinavir-ritonavir treatment beyond standard care [14]. Further studies and case reports have reinforced these findings, and lopinavir-ritonavir is generally not recommended for treatment of COVID-19 [18,19]. If consumers use lopinavir-ritonavir in efforts to combat a COVID-19 infection, they would not only be using an ineffective treatment but would also be exposing themselves to unnecessary side effects.

We sought to assess the accessibility of dexamethasone, hydroxychloroquine, and lopinavir-ritonavir online during the COVID-19 pandemic and to analyze their implications for medication safety. In doing so, we recorded medication prices, marketing practices, and statements related to COVID-19 from websites selling these medications. Our aim was to assess what US consumers would find if they utilized online pharmacies looking for medications to treat COVID-19 amid the pressures of a global pandemic.

Methods

We searched for online pharmacy websites selling dexamethasone, hydroxychloroquine, or lopinavir-ritonavir

using 3 search engines (Google, Bing, and Yahoo!) between June 2020 and August 2020. Two searches were conducted on each search engine using the brand and generic names of each medication. We used the search terms "buy [drug name] online" (eg, "buy lopinavir-ritonavir online" and "buy Kaletra online") to simulate patients seeking to buy these treatments online. We screened the first 100 search results for every search term and recorded the results of our searches. Websites were included in this analysis if they were published in the English language, were free to access, were active, claimed to sell the drugs of interest, had a unique URL, and were classified by LegitScript. Websites were excluded if they did not sell the medications of interest or did not ship to the United States. Screenshots of the web pages were taken at the time the pages were accessed.

The legitimacy of included websites was assessed by LegitScript, an online service that monitors online pharmacies for compliance with applicable laws and regulations. LegitScript classifies online pharmacies based on licensure or registration in appropriate jurisdictions, sales of controlled substances, history of disciplinary sanctions, requirement of valid prescription, compliance with applicable laws, protection of privacy, patient services offered, transparency, and domain name registration [4]. This analysis utilized LegitScript's classification, where *rogue* pharmacies "engage in illegal, unsafe, or misleading activities like selling prescription drugs without a prescription," *unapproved* pharmacies face "some problem with regulatory compliance or risk, such as operating legally in one jurisdiction but not in others," and *legitimate pharmacies* "passed LegitScript's certification criteria" [4]. Rogue and unapproved pharmacies were considered illegitimate pharmacies in this analysis.

In order to understand how online pharmacies attend to patient safety, we assessed whether prescriptions were required to purchase these medications or if patients needed to fill out a health-related questionnaire prior to ordering medications. We assessed whether pharmacist counseling was available, appropriate drug information was on the drug product page, warnings in using the medications were noted, and there was a quantity limit on purchases. Quantity control was defined as the website setting a maximum allowable quantity (or day supply) of medication that was available for purchase on the checkout page. Claims made related to the efficacy of these medications in treating COVID-19 were also abstracted from the websites. Patient safety analyses were conducted for each drug individually. Chi-squared tests were conducted to examine differences in patient safety characteristics by pharmacy legitimacy and across medications.

We recorded some marketing characteristics of websites, including whether the website claimed a price discount compared with brick-and-mortar pharmacies, availability of bulk product price discounts, and offers of coupons or promotion codes. Marketing characteristics of rogue, unapproved, and legitimate sites were compared using chi-squared tests. We tracked whether online pharmacies offered phone numbers or WhatsApp accounts and whether consumers could speak with sales associates. Websites that claimed to be registered with pharmacy-governing organizations were recorded, as well as customer testimonies and privacy assurances. Marketing of COVID-19–related products such as ads for masks, sanitizing wipes, and hand sanitizers, as well as explicit mentions of COVID-19 on websites, were also recorded. Quotes about COVID-19 from these websites were classified by website legitimacy and were analyzed qualitatively, examining themes that emerged from texts. Unique websites were defined as those with unique URLs, and marketing analyses were conducted once per unique website (ie, if a website sold 2 of our medications of interest, we reported the website's marketing characteristic once).

Prices and shipping costs for obtaining 60 dexamethasone 0.5 mg tablets, hydroxychloroquine 200 mg capsules, and lopinavir-ritonavir 200 mg-50 mg tablets were collected from each website. These quantity and strengths were chosen as they were the most commonly available for patients to select and purchase presented on the web pages. Online pharmacy prices at checkout were compared with prices offered through GoodRx, which tracks prescription drug prices in the United States. Where possible, we compared prices of generic versions of the medications. However, the GoodRx price for lopinavir-ritonavir reflected the price for the brand name drug Kaletra in the United States, as a generic version had not been approved for use in the United States. Country locations reported on pharmacy websites were also recorded and compared with registered locations of the IP addresses identified via IP2location [20]. Where available, we assessed the monthly traffic volume of pharmacy sites using SimilarWeb, a site that specializes in web analytics and reports traffic volumes from open exchanges of first-party data, and by surveying public data sources [21].

Results

Across 3 search engines, we identified a total of 117 websites that claimed to sell dexamethasone, hydroxychloroquine, or lopinavir-ritonavir online. This included 30 websites selling dexamethasone, 39 sites selling hydroxychloroquine, and 48 sites selling lopinavir-ritonavir. The majority of websites were illegitimate—we only found 4 (4/30, 13%), 5 (5/39, 13%), and 1 (1/48, 2%) legitimate websites selling dexamethasone, hydroxychloroquine, and lopinavir-ritonavir, respectively. We found that 63% (19/30) of websites selling dexamethasone, 56% (22/39) of sites selling hydroxychloroquine, and 69% (33/48) of sites selling lopinavir-ritonavir were rogue based on LegitScript classifications. An additional 26 websites that were not classified by LegitScript were excluded from our analysis.

Rogue websites tended to be distinct from unapproved (31/33, 94%) and legitimate sites (10/10, 100%), with only 32% (24/74) of sites requiring prescriptions to buy these medications (P<.001; Table 1). Health-related questionnaires were seldom used across all websites (utilized by 1 rogue and 7 unapproved websites). Overall, few (15/117, 12.8%) websites made overt offers for consumers to speak with a pharmacist, including legitimate sites (1/10, 10%). Medication warnings were often missing from unapproved websites (13/33, 39%; P<.001). Quantity control was rarely seen in legitimate sites, as prescriptions were meant to limit purchasable quantity.

Table 1. Patient safety characteristics stratified by rogue, unapproved, and legitimate online pharmacies.

Patient safety characteristics	Rogue (n=74), n (%)	Unapproved (n=33), n (%)	Legitimate (n=10), n (%)	*P* value
Prescription required	24 (32)	31 (94)	10 (100)	<.001
Health-related questionnaire	1 (1)	7 (21)	0 (0)	<.001
Offer to speak with pharmacist	4 (5)	10 (30)	1 (10)	.002
Drug information on product page	44 (59)	18 (55)	9 (90)	.12
Drug related warnings on product page	60 (81)	13 (39)	8 (80)	<.001
Quantity control	45 (61)	27 (82)	2 (20)	.001

Across medications, many illegitimate websites did not require prescriptions to obtain dexamethasone (21/26, 81%), compared with hydroxychloroquine (11/34, 32%) and lopinavir-ritonavir (20/47, 43%; *P*=.02; Table 2). Rogue websites by far had the most lenient prescription requirements, with none (0/19, 0%) of the rogue websites selling dexamethasone requiring prescriptions, while 50% (11/22) and 39% (13/33) of rogue websites selling hydroxychloroquine and lopinavir/ritonavir, respectively, required prescriptions. Medication information and warnings were particularly lacking for illegitimate websites selling hydroxychloroquine and lopinavir-ritonavir, with only 65% (22/34) and 36% (17/47) of websites, respectively, providing accurate drug information. Among illegitimate websites, 53% (18/34) selling hydroxychloroquine and 77% (36/47) selling lopinavir-ritonavir provided medication-related warnings. Across all websites selling dexamethasone, 87% (26/30) included medicine information, and 73% (22/30) provided medication-related warnings on their web pages.

Table 2. Patient safety characteristics stratified by online pharmacy legitimacy and medication.

Patient safety characteristics	Rogue, n (%)			Unapproved, n (%)			Legitimate, n (%)			*P* value
	DEX[a] (n=19)	HCQ[b] (n=22)	L-R[c] (n=33)	DEX (n=7)	HCQ (n=12)	L-R (n=14)	DEX (n=4)	HCQ (n=5)	L-R (n=1)	
Prescription required(yes)	0 (0)	11 (50)	13 (39)	5 (71)	12 (100)	14 (100)	4 (100)	5 (100)	1 (100)	.02
Health-related questionnaire (yes)	0 (0)	1 (5)	0 (0)	0 (0)	3 (25)	4 (29)	0 (0)	0 (0)	0 (0)	.29
Offer to speak with pharmacist(yes)	1 (5)	2 (9)	1 (3)	1 (14)	6 (50)	3 (21)	0 (0)	1 (20)	0 (0)	.87
Drug information on product page(yes)	18 (95)	14 (64)	12 (36)	5 (71)	8 (67)	5 (36)	3 (75)	5 (100)	1 (100)	.59
Drug-related warnings on product page (yes)	18 (95)	12 (54)	30 (91)	1 (14)	6 (50)	6 (43)	3 (75)	4 (80)	1 (100)	.06
Quantity control (yes)	15 (79)	11 (50)	19 (58)	7 (100)	12 (100)	8 (57)	1 (25)	1 (20)	0 (0)	.37

[a]DEX: dexamethasone.

[b]HCQ: hydroxychloroquine.

[c]L-R: lopinavir-ritonavir.

Marketing characteristics were examined across unique websites. We identified 89 unique websites that were classified by LegitScript, as 28 websites sold more than one product of interest. Among the 89 websites, 62 (70%) were identified as rogue, 20 (22%) were unapproved, and only 7 (8%) websites were legitimate.

When examining marketing characteristics of websites, it was more difficult to distinguish between rogue, unapproved, and legitimate online pharmacies (Table 3). Privacy assurances were most frequently offered by unapproved pharmacies (17/20, 85%), compared with 52% (32/62) for rogue and 57% (4/7) for legitimate pharmacies (*P*=.03). Rogue and unapproved websites appeared to be more likely to claim price discounts (58/62, 94% and 18/20, 90% respectively), while 71% (5/7) of legitimate websites made a similar claim (*P*=.12). Rogue and unapproved websites tended to offer more bulk discounts (41/62, 66% and 13/20, 65%, respectively) compared with legitimate websites (2/7, 29%; *P*=.15). It is notable that 32% (20/62) of rogue websites and 60% (12/20) of unapproved websites claimed to be registered by pharmacy-governing organizations. The most common registration claims made by illegitimate websites included the Canadian International Pharmacy Association (CIPARx; 33/82, 40%) and PharmacyChecker (25/82, 30%). Legitimate websites mostly claimed registration with the National Association of Boards of Pharmacy (2/7, 29%), the Better Business Bureau (4/7, 57%), or LegitScript (5/7, 71%).

Table 3. Marketing characteristics stratified by rogue, unapproved, and legitimate online pharmacies (n=89).

Marketing characteristics	Rogue (n=62), n (%)	Unapproved (n=20), n (%)	Legitimate (n=7), n (%)	*P* value[a]
Claims price discount (yes)	58 (94)	18 (90)	5 (71)	.12
Bulk discounts (yes)	41 (66)	13 (65)	2 (29)	.15
Coupon or promo code (yes)	37 (60)	8 (40)	4 (57)	.29
Phone # or WhatsApp (yes)	56 (90)	19 (95)	7 (100)	.56
Offer to speak with an associate (yes)	45 (72)	16 (80)	6 (86)	.60
Registration claims (yes)	20 (32)	12 (60)	3 (43)	.08
Customer testimonials (yes)	39 (63)	8 (40)	5 (71)	.15
Privacy claims (yes)	32 (52)	17 (85)	4 (57)	.03

[a]Analysis was conducted across websites selling dexamethasone, hydroxychloroquine, and/or lopinavir-ritonavir, which were classified by LegitScript for legitimacy.

A total of 7 illegitimate websites made unsubstantiated claims regarding the efficacy of hydroxychloroquine (n=4) or lopinavir-ritonavir (n=3) in treating COVID-19 (Table 4). Illegitimate pharmacies made a wide variety of uncorroborated medication efficacy claims from “hydroxychloroquine has shown positive results when being used to treat patients with COVID-19” to “[lopinavir-ritonavir] has been tested and included in the protocols of treatment of the novel coronavirus COVID-19.” One illegitimate website quoted former US President Donald Trump’s Twitter account to note that hydroxychloroquine should be used to treat COVID-19. Four illegitimate websites created a COVID-19 medication category and tagged hydroxychloroquine or lopinavir-ritonavir. Illegitimate websites also noted supply limitations: “[Hydroxychloroquine is] not available at this time due to COVID-19 shipping disruptions.” COVID-19–related supplies such as gloves, masks, or test kits were advertised by 4 illegitimate websites.

On the other hand, legitimate pharmacy websites rarely mentioned COVID-19 on their web pages, neither claiming nor denying the efficacy of these medications related to COVID-19. Two legitimate websites mentioned limitations in dispensing hydroxychloroquine due to COVID-19, limiting supplies to existing hydroxychloroquine patients or restricting hydroxychloroquine to only patients with a positive COVID-19 test. One legitimate website advertised hand sanitizers and masks alongside these medications.

Prices, with and without standard shipping, for 60 tablets of each medication bought online (0.5 mg tablets of dexamethasone, 200 mg capsules of hydroxychloroquine, and 200 mg lopinavir and 50 mg ritonavir tablets) were compared with the equivalent quantity price at brick-and-mortar pharmacies listed on GoodRx (Figure 1). Dexamethasone and hydroxychloroquine were both more expensive online, with or without shipping, compared with listed average GoodRx prices. Average prices were lower at brick-and-mortar stores for 0.5 mg tablets of dexamethasone at US $10.74, compared with US $38.07 for the medication online and US $50.54 with shipping. Similarly, 200 mg capsules of hydroxychloroquine were cheaper at brick-and-mortar stores at US $39.64 on average, compared with US $83.22 online and US $96.04 with shipping. A generic version of lopinavir-ritonavir was available online for US consumers and sold on average at US $211.77 (US $229.52 with shipping), even though this generic drug has not been approved for use in the United States. This unapproved generic lopinavir-ritonavir was much cheaper online than average GoodRx prices for brand-name drug Kaletra at US $532.40.

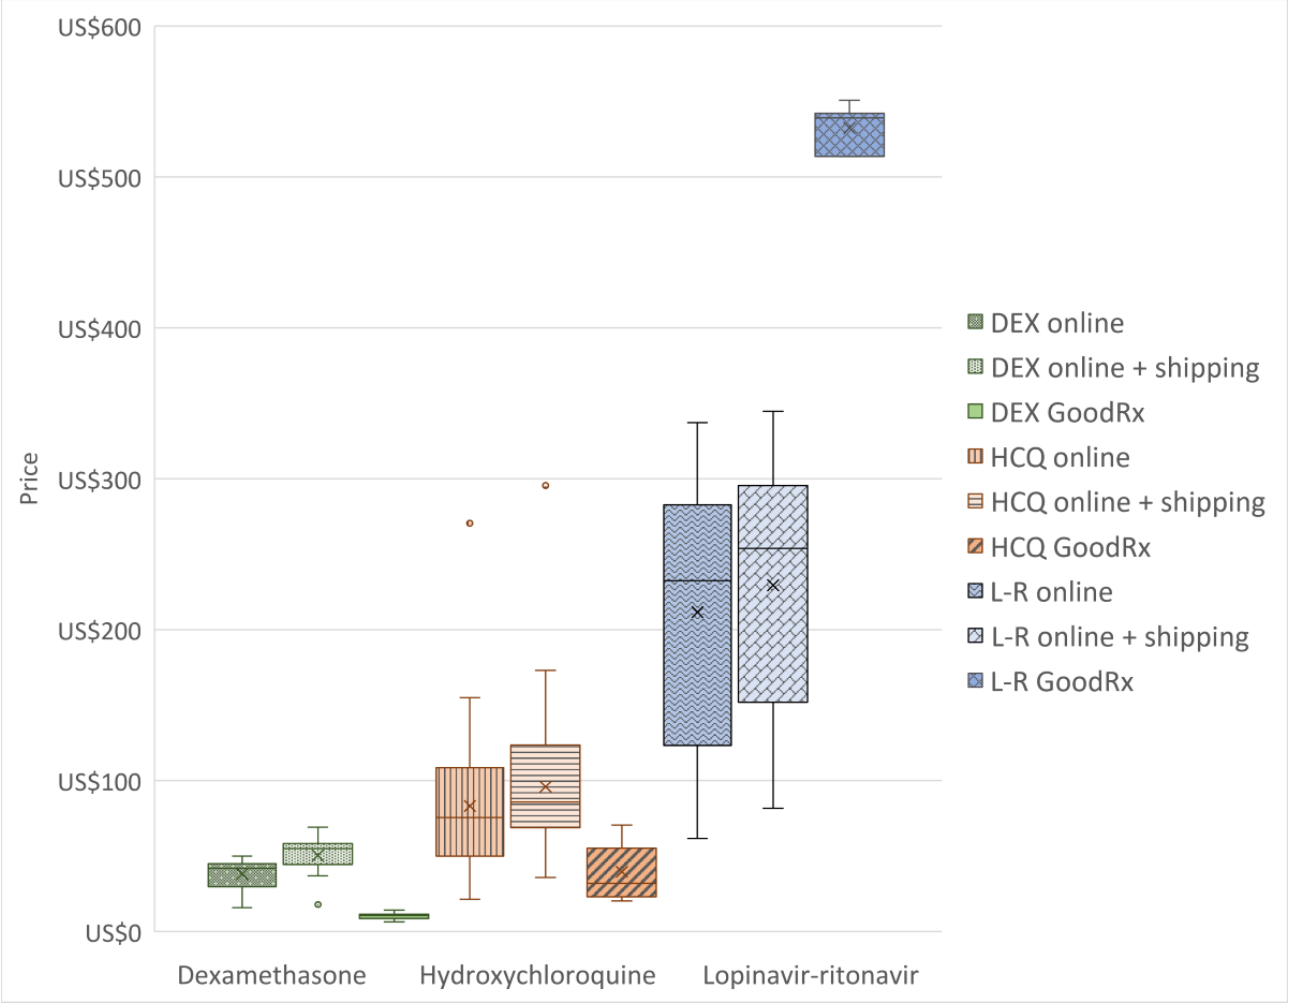
Table 4. COVID-19 mentions on illegitimate and legitimate online pharmacy websites.

Type of COVID-19 mentions	Quotes	Mentions[a]
Quotes from illegitimate pharmacies		
Direct claims that medication may be effective for COVID-19	• "drug [hydroxychloroquine] confirmed effective on COVID-19" • "It was announced by American president that Hydroxychlorquine should be used to treat coronavirus, Donald Trump said this in his Twitter on March 21 2020." • "[study] proved that Hydroxychloroquine… can cut the death rate significantly in sick, hospitalized COVID patients without heart-related side effects... The analysis of the study shows hydroxychloroquine helped save lives." • "Hydroxychloroquinine has shown positive results when being used to treat patients with Covid-19 (coronavirus)." • "it was found out that Kaletra shows positive results in a blockage of a COVID-19 viral replication" • "This HIV medication [lopinavir-ritonavir] is one of the few drugs effective for COVID-19 treatment)" • "It [lopinavir-ritanovir] has been tested and included in the protocols of treatment of the novel coronavirus COVID-19"	7
Claims medication may be effective for COVID-19	• "Reports have shown that this medicine [hydroxychloroquine] might be effective against Coronavirus, but it has not been proven" • "Reports have shown that this medicine [lopinavir-ritonavir] might be effective against Coronavirus, but it has not been proven."	2
Supply/shipping limitation due to COVID-19	• "…New Zealand, in an effort to preserve adequate stocks of this medicine for their own people during the Covid-19 pandemic have halted all exports until further notice" • "Limited supply. Currently being dispensed to existing Plaquenil patients only" • "Not available at this time due to COVID-19 shipping disruptions."	3
Precaution regarding efficacy in COVID-19	• "Taking this medication will not prevent you from passing HIV or COVID-19 to other people"	1
Medication included in COVID-19 medication category	• Tag[b]: COVID-19 [hydroxychloroquine] • Tag[b]: coronavirus [lopinavir-ritanovir] [hydroxychloroquine] • Tag[b]: covid19 treatment, covid19 medications uk [lopinavir-ritanovir]	4
Ads for products related to COVID-19	• Gloves • COVID test kits • Masks	4
Quotes from legitimate pharmacies		
Indication limitation or dispense restriction due to COVID-19	• "we are ONLY dispensing Hydroxychloroquine to patients with history of use for an autoimmune disorder … prior to 3/1/2020 or a positive diagnosis of COVID-19… Doctors prescribing outside of their scope of practice will be DENIED" • "Due to the national shortage, we can only dispense this drug [hydroxychloroquine] if you have tested positive for coronavirus/COVID-19."	2
Ads for products related to COVID-19	• Sanitizer and masks	1

[a]Denotes the number of online pharmacy websites per type of COVID-19 mention.

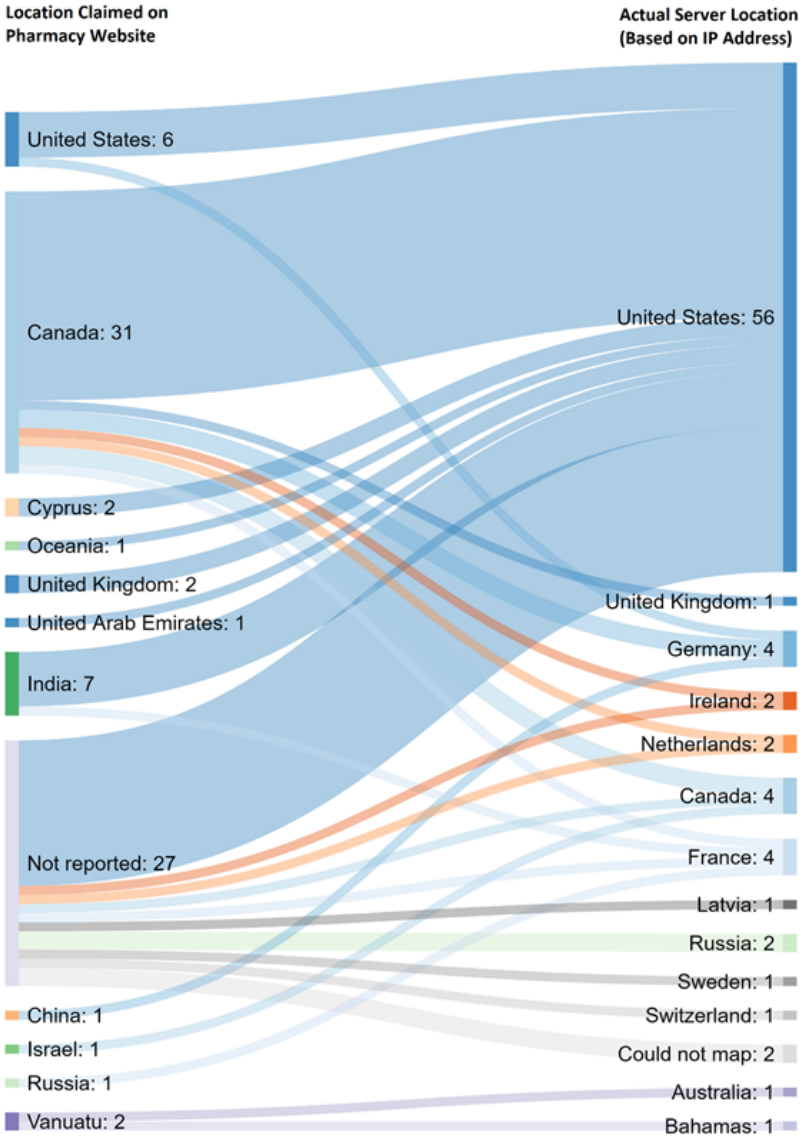
[b]These websites created COVID-19 medication categories or categorized the medication under a specific tag on the product pages.

Figure 1. Prices to purchase 60 tablets/capsules of dexamethasone (DEX), hydroxychloroquine (HCQ), and lopinavir-ritonavir (L-R) online versus GoodRx.



Large numbers of countries were involved in hosting online pharmacies, either where online pharmacies claimed to be or where their servers were located (Figure 2). Most of the illegitimate websites (75/82, 92%) hosted their servers in a country different from that listed on their website. The majority of illegitimate websites (58/82, 71%) either claimed to be a Canadian pharmacy (31/82, 38%) or did not list any country location (27/82, 33%) on their websites. Of the websites claiming to be located in Canada or India (38/82, 46%), the majority actually had IP addresses with a registered server in the United States (29/38, 76%). All legitimate websites (n=7) claimed to be in the United States and had IP addresses that indicated US servers. Website traffic data were available on SimilarWeb for 9 websites (3 rogue and 6 legitimate sites). Average website traffic for legitimate websites ranged from 10,200 to 10,900,000 monthly views, while rogue websites ranged from 10,000 to 20,000 monthly views.

Figure 2. Reported versus server locations of illegitimate online pharmacies (n=82).



Discussion

Principal Findings

We found that illegitimate pharmacy websites claiming to sell dexamethasone, hydroxychloroquine, and lopinavir-ritonavir endanger patient safety by bypassing prescription requirements, denying pharmacist counseling, and making false claims regarding efficacy in treating COVID-19 infections. We demonstrated that these websites are easy to find using common search engines and that they attempt to garner attention from potential consumers by claiming discounted prices and offering bulk discounts. We discuss in the following sections the reasons why these websites are harmful (lack of prescriptions, no pharmacist contact, and use of these medications for COVID-19 treatment) and how they try to lure consumers (medicine prices, online pharmacy marketing, and global transactions) [22].

Lack of Prescriptions

Many illegitimate websites we found selling dexamethasone (21/26, 81%), hydroxychloroquine (11/34, 32%), and lopinavir-ritonavir (20/47, 43%) did not require prescriptions. This is a recipe for tragedy as prescriptions ensure that health care providers have reviewed patients' medical histories and that selected medications are safe and appropriate. The lack of prescriptions needed to access these medications through online pharmacies is an immense patient safety concern, as these medications require intensive monitoring for side effects and therapeutic effects when they are initiated.

For example, dexamethasone requires a physician-guided dosing taper for safe and effective use. If dexamethasone is stopped abruptly after long-term use, it can cause hypothalamic-pituitary adrenal axis suppression, which can lead to a decreased immune response against infection or trauma [13]. Moreover, side effects of taking dexamethasone include hypertension, endocrine abnormalities, vision problems, pancreatitis, and osteoporosis [13]. For hydroxychloroquine, there have been reports of fatal cardiomyopathy and arrythmias with its use, which have led to recommendations for intensive cardiac monitoring during therapy initiation [23]. Hydroxychloroquine also has the potential to cause adverse effects to the liver, kidney, cerebellar cortex, pancreas, and eyes [23,24]. Lopinavir-ritonavir requires provider guidance for safe dosing and administration. An

overdose of lopinavir-ritonavir can result in cardiac toxicity, renal failure, and central nervous system depression [25].

No Pharmacist Contact

We also found that very few websites (15/117, 12.8%) offered pharmacist counseling before consumers purchase these medications, including even legitimate sites (1/10, 10%). Pharmacists ensure medication appropriateness and safety by ensuring that patients have the opportunity to clarify any dosing instructions, interactions, or side effects before they take medications [26]. With no pharmacist oversight, patients are more likely to experience drug interactions, incorrect dosing, or side effects that could have been avoided with counseling. For example, previous studies have examined the association between online pharmacy use, medication use, and health outcomes, where patients who obtained medications online were more likely to use medications at higher doses and more frequently and experience adverse events compared with patients obtaining medications from brick-and-mortar stores [27]. Additionally, most states in the United States have regulations in place where an offer to counsel with a pharmacist must be made at the time of medication dispensing [28]. Buying medications through online pharmacies bypasses these important patient safety measures and regulations.

Some adverse events specific to these medications could be avoided if pharmacists are able to review patients' profiles to analyze for interacting medications and counsel patients on potential side effects. For example, patients taking dexamethasone should not take nonsteroidal anti-inflammatory drugs as using both increases the risk of gastrointestinal side effects [13]. Since dexamethasone is metabolized in the liver, other medications that affect hepatic enzymes can also affect the metabolism of dexamethasone [13]. Likewise, hydroxychloroquine should also be used with caution in patients taking hepatotoxic medications or with hepatic disease [23]. Since hydroxychloroquine and lopinavir-ritonavir can increase the risk for cardiac arrythmia, it is important to avoid other medications that have a similar cardiac effect where possible [23,25]. Moreover, lopinavir-ritonavir interacts with any medications that induce, inhibit, or are metabolized by CYP3A, a very common metabolic liver enzyme [25]. If taken with a medication that is primarily cleared by CYP3A, lopinavir-ritonavir can cause buildup of the medication, which can lead to life-threatening side effects [25]. These examples demonstrate the importance for all online pharmacies to facilitate consumer interactions with pharmacists.

Use of These Medications for COVID-19 Treatment

Although some online pharmacy sites have touted the efficacy of these medications in treating COVID-19, current clinical evidence does not support their use for self-treatment of COVID-19 infections. Dexamethasone was found to be effective in reducing mortality in patients with COVID-19 in the RECOVERY trial; however, the benefit was only seen among patients with severe disease requiring supplemental oxygen or invasive mechanical ventilation [9]. Online purchasing of dexamethasone for self-treatment of COVID-19 is therefore not appropriate.

One of the most common references to medicine efficacy for COVID-19 treatment on pharmacy websites was related to hydroxychloroquine (n=14). Four illegitimate websites claimed hydroxychloroquine as an effective treatment for COVID-19, with 1 site citing former US President Trump's Twitter account as the source for this claim rather than scientific sources. Other sites created a COVID-19 medication category and deceptively included hydroxychloroquine in the category page. Hydroxychloroquine was one of the most studied medications during the early phase of the pandemic, with more than 50 registered clinical trials by May 2020 [29,30]. On April 27, 2020, the Food and Drug Administration (FDA) issued an emergency use authorization (EUA) for the use of hydroxychloroquine to treat adults and adolescents hospitalized with COVID-19 who are not able to participate in clinical trials. However, this EUA was revoked on June 15, 2020 after the FDA reviewed clinical evidence [31]. The FDA concluded that hydroxychloroquine is unlikely to be effective and the potential benefit of using the treatment no longer outweighs the risks of serious cardiac adverse events and other side effects associated with the medication [31]. The RECOVERY trial in the United Kingdom found no mortality benefit with hydroxychloroquine, while the Solidarity Trial coordinated by the World Health Organization terminated the hydroxychloroquine arm early based on interim analysis results that showed little or no reduction of mortality in hospitalized patients with COVID-19 [18,32].

We found one illegitimate website falsely claiming that lopinavir-ritonavir showed positive results in blocking COVID-19 viral replication. Such false statements can be hazardous for patients seeking reliable information. Similar to hydroxychloroquine, lopinavir-ritonavir was a popular explorative treatment at first, as a systematic review in 2020 including 9152 hospitalized patients found that it was the most frequently administered treatment, received by 21.9% of patients [33]. However, the RECOVERY trial also found the medication to not be effective, and the Solidarity Trial discontinued its lopinavir-ritonavir arm based on an interim analysis showing similar results [18,19].

Medicine Prices

Prior studies have suggested that the cost of medications online vis-à-vis brick-and-mortar stores differs depending on the product [34-37]. Here, we report similar findings. While the majority (76/82, 93%) of illegitimate online pharmacies claimed price discounts on their products, it was cheaper on average to purchase dexamethasone and hydroxychloroquine at brick-and-mortar pharmacies. We found that average online prices (excluding shipping) for dexamethasone and hydroxychloroquine were 285% and 110% more expensive, respectively, than GoodRx.

On the other hand, prices for lopinavir-ritonavir were cheaper on online pharmacies. In the United States, lopinavir-ritonavir 200 mg-50 mg tablets are only available as a brand name product, Kaletra, at an average GoodRx price of US $532.40. Meanwhile, illegitimate online pharmacies advertised a generic lopinavir-ritonavir that has not been approved in the United States at an average price of US $211.77. The availability of an

unapproved and cheaper "generic" lopinavir-ritonavir through online pharmacies means US consumers could in fact obtain a different medicine, a generic drug not approved in the United States, with significant safety concerns.

Online Pharmacy Marketing

Illegitimate websites were more likely to claim price discounts (76/82, 93%) than legitimate websites (5/7, 71%). They were also more likely to offer bulk discounts if the customer placed larger orders. Many illegitimate websites also made claims to be registered by pharmacy-governing organizations, claiming to be approved by various sites as a legitimate business practice. These registration claims often cited CIPARx or PharmacyChecker. It is important to note that LegitScript has found that CIPARx and PharmacyChecker have previously given approval to websites legally found to be illegitimate [17]. The lack of reliability of such accreditation sites are problematic and need to be corrected as less savvy customers may see a symbol of accreditation and believe the website to be legitimate.

Global Transactions

Most of the illegitimate online pharmacy websites analyzed in this study (75/82, 92%) hosted their servers in a country different from that listed on their website. This is in line with other studies that have reported similar differences in server and listed locations [35]. Although this difference does not verify that online pharmacies' physical locations are different from what are reported, it does raise the concern that many of these pharmacies are misleading patients by reporting to be located in one country but are actually dispensing from another country. The discrepancies also increase barriers to enforcement agencies' regulations. In addition, the pharmacies may be obtaining their medications from international manufacturers and suppliers that do not comply with US FDA regulations and good manufacturing practices. Worse yet, the medications dispensed by these illegitimate online pharmacies may be substandard or falsified and could cause harm to patients [38]. As 1 in 10 essential medications sold in low- and middle-income countries have been found to be substandard or falsified, some medications sold through online pharmacies could be substandard or falsified [39,40]. Global transactions facilitated by online pharmacies can be an especially opportunistic market during pandemics, when demand for COVID-19 treatments is high and regulatory actions may be inadequate [41]. Interventions are needed globally to ensure access to safe, quality-assured, and effective medications during the COVID-19 pandemic and beyond, with protections to minimize medication harm.

There is a number of limitations of our study to note. First, we did not attempt to capture the entirety of the online pharmacy landscape and were only able to present a snapshot of results at a point in time. We utilized 3 most commonly used search engines, conducted searches from the United States, conducted searches from the United States, and included unique sites from the first 10 pages of search results, imitating the behavior of a typical US consumer who may try to find online pharmacy websites selling these medications. We present a cross-sectional study where our data collection occurred in the summer of 2020. There may have been temporal changes to the availability of these medications and alterations in marketing tactics employed by online pharmacies since then. Second, this study focused solely on dexamethasone, hydroxychloroquine, and lopinavir-ritonavir, when the demand and supply for other medications to treat COVID-19 may have also been affected during this pandemic. Our medications of study were chosen based on their high publicity as a potential COVID-19 treatment during the first half of 2020.

We were also unable to uncover the actual purchasing frequency on these sites. We note that the web traffic to illegitimate online pharmacies may not be reflective of actual transaction volume, as many sites regularly close and open with new URLs or redirect links to avoid detection and regulation. However, the results we found demonstrate a snapshot of what an average US consumer may view while purchasing. Moreover, due to ethical concerns regarding providing fake prescriptions to these websites, we did not actually purchase medications from these online pharmacies. Therefore, we were unable to investigate the actual dispensing locations or test the quality of medications. Without following through with the full purchasing process, we could not confirm if pharmacist counseling is indeed offered after checkout. However, despite these limitations, we followed the systemic approach outlined in the methodology to assess the availability of high-profile medications during the COVID-19 pandemic from online pharmacies.

Conclusion

This analysis illustrates how easy it is to go online to buy medications that are touted to treat COVID-19 even when current clinical evidence does not support their use for self-treatment. Illegitimate online pharmacies endanger patient safety by sidestepping prescription requirements, skirting pharmacist counseling, and making false claims regarding efficacy in treating COVID-19 infections. It is important for health care providers to recognize the ease of access to these medications and raise awareness about current clinical evidence especially during the pandemic. Health care providers should also educate the public about the risks of purchasing medications from illegitimate websites, highlighting the importance of prescriptions and appropriate monitoring of therapeutic response, drug interactions, and adverse effects by pharmacists [42]. The amount of illegitimate online pharmacies that surfaced with our search also suggests a need for better search algorithms and stricter monitoring and regulations to prevent illegitimate pharmacies from being easily accessible online.

Abstract

Background: Multimorbidity represents a global health challenge, which requires a more global understanding of multimorbidity patterns and trends. However, the majority of studies completed to date have often relied on self-reported conditions, and a simultaneous assessment of the entire spectrum of chronic disease co-occurrence, especially in developing regions, has not yet been performed.

Objective: We attempted to provide a multidimensional approach to understand the full spectrum of chronic disease co-occurrence among general inpatients in southwest China, in order to investigate multimorbidity patterns and temporal trends, and assess their age and sex differences.

Methods: We conducted a retrospective cohort analysis based on 8.8 million hospital discharge records of about 5.0 million individuals of all ages from 2015 to 2019 in a megacity in southwest China. We examined all chronic diagnoses using the ICD-10 (International Classification of Diseases, 10th revision) codes at 3 digits and focused on chronic diseases with ≥1% prevalence for each of the age and sex strata, which resulted in a total of 149 and 145 chronic diseases in males and females, respectively. We constructed multimorbidity networks in the general population based on sex and age, and used the cosine index to measure the co-occurrence of chronic diseases. Then, we divided the networks into communities and assessed their temporal trends.

Results: The results showed complex interactions among chronic diseases, with more intensive connections among males and inpatients ≥40 years old. A total of 9 chronic diseases were simultaneously classified as central diseases, hubs, and bursts in the multimorbidity networks. Among them, 5 diseases were common to both males and females, including hypertension, chronic ischemic heart disease, cerebral infarction, other cerebrovascular diseases, and atherosclerosis. The earliest leaps (degree leaps ≥6) appeared at a disorder of glycoprotein metabolism that happened at 25-29 years in males, about 15 years earlier than in females. The number of chronic diseases in the community increased over time, but the new entrants did not replace the root of the community.

Conclusions: Our multimorbidity network analysis identified specific differences in the co-occurrence of chronic diagnoses by sex and age, which could help in the design of clinical interventions for inpatient multimorbidity.

Introduction

With the recent improvements in clinical interventions, advances in public health, lifestyle changes, and environmental exposures, multimorbidity has been a growing global health challenge [1-3]. Although multimorbidity is widely considered as the norm, not the exception, it still has an inconsistent definition and heterogeneity in methodology, which makes it difficult to gauge its prevalence and pattern in the general population [4-6]. In light of the increased mortality, lower quality of life, and higher utilization of health care services associated with multimorbidity [7-11], a global understanding of the multimorbidity pattern and trend is needed. Although a variety of studies have investigated the patterns of multimorbidity [12-16], most of them were conducted using cross-sectional surveys, which were generally limited either by their small number of self-reported conditions or by a small sample size. Therefore, a multidimensional approach is still needed to understand the full spectrum of multimorbidity networks, time trends, and patterns in age and sex, particularly in developing countries or regions [17].

With the enhancement of the storage capacity and accessibility of electronic information systems, digitized clinical record keeping has made routinely collected administrative data of unprecedented depth and variability available to researchers. This provides an opportunity for the application of network analysis to extract conceptual insights from large and messy data sets [18-20]. Although notable studies are few and mostly carried out in developed countries, they have provided promising findings in human phenotypic multimorbidity networks. For instance, based on the disease history of more than 30 million patients collected from hospital claims, correlations for more than 10,000 comorbid disease pairs were calculated and visualized in a phenotypic disease network [19]. Differences in identified multimorbidity across sex and racial groups were identified through macro analyses at the organ level [21,22]. Additionally, a study in Taiwan constructed an epidemiological disease network and examined its temporal pattern [23]. However, it is difficult to investigate the true extent of multimorbidity associations from these studies because of the differential definition of multimorbidity at the cross-sectional level or over a lifetime period, the difference in the measurement of associations, and the study settings that were mainly dominated by developed countries or regions.

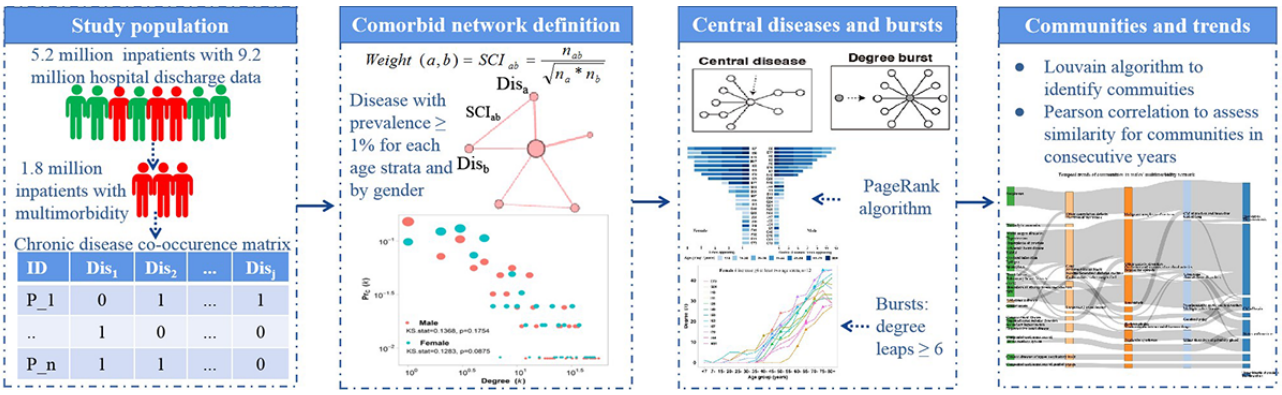
To address these gaps, we performed a retrospective study based on all inpatients living in a megacity in southwest China. We applied the standardized definition and classification system of multimorbidity [24]. Our major aim is to provide a multidimensional approach to understand the complex comorbid relationships among the full spectrum of chronic diseases in general multimorbidity inpatients in southwest China. Furthermore, this study aimed to assess age and sex differences in the multimorbidity pattern and investigate highly correlated communities and their temporal trends.

Methods

Overview

The workflow of this study is shown in Figure 1. First, we assessed the quality of the data set and confirmed the study population. Then, the cosine index was selected to construct sex- and age-specific multimorbidity networks. Next, we identified central diseases and bursts, and examined their differences across sex and age. Finally, we divided the networks into communities and assessed their temporal trends. Below, we provide more details on each step of the analysis.

Figure 1. Study workflow. SCI: Salton cosine index. Dis: chronic disease.



Ethics Approval

This study was approved by the Ethics Committee of the Health Information Center of Sichuan Province. The data were analyzed anonymously to maintain the privacy of inpatient data. As a study of previously collected administrative data, this work was exempt from informed consent requirements.

Data Source and Study Design

In this retrospective cohort analysis, we used the regional database of longitudinal clinical data for inpatients, which was provided by the Health Information Center of Sichuan Province. This regional database includes the anonymized hospital discharge reports (HDRs) collected from all of the 534

secondary hospitals and 144 tertiary hospitals in Sichuan Province; therefore, each inpatient's longitudinal clinical data were available. Each HDR contained information on the anonymized identity, age, sex, residential address, visit and discharge dates, principal discharge diagnosis, and up to 15 secondary diagnoses. All diseases were specified according to the ICD-10 (International Classification of Diseases, 10th revision) codes at 3 digits.

The eligibility criteria included inpatients who were residents of Chengdu and alive for the entire study period. A total of 5.2 million individuals (about 31.5% of Chengdu's population) with 9.2 million HDRs from 2015 to 2019 were included. As we were interested in diseases (ICD-10: A00-R99), hospitalizations in which the patients were marked only for general symptoms [24] (226,193 cases in total) were removed. According to the sex-specific diagnoses [21,24], 2329 male inpatients and 31 female inpatients were further removed due to conflicts between diagnoses and sex. Finally, the data preprocessing resulted in a total of 8.8 million hospitalizations corresponding to about 5.0 million individuals of all ages, and the sample was large enough to estimate age- and sex-specific multimorbidity patterns.

Network-Based Analysis

Chronic Diseases and Multimorbidity Definition

In 2018, the Academy of Medical Sciences recommended the adoption of a uniform definition and reporting system for multimorbidity [25], which identified multimorbidity as the co-existence of two or more chronic conditions (a physical noncommunicable disease, a mental health condition, or an infectious disease of long duration). Since chronic conditions would not be expected to go away in a single hospitalization period, we considered a 5-year period [13] rather than a single hospitalization for the definition of multimorbidity. The Chronic Condition Indicator [26], developed as part of the Healthcare Cost and Utilization Project, was used to differentiate between acute and chronic ICD-10 codes at 3 digits [24]. A total of 489 and 505 chronic disease codes were separately retained in males and females, respectively.

In order to generate more consistent and reliable estimates, we focused on chronic diseases with ≥1% prevalence for each of the following age strata: <7, 7-14, 15-19, 20-24, 25-29, 30-34, 35-39, 40-44, 45-49, 50-54, 55-59, 60-64, 65-69, 70-74, 75-79, and 80+ years, and for both males and females [20], resulting in a total of 149 and 145 chronic diseases, respectively, which were further used in downstream analyses (Multimedia Appendix 1).

Multimorbidity Network Generation and Network Properties Calculation

A multimorbidity network developed from inpatients contains a set of nodes that are connected through edges. The node represents a chronic disease (ICD-10 codes at 3 digits), such that the node size is proportional to the disease prevalence and its color identifies the ICD-10 category.

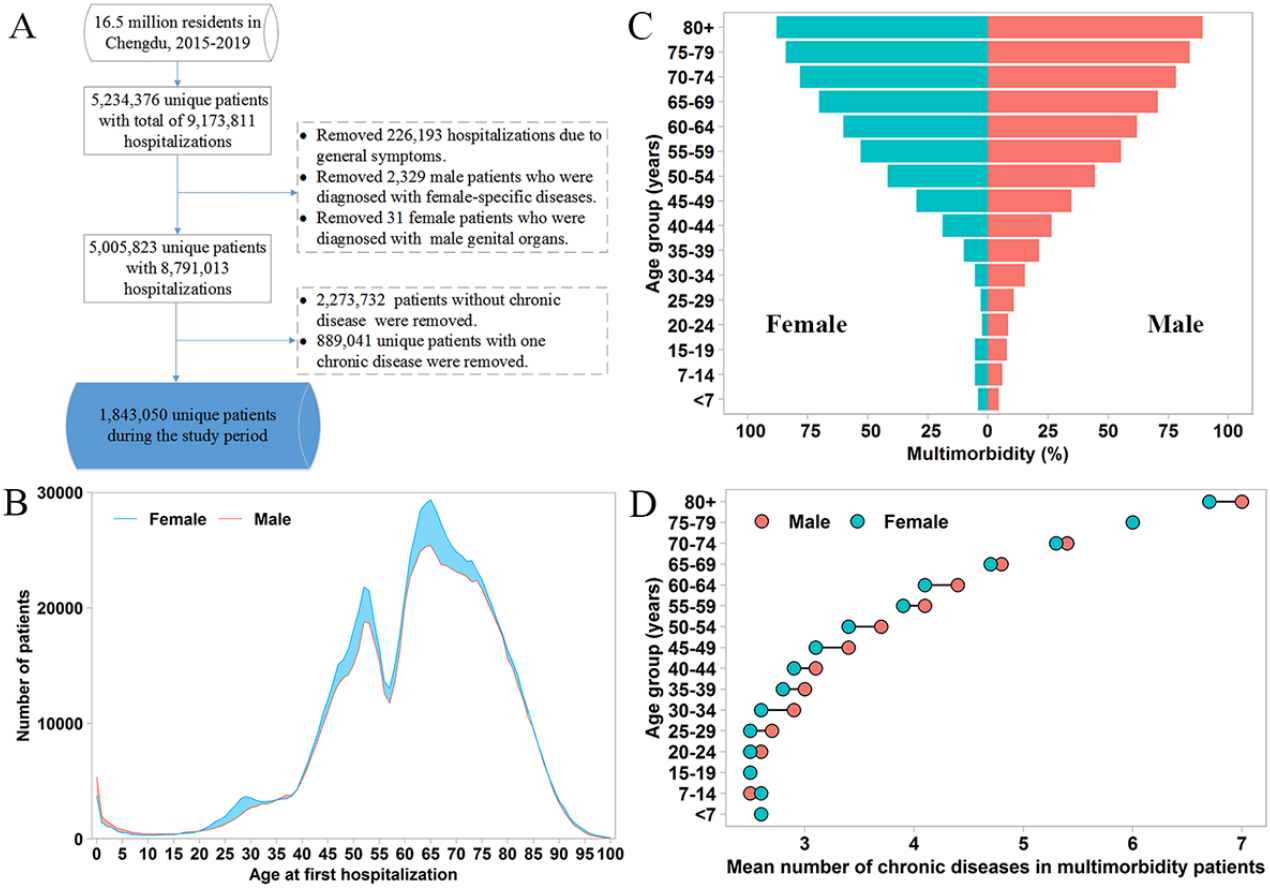
The edge in the multimorbidity network denotes the comorbid strength between co-existence diseases. Typically, the higher the comorbid strength of a disease pair, the lower the probability of co-existence by chance alone [19,20,27]. The relative risk (RR; calculated in Equation 1) or Pearson correlation coefficient (φ, calculated in Equation 2) was often used to quantify the comorbid strengths of disease pairs [19,20,27]. These 2 measures are not entirely independent of each other, as they are both affected by the sample size and have intrinsic bias [19]. As we were interested in tightly interconnected disease pairs, mutually exclusive disease pairs with negative comorbid strengths (RR < 1 or φ < 0) were excluded. Since the Salton cosine index (SCI; calculated in Equation 4) is immune to the sample size and only considers the co-occurrences and the prevalence of multimorbidity [28], we selected it to construct and compare the multimorbidity networks with a widely varied sample size in each of the sex- and age-specific groups.

where n_{ab} denotes the number of co-occurrences of diseases a and b, n_a and n_b represent the number of occurrences of diseases a and b, respectively, and N_{total} is the total number of inpatients in the sex/age-specific group.

Generally, a cutoff for the SCI is defined by assessing the relationship between the Pearson correlation and SCI, where the number of significantly correlated diseases is equal in both networks [29]. For each sex- and age-specific stratum, the steps to find a cutoff for the SCI are as follows: Step 1, Calculate the Pearson correlation coefficient (φ, calculated in Equation 2) and select the statistically significant correlations at α=.01 (calculated in Equation 3); Step 2, Find the minimum number of disease pairs  , where p, the maximum number of edges possible among n nodes detected in step 1, is equal to $n(n\text{-}1)/2$; Step 3, Find the number of pairs (q), where $n_{ab} \geq n_{ab\_minimum}$; Step 4, Find the SCI cutoff (Figure 2B), where the number of pairs is equal to q, detected in step 3. The above steps were used to create networks for males and females in each of the 16 age groups and then merge the same edges in different age groups into the general networks for males and females.

The Kolmogorov-Smirnov test was applied to investigate whether the degree distribution follows a power law. The structural properties can be measured using several network indices, such as the density, diameter, average path length, degree, weighted degree, closeness centrality, and betweenness centrality [30]. The closeness centrality measures the shortest distance of the disease away from other chronic diseases. Hence, the higher the closeness centrality of a disease, the higher the risk of co-occurrence with different diseases in fewer number of steps. The betweenness centrality denotes the number of shortest paths through a disease. Then, the higher the betweenness centrality of a disease, the higher the likelihood to form bridges between other diseases.

Figure 2. Characteristics of the study population. (A) Selection flow of the study population with multimorbidity. (B) Age and sex distribution for 1.8 million unique inpatients with multimorbidity. (C) Age- and sex-specific percentages of inpatients with multimorbidity among 5.0 million unique inpatients. (D) Age- and sex-specific mean numbers of chronic diseases among 1.8 million unique inpatients with multimorbidity.



