Abstract

Background: Access to digital technology is among the major social determinants of health, and digital divide impacts health inequality. Yet, the impact of digital connectivity on the well-being and psychosocial outcomes in adults has not been fully studied.

Objective: The aim of this study was to investigate the association of home broadband connection with health and well-being of middle-aged adults and adults older than 45 years in China.

Methods: A panel data study design of the national sample of China Health and Retirement Longitudinal Study (CHARLS) was conducted in 2015, 2018, and 2020. This study included 16,185 participants older than 45 years. The associations between digital connectivity (home broadband connection), loneliness, social participation, and life satisfaction were assessed using mixed effects logistic regression models, adjusting for socioeconomic factors, behavioral factors, and locality. Broadband internet connectivity, feelings of loneliness, social participation, and satisfaction with life were measured using the self-reported CHARLS questionnaire.

Results: We observed a substantial increase in digital connectivity from 29.5% in 2015 to 59.8% in 2020. Broadband internet connection at home was positively correlated with social participation (adjusted odds ratio [AOR] 1.34, 95% CI 1.28-1.41) and life satisfaction (AOR 1.30, 95% CI 1.20-1.40), after adjusting for confounding factors, while the absence of broadband internet connection was associated with increased loneliness (AOR 0.81, 95% CI 0.77-0.86). These associations were consistent across age, gender, socioeconomic groups, and geographic areas.

Conclusions: This study highlights the potential additional health benefits of digital connectivity beyond the known advantages. Our results suggest the importance of expanding broadband access to enhance social inclusion and life satisfaction. Further research is needed to understand the broader implications and digital determinants of health associated with digital connectivity.

Introduction

Loneliness and social isolation are clearly recognized as significant threats to public health [1]. Although social isolation is defined as an objective lack of interactions with others or the wider community, loneliness is a subjective feeling of the absence of a social network or a companion [2]. These 2 concepts do not necessarily coexist: a person may be socially isolated but not lonely or socially connected but still feel lonely. However, both social isolation and loneliness lead to poorer health outcomes and higher health care expenditure [3,4]. Notably, the COVID-19 pandemic led to a significant increase in social isolation and loneliness among older adults in some countries; for example, in Canada, there was a 37%-67% increase in loneliness during April-December 2020 compared to 2011-2015 [5,6]. Throughout the pandemic, governments, organizations, and technology companies made efforts to help prevent and address social isolation and loneliness [1]. Broadband connection at home provides a faster way to connect older adults to reduce feelings of loneliness and isolation via online discussion forums, online peer support platforms, social media, and telehealth [5,7,8]. The availability of home broadband means faster, reliable delivery of internet-based services and facilitates access to a spectrum of resources that encompass education, social activities, and health care services, all of which help to foster a broader and deeper level of digital engagement [9,10].

In our ever-connected society, home broadband connection has become essential for daily living. Globally, there has been a rapid increase in the number of households equipped with broadband internet service in recent years [11,12]. According to the Organization for Economic Co-operation and Development broadband portal data, the broadband subscriptions in 32 countries grew to 2.25 billion in December 2022, up from 1.99 billion at the end of 2019—an increase of 260 million in 3 years [13]. As of 2023, China is the leading market for the number of internet users in the world, followed by India and the United States [14]. According to the latest data from the China Internet Network Information Center, 2023 witnessed 1.11 billion internet broadband access ports actively connected, with a reported household broadband penetration rate exceeding 90% in 2020 [15]. However, there still remains a substantial gap between the most developed regions in China and the rest of the country, contributing to a widening digital divide [16]. Findings from 5 longitudinal cohort studies across 23 countries, including China, underscored a significant association between digital exclusion and difficulties in performing daily activities [17]. Furthermore, the China Household Finance Survey data suggest that while the digital divide index has gradually reduced from 58.36 in 2017 to 49.89 in 2019, its effect has led to a significant reduction in household consumption. This reduction is more prominent within the older, less educated, unhealthy, and low-income groups [16].

The rapid acceleration of the aging population has created a major challenge for health care services and industrial transformation process in China [18,19]. To understand more about these challenges, the China Health and Retirement Longitudinal Study (CHARLS) was designed to be comparable with the US Health and Retirement Study and related aging surveys around the world (eg, the English Longitudinal Survey of Aging and the Survey of Health, Aging, and Retirement in Europe), while being sensitive to the specific conditions of China [20]. The national baseline survey was conducted in 2011-2012, with continued waves in 2013, 2015, 2018, and most recently in 2020. Historically, CHARLS datasets have been used to provide individual social, economic, behavioral, and health data to understand and serve the needs of older adults, which have greatly enriched the international landscape of aging studies [21]. The introduction of the national-level Smart Eldercare action plan in 2017 [22] led to an increase in internet-related health research among older adults, such as internet use and its association with physical, mental, and subjective health through to health disparities, social activities, incidence of chronic diseases, and disease management [23-27]. The most recent study on internet access from CHARLS, using data from 2011-2018, identified that internet access improves older adults' self-reported health, mental health, and activities of daily living [28]. Another study used CHARLS data from 2011 and 2015 and reported that social isolation, rather than loneliness, was significantly associated with functional disability over 4 years among women (but not men) [29]. However, we are not aware of any recently published research on home broadband connection and its impact on the well-being and psychosocial outcomes among older people. This gap is critical for 3 reasons. First, broadband availability is associated with greater frequency of internet use and more engagement with internet activities [10]. Second, older adults showed higher preferences for home care [30]. Third, the recent advances in the internet of things technologies [31] have made home care solutions viable and appealing for older people who wish to age at home.

Digital technologies are now being recognized as important determinants of health [32]. In 2021, the Geneva Charter for Well-Being called for action to address the digital determinants of health [33]. It recognized that avoiding digital exclusion is the key to achieve universal health coverage, making full use of the digital transformation and ensuring access and meaningful participation. Alongside this, the World Health Organization highlighted the role of broadband and the internet as an example of the digital determinants of health [34]. Moreover, the US Federal Communications Commission reported that not having access to broadband internet had impact on physical or mental disability, as telemedicine requires high-speed internet access [35]. China has positioned the broadband network as a national strategic infrastructure for economic and social development since 2013 [36]. Notably, despite over 90% penetration now, the broadband penetration rate was only around 60% in 2020 when the CHARLS survey was conducted, which presents an opportunity to examine the potential impact of this technology in different social contexts. Yet, to date, no study has examined the relationship of home broadband connection with life satisfaction, loneliness, and social participation in China. This paper aims to fill this gap by being the first to analyze population-based nationally representative data from 2015 to 2020, to explore whether home broadband connection is associated with well-being and psychosocial characteristics such

XSL•FO
RenderX

as life satisfaction, loneliness, and social participation among older adults in China.

Methods

Study Design and Participants

This study complies with PRICSSA (Preferred Reporting Items for Complex Sample Survey Analysis) guidelines. Data were obtained from CHARLS in 2015, 2018, and 2020, which collects information on individuals aged 45 years or older in China and their household characteristics. Thirty province-level administrative units were selected by stratified random sampling with probabilities proportional to the size to be representative of the general population aged 45 years and older [37]. There were 17,708 respondents in the national baseline survey in 2011 who were followed up using a face-to-face computer-assisted personal interview every 2 years. A detailed description of CHARLS is published elsewhere [38]. For this study, we included data from participants who were included for all 3 waves in 2015, 2018, and 2020, after China introduced "Broadband China" Strategy and Implementation Plan in 2013. After data cleaning, the sample comprised 16,185 individuals.

Ethics Approval

The original CHARLS was approved by the ethics review committee of Peking University (IRB00001052-11015), and all participants signed informed consent at the time of participation. For this study, we examined the home broadband connection status of all adults aged 45 years and older in the deidentified datasets.

Measures

The key predictor is home broadband connection. Respondents who answered affirmatively to the question "Does your residence have broadband internet connection?" were defined as having a home broadband connection.

Demographic Characteristics

Demographic variables included area of living (rural/urban), gender, age, marital status (married and partnered, unmarried, and others), education level (primary school and below, secondary school, and college and above), work status (yes or no), socioeconomic groups, and health insurance (Urban Employee Basic Medical Insurance, Urban Resident Basic Medical Insurance, New Rural Cooperative Medical Scheme, other insurance, and without insurance). Specifically, we used annual per capita consumption spending as a proxy for socioeconomic status. We defined 4 socioeconomic groups on the basis of quartiles of per capita household consumption expenditure [39].

Dependent Variables

Life satisfaction was measured in the questionnaire "Please think about your life-as-a-whole. How satisfied are you with it? Are you completely satisfied, very satisfied, somewhat satisfied, not very satisfied, or not at all satisfied?" with 5 Likert scale responses ranging from "1=completely satisfied," "2=very satisfied," "3=somewhat satisfied," "4=not very satisfied," and "5=not at all satisfied." To enable the use of a chi-square test, scales 1, 2, 3 were recoded as "satisfied" and scales 4-5 were recoded as "not satisfied."

Loneliness

Loneliness was measured with a direct single question in the questionnaire "I felt lonely." The 4-point response scale ranged from "1=rarely or none of the time (<1 day)," "2=some or a little of the time (1-2 days)," "3=occasionally or a moderate amount of the time (3-4 days)," to "4=most or all of the time (5-7 days)." To ensure use of a chi-square test, scale 1 was recoded as "no loneliness" and scales 2-3 were recoded as "yes loneliness."

Social Participation

Social participation status was measured from the question "Have you done any of these activities in the last month?" For social participation, which coded as 1=Yes, it means that the participants checked the following social activities: interacted with friends; played Mah-Jong (a tile-based game developed and widely played in China), played cards, or went to a community club; went to a sporting event or participated in a social group; provided help to family, friends, or neighbors who do not live together; went to a sport, social, or other kind of club; took part in a community-related organization; participated in voluntary or charity work; and attended an educational or training course. For those participants who did not check any of the above social activities, this was coded as 0=No.

Covariates

We included demographic characteristics as covariates. Some health-related variables were also included, such as self-report health status, duration of sleep, and number of noncommunicable diseases. Self-report health status was measured by: "How is your health, overall?" The response options lay on a 4-point Likert scale: very good=0, good=1, not so good=2, and not good at all=3. We recoded the scale to good=1, fair=2, and poor=3, so that higher scores reflected poorer self-rated health condition. Fifteen self-reported chronic diseases, each prompted by "Has a doctor or nurse ever told you that you have…," were asked to the respondents. The number of chronic diseases was considered in this study, which comprises arthritis, heart diseases, diabetes, stroke, chronic lung disease, kidney disease, stomach or other digestive diseases, asthma, depression, hypertension, dyslipidemia, Alzheimer disease, cancer, dementia, and liver illness.

Statistical Analyses

We used a panel data approach of mixed effects logistic regression to examine the associations between home broadband connection and life satisfaction, loneliness, and social participation. Frequencies, percentages, mean, and standard deviations were used to report descriptive data. The chi-square test was used to compare the differences in the demographic characteristics, health behavior, health status, and access to broadband internet connection with the outcome measures (life satisfaction, social participation, and loneliness). To explore the differential effect in population groups, we conducted subgroup analyses, stratified by age group, gender, area of residence, and socioeconomic status. To examine the possible heterogeneity in the relationships between home broadband

XSL•FO
RenderX

connection and psychosocial outcomes, we conducted a series of stratified analyses by age, gender, rural-urban, and socioeconomic groups. All tests were conducted using STATA software, and statistical significance was considered at $P<.05$.

Results

Descriptive Analysis

There were 16,185 respondents aged 45 years and older who completed the CHARLS survey in all 2015, 2018, and 2020 waves, which were included in the analysis. There were 2735 participants who did not have home broadband connection in 2015 and 2018 but had home broadband connection in 2020. Most of the participants were in the 45-60 years age group (6914/15,958, 43.3%) and 60-70 years age group (5534/15,958, 34.7%); 7526 (46.8%) participants were males, 8562 (53.2%) were females, and 12,830 (79.4%) were married or partnered. A total of 8958 (66.8%) participants had primary education or below, and 13,362 (74.8%) were residing in rural areas; 15,713 (94.1%) had at least one kind of health insurance, with 10,442 (67.5%) respondents enrolled in the New Rural Cooperative Medical Scheme.

Multimedia Appendix 1 shows the prevalence of social participation, life satisfaction, and loneliness from 2015 to 2020 by the status of home broadband connection. The proportion of people with home broadband connection increased substantially over time. In 2015, the overall prevalence of broadband connection was 29.5% (4741/16,070), while the prevalence increased to 45.7% (7382/16,143) in 2018 and 59.8% (9659/16,161) in 2020. The mean age of the respondents was 61.6 years in 2020. Table 1 presents the findings of the association of home broadband connection with socioeconomic and demographic characteristics, health behavior characteristics, health status, social participation, life satisfaction, and loneliness. For those who had home broadband connection, they were more likely to be within the age group of 45-60 years, married or in partnership, having higher education level, living in rural areas, having New Rural Cooperative Medical Scheme, having higher socioeconomic status (quartile 4), not drinking alcohol, having more sleep, self-rating their health status as good or fair, having participated in social activities, not feeling lonely, and satisfied with life. Interestingly, in both 2015 and 2018, for those who had home broadband connection, they were more likely to have no chronic diseases, while in 2020, those who had home broadband connection were more likely to have more than 3 types of chronic diseases. In 2015 and 2018, for those who had home broadband connection, they were more likely to be nonsmokers, while in 2020, this relationship was not significant.

Home Broadband Connection and Social Participation

Table 1 shows that the prevalence of social participation among home broadband users was 65.5% (3632/5543) as compared to 50.1% (6743/13,466) among nonusers—a difference of 15.4% in 2015. Similarly, there was a difference of 17.3% and 12.5% between home broadband users and nonusers in 2018 and 2020, respectively. Overall, we noticed that social participation rates decreased in both groups from 2015 to 2020. After adjusting for covariates (Table 2), broadband users were 34% more likely to participate in social activities as compared to nonusers (odds ratio 1.34, 95% CI 1.28-1.41). Stratified analyses (Figures 1-4) showed that home broadband connection and social participation do not have significant relationships among those older than 80 years but still have a significant relationship across gender, socioeconomic groups, and areas of residence.

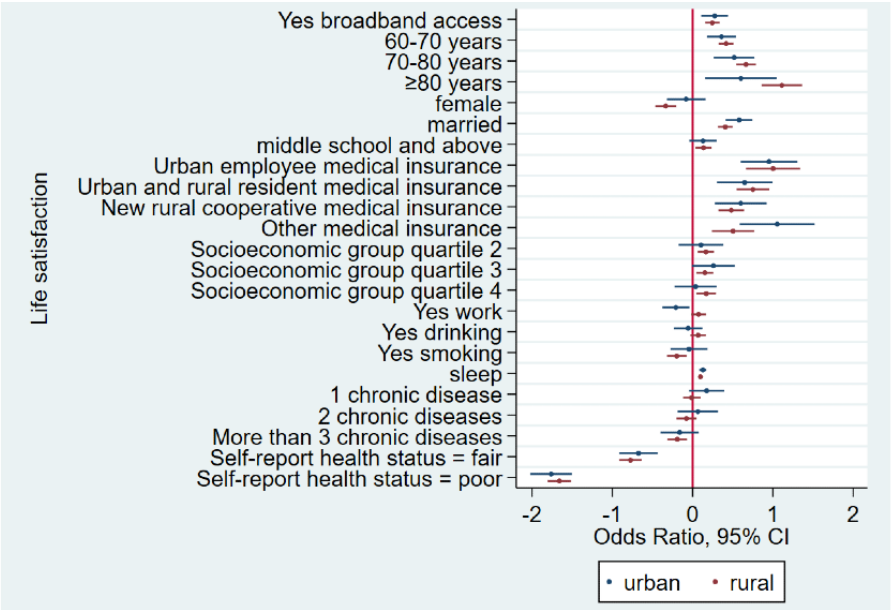

Figure 4. Coefficient plots showing multivariate logistic regression analysis of the association between home broadband connection and social participation by socioeconomic status from the lowest to the highest (quartile 1/quartile 2/quartile 3/quartile 4).

Home Broadband Connection at Home and Life Satisfaction

Table 1 shows that the prevalence of life satisfaction among broadband users was 94.1% (5397/5736) as compared to 90.4% (12,126/13,413) among nonusers—a difference of 3.7% in 2015. Similarly, there was a difference of 4.9% and 4% in 2018 and 2020, respectively. Overall, life satisfaction rates decreased in the broadband user group. After adjusting for covariates, Table 2 shows that broadband users were 1.30 times more likely to feel life satisfaction when compared to nonusers (adjusted odds ratio 1.30, 95% CI 1.20-1.40). Stratified analyses (Figures 5-8) showed that home broadband connection and life satisfaction still have a significant relationship across various ages, genders, socioeconomic groups, and geographic areas.

Home Broadband Connection at Home and Loneliness

Table 1 shows that the prevalence of loneliness among broadband users was 17.5% (1005/5730) as compared to 28.5% (3814/13376) among nonusers—a difference of 11% in 2015. Similarly, there was a difference of 9.6% and 9.8% in 2018 and 2020, respectively. Overall, loneliness rates decreased in both groups in 2015 and 2018 but remained similar in 2020. After adjusting for covariates, Table 2 shows that broadband users were 19% less likely to feel loneliness when compared to nonusers (adjusted odds ratio 0.81, 95% CI 0.77-0.86). Stratified analyses (Figures 9-12) showed that the relationship between home broadband connection and loneliness was consistent across various ages, genders, socioeconomic groups, and geographic areas.

Discussion

Principal Findings

Different from previous analyses of the CHARLS dataset on the association between broadband or internet connection and health-related characteristics, this study examines the broader potential contribution of home broadband connection related to social participation, life satisfaction, and loneliness based on a national longitudinal sample from China. There are 3 key findings from this research: (1) home broadband connection has a positive impact on life satisfaction, (2) social activities increased with broadband connection at home, and (3) feelings of loneliness were decreased with home broadband connection. This research contributes to the existing literature in this field of digital determinants of health in 2 ways. First, our study utilizes the latest CHARLS datasets from 2015 to 2020, whereas other similar works focused on the earlier datasets or only used 1 dataset as the cross-sectional study [24,28]. Second, this study is the first to not only explore the changes of home broadband connection from 2015 to 2020 but also show the impact of home broadband connection on psychosocial characteristics among people older than 45 years in China.

Consistent with previous findings, home broadband connection has a positive impact on life satisfaction [40-42]. The study using the 2019 Chinese Social Survey data of 2105 adults older than 60 years showed that internet use was positively associated with older adults' life satisfaction [42]. Moreover, findings from a large-scale survey of Israel from 2003 to 2012 revealed that internet adoption increases life satisfaction [43]. A UK study using waves 6-8 of the English Longitudinal Study of Aging found that infrequent internet use (monthly or less vs daily) was predictive of deteriorating life satisfaction [44]. Since the COVID-19 pandemic, there has been an increase in the literature focusing on internet addiction or problematic internet use, associated with negative life satisfaction, especially among younger adults [45,46]. Further, studies from the United States reported that time spent browsing the web was negatively related to life satisfaction based on cross-sectional data collected from adult residents in 2004 and 2005 [47]. This discrepancy may be the result of differences in age groups and frequency of internet use. Given the emerging evidence on the importance of home broadband connection impacting life satisfaction, policy makers could consider using broadband internet connectivity as a platform to improve psychosocial outcomes.

The second finding is that, interestingly, the likelihood of having social activities increased with home broadband connection. This result is in accordance with a previous study, suggesting that internet use promotes social activities compared with those who do not use the internet [48]. In addition, there are studies showing that frequent internet use was associated with reductions in the likelihood of visiting family or friends [48,49]. Older adults and people with disabilities and chronic diseases are more vulnerable to social isolation than the rest of the population; it can be challenging for them to maintain regular social participation, especially for those living alone [50-52]. Increasing research demonstrates that digital technologies can be impactful tools for generating and supporting social participation [53,54]. Access to information and communication technologies such as the use of internet-based platforms and telehealth services has been found to increase the quality of life of those populations by saving travel time and expenditure [55-57]. However, such research is underdeveloped for those vulnerable populations; although online social participation expands social experiences and connections, face-to-face experiences were more valued [58]. There is a need to understand the broad range of technologies that are being applied to address social participation and research-integrated (online-offline) social participation to develop a connected life for those populations.

The third finding of this study suggests that the likelihood of feeling lonely was decreased by home broadband connection, which is in line with that reported in other studies in Ireland

[10], Germany [59], and the United States [60]. An Irish study that examined patterns of internet use and psychosocial outcomes for over 3500 people older than 50 years found that high-speed broadband availability was associated with higher reported levels of home internet access, greater frequency of internet use, and more engagement with internet activities and that loneliness scores were significantly lower among those who used the internet daily compared with those who never used the internet [10]. The reason can be explained by that those with access to broadband internet showed higher digital literacy [10], which plays an important role in bridging the digital divide, facilitating digital engagement and allowing for a connected society [61]. In contrast, there are studies indicating that internet addiction or problematic internet use could induce loneliness [62,63]. There are growing research evidences of the biological, psychological, social, and economic impacts of loneliness, which has drawn knowledge, service providers, and policy makers together, in order to raise awareness and reduce the negative effects of loneliness [64,65]. Use of the internet has been shown to enrich the lives of isolated older adults by lowering perceived life stress and increasing perceptions of self-efficacy [66]. Although there is evidence that broadband use among older people has been expanded due to COVID-19 experience [10], more evidence is required for exploring the role of home broadband connection beyond COVID-19. Interventions to reduce loneliness and its health consequences may need to consider the home broadband connection. Such findings may help inform governmental policies on areas such as active aging, infrastructure provision, and digital skills development.

Policy Implications From This Research

As broadband internet connectivity is one of the social determinants of health [67], which affects health care delivery, health outcomes, health education, public health prevention and promotion, advocating for digital equity is vital to people, community, and government. According to our research, having a home broadband connection is associated with higher satisfaction of life and social participation in China. As such, it is important to continue providing broadband connectivity and improve digital infrastructure, especially for those older adults feeling lonely and needing social connection. Since 2015, China has created an “Internet Plus” initiative aiming at connecting a growing economy to the power of connected services, from manufacturing to agriculture, which includes health management services using the internet to exchange health data to achieve quicker, safer, and more integrative care. This national initiative is not only aligned with the sustainable development goals, focusing on areas such as decent work and economic growth, but it also contributes to the enhancement of public health and the reduction of health disparities. Although “Internet plus” should progress to support novel applications of digital health such as artificial intelligence, internet of things, virtual reality, augmented reality, and big data analytics [68], it requires strong governance and political efforts. Moreover, as internet promotes active aging, China has developed National Action Plans for the Development of Smart Health and Eldercare Industry, which integrates digital technology with the older adult care service industry, addressing the needs and health status of older adults [22]. Aligned with World Health Organization’s Universal Health Coverage (all people have access to the full range of quality health services they need, when, and where they need them), this evidence-based research on well-being and psychosocial outcomes can inform policy makers consider reducing health inequality and improving social capital and cohesion, while expanding the home broadband connection.

Strengths and Limitations

Our study’s strengths lie in its use of data from a period marked by the expansion of broadband internet connection, allowing for meaningful comparisons between individuals with and without such connectivity. The meaning of home broadband connection is one of the limitations, as it does not include the speed of the internet or whether it is mobile broadband or fixed broadband, which requires more granular detail to determine what people are doing with this internet access. The variable we used (home broadband connection) may not capture all types of internet connections. Hence, our findings may not apply to access for all types of internet connections (including broadband connection outside home). Utilizing a panel data study design with a national sample, this research ensures robust findings. Moreover, the study effectively adjusts for socioeconomic factors, behavioral factors, and locality, enhancing the control over potential confounding variables. However, as an observational study, causal conclusions are limited, and potential omitted variable bias and unobserved factors may impact associations. Evidence from randomized controlled trials or quasi-experience study designs is needed to provide more robust evidence on the link between broadband connectivity on health and well-being.

Conclusion

In conclusion, this paper contributes some important insights to the field of digital determinants of health by highlighting the potential additional benefits of broadband internet connectivity on well-being and psychosocial outcomes, beyond the known advantages. Since the internet may be beneficial for decreasing loneliness and increasing social participation and life satisfaction, this study underscores the need for further research to fully understand the intricate relationship between broadband internet connection, interactions with the health system and society, and their implications for health and well-being.

Acknowledgments

We thank all the participants of the China Health and Retirement Longitudinal Study as well as the recruitment staff. LY is funded by the National Social Science Fund of China Program (21BRK019). JTL is funded by the Yushan Fellow Program by the Ministry of Education, Republic of China (MOE-112-YSFMN-0003-002-P1).

Abstract

Background: Canada's immigrant and refugee older adult population is projected to grow substantially, making equitable access to information and communications technologies (ICTs) vital for enhancing quality of life in older age. Strengthening the digital competence of immigrant and refugee older adults can improve their social connectedness and access to local information.

Objective: This study explored the digital competence of Arabic-speaking immigrant and refugee older adults, focusing on how they engage with ICTs to meet their information and communication needs and the strategies they use to navigate digital barriers.

Methods: A qualitative descriptive methodology within a social constructivist paradigm was adopted, incorporating triangulated data collection and iterative co-design cycles. The qualitative approach facilitated an in-depth exploration of participants' experiences, skills, and emotions and the contextual factors influencing their digital competence. Data were collected through storytelling approaches, qualitative interviews, and focus group discussions, which were effective in capturing the experiential aspects of aging and technology use. Co-design cycles informed 6 digital learning sessions tailored to participants' immediate learning needs, fostering motivation and engagement and allowing for observation of ICT use. Digital competence was mapped across the learning domains of the Digital Competence Framework for Citizens 2.2.

Results: This study engaged 31 Arabic-speaking immigrant and refugee older adults residing in Canada. Most participants had limited formal education (19/31, 61%), lived with family (22/31, 70%), and reported a low income (21/31, 68%). All participants (31/31, 100%) used smartphones as their primary ICT device, whereas few (3/31, 10%) had access to a computer. In total, 3 themes were identified from the analysis, grounded in Digital Competence Framework for Citizens 2.2 competencies on information and data literacy, communication and collaboration, and safety and problem-solving. The themes focused on agency, which is enhanced or constrained using ICTs, impacting older adults' desire and ability to use these technologies to independently meet their daily needs.

Conclusions: Immigrant and refugee older adults require support to navigate digital barriers and gain digital competence. Smartphones serve as a critical tool for enhancing digital agency, which can lead to greater social connectedness and improved access to local resources in older age. The findings will inform the design of future digital competence programs for older migrants, emphasizing community partnership and reciprocal learning.

Introduction

Background

Information and communications technologies (ICTs) are defined as the spectrum of digital and social media used for communication and access to information [1]. Internet access rates have more than doubled for those aged ≥65 years in Canada [2]. Access to ICTs has been declared a fundamental human right, with strong evidence that the digital divide—lack of or limited access to the benefits of technology—impacts quality of life in older age [3]. ICTs provide several benefits for older adults, including social connectivity, opportunities for continuous learning, access to health-related information, and entertainment [4-8]. The benefits that older adults obtain from technology depend on the types of technologies adopted and their digital competence [9-12].

Digital competence is defined as "the confident, critical and responsible use of, and engagement with, digital technologies for learning, at work, and for participation in society. It includes information and data literacy, communication and collaboration, media literacy, digital content creation (including programming), safety (including digital well-being and competences related to cybersecurity), intellectual property related questions, problem solving and critical thinking" [13]. Digital competence is a newer concept in comparison to digital literacy, with both terms being used interchangeably [14] or viewed as different with some shared dimensions related to technological knowledge, skills, and attitudes [15,16]. Digital competence is a useful concept for older adults as it incorporates attitudes and motivations that are essential predictors of ICT use in older age [17-19]. Enhancing the benefits of using ICTs requires not only improving technological skills and knowledge but also understanding the attitudinal and socioemotional aspects of technology use [20]. Older adults are willing to adopt technology that is deemed beneficial to them and that has positive implications for their daily life [6,21,22]. Older adults use ICTs to maintain social connections, strengthen family ties, and support activities of daily living and leisure [22,23]. These digital tools can enhance older adults' independence, autonomy, and self-confidence [12,22]; however, the digital divide persists due to a range of factors, such as living with disabilities, lack of social support, lower educational level, and low income [12,24]. During the COVID-19 pandemic, physical distancing and the health risks to older adults necessitated creative digital solutions, such as ICT-mediated social and recreation programs, which reinforced the potential benefits of ICTs [25,26].

Improving digital access and competence is one strategy to support healthy aging in migrant populations. Canada continues to welcome high numbers of immigrants and refugees, with an increasing percentage from Arabic-speaking countries [27]. Younger cohorts of immigrants demonstrate high levels of proficiency in using technologies to adapt within postmigration contexts [28-30]. The extent to which this proficiency applies to immigrant and refugee older adults has been less explored despite well-documented ICT adoption to facilitate social engagement and sustain family ties [31,32]. Older Arabic-speaking migrants experience loneliness, social isolation, and barriers to access and use of aging-supportive services [33,34]. Arab migrants traditionally belong to extended family models and value close interpersonal relationships within local and transnational kin networks [35,36], with the adoption of ICTs influenced by social identities and roles [37,38]. In addition, gender, income, educational level, and technology infrastructure in their countries of origin shape the use of technologies and motivations to develop particular knowledge and skills [24,39,40].

To support digital competence and create avenues for digital learning, it is critical to understand the individual and social influences on ICT use among older migrants [41]. The lack of theorization linking aging and technology use is well cited in the literature [42], with little integration of immigrant and refugee older adult perspectives in gerontechnology [37]. This study aimed to explore the "messiness of practice" [43] that sheds light on the ways in which immigrant and refugee older adults interact with technologies in their daily lives to solve problems, their exercise of agency, and their digital competence.

Objectives

This study aimed to explore the digital competence of immigrant and refugee older adults with a specific focus on (1) the ways in which immigrant and refugee older adults engage with ICTs to meet their needs for accessing information and communication and (2) the strategies used to problem solve and navigate barriers to using ICTs.

Conceptual Framework

The Digital Competence Framework for Citizens (DigComp) 2.2 encompasses 5 key areas defining the scope of digital competence: information and data literacy, communication and collaboration, digital content creation, safety, and problem-solving [44]. The initial 3 domains focus on competencies associated with particular tasks and applications. The fourth and fifth domains, "safety" and "problem-solving," are relevant across all digital activities. Each competence area incorporates skills, knowledge, and attitudes that are essential for digitally literate citizens, with proficiencies that range from basic to advanced and that can be used to design competence assessment tools, support education, and tailor training [45]. This framework was selected for its comprehensiveness and its attention to attitudes across the range of competence areas that were deemed relevant to older adults in a growing technology-dependent world [5,46,47].

Methods

Research Design

A qualitative descriptive methodology within a social constructivist paradigm was used and included triangulated data collection methods and iterative co-design cycles with immigrant and refugee older adults to explore ICT use, digital competence, and related learning needs. A qualitative approach was selected to allow for in-depth experiential explorations of digital competencies. The goal was to conduct a holistic investigation into the ways in which older adults engaged with technologies, including their skills, knowledges, emotions, and influencing contextual factors. Triangulation of data sources over a period

XSL•FO
RenderX

is required to obtain descriptively rich insights on technology use in older age [48]. In addition, older adults respond best to storytelling approaches for data collection that are flexible and engaging, which makes qualitative interviews and focus group (FG) discussions most effective in expanding understandings of aging [49]. Co-design cycles informed a sequence of 6 learning sessions to address immediate learning needs identified over the course of data collection as older adults' motivation and interests are key drivers of digital engagement [12,20]. Reciprocity via supporting their immediate digital learning needs helped meet ethical obligations to the community and build sustainable partnerships [50].

Ethical Considerations

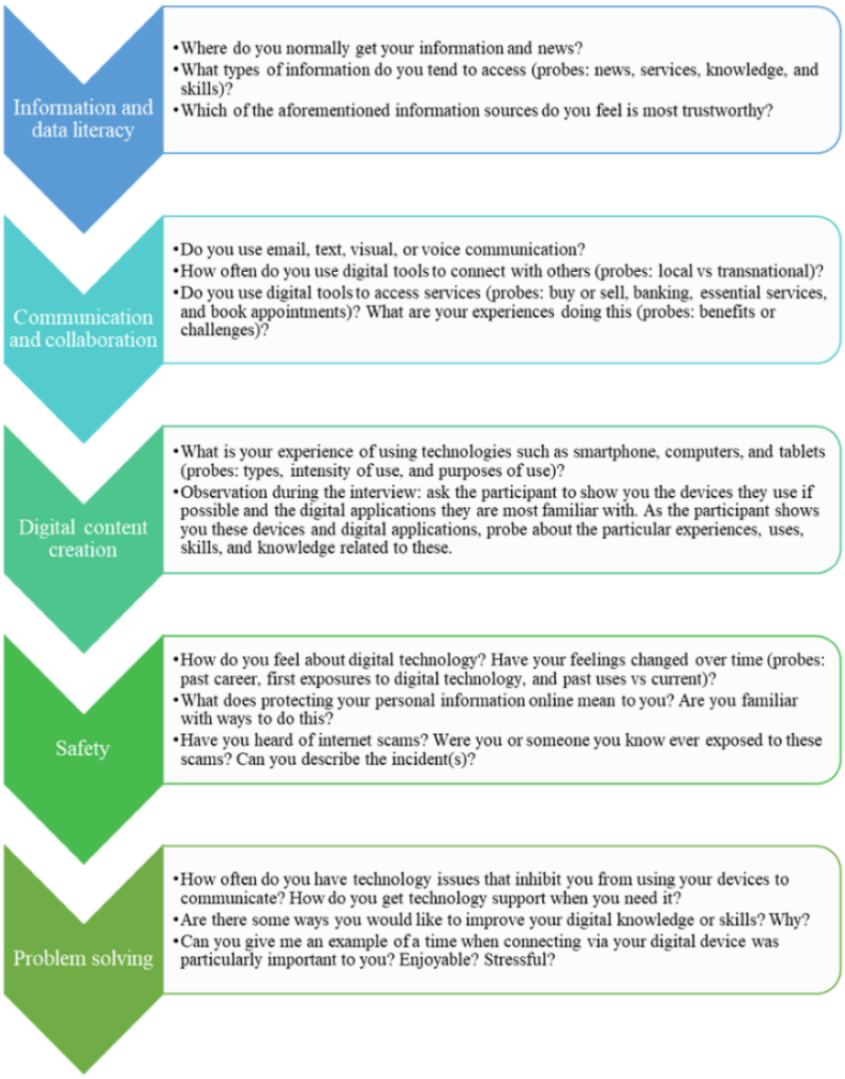
This study received ethics approval from the University of Alberta Research Ethics Board (ethics number Pro00103587). All participants provided informed consent before data collection and were informed of their right to withdraw at any time during the study. Identifying information was removed from interview and FG transcripts and from observation notes and then shared with the research team for analysis and knowledge dissemination. Participants were provided with an honorarium of CAD $50 (US $35.20) for participation in the data collection sessions.

Sample and Recruitment

Study participants were community-dwelling individuals who (1) were aged ≥55 years, (2) self-identified as first-generation Arabic-speaking migrants, and (3) reported using ICTs in their daily lives. We selected the age of ≥55 years to define "older adult" because some refugees in the Arab community identified as older adults at <65 years [51,52]. Despite the World Health Organization using the age of ≥60 years to define older adults, the definition acknowledges variations in life expectancy and cultural perceptions of aging worldwide [53]. Cohorts of Arab-Canadian migrants differ in levels of education, reasons for migration, religious traditions, and experiences of macro and micro historical and political events [54]. Most Arab older adults in this study were Syrian, Lebanese, Jordanian, or Palestinian; ascribed to the Muslim faith; and had varying levels of education, income levels, and English-language fluency. A social service organization that catered to newcomers and a mosque that included a congregation of Arabic-speaking older adults supported the project by hosting the data collection sessions and aiding recruitment. Flyers in English and Arabic were distributed by the 2 partner organizations, and staff helped explain the purpose of the study to potential participants. These organizations also provided space for the group-based digital learning sessions. Purposive sampling began with service providers at these organizations connecting with immigrant and refugee older adults via phone calls and in person to introduce the study. Immigrant and refugee older adults with interest in participating were then contacted by the research team for screening and formal consent to participate. Data saturation was determined by repetitive patterns of experiences, perceptions, and needs identified in the data over the course of the study.

Data Collection

Overview



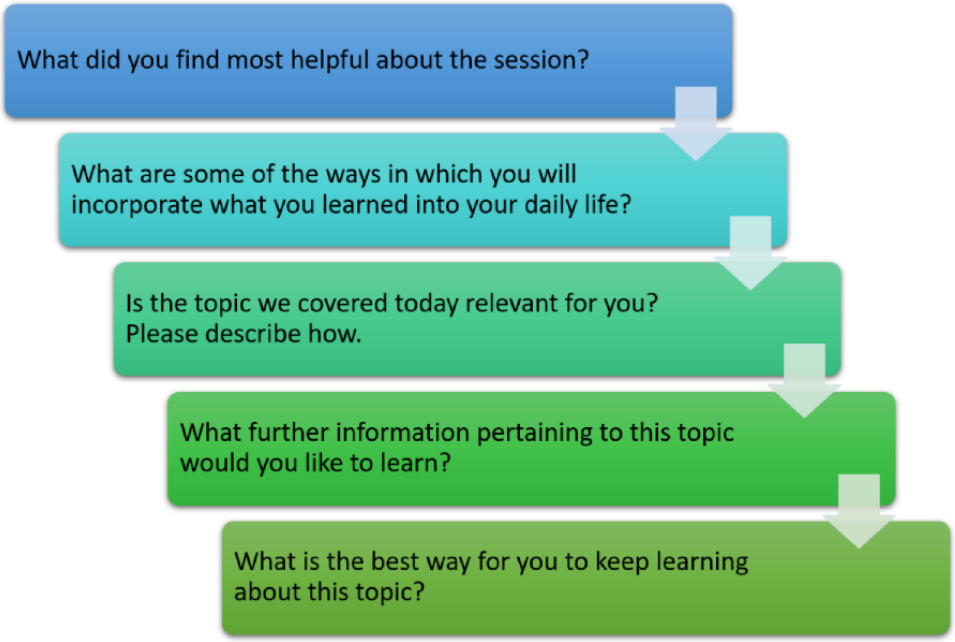
Data collection included 2 phases. Phase 1 involved individual (n=8) and group (n=2) semistructured interviews to explore experiences of using ICTs. Phase 2 included digital learning sessions where observations and FGs facilitated a detailed documentation of immigrant and refugee older adults' digital competencies and learning needs. Triangulation of data sources over a period allows for access to descriptively rich insights on technology use in older age [22,38]. All individual interviews and FGs were audiotaped and transcribed verbatim by a professional transcriptionist trained in the Arabic language.

Semistructured Interviews

Individual interviews were conducted in participants' homes from April 2022 to June 2022 by an Arabic-speaking interviewer and lasted, on average, 1 to 1.5 hours. For the first phase, an interview guide using the DigComp 2.2 guided the types of questions asked (Figure 1). Learning session topics were derived from the priority areas identified in the phase-1 interviews and included learning about the essentials of smartphone hardware and software, social media communication tools such as Facebook and WhatsApp, and using email and online access to information.

XSL•FO
RenderX

Figure 1. Phase 1 interview questions from the Digital Competence Framework for Citizens 2.2.



Co-Design Sessions

In phase 2, we used a participatory framework [12,20] to co-design ICT learning sessions between September 2022 and November 2022. The session instructor was a computer engineering university student, and he was supported by an Arabic-speaking research assistant who translated for participants who only spoke Arabic. The participatory co-design framework facilitated collaborative approaches that actively involved older adults in the design and decision-making processes of the learning sessions to ensure that the sessions were engaging, built on the lived experiences of participants, and met their self-identified learning needs [12,20] (Au et al [55] reported in detail on the co-design process). The project lead, who mentored the session instructor and research assistant, had >10 years of experience in participatory research methods and provided training on co-design processes during weekly team meetings. In each session, participants started with a 30- to 45-minute FG discussion related to the main learning topic of the day to identify the ways in which they engaged with that particular ICT in their daily lives; the challenges they faced; and their attitudes, emotions, and learning needs (Figure 2). Phase 2 FGs were used to deepen insights from phase 1, triangulate data for validation, tailor learning sessions to participants' needs, and engage them in identifying their learning requirements and experiences with digital technologies. Feedback on each learning session helped the instructor refine subsequent session delivery and content. The purpose of this study was not to develop or test a complete digital learning program; rather, the purpose was to create a supportive environment where immigrant and refugee older adults had some direct benefit from participating in the research study while the research team gained in-depth understanding of their digital practices. Participants for these sessions were divided into 3 groups, with separate men's (3/21, 14%) and women's (10/21, 48%) groups in the faith-based organization and a mixed-gender group (8/21, 38%) in the social service organization. Observations (54 hours of observational data) that occurred during these sessions entailed a researcher documenting group learning processes and the digital competencies of participants as they navigated their devices and worked together through lesson material.

Data Analysis

Arabic conversations were initially analyzed by bilingual team members, with key quotes and codes then translated into English for team discussion and use in knowledge dissemination. A reflexive thematic data analysis approach was used to identify, analyze, and report patterns within the data [56] facilitated by the NVivo qualitative data management software (QSR International). The 6-phase approach included familiarizing ourselves with the data, generating initial codes, searching for themes, reviewing themes, defining and naming themes, and writing a report [57]. Initial codes were organized around the DigComp 2.2 competencies, followed by linking and comparing codes within and across competencies to arrive at overall patterns of understanding about participants' experiences of engaging with and learning about ICTs (Figure 3).