The Central Diseases, Hubs, and Bursts

In order to distinguish the node centrality in the network, the PageRank algorithm [31] was applied, which considers the edge weights. The higher the PageRank value, the more "central" the disease [32]. The parameters were set as commonly assumed, where epsilon = 0.001 and probability = 0.85. Since no established guideline exists for how many nodes are central and since the number of nodes hugely differed among all the age groups in our study, we defined the central diseases as the nodes with the top 10 percentile of the PageRank value across the 16 age strata of males and females.

The connectivity of disease *a* is defined as the sum of all weights of all edges attached to it, which quantifies how strongly a disease is connected to the others. Diseases with larger connectivity are more likely to have a "system-wide" impact on the network. In the study, diseases with the top 10 percentile connectivity values for each of the 16 age strata of males and females have been referred to as the corresponding hubs.

In order to find the nodes with a vastly increased number of edges across age groups (defined as bursts) and to explore the sex difference in the age where the first large leaps occurred, we separately constructed male and female age-based trajectories of degree (k) for each node. The nodes with degree leaps ≥6 in the consecutive age groups with such leaps appearing at least one time in the subsequent stratum were defined as bursts. These bursts play essential roles in increasing the multimorbidity burden. Therefore, detecting the age of the first large leaps can help to understand the progression of multimorbidity.

Community Detection and Temporal Trends of Communities

Community detection separates the nodes of a generic undirected network into communities, such that connections within communities are stronger than those between them [33,34]. In order to identify distinct clusters of co-occurring diseases, we applied the Louvain method, a heuristic method based on modularity optimization [35]. Modularity Q is widely used to compare the partition quality and as an objective function to be optimized [35]. Furthermore, the community detection algorithm used in our analysis considers the weight of the links. Eigenvector centrality measures the influence of a node in a network [36]. The node with the largest eigenvector centrality in the community was therefore considered as the community root.

Observing how communities change over time can also provide valuable information about the network [23]. We applied the same methodology year by year and compared the results across time. As a result, we obtained the temporal trends of the multimorbidity networks. The Pearson correlation coefficient was used to measure the correlation for communities received in consecutive years.

All statistical analyses, network constructions, and visualizations were conducted in R software (version 3.5.1; R Development Core Team).

Results

Chronic Diseases and the Prevalence of Multimorbidity

About 5.0 million unique inpatients (representing about 30.3% of the overall Chengdu population) were enrolled in the study, among which 36.8% (a total of 1,843,050 unique inpatients, about 11.2% of the Chengdu population) had two or more chronic diseases (Figure 2). Demographically, the 1.8 million unique inpatients with multimorbidity consisted of inpatients of all ages with a higher percentage of females (52.1%). Generally, males had a statistically higher percentage of multimorbidity compared with females, except for the age group of 70-79 years (as shown in Multimedia Appendix 2). In addition, males in the middle-age (30-34 years and 45-64 years) and older elderly (80+ years) age groups had a large number of chronic diseases compared with females.

Properties of Age- and Sex-Specific Multimorbidity Networks

The phenotypic multimorbidity network analysis identified the network's global structure and uncovered chronic diseases with a closer co-occurrence (Figure 3). The RR and Pearson correlation coefficient used to measure disease co-occurrence are not entirely independent of each other (Figure 3A). Therefore, the SCI was used to measure the strength of comorbid diseases, and the cutoff of the SCI was determined by assessing the relationship between the Pearson correlation coefficient and SCI (Figure 3B). The cumulative distribution of the number of edges by nodes (degree (k) distribution) presented exponential decays (Figure 3C). Both the multimorbidity networks of males and females were scale-free as the distribution followed a power law (Kolmogorov-Smirnov test, P=.18 in the male network and P=.09 in the female network). The number of nodes and edges for the multimorbidity networks across age strata and by sex ranged from 22 to 74 and 18 to 579, respectively (Figure 3D and 3E). For patients above the age of 30 years, the number of edges we found was more significant in the male multimorbidity network. The number of edges became smaller in the lower age groups, but stronger disease connections were identified (Figure 3F). Table 1 lists the topological properties of each network. Generally, the multimorbidity networks in the younger age groups (≤40 years old) were sparser, except for females <7 years old. The maximum diameter and average path length of the female multimorbidity network were 10 and 4, respectively, which were larger than those of the male network (8 and 2.8, respectively). The average closeness centrality in the multimorbidity network of middle-aged (30-54 years) males was significantly higher than that for females (Wilcoxon test, both P<.05).

Figure 3. The properties of sex-specific phenotypic multimorbidity networks. (A) Scatter plot between the relative risk (RR) and the Pearson correlation coefficient of disease pairs; due to the interest of tightly interconnected diseases, we excluded mutually exclusive disease pairs with RR <1 or correlation <0. (B) The cutoff of the Sclton cosine index (SCI) where the numbers of significant disease pairs are equal in networks using the Pearson correlation coefficient and SCI. (C) Degree (k) distributions for sex-specific multimorbidity networks using the SCI. (D) and (E) The numbers of connected nodes and edges in each multimorbidity network across age strata and by sex. (F) Box plot of the SCI across age strata and by sex. The width of the box is proportion to the number of edges in each strata's network.

Age- and Sex-Specific Differences in Central Diseases, Hubs, and Bursts

The female and male multimorbidity networks are visualized in Figure 4A and 4B, respectively. According to the frequency and comorbidity strength, the top 20 comorbid disease pairs involved 13 diseases, among which 11 diseases (E11, E78, I10, I11, I25, I27, I50, I63, I67, I70, and J44) were common to both males and females, and 2 diseases were sex specific (hyperplasia of the prostate [N40] in males and spondylosis [M47] in females). The most comorbid disease pair was essential hypertension (I10) with cerebral infarction (I63), which occurred in males older than 30 years and females older than 40 years. Notably, there existed a few disease pairs that exhibited strong comorbid strengths but only occurred in a typical age group, for instance, congenital malformation co-existence in children <7 years old. Based on the PageRank algorithm, 23 and 26 chronic diseases were identified as central diseases in the female and male multimorbidity networks. Among these diseases, 14 chronic diseases were common to both males and females, and comprised critical diseases across different ages, such as heart failure (I50), essential hypertension (I10), glycoprotein metabolism disorders (E77), and lipoprotein metabolism disorders (E78) (Figure 4C). Interestingly, depressive episodes (F32) and other anxiety disorders (F41) represented the central diseases among females aged 7-14 years and 25-29 years, respectively. A total of 26 unique diseases were hubs in the multimorbidity networks, including 19 hubs common to both males and females, 1 female-specific hub (spondylosis at 50-59 years), and 6 male-specific hubs (Figure 4D). Furthermore, for each burst, which had at least 2 degree leaps ≥6 through consecutive age groups, connectivity trajectories across age groups are presented in Figure 4E and 4F. A total of 7 burst nodes were common to both males and females, among which essential hypertension (I10) first occurred in men aged 30 to 34 years. Among the 4 male-specific burst nodes, the earliest leaps were glycoprotein metabolism disorders (E77), which happened at 25-29 years. Remarkably, 9 diseases were classified as not only central diseases, but also hubs and bursts. Among them, 5 were common to both males and females, including essential hypertension (I10), chronic ischemic heart disease (I25), cerebral infarction (I63), other cerebrovascular diseases (I67), and atherosclerosis (I70). Therefore, particular diseases act as both bursts for increasing the network complex and as hubs for having a “system-wide” impact on the network, and some of these act as central diseases for playing the most important role in the network.

Disease progression by age was evaluated by analyzing the connectivity trajectories of each disease (Figure 5). Males had a higher connectivity, except for the youngest age groups (≤14 years old). In contrast, females had a steeper slope, particularly those aged 55+ years. The central diseases in both males and females showed a higher connectivity compared with noncentral diseases, and the connectivity difference between central diseases and noncentral diseases increased with age among males and females older than 35 years. A similar pattern also appeared in the hubs, but its connectivity difference was more conspicuous at a younger age compared with that in central diseases, which is consistent with the network topology. Subsequently, the bursts in males and females had a higher connectivity after the initial degree leaps ≥6 occurred (males older than 35 years and females older than 40 years).

Figure 4. Multimorbidity networks, central diseases, hubs, and connectivity trajectories. Age-adjusted multimorbidity network in females (A) and males (B). Nodes represent chronic diseases (ICD-10 [International Classification of Diseases, 10th revision] codes at 3 digits), such that the node size is proportional to the disease prevalence among multimorbidity patients and its color identifies the ICD-10 category. Link weights are proportional to the magnitudes of the cosine index. (C) The central diseases in each age strata by sex. Diseases with the top 10 percentiles for PageRank in each strata were identified as central diseases. (D) The hubs in each age strata and by sex. Nodes with the top 10 percentiles for hubs in each strata were identified as hubs. The age-based trajectories of the degree (k) of bursts in females (E) and males (F). The triangles indicate degree leaps ≥6 through the consecutive age groups. The disease with at least two such degree leaps was defined as a burst, which means the bursts of disease associations leading to multimorbidity.

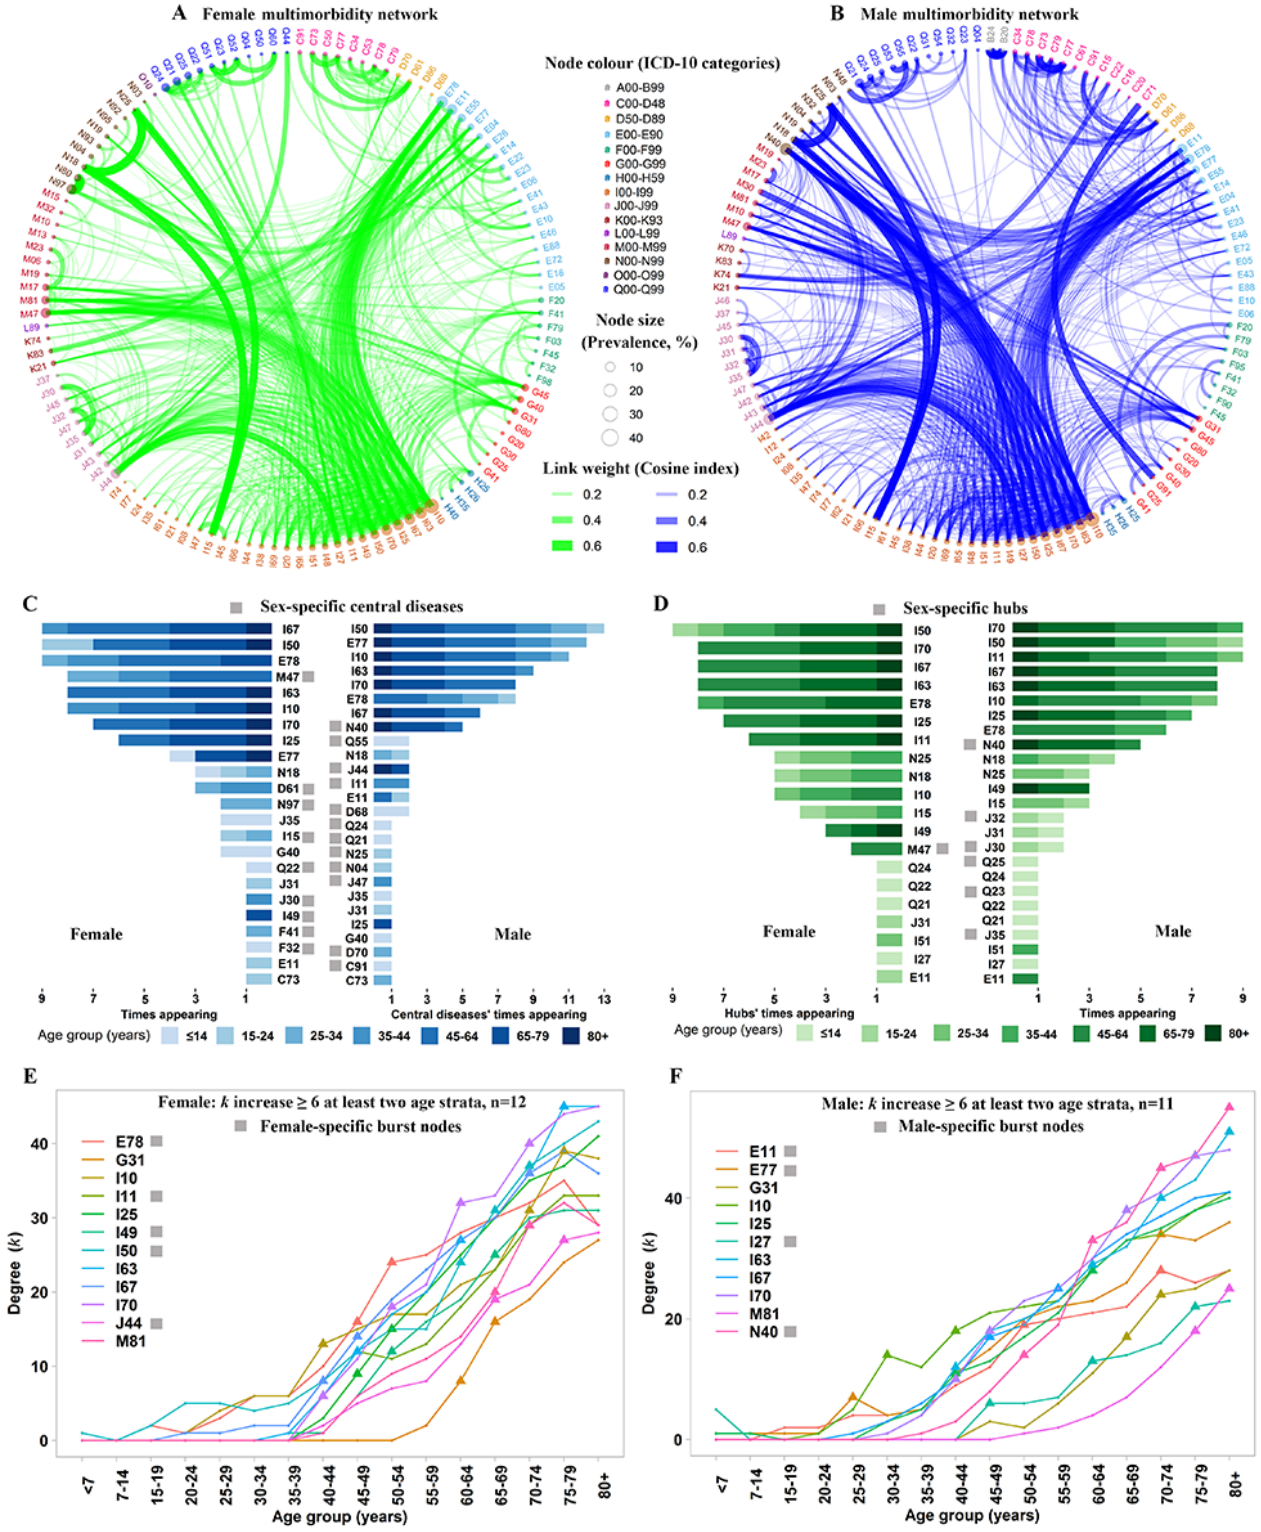

Figure 5. Sex-specific connectivity (cumulative of the node-average Sclton cosine index [SCI]) across age groups. All nodes (A), central diseases vs noncentral diseases (B), hubs vs nonhubs (C), and bursts vs nonbursts (D).

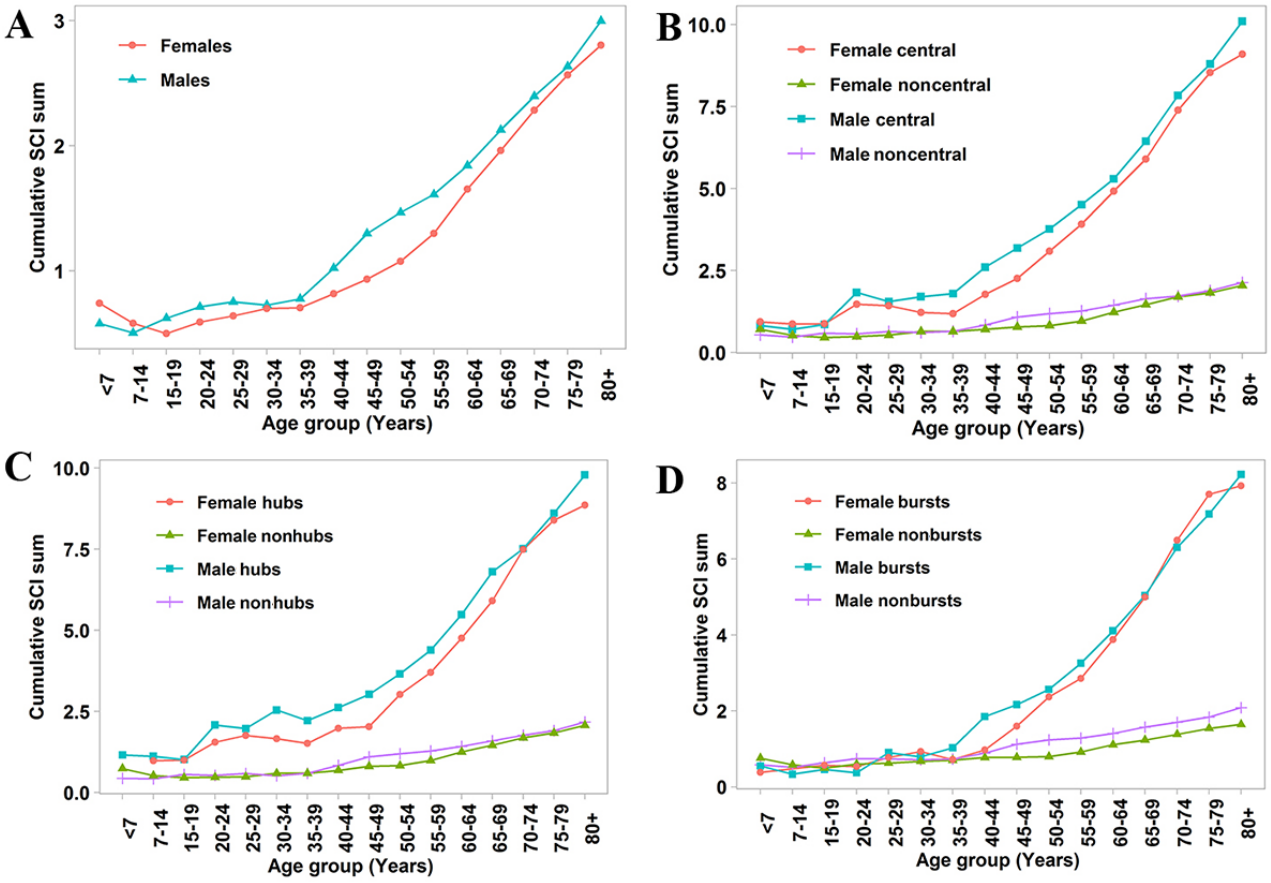
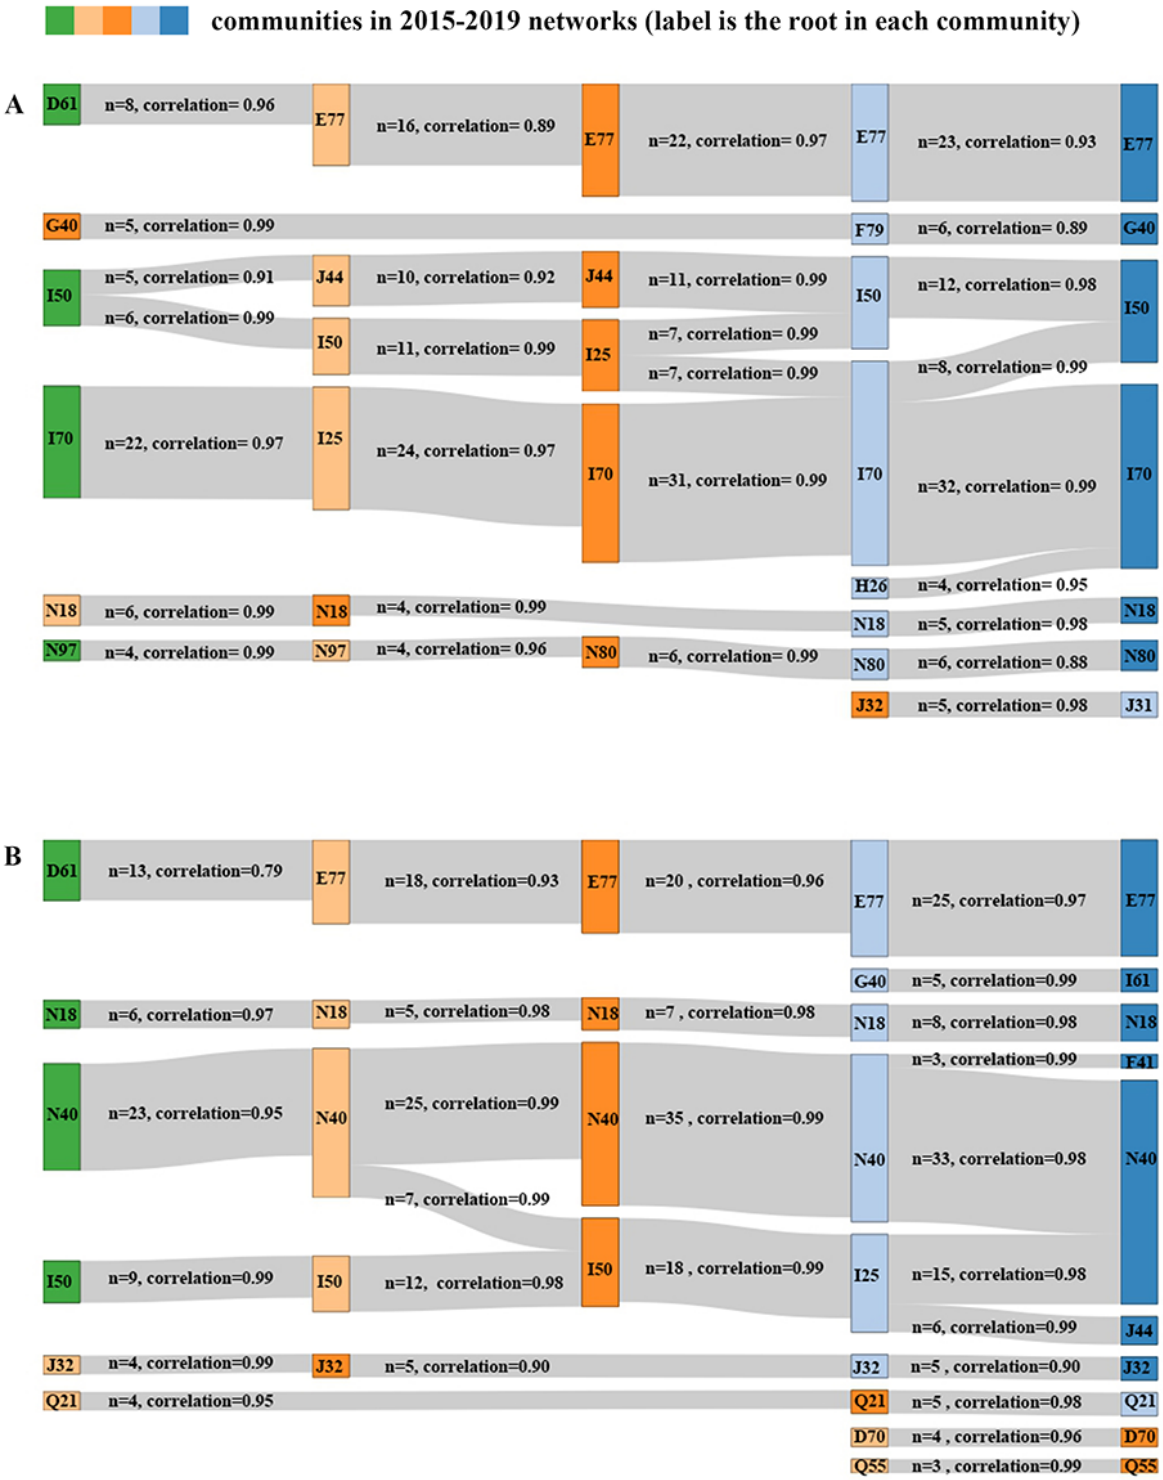


Temporal Trends of Communities

The community structures showed little variation across time, while the community root tended to be stable throughout time (Figure 6). The number of chronic diseases in the community increased over time, consistently in both males and females, and the new entrants did not replace the community root. For instance, the number of diseases in the community, among which the disorder of glycoprotein metabolism (E77) or other aplastic anemias (D61) was identified as the root, increased from 8 to 23 in the female community and from 13 to 25 in the male community. In addition, the community common to both males and females was defined as having the same root within the community, where many diseases were common to both sex groups and few diseases were sex specific. For instance, in the community with chronic renal failure (N18) as the root, both the female and male communities included the same diseases, such as secondary hypertension (I15), chronic nephritic syndrome (N03), nephrotic syndrome (N04), and disorders resulting from impaired renal tubular function (N25), while the male community also included vitamin D deficiency (E55) and the female community also included gout (M10) and systemic lupus erythematosus (M32). The clustering of mental health disorders, including depressive episode (F32), other anxiety disorders (F41), and somatoform disorders (F45), differed by sex. For example, the male community included only mental health disorders, while the female community included mental health disorders and various physical diseases. As for sex-specific diseases, the majority of female-specific diseases were in a separate community, with female infertility (N97) or endometriosis (N80) as the root. As for male-specific diseases, hyperplasia of the prostate (N40) was consistent throughout time, and its eigenvector centrality was even higher than that of atherosclerosis, heart failure, or cerebral infarction.

Figure 6. Temporal trends of communities in the female (A) and male (B) multimorbidity networks. By conducting networks year by year and comparing across time, we were able to obtain the temporal trends of the communities. The root, defined as the node with the highest eigenvector centrality within the community, is labeled using ICD-10 (International Classification of Diseases, 10th revision) at 3 digits. Similarity over time is assessed using the Pearson correlation coefficient for communities obtained in consecutive years, and unsignificant (*P*>.05) similarities are excluded. The "n" value is the number of chronic diseases consistent in the consecutive years.



Discussion

Principal Findings

We constructed multimorbidity networks among multimorbidity inpatients (about 11.2% of the Chengdu population) consisting of all ages, which established the connections between chronic diseases in the general hospitalized population from a megacity with 16.5 million residents in southwest China. Multimorbidity affected people of all ages, and their complex interactions were more intensive among males and inpatients ≥40 years old. Notably, in the female multimorbidity network, mental health

disorders co-occurred with various mental and physical diseases (eg, metabolic disorders, cardiovascular diseases, and neurodegeneration diseases), among which the co-existence of a depressive episode with other anxiety disorders was detected in 14 age groups of 7-79 years. Moreover, disease connectivity leaps, central diseases, and highly interlinked communities were detected. To the best of our knowledge, this is the first regional study within a developing country that applied regional hospital discharge records rather than self-reported survey data to provide an overview of the prevalence of multimorbidity, obtain multimorbidity patterns, and assess the sex and age differences. Our results demonstrate that the application of network-based algorithms to routinely collected health care data might provide a way to better screen and identify the complex interactions among chronic diseases.

Multimorbidity Affects People of All Ages

Multimorbidity affects people of all ages, even children who are inpatients (≤14 years old), where 5% of these children have at least two chronic diseases. The findings were in accordance with what was reported in previous studies based on the general population because the prevalence differed by age range, sex, ethnicity, socioeconomic status, and lifestyle, cultural, and health-seeking behaviors [6,13,37-39]. Our results showed that 36.8% of the inpatients living in Chengdu during the 2015-2019 time period had at least two chronic diseases, which is lower than that in the Netherlands (multimorbidity prevalence of 57%) [39], Spain (multimorbidity prevalence of 43.2%) [40], and Canada (multimorbidity prevalence of 53.3%) [6], but higher than that in the United Kingdom (multimorbidity prevalence of 19%) [14], Scotland (multimorbidity prevalence of 31.1%) [41], Singapore (multimorbidity prevalence of 26.2%) [42], Italy (multimorbidity prevalence of 15.3%) [43], and Denmark (multimorbidity prevalence of 21.6%) [44]. A scoping review found a wide range in multimorbidity prevalence in the general population as reported in studies using a large data set, from 15.3% to 68.4% [45]. The reported multimorbidity prevalence is still highly varied due to inconsistent measurements of chronic conditions and multimorbidity [45,46]. Additionally, a study using claims data in Beijing reported that the prevalence of multimorbidity was 51.6% and 81.3% for middle-aged adults (45-59 years) and older adults (≥60 years), respectively [47], which were higher than the respective prevalences of 41.7% and 75.2% in our study. One explanation might be related to the differential study design, since the study in Beijing used both outpatient and inpatient clinical diagnoses for the measurement of multimorbidity. However, the study in Beijing only used 13 most frequently mentioned diseases to measure multimorbidity and the study population was restricted to people who had been employed, which would limit its generalizability to a general population. Therefore, estimating the prevalence of multimorbidity based on a regional database is essential for the design of health care strategies. To the best of our knowledge, this is the first regional study within a developing country to provide an overview of the prevalence of multimorbidity using regional hospital discharge records rather than self-reported survey data. The prevalence of multimorbidity increased with age, which is in line with the findings of previous epidemiological studies that the prevalence of multimorbidity may be increasing, at least in part, because of population aging [5,6,8,41].

Age and Sex Differences in Multimorbidity Patterns

We identified the multimorbidity patterns in age- and sex-specific inpatient groups, which were comparable with previous studies in developed countries or regions [6,16,20,21]. For instance, Ioakeim-Skoufa et al [16] found associations of respiratory disorders with circulatory diseases, and depression and anxiety with chronic musculoskeletal diseases. In our study, we identified the most frequent and strongest comorbid disease pairs, such as the associations of circulatory diseases with endocrine diseases, diseases of the musculoskeletal system, and respiratory disorders, which co-occurred more frequently than expected by random chance. Our data set consisted of hospitalizations of all ages, and thus contained information about the diseases that are common and specific among age and sex groups. For example, we identified some disease pairs that occurred throughout life (eg, heart failure co-occurring with complications of heart disease and lipoprotein metabolism disorders co-occurring with diabetes mellitus) and some pairs with a stronger comorbid strength but only occurrence among a typical age group (eg, congenital malformation co-existence in children <7 years old). Intuitively, chronic diseases would be expected to co-occur in an individual if their resilience or vulnerability was altered or if they shared a common pattern of influence [48-50]. Thus, as in previous studies assessing the disease trajectory in patients with depression [51] and type 2 diabetes [52], and the general population [24], regional databases collecting HDRs spanning a sufficient time period (generally 10+ years as in the above mentioned studies) will support further studies to explore the potential causal directions among complex correlations. In accordance with previous studies [21,53], we identified a difference in the associations of mental disorders with physical diseases among different sex groups, and generally stronger associations were found in females than in males. This sex difference within mental health multimorbidity may be related to differences in the patient care–seeking behaviors between males and females, as indicated in a previous study that reported on how social factors can discourage males from seeking mental health care [54]. Our findings support the development of interdisciplinary and multidisciplinary treatment strategies for patients with depression or anxiety [53,55,56], since they frequently had physical diseases, such as metabolic disorders, Alzheimer disease, epilepsy, hypertension, chronic ischemic heart disease, heart failure, cerebral infraction, atherosclerosis, gastroesophageal reflux disease, decubitus ulcer, and spondylosis. The data-driven discovery of diseases co-occurring might be useful to generate potential hypotheses for coexisting diseases (eg, sharing the same gene, having common risk factors, and displaying a consistent temporal progression trend [57,58]) and their differences in age and sex (eg, physical, hormonal, and even genetic differences by sex [59,60] and disease progression with age [24]). Additionally, the data-driven discovery of diseases co-occurring, especially based on a complete population with a high-quality health care database, might have impacts on disease management [50].

We found lifelong comorbid disease pairs among multimorbidity inpatients, for example, lipoprotein metabolism disorders (E78)

co-occurring with diabetes mellitus (E11) in both males and females ≥15 years old, heart failure (I50) co-occurring with complications of heart disease (I51) in females ≥15 years old, and a depressive episode (F32) co-occurring with other anxiety disorders (F41) in females aged 7-79 years. Congenital malformations, generally the earliest diagnosed diseases in life (ie, pre- or perinatally), had a higher prevalence in multimorbid girls (<7 years) than in boys (<7 years) in our study, especially congenital malformations of the circulatory system (including congenital malformations of the cardiac septa, Q21; congenital malformations of the pulmonary and tricuspid valves, Q22; congenital malformations of the aortic and mitral valves, Q23; other congenital malformations of the heart, Q24; and congenital malformations of the great arteries, Q25). The prevalence of congenital heart disease in girls was higher than in boys [61], and treatment or progression of congenital heart disease could cause complications of heart disease and heart failure [62,63], which may support the finding in our study that heart failure co-occurring with complications of heart disease was earlier in females than in males. Chronic diseases with the earliest connectivity leaps begin at 25-29 years in males, about 15 years earlier than in females. These findings indicate the need to appropriately handle multimorbidity among youth or middle-aged patients [2,64]. Attention and activities are required to prevent such people from entering the multimorbidity category, especially for lipoprotein metabolism disorders, diabetes mellitus, hypertension, heart failure, spondylosis, chronic renal failure, fibrosis and cirrhosis of the liver, and gout. In addition, appropriate guidelines and flexible care management support systems are required across a broader age range.

Within each multimorbidity network, we identified the central disease, which played the most important role in the network (eg, having a large number of comorbid diseases and thus increasing the scale of network, having a relatively smaller number of comorbid diseases but exhibiting stronger comorbid strengths, and playing the role of connectivity to connect those unconnected diseases). In the biomedical scenario, central diseases may be interpreted as those that are more likely to appear in patients with multimorbidity or lead to multimorbidity. Therefore, common causal genes and molecular processes or signaling pathways may be shared among central diseases and their neighbors [27,65]. We found that circulatory diseases and metabolic diseases were the most important diseases among almost all age groups; thus, clinical studies of the identified central diseases may be helpful to improve prevention strategies and health care policies [2]. Notably, younger females should receive more attention on 2 mental health disorders, depressive episodes and other anxiety disorders, which significantly increased the scale of their multimorbidity network. The observations of central diseases could have important implications on the design of health care prevention, such that measurements targeting a specific factor may benefit many related diseases.

Furthermore, we observed that some communities remained stable across time, while others became more extensive due to the occurrence of more diseases. Few studies have observed the temporal trends of networks or communities [23,37]. Jiang et al found that the network structure, connectivity, and module structure varied across time [23]. The work of van Oostrom et al [66] showed that the prevalence of chronic diseases in the general practice registration over the period between 2004 and 2011 increased from 34.9% to 41.8%, and this increase could be only partially explained by the aging of the population. In our study, the community of mental health disorders in the male multimorbidity network consisted of depressive episodes, other anxiety disorders, and somatoform disorders, which seemed independent with physical diseases, while the community involving females additionally included various physical diseases, such as disorders of lipoprotein metabolism and other lipidemias (E78), essential hypertension (I10), hypertensive heart disease (I11), cerebral infarction (I63), atherosclerosis (I70), gastroesophageal reflux disease (K21), and spondylosis (M47). The clustering difference in mental health disorders according to sex might be related with the higher underdiagnosis rate of mental health disorders in males [67] and provide evidence for differential strategies in diagnosis and treatment for males and females. For instance, when 2 diseases are discordant in terms of their pathogenesis (eg, depression co-occurring with cerebrovascular disease in females), they may require separate time-intensive treatment plans [56,68-70]. Additionally, within the community, both concordant and discordant diseases in terms of their pathogenesis were included (eg, a female community with atherosclerosis as the root and including diabetes mellitus, hypertension, cerebrovascular diseases, mental health disorders, and spondylosis), which might lead to very different management needs and treatment strategies [56,68-71]. Communities can describe the interconnections among chronic diseases, with more tight connections between those in the same community. In a further study, it will be of interest to examine the direction of these interconnections or to explore their common risk factors for priority management.

Strengths and Limitations

The main strengths of this study can be summarized as follows. First, this is the first regional study in developing countries based on a large-scale data set (8.8 million hospital discharge records) to examine multimorbidity patterns and trends, and their differences across age and sex. Additionally, a network-based approach is applied to extract conceptual insights from routinely collected hospital discharge records. The use of this method can be extended to other health care data sets. Lastly, the use of routinely collected administrative data at a regional level is advantageous because the data are uniformity distributed and unbiased, which provides an opportunity to identify the co-occurrence of rare clinical diseases.

This study has some limitations. First, the main limitation of this study is the unavailability of individual-level socioeconomic status, lifestyle, and clinical variables. These factors would play essential roles in understanding the differences among multimorbidity patterns [23]. This limitation is common among studies that use routinely collected health care data sets. Second, the data set that was used did not contain information on the outpatients who were seeking solely outpatient care. Hence, it is vital to interpret our findings in the context of the inpatient population in a developing country. Third, we excluded individuals who were not alive during the study period to obtain a more homogenous study population, which may underestimate

the diseases that have high mortality rates. However, it was demonstrated by a previous study that this exclusion criterion did not drastically impact the results [37].

Conclusions

In this paper, we performed a network-based analysis of 8.8 million hospital discharge records and identified age and sex differences in multimorbidity patterns and the evolution of multimorbidity over time. This longitudinal study provides the first evidence from a developing country that multimorbidity affects people of all ages and their complex interactions are more intensive among males and inpatients ≥40 years old. Mental health disorders were comorbid with more various mental and physical diseases in females than in males. The lifelong comorbid disease pairs, disease connectivity leaps, central diseases, highly interlinked communities, and age- and sex-specific comorbidity patterns detected in the study might provide suggestions for enhancing integrated management in multimorbidity patients. Meanwhile, the network-based approach applied in our study could investigate all the multimorbidity connections at the population level, which could be used within health care data sets in other settings.

Abstract

Background: Digital pills are pills combined with a sensor, which sends a signal to a patch connected to a smartphone when the pills are ingested. Health care professionals can access patient data from digital pills online via their own interface, thus allowing them to check whether a patient took the drug. Digital pills were developed for the stated goal of improving treatment adherence. The US Food and Drug Administration approved the first digital pills in November 2017, but the manufacturer withdrew its application to the European Medicines Agency in July 2020 because of insufficient evaluation.

Objective: As recommended for the evaluation of health technologies, this study assesses the prospective acceptability of and willingness to take digital pills among patients, the public, and health care professionals.

Methods: Participants were patients who were receiving long-term treatment for a chronic condition, public participants (both groups recruited from a representative sample), and health care professionals. Participants answered 5 open-ended questions regarding the acceptability of digital pills and 1 close-ended question regarding the willingness to take digital pills, which were developed in a preliminary qualitative study. We explored the 5 theoretical dimensions of acceptability by performing an abductive qualitative content analysis of all free-text responses. We assessed data saturation with mathematical models. We fitted a multivariate logistic regression model to identify the sociodemographic and health characteristics associated with the willingness to take digital pills.

Results: Between January 29, 2020, and April 18, 2020, 767 patients, 1238 public participants, and 246 health care professionals provided 11,451 free-text responses. We identified 98 codes related to the acceptability of digital pills: 29 codes on perceived clinical effectiveness (eg, sensor safety cited by 66/2251 participants, 29.5%), 6 on perceived burden (eg, increased doctors' workload, 164/2251 participants, 7.3%), 25 on perceived ethicality (eg, policing, 345/2251 participants, 15.3%), 30 codes on perceived opportunity (eg, exclusively negative perception, 690/2251 participants, 30.7%), and 8 on affective attitude (eg, anger,

541/2251, 24%). Overall, 271/767 (35.3%) patients, 376/1238 (30.4%) public participants, and 39/246 (15.8%) health care professionals reported willingness to take digital pills. This willingness was associated with male sex (odds ratio 1.98, 95% CI 1.62-2.43) and current use of a connected device to record health settings (with a dose–response relationship).

Conclusions: The prospective acceptability of and willingness to take digital pills were limited by clinical and ethical concerns both at the individual and societal level. Our results suggest that digital pills should not be considered a mere change in the form of drug administration but a complex intervention requiring specific evaluation before extended use in clinical routine practice as well as an ethical and legal framework to ensure safe and ethical collection and use of health data through a patient-centered approach.

Introduction

More than one-third of people worldwide live with at least 2 chronic conditions; hence, an increasing number of people are receiving long-term treatment [1]. Control of many of these conditions depends on adherence to treatment, which can be defined as the degree to which the use of medication by the patient corresponds with the prescribed regimen [2]. However, about half of patients with chronic conditions do not take their medications as prescribed. Poor treatment adherence leads to a range of negative consequences such as poor control of disease, life-threatening events, treatment resistance, and increasing costs [3-8]. In 2003, the World Health Organization suggested that improving treatment adherence would have a greater impact than any improvement in specific medical treatments, and this has led to a continuous search for effective interventions to monitor and improve medication adherence (eg, blood drug dosage, self-reported patient diaries, smart pill dispensers) [2,9,10].

The most recent monitoring tool, approved in 2017 by the US Food and Drug Administration, is called a “digital pill.” Digital pills are pills combined with a sensor, which sends a signal to a patch connected to the smartphone of the patient when the pill is ingested. Health care professionals and caregivers can access patient data (eg, adherence, activity, heart rate) from digital pills online via their own interface, thus allowing them to check whether a patient took the drug. The sensor is an ingestible event marker made from a copper–magnesium pair of electrodes within a silicon insulating skirt disk 5 mm in diameter and 0.3 mm thick. On contact with gastric fluid, the sensor sends a unique digital code to allow identification and timestamping of the medication and dose form [11]. The first digital pill was an antipsychotic (aripiprazole) used for schizophrenia or bipolar disorder treatment, which was rapidly followed by a range of other digital pills for multiple medical conditions (eg, antihypertension, diabetes, viral diseases) [12].

Digital pills have been developed for the stated goal of improving medication adherence and optimizing treatment management; these are used to identify nonadherence to first-line therapies before more expensive second-line therapies can be considered [10,13]. The European Medicines Agency declared that the evaluation for the digital pill submitted was inadequate and withdrew the application on July 26, 2020; the quality of the available studies (observational studies or small trials) and the lack of clinical relevance of the outcomes (short-term outcomes related to adherence to digital pills, safety outcomes restricted to tolerance of the patch) were points of criticism that led to this withdrawal [12,14-17].

Moreover, guidelines for the evaluation of health technologies recommend taking into account patient and public perspectives, which has not been done yet for digital pills [18]. Acceptability is a multifaceted construct that reflects the extent to which people delivering or receiving a health care intervention consider it appropriate based on anticipated, present, or retrospective responses to the intervention [19]. It includes the extent to which the intervention is perceived likely to achieve its purpose (perceived clinical effectiveness), the amount of effort required to participate in the intervention (perceived burden), the extent to which the intervention aligns with individual values (perceived ethicality), the extent to which benefits/values must be compromised to engage in the intervention (perceived opportunity), and how people feel about the intervention (affective attitude) [19].

As part of new health technology assessment, this study aims at evaluating the prospective acceptability of and willingness to take digital pills by 3 subpopulations (patients, public participants, and health care professionals).

Methods

We conducted an online survey by recruiting a representative sample of the French general population, dichotomized into patients and public participants, and an additional convenience sample of health care professionals. The survey included 5 open-ended questions related to the acceptability of digital pills and 1 close-ended question regarding the willingness to take digital pills (Multimedia Appendices 1 and 2).

Participants and Recruitment

Patients were adults (≥18 years old) with at least one self-reported chronic condition for >6 months and who were prescribed long-term treatment for >1 month. Public participants included adults (≥18 years old) who did not meet the eligibility criteria to be classified as patients. Health care professionals were professionals prescribing, delivering, or monitoring pharmaceutical treatments (physicians, nurses, pharmacists, and

midwives). All participants were living in France, spoke French, and had access to the internet.

We used the 2 distinct methods to recruit participants:

- The representative sample was recruited using a quota sampling method in the IPSOS Access Panel [20]. Quotas were based on the known profile of the French population in terms of sex, age, socioprofessional category, and population density of the residential area. This sample was secondarily classified into patients and public participants according to the eligibility criteria. We calculated weights with the rim weighting method—raking (Multimedia Appendices 3) [21].
- The additional convenience sample of health care professionals was recruited via an online campaign by sending emails to professional associations and posting advertisements on social networks (Multimedia Appendices 4).

All participants provided informed electronic consent before enrollment. The Institutional Review Board CERAPHP.5, Paris, France, gave ethical approval (IRB0001198).

To recruit patients with various combinations of chronic conditions and socioeconomic status, perform quantitative analysis using logistic regression, and ensure that data saturation was reached based on previous experience with an online survey and considering the fact that 34.5% of the French population lives with a chronic condition, we targeted a representative sample of 2000 participants [22,23]. Regarding the convenience sample of health care professionals, we decided to stop recruitment after reaching 95% data saturation [22].

Survey Development and Data Collection

We conducted a preliminary qualitative study to draft the questions (wording, formatting, and content) of the survey and provide the investigators with a contextual framework for analyzing and interpreting textual data. A researcher trained in qualitative methods (AC) conducted face-to-face collaborative interviews with 5 patients, 5 public participants, and 3 health care professionals (Multimedia Appendix 5). From the results of this preliminary study, we developed an illustrated explanation of digital pills, 5 open-ended questions on the acceptability (Textbox 1) and 1 close-ended question on the willingness to take digital pills ("Would you agree to use this device for yourself?") (Multimedia Appendices 1 and 2).

Textbox 1. Open-ended questions to all participants on the acceptability of digital pills.

- What do you think of this device (transmitter + Bluetooth patch + smartphone app + access to data)? We want to know your immediate reaction: try to write down all the ideas that came to you when you first saw this device.
- What do you envisage are the positive aspects of this device (transmitter + Bluetooth patch + smartphone app + access to data)? For example, in what situation(s)/for whom could it be useful, what kind of benefit could it bring?
- What do you envisage are the negative aspects of this device (transmitter + Bluetooth patch + smartphone app + access to data)? For example, what drawbacks or risks do you foresee?
- If your doctor suggested a treatment using this device (transmitter + Bluetooth patch + smartphone app + access to data), what would your reaction be? What would you think of his/her approach?
- The manufacturer says that this device will allow for greater consistency between the prescription and the actual taking of medications. In your opinion, why would a person take their treatment more consistently if they were equipped with this device?

In addition, we collected sociodemographic data (eg, sex, age, level of education) for patients and public participants, professional status data (profession and duration of professional experience) for health care professionals, and health characteristics for all participants (eg, chronic condition, current use of a connected device to collect health data) (Multimedia Appendices 1 and 2).

The survey for patients and public participants was available online in a dedicated IPSOS platform. The survey for health care professionals was available in a LimeSurvey form. Both surveys were tested online for usability, clarity, and wording in a convenience sample of 10 patients, 20 public participants, and 5 health care professionals, whose feedback helped improve the final version.

Analyses

Acceptability of Digital Pills

We conducted a multiple-round qualitative content analysis of each free-text response by following a 3-step approach: inductive open coding of all units of meaning related to the acceptability of digital pills, inductive condensation of the codes, and inductive development of the themes and deductive classification of the themes in the 5 dimensions of acceptability [19,24].

In the first step, the team of coders (AC, AF, AJ, FD) read and reread the responses at the individual level (all responses to all questions individual by individual) and at the question level (all responses for all individuals question by question). The process of coding identified in each response units of meaning and assigned a code. A unit of meaning was defined as any expression in the text related to the acceptability of digital pills, as explained by Sekhon et al [19]. The coding was limited to the manifest content of the responses, except for the first open-ended question on the emotional reaction to the digital pill, for which the latent emotional content was interpreted when possible [25]. During a face-to-face meeting, all researchers coded together all responses for 100/2005 (5%) individuals of the representative sample and 50/246 (20%) individuals in the sample of health care professionals. Then, 1 researcher coded all responses (AC) and 3 others double-checked the codes (AF, AJ, FD). In case of discrepancies, consensus was reached by discussion with another researcher (SS). To reduce interpretation

bias, coders had different backgrounds and training (psychiatry, family medicine, training in clinical research, social science, cognitive psychology, and medical ethics).

The second and third steps occurred in a meeting in which the 4 coders and SS inductively condensed all the codes using semantic, psychological, and anthropological considerations. Then, they categorized the codes inductively into themes and classified them deductively into the 5 theoretical dimensions of acceptability [19].

We then calculated the number of citations for each code identified with the qualitative content analysis in each group using the weighted data for patients and public participants.

Data saturation was assessed for patients, public participants, and health care professionals with a mathematical model [22].

Willingness to Take Digital Pills

We calculated the number and proportion of participants who agreed to take digital pills. We estimated odds ratios (ORs) and 95% CIs using the weighted data of the representative sample to calculate the association of the willingness to take digital pills with all socioeconomic and health characteristics. We used the same data for a multivariate logistic regression model, including sex, age, socioprofessional status, residential area, chronic condition, current use of a connected device to collect health data, and ease to talk about treatment with the doctor. For the regression, we considered the response "I do not wish to answer" to be a refusal to take digital pills. The significance threshold for *P* values was calculated with Bonferroni correction to correct for multiple testing.

All quantitative analyses involved using the free software R v3.3 (R Foundation for Statistical Computing), and the package "survey."

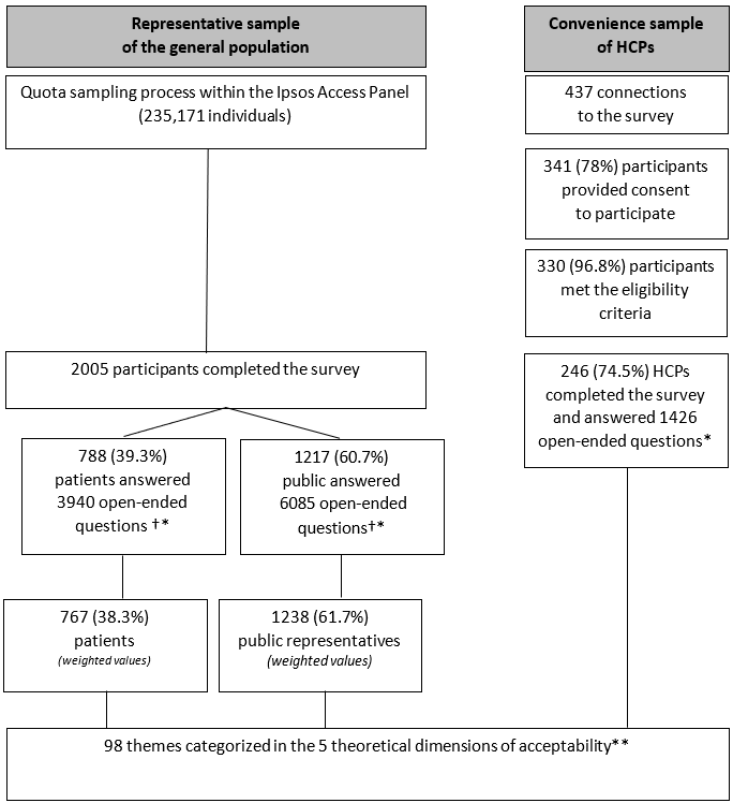
Data Sharing Statement

The deidentified quantitative data set will be shared on request (astrid.chevance@gmail.com).The textual data set will not be shared because of ethical restrictions.

Results

Between January 29, 2020, and February 5, 2020, IPSOS recruited a representative sample of 2005 participants (767 patients, 38.3%; 1238 public participants, 61.7%) (Figure 1). We recruited a convenience sample of 246 health care professionals between February 4, 2020, and April 18, 2020.

Figure 1. Flowchart. HCP: health care professional. †Unweighted numbers and proportions of patients and public representatives. *Participants answered 5 open-ended questions (panel 1). We added the number of open-ended questions answered for each type of participant. **Results presented in Figure 3 and Multimedia Appendix 10.



Participants

Among patients, 396/767 (51.6%) were women and the mean age was 54.6 (SD 15.6) years (Table 1). Hypertension was the most reported chronic condition (169/767, 22%), followed by diabetes (135/767, 17.6%) and chronic pain (81/767, 10.6%) (Multimedia Appendix 6).

Table 1. Sociodemographic and health characteristics of the representative sample and subgroups of patients and public participants.

Sociodemographic and health characteristics	Total (N=2005), n (%)	Patients[a] (n=767), n (%)	Public participants (n=1238), n (%)

[a]Chronic condition was defined as at least 1 long-term treatment and 1 self-reported condition. The most common chronic conditions were hypertension, diabetes, chronic pain, thyroid disease, heart disease, asthma, and dyslipidemia. All chronic conditions are presented in Multimedia Appendix 6.

[b]N/A: not applicable.

A total of 99/767 (12.9%) patients and 120/1238 (9.7%) public participants reported checking health data recorded by a connected device daily, and 524/767 (68.3%) patients and 902/1238 (72.9%) public participants reported rarely checking or never checking data (Table 1).

Among health care professionals, there were 86/246 (35%) general practitioners, 50/246 (20.3%) psychiatrists, and 40/246 (16.3%) nurses (Table 2; Multimedia Appendix 7).

Table 2. Sociodemographic and health characteristics of the health care professionals (N=246).

[b]For clarity, we report the results for only the 3 most prevalent medical specialties. The other medical specialists were anesthetists, intensive care unit physicians, emergency physicians, child psychiatrists, surgeons, obstetricians-gynecologists, hematologists, neurologist, gastroenterologists, dermatologists, endocrinologists, oncologists, pneumologists, infectious diseases specialists, rheumatologists, nephrologists, pediatric care specialists, palliative care specialists.

[c]Chronic condition was defined as at least 1 long-term treatment and 1 self-reported condition.

Acceptability of Digital Pills

The qualitative content analysis of the 11,451 open-text responses identified 98 codes related to acceptability. Data saturation was reached for patients (99.4%), public participants (100%), and health care professionals (97.7%) (Multimedia Appendix 8). We classified the 98 codes into the 5 theoretical dimensions of acceptability: perceived clinical effectiveness (29 codes, 29%), perceived burden (6 codes, 6%), perceived ethicality (25 codes, 25%), perceived opportunity (30 codes, 30%), and affective attitude (8 codes, 8%) [19]. We report the most-cited codes for each dimension with the proportion of citation and participants' quotes in Table 3. Figure 2 and Multimedia Appendix 9 report all 98 codes.

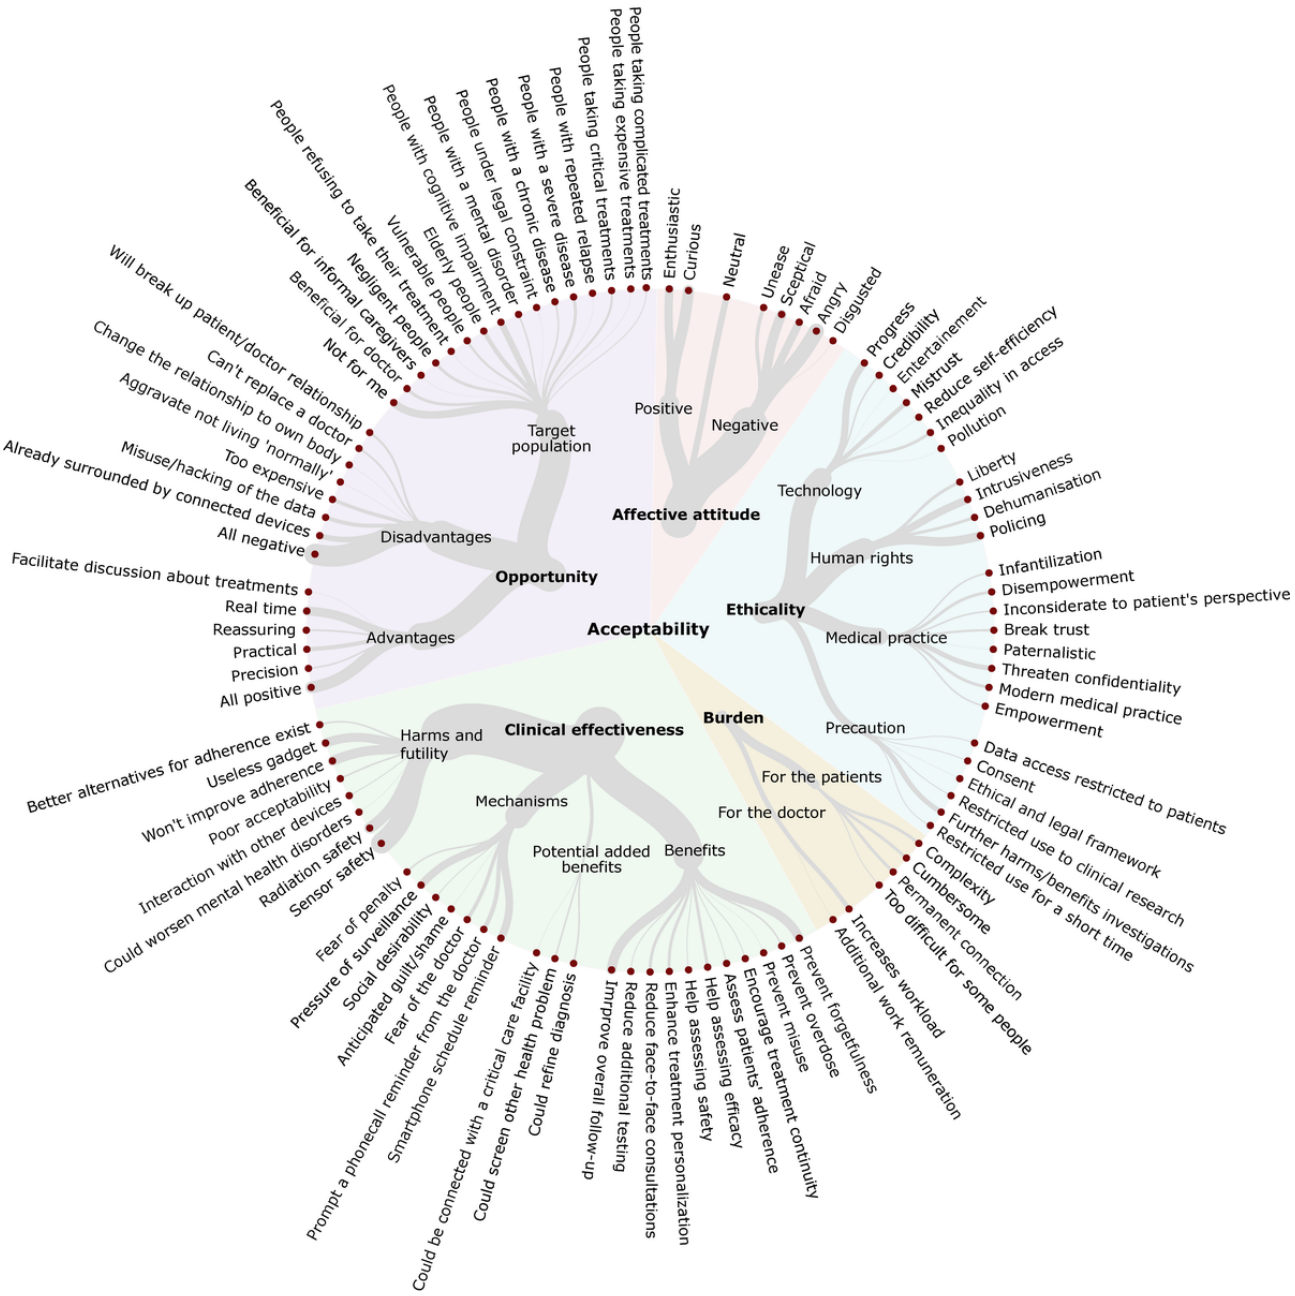
Table 3. Quotes of patients, public participants, and health care professionals that illustrate some of the codes regarding acceptability of digital pills.

Code	Patients (n=767)	Public participants (n=1238)	HCPs[a] (n=246)	Examples of quotes
Congruent with value of progress	59 (7.7)	131 (10.6)	29 (11.8)	• "I will try it because I have the culture of new technologies." (Public participant, man, 34 years old) • "I am for, because I believe in modernity and artificial intelligence." (Public participant, man, 43 years old) • "Only by accepting certain methods can one advance in medicine." (Nurse, woman, 46 years old)
Congruent with value of credibility	12 (1.6)	30 (2.4)	9 (3.7)	• "It's interesting, it's as close to reality as possible and probably the truth." (Public participant, man, 31 years old) • "There will no longer be any doubt about taking or forgetting to take medication, and the monitoring by the doctor that imposes honesty on the patient." (Public participant, man, 39 years old) • "This helps to avoid the medical errors that often occur when a patient lies about taking their medication." (Public participant, man, 29 years old)
Intrusiveness (conflict of value with privacy)	66 (8.6)	150 (12.1)	62 (25.2)	• "This is spying from inside my body. I would be worried about the side effects too." (Patient, woman, 64 years old) • "There is far too much indiscretion and invasion of privacy." (Public participant, woman, 55 years old) • "It's horrible! It feels as if it's really touching on intimacy. Ethically, it is frightening. That we use applications is one thing because we can limit its use in, in time, but a pill that we ingest is really to futuristic and too invasive." (Public participant, woman, 33 years old) • "It is a categorical refusal, I still prefer to take a drug that has less effect but I will never consciously swallow a capsule that allows other people to follow me or my lifestyle, even if already in society we are monitored in many areas without knowing it, my doctor has the right to suggest it after it is up to the person to accept it or not" (Patient, woman, 44 years old)
Dehumanization of patients	32 (4.2)	46 (3.7)	41 (16.7)	• "We're already guinea pigs and we're becoming robots... "(Patient, man, 64 years old) • "When you're sick, you're already dispossessed of your 'medical' life, especially in a hospital environment, so with that on top of it, no thanks." (Patient, woman, 53 years old) • "No thanks, I won't take any connected medication, I don't want to be kept under surveillance that much. It contributes to the dehumanisation of our society." (Neurologist, woman, 29 years old)
Inconsiderate to patient's perspective	25 (3.3)	21 (1.7)	30 (12.2)	• "Very bad idea, we're not in a dictatorship. People are free to take care of themselves or not. Even the sick are free." (Patient, man, 75 years old) • "Policing, (no) more freedom for the patient to stop a treatment that seems to be harming him without being observed." (Public participant, woman, 40 years old) • "A medication such as you're presenting it to me makes me think of forced treatment. If we refuse to take the medication or forget about it will our doctor contact us to explain ourselves?" (Patient, woman, 25 years old)

Code	Patients (n=767)	Public participants (n=1238)	HCPs[a] (n=246)	Examples of quotes
Improves overall follow-up	105 (13.7)	170 (13.7)	9 (3.7)	• "It allows us to monitor the effectiveness, which is already good! And also, that the doctor cares a little bit about his patient through closer monitoring." (Patient, man, 57 years old) • "The family doctor or specialist may monitor the illness on a day-to-day basis, whether good or bad, and may modify treatment or dosage if there are any problems, undesirable side effects or worsening of the patient's health. In addition, this device could also alert to new complications or illnesses that were not previously detected and that could be managed more quickly." (Public participant, man, 74 years old)
Poor acceptability	24 (3.1)	22 (1.8)	42 (17)	• "That's the problem: if a person doesn't follow a prescription, why would they want it to be known that they're doing whatever." (Patient, woman, 59 years old) • "In psychiatry, this process can be complicated for patients who are very often suspicious and persecuted, and all the more so if 'something enters their body' to keep them under surveillance... For the elderly, connected tools are not news except for the next generation." (Nurse, woman, 51 years old) • "I don't really see the point of such a complex system, when most of the information can be gathered through interrogation. The patients who are going to accept this device will probably be compliant patients and not the most problematic ones. Compliance is also a matter of education and not 'policing'. I don't see how being constantly kept under surveillance is going to get the patient to take their medication, other than by telling them they're going to get shouted at by their doctor, which is not our role." (Dermatologist, woman, 26 years old)
Useful for people with cognitive disorder	87 (11.3)	87 (7)	29 (11.8)	• "Unless I'm losing my mind, I wouldn't want to be kept under surveillance all the time." (Patient, woman, 77 years old) • "It might perhaps be useful for animals, but for humans, I don't see it. Unless, the person is not autonomous (e.g., senile dementia)." (Public participant, woman, 31 years old) • "For the elderly or people with amnesia: allows for better remote monitoring (and less cost for nurses to travel to the home)." (Patient, woman, 62 years old) • "I don't see the point in it for me, but for people who are out of their minds, why not? It's not very moral, but why not put it on for people without asking their opinion..." (Public participant, woman, 36 years old)

[a]HCPs: health care professionals.

Figure 2. Acceptability of connected drugs. Dots represent codes regarding acceptability of treatments identified by the qualitative content analysis of the responses for 767 patients, 1238 public participants, and 246 health care professionals. The width of the line is proportional to the number of spontaneous citations of the codes by the representative sample of patients and public participants (N=2005). The overarching categories in bold correspond to the 5 dimensions of the theoretical model of acceptability by Sekhon et al.



In Figure 2, which shows the acceptability of connected drugs, the dots represent codes regarding acceptability of treatments identified by the qualitative content analysis of the responses for 767 patients, 1238 public participants, and 246 health care professionals. The width of the line is proportional to the number of spontaneous citations of the codes by the representative sample of patients and public participants (N=2005). The overarching categories in bold correspond to the 5 dimensions of the theoretical model of acceptability by Sekhon et al [19]. *Perceived clinical effectiveness* is the extent to which the intervention is likely to achieve its purpose. *Perceived burden* is the amount of effort required to participate in the intervention. *Perceived ethicality* is the extent to which the intervention fits well with individual values. *Perceived opportunity* is the extent to which benefits/values must be given up to engage in the intervention. *Affective attitude* indicates how people feel about the intervention.

Perceived Clinical Effectiveness

Participants reported perceived benefits (11/98 codes, 11%) and harms (8/98 codes, 8%) and proposed further developments to the device to improve benefits (3/98 codes, 3%). Finally, they determined the underlying mechanisms of digital pills to improve medication adherence (7/98 codes, 7%).

Patients (105/767, 13.7%) and public participants (170/1238, 13.7%) believed that digital pills could improve follow-up. Potential harms cited were adverse events due to sensor ingestion (190/767 patients, 24.8%; 415/1238 public participants, 33.5%) or radiation from wireless technology

(102/767 patients, 13.3%; 212/1238 public participants, 17.1%). The underlying mechanisms cited to lead to a potential improvement in adherence included behavioral mechanisms such as a smartphone schedule reminder (96/767 patients, 12.5%; 122/1238 public participants, 9.9%) and the pressure of surveillance (77/767 patients, 10%; 141/1238 public participants, 11.4%).

Out of the 246 health care professionals, 64 (26%) considered digital pills to be useless gadgets, and 60 (24.4%) doubted the safety of the sensor. The mechanisms most cited to lead to improved adherence were the pressure of surveillance (73/246, 29.7%) and fear of arguing with the doctor (44/246, 17.9%).

Participants described the pressure of surveillance as a disciplinary mechanism based on social desirability, fear of being reprimanded, fear of social disqualification as a "bad patient," and fear of shame or guilt. Therefore, participants raised concerns about a policing patient–doctor relationship and the meaning of care in the future.

> *The fear of being kept under surveillance; it is being treated like a child, I find it, and even degrading.* [Patient, woman, 71 years old]

> *The person would take their treatment because they would know that the doctor has access to the actual taking. It is a social pressure: the doctor has particular expectations that the patient will want to respect.* [Patient, woman, 19 years old]

Perceived Burden

Participants distinguished doctors' burden (2/98 codes, 2%) from patients' burden (4/98 codes, 4%).

Patients and public participants mostly cited the complexity of the device (32/767, 4.2% and 46/ 1238, 3.7%, respectively) and the wearing of a cumbersome device (34/767, 4.4% and 41/1238, 3.3%, respectively) to be burdensome. Participants (62/767 patients, 8.1%; 65/1238 public participants, 5.3%) also reported the increased workload due to the processing of a large amount of data to be a problem.

Participants (12/767 patients, 1.6%; 14/1238 public participants, 1.1%; 15/246 health care professionals, 6.1%) identified contradictions in digital pills and found it unconvincing. Participants reported that taking medication seemed easier than applying a patch, activating the Bluetooth function, and ingesting the medication, especially for people who needed assistance with taking medication (eg, older people, individuals with cognitive impairment).

> *There will be better monitoring if the sick person is a mobile phone enthusiast: true for the young, less obvious for the elderly.* [Patient, man, 71 years old]

> *I find it hard to imagine someone who needs monitoring of their medication intake (dependent person, elderly, etc...) having such a patch device / smartphone.* [Patient, man, 36 years old]

Perceived Ethicality

Participants described whether taking a digital pill aligned with their values related to technology (7/98 codes, 7%), human rights (4/98 codes, 4%), and medical practice (8/98 codes). Participants also suggested precautions to limit the unethical use of digital pills (6/98 codes).

Regarding ethicality of the technology, patients and public participants mentioned that digital pills align with their values related to progress (59/767, 7.7% and 131/ 1238, 10.6%, respectively) and contradicted their values related to ecology (23/ 767, 3% and 44/1238, 3.5%, respectively). With respect to human rights, patients and public participants considered digital pills to be a policing tool (112/767, 14.6% and 143/1238, 11.6%, respectively) and worried about the associated intrusiveness (66/767, 8.6% and 150/1238, 12.1%, respectively). Regarding medical care, patients and public participants mostly reported concerns with confidentiality (44/767, 5.7% and 95/1238, 7.7%, respectively) and disempowerment of patients (44/767, 5.7% and 44/1238, 3.6%, respectively). To prevent the unethical use of digital pills, they requested further investigation of the associated harms and benefits (50/ 767 patients, 6.5%; 96/ 1238 public participants, 7.8%) and that the use of these pills be restricted to clinical research (9/767 patients, 1.2%; 11/1238 public participants, 0.9%).

In total, 29/246 (11.8%) health care professionals considered digital pills to be part of technological progress that aligned with their values; they mostly worried about policing (90/246, 36.6%) and intrusiveness (62/246, 25.2%).

Participants were afraid that digital pills might cause a breakdown in trust between patients and doctors (36/767 patients, 4.7%; 39/1238 public participants, 3.1%; 147/246 health care professionals, 59.8%), which is seen as the cornerstone of the patient–doctor relationship.

> *I don't like being kept under surveillance. There is a relationship of trust between my GP, my psychiatrist and me. This would undermine that trust because I would be policed.* [Patient, woman, 51 years old]

> *Ethically it's very questionable, it makes it look like we're 'spying on'/'policing' the patient. What about the patient's freedom? Could such a device really improve patient compliance? A good motivational interview seems more relevant. (It is better to act upstream = prevention and health promotion, therapeutic education, rather than downstream = bad compliance to be 'reprimanded') Not to mention that this would put the patient at odds vis-à-vis the doctor in case of poor compliance... And in this case, what about the doctor-patient trust relationship?* [General practitioner, woman, 29 years old]

Perceived Opportunity

Participants identified advantages (6/98 codes, 6%), disadvantages (8/98 codes, 8%), and specific target populations for whom they considered digital pills would be beneficial (16/98 codes, 16%).

A total of 135/767 (17.6%) patients and 200/1238 (16.2%) public participants had an overall positive perception of digital pills, and 213/767 (27.8%) patients and 408/1238 (33%) public participants had an overall negative perception of digital pills.

Patients and public participants mostly reported real-time data (70/767, 9.1% and 181/1238, 14.6%, respectively) as an advantage and the addition of another connected device in an already saturated environment (74/767, 9.6% and 86/1238, 6.9%, respectively) as a disadvantage. Regarding potential target populations, some highlighted that digital pills were not suitable for themselves (107/767 patients, 14%; 106/1238 public participants, 8.6%) and reported mostly people with cognitive impairment (87/767 patients, 11.3%; 87/1238 public participants, 7%) or older people (48/767 patients, 6.3%; 81/1238 public participants, 6.5%) to be suitable candidates.

Health care professionals pointed out the precision of digital pills (15/246, 6.1%) and the ease to discuss treatment (eg, tolerance, benefits, adherence) (11/246, 4.5%) as advantages and the cost (41/246, 16.7%) as a disadvantage. They identified people with cognitive impairment (29/246, 11.8%) and chronic conditions (19/246, 7.8%) as the main target population.

Participants identified people living under judicial constraint as a potential target population for digital pills (1/767 patients, 0.9%; 6/1238 public participants, 0.5%; 2/246 health care professionals, 4.6%); these people were depicted as dangerous, unwilling to undergo treatment, and already under surveillance and deprived of liberty, which—according to participants—would make the ethical regimen more flexible for them:

> *The person will take his treatment because he is compelled to do so by a court order. He is either a delinquent or a criminal. For someone who has not broken the law, there is no reason to proceed in this way.* [Public participant, man, 39 years old]

> *I think it can be a good idea for people who are sick (Alzheimer's for example) and forget to take their medication. Or for more complex cases such as people who are dangerous to society and the doctor needs to be sure that the person's treatment has been taken.* [Public participant, woman, 43 years old]

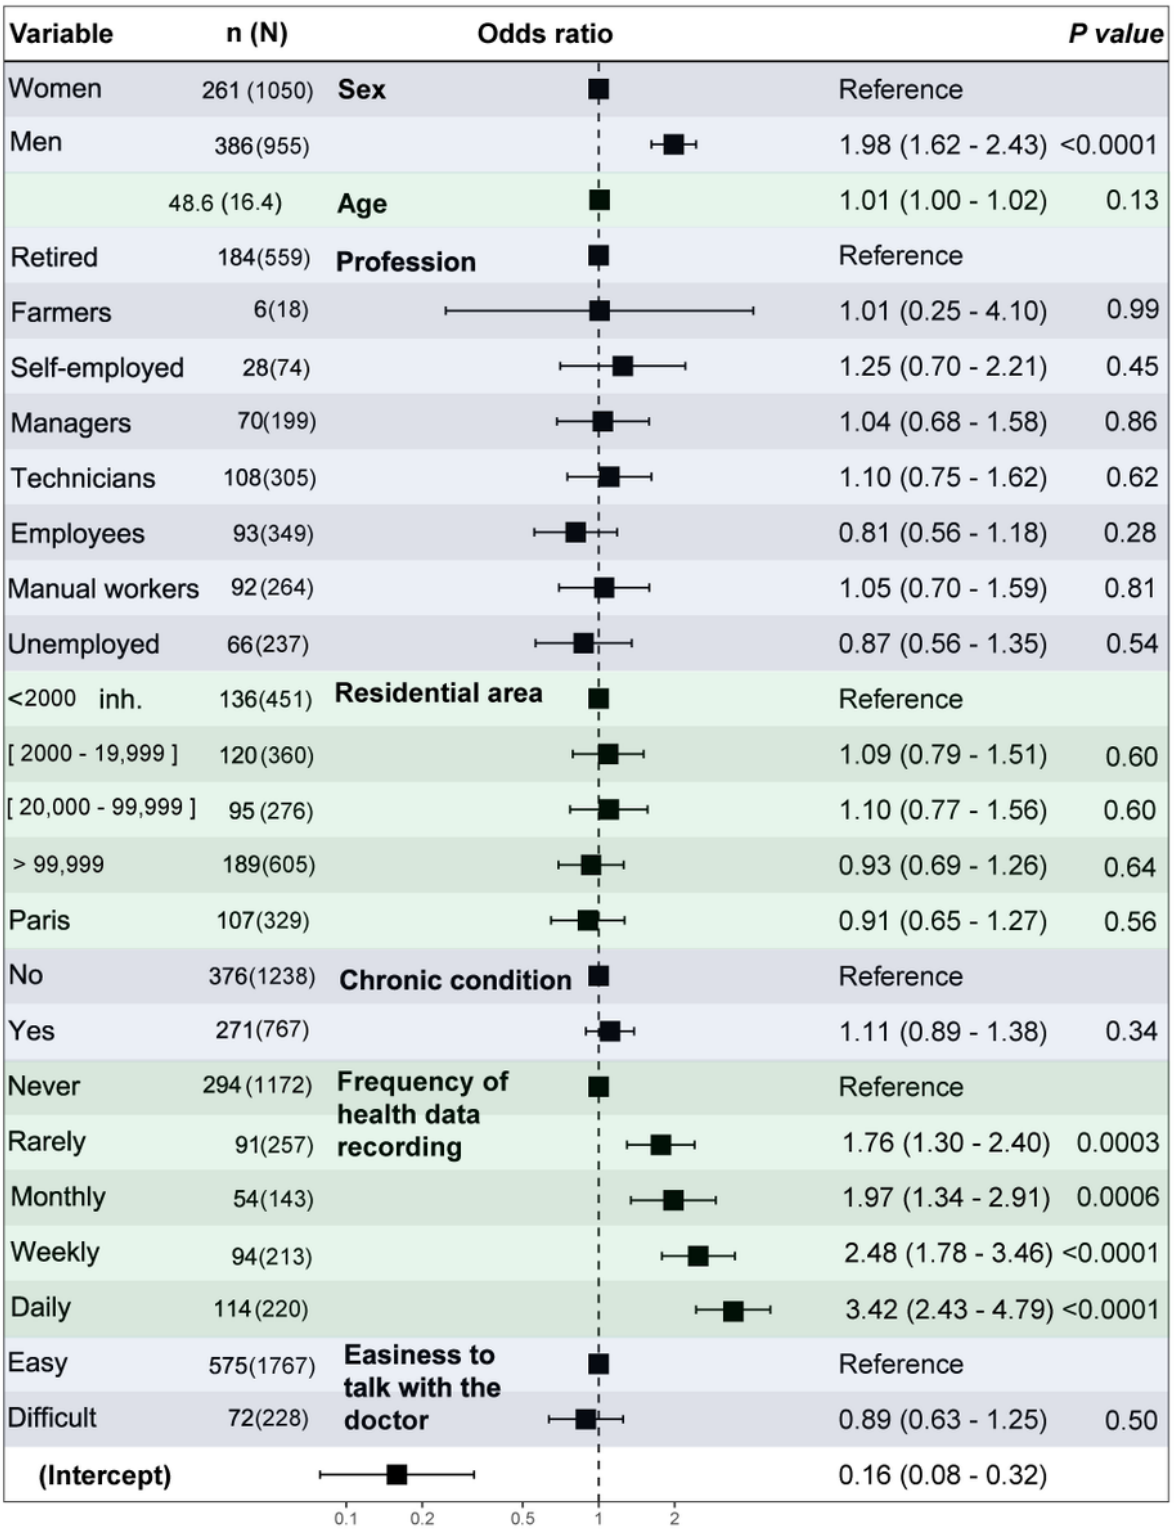
Affective Attitude

We identified 8 affective attitudes toward digital pills: enthusiasm (100/767 patients, 13%; 146/1238 public participants, 11.8%; 20/246 health care professionals, 8.1%), curiosity (141/767 patients, 18.4%; 170/1238 public participants, 13.7%; 31/246 health care professionals, 12.6%), balanced attitude (70/767 patients, 9.1%; 111/1238 public participants, 9%; 41/246 health care professionals, 16.7%), unease (32/767 patients, 4.2%; 70/1238 public participants, 5.7%; 7/246 health care professionals, 2.9%), skepticism (114/767 patients, 14.9%; 168/1238 public participants, 13.6%; 31/246 health care professionals, 5.3%); fear (56/767 patients, 7.3%; 175/1238 public participants, 14.1%; 13/246 health care professionals, 5.3%), anger (178/767 patients, 23.2%; 255/1238 public participants, 20.6%; 108/246 health care professionals, 43.9%), and disgust (7/767 patients, 0.9%; 4/1238 public participants, 0.3%; 1/246 health care professional, 0.4%). Because of lack of clarity and risk of overinterpretation, we could not code the affective attitude of 69/767 (9%) patients, 139/1238 (11.2%) public participants, and 12/246 health care professionals (4.9%). Compared to public participants, patients had more positive reactions (316/1238, 25.5% vs 241/767, 31.4%) and less negative reactions (672/1238, 54.3% vs 387/ 767, 50.5%). Compared to patients and public participants, health care professionals expressed more negative attitudes (142/246, 57.7%) and less positive attitudes (51/246, 20.7%).

Willingness to Take Digital Pills

In the representative sample, 647/2005 (32.3%) participants declared that they would use a digital pill: 271/767 (35.3%) patients, 376/1238 (30.4%) public participants, and 39/246 (15.8%) health care professionals. After adjustment, willingness to take digital pills by patients and public participants was significantly associated with male sex (OR 1.98, 95% CI 1.62-2.43) and integration of currently used connected devices to monitor health daily (OR 3.42, 95% CI 2.43-4.79) or rarely (OR 1.76, 95% CI 1.30-2.40), with a dose–response relationship (Figure 3). Complete analysis of other characteristics associated with the willingness to take a digital pill is presented with crude and adjusted ORs and 95% CIs in Multimedia Appendix 10. The forest plot (Figure 3) presents the ORs with their 95% CIs and the *P* value obtained with the logistic regression analysis of the association of the willingness to take connected drugs by sex, age, profession, population density of the residential area ("residential area"), chronic condition, frequency of health data recording with a connected device, and ease to talk about treatments with the doctor. The plot shows the number of participants per category (n) willing to take a connected drug among the total number of participants in the given category (N). The corrected threshold for statistical significance is *P*=.003. For the continuous variable "age," we present the mean age of the whole sample and the standard deviation.

Figure 3. Determinants of the willingness to take connected drugs among the representative sample of patients and public participants (N=2005). The second column present the number of people willing to take connected drugs (n) over the total number in the patient and public sample (N), except fot the variable "Age", presenting the mean and standard deviation (sd) of people willing to take connected drugs. inh.: inhabitants.



Discussion

Principal Findings

Overall, two-third of patients and public participants in this study refused to take digital pills. Their arguments were grounded in the fear of possible serious clinical and ethical harms. Health care professionals largely refused (177/246, 72%) to take digital pills citing disagreement with their professional deontology and ethics. Participants who accepted digital pills had positive a priori for technology considered as progress: people agreed to take it in the framework of research for a limited investigation time to help medical progress.

Participants who refused to take connected drugs, reported that these would be useful for other people, such as individuals with

cognitive impairment, individuals with chronic conditions or mental disorders, and those incarcerated, highlighting the view that potential clinical or ethical harms would be acceptable for these already vulnerable people. Given the condition of the designated populations, the intervention may be stigmatizing and may increase vulnerability.

To our knowledge, this study is the first to explore the acceptability of connected drugs in line with the recommendation that health technology assessment take into account patient and public perspectives [18]. We used a representative sample of the French population, thus allowing for generalizable results in the subsamples of patients and the public. In France, medication for chronic conditions is fully reimbursed, so when participants answered the questionnaire, they were not prematurely restricted by individual economic concerns but could detail their preferences. To limit the risk of capturing only a "hot reaction" and to mimic the process of a rational and balanced deliberation, we used 5 open-ended questions and asked the close-ended question about willingness to use connected drugs at the end of the survey. Only 16.7% of patients and public participants found no cons and 31% found no pros.

Limitations

The first limitation is the restriction to only 1 country as a consequence of the choice to recruit a representative sample. Because culture and health care system may affect the acceptability of digital pills, further studies are required in different settings.

A common limitation of using an online survey is the risk of selection bias because of the need for internet access. However, the target population for the digital pill must have access to smartphones and the internet. While the use of an online survey may have overestimated the acceptability of digital pills in the general population, it may not have done so in the target population. Moreover, to limit potential selection bias due to reading level, we created the questionnaire during a qualitative preliminary study and tested it for clarity.

We could have increased the reliability of the results by verifying the final codes and themes with the participants, but we minimized the risk of misinterpretation by limiting the condensation of codes to synonyms only, halting the inductive interpretation at a very basic level—which led to 98 codes in the final results—and using the participants' wording.

Another limitation is that the sample of health care professionals was not representative of the larger population of health care professionals.

Finally, we only investigated the prospective acceptability because digital pills were not available in France at the time of our study. Studies about concurrent acceptability (while taking connected drugs) and retrospective acceptability (after taking connected drugs) may be complementary and lead to different results.

Comparison With Prior Work

Our results are consistent with the concurrent and retrospective acceptability discussed in 18 observational studies and trials of digital pills, which involved small samples of 5 to 129 patients [26]. Moreover, some participants who refused digital pills for themselves found them useful for other people considered vulnerable (eg, people with cognitive or mental disorders or those incarcerated), which would lead to a risk of stigmatizing the use of digital pills.

This study added further ethical concerns to the well-known topics raised in the scientific literature (eg, consent, confidentiality, privacy) [12,26-30]. This shows the substantial importance of including patient and public perspectives in health technology assessment, as is already recommended but marginally done, with the risk of neglecting social, ethical, and political aspects of these technologies that are critical determinants of treatment effectiveness in real life settings [18]. A further strength is the use of a representative sample, which allows for generalizable results.

This survey contributes to advanced scientific and clinical reflections about medication adherence. As underlined by participants, digital pills seem to be a naïve solution considering the complexity of what determines medication adherence and nonadherence [12,31,32]. Digital pills appear to be burdensome and expensive reminders with an apparent contradiction—whether unintentional or intentional—between their complexity and the ability of those needing support for adherence. Particularly in the case of intentional nonadherence, digital pills would be either useless or efficient at the cost of intrusiveness, policing, and negative effects on the patient–doctor relationship.

Finally, digital pills could be useful to assess treatment efficacy in explanatory trials, but there are 2 prerequisites for extending their use in clinical practice. First, digital pills should be evaluated as a complex intervention according to specific standards and not as if they are a mere change in the form of drug administration [17,33]. Second, there is urgent need to develop an ethical and legal framework to ensure the safe and ethical collection and use of health data through a patient-centered approach [12,27,28].

Conclusion

Our results suggest that patients, the public, and health care professionals view connected drugs not as a promising new medical device to better monitor medication adherence but as a complex intervention with a possible impact on patient–doctor relationship and patient autonomy. The participants also raised additional concerns about burden of treatment, cost-effectiveness, and privacy, which need to be addressed in further investigations. Future studies should take into account the views of all stakeholders, ie, patients, potential prescribers, as well as health regulatory authorities and researchers, to ensure the safe and ethical collection and use of health data through a patient-centered approach.

Acknowledgments

We thank Florence Weber for the expert advice in social anthropology and Marion Plaze for expert advice in cognitive psychology. We thank Raphaël Porcher for statistical guidance, Elise Diard for expertise in the design of the figures, Nivantha Naidoo for help in interpreting the data, and Laura Smales for copyediting the manuscript. The study received a grant from the Fondation Université de Paris (19_DON22_001_U4). The funder had no role in the study design, data collection, data analysis, data interpretation, writing of the report, or decision to publish.

Authors' Contributions

AC is the guarantor of the study. AC, AJ, SS, PhR, and M-FM conceived and designed the analysis. AC, AJ, SS, and AF collected the data. AC, AJ, SS, AF, and FD performed the analysis. AC wrote the first draft. AC, SS, PhR, M-FM, FD, AF, and AJ edited the manuscript. The corresponding author attests that all listed authors meet authorship criteria and that no others meeting the criteria have been omitted.

The manuscript's guarantor (AC) affirms that the manuscript is an honest, accurate, and transparent account of the study being reported; that no important aspects of the study have been omitted; and that any discrepancies from the study as originally planned (and, if relevant, registered) have been explained. All authors confirm that they had full access to all the data in the study and accept responsibility to submit for publication.

Abstract

Background: Stress management in the workplace is essential for a healthy mental and physical state. Due to technological advancements, individually tailored therapy and online cognitive behavioral therapy (CBT) are on the rise.

Objective: This study analyzed the efficacy of a smartphone app based on third-wave CBT tailored to an individual.

Methods: A randomized controlled trial was conducted with 126 participants who were divided into 2 groups. The intervention group used the smartphone app BetterLife for 10 weeks, while the control group was placed on a waiting list for the same duration. The Perceived Stress Scale–10 (PSS), Korean Utrecht Work Engagement Scale–9 (UWES), World Health Organization Quality of Life Assessment (WHOQOL), Beck Depression Inventory–II (BDI), and Beck Anxiety Inventory (BAI) were administered at baseline and after 10 weeks to both groups.

Results: Of the 126 participants, 11 dropped out during the trial. A 2-way repeated measure analysis of covariance was conducted, controlling for baseline BDI. There were greater improvements in PSS (F=24.33, P<.001, η^2=0.17) and UWESK scores (F=8.32, P=.0046, η^2=0.06) in the intervention group than in the control group. WHOQOL scores exhibited statistically significant improvement in the intervention group in the overall quality of life (F=8.19, P=.0049, η^2=0.06), physical health (F=8.87, P=.003, η^2=0.07), psychological health (F=13.32, P<.001, η^2=0.10), social relationships (F=19.43, P<.001, η^2=0.14), and environmental domains (F=10.14, P=.002, η^2=0.08) but not overall health (F=1.68, P=.20). BDI (F=7.17, P=.008, η^2=0.06) and BAI (F=6.00, P=.02, η^2=0.05) showed a statistically significant improvement in the intervention group, but this significance did not survive the Bonferroni correction (P<.005).

Conclusions: These results provide evidence that smartphone-based CBT is a viable option for reducing stress in the workplace.

KEYWORDS

stress reduction; third-wave cognitive behavioral therapy; individual tailored treatment; randomized controlled trial; digital therapeutics

Introduction

Stress management is undoubtedly crucial to the mental health as well as physical health of individuals. Chronic and high stress have been linked to depression [1], anxiety [2], coronary heart disease [3], and increased mortality [4]. Stress can be acquired from all aspects of life. Nevertheless, work-related stress has been of interest to researchers, especially in South Korea, which

has one of the longest working hours within the Organization for Economic Cooperation and Development countries [5]. High stress within the workplace has also been associated with calculable economic burdens [6] and various long-term complications [7]. Therefore, stress management within the workplace is vital for both employees and employers.

Of the known methods for stress management, cognitive behavioral therapy (CBT) has been identified as effective [8,9]. Traditional CBT is performed by trained professionals such as psychiatrists or psychologists. It is usually conducted face to face or in a group setting. However, advancements in technology have allowed CBT to be computerized and administered via the internet, allowing it to be administered automatically with minimal guidance [8,10,11]. Such online CBTs have demonstrated efficacy in several areas, including the reduction of stress [12], depression, anxiety [13], and insomnia [14].

Although online CBT has advantages over traditional CBT in terms of anonymity and accessibility [15], in traditional CBT, the therapist can tailor the structured CBT to suit the client. This contrasts with most online CBTs, in which participants usually receive the same program that cannot be changed. Tailored online CBT has been implemented in treating depression and is effective, as shown in a meta-analysis [16]. However, Johansson et al [17] argued that tailored treatment is essential in addressing comorbidity, showing that tailored CBT may be more effective than ordinary internet CBT in treating depression. Stress is also associated with various disorders [1,2]. Thus, we developed an individualized CBT for stress management and performed a randomized controlled trial (RCT) to demonstrate its efficacy.

We hypothesized that using an online CBT-based app designed to help manage work stress for 10 weeks would result in a statistically significant improvement in stress-related scales compared to a waiting group.

Methods

Sample Size

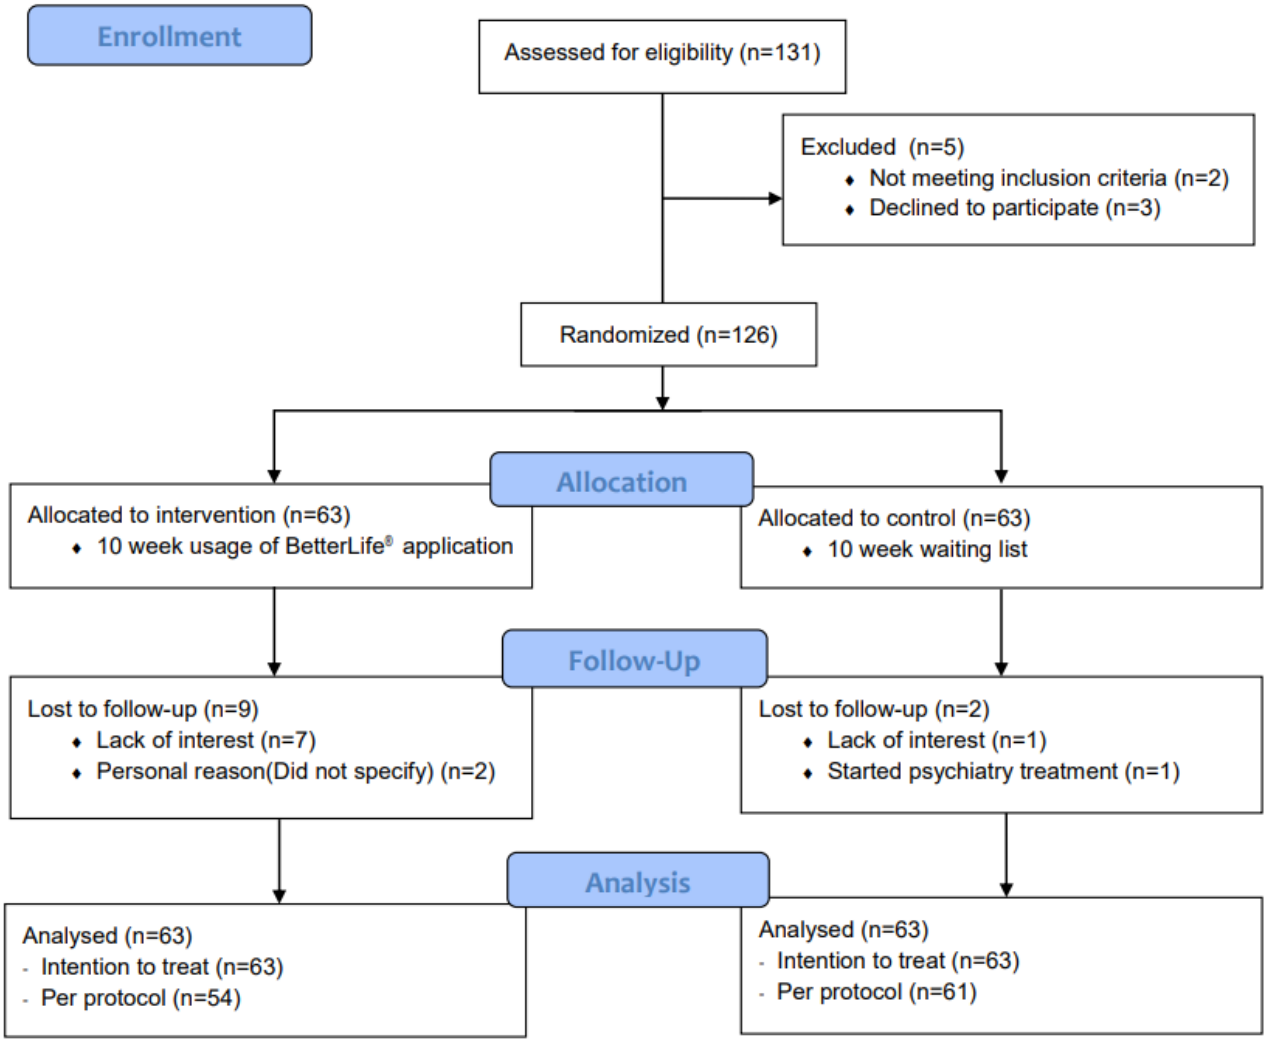
The sample size was calculated using G*Power (Heinrich-Heine-Universität Düsseldorf), based on a statistical test on repeated measure analysis of variance (ANOVA), since the covariance number was not determined. A type I error of .05 and statistical power of 0.8 were used. The correlation among repeated measures was set conservatively at 0, and based on previous similar studies [8], a mild to moderate effect size was estimated (effect size f=0.20). Based on these calculations, 51 participants were needed in each group, and after calculating a 20% dropout rate, the required total sample size was set at 128 participants.

Participants

Participants were recruited through billboard advertisements between November 2019 and January 2020. The inclusion criteria for the trial were as follows: (1) elevated perceived stress defined by a score of 14 or higher on the Perceived Stress Scale–10 (PSS); (2) indication that the reason for stress was mainly work-related (the reason for stress was considered to be work-related if the participant could identify one or more stress-related factors that they experienced in the work environment and stress in other areas such as family were minor in comparison to work-related stress); (3) employment of at least 20 hours per week and not self-employed; (4) aged 18 to 60 years; and (5) ability to provide informed consent to participate after being given information about the trial and other information that the participant must know to participate. The exclusion criteria were as follows: (1) inability to provide informed consent; (2) education level below the 9th grade; (3) history of congenital brain disorder, cerebral palsy, or other acquired brain injuries; (4) history of neurological disorders; (5) severe anxiety, depression, or psychotic disorder as assessed by the Korean Symptom Checklist–95; or (6) history of drug or alcohol abuse.

In total, 131 individuals who had work-related stress expressed interest in the trial. Of these, 3 withdrew participation after being informed of the detailed trial protocol; written consent was received from the remaining 128 participants. Two patients were excluded because of clinically relevant scores in the Korean Symptom Checklist–95. A total of 126 participants were included in the trial and randomized into 2 parallel groups with equal allocation ratios (Figure 1). Randomization was performed by an external researcher from a separate institute, and simple randomization via a random number generator using Excel (Microsoft Corp) was used. Each participant was assigned a random trial number at enrollment, and the external researcher was only provided with the individual trial number to ensure blinded randomization. The researcher performing data analysis (DHH) was also provided only with the individual trial number to blind the outcome assessment.

Figure 1. CONSORT 2010 flow diagram of enrollment.



The intervention group was given a random individual application ID to access the app, a link for downloading the app, and a manual of the program. Further, they were instructed to use the BetterLife program for 50 minutes per week for 10 weeks. They had the option to contact a designated person to ask for help in operating the app. Participants were sent a text message as a prompt to notify them of their app use every week during the trial. Members of the control group were placed on a waiting list for 10 weeks after which they were given access to the BetterLife program for the next 10 weeks. This was primarily done for ethical reasons, and data collected from the control group after using the BetterLife program were not used in this analysis. These data are being considered for use in secondary analyses, which can strengthen our research. This trial was approved by the institutional review board of Chung-Ang University Hospital (1712-008-304) and registered in the Clinical Research Information Service of Republic of Korea (KCT0003231), a member of the WHO International Clinical Trials Registry Platform. All participants enrolled in the trial provided written informed consent.

Of the 126 participants, 11 dropped out of the trial: 9 from the intervention group (14.3%) and 2 from the control group (3.2%). Of the 9 participants who were excluded from the intervention group, 2 left the trial due to personal reasons and 7 wished to leave due to lack of interest. Of the 2 participants who were excluded from the control group, 1 wished to leave the trial due to lack of interest and 1 was excluded because they were starting psychiatric treatment. Finally, 115 participants—54 in the intervention group and 61 in the control group—completed the 10-week trial and post-10-week data were collected. The 11 excluded participants' post-10-week data were produced by the baseline observation carried forward method, and data were analyzed using an intention-to-treat method. The average use time of the program was 56.40 (SD 8.42) minutes per week; this was calculated by using the program time of the 54 participants who finished the 10-week program only. No substantial harm or unintended effects were observed.

Data Collection

Participant demographic data were collected including age, sex, education level, marital status, alcohol consumption, and smoking habits. Information on employment was also collected, including company size, work field, type of employment, job grade, whether they handle direct customer complaints, income, workdays per week, work hours per day, work experience in the current work field, and job. Information regarding the number of late days, early leave days, and absent days of the

past month was also collected. The participants were asked to complete the PSS, Korean Utrecht Work Engagement Scale–9 (UWES), abbreviated version of the World Health Organization Quality of Life Assessment (WHOQOL), Beck Depression Inventory–II (BDI), and Beck Anxiety Inventory (BAI) to assess psychological and work stress-related status at baseline and after the 10-week intervention. PSS and the overall quality of life score of the WHOQOL at 10 weeks were set as the primary outcomes. Data were collected in a face-to-face setting by the researchers of Chung-Ang University Hospital at a separate location preferred by the participant. Participants received 100,000 Won (US $83) as compensation for their travel fees.

Perceived Stress Scale–10

The PSS was developed by Cohen et al [18] and validated in Korea by Park et al [19]. It is a widely used scale consisting of 10 items on a 5-point scale and is designed to measure the degree of stress experienced by individuals, with a high score indicating high perceived stress. Although the scale authors did not develop the scale with a cutoff value, the scores are often divided into 3 parts for clinical use: 0 to 13, low stress; 14 to 26, moderate stress; and >27, severe stress [20].

Korean Utrecht Work Engagement Scale–9

UWES is one of the most frequently used scales related to work engagement. It calculates work engagement by measuring vigor, dedication, and work absorption through a 7-point frequency rating scale ranging from 0 (never) to 6 (always). It was developed by Schaufeli et al [21] and has been validated in Korea by Kim et al [22].

World Health Organization Quality of Life Assessment, Abbreviated

WHOQOL was developed by the WHO as a measure to assess the quality of life (QoL) in individuals across different cultures [23]. It has been validated in Korea by Min et al [24]. The WHOQOL consists of 26 questions and uses a 5-point scale from 1 to 5, with a higher score indicating better QoL. One question pertains to overall perception of QoL (overall QoL); another pertains to overall perception of health (overall health). The remaining 24 questions were calculated to measure an individual's QoL in each of 4 domains: physical health, psychological health, social relationships, and environment. The raw scores were converted into transformed scores (0 to 100) using the developers' suggested method for easier comparison.

Beck Depression Inventory–II

The BDI was initially developed by Beck in 1961 and revised in 1979 to BDI-IA and finally to BDI-II in 1996 to accommodate the changes in the *Diagnostic and Statistical Manual of Mental Disorders, fourth edition* diagnosis for depressive disorders [25]. It is a self-report questionnaire with 21 items, and each item is rated on a 4-point scale from 0 to 3. It has been validated in many countries across the world, including Korea [26]. The BDI was designed to measure the depressive symptoms of an individual during the past 2 weeks.

Beck Anxiety Inventory

The BAI was developed by Beck in 1988 [27]. It is a self-report questionnaire with 21 items. Similar to the previous BDI, it rates each item from 0 to 3 on a 4-point scale. The BAI is designed to measure anxiety independent of depressive symptoms and was validated in Korea by Yook et al [28] in 1997.

Intervention

BetterLife is a smartphone-based program for the treatment of stress, depression, anxiety, and sleep disorders used for guided self-help therapy; it can be used for both prevention and treatment. It is designed for anonymous treatment, targeting individuals with mild or moderate symptoms. BetterLife uses recognized manuals for CBT and problem-solving therapy and consists of approximately 600 modules of 7 types: test modules, psychoeducational modules, cognitive exercises, practical exercises, diary modules, notification modules, and comment modules. The test modules included the World Health Organization Well-Being Index (WHO-5) [29], the Major Depression Inventory (MDI) [30,31], the General Anxiety Test–7 (GAD-7) [32], and a short version of the Copenhagen Psychosocial Questionnaire [33]; the latter is used for assessment of work-related stressors. Psychoeducational modules are e-learning modules that provide knowledge about illnesses, treatment methods, and background information. They have talking-head videos with an overlay of animated graphical visuals. Cognitive exercises are interactive exercises programmed in HTML5, providing opportunities for users to work with their thoughts and feelings. The interactivity makes it possible for the user to work with their data registered in a database on a server. Practical exercises include physical exercises, relaxation exercises such as meditation, and exercises away from home. Diary modules are used to map activities and the development of mental conditions over time. Data from the registrations in the diary modules are saved so the user can see them. Notification modules ensure the user's adherence to the treatment flows, and comment modules provide feedback to the user's treatment progression. Comment modules follow tests and exercises.