To ensure trustworthiness in data analysis, we used peer debriefing, data triangulation, and reflexivity [58]. Peer debriefing provides external validation, which was done through weekly team conversations to discuss the ways in which observation, FG, and interview data reflected particular competencies. Data were analyzed iteratively, meaning that the data were coded systematically once collected and then recoded as codes became more refined over time with deeper understanding. Team consensus was reached with a topical coding tree based on the DigComp 2.2 competencies. One team member (JS) led the refinement of coding to develop the final themes for this paper, and all coauthors provided critical feedback at multiple points during this process. The authors have expertise in qualitative methods, aging, and migration. In total, 2 authors are bilingual Arabic-speaking academics, with the remaining authors being second-generation or first-generation immigrants to Canada and academic researchers.

Results

Overview

A total of 31 immigrant and refugee older adults participated in this study, with an average age of 64.1 (SD 7.7) years. Most participants were women (20/31, 65%), identified as Arab (29/31, 93%), and were immigrants (19/31, 61%) or refugees (10/31, 32%). The highest level of education was primary or secondary school for most participants (19/31, 61%). In total, 2 non–Arabic-speaking participants were included because they were spouses of Arabic-speaking participants attending the program. More than half of the participants lived with their spouse, their children, or both (22/31, 71%); reported a family income of <CAD $20,000 (US $14,078.30; 21/31, 68%), which is categorized as low income in Canada; and received some form of government financial support (21/31,68%; Table 1).

All study participants (31/31, 100%) used smartphones as their primary ICTs, with only a few (3/31, 10%) reporting having access to and knowing how to use computers. Smartphones were cost-effective, accessible, and familiar to immigrant and refugee older adults, and hence, the focus of the learning sessions throughout this study was on exploring ICT use through these devices. The themes highlight the ways in which agency is enhanced or constrained using ICTs and draw attention to older adults' desire to use these technologies independently to meet their daily needs. The 3 themes were developed from across four dimensions of the DigComp 2.2: (1) information and data literacy, (2) communication and collaboration, (3) safety, and (4) problem-solving. The dimension of "digital content creation" was not inductively discussed by participants, and the scope was beyond the capacity of this study to address (Multimedia Appendix 1).

Theme 1: "Here You Need to Go on the Website and See for Yourself" (Access to Information)

All participants described using their smartphones to access information via social media platforms, with WhatsApp and Facebook being the most used, followed by YouTube. Search engines such as Google were rarely described as information sources by participants. All participants were skeptical about the credibility and authenticity of the information on social media. Participants most often used family and friends for information checks to confirm or disconfirm what they viewed on these platforms:

> *Yes, I subscribed with (news media channel) two or three times but I've seen fake news on there because we hear things and they broadcast different and fake things. We ask our friends and family in Iraq if the stuff they talked about has really happened there and they say "no," so all their news is fake.* [P5; older man; interview]

Immigrant and refugee older adults were savvy in evaluating information, especially with regard to world events. The information accessed related to Canada and their countries of origin as they followed ongoing political and social events. Accessing trustworthy information was heavily reliant on connections within transnational social networks that were made possible via the use of ICTs to communicate at a distance via free social media apps that allowed for texting, voice messages, and phone calls to gather information in real time:

> *Nowadays, to get the right information, sometimes I have to check more than one source and I compare the information...I exchange information with my friends and see if it's accurate. See what they've heard, so they tell me just to try to get the most accurate information...some [friends] are here, and some are back home. It depends. Some in Egypt, some in a different country.* [P12; older man; interview]

Beyond social and political news, participants used ICTs to search for information related to their hobbies and religious practices and to resources for immigration and health information:

> *For entertainment on YouTube I go and see how to bake a cake, I tried banana bread, amazing. I make things if I like the recipes.* [P5; older woman; FG]

Participants often received links to videos and images on social media that allowed them to explore a range of topics of interest, and many reported high daily uses for entertainment and information access:

> *Sometimes you will find it [health information] on YouTube and sometimes on Facebook. I type the name of the doctor on YouTube and I listen to what he says about health and about medicinal herbs...if I think the information is correct I follow it and if I do not think it is correct I do not follow it.* [P1; older woman; FG]

Refugee newcomers struggled as they quickly realized that they were expected to access online information needed for settlement. These participants were socially isolated during the COVID-19 pandemic and struggled to use email to access information critical to their daily lives, such as opening newsletters, paying utility bills, reading and responding to government emails, and accessing online banking:

> *No, so they don't know anything about accessing health information or banking information online, or any essential services, my understanding.* [Translator for P1 and P2; older couple; group interview]

While newcomers are connected to a settlement worker in Canada for their first year, this support was not always consistent or available in a timely manner or did not continue for a sufficient length of time:

> *Even here when you go to a government office to do anything, for example, they give you a website and ask you to see for yourself...in Syria, they would do that for you, if you needed anything, government employees would communicate clear instructions and you would get it done. Here you need to go on the website and see for yourself and this is hard for seniors, other than the language problem, they don't even know how to open or go on a website. For example, even though I am able to rely on myself, I still find it difficult because of the language. Even when I go on certain websites, their website design is sometimes a little different in comparison to what I was used to.* [P12; older man; interview]

All participants spoke Arabic, Kurdish, or Farsi as their native language, displaying diverse levels of proficiency in both written and spoken English. Language posed a challenge to browsing, searching, and filtering digital content in English. Consuming information via social media and specifically audiovisuals was easier for participants. Accessing information via ICTs was challenging not only due to lower digital competence and language barriers but also due to skepticism about the trustworthiness of the information and the applicability of this information to their unique situations. Furthermore, newcomers struggled with engaging with ICTs after migration due to the difference between technology in Canada and in their home country as they had shifted into a digital world later in life driven by the necessities of migration.

Finding trustworthy sources of information can be difficult for isolated immigrant and refugee older adults who do not have strong local social networks. Language barriers prevented accessing local trusted sources of information, such as health care practitioners and service providers:

> *There are issues with accessing banking or health information because often we opted to ask people around us locally, but have found that the information that we gathered could be inaccurate and the wrong information can spread quickly.* [P6 and P7; older couple; group interview]

Finding these trusted individuals was especially challenging for newcomers who might not know how to find a physician who speaks their language or might be unaware of older adult service providers in their local region. Arabic social media groups and

XSL•FO
RenderX

social media influencers who shared information after migration about settlement in Arabic were especially helpful:

> *In relation to the YouTube English lessons, someone who used to be an engineer in Syria, he started making YouTube videos in Edmonton that is English and Syrian translation. This is the content that they watch and he get the video link through WhatsApp through his cousin. They shared that thanks to the YouTube algorithm, they can watch the rest of his videos on his channel.* [P7; older man; interview]

Immigrant and refugee older adults who had English-language fluency or strong social connections within local Arabic-speaking communities were better connected to needed information and did not report these challenges. These participants reported more nuanced challenges such as storing and retrieving information:

> *I don't know how to [retrieve and save information that I have accessed]...I don't know where to save it.* [P2; older man; FG]

Others struggled with understanding search algorithms and the ways in which data were filtered by social media platforms, which caused frustration and inhibited access to preferred information:

> *P3 has a question about how to cancel certain posts that she sees on Facebook. She is confused as to why they show up when she has never pressed "like" on these posts.* [Older woman; observation]

In summary, immigrant and refugee older adults described a high level of skepticism about the information they found on social media, but often this was the most accessible source of information for those who were isolated with low digital competence and language barriers. Immigrant and refugee older adults were more comfortable navigating social media platforms in Arabic, and the availability of voice and video options supported those with low reading literacy. This meant that immigrant and refugee older adults were subjected to social media trends and algorithms that might bias what information they saw. This was countered by a reliance on trusted social contacts locally and transnationally to verify information from these digital sources. This coping strategy was ineffective in local contexts, where newcomers with few social contacts lacked access to reliable and needed information about their health and aging-supportive resources after migration.

Theme 2: "We Are Mute" (Active Engagement in Digital Communication)

A variety of platforms were used to meet participants' needs to communicate with family, friends, and others in their social networks. The most common social media platforms used were WhatsApp and Facebook. For participants who were illiterate or had low literacy, the voice message and video features of these platforms allowed them to engage with others. Some individuals used Zoom for group lessons and meetings with family. Email was the least used communication tool. Having left Syria before electricity and the internet were widely available in their village, one participant explained how the need and opportunity to use social media to connect with family began with their migration journey to Turkey—"We didn't know Facebook in Syria not even WhatsApp...when we went to Turkey we started a little to learn" (P1; older man; FG)—whereas the use of email followed to communicate with immigration officials and service providers in Canada. Responding to emails can be particularly important to access government social and health services, but a combination of language barriers and digital competence struggles prevented some newcomer refugees from using this communication tool:

> *P1 after seeing this slide has mentioned that she gets email messages and she doesn't understand, she doesn't open the message and it is left unread. Doesn't know how to respond to voicemail.* [Older woman; observation]
>
> *Participant knows how to open Arabic emails and uses it to track for school or government, doesn't send emails himself due to English barrier, and he communicates through social media more.* [Older man; observation]

Agency to create a digital identity and manage communication with others was important for participants. Some participants only received communication and were not able to reciprocate or initiate communication, which was a source of frustration:

> *I have been here 46 years, I went to school, I went to high school, I went to university, I did my education. At the time, I did all those but no technology was at the time, and now I have been retired for 10 years. Like on Facebook, if somebody sends me a message, I go back and answer them but for me to open my telephone and call them or send them a message, I do not know how.* [P8; older woman; interview]

Similar comments were made by women in the study, who reported wanting to learn to use email to expand beyond the usual familiar tools:

> *To enter into society...meaning if my friend sends me an email, I want to learn to respond to her...we read the message but we don't know how to respond.* [P6; older woman; FG]

Other participants reported communicating by proxy, where family members navigated their devices for them, responding to emails for communication with service providers and initiating contact with family and friends:

> *Sometimes there are things like the skype and internet-related things like video calls when I talk with my kids, my wife helps me with that. I am not very good with technology because we're a bit old school.* [P10; older man; interview]

While this support was appreciated by some, most reported wanting independence to alleviate the burden on their children. There were frequent comments about frustration with not keeping up with the times, being behind their grandkids in understanding ICTs, and not being able to maximize the use of their devices:

> *...but how much help from your kids! You know they are always busy, especially for mama, ok later later,*

XSL•FO
RenderX

> *tomorrow, tomorrow, and then tomorrow they never showed up for me.* [P8; older woman; FG]

For most, the lack of agency was revealed in observations during learning sessions despite their assertion initially that ICTs were accessible and had a high degree of integration into their daily lives. Immigrant and refugee older adults had difficulty creating digital content, such as initiating picture sharing, starting conversations, and deleting posts. Most participants struggled with these skills and required assistance to learn how to complete them during the learning sessions:

> *P1 knows how to share existing posts, is unable to save her own picture and share it.* [Observation]

This resulted in engagement being one-sided, eliminating the participants' autonomy to connect on their own terms to support preferences and needs. Passive use of ICTs, where participants observed but did not comment or create digital content, was common:

> *I access Facebook daily. I do not participate much but I benefit from world news, political news, religious news.* [P8; older woman; FG]

> *A lot of the participants don't post, rather they are looking at posts.* [Observation]

For those who had basic competence levels to communicate by posting, sending voice or text-based messages, and responding to social media posts, the more technical features of these applications were cited as challenging, such as deleting posts, adding friends, hiding posts, and creating private groups. Learning to block others, create private groups for discussion, and add or delete contacts is essential for agency in digital spaces:

> *P3 mentioned that she only blocks people on her phone, not on Facebook. She thinks it is really important to learn how to do this. Going over the Facebook slide, P4 wants to learn more about it...She knows how to add people and to search for content. She doesn't know how to block people on Facebook.* [Observation]

Transnational communication was prevalent within this population, and many participants connected with family, friends, and acquaintances overseas, with the lack of digital skills translating to some evidence of gendered power inequities, where women reported not being able to filter information or restrict access by families within transnational spaces:

> *P5 has a large friend request list containing her in-law side of the family. Although P5 knows them, she didn't want to add them as her friends on Facebook. She wants to keep her privacy, and noted that her husband has a large family (largest family in town), and she doesn't want them on her Facebook. But G. noticed that she also doesn't really post. H. wonders if once we teach them how to manage privacy settings on posts, maybe she may want to post more and may feel more comfortable to do so.* [Observation]

Communication via ICTs was an ongoing feature of participants' lives, and for some who were physically more isolated, it was the main source of daily communication. While, on the surface, it appeared that immigrant and refugee older adults had a high degree of competence due to their intense reliance on ICTs, it became apparent that agency was constrained due to limited control over how, when, and what was communicated. Creating digital content, communicating with preferred social contacts, and using communication to access local sources of support were major challenges.

Theme 3: "Don't Give Me a Fish, but Teach Me How to Catch It" (Troubleshooting ICTs)

Safety online and troubleshooting to address issues such as storage, function changes, and device accessibility were challenges for immigrant and refugee older adults. Safety related to sharing information online, password management, and privacy in online communication. Participants relied on practical approaches to store their passwords, such as digital word documents, notebooks, or family members. Learning sessions were often interrupted to troubleshoot password and security functions of their devices:

> *Their bewilderment and lack of awareness says a lot—they're learning that their children have set up a lot of the functions on their phones for them...so the participants never needed to deal with the set-up process and account/password management.* [Observation]

One participant described using the Notes app on their phone to store their passwords but was fearful as to what would happen to their digital identity if they misplaced their phone:

> *She has issues with remembering her passwords. She had written down her passwords in her phone but when she lost her phone, she couldn't recover her passwords.* [P6; older woman; FG]

Participants had a difficult time creating strong passwords and tended to use the same password across applications. They reported trouble remembering passwords and were required to use the password reset feature, which posed additional complexities. One participant felt overwhelmed with the number of passwords that are required to use ICTs and the need to synthesize complex passwords:

> *Yeah, I can't deal with, you know, like if I want to search about something on a Google, I pray, I go, or if they ask me to put my password, probably I have 200 passwords and I don't know which one. You know, like I'm not capable to action and I write down my password. I write down my email, whatever, and the next day I forgot something or some letter.* [P10; older man; interview]

Generally, the participants were well equipped to deal with security issues. There were instances in which participants could recognize scam calls and phishing emails. They were hesitant about making new friends online, joining Facebook groups that they did not recognize, and sharing photographs online. This hesitance was outlined by one participant:

> *You don't trust like on the Internet to find somebody new, or you don't know nothing, and you don't know*

XSL•FO
RenderX

> *if he's a con artist or thieves or, you know, eat your life. I don't like to meet those people that I don't know them. But if I knew a neighbour, you know, "Good morning, good afternoon." She visits me, I visit her. Yeah, I would like to communicate and be a friend and help her and she help me, accepted. But somebody like introduced, met on a—or I met on the Internet, and I don't believe those to be follow.* [Older woman; FG]

Instances of scams were not described by participants except for one who talked about learning to avoid accepting phone calls from unknown numbers. While most participants reported not responding to calls from individuals whom they did not know, this participant described in detail learning to be safer using ICTs after falling victim to a scam:

> *In the beginning, I have many problems with this. Sometimes I answer and I give my, you know, my information. Yeah, because, when I came here, I thought that it's trustworthy...this is a country of laws and never imagined this type of stuff would happen here to be honest. I had a few issues and I even had to cancel my credit card and so I learned, so now, whatever I don't understand, I don't engage in...Sometimes I don't even answer and I miss appointments... Sometimes they are calls from Canada that are important for me and I miss them.* [P12; older woman; interview]

Privacy when using digital devices was of concern for most participants, who tried to navigate this by not sharing or posting on social media and not adding people who were not part of their social network:

> *Daily I get friend requests...people I don't know so I ignore them completely.* [P3; older woman; FG]

Privacy for women related to religious and cultural expectations of modesty and to perceptions of avoiding envy or gossip. Simply not posting was easier versus restricting privacy settings so only certain people could view the posts. According to one participant, "I do not post my pictures on Facebook" (P4; older woman; FG). Another participant agreed and added that "because this is something private, it is not necessary for the whole world to know about it" (P3; older woman; FG). A group of women discussed an incident in which a video of their social gathering, involving clapping and singing, was shared without the consent of one of the participants on social media. Due to religious views about modesty, the women requested that this video be removed. The conversation centered on the importance of privacy and consent when posting content on public forums:

> *It was a misunderstanding...we let our guard down with our friends...she was afraid and didn't want this to spread.* [P4; older woman; FG 3]

However, often, immigrant and refugee older adults were unaware of how to navigate privacy settings on different devices and platforms:

> *Activity on how to make account more private: Participants needed to be verbally and individually guided to find the settings menu for privacy. All participants changed their settings to be more private for friends' requests, even when facilitators described it in a neutral way.* [Observation]

Troubleshooting for accessibility of devices was an issue in that not everyone knew the possibilities with Google Translate and other apps. Many participants were only literate in their first language, Arabic, and some were illiterate in Arabic, so they used their phones to watch and listen but not to read:

> *The message comes to us via phone and we understand a little of it but we then take it to someone who reads English, a friend...I send it to him via phone and he tell me what it is about.* [Older man; FG]

The use of text-to-voice apps and translation functions was not described by most participants outside of receiving and sending voice messages using social media platforms. Most participants who had family living with them or nearby used them for support with troubleshooting their devices. Immigrant and refugee older adults all preferred to learn how to troubleshoot on their own without relying on family and wanted community supports to help expand their digital competence. One participant shared that "They don't have time" (P6; older woman; FG). Another participant agreed and shared that family members lacked patience as "They take the device from you, do this and that, okay, how did you do that? How will you learn it if you are not doing it? Don't give me a fish, but teach me how to catch it" (P1; older woman; FG).

Some immigrant and refugee older adults did not have family or friends nearby or lived alone:

> *I don't have somebody live with me, so when I stuck, I get so upset so that's why I never try again.* [P4; older woman; interview]

These individuals reported frustration and a desire to access support to enhance their digital competence, citing this as a main reason for joining the digital learning sessions. Participants rarely reported accessing services or programs that help with digital competence, especially those who were newcomers to Canada and felt unfamiliar with avenues for this type of support. None reported using the library or other mainstream technology support programs for older adults. Local ethnocultural and faith-based organizations and acquaintances were cited as helping at times:

> *...there is no one to help us, we do not have children here, they are all in Syria and Jordan and Lebanon...We take it to the mosque or to someone we know.* [Older men and women; FG]

Overall, immigrant and refugee older adults experienced significant challenges navigating the technical features of their devices, which, in turn, restricted the scope and range of digital engagement. Assistance from family, when available, was often a source of support to use ICTs. Immigrant and refugee older adults preferred to expand their knowledge and skills to gain further independence in navigating their devices. Participants did not report enrolling in any formal digital learning programs before taking part in this research project.

Discussion

Principal Findings

This study explored the ways in which immigrant and refugee older adults use ICTs in their daily lives, their sense of agency, and their digital competence. This study addressed a significant gap by focusing on digital competence among Arabic-speaking older adults, a population largely overlooked in existing research. While the DigComp 2.2 framework has seen limited application with older adults, its detailed competency structure offers valuable insights into learning needs and serves as a robust tool for future research and interventions. The findings highlight how personal digital competence influences older migrants' engagement with ICTs for local and transnational purposes, providing actionable insights for designing interventions or exploring specific competencies. In addition, digital agency emerged as a critical yet understudied construct, particularly within the context of aging and migration, warranting further exploration.

The sociotechnical dimensions of ICT are described as the broader social practices and structures within which immigrant and refugee older adults are embedded and which shape their ICT use and choices [59,60]. Participants primarily relied on social media platforms to access information, entertainment, and social connections. Similarly to other migrant populations, Arabic-speaking older adults use a range of technologies to maintain transnational social networks, cultivate belonging to places of origin, practice valued social roles such as grandparenting, and navigate barriers to local integration [38,61,62]. Observing older adults use ICTs during the learning sessions was a rich data source, highlighting their creativity and agency despite constraints imposed by low digital competence.

Agency relates to using ICTs in ways that meets one's preferences and needs [5]. Agency has been a core concept in understanding the interplay of internal and external factors that shape technology adoption and the impacts of technology use [60]. Participants in this study struggled to meet their needs via ICTs and, simultaneously, exercised agency to overcome digital barriers. Digital use was on a spectrum from low to advanced agency in managing digital tools to meet needs and preferences during and after settlement in Canada. Constrained agency was most evident when lower digital competence was coupled with minimal environmental and social support to engage with ICTs. This was demonstrated when participants could not search for needed information on online platforms, were unable to control who they communicated with via blocking a contact or creating a private friend group, and stopped using particular apps or phone features because they did not know how to troubleshoot their devices. While immigrant and refugee older adults lacked individual digital competence (microlevel barrier), they were also disadvantaged by technosocial systems that were not designed with and for older migrants (system-level barrier).

Digital competence in searching for and filtering information was limited, especially when seeking information related to settlement or aging-supportive resources. This study showcases multiple exemplars of unsupportive technosocial systems for older migrants. Information about services for older adults is increasingly digitized, which makes it inaccessible to those with poorer digital and other literacies. A mismatch was evident between what services were available and what immigrant and refugee older adults had access to, which is mirrored in other studies on service access barriers [37]. Arabic translations of social and health service information are sparse in Canada despite the Arabic-speaking demographic increasing steadily over time. While immigrant and refugee older adults preferred information shared through trusted social networks, either in person or ICT mediated, newcomers had limited access to this avenue after migration. This was especially evident for refugee newcomers who had arrived during the pandemic, which mirrors what has been reported elsewhere [63,64]. While Arabic social media platforms are readily available, participants felt that the information was not always trustworthy or tailored to their local needs. Technologies, even when not adopted by older adults, influence their lives by changing the social world around them [59]. Study participants were deprived of local knowledge due to limited access to government websites and difficulty searching for online information in English, whereas the Arabic social media platforms that they did use were not specifically oriented to older adults living in Canada. The example of an Arabic-speaking social media influencer who provided local knowledge of the city showcases the potential for social media as a place for effective knowledge dissemination to older migrants.

Despite constrained agency, immigrant and refugee older adults were not always passive ICT users but rather adapted to, overcame, or disengaged from these technologies [59]. Participants disengaged from some ICT-mediated activities such as sharing content on social media because of privacy concerns and their lack of competence in controlling privacy settings or creating private groups. Participants used creative ways to store information, such as sending the information to a peer via WhatsApp so that it was stored in the conversation thread. "Hybrid practices," where technology is used to adapt ways of doing things [5], were also evident, such as accessing information via social media and then cross-checking accuracy with a trusted social network. Stereotypes of older adults influence the technologies that become available and adapted for them and also shape older adults' self-perceptions of their digital capabilities [12,24,65]. It is critical to challenge stereotypes of older migrants as nonusers and passive users of ICTs to ensure that these technologies continue to adapt while considering older adults as a key user demographic.

Family is a central source of support for older adults' adoption and navigation of new technologies [21,41], which mirrors the findings of this study. However, participants wanted to improve their digital competence to navigate ICTs independently and were engaged in the learning sessions. Challenges with troubleshooting their devices were a cause of frustration, and some participants reported an overreliance on family to facilitate technology use, which was not always effective in improving their digital knowledge and skills. Other studies have shown the importance of social support from family and friends in facilitating older adults' access to and use of technologies [12,24], and this holds true for immigrant and refugee older adults. Family members of some immigrant and refugee older

XSL•FO
RenderX

adults may also have limited digital competence, or immigrant and refugee older adults might be socially isolated without family support. Offering digital learning opportunities to increase their competence is a way to enhance digital agency [24]. Older adults might use technologies for necessity or leisure, so developing safe and engaging learning environments that meet their preferred needs is critical [12,21,22].

This study expands on existing literature on older migrants and ICT use [38,62,66] by exploring the digital competence of Arabic-speaking immigrant and refugee older adults who creatively circumvent challenges as they navigate the digital divide [24]. Migration shapes motives and needs for ICT adoption, with particular challenges arising for older migrants. Older migrants desire to stay connected with those left behind in their countries of origin, and they need to access local sources of support in their new country. ICTs will continue to play a vital role in communication patterns and information sharing for this population. Effective digital learning programs must be designed to overcome the intersecting barriers of age-related disabilities, cultural differences, language barriers, and low literacies. Canada has digital competence programs that target underserved older adults, such as the Digital Literacy Exchange Program [67] and the SUCCESS Digital Literacy Exchange Program for newcomers [68]. Participants in this study did not report accessing digital competence programs outside of the research study. While agism is often associated with the digital divide [24,59,65], digital exclusion based on language and language minority status must also be addressed when considering the opportunities available to older adults. Digital learning programs that integrate elements of English-as-an-additional-language learning, focus on problem-solving and creative uses of technologies, and tailor learning outcomes to the pragmatic needs of older migrants for transnational communication and local integration are likely to be the most successful. Finally, a discussion of ICT design is beyond the scope of this paper, but digital technologies that are acceptable to older adults and meet their needs, including for older adults with language and literacy barriers, are much needed as this demographic continues to grow worldwide.

Strengths and Limitations

This study allowed for an in-depth exploration over a short period of Arabic-speaking immigrant and refugee older adults' digital competence. A longitudinal design over a longer period could add further insights into evolving digital competencies in migrant older adults. Most study participants (20/31, 65%) were women, and hence, we were unable to explore gender differences. Some exceptions in this study related to women who reported constrained communication choices within transnational families and the importance of privacy in social media interactions. Other studies have shown how gender shapes the use of and access to technologies [40,69-71], and this is an area for further exploration. Most participants were healthy and younger older adults. Digital technology use and health are linked [12,72]; hence, further exploration of technology use in frail older migrants is required to meet their needs for social connectivity and information access. With the central role of social support and family in ICT adoption, future studies that include the perspectives of family members and caregivers might be critical in designing digital interventions for this population. Finally, the focus on Arabic-speaking older adults means that other populations of migrants might have differing experiences that warrant investigation.

Conclusions

Canada's immigrant and refugee older adult population will continue to grow, and addressing equitable access to ICTs is imperative to enhance quality of life in older age. Strengthening agency to use ICTs has the potential to markedly improve their social connectedness and access to local information. Digital competence education tailored to the needs of older migrants can empower active participation in the digital world and meet settlement needs after migration. These programs would need to focus on the competencies of communication and information access with attention to language preferences, transnational ICT-mediated practices, different types of literacies (eg, basic and informational), and creative troubleshooting strategies. Further research is needed to inform policy on innovative strategies for disseminating local information and resources to older migrants, such as leveraging social media platforms as well as developing ICTs that meet the needs of older adults more generally.

Acknowledgments

The authors would like to express their sincere gratitude and appreciation to the Edmonton community organizations, Al-Rashid Mosque and the Islamic Family and Social Services Association, who contributed generously to the activities of this project. The authors are indebted to the participants of this study, who shared their time and knowledge. They also want to thank Hesham Shammy, who was the instructor for the sessions. This work was supported by a Social Sciences and Humanities Research Council of Canada Insight Development Grant (RES0049609).

Data Availability

The datasets generated or analyzed during this study are not publicly available, due the nature of qualitative data where migrant research participants might be easily identifiable, but are available from the corresponding author on reasonable request.

Abstract

Background: People with severe mental illness (SMI) face profound health inequalities, which may be exacerbated by increased rates of digital exclusion, especially as health services move to online provision. The activities that people carry out online can affect how they feel about the internet and may determine whether a person has a positive or negative experience when using the internet. This, in turn, could affect their mental health. To support people with SMI in using digital technology and the internet safely, it is important to understand the internet and digital technology use of those with SMI and their perceived positive or negative impact on their mental health.

Objective: This study aimed to explore the internet and digital technology use of those with SMI, with particular focus on any association between greater use of the internet and poorer self-reported mental health.

Methods: We carried out a qualitative interview study with 16 people with SMI. The sample was drawn from a wider investigation of the impact of the pandemic and its restrictions on the health and well-being of 367 people with SMI. We purposively sampled from the wider study based on age, gender, frequency of internet use, and self-reported mental health. The data were analyzed by 2 researchers using framework analysis.

Results: Participant experiences fell into 3 broad categories: those who had a positive or neutral internet-based experience, those who had negative or difficult experiences, and low users or those with poor digital literacy. Those who had positive or neutral experiences could be broken down into 2 subcategories: first, those with positive or neutral experiences of the internet who were similar in terms of the activities participated in, feelings reported, and their concerns about the internet, and second, conscious users who were mindful of their interaction with the internet world. Participants with difficult experiences fell into 2 categories: those with worries and fears related to using the internet and those who had difficulty limiting their internet use.

Conclusions: People with SMI, similarly the general population, are expected to conduct more of their activities of daily living online in the postpandemic world. This research shows that most internet users with SMI have positive or neutral experiences. However, our typology reveals subgroups of the population with SMI for whom there is a relationship between internet use and difficult feelings. These subgroups can be identified by asking questions about online activities; time spent online; feelings, difficulties, or issues experienced; and use of gambling, dating, adult content, and conspiracy theory websites. Our findings point to further work in collaboration with people with lived experience to modify and test this typology.

Introduction

Background

In the general UK population, changes in internet use and its effects on mental health and well-being occurred during the COVID-19 pandemic. For example, consumption of COVID-19–related news on social media was associated with increased depression and anxiety, but during the pandemic, approximately 50% of UK internet users disclosed going online to support their mental and physical health and to feel less lonely [1,2]. Understanding the experiences of use of the internet in people with mental illness, especially those with severe mental illness (SMI), is important as they may experience unique challenges. People with SMI already experience significant health inequalities compared with people without SMI, including greater levels of physical illness and reduced life expectancy, with an estimated 20-year mortality gap [3,4]. People with SMI are at risk of digital exclusion, which, in the context of increased digital provision of health and other services (eg, video consultations, websites, and apps), could compound these health inequalities.

Research carried out before the COVID-19 pandemic presented a mixed picture of digital engagement and exclusion among people with SMI. Levels of digital exclusion decreased between 2011 (30% digitally excluded) and 2016 (18% digitally excluded) in a longitudinal study of people with psychosis [5]. However, high levels of digital exclusion were observed in people requiring community mental health rehabilitation support (such as residential placements and supported living), where only 14% used the internet [6]. Previous research suggests that most people with SMI have access to a digital device, such as a computer or smartphone. However, low rates of smartphone ownership, particularly in those with psychosis-spectrum disorders, have been reported [7-9].

A qualitative study of digital exclusion in 20 mental health service users (half of whom had psychosis) explored the factors that drive digital exclusion, highlighting a perceived lack of knowledge, being unable to access the necessary technology and services owing to personal circumstances, and the barriers presented by mental health difficulties [10]. Specific facilitators for overcoming digital exclusion included intrinsic motivation and a personalized learning format that reflects the individual's unique needs and preferences [10]. A qualitative study investigating how service users feel about digital health interventions for people experiencing SMI found that participants reported feelings of empowerment and being liberated because of an increase in choice, tools, and control [11]. The aforementioned study also identified barriers to accessing digital health interventions, with the assumption that these would replace face-to-face care, excluding those with poor access or abilities, and would be problematic for data protection [11].

Previously, people with SMI have reported that they would be less likely to use digital technology when unwell in comparison to when they are feeling well [7]. Research focused on internet use in general and internet use related to mental health for those with psychosis (eg, digital mental health tools, internet-based communities, and discussion boards) has found that general internet use is higher for younger people and those with low symptom severity and fewer cognitive difficulties [12]. Interestingly, use of the internet for mental health information was not associated with symptom severity or cognitive difficulties, indicating that there were no differences in interest in accessing online mental health resources between those with high symptom severity and cognitive difficulties and those with low symptom severity and cognitive difficulties [12].

During the COVID-19 pandemic, we explored the use of the internet, digital skills, and mental health in people with SMI. We found that most (61%) people with SMI were limited or nonusers of the internet despite most (approximately 80%) having access to a digital device and the internet at home [13]. We found that using the internet "a lot" (vs "just a bit" or "not at all") was associated with younger age, a diagnosis of bipolar disorder compared to a psychosis-spectrum disorder, and a report of a decline in mental health [14]. This finding that high internet use was associated with poorer self-reported mental health was somewhat counterintuitive as we expected greater digital engagement to contribute to greater support and inclusivity. However, we appreciated that it is not only how engaged someone is with the internet but what people do when they are online that affects this. This could determine whether a person has a positive or negative experience using the internet, which could affect their mental health (eg, being online to access support or being online to access potentially scary and stressful information).

In an era in which the use of the internet is becoming increasingly important to access public services, health care, and leisure, it is important to explore the association between greater use of the internet and poorer self-reported mental health to support people with SMI in using digital technology and the internet safely. To do this, we carried out a qualitative study to explore the internet and digital technology use of those with SMI, focusing on time spent online, types of activities, and their perceived positive or negative impact on mental health.

Objectives

Therefore, the aim of this study was to explore the internet and digital technology use of those with SMI, with a particular focus on any association between greater use of the internet and poorer self-reported mental health.

XSL•FO
RenderX

Methods

Participants

Between June 2021 and October 2021, qualitative interviews were undertaken via telephone to explore internet use and abilities for adults who have SMI.

A purposive sample was drawn from the wider Optimising Wellbeing During Self-Isolation (OWLS) study [13]. The OWLS study was a series of 5 surveys tracking the health and well-being of people with SMI during the COVID-19 pandemic. In the initial OWLS study, we asked people whether they would consent to taking part in a qualitative study. From those who consented, we purposively sampled based on age, gender, frequency of internet use, and self-reported mental health. As this study aimed to explore the drivers of the relationship between high internet use and poorer self-reported mental health, the sample was chosen to include individuals with a high use of the internet. In this survey study, we purposively sampled from a group known to use the internet more. This means that the sample reported in this paper had a higher-than-average level of digital skills.

The study team approached 28 participants who had expressed an interest in taking part in an interview study, and 16 (57%) gave informed consent and completed the interviews. After interviewing 16 participants, no new data emerged, and therefore, data saturation was achieved. The final sample included 56% (9/16) female and 44% (7/16) male participants aged between 24 and 68 years; 56% (9/16) of the participants had a schizophrenia-spectrum disorder diagnosis, 25% (4/16) had a diagnosis of bipolar disorder, and 19% (3/16) were diagnosed with another SMI. In total 19% (3/16) of the participants reported outstanding knowledge with regard to use of the internet, 38% (6/16) reported good knowledge, 25% (4/16) reported fair knowledge, and 19% (3/16) reported poor knowledge. Most participants (15/16, 94%) were White British. Most (13/16, 81%) were not employed at the time of the interview. The participants varied in the extent to which they used digital devices and the internet, from limited use to frequent use.

Interviews

Semistructured interviews were conducted following a topic guide (Multimedia Appendix 1). This was devised from previous findings of the OWLS survey to elaborate on information gathered regarding internet and digital device use in the previous 12 months and the importance of digital skills. The aim of the interviews was to explore how much people were using the internet, what they were using it for, and how using the internet made them feel. This was to further understand the relationship we had previously noted between high internet use and poorer self-reported mental health. Before conducting the interviews, the topic guide was piloted with a member of the OWLS lived-experience advisory group. The interviews were conducted between June 2021 and October 2021 by RW, PH, and LW. The researchers conducting the interviews had either a PhD or Master of Science and were a mix of ages and genders; one of the interviewers has lived experience of SMI. The interviews typically lasted between 30 and 40 minutes.

The topic guide began with introductory questions to gather general information regarding the frequency, duration and main purpose of internet use (eg, “Roughly how many hours a day do you spend doing things online” and “Could you tell me about the different types of activities you do online?”). This was followed by questions to gain an insight into the thoughts and feelings of participants when they used the internet (eg, “Do you think the online activities you do affect your mental health in any way?”). We did not specifically include questions about the use of the internet to receive formal or informal mental health services. This did not preclude participants talking about support via the internet, if they felt it was relevant to their experiences. The interview recordings were transcribed verbatim.

Analysis

An analysis was conducted with the aim of *exploring the relationship between higher internet use and poorer self-reported mental health.* Following a preliminary analysis by OT, the transcripts were analyzed by LW and EP using framework analysis. This method was chosen as it allows for the identification, description, and interpretation of key patterns in datasets where there is some comparison between groups or concepts to answer a research question. Framework analysis was originally developed for policy research in the 1980s by Richie and Spencer [15] but since then has been used across disciplines (eg, health research and psychology), usually with but not limited to datasets in which there is some comparison between groups or concepts [16,17]:

> *Framework analysis and applied qualitative research can be a perfect match, in large part because framework analysis was developed for the explicit purpose of analysing qualitative data in applied policy research.*

The five stages of framework analysis were followed: (1) data familiarization; (2) framework identification—deductive themes were derived from the research question, interview schedule, and literature and confirmed from data familiarization [18], and these themes were used to create a framework; (3) indexing—researchers (LW and EJP) coded the transcripts to the framework; (4) charting—the data were abstracted and tabulated; and (5) mapping and interpretation—this led to the creation of a typology.

Findings from a 2019 study that looked at internet use in people with mental illness in Poland created clusters of user types (leisure-seeking omnivores, gamers, and passive-selective users) [18]. To create these clusters, they used an adapted version of the Classification of Internet Usage Activities (Table 1) by van Deursen and van Dijk [19]. We used the adaptation by Ng et al [18] as a basis for our classification of what people were doing online, with the further addition of gambling, dating, and adult content websites (from our topic guide), and then divided these activities into consuming (passive internet use), including searching for information and news and shopping, or interaction (active internet use), including social media, study (attending education online), and some types of gaming. This division was made as, from immersion in the transcripts, we speculated that

XSL•FO
RenderX

there might be a different experience between those interacting with others online and those with more passive internet use.

Table 1. Original classification of activities that the internet may be used for by van Deursen and van Dijk [19] on which Ng et al [18] based their clusters.

Factor	Items
Personal development	• Finding online courses and training • Following online courses • Find vacancies and applying for jobs • Independent learning
Leisure	• Downloading music and video • Hobbies • Free surfing
Commercial transaction	• Using sites such as eBay • Acquiring product information • Shopping or ordering products
Social interaction	• Using social networking sites • Chatting • Sharing photos and videos
Information	• Using search systems • Searching for information
News	• News services • Newspapers and online magazines
Gaming	• Playing games on the internet

Typology (Mapping and Interpretation)

One of the researchers (LW) created a chart to answer questions about activities participated in online, feelings about the online experience, time spent online each day, and any particular issues or difficulties. A typology was developed from the charting process that categorized participants as having positive or neutral experiences, negative or difficult experiences, and low digital literacy or minimal use. The low digital literacy or minimal use category was classified separately as any feelings or experiences seemed to be in response to apprehension about the unknown or lack of digital skills. As these participants were online for <5 minutes per day, their experiences were not categorized as a response to what they were doing online.

Ethics Approval

Ethics approval was granted by the Health Research Authority North West – Liverpool Central Research Ethics Committee (reference 20/NW/0276), and all participants gave informed consent before taking part in an interview. Only the researcher who conducted the interview had access to the original recordings, which were securely stored and protected. To ensure anonymity, all participants were assigned unique codes, and personal identifiers were removed during data transcription to safeguard the privacy of the participants. Participants were offered a £20 (US $25.46) voucher as a token of thanks for their time.

Results

Overview

Our results originally showed 6 different types of internet users (Table 2). Table 3 shows a simplified version of the typology. Participants with positive and neutral experiences were merged into 1 category as there were few differences between the 2 groups in terms of activities participated in and feelings reported (no particular strong feelings were described), and the 2 groups were similar in terms of their concerns (mainly regarding scam attempts). For the purposes of answering the research question, separating the neutral and positive categories did not provide any additional insights.

XSL•FO
RenderX

Table 2. Charting of the activities that people conducted online in terms of frequency of activity and whether carrying out the activity was a positive, negative, or neutral experience.

	Negative or difficult experiences		Positive or neutral experiences			Low use—low digital literacy
	Worries and fears	Difficulties limiting use	Positive	Neutral	Conscious users	
Time daily	• Low; average of 45 min	• High; average of 9 h, 30 min	• Medium; average of 3 h	• Low but up from before the pandemic; average of 1 h, 10 min	• Medium; average of 4.5 h	• Very low; average of <5 min
Activities	• Participated in leisure; commercial—retail; information; and gambling, dating, adult content, or conspiracy theory websites • Did not participate in social, study, career, news, and gaming	• Participated in leisure; commercial—retail; social; career; information; news; gaming; and gambling, dating, adult content, or conspiracy theory websites • Did not participate in study	• Participated in leisure, commercial—retail, study, and information • Did not participate in: career; gaming; and gambling, dating, adult content, or conspiracy theory websites • Mixed responses: social	• Participated in leisure, commercial—retail, commercial—services, social—video calls and email only, study, and information • Did not participate in career; gaming; and gambling, dating, adult content, or conspiracy theory websites	• Participated in leisure, commercial—retail, commercial—services, social, study, information, and news • Did not participate in gaming; gambling; and dating, adult content, or conspiracy theory websites	• Participated in leisure, commercial—services, and social—video calls and email only • Did not participate in study; career; information; news; gaming; and gambling, dating, adult content, or conspiracy theory websites
Feelings	• Strong negative (fear based)	• Negative (boredom and exhaustion based)	• Positive	• Neutral	• Less about feeling and more about choices; both mentioned spiritual belief	• Neutral mixed with some distrust and apprehension
Difficulties or issues	• Worries and fears about being tracked	• Did not necessarily see their high internet use as a problem	• Hard to use, scam attempts, or reading bad news	• Concerns about online banking and scams	• Choosing and being mindful	• Lack of understanding or distrust

Table 3. Characteristics of the 6 different types of internet users.

	Type of internet-based experience					
	Negative or difficult experiences			Positive or neutral experiences		Low digital literacy or low use
	Worries and fears	Difficulty limiting use	Polarized	Positive or neutral	Conscious users	
Time spent online	Low	High	Moderate	Moderate	Moderate	Very low
Activities done online	Consuming only	Interacting, consuming, and gaming	Interacting and consuming	Interacting and consuming	Interacting and consuming	Interacting and consuming
Do these activities include dating, adult content, or conspiracy sites?	Yes	Yes	Yes	No	No	No
Feelings about the experience with the internet	Strong negative (fear based)	Negative (boredom and exhaustion based)	Mixed	Positive or neutral	Choices over feelings	Neutral feelings about actual use (fear of the unknown)

RenderX

The following sections use quotes from the transcripts to illustrate the main findings for each of the original 6 groups and to link the typology to the original data.