All treatment components in the program are based on evidence-based methods documented in scientific studies [11,34]. BetterLife is powered by an advanced treatment flow engine that enables individualized transdiagnostic treatment and continuous follow-up of treatment results carried out in a dialog form with the user. This dialog also includes an online dialog with an attached therapist and a chosen friend (helper) who can help the user understand the psychoeducational parts and conduct cognitive and practical exercises. The tests in the program are used both for reference to the individual treatment interventions in the program and for the continuous monitoring of treatment progression. If severe symptoms are detected, the user is referred for external psychological help in a clinic or hospital—in case of suicidal thoughts by call function directly to an acute clinic. The user sees graphical charts of the test result history to experience treatment progression. BetterLife has a toolbox with all tests and exercises in the program from where the user can choose to redo a test or exercise at any time. The

primary test and exercise results are always visible on the main page of the BetterLife program.

The chance to use the WHO-5 questionnaire was provided every week to tailor to each user. Thus, the user could follow the improvement over time, even in a graph. If the test value is low (meaning low well-being), the user is referred to the depression (MDI) and anxiety (GAD-7) modules. When acceptable values of these tests are obtained (showing a low degree of depression and anxiety symptoms), the user automatically returns to the other parts of the program. Another feature to personalize the program to the user is the user's own estimation of stressors in work and daily life. The user is guided to modules specifically concerning the problems pinpointed by the user. An overview of the program can be found in the supplements (Multimedia Appendices 1 and 2).

Statistical Analysis

All data were analyzed using SPSS (version 19.0, IBM Corp). The data presented here concern the intervention group compared to the waiting list group (controls) at baseline and follow-up. Data on the controls after using the BetterLife program and those on the program's long-term effects are not presented. Baseline information, including demographic and psychological scales, was compared using the chi-square test, Fisher exact test, and independent *t* test. Intervention outcomes were measured using work-related scales and psychological scores. Changes in late days, early leave days, and absent days in the past month were also collected to determine whether the app could have a tangible effect on work life.

For all participant data, univariate logistic regression analyses were conducted to determine whether variables of independent factors—such as age, gender ratio, education level, marital status, alcohol consumption, smoking, BDI scores, BAI scores, type of work field, workdays, work hours, and work experience—could explain a significant amount of variance in the dependent variable (high perceived stress) after considering all other variables. Statistically significant independent factors were evaluated using a multivariate logistic regression analysis using a stepwise forward conditional method. High perceived stress was defined as a PSS score of 27 or higher.

Using 2-way repeated-measures analysis of covariance (ANCOVA; split-plot ANCOVA) with time as a within-factor and group as a between-factor, controlling covariates determined from the logistic regression and the changes in PSS, UWES, WHOQOL, BDI, and BAI scores were calculated. Bonferroni correction was used to compensate for multiple comparisons, and α=.05/10=.005. P<.005 was considered statistically significant. The number of late days, early leave days, and absent days were analyzed separately by 2-way repeated measure ANOVA with time as a within-factor and group as a between-factor since they were not collected as part of the initial intervention outcome.

Results

Comparison of Demographic Characteristics and Psychological Scale Scores between the Intervention and Control Groups

There were no significant differences in age, gender ratio, education level, marital status, alcohol consumption, smoking, company size, work field, type of employment, job grade, direct customer complaint handling, workdays, work hours, work experience, and late days, early leave days, and absent days in the past month between the intervention and control groups (Table 1). At baseline, there were no significant differences in PSS, UWES, WHOQOL, BDI, and BAI scores (Table 2).

Comparison of Symptom Improvement Between the Intervention and Control Groups

In logistic regression analysis, only baseline BDI scores in all participants were positively correlated with high perceived stress (B=0.20, Exp(B)=1.22, *P*<.001; Table 3). A separate paired *t* test of the repeated measures of the control group showed no significant differences after the Bonferroni correction (Multimedia Appendix 3).

Table 3. Results of univariate and multivariate logistic regression analysis for high perceived stress.[a]

	B[b]	*P* value	Exp(B)[c]

[a]Multivariate logistic regression analysis was conducted with BDI and BAI as independent variables.

[b]B: logistic regression coefficient.

[c]Exp(B): e to the power of B (odds ratio).

[d]Not applicable.

[e]BDI: Beck Depression Inventory–II.

[f]BAI: Beck Anxiety Inventory.

In the split-plot ANCOVA, there was homogeneity of variances (P>.05) and covariances (P>.001), as assessed by the Levene test of homogeneity of variances and Box M test, respectively, in all categories except for the number of late days, early leave days, and absent days in the past month. The Mauchly test of sphericity was ignored because there were only two groups for each factor. Controlling baseline BDI scores, the intervention group showed greater improvement in the changes in PSS (F=24.33, P<.001, η^2=0.17) and UWESK scores (F=8.32, P=.0046, η^2=0.06) compared to the control group (Figure 2). WHOQOL scores also demonstrated a statistically significant interaction between treatment groups and pretests/posttests in overall QoL (F=8.19, P=.0049, η^2=0.06) and physical health (F=8.87, P=.003, η^2=0.07), psychological (F=13.32, P<.001, η^2=0.10), social relationships (F=19.43, P<.001, η^2=0.14), and environmental domains (F=10.14, P=.002, η^2=0.08) but not overall health (F=1.68, P=.20; Table 4). Although BDI (F=7.17, P=.008) and BAI (F=6.00, P=.02) showed traditionally low P values, they did not survive the Bonferroni correction. Unadjusted ANOVA yielded similar results except for BDI (F=9.67, P=.002, η^2=0.07), which showed a significant interaction between treatment groups and pretests/posttests (Multimedia Appendix 4).

Figure 2. Repeated measure analysis of covariance controlling baseline Beck depressive inventory scores. Left: comparison of changes in Perceived Stress Scale (PSS) scores between intervention group and control group (F=24.33, P<.001). Right: comparison of changes in the Utrecht Work Engagement Scale–Korean Version (UWES) scores between intervention group and control group (F=8.32, P=.0046).

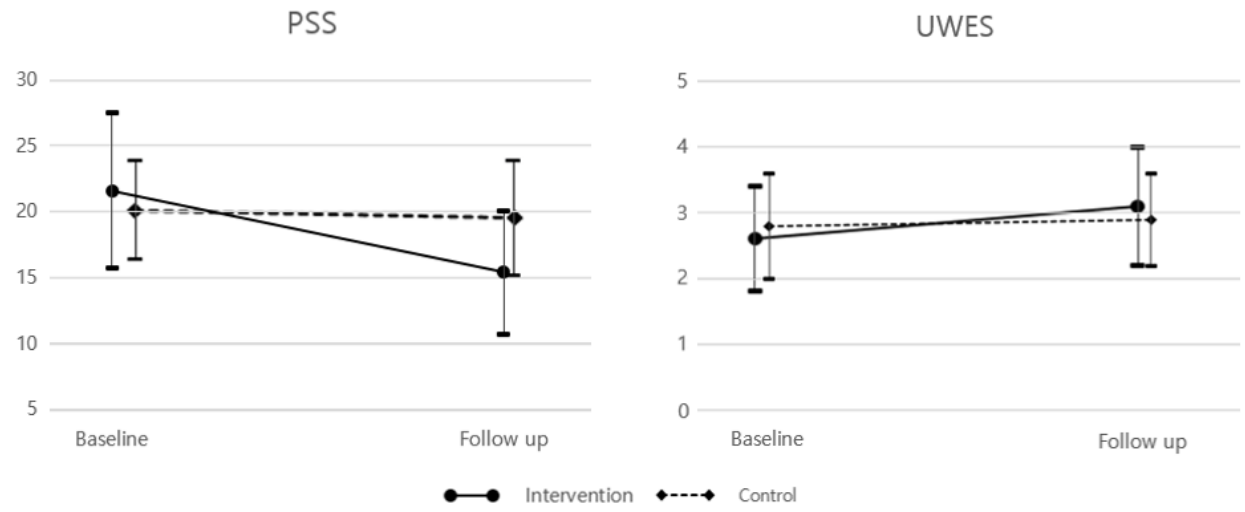

Table 4. Results of split-plot analysis of covariance for stress-related factors.

	Intervention (n=63)		Control (n=63)		Test statistics[a]		P value[b]

Similarly, in the repeated measures ANOVA, homogeneity of variances (P>.05) and covariances (P>.001) were assessed by the Levene test of homogeneity of variances and Box M test, and the Mauchly test of sphericity was ignored. There were no significant interactions in the number of late days, early leave days, and absent days in the past month between the treatment groups and pretests/posttests (Table 5).

Table 5. Results of split-plot analysis of variance for the additional outcome.

	Intervention (n=63)		Control (n=63)		Test statistic[a,b]	*P* value
	Baseline	Follow-up	Baseline	Follow-up		
Number of late days in past month	0.7 (1.8)	0.4 (1.1)	0.8 (1.9)	0.7 (1.7)	0.48	.49
Number of early leave days in past month	0.3 (0.6)	0.1 (0.4)	0.3 (0.9)	0.3 (0.9)	0.74	.39
Number of absent days in past month	0.1 (0.2)	<0.1 (0.2)	<0.1 (0.1)	<0.1 (0.3)	0.49	.48

[a]Statistics (*F* test) reported are for the interaction between intervention and time of each variable.

[b]degree of freedom: 1124.

Sensitivity and Dropout Analyses

A sensitivity analysis was performed with the 54 intervention group and 61 control group participants who completed the trial. These data were evaluated separately using per-protocol analysis. Results showed a significant interaction between treatment groups and pretests/posttests in all scales except for the overall health of WHOQOL. Compared to the intention-to-treat analysis, the per-protocol analysis showed overall more significant (lower) *P* values and higher effect sizes (Multimedia Appendix 5). Little difference was found between the 2 analyses on the number of late days, early leave days, and absent days (Multimedia Appendix 6).

Dropout analysis was also performed, comparing the baseline values of the 11 participants who dropped out and the 115 participants who completed the trial. In the demographic data, work hours per day were significantly lower in the dropout group (t=3.63, P<.001; Multimedia Appendix 7). When comparing the baseline work-related stress and psychological scales, the dropout group showed significantly lower PSS scores (t=3.63, P<.001) and social relationship scores in the WHOQOL (t=–2.19, P=.03; Multimedia Appendix 8). The number of early leave days was also significantly lower in the dropout group (t=4.25, P<.001).

Discussion

Principal Findings

The BetterLife app, a program developed for the management of stress, effectively improved the degree of stress in people with work-related stress measured by PSS compared with control groups on a waiting list. It also improved work engagement as determined by the UWES. Furthermore, QoL improved in all domains except for overall health, according to the WHOQOL. However, the total number of late days, early leave days, and absent days showed no improvement in the 2 groups.

Intervention Effectiveness on Stress Reduction and Work Engagement

The effects of CBT on stress management in online settings have been well documented in previous studies [8,35]. A meta-analysis of web- and computer-based stress management interventions showed that these interventions effectively reduced stress and, on average, had a moderate effect size (Cohen d=0.43) on stress reduction [8]. However, recent studies have shown larger effect sizes. Asplund et al [36] identified a significant reduction in stress with a moderate to large effect size through an RCT with a guided internet-based stress management intervention. Ebert et al [10] also observed a large effect size in stress reduction using an internet- and mobile-based stress management program [10]. Our study showed that the intervention group had a significantly higher reduction in the PSS score from baseline to posttreatment when compared to the control group with a large effect size (F=24.83, P<.001, η^2=0.17). We estimate this large effect size to be because of meditation, emotional acceptance, and other third-wave CBT qualities incorporated in the program. Asplund et al [36] and Ebert et al [10] also used parts of third-wave CBT interventions, which could explain the large effect sizes of the results. Third-wave CBT helps participants to be more aware and accepting of their thoughts through ways such as meditation or behavior activation [37]. It has demonstrated strong efficacy in stress reduction [38].

The intervention group also showed improved work engagement, represented by improvements in the UWES. Work engagement, often considered the opposite of burnout, is a positive work-associated mindset with characteristics such as vigor, dedication, and absorption [39]. Extensive literature supports the positive benefits of work engagement. Halbesleben et al [40] demonstrated, through a study conducted on 587 employees in various occupations, that work engagement shared variance with job performance, implying that developing work engagement leads to positive outcomes in job performance and job retention. A meta-analysis of 7939 business units concluded that work engagement is related to meaningful business outcomes [41]. The authors of this study also implied that this improvement in employee work engagement and satisfaction could increase profits for businesses. Work engagement has also been known to affect absenteeism [42] and overall sickness absence [43]. However, our data did not show a significant difference in the number of sick days, early leave days, and absent days between baseline and postintervention. We estimate this to be because of the small number of sick, early leave, and absent days at baseline, subsequently requiring more statistical power than the trial's original design. However, several similar studies failed to demonstrate a significant improvement in sick leave days even with symptom improvement [44], which could imply that symptom improvement through CBT alone might not be enough for a tangible improvement in sick leave.

Intervention Effectiveness on Quality of Life

Improvement of QoL in all domains, including overall QoL, was seen in the intervention group. However, the perception of

overall health did not differ between the control and intervention groups. QoL improvement by CBT has been observed in literature: Hofmann et al [45] used a meta-analysis to observe the effect of CBT on QoL in anxiety disorders and found it to be effective. An RCT conducted using an internet-based self-guided stress management intervention for employees, similar to that in this study, also exhibited improvements in QoL [10], but only the mental health component of QoL improved (not the physical health component), which was similar to our findings. Although the physical domain of WHOQOL in our trial showed significant improvements, the effect size was the smallest among the 4 domains, and overall perception of health showed no significant improvement. This may be because improving physical health and related QoL is significantly more complex than improving mental health and related QoL, although possible. Therapies with a meditative component, such as yoga and mindfulness-based cognitive therapy, have been shown to improve health-related QoL [46]. CBT that improves sleep disturbance also induces an improvement in health-related QoL [47]. Furthermore, our program had separate modules dedicated to sleep improvement and meditation. A few participants gave positive feedback on the meditation module, which could have resulted in the mixed health-related QoL improvements. Future programs should emphasize this in CBT for further improvement in physical health.

The social relationship domain of QoL had the most significant effect size (η^2=0.14), in addition to our primary result, perceived stress. We attribute this improvement to the helper system that asked participants to find a helper, someone who can talk to and confide in about work. Participants also provided feedback that using this app with a helper allowed them to be more engaged in using the program and made the work environment more enjoyable. Improved social relationships within the workplace are estimated to increase employee well-being and company efficiency [48], constituting one reason for including CBT.

Changes in Depression and Anxiety Levels and Other Characteristics of the Program

Although our initial analysis showed that the BetterLife program significantly improved BDI and BAI levels, this significance did not survive the Bonferroni correction. We assume that this is because of the baseline observation carried forward method used to create the missing data of the participants who dropped out, which is one of the most conservative ways to estimate missing data. Notably, the per-protocol analysis showed that BDI and BAI scores were significantly improved using the BetterLife program with moderate effect size (F=10.15, P=.002, η^2=0.08 and F=8.21, P=.0049, η^2=0.07, respectively). The program incorporated modules that directly help deal with depression and anxiety, as controlling psychological symptoms is essential in reducing perceived stress. The efficacy of web-based CBTs has been proven in patients with major depressive disorder and anxiety disorder with mild and moderate symptoms [13]. Although the current intervention was aimed at employees with work stress, future trials could be performed on clinical groups to explore the program's effects.

The dropout rate of the intervention was 14.3%, slightly lower than the average dropout rate of internet-based CBTs according to a recent meta-analysis [49]. This, along with improved stress reduction, work engagement, and QoL, could result from the way the program was tailored for each participant, as described in the intervention section. The use of a helper combined with personalization as the user was guided through the program is a unique feature that makes BetterLife different from other internet-based programs dealing with stress. The feedback from the tests that participants took during the trial might also be a reason for the low degree of dropouts.

Although our study design did not include a direct comparison with face-to-face CBT, recent research comparing internet-based and face-to-face CBT showed similar results. Peter et al [14] showed similar efficacy in treating insomnia when comparing an online CBT with face-to-face CBT. A recent randomized noninferiority clinical trial showed online CBT to be noninferior to face-to-face CBT for health anxiety [50]. A systemic review and meta-analysis comparing online CBT and face-to-face CBT in psychiatric and somatic disorders reported that most disorders showed equivalent effects between the two groups [49]. These results emphasize the opinion that online CBT has become a viable and cost-effective option for face-to-face CBT, possibly because of advancements in technology and our familiarity with it. Unfortunately, we could not find any studies comparing online CBT with face-to-face CBT for stress reduction. Future studies are needed for stress management in this context.

Limitations

Our study has several limitations. First, only psychological scales were used in the trial. Although using objective measurements such as heart rate variance or blood cortisol levels would have complemented the results, we avoided this so that the participants would not have to visit a psychiatric clinic. Stigma regarding psychiatric interventions remains widespread in Korea, and having participants with work stress visit a psychiatric ward could negatively impact the trial [51]. Second, the average perceived stress was relatively high in both groups. Generalizing this result to a population with low perceived stress would be difficult with the current data. Third, most participants were female, and most had an education level of college diploma or higher. Although there are similar findings regarding demographics [12,46], this should be accounted for when applying the results to a broader population. Finally, only pre- and postintervention data were collected. Additional data from months after the intervention are needed to examine if the effects of the intervention persist over time.

Conclusions

BetterLife, a smartphone-based individually tailored CBT, effectively reduced stress and increased work engagement and QoL in people with work-related stress. This is a viable option for reducing workplace stress.

We congratulate Neely and colleagues on their recent work [1] describing the utilization of social media platforms as a source of information regarding the COVID-19 pandemic. The authors suggested that the majority of health information disseminated on social media was not fact-checked with a health care professional [1]. Furthermore, their results demonstrated that subjects following more credible scientific sources on social media were more likely to receive the COVID-19 vaccine [1]. These findings are corroborated by a recent study that concluded that there is a statistically significant relationship between disinformation regarding COVID-19 and lower vaccination rates [2]. However, both studies primarily focused on individual consumers of social media. While these studies are representative samples of the US population, they are unlikely to adequately describe the >200 million Twitter users and are likely subject to selection and recall bias from participants. While analysis of the consumer is revealing, understanding the publishers of information is of equal intrigue and utility.

An alternative methodology for addressing the investigative question proposed by Neely and associates would be to quantify content related to the COVID-19 vaccine and vaccination efforts and further classify this content as informed or misinformed. Data points could include the number of views and the frequency these posts receive subsequent dissemination. This approach would transition the focus from the consumers to the producers of this information. Studies of the aforementioned design come with their own set of limitations; however, we feel it is better suited to address the questions of the authors. Regardless of the study or methodology, social media platforms continue to grow, and health care professionals must recognize the potential effect they can have on social media.

Across social media platforms, it has been previously demonstrated that pro-vaccine individuals are more likely to reference credible sources than those from "antivaccine" groups [3]. Major social media platforms such as Facebook, Twitter, and Instagram have partnered with the World Health Organization in an attempt to target and flag misinformation

[3,4]. This served to counter misinformed COVID-19 and other health information on social media. Given social media's high availability and massive user base, there is a tremendous opportunity for physicians and health care organizations to interact with the American public through these virtual platforms. Establishing a stronger social media presence at both the systems (hospital, national governing medical body, academic center) and individual level is an underutilized opportunity for disseminating health information in an accurate manner. Most physicians (90%) have a presence on social media; however, it is unclear what advocacy impact these accounts have [5]. The introduction of a verification process for posts containing health information may have merit. Implementation of such a policy may increase consumer faith in factual health information, potentially enhancing public health advocacy in campaigns such as COVID-19 vaccinations. It appears that social media has a role to play in health care; an enhanced understanding of social media's scope of influence and increased physician representation may have a far-reaching impact.

technology-enabled care; video consultations; quality improvement; COVID-19; PERCS framework; remote consultation; Scotland; general practice; digital inclusion; digital divide; digital health equity

This insightful paper by Wherton et al [1] suggests groundwork before the pandemic allowed health care services to rapidly extend the use of video consultations across Scotland. As a general practitioner and digital champion, working in a deprived area in a city in Scotland, I agree but strongly believe that front-line staff is fundamental to further increase use. The "asymmetric development, driven in some places by particular local enthusiasts" noted before the pandemic certainly continues, and additional local "champions" are key to further increased use.

The finding relating to the "focus on region-by-region" quality improvement approach noted can be explained by how the National Health Service is set up across Scotland, with 14 different health boards [2]. Although it is pertinent to point out the challenges of providing rural care, most citizens in Scotland live in nonrural areas [3].

My urban general practice embraced the opportunity to perform video consultations. We implemented these by deciding to "convert" telephone consultations to video consultations, when clinically appropriate. This occurred if the patient agreed and had the appropriate technology. We welcomed the improvement allowing the Near Me video service to send direct links to the virtual waiting room.

However, despite this improvement, when discussing video consultations with colleagues, we perceived that many patients then faced technical and accessibility issues. Patients frequently could not enter the virtual waiting room due to low levels of digital literacy.

A recent internal practice audit performed in August 2021 showed that only around half of the patients opted for a video consultation (n=67, 46%) if offered instead of a telephone consultation. Furthermore, of those who requested a video consultation, a large proportion was unsuccessful (n=31, 45%).

If a patient was unable to connect to the video consultation, they would not have the opportunity to complete the patient satisfaction survey, which is given out after the video consultation. Therefore, the patient survey, which reported that the majority of video consultations had no technical problems (n=18,817, 78%), is potentially an underestimate as it does not include some consultations in which patients were unable to access the service at all.

I am pleased to report that the Near Me video service has just been upgraded to include a Consult Now feature. This enables a one-time-only link to be sent, bringing the patient directly to the video call, without having to enter their details and access the virtual waiting room.

In an attempt to offer patients choice, I believe patients should be offered a video consultation instead of a telephone consultation, if they prefer. A video consultation may not objectively aid the consultation; however, it can assist with the clinical relationship.

To do this while addressing digital inclusion, including digital access support is fundamental. We must be mindful to continue to strive to reduce health inequalities and address the "digital inverse care law." I am personally very supportive of Scotland's digital health and care strategy, which aims to achieve world-leading levels of digital inclusion [4].

KEYWORDS

social media; internet; communication; public health; COVID-19; usage; United States; information seeking; web-based health information; online health information; survey; mistrust; vaccination; misinformation

We appreciate Boudreau and colleagues' [1] thoughtful consideration of our recent survey study [2], which examined American people's use of social networking sites (SNS) to learn and stay informed about the COVID-19 pandemic. As they point out, we surveyed a representative sample of American adults (N=1003) and found that most SNS users had not fact-checked COVID-19–related information with a medical professional, and those who had opted to follow credible, scientific sources on social media were significantly more likely to undergo vaccination [2]. In reply, Boudreau and colleagues noted that our study—and others like it—has focused primarily on consumers rather than the producers and publishers of medical content on social media [1]. They propose that researchers should shift their focus "from the consumers to the producers of this information," and, in particular, they emphasize the possibility of developing tools to assess and classify health-related posts on social media in order to help consumers distinguish medically valid guidance from potential misinformation.

We understand and affirm the underlying spirit of Boudreau et al's [1] recommendation, and building on that, we would endorse an "all of the above" approach to the study of social media moving forward. A comprehensive research agenda—drawing on a diverse range of perspectives and methodological techniques—will be needed in order to understand and keep pace with social media's growing and evolving role in health information seeking. This includes greater attention to issues of content and publisher credibility, as the authors suggest, though it should be noted that social media often obscures the distinction between publishers and consumers [3]. It also means that health professionals will need to gain awareness of and interpret emerging techniques in data mining, natural language processing, and network analysis. These are essential to identifying influential network nodes and understanding how

health information spreads in complex social networks. For reference, we conducted a similar analysis during the 2015-2016 Zika virus outbreak [4].

However, in pursuing a comprehensive research agenda around social media, it is critical that researchers not lose sight of the consumer perspective. We agree that promoting and affirming accuracy "at the source" is critical, but so too is understanding which sources of health information consumers encounter, trust, and rely on. Unfortunately, recent studies have noted declining trust in science among many Americans, including the Institution of Medicine [5,6]. This is especially salient in the case of politicized public health emergencies, such as the COVID-19 pandemic. Add to this the politicization and fragmentation of social media platforms themselves, and we find ourselves immersed in an information environment where even quality markers are often interpreted as political statements. While health professionals are not to blame for these trends, it is nonetheless important that they be aware of and responsive to them. This means that it is critical for research and scholars to stay focused on understanding consumer-level preferences, behaviors, and outcomes while also working to improve health messaging at its source.

KEYWORDS

COVID-19; vaccine; vaccination; Twitter; infodemiology; infoveillance; topic; sentiment; opinion; discussion; communication; social media; perception; concern; emotion; natural language processing

Lyu et al [1] used natural language processing techniques to analyze the topics and sentiment of Twitter conversations related to the COVID-19 vaccine using the Twitter chatter data set created by Georgia State University's Panacea Lab. Tweets that contained any of the following keywords "vaccination," "vaccinations," "vaccine," "vaccines," "immunization," "vaccinate," and "vaccinated" were selected for further analysis (eg, topic modeling and sentiment analysis).

I would suggest that the study might be enhanced by including additional keyword searches for vaccination synonyms identified by a method such as the Continuous Bag of Words (CBOW) word2vec model [2]. While the study focused on formal language such as "vaccination" and "vaccine," other colloquial terms are commonly used on Twitter and other social media platforms to describe the vaccination process.

I identified synonyms for "vaccination" commonly used on Twitter by using the *gensim* implementation of the CBOW word2vec model [3]. This model predicts synonyms and related words by creating vector representations of words. Words with similar vector representations are more likely to be synonyms than words with dissimilar vector representations. I trained the CBOW word2vec model on 503,862 tweets containing the keyword "covid" or "corona" from June 24-27, 2021, collected through the *rtweet* package [4]. The keyword pattern search results included tweets using words related to COVID-19 such as "covid-19" or "coronavirus."

Out of the 503,862 COVID-19–related tweets downloaded with *rtweet*, 94,768 contained at least one of the words searched for in the study by Lyu et al [1]. In addition, a total of 22,587 tweets used the terms "shot," "shots," "jab," "jabs," "jabbed," "vax," or "vaxxed." The words "shot" or "shots" were used in 9017 tweets. The words "jab," "jabs," or "jabbed" were used in 7021 tweets. The words "vax" or "vaxxed" were used in 4081 tweets. Out of the 22,587 tweets that contained these alternative terms, 15,855 (70.2%) were tweeted by users who self-disclosed their location on their user profile. Using the Nominatim application programming interface, it was possible to identify geocoded location, including country, for 13,101 of the 15,855 user-disclosed locations [5]. Of these 13,101 geocoded tweets, 3111 were from the United Kingdom, of which 2261 used "jab," "jabbed," or "jabs." Among the geocoded tweets, 4910 were from the United States; of these, 2704 included "shot" or "shots" and 1130 used "vax" and "vaxxed."

I would propose that researchers performing keyword searches on social media chatter consider using the CBOW word2vec model to enhance their studies by expanding the number of comments they capture and to reduce geographic or population bias that may occur from the preselection of terminology. The CBOW word2vec model can help capture more completely the full range of word choices used by social media users.

Abstract

In the Czech Republic, the strategic data-based and organizational support for individual regions and for providers of acute care at the nationwide level is coordinated by the Ministry of Health. At the beginning of the COVID-19 pandemic, the country needed to very quickly implement a system for the monitoring, reporting, and overall management of hospital capacities. The aim of this viewpoint is to describe the purpose and basic functions of a web-based application named “Control Centre for Intensive Care,” which was developed and made available to meet the needs of systematic online technical support for the management of intensive inpatient care across the Czech Republic during the first wave of the pandemic in spring 2020. Two tools of key importance are described in the context of national methodology: one module for regular online updates and overall monitoring of currently free capacities of intensive care in real time, and a second module for online entering and overall record-keeping of requirements on medications for COVID-19 patients. A total of 134 intensive care providers and 927 users from hospitals across all 14 regions of the Czech Republic were registered in the central Control Centre for Intensive Care database as of March 31, 2021. This web-based application enabled continuous monitoring and decision-making during the mass surge of critical care from autumn 2020 to spring 2021. The Control Center for Intensive Care has become an indispensable part of a set of online tools that are employed on a regular basis for crisis management at the time of the COVID-19 pandemic.

(J Med Internet Res 2022;24(2):e33149) doi:10.2196/33149

Introduction

The COVID-19 pandemic has placed an urgent burden on health care systems, communication among their components, and health care management. Although the majority of patients have a mild or even asymptomatic course of the disease, approximately 8% to 15% of patients require hospitalization during the infection or afterward [1]. Approximately 21% to 36% of patients hospitalized due to COVID-19 are admitted to the intensive care unit (ICU) [2-4], and the average mortality of those admitted to the ICU is approximately 30% [5,6].

In the majority of developed countries, ICU beds are often close to their full capacity even under normal circumstances, let alone during the COVID-19 pandemic. Modeling studies suggest that a pandemic of severe influenza or another similar disease would require ICU and mechanic ventilation capacity that is significantly greater than what is available and that many patients who would require a ventilator might not have access to one [7,8].

By definition, epidemics and disasters will result in many patients arriving in a continuous stream, with shortages of necessary technology, beds, oxygen support, ventilators, medications, as well as trained health care personnel. The high likelihood of such conditions emphasizes the importance of having a framework that is suitably constructed to allow users to anticipate and adapt to these inevitable complexities and challenges [8]. Beds, equipment, and medications should be monitored ideally in “real time” and electronically, with knowledge of both their absolute numbers and whereabouts immediately available to system leaders [9]. For example, ventilatory support is an absolute necessity for the survival of critically ill patients and may be the single most important therapy that dictates the outcomes. Moreover, ventilators are highly demanding for staff qualification; they are therefore likely to be the limiting factor in any hospital’s ability to accommodate a large surge of mass critical care [10]. The COVID-19 pandemic has generated a sense of urgency that will allow the adoption of innovation without the logistical barriers and path dependencies that we have become accustomed to. Web-based solutions can fill a critical gap for the allocation of health care resources [11].

The Czech National Control Centre for Acute Inpatient Care (CNCC-AIC) was established under the auspices of the Ministry of Health of the Czech Republic in May 2020 to provide strategic data-based and organizational support for individual regions and for providers of acute care at the nationwide level. Its main purpose is to monitor hospital capacities, to provide analytical reporting on these capacities, and to enable the overall management of health care facilities run by all inpatient care providers in the Czech Republic.

The operative online tools of key importance employed by the CNCC-AIC involve the Control Centre for Intensive Care (CC-IC) [12], an online database updated on a daily basis, which provides an overview of capacities of inpatient care (classified into categories of acute, long-term, and supportive care) and a dedicated “Clinic” module, which is part of the Information System of Infectious Diseases (a database of people with laboratory-confirmed COVID-19).

In accordance with the defined methodology, the CC-IC was brought into operation in April 2020 to enable the continuous monitoring as well as daily reporting of available data on the occupancy rate of inpatient beds. The aim of this viewpoint paper is to present the methodology of managing capacities in Czech hospitals during the ongoing COVID-19 pandemic. A newly developed and robust technical solution, namely the CC-IC, is also introduced. The methodological background of the design and implementation of this unique practical operative tool, which is built on the long-term experience of experts across the Czech health care system, and experience with its practical use are presented.

Structure of the CC-IC

Overview

The CC-IC is an entirely new platform that has been developed since the start of the COVID-19 pandemic. This has been achieved in mutual cooperation among the following groups of involved stakeholders and experts to assess recent progress of the epidemic and recommend measures for crisis situations caused by the COVID-19 epidemic in the Czech Republic: (1) a team of regional coordinators of intensive care; (2) the Integrated Central Management Team, which includes representatives from the Ministry of Health, Czech Armed Forces, National Institute of Public Health, National Agency for Communication and Information Technologies, and Institute of Health Information and Statistics of the Czech Republic; and (3) a team of developers from a joint workplace of the Institute of Health Information and Statistics of the Czech Republic and the Institute of Biostatistics and Analyses at the Faculty of Medicine of Masaryk University.

The CC-IC provides two tools of key importance to offer effective support for the CNCC-AIC: (1) a module for regular online updates and overall monitoring of currently free capacities in hospitals (health care technology/medical devices, beds, staff) in real time, and (2) a module for online entering and overall record-keeping of requirements on medications for COVID-19 patients. No patient personal data or medical records are stored in the CC-IC application; thus, no anonymization or pseudonymization algorithms are used.

The CC-IC also specifically monitors the reprofiled capacity (ie, beds that had previously, under normal circumstances, in a given health care facility) been intended for the provision of care of another type or another specialty.

The CC-IC is a web application that has been continuously developed and run by the Institute of Health Information and Statistics of the Czech Republic, which cooperates closely with the Ministry of Health of the Czech Republic. Since the very beginning, the development has been based on requirements and needs for the coordination of intensive care, as required by health care facilities in the Czech Republic (Figure 1).

Use of the application (available in the Czech language only) relies on several basic principles: (1) user authentication and

authorization, (2) definition of user roles and rights to edit and read, (3) each new user registration is approved by the CNCC-AIC, and (4) private and free email addresses are not allowed. CC-IC users include representatives of individual health care facilities (management, coordinators of intensive care, physicians, and nurses), emergency medical service workers, pharmacy workers, and members of the Integrated Central Management Team.

The use case diagram in Figure 2 provides an overview of the entire CC-IC system, including key functions assigned to users in specific roles. The main objective of this diagram is to depict the various actors as well as interactions that are available to these actors.

Use cases provide insight into the basic structure of CC-IC functional requirements. Based on modeling of individual use cases, which are associated with the primary actors, we can see individual parts of the system so that we can decompose and divide the whole system into separate submodules. Moreover, the CC-IC provides an authenticated application programming interface (API) for secure sharing of selected data sets, which consists of access to a list of requirements on medications and an export of currently free capacities in hospitals, including their history.

Figure 1. Schematic diagram of the Control Centre for Intensive Care (CC-IC).

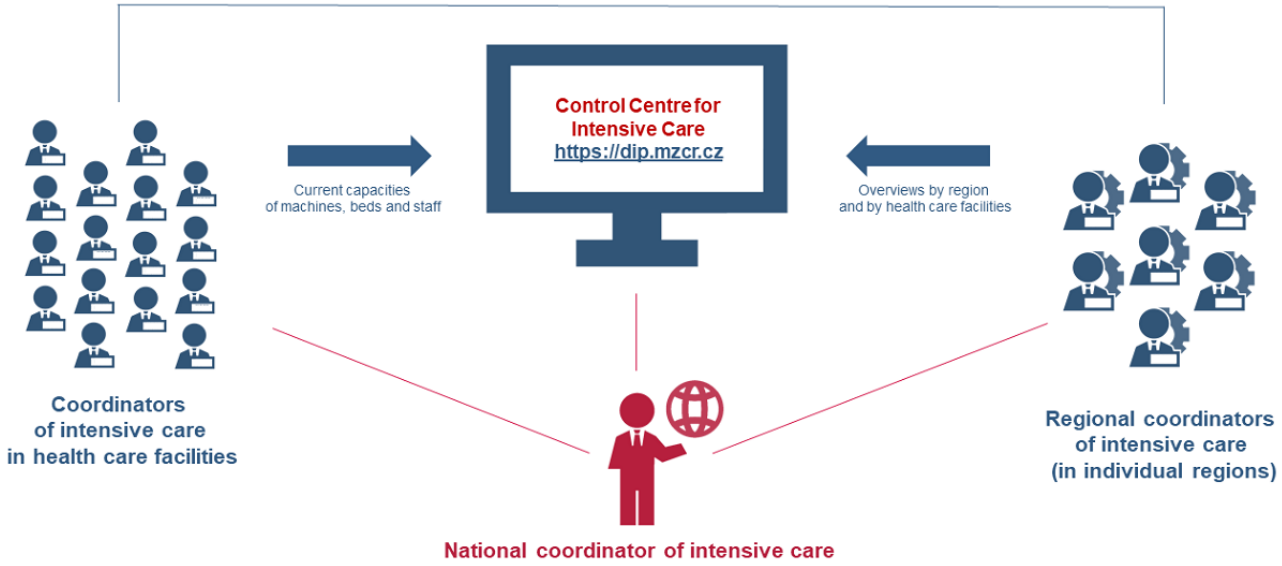

Figure 2. Use case diagram for the Control Centre for Intensive Care system. API: application programming interface.

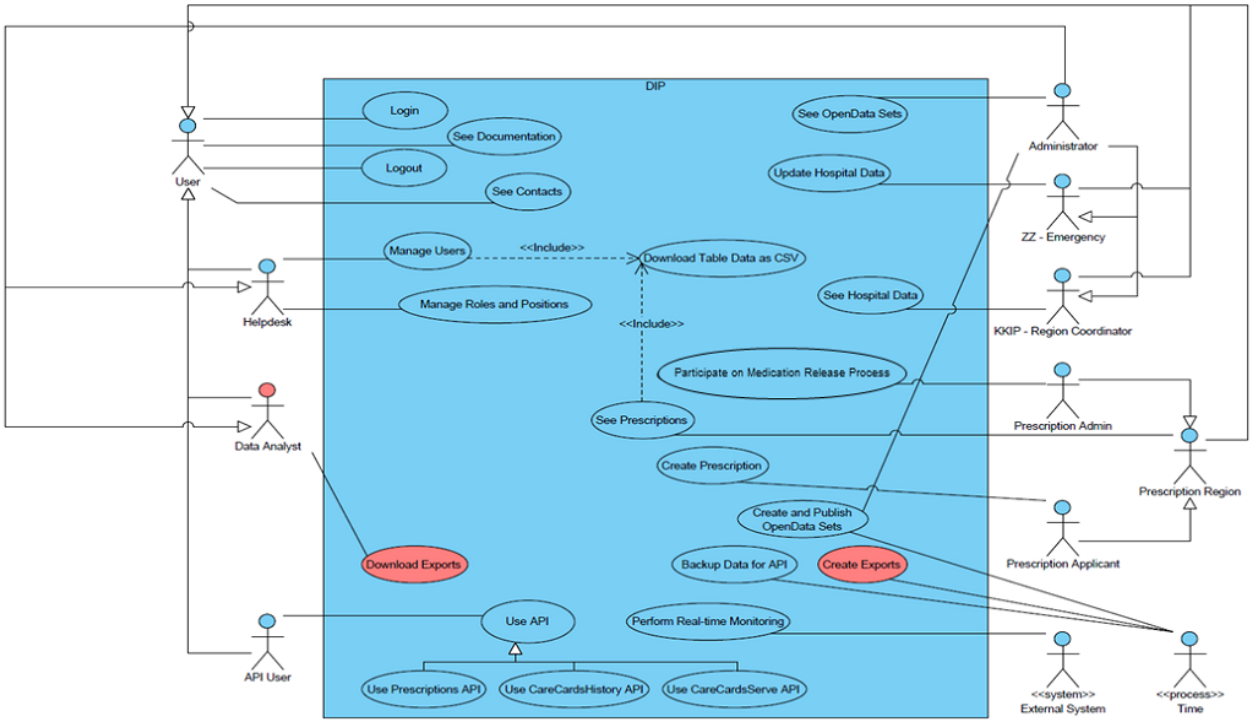


Regular Monitoring of Health Care Providers and the ICU Network

On April 9, 2020, the Ministry of Health of the Czech Republic adopted an exceptional measure, ordering all acute care providers to use the CC-IC to immediately report any changes in capacities of intensive care related to COVID-19 patients. Since the launch of the CC-IC, the availability of free capacity of machines, beds, and staff has been monitored on a regular basis (Textbox 1). Hospitals have been requested to report their intensive care capacities on a daily basis, usually at the end of the day. The system allows for continuous updates at any time; more frequent entering of the latest data would nevertheless bring an unnecessary burden to hospital staff at the time of a significant shortage of capacities in terms of personnel, time, and equipment.

Based on data in the CC-IC, it is possible to coordinate the provision of inpatient care centrally, on a nationwide level. In each individual region, hospitalizations of patients who need admission to an intensive care facility (ICU and/or emergency department) are managed and coordinated by the so-called regional coordinator of intensive care, who is a physician specialized in anesthesiology and intensive care medicine. These physicians cooperate closely with regional emergency medical services and with representatives of regional authorities. Apart from that, each health care facility has prepared emergency beds (ie, inpatient beds that could be used to provide care for COVID-19 patients if all existing capacities are occupied).

The system reacts to immediate needs by individual regions, depending on the current occupancy rate of machines and beds, combined with the number of COVID-19 patients. If an increase in the number of new patients is detected within the CC-IC, it is necessary to prepare health care facilities for a crisis situation. This involves limiting capacities for patient admissions (ie, only admit patients who require intensive and emergency care, and suspend the provision of nonemergency care); discharging as many patients as possible to home care; plan an increased bed supply in health care facilities for an increase in COVID-19 patients; and provide a sufficient number of competent health care professionals.

The module for regular online updates and overall monitoring of the currently free capacities of intensive care in real time is predominantly used by coordinators of intensive care in individual health care facilities. A total of 134 intensive care providers from all 14 regions of the Czech Republic are registered in the central CC-IC database. As of March 31, 2021, a total of 927 users were registered who used this module to update data on intensive care capacities in predefined intervals (ie, at least once a day during critical periods of the COVID-19 pandemic), who made 86,565 sessions in total.

A user-friendly and simple interface (Figure 3) is available to users, who can therefore update occupancy rates of available capacities (in terms of machines, beds, and staff) very easily. The entire application is fully responsive and therefore entirely compatible with all types of devices, namely smartphones, tablets, laptops, and desktops. Free capacities for COVID-19–positive versus COVID-19–negative patients are distinguished only for beds. Entering a free bed into the system means that this bed is fully functional (ie, all required equipment and corresponding health care professionals are available). Monitoring of staff and equipment in and out of service has turned out to be ineffective and unsustainable on a long-term basis; this function was therefore removed from the system upon the decision of the Central Integrated Management Team. Across the entire module, each individual card has one of three background colors to provide a quick overview of free capacities: white, <30% to 100%> free capacity; yellow, <10% to 30% free capacity; and red, <0% to 10% of free capacity.

Textbox 1. Overview of monitored information on capacities of health care facilities providing inpatient care in the Czech Republic.

Health care technology/medical devices

- Extracorporeal membrane oxygenation
- Mechanical ventilation in accident and emergency (A&E) departments and in intensive care units (ICUs) for adults
- Continuous renal replacement therapy
- Intermittent renal replacement therapy
- Transport ventilators
- Anesthesia machine with mechanical ventilator

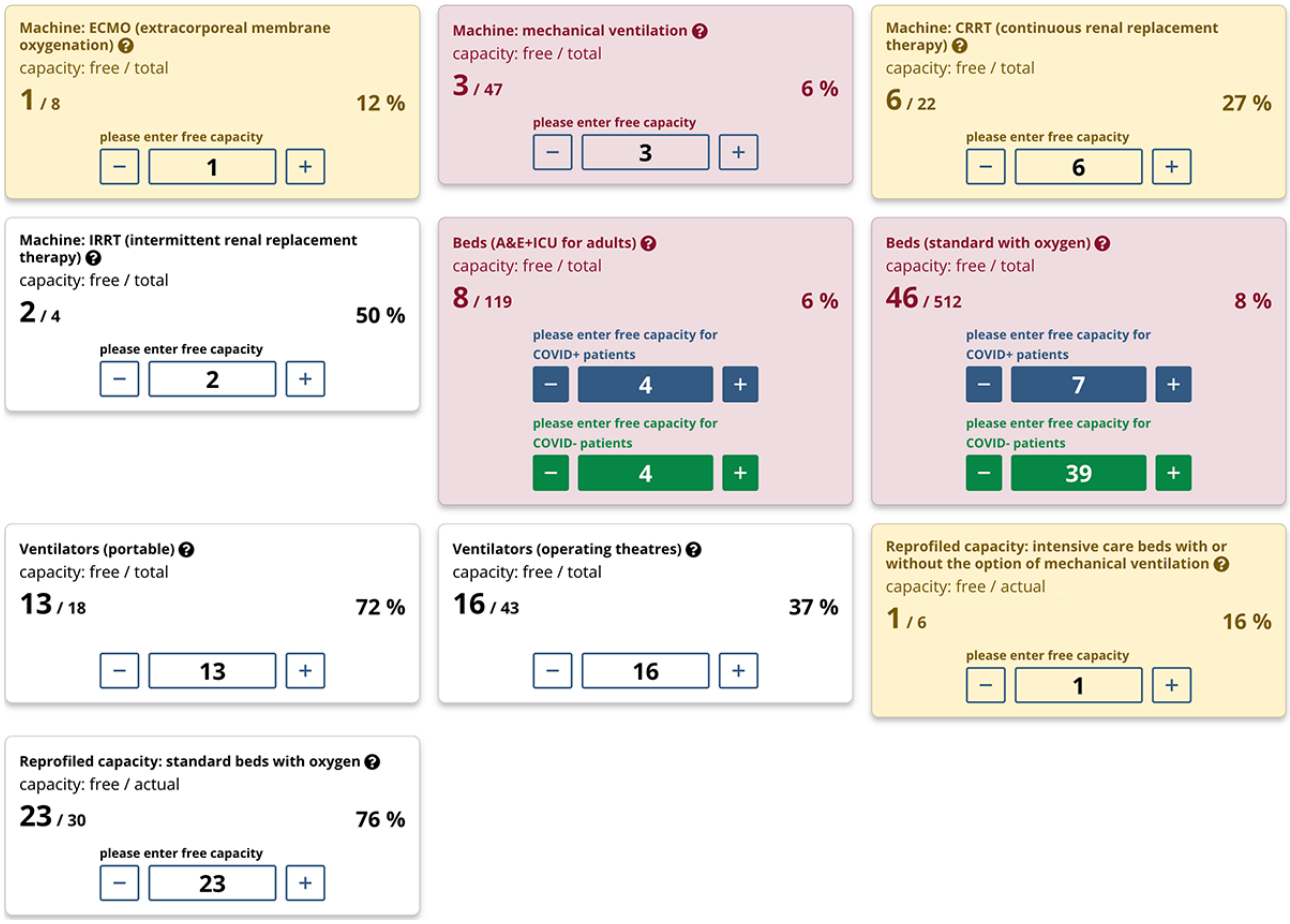
Hospital beds

- A&E and ICU beds for adults; a distinction is made between beds for COVID-19–positive and COVID-19–negative patients
- Standard beds with oxygen; a distinction is made between beds for COVID-19–positive and COVID-19–negative patients
- Reprofiled capacity: beds with or without the option of ventilatory support devices

Staff

- Physicians (A&E and ICU for adults)
- Nurses (A&E and ICU for adults)

Figure 3. Interface for updates of free capacities. Overview of intensive care capacities for the capital, Prague, as of December 30, 2020. A&E: accident and emergency; ICU: intensive care unit.



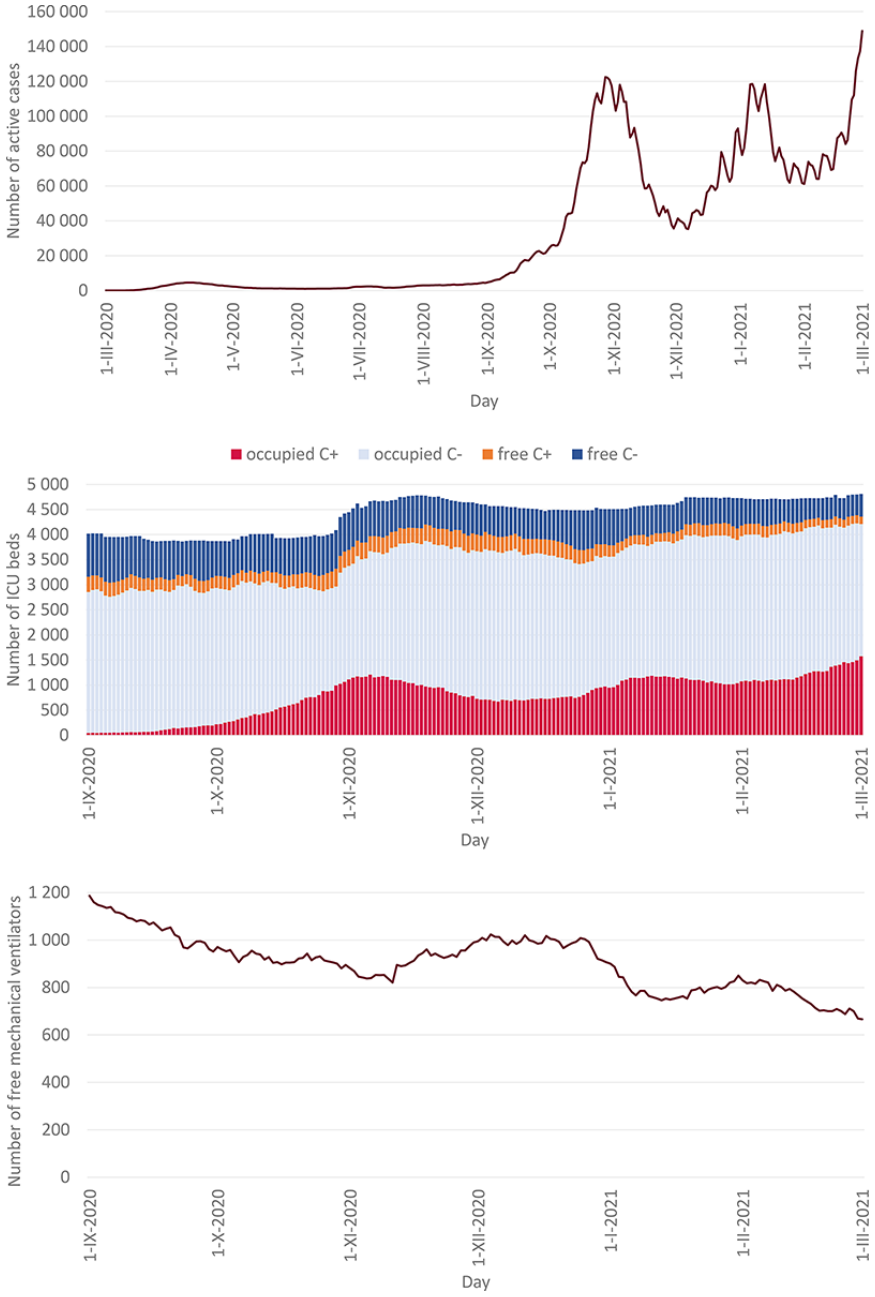
Two different reports are available to provide a quick overview of the latest data. These reports are primarily used by regional coordinators of intensive care, members of the operational team of the CNCC-AIC, members of management of individual health care facilities, and top officials of the Ministry of Health of the Czech Republic. The first report is a summary data table providing a clearly arranged view of all health care facilities, including real-time absolute and relative occupancy numbers as regard to available capacities. The second is an aggregated visualization in the form of context cards, which also show real-time absolute and relative occupancy numbers in regard to available capacities, but users can further choose among the nationwide view, views for individual regions, or those for individual health care facilities.

The example screenshot from the CC-IC application in Figure 3 also demonstrates an aggregated visualization of key parameters monitored in real time for the capital, Prague. Four cards have a yellow background because the available capacity of corresponding parameters was reported to be below 30% at the time.

Owing to the timely and strict measures at the national level, the first COVID-19 wave in the spring of 2020 did not bring significant pressure to hospital-based care, with a maximum daily prevalence of around 4500 active cases and less than 100 ICU beds being occupied with COVID-19 patients among the Czech population of over 10 million people. The situation changed in the autumn of 2020; the number of active cases peaked twice to approximately 120,000, first in early November 2020 and then in early January 2021 (Figure 4, top). The number of patients requiring intensive care at the ICU fluctuated at around 1200 in these periods. Requirements for intensive care increased to an even more critical level in the second half of February 2021, with 1574 ICU beds occupied by COVID-19 patients on March 1, 2021 (Figure 4, middle).

The increasing numbers of hospitalized patients with COVID-19 during October 2020, as steadily monitored by the CC-IC, required increased capacities of standard beds and ICU beds. The total numbers of both types of beds were increased by repurposing the existing beds and adding new beds, according to the capabilities of individual hospitals. The availability of mechanical ventilators as an essential equipment of intensive care followed the overall trends: it decreased from nearly 1200 machines on September 1, 2020, to less than 700 at the end of February 2021 (Figure 4, bottom). If a temporary depletion of ICU capacities occurred in some regions, patients were transferred to hospitals in other regions in which free capacities were available according to the CC-IC report. Over 100 patients were transferred between hospitals during autumn 2020 and winter 2021, usually from small local hospitals to large hospitals in regional capitals or in Prague. All of these decisions were taken by the national and regional intensive care coordinators in cooperation with the Central Integrated Management Team.

Figure 4. Time trends of COVID-19 cases and related intensive care, from top to bottom: number of active cases (prevalence), occupied and free intensive care unit (ICU) beds for COVID-19 patients and other patients, and availability of mechanical ventilators.



Prescription of COVID-19 Medications

With an increasing number of hospital admissions of COVID-19 patients who need medication to manage the disease, it was necessary to secure the systematic record-keeping and distribution of these medications to individual health care facilities. For this reason, a dedicated module was developed within the CC-IC, making it possible to request any of three therapies against COVID-19: remdesivir, convalescent plasma, and favipiravir. The tool has been intentionally designed in a rather flexible manner so that it can be easily adapted and employed after the end of the pandemic, thus providing a generally applicable ordering system for any medication.

The CC-IC enables physicians from any involved health care facility to request a certain medication for a specific patient. The module has three basic user roles: (1) applicant for medication (physician), which has been assigned to an approved group of registered users from individual health care facilities who are thus entitled to enter new requests from their respective health care facility; (2) regional coordinator of intensive care, who is entitled to enter new requests from health care facilities from across the entire region and can also see an overview of requests not only from the region but from the Czech Republic as a whole; (3) virtual indication group, with members entitled to approve requests for medications from the respective region and they can also see an overview of requests from across the Czech Republic; and (4) contact persons from pharmacies linked to specific health care facilities, who are entitled to supply the approved medications.

Mutual cooperation among representatives of the Ministry of Health of the Czech Republic, regional coordinators of intensive care, members of the virtual indication group, and

representatives of pharmacies led to the development of a structured form that is employed to send a request for a specific medication. The form consists of three parts: (1) health care facility, containing information on the physician and hospital requesting the medication; (2) specification of therapy, containing information on the requested medication and the date of supply; and (3) patient description, which is an anonymized description of the patient's condition and their risk factors (without mentioning any personal data in conformity with personal data protection according to General Data Protection Regulation).

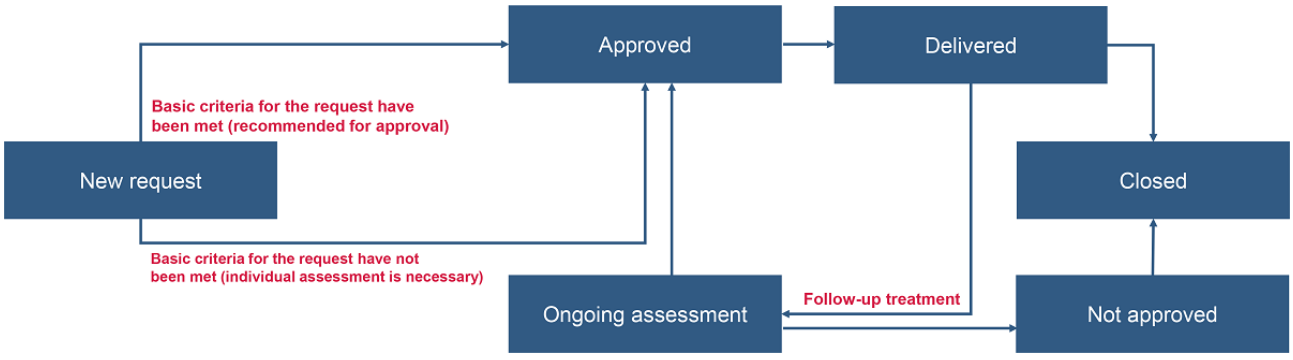
After the form is filled out and sent, validation of individual items is performed within the CC-IC, the request is stored in the central database, and a notification is sent to all users involved (physician, member of the virtual indication group in the respective region, pharmacy). The medication must be explicitly approved before being supplied by a respective pharmacy that secures supplies for a given health care facility. In the final step, the request is closed for the purpose of archiving and subsequent statement of charges for the respective health insurance company. In exceptional cases, request for follow-up treatment can occur after the administration of remdesivir; such requests can also be processed by the CC-IC. The life cycle of a request for a medication within the CC-IC is shown in Figure 5.

All health care facilities providing acute care began to report, by means of the CC-IC, the current use of these capacities on April 9, 2020, when the first version of the system was launched. The first version only contained one module, which enabled regular online updates and overall monitoring of currently free capacities of intensive care in real time. On June 10, 2020, the second module was launched for the online entering and overall record-keeping of requirements on medications for COVID-19 patients.

A major added value of the entire CC-IC system is the fact that it was designed to meet the current needs of acute medicine in response to the unexpected burden on inpatient care capacity caused by the COVID-19 pandemic. The data that the CC-IC allows to collect provide a key support for data-oriented decision-making processes within ICU occupancy crisis management. Thanks to the CNCC-AIC and a proper methodological setup, it is possible to effectively coordinate, for example, elective care, which can have a negative effect on patients' health when being moved or postponed. The following paragraphs briefly describe the functions of both of the above-mentioned modules as well as analytical reports and open data sets that have been provided as an outcome of the CC-IC database.

As of December 30, 2020, a total of 4759 requests for medication were registered in the CC-IC, out of which 4666 (98.05%) were requests for remdesivir. The remaining 93 (1.95%) requests were for convalescent plasma. On that date, a total of 496 users entitled to work with requests for medications were registered in the system; these users included physicians in individual health care facilities, regional coordinators of intensive care, pharmacy workers, and members of the virtual indication group. Between the first wave and the second wave of the COVID-19 pandemic, there was a major change in the functioning of the module for the sending and record-keeping of requests for medications. A new version was implemented in September 2020, fully supporting the entire process of requests for medications (entering, validation of entered data, sending, approval/rejection, supply, conclusion), including email notifications. The form itself for sending a request contains a list of key information necessary for subsequent approval and the supply of a specific medicine (see Multimedia Appendix 1).

Figure 5. Description of the life cycle of a request for a medication in the Control Centre for Intensive Care (CC-IC).



Practical Use of Open Data

Data on free capacities are available as records in the National Catalogue of Open Data [13,14] in a regularly updated data set that describes two waves of the COVID-19 pandemic in the Czech Republic.

The data set contains overviews of machine equipment (extracorporeal membrane oxygenation, mechanical ventilation, continuous renal replacement therapy, intermittent hemodialysis, ventilators—portable and those in operating theaters) and occupancy rate of inpatient beds (only beds in the emergency department and ICU for adults and standard beds with oxygen in the entire hospital). Data are regularly updated for beds suitable for the provision of the requested type of care (ie, necessary staff as well as corresponding material and technical equipment must also be available). The definition of the necessary number of staff for a given type of bed can be different among individual hospitals. These data have been available since September 1, 2020, when the obligation for hospitals to update free capacity was reset to a 1-day interval.

On top of that, for the purpose of the transfer of record-based (nonaggregated) data directly from the CC-IC to the Institute of Health Information and Statistics of the Czech Republic analytical team and to external authorized systems (run by the leadership of the Capital of Prague, for example), an API was developed to provide a machine-readable alternative to user access. For a secure transfer of data, each user must be authenticated and authorized, and the following conditions must be met: (1) each new user of the API must first register in the CC-IC system and must be explicitly approved for a given user role; (2) each request must contain the so-called API key (api_key), which is an integral part of the query (query string); (3) other parameters can also be part of the query string parameter, which are listed at specific endpoints; and (4) for each user, there is a defined list of allowed endpoints, IP addresses, and parameter values. If the user's request does not pass through the authorization process, the user will obtain the response "401 Unauthorized."

Data from the CC-IC, along with information from other registries (eg, the Information System of Infectious Diseases), are regularly processed for the purpose of daily reporting, which is provided to the team of the CNCC-AIC. Among dozens of analytical outputs (as of December 23, 2020), one of them monitors—on a daily basis—the situation in the Czech Republic from the points of view of currently hospitalized patients, new admissions to hospitals, new discharges from hospitals, as well as the utilization of health care facilities in individual regions, expressed by their free capacity [15].

Discussion

The Czech Republic was one of the most affected countries during the COVID-19 pandemic waves in autumn 2020 and winter 2021 in terms of incidence, hospitalizations, and deaths. The CC-IC was one of the key tools developed to manage the capacities of standard and ICU beds in the entire country, and to ensure that appropriate care was provided not only to patients with COVID-19 but also to other patients.

The Czech Republic has by far the highest density of ICU beds (43.2 beds per 100,000 population) and one of the longest average hospital stays (9.5 days) among the Organization for Economic Cooperation and Development countries [16]. There is also a high level of centralization of hospital-based care, because all large hospitals are under the control of either the Ministry of Health or regional authorities. These factors enabled a very quick response and management of intensive care, including the compulsory reporting of current capacities into the central system.

The spread of COVID-19 has usually not been uniform, and there have been different ICU demands within the affected countries and their regions. Central reporting systems for the monitoring of ICU capacities were therefore established in some countries [17]. The absence of such a platform, often combined with a fragmented health care system and small ICU facilities, may slow down the response and hold back the provision of appropriate care to critically ill patients, both with and without COVID-19 [18].

The systems for ICU capacities monitoring employed in various countries are usually operated under the auspices of national authorities (ie, government, ministries, and armed forces). They have been designed to provide near real-time data for crisis management and decision-making [19-21]. Short- and long-term estimates of ICU bed occupancy in the upcoming days and weeks using statistical models are another important output [21,22].

The CC-IC platform has been designed and developed in a tailor-made manner, responding to needs of the leadership of the Ministry of Health of the Czech Republic and crisis teams that are actively involved in the management of the COVID-19 epidemic in the Czech Republic. Based on the need to quickly and effectively resolve various crisis situations related to the capacity of ICUs, the CC-IC system was incorporated into the Czech legislation. Experience with the COVID-19 pandemic has clearly shown the requirement for long-term monitoring of ICU bed occupancy. This is the main reason why the obligation to update the occupancy on a daily basis for all health care facilities providing inpatient care in the Czech Republic is now enshrined in the Czech legislation. As part of international cooperation, the possibility of transfer of this online tool to other countries is being discussed. With respect to the general concept of the CC-IC design, the transferability of this tool to other countries should be trouble-free provided that the basic methodology for capacity monitoring in health care facilities is adhered to. It is of key importance that new requirements are collected from health care professionals themselves, even in the future. Intensivists should be part of strategic planning committees before, during, and after pandemics to coordinate ICU responses with hospital and regional efforts for triage, clinical care, and infection control [7]. Regular evaluation includes the analysis of user behavior and further optimization of the whole platform, so that it can continue to function as the primary support tool for all involved stakeholders.

Conclusions

The web platform CC-IC has been developed as a reaction to the urgent need of strategic data-based and organizational support for individual regions and providers of acute care on a nationwide level. The platform is intended for online real-time reporting of changes of free capacity of hospitals, real-time reporting of occupancy rate and availability of beds, a clearly arranged reporting of health care facilities, and the basis for quick decision-making of crisis management during the COVID-19 pandemic. Delegated representatives of health care facilities (coordinators of intensive care) are tasked with reporting the remaining free capacity of machines and beds that are available for patients hospitalized with COVID-19. Information on newly reported current capacity is immediately available to the Integrated Central Management Team, which continuously monitors the situation across the Czech Republic. Online entering and nationwide record-keeping of requests for medications intended for COVID-19 patients are processed by a standalone module. This system can be accessed by users from individual health care facilities providing acute care; the users typically involve several physicians and management representatives from the same health care facility, so that they can stand in for each other and share the latest information.

Development of the CC-IC is far from complete; the system has been further improved, partly based on requirements by members of the team of the CNCC-AIC and partly in response to suggestions by users themselves.

Abstract

Background: COVID-19 forced the implementation of restrictive measures in Spain, such as lockdown, home confinement, social distancing, and isolation. It is necessary to study whether limited access to basic services and decreased family and social support could have deleterious effects on cognition, quality of life, and mental health in vulnerable older people.

Objective: This study aims to explore the impact of the COVID-19 outbreak on cognition in older adults with mild cognitive impairment or dementia as the main outcome and the quality of life, perceived health status, and depression as secondary outcomes and to analyze the association of living alone and a change in living arrangements with those outcomes and other variables related with the use of technology and health services. Likewise, this study aims to analyze the association of high and low technophilia with those variables, to explore the access and use of health care and social support services, and, finally, to explore the informative-, cognitive-, entertainment-, and socialization-related uses of information and communications technologies (ICTs) during the COVID-19 outbreak.

Methods: This cohort study was conducted in Málaga (Spain). In total, 151 participants with mild cognitive impairment or mild dementia, from the SMART4MD (n=75, 49.7%) and TV-AssistDem (n=76, 50.3%) randomized clinical trials, were interviewed by telephone between May 11 and June 26, 2020. All participants had undergone 1-3 assessments (in 6-month intervals) on cognition, quality of life, and mood prior to the COVID-19 breakout.

Results: The outbreak did not significantly impact the cognition, quality of life, and mood of our study population when making comparisons with baseline assessments prior to the outbreak. Perceived stress was reported as moderate during the outbreak. After correction for multiple comparisons, living alone, a change in living arrangements, and technophilia were not associated with negative mental health outcomes. However, being alone was nominally associated with self-perceived fear and depression, and higher technophilia with better quality of life, less boredom, perceived stress and depression, and also less calmness. Overall, health care and social support service access and utilization were high. The most used ICTs during the COVID-19 outbreak were the television for informative, cognitive, and entertainment-related uses and the smartphone for socialization.

Conclusions: Our findings show that the first months of the outbreak did not significantly impact the cognition, quality of life, perceived health status, and depression of our study population when making comparisons with baseline assessments prior to the outbreak. Living alone and low technophilia require further research to establish whether they are risk factors of mental health problems during lockdowns in vulnerable populations. Moreover, although ICTs have proven to be useful for informative-, cognitive-, entertainment-, and socialization-related uses during the pandemic, more evidence is needed to support these interventions.

Introduction

COVID-19 was declared a worldwide pandemic by the World Health Organization on March 11, 2020 [1]. To avoid the serious collapse of health systems in response to the rising number of cases and deaths, European countries, as in other continents, decided to implement different measures to control the pandemic.

In Spain, the government decided to declare a national state of alarm, implementing restrictive measures from March 15 until June 21, 2020. The measures included lockdown, home confinement, social distancing, and isolation (activities were limited to basic needs, such as buying food or medication, attending health care centers and financial institutions); closure of schools and nonessential activities; ban of all internal travels except for essential ones; and border closure [2]. These measures also led to a change in health care access: Only critical attention was guaranteed, patient care changed from on-site interviews to telephonic attention, visits with medical specialists were suspended, and there was a lack of monitoring of chronic pathologies.

The elderly population is 1 of the groups most socially vulnerable to this disease. Age alone is by far the most significant factor for death due to COVID-19 [3]. Although COVID-19 infects people of all ages, the risk of becoming seriously ill increases in adults aged over 40 years, and especially in those aged over 60 years. In Spain, 68% of all hospitalizations due to coronavirus and 95% of all deaths correspond to the population over the age of 60 years, with a notable increase after the age of 80 years [4].

Recent data suggest that in addition to old age and medical comorbidities (eg, hypertension, diabetes, obesity), dementia is associated with an increased risk of having severe COVID‐19 and related mortality [5-8]. In addition, restrictive measures, such as confinement, may pose a risk for people with mild cognitive impairment (MCI) or mild dementia (MD). COVID-19 confinement has resulted in an increase in known risk factors for dementia, such as inactivity [9], limited access to basic services [10], isolation [11], and decreased family and social support [12]. These factors could have deleterious effects on cognition, quality of life, and overall health [13]. Therefore, the pandemic has not only a health impact on people with MCI/MD but also a social impact.

Loneliness and social isolation often coexist and are all too common in older adults. Loneliness refers to the subjective state of feeling alone, separated, or apart from others. Social isolation, in contrast, is defined as the objective physical separation from other people, such as living alone, in which one has few social relationships or there is a low frequency of interaction with others [14].

Considering the latter definition, we can understand that the COVID-19 pandemic has increased the social isolation of older adults as restrictive measures have enforced staying at home, distancing, and shutting down all nonessential activities. This has meant that people have been forced to minimize their social interactions to avoid the spread of the virus, leaving those who live alone completely isolated. Social isolation has been identified as a health risk factor as it reduces well-being and is associated with higher prevalence of depression [15] and cognitive impairment [16]. In older adults, it has a greater impact due to decreased social resources, functional and mobility limitations, death of family members, and changes in family structures [17].

During quarantine, factors such as boredom and a lack of activities play an important role. They can contribute to depression [18] and have an impact on the quality of life and functional dependence [19]. Mental activity, in contrast, may improve cognitive function and reduce overall dementia risk [20].

In the “information age,” information and communications technologies (ICTs) have emerged for combating loneliness and social isolation [21]. Although the age-related digital divide and health-related conditions (cognitive, visual, motor, etc) may compromise the use of technologies in the elderly, the extensive home penetration of ICTs has facilitated remote, home-based interventions. These interventions reduce the risk of viral exposure and prevent health-related negative outcomes of social isolation through health care delivery, cognitive stimulation, social connection, information sharing, and leisure entertainment [22].

The aims of this study were (1) to explore the impact of the COVID-19 outbreak on cognition in community-dwelling older

adults with MCI/MD as the main outcome and the quality of life, perceived health status, and depression as secondary outcomes; (2) to analyze the differences between individuals living alone and living with others regarding mental health, and other variables related with the use of technology and health services during the COVID-19 outbreak and, likewise, to explore the effect of a change in living arrangements on cognition, quality of life, perceived health status, and depression; (3) to analyze the differences between individuals with high and low technophilia regarding mental health and other variables related with use of technology and health services during the COVID-19 outbreak; (4) to explore the access and use of health care and social support services during the COVID-19 outbreak; and finally (5) to explore the informative-, cognitive-, entertainment-, and socialization-related uses of ICTs during the COVID-19 outbreak.

Methods

Study Design

This cohort study was conducted in the Spanish region of Málaga (Andalucía) and approved by the North-East Malaga Ethics Committee (1078-N-20). Interviews were telephone-administered to guarantee the safest means to communicate during the COVID-19 pandemic. Researchers contacted participants by telephone, explained the study in detail, answered any questions that arose, and obtained consent from those willing to participate in the study [23].

Ethics Approval and Consent to Participate

The study was approved by the North-East Malaga Ethics Committee (1078-N-20). Participants provided written consent before taking part.

Trial Registration

This study was registered in ClinicalTrials.gov (NCT04385797).

Setting

Participants were identified from the Support, Monitoring and Reminder Technology for Mild Dementia (SMART4MD; NCT03325699) [24] and TV-Based Assistive Integrated Service to Support European Adults Living with Dementia (TV-AssistDem; NCT03653234) [25] randomized clinical trials (RCTs), which aimed to assess the effects of ICTs to support MCI/MD using a tablet-based health application and a television-based assistive integrated service, respectively. In both RCTs, a broad definition of MCI, a subjective memory deterioration sustained over time, was considered. All participants had undergone 1-3 previous assessments (in 6-month intervals) in the RCTs on cognition, quality of life, and depression prior to the COVID-19 breakout.

Participants

Researchers from the Biomedical Research Institute of Malaga contacted 210 potential respondents from the SMART4MD (n=111, 52.9%) and TV-AssistDem (n=99, 47.1%) RCTs by telephone. In total, 151 participants, SMART4MD (n=75, 49.7%) and TV-AssistDem (n=76, 50.3%), agreed to participate. However, for 8 (5.3%) of them, it was not possible to assess the main variable (cognition) and the secondaries variables (quality of life, perceived health status, and depression), because their abilities to answer the questionnaires were compromised during the time of assessment.

Participants were eligible for inclusion when the following criteria applied: participating in the SMART4MD and TV-AssistDem RCTs and agreeing to participate by giving consent. Eligibility criteria of the aforementioned RCTs were age>55 years or >60 years, perception of memory problems for at least 6 months, score of 20-28 or 23-27 points in the Mini-Mental State Exam (MMSE), independently living, having an informal caregiver, and taking care of their medical prescription. Patients with a score above 11 on the Geriatric Depression Scale (GDS), a terminal illness, or specific cognitive or physical conditions that would reduce their ability to use a tablet or a television were excluded.

Interview Process

Participants were contacted by telephone by 5 health care professionals (2 neuropsychologists, 1 clinical psychologist, 1 psychologist, and 1 psychiatric and mental health clinical nurse specialist). Researchers had previously established relationships with participants during both RCTs. Quantitative and qualitative strategies were used to create an unstandardized ad hoc telephone-based survey in order to gather as much information as soon as possible. The exceptional situation did not allow us to test the instrument prior to its implementation by phone. To minimize the interference of this situation in the results, validated phone versions tests were used.

The survey was a useful tool for guiding the interviewers and gathering information simultaneously in a homogenous way. A model of the questionnaire used is attached in Annex 1 in Multimedia Appendix 1.

Researchers interviewed the participants between May 11 and June 26, 2020. The variables of sociodemographic data (age, sex, and living arrangements), health perception-management (change in living arrangements due to lockdown, presence of COVID-19 symptoms, frequency of access to COVID-19 information), sleep-rest patterns, types of ICTs (smartphone, tablet, television, laptop), and their uses (informative, cognitive, entertainment, and socialization) were collected from the participants unless their abilities to answer such a long interview were compromised, in which case the caregivers were interviewed on their behalf. The questionnaires that evaluated the main variables (cognition, quality of life, depression, perceived stress, and technophilia) were answered by the participants.

The mean time from the start of the lockdown and home confinement measures to the interview was 70.36 days (SD 12.40, range 52-102).

Instruments Used Before and After the Lockdown

Cognition

The primary outcome variable was cognition. During the assessment prior to the COVID-19 outbreak (T0), the MMSE [26] was used to assess the cognitive function of the participants with MCI/MD. We decided to use as eligibility criteria a broad

spectrum, because although the common cut-off score for cognitive impairment is 24, it has been shown that an MMSE cut-off score of 28 provides high sensitivity and specificity for detecting MD in a well-educated population with self-reported memory complaints [27].

During the COVID-19 outbreak (T1), the validated telephone version of the MMSE had to be used to maintain health and safety measures. This phone version has a maximum score of 22 because it cannot cover all sections [28]. For example, on the spatial orientation section, researchers were not able to check on which floor the patient was. Motor skills or some language skills could not be measured either. In the telephone version, the subject is asked only to repeat a phrase and name 1 item. The items of the original version, such as naming a second word, asking to follow a 3-stage command, reading and obeying a sentence, writing a sentence, or copying an intersecting pentagon, could not be measured.

Although the full version of the MMSE was used in the T0 assessment, for data analysis, the scoring was based on the 22 items of the phone version.

Quality of Life and Perceived Health Status

The health-related quality of life (HRQoL) of the participants was measured in both assessments using the total score of the Quality of Life-Alzheimer's Disease Scale (QoL-AD) [29]. The QoL-AD is a 13-item measure, in which responses are 4-point multiple-choice options (1=poor, 2=fair, 3=good, 4=excellent). It includes questions related to the interpersonal, environmental, functional, physical, and psychological status of a person with dementia, and thus, it is a global measure for the quality of life. Scale scores range from 13 to 52, with higher scores indicating a greater quality of life. In cases where patients had compromised cognitive function, informal caregivers completed the QoL-AD in parallel and on behalf of the people with MCI/MD.

The European Quality of Life 5 Dimensions 3 Levels (EuroQoL-5D-3L) [30] was also administered in both assessments. Currently, the EuroQoL-5D-3L is 1 of the most widely used generic preference-based measures in the world. It assesses an individual's HRQoL [31]. It has been shown to be valid in different patient groups and settings [32], including patients with cognitive impairment and dementia [33].

The EuroQoL-5D-3L consists of 5 questions along with a visual analog scale (VAS). The VAS records the patient's self-rated health on a vertical scale, where the endpoints are "the best health you can imagine" and "the worst health you can imagine." Due to the impossibility of the patients to see the VAS during the T1 assessment, they were asked to rate their health status. Only the VAS-perceived health status assessment was used for this study, combined with the Qol-AD.

Depression

The short form of the GDS was used during the T0 assessment [34]. It is a scale with 15 items and a range of scores, where 0-4 is considered normal, 5-8 indicates mild depression, 9-11 indicates moderate depression, and 12-15 indicates severe depression.

During the COVID-19 lockdown (T1), the telephone version of the GDS [35] was used. This version has high internal consistency and is highly correlated with the validated face-to-face administration of the scale, indicating that it is a valid instrument for screening depression among elderly people in special situations, such as the COVID-19 outbreak.

Instruments Used Only After the Lockdown

Technophilia

To measure older people's attitudes and enthusiasm toward technologies, the Instrument for Measuring Older People's Attitudes Toward Technology (TechPH) was used during the T1 assessment [36]. This questionnaire is designed to specifically assess technophilia in the older population and includes 6 items assessed on a 5-point Likert scale from 1 (fully disagree) to 5 (fully agree). The scale has 2 factors to define technophilia: technology enthusiasm and technology anxiety. It refers to a person's enthusiasm and positive feelings toward their technology use and the absence of fears and doubts about their ability to manage it.

Perceived Stress

The Perceived Stress Scale (PSS) [37] measures the degree to which situations in one's life are appraised as stressful. The scale has 14 questions regarding feelings and thoughts during the past month and are rated according to frequency (0=never, 1=almost never, 2=sometimes, 3=fairly often, 4=very often). PSS scores are obtained by reversing responses (eg, 0=4, 1=3, 2=2, 3=1, 4=0) to the 7 positively stated items (items 4, 5, 6, 7, 9, 10, and 13) and then summing across the entire 14-scale item. A higher score indicates a higher level of perceived stress. This questionnaire was used only during the T1 assessment. Studies report that the reduced version, PSS-10, has optimal psychometric properties in the general population and people exposed to confinement to assess perceived stress [38,39].

Other Variables

Other variables were sociodemographic data, including age, sex, and living arrangements; health perception-management (ie, change in living arrangements due to lockdown, presence of COVID-19 symptoms, frequency of access to COVID-19 information); coping-stress tolerance (ie, self-perceived mental health and well-being and mood); sleep-rest patterns (ie, self-perceived alterations in usual sleep patterns); and types of ICTs (smartphone, tablet, television, laptop) and their uses (informative, cognitive, entertainment, and socialization).

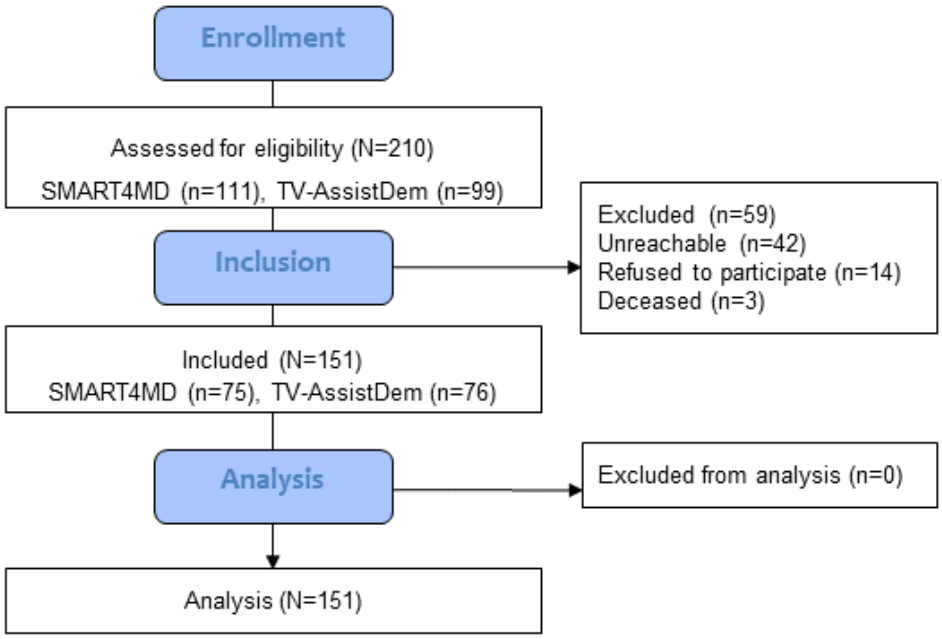
The survey data followed Gordon's Functional Health Patterns (Multimedia Appendix 1) [40]. To collect data on health perception, health management, and sleep-rest patterns, questions with numerically rated items were used. Open questions were included for the qualitative assessment of the patterns of coping-stress tolerance, activity-exercise, and role-relationship.

Data Analysis

The flow of participants is shown schematically with counts in a participant flow diagram (Figure 1). Statistics considered for presentation for continuous measures were the mean and SD, and if the criterion of normality was not met, the median and

the first and third quartiles. Categorical variables were summarized using counts and percentages.

Figure 1. Participant flow diagram. SMART4MD: Support, Monitoring and Reminder Technology for Mild Dementia; TV-AssistDem: TV-based ASSistive Integrated Service to supporT European adults living with mild DEMentia or mild cognitive impairment.



The change in means in the main outcome (cognition) and in the secondary outcomes (quality of life, perceived health status, and depression) were analyzed with respect to the last assessment of the RCTs (SMART4MD and TV-AssistDem) using the repeated measure *t* test or the nonparametric Wilcoxon test, if appropriate (considering significant values of α<.05). In the secondary outcomes, we applied Bonferroni correction for 3 comparisons (considering significant values of α<.017).

For the analysis of groups based on living arrangements (living alone vs living with others), the *t* test was used for continuous variables and the chi-square test for categorical variables. To evaluate the association of this variable with mental health outcomes, multivariate logistic regression for binary variables or linear regression for continuous variables was performed to adjust for confounders: age, sex, and technophilia. In addition, we explored the association between a change in living arrangements during the pandemic and cognition, depression, quality of life, and perceived health status with univariate and multivariate linear regression (adjusting for the following confounders: sex, age, and current living arrangements). For this comparison, we applied Bonferroni correction for 4 comparisons (considering significant values of α<.013).

For the analysis using groups based on the score in technophilia (based on the median of the TechPH index as the cut-off point), the *t* test or nonparametric Wilcoxon test was used for continuous variables and the chi-square test for categorical variables. To evaluate the association of this variable with mental health outcomes, multivariate logistic regression for binary variables or linear regression for continuous variables was performed to adjust for confounders: age, sex, and living arrangements.

To establish the Bonferroni correction for multiple comparisons (regarding living arrangements and technophilia groups), the number of independent tests was estimated with principal component analysis. Of the 37 variables analyzed, the first 35 components explained >99% (99.3%) of the variance. Thus, we considered the values significant with α<.0014.

To analyze the assumptions of all linear regression models, the Ramsey RESET linearity test, the Breusch-Pagan homoscedasticity test, and the Shapiro-Wilk normality test of the model residuals were used (see Annex 2 in Multimedia Appendix 1). When cognition, quality of life, health status, and depression were used as dependent variables, the assumption of the normality of the residuals of the model was not fulfilled, and transformation did not solve the problem, robust linear regression models were used (using the *robustbase* package and the *lmrob* function in R).

The R version 4.0.4 program was used for all statistical analysis [41].

Results

Participants

Of the 210 potential respondents (n=111 [52.9%] from SMART4MD and n=99 [47.1%] from TV-AssistDem), a total of 165 (78.6%) of 210 respondents was successfully reached, of which 151 (91.5%) agreed to participate (Figure 1). In addition, 150 (99.3%) participants completed the full interview without assistance, and 15 informal caregivers were interviewed on behalf of participants whose abilities to answer such a long interview were compromised. Of these 15 participants, 11 (73%) answered the main variables questionnaires and 4 (27%) were unable to do so. Given the complexity of MCI/MD, to not skew

the results of patients with a greater decline, all data were considered.

The mean time between the last assessment of the RCTs (T0) and the interview during the lockdown (T1) was 199.33 days (SD 52.43, range 67-395), and the mean duration of the calls was 50.14 minutes (SD 16.40).

Sociodemographics

The mean age of the sample was 74.31 years (SD 6.48), 97 (64.2%) of 151 participants were women, 36 (23.8%) lived alone, and 80 (53.3%) had high attraction to technology (high technophilia). The COVID-19 outbreak forced 22 (14.6%) of 151 participants to change their living arrangements (Table 1).

Table 1. Sample sociodemographic characteristics and differences between living alone and living with others, and high technophilia and low technophilia.

Characteristics	Total participants (N=151)	Living alone (n=36)	Living with others (n=115)	Statistics	*P* value	High technophilia (n=80)	Low technophilia (n=65)	Statistics	*P* value

Differences in Cognition, Quality of Life, Perceived Health Status, and Depression Prior to and During the COVID-19 Outbreak

Regarding the differences between the period before and during the outbreak, there were no differences in the main outcome: cognition. After correction for multiple comparisons, there were no statistically significant differences in the quality of life, perceived health status, or depression between the 2 periods (Table 2).

Table 2. Differences in cognition, quality of life, perceived health status, and depression prior to and during the COVID-19 outbreak.

Outcomes	Before the COVID-19 outbreak	During the COVID-19 outbreak	Statistics	*P* value
Main outcome				
Cognition (MMSE[a]), median (IQR)	19 (17-20)	19 (17-21)	Z=–0.798	.43
Secondary outcomes[b]				
QoL-AD[c], mean (SD)	35.97 (4.74)	36.25 (5.44)	t_{144}=–0.80	.43
Perceived health status (EuroQoL-5D-3L[d] thermometer), median (IQR)	70 (50-80)	70 (60-85)	Z=–1.94	.05
Depression (GDS[e]), median (IQR)	3 (1-5)	2 (1-4)	Z=–0.01	.99

[e]GDS: Geriatric Depression Scale.

Differences Between Individuals Living Alone and Living With Others, and With Change in Living Arrangements

Regarding social isolation (living alone and living with others), after Bonferroni correction, there was no significant association between the variables of the study (Table 3). Some factors reached nominally significance: self-perceived fear (being alone 36.1% vs 18.4%; χ^2=4.27; *P*=.04) and depression (being alone 3 vs 2; Z=–2.10; *P*=.04). In the multivariate models, depression did not reach nominally statistically significance (B=0.83; *P*=.06); see Table 3 (note: significant results with *P*<0.001). After Bonferroni correction, there were statistically significant differences regarding home visits, with those living alone (being alone 82.9% vs 51.3%; χ^2=10.97; *P*<.001) receiving more visits than those living with others. There was no significant

association regarding other variables (only a nominal significant association regarding the more frequent use of the newspaper in those living with others).

The change in living arrangements was not associated with cognition (unadjusted model: B=–0.21, *P*=.65; adjusted model: B=0.36, *P*=.44), quality of life (unadjusted model: B=–0.74, *P*=.40; adjusted model: B=1.05, *P*=.21), perceived health status (unadjusted model: B=3.34, *P*=.41; adjusted model: B=3.34, *P*=.41), or depression (unadjusted model: B=–0.15, *P*=.74; adjusted model: B=–0.25, *P*=.56). After correction for multiple comparisons, there was no association with less perceived stress (unadjusted model: B=–4.72, *P*=.01; adjusted model: B=–0.26, *P*=.02) but the results reached nominal significance. Annex 2 in Multimedia Appendix 1 shows more detailed information about linear regression models.

Table 3. Health perception-management, coping-stress tolerance, and sleep-rest functional health patterns during the COVID-19 outbreak and differences between living alone and with others.

[i]As the residuals of the model were not normal, we transformed the dependent variable in its logarithmic form.

Differences Between High- and Low-Technophilia Groups

After correction for multiple comparisons, there was no significant association between technophilia and the variables of the study. Only some variables reached nominal significant associations: self-perceived boredom (high technophilia 10.1% vs 27.7%; χ^2=7.44; *P*=.01), calmness (high technophilia 31.6% vs 52.3%; χ^2=6.30; *P*=.01), perceived stress (high technophilia 18.1 vs 21.23; *t*=2.19; *P*=.03), depression (high technophilia 2 vs 3; *Z*=2.16; *P*=.03), and quality of life (high technophilia 37.3

vs 35.3; t=2.24; P=.03). In the multivariate models, after controlling for possible confounders, the associations only maintained nominally statistical significance and the perceived health status reached nominal significance (B=6.44, P=.04); see Table 4 (note: significant results with P<.001).

Table 4. Health perception-management, coping-stress tolerance, and sleep-rest functional health patterns during the COVID-19 outbreak and differences between the high- and low-technophilia groups.

Health Care and Social Support Services Access and Utilization and Informative-Related Uses of ICTs During the COVID-19 Outbreak

Of 148 participants, 39 (26.4%) reported accessing extreme and 32 (21.6%) reported accessing too much COVID-19 information. The most frequent ICT used to access COVID-19 information was mainly the television (134/147, 91.2%), and most participants were also informed through family and friends (120/148, 81.1%). Furthermore, only 46 (30.7%) of 150 participants did not contact health or social services (Table 5; note: significant results with $P<.001$).

Table 5. Health care and social support service access and utilization and informative-related uses of ICTs[a] during the COVID-19 outbreak and differences between living alone and with others, and high and low technophilia.

[a]ICT: information and communications technology.

Cognitive-, Entertainment-, and Socialization-related Uses of ICTs During the COVID-19 Outbreak

Although most of the participants (46/151, 30.7%) preferred paper-based memory exercises, the most frequent ICT used for cognition was the television (16/151, 10.7%). The most used ICTs for entertainment were the television (138/151, 92%), followed by the smartphone (60/151, 40%), and for socialization, the smartphone (75/151, 50.3%). Detailed information is given in Table 6 (note: significant results with $P<.001$).

Table 6. Cognitive-, entertainment-, and socialization-related uses of ICTs[a] during the COVID-19 outbreak and differences between living alone and living with others, and high and low technophilia.

[a]ICT: information and communications technology.

Discussion

Principal Findings

This cohort study was conducted to understand the impact of restrictive measures in community-dwelling older adults with MCI and MD during the first COVID-19 outbreak.

Our findings show that the first months of the outbreak did not significantly impact the cognition, quality of life, perceived health status, and depression of our study population when making comparisons with baseline assessments prior to the outbreak. Change in living arrangements had no influence on these variables either. Living alone and technophilia were not associated with mental health–related variables after correction for multiple comparisons. However, being alone was nominally associated with self-perceived fear and depression, and higher technophilia with better quality of life, less boredom, perceived stress, and depression but also less calmness. Overall, health care and social support service access and utilization were high. The most used ICTs during the COVID-19 outbreak were the television for informative-, cognitive-, and entertainment-related uses and the smartphone for socialization.

Comparison With Prior Work

To the best of our knowledge, few studies have addressed the consequences of the COVID-19 outbreak on the cognition of the elderly, and the use of technologies during this ongoing societal change.

Several studies have shown that quarantine measures have changed the behaviors and lifestyle of older people with cognitive decline [42], although in some cases, these changes have been less important than expected [43]. Lifestyle changes can increase the risk of dementia and cause cognitive impairment. However, our study showed that in our sample, the first stages of the COVID-19 outbreak did not cause significant cognitive decline in comparison with a previous assessment. This result could be explained by 2 reasons. On the one hand, the evaluation was carried out on an average of 70 days after the start of the home confinement restrictions and, likely, this time was not enough to influence cognitive decline. On the other hand, the data of our study show that most of the participants maintained an active lifestyle and used new technologies for cognitive stimulation, information access, leisure, and social connectedness. This combination of healthy lifestyle factors and opportunities for cognitive and social stimulation has proved to be important in reducing the risk of cognitive decline [44].

Regarding the lack of differences in the quality of life and perceived health status before and during the outbreak in people with MCI/MD, a similar conclusion was reached by another cohort study in a similar population in Spain using the EuroQoL-5D-3L [45]. Other studies on quality of life in different population groups during the pandemic have also not found a perception of poor quality of life in the elderly [46]. Our results could be explained because our sample has continued to carry out cognitive, entertainment, and social activities, which are associated with the definition of a good quality of life by

the elderly [47]. Another factor that can lead to a good quality of life is maintaining well-being and good sleep quality. Poor sleep quality is known to have a significant impact on lower levels of life satisfaction and mood [48].

Regarding mental health, longitudinal studies have established that it is has been affected by the pandemic [49-51], but frequently, the impact has been higher in the younger population and those more economically vulnerable [51,52]. Likewise, another longitudinal study in Spain with a sample of older adults with dementia or cognitive impairment found an increase in depressive and anxious symptoms after the confinement [53]. Furthermore, attention has been drawn to the possible harmful effects of the excessively dramatic presentation of the consequences of the restrictions due to the pandemic, which are based mainly on survey studies, in many cases carried out without the required rigor [54]. However, the results are mixed, and, for example, some longitudinal studies in Spain [55] and Greece [56] did not find differences regarding depression when comparing the period before and after confinement, and another Dutch community study did not find an increase in depressive symptoms in the general population [57]. In a cross-sectional study comparing populations over and under the age of 60 years during the peak of the COVID-19 pandemic in Spain, the elderly did not demonstrate special vulnerability to acute stress and no sex differences were found. This study hypothesized a greater resilience in the elderly due to the economic and social difficulties experienced throughout their lives during the Spanish post–Civil War period (1939-1960), increasing their ability to cope with stress and face the pandemic resiliently [52]. The results of this study in which no differences were found in depressive symptoms could also be explained by the specific characteristics of the study sample, which present MCI and mainly maintain autonomy to live independently. In addition, the evaluations were conducted when the stricter measures of the first lockdown in Spain were being brought down. Moreover, the small incidence of the COVID-19 virus at the time of assessment could have influenced the results (infections less than 1%). These results show the complexity of the effects of the pandemic, highlighting the need for more longitudinal studies in different populations to evaluate the effects of the social restrictions and the pandemic.

Another factor to consider was whether living alone during COVID-19 confinement was associated with a higher prevalence of depression. Although several studies have found a significant association between depression and living alone during the pandemic [42,58], others have shown otherwise [59,60]. Our results are in line with the second ones, showing no significant differences in GDS scores. However, more studies are necessary to determine whether living alone is a risk factor for depression during the pandemic. The results are in line with our previous findings [61] that associated living alone with worse mental health at the beginning of the outbreak (without correcting for multiple comparisons). The way our sample used the ICTs, through online communication, remote social interactions, or video calls, could have been useful to address social isolation during the pandemic [62].

Regarding technophilia, our study did not find an association between a better attitude toward technology and better mental health. In line with these results, a multicenter study conducted in Norway, the United Kingdom, the United States, and Australia also found no change in loneliness and the quality of life in adults over 70 years who used ICTs to maintain social contact during the COVID outbreak [63]. However, we showed in a previous study based on the TV-AssistDem RCT how technology could be useful to maintain cognitive activities [61], and more studies need to clarify whether the evidence supports the recommendations on interventions that may improve the knowledge of ICTs and are related with the use of technology to maintain social connections and cognitive activities [64].

Limitations

A main limitation of this study was changing the interview administration from face-to-face before the outbreak to telephonic during the outbreak. Interviews were performed by the same professionals in both cases to reduce this possible bias, the measures were rescaled accordingly, and the validated phone versions of the tests were used. In addition, the interview had a mean duration of 50.14 minutes, which could cause fatigue in this population and alter their performance.

Another limitation is that the sample came from 2 RCTs and the participants who agreed to participate in the RCTs may have special characteristics that make them not representative of the general population. Furthermore, the sample was from only 1 center in Andalusia. However, it is a larger sample than in other studies carried out in Spain to date with this type of population.

Moreover, 15 caregivers answered on behalf of patients whose ability to answer for themselves was compromised. Although they did not respond to the questionnaires that evaluated the main variables, their answers may have interfered with the results.

The Bonferroni correction for multiple comparisons is conservative and could have increased type II errors.

Some studies have pointed out that the effects of changes during the lockdown may be temporary compared to long-lasting ones. Therefore, future effects will need to be explored as it is possible that once the lockdown is over, many people may not return to their “normal routine” as before the pandemic and will continue to avoid face-to-face activities, especially those regarding social and physical activity due to the fear of the contagion [42].

Conclusions

During the COVID-19 outbreak, governments’ restrictive measures demonstrated being effective in viral spread prevention. Although these restrictions have had negative effects on health and well-being and have changed lifestyles worldwide, our study showed how a presumably vulnerable population has shown more resilience to restrictive measures than expected. The people with MCI/MD did not experience a significant decline in cognition, quality of life, perceived health status, or depression during the period of the COVID-19 outbreak. The study also showed that being alone and a negative attitude toward technology are not associated with worse mental health after correcting for multiple comparisons. In addition, the data were collected over a short period, and further research is needed to explore whether maintaining restrictive measures for longer

influences a worsening of cognitive abilities, quality of life, perceived health status, or depression and which factors increase the risk of poor mental health in this population. They reported overall well-being, maintained sleep quality, and presented moderate perceived stress. This could be related to the fact that our sample continued participating in daily activities, which plays a crucial role in enhancing and maintaining cognition [65,66], just like keeping social interaction. The use of ICTs was essential to carry out these activities during the restrictions. Television was the most widely used ICT for informational-, cognitive-, and entertainment-related uses, and the smartphone for socialization.

Authors' Contributions

The authorship of this manuscript follows the International Committee of Medical Journal Editors standards. EDP, JMGC, AVN, CGSL, FMC, and JGP made substantial contributions to the conception and design of the work; EDP, JMGC, GGP, AVN, EVM, MG, MQ, and PBF acquired the data; JGP analyzed and interpreted the data; and EDP, JMGC, and JGP drafted the work. All authors revised it critically for important intellectual content and gave final approval of the version to be published.

Conflicts of Interest

None declared.

Abstract

Background: The COVID-19 pandemic and the lockdowns for controlling the spread of infection have led to a surge in telehealth adoption by many health care organizations. It is unclear how this pandemic has impacted health professionals' view about telehealth. The analysis of textual data, such as comments posted on a discussion forum, can uncover information that may not be captured by a structured survey.

Objective: This study aims to examine the opinions of health care workers about telehealth services during the time frame of March 2013-December 2020.

Methods: Comments about telehealth posted by health care workers from at least 46 countries were collected from an online discussion forum dedicated to health professionals. The analysis included the computation of sentiment scores from the textual data and the use of structural topic modeling to identify the topics of discussions as well as the factors that may be associated with the prevalence of these topics.

Results: The analysis of the comments revealed positive opinions about the perceived benefits of telehealth services before and during the pandemic, especially the ability to reach patients who cannot come to the health facility for diverse reasons. However, opinions about these benefits were less positive during the pandemic compared to the prepandemic period. Specific issues raised during the pandemic included technical difficulties encountered during telehealth sessions and the inability to perform certain care routines through telehealth platforms. Although comments on the quality of care provided through telehealth were associated with a negative sentiment score overall, the average score was less negative during the pandemic compared to the prepandemic period, signaling a shift in opinion about the quality of telehealth services. In addition, the analysis uncovered obstacles to the adoption of telehealth, including the absence of adequate legal dispositions for telehealth services and issues regarding the payment of these services by health insurance organizations.

Conclusions: Enhancing the adoption of telehealth services beyond the pandemic requires addressing issues related to the quality of care, payment of services, and legal dispositions for delivering these services.

telehealth; telemedicine; COVID-19; pandemic; physical examination; sentiment score; structural topic modeling; opinion; health care worker; social media; discussion

Introduction

Telehealth services have been described by the World Health Organization as having a "great potential to address some of the challenges faced by both developed and developing countries in providing accessible, cost-effective, high-quality health care services" [1]. Multiple efforts have been undertaken across countries to increase the scope and reach of these services. Although the rate of adoption of telehealth by health care

organizations in the United States has been steadily increasing, the percentage of hospitals using telehealth services is still relatively low [2,3]. Only 15% of physicians in the United States worked in health practices that used telehealth services in 2016 [3].

The COVID-19 pandemic and the lockdowns mandated by public authorities to reduce the spread of infection have led to a renewed interest from health care organizations in adopting telehealth platforms for some of their routine patient care operations. Event system theory posits that organizations are dynamic entities that can respond to events that are novel, critical (ie, the extent to which the event is deemed significant for the organization), and disruptive by altering their routine practices so that they can adapt to these events [4]. These unexpected events, because of their novel nature, usually find the organizations ill-prepared, causing the interruption of day-to-day operations and requiring changes to existing practices or the adoption of new ones [5]. Hence, it is not surprising that health care organizations have turned to telehealth services to accommodate the disruptions in patient care operations that were caused by the pandemic. Telehealth services allow long-distance patient care through telecommunication channels and thus do not require that patients and health care workers involved in the care process be physically in the same room. This feature made telehealth useful for adapting to the mandated lockdowns and the safe physical distancing measures advocated during the pandemic.

However, the successful implementation of changes in processes requires the adherence of organizational members. An unexpected event disrupts not only the routines of organizations but also the automatic cognitive processing employees use to perform their tasks [6]. Automatic cognitive processing, also called automatic information processing, is built through "repetitive training on the same task" and allows performing job-related tasks relatively swiftly and efficiently with reduced cognitive effort [7]. For instance, clinicians who have conducted physical examinations of hundreds or thousands of patients have developed heuristics and routinized practices for arriving at a diagnosis after detecting specific lung or heart sounds during auscultation. The disruption in automatic cognitive processing and the need to acquire new skills proper for the new circumstances created by a disruptive event impose undue burden on the employees and can lead to occupational stress and job dissatisfaction. However, the adoption of new practices can also be positively perceived and considered the rightful way for navigating the challenges created by the disruptive event.

The objective of this research is to examine the opinions of health care workers about telehealth services expressed before and during the COVID-19 pandemic. Comparing comments posted during the 2 time frames will illustrate the influence of the pandemic on the viewpoints of these health care workers on telehealth. The analysis of these opinions can shed light on the obstacles encountered by health care professionals using these services and help identify solutions to promote the adoption of these services.

Methods

Definition of Telehealth

The definitions of telehealth and telemedicine often vary across authors. In this manuscript, *telehealth* is defined as the umbrella term for a set of activities and services performed by health care professionals through telecommunication technologies to "support and promote long-distance clinical health care, patient and professional health-related education, public health and health administration" [8]. Hence, telehealth includes collaboration among health care workers discussing and sharing patients' information through telecommunication channels, data collection and remote monitoring of patients' health outcomes through digital wearables, and electronic transmission of prescriptions to pharmacists (e-prescribing). *Telemedicine*, a subset of telehealth, is strictly defined as the diagnosis and treatment of patients through telecommunication technologies. Nevertheless, the term *telehealth* will be used throughout the manuscript, except when analyzing or quoting health care workers' comments, to encompass all health care operations performed through telecommunication technologies.

Data Collection

The comments were collected from Medscape, an online platform that provides health care–related news to health professionals and hosts forums on health-related issues. According to the web analytics company similarweb, the online platform Medscape had more than 21 million visits per month during the summer and fall seasons of the year 2020. Most of the visits were from the United States (53%). The list of countries of the platform visitors included the United Kingdom (4%), Australia (4%), Canada (4%), India (3%), the Philippines (2%), and Brazil (2%). The keywords used to search for the comments were *telemedicine*, *telehealth*, *televisit*, *virtual visit*, *online visit*, and *video visit*. Available data on the characteristics of the commenters were collected as well, including the country of residence, occupation, and medical specialty when the commenter was a physician. Since the comments posted on the platform are publicly available and can be accessed by anyone, the institutional review board of the University of Oklahoma, USA, determined that this investigation did not require ethics committee approval.