Negative or Difficult Experiences

Participants who had negative or difficult experiences of the internet could be divided into 2 types: those who had worries or fears and those who had difficulties limiting their internet use.

Worries and Fears

This was a group of participants with worries and fears about being online who described strong negative (fear based) emotions in relation to their internet use; did a limited number of activities online, which involved mainly consuming content and very little interacting; had used gambling, dating, adult content, or conspiracy theory websites (specifically, conspiracy theory websites were mentioned); and spent an average of 45 minutes per day online. The participant quotes from this group illustrate the participant experiences typical of this group in terms of time spent online; activities participated in; feelings, issues, or difficulties; and experiences with gambling, dating, adult content, or conspiracy theory websites (Textbox 1).

Textbox 1. Participant quotes from the worries and fears group.

Time

- "So, I mean I've gone through different periods of using the internet. Sometimes we use if quite intensely over times like now I'm just using it for, like I don't know, I'm looking at computer programming at the minute. So I just usually look for bits of information about computer programming that I need and things like that and [unclear]. About half an hour a day or summat like that I'd say." [Participant 274]
- "My general use no more than, definitely no more than an hour." [Participant 167]

Activities

- "Amazon, I've used Amazon to get a few pairs of tracksuit bottoms and things like that...Yeah, I actually do quite a bit of shopping on-line to be fair. I get quite a lot of books on the internet." [Participant 274]
- "Yeah just food shop and sometimes a little bit of, you know, search words or shops and that on Google search and that but pretty much just shopping and that's it. Not very often like or I might check my bank on-line, you know, things like that or I pay a bill or summat." [Participant 167]
- "YouTube is a big one. I don't know much about Netflix. My brother bought me an Android tablet and put Netflix on it but I can't remember what's happened with that though." [Participant 274]

Feelings

- "I don't know the best way to describe how it makes me feel. It doesn't make me feel good I know that much." [Participant 167]
- "Yeah, well it (the internet) has and it hasn't (had a positive impact on my mental health) because I've tried to kill me self and finished up in hospital." [Participant 274]

Issues or difficulties

- "I recently went on Facebook for probably the second time I've been on Facebook. What I don't like about Facebook is that you set up an account and then you can't delete it, so in a way it's a bit...there's no-one to look after you on Facebook. I mean you can report stuff that you think is not there to be put up on-line, you can report things and stuff like that. There's no-one for you to contact if you want to delete your account. You can't get rid of it and stuff like that. Plus, I think to be fair it's a bit spooky because I don't know if police can pull you for certain things if you've been doing something and you've mentioned it all on Facebook." [Participant 274]

Gambling, dating, adult content, or conspiracy theory websites

- "Yeah, I used to do a bit of [unclear] years ago, you know, not very often but, you know, here and there like but that's not summat I've done in over 4 years." [Participant 167]
- "Well I've never really been a gambler if I'm being honest but other things, you know." [Participant 167]

Difficulties Limiting Internet Use

This was a group of participants who had difficulties limiting their internet use who described negative feelings regarding boredom and exhaustion in relation to their internet use; did many different things online (this was the only group that reported gaming); used gambling, dating, adult content, or conspiracy theory websites (specifically, gambling and dating sites); and spent an average of 9 and a half hours per day online. The participant quotes from this group illustrate the participant experiences typical of this group in terms of time spent online; activities participated in; feelings, issues, or difficulties; and experiences with gambling, dating, adult content, or conspiracy theory websites (Textbox 2).

XSL•FO
RenderX

Textbox 2. Participant quotes from the difficulties limiting internet use group.

Time

- "Most of them [hours] when I'm not asleep. A lot of hours, most of the day I use the internet...I work from home so I'm on a laptop from about 8 till 4 or 9 to 5. I game a lot in the evening, use the night on-line services. TV is on a lot. Always on my phone, so constantly." [Participant 216]

Activities

- "I do tend to look at quite a lot of stuff and buy quite a lot of stuff which I probably don't need. I think the tablets make me do that as well [The medication that I take]." [Participant 215]
- "My screen time on my phone is quite high, so I'll scroll through Twitter throughout the day, that's where I get most of my news. If something big has happened that's where I'll usually see it first. Tik Tok is really bad for a rabbit hole so I just keep scrolling because it's addictive. Facebook chatting with my friends. Instagram. Yeah all of my banking is on my phone. Pretty much everything I do is on my phone, so I use contactless payments, I don't even use cards, like physical cards. Let me just look at the apps I have. Uber, so I use that like all the time. I haven't got that much public transport. I have an electric toothbrush that has an app. My toothbrush is connected to the internet." [Participant 216]

Feelings

- "Well I think it's due to my isolation and the tablets that I take, I'm sort of bored, so I'll try and buy something, electrical goods or something or something else that I don't need, normally anyway. Yeah, that's quite a big part of my internet usage. I'm trying to cut down on that. But yeah, it's quite interesting. It's quite engaging." [Participant 215]
- "Well yeah it means that I'm glued to a screen all day and there's no like face to face meetings to communicate with people, it's really different and it seems to be more exhausting and I Googled why, it's because you can't interpret people's body language or like the only communication you've really got is speech and that's quite exhausting trying to work out things about other people." [Participant 216]

Difficulties or Issues

- "It makes me want to buy stuff more. I would say to sort of fill any other void in yourself, I'll buy something I'll treat myself to something. It's all the time. I've realised that I do it quite a lot." [Participant 215]
- "I find it hard to go outside now because I'm so used to being in and talking to people online." [Participant 216]
- "So like I'll scroll through my phone in bed a lot, it's harder to switch off and because obviously blue light from screens that I'm looking at all the time, it's harder to go to sleep and even...because we don't have an aerial in our house. We just use like YouTube and stuff, so literally everything we do is, it's not even like going through into the TV, it's just the internet all the time. If the internet goes down then my life is ruined." [Participant 216]

Gambling, dating, adult content, or conspiracy theory websites

- "I get addicted to things quite easily. So, if I think something is unhealthy, like mentally, I probably [unclear]. I've gambled a little bit." [Participant 216]
- "Not for a while anyway, not since I was younger, so yeah. Yeah, I don't really use any of that stuff to be honest. I've tried internet dating once or twice but that never works. That's about it really." [Participant 215]

Positive or Neutral Experiences

Overview

Those who had positive or neutral experiences were categorized into 3 groups: those with positive experiences of being online, those describing neutral experiences, and conscious users. The positive and neutral experience groups were merged into 1 category as the 2 groups did not appear to be significantly different from each other.

Those with positive and neutral experiences were a group of participants who described positive or neutral feelings in relation to their internet use; did a mixture of things online involving both interacting and consuming; did not use gambling, dating, adult content, or conspiracy theory websites; and spent 1 to 3 hours per day online. The participant quotes from this group illustrate the participant experiences typical of this group in terms of time spent online; activities participated in; feelings, issues, or difficulties; and experiences with gambling, dating, adult content, or conspiracy theory websites (Textbox 3).

XSL•FO
RenderX

Textbox 3. Participant quotes from the group with positive and neutral experiences.

Positive

Time:

- "I suppose then these days when I get up and look at my phone, I will go through WhatsApp and I will look at emails and, you know, sometimes there's the odd message from somebody that doesn't use WhatsApp. But I'd say generally [unclear 28.20] spend an hour or so messing about on it. To me it's a lot, remember people of my age didn't get used to computers at school and all that, you know, we are the older generation." [Participant 533]
- "Not much at all. Two hours." [Participant 182]

Activities:

- "Like I say I've got my bank account and mobile banking on my phone. I use all that which is handy as hell. I use it all the time. I'm forever doing that. I transfer money." [Participant 348]
- "Googling stuff about me own mental health...I like to read up on that...It was giving us more information about what was actually going on in me head." [Participant 183]
- "It's mainly social media, Twitter, Instagram, Facebook, catching up with family and friends really and messaging." [Participant 182]

Feelings:

- "I wouldn't say it's [internet activities] have any negative effects on us, no." [Participant 183]
- "Yeah I would say it's helped us [having the internet]. Just having that extra thing there. Just like keep your mind ticking over, you know, help." [Participant 183]
- "Oh yeah very pleasurable especially with the jokes and knowing that some people enjoyed some jokes and it's a laugh and then they send you a little smiley face back. I think that's all very positive especially in the pandemic. It has for me become the normal way to contact people." [Participant 533]
- "I suppose I wanted to feel part of the world if you know what I mean, part of like by going on twitter and Facebook, it felt like I was participating." [Participant 182]
- "Music tends to chill me out and calm me down, so I just listen to that over again. I mean YouTube, all your songs are there for you and it's free too." [Participant 183]

Difficulties or issues:

- "I wish they were easier to use sometimes, some of these websites...They don't always have instructions as you're going along, you have to find out what to do yourself or they say press there and it comes up with something else. Some of them are just quite difficult to use." [Participant 182]
- "I've given up watching the news years and years ago because being bipolar you just don't want to listen to the news because it's all bad news. So it's just that really. You get your bad news through the internet now, not necessarily listening to the news on TV or reading newspapers but that's just the way things are, isn't it." [Participant 533]
- "I've had a few cranks that have come over the internet and tried to get money out of me but, you know, I've just got rid of them, so that's happened. And I've had a few people try to extort money out of me over the internet which I didn't fall for. I was just laughing at them. I knew what they were doing, so I just played along with it and then when they realised that I wasn't going to pay out any money they soon got rid of me." [Participant 348]

Gambling, dating, adult content, or conspiracy theory websites:

- "So, I wouldn't say that...the negative content, you know, it is an issue, I just don't bother with it. I don't read it. I read hardly anything. I don't get in contact with stuff that stresses me apart from the adverts." [Participant 533]
- "Well what I did was I got this bloody, it was [name] next door and it was one of these dating apps, you know these dating app things. I just wanted rid of it. But I got it and I thought this is absolutely useless. I don't know why I went on and it took me ages to get rid of it. I didn't like it. I just want to meet people naturally rather than going on-line and doing it." [Participant 348]

Neutral

Time:

- "Not a lot to tell you the truth. Oh, I'd say about 20minutes, if that." [Participant 314]
- "Oh roughly? Probably about an hour." [Participant 332]

Activities:

- "So, we have a club in our village, the supper club which meets once a month and obviously we weren't able to meet, so they did run some Zoom sessions on that. Yeah that was a good social thing." [Participant 317]

XSL•FO
RenderX

- "As I say my husband tends to use it more than I do. I do try learn off him, you know, what he's doing and stuff and that's it really." [Participant 314]
- "Well I've been doing shopping. What else? Looking up holidays and things like that...Oh I've been on Zoom talking to people [family and friends]...I was playing scrabble at one time and doing jigsaws on-line as well." [Participant 332]
- "I don't do the social media stuff. I don't get involved in it at all." [Participant 317]

Feelings:

- "...yes, it [online scrabble and jigsaws] helps me sort of unwind a bit." [Participant 332]
- "I'm still a bit apprehensive about it [online banking] because I'm frightened that we're going to get conned [laugh]." [Participant 314]
- "Yeah I would probably say that, yeah it [use of the internet] probably wasn't a bad thing when we were in lockdown." [Participant 317]

Difficulties or issues:

- "I'm frightened, you know, that something will happen and we'll lose money. But I mean, touch wood, since we've been doing it we seem to be doing it right and we've had no problems with it." [Participant 314]

Gambling, dating, adult content, or conspiracy theory websites:

- "No, I don't gamble. I don't go on the adult sites or anything like that. In fact, I wouldn't know how to get on them I don't think, so yeah...No I don't do anything like that." [Participant 314]

Conscious Users

This was a group of participants who used the internet consciously who talked more about choices over online activity than feelings; used the internet for many things (with the exception of gaming); may have come across gambling, dating, adult content, or conspiracy theory websites and chose not to use them; and spent an average of 4 and a half hours per day online. The participant quotes from this group illustrate the participant experiences typical of this group in terms of time spent online; activities participated in; feelings, issues, or difficulties; and experiences with gambling, dating, adult content, or conspiracy theory websites (Textbox 4).

XSL•FO
RenderX

Textbox 4. Participant quotes from the group of conscious users.

Time

- "So probably about 3 to 4 hours at work and maybe 2 hours at home." [Participant 178]
- "I don't know. It fluctuates. It would be, you know, going on...I don't actually have a laptop. I either go on the phone or we have an iPad." [Participant 352]

Activities

- "So, you know, even during that time I'll be mostly using systems, you know, using Chrome, using different systems for work. Maybe have some music while I'm working." [Participant 352]
- "Yeah, I mean Facebook, Amazon. Yeah, you know, I've just acquired a kindle, so yeah. Facebook, Outlook, WhatsApp, Amazon, I've got Prime which is a blessing! You know maybe reading or listening to something like a Jewish Torah lecture or something like this. Lesser organise Instagram. I've not done this in a while but I was actually using Zoom so in addition to these like, you know, communal Zoom calls that I mentioned like courses that I do, I was using Zoom for some remote one to one Alexander technique lessons." [Participant 352]
- "Yeah, so at work I do a lot of academic research, reviewing papers and stuff and ordering, stuff like that. At home it tends to be kind of messaging, social media based kind of stuff." [Participant 178]
- "I use banking like once a week to make sure everything looks fine and sometimes we order online but only kind of a necessity really." [Participant 178]

Feelings

- "Yeah I'm definitely not negative. Just probably being mindful, you know, for example, Amazon not to spend too much. To get unnecessary items." [Participant 352]
- "I think maybe also realising how much time I was spending on it because I'm now a lot more conscious about how much I am spending on the internet and a lot of the time not being very productive and I've realised I would rather be doing other things. I think it was helpful in different ways at times but there was definitely a point where it was more harm than good because a lot of the time scrolling social media was just like doom and gloom and it was really hard not to focus on it." [Participant 178]

Difficulties or issues

- "...keep in touch with people and that became quite difficult and I had to make some self-preservation decisions. I don't need to be up-to-date with how my friends are right now so maybe stepping away from that." [Participant 178]
- "Okay. I mean yeah, I mean yeah what to say. I mean pornography. I mean I think, you know, our society, you know, pornography...look before you even get to hard core stuff that's on-line, you know, on the various sites but I mean just the objectification pictures and kind of stuff. I mean you don't even have to go on sites on the internet to see that, that's on mainstream tv shows now, you know, or, you know. I mean just not even looking for it, I mean this is what people post really. I mean people are posting all kinds of stuff on Instagram, Facebook. Yeah even before you get to like all the kinds of specific like hard core stuff you can get into on the internet. I mean there's plenty more you can get on, it's just out there. I mean Netflix or whatever, you know." [Participant 352]

Gambling, dating, adult content, or conspiracy theory websites

- "...very easily accessible, objectification images there when not looking for them." [Participant 352]
- "I don't really use any of them. I don't gamble or anything like that because I would lose all my money, so yeah. I don't think I have much to contribute to that one." [Participant 178]

Low Digital Literacy or Low Use

This was a group of participants with low digital literacy and minimal use who described neutral feelings about their actual internet use and expressed distrust with regard to potential use. This group described using the internet for leisure, services, and emails or video calls only and mentioned others in the household doing internet-based tasks on their behalf; did not use gambling, dating, adult content, or conspiracy theory websites; and typically spent 0 to 5 minutes a day online. The participant quotes from this group illustrate the participant experiences typical of this group in terms of time spent online; activities participated in; feelings, issues, or difficulties; and experiences with gambling, dating, adult content, or conspiracy theory websites (Textbox 5).

XSL•FO
RenderX

Textbox 5. Participant quotes from the group with low digital literacy or low use.

Time

- "Oh, very little. I might get on it once a month." [Participant 143]
- "Not hours but minutes [per day]." [Participant 159]

Activities

- "I only do sort of like go on YouTube and I don't really do anything else." [Participant 159]
- "I do emails. Hmm what else? Finding things out and that's about it." [Participant 143]

Feelings

- "I'm still a bit apprehensive about it because I am frightened that we're going to get conned...I'm frightened, you know, that something will happen and we'll lose money." [Participant 143]
- "I've never bought anything on-line because I basically don't trust with my card details on the internet. I'd rather go to a shop." [Participant 159]
- "I'm very aware of problems with the computer, so I'm always a bit careful what I'm doing and when. I don't particularly trust them. I've always been like that." [Participant 143]

Difficulties or issues

- "Well if you're trying to find something out, you can't get to the right page or you don't seem to have the information to hand and I find it takes me ages to do anything." [Participant 143]
- "...tried Facebook but couldn't work out how to use it and tried to read the instructions for Facebook." [Participant 159]

Gambling, dating, adult content, or conspiracy theory websites

- "I wouldn't know how to do any of that at all or do that myself, no." [Participant 159]

Discussion

Principal Findings

The patterns of internet use and feelings in people with SMI described in the typology are of interest because, as more of an online presence is necessary for many life tasks and situations, including access to health services, it is important to understand the barriers to inclusion that specific populations may face [20]. The typology of internet users with SMI demonstrates a breadth of experiences and challenges when using the internet. When thinking about addressing the digital divide in this population, a generic approach to digital upskilling (eg, a self-navigated online course) is unlikely to be sufficient.

In response to the findings of the OWLS survey and qualitative work that highlighted a lack of digital skills as the driver of the digital divide in the population with SMI, there may be moves to support people with SMI in increasing their digital skills [13,14]. The experiences of specific subsections of this potentially vulnerable population need to be understood and considered to provide tailored support that understands population-specific barriers and use patterns.

The typology developed in this work revealed patterns that deserve further investigation and offers some guidance at this stage for potential subsections of the population with SMI for whom being online could be problematic.

The *worries and fears* group seemed to try to limit their internet use to mainly consumption activities. Their descriptions of their experiences and feelings suggest that interacting online could be problematic for their mental health. The group who struggled to limit their internet use did a wide range of activities online (including consuming and interacting activities), said that they might seriously struggle without the internet, and talked about shopping in response to isolation and boredom.

Interestingly, both groups of participants who described negative or difficult experiences described using or having previously used gambling, dating, adult content, or conspiracy theory websites, whereas those with positive or neutral experiences or low digital literacy did not report internet use of this type. The exception to this was the conscious use group, in which a participant described this kind of content being difficult to avoid but choosing not to engage with it.

Conscious use is of interest in that these participants described a specific type of relationship to their internet use where they were aware of the possible downsides and negative impacts of the web and made active choices to mitigate these effects. Perhaps there is some learning from the experiences of the conscious user group that could be applied to the group with negative or difficult experiences. This could include the option of conscious limitation of internet use to consumption activities (rather than interaction) for people whose experiences most closely align with the *worries and fears* group; the option of mindfulness about time spent online and types of activities for the group who find it difficult to limit their use; and potential co-designed education on ways to handle internet-based content such as gambling, dating, adult content, and conspiracy theory websites. Perhaps any attempts to increase presence online for this population could include a mindful internet use session created in collaboration with people with SMI.

XSL•FO
RenderX

These postulations about the potential application of the insights from this interview study suggest a very strong case for collaborative work with people with lived experience of SMI. This typology could be shared for validation or otherwise from a lived-experience perspective, and such input could be used to modify and refine the typology. Following this, any advice on internet use for subsections of the population with SMI should be created and verified from a lived-experience perspective (co-design) and eventually tested in a larger, probably quantitative study.

From the standpoint of the results of this work so far, services that support people with SMI should be mindful and understanding of their concerns and barriers faced in relation to using the internet and doing online activities. People with SMI should be offered a one-to-one conversation before embarking on digital upskilling to identify any concerns that may require tailored support.

Any digital upskilling endeavors with people with SMI should devote time to informing them how to safely use the internet and also reassuring them that it is possible to keep themselves safe online.

Limitations and Strengths

Although this research was carried out during the COVID-19 pandemic, we believe that many of the difficulties described by the participants, such as fears about internet scams, are applicable to the postpandemic world [21,22]. The *worries and fears* participants described little or no change in their internet use as compared to before the pandemic in terms of time spent online. Changes to services and activities demand a greater web presence, particularly access to health services [20]. Corresponding author LW has direct lived experience of SMI and brings this perspective to the work. LW can only bring their own perspective to this work, and their background in coproduced research leads them to believe that further collaborative and coproduced work is required in this area.

Comparison With Prior Work

A 2015 systematic review showed that people with psychosis seem to spend more time in chat rooms or playing online games than control groups. The use of other internet-based tools such as Facebook or communication through email was lower or the same as that of controls. Online social networking was used by people with psychosis for establishing new relationships, maintaining relationships or reconnecting with people, and receiving online peer support [23]. Our findings suggest that a subgroup of people with SMI may use the internet in these ways and have trouble limiting their use.

Previous research conducted internationally [24] reveals a similar level of internet use in inpatients with schizophrenia to that of the general population and a difference in terms of higher use of the internet as a source of health information than in the general population. Patterns and levels of use may vary depending on global location and inpatient or community settings.

As far as the authors are aware, there has been little research specifically looking at the link between greater internet use and poorer self-reported mental health in people with SMI. This work builds on a previous body of work rather than acting as a comparator with previous findings.

This typology builds on our series of previous publications [13,14,25] investigating internet use, digital health literacy, and the digital divide in people with SMI. We know from previous quantitative research that people with SMI are more likely to be limited users or nonusers of the internet [13] and, as a population, are lacking digital skills [14]. For some of the participants in this study, the internet was seen as useful for practical tasks such as internet shopping and banking. It was important for staying connected and accessing health information. Participants did not always speak directly about internet use affecting their mental health. Worries, fears, and difficulty limiting internet use, as well as feelings of distrust and apprehension about using the internet, were notable, and a subsection of participants appeared to be having negative experiences in relation to going online.

In a previous study, people with SMI were found to increase their use of the internet over the course of the pandemic, but approximately half rated their knowledge of the internet as fair or worse than fair [14]. In addition, this group was found to have moderate levels of digital health literacy. This underpins the need for digital skill training for people with SMI who would like to access this, with a focus on digital health literacy (eg, the ability to find and understand health-related information online and apply this knowledge to make health care decisions and self-manage their conditions). A partnership approach with a clinician for seeking mental health information has been found to be useful for people with psychosis, and this should also be considered [26].

Conclusions

This was a small sample, and our findings require further investigation. They are not generalizable. However, as far as we know, there is little research looking at patterns of internet use and feelings in this population, and the authors believe that the findings and typology can provide the beginnings of guidance for tailored support for people with SMI who wish to increase their digital skills or presence on the internet.

Our research shows that most internet users with SMI have positive or neutral experiences. However, our typology reveals subgroups of the population with SMI for whom there is a relationship between internet use and difficult feelings. These subgroups can be identified by asking questions about online activities; time spent online; feelings, difficulties, or issues experienced; and use of gambling, dating, adult content, and conspiracy theory websites. This exploration is particularly pertinent in light of findings highlighting the need for training and support among people with SMI to increase digital skills, facilitate digital engagement, and reduce digital exclusion [25]. Our conclusions point to further work in collaboration with people with lived experience to modify and test this typology.

Abstract

Background: Oral microenvironmental disorders are associated with an increased risk of heart failure with preserved ejection fraction (HFpEF). Hyperspectral imaging (HSI) technology enables the detection of substances that are visually indistinguishable to the human eye, providing a noninvasive approach with extensive applications in medical diagnostics.

Objective: The objective of this study is to develop and validate a digital, noninvasive oral diagnostic model for patients with HFpEF using HSI combined with various machine learning algorithms.

Methods: Between April 2023 and August 2023, a total of 140 patients were recruited from Renmin Hospital of Wuhan University to serve as the training and internal testing groups for this study. Subsequently, from August 2024 to September 2024, an additional 35 patients were enrolled from Three Gorges University and Yichang Central People's Hospital to constitute the external testing group. After preprocessing to ensure image quality, spectral and textural features were extracted from the images. We extracted 25 spectral bands from each patient image and obtained 8 corresponding texture features to evaluate the performance of 28 machine learning algorithms for their ability to distinguish control participants from participants with HFpEF. The model demonstrating the optimal performance in both internal and external testing groups was selected to construct the HFpEF diagnostic model. Hyperspectral bands significant for identifying participants with HFpEF were identified for further interpretative analysis. The Shapley Additive Explanations (SHAP) model was used to provide analytical insights into feature importance.

Results: Participants were divided into a training group (n=105), internal testing group (n=35), and external testing group (n=35), with consistent baseline characteristics across groups. Among the 28 algorithms tested, the random forest algorithm demonstrated superior performance with an area under the receiver operating characteristic curve (AUC) of 0.884 and an accuracy of 82.9%

XSL•FO
RenderX

in the internal testing group, as well as an AUC of 0.812 and an accuracy of 85.7% in the external testing group. For model interpretation, we used the top 25 features identified by the random forest algorithm. The SHAP analysis revealed discernible distinctions between control participants and participants with HFpEF, thereby validating the diagnostic model's capacity to accurately identify participants with HFpEF.

Conclusions: This noninvasive and efficient model facilitates the identification of individuals with HFpEF, thereby promoting early detection, diagnosis, and treatment. Our research presents a clinically advanced diagnostic framework for HFpEF, validated using independent data sets and demonstrating significant potential to enhance patient care.

Introduction

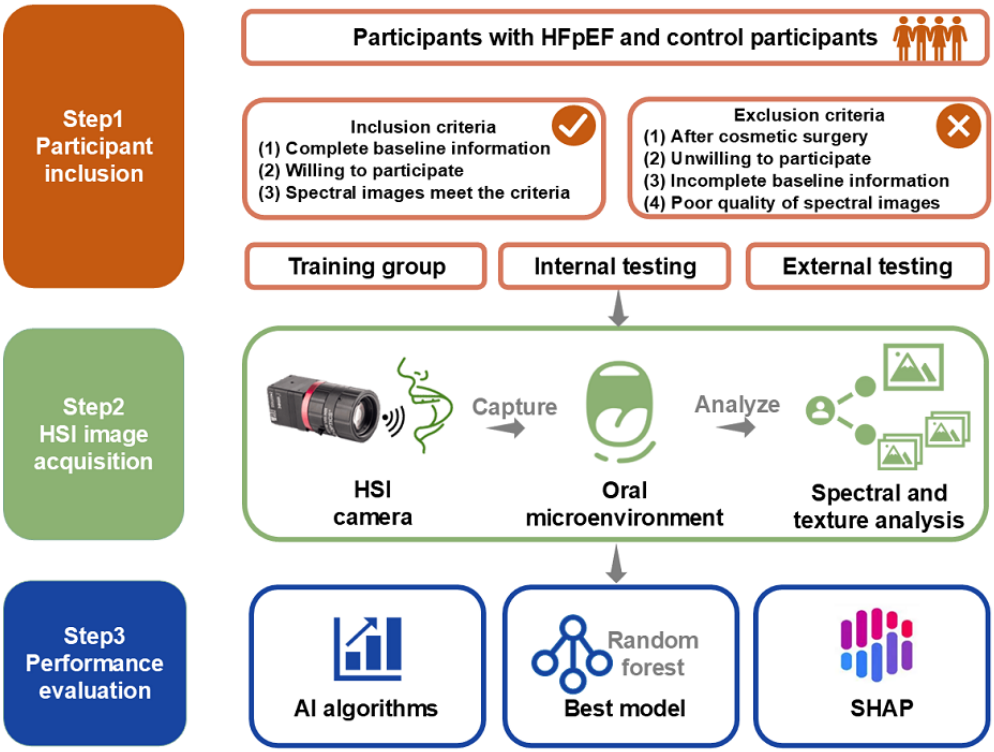
About one-half of patients with chronic heart failure have heart failure with preserved ejection fraction (HFpEF), which has received wide attention in recent years and poses a serious threat to the management of patient health [1,2]. The pathogenesis of HFpEF is complex, and the pathological mechanism is still unclear, so a swift, noninvasive diagnostic strategy is still lacking [3]. Early diagnosis of HFpEF is often difficult because the left ventricular ejection fraction of patients with HFpEF is within the normal range and the symptoms of heart failure are often nonspecific. The diagnosis of HFpEF depends on clinical symptoms, laboratory tests, echocardiography, and an invasive hemodynamics test [4]. However, descriptions of clinical symptoms are subjective, and different clinical symptoms cannot be measured using a unified standard. Echocardiography and hemodynamics tests need to be performed by experienced clinicians in hospitals, thus limiting early identification and timely diagnosis of HFpEF, which introduces obstacles to the health management of individuals with HFpEF [5].

The health of the oral environment has an important impact on cardiovascular health, and oral microenvironmental disorders have been associated with an increased risk of HFpEF [6]. Poor oral health may cause an inflammatory response that is strongly associated with heart failure [7,8]. The tongue, as an important part of the oral cavity, plays an important role in oral health, and the dorsum of the tongue carries the largest number of microbial species, which is an important part of oral health [9]. Inflammation and oxidative stress in the body caused by alterations in the oral microbiome are associated with the risk of developing heart failure [10]. Observing the oral microenvironment of individuals with HFpEF can reflect their lifestyle, dietary habits, and intestinal health [11]. An automated device or system that allows doctors to perform a quick tongue-based diagnosis would be helpful in clinical practice.

Light, which is a single color before dispersion, becomes a pattern of colors arranged in order of wavelength after dispersion; this is called the optical spectrum or optical band [12]. Hyperspectral imaging (HSI) consists of narrower bands, is a technique that captures and analyzes the details of each band in a region, can therefore detect substances that are visually indistinguishable to humans, and has a wide range of applications in many fields [13]. In recent years, many studies have explored the application of HSI technology in medicine [14]. The emergence of handheld HSI cameras, which allow users to quickly capture spectral images, has boosted the application of spectral imaging in medicine [15]. HSI technology has been used in patient information acquisition, medical image analysis, and disease diagnosis [16,17]. HSI is expected to promote the management of patient health. Notably, numerous innovative heart failure prediction models have been developed using common clinical indicators and advanced machine learning techniques [18-23]. These studies primarily focused on the prognosis of heart failure or enhanced existing diagnostic modalities such as echocardiography [24-26]. There exists a significant need for the development of noninvasive, easily accessible diagnostic tools specifically targeting HFpEF, which is a subtype of heart failure characterized by subtle clinical manifestations and complex pathophysiology.

In this study, we collected HSI information of the oral environment, and multiple algorithms were used to select the most characteristic spectral bands of individuals with HFpEF. The best model was selected for internal and external testing, and we used the Shapley Additive Explanations (SHAP) model to additively interpret the best model. The digital HSI HFpEF diagnostic model constructed in this study can help with early detection and management of individuals with HFpEF.

Methods



Study Populations

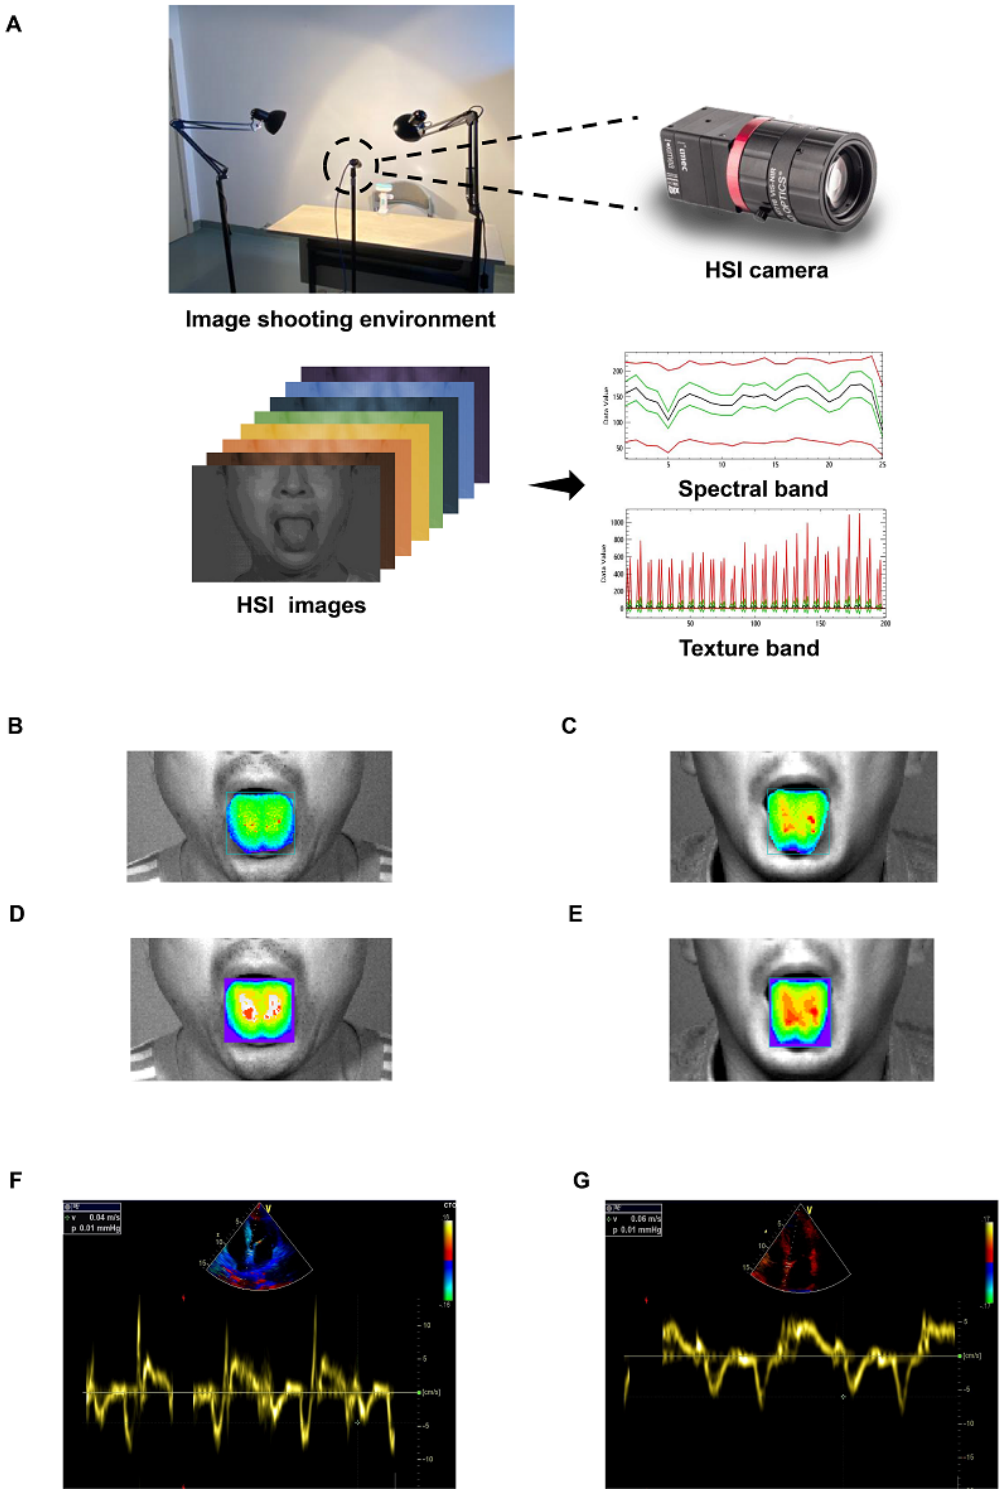
We included 196 patients who visited Renmin Hospital Wuhan University from April 2023 to August 2023; they comprised the training group and internal testing groups. We included 53 patients who visited Yichang Central People's Hospital from August 2024 to September 2024 as the external testing group (Figure 1). For all participants, HSI and clinical information were collected, and routine tests were conducted. Participants were selected according to the inclusion and exclusion criteria. HFpEF was diagnosed using international standards [4], including (1) typical signs and symptoms of heart failure; (2) left ventricular ejection fraction ≥50%, as assessed by echocardiography performed by a proficient physician; and (3)

XSL•FO
RenderX

brain natriuretic peptide >35 ng/L or amino-terminal pro-brain natriuretic peptide >125 ng/L. In addition to these criteria, participants also had to have at least left ventricular hypertrophy or left atrial enlargement with abnormal diastolic function. Individuals were excluded for any of the following reasons: previous cosmetic surgery and facial aesthetics, severe hepatic or renal organ insufficiency, mental or legal incapacity, malignancy-related diseases, other diseases such as psychiatric or neurological disorders, and unable to complete the study activities. Participants were consecutively included in the training and internal testing groups (140 of 196 participants) before randomization using a ratio of 3:1, while participants in the external testing group (35 of 53 participants) were also consecutively included [19]. The manuscript was written in strict accordance with the Guidelines for Developing and Reporting Machine Learning Predictive Models in Biomedical Research [20,21].

Figure 1. Study protocol. AI: artificial intelligence; HFpEF: heart failure with preserved ejection fraction; HSI: hyperspectral imaging; SHAP: Shapley Additive Explanations.

Ethical Considerations



All participants were informed about the study and signed an informed consent document. The study protocol was reviewed and approved by the Ethics Committee of Renmin Hospital of Wuhan University (number WDRM2023-K174) and Yichang Central People's Hospital (number 2024-216-01).

HSI Collection

We prepared a room with good light avoidance conditions and created a dark environment using curtains, blackboards, and other items to avoid external light interference as much as possible to ensure that all participants were in the same light environment for image acquisition. A halogen lamp was chosen as the only light source. The participant's head and face were fixed to ensure that there were no accessories nor hair to obscure facial features. The distance between the HSI camera and the participants was maintained to ensure that the size of the facial features was in the same area of each spectral image and that all participants had the same image size and clarity. We asked participants to expose their tongues for HSI acquisition (Figure 2A). Each participant was provided with a single hyperspectral photomicrograph, and only 1 oral spectral image meeting the criteria was captured.

XSL•FO
RenderX

Figure 2. (A) Hyperspectral imaging (HSI) acquisition environment, (B) processing of a spectral image for a control participant, (C) processing of a spectral image for a participant with heart failure with preserved ejection fraction (HFpEF), (D) processing of a texture image for a control participant, (E) processing of a texture image for a participant with HFpEF, (F) representative HSI and echocardiogram of a control participant, and (G) representative HSI and echocardiogram of a participant with HFpEF.

An HSI camera (MQ0220HG-IM-SM4X4-VIS; XIMEA) captured 25 spectral bands in the 665 nm to 960 nm spectral range. The camera has a pixel resolution of 644 × 484 (black and white) or 640 × 480 (color), pixel size of 7.4 × 7.4 µm, active area size of 4.8 × 3.6 mm, sensor diagonal of 5.9 mm, and dynamic range of 60 dB. The camera has an exposure time of 54 µs to 1 s with a step of 7.56 µs, with a capture time less than 1 s per image (Figure 2A). We checked image quality after image capture to ensure that all images had the same luminance, were in sharp focus, and were of good quality.

HSI Analysis

We preprocessed the obtained images [22,23]. HSI preprocessing methods are of great importance in HSI analysis. Effective preprocessing methods can minimize or even eliminate the influence of extraneous information (eg, sample background,

XSL•FO
RenderX

electrical noise, stray light). We first checked the image quality of all oral images, and when poor image quality was found, the participant's oral images were taken repeatedly in the same environment to ensure that the images could be qualified and used for further analysis. We preprocessed the images using the median filtering method to reduce any noise. HSI was preprocessed using a normalized method to reduce redundant information from the original bands and improve the precision of the HSI [27].

All images were edited using image analysis software (ENVI [Environment for Visualizing Images], version 5.3; NV5 Geospatial Solutions Inc). Backgrounds and clothing were cropped out, and the tongue images were retained. The spectral data of the features were initially extracted from the cropped images to obtain the mean and SD for each spectral photograph. Each spectral image was capable of extracting information for 25 spectral bands. Subsequently, texture analysis was conducted on the image, resulting in the generation of 8 texture features based on the mean and SD values for each band. For each participant, their spectral image could be obtained with 50 original band values and 400 band texture values.

Machine Learning Methods

In order to find the most suitable algorithm for the model, we used as many of the currently known machine learning algorithms as possible, resulting in a total of 28 machine learning algorithms. The single algorithms included linear models, such as linear regression, logistic regression, least absolute shrinkage and selection operator (LASSO) regression, ridge regression, and ElasticNet regression. Other types of single algorithms were also used such as decision tree algorithms, neural network algorithms, and support vector machine (SVM) algorithms. The ensemble models included both a boosting algorithm and bagging algorithm; the boosting algorithms included XGBoost algorithms, and the bagging models included random forest algorithms. For probabilistic models, we used Bayesian algorithms, Bernoulli naïve Bayes algorithms, and Gaussian naïve Bayes algorithms.

We performed 5-fold cross-validation in the training group, which was randomly divided into 5 subsets, each with the same sample size. The model was constructed using 4 subsets, and the model performance was assessed using the remaining data. Next, the model was constructed with another combination of the 4 subsets, and the model performance was assessed using the remaining data. The 5 cycles were performed in sequence, and the results obtained for the model performances were summarized. After constructing the model in the training group, model performance was evaluated in the testing group. We evaluated the importance of features using a random forest variable importance ranking method, where the importance of a feature is typically measured by calculating how often the feature is used in a decision tree: the more often a feature is used in the decision tree or the more it contributes to dividing the data, the higher its importance score. The results of all the decision trees' assessments of feature importance were summarized to obtain an importance score for each feature in the entire random forest model. Each machine learning model was constructed by incorporating these rankings until the performance of the model could not be improved; the incorporation of features was then stopped, enabling the construction of the model [28].