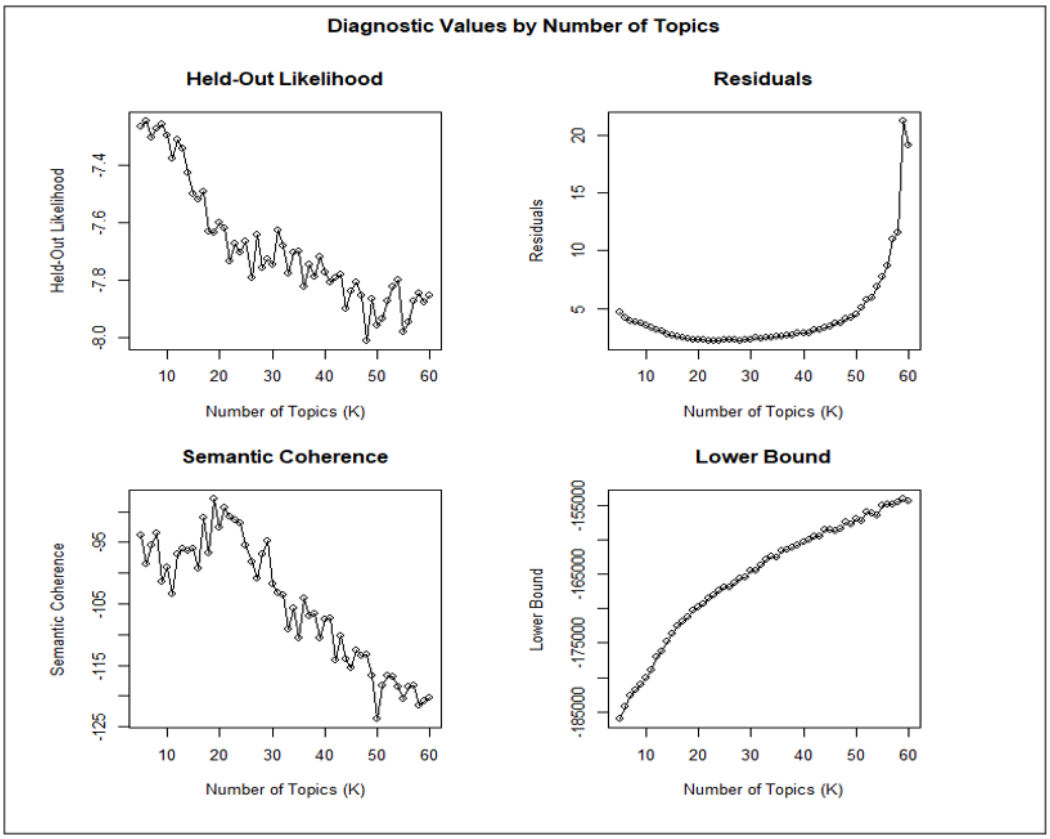
Data Analysis

The sentiment scores of the collected comments were computed using the R package *sentiment*, which considers valence shifters (eg, happy vs not happy) and (de-)amplifying words (eg, very worried vs slightly worried) [9]. A mixed-effect model with random intercepts was fitted to assess the association between sentiment scores and the following independent variables: residence of the commenter (US vs non-US), occupation (physician, nurse, health administrator, other) of the commenter, and the year in which the comment was made. The restricted maximum likelihood method was used to estimate the model parameters, and the covariance pattern of the model was set to unstructured.

Examining the prevalence of discussion topics across time frames and commenters' characteristics can shed light on the

opinions or concerns about telehealth that are specific to these time frames and these individual characteristics. Structural topic modeling (STM) was used to identify the topics discussed in the comments. STM allows the analyst to incorporate information about the characteristics (metadata) and content of the documents into the modeling process [10]. The following metadata were used as independent variables to estimate the topic prevalence in the comments: the residence (US vs non-US) and occupation (physician, nurse, health administrator, other) of the commenter, the time frame in which the comment was posted (before vs during the pandemic), and the average sentiment score of the comment. The date of March 11, 2020, the day the World Health Organization declared the COVID-19 outbreak a pandemic, was used as the cut-off date for defining the time period [11]. First, the texts of the comments were processed by removing stop words using the System for the Mechanical Analysis and Retrieval of Text (SMART) stop word list. Then, nouns in plural were converted to their singular forms. No stemming was performed. The appropriate number of topics for the corpus of comments was determined to be between 10 and 25 by examining the values for the held-out likelihood, semantic coherence, residuals, and lower bound [12]. See Figure 1. The appropriate number of topics to extract was determined by selecting the model that yielded both the highest semantic coherence and the highest exclusivity values. The number of topics found to have optimal exclusivity was 13, and thus, 13 topics were selected for modeling. Spectral initialization was used for the topic modeling, which converged after 500 iterations, and 4 single-word comments were dropped during the modeling process. The final model consisted of 13 topics, 910 documents, and a 3252-word dictionary. The correlations among the identified topics were computed with the maximum a posteriori estimates of the topic proportions. A threshold of r=0.15 for the correlation was set to determine whether 2 topics were correlated; that is, 2 topics were considered uncorrelated if their pairwise correlation was less than 0.15. STM was performed using the R package *stm* [12].

Figure 1. Diagnostic values by number of topics.



Results

Characteristics of Health Care Workers

A total of 914 comments made by 705 health care workers were collected from the forums. The dates of the comments spanned from the year 2013 through 2020, and the commenters were from at least 46 countries in 6 continents (Africa, Asia, Australia, Europe, North America, and South America). The majority of commenters were physicians (n=468, 66.4%) and lived in the United States (n=561, 79.6%). The characteristics of the 705 health care workers are presented in Table 1. Of the 914 comments, 583 (63.8%) were posted from the year 2013 up to the day the COVID-19 outbreak was declared a pandemic by the World Health Organization on March 11, 2020, and 331 (36.2%) were posted during the pandemic (ie, mid-March 2020-December 2020). The lengths of the comments ranged from 1 word to 630 words (mean=81.9, median=60.5, SD 80.4).

Table 1. Characteristics of health care workers who commented on telehealth.

Characteristics	Individuals' frequency, n (%)
Region (N=705)	
Northern America	561 (79.6)
Asia	37 (5.2)
Europe	23 (3.3)
Africa	19 (2.7)
Central or South America	12 (1.7)
Australia or New Zealand	10 (1.4)
Unknown	43 (6.1)
Occupation/position (N=705)	
Physicians	468 (66.4)
Nurses	89 (12.6)
Health administration professionals	42 (6.0)
Other health occupation	105 (14.9)
Unknown	1 (0.1)
Physicians' medical specialties (N=468)	
Family medicine/general practice	106 (22.7)
Clinical medicine specialties	254 (54.3)
Surgery and surgical specialties	45 (9.6)
Mental health	45 (9.6)
Other specialty	5 (1.1)

Sentiment Scores of Comments

The mixed-effect model with the comment sentiment score as the dependent variable showed that, in general, comments made by health care workers living in the United States were less positive compared to their counterparts residing outside the United States. There were no statistically significant differences in average sentiment scores among occupations (physician, nurse, health administration professional, other) or across years in which comments were posted (2013-2020). Hence, overall, the sentiment scores of comments posted during the pandemic were comparable to those of comments made before the pandemic. See Table 2, Textbox 1, and Figure 2.

Table 2. Fixed-effect estimates of independent variables on sentiment scores of comments about telehealth services.

Independent variable	Coefficient estimate (95% CI)	*P* value
Residence: non-US vs US	0.06 (0.02-0.10)	.003[a]
Occupation: nurse vs physician	0.03 (–0.02-0.08)	.23
Occupation: health administration vs physician	0.03 (–0.04-0.10)	.38
Occupation: other vs physician	0 (–0.05-0.04)	.85

Topics of Discussions

STM identified 13 topics presented in Table 3. The relationships between the prevalence of the identified topics and the characteristics of the comments or commenters are presented in Table 4. There was no correlation among the 13 identified topics, that is, all pairwise correlations among topics were less than 0.15. The 3 most discussed topics were virtual visits (topic 1; 10.2% of comments), which are live encounters between a patient and a health care worker through a telecommunication channel (video, telephone, etc); the potential benefits of telehealth (topic 2; 10%); and criticisms of telehealth (topic 3; 9.4%).

Table 3. Identified topics from comments (N=914) about telehealth made by health care workers.

Topic	Percentage of Topic in Corpus	Top 10 highest-probability words	Quotes
Topic 1: virtual visits	10.2	visit, patient, virtual, office, time, doctor, video, work	• *My physician's office is seeing patients using virtual visits, when possible, through May.* • *Anyone who thinks a virtual office visit provides the same quality of care as an in-person office visit is seriously deluded. Yet, there clearly is a benefit from this technology in terms of accessibility, and I have used it myself to help people who are unable to visit my office because of debility.*
Topic 2: benefits of telehealth	10.0	care, patient, technology, good, provider, great, telemedicine, service	• *Telemedicine is good if a patient unable to go to their doctors because of many reasons.* • *You are missing the point of telemedicine. It is designed to provide quicker service, [lessen the] burden of travel expenses for the patient, and increase the point of access of care to allow observation and improved treatment plan adherence. Overall, if this is done responsibly, more patients are provided better service, [and] compliance recidivism decreases.*
Topic 3: criticisms of telehealth	9.4	telemedicine, patient, exam, physical, care, antibiotic, medicine, physician	• *I would opt for physical examination of the physical body, rather than virtual examination via telemedicine, every time.* • *There are already studies that show that clinicians using telemedicine are more likely to (over)prescribe antibiotics.*
Topic 4: insurance payment for telehealth services	8.8	patient, phone, care, time, pay, make, insurance, practice	• *I've found 90% of cases can be managed over [the] phone or videoconference. If they offer similar reimbursement from insurance, this may be the way to practice in the future.* • *The government allows doctors to practice telemedicine across state lines but won't allow insurance companies to bid and provide across state lines?*
Topic 5: telehealth over the phone	8.0	telehealth, physician, health, work, patient, call, medicine, clinic	• *Vomiting and diarrhea on Saturday morning. Call primary care physician (35-year history as doctor/patient) for prescription. Answering service: "Sorry, can't prescribe by phone. Go to convenient care." "Can't. Too sick." (Silence.) "Hello, telehealth."* • *We do a follow-up telehealth call to reach out to review labs, etc, with the patients about 2 weeks later. Great for our shut-in patients. They are willing to pay the extra fees associated for the convenience of this service.*
Topic 6: legal dispositions for telehealth	7.6	state, medicine, license, practice, board, health care, patient, telemedicine	• *The current system requires that doctors who practice telemedicine need a license in each state where potential telemedicine patients are. Consequently, a telemedicine doctor in Utah [who] treats patients in Wyoming needs both state licenses.* • *Can a physician licensed in a foreign country provide telehealth services to patients in said country while being on US soil?*
Topic 7: practice of medicine in the era of telehealth	7.4	medicine, patient, doctor, clinical, care, practice, physician, service	• *Let the primary physician do the family practice and refer the cases to the respective specialties. Otherwise, patients will become "Amish."* • *The inhibition of the nonavailability of direct physical assessments is the major legal hurdle for legalizing the authority of prescribing medicines to telemedicine physicians. But dear, this needs to be seen as follows: To overcome these inhibitions, a doctor who is competent in subject could assess the complaints, in the absence of physical findings, by virtue of [their] experience in assessing the clinical value of complaints of telepatients, who currently use teleservices for [a] second opinion.*
Topic 8: moving consultations to the patients' home	7.4	people, patient, health care, work, year, home, telemedicine, health	• *Allowing the patient to be seen in the familiar comfort of their home seems to provide a more optimal environment for cooperation.* • *Huge opportunity for technology to improve health care delivery. The fact that 90% of people have a smartphone opens up endless possibilities to improve how we interact with and support patients. Despite the long-standing emphasis on traditional office visits, the effectiveness of these encounters is not reassuring.*

Topic	Percentage of Topic in Corpus	Top 10 highest-probability words	Quotes
Topic 9: impact on patient-physician relationship	7.1	physician, patient, primary care, relationship, medicine, system, health care, doctor	• *This certainly creates distance between the patient and physician, decreasing the interpersonal relationship and the comfort of human touch, which is tremendously important in [a] bedside manner.* • *Believe it or not, there is no perfect technology that will replace the personal relationship of a doctor with the patient.*
Topic 10: physical examination in the era of telehealth	6.4	patient, exam, care, hand, medicine, system, test, doctor	• *The basic tenet of medicine is laying your hands on the patient and examining what's wrong. Telemedicine is junk medicine except for maybe psychiatric consultations. It will drive up costs gradually, with doctors ordering unnecessary diagnostic tests and reviewing results online and treating results instead of the patient. Instead of unifying care and the concept of a medical home, it will splinter care.* • *In-office visits will soon become archaic remnants of a past rooted in blindly following the old ways. Why would a patient be subject to the time, inconvenience, and danger by subjecting themselves to an in-office visit? And likewise, why would the health care system subject itself to the expense of maintaining staff and facilities necessary for in-office visits? Use of facilities should be restricted to hands-on procedures and assessments only or those requiring specialized equipment.*
Topic 11: impact of telehealth on care quality	6.2	doctor, patient, time, medicine, bad, family, day, registered nurse (RN)	• *The issue of bad medicine is rampant; a consumer requests something, and the prescribing doctor writes for it to make them happy. Telemedicine just makes this problem worse.* • *Medical boards will become involved in it at some point when a bad outcome occurs and family members get upset over that bad outcome. There will have to be some sort of informed consent that the patient will have to accept the risks of no physical assessment and perhaps an incorrect diagnosis.*
Topic 12: issues related to telehealth patient appointment and follow-up	5.9	patient, phone, call, appointment, follow, issue, physician, telemedicine	• *It is also burdensome to contact any health care provider via a telephone call. So, what are patients and health care providers without access to the necessary technology supposed to do regarding annual follow-up appointments and other medical visits requiring actual physical re-examinations.* • *Physicians should certainly be reimbursed for patient care, including videoconferencing, and follow-up phone calls.*
Topic 13: advantages of telehealth for remote and rural areas	5.6	telemedicine, patient, rural, clinic, medicine, hospital, care, remote	• *Definitely virtual doctors are a boon to remote, rural areas where [a] doctor is a rare commodity.* • *This works great for people living in rural areas, with limited access to health care services.*

Table 4. Coefficient estimates of independent variables across the 13 identified topics.

[a]*P*<.01.

[b]*P*<.05.

The frequently mentioned benefits (topic 2) included the possibility telehealth offers to reach patients who cannot come to the health care facility for some reasons (living with a disability, residing in a remote area, etc), the decrease in the transportation time and cost for the patient, and the improvement in patients' access to care and to medical specialists. Some of these benefits were emphasized during the pandemic:

> *[The] majority of my patients have been so glad that we were able to continue with therapy during the pandemic. Some will be happy to get back to face-to-face therapy, but most have seen no change in the sessions.*

Although the topic on the benefits of telehealth (topic 2) was associated with a positive sentiment score overall, the sentiment score for that topic was less positive during the pandemic compared to its prepandemic value. A deeper examination of the comments revealed that this decrease in the sentiment score may have stemmed from the changes in routine care processes due to pandemic lockdowns and from the technical difficulties encountered by health care workers who had acknowledged the value of telehealth services:

> *Change is difficult, but telehealth works great for the provider as well as the patient.*
>
> *Virtual visits for pediatrics will be quite difficult. Limited virtual consultation may be possible, particularly with visually obvious abnormalities that can be followed visually. I cannot visualize evaluations of children with epilepsy, asthma, autism spectrum, cerebral palsy . . . being done by virtual video visits.*
>
> *Sure, telemedicine during a global pandemic to enable social distancing is to be expected, but it is far from a panacea . . . No one also talks about technological limitations . . . I didn't go into health care to troubleshoot people's internet connections. I'd say 50% of my telemedicine encounters have some sort of technical issue that we spend easily the first 10 minutes dealing with.*

Criticisms of telehealth (topic 3) included the impracticality to perform a physical examination of the patient, which may lead to misdiagnoses, and the overprescription of certain medications by health care providers who used telemedicine (eg, antibiotics).

Health care workers who raised these criticisms opined that telehealth devalues "the art and science" of medicine:

> *Telemedicine makes a mockery of the art of medicine.*
>
> *Say goodbye to the thorough, hands-on assessment and the art of medicine.*

Some commenters argued that the resistance to telehealth from some health care professionals may be due the noninclusion of telehealth services into the curricula of training institutions:

> *The problem with telemedicine is that it flies in the face of how many of us were trained. We were constantly told to examine the patient and pay less attention to labs and radiology.*
>
> *Worst of all, very few have really been trained on telemedicine, and how to handle its limitations and pitfalls.*

Other workers stated that adequate training may help decrease the observed resistance to telehealth services and lead to improved quality of these services:

> *With proper training and some careful forethought, telehealth can be done well for those with serious illness.*
>
> *With appropriate training regarding the manner in which this kind of therapeutic contact is to be carried out, videoconferencing can be a valuable conduit for the delivery of clinical treatment or educational services.*

Other topics raised by commenters included the payment of telehealth services by insurance companies (topic 4; 8.8%) and the legal dispositions necessary for the practice of telehealth (topic 6; 7.6%), especially an interstate medical licence for physicians who practice in the United States. Comments on the lack of proper legal dispositions for telehealth were not specific to health care workers from the United States, however. For instance, a physician from Brazil noted that

> *Here where I am (Brazil), there are a series of legal requirements that still discourage (or scare) a professional using video calls. Psychologists are more advanced on this topic, but doctors are not yet. The COVID-19 pandemic is accelerating the discussion, but there are still many barriers and doubts.*

Virtual visits (topic 1), criticisms of telehealth (topic 3), telehealth services (topic 5), moving consultations to patients' homes (topic 8), and the advantages of telehealth for remote areas (topic 13) were more frequently discussed during the COVID-19 pandemic compared to the prepandemic period. In contrast, the benefits of telehealth (topic 2), the practice of medicine (topic 7), physical examination in the era of telehealth (topic 10), and the impact of telehealth on care quality (topic 11) were less frequently discussed during the pandemic compared to before the pandemic. Compared to their counterparts living in other countries, health care workers in the United States discussed insurance payment of telehealth services (topic 4), the legal dispositions for telehealth (topic 6), and physical examination in the era of telehealth (topic 10) more frequently. Non-US health care workers, instead, discussed the practice of medicine in the era of telehealth (topic 7) more frequently than their US counterparts. In general, criticisms of telehealth (topic 2) were less frequently discussed by nurses and health administrators compared to physicians. However, nurses and health administrators discussed issues related to telehealth patient appointments and follow-ups (topic 12) more than physicians.

Although the topic of the impact of telehealth on care quality (topic 11) was associated with a negative sentiment score overall, the score was less negative during the pandemic compared to the prepandemic period, signaling a shift in opinion. Such shift can be seen in comments such as the following posted during the pandemic:

> *Having previously been against telemedicine, now I see a lot of its positive qualities, specifically for the elderly and for the young, however, too.*
>
> *The telemedicine services were underutilized. The new pandemic shows the importance of telemedicine. The wider use of smartphones is also helpful in this direction.*

However, the adoption of telehealth services by some health care workers may not outlast the pandemic, as illustrated by this statement posted by a physician:

> *The telemedicine visit was important for the first 3 months of the pandemic. However, as soon as we were able to see patients in the office, then that became my preferred method to evaluate patients. I agree that [a] lack of the physical exam was the major reason to encourage in-office visits, even with stable, chronic disease patients.*

Discussion

Principal Findings

The objective of this research was to examine the opinions of health care workers about telehealth services and to explore the impact the COVID-19 pandemic may have had on these opinions. The analysis showed that the COVID-19 pandemic did not significantly alter the opinions about telehealth services expressed by health care workers on the discussion forum of the study. Although some topics were more (eg, topic 1: virtual visits) or less (eg, topic 7: practice of medicine) frequently discussed during the pandemic compared to the prepandemic period, the same issues about telehealth services were raised during both time frames. Furthermore, the topic of telehealth benefits (topic 2) was associated with a less positive sentiment during the pandemic compared to before the pandemic. However, the topic of the quality of care of telehealth services (topic 11) had a higher positive sentiment score during the pandemic compared to the prepandemic time frame. This finding may be reflecting the opinion among some health care workers that telehealth can enhance the quality of care only in unusual situations when an in-person encounter between patient and clinician is not feasible, as was the case during the pandemic.

Differences in Comment Sentiment Scores

The sentiment scores of comments posted by health care professionals living in the United States were less positive than those of opinions expressed by their counterparts living in other countries. The lack of additional information about the characteristics of the commenters (eg, sociodemographics, computer knowledge) did not allow the assessment of whether this association between location of residence and sentiment scores was due to differences in sociodemographics or in the knowledge of information technology (IT) between commenters from the United States and their counterparts from other countries. Indeed, previous studies have reported that the attitude toward technology may differ by age, occupational seniority, and level of training in IT [13,14]. It is worth emphasizing that the general trends in sentiment scores do not necessary reflect sentiments about telehealth per se, as demonstrated by the multiple topics and the associated sentiment scores uncovered by the analysis. Rather, these general trends show the aggregate sentiment of the concerns or expectations elicited by discussions of telehealth.

Discussion Topics Associated With Negative Sentiment Scores

Although the pandemic may have offered the opportunity to some health care workers to change their opinions about telehealth services, criticisms of these services were still relatively prevalent among the commenters during the pandemic. Reports on the drawbacks of telehealth, such as the overprescription of antibiotics in direct-to-consumer (DTC) telehealth visits, were frequently mentioned by health care workers who had an unfavorable opinion of telehealth services [15]. DTC telehealth providers offer virtual consultations with health care workers to customers or patients through applications installed on the IT devices of these patients. Patients enter their symptoms or motives of consultation in the application and are then assigned to a health care worker in the network of the DTC telehealth company. The interaction between the patient and the health professional is entirely virtual, and the latter may prescribe a treatment at the end of the encounter. DTC telehealth has often been associated with reduced care quality [16]. It should be mentioned that other types of telehealth services that involve some degree of clinical or paraclinical examination have yielded good quality care [17-19]. Another disadvantage of telehealth that was frequently mentioned before and during the pandemic was the inability to perform a physical examination. Conducting physical examinations has been reported to be perceived by health care workers as part of their identity [20]. Hence, telehealth platforms that do not offer the possibility to perform a physical examination are perceived to threaten that identity. Statements such as “telemedicine makes a mockery of the art of medicine” can be interpreted through the lens of the perceived threat to this occupational identity. It is worth noting that some solutions exist to address the issue of physical exam during telehealth sessions. These solutions include facilitated virtual visits, which require the patient to be examined in a designated facility (originating site), usually by a health care professional (facilitator), during the virtual visit. Information about the physical exam is then transmitted by the facilitator to the patient health provider participating in this telehealth session. Another solution for addressing the issue of physical examination is the use of diagnostic tools (eg, digital stethoscope) that can transmit data from the physical examination remotely [21].

Promoting the Adoption of Telehealth Services

Researchers have shown that the technology acceptance model [22], which posits that the individuals’ perceptions of the technology’s usefulness and ease of use influence their acceptance of that technology, was an adequate framework for predicting health care professionals’ intention to use telehealth services [23,24]. Hence, promoting the usefulness of telehealth services and implementing systems that are perceived as easy to use can boost the adoption of telehealth by health professionals. In this study, topics related to the ease of use of telehealth included not only its limitation for conducting a physical examination (topic 10) but also the lack of appropriate legal and service reimbursement dispositions for its adoption (topics 4 and 6). Hence, enhancing telehealth adoption requires addressing these barriers to its usage. Topics related to the perceived usefulness of telehealth included discussions of its benefits (topic 2) and the advantages it offers for the care of patients living in remote or rural areas (topic 13). However, the promotion of the usefulness of telehealth will need to address the perceived drawbacks of its adoption, namely its reported or perceived negative impact on the quality of care (topic 11) and the practice of medicine (topic 3).

Serrano and Karahanna [25] proposed that a successful session of a telehealth visit requires 3 ingredients: the ability of the patient to relay the relevant information through the technology, the competence of the clinician in eliciting from the patient the appropriate information needed to perform the clinical service, and the capacity of the technology to transmit and present the relevant information to both the clinician and the patient. Health professionals’ frustrations from telehealth may come from the patients’ lack of knowledge on how to use the technology to convey information relevant to their condition. A physician wrote,

> *I put myself in the place of a patient who only knows Skype and who, from one moment to the next, to talk to his doctor, will need to use a platform he has never seen . . . it must be very embarrassing.*

Hence, educating patients on how to use a telehealth platform should be among the measures implemented to improve the quality of telehealth services. Health care professionals providing telehealth services should be trained as well, not only on how to navigate the technological features of the platform, but also on how to foster a virtual environment that promotes a good patient-clinician relationship that can help obtain relevant clinical information from the patient. As demonstrated by Serrano and Karahanna [25], a clinician task-specific capability (eg, competency in patient history enquiry) can compensate for the limitations of technology in performing certain tasks. In addition, the technology should fit the clinical task to be performed. Many of the criticisms against telehealth from clinicians included the difficulty or impossibility to obtain certain information through the platform. Under the task-technology-fit framework, the platform used for the

telehealth should include features that enhance image or sound quality so that the virtual patient-clinician encounter can be as close as possible to an in-person interaction [25]. Additional technological requirements include a secure and adequate internet connection and easy-to-use software [21]. There are platforms that allow performing a certain number of physical examinations (called provider access software), but their capabilities are still limited [21]. Finally, a technological support team should be available when the system malfunctions.

Factors that may improve health care workers' perceptions about telehealth include involving them in the design and implementation of the organization's telehealth platforms [26], having opinion leaders express their support for these services and making resources and technical support available [27], and training adequately workers in utilizing these services [28].

The absence of adequate legal dispositions and the differences in telehealth service payment policies by health insurance companies, as noted by some commenters, can hamper the adoption of telehealth [29]. Adler-Milstein et al [30] reported that in the United States, the promotion of private payer reimbursement policies for telehealth services enhances telehealth adoption, while the requirement of an out-of-state licensure for telehealth decreases its adoption. Hence, wider structural changes beyond individual health care organizations are needed as well to foster the adoption of telehealth services.

Limitations

The study had some limitations. First, the sample of health care workers who posted their comments on telehealth are not necessarily representative of the population of health care professionals working in the United States or in other countries. In addition, the relatively small number of comments collected may not have been exhaustive enough to identify other prevalent viewpoints about telehealth. Finally, there is no available method for determining the exact number of topics to be extracted from a corpus. Methods available are all approximate and use different criteria for selecting the number of topics to extract. Thus, it is possible that methods different from the ones used in this paper (semantic coherence, held-out likelihood, and exclusivity) may have yielded a different value for the number of topics to be extracted. Despite these limitations, the analysis of the collected comments provided a valuable insight into the opinions of health care workers about telehealth services over a period of 8 years (2013-2020).

Conclusion

The COVID-19 pandemic and the lockdowns mandated by public officials to control the spread of infection have fostered an interest in expanding telehealth services among health care organizations. However, hurdles to the widespread adoption of these services still remain, including some health care workers' resistance to telehealth, insufficient or inadequate legal dispositions for providing these services, and a lack of coverage of these services by insurance companies. Promoting changes in the unfavorable attitude toward telehealth among health care professionals may require the promotion of evidence-based literature that demonstrates high satisfaction of both patients and clinicians about telehealth. Furthermore, including telehealth service training into the curricula of health care professional training institutions can help prepare these workers perform these services.

Abstract

Background: The COVID-19 pandemic has created a pressing need for integrating information from disparate sources in order to assist decision makers. Social media is important in this respect; however, to make sense of the textual information it provides and be able to automate the processing of large amounts of data, natural language processing methods are needed. Social media posts are often noisy, yet they may provide valuable insights regarding the severity and prevalence of the disease in the population. Here, we adopt a triage and diagnosis approach to analyzing social media posts using machine learning techniques for the purpose of disease detection and surveillance. We thus obtain useful prevalence and incidence statistics to identify disease symptoms and their severities, motivated by public health concerns.

Objective: This study aims to develop an end-to-end natural language processing pipeline for triage and diagnosis of COVID-19 from patient-authored social media posts in order to provide researchers and public health practitioners with additional information on the symptoms, severity, and prevalence of the disease rather than to provide an actionable decision at the individual level.

Methods: The text processing pipeline first extracted COVID-19 symptoms and related concepts, such as severity, duration, negations, and body parts, from patients' posts using conditional random fields. An unsupervised rule-based algorithm was then applied to establish relations between concepts in the next step of the pipeline. The extracted concepts and relations were subsequently used to construct 2 different vector representations of each post. These vectors were separately applied to build support vector machine learning models to triage patients into 3 categories and diagnose them for COVID-19.

Results: We reported macro- and microaveraged F_1 scores in the range of 71%-96% and 61%-87%, respectively, for the triage and diagnosis of COVID-19 when the models were trained on human-labeled data. Our experimental results indicated that similar performance can be achieved when the models are trained using predicted labels from concept extraction and rule-based classifiers, thus yielding end-to-end machine learning. In addition, we highlighted important features uncovered by our diagnostic machine learning models and compared them with the most frequent symptoms revealed in another COVID-19 data set. In particular, we found that the most important features are not always the most frequent ones.

Conclusions: Our preliminary results show that it is possible to automatically triage and diagnose patients for COVID-19 from social media natural language narratives, using a machine learning pipeline in order to provide information on the severity and prevalence of the disease for use within health surveillance systems.

Introduction

Overview

During the ongoing coronavirus pandemic, hospitals have been continuously at risk of being overwhelmed by the number of people developing serious illness. People in the United Kingdom were advised to stay at home if they had coronavirus symptoms and to seek assistance through the National Health Service (NHS) helpline if they needed to [1]. Consequently, there is an urgent need to develop novel, practical approaches to assist medical staff. A variety of methods have been recently developed that involve *natural language processing* (NLP) techniques; the concerns of these methods range from the level of the individual (see, for example, [2,3]) up to the population level [4,5].

Herein, we take a diagnostic approach and propose an end-to-end NLP pipeline to automatically triage and diagnose COVID-19 cases from patient-authored medical social media posts. The triage may inform decision makers about the severity of COVID-19, and diagnosis could help in gauging the prevalence of infections in the population. Attempting a clinical diagnosis of influenza, or in our case a diagnosis of COVID-19, purely based on the information provided in a social media post is unlikely to be sufficiently accurate to be actionable at an individual level, since the quality of this information will be typically noisy and incomplete. However, it is not necessary to have actionable diagnoses at the individual level in order to identify interesting patterns at the population level, which may be useful within public health surveillance systems. For example, text messages from the microblogging site Twitter were used to identify influenza outbreaks [6]. In addition, Twitter data in conjunction with a US Centers for Disease Control and Prevention (CDC) data set were used to predict the percentage of influenza-like illness in the US population [7].

One of our key concerns is in the production of a high-quality human-labeled data set on which to build our pipeline. Here, we give a brief overview of our pipeline and how we developed our data set. The first step in the pipeline was attained by developing an annotation application that detects and highlights COVID-19-related symptoms with their severity and duration in a social media post, henceforth collectively termed as *concepts*. During the second step, relations between symptoms and other relevant concepts were also automatically identified and annotated. For example, *breathing hurts* is a symptom, which is related to a body part, the *upper chest area*.

One author manually annotated our data with concepts and relations, allowing us to present posts highlighted with identified concepts and relations to 3 experts, along with several questions, as shown in Figure 1. The first question asked the experts to triage a patient into 1 of the following 3 categories: *Stay at home*, *Send to a GP* (where GP stands for general physician), or *Send to a hospital*. The second question asked to diagnose the likelihood of COVID-19 on a Likert scale of 1-5 [8].

The 3 experts are junior doctors working in the United Kingdom who were redeployed to work on COVID-19 wards during the first wave of the pandemic, between March and July 2020. Their roles involved the diagnosis and management of patients with COVID-19, including patients who were particularly unwell and required either noninvasive or invasive ventilation. There were some training sessions organized for doctors working in COVID-19 wards. However, these were only provided toward the end of the first wave, as there was initially little knowledge of the virus and how to treat it. In the hospital, the doctors followed local protocols, which were adjusted as more experience was gained about the virus.

We also asked the doctors to indicate whether the highlighted text presented is sufficient in reaching their decision in order to understand its usefulness when we incorporate it in the annotation interface. The annotations were found to be sufficient in as many as 85% of the posts, on average, as indicated by the doctors' answers to question 3 in Figure 1.

The posts labeled by the doctors were then used to construct 2 types of predictive machine learning model using *support vector machines* (SVMs) [9,10]; see the Step 4: Triage and Diagnosis subsection in the Methods section. The *triage models* use hierarchical binary classifiers, which consider the risk averseness or tolerance of the doctors when making the diagnosis [11]. The *diagnostic models* first calculate the probability of a patient having COVID-19 from doctors' ratings. The probabilities are then used to construct 3 different decision functions for classifying *COVID* and *NO_COVID* classes; these are detailed in the Problem Setting subsection in the Methods section.

We trained the SVM models in 2 different ways: first with ground-truth annotations and second using predictions from the concept and relation extraction step described before. Predictions obtained from the concept extraction step make use of *conditional random fields* (CRFs) [12]; see the Step 1: Concept Extraction subsection in the Methods section for implementation details. Relations are obtained from these predicted concepts using an unsupervised *rule-based* (RB) classifier [13]; see the Step 2: Relation Extraction subsection in the Methods section.

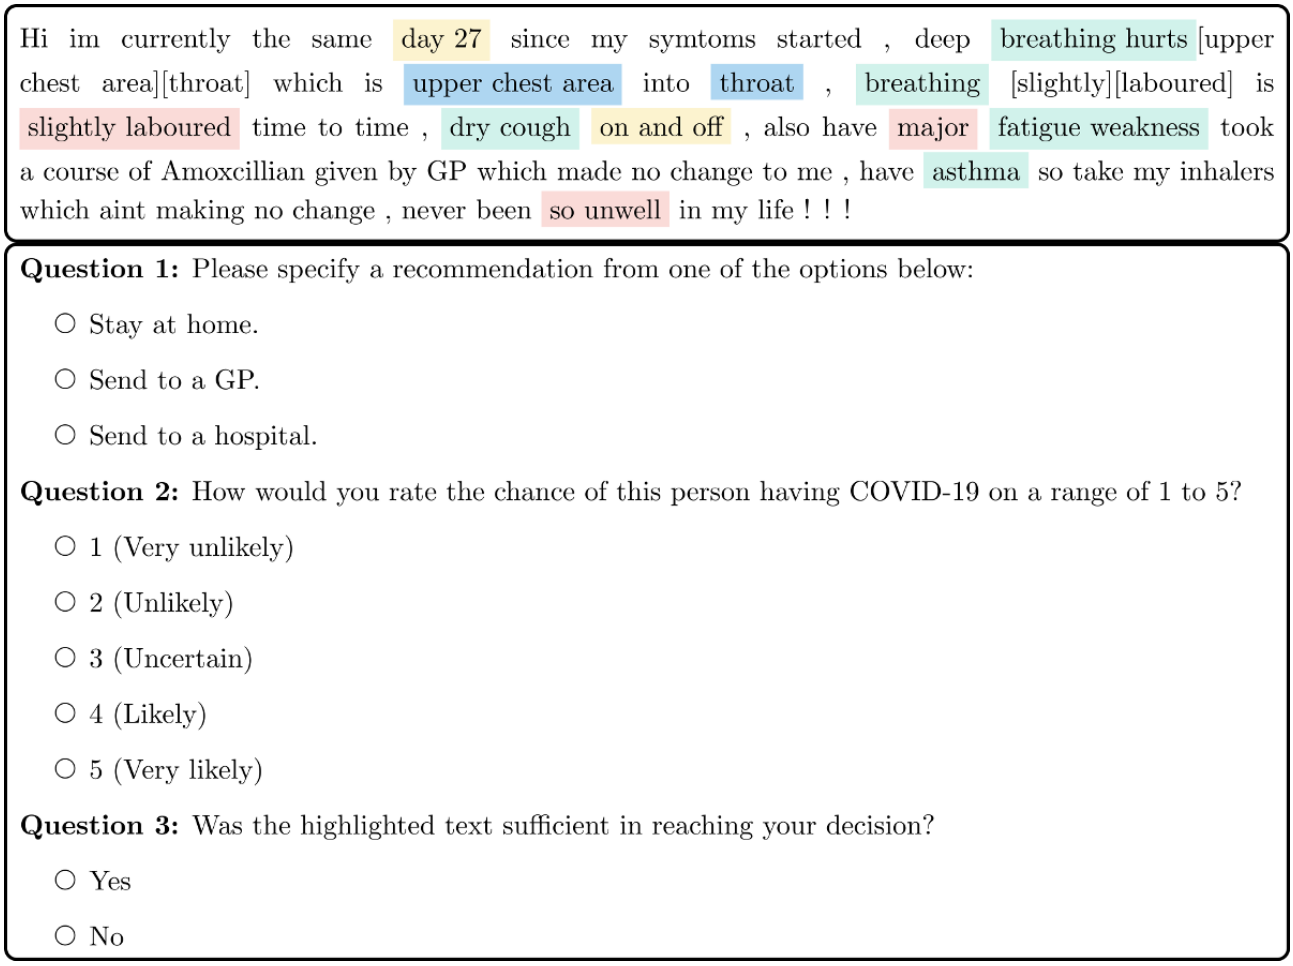
We also discussed the feature importance obtained from the constructed COVID-19 diagnostic models and compared it with the most frequent symptoms from Sarker et al [4] and our data set. We found that symptoms such as anosmia/ageusia (loss of smell/taste) rank in the top 5 most important features, whereas they do not rank in the top 5 most frequent symptoms; see the Discussion section. Overall, we made several contributions as follows:

- We showed that it is possible to take an approach that aims at disease detection to augment public health surveillance systems, by constructing machine learning models to triage and diagnose COVID-19 from patients' natural language narratives. To the best of our knowledge, no other previous

work has attempted to triage or diagnose COVID-19 from social media posts.

- We also built an end-to-end NLP pipeline by making use of automated concept and relation extraction. Our experiments showed that the models built using predictions from concept and relation extraction produce similar results to those built using ground-truth human concept annotation.

Figure 1. A patient-authored social media post is annotated with symptoms (light green), affected body parts (pale blue), duration (light yellow), and severities (pink). The phrases in square brackets show relations between a symptom and a body part/duration/severity when the distance is greater than 1. This annotated post was presented to 3 doctors to triage and diagnose the author of the post by answering questions 1 and 2, respectively. GP: general physician.



Related Work

Data derived from social media have been successfully used to facilitate the detection of influenza epidemics [6,7]. In addition, Edo-Osagie et al [14] provide a thorough review of the use of Twitter in public health surveillance for the purpose of monitoring, detecting, and forecasting influenza-like illnesses. Since the start of the COVID-19 pandemic, a number of mobile application–based, self-reported symptom tools have emerged to track novel symptoms [15]. The mobile application in Menni et al [16] applied logistic regression (LR) to predict the percentage of probable infected cases among the total application users in the United States and United Kingdom combined. Mizrahi et al [17] performed a statistical analysis on primary care electronic health record (EHR) data to find longitudinal dynamics of symptoms prior to and throughout the infection.

At an individual diagnostic level, Zimmerman et al [18] applied classification and regression trees to determine the likelihood of symptom severity of influenza in clinical settings. Moreover, machine learning algorithms, such as decision trees, have shown promising results in detecting COVID-19 from blood test analyses [19]. Here, we focus on features extracted from a textual source to triage and diagnose COVID-19 for the purpose of providing population-level statistics in the context of public health surveillance. Studies related to our work deploy features obtained from online portals, telehealth visits, and structured and unstructured patient/doctor notes from EHRs. In general, COVID-19 clinical prediction models can broadly be categorized into risk, diagnosis, and prognosis models [20].

In Judson et al [21], a portal-based COVID-19 self-triage and self-scheduling tool was used to segment patients into 4 risk categories: emergent, urgent, nonurgent, and self-care, whereas the online telemedicine system in Liu et al [22] used LR to predict low-, moderate-, and high-risk patients by utilizing demographic information, clinical symptoms, blood tests, and computed tomography (CT) scan results.

In Schwab et al [3], various machine learning models were developed to predict patient outcomes from clinical, laboratory,

and demographic features found in EHRs [23]. The authors reported that gradient boosting (XGB), random forests, and SVMs are the best-performing models for predicting COVID-19 test results, hospital admissions, and intensive care unit admissions for positive patients, respectively. A detailed list of clinical and laboratory features can be found in Wang et al [24], where the authors developed predictive models for the inpatient mortality in Wuhan using an ensemble of XGB models. Similarly, in Vaid et al [25], mortality and critical events for patients using XGB classifiers were predicted. Finally, a critical review on various diagnostic and prognostic models of COVID-19 used in clinical settings can be found in Wynants et al [20].

In Wagner et al [26], COVID-19 symptoms from unstructured clinical notes in the EHRs of patients subjected to COVID-19 polymerase chain reaction (PCR) testing were extracted. In addition, COVID-19 SignSym [27] was designed to automatically extract symptoms and related attributes from free text. Furthermore, the study by López-Úbeda et al [28] utilized radiological text reports from lung CT scans to diagnose COVID-19. Similar to our approach, López-Úbeda et al [28] first extracted concepts using a popular medical ontology [29] and then constructed a document representation using word embeddings [30] and concept vectors [28]. However, our methodology differs from theirs with respect to the extraction of relations between concepts, and moreover, our data set, comprising posts obtained from medical social media, is more challenging to work with, since social media posts exhibit greater heterogeneity in language than radiological text reports.

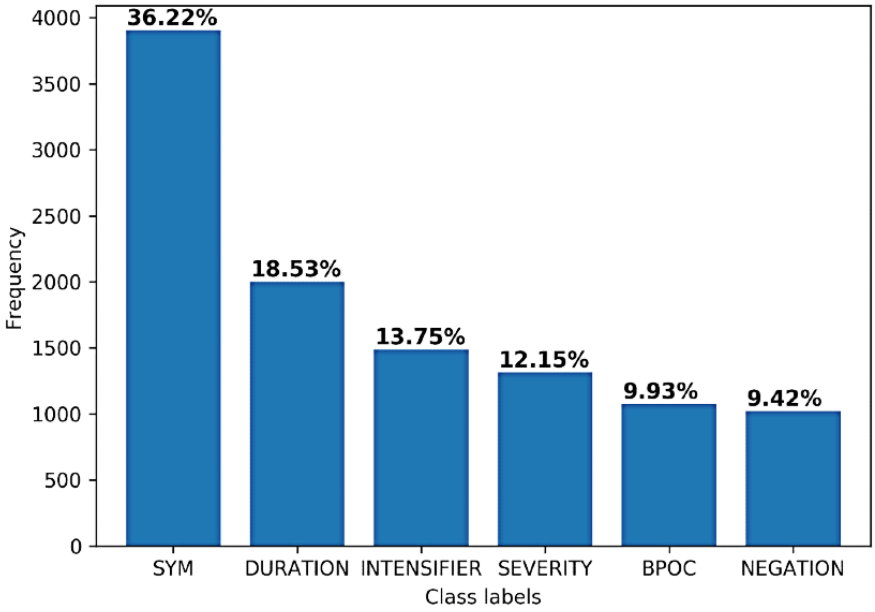
Finally, Sarker et al [4] published a COVID-19 symptom lexicon extracted from Twitter, which we compared our work to in the Discussion section.

Methods

Data

We collected social media posts discussing COVID-19 medical conditions from a forum called *Patient* [31]. This a public forum that was created at the onset of the coronavirus outbreak in the United Kingdom. We obtained permission from the site administrator to scrape publicly available posts dated between April and June 2020. In addition, all user IDs and metadata were removed from the posts for the purpose of the study. After the posts were anonymized, and duplicates were removed, we randomly selected 500 distinct posts. The first author annotated these posts with the classes shown in Figure 2. The class labels represent symptoms and the related concepts: (1) duration; (2) intensifier, which increases the level of symptom severity; (3) severity; (4) negation, which denotes the presence or absence of the symptom or severity; and (5) affected body parts. We also annotated relations between a symptom and other concepts that exist at the sentence level. For example, the relation between a symptom and a severity concept is denoted as *(SYM, SEVERITY)*. The posts were then marked with concepts in different colors, and the relations were placed right after the symptom in square brackets, as shown in Figure 1. Each marked post was presented to the doctors using a web application, and they were asked 3 questions independently; see Figure 1. We called the doctors' answers to questions 1 and 2 as the COVID-19 symptom triage and diagnosis, respectively. Thus, for each post, we had 3 independent answers from 3 doctors, which we denoted as A, B, and C, respectively; these corresponded to the last 3 authors of the paper and were assigned randomly.

Figure 2. Frequency distribution of annotated classes/concepts from the text are shown. We have also shown the percentage of each class after discounting the OTHER labels. The average number of tokens per post was 130.17 (SD 97.83). BPOC: body part, organ, or organ component; SYM: symptoms.



Measurement of Agreement

To measure the agreement between the answers (recommendations and ratings) of the 3 doctors to questions 1 and 2 of Figure 1, we first calculated the proportion of observed agreement (ρ_o), as suggested by de Vet et al [32], who stipulated that Cohen κ is actually a measure of reliability rather than

agreement; we observed that ρ_o was high in all cases, as can be seen in Table 1. We noted that the paradoxical behavior of Cohen κ can arise when the absolute agreement (ρ_o) is high [33]. This may occur when there is a substantial imbalance in the marginal totals of the answers, which we observed in the answers to question 1. Consequently, in addition to Cohen κ, we deployed a common solution to this problem, called the AC1 statistic devised by Gwet and coworkers [34,35].

We found that for question 1, the AC1 measure showed moderate agreement (in the middle of the moderate range) between A and B (0.55) and substantial agreement between A and C (0.72); see Landis and Koch [36] for the benchmark scale for the strength of agreement. For question 2, it turned out that said paradox did not occur, resulting in similar values for κ and AC1. The agreement between A and B (κ=0.64, AC1=0.67) and between B and C (κ=0.64, AC1=0.67) was substantial, while the agreement between A and C (κ=0.40, AC1=0.40) was on the boundary of fair and moderate; see Table 1.

It is important to note that COVID-19 is a novel virus disease, for which the doctors did not have prior experience or training before the first wave of the pandemic, and thus one would expect some difference of opinion. (We bear in mind that in our setting, the doctors can only see the posts and thus cannot interact with the patients as they would in a normal scenario.) Moreover, there are probable differences in risk tolerances between the doctors, which would lead to potentially different decisions and diagnoses.

Table 1. Pairwise agreement between pairs of doctors' answers to questions 1 and 2; see Figure 1 for an example.

Pair	Question 1			Question 2		
	ρ_o	κ	AC1	ρ_o	κ	AC1
AB	0.65	0.26	0.55	0.73	0.64	0.67
BC	0.63	0.14	0.53	0.73	0.64	0.67
AC	0.77	0.28	0.72	0.51	0.40	0.40

Problem Setting

Triage Classification for Question 1

We mapped the doctors' recommendations from question 1 to ordinal values; the options *Stay at home*, *Send to a GP*, or *Send to a hospital* were transformed to the values 1, 2, and 3, respectively. To combine recommendations from 2 or more doctors, we first took their average. This result was rounded to an integer in 1 of 2 ways: either by taking the floor or by taking the ceiling. Considering the risk attitude prevalent among medical practitioners [11], we categorized the ceiling of the average to be *risk averse*, denoted by, for example, AB(R-a), and the floor to be *risk tolerant*, denoted by, for example, AB(R-t). Thus, for each patient's post, we had in total 11 recommendations from 3 doctors for question 1. We constructed a hierarchical classification model for each of these recommendations, where the goal was to classify a post into 1 of the 3 options.

Diagnosis Classification for Question 2

To diagnose whether a patient has COVID-19 from their post, we first estimated the probability of having the disease by normalizing the rating (ie, given a rating, r, the probability of COVID-19, *P*r(COVID|r), which we termed the *ground-truth probability* (GTP), was simply *P*r(COVID|r) = (r – 1)/4.

Given our GTP estimates were discrete, we investigated 3 decision boundaries, denoted by LE, LT, and NEQ, based on a threshold value of 0.5 to classify a post as follows:

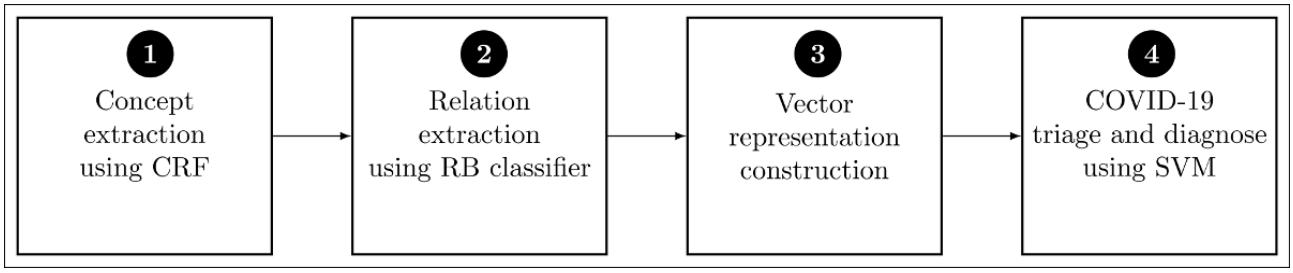
- LE: If Pr(COVID|r)≤0.5, then NO_COVID, else COVID.
- LT: If Pr(COVID|r)<0.5, then NO_COVID, else COVID.
- NEQ: If Pr(COVID|r)<0.5, then NO_COVID, elseif Pr(COVID|r)>0.5, then COVID.

Note that NEQ ignores cases on the 0.5 boundary.

Methodology

A schematic of our methodology to triage and diagnose patients based on their social posts is shown in Figure 3. Here, the circles denote the steps followed in the pipeline. We now detail each of these steps.

Figure 3. A block diagram of the COVID-19 triage-and-diagnosis text processing pipeline. CRF: conditional random field; RB: rule based; SVM: support vector machine.



Step 1: Concept Extraction

In the first step, we preprocessed each patient's post by splitting it into sentences and tokens using General Architecture for Text Engineering (GATE) software's (University of Sheffield) [37] built-in NLP pipeline. For each token in a sentence, we built discrete features that signal whether the token is a member of 1 of the following dictionaries: (1) Symptom, (2) Severity, (3) Duration, (4) Intensifier, and (5) Negation. The dictionaries were built by analyzing the posts while annotating them. We also utilized the MetaMap system [29], assuming that it contains all the necessary technical terms, to map tokens to 3 useful semantic categories: *Sign or Symptom*; *Disease or Syndrome*; and *Body Part, Organ, or Organ Component*. Due to the assumption regarding medical terms, the system does not expect any new additional terms, and thus we were justified in extracting concepts and relations in preprocessing steps. The preprocessed text was then used to build a concept extraction module to recognize the classes, shown in Figure 2, by applying a CRF [12]. A detailed description of our CRF training methodology can be found in Hasan et al [38]. The extracted concepts were then used for our next step to recognize the relations between concepts.

Step 2: Relation Extraction

The semantic relation between a symptom and other concepts, which we formally termed *modifiers*, was resolved using an unsupervised RB classifier algorithm. We first filtered all symptom and modifier pairs from a sentence within a predefined distance and then selected the closest modifier to a symptom to construct a relation. In total, we extracted 5 kinds of relations as follows: *(SYM, SEVERITY)*, *(SYM, DURATION)*, *(SYM, BPOC)*, *(SYM, NEGATION)*, and *(SYM, ?)*—here, SYM and BPOC refer to symptoms, and body part, organ, or organ component, respectively.

The severity modifiers were mapped to a scale of 1-5; the semantic meaning of the scale was *very mild*, *mild*, *moderate*, *severe*, and *very severe*, respectively. The duration modifiers were also mapped to real values in chunks of weeks. So, for example, *10 days* was mapped to the value *1.43*.

Step 3: Vector Representation

Fixed-length vector representations suitable as input for SVM classifiers were built as follows:

- *Symptom-only* vector representation: Let $<S_0, S_1, \ldots, S_n>$ be a vector of symptoms constructed from the symptom vocabulary; for our data set, the number of unique symptom words/phrases was n=871. To construct the vector representation for a post, we extracted the concept, *SYM*, and the relation (*SYM*, *NEGATION*) and set S_i to 1, 0, or –1 according to whether the symptom was present, not present, or negated, respectively.
- *Symptom-modifier relation vector* representation: The symptom-modifier relation vector is a much larger vector than the symptom-only vector and comprises 3 appended vectors containing (1) the absence or presence of 110 unique body parts, (2) the absence or value of a symptom duration, and (3) the absence, negation, or value or a symptom severity.

Step 4: Triage and Diagnosis

We utilized SVM classification and regression models to triage and diagnose patients' posts, respectively, from the vector representations described earlier. For question 1, the recommendation from a doctor or a combination of doctors was the class label of the post; see the Problem setting subsection in the Methods section for a description. To build a binary classifier, we first combined the *Send to a GP* and *Send to a hospital* recommendations to represent a single class, *Send*. The SVM was trained to distinguish between the *Stay at home* and the *Send* options; we called this *SVM classifier 1*. Next, the posts labeled as *Stay at home* were discarded and *SVM classifier 2* was built utilizing the remaining posts to classify the *Send to a GP* and *Send to a hospital* recommendations. This resulted in a hierarchical classifier for COVID-19 triage.

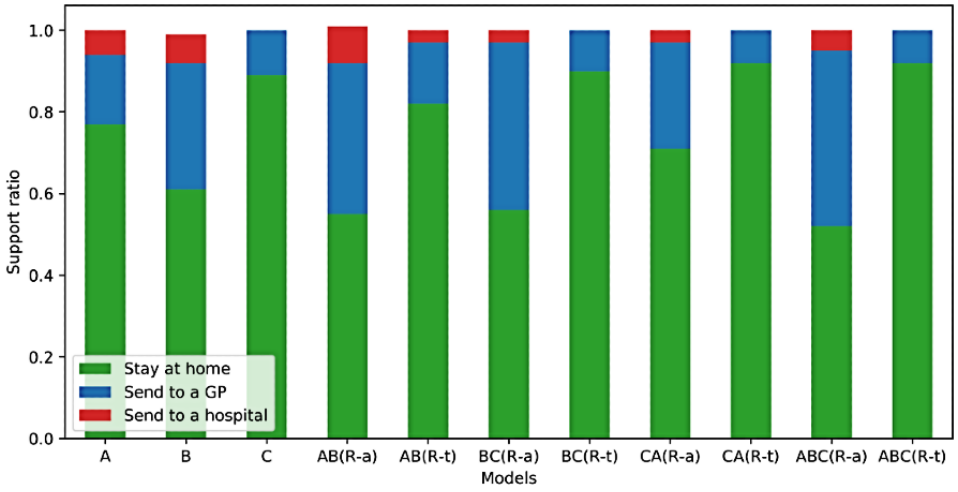
For diagnosing COVID-19 cases, we deployed a variant of the SVM, called *support vector regression* (SVR) [9], to estimate the probability of COVID-19. We used the GTP that was derived from answers to question 2 as the dependent variable. SVR takes as input a high-dimensional feature vector, such as a symptom-only or a symptom-modifier relation vector representation, as described earlier. Classification was performed using the 3 decision functions, LE, LT, and NEQ, described previously.

Results

Evaluation

We evaluated the performance of the CRF and SVM classification algorithms using the standard measures of precision, recall, and macro- and microaveraged F_1 scores [39]. Macroaveraged scores were computed by considering the score independently for each class and then taking the average, while microaveraged scores were computed by considering all the classes together. As our data set was not balanced with *COVID* and *NO_COVID* classes, as can be seen in Figure 4, and we wished to give equal weight to all instances, we reported microaveraged scores for the SVR classification. In contrast, in the case of concept extraction, the *Other* class dominated. So, in this case, we reported the macroaveraged scores for the CRF classification results.

Figure 4. Support ratio of triage classes across models for question 1 classification tasks. Absolute numbers for the "Send to a hospital" class in test sets were as follows: A=10, B=12, AB(R-a)=14, AB(R-t)=5, BC(R-a)=6, AC(R-a)=5, and ABC(R-a)=9; the value for the remaining models was 0. GP: general physician.



Experimental Setup

For the CRF, we reported 3-fold cross-validated macroaveraged results. Specifically, we trained each fold by a Python wrapper [40] for CRFsuite; see Okazaki [41]. For relation extraction, we ran our unsupervised RB algorithm on the 500 posts and calculated the F_1 scores by varying distances considering the 2 cases with and without stop words.

We constructed SVM binary classifiers, SVM classifier 1 and SVM classifier 2, using the Python wrapper for LIBSVM [42] implemented in Sklearn [43] with both linear and Gaussian *radial basis function* (RBF) kernels [10]. Similarly, SVR [44] was implemented using LIBSVM and was built with both linear and RBF kernels. The hyperparameters (C=10 for the penalty, γ=0.01 for the RBF kernel, and ε=0.5 for the threshold) were discovered using a grid search [43].

We simulated 2 cases for COVID-19 triage and diagnosis. First SVM and SVR models were trained with the ground truth to examine the predictive performance when they are deployed as stand-alone applications. Second, when trained with the predictions from the CRF and RB classifier, they resembled an end-to-end NLP application. To obtain a comparable result, the models were always tested with the ground truth. As a measure of performance, we reported macro- and microaveraged F_1 scores for SVM classifiers and SVR, respectively.

Evaluation Outcomes

The concept and relation extraction phases produced excellent and good predictive performances, respectively; see Tables 2 and 3. The triage classification results from question 1 are shown in Tables 4 and 5; the full enumeration can be seen in the first column. When we trained the models with the symptom-modifier vector representations from the ground truth, the results of SVM classifier 1 and SVM classifier 2 were in the range of 72%-93% and 83%-96%, respectively. The symptom-only vector representations produced results in the range of 71%-94% and 79%-95%. These results suggested that we can achieve good predictive performance for classifying *Stay at home* and *Send* and for *Send to a GP* and *Send to a hospital*. In general, risk-tolerant models achieved better performance than risk-averse models. However, since in the test set, posts with the label *Send to a hospital* were missing for some models (as can be seen from Figure 5), we could not report them. We reported macroaveraged F_1 score results since question 1 was framed as a decision problem, where weights for the classes are a priori equal. The results obtained after training with CRF predictions were in similar ranges for both representations and classifiers. This is important, because it indicated that an end-to-end NLP application is likely to produce similar predictive performance.

Regarding question 2, when we trained the models with the symptom-modifier vector representation from the ground truth, the results of COVID-19 diagnosis were in the range of 72%-87%, 61%-76%, and 74%-87% for the LE, LT, and NEQ decision functions, respectively; see Table 6. The symptom-only vector representation produced results in the range of 70%-88%, 59%-79%, and 74%-87% for the LE, LT, and NEQ decision functions, respectively.

In general, NEQ models perform better due to the omission of borderline cases where the GTPs are exactly 0.5. The support ratios for each model for different decision functions are shown in Figure 4. When we trained the models with the symptom-modifier vector representation from the CRF predictions, the results were in the range of 68%-86%, 64%-76%, and 73%-87% for the LE, LT, and NEQ decision functions, respectively. This indicated that for diagnosis as well as triage, an end-to-end NLP application is likely to perform similarly to stand-alone applications. Here, we reported microaveraged F_1 scores since, in our data set, *NO_COVID* cases dominated; this largely resembled the natural distribution in the population, where people who tested positive for coronavirus are a relatively low percentage in the whole population, even when the prevalence of the virus is high.

Finally, we trained our models using a linear kernel but found that the RBF dominates in most of the cases; however, linear kernels are useful in finding feature importance [45].

Discussion

Principal Findings

This study demonstrates the potential to triage and diagnose COVID-19 patients from their social media posts. We presented a proof-of-concept system to predict a patient's health state by building machine learning models from their narrative. The models were trained in 2 ways: using (1) ground-truth labels and (2) predictions obtained from the NLP pipeline. Trained models are always tested on ground-truth labels. We obtained good performances in both cases, which indicates that an automated NLP pipeline could be used to triage and diagnose patients from their narrative; see the Evaluation Outcomes subsection in the Results section. In general, health professionals and researchers could deploys triage models to determine the severity of COVID-19 cases in the population and diagnostic models to gauge the prevalence of the pandemic.

Comparison With Prior Work

To quantify the important predictive features in the training set, we experimented with COVID-19 diagnosis using linear kernel SVR regression. More specifically, we used the symptom-only vector representation constructed from the ground truth. We summed feature weights for each S_i in $<S_0, S_1, \ldots, S_n>$ from the 7 models and the 3 decision functions; see the Methods section. The features were then mapped to the categories found in the Twitter COVID-19 lexicon complied by Sarker et al [4]. The top 5 important features in our data set were *cough*, *anosmia/agusia*, *dyspnea*, *pyrexia*, and *fatigue*. Mizrahi et al [17] quoted 4 of these symptoms as the most prevalent coronavirus symptoms, strongly correlating with our findings.

To compare our importance ranking with that of Sarker et al's [4] frequent categories, we compiled the corresponding frequencies of our 5 most important symptoms. Normalized weights and frequencies were then plotted in Figure 6. The top-left stacked bar chart compares our 5 most important features with Sarker et al's [4] frequencies. Cough was the most important symptom from our data set, where it was the second-most frequent. Anosmia/ageusia ranked second in our importance list, while it was seventh in the most frequent list. Pyrexia came first and fourth in both the frequent and importance lists, respectively.

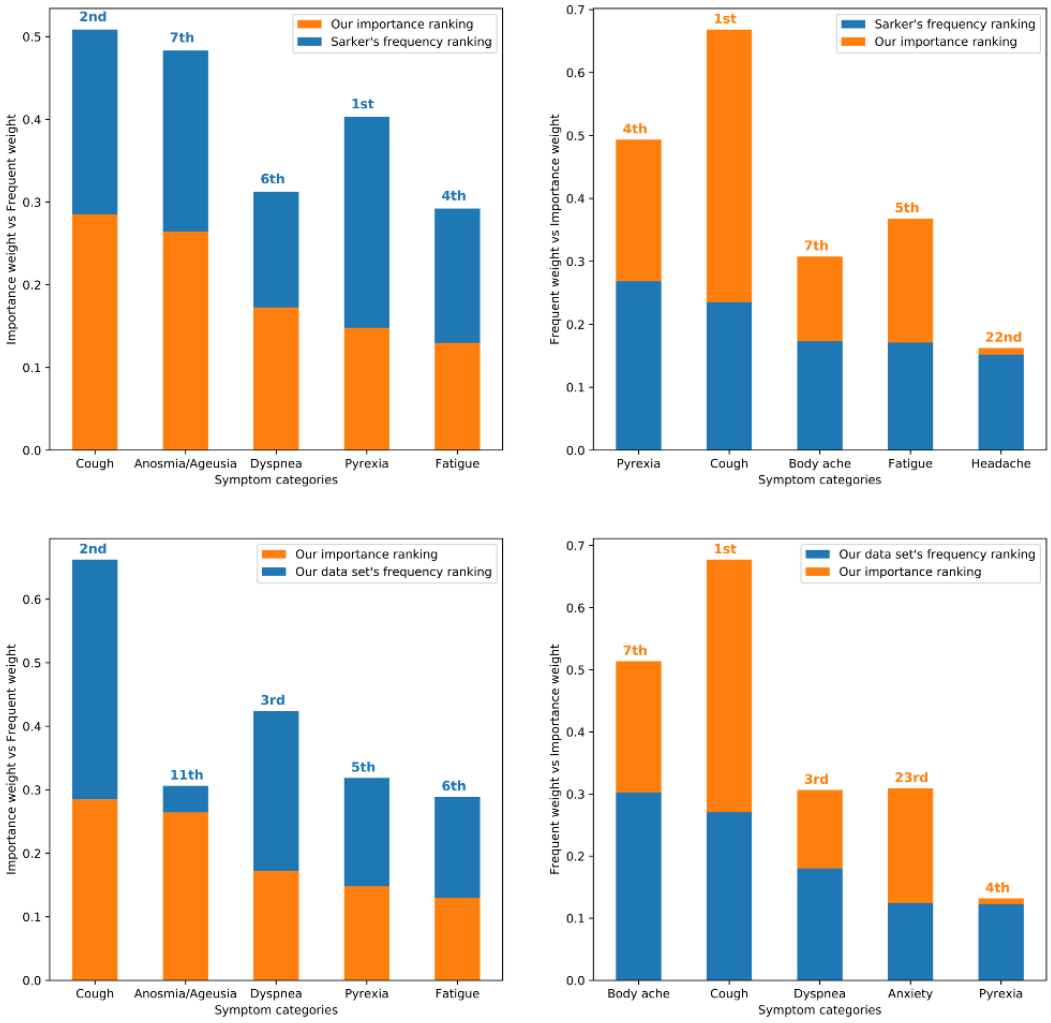
The top-right chart in Figure 6 shows a comparison between Sarker et al's [4] frequency ranking and our importance ranking. Here, we selected the top 5 most frequent symptoms from Sarker et al's [4] frequency list and normalized them. These are *pyrexia*, *cough*, *body ache*, *fatigue*, and *headache*. We took the corresponding importance weights of these symptoms and plotted them in a stacked bar chart. Here, headache ranked 22nd in our importance ranking, while it was 5th in the frequency ranking. We found a large difference between the 2 rankings, implying that the top-most frequent symptoms are not necessarily the most important ones.

Next, we compared our most important feature weights with our data set's frequency ranking using the methods described earlier. From the bottom-left stacked bar chart of Figure 6, we observed that anosmia/ageusia were relatively low in order in

the frequency ranking (ie, 11th). As in Sarker et al's [4] ranking, cough came second in our data set's frequency ranking.

Finally, the bottom-right chart in Figure 6 refers to the comparison between our data set's frequency and importance rankings for the corresponding symptoms. We observed that anxiety ranked 4th in the frequency list, while it was low (ie, 23rd) in the importance ranking.

Figure 6. Feature comparison between our most important features and Sarker et al's [4] most frequent symptoms (top row) and between our most important features and our most frequent symptoms (bottom row). The feature importance rankings are obtained from an SVM linear kernel using the symptom-only vector representation. SVM: support vector machine.



Limitations

It is worth reiterating that social media posts, which are known to be noisy, are not on a par with the consultation that a patient would have with a doctor. We stress that the aim of this study is to extract useful information at a population level, rather than to provide an actionable decision for an individual via social media posts. Our manually annotated data set has 2 main limitations. First, having only 3 experts limited the quality of our labeling, although we deem this study to be a proof of concept. A larger number of experts, including more senior doctors, would be beneficial in a follow-up study. The robustness of our results could be further improved by both increasing the size of our data set and introducing posts from several alternate sources. Given that the posts come from social media, it is not clear whether the results could be used as such in a diagnostic system, without combining them with actual consultations. However, it is worth noting that medical social media, such as the posts we used herein, may uncover novel information regarding COVID-19.

Conclusion

The coronavirus pandemic has drawn a spotlight on the need to develop automated processes to provide additional information to researchers, health professionals, and decision makers. Medical social media comprises a rich resource of timely information that could fit this purpose. We have demonstrated that it is possible to take an approach that aims at the detection of COVID-19 using an automated triage and diagnosis system in order to augment public health surveillance systems, despite the heterogeneous nature of typical social media posts. The outputs from such an approach could be used to indicate the severity and estimate the prevalence of the disease in the population.

Abstract

Background: COVID-19 vaccines are one of the most effective preventive strategies for containing the pandemic. Having a better understanding of the public's conceptions of COVID-19 vaccines may aid in the effort to promptly and thoroughly vaccinate the community. However, because no empirical research has yet fully explored the public's vaccine awareness through sentiment–based topic modeling, little is known about the evolution of public attitude since the rollout of COVID-19 vaccines.

Objective: In this study, we specifically focused on tweets about COVID-19 vaccines (Pfizer, Moderna, AstraZeneca, and Johnson & Johnson) after vaccines became publicly available. We aimed to explore the overall sentiments and topics of tweets about COVID-19 vaccines, as well as how such sentiments and main concerns evolved.

Methods: We collected 1,122,139 tweets related to COVID-19 vaccines from December 14, 2020, to April 30, 2021, using Twitter's application programming interface. We removed retweets and duplicate tweets to avoid data redundancy, which resulted in 857,128 tweets. We then applied sentiment–based topic modeling by using the compound score to determine sentiment polarity and the coherence score to determine the optimal topic number for different sentiment polarity categories. Finally, we calculated the topic distribution to illustrate the topic evolution of main concerns.

Results: Overall, 398,661 (46.51%) were positive, 204,084 (23.81%) were negative, 245,976 (28.70%) were neutral, 6899 (0.80%) were highly positive, and 1508 (0.18%) were highly negative sentiments. The main topics of positive and highly positive tweets were planning for getting vaccination (251,979/405,560, 62.13%), getting vaccination (76,029/405,560, 18.75%), and vaccine information and knowledge (21,127/405,560, 5.21%). The main concerns in negative and highly negative tweets were vaccine hesitancy (115,206/205,592, 56.04%), extreme side effects of the vaccines (19,690/205,592, 9.58%), and vaccine supply and rollout (17,154/205,592, 8.34%). During the study period, negative sentiment trends were stable, while positive sentiments could be easily influenced. Topic heatmap visualization demonstrated how main concerns changed during the current widespread vaccination campaign.

Conclusions: To the best of our knowledge, this is the first study to evaluate public COVID-19 vaccine awareness and awareness trends on social media with automated sentiment–based topic modeling after vaccine rollout. Our results can help policymakers and research communities track public attitudes toward COVID-19 vaccines and help them make decisions to promote the vaccination campaign.

COVID-19; COVID-19 vaccine; sentiment evolution; topic modeling; social media; text mining

Introduction

Background

COVID-19 vaccines are one of the most effective preventive strategies for containing the pandemic and restoring normal life [1]. The outcomes of this strategy highly depend on vaccination coverage, wherein herd immunity requires at least 70% of the population to be immune, depending on how contagious the COVID-19 variant in question is and how effective the vaccine is [2]. However, such a high rate of vaccination cannot be reached without the cooperation of the general public [3-5]. In general, there are a variety of factors that may negatively impact how the public perceives and reacts to these vaccines. Such barriers may stem from conspiracy theories [6], general hesitancy toward vaccines [4], and doubts regarding new mRNA vaccine technologies [7]. Infodemic management, that is, managing information overload, including false or misleading information [8], should be used during the COVID-19 pandemic, by listening to community concerns, preventing the spread of misleading information [9], and examining the human factors contributing to COVID-19 transmission [10]. Thus, to promote vaccine awareness and facilitate vaccine rollout, it is imperative to gain a timely understanding of the public's attitude toward vaccination and develop tailored communication strategies to address their concerns.

Generally, characterizing public vaccine attitudes as part of public health surveillance can be achieved via social media–based text mining or other traditional methodologies, such as conducting surveys or experiments. Social media–based text mining has become increasingly popular because of its effectiveness and efficiency; the major merit of this big data analysis is that it addresses several of the limitations of traditional methodologies, such as the inability to track real-time trends [4,11]. Public health monitoring on social media has proven to be a powerful tool for analyzing public health discussions on a variety of topics, such as pandemics and vaccination [12-24]. Such work has been conducted for the COVID-19 pandemic (Multimedia Appendix 1). However, because of the rapid COVID-19 vaccine rollout, dedicated social media–based sentiment analysis studies on vaccine awareness have just started to emerge [3,22-24]. Some of these studies [3,22] relied on natural language processing techniques to conduct large-scale sentiment analysis about vaccines, while others [23,24] investigated vaccination hesitancy using manual content analysis, but overall, these studies lacked either the capability to automatically track public attitudes (in manual content analysis) or a comprehensive view of both topics and associated sentiments. Furthermore, exploring the public sentiment and concern evolution throughout the current vaccination campaign may allow policymakers to make timely and informed decisions to encourage vaccination.

Study Objectives

We aimed to combine sentiment analysis and topic modeling in order to address the following research questions: What are the general sentiments on COVID-19 vaccines? What are the topics that shape the sentiments? How do concerns (ie, topics with negative sentiments) evolve over time?

Methods

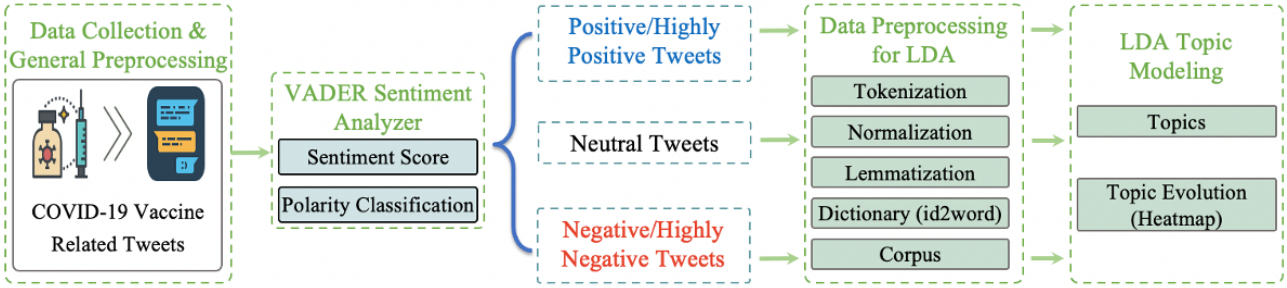
Data Collection

We collected COVID-19 vaccine–related tweets containing a variety of predefined hashtags, including #CovidVaccine, #GetVaccinated, #covid19vaccine, #vaccination, #AstraZeneca, #Johnson & Johnson, #Pfizer and #Moderna, from December 14, 2020 (after the first COVID-19 vaccine in the world was approved) to April 30, 2021. We collected 1,122,139 tweets (Table 1). To avoid data redundancy, we removed retweets and duplicate tweets, and we focused on tweets in English (Figure 1). After data preprocessing, the data set contained 857,128 tweets.

Table 1. Tweet hashtags.

Hashtag	Tweets (N=1,122,139), n
#CovidVaccine	345,537
#GetVaccinated	73,817
#covid19vaccine	130,043
#vaccination	132,327
#AstraZeneca	126,954
#Johnson & Johnson	211,731
#Pfizer	61,979
#Moderna	39,751

Figure 1. Data processing workflow. LDA: latent Dirichlet allocation; VADER: Valence Aware Dictionary for Sentiment Reasoning.



Sentiment Analysis

We used the Valence Aware Dictionary for Sentiment Reasoning (VADER) lexicon for analysis. During preprocessing, we did not remove the hashtag content because it often contained meaningful information such as the brand of the vaccine. VADER is a rule–based sentiment analysis tool that has been proven to perform as well as or even better than other sentiment analysis tools on social media texts in most cases, since it is specifically attuned to sentiments expressed on social media [25]. Generally, VADER produces 4 scores: positive, neutral, negative, and compound scores. Positive, neutral, and negative scores each represent the proportion of words that fall into the given category. The compound score is calculated by summing the valence scores of each word in the lexicon, adjusting the value according to heuristic rules, and normalizing between −1 and +1 [25]. The compound score is a useful metric for measuring the sentiment of each given text in a single dimension.

We classified each tweet into 1 of 5 groups (Table 2), based on compound, positive, and negative score distributions—highly positive (compound score >0.001 and positive sentiment score >0.5), positive (compound score >0.001 and positive sentiment score <0.5), highly negative (compound score <0.001 and negative sentiment score >0.5), and negative (compound score <0.001 and negative sentiment score <0.5), and neutral (if none of the conditions was satisfied).

Table 2. Sentiment polarity examples.

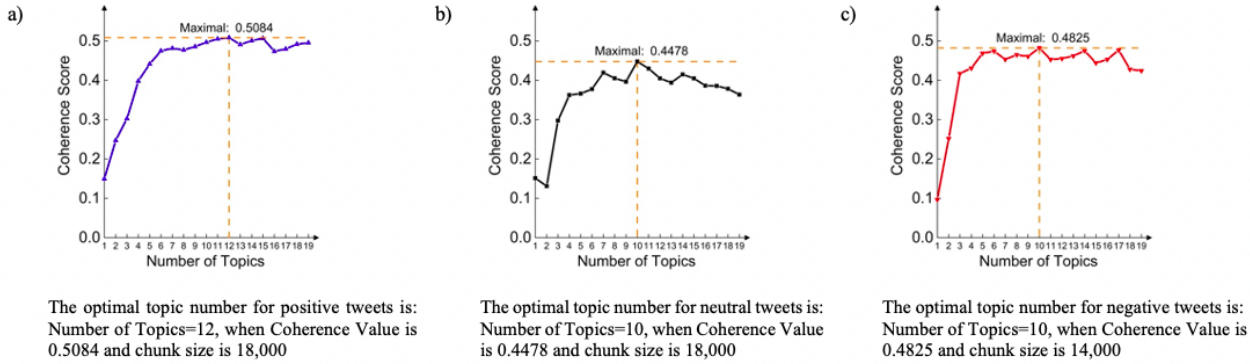
Sentiment polarity	Example
Highly positive	“thank god vaccination vaccinessavelives vaccineswork”
Positive	“it s an exciting day with the arrival of the first coronavirusvaccine it gives me great hope for 2021 covid19vaccine”
Highly negative	“it s fake you re all stupid covidvaccine”
Negative	“how do we know that after 6 9 months there are no adverse effects of the vaccine or that it s ineffective and what s the response if in the event these emergency approvals have larger ramifications any mechanism being put together covid_19 covid19vaccine”
Neutral	“help is on the way 1st doses of covid19vaccine arrived in north carolina initial vaccine supply is limited and will go to a small number of public health and hospital workers at high risk of exposure more doses are on the way but until then practice your 3ws”

Topic Modeling

Latent Dirichlet allocation (LDA), as a popular and well-established approach for topic analysis [26], is a three-level hierarchical Bayesian model that relies on the bag-of-words model [27]. LDA generates a probability distribution for the text corpus; it assumes that each topic can be characterized by a distribution of words. The number of topics is a key parameter of the LDA model. To prevent the misclassification of other topics into vaccine and nonvaccine topics, we removed some vaccine-related keywords, including “vaccine,” “vaccines,” “vaccination,” “covidvaccine,” and “covid.” This data preprocessing decision is also well supported by experimental results, which suggested that up to 96% of tweets were classified into one main topic with less meaningful information without removal of specific words.

To determine the optimal number of topics with favorable model performance, we used a coherence score; however, because the number of samples for highly positive and negative groups were small, we combined positive and highly positive groups (into a positive group) and negative and highly negative groups (into a negative group). Then, we applied topic modeling algorithms on 3 groups: positive, neutral, and negative. We used the topic coherence value to measure the modeling performance. Since the data set was very large, the experiments were run under the server environment with C5 computing type series IV 64-core CPU and 128 GB RAM. Then, based on the performance, we selected the optimal number of topics for each polarity group. The optimal topic numbers for positive, neutral, and negative were 12, 10, and 10, respectively (Figure 2).

Figure 2. Model performance for topic numbers for (a) positive, (b) neutral, and (c) negative tweets.



Results

Sentiment Analysis

Overall, positive sentiment was stronger than negative sentiment (Figure 3 and Figure 4). Notably, there was a sharp decline in the positive score around April 13, 2020 (Figure 3), which appeared to coincide with news released on that date: The US Federal Drug Administration (FDA) and Centers for Disease Control (CDC) called for a pause on the use of the Johnson & Johnson vaccine after discovering "extremely rare" cases of blood clots [28], and the number of tweets about the Johnson & Johnson vaccine peaked, reaching 23,729 tweets, which affect the average sentiment.

There were 6899 highly positive tweets, 398,661 positive tweets, 245,976 neutral tweets, 204,084 negative tweets, and 1508 highly negative tweets (Figure 5).

Figure 3. Overall daily average sentiment score.

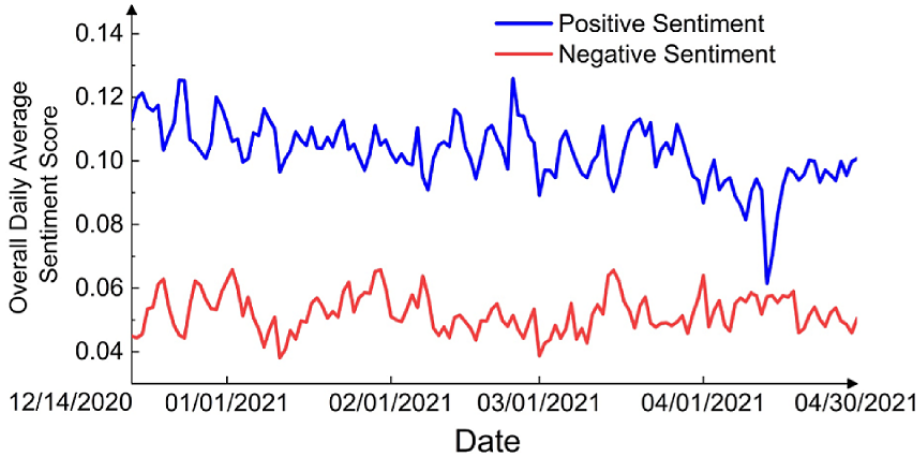


Figure 4. Overall sentiment trend.

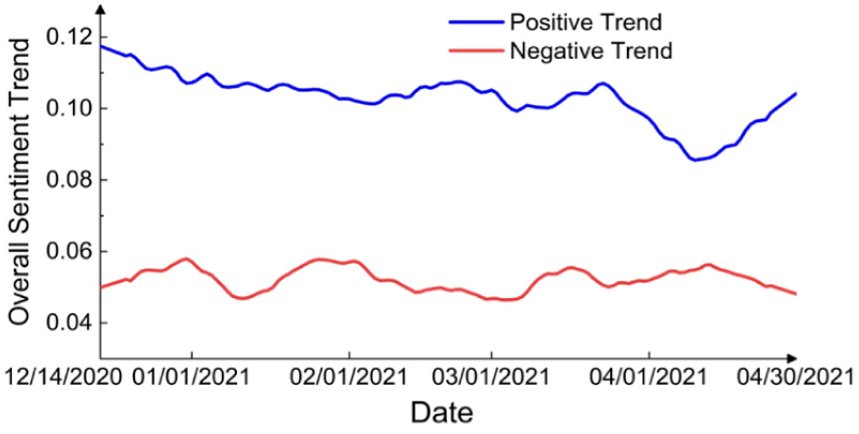

Figure 5. Sentiment polarity category distribution.

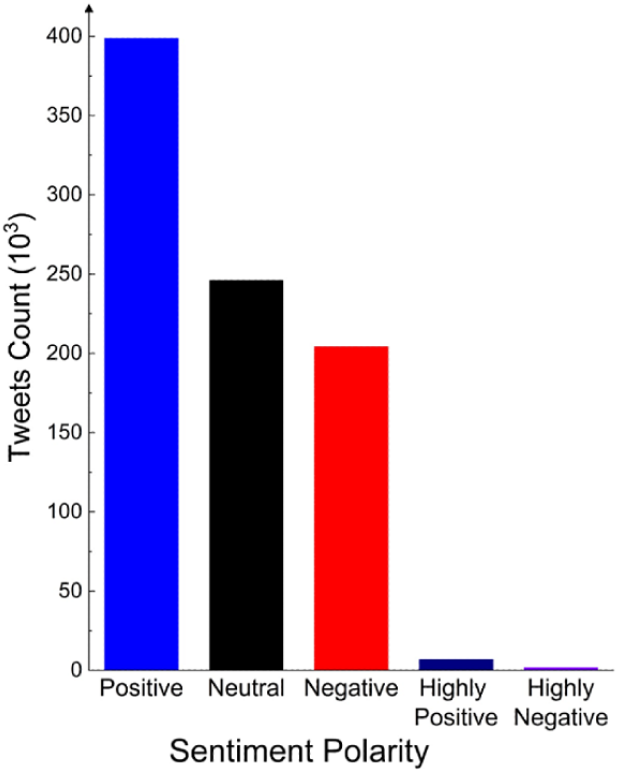

The percentage of negative sentiments was stable (Figure 6), but the percentage of positive sentiments decreased by month, and the percentage of neutral sentiments increased by month. Positive sentiment likely decreased due to the pause in the use of the Johnson & Johnson and AstraZeneca vaccinations in late March and April 2021 [28]. The neutral sentiment trend moved opposite to the positive sentiment trend.

Figure 6. Sentiment polarity distribution by month.

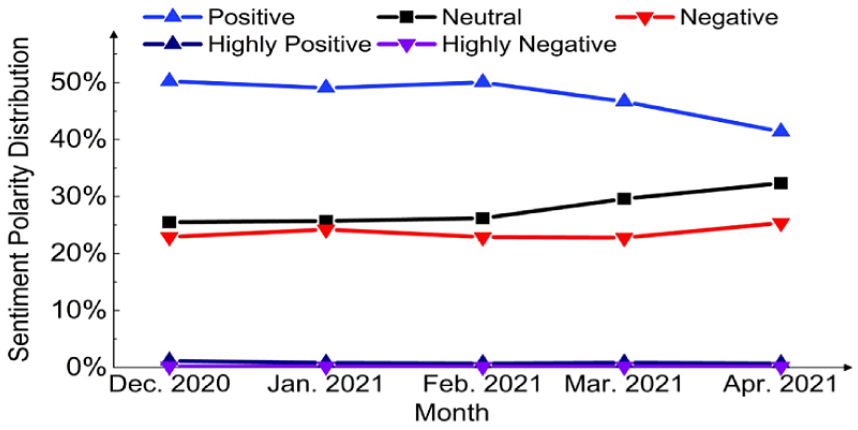

Figure 7 shows word clouds with profanities removed for highly positive, highly negative, positive, and negative tweets. Except for “vaccine” and “COVID,” which exhibited the highest frequency, the most common positive words in the highly positive group were “great,” “happy,” and “love”; the most common negative words in the highly negative group were “kill,” “bad,” and “death”; the most common positive words in the positive group were “thank,” “like,” and “health”; and the most common negative words in the negative group were “death,” “clot,” and “risk.”

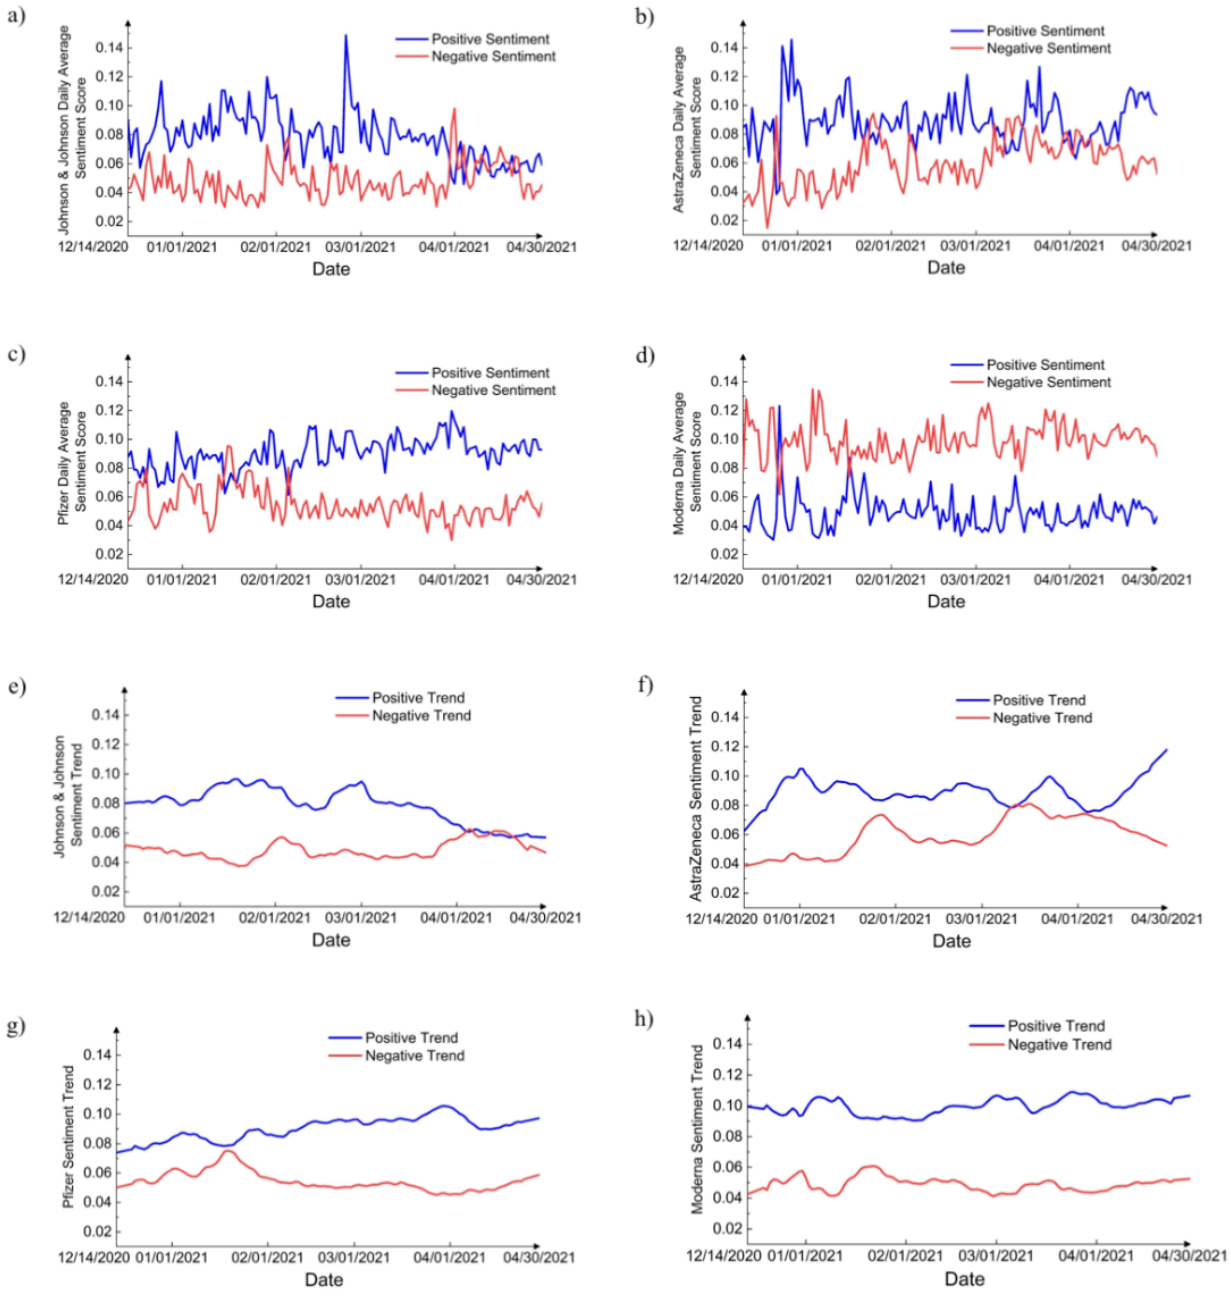
Figure 7. Common words for (a) highly positive, (b) highly negative, (c) positive, and (d) negative tweets.

Additionally, the names of COVID-19 vaccine manufacturers *Johnson & Johnson* and *AstraZeneca* exhibited a high frequency in the negative groups.

Figure 8 shows that positive sentiment and negative sentiment scores changed daily for each vaccine and positive sentiment was stronger than negative sentiment; however, for Johnson & Johnson and AstraZeneca vaccines, the average positive and negative curves were found to intersect frequently, and the differences were small. From March 11 to March 16, 2021, distribution of the AstraZeneca vaccine was suspended in Europe [29]; however, on March 18, 2021, use of the AstraZeneca vaccine resumed in Europe after a review was conducted by the European Medicines Agency [30], which may be why positive and negative sentiment curves intersect in March 2021 and positive sentiment increased soon afterward. On April 13, 2021, FDA and CDC paused the use of the Johnson & Johnson vaccine due to several reports claimed that Johnson & Johnson might be linked to a very rare serious type of blood clotting in the vaccinated individuals. This explains why the negative sentiment trend increased and positive sentiment trend decreased in April 2021, even surpassing that of positive sentiments. On April 23, 2021, the FDA and CDC lifted the pause, but the positive trend was stable and remained low, which reflected the public's concerns about the Johnson & Johnson and AstraZeneca vaccines.

Figure 8. Daily average positive and negative sentiment scores for (a) Johnson & Johnson, (b) AstraZeneca, (c) Pfizer, and (d) Moderna vaccines and sentiment trends for (e) Johnson & Johnson, (f) AstraZeneca, (g) Pfizer, and (h) Moderna vaccines.



For Pfizer and Moderna vaccines, positive and negative sentiment curves were found to intersect only in December 2020 and January 2021, and the sentiment trends were stable, which reflected public concerns in the beginning, when the vaccines were first approved, followed by increasing levels of confidence in the vaccines as more and more people became vaccinated.

Figure 9 shows the standard deviation of sentiments for each vaccine. For the Pfizer and Moderna vaccines, the standard deviation lines are flat, which means that the sentiments for these vaccines were very stable and did not exhibit much fluctuation. However, for Johnson & Johnson and AstraZeneca vaccines, the standard deviation of sentiments changed drastically over time. For instance, the standard deviation of the Johnson & Johnson vaccine decreased, implying a higher degree of consensus regarding this specific vaccine. However, the opposite was true for the AstraZeneca vaccine, and the increased sentiment variation indicated the attitudes toward it were found to be more divided over time.

Figure 10 shows the percentages of tweets for each vaccine in each sentiment polarity; the percentages in each sentiment group are very close to each other.

Figure 9. Daily standard deviation of sentiments for (a) Johnson & Johnson, (b) AstraZeneca, (c) Pfizer, and (d) Moderna vaccines.

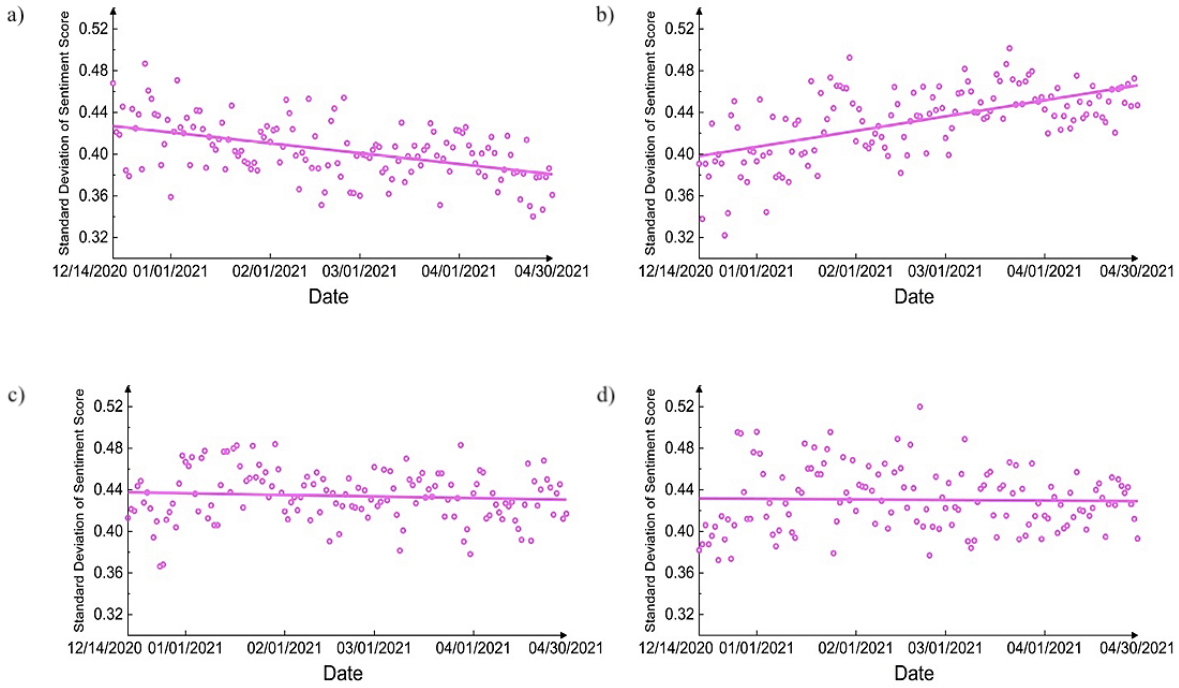


Figure 10. Sentiment polarity distributions for Pfizer, AstraZeneca, Johnson & Johnson, and Moderna vaccines.

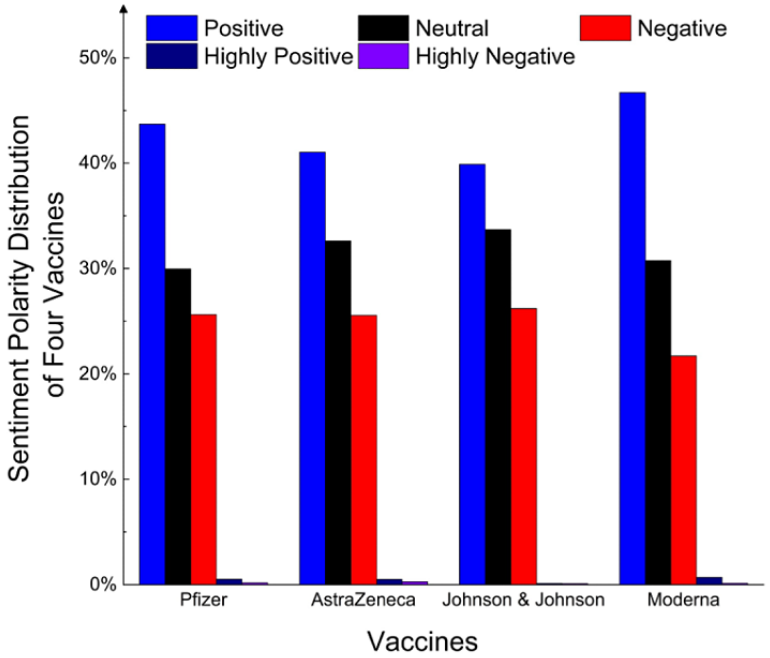


Topic Modeling

Positive Topics

Topics suggested that people felt happy and grateful that a vaccine had been approved (Table 3), that it is important to get vaccinated, that they were thankful to the health care staff for their efforts, and that they were waiting to be eligible for vaccination.

Table 3. Top 5 positive (including highly positive) topics.

Topic ID	Tweets, n (%)	Keywords	Topic
POS_05	251,979 (62.13)	people, take, say, make, go, good, need, help, well, give	Planning for getting vaccination
POS_07	76,029 (18.75)	get, today, dose, first, feel, shoot, day, second, shot, be	Getting vaccinated
POS_09	21,127 (5.21)	share, read, important, health, join, question, public, information, community, concern	Vaccine information and knowledge
POS_11	14,286 (3.52)	thank, clinic, staff, support, team, volunteer, work, process, amazing, effort	Thanks for healthcare worker
POS_01	6,963 (1.72)	effective, risk, variant, pause, blood_clot, virus, benefit, less, rare, infection	Side effects

Neutral Topics

The main neutral topics were vaccination appointment (79,710/245,976, 32.41%) and getting vaccinated (40,532/245,976, 16.48%) (Table 4). Even though the topics were neutral, they revealed favorable attitudes toward COVID-19 vaccines. In addition, 12.77% (31,409/245,976) of neutral tweets demonstrated that people felt some hesitancy toward receiving the vaccine or that they need more time to think and make a decision.

Table 4. Top 5 neutral topics.

Topic ID	Tweets, n (%)	Keywords	Topic
NEU_05	79,710 (32.41)	get, today, appointment, shoot, available, be, call, wait, come, schedule	Vaccination appointment
NEU_02	40,532 (16.48)	dose, first, receive, second, shot, pfizer, day, week, administer, fully	Getting vaccinated
NEU_09	31,409 (12.77)	say, take, go, people, time, still, need, rare, would, think	Vaccine hesitancy
NEU_03	17,156 (6.97)	update, read, find, late, live, news, check, watch, question, link	Vaccine news
NEU_06	17,129 (6.96)	may, start, age, year, week, open, next, eligible, site, begin	Vaccine eligibility

Negative Topics

Negative topics (Table 5) demonstrated the public's main concerns regarding COVID-19 vaccines. In general, the public mainly cared about the side effects of vaccines, including common side effects, such as soreness after receiving a vaccine, and serious adverse reactions, such as death. However, given the strict storage requirement, the vaccines' supply chain and rollout were the second most important issue that concerned the public. Other negative topics involved the vaccination appointment, coronavirus variants, vaccination for women and patients with cancer (people who are at high risk), fake news, and misinformation.

Table 5. Negative (including highly negative) topics.

Topic ID	Tweets, n (%)	Keywords	Topics
NEG_05	115,206 (56.04)	get, people, take, go, say, make, know, stop, need, still	Vaccine hesitancy
NEG_00	19,690 (9.58)	risk, death, case, report, blood_clot, rare, severe, low, receive, blood	Extreme side effects
NEG_06	17,154 (8.34)	government, country, pay, company, rollout, state, plan, fail, stock, supply	Vaccine supply and rollout
NEG_04	14,125 (6.87)	get, shoot, feel, arm, day, hour, today, shot, sore, second	Common side effects
NEG_07	10,248 (4.98)	appointment, wait, available, age, site, open, today, hospital, group, offer	Vaccination appointment
NEG_03	8080 (3.93)	use, emergency, say, suspend, break, astrazeneca, official, country, shortage, pause	AstraZeneca suspension
NEG_02	7100 (3.45)	dose, week, first, second, receive, next, day, ruin, delay, administer	Vaccine administration
NEG_09	6151 (2.99)	read, question, health, public, story, information, hesitancy, register, community, explain	Vaccine information and community
NEG_01	4471 (2.17)	pandemic, virus, new, fight, variant, lockdown, avoid, coronavirus, spread, restriction	Spread avoidance
NEG_08	3367 (1.64)	cause, cancer, clot, woman, trust, product, doctor, body, choice, damage	Extreme side effects on vulnerable groups

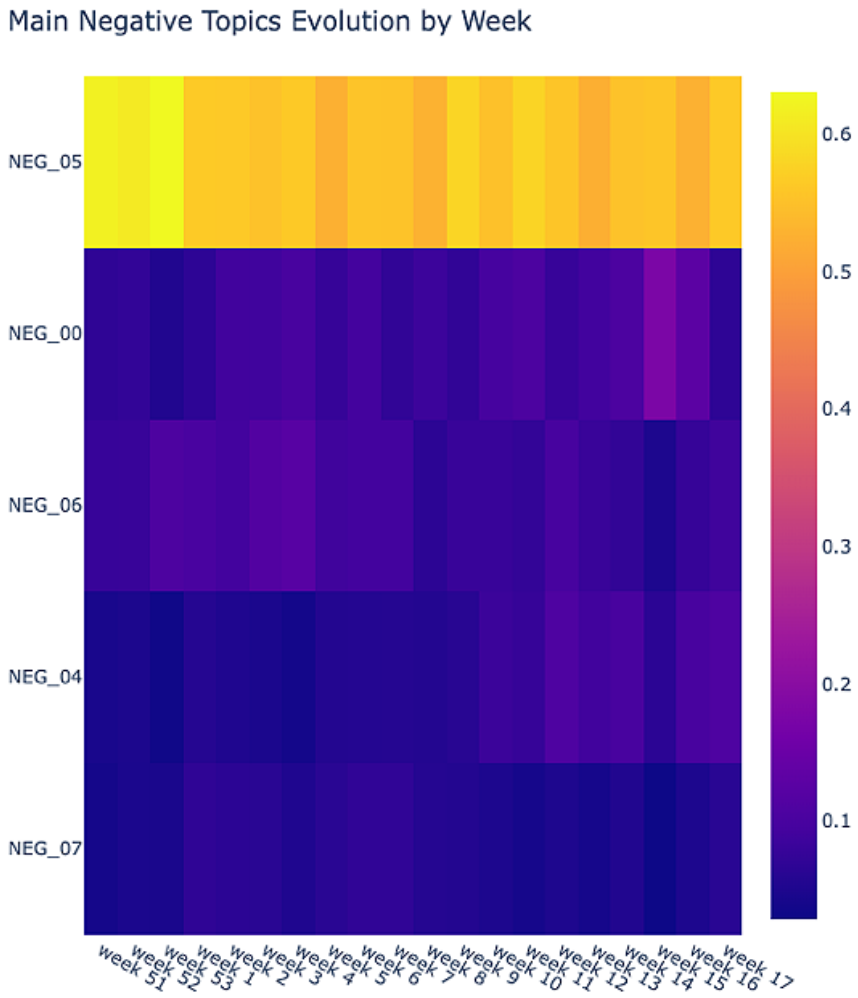
We found that 47.32% of the tweets (405,560/857,128), demonstrated positive (including highly positive) attitudes toward COVID-19 vaccines. The main topics included encouraging people to get vaccinated and conveying hope and gratitude for future life as a result of vaccine approval. Overall, 23.99% of the tweets (205,592/857,128) expressed negative (including highly negative) attitudes and concerns. The main

concerns regarding COVID-19 vaccines were side effects of vaccination, serious adverse reactions, and vaccine supply.