Evaluation of Model Performance

Based on the previously mentioned diagnostic criteria for HFpEF, we categorized all participants using a bivariate category. During the model construction process, we evaluated the ability of each model to be able to distinguish between participants with HFpEF and control participants. We evaluated the performance of each model by comparing the ability of the model to accurately identify participants with HFpEF. We assessed the performance of all algorithms; the accuracy, sensitivity, specificity, F_1-score, positive predictive value (PPV), and negative predictive value (NPV) of each algorithm were calculated separately. The results are presented in a table. Receiver operating characteristic (ROC) curves of the 5 best performing models for the internal testing and external testing groups were drawn, and the area under the ROC curve (AUC) was calculated. Decision curve analysis (DCA) of the 5 best performing models was implemented to assess the clinical usefulness of the models. Calibration curves of the 5 best performing models were plotted to assess the calibration.

SHAP Model Interpretation

We used the SHAP model to explain the best machine learning algorithm [29]. SHAP is a method of interpreting the output of a machine learning model and assigns weights to the optimal indexes using the Shapley values derived from the analysis; we used it to quantify the contribution of different features to the predicted values [30]. The SHAP value allows visual identification of the impact of different features on the model prediction results. In addition, the SHAP value explains the prediction results for each individual in the training group, helping to understand why the model made a particular prediction. It is also possible to perform an aggregated global interpretation of Shapley values for multiple data points in order to provide a total interpretation of the model and to demonstrate the interconnections between different features. SHAP analysis was implemented using Python software, and the results are presented using visualization methods. We first demonstrated the contribution of the bands selected by the best model and ranking by the contribution of different features. We then ranked the contribution of each individual in the study to the model and showed the SHAP analysis results for 1 participant with HFpEF and 1 control participant using intuitive visualization methods to reveal the contribution of different features.

Statistical Analysis

The data in this study were analyzed using SPSS 23.0 (IBM Corp). Model construction and graphic drawing were completed using R version 3.6.1 (R Foundation for Statistical Computing). We used the Shapiro-Wilk normality test to check the distribution of the data. A 1-way ANOVA was used to compare continuous variables that had a normal distribution, and the results are shown as mean (SD). The Kruskal-Wallis *H* test was used to compare continuous variables with nonnormal distributions, and the results are shown as median (IQR). The Fisher exact test was used to compare categorical data, and the

XSL•FO
RenderX

results are reported as counts and percentages. $P<.05$ was considered statistically significant.

Results

Study Population

Individuals who visited Renmin Hospital of Wuhan University from April 2023 to July 2023 were enrolled. A total of 196 participants were included in this study after excluding individuals who did not meet the inclusion criteria, had incomplete baseline data, did not cooperate with spectral acquisition, or had poor image quality. Data were collected for a total of 140 participants in the training and testing groups (Figure 1). Individuals who visited Yichang Central People's Hospital from August 2024 to September 2024 were also enrolled. A total of 53 participants were included in this study after excluding individuals who did not meet the inclusion criteria, had incomplete baseline data, did not cooperate with spectral acquisition, or had poor image quality. Data were collected for a total of 35 patients in the external testing groups (Figure 1). The participants were divided into training (n=105), internal testing (n=35), and external testing (n=35) groups. The baseline information, which included basic information, previous medical history, and basic examination and test results, for the training and testing groups was compared (Table 1). There were no significant differences in the baseline data between the training, internal testing, and external testing groups.

Image Processing and Machine Learning Algorithm Comparison

HSI data were collected for the training, internal testing, and external testing groups. Poor image quality for 4 participants in the training group, 1 participant in the internal testing group, and 2 participants in the external testing group made analysis difficult. Therefore, we acquired oral HSI in the same environmental conditions for those participants again and used those images for the next analysis after ensuring that the image quality met the standards. After preprocessing the images, spectral values and texture values of the images were extracted. We present the characteristic tongue HSI and echocardiography images of control participants and participants with HFpEF in Figures 2B-2G. We used 28 algorithms to filter the characteristic spectral bands of images from participants with HFpEF. We used 5-fold cross-validation in the training group, and the model performance was evaluated in the testing group. The accuracy, F_1-score, PPV, NPV, sensitivity, specificity, and AUC of the different algorithms were calculated separately, and the results for the 28 algorithms are listed in Table S1 in Multimedia Appendix 1. Among all the models constructed, the Tweedie, SVM, partial least squares, Huber, and random forest algorithms were the top 5 in terms of performance, showing good ability to identify participants with HFpEF. The ROC curves (Figure 3A), calibration curves (Figure 3B), and DCA (Figure 3C) of the top 5 algorithms were plotted, and the AUCs were calculated (Table S1 in Multimedia Appendix 1). The AUCs in the internal testing group were 0.884 (95% CI 0.769-1.000) for random forest, 0.795 (95% CI 0.633-0.958) for Tweedie, 0.814 (95% CI 0.657-0.972) for SVM, 0.803 (95% CI 0.659-0.947) for Huber, and 0.799 (95% CI 0.640-0.959) for partial least squares.

Figure 3. (A) Receiver operating characteristic (ROC) curve, (B) calibration curve, and (C) decision curve analysis (DCA) for the internal testing group and (D) ROC curve, (E) calibration curve, and (F) DCA for the external testing group.

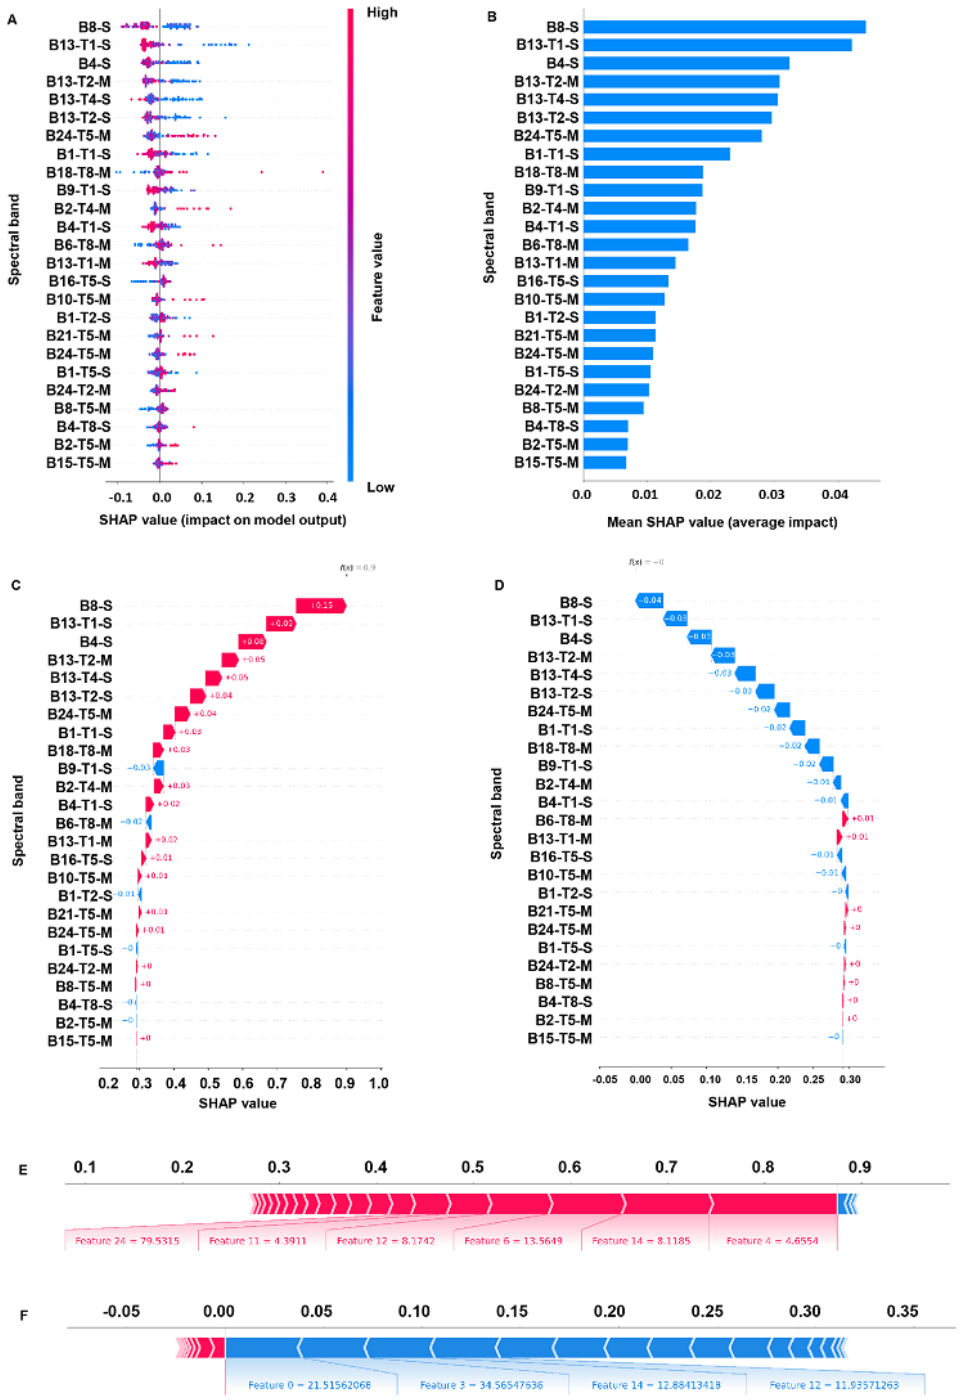
RenderX

External Validation of the Top 5 Algorithms



The HSI collected in the external testing group were preprocessed in the same way, and the spectral values and texture values were extracted and analyzed. We used the top 5 best performance models in the internal testing group to analyze the external testing data. The accuracy, F_1-score, PPV, NPV, sensitivity, specificity, and AUC of the different algorithms were also calculated separately, and the results for the 5 algorithms are listed in Table S2 in Multimedia Appendix 1. The random forest algorithm still had the best model performance among the 5 algorithms. The ROC curves (Figure 3D), calibration curves (Figure 3E), and DCA (Figure 3F) of the 5 algorithms were plotted, and the AUCs were calculated (Table S2 in Multimedia Appendix 1). The AUCs in the external testing group were 0.812 (95% CI 0.633-0.992) for random forest, 0.676 (95% CI 0.438-0.914) for Tweedie, 0.792 (95% CI 0.632-0.951) for SVM, 0.634 (95% CI 0.428-0.841) for Huber, and 0.671 (95% CI 0.428-0.915) for partial least squares. We extracted the features selected by random forest for further interpretation.

SHAP Interpretation of the Best Algorithms

We used the SHAP model for additive interpretation. The Shapley value was calculated to assign the benefit each characteristic brings to the overall model, showing the contribution of each characteristic to the model's predicted results. We present the characteristics of the top 5 best performing models in order of their contribution to the overall models in Table S3 in Multimedia Appendix 1. The summary plot (Figure 4A) shows the feature importance ranking and distribution via the Shapley value of each spectral band, where the blue bar indicates that the eigenvalue positively affected the model and the red bar indicates that the eigenvalue negatively affected the model. The Shapley value represents the magnitude of each feature's impact on the predicted results, with the point farthest from the centerline indicating a greater influence on the model output. The SHAP feature importance map ranks each characteristic by their contribution (Figure 4B), with features at the top having a greater impact on the model output and those near the bottom having a lesser total impact. SHAP waterfall plots and SHAP bar charts (Figure 4C-4F) were used to visualize the Shapley values of individual samples and their individual results. We visualized the model's ability to recognize HFpEF using a waterfall plot (Figure 4C) and bar chart (Figure 4E) for a control participant and a waterfall plot (Figure 4D) and bar chart (Figure 4F) for a participant with HFpEF. In the waterfall plot, the contribution of each feature is represented by a bar. The length of the bar indicates the magnitude of the feature's influence on the predicted value. A blue bar indicates that the feature increased the predicted value, and a red bar indicates that the feature decreased the predicted value. There was an intuitive difference between the SHAP results for control participants and those for participants with HFpEF. The HFpEF diagnostic model constructed in this study was able to distinguish control participants from participants with HFpEF.

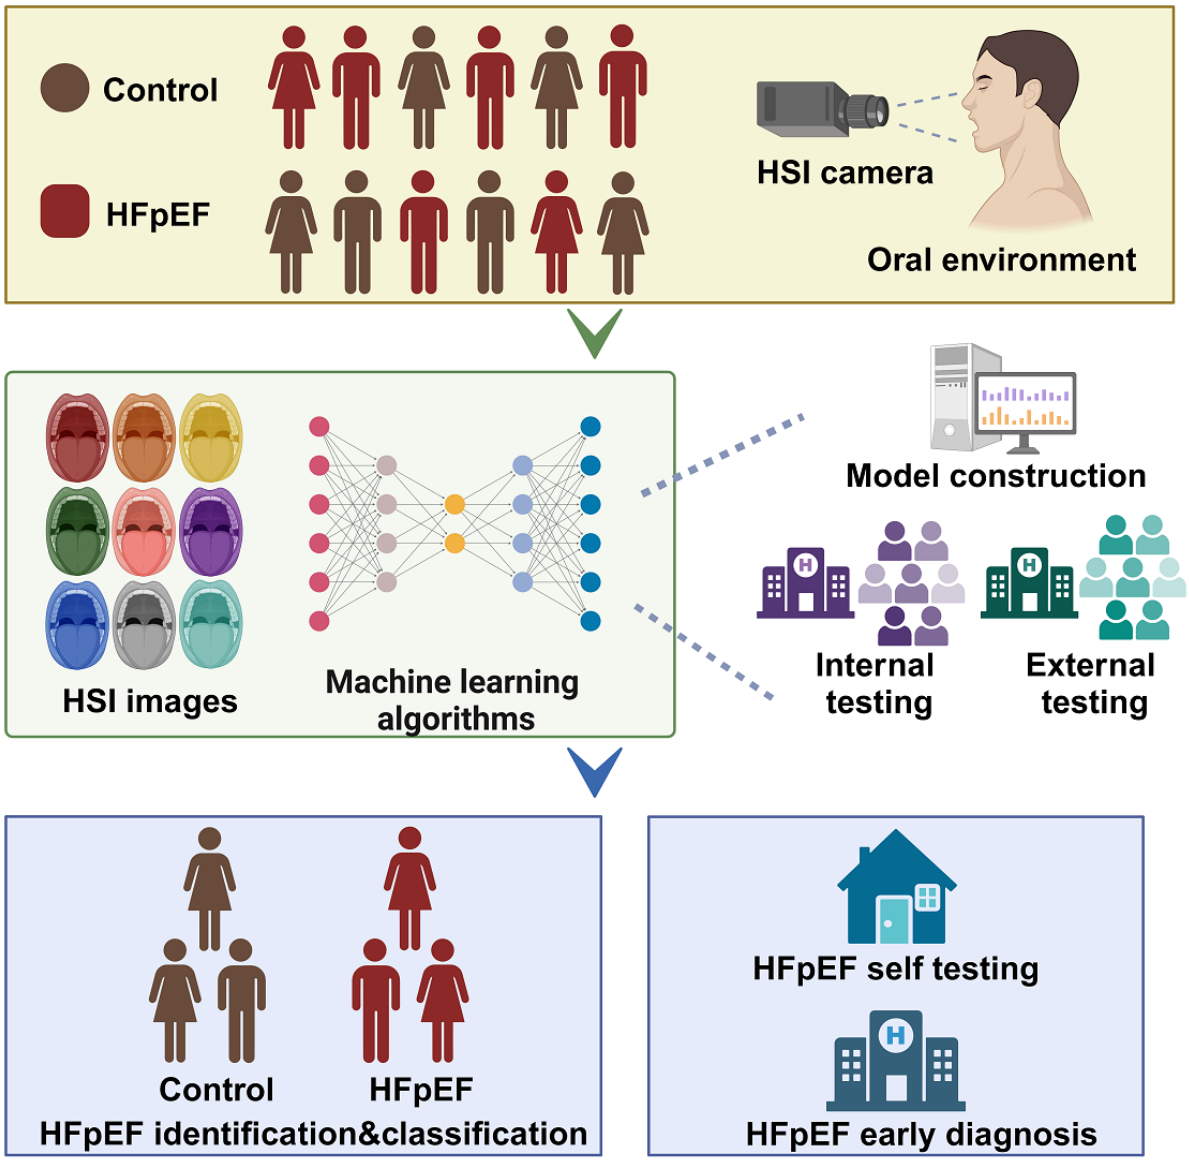
Shapley Additive Explanations (SHAP) of the best algorithm: (A) summary plot, (B) feature importance map, (C) waterfall plot for a control participant, (D) waterfall plot for a participant with heart failure with preserved ejection fraction (HFpEF), (E) bar chart for a control participant, (F) bar chart for a participant with HFpEF.

Discussion

Principal Findings

In this study, we innovatively used HSI to acquire oral images of control participants and participants with HFpEF, extracted the spectral and textural information of the HSI, and characterized the HSI using a variety of machine learning algorithms. The optimal algorithm was selected for the construction of the HFpEF diagnostic model, the model performance was validated in the internal and external testing groups, and the SHAP model was used for additive interpretation.

Digital health care is the future of medicine, introducing considerable convenience to the management of people's health [31]. As artificial intelligence and machine learning continue to advance, enabling automated interpretation and classification of HSI will allow researchers to focus more on deep analysis and decision-making [32]. A large amount of data redundancy is present for HSI data, and traditional image data processing methods struggle to meet processing and analyzing needs; therefore, we generated a series of feature extraction and



XSL•FO
RenderX

classification methods for spectral information. The use of multiple artificial intelligence algorithms helps to identify the characteristic bands and textures in large amounts of HSI information [33]. The use of artificial intelligence and machine learning can increase the interpretability of HSI data [34]. To select the most suitable machine learning algorithms for oral spectral images of individuals with HFpEF, we incorporated as many of the current mainstream machine learning models as possible [22]. We analyzed the obtained HSI using 28 machine learning algorithms and filtered the top 5 algorithms for external testing. The random forest algorithm showed good prediction performance in both the internal and external testing groups, so we used the spectral features screened by the random forest algorithm for further analysis. We also performed subgroup analysis based on age and gender in both internal and external testing groups, and the random forest algorithm showed good performance (Figure S1 in Multimedia Appendix 1). Although studies have investigated the use of artificial intelligence for HFpEF diagnosis [19,35,36], these studies primarily focused on constructing echocardiography-based diagnostic models for HFpEF. However, the reliance on specialty physicians to interpret echocardiography exams hinders the early identification of individuals with HFpEF [37]. Moreover, considering the existing diagnostic challenges and limited availability of imaging data during the initial stages of HFpEF, attention should be directed toward noninvasive imaging techniques for diagnosis and management. Therefore, it is imperative to integrate machine learning approaches to develop predictive models for early screening. In our study, we identified spectral bands and textural features that exhibit a close association with the pathophysiological changes observed in HFpEF. This condition is characterized by microvascular dysfunction, inflammation, and oxidative stress leading to alterations in optical properties of oral tissues [3]. HSI effectively captures these subtle changes by detecting variations in light absorption and scattering at different wavelengths. Our model significantly contributes to identifying HFpEF at an early stage, enabling clinicians to promptly initiate appropriate therapies while potentially slowing down disease progression and improving patient health care.

To effectively integrate our diagnostic model into existing health care management for HFpEF, we used an additive interpretation of this digital diagnostic model using the SHAP model. This allowed us to evaluate the contribution of each feature to the prediction, quantify the capability of these features to contribute to the overall model, and demonstrate their impact on the final predictive and diagnostic performance [28]. The SHAP model allows each parameter to be analyzed individually, which can be useful in understanding the decisions made by the model and to improve and rationalize the results of the model [38]. In the macrointerpretation of the SHAP model, the ranking of the contribution of the 25 features screened by random forest to the overall model and the ability of each feature to explain the overall model performance can be clearly seen. In the microinterpretation of the SHAP model, we show the SHAP values for each feature during model evaluation separately for control participants and participants with HFpEF. In the random forest HFpEF diagnostic model, there was a relatively straightforward difference between control participants and participants with HFpEF. The SHAP model demonstrates more intuitively the discriminatory power of the random forest algorithm for participants with HFpEF. Hence, through the provision of intelligent diagnoses, our model effectively bridges the gap between health care professionals and patients, thereby addressing the prevalent issue of frequent misdiagnosis or underdiagnosis and ultimately enhancing the overall quality of care. Furthermore, users can independently access data about oral characteristics at home and transmit the data to health care professionals for expert evaluation through a smartphone app, facilitating continuous monitoring of cardiac health [39]. In addition, in underserved remote areas with limited medical resources, this portable device can be used by mobile medical teams to offer diagnostic screening services to local residents [40], thereby enhancing public health in these regions. Precision medicine and personalized health care represent the future of medical development [41], and our research can also contribute to formulating individualized treatment plans whereby the medical team can gain comprehensive insights into the patient's condition through remotely collected digital data (Figure 5).

Figure 5. Future application scenarios. HFpEF: heart failure with preserved ejection fraction; HSI: hyperspectral imaging.

Limitations

First, in this study, model construction and internal testing were conducted in only 1 center, and external testing was conducted in 1 center. Further improvement of the model for the diagnosis of HFpEF should be conducted in multiple centers. Second, this study used multiple algorithms to select the characteristic hyperspectral bands; however, we did not identify images using deep learning algorithms, which could be used for direct image analysis for HFpEF diagnosis. Third, although we used some means to reduce data redundancy and overfitting, these may still exist. Fourth, different demographic information may affect the results. In future model optimization studies, the applicability of the model in different subgroups and including easily accessible clinical information should be considered. The promotion of HSI technology in HFpEF diagnosis has prospective, broader clinical applications that need to be further explored and developed.

Conclusion

This study demonstrates the innovative use of HSI technology to capture oral images and machine learning algorithms to construct a digital model to diagnose HFpEF. This technology was validated to have excellent performance in both internal and external testing groups. This study offers novel insights into the development of portable devices for rapid identification of HFpEF, thereby facilitating the advancement of digital diagnosis and treatment approaches for HFpEF and ultimately leading to improved patient outcomes and reduced health care costs.

Abstract

Background: Uncertainty in the diagnosis of lung nodules is a challenge for both patients and physicians. Artificial intelligence (AI) systems are increasingly being integrated into medical imaging to assist diagnostic procedures. However, the accuracy of AI systems in identifying and measuring lung nodules on chest computed tomography (CT) scans remains unclear, which requires further evaluation.

Objective: This study aimed to evaluate the impact of an AI-assisted diagnostic system on the diagnostic efficiency of radiologists. It specifically examined the report modification rates and missed and misdiagnosed rates of junior radiologists with and without AI assistance.

Methods: We obtained effective data from 12,889 patients in 2 tertiary hospitals in Beijing before and after the implementation of the AI system, covering the period from April 2018 to March 2022. Diagnostic reports written by both junior and senior radiologists were included in each case. Using reports by senior radiologists as a reference, we compared the modification rates of reports written by junior radiologists with and without AI assistance. We further evaluated alterations in lung nodule detection capability over 3 years after the integration of the AI system. Evaluation metrics of this study include lung nodule detection rate, accuracy, false negative rate, false positive rate, and positive predictive value. The statistical analyses included descriptive statistics and chi-square, Cochran-Armitage, and Mann-Kendall tests.

Results: The AI system was implemented in Beijing Anzhen Hospital (Hospital A) in January 2019 and Tsinghua Changgung Hospital (Hospital C) in June 2021. The modification rate of diagnostic reports in the detection of lung nodules increased from 4.73% to 7.23% (χ^2_1=12.15; *P*<.001) at Hospital A. In terms of lung nodule detection rates postimplementation, Hospital C increased from 46.19% to 53.45% (χ^2_1=25.48; *P*<.001) and Hospital A increased from 39.29% to 55.22% (χ^2_1=122.55; *P*<.001). At Hospital A, the false negative rate decreased from 8.4% to 5.16% (χ^2_1=9.85; *P*=.002), while the false positive rate increased from 2.36% to 9.77% (χ^2_1=53.48; *P*<.001). The detection accuracy demonstrated a decrease from 93.33% to 92.23% for Hospital A and from 95.27% to 92.77% for Hospital C. Regarding the changes in lung nodule detection capability over a 3-year period following the integration of the AI system, the detection rates for lung nodules exhibited a modest increase from 54.6% to 55.84%, while the overall accuracy demonstrated a slight improvement from 92.79% to 93.92%.

XSL•FO
RenderX

Conclusions: The AI system enhanced lung nodule detection, offering the possibility of earlier disease identification and timely intervention. Nevertheless, the initial reduction in accuracy underscores the need for standardized diagnostic criteria and comprehensive training for radiologists to maximize the effectiveness of AI-enabled diagnostic systems.

KEYWORDS

artificial intelligence; diagnostic accuracy; lung nodule; radiology; AI system

Introduction

In the rapidly evolving field of medical imaging, the integration of artificial intelligence (AI) systems is increasingly disrupting common methods of interpreting radiological images [1]. Traditionally, radiologists have been at the forefront of interpreting complex details within medical images, using their clinical expertise and experience [2]. The growing volume and complexity of medical imaging studies, however, have highlighted the limitations of human cognition [3,4]. In turn, AI systems, undeterred by the data volume, offer the potential solution for efficient, consistent, and accurate image analysis, marking a transformative change in radiological practice [5]. In practice, the China National Medical Products Administration and the US Food and Drug Administration have approved some of the AI image-assisted diagnostic systems to be marketed with the aim of improving efficiency and performance [6]. Therefore, there is an urgent need to evaluate the clinical impact before and after the implementation of AI systems in order to gather sufficient clinical evidence for their broader adoption.

In medical imaging, accurate diagnoses are crucial as such data inform clinical decisions, guide treatment plans, and significantly impact patient outcomes [7]. Radiologists are tasked with detecting abnormalities ranging from early-stage diseases to minor structural changes [8]. Any decrease in diagnostic accuracy can lead to delayed interventions, misdiagnoses, and undesired health outcomes [7]. Thus, given the impact of radiological findings on clinical decisions, improving the diagnostic accuracy of human-generated imaging reports has been a constant endeavor [9].

Several radiological studies have shown the efficacy of AI system applications in enhancing sensitivity (true positive rate) of detecting lung-related diseases [10-12], breast cancer [13,14], thyroid nodules [15], and fractures [16]. These studies, however, have been less consistent in evaluating the effect of AI systems in improving the specificity (true negative rate) of diagnosis. Lung nodule screening, a routine medical screening service, is critical for early lung cancer detection [17]. Various AI-based computer-aided diagnosis systems have been reported to substantially enhance radiologists' performance when used as a second reader [18-20]. However, prioritizing sensitivity improvement over specificity could lead to a high number of false positives, causing unnecessary stress for patients and potentially wasting medical resources due to overuse of interventions [21].

To address the lack of studies measuring the improvement of diagnosis specificity in radiology using AI systems, this study aims to evaluate the impact of an AI-assisted lung nodule diagnostic system on the diagnostic accuracy of junior radiologists examining chest computed tomography (CT) scans. The results of this study could influence the future development of AI-assisted diagnostic systems to advance the accuracy of radiological diagnosis and treatment of lung nodules [22].

Methods

Study Design

This study was carried out at 2 tertiary care facilities in China, Hospital A, and Hospital C, from April 2018 to March 2022. Hospital A, in close collaboration with the Capital Medical University, offers a comprehensive radiology department consisting of 27 radiologists conducting and reviewing over 200,000 CT exams annually. Hospital C, affiliated with Tsinghua University, maintains a radiology department with over 20 radiologists. Both health care institutions provide an extensive spectrum of medical imaging services, comprehensive whole-body CT and magnetic resonance imaging scans, specialized breast imaging, as well as an array of interventional diagnostic and therapeutic procedures.

The AI-assisted diagnostic system used in this research embodies cutting-edge technology crafted to assist radiologists in the interpretation of medical images, with a specific emphasis on lung nodules. These lung nodule AI systems were developed and integrated by Care.ai [23] (Yitu, integrated into Deepwise's framework in 2021) and Dr.Wise [24] (Deepwise) to operate at Hospital A (since January 2019) and Hospital C (since June 2021), respectively. These systems harness advanced machine learning algorithms and deep neural networks to analyze radiological images, with a primary focus on the automated detection, categorization, and characterization of abnormalities, particularly lung nodules [25].

The comprehensive and seamless integration of the AI tool within the clinical platform of either hospital enables a thorough assessment of lung nodules integrated into the radiologist's diagnostic workflow (Figure 1), the AI system processes image data, generates annotations or highlights specific regions of interest, such as lung nodules, nodule location, and quantitative data, including nodule size, density, and other relevant parameters [24] (Figure 2). Junior and senior radiologists can scrutinize these findings and seamlessly integrate them into their diagnostic evaluations, thus enabling a comprehensive assessment of lung nodules (Figure 1).

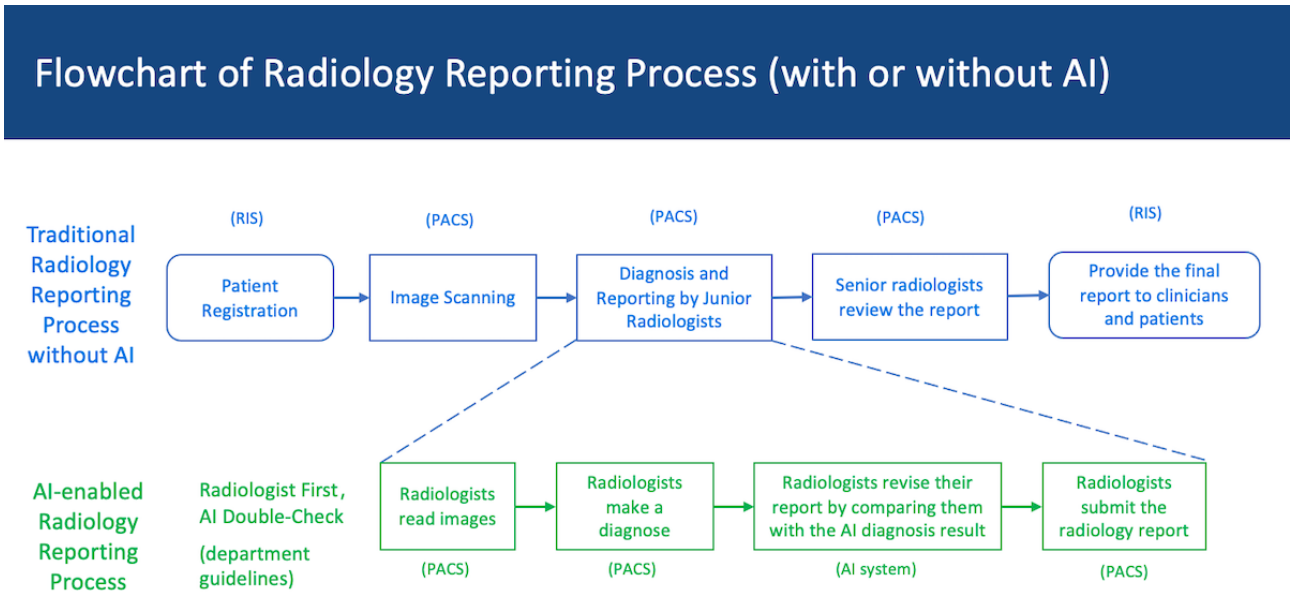
RenderX

Figure 1. Radiologist's diagnostic workflow with or without the artificial intelligence (AI) system. Note: AI medical devices are regulated to aid in diagnosis. All diagnoses should be made by radiologists and then checked by AI. Some radiologists may rely on the results given by the AI to double-check and modify the results. PACS: picture archiving and communication system; RIS: radiology information system.



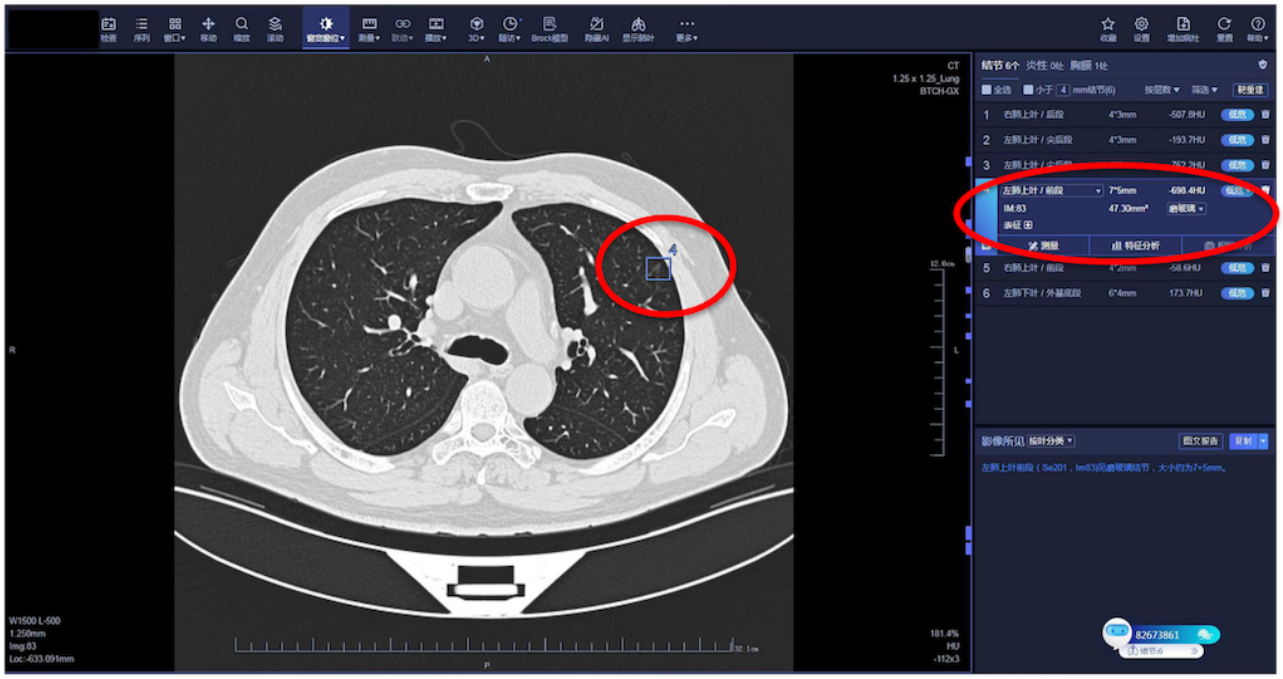


Figure 2. Working window of the artificial intelligence (AI) system.

To enhance efficiency and ensure accuracy, hospitals in China typically implement a 2-tiered system for radiology reporting (Figure 1). This process involves a less experienced radiologist, often a junior radiologist, who initially examines the medical images and drafts the report. This preliminary report is then passed on to a more experienced senior radiologist for further evaluation and revision. Once the report has been carefully reviewed and amended as necessary, it is finally forwarded to the physician responsible for diagnosis and also provided to the patient. In some instances, the same senior radiologist is responsible for both composing and reviewing the report. However, given that this study aimed to assess the impact of AI system introduction on the diagnostic accuracy of junior radiologists, those types of reports were excluded from the experimental sample.

We conducted a patient-specific evaluation of the reporting accuracy of junior radiologists for CT imaging. The analysis encompassed data collected from both Hospital A and Hospital C and spanned from April 2018 to March 2022. However, specific intervals, encompassing January 2019 to March 2019, January 2020 to August 2020, and April 2021 to August 2021, were excluded from the analysis due to the substantial impact of the COVID-19 pandemic [26], the implementation of the AI

XSL•FO
RenderX

system, and the Spring Festival vacation on patterns of health-seeking behavior.

Data Collection

The sample size for this study was computed with the assistance of the University of California, San Francisco calculator [27]. The aim was to detect a 30% increase (estimated risk ratio=1.3) in the efficacy of the AI intervention. To achieve 80% statistical power and significance (α=.05, 2-tailed), the study necessitated a sample size of 1594. To adhere to these criteria, the researchers adopted a systematic approach. Each month, they used Microsoft Excel for Mac (version 16.77.1), specifically using the random number sampling function to select approximately 200 patients from the complete pool of individuals who had undergone lung CT examinations at both hospitals during the study period. This methodology ensured that the selection process was unbiased and representative.

A meticulous quality control approach was followed to ensure data validity. The validation entailed the assignment of two researchers to conduct data collection and analysis, with all data undergoing a thorough anonymization process. Data were primarily collected from diagnostic reports written by junior and senior radiologists and captured in the picture archiving and communication system. The picture archiving and communication system allowed for transparent documentation of modifications made by senior radiologists to the reports initially generated by junior radiologists. Since these reports could not be directly exported from the system, photographs were taken, and the researchers summarized diagnostic report modification records. One researcher transcribed the original reports based on the photographic documentation and made adjustments pertaining to the detection of lung nodules and changes in lung lesion morphology, including modifications regarding the number, size, location, and diagnosis of lung nodules. Subsequently, another researcher thoroughly reviewed these entries to ensure accuracy. In cases of disagreement between the two entries, consultation with an expert radiologist who had more than a decade of clinical experience was sought. Due to the 2-tiered system for radiology reporting, the diagnostic results of senior radiologists were used as the reference standard to assess whether the diagnostic accuracy of junior radiologists improved after the AI system was launched. Senior radiologists set the rules for entering data on lung nodules and lung lesion morphology changes. The inclusion criteria for lung nodules included reports describing nodular shadow, punctate hyperdense shadow, and sclerotic foci. For lung lesion morphology changes, reports describing striated hyperdense shadow, patchy shadow, and ground-glass density shadow were included.

Statistical Analysis

The primary outcome measures of this study included lung nodule detection rate, rate of missed diagnoses, rate of misdiagnoses, sensitivity, and positive predictive value. The detection rate was defined as the percentage of all patients in the study who were ultimately reported to have a lung nodule. The rate of missed diagnoses referred to the percentage of lung nodules that were not identified by the junior radiologists but were reported after review by the senior radiologists. The rate of misdiagnoses referred to instances where the junior radiologists incorrectly reported a lung nodule. Sensitivity was defined as a junior radiologist's ability to correctly identify a true positive case, as compared with the diagnosis of a senior radiologist, which was considered the reference standard. The positive predictive value was described as the proportion of correctly identified positive cases in the diagnosis.

This study used descriptive statistics, specifically frequencies and percentages, to concisely present categorical data, particularly diagnostic outcomes. To assess statistical significance, we used the chi-square, Cochran-Armitage, and Mann-Kendall tests. The chi-square test was used to evaluate changes in both the lung nodule's detection modification rate and detection ability as well as the lung's morphological lesions before and after AI launch. The Cochran-Armitage and Mann-Kendall tests were used to compare the directional trend in the detection modification rate and detection ability of lung nodules and lung morphological lesions in relation to the duration of AI's online presence. The chi-square test was used to assess relationships between categorical variables, while the Cochran-Armitage and Mann-Kendall tests addressed trend analysis. Together, these methods effectively met our study's goals of examining intergroup relationships and temporal trends. The raw variables met the distributional assumptions of the applied tests (eg, the chi-square test does not require normality, while the Cochran-Armitage and Mann-Kendall tests are suited to nonparametric data). Therefore, raw values were used for statistical analysis. Significance was established when *P* values fell below the .05 threshold. Data analysis was carried out using R version 4.1.2 (R Development Core Team) [28], and the resulting findings were visualized using tables and graphs for enhanced interpretability.

Ethical Considerations

This study was approved by the Institutional Review Board of the Johns Hopkins Bloomberg School of Public Health (reference number FWA 00000287). The use of data was also approved by the institutional review boards of the Tsinghua Changgung Hospital (reference number 23352-4-01) and the Beijing Anzhen Hospital (reference number 2023078X). The data used in this study were anonymous and did not contain any personally identifiable information. Furthermore, no patients can be identified in any images contained within the manuscript or its supplementary materials.

Results

Patient Characteristics

This study analyzed patient data collected from both hospitals before and after the implementation of the AI system. The study population included a total of 12,889 patients, with 6439 patients having an encounter with Hospital C and 6450 patients from Hospital A. The demographic characteristics of the patients are presented in Table 1.

XSL•FO

[a]AI: artificial intelligence.

Diagnostic Accuracy

Alterations in diagnostic accuracy for the identification of lung nodules and the assessment of lung lesion morphology were measured by comparing the reports of junior and senior radiologists (Table 2). The modification rate was defined as the ratio of changes made by senior radiologists to the diagnostic reports authored by junior radiologists, divided by the total number of radiology reports. Concerning lung nodule detection, both hospitals experienced an increase in their report modification rates after the introduction of the AI system, with Hospital A showing a statistically significant rise from 4.73% to 7.23% (χ^2_1=12.15; P<.001) in the modification rate. Conversely, in the case of lung lesion morphology, serving as a negative control, no significant differences were observed between the two hospitals before and after the implementation of the diagnostic AI system.

Table 2. Diagnostic accuracy of lung nodule detection and lung lesion morphology detection before and after artificial intelligence (AI) launch.

Modified or not	Hospital C (n=6439)				Hospital A (n=6450)			
	Before AI[a] (n=4830), n (%)	After AI (n=1609), n (%)	Chi-square (*df*)	*P* value	Before AI (n=1606), n (%)	After AI (n=4844), n (%)	Chi-square (*df*)	*P* value
Lung nodule			2.27 (1)	.13			12.15 (1)	<.001

[a]AI: artificial intelligence.

Lung Nodule Detection Ability

Alteration in lung nodule detection proficiency after the introduction of the AI system was also measured by comparing the reports of junior and senior radiologists (Table 3). At Hospital C, a notable and statistically significant rise in the detection rate was observed, increasing from 46.19% to 53.45% (χ^2_1=25.48; P<.001) after adopting the AI-assisted system. While a slight increase in the false negative rate and a decrease in accuracy were observed, the positive predictive value remained relatively consistent. Conversely, at Hospital A, the

XSL•FO
RenderX

AI system led to a significant enhancement in the detection rate of lung nodules, elevating the rate from 39.29% to 55.22% (χ^2_1=122.55; *P*<.001). Finally, the rollout of the AI system resulted in a reduction of the false negative rate from 8.4% to 5.16% (χ^2_1=9.85; *P*=.002) but led to an increase in the false positive rate from 2.36% to 9.77% (χ^2_1=53.48; *P*<.001). Nonetheless, the detection accuracy exhibited a decline, leading to a decrease in the positive predictive value, the rate from 96.17% to 92.29% (χ^2_1=11.41; *P*<.001).