Topic Evolution

Side effects, such as pain at the injection site (ie, NEG_05) were discussed the most (of all negative topics) throughout the period (Figure 11). Moreover, with the increase in the number of people who received the vaccine, the discussion on side effects increased. Topics such as vaccine supply (ie, NEG_00) and extreme side effects (ie, NEG_06) were discussed less but a consistent amount throughout the period.

Figure 11. Heatmap of negative topic evolution. The x-axis represents the week in the year. Lighter colors correspond to topics that are discussed more.



Discussion

General Sentiments

Most sentiments toward COVID-19 vaccines were neutral and positive. Positive sentiment was stronger than negative sentiment throughout the period. Previous results from research conducted from March 1 to November 22, 2020 (before vaccines were available) [3] were similar—the dominant sentiments were positive and neutral; however, in this study, negative sentiment (205,592/857,128, 23.99%) was lower than that in [3] (30.57%). This suggests that after the COVID-19 vaccines became available, their effectiveness in reducing the risk of infection started to manifest in the real world, and people started having fewer doubts on social media toward vaccines. Vaccine trials, social media, and government interventions may contribute to alleviating public concerns [31].

Concerns and Topics That Shape Attitudes

By applying topic modeling to our data set, we found that the main topic in the positive and neutral domain was encouraging people to get vaccinated. In general, we discovered that vaccines are becoming widely accepted by the public as time passes. The main topic of our negative data set was the severe side effects of vaccination. When some social media outlets reported possible vaccination side effects, the concerns were discussed frequently on different social media platforms, such as Twitter, and possibly impacted individual decisions. Before vaccines were available, discussions on vaccines were centered around clinical trials and vaccine availability [12]. However, upon vaccine rollout, the concerns shifted dramatically to common side effects, which dominated the discussion throughout the study period (from December 14, 2020 to April 30, 2021). Hence, timely monitoring of the public attitude can help guide

public health officials to communicate more effectively with the public.

We also found that among the negative tweets, other than vaccine hesitancy, the main concerns regarding side effects (NEG_00 and NEG_04) were vaccine supply and rollout (NEG_06). This finding is consistent with those from previous studies [24,32,33]. For example, in a study on vaccination hesitancy in Canada [24], it was found that vaccination hesitancy stemmed from mistrust toward vaccine development, lack of knowledge about COVID-19 vaccines, and suspicion about political and authority figures who were not taking the vaccine. In another study [32] employing a questionnaire for the Israeli population, the results showed that the top 3 concerns regarding COVID-19 vaccines were quality control, side effects, and doubtful efficiency. Another survey conducted in the United States and Canada showed that vaccine rejection is very strongly related to vaccine benefits, vaccine safety, and unforeseen future effects [33]. Overall, our findings were similar—the top concerns were vaccine safety, side effects, vaccine supply, and government policy.

Changes by Month

Overall, it was observed that positive sentiment distribution decreased, neutral sentiment distribution increased, and negative sentiment distribution was stable. However, positive sentiment was dominant throughout the study period (December 14, 2020 to April 30, 2021). Positive sentiment decreased in March and April 2021, likely because of the extreme side effects (blood clotting) reported in the news for Johnson & Johnson and AstraZeneca vaccines. Use of the AstraZeneca vaccine was even stopped in Europe briefly [29], and the FDA and CDC called for a pause on the use of the Johnson & Johnson vaccine in the United States [28]. This may have caused positive sentiment to decrease, while neutral sentiment rather than negative sentiment increased, because people tended to feel neutral rather than very negative, toward such a pause.

In the very beginning, such side effects were extensively discussed. Some news outlets reported severe side effects, such as Bell palsy and even death [34], after receiving the vaccine, which seemed to coincide with more negative sentiments. Both Pfizer and Moderna vaccines are mRNA vaccines, which is a new type of vaccine that has not been used before [35]. This caused the general public to have concerns regarding the long-term side effects of these novel vaccines [7]. In the beginning, the lack of knowledge about COVID-19 and mRNA vaccines shaped the public's concerns. However, as more people were vaccinated over time, more people were able to observe how these vaccines helped steadily decrease the number of new cases and deaths per day as well as the hospitalization rates, implying that the pandemic is under control thanks to these vaccines. This in turn resulted in an increasing number of people seeking to become vaccinated, because extreme side effects are very rare and might be associated with misinformation and because the common side effects are regarded as tolerable.

Sentiment trend findings were consistent with those from a previous study [22] in which a vaccine acceptance experiment using Weibo Sina (a popular social media platform in China) demonstrated that positive attitudes were dominant, that the Chinese population were inclined to be positive about the side effects over time, and that one of the concerns that affects vaccine acceptance are misunderstandings about vaccination.

Limitations and Future Work

In this study, we mainly focused on textual information from the Twitter platform. However, users may be distributed among different social media platforms and different locations according to their usage, language, and preferences. Therefore, the methods used in our study can be extended to different social media platforms. It is also possible to use geographical filters on location information or to work on other languages to precisely differentiate between the significant issues and concerns among the different cultures or demographics.

Furthermore, our model can be extended to other research problems. For example, future studies should focus on negative tweets to determine whether misinformation exists or to identify misinformation on social media and propose suggestions for how to minimize the spread of such misinformation. Moreover, it may be plausible in the future to train a topic model with LDA and deep learning to forecast event topics and trends.

Conclusions

Our work profiles the spectrum of public sentiments toward vaccination and the main concerns underlying these views since the rollout of vaccines. These findings demonstrate the effectiveness of sentiment–based topic modeling in identifying topics and trends in polarity groups and in revealing the dynamic nature of public attitudes toward vaccination in the midst of evolving situations and changing public measures during the pandemic. Adding sentiment analysis and topic modeling when monitoring COVID-19 vaccine awareness can help researchers uncover time–based viewpoints underlying the dynamic public attitude toward vaccination on a large scale and devise tailored communication strategies to promote vaccination.

Abstract

Background: The COVID-19 pandemic continues to challenge the world's population, with approximately 266 million cases and 5 million deaths to date. COVID-19 misinformation and disinformation led to vaccine hesitancy among the public, particularly in vulnerable communities, which persists today. Social media companies are attempting to curb the ongoing spread of an overwhelming amount of COVID-19 misinformation on their platforms. In response to this problem, the authors hosted *INFODEMIC: A Stanford Conference on Social Media and COVID-19 Misinformation* (INFODEMIC) to develop best practices for social media companies to mitigate online misinformation and disinformation.

Objective: The primary aim of this study was to develop recommendations for social media companies to address the COVID-19 infodemic. We report the methods used to execute the INFODEMIC conference, conference attendee engagement and analytics, and a qualitative thematic analysis of the conference presentations. The primary study outcomes were the identified themes and corresponding recommendations.

Methods: Using a constructivist paradigm, we conducted a thematic analysis of the 6-hour conference transcript to develop best practice recommendations. The INFODEMIC conference was the study intervention, the conference speakers were the study participants, and transcripts of their presentations were the data for this study. We followed the 6-step framework for thematic analysis described by Braun and Clarke. We also used descriptive statistics to report measures of conference engagement including registrations, viewership, post-conference asynchronous participation, and conference evaluations.

Results: A total of 26 participants spoke at the virtual conference and represented a wide array of occupations, expertise, and countries of origin. From their remarks, we identified 18 response categories and 4 themes: trust, equity, social media practices, and interorganizational partnerships. From these, a total of 16 best practice recommendations were formulated for social media companies, health care organizations, and the general public. These recommendations focused on rebuilding trust in science and medicine among certain communities, redesigning social media platforms and algorithms to reduce the spread of misinformation, improving partnerships between key stakeholders, and educating the public to critically analyze online information. Of the 1090 conference registrants, 587 (53.9%) attended the live conference, and another 9996 individuals viewed or listened to the conference recordings asynchronously. Conference evaluations averaged 8.9 (best=10).

Conclusions: Social media companies play a significant role in the COVID-19 infodemic and should adopt evidence-based measures to mitigate misinformation on their platforms.

KEYWORDS

COVID-19; infodemic; misinformation; disinformation; vaccine; social media; thematic analysis; qualitative

Introduction

The COVID-19 pandemic has taken a huge toll on the world. COVID-19 is currently the third leading cause of death after heart disease and cancer, with approximately 266 million cases and 5 million deaths to date [1,2]. More than 780,000 Americans have died from COVID-19, and new variants of the virus continue to emerge. However, after an initial year of staggering case numbers, we finally have observed a decrease in the number of new infections requiring hospitalization as more people get vaccinated against the virus [1]. As of December 2021, 60% of the US adult population had received 2 doses of the COVID-19 vaccine [3,4]. Still, this fell short of the US Centers for Disease Control and Prevention (CDC) goal of 70% vaccination of the US population by July 4, 2021 [5]. This disparity persists despite widespread vaccine access [3].

Throughout the COVID-19 pandemic, there has been a proliferation of both misinformation and disinformation about the virus, its origin, the vaccines, and potential treatments. Misinformation refers to inaccurate information disseminated without malice, while disinformation is the purposeful spread of inaccurate information with malicious intent (Table 1). Taken together, the escalation of inaccurate information surrounding the pandemic can be accurately described as the COVID-19 infodemic. According to the World Health Organization, an infodemic is "too much information including false or misleading information in digital and physical environments during a disease outbreak" [6]. The COVID-19 infodemic has significantly contributed to vaccine hesitancy, which is the refusal of vaccines when access is not a limiting factor [7], across the United States. In the case of COVID-19, this hesitancy occurs despite an excellent vaccine safety profile. COVID-19 vaccine hesitancy is higher in some demographic groups who have even lower vaccination rates than the general population, demonstrating that the infodemic may disproportionately affect some communities [8,9].

Table 1. List of key terms and definitions.

Key terms	Definitions
Misinformation	False or incorrect information that is spread without malice
Disinformation	Inaccurate information that is spread deliberately with a deceitful or harmful intent
Infodemic	Excess amount of information on a topic that usually spreads rapidly and is confusing or unreliable
Vaccine confidence	Belief that vaccines are effective and safe
Vaccine hesitancy	Delay in acceptance or refusal of vaccinations despite vaccine availability
Vaccine refusal	Refusal of all vaccines including childhood vaccines

Social media platforms accelerated the dissemination of inaccurate information about the pandemic, contributing greatly to the COVID-19 infodemic and its health effects [10]. Social media has been shown to be more effective at promoting vaccine hesitancy than uptake, leading to a reduced effectiveness of public health measures and to decreased public engagement in disease prevention activities [7]. This was made worse by influential political representatives and cultural figures who spread misinformation and disinformation across all major social media platforms, which is referred to as top-down misinformation [11]. Although the connection between vaccination rates and the presence of misinformation online is known, best practices for mitigating the COVID-19 infodemic are yet to be determined. Thus far, there are no uniform efforts and policies by social media companies to combat harmful misinformation and disinformation present on their platforms. Additionally, the effect of a coordinated effort by social media companies to act against the COVID-19 infodemic is untested.

In August 2021, we hosted *INFODEMIC: A Stanford Conference on Social Media and COVID-19 Misinformation* to address issues related to the ongoing COVID-19 infodemic. Our primary aim for the conference was to develop best practices for social media companies to mitigate the COVID-19 infodemic online. In this paper, we report (1) the methods used to execute the virtual conference, (2) conference attendee engagement and analytics, (3) our qualitative analysis of the conference presentations, and (4) best practice recommendations.

Methods

Study Design, Setting, and Population

We conducted a thematic analysis of the transcript of a 6-hour, virtual conference about the COVID-19 infodemic. Our study aim was to identify best practices for social media companies to combat COVID-19 misinformation online; results of our thematic analysis represent the primary outcomes of the study. The transcript of the conference presentations formed the data for this study.

The conference was called *INFODEMIC: A Stanford Conference on Social Media and COVID-19 Misinformation*, and it was sponsored by Stanford University (Stanford, CA) [12]. It occurred on August 26, 2021, and data analysis was completed between October 2021 and November 2021. The study participants each consented to have their presentations recorded. These videos are now in the public domain; thus, no further consent was sought for this analysis. The Institutional Review Board (IRB) of Stanford University (IRB# 63151) deemed this study exempt.

The complete video recording of "INFODEMIC: A Stanford Conference on Social Media and COVID-19 Misinformation" is provided in Multimedia Appendix 1. This represents the raw data used for our qualitative thematic analysis.

Study Intervention

To meet our study aim, deliberate design and optimal execution of the conference were pivotal to the collection of meaningful data. We (RAB, MAG) convened 2 committees to assist with the project, one advisory and one for conference planning. First, we recruited a steering committee to oversee the project and provide strategic direction. The steering committee consisted of individuals from the following entities at Stanford University: the School of Medicine, the Internet Observatory, the Social Media Lab, the Digital Civil Society Lab, and the Health Communication Initiative. Members of the steering committee helped select and recruit some of the conference speakers, chose a date for the conference, and addressed day-of-conference logistics. Additionally, we recruited a planning committee (DC, TML, AR, AS, AX) that met weekly in the months leading up to the conference. The planning committee was comprised of Stanford students who successfully completed a course on the use of social media for knowledge translation in medicine. Students planned the conference under the direction of the steering committee and principal investigators.

We organized a conference agenda consisting of panel discussions and brief didactic presentations on a broad range of topics related to the COVID-19 infodemic and our study aim. We recruited expert speakers based on these topics from a variety of geographical, cultural, and academic backgrounds with special consideration of individuals who have power to influence vaccine-hesitant individuals. We used a diversity and inclusion lens to ensure a racial, ethnic, and gender balance of the participants in an attempt to mirror the general population who use social media platforms.

We created a conference website using Squarespace (Squarespace Inc, New York, NY) that served as the conference program, registration portal, and a platform to host 2 public calls for scholarly works [12]. The website and conference information were open-access, and conference registration was free. In addition to registration and advertising, the website promoted a call for research abstracts to be presented at the conference and a call for papers for a special theme issue of the *Journal of Medical Internet Research (JMIR)*: "Social Media, Ethics, and COVID-19 Misinformation." We scored submitted abstracts using Google Form (Google, Mountain View, CA) and selected the best submissions for presentation during a research symposium that immediately followed the conference. The research symposium served as a means of crowdsourcing additional information that might inform our study aim and allowed for presentation of relevant new research in the field. JMIR guest editors reviewed manuscript submissions to the theme issue separate from our study team.

We advertised the conference to potential attendees through social media and email outreach. We created Twitter (Twitter, San Francisco, CA) and Instagram (Meta Platforms Inc, Menlo Park, CA) accounts 4 months prior to the conference. We posted educational content, speaker spotlights, and promotional information to these accounts biweekly, increasing in frequency as the conference date approached. These accounts were also used for same-day conference backchanneling. We encouraged the participants to publicize the conference on their social media accounts, and we promoted the conference through Stanford Healthcare email distribution lists and newsletters.

Given COVID-19 travel restrictions, we held the conference virtually and opened registration to the public. We selected Hopin (Hopin Ltd, London, England) as our virtual conference platform because it provided important features necessary for moderated panel discussions: multiple speakers on the screen at the same time, audience interaction through chat or microphone, polling, and question and answer functions. We selected August 26, 2021 for the conference date based on our steering committee's accurate prediction of a COVID-19 vaccine surplus in the United States and the peak of news media attention about vaccine hesitancy. This date also minimized speaker conflicts and allowed enough time to plan the conference. INFODEMIC occurred 4 days after the US Food and Drug Administration formally approved the Pfizer (Pfizer Inc, New York, NY) COVID-19 vaccine, at a time of great public discourse over COVID-19 vaccine hesitancy.

On the day of the conference, we (RAB, MAG) met in person to manage conference logistics such as speaker login, backstage preparation, and online platform management. Virtually, other planning committee members (DC, TML, AR, AS, AX) oversaw the audience chat, monitored the questions and answers, took notes on key proceedings, and shared updates from the conference on social media. Abstract presentations followed the main conference program, as did a Stanford University student panel discussion on vaccine hesitancy led by the planning committee.

Participant Sampling and Data Collection and Analysis

We used a combination of purposive and snowball sampling to identify a diverse participant cohort [13,14]. We first determined the topics of the participant panel discussions based on the study aim, desired flow of the conference agenda, and format (eg, number of sessions, topics, length). We then identified expert participants for each panel via internet searches, past publications, the organizations they represented, social media platform searches, word-of-mouth recommendations, and steering committee recommendations. Our a priori search criteria identified participants for 7 of the 10 scheduled presentations. The remaining 3 presentations had participants who were referred to us by these experts (these included panels of social media representatives, government or religious leaders, and ethicists). We digitally recorded the conference and used Zoom (Zoom Video Communications Inc, San Jose, CA) to transcribe the 10 individual presentations.

Using a constructivist paradigm, we performed a thematic analysis of these transcripts to identify best practice recommendations for addressing COVID-19 misinformation and disinformation online [15-17]. We followed the 6-step framework for thematic analysis described by Braun and Clarke [17]. We inductively coded the transcript data for the existence of concepts related to COVID-19 misinformation, not the frequency they appeared in the transcript [17,18]. We analyzed

the transcripts to the level of sentences, grouped these responses into loose categories or concepts that were not predefined, and ignored irrelevant words [19]. Six study team members agreed on this preliminary coding approach and crafted rules before independently coding the content. We then met frequently to discuss code generation and meaning. Two study investigators were assigned to code each of the 10 transcripts separately, and these pairings were different for each transcript. Our final codebook consisted of codes agreed upon between the rater pairs. Using a consensus approach, we then conducted a team-based thematic analysis of the codes in a series of discussions among all of our investigators [15-17].

We used descriptive statistics to report measures of conference participation, engagement, and other analytics.

Reflexivity

We acknowledge that the experiences and opinions of our study investigators may have influenced our data analysis in this constructivist paradigm. Our senior investigator (MAG) is an emergency physician and medical education researcher who teaches a course on social media in medicine called, "Does Social Media Make Better Physicians?" Our study team includes 6 Stanford University undergraduate students (RAB, DC, TML, AR, AS, AX) who each completed that social media course and a subsequent research course that facilitated this study. Because of their common experiences in these 2 courses, all of our study investigators may have shared a preconceived perspective and understanding of the COVID-19 infodemic; we explicitly examined this bias throughout the generation of codes and themes. The students were novices to qualitative research; however, the senior investigator has ample experience with the analytic approach used and oversaw each methodological step. All coding was done in pairs of undergraduate students to balance prior experiences and assumptions. We designated our senior investigator as a potential third reviewer for the few coding disagreements that required adjudication. We maintained a research diary during the study that recorded all coding sessions, group discussions, and decisions during analysis of the transcripts. We reflected on the experience of engaging in this study at each team meeting.

Results

Conference Participation, Engagement, and Analytics

Participants

We recruited 26 conference participants with diverse expertise and occupations (Table 2). The participants were assigned to speak individually or in panels based on their areas of expertise (Table 3). We selected 9 abstracts for presentation in the research symposium. The authors represented 8 different countries.

Table 2. Demographic characteristics of the conference participants (age, gender, and race were not collected from participants).

Occupation (n=26)	Results, n (%)[a]
Physician	10 (38)
Ethicist	4 (15)
Social media influencer	4 (15)

Table 3. Summary of the INFODEMIC conference presentations and participants.

Presentation title	Speaker(s)	Affiliation(s)	Presentation summary
Welcome Address	Seema Yasmin, MD	Stanford University	As the COVID-19 pandemic continues through its second year, the need for a strong public health infrastructure remains critical to mitigating the spread of misinformation. Partnerships with public health institutions are more effective than dissociating from them.
COVID-19 Update	Yvonne Maldonado, MD	Stanford University	Five billion vaccines have been administered worldwide, with 350 million administered in the United States alone. However, reaching marginalized populations remains a challenge, and access through community organizations must be a priority.
Vaccine Confidence	Heidi Larson, PhD	London School of Hygiene & Tropical Health	Much attention has been given to the sheer amount of misinformation flooding the public, but more important is the dynamic, fast-moving nature of misinformation that undermines credible science. Trust, rumors, and receptivity have played a large role in the disparate impacts and levels of confidence in misinformation observed between different countries.
Vaccine Hesitancy	Agnes Binagwaho, MD, PhD, MA; Gloria Giraldo, PhD, MPH; Aida Habtezion, MD, MSc; Seema Yasmin, MD (moderator)	University of Global Health Equity (AB); Latino Health Access (GG); Pfizer Inc (AH); Stanford University (AH, SY)	More than vaccine hesitancy, issues about vaccine equity and access must be addressed, especially because global pandemic inequities have been so apparent. Trust is the best way to minimize vaccine hesitancy—trust in government officials, trust in physicians, and trust in the local community. This trust cannot be built overnight but must be built in a grassroots, day-to-day manner. Global vaccine access disparities are alarming because of mismanaged vaccine distribution in high-income countries, leaving low-income, at-risk nations vulnerable.
COVID-19 and Distrust of Healthcare	Italo Brown, MD, MPH	Stanford University	There are significant racial disparities in vaccine acceptance, especially among the Black and Latinx communities. Combating these disparities means "fighting the misinformation Olympics," which refers to some communities having access to adequate information versus those who do not have credible information and trusted messengers. The embedded distrust of the health care system is an important etiology of vaccine hesitancy, and it must be contextualized in the history of communities of color, such as the devaluation of Black lives. There needs to be more communication of accurate information to communities of color, especially since information can often change and be distorted as it spreads. There also needs to be focus on restorative justice and validating mistrust; activating trusted messengers to enact change within communities and combat misinformation is essential.
Achieving COVID-19 Vaccine Equity	Tom Bollyky, JD; William A. Haseltine, PhD (moderator); Lisa Menning; Danielle Pacia, MBE	Council on Foreign Relations (TB); ACCESS Health International (WAH); World Health Organization (LM); The Hastings Center (DP)	A global approach to COVID-19 vaccinations is critical to ensure vaccine equity around the world. Thus far, vaccines have not been distributed to countries at highest risk, but instead 10 of the wealthiest countries are overrepresented in vaccine doses received. This is due to hoarding within wealthier countries, a lack of global cooperation and distribution, and a vaccine shortage worldwide. Knowledge sharing and infrastructure sharing are part of an important, related global disparity. In order to combat these issues, there needs to be greater transparency, more international cooperation, and delay of vaccine boosters until there is more universal coverage.

Presentation title	Speaker(s)	Affiliation(s)	Presentation summary
The Role of Social Media Companies	Aaron Berman; Brian Clarke; Renee DiResta (moderator); Anne Merritt, MD	Facebook (AB); Twitter (BC); Stanford Internet Observatory (RD); Google Search (AM); Stanford University (AM)	Twitter, Facebook, and Google each have policies for removing misleading content, adding warning labels, and deactivating accounts that promote misinformation. A major challenge for these companies is the removal of a huge influx of disinformation while promoting quickly evolving, high-quality, and medically accurate content. Collaborative efforts between social media companies and public health experts help fact-check and spread accurate information online. In the process of regulating online content, it is important for social media companies to balance free speech, censorship, and safety.
Leveraging Physician Influencers: The New Public Health Educators	Vin Gupta, MD, MPA	University of Washington; MSNBC Contributor	Social media platforms can be used effectively to tell stories and powerfully amplify accurate information, especially through visual media like videos and graphics. These platforms generate useful ideas, distribute actionable advice, build trust, and hold sources of misinformation accountable. Impactful, accurate medical information can be communicated online by leveraging multiple forms of media to engage different audience constituencies.
Do Social Media Influencers Affect Vaccination Rates?	Sanjay Juneja, MD; Jessica Malaty Rivera, MS; Cedric "Jamie" Rutland, MD	Baton Rouge General (SJ); Infectious Disease Expert at the COVID Tracking Project (JMR); West Lung (CR); Vice President of Association for Healthcare Social Media (CR)	Social media influencers can affect vaccination rates through effective science communication. Their messaging can make people confident about the vaccine, allow them to make choices out of a place of knowledge, and teach them to be discerners of truth. Empathy, respect, and relatability are crucial to empowering listeners to seek information, rather than antagonizing and shaming. Mitigating misinformation can come from debunking myths and anticipating logical fallacy traps people may espouse.
Role of Government and Religious Leaders in Mitigation Disinformation	Adrian Perkins; Gabriel Salguero, PhD; Matthew Strehlow, MD (moderator)	Mayor of Shreveport, Louisiana (AP); Reverend of the Gathering Place (GS); President of the National Latino Evangelical Coalition (GS); Stanford University (MS)	Combating COVID-19 disinformation relies heavily on collaborative partnerships. The partnership between public health and religious figures inspires trust and increases receptivity for the public, especially as trust in government officials declines. The politicization of the pandemic has contributed to distrust between opposing parties and threatened the mission of the faith community. Thus, spreading verified information and amplifying trusted voices within religious spaces are crucial to ensure that messages are communicated safely and reliably.
Ethical Imperatives for Social Media Companies and Influencers to Act	Nancy Berlinger, PhD (moderator); Arthur Caplan, PhD; Travis Rieder, PhD	The Hastings Center (NB); New York University (AC); Johns Hopkins University (TR); Berman Institute of Bioethics (TR)	Both effective science communication and ethical communication must be prioritized throughout the pandemic. The ethical imperatives of social media companies should include stricter self-regulation and refined presentations of information for the public. Social media companies are information disseminators, not journalists or reputable news people.

Same-Day Engagement

A total of 1090 conference registrants came from 71 different countries, and 587 registrants (587/1090, 53.9%) viewed the meeting live. Most registrations occurred during the days leading up to the conference (Figure 1). Peak attendance was 312 viewers (312/587, 53.2%) at any one time, and the average viewing time was 2 hours 44 minutes (164/360 contiguous minutes, 45.6%; Figure 2). The mean rating by attendees of the conference quality was 8.9 (lowest: 0 to highest: 10). Table 4 summarizes the complete conference analytics.

Figure 1. Most registrations occurred in the same week as the conference.

Asynchronous Engagement

We distributed a complete recording of the conference to all registrants for asynchronous viewing, including the 503 registrants who did not view the live broadcast. Additionally, a recording of the conference and its individual presentations is available via YouTube, and each presentation was recorded as individual podcast episodes hosted by the *Academic Life in Emergency Medicine* Podcast via Podbean (New York, NY) [22-24]. This adds asynchronous INFODEMIC "attendees" totaling 929 viewers and 9067 listeners as of December 1, 2021. Our conference Twitter and Instagram accounts had a combined following of 521 users and reached tens of thousands of others (Figure 3). Our website had approximately 5900 unique visitors and 12,000 page views (Figure 4).

Figure 3. Engagement with our social media accounts by date: (A) unique Instagram accounts reached and (B) Twitter impressions.

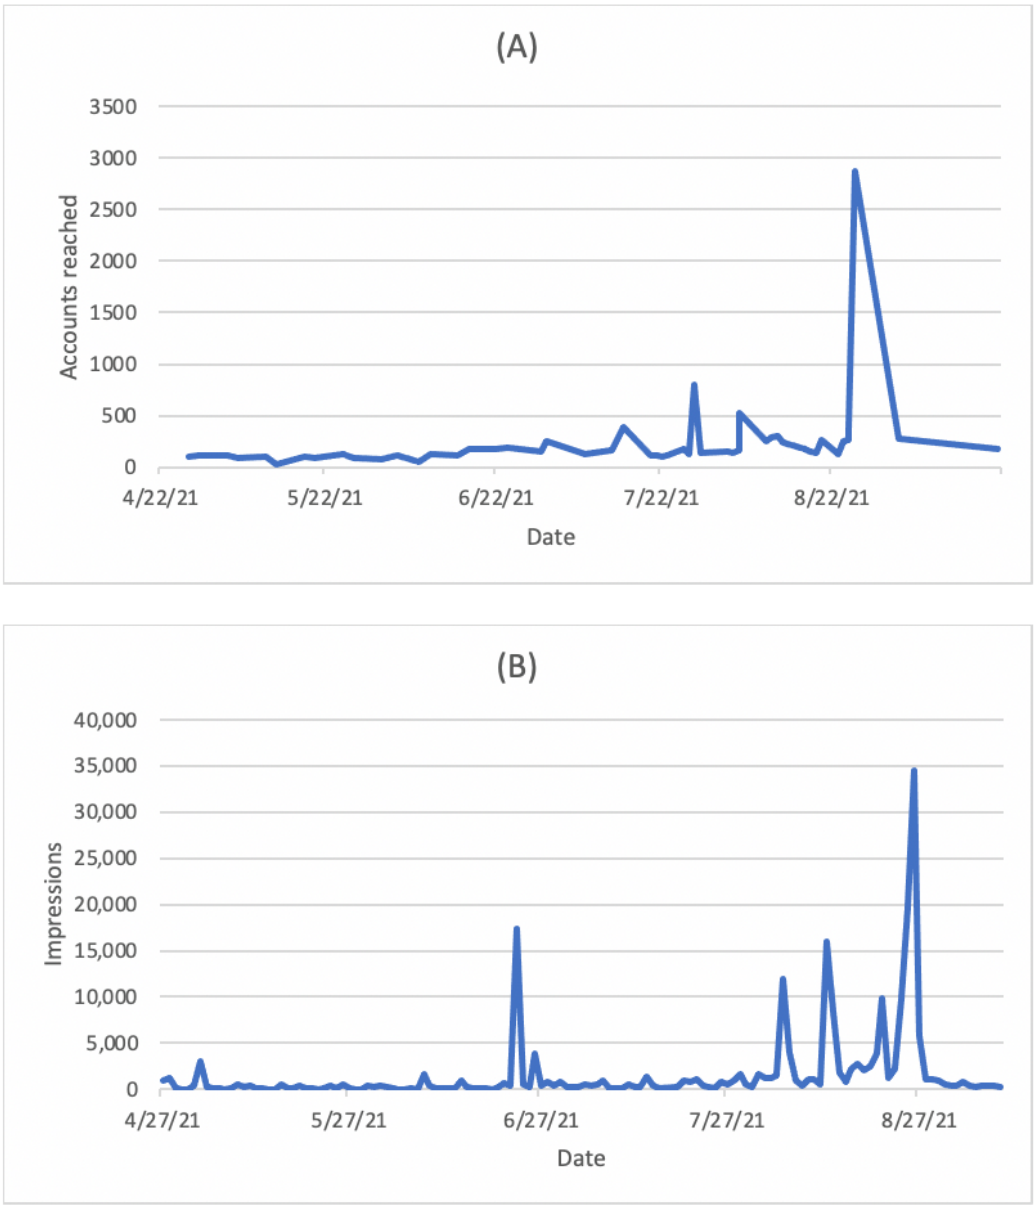

Figure 4. Website analytics showing a peak in visits during the week of the conference, August 22, 2021.

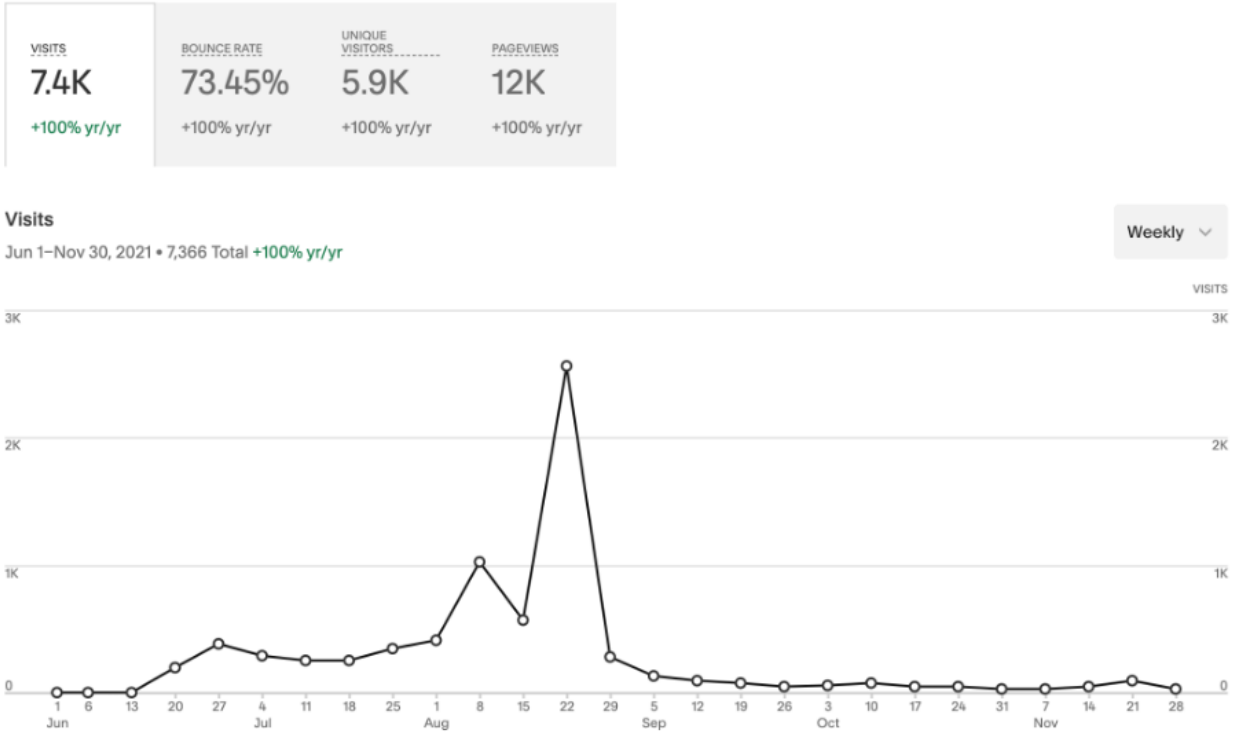

Thematic Analysis

Overview

The digital recordings of the 10 individual presentations resulted in 297 pages of transcribed text. Our analysis of this complete transcript resulted in 18 loosely associated categories of participant responses. These led to the identification of 4 major themes: trust, equity, social media practices, and interorganizational partnerships (Figure 5). These categories and themes broadly reflected the lack of access to both information and vaccines within marginalized populations, the global impact of COVID-19, and actions to minimize the spread of online misinformation (Table 5). Participants affirmed the ethical imperative on social media companies to use their platforms to curb the spread of COVID-19 misinformation because it continues to drive vaccine hesitancy and inequity.

Figure 5. Overview of our data analysis.

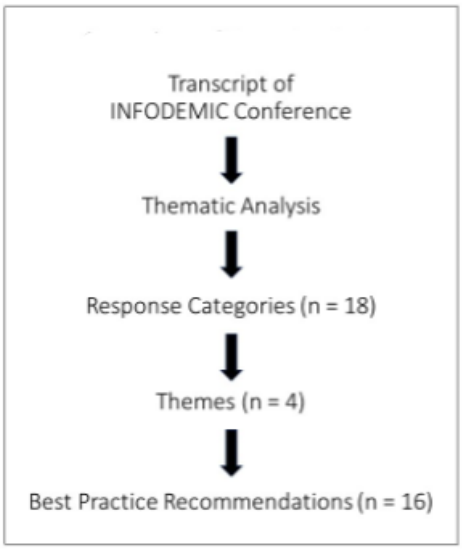

Table 5. The 4 themes and 18 response categories identified in the data analysis.

Theme	Categories
Trust	1. Historical mistreatment of marginalized populations contributes to their present-day distrust of health care. 2. Rumors, infodemics, and mistrust contribute to the spread of misinformation. 3. Community-based outreach is important for building trust. 4. Individual, collective, and commercial accountability is needed to reduce COVID-19 misinformation.
Equity	1. Inequitable access to accurate COVID-19 information fuels vaccine hesitancy and the disparate vaccination rates observed in some communities. 2. Inequitable access to accurate information results from the lack of representation of persons of color in communications and media. 3. COVID-19 vaccine access is more important than vaccine hesitancy globally. 4. Health disparities are directly related to social determinants of health.
Social media practices	1. Strategic design of social media platforms can reduce misinformation. 2. Empathy and respect are critical when communicating online with people who disagree with you. 3. Social media involves managing the different values and interests of users. 4. A balanced approach to free speech, censorship, and psychological safety is needed. 5. Social media companies can educate users by flagging and removing misinformation and promoting correct information. 6. Social media users can be taught how to critically analyze online information.
Interorganizational partnerships	1. Public health institutions should partner to combat the global impact of COVID-19. 2. Community health initiatives can fight COVID-19 misinformation. 3. Partnerships between social media companies and public health organizations can disseminate credible health information and fact-check online information. 4. Social media platforms can connect the science community with governmental agencies, commercial brands, and local health organizations.

Trust

Trust was the fundamental issue in discussions of COVID-19 vaccine hesitancy throughout the conference. Our participants described how disparities in COVID-19 vaccine acceptance disproportionately affected marginalized populations due to the "historical lack of trust by some communities because they have been mistreated by science, mistreated by politicians, mistreated by the judiciary system, and are still mistreated by [law enforcement]...so they don't trust." One participant recounted numerous instances where members of the Black community were mistreated, emphasizing how "the abuse of Black bodies creates the bedrock for this [modern] distrust" and "[currently] we still see elements of mistreatment in the medical system. So, it would make complete sense to know that Black communities have a lasting and lingering distrust of health care." Participants described how marginalized communities also suffer from a lack of "access to adequate information" because "having trusted messengers, people who can interpret messaging [and] can deliver adequate truthful information, is a commodity, [but] it is a rarity and it's scarce in [marginalized] communities."

One participant noted that "credible information and trusted voices have a viral nature, which [is] important in the context of the rampant mis- and disinformation" and that "a crucial factor that determines the spread of information is trust." The influence of rumors that threaten trust within different countries was emphasized, as in "one country, [rumors] fizzle out and die, [while] in another country, it disrupts a program and [shuts] down a vaccination initiative. It all depends on the receptivity and fertile ground [within each country that] either amplifies or mitigates the spread." Participants described "the process of building trust" through community-based organizations, which may not be an issue of "restoring trust but building trust with the public for the first time given long histories of exploitation." Several participants underscored the importance of ensuring individual, collective, and commercial accountability when dealing with COVID-19 misinformation on social media.

Equity

Our participants described how the COVID-19 pandemic highlighted countless global inequities in health care infrastructure and access to information and care. One participant said, "nothing to do with this pandemic is equal, from mortality and morbidity rate[s], from who's most susceptible to infection, [to] the inequitable access to vaccine." Participants said that social determinants of health such as poverty, frontline jobs, crowded living spaces, crowded public transit, food deserts, and inadequate insurance coverage can "lead to higher risk for COVID disease but also serve to alienate and isolate people from good information and leave them vulnerable to local pockets of misinformation." Another participant offered the example that, for pediatric deaths from COVID-19 around the world, "low- and middle-income countries have two and a half times the risk of deaths than high-income countries." The participants discussed how the pandemic has revealed this "uneven playing field," especially in denying equitable access to the vaccine among poorer countries. A participant cited a study done by the Africa CDC showing that 80% of people in African countries, 65% in the United States, and 60% in France are willing to get vaccinated, but "as of May 2021...only 2% of the African population has got access to the vaccine." Our participants agreed that vaccine access is more important than vaccine hesitancy in much of the world. These inequities not only are global but also plague

people within small communities, as one participant noted, "[sometimes] it's only a 15-mile difference" between having and not having access to a continuous medical system.

In the same way that inequities cause access challenges to vaccines and health care services, one participant explained that there are also some communities that are "more vulnerable to being targeted by disinformation campaigns and are more susceptible to believing misinformation." Our participants discussed how Pfizer focused on equitable access to vaccine information and clinical trials while developing their vaccine, describing that Pfizer put in the effort to "involve and ensure diverse populations are included." In addition to including minority groups in clinical trials, one participant described how the Pfizer vaccine development process involved partnering with "trusted civil societies and NGO [nongovernmental organizations] like the NAACP [National Association for the Advancement of Colored People], the National Black Nurses Association, the National Hispanic Medical Association" to approach vaccine development in an equitable and "culturally sensitive way," considering factors such as "removing barriers in enrollment like language."

Social Media and Best Practices

Social media companies and influencers both play important roles in limiting misinformation online, as well as spreading accurate and credible content. Participants acknowledged that online platforms including Twitter, Facebook, and Google all have policies for removing inaccurate information, flagging misleading content, and deactivating accounts that promote misinformation. For example, one participant shared that Twitter "remove[s] content with the highest propensity of harm and content that may invoke deliberate conspiracy theories relating to COVID-19 and COVID-19 vaccines," mitigating its spread. Social media companies have also been able to promote and amplify high-quality, medically accurate information via COVID-19 information pages and links labeling relevant posts. Through these efforts, Facebook has been able to "direct more than 2 billion people worldwide to expert health resources through [their] virus information center," and Google developed search features to "provide direct access to information from health authorities." Participants said that artificial intelligence systems can help "scale the impact" of misinformation and send it to "fact-checking partners around the world [that can] rate [the] content and reduce the distribution of it" if deemed harmful. Continual monitoring and tracking of online discussions allow companies to "have a better sense from a policy perspective where to start shifting [their] resources and where to start really understanding the patterns associated with it." The companies are working to navigate the challenge of regulating their platforms by finding a balance between "enabling people to express themselves freely while protecting the safety of [their] user community."

Health care influencers on social media can also impact vaccination rates by communicating information responsibly and effectively on their platforms. One way is by storytelling and giving actionable advice through a variety of media, whether that be "threads on Twitter, videos, [or] graphics"—all powerful ways of "leveraging the impact of multiple forms of media to their greatest extent" and increasing audience engagement. Influencers can use their platforms to build trust and generate ideas as ways to "transform people's minds, to bring them out of fear and into confidence about the vaccine—everything from flu to even COVID-19 and HPV [human papillomavirus]." Participants agreed that influencers can also help increase science literacy and teach viewers to make choices "out of a place of knowledge" and "increase people's ability to discern what is good data, what is bad data, and even how to read charts." Although educating viewers, it is crucial for health influencers to express empathy as an "undertone of the way in which [they] communicate...and empower people to seek this information out." Antagonizing and "shame-based motivation to seek information sends [people] to the darkest places of the internet" and is not as effective as coming from a place of understanding and respect.

Interorganizational Partnerships

The final theme that emerged from our conference was the dire need for interorganizational partnerships. From the first panel to the last, our participants emphasized the importance of partnering with like-minded organizations to improve public health and the information disseminated on social media. One participant advocated that health experts "should partner with public health and not dissociate ourselves from them because we need to build [the] public health infrastructure...[to] not only get through the pandemic, but all public health issues." They asserted the need to utilize "existing community engagement structures, local community leaders, faith-based organizations, community groups, and health centers" to "disseminate transparent and comprehensive information" for public good. These sentiments were echoed throughout the conference. As one participant stated, "partnerships are essential [and National Latino Evangelical Coalition] partners with the CDC and the Office of Health and Human Services to have webinars in the target language" to eliminate distrust in the health care system among the Latino community.

Lastly, participants agreed that social media companies have a responsibility to partner with health organizations to ensure that their platforms are "[addressing] a wide range of misinformation and the associated harms...[while] amplifying authoritative health information." One participant noted that Facebook is "partnering with other organizations to reach low vaccination rate communities such as campaigns featuring Black doctors or nurses or Spanish language campaigns" and "using that data that [they're] collecting in partnerships with academic institutions to judge the impact [on the pandemic] over time." Participants also discussed partnerships that Facebook maintains with health experts to "remove content that has been debunked as false and leading to physical harm" as well as partnerships with "the global network of more than 80 fact-checking organizations around the world in more than 60 languages" to identify misinformation about COVID-19 or the vaccine. Similarly, it was noted that Google has similar partnerships with "national public health authorities" to "display their content front and center" so users have "direct access" to it.

Discussion

Principal Findings

Health misinformation on social media poses a threat to public safety, especially in the midst of the COVID-19 pandemic. Our participants described how the increased use of social media during the pandemic paved the way for misinformation, conspiracy theories, and rumors to flourish, thus increasing fear and reluctance around the vaccine. With the emergence of new COVID-19 variants, it is especially vital that we combat vaccine hesitancy and vaccine inequity around the world. In particular, many of our participants acknowledged that social media companies have an ethical obligation to act against the spread of harmful misinformation on their platforms. Presently, social media companies are making efforts to mitigate misinformation—however, more could be done.

After analyzing transcripts from the INFODEMIC conference, we recommend 9 ways in which social media companies can better combat COVID-19 misinformation online (Table 6). While our intended goal was to make recommendations about COVID-19 misinformation to social media companies alone, our data were so rich that our analysis led to recommendations for health care professionals and the general public as well. During our analysis, we also identified several response categories specific to health care professionals and the general public, so we generated additional recommendations for each of these respective groups. Our findings are especially timely and important, as the literature has relatively few evidence-based guidelines for how social media companies should effectively manage the COVID-19 infodemic [25-27]. In addition, many health care professionals and social media users are unaware of the potential benefits of social media for the dissemination of factual scientific information and the promotion of COVID-19 vaccines [25,28,29].

Table 6. List of recommendations for social media companies, health care professionals, and the general public to mitigate COVID-19 misinformation.

Target	Recommendations
Social media companies	1. Increase representation by people of color as messengers of factual information to build trust in medicine and science within marginalized communities. 2. Promote posts from trusted sources of credible information. 3. Fact-check, flag, and remove posts that propagate the spread of misinformation. 4. Adjust search engines and other algorithms that push misinformation. 5. Use easily understandable information, infographics, and messaging. 6. Remind users to be critical of information they read online. 7. Partner with public health organizations to spread credible information. 8. Partner with one another in a coordinated effort to combat COVID-19 misinformation. 9. Encourage vaccinations and equitable access to vaccines.
Health care professionals	1. Engage in public health education online. 2. Use social media platforms to connect scientists, government officials, and health care organizations with the general public. 3. Be mindful of global health disparities when messaging about the vaccines.
General public	1. Critically analyze social media content related to COVID-19. 2. Disseminate scientific facts and evidence-based information. 3. Search for information rather than rely on social media algorithms to push content to you. 4. Be patient and empathetic in conversations with vaccine-hesitant individuals.

Some pre-COVID literature addressed health misinformation on social media platforms. Although these papers predate the current COVID-19 infodemic, our data support their overarching themes and recommendations. Chou et al [29] recommended a strong clinician-patient relationship for optimal health communication, and our findings underscore this importance of building patient trust in science, medicine, and health information messengers. Similarly, we found that individual and commercial accountability is needed to reduce COVID-19 misinformation. Chou et al [29] also recommended that social media companies implement mechanisms to validate information on their platforms. Our analysis yielded more detailed recommendations for social media companies to (1) flag and remove posts that propagate the spread of misinformation, (2) promote posts from trusted sources such as easily understood information and infographics, and (3) promote reminders to the public to be critical of what they see online [29]. Finally, Walter et al [25] performed a meta-analysis of pre-COVID studies that found that the most effective messenger of health information is a recognized expert in a given field, which aligns with the findings in our study as well.

Several unique aspects of the INFODEMIC conference planning and this subsequent study are noteworthy. The INFODEMIC planning committee and this author team were comprised primarily of undergraduate students (DC, TML, AR, AS, AX) who executed the event and this analysis as class projects. The students learned how to effectively work as a team, communicate with professional speakers, plan the logistics of a conference, operate the digital conference platform, and perform a qualitative analysis of conference transcripts. Second, our speaker selection was carefully planned so that a diverse group of fields was represented. For instance, we thought it was important to include religious leaders and physicians in discussions of social media regulations, a space normally dominated by social media companies and the government. The broad diversity of expert speakers was intentional, and this qualitative analysis was meant to discover commonalities among

their approaches to health misinformation. Finally, we believe that our thematic analysis of a full conference transcript is uncommon in the literature and represents a rigorous method of summarizing knowledge generated at a scientific meeting.

Lastly, our experiences hosting an online conference are instructive. The virtual platform allowed us to convene a panel of experts from locations in North America, Africa, and Europe simultaneously. It is unlikely that we could have recruited the same panel to a live conference due to costs, travel during a pandemic, and schedule availability. Conference registrants similarly represented an international audience. We also purposefully recorded the conference and made it freely accessible online through YouTube videos and Podbean podcasts. This ensures that the conference has continued impact, as evidenced by the 10-fold increase in asynchronous, on-demand viewers to date compared with live conference attendees. Additionally, registrations peaked in the final 48 hours prior to the conference, an unanticipated finding that is anecdotally common for virtual conferences. This may have been due to simultaneously higher social media activity about the conference in the days prior, both from the INFODEMIC planning committee and the invited speakers. These experiences are consistent with expert guidelines for planning virtual meetings [30,31].

Limitations

We acknowledge several important limitations of our qualitative study design. Most notably, our sampling technique is subject to selection bias, and thus, our data were contingent on the specific participants or panel discussion topics chosen. However, it is unclear if similarly selected content experts would have offered substantively divergent perspectives. We tried to address this issue by creating a diverse conference agenda, recruiting participants with content expertise, and performing a thematic analysis across all 10 of the conference presentations to increase the variety of participants' responses in the data set. Two notably absent participant types were vaccine-hesitant individuals and "antivaccine" individuals. Though we initially intended to include a vaccine-hesitant participant, we eventually chose not to recruit any because of the difficulty of ensuring their psychological safety during the conference. Additionally, we were concerned that an "antivax" (vaccine-refusing rather than vaccine-hesitant) participant might have led the conference astray from its primary objective. Such individuals may have interacted with our participants during their presentations anyway, using the virtual conference platform chat function; this is not clearly reflected in our data set as the transcripts captured audio-only content, not chat room discussions.

Additionally, several biases reflective of participant comfort during the live, internationally broadcast conference may have affected the results; these include social desirability bias, acquiescence bias, and sponsor bias. Each of these response biases were partially mitigated by the use of open-ended questions and panel moderation by participants rather than sponsors. Similarly, status quo bias may have affected the responses of participants representing social media companies. Some responses may have been further biased by the use of a virtual conference platform to host the conference. Although this format allows for a global audience, technology itself can be a barrier for participants and alter their engagement and responses. Moreover, the conference was held in English without closed captioning or translation services, which may have affected attendee interaction with the participants via the chat function. Finally, our results may be subject to confirmation bias and to the experiential bias of the co-investigators who planned the conference and wanted to ensure its success. These were addressed by the use of paired investigators to code data and through direct supervision and instruction by the first author who has expertise in this methodology.

Conclusions

The Stanford INFODEMIC conference brought together experts from various fields and backgrounds to discuss the etiologies of vaccine hesitancy and the power of social media to increase COVID-19 vaccination rates. There were common themes to the participant remarks: improving trust in science and medicine, promoting equity in vaccine access and health care, identifying social media best practices, and creating interorganizational partnerships. As the future course of the pandemic continues to be uncertain, we offered specific recommendations that social media companies, health care professionals, and the general public can adopt to better mitigate online health misinformation.

Acknowledgments

Funding for the conference came from a Stanford University Ethics, Society, and Technology Hub Seed Grant from the McCoy Family Center for Ethics in Society, Stanford University Introductory Seminars, and the Stanford University Department of Emergency Medicine. We thank the following individuals for their various contributions to the INFODEMIC Conference: Jonathan Berek, Samantha Bradshaw, Susan Coppa, Renee DiResta, Jeffrey Hancock, Kristen Kayser, Ashley Neis, Matthew Strehlow, and Seema Yasmin.

Authors' Contributions

MAG, RAB, DC, TL, AR, AS, and AX contributed to the study design, data collection and analysis, and manuscript preparation.

Conflicts of Interest

None declared.