Table 3. Lung nodule detection ability before and after artificial intelligence (AI) launch.

Hospital	Diagnostic method	Detection rate, %	False negative rate, %	False positive rate, %	Accuracy, %	Positive predictive value[a], %
Hospital C	CT[b] examination	46.19	10.98	2.96	93.33	96.27
	AI-assisted[c] system + CT examination	53.45	11.28	3.74	92.23	96.46

	AI-assisted system + CT examination	55.22	5.16	9.77	92.77	92.29

[a]Positive predictive value: The proportion of correctly identified positive cases in the diagnosis.

[b]CT: computed tomography.

[c]AI-assisted: artificial intelligence–assisted.

Subgroup Analysis of Different AI Launch Times

To examine the patterns of diagnostic accuracy and detection ability of the AI system over time, we conducted subgroup analyses of different AI launch times (Table 4). Regarding lung nodules, the percentage of modified diagnoses increased from 7.21% in the first year to 8.40% in the second year but then decreased to 6.08% in the third year. Based on the Mann-Kendall test, the *z* score of –1.25 indicated a nonsignificant trend (*P*=.21). As for lung lesion morphology, the percentage of modified diagnoses remained relatively stable, with a slight increase to 4.42% in the third year. The *z* score of 0.83 also indicated a nonsignificant trend (*P*=.41). Most diagnoses remained unchanged during the 3 years following the launch of the AI system.

Table 4. Time trend analysis of lung nodule diagnostic accuracy from different artificial intelligence (AI) launch times at Hospital A.

Modified or not	1 year after AI[a] launch (n=1608), n (%)	2 years after AI launch (n=1608), n (%)	3 years after AI launch (n=1628), n (%)	*z*[b] score	*P* value
Lung nodule				–1.25	.21
Modified	116 (7.21)	135 (8.4)	99 (6.08)		
Not modified	1492 (92.79)	1473 (91.6)	1529 (93.92)

[b]The test statistic for the Mann-Kendall test.

Alterations in lung nodule detection capability were measured over 3 years after the integration of the AI system (Table 5). The detection rates for lung nodules displayed a slight increase from 54.6% to 55.84%. In parallel, the false negative rates decreased from 7.06% to 4.07%. Nevertheless, the false positive rates exhibited fluctuations, reaching a peak of 13.33% in the second year. Despite these variations, the overall accuracy remained notably high, with a slight increase from 92.79% to 93.92%. Similarly, the positive predictive value demonstrated a comparable trend, with a minor decline in the second year.

Table 5. Time trend analysis of lung nodule detection ability from different artificial intelligence (AI) launch times at Hospital A.

Examination time	Detection rate, %	False negative rate, %	False positive rate, %	Accuracy, %	Positive predictive value[a], %
1 year after AI[b] launch	54.6	7.06	7.4	92.79	93.79
2 years after AI launch	55.22	4.39	13.33	91.6	89.84
3 years after AI launch	55.84	4.07	8.62	93.92	93.36

[a]Positive predictive value: The proportion of correctly identified positive cases in the diagnosis.

[b]AI: artificial intelligence.

Discussion

Enhanced Detection of Lung Nodules

Our study noted a substantial improvement in the detection rate of lung nodules following the implementation of the AI system. This improvement can be attributed to the AI's capability to augment radiologists' ability to spot small nodules that might indicate an underlying disease. AI algorithms are designed to methodically examine a wide range of medical images, thereby highlighting potential abnormalities that the human eye might miss. Furthermore, small lung nodules are often linked to early-stage diseases, which provide additional time for effective interventions, thus increasing the value of AI diagnostic systems in improving the detection of lung nodules in CT scans as well as the overall outcome of such patients [10].

Initial Decrease in Diagnostic Accuracy

Interestingly, compared with the diagnostic results of radiologists without AI assistance, our study observed a decline in the diagnostic accuracy of lung nodules within 3 years of the introduction of the AI system, mainly due to a significant rise in misdiagnosis rates. This intriguing observation calls for a more detailed investigation into the complex relationship between AI technology and radiologists' clinical decision-making. The increase in misdiagnosis rates could be due to the following reasons. First, the inherent characteristics of lung nodules present challenges for accurate detection. Specifically, CT imaging can be difficult when nodules are small, faint, or located in endobronchial or hilar regions [29]. In addition, pulmonary vasculature and artifacts were two of the main causes of false positive findings [30]. In addition, varying clinical attitudes of radiologists on reporting very small, and often microscopic, nodules may affect the detection accuracy. Radiologists may differ in their evaluation of clinical significance, resulting in varied reporting practices [31-33]. Furthermore, while the AI system is proficient in detecting nodules, it may also lead to a surge in cases with minimal clinical relevance, contributing to higher misdiagnosis rates. In order to reduce the false positives brought about by the introduced AI system, it is necessary to take comprehensive measures to maximize the effectiveness of the AI system in the future. In terms of algorithms, some algorithms have attempted to use a 2-step strategy, with the first step being the detection of candidate nodules with high specificity, followed by a false-positive reduction step in recent years [34]. For radiologists, before formally applying AI in the clinic, radiologists should receive training [35,36], which requires standardized diagnostic criteria to avoid diagnostic alterations due to differing attitudes of radiologists towards microscopic nodules. Meanwhile, promoting the standardized application of Chinese expert consensus on the diagnosis and treatment of pulmonary nodules (2024) in clinical practice is essential [6].

Long-Term Use and Temporal Trends

Our study revealed intriguing temporal trends in the diagnostic accuracy of lung nodules. Over time, we noticed a steady improvement in accuracy, indicating a dynamic process of adaptation and refinement. Several factors could potentially explain this phenomenon. One likely reason could be the ongoing optimization of AI algorithms through machine learning and feedback from actual clinical use [37,38]. As AI systems gain more experience in interpreting medical images and learning from radiologists' diagnostic patterns, their performance becomes increasingly refined. Furthermore, the growing familiarity and acceptance of AI systems among physicians could enhance their ability to work in tandem with these tools, thereby leading to improved diagnostic accuracy [39,40]. These pieces of evidence suggest that the AI system is expected to identify the unique features of lung nodules that differentiate them from other anatomies, as well as develop the capability for 3D reconstruction.

Strengths and Limitations

This study has several strengths. First, we conducted a statistical analysis of 12,889 diagnostic reports before and after the implementation of the AI system in 2 tertiary hospitals in China. The large sample size enabled us to draw reliable conclusions about the impact of the AI system on radiologists' performance. Second, we specifically selected the widely used lung nodule AI system to analyze detection rates and diagnostic accuracy, aiming to improve the quality of care and patient diagnosis in a real-world scenario. Finally, to evaluate the long-term application of the AI system, we included a random sample of diagnostic reports spanning 4 years, thus allowing us to conclude the temporal trends in the ongoing optimization process.

This study also has limitations. First, the research was conducted exclusively in 2 tertiary hospitals situated in Beijing, China. It is essential to recognize that junior radiologists, despite having relatively limited diagnostic experience, boast a high educational background and medical proficiency. Therefore, the influence detected by the introduction of the AI system in our study might not be generalizable to other institutions, specifically primary care settings. Furthermore, it is pertinent to acknowledge that our comparative benchmark was based on the diagnostic outcomes of senior radiologists. While the diagnoses rendered by senior radiologists are undoubtedly a robust reference, it is important to acknowledge that distinctions between clinical and

XSL•FO
RenderX

pathological assessments may exist, and senior radiologists' evaluation and revision can be influenced by the implementation of AI systems too.

For future investigations, it is advisable to contemplate the collection of prospective data and the incorporation of pathological results to enable a more comprehensive evaluation.

Conclusion

In summary, the integration of AI systems has yielded significant enhancements in lung nodule detection rates, particularly in the case of small nodules. This advancement, however, has been accompanied by a temporary decrease in diagnostic accuracy, primarily attributed to increased misdiagnosis rates, potentially arising from the influence of varying diagnostic criteria following the integration of AI systems and the performance of AI proficiency in detecting tiny lung nodules while ignoring clinical significance. Nonetheless, our research reveals encouraging trends over time, with diagnostic precision gradually ameliorating. This improvement can be ascribed to the continual refinement of AI algorithms and more effective collaboration among radiologists. Overall, our study underscores the promising role of AI in clinical settings, thus presenting opportunities for early disease identification and personalized patient care.

Data Availability

The datasets generated during and/or analyzed during this study are not publicly available due to restricted usage imposed by the patient privacy protection policy from Beijing Anzhen Hospital (Hospital A) and Tsinghua Changgung Hospital (Hospital C). The dataset applied in this study can be accessed with permission from the institutional review boards of Hospital A and Hospital C.

Authors' Contributions

WL contributed to study concepts and design, literature research, experimental studies, data analysis, statistical analysis, and manuscript preparation. YW was involved in study concepts and design, statistical analysis, and manuscript editing. ZZ participated in clinical studies and experimental studies. MB contributed to the study concepts and design. WY was involved in study concepts and design, clinical studies, experimental studies, and manuscript editing. HK acted as the guarantor of the integrity of the entire study and contributed to study concepts and design and manuscript editing.

Abstract

Background: A meta-analysis is a quantitative, formal study design in epidemiology and clinical medicine that systematically integrates and quantitatively synthesizes findings from multiple independent studies. This approach not only enhances statistical power but also enables the exploration of effects across diverse populations and helps resolve controversies arising from conflicting studies.

Objective: This study aims to develop and implement a user-friendly tool for conducting meta-analyses, addressing the need for an accessible platform that simplifies the complex statistical procedures required for evidence synthesis while maintaining methodological rigor.

Methods: The platform available at MetaAnalysisOnline.com enables comprehensive meta-analyses through an intuitive web interface, requiring no programming expertise or command-line operations. The system accommodates diverse data types including binary (total and event numbers), continuous (mean and SD), and time-to-event data (hazard rates with CIs), while implementing both fixed-effect and random-effect models using established statistical approaches such as DerSimonian-Laird, Mantel-Haenszel, and inverse variance methods for effect size estimation and heterogeneity assessment.

Results: In addition to statistical tests, graphical representations including the forest plot, the funnel plot, and the *z* score plot can be drawn. A forest plot is highly effective in illustrating heterogeneity and pooled results. The risk of publication bias can be revealed by a funnel plot. A *z* score plot provides a visual assessment of whether more research is needed to establish a reliable conclusion. All the discussed models and visualization options are integrated into the registration-free web-based portal. Leveraging MetaAnalysisOnline.com's capabilities, we examined treatment-related adverse events in patients with cancer receiving perioperative anti–PD-1 immunotherapy through a systematic review encompassing 10 studies with 8099 total participants. Meta-analysis revealed that anti–PD-1 therapy doubled the risk of adverse events (risk ratio 2.15, 95% CI 1.39-3.32), with significant between-study heterogeneity (I^2=95%) and publication bias detected through the Egger test (*P*=.02). While these findings suggest increased toxicity associated with anti–PD-1 treatment, the *z* score analysis indicated that additional studies are needed for definitive conclusions.

Conclusions: In summary, the web-based tool aims to bridge the void for clinical and life science researchers by offering a user-friendly alternative for the swift and reproducible meta-analysis of clinical and epidemiological trials.

Introduction

Systematic literature reviews in medicine summarize the best-proven knowledge from a research domain into a single paper [1]. A meta-analysis is the statistical combination of results from at least 2 separate studies which can serve as a powerful tool for summarizing, integrating, and interpreting quantitative research findings from the collected sources. The first potential advantage of a meta-analysis is its capacity to enhance precision. Many studies, when considered in isolation, may be too small to provide convincing evidence about intervention effects, and a meta-analysis of multiple studies can provide the necessary power to investigate whether interventions have an impact on the incidence of rare events.

Second, meta-analyses allow for the exploration of questions not explicitly addressed by individual studies. Primary studies often focus on specific participant types and interventions with well-defined parameters. By incorporating studies with diverse characteristics, it becomes possible to investigate the consistency of effects across a broader range of populations and interventions. Additionally, this approach may shed light on reasons for variations in effect estimates.

Third, meta-analyses can play a role in settling controversies that may arise from apparently conflicting studies or in generating new hypotheses. The statistical synthesis of findings enables formal assessment of conflicting results, providing a means to explore and quantify the reasons for different outcomes.

On the other hand, meta-analyses can be limited by inadequate search strategies, lack of clarity on comparators, insufficient assessment of risk of bias in primary studies, failure to address heterogeneity across studies, and the use of inappropriate or nonstandard methodological approaches, all of which can undermine the reliability and validity of the conclusions drawn [2]. Recent systematic evaluation of meta-analyses focusing on digital biomarker interventions revealed significant methodological inadequacies, with 92% of studies demonstrating critically low quality, highlighting the need for more rigorous methodological approaches in meta-analytic research [3]. Furthermore, meta-analyses often fail to adequately consider important demographic factors and subgroup analyses, as evidenced by a recent overview of systematic reviews on digital technologies in chronic obstructive pulmonary disease where only 1 out of 30 reviews included age-based subgroup analysis, despite the potential impact of such factors on treatment outcomes and clinical applicability [4].

Here, the study aims to establish a new web portal for the simple and rapid execution of meta-analysis studies. In a meta-analysis, first, a summary statistic is computed for each study to describe the observed intervention effect uniformly across all studies. Then, a combined intervention effect estimate is calculated as a weighted average of the intervention effects estimated in the individual studies. We list options used by our web-based tool and for an all-inclusive description of the different approaches we suggest consulting statistical papers like the publications by Haidich [5] and by Tawfik et al [6]. In the last part of our paper, we describe a sample application where we analyzed the correlation between immune checkpoint blockade and adverse events.

Methods

Web-Based Meta-Analysis Portal

Our main goal was to create a web-based application that allows users to perform a complete meta-analysis of clinical trials with minimal effort. For this, we established a user-friendly portal that is accessible in any major web browser. The web application is running on an Ubuntu server (Canonical Ltd) powered by Apache. The application can be used to perform meta-analyses using binary (using total and event numbers), continuous (using mean and SD data), and time-to-event data (using hazard ratio and CI data). The results of each study can be pasted from commonly used spreadsheet applications like Microsoft Excel.

The calculations and plots used by the web-based system are done using *meta*, *RTSA*, and *metafor* packages in R programming environments (version 4.2.2; R Foundation for Statistical Computing). The Shiny user interface was created by using the *shinyjs*, *shinydashboard*, and *rhandsontable* R packages. The portal generates a forest plot to summarize the results of the meta-analysis. A 2-tailed *P* value below .05 indicates significance and is displayed in the analysis results. MetaAnalysisOnline.com uses the DerSimonian-Laird estimator to estimate tau-square [7].

In addition to the forest plot, a funnel plot is displayed to detect potential bias visually, and a *z* score plot is used for assessing the power achieved by the cumulative sample number. While there is commercial software available for performing a meta-analysis [8], the portal we developed can be accessed completely free, without the need for registration or logging in.

The Implemented Statistical Methods

Experimental data are typically classified into 2 main categories: clinical data, which detail the effects of specific treatments on individual participants; and epidemiological data, which unveil patterns of disease or mortality in groups of participants exposed to either single agents or various substances. The most common classification in such studies uses categorical variables. A categorical variable is nonnumerical, relying on qualitative properties such as treatment arm, race, or gender, among others. Unlike numerical variables, categorical variables lack a specific ordering and assume values from a finite set of possibilities.

In MetaAnalysisOnline.com, the 2 study arms can be compared by either the fixed-effect model or the random-effect model. The fixed effect model operates on the assumption that a single true effect size underlies all studies in the meta-analysis, hence the term “fixed effect” or “common-effect” or sometimes “equal-effects.” Any variations in observed effects are attributed to sampling error. The random effects model posits that the true effect may vary across studies due to inherent differences or heterogeneity between them. As studies encompass diverse participant compositions and different interventions, individual studies may yield varying effect sizes. If an infinite number of studies were conducted, the effect estimates from all studies would conform to a normal distribution and the pooled estimate would then represent the mean or average effect. The assumption

XSL•FO
RenderX

is that the effect sizes observed in conducted studies represent a random sample from the universe of all possible effect sizes, hence the term "random effects" [9]. The random effects approach for aggregating evidence from a series of experiments that compare 2 treatments was originally proposed by DerSimonian and Laird [7]. They integrated the heterogeneity of effects into the analysis, providing a comprehensive assessment of the overall treatment efficacy. The heterogeneity can be assessed using the I^2 and ^{2} statistics, where the ^{2} represents the between-trial variance of the effect size. The square root of the ^{2} provides an estimate of the SD of the effects in the analyzed studies. High values of ^{2} indicate substantial heterogeneity among the effect sizes, suggesting that the true effects are not consistent across studies and may be influenced by other factors [10]. The I^2 method, developed by Higgins and Thompson [11], offers a percentage value representing the variability observed in the effect size, independent of sampling error. One of its advantages lies in the ease of interpreting its results: I^2 percentages of 25% correspond to low, 50% to medium, and 75% to high levels of heterogeneity, respectively [12].

There are 4 commonly used methods of meta-analysis for dichotomous outcomes: 4 fixed-effect methods (Mantel-Haenszel [13], Peto, Bakbergenuly [14], and inverse variance) and 1 random-effect method (DerSimonian and Laird inverse variance [7]). The Peto method is limited to combining odds ratios (ORs), while the other 3 methods can combine ORs, risk ratios, or risk differences. The Mantel-Haenszel method is a fixed effect meta-analysis method that uses a different weighting scheme depending on the type of effect measure being used (eg, risk ratio or OR) [13]. A relatively recent development is the Bakbergenuly sample-size-weighted estimator approach, which offers an alternative by using a weighted average where each study's weight is determined by its effective sample size [14]. In the fixed effect model, the weights are calculated as $w_i=1/v_1$ where v_1 represents the variance of the study. In the calculation, also known as the inverse variance method, studies with lower variances are weighted higher. In the random effect model, the calculation of weights is different, and the formula is $_i=1/(\ ^2+v_i)$, where ^{2} represents the square of the variance of the distribution of true effect sizes. The inverse-variance method's key advantage is its wide applicability, as it can be used for all effect measures and not only for OR, risk ratio, or risk difference. For its execution, we need to have the point estimate and the variance of the treatment effect in each study [7].

Quantitative variables can be either discrete or continuous. Discrete variables are constrained to a finite number of values (such as whole numbers), whereas continuous variables can assume any value, including all possible values within a given range (extending to an infinite number of decimal places). Standard methods for meta-analysis of continuous data rely on the assumption that the outcomes follow a normal distribution within each intervention arm in each study. The 3 commonly used summary statistics for a meta-analysis of continuous data include the mean difference (MD), the standardized mean difference (SMD), and the ratio of means. The choice of summary statistics for continuous data primarily depends on whether studies report the outcome using the same scale (in which case MD is used) or different scales (in which case the SMD is typically used). In the MD approach, the SDs and sample sizes are used to calculate the weight assigned to each study and studies with smaller SDs are given relatively larger weights. In the SMD approach, the SDs are used to standardize the MDs to a single scale and are also used in the computation of study weights. When comparing with MD, interpreting the results can be challenging due to the need to categorize the SMD. Typically, we use the categories outlined by Cohen, which indicate that an SMD of approximately 0.2 corresponds to a small effect, around 0.5 signifies a moderate effect, and approximately 0.8 indicates a large effect [15]. In addition to MD and SMD, MetaAnalysisOnline.com also includes the ratio of means, a more recent solution where instead of using the difference between groups, the log-transformed ratio of the means of the groups is used in the analysis. The advantage of this approach is that the output of the result is easily interpretable similar to the odds or risk ratio [16].

Demonstration: The Correlation Between Immune Checkpoint Blockade and Adverse Events

In recent years, the addition of immune checkpoint blockade using anti–PD-1 drugs, such as pembrolizumab, nivolumab, and cemiplimab, into cancer therapy has improved clinical outcomes. However, the safety of the immune checkpoint blockade needs further evaluation. As a demonstration of the functionalities of MetaAnalysisOnline.com, a set of previous studies was analyzed to assess how incorporating immune checkpoint blockade into perioperative cancer therapy affects treatment-related adverse events in patients treated with anti–PD-1 therapy.

Results

Graphical Representation of the Overall Effect: The Forest Plot

A comprehensive forest plot displays a set of the following information.

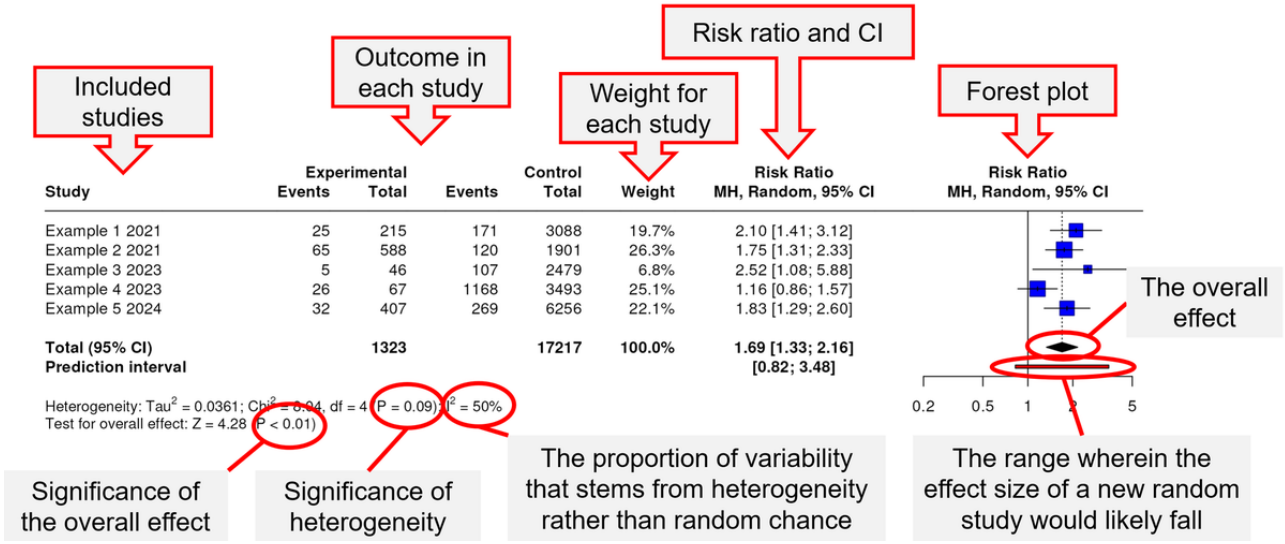
- The name of the original studies used in the meta-analysis. It is crucial to ensure the uniqueness of study names, particularly when an author or study name is listed more than once.
- The number of events and the total number of participants in each group of the study.
- A graph representing the relative risk and 95% CIs. Each square in the plot embodies the study results, centered on the point estimate, with a horizontal line indicating the 95% CI. The diamond represents the overall meta-analysis estimate, with the center signifying the pooled estimate and the prediction interval indicating the confidence limits. The CI depicts the range of intervention effects compatible with the study's result, while the size of the block draws attention to the studies with larger weight, which dominates the calculation of the summary result presented by the diamond at the bottom.

XSL•FO
RenderX

- The risk ratio or hazard ratio and 95% CI for each individual study and the overall meta-analysis.
- The percentage of weight assigned to each study, particularly when presenting pooled results. Studies with higher sample numbers or those with narrower CIs receive higher weights.
- Finally, at the bottom of the plot, the heterogeneity and the overall effect values. A significant *P* value for heterogeneity indicates a substantial difference between studies. However, they heavily rely on the assumption of a normal distribution for the effects across studies and can present challenges when the number of studies is small, potentially leading to artificially wide or narrow intervals.

The features discussed in this section are marked in the plot generated by demo data in Figure 1. In addition, a screenshot of the analysis page with a generated forest plot is shown in Figure 2.

Figure 1. Components of a forest plot.



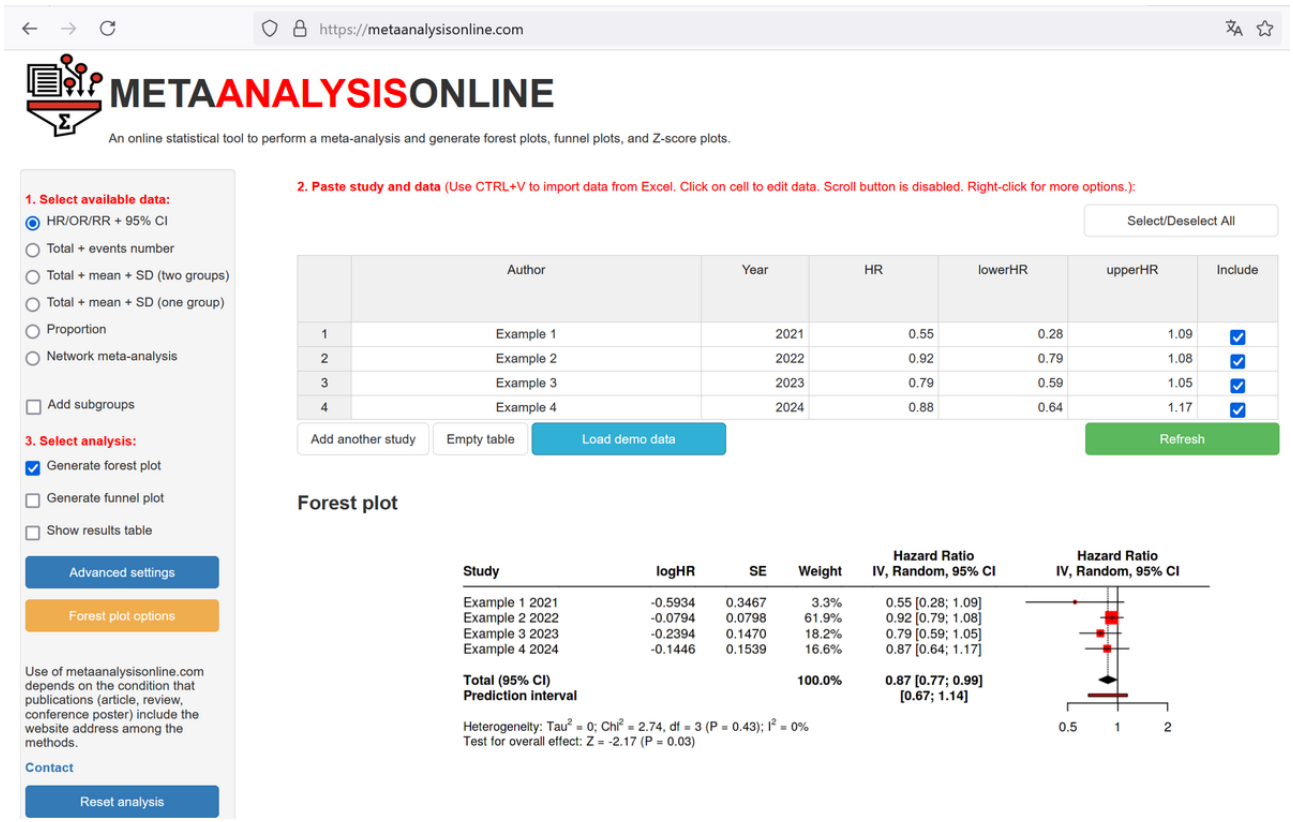


Figure 2. Screenshot of the web-based analysis interface showing the demonstration data and the generated forest plot.

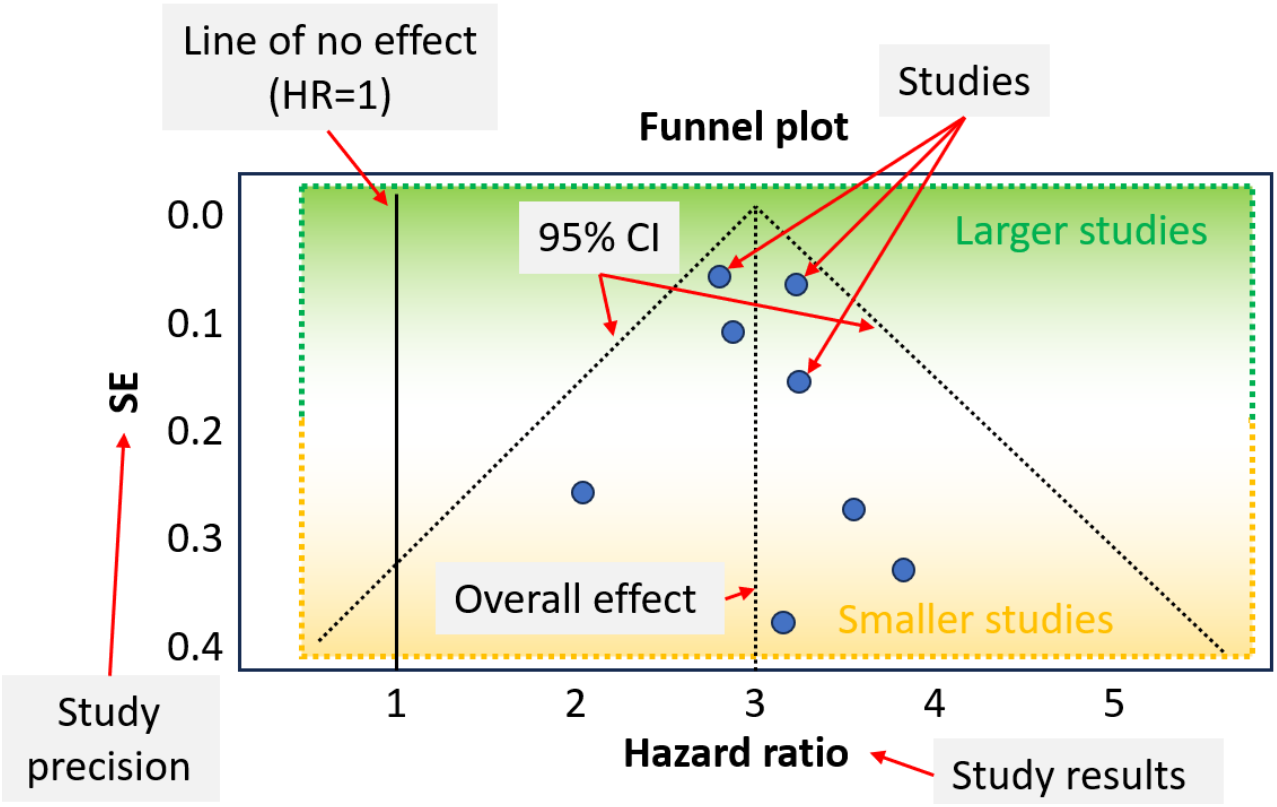
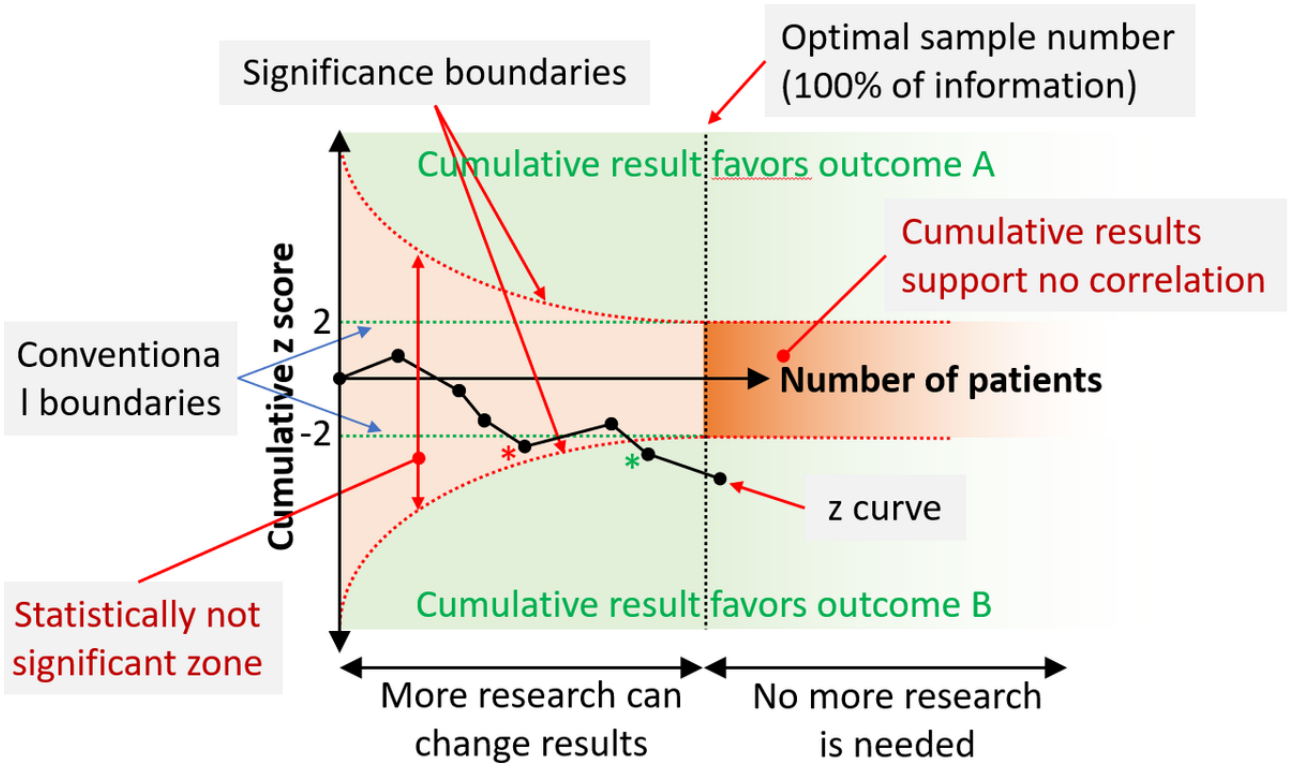


XSL•FO
RenderX

Graphical Representation of Heterogeneity: The Funnel Plot

The second analysis available in MetaAnalysisOnline.com is the funnel plot designed to detect publication bias. Whether the primary studies for pooling are observational studies or randomized controlled trials, heterogeneity between studies is probable. We show the components of a funnel plot used to assess study heterogeneity in Figure 3. Each dot on the plot represents an individual study. The x-axis represents the hazard ratio, or in other cases the log of OR, indicating the effect size of the treatment in each study. The y-axis represents the standard error, reflecting study precision, with larger studies having better precision (within the green area) and smaller studies having worse precision (within the orange area). In the plot, the vertical solid black or red line serves as the reference line corresponding to no effect or a hazard rate of 1 (or log OR=0). The overall effect and 95% CIs are depicted by the dashed black lines.

Figure 3. Components of a funnel plot. HR: hazard ratio.



If the funnel plot suggests the presence of publication bias, the trim-and-fill method can be used to estimate the number of missing studies and impute their effect sizes. This allows the meta-analysis to be “trimmed” of asymmetric studies, and “filled” with the estimated missing studies to create a more symmetric funnel plot. The web-based platform automatically displays a button to generate trim-and-fill plots in case of a significant Egger test.

Trial Sequential Analysis and the z Score Plot

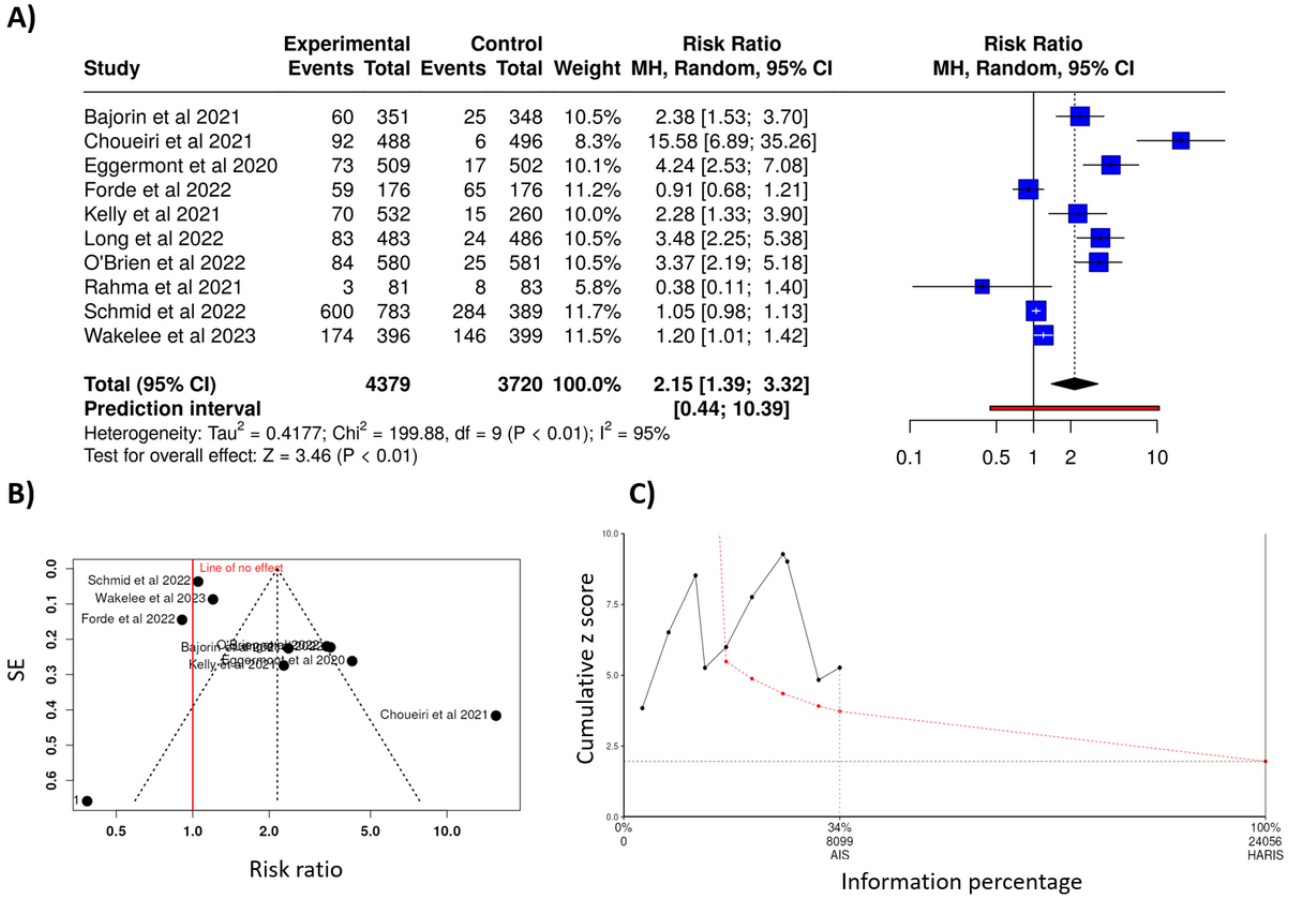
MetaAnalysisOnline.com performs a trial sequential analysis by drawing the *z* score plot to illustrate the reliability of the sample size. The y-axis of a *z* score plot depicts the cumulative *z* score and the x-axis the cumulative sample size. The cumulative *z* curve is built by sequentially adding studies based on chronological order. The plot depicts the relationship between the collective sample size and the achieved significance. When the ideal sample size is attained, a decisive conclusion regarding the examined condition can be made. The components of a *z* score plot are visualized in Figure 4.

XSL•FO
RenderX

Figure 4. The z score plot visualizes the robustness of the sample number. The plot displays the correlation between the cumulative sample number and significance after the addition of each new study. Once the optimal sample number is reached, a definitive conclusion can be drawn about the investigated condition. As the displayed z curve includes more and more patients, it seems to favor outcome B by the conventional cut-offs—however, this sample number is not yet sufficient for statistical significance (red asterisk). As further studies are included, the cumulative outcome reaches statistical significance (green asterisk). Finally, after adding the last study, the z curve surpasses the optimal sample number indicating that no further research is needed.

At the end of the *z* curve lies the most recently added study, falling into one of the following zones: "favoring outcome A," "favoring outcome B," "no correlation," or "statistically not significant." The first 2 zones indicate statistically significant results, which may vary until the optimal sample size is reached, but after this, a reliable final conclusion can be determined. Placement in the "no correlation" signifies strong evidence suggesting that subsequent studies are unlikely to alter the no-effect outcome significantly. Placement within the "not statistically significant" zone indicates the definitive requirement for further studies as neither correlation nor missing correlation could be determined.

Independent Validation



To verify the output of the digital portal, a set of 10 samples was drawn from the dataset of a simulated randomized trial developed for the *metafor* package and a meta-analysis was performed. Analysis was repeated using IBM SPSS (version 29). The following outputs were compared: OR, the calculated weight, overall effect, as well as measures of heterogeneity (I^2 and τ^2). For all parameters, the corresponding 95% CIs were also checked. The output results of the 2 methods were identical, indicating sufficient reliability of the implemented procedures.

Demonstration: Immune Checkpoint Blockade and Adverse Events

To show the entire analysis pipeline, the association between immune checkpoint blockade using anti–PD-1 agents and adverse events was analyzed. Altogether 10 studies were included with a total of 4379 participants in the anti–PD-1–treated cohort and 3720 participants in the control cohort [17-26]. Based on the analysis performed using the random effects model with the Mantel-Haenszel method to compare the risk ratio, there is a statistical difference between the 2 cohorts, the overall risk ratio is 2.15 with a 95% CI of 1.39-3.32. The test for overall effect reached significance as depicted in Figure 5A.

XSL•FO
RenderX

Figure 5. (A) Immune checkpoint blockade by anti-PD-1 drug class significantly increases adverse events. However, the funnel plot shows a (B) potential publication bias and (C) the z score plot indicates insufficient patient number of patients to draw a definitive conclusion (at significance=.05, type II error level=.2, and minimal clinically relevant outcome=30%) [30-39]. AIS: actual information size; HARIS: heterogeneity adjusted recommended information size; MH: Mantel-Haenszel method.

Notably, substantial heterogeneity was detected, suggesting inconsistent effects in magnitude and/or direction. The I^2 value indicates that 95% of the variability among studies stems from heterogeneity rather than random chance.

The funnel plot indicates a potential publication bias. The Egger test supports the presence of funnel plot asymmetry (intercept: 3.85, 95% CI 1.39-6.3; t_8=3.072; P=.02; visualized in Figure 5B).

Based on the *z* score plot, the total number of samples did not reach the optimal number, and more research is needed to establish a conclusion (Figure 5C).

Discussion

Here, we have established a new aid for those performing systematic reviews and meta-analyses. A major advantage of our tool is its direct design for life sciences researchers and medical professionals who generally lack extensive statistical and bioinformatic skills. The user-friendly interface enables the execution of the analysis in real-time. Entering the data is possible by directly copying from a database with a single click. The tool generates the 3 most important graphical representations–a forest plot, a funnel plot, and a *z* score plot—in real-time. The most important advantage of the tool over other software lies in its extremely user-friendly setup—neither installation nor registration is necessary for the use and the input page was set up to enable prompt copying of data from popular spreadsheet applications.

The most important graphical result provided by MetaAnalysisOnline.com is a forest plot, which serves as a visual depiction of both the outcomes from individual studies and the overall results of the analysis [27]. Additionally, it illustrates overall effect estimates and the heterogeneity of studies, reflecting the variation in results among individual studies [28]. The plot also includes the prediction interval, which is widely used to express the amount of heterogeneity in a meta-analysis [29]. Notably, many reviews in the literature use slightly different forest plots as there is no uniform standardization on their appearance. A previous study investigating over 2000 forest plots from the literature identified highly standardized plots in Cochrane reviews but missing key elements in non-Cochrane reviews. Certain formats were not optimal for information exchange, and a significant number of plots contained insufficient data to be considered useful [30].

The second implemented visual result is the funnel plot. In this, results from smaller studies will scatter broadly at the bottom of the graph, while the dispersion is likely to decrease among larger studies. In the absence of bias, the plot will take on the appearance of a symmetrical, inverted funnel, with asymmetry suggesting the presence of a risk of publication bias [31]. A

XSL•FO
RenderX

significant Egger test result means that the points on the funnel plot are not symmetric. It is important to acknowledge that in practical scenarios, the source of heterogeneity cannot be determined and is often unknown. It is important to distinguish between various types of heterogeneity. Clinical heterogeneity refers to variability in participants, interventions, and outcomes studied, while methodological heterogeneity pertains to variability in study design, outcome measurement tools, and risk of bias. Statistical heterogeneity arises from variability in the intervention effects being evaluated in different studies, which can be a result of clinical or methodological diversity, or both. I^2 and ^{2} statistics can be used to assess study heterogeneity [32] and although the funnel plot is primarily used to detect publication bias, it can also be used to visualize the heterogeneity [33]. To provide a meaningful summary, it is crucial to ensure that the group of studies is sufficiently homogeneous in terms of participants, interventions, and outcomes before conducting a meta-analysis.

A fundamental question omitted in many performed meta-analyses is assessing the robustness of the sample number reached [34]. In particular, meta-analyses face the risk of yielding misleading outcomes due to significant results that may be false positives (type I errors; α) or falsely insignificant findings (type II errors; β). These errors can stem from various sources such as low-quality or underpowered trials, publication bias, and excessive significance testing. To address this issue, trial sequential analysis (TSA) has been devised as a cumulative meta-analysis technique [35]. TSA aims to account for both type I and type II errors, providing a means to estimate the point at which the observed effect size becomes robust enough to resist further influence from additional studies. In other words, TSA offers guidance on the necessity of further studies and helps clinicians prevent unnecessary trials [36].

Our tool was established to incorporate a simple way to conduct subgroup analysis as well—to examine the potential variability of treatment effects among different subgroups of patients or trials [37]. Subgroup analysis involves dividing all participant data in the meta-analysis into subsets based on patient characteristics (eg, age) or trial characteristics (eg, location), and then performing a meta-analysis on one or more of these subsets. These analyses can help to estimate treatment effects for clinically relevant subgroups of patients or to identify sources of heterogeneity [38]. The decision to conduct such analyses may be based on prior research suggesting that treatment effects could differ among different patient subgroups.

Two considerations should be kept in mind when running the statistical analysis using MetaAnalysisOnline.com. Sometimes the data points scatter over a wide range and truncating the data is advisable (to constrain the length of the follow-up time, the applied treatment dose, or any other descriptive characteristics of the participants) at a selected threshold in case of scarcity of data above the threshold value. A second issue refers to the inherent differences between the studies due to the varying number of included participants. To achieve the most robust results, studies should be weighed for sample size to better reflect the characteristics of the general population.

We demonstrate the use of MetaAnalysisOnline.com by performing a meta-analysis of studies examining the association between immune checkpoint blockade for anti-PD-1 agents and adverse events [39]. Although immune checkpoint blockade significantly increased the rate of adverse events, we observed a significant heterogeneity, and we can conclude that more research is needed to establish an accurate correlation.

Despite the meta-analysis's aim to identify and evaluate all relevant studies meeting inclusion criteria, this goal may not always be fully realized. Some studies might be overlooked, particularly if they are not published in English or if they report nonsignificant results, making them less likely to be published. Understanding and accounting for these factors is essential for a comprehensive and critical appraisal of a meta-analysis.

Finally, we have to discuss some limitations of our tool. In order to retain user-friendliness, we had to make some compromises. The maximal number of studies in 1 analysis is limited to 100. We have established a default format for the plots, and the graphical parameters (eg, font type and size, spacing, and line thickness) cannot be changed. In addition, we used Shiny to enable seamless visualization and scaling. Because of this, the server behind the platform can sometimes slow down when a large number of studies are analyzed in 1 setting.

In summary, MetaAnlysisOnline.com can be used for a quick and comprehensive meta-analysis in clinical and epidemiological trials. When presenting the results of a meta-analysis, 3 key aspects need to be considered. First, we have to examine the pooled result, representing the overall combined outcome obtained by pooling the individual studies in a forest plot. While providing a synthesized perspective on the collective findings, we have to consider heterogeneity, which relates to variations in results, methodology, or study populations across the included studies. Second, we must assess the potential presence of the risk of publication bias. Finally, the *z* score plot can be used to determine whether the cumulative sample number is sufficient for a definitive conclusion, or whether additional studies are still needed.

Acknowledgments

The 4.0 version of ChatGPT, developed by OpenAI, was used as a language tool to refine our writing and enhance the clarity of our work. This project was supported by the National Research, Development, and Innovation Office (PharmaLab, RRF-2.3.1-21-2022-00015). Authors' Contributions

FJT contributed to the study by developing the conceptual framework and designing the methodology. He curated and analyzed the data, ensuring the accuracy and validity of the findings. His expertise in software development and visualization allowed for the effective presentation of results. Throughout the research process, FJT played a key role in validating the data and refining the study through critical review and editing. BG provided the overall direction of the project, securing funding and managing resources to support its execution. He played a central role in conceptualizing the study, overseeing methodological development, and ensuring the validity of the findings. BG took the lead in drafting the original manuscript and also contributed to data visualization.

Abstract

Background: The myth of Sisyphus teaches about resilience in the face of life challenges. Detransition after an initial gender transition is an emerging experience that requires sensitive and community-driven research. However, there are significant complexities and costs that researchers must confront to collect reliable data to better understand this phenomenon, including the lack of a uniform definition and challenges with recruitment.

Objective: This paper presents the sampling and recruitment methods of a new study on detransition-related phenomena among lesbian, gay, bisexual, transgender, queer, and 2-spirit (LGBTQ2S+) populations. It introduces a novel protocol for identifying and removing bot, scam, and ineligible responses from survey datasets and presents preliminary descriptive sociodemographic results of the sample. This analysis does not present gender-affirming health care outcomes.

Methods: To attract a large and heterogeneous sample, 3 different study flyers were created in English, French, and Spanish. Between December 1, 2023, and May 1, 2024, these flyers were distributed to >615 sexual and gender minority organizations and gender care providers in the United States and Canada, and paid advertisements totaling >CAD $7400 (US $5551) were promoted on 5 different social media platforms. Although many social media promotions were rejected or removed, the advertisements reached >7.7 million accounts. Study website visitors were directed from 35 different traffic sources, with the top 5 being Facebook (3,577,520/7,777,218, 46%), direct link (2,255,393/7,777,218, 29%), Reddit (1,011,038/7,777,218, 13%), Instagram (466,633/7,777,218, 6%), and X (formerly known as Twitter; 233,317/7,777,218, 3%). A systematic protocol was developed to identify scam, nonsense, and ineligible responses and to conduct web-based Zoom video platform screening with select participants.

Results: Of the 1377 completed survey responses, 957 (69.5%) were deemed eligible and included in the analytic dataset after applying the exclusion protocol and conducting 113 virtual screenings. The mean age of the sample was 25.87 (SD 7.77; median 24, IQR 21-29 years). A majority of the participants were White (Canadian, American, or of European descent; 748/950, 78.7%),

XSL•FO
RenderX

living in the United States (704/957, 73.6%), and assigned female at birth (754/953, 79.1%). Many participants reported having a sexual minority identity, with more than half the sample (543/955, 56.8%) indicating plurisexual orientations, such as bisexual or pansexual identities. A minority of participants (108/955, 11.3%) identified as straight or heterosexual. When asked about their gender-diverse identities after stopping or reversing gender transition, 33.2% (318/957) reported being nonbinary, 43.2% (413/957) transgender, and 40.5% (388/957) identified as detransitioned.

Conclusions: Despite challenges encountered during the study promotion and data collection phases, a heterogeneous sample of >950 eligible participants was obtained, presenting opportunities for future analyses to better understand these LGBTQ2S+ experiences. This study is among the first to introduce an innovative strategy to sample a hard-to-reach and equity-deserving group, and to present an approach to remove fraudulent responses.

Introduction

Background

In the past several years, the topic of detransition has garnered significant attention in the mainstream media and academic literature as an emerging sociomedical phenomenon in need of further research and care provision [1-3]. Detransition is an umbrella term inclusive of stopping, shifting, or reversing the social, legal, and medical interventions undertaken during an initial gender transition [4-6]. Depending on the social, legal, and medical steps taken for an initial gender transition, detransition may include shifting sexual and gender minority (SGM) identities and gender expression, social detransition such as reverting to using pronouns and a gender expression aligned with the assigned-at-birth gender, legal change of name or gender marker, and the discontinuation or reversal of gender-related medical treatments [4,5,7]. Transgender and gender-diverse (TGD) people may stop taking gender-related hormonal treatments for reasons unrelated to identity shifts, and it is important to recognize that detransition is distinct from—but sometimes overlaps with—the temporary or permanent discontinuation of gender-related medical care. Depending on definitions and measurement decisions, studies conducted in the United States, Canada, the United Kingdom, Australia, and the Netherlands estimate that between 1% and 13.1% of TGD people experience detransition at some point in their lives [4,8-10]. However, due to study designs, it can be difficult to know the extent to which stopping treatments or detransition is temporary or permanent.

Researchers, gender-affirming care guidelines, and TGD scholars themselves have highlighted a need for qualitative and quantitative research to understand long-term outcomes after gender transition, including detransition and gender identity evolution [10-14]. However, several challenges can hamper efforts to produce this knowledge. Topping the list includes the stigmatization and politicization of detransition, concerns that publishing negative or unexpected results about gender transition are being weaponized against TGD populations and access to gender care, and a lack of scholarly agreement about concepts—all of which contribute to limitations in studying this issue [7].

There are also opportunities to overcome these barriers by using comprehensively designed, SGM (eg, lesbian, gay, bisexual, transgender, queer, and 2-spirit [LGBTQ2S+]) community–led research studies. Nonprobability web-based sampling and recruitment offers specific strengths in researching gender minority populations [15]. This approach to recruitment is recommended to periodically explore health and social issues affecting LGBTQ2S+ communities [16], and it has been shown to be effective alongside in-person recruitment [17]. However, there are important considerations and challenges in conducting web-based research generally; for example, web-based research has always presented issues with fraudulent or “impostor” responses to surveys, but this activity has surged since the COVID-19 pandemic [18]. Many research projects have been affected by bots and impostor responders, often motivated by financial incentive [19,20].

The integrity of web-based research faces threats on several fronts; for example, identifying and removing bot, scam, or ineligible responses from datasets is an emerging priority [21,22]. TGD and detransition research, in particular, has been subject to scam responses and sabotage efforts [23-25]. Haverkamp et al [23] identified that 50 out of 349 responses to a web-based survey designed for TGD students included slurs or hate speech. One detransition study received invalid responses to skew results [24]. While web-based survey platforms often include automatic bot detection methods such as CAPTCHA (Completely Automated Public Turing Test to Tell Computers and Humans Apart) [21] and the identification of nonunique IP addresses, these alone are not effective at identifying fraudulent or malicious responses [26]. Additional techniques used to identify and deter scam responses include collecting IP addresses or geolocation data, conducting video screenings, and incorporating scam detection questions that legitimate participants would not answer affirmatively; for example, the study by Hays et al [27] included asking participants about being diagnosed with fictitious conditions. Participants who affirmed such diagnoses were deemed ineligible. Other studies have set exclusion criteria based on mining survey responses for specific nonsense or incoherent responses [25]. A technique that has been used in studies of detransition involves personal video interviews, which remove anonymity and require participants to verify demographic details such as age and location to ensure consistency with their survey responses [24]. Requiring

XSL•FO
RenderX

participants to appear on camera has also been identified as a deterrent to scam responses [24,25].

Objectives

Following from these considerations, we present a novel sampling and recruitment methodology of a study designed to generate knowledge about detransition. Its aims are four-fold: (1) to present survey design, sampling, and recruitment decisions; (2) to illustrate comprehensive study design guidance for future researchers who are studying detransition-related phenomena; (3) to highlight a protocol for identifying and excluding scam, nonsense, and ineligible survey responses; and (4) to present sociodemographic study results that demonstrate that these efforts obtained a heterogeneous SGM sample.

The Detransition Analysis, Representation, and Exploration (DARE) study was launched in December 2023 to understand sociodemographic characteristics, LGBTQ2S+ identities, life histories, minority stressors, and gender care encounters of individuals with experience of stopping, shifting, or reversing an initial gender transition (eg, detransition). This project was designed to overcome challenges in reaching people with these experiences. The study design, sampling, and study promotion decisions were all made purposefully to include individuals connected with—or disconnected from—gender care providers, organizations serving TGD and LGBTQ2S+ populations, and web-based networks for detransitioned (detrans) people. These decisions aimed to mitigate sampling bias and limitations from past research and to include hard-to-reach disparate TGD and detrans communities with the goal of building theoretical, empirical, and practice-oriented knowledge.

Exploratory Theories of Detransition Developed From Community and Clinical Samples

Diverse theories proposed to understand pathways to detransition have been developed via community and clinical samples, and they comprise internal (eg, internal change in SGM identity and medical complications), system-level (eg, health care availability and access), and external (discrimination, stigma, and lack of support for TGD identities) factors. Taken together, two primary experiences seem to occur with detransition: (1) a shift in one's internal self-conceptualization of sex, gender, and/or sexual orientation identity *after* an initial gender transition and (2) discontinuation or reversal of *prior* gender-affirming medical, legal, and social interventions [4,24,28-32].

However, existing theories should be considered preliminary, given the issues of study design and methodological limitations; for instance, disparate conceptualizations of detransition are applied in the literature, and there are issues of sampling and selection bias and potentially unreliable data collection instruments. Notable examples include analyses of medical case notes [32-34], community surveys administered to TGD populations [9], and surveys administered to web-based detrans communities [24,30,35].

Sampling and Selection Bias in Clinical and Community-Derived Samples

Prior research examining detransition has been limited by sampling strategy, often due to restrictive inclusion criteria such as reidentifying with birth-assigned gender to be counted as a detransition; for instance, studying detransition with clinical data (eg, medical case notes and recruiting from health care clinics) carries several limitations. North American gender clinics rarely have the resources to conduct long-term follow-up, and some TGD people emigrate; decline to participate in research studies; or move from pediatric to adult services, which can introduce survivorship bias [7]. Case series studies carry the risk of excluding patients who discontinue treatment, detransition, and disconnect from care or avoid care providers due to feelings of shame or fear of judgment—experiences identified in past research [28,35,36]. Short data collection periods in clinical samples can also hinder estimating detransition prevalence and understanding identity evolution that—when these outcomes do occur—often happen several years after initiating a medical transition [5,37]. Community-derived samples obtained via organizations and social media can provide useful data on individuals who are no longer connected to the same care providers or the health care system and who are otherwise considered hard to reach due to systemic marginalization.

One notable example is the 2015 United States Transgender Survey (USTS)—a large cross-sectional nonprobability community-driven study [9]. Finding that detransition among TGD adults is largely driven by external pressures such as lack of support and social stigma, Turban et al [9] analyzed a subsample of the 2015 USTS dataset—17,151 TGD adults who had ever initiated a gender transition. The authors found that 2242 (13.07%) of the 17,151 participants responded positively to the question "Have you ever de-transitioned? In other words, have you ever gone back to living as your sex assigned at birth, at least for a while?" Between the cross-sectional design of the study and the wording of this question, it is difficult to know whether respondents detransitioned temporarily, permanently, or both. The survey, developed by the National Center for Transgender Equality, favored external factors and pressure-related reasons in its predetermined list of reasons for detransition. Participants were shown 10 reasons for detransition that included external factors and pressure-related reasons (eg, "pressure from a parent" and "pressure from family members"), and they were shown only 2 nonexternal reasons (ie, "I realized gender transition was not for me" and "not listed above [please specify]"). Study promotion and recruitment efforts comprehensively targeted 800 TGD-serving, LGBTQ2S+, and allied community organizations [38]. Support groups for detransitioning were likely nonexistent at the time of data collection and were thus not involved in study promotion or recruitment. Moreover, individuals with a history of gender transition who detransitioned and no longer held a TGD identity would have been excluded per the USTS inclusion criteria [38]. A majority of the respondents were TGD adults aged ≥25 years (65.5%) and transfeminine individuals assigned male at birth (AMAB; 55%).

Similarly, cross-sectional community surveys conducted through web-based detrans networks present limitations in sampling and study-related decisions that prioritize detransitioned individuals who stopped identifying as TGD or disconnected from TGD communities. The survey conducted in 2019 [39]

XSL•FO
RenderX

by Vandenbussche [30] aimed to explore the care needs of the web-based detrans community via the Post Trans project [40] and other web-based groups largely serving female detransitioners on Facebook, Instagram, Twitter (subsequently rebranded as X), and Reddit (r/detrans). No TGD or LGBTQ2S+ organizations seem to have been involved in participant recruitment [30]. The survey recruited 237 participants (92% female or assigned female at birth [AFAB] individuals). Of this sample, 65% transitioned both socially and medically, while 31% transitioned only socially. Although the survey provided a question on gender and gender identity ("How do you see yourself now?" with the following response options: "woman," "man," "trans man," "trans woman," "female detransitioner," "male detransitioner," "non-binary," and "other"), no results are presented to discern whether any participants in the sample affirmed a TGD identity when they took the survey—participants are referred to as either "female detransitioners" or "male detransitioners."

Another survey of 100 people (69% female or AFAB individuals) who discontinued or reversed gender-related medical interventions recruited participants from largely web-based sources from December 2016 to April 2017 (4.5 mo) via Twitter, Tumblr, Reddit, and closed detransition groups [35]. This survey was also circulated on professional listserves via the American Psychological Association, the World Professional Association of Transgender Health, and SEXNET. The inclusion criteria required participants to have undergone medical transition (those with only social transition experiences were excluded). While participants in this survey had the option to indicate a current TGD identity, only 39% reported a TGD identity.

In comparison to the 2015 USTS instrument that prioritized external pressure–related reasons for detransition, the surveys administered by Vandenbussche [30] and Littman [35] favored internal, psychological, and physical health–related factors in their predetermined reasons for detransition. However, these surveys also included structural (eg, financial barriers) and externally driven factors, such as a lack of support and discrimination. Both surveys recruited a majority of female or AFAB individuals and favored individual-level driving factors motivating detransition. However, these studies were limited by small sample sizes and selection bias in that the recruitment and inclusion criteria focused primarily on individuals who understood themselves as *detransitioners* or as having been *detransitioned* at the time of data collection—terminology that can be divisive [41].

Some detransitioned people report experiencing rejection from TGD and LGBTQ2S+ communities and organizations [30,42], meaning that these individuals may be hard to reach for investigators whose networks are composed primarily of LGBTQ2S+ contacts. Therefore, sampling and recruitment that takes a broad approach is necessary to include individuals who may have become disconnected from SGM networks.

Methods

Study Population

To overcome past limitations and to understand the life experiences, minority stressors, and SGM identities of people who self-identify with experiences related to detransitioning, we conducted a binational, cross-sectional, mixed methods study in Canada and the United States. Our objective was to target a large and heterogeneous sample of 500 to 1000 participants (including detrans, TGD, and LGBTQ2S+ people). This target sample size of >500 was selected due to the anticipated heterogeneity of the group and requiring a large sample to explore and characterize detransition broadly [43]. The mixed quantitative and qualitative approach was selected to quantify different pathways (reasons for detransitioning) and to understand qualitatively the care needs specific to various pathways.

Inclusion and Exclusion Criteria

To be eligible, participants had to be aged ≥16 years; able to fill out a survey in English, Spanish, or French; and had to report a life experience of stopping, shifting, or reversing a gender transition. Gender transition was defined as inclusive of social, legal, and medical transition, and it was not a requirement to have accessed gender-related medical treatments to be eligible. We included social-only, social+medical, and medical-only transition experiences. This decision was supported by the range of inclusion criteria from past studies [9,30,41,42,44] and aligned with our aim of building knowledge about individuals who self-identify with detransition-related experiences. As has been pointed out, some individuals may detransition socially or medically and continue to affirm a TGD identity, while others may shift from a TGD identity to a detransitioner identity without ever being able to detransition socially or medically [4,30,41]. Recruitment and study promotional materials stated that the study was open to anyone with a history of shifting gender identity; stopping or reversing a gender transition; or detransitioning for any reason, such as a loss of access to gender-affirming health care, medical complications, misdiagnosis, discrimination and lack of support, or an identity change.

To be eligible, participants also had to be living in the United States or Canada during the study period, and IP addresses and geolocation data were collected. The United States was included as a geographic region of interest, in addition to Canada, due to the US political and legislative context surrounding gender-affirming health care restrictions [45], antitransgender rhetoric, and proximity to Canada [46]. As it is likely that some TGD people may be forced to detransition due to the reduced availability of gender-affirming health care, legislative restrictions, and antitransgender rhetoric, one of the DARE study flyers was designed specifically to invite participants who were forced to stop transitioning or detransition due to the loss of gender-affirming health care.

The minimum age for participation was set at 16 years for 3 reasons. First, many Canadian research ethics boards recognize this as the minimum legal age for providing independent informed consent for research studies. Second, we aimed to

XSL•FO
RenderX

examine the unique experiences of detransitioning during the teen years compared to adulthood. Third, given that the time between transition and detransition can span years, setting the minimum age at 16 years meant that we would be likely to include some individuals who began their initial transition in childhood. No maximum age limit was imposed to ensure a diverse sample with broad sociodemographic backgrounds and life experiences.

Survey Development and Measures

Reflexivity and Community Engagement

The English-language survey was developed collaboratively by the full DARE study team—a multidisciplinary group of social work and public health researchers who study the health and well-being of SGM populations. The team includes a majority of TGD (spanning the transfeminine and transmasculine spectrums) and SGM individuals and includes a gender-affirming clinician. Following the recommendations by Hildebrand-Chupp [41] on language considerations for detrans research, we developed the survey using neutral language designed to be sensitive to diverse TGD and detrans populations; for example, after detransition, some individuals feel affirmed by terms and language associated with sex rather than gender identity, and past qualitative studies with detrans young people illustrate that some feel that they do not have a gender identity [28]. To be inclusive of all respondents, the survey posed the question "What term(s) best describe your current *gender*?" rather than asking about *gender identity*. Participants were also asked a series of questions about whether, after stopping or reversing transition, they understand themselves as transgender, nonbinary, cisgender, or detransitioned (the response options were "yes," "no," and "unsure"). These questions were not mutually exclusive.

We used community-engaged research strategies. The survey was reviewed for language accuracy by an English-speaking person in the United States with experience of detransition who received a gift card valued at US $150. The survey was initially pilot-tested in English by members of the DARE study team (n=9). Subsequently, external pilot testers were recruited through personal and professional networks, including TGD and non-TGD detransitioned people, and a gender care provider—including AFAB and AMAB individuals (n=4). Pilot testers were asked to comment on the appropriateness of the language, survey completion time, the flow and organization of the survey, broken links, the coherent ordering of questions, questions that were challenging to understand, and overall comments. After pilot testing, the revised English survey was translated into French and Spanish. The translated French and Spanish surveys were reviewed and pilot-tested by native speakers. External pilot testers received gift cards worth CAD $50 (US $37) or US $50, depending on their country of residence.

Survey Development

The comprehensive survey was programmed in Qualtrics (Qualtrics International Inc) and made available through a Qualtrics platform accessible from a dedicated web page. On the basis of pilot testing, it was anticipated that participants would take 35 to 60 minutes to complete the survey. It was programmed using skip logics that were sensitive to individualized transition experiences reported by participants (those who had engaged in both a social and a medical transition were shown the greatest number of questions; those responding "no" to initiating a medical transition were not shown questions pertaining to medical or surgical interventions). The survey included extensive sociodemographic items and integrated measures from several prior health questionnaires delivered to SGM communities [47] and individuals who had detransitioned [9,35].

To ensure that the survey was community and data driven as well as inclusive of a wide range of detransition pathways, participants were presented with a Likert scale listing 21 possible reasons for stopping or reversing their initial gender transition. The Likert scale was developed from prior empirical studies with TGD and detransitioned people [9,28-31,35,48]. The survey transparently highlighted 4 different thematic categories, prompting participants to indicate to what extent a cluster of various reasons contributed to their decision (Multimedia Appendix 1). Whereas Turban et al [9] retrospectively organized reasons for detransition into "internal" and "external" reasons, the DARE survey explicitly organized reasons a priori into 4 dimensions. Participants were shown grouped factors as follows: (1) mental health or psychological reasons (eg, "My mental health did not improve while transitioning" and "My mental health was worse while transitioning"), (2) physical reasons (eg, "Satisfied with the physical results of transition" and "My physical health was worse while transitioning"), (3) external reasons (eg, "I felt discriminated against," "I did not have enough support in my life to continue transitioning," "I had trouble paying for hormones or surgery," and "Legislative bans on gender care required me to stop transitioning"), and (4) social or internal reasons (eg, "My personal definition of woman or man changed and I became more comfortable with my birth sex" and "My identity changed and I no longer felt a need for medical interventions"). Unlike prior studies, participants were asked to rate these reasons using a Likert scale (eg, "not at all," "a little," "somewhat," and "a lot") rather than categorically ("yes" or "no") to reflect the possibility that participants may cite multidimensional pathways.

Study Promotion and Participant Recruitment

Overview

To provide information about the study and direct prospective participants to the informed consent form and survey, an English-language website was created. This website featured a promotional video about the study and provided buttons linking to the English, French, and Spanish versions of the consent form and survey. The website also contained information about the study funder, the study team, project objectives, and recruitment flyers.

Study promotion materials were intentionally broad and neutral due to narratives of detransition being polarized. As the study objective was to reach heterogeneous populations, including TGD, SGM, and non-TGD detransitioned people, we aimed to be inclusive. To reach a diverse sample, 3 different tailored recruitment flyers were designed with a variety of language

XSL•FO
RenderX

choices and color schemes that were anticipated to attract people with a range of experiences (Multimedia Appendix 2). One flyer used language that focused on attracting TGD people who had experienced shifts in gender identity, and another applied TGD-coded colors (pink and blue) to attract participants who were forced to detransition due to external factors. A third flyer used colors (green and blue) and language choices anticipated to attract detrans populations who no longer identify as TGD. The term *detransition* was included on all recruitment materials, the study website, and in the informed consent form. The French and Spanish versions of these 3 flyers were also advertised widely across social media platforms and distributed to organizations and care providers in the United States and Canada.

LGBTQ2S+ Organizations and Gender Care Providers

Direct invitation emails were sent to >615 TGD or LGBTQ2S+ organizations and gender care providers, most of them serving English-speaking or multilingual populations. Efforts were made to contact organizations, gender clinics, and gender therapists who work with TGD, LGBTQ2S+, and detransitioning people. The direct emails disproportionately focused on English speakers because French and Spanish are spoken by a minority of people in North America. Hence, 21 French-speaking organizations were contacted directly by email, 5 French-speaking organizations were contacted via LinkedIn, and the flyer was shared directly with Francophone groups for parents of TGD individuals. In addition, 9 Spanish-speaking organizations were contacted. The Spanish recruitment flyers were shared on social media by another researcher studying Spanish-speaking TGD and detrans populations.

We offered to meet with 5 LGBTQ2S+ youth groups in the Greater Toronto Area, Ontario, Canada, to engage in direct study promotion and recruitment and answer questions about the study. None of these organizations responded to the offer. One LGBTQ2S+ organization in Toronto; 1 organization serving TGD populations in British Columbia, Canada; and at least 2 gender clinics in the United States and in Canada confirmed posting physical recruitment flyers in high-traffic areas to support recruitment efforts. There may have been additional physical posters publicized by organizational contacts without our awareness.

Webinar

Toward the end of the data collection phase in April 2024, we privately invited select stakeholders from LGBTQ2S+ organizations, gender clinics, and TGD and detransitioned people within our networks to a webinar presenting preliminary data to aid in further study promotion. Of the 83 people who registered for the event, 38 (46%) attended. The webinar presented the objectives and methodology of the study, preliminary results, and ended with a direct request for support with participant recruitment. The webinar was not recorded or posted on the web.

Former LGBTQ2S+ Research Participants

Participants from prior team research studies who had consented to being contacted for future research opportunities were emailed information about the study. These were largely Canadian former participants of 2 different studies related to LGBTQ2S+ affirmation (N=1181) and detransition and identity fluidity (N=27). The majority (1014/1208, 83.9%) were Anglophone and sent English recruitment materials; the rest (194/1208, 16.1%) were Francophone and sent French recruitment materials.

Paid and Unpaid Social Media Advertisements

Between December 1, 2023, and May 1, 2024, flyers in all 3 study languages were widely distributed on the web via paid and unpaid social media posts and advertisements across TikTok, Instagram, Facebook, Tumblr, X, Reddit, Discord, and Grindr (Multimedia Appendices 3-5). Where possible, we also advertised in English-speaking private groups on social networking sites for TGD and detrans people, as well as parents of TGD youth. Of note, the DARE study principal investigator maintains a TikTok account with >29,500 followers, where they discuss TGD and detrans research. To enhance engagement and promote the study using audiovisuals, several TikTok videos about the study, as well as YouTube videos, were produced and shared on the web. TikTok has a powerful algorithm that is able to reach large numbers of people and is recognized as a useful platform in community-engaged TGD and gender care knowledge sharing [49]. To estimate the reach and impact of our advertisements, at the end of the data collection period, we reviewed impressions, likes, and shares across all social media platforms used. We summed analytics data from each platform.

Excluding Scam and Ineligible Survey Responses

To enhance the reliability of the survey data, we followed guidance from prior studies [25,26,50]. Adding 2 fictitious conditions—"chekalism" and "syndomitis"—has been recommended as an effective way of identifying scam responses [27]. These 2 items were included in the survey and shown to all participants (eg, "At any point while transitioning, did you develop chekalism?" with the following response options: "yes," "no," and "unsure"). We further flagged potential scam responses based on nonsense, incoherent, or hateful email addresses, as advised by Pullen Sansfaçon et al [25] and Haverkamp et al [23].

To remove bot, scam, and ineligible responses from the dataset, a protocol was developed using guidelines and recommendations from previous studies. First, we removed any responses from IP addresses that had submitted multiple completed surveys [50], as well as those originating from outside the United States or Canada (based on IP address and geolocation data). Next, to remove any bot responses, we followed the guidelines suggested by Google and Qualtrics developers and excluded any responses with a reCAPTCHA score of <0.5 [26]. We then excluded respondents who indicated that they had neither socially nor medically transitioned (they were deemed ineligible based on the study's inclusion and exclusion criteria). Participants who indicated "yes" to having either of the 2 fictitious conditions were also excluded. In addition, we left out participants who reported no discordance between their past and current gender, as well as those whose reported sex assigned at birth conflicted with the hormone they indicated taking during their initial medical transition (eg, a female or AFAB individual who reported taking estrogen or a male or AMAB individual who

XSL•FO
RenderX

reported taking testosterone). Survey responses with a completion time of <12 minutes were also removed, given that pilot testing estimated a typical completion time of 35 to 60 minutes.

Participants identified as potentially scam or ineligible for the study who had consented to being contacted were invited via email to complete a screening interview over Zoom (Zoom Video Communications, Inc) to verify their survey responses. If the research team could validate their eligibility and the accuracy of their survey responses, their survey data were readded to the dataset. As part of the screening process, interview participants were required to turn on their cameras for identification at the beginning of the interview, following guidelines suggested by previous literature [18,25]. Each screening interview was audio recorded. The screening questions were designed to be easy for genuine participants to answer. Those interviewing potential scam participants were also asked to document additional indicators of scams, such as poor or unusual audio quality and sounds, inconsistencies in daylight relative to the participant's reported time zone, and vague and brief responses [25]. The screening interview included the following six questions:

1. Can you please confirm your age?
2. Can you please confirm the country, province (or state), and city you are currently living in?
3. Can you please tell us the country, province (or state), and city you were in when you accessed the survey?
4. Can you please confirm what terms best describe your current gender?
5. For your initial transition, did you socially transition, and if so, in which year?
6. Could you please describe the main reasons you detransitioned?

Participants who could not answer these questions or provided answers inconsistent with their survey responses were excluded. During the process of screening potential scam responses, team members had participants select an interview time via the Calendly website, which allowed the interviewer to confirm the participant's email address and time zone. This verification process was also applied to 4 gift card raffle winners and participants who were screened before the qualitative interview phase.

We removed from the analytic sample all potential scam and ineligible respondents flagged by this protocol who did not consent to being contacted by the research team, did not provide a follow-up email, or did not respond to an invitation to complete the Zoom interview. During the screening process, 2 recurring anomalies were observed: first, Calendly showed an unexpected number of sign-ups from the West African time zone; second, there were several sign-ups for screening from email addresses that we had not personally contacted. This suggests that our email invitation to the screening process had been shared with additional individuals who had never participated in the DARE survey.

Ethics Approval

The study (protocol #3964) received ethics approval from York University (e2023-298), and all participants provided written informed consent to take the survey. This consent included providing explicit agreement to publishing anonymized data for research. Most survey questions were optional, and participants could exit the survey at any time. At any point while taking the survey, participants could access a list of mental health care resources for youth and adults. After providing informed consent, participants were given the opportunity to enter a raffle for a US $50 or CAD $50 (US $37) gift card, which was also advertised in study promotional materials.

Results

Overview

Between December 1, 2023, and May 1, 2024, we widely distributed 3 different study flyers in English, French, and Spanish via direct emails and social media platforms. Paid and unpaid advertising on social media served as a primary recruitment strategy, and paid advertisements totaling CAD $7494.81 (US $5551.71) were promoted on 5 different platforms that targeted >40 unique groups and networks (Table 1; Multimedia Appendices 4 and 5).

Table 1. Paid advertisements (December 13, 2023-April 25, 2024) per social media platform (total cost: CAD $7494.81 [US $5551.71]).

Social media platforms	Cost (CAD $[a]), n (%)
Grindr (US $ converted to CAD $)	1028.60 (13.7)
Instagram and Facebook	2808.18 (37.5)
Reddit	2166.34 (28.9)
TikTok	659.40 (8.8)
Tumblr (US $ converted to CAD $)	832.29 (11.1)
X (no paid advertising accepted)	0 (0)

[a]A currency exchange rate of CAD $1=US $1.35 is applicable.

According to data provided by each social media platform, paid and unpaid study advertisements reached >7.7 million accounts (Table 2). Although efforts were made to equally promote all study posters in 3 languages, discrepancies arose because some posts seemed to receive more positive or negative attention and engagement, which likely affected engagement levels and overall promotion and views. Analytics data from TikTok indicated that flyer 3 ("forced detransition") received a higher number of shares between users and "likes," which may have amplified its views and impressions (Multimedia Appendix 3).

XSL•FO
RenderX

During the study promotion period, 30 different Reddit subreddits were targeted via paid advertisements totaling CAD $2166.34 (US $1604.69) and unpaid posts from our study team or other users (Table 1; Multimedia Appendix 4). Instagram and Facebook were also frequently reported as referral sources, with 8 private Facebook groups targeted and advertising expenses totaling CAD $2808.18. Additional study promotion took place on Tumblr and Discord. Advertisements on Grindr began in December 2023 but were discontinued after approximately 1 month due to high advertising costs and low recruitment yield (1/957, 0.1%).

Table 2. Social media impressions, views, and likes (N=7,777,218).

Social media platforms	Impressions (n=7,617,166), n (%)	Views (n=154,430), n (%)	Likes (n=5622), n (%)
Facebook	—[a]	—	43 (0.8)
Instagram	5,725,940 (75.2)	—	1447 (25.7)
Reddit (account 1)	235,772 (3.1)	—	—
Reddit (account 2: DARE[b] study)	1,352,388 (17.8)	—	—
TikTok	51,765 (0.7)	51,765 (33.5)	2041 (36.3)
Tumblr	—	—	677 (12)
Tumblr Blaze advertisements	245,690 (3.2)	—	1021 (18.2)
X	—	102,124 (66.1)	375 (6.7)
YouTube	5611 (0.1)	541 (0.4)	18 (0.3)
Discord	—	—	—

[b]DARE: Detransition Analysis, Representation, and Exploration.

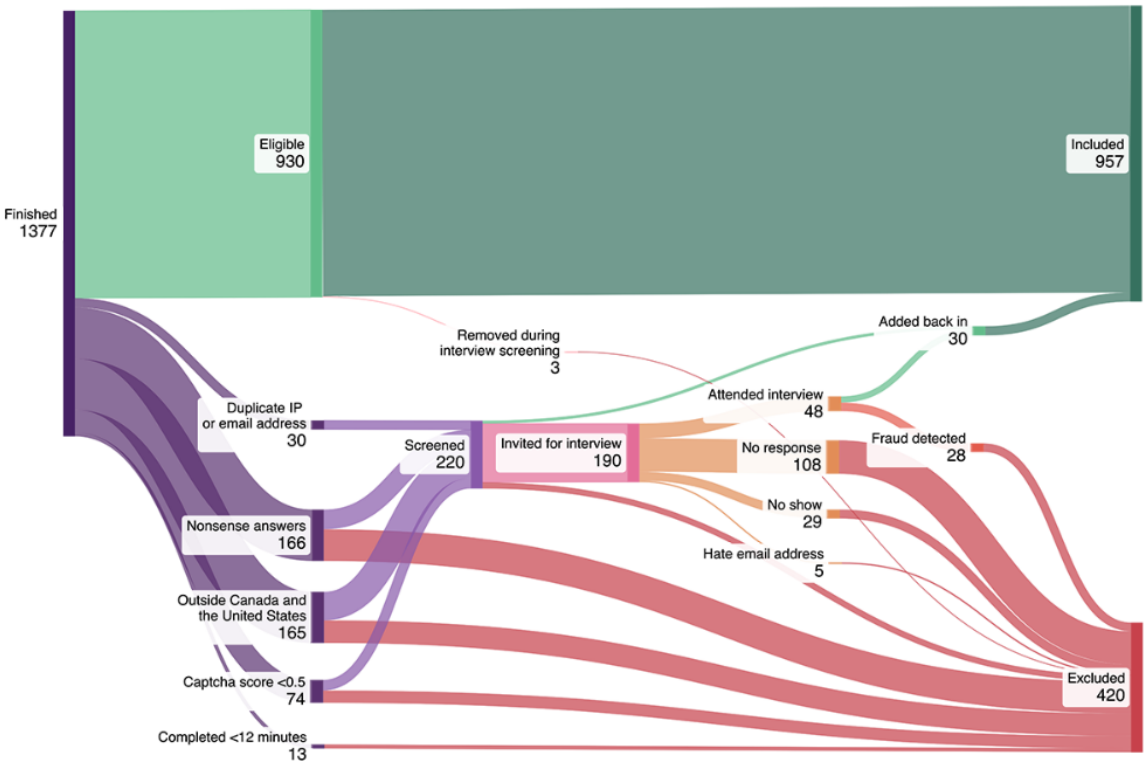
Challenges and Controversies During Recruitment and Data Collection

The DARE study was successful in reaching diverse and disparate web-based networks and was therefore discussed, promoted, and commented on by people with various sociodemographic backgrounds who shared divergent political perspectives as well as expectations about the study itself. These activities may have driven awareness about the study and notified more eligible people. However, it may have also biased various web-based communities' perceptions (eg, negative or positive) of the study objectives; for example, a Tumblr post encouraged participation in the study but noted that, because the principal investigator's past detransition research included nonbinary people, he "has an agenda" [51]. On Reddit, posts within LGBTQ2S+ and TGD subreddits introduced the DARE study as triggering feelings of "disgust" (r/LGBT) [52] or specifically encouraged TGD people who had detransitioned or retransitioned without regret to participate because "anti-trans grifters are trying to skew results of this study" (r/MtF) [53]. Five completed surveys, primarily originating from antidetransition spam email addresses, included hate speech, and these were removed by the scam and nonsense protocol (Figure 1). In private TGD or detrans-focused groups on Facebook, members occasionally questioned the study or hesitated to post recruitment flyers. A few times, Facebook group moderators removed posts about the study; however, in most cases, after the research team clarified the study's goal of building care and support, moderators reversed the decision.

Several barriers to study promotion and data collection were encountered with paid social media advertising campaigns. Some advertising campaigns were rejected outright or removed shortly after launch by Reddit, Tumblr, and X (Figure 2). After 3 weeks of carrying paid advertising for flyers 1 and 2 via the study principal investigator's verified professional account, Reddit removed both campaigns, citing a violation of its restricted policy for promoting "health and wellness," which required special approval [54]. The Reddit advertising division was contacted several times for support in having the advertisements approved, but these emails went unanswered. Later, using a different Reddit user account, the 3 advertisements (in all 3 languages) were successfully promoted via paid advertising campaigns for approximately 4 weeks. However, all 3 posters were eventually removed again, with Reddit citing a violation of "style" policies.

XSL•FO
RenderX

Figure 1. Sankey diagram of the number of survey responses removed for each criterion.



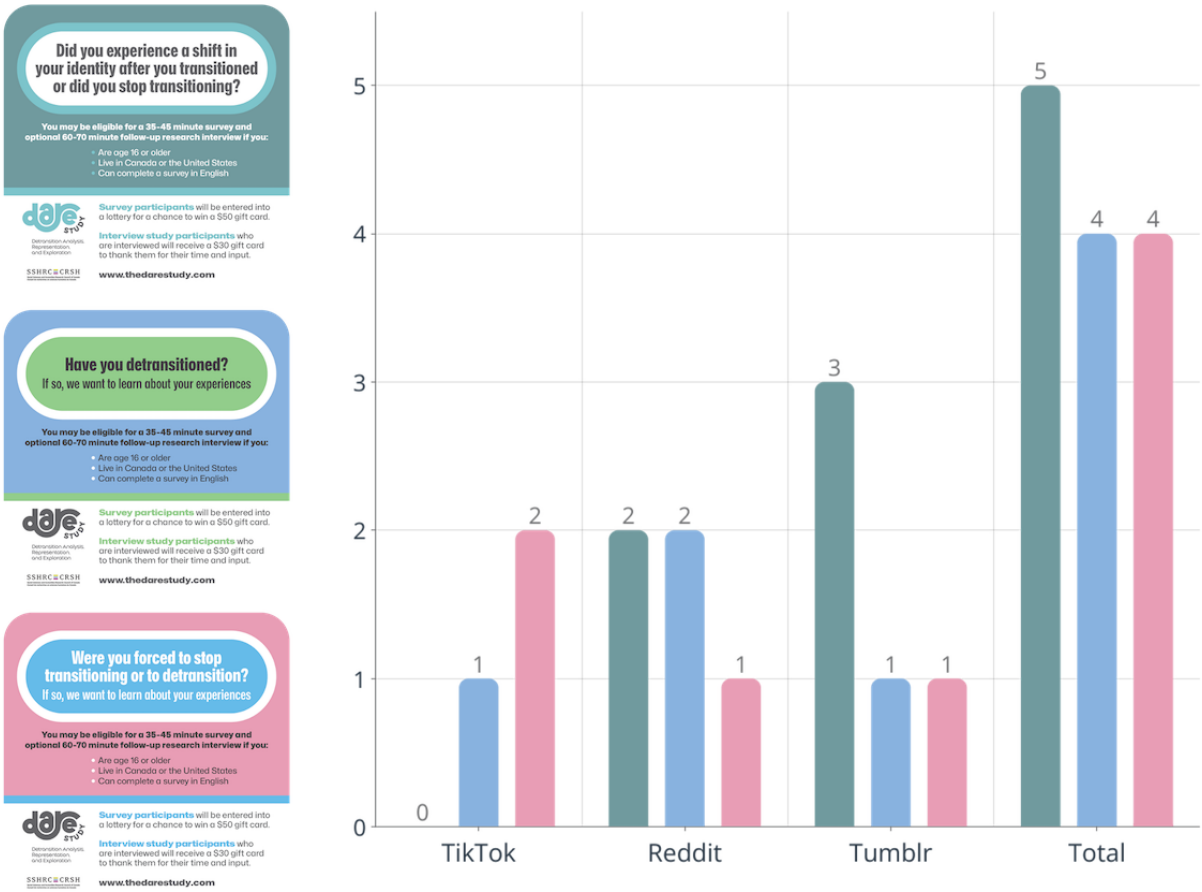


Figure 2. Rejected or removed paid advertisements.

Similar issues were encountered on other platforms. Tumblr rejected several requests for paid “Blaze” advertising campaigns, while, on 2 occasions, TikTok either rejected the application for paid promotion (for flyers 2 and 3) or discontinued promoting a video after accepting payment. TikTok also temporarily suspended the principal investigator’s account after a paid promotion for the study had been purchased. Instagram and Facebook did not remove or reject any paid advertising, to

XSL•FO
RenderX

our knowledge, for any of the flyers. Despite numerous emails, X never approved any advertising campaigns or responded to efforts to purchase promotions.

According to TikTok analytics, the platform's algorithm promoted flyer 3 ("forced detransition") to a greater degree than the other 2 flyers (Multimedia Appendix 3). This may be explained by flyer 3 receiving more "likes" and shares among users, which likely contributed to higher engagement and led the algorithm to pushing the video to a wider audience, a known feature of TikTok's algorithm [49].

Website Traffic, Completed Surveys, and Participant Self-Report About Study Promotion Sources

The study website had 12,272 unique visitors from December 1, 2023, to April 30, 2024, from 78 countries. To access the website, 90.1% (11,167/12,272) of the visitors used a mobile phone, 8% (982/12,272) used a desktop computer, and 1% (123/12,272) used a tablet. Of the 12,272 visitors, 11,412 (93%) were from Canada and the United States, with a majority (n=7609, 66.68%) coming from the United States. The visitors were directed from 35 different traffic sources, with the top 5 being Facebook (3,577,520/7,777,218, 46%), direct link (2,255,393/7,777,218, 29%), Reddit (1,011,038/7,777,218, 13%), Instagram (466,633/7,777,218, 6%), and X (233,317/7,777,218, 3%). These website traffic data contrasted with participants' self-reports. For instance, survey data indicated that Tumblr (286/957, 26.7%) and Reddit (247/957, 23%) were the most frequently reported platforms where participants learned about the study. Notably, Tumblr was not a predefined survey option but was commonly selected as an "other" response. These sources were followed by Meta (198/957, 18.5%), a friend (78/957, 7%), Twitter/X (61/957, 6%), and a referral from a researcher (61/957, 6%). The remaining self-reported survey sources included TikTok, Discord, word of mouth, LGBTQ+ organizations, care providers, Grindr, and other sources (141/957, 13.2%). Despite directly emailing >1800 organizations, care providers, and former research contacts, direct email referrals did not seem to be a popular source: <7% (67/957) of the participants reported a direct email referral source (eg, from a researcher or care provider). Participants completed surveys in the following languages: English (1354/1377, 98.3%), Spanish (5/1377, 0.4%), and French (18/1377, 1%).

Of the 190 participants suspected of scam who shared their e-mail address and were invited to verify their responses via a Zoom interview, 48 (25.3%) attended. After the screenings, we excluded 28 (58%) of these 48 participants. After applying the scam screening exclusion protocol and conducting Zoom screenings, 957 (69.5%) of the 1377 completed survey responses were determined to be eligible and included in the analytic dataset. Figure 1 and Table 3 highlight this process, including the number of, and rationale for, exclusions.

Table 3. Total exclusions before Zoom screenings. The exclusion criteria were applied in the order listed in the table (n=448).

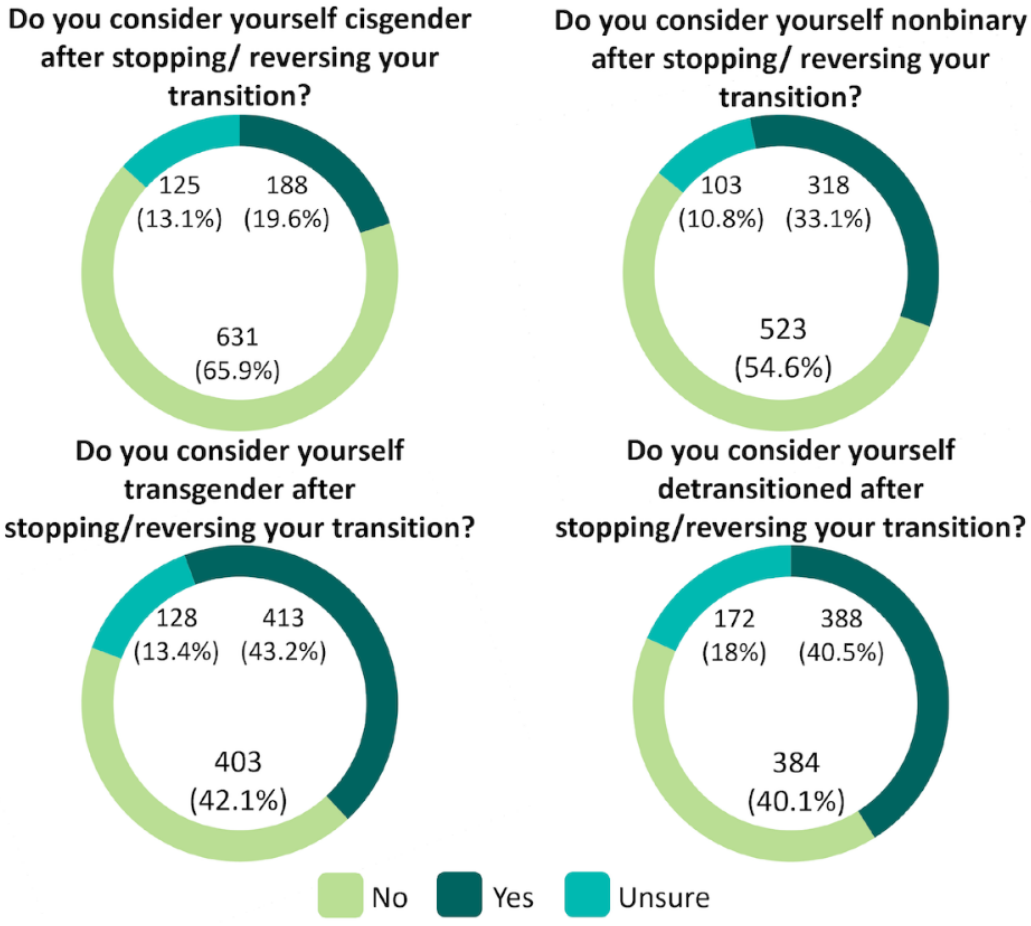
Exclusion criteria	Participants excluded, n (%)
Ineligible and nonsense answers	166 (37.1)
Survey completed outside Canada and the United States	165 (36.8)
reCAPTCHA[a] score of <0.5	74 (17)
Duplicated "identity" (duplicate email or IP address)	30 (7)
Survey completion time <12 min	13 (3)

[a]CAPTCHA: Completely Automated Public Turing Test to Tell Computers and Humans Apart.

Sociodemographics and Geographic Distribution of the Analytic Sample

After exclusions, 957 eligible participants were included in the analytic dataset. The sample was homogenous in terms of race and sex assigned at birth. A large majority identified as White (Canadian, American, or of European descent; Table 4), and a large majority were AFAB (754/953, 79.1%). Out of 957 participants, 4 (0.4%) skipped the question on sex recorded on birth certificate.

Participants were diverse in terms of age distribution and SGM identities (eg, TGD, detransitioned, cisgender, bisexual, lesbian, gay, heterosexual, and asexual; refer to Figure 3 and Table 5 for a complete breakdown of SGM status). As shown in Figure 4, the mean age of the sample was 25.87 (SD 7.77; range 16-74) years.



A majority of the participants were living in the United States (704/957, 73.6%). While the geographic distribution of the sample was fairly representative, with participants from most of the US states and Canadian provinces (Figure 5), there were a few provinces and states with no participants, such as Canada's northern territories (Yukon, Northwest Territories, and Nunavut) and Prince Edward Island, as well as Alaska, North Dakota, Wyoming, and Mississippi in the United States.

XSL•FO
RenderX

Table 4. Self-identified racial and ethnic backgrounds. Of the 957 participants, 7 (0.7%) skipped this question. Participants could choose multiple options.

Racial and ethnic backgrounds	Participants (n=950), n (%)
Black African (eg, Ghana, Kenya, or Somalia)	12 (1.3)
Black Canadian or African American	33 (3.5)
Black Caribbean (eg, Jamaica or Haiti)	13 (1.4)
Central Asian	1 (0.1)
East Asian (eg, China, Japan, Korea, or Taiwan)	36 (3.7)
Indigenous (eg, First Nations, Metis, Inuit, or American Indian)	76 (7.9)
Indo-Caribbean (eg, Guyanese with origins in India)	2 (0.2)
Jewish	98 (10.2)
Latin American (eg, Argentina, Mexico, or Nicaragua)	70 (7.3)
Middle Eastern (eg, Egypt, Iran, Israel, or Saudi Arabia)	26 (2.7)
Pacific Islander or Polynesian	2 (0.2)
South Asian (eg, India, Sri Lanka, or Pakistan)	4 (0.4)
Southeast Asian (eg, Vietnam, Malaysia, or the Philippines)	14 (1.5)
Romany	1 (0.1)
White Canadian or White American	748 (78.2)
White European (eg, United Kingdom, Greece, Sweden, or Russia)	194 (20.3)

Figure 3. Self-identification as cisgender, nonbinary, transgender, and detransitioned. Participants could select “yes” to >1 option.

Discussion

Summary

The DARE study attracted a large and diverse US and Canadian sample of 957 LGBTQ2S+ individuals with experience of stopping, shifting, or reversing an initial gender transition. To obtain this nonprobability sample, >1800 organizations, care providers, and former research participants living in the United States or Canada were individually emailed information about the study. A major advertising and recruitment strategy involved paid study promotions (featuring 3 flyers in 3 different languages) totaling >CAD $7400 (US $5551) on popular social media platforms and social networking sites. We reached >7.7 million accounts. These efforts attracted 12,272 unique visitors to our study website, with 1377 (11.22%) completing the survey. Compared to study promotions on other platforms, those on Instagram and Facebook encountered fewer barriers to advertising and were among the top referral sources to the study website, a finding consistent with a prior SGM web-based survey [16]. In light of these results, we discuss and reflect on the Sisyphean efforts to sampling and recruitment procedures for this community-driven study, as well as the strengths and limitations of our novel approach.

Study Promotion and Recruitment With LGBTQ2S+ and Detrans Communities

The DARE study encountered both support and challenges in study promotion and data collection, as reflected by public posts on Reddit and Tumblr as well as difficulties in placing advertisements. Given the prominence of antitransgender rhetoric and the politicization of detransition by right-wing actors [55], SGM people who have detransitioned may be reluctant to participate in studies designed to examine their experiences due to concerns about nefarious actors. This may also explain some of the discussion about the study in the r/LGBT and r/MtF subreddits, as well as several malicious antidetransition responses received. Given this, despite a large majority of our participants identifying as SGM, many LGBTQ2S+ organizations and gender clinics might have felt unable to show outward support for this research [56]. This could explain why only a small minority of participants (15/957, ~2%) reported these referral sources.

As well, some detransitioned people disconnect from LGBTQ2S+ communities or gender clinics, a phenomenon identified in previous research [36,42]. People with fluid gender identities are also more likely to avoid health care than gender-consistent TGD individuals [57]. These challenges were proactively anticipated when designing the study, which informed the decision to use social media advertising and promote multiple study flyers—particularly flyer 2 (“stopping transition or identity shift”) and flyer 3 (“forced detransition”). Although it is possible that even including the term “detransition” in our study title created apprehension, SGM researchers should note that entirely avoiding using “detransition” in favor of alternative, euphemistic terminology risks alienating some people who relate to this language [7]. Due to polarization, particularly within both TGD and detrans community networks, there can be mistrust of researchers. Language choices and advertising designs that prioritize one detransition experience over another may inherently create selection bias. Using multiple, relatively neutral flyers tailored to include disparate perspectives and experiences is one solution that seemed to attract heterogeneous identities.

Bot, Scam, and Nonsense Detection and Exclusion Criteria: Lessons for Researchers

Potentially amplified by the US $50 or CAD $50 (US $37) gift card raffle incentive, the study attracted many scam as well as ineligible and nonsense survey responses. Given that more than a quarter of the completed surveys (420/1377, 30.5%) were deemed ineligible, our results in identifying and excluding scam and nonsense survey responses offer important lessons on internet-based sampling. Early in the data collection phase, we realized that many of the completed survey responses seemed suspicious; therefore, we created a protocol to identify and remove these responses from the dataset (refer to the Methods section). Making these adjustments required a protocol amendment and approval from the research ethics board. The scam screening process, including email communications and virtual video interviews, was both time and resource intensive. Despite these additional time and resource costs, the Zoom screening process enabled us to confirm that, of the 220 responses flagged as suspicious, 30 (13.7%) were valid and could be readded to the dataset. An additional 179 participants who agreed to be contacted for qualitative interviews for the second phase of the study were also invited to complete verification screening. These participants were not flagged as potential scam or fraud and after completing 65 preinterview Zoom screenings, only 3 scam cases were identified. Lower-resourced projects may decide to exclude all suspicious responses, given the relatively low odds of identifying eligible respondents.

Sample Sociodemographics and Geographic Distribution

The final sample was heterogeneous in terms of LGBTQ2S+ identities, age (including adolescents, young adults, and adults aged >35 y), geographic distribution across US states and Canadian provinces, and other sociodemographic variables. Interestingly, ~11% (105/957) of the participants were living in Ontario, Canada. While Ontario is the most populous province in Canada, with 15.6 million residents [58]—of whom >39,000 are TGD individuals aged >15 years [59]—this is still disproportionate representation in comparison to many US states (eg, California).

There are a few possible explanations for this finding. First, much of the in-person study promotion and posting of physical flyers occurred at Ontario-based gender clinics and LGBTQ2S+ support spaces. In addition, a majority of the study team members (5/7, 71%) have extensive LGBTQ2S+ professional and social networks in Ontario. Another interpretation is that social media promotion was largely based out of Toronto and southern Ontario, which may have led algorithms to prioritize sharing content and advertisements locally and through our team’s existing social media networks (eg, TikTok and Instagram). A third explanation is that, in comparison to other US and Canadian regions, a Toronto-based child gender clinic

XSL•FO
RenderX

was among the first in the world to begin referring children and adolescents for gender-affirming medical interventions in the early 2000s [60]. It is plausible that some of those individuals may have detransitioned as adults and participated in the study. Regions with wider access to gender-affirming health care may also see greater distribution of these experiences, whereas areas with a hostile climate toward gender diversity and poor access to gender-affirming health care may see fewer instances of detransition.

Limitations

This study took efforts to sample a large and heterogeneous group in terms of transition-related experiences and pathways to detransition, LGBTQ2S+ identities, assigned sex and gender, race and ethnicity, age, geographic location, and other sociodemographic factors. Evenly distributing the 3 flyers via paid advertisements proved difficult, which may have created selection bias favoring some experiences over others. There were 13 total rejections and removals of the 3 flyers and disparities in views, likes, and engagement. These issues may have arisen because the study advertisements were reported by other users; for instance, TikTok is known to "shadow ban" or censor some LGBTQ2S+ content [49] and sexuality-related topics [61]. X, TikTok, and Reddit posed more substantial barriers to placing paid advertisements than Tumblr, Instagram, and Facebook. On Reddit, the study was advertised via paid or unpaid methods across 30 different subreddits, including those focused on TGD, LGBTQ2S+, detrans, and general topics. The relative success with web-based recruitment channels versus organizational and care provider referrals may have introduced a bias favoring younger participants.

Furthermore, most of the participants were White (Canadian, American, or of European descent) and AFAB (754/953, 79.1%), and were living in the United States (704/957, 73.4%). While this indicates homogeneity in these particular demographic characteristics, these demographics are also roughly consistent with the general TGD adolescent and young adult population diagnosed with gender dysphoria and who have socially or medically transitioned in North America [62,63]. Per Canadian gender clinic and community samples, approximately 80% of TGD adolescents and young adults are estimated to be transmasculine and AFAB, and a large majority are White (75%-78%) [64,65]. A representative US sample of TGD people showed that the increase in the prevalence of TGD identities observed between 2014 and 2022 was disproportionately driven by White, AFAB, young adults [66]. Still, there may be important distinctions between AMAB individuals and racialized LGBTQ2S+ people, which future analyses with this dataset will examine.

While the sample had a wide age range (16-74 y), the mean age of the sample was 25.87 (SD 7.77) years. This may be partly because a majority of the sample (811/957, 84.7%) reported learning about the study through social media and because the survey was only available on the web. In addition, those without access to a computer, smartphone, or tablet would have been unable to take the survey, which may have excluded some older individuals. Another Canadian and US study that examined TGD gender-affirming medical treatment discontinuation found that those who stopped or reversed treatment had a mean age of 22 years [65]. Overall, while many studies on detransition show samples with a majority of participants aged ≤29 years [7], greater efforts to include older adults are warranted.

To identify and remove ineligible and scam responses, we developed a protocol. We encourage other researchers to review and build from this approach because recent surges in bot and scam activity pose a threat to web-based research. We recognize that this approach may have risked excluding individuals who were indeed eligible but who misread questions or incorrectly filled out parts of the survey (eg, by accidentally indicating "yes" to a fictitious disorder question).

Conclusions

Several new studies examining the discontinuation of gender-affirming medical treatments, detransition, and gender identity fluidity have been published recently, and this study extends this body of literature [8,67-70]. However, there is still no mutually agreed-upon or uniform conceptualization for detransition. This, together with the antitransgender politicization of these experiences and the prevalence of bot and scam responses in web-based research, presented many challenges to sampling and recruitment. Persistence in light of these challenges during the study promotion and data collection phases of our study culminated in a Sisyphean LGBTQ2S+ community–engaged project that successfully obtained a large and diverse SGM sample. As writing about detrans people now appears in major publications such as *Nature* [6], future analyses of this dataset can support the development of robust and empirically rich characterization and conceptualization of this understudied SGM experience.

Acknowledgments

The Detransition Analysis, Representation, and Exploration (DARE) study research team appreciates all survey participants for their time and engagement. This study was funded by an Insight Grant (*#435-2023-1099)* provided by the Social Sciences and Humanities Research Council of Canada.

Abstract

Background: For hospitalized patients, the discharge letter serves as a crucial source of medical information, outlining important discharge instructions and health management tasks. However, these letters are often written in professional jargon, making them difficult for patients with limited medical knowledge to understand. Large language models, such as GPT, have the potential to transform these discharge summaries into patient-friendly letters, improving accessibility and understanding.

Objective: This study aims to use GPT-4 to convert discharge letters into more readable patient-centered letters. We evaluated how effectively and comprehensively GPT-4 identified and transferred patient safety–relevant information from the discharge letters to the transformed patient letters.

Methods: Three discharge letters were created based on common medical conditions, containing 72 patient safety–relevant pieces of information, referred to as "learning objectives." GPT-4 was prompted to transform these discharge letters into patient-centered letters. The resulting patient letters were analyzed for medical accuracy, patient centricity, and the ability to identify and translate the learning objectives. Bloom's taxonomy was applied to analyze and categorize the learning objectives.

Results: GPT-4 addressed the majority (56/72, 78%) of the learning objectives from the discharge letters. However, 11 of the 72 (15%) learning objectives were not included in the majority of the patient-centered letters. A qualitative analysis based on Bloom's taxonomy revealed that learning objectives in the "Understand" category (9/11) were more frequently omitted than those in the "Remember" category (2/11). Most of the missing learning objectives were related to the content field of "prevention of complications." By contrast, learning objectives regarding "lifestyle" and "organizational" aspects were addressed more frequently. Medical errors were found in a small proportion of sentences (31/787, 3.9%). In terms of patient centricity, the patient-centered letters demonstrated better readability than the discharge letters. Compared with discharge letters, they included fewer medical terms (132/860, 15.3%, vs 165/273, 60/4%), fewer abbreviations (43/860, 5%, vs 49/273, 17.9%), and more explanations of medical terms (121/131, 92.4%, vs 0/165, 0%).

Conclusions: Our study demonstrates that GPT-4 has the potential to transform discharge letters into more patient-centered communication. While the readability and patient centricity of the transformed letters are well-established, they do not fully

XSL•FO
RenderX

address all patient safety–relevant information, resulting in the omission of key aspects. Further optimization of prompt engineering may help address this issue and improve the completeness of the transformation.

Introduction

Ensuring patient safety is fundamental in health care. A key aspect of patient safety is adherence to treatments and interventions prescribed by medical providers, as it is essential for preventing long-term disease progression, reducing complications, and improving quality of life [1]. However, in clinical practice, nonadherence remains a widespread problem. According to the World Health Organization (WHO), only 50% of patients with chronic diseases in developed countries adhere to their prescribed therapy regimens [2]. A common factor driving nonadherence is patients' lack of understanding of their disease and the underlying principles of therapy [3]. Historically, the patient-health care worker relationship followed a "paternalistic" model, where the patient was a "passive spectator in their own healing process" [4]. Fortunately, this dynamic has changed in recent years. Nonetheless, empowering patients to comprehensively understand their individual health issues remains a promising approach to improving adherence and, consequently, promoting patient safety [3].

For hospitalized patients, the discharge letter is an important source of medical information that complements the conversation with the physician. It also plays a vital role in facilitating communication between hospital doctors and other health care providers, such as primary care physicians [5]. Effective communication during the transition from inpatient to outpatient care is essential for ensuring patient safety [6]. Forster et al [7] found that 59% of preventable adverse events after hospital discharge were attributed to poor communication between hospital caregivers and either the patient or the primary care physician. After discharge, patients with chronic conditions, in particular, face numerous self-management challenges, such as adhering to prescribed medication regimens, maintaining a specific diet, and engaging in physical activity. Failure to adhere to these aspects can result in serious health consequences.

However, in clinical practice, discharge letters are typically addressed to general practitioners or other medical professionals and are often laden with professional jargon, making them inaccessible to patients with limited medical knowledge [8]. Developing patient-centered discharge letters with improved readability has been shown to enhance patient understanding [9,10]. However, in the hospital setting, time for preparing additional, individualized patient letters is often limited, as a significant portion of working hours is devoted to nonpatient-related tasks and documentation [11].

In this context, advances in artificial intelligence (AI) offer a promising approach to providing personalized and scalable support for helping patients understand medical information. Various studies have demonstrated the substantial medical knowledge of large language models (LLMs), such as GPTs [12-15]. Zaretsky et al [16] utilized LLMs to translate discharge summaries into patient-friendly language, addressing common readability metrics and the Patient Education Materials Assessment Tool (PEMAT) scoring. However, they encountered significant limitations in both accuracy and completeness [16]. By contrast, the use of readability scores has been a topic of controversy in the literature [17]. In our own work, we demonstrated GPT-4's ability to answer psychosomatic medicine examination questions [18]. A qualitative analysis of incorrect answers, based on Bloom's revised taxonomy [19,20], revealed that errors varied depending on the cognitive level. It remains unclear whether this effect is also observed in patient letters generated by GPT-4. Additionally, the extent to which GPT-4 addresses comprehensive patient safety–relevant information—a key aspect of discharge letters—has yet to be clarified.

In this study, we further investigated a related topic. We used GPT-4 to transform discharge letters into accessible, patient-centered letters and evaluated its ability to identify and incorporate patient safety–relevant information. To pinpoint potential errors or gaps in the AI-driven transformation process, patient safety–relevant information was categorized and analyzed based on Bloom's revised taxonomy (Remember, Understand) [19,20].

In summary, our study addresses the following questions:

Major objective:

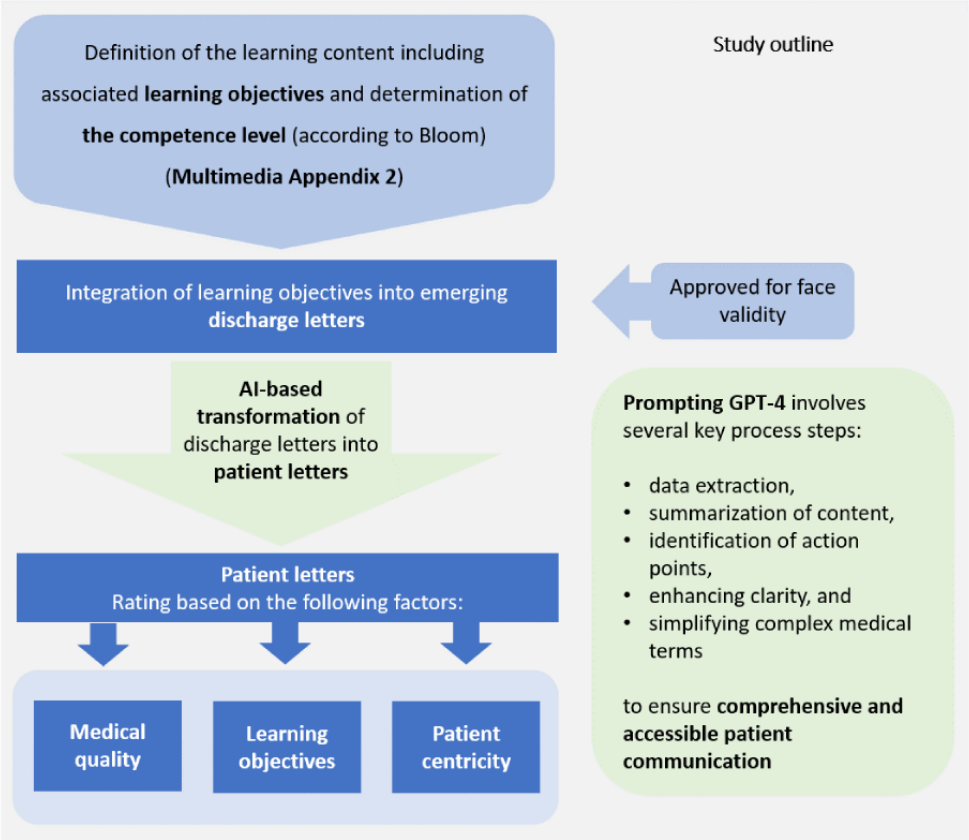
- How comprehensively does GPT-4 identify and transform patient safety–relevant information, as measured by the learning objectives, from discharge letters into patient-centered letters?

Minor objectives:

- How do GPT-4–generated patient-centered letters perform in terms of medical correctness, measured by medical accuracy, case-specific relevance, and the sources of information used in the constituent sentences?
- How well do GPT-4–generated patient-centered letters perform in terms of patient centricity compared with discharge letters, with patient-centered language measured by standard readability scores, word and sentence count, and the use of medical jargon, explanations, abbreviations, repetitions, and direct addressing?

Methods

Study Outline



As the primary goal of patient-centered letters is to convey important information to patients in alignment with specific didactic "learning objectives," we defined learning objectives

XSL•FO
RenderX

for 3 common medical conditions, including the corresponding competence levels based on Bloom's taxonomy. Using these learning objectives and associated medical conditions, we created 3 discharge letters (Figure 1 and Multimedia Appendix 1). We then prompted GPT-4 to generate a patient-centered letter for each discharge letter (Multimedia Appendix 1). To account for variability in GPT-4's output, we repeated the generation of each patient-centered letter 5 times using the same prompt.

The resulting patient-centered letters were analyzed by a team of 2 experienced clinicians (FE and FH) in terms of medical quality, patient centricity, and their potential to convey safety-relevant medical information. The discharge letters, the GPT-4 prompt, and the processing of the prompts by GPT-4 to create the patient-centered letters were all conducted in German. DeepL Translate (DeepL SE) was used to translate the discharge letters, patient letters, and the prompts (Multimedia Appendix 1).

Figure 1. Comprehensive overview of the study's structure and progression. Prompting steps are illustrated in the green box. AI: artificial intelligence.

Development of Discharge Letters

For the development of the discharge letters, we meticulously structured a multistep process (Multimedia Appendix 2) to cluster critical patient information, which GPT-4 was prompted to extract from the discharge letters at various structural levels. These levels enabled us to assess GPT-4's effectiveness in retrieving critical patient information during the evaluation process based on multiple criteria. This approach provided a clearer depiction of GPT-4's competence in this specific task area. To demonstrate the transferability of our findings, it was essential to establish the extent to which GPT-4's ability to identify patient-important information was context-independent. Accordingly, we developed 3 distinct scenarios, each with different disease profiles and care settings.

Stepwise approach:

- Step 1: We selected 3 common diseases based on their high prevalence—arterial hypertension (AHT), type 2 diabetes mellitus (DM), and diabetic kidney disease (DKD).
- Step 2: The setting for each scenario was chosen, encompassing either outpatient consultations with diagnostics or inpatient treatment for initial diagnosis or follow-up care.
- Step 3: To construct relevant educational content for each scenario, we aligned all learning content with the cognitive process dimension of factual knowledge in Bloom's revised taxonomy [20].
- Step 4: The educational content was then categorized into 4 distinct fields: (1) organizational aspects, (2) medication protocols, (3) prevention of complications, and (4) disease management and lifestyle changes.
- Step 5: For each piece of learning content, we developed 2 corresponding learning objectives (Multimedia Appendix 1): one at the Remember level (eg, the patient knows they need to conduct a 24-hour urine collection test), and another at the Understand level (eg, the patient understands that the 24-hour urine collection is necessary to rule out hormonal causes of hypertension). Each discharge letter thus comprised 12 pieces of learning content, distributed across

XSL•FO
RenderX

the 4 content fields, resulting in 24 learning objectives per letter.

- Step 6: These learning objectives were then systematically integrated into the format of a typical discharge letter. The discharge letters were developed by 2 experienced physicians (FE and FH) and validated for face validity by 2 additional board-certified internal medicine and nephrology specialists (MM and MG).

Prompt Development and Creation of Patient-Centered Letters

To the best of our knowledge, there is currently no ideal model for the structure of patient-centered letters. Our group focused first on expert-formulated learning objectives based on content deemed important from a medical perspective, and second on patient-centered language. This approach provided us with a basic letter structure to aim for.

We utilized GPT-4 (gpt-4-0613, accessed December 2023) to generate the patient-centered letters, maintaining the model's default parameters and setting the temperature to the default value of 1.0. The original prompt can be found in Multimedia Appendix 1. The AI-generated patient-centered letter development process was divided into multiple stages (Textbox 1; Multimedia Appendix 3), leveraging methodologies involving LLMs as agents.

Further refinement involved adversarial prompting to identify and simplify complex medical terms and jargon, tailoring the content to a comprehension level equivalent to an eighth-grade reading ability [21]. The result of this process was a restructured and more comprehensible summary of actionable points, designed to effectively communicate essential medical information to patients.

Textbox 1. Stages in the artificial intelligence–generated patient-centered letter development process.

1. Stage 1

- Essential descriptions from the original discharge letters were transformed into concise, comprehensible summaries, referred to as "structured info," using a specialized system prompt for data extraction.

2. Stage 2

- A general summary of the original letter was created to provide an overview of the information, using a straightforward system prompt without specific constraints to minimize redundancy.

3. Stage 3

- This final stage focused on extracting detailed "action points" critical for patient understanding and compliance.
- This multistep process, known as "prompt chaining," began with segmenting the original letter to isolate key instructions and reasons for necessary behavioral changes.
- Each segment was processed to reduce redundancy and enhance clarity, using structured prompts to request information in a predefined JSON format.

Ethical Considerations

This study was approved by the local ethics committee (approval number 778/2023BO2) of the University Hospital of Tübingen. As the discharge letters were prepared by a team of medical experts based on general clinical cases and without direct reference to specific patients, informed consent was not required. As the discharge letters do not contain any individual patient data that could be traced back to specific persons, anonymization was also unnecessary. Furthermore, no compensation payments are expected due to the chosen methodological approach.

Analysis of Patient-Centered and Discharge Letters

Rating Process

Two experienced clinicians (FE and FH) independently rated the discharge letters and the patient-centered letters. For the rating process, each letter was divided into sentences. A sentence was defined as a unit of 1 or more words ending with a period, colon, or a new paragraph (typically, but not exclusively, representing complete sentences). Specific titles in the patient-centered letters, such as "Main Diagnosis," were predefined using established terms and excluded from the rating.

Each sentence was assessed individually by both raters. To ensure a standardized rating process, a general rating structure was defined in advance, using an ordinal scale from 0 (not fulfilled) to 2 (fully fulfilled; Tables 1 and 2). In cases of uncertainty, the raters discussed the issues until a consensus was reached. The results are presented as overall comparisons (patient-centered letters vs discharge letters) and as a subgroup analysis (subgroups: letters on AHT, DM, and DKD).

XSL•FO
RenderX

Table 1. Schematic rating scale (learning objectives).[a]

Content field	Common disease, Bloom's category, learning objective, and rating examples		
Medication	**Type 2 diabetes mellitus**		
	Remember	Take new medication atorvastatin 20 mg in the morning	2: "One tablet (20mg) atorvastatin in the morning (...)" 1: "Atorvastatin: Take one tablet every morning."
	Understand	Atorvastatin helps to control lipid levels.	2: "Atorvastatin: (...) can help keep cholesterol low and protect your heart." 1: "You have also been given medication to lower high cholesterol, which is important in reducing the risk of heart disease."
Prevention of complications	**Diabetic nephropathy**		
	Remember	Avoid NSAIDs[b] such as ibuprofen	2: "Ibuprofen: You should avoid this painkiller (…)." 1: "It is important for you to avoid anti-inflammatory pain medications."
	Understand	Avoiding NSAIDs is important to prevent kidney damage	2: "Ibuprofen: (…) as it can impair your kidneys." 1: "You had been taking painkillers regularly, which may have also strained your kidneys."

[a]This is an illustration of the rating scale used to analyze the learning objectives. It includes rating examples of learning objectives that were either fully (2) or partially (1) rendered in the patient-centered letters.

[b]NSAID: nonsteroidal anti-inflammatory drug.

XSL•FO
RenderX

Table 2. Rating scale (medical quality and patient centricity). The table describes the rating scale used to evaluate the patient-centered letters for medical quality and patient centricity. Examples from the patient-centered letters or discharge letters are presented within quotation marks.

Rating scales	Definition	Example from patient letters or discharge letters
Medical correctness		
Medically correct	The sentence is medically correct.	"It is important that you reduce your alcohol consumption, as alcohol can affect blood sugar levels and increase the risk of other health problems."
Medically incorrect	The sentence is medically not correct (normal HbA_{1c}[a] is below 5.7%).	"The HbA_{1c} value, which tells me how my blood sugar has been over the last few weeks, is 14.1%, which is also very high (normal below 6%)."
Case-specific relevance		
Very relevant	Information is related to the primary diagnosis.	"During your stay in hospital, you were diagnosed with type 2 diabetes for the first time, which means that your blood glucose levels are too high."
Rather relevant	Information is related to the secondary diagnosis.	"You had an appendectomy in 1972."
Neither/nor relevant	Not attributable to a primary or secondary diagnosis.	"In plain language, your hospital stay can be summarized as follows:"
Source of information		
Discharge letter	Information is derived from the discharge letter.	"You have chronic kidney disease caused by diabetes and high blood pressure."
Not from discharge letter	Information was added by GPT-4.	"They performed a kidney biopsy in which they obtained a small sample of tissue from your kidney to examine it under a microscope."
Medical terms		
Use of the medical term	The medical term is used in the sentence.	"We ask for the completion of a 24h urine collection for metanephrine to investigate a pheochromocytoma."
No special term	No special term is used in the sentence.	"You should also try to reduce your weight, eat more healthily (lots of fruit and vegetables, less fatty dairy products) and use less salt."
Explanations		
Medical term explained	The medical term is explained in everyday language.	"Sleep apnea syndrome is a condition in which breathing stops during sleep, which can also affect blood pressure."
Medical terms not explained	Medical term is not explained.	"In addition, sleep apnea syndrome should be ruled out in the outpatient setting."
Abbreviations		
Use of abbreviations	An abbreviation is used in the sentence.	"CVRF[b]:"
No use of abbreviations	An abbreviation is not used in the sentence.	"This is called hypertension."
Repetitions		
Use of repetitions	Repetition of a fact in the sentence.	"It is also recommended that you regularly measure your blood pressure at home (…) Measure your blood pressure regularly at home (…)"
No use of repetitions	No repetition of a fact in the sentence.	"Drink about 2 liters of water a day unless your doctor says otherwise."
Addressing		
Directly addressed	The patient is directly addressed.	"You should take one tablet every morning."
Not directly addressed	The patient is not directly addressed.	"We therefore recommend initiation of atorvastatin as indicated above."
Not applicable	Not applicable because there is no person to be addressed in the sentence.	"An ultrasound of the pancreas showed no evidence of a malignancy."

[a]HbA_{1c}: glycated hemoglobin.

[b]CVRF: Cardiovascular Risk Factors.

XSL•FO
RenderX

Learning Objectives

The GPT-4–generated patient-centered letters were rated based on how many of the learning objectives were identified and addressed. To better understand GPT-4's ability to highlight patient safety–relevant information, a descriptive analysis of the learning objectives was performed. This analysis determined whether the learning objectives were fully addressed, partially addressed, or missed entirely (Table 1).

Indicators of Patient Centricity

All letters were rated for readability using the Flesch Reading Ease test and the Swedish Läsbarhetsindex (LIX) and the Readability Index (RIX). The Flesch Reading Ease score ranges from 0 (very difficult to read) to 100 (very easy to read) [22]. The Swedish LIX typically ranges from 20 (very easy to read) to 60 (very difficult to read) [23]. The RIX is a modified version of the LIX, with a higher number indicating a more complex text [24]. Because of the fragmented nature of some discharge letter sentences (Multimedia Appendix 1), only the sections on the procedure and the medical discharge summary were used to calculate the readability score. By contrast, patient-centered letters, written in complete sentences, were evaluated as a whole for readability. To identify potential barriers for nonmedical readers, the use of medical terms, explanations of medical terms, abbreviations, and repetitions were analyzed for each sentence (Multimedia Appendix 4). Additionally, it was assessed whether the recipient of the letter (patient-centered letter: patient; discharge letter: general practitioner) was directly addressed in each sentence, where applicable.

Medical Correctness, Case-Specific Relevance, and Source of Information

All sentences were rated for medical correctness (Multimedia Appendix 4). To gain deeper insights into medical errors in the patient letters, a qualitative analysis of the incorrect sentences was conducted using the Braun-Clarke inductive approach [25]. Sentences were also evaluated for their case-specific relevance: sentences referring to the primary diagnosis were rated as highly relevant, those related to secondary diagnoses were considered moderately relevant, and all other sentences were classified as neither relevant nor irrelevant, as no irrelevant information was found in the letters. Additionally, it was assessed whether the medical information in the patient letters originated from the discharge letter or was generated by GPT-4.

Statistical Analysis

Statistical analysis and figure generation were conducted using R statistical software (version 4.3.1; R Foundation for Statistical Computing). Data were presented as total counts (n) and percentages, or, when not normally distributed, as medians with interquartile ranges (25th and 75th percentiles). Decimal numbers were rounded to whole numbers for clarity.

Results

Quantitative Analysis of Letter Structure

For the discharge letters, the number of sentences per letter and the median word count per sentence showed minimal variation across the 3 disease entities (Table 3).

For the patient-centered letters, GPT-4 generated a total of 952 sentences, with 860 sentences remaining after excluding those predefined in the prompts. The median word count per sentence was 15 (IQR 8-20) words. The number of sentences per patient-centered letter varied slightly between the medical conditions of AHT, DM, and DKD. The highest number of sentences was recorded in the discharge and patient-centered letters for DKD, while the fewest sentences were found in the patient-centered letters on DM.

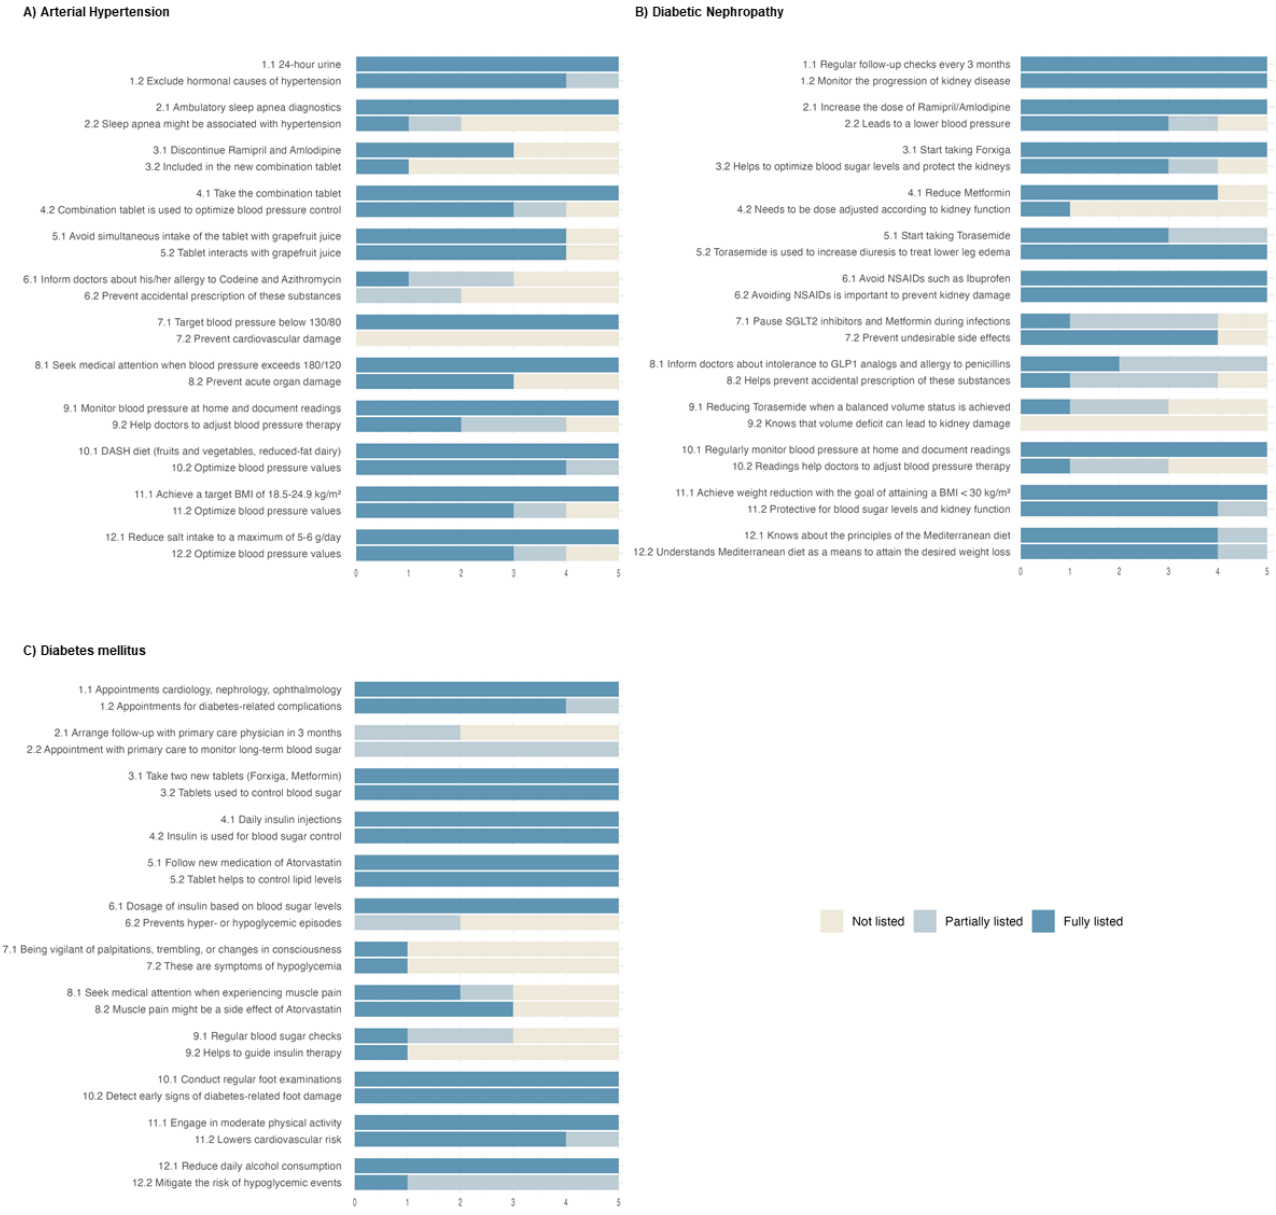
Table 3. Quantitative analysis of letter structure.

Analysis	Overall	Arterial hypertension	Diabetes mellitus	Diabetic kidney disease
Number of sentences				
Discharge letter, n	273	83	92	98
Patient letter, n	860	278	271	311
Sentences per letter				
Discharge letter, n	92	83	92	98
Patient letter, median (IQR)	56 (54-59)	55 (52-57)	54 (53-58)	58 (56-65)
Words per sentence, median (IQR)				
Discharge letter	8 (3-13)	9 (4-14)	8 (3-13)	7 (3-13)
Patient letter	15 (8-20)	15 (9-21)	14 (9-21)	14 (8-19)

Learning Objectives in GPT-4–Generated Patient-Centered Letters

A detailed illustration of the learning objectives addressed in the patient-centered letters is provided in Figure 2. Out of the 72 learning objectives (24 per medical condition across 3 conditions), 57 were identified and addressed in the majority (≥3/5 letters per disease). However, no patient-centered letter included all the learning objectives present in the corresponding discharge letter. There was no significant difference in the coverage of learning objectives across the 3 diseases (AHT, DM, and DKD).

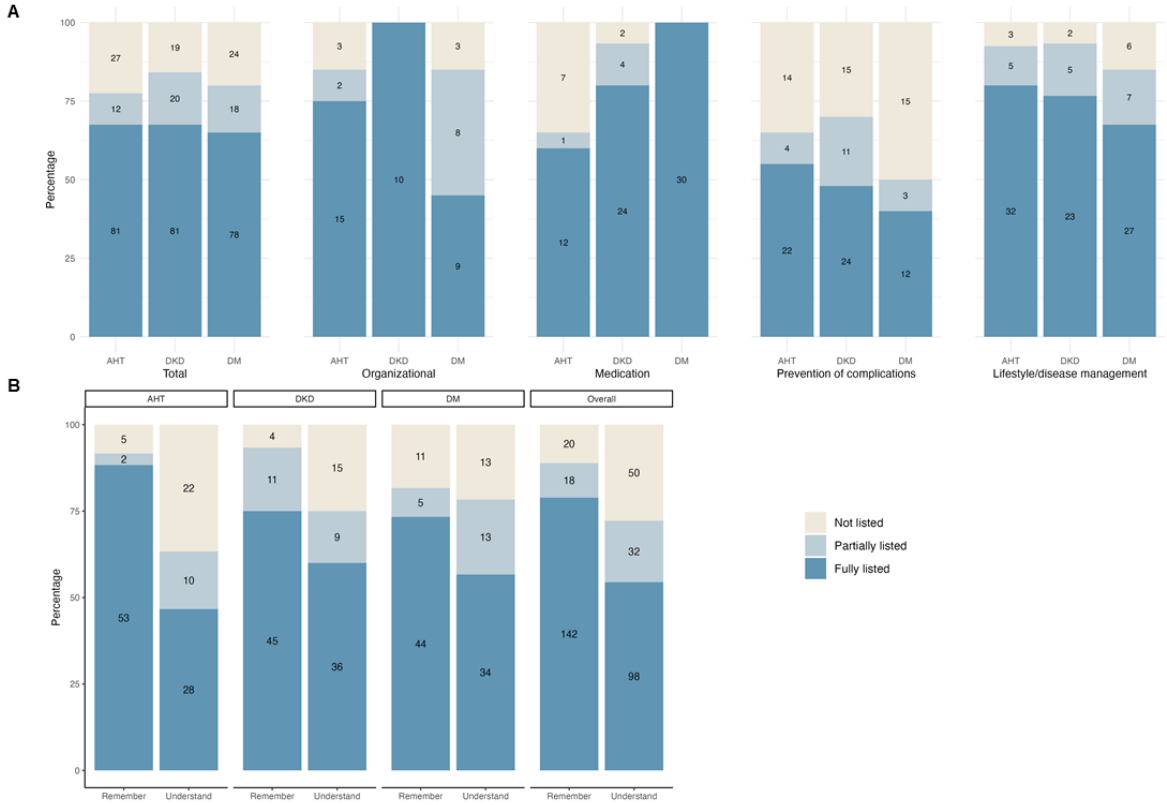
Figure 3 illustrates the learning objectives categorized according to Bloom's taxonomy and content field. Notably, the figure reveals that learning objectives classified under Bloom's "Remember" category were more frequently addressed in the



XSL•FO
RenderX

patient-centered letters compared with those in the "Understand" category.

Some learning objectives were only partially addressed in the majority (≥3 of 5 letters) of the patient-centered letters (5/72). Examples of these partially addressed learning objectives are provided in Multimedia Appendix 5. The missing information in these cases could be categorized into different areas (eg, responsibility, frequency, dosage). However, no systematic categorical errors were identified in the analysis of the partially addressed learning objectives.



Of the 72 learning objectives, 11 were completely omitted in the majority (≥3 of 5 letters) of the patient-centered letters (Multimedia Appendix 4). Of these, only 2 belonged to the Remember category, while the majority were under the Understand category. Furthermore, most of the missing learning objectives (6/11) were related to the field of "prevention of complications." By contrast, learning objectives related to "lifestyle" and "organizational" aspects were more frequently included in the patient-centered letters by GPT-4.

Figure 2. (A-C) Illustration of the learning objectives described in the discharge letters and their representation in the patient-centered letters. The colors indicate the extent to which each learning objective has been addressed in the patient-centered letters (dark blue: fully listed; light blue: partially listed; and yellow: not listed). The learning objectives are described on the y-axis and the number of patient letters per disease on the x-axis. GLP1: glucagon-like peptide-1; NSAID: nonsteroidal anti-inflammatory drug; SGLT2: sodium-glucose cotransporter 2;.

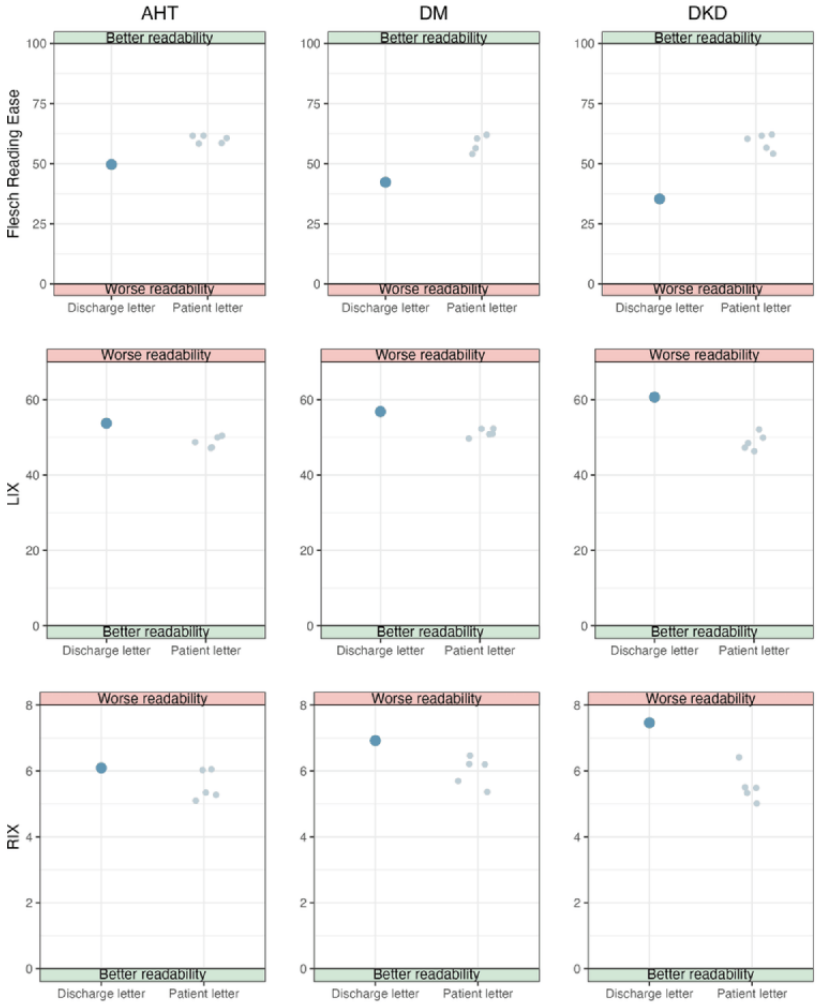
XSL•FO
RenderX

Figure 3. (A) Classification of learning objectives according to the relevant content field (organizational, medication, prevention of complications, and lifestyle). (B) Classification of learning objectives based on Bloom's revised taxonomy (Remember, Understand). The colors indicate the extent to which the learning outcome is included in the patient letter (dark blue: fully included; light blue: partially included; and yellow: not included). AHT: arterial hypertension; DKD: diabetic kidney disease; DM: diabetes mellitus.

Indicators of Patient Centricity

The Flesch Reading Ease test scores for both the discharge letters and the patient-centered letters are shown in Figure 4. The patient-centered letters scored around 60, which corresponds to a "standard" reading level [26]. By contrast, the discharge letters scored around 40, indicating a "difficult" reading level. As illustrated in Figure 4, the patient-centered letters have an LIX score of approximately 50, while the discharge letters scored around 60, suggesting greater difficulty in reading. The patient-centered letters also scored lower than the discharge letters on the RIX, further demonstrating better readability.

Abbreviations were used in 49 of 273 (17.9%) discharge letter sentences, compared with 43 of 860 (5%) in the patient-centered letters. The abbreviation rate remained consistent across all patient letters (AHT: 14/273, 5.1%; DM: 14/273, 5.1%; and DKD: 15/273, 5.5%).



Repetitions were found in 37 of 273 (13.6%) discharge letter sentences and 207 of 860 (24.1%) patient-centered letter sentences. The number of repetitions varied slightly across the patient-centered letters (AHT: 60/278, 21.6%; DM: 75/271, 27.7%; and DKD: 72/311, 23.2%).

Medical terms appeared in 165 of 273 (60.4%) discharge letter sentences but in only 132 of 860 (15.3%) patient-centered letters. Of the medical terms used in patient-centered letters, 121 of 132 (91.7%) were explained.

Patients were directly addressed in 502 of 860 (58.4%) sentences in the patient-centered letters. This varied slightly between the different patient-centered letters (AHT: 151/278, 54.3%; DM: 149/271, 55%; DKD: 202/311, 65%).

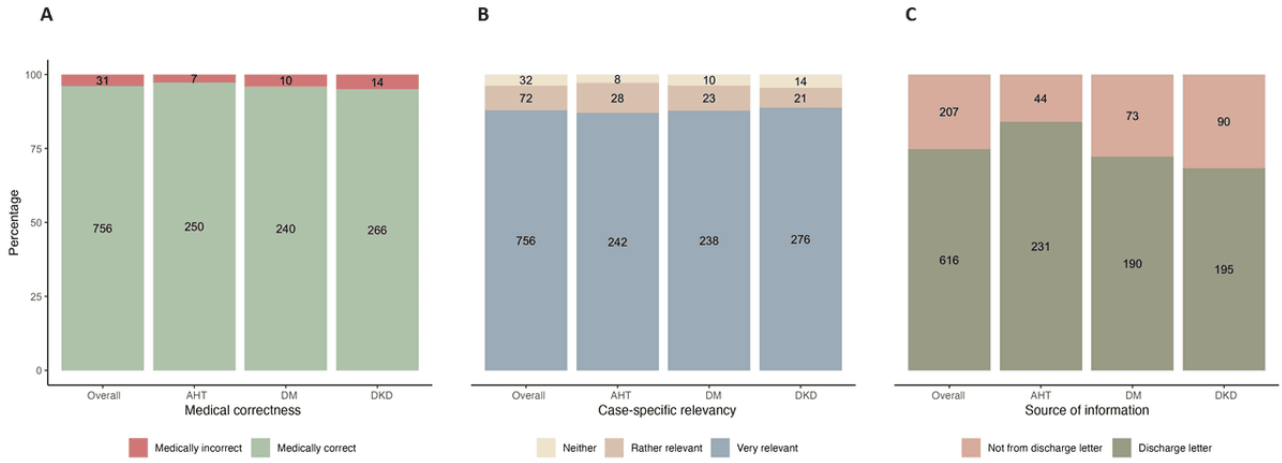
XSL•FO
RenderX

Figure 4. The graph shows the readability scores for the discharge letters and the patient-centered letters. In the Flesch Reading Ease test, a higher score indicates a better readability (green, good readability), whereas in the Läsbarhetsindex (LIX) and Readability Index (RIX), a higher score represents lower readability (red, worse readability). AHT: arterial hypertension; DKD: diabetic kidney disease; DM: diabetes mellitus.

Medical Correctness, Case-Specific Relevance, and Source of Information

Of the 860 patient letters, 756 sentences (87.9%) were medically correct, while 31 were medically incorrect. The rate of medically correct sentences was comparable among the patient letters for AHT (250/278, 89.9%), DM (240/271, 88.6%), and DKD (266/311, 85.5%). Medical errors were found in 7 of 278 (2.5%) sentences in the patient-centered letters on AHT, 10 of 271 (3.7%) letters on DM, and 14 of 311 (4.5%) letters on DKD (Figure 5).

Regarding case-specific relevance, 756 of 860 (87.9%) sentences in the patient-centered letters were very relevant, while 72 of 860 (8.4%) were rather relevant. By contrast, 32 of 860 (3.7%) sentences were not relevant. The proportion of highly relevant sentences was similar across the patient-centered letters on AHT, DM, and DKD (Figure 5).



The information in the patient-centered letters was derived from the discharge letters in 616 of 860 (71.6%) sentences. Additional medical information was provided by GPT-4 in 207 of 860 (24.1%) sentences. However, these proportions varied across the specific conditions. For instance, the patient-centered letters on AHT were based on the discharge letters in 231 of 278 (83.1%) sentences, compared with 190/271 (70.1%) for DM and 195/311 (62.7%) for DKD. Further details are shown in Figure 5.

A qualitative analysis of the medical errors, conducted using thematic analysis based on Braun and Clarke [25], can be found in Multimedia Appendix 6.

No discernible pattern was observed in the errors within the patient-centered letters. Some errors were due to imprecision or incomplete information, while others resulted from incorrect assumptions made by GPT-4. Overall, most of the sentences (182/204, 89.2%) generated by GPT-4 were medically correct. However, of the medically incorrect sentences, the majority (22/31, 71%) contained information provided solely by GPT-4.

XSL•FO
RenderX

Figure 5. (A) Illustration of medically correct (green) and incorrect (red) sentences in the patient-centered letters with the absolute number of sentences displayed within the bars. (B) Representation of the case-specific relevance of the sentences in the patient-centered letters (blue: very relevant; brown: rather relevant; and yellow: neither/nor relevant). The absolute number of sentences is shown in the bars. (C) Proportion of sentences derived from the discharge letter (gray) and from GPT-4 (red) with the absolute number of sentences displayed within the bars. AHT: arterial hypertension; DKD: diabetic kidney disease; DM: diabetes mellitus.

Discussion

Principal Findings

This study demonstrates the potential of GPT-4 to transform discharge letters into more readable, patient-centered letters. While this aligns with previous studies that show GPT-4's ability to generate patient-centered letters based on discharge letters or shorthand clinical instructions [16,27], our study goes beyond simply proving the concept of patient letter generation. We focused specifically on communicating relevant information from a patient-safety perspective. To our knowledge, this is the first study to analyze this aspect in AI-generated patient-centered letters.

Automated Learning Objective Identification and Transformation of Treatment and Patient Safety–Relevant Information

Our primary focus was on identifying and transferring information relevant to patient safety, defined as "learning objectives," in GPT-4–generated patient-centered letters. Overall, GPT-4 effectively identified and addressed 56 of the 72 learning objectives, with 5 partially addressed and 11 omitted entirely.

A key finding was that no significant differences were observed between the 3 diseases (AHT, DM, and DKD) in terms of the quality of GPT-4's identification and transformation of learning objectives.

Another important finding is that GPT-4 fully identified and transformed 56 of the 72 (78%) learning objectives from the discharge letters. In 5 of 72 (7%) cases, GPT-4 identified relevant learning objectives related to treatment and patient safety but omitted certain aspects during the transformation into patient-centered letters. In 11 of 72 (15%) cases, GPT-4 failed to identify any learning objectives, and thus, did not transform or include them in the patient-centered letters.

Consistent with previous studies in the medical field, we observed that the omission of relevant key information in the medical context, as highlighted in AI research, remains a prevalent issue [16,27].

Given that the partial omission of relevant key information in the medical context is highly pertinent to the quality and safety of patient care, we have, to the best of our knowledge, examined this phenomenon in detail for the first time in this study.

From our perspective, it is particularly noteworthy that we observed more frequent omissions by GPT-4 in relation to more complex medical requirements. These omissions were primarily associated with learning objectives that demand a deeper understanding (Bloom's category: Understand), as opposed to simpler objectives (Bloom's category: Remember). Basic topics, such as "lifestyle" and "organizational" aspects of self-management (eg, regularly attending follow-up examinations every 3 months), were more often identified and effectively transformed into patient-friendly language by GPT-4. More complex content, such as "prevention of complications" (eg, interactions between certain foods and medications), was less frequently addressed by GPT-4. This phenomenon was particularly evident in the processing and transformation of complex logical structures involving multiple dependencies.

To address this challenge effectively, strategies such as "few-shot learning," where the AI model is guided by several concise examples, and "chain-of-thought" prompts, which break down complex, multilevel problems into intermediate steps, could be promising. These approaches may enhance GPT-4's ability to translate complex medical information into clear, easily understandable statements and actionable directions [28,29].

In our case, "chain-of-thought" prompting would need to begin with an initial step that clarifies to the AI why the patient should adhere to the respective learning objective. For example, the first step could involve identifying the content relevant to the patient (eg, "pay attention to interactions"). The next step would be for the AI to break this content down into individual components (eg, medication, diet, kidney function). In the final step, the AI should organize these components in the correct

XSL•FO
RenderX

order. Only in the subsequent step should the AI check this order for existing dependencies between the individual information units and adjust it if necessary. This could help prevent the omission of complex learning objectives that are crucial for patient safety and quality of care. It should be noted that this approach extends the AI prompting, which may affect its performance in other areas. Therefore, this potentially promising strategy should be specifically explored in future studies to enhance the complete translation of complex medical information by GPT-4 into more easily understandable information for patients.

Regarding the learning objectives that were only partially transformed by GPT-4 from the discharge letters to the patient letters, we were unable to identify a clear connection with the content. Previous studies have demonstrated GPT-4's ability to extract specific information from medical notes with a high degree of accuracy. However, in those studies, GPT-4 focused exclusively on the task of information extraction.

By contrast, our study involved a multitasking prompt that required both the identification of learning objectives and the subsequent transformation of these medical facts into the correct context and simple language for the creation of patient-centered letters. Similar to the findings related to the complete omission of complex learning objectives, the challenge for AI in processing and reproducing complex logical structures with multiple dependencies was also evident in this case.

Particularly challenging for GPT-4 appeared to be learning objectives from which no immediate or simple logical pattern could be derived. This may be attributed to the multitasking prompts (identification, summarization, and simplification of medical information) and the overall high complexity of medical issues when translated into accessible language for patients. An alternative approach for the prompt could involve implementing "action points" to clearly structure the learning objectives into required actions, success criteria, and potential consequences. This strategy warrants further investigation in future studies.

Quality of Medical Information After Transformation by GPT-4

In this study, it was particularly important for us to assess the medical accuracy of the information transformed by GPT-4 in the patient-centered letters, as this is crucial for patient safety and quality of care. Any inaccuracies must therefore be regarded as a potential risk in the use of LLMs in a medical context.

Our results demonstrate that the patient-centered letters generated by GPT-4 exhibited a high degree of medical accuracy. The low error rate observed in our study may be attributed to the detailed medical information contained in the discharge letters, which GPT-4 accessed during the transformation process. This extensive data set enabled GPT-4 to accurately translate the medical information into patient-friendly language. Previous studies have shown that, in addition to information omissions, factors such as the type of task (eg, text summarization) and the specific field of application (eg, medical writing, question-answer format) influence the accuracy of LLM transformations [30]. Notably, our study demonstrates a significant improvement in medical accuracy and overall result quality compared with prior work examining various scenarios for the use of LLMs in the medical context [27,31].

A critical issue in transforming medical information using LLMs is the phenomenon of "hallucinations," where coherent and grammatically correct, yet factually incorrect or misleading, information is generated [32,33]. These hallucinations can jeopardize patient safety and the quality of care. While previous studies have reported hallucination rates as high as 40%, our study encountered this phenomenon only in isolated cases [34]. Nevertheless, despite the observed downward trend, the risk remains significant with the ongoing development of LLMs, as the following example illustrates:

Discharge letter: *(...) An ultrasound of the pancreas showed no signs of a mass. (...)*

Patient-centered letter: *(...) they also tested to see if your pancreas has any issues, which it does not (...).*

Here, GPT-4 makes a general statement about the unremarkable ultrasound of the pancreas, despite the fact that medically, only a malignant disease was excluded, and other potential pathologies were not examined at all. While these types of errors, resulting from the hallucination phenomenon, occurred only very rarely, they still pose a significant risk to patient safety and the quality of care. Therefore, despite their low frequency, this phenomenon must be considered a substantial limitation to the use of LLMs in medical contexts and should be specifically addressed in future studies.

When using LLMs such as GPT-4 with sensitive medical information, ensuring compliance with data protection and information security requirements is paramount. Before deploying LLMs in health care settings, relevant experts must be consulted for each specific application scenario to define appropriate regulations for anonymizing medical information and to establish a secure and resilient infrastructure.

Patient Centricity

In terms of readability and patient centricity—measured by standard readability scores, word and sentence counts, and the use of specialized terminology, explanations, abbreviations, and direct patient address—the GPT-4–generated patient-centered letters significantly outperformed the conventional discharge letters.

This is consistent with previous studies that analyzed AI-generated patient letters, although using less comprehensive methodologies, which showed high readability ranging from the sixth [16] to the ninth [27] grade level. It is important to note that these studies typically used the Flesch Reading Ease, the Flesch-Kincaid Reading Level, or the PEMAT score for readability assessments [16,35].

The Flesch Reading Ease is one of the most commonly used tools for evaluating readability in medical literature, with scores ranging from 0 (unreadable) to 100 (very easy to read) [22]. However, a major limitation of this approach is that it only considers sentence and word length, failing to adequately account for the level of medical knowledge required by patients or the frequency of medical terms used.

XSL•FO
RenderX

From the authors' perspective, these factors, along with directly addressing patients, are crucial for how discharge letters are perceived and understood. Previous studies have shown that avoiding abbreviations and explaining medical terms in layperson's terms significantly improve the comprehensibility of discharge letters from the patient's viewpoint [36]. Additionally, medical letters are demonstrably better received by patients when they are personally addressed in the letter [37].

For this study, we implemented additional methodological approaches to analyze, for the first time, the patient-centered transformation of medical information by GPT-4. These advanced methods not only accounted for the use of medical terms and abbreviations but also included their explanations and the occurrence of repetitions.

It is noteworthy that the patient-centered letters transformed by GPT-4 demonstrated a significantly higher level of patient centricity than conventional discharge letters, even when accounting for these advanced parameters, which were examined for the first time. The GPT-4–generated letters contained notably fewer medical terms and abbreviations, explained medical terms in simple language, and directly addressed the patients.

Limitations

Our study has several limitations. First, GPT-4's generation of patient-centered letters was based solely on extensive prompting techniques. In the long term—especially with the increasing availability of additional LLMs [38,39]—fine-tuning (both general and domain-specific) and the potential application of specialized LLMs should be considered for the creation of patient-centered letters. Second, our investigation focused on major widespread diseases that occur frequently but did not encompass all medical specialties. As a result, our findings may not be fully transferable to all medical specialties. Another limitation is the exclusive use of the LLM "GPT-4," which prevents us from drawing conclusions about the performance of other LLMs in generating patient-centered letters based on discharge letters.

Furthermore, we used a new multidimensional approach to assess the patient centricity of GPT-4–based communication of medical information. This approach considered factors such as the use of medical terms, abbreviations, and repetitions. While these variables are objectively measurable and part of common readability standards, they have not been sufficiently validated in the context of LLM-based communication. Therefore, further studies are needed to explicitly examine how patients perceive and understand the patient letters created by LLMs, as well as how this innovative form of patient-centered communication impacts patient empowerment and self-management of their health. Additionally, the perspective of the treating physicians on this promising form of patient-centered communication was not explored in our study. This aspect should also be considered in future research.

Additionally, the discharge letters, prompts, and patient letters were written in German, and all content was translated into English for the preparation of the manuscript. As a limitation, it should be noted that the transferability of our study results to the use of GPT in other languages requires further investigation.

Conclusions

In summary, our study demonstrates that GPT-4 has the potential to significantly enhance the patient-centeredness of discharge letters. While we used a detailed prompting technique and GPT-4 generally exhibits a high degree of medical accuracy when transforming discharge letters into more patient-friendly formats, it is not yet fully suitable for patient care without review by medical professionals, particularly due to the noted omissions and hallucinations. Despite the already strong readability and patient orientation, even an advanced language model like GPT-4 did not fully account for all information relevant to patient safety and quality of care in the patient-centered letters. Further advancements in prompting techniques and the targeted development of language models for the medical field could help minimize these limitations. If these challenges are addressed, GPT-4 could offer enhanced potential to support health care professionals in patient-centered communication and improve patients' understanding of their medical conditions. This would mark a significant step toward better patient safety and improved quality of care.

Abstract

Background: Patient-centered care promotes the involvement of patients in decision-making related to their health care. The adoption and implementation of shared decision-making (SDM) into routine care are constrained by several obstacles, including technical and time constraints, clinician and patient attitudes and perceptions, and processes that exist outside the standardized clinical workflow.

Objective: We aimed to understand the integration and implementation characteristics of reported SDM interventions integrated into an electronic health record (EHR) system.

Methods: We conducted a scoping review using the methodological framework by Arksey and O'Malley with guidance from the Joanna Briggs Institute. Eligibility criteria included original research and reviews focusing on SDM situations in a real-world clinical setting and EHR integration of SDM tools and processes. We excluded retrospective studies, conference abstracts, simulation studies, user design studies, opinion pieces, and editorials. To identify eligible studies, we searched the following databases on January 11, 2021: MEDLINE, Embase, CINAHL Complete, Cochrane Library including CENTRAL, PsycINFO, Scopus, and Web of Science Core Collection. We systematically categorized descriptive data and key findings in a tabular format using predetermined data charting forms. Results were summarized using tables and associated narratives related to the review questions.

Results: Of the 2153 studies, 18 (0.84%) were included in the final review. There was a high degree of variation across studies, including SDM definitions, standardized measures, technical integration, and implementation strategies. SDM tools that targeted established health care processes promoted their use. Integrating SDM templates and tools into an EHR appeared to improve the targeted outcomes of most (17/18, 94%) studies. Most SDM interventions were designed for clinicians. Patient-specific goals and values were included in 56% (10/18) of studies. The 2 most common study outcome measures were SDM-related measures and SDM tool use.

Conclusions: Understanding how to integrate SDM tools directly into a clinician's workflow within the EHR is a logical approach to promoting SDM into routine clinical practice. This review contributes to the literature by illuminating features of SDM tools that have been integrated into an EHR system. Standardization of SDM tools and processes, including the use of patient decision aids, is needed for consistency across SDM studies. The implementation approaches for SDM applications showed varying levels of planning and effort to promote SDM intervention awareness. Targeting accepted and established clinical processes

XSL•FO
RenderX

may enhance the adoption and use of SDM tools. Future studies designed as randomized controlled trials are needed to expand the quality of the evidence base. This includes the study of integration methods into EHR systems as well as implementation methods and strategies deployed to operationalize the uptake of the SDM-integrated tools. Emphasizing patients' goals and values is another key area for future studies.

KEYWORDS

shared decision-making; patient engagement; decision support; electronic health records

Introduction

Background

Shared decision-making (SDM) is a model of patient-centered care that encourages patients and clinicians to work together to reach medical decisions by weighing the risks and benefits of various options within the context of the values and goals of the patient [1]. SDM is the process of communication, deliberation, and decision-making between clinicians and their patients [2,3]. During this process, treatment options, including risks and benefits, are discussed and patient preferences are explored to inform decision-making. Previous research has shown that SDM increases patient engagement, knowledge, risk comprehension, and participation in decision-making [4-6]. Furthermore, SDM has been shown to improve patient–health care provider communication, patient satisfaction, compliance, and clinical outcomes [7,8]. Notably, the US Preventive Services Task Force considers SDM an ethical right of all patients, independent of health outcomes [9].

Currently, SDM is not routinely required by large health care payers, such as the Centers for Medicare and Medicaid Services, which is a US federal agency providing health care for patients with low income or older adult patients. Medicare is the largest single payer for health care in the United States [10]. The Centers for Medicare and Medicaid Services is slowly adopting SDM standards for limited and specific procedures, conditions, and devices, including lung cancer screening, atrial fibrillation, and implantable defibrillators [11]. US states such as Washington and Vermont are also beginning to mandate SDM for specific conditions and other states such as Connecticut, Massachusetts, Maine, Minnesota, New Hampshire, and Oklahoma are considering legislation [12].

The Health Information Technology for Economic and Clinical Health Act was adopted in the United States in 2009, enabling the widespread adoption of electronic health record (EHR) systems across the US health care system [13]. Leveraging EHR systems to promote the use and uptake of SDM appears to be a logical approach to operationalizing SDM programs. For example, Kuo et al [7] found several positive effects of integrating SDM tools within an EHR system, which include improved clinical outcomes, positive lifestyle behavior changes, more deliberation with clinicians, and less decisional conflict. Despite the interest in incorporating SDM into routine care, current research studies identify a variety of obstacles that limit SDM adoption. Some of these obstacles include technical integration issues; logistical and workflow challenges; and psychological impediments, such as uncertainty and legacy belief systems, which continue to impede progress [14-16]. Integrating SDM tools and processes into EHR systems is often a complex and difficult problem [17-21].

SDM may involve the use of a decision aid, a type of tool that helps patients consider options for medical decision-making by increasing patient knowledge; illuminating treatment options including risks, benefits, and efficacy; and exploring patient preferences and values [22-24]. The Ottawa Decision Support Framework provides recommendations and guidelines for health care decisions and standardized checklists for the development and evaluation of decision aids based on the International Patient Decision Aid Standards [25]. SDM components found within the International Patient Decision Aid Standards include clarifying patient values, coaching and guiding patients when making decisions, and ensuring literacy levels are addressed [26-28]. Decision aids developed using the Ottawa Decision Support Framework as well as other decision aids outperformed the usual care for performance in a large overview of systematic reviews [25,28]. Patient decision aids can play a key role in facilitating the occurrence of SDM at the point of care as clinicians may use a decision aid to support SDM conversations. Furthermore, decision aids may provide a way to standardize SDM experiences. Notably, decision aid research developed before the widespread adoption of EHRs [29-32]. Decision aids are not synonymous with SDM processes as SDM processes may incorporate the use of a decision aid or may use a conversation between patient and clinician without the use of a decision aid. Decision aids typically contain patient education as part of the decision aid content; however, a clinician may choose to verbally educate a patient without the use of a decision aid. Previous research has shown that decision aids integrated into an EHR system show improvement in patient-centered outcomes, including a reduction in decisional conflict. However, there are significant barriers and complexities to overcome when integrating them into commercial EHR systems [33-35].

Both decision aids and SDM tools still face substantial hurdles to clinician uptake [15,32,36-38]. Gaining the attention of health care providers can be difficult as SDM relies on health care provider discretion, time, and required effort [15,39-41]. Integration into the EHR system is recognized as an important strategy as it enables SDM to be part of clinical workflow [42]. However, integration can also pose challenges because unavoidable health care provider alerts run the risk of high levels of alert fatigue or reactance. SDM tool developers and health care systems must be judicious in their choice of tools to develop and integrate. It is important to understand the characteristics of SDM tools that have been integrated into EHR systems.

XSL•FO
RenderX

Objectives

A literature review revealed limited studies describing the integration and implementation of SDM tools within an EHR workflow [43-46]. A number of recent systematic reviews have been published on the general topic of SDM [19,33,47-58]. These studies focused on a range of SDM topics, including SDM within specific surgical specialties, behavioral theories underpinning SDM, organizational characteristics to support implementation, validated SDM measurement tools, SDM key components, and quality of SDM. However, at the time of the protocol registration, we were unable to identify a systematic or scoping review that specifically addressed the characteristics of SDM tools that have been integrated into an EHR. Thus, this study aimed to understand the *characteristics of SDM tools* that have been integrated into an EHR system and implemented within a health care system by conducting a scoping review.

Methods

Overview

This scoping review followed methods described by Arksey and O'Malley [59], Levac et al [60], and the Joanna Briggs Institute (JBI) [61]. The study protocol is published with the Protocol Registry of Evidence Reviews at the University of Utah. Consensus was achieved on the inclusion and exclusion criteria and primary research question. For transparency and reproducibility, we followed the PRISMA-ScR (Preferred Reporting Items For Systematic Reviews And Meta-Analyses Extension For Scoping Reviews) and PRISMA-S (Preferred Reporting Items For Systematic Reviews And Meta-Analyses Search Extension) reporting guidelines for the scoping review protocol and manuscript [62,63].

Study Identification

An information specialist developed the search strategies using database-specific subject headings, keywords, and team feedback for the key concepts of SDM, patient engagement, decision support, and EHRs. Example publications were provided to the information specialist for strategy development and term harvesting. The search strategy was evaluated by a librarian coauthor using the Peer Review of Electronic Search Strategies guidelines [64]. EndNote (version 20; Clarivate) was used to manage citations and remove duplicates. Covidence (Veritas Health Innovation) provided a second pass for duplicate removal. Search strategies are provided in Multimedia Appendix 1.

The following databases were used to identify eligible studies between 2009 and 2021: MEDLINE (via Ovid platform), Embase (via Embase platform), CINAHL Complete (via EBSCOhost platform), Cochrane Library (via Wiley platform) including CENTRAL (via Wiley platform), PsycINFO (via EBSCOhost platform), Scopus (via Scopus platform), and Web of Science Core Collection (via Clarivate Analytics). No filters other than date limits were applied. The date limit from 2009 corresponds to the adoption of the Health Information Technology for Economic and Clinical Health Act in the United States [65].

Study Screening

Covidence software was used for screening. Four researchers independently screened titles and abstracts for inclusion and exclusion criteria and met for discussion. The protocol was modified during this phase to expand inclusion criteria based on discussions among the screeners. For example, after finding a number of design studies and concept papers, we added the requirement that all studies must have SDM tools that have been implemented into a real-world clinical setting. Furthermore, we excluded retrospective studies after identifying studies that focused on a retrospective analysis of clinical notes and activities. Changes to the protocol are listed in Textbox 1. Following the screening process, 303 (10%) of the 3017 articles were identified for full eligibility assessment.

Expanded screening criteria were added to the original inclusion and exclusion criteria identified in the research protocol, as noted in Textbox 1. The additional categories were identified and added as the team recognized additional screening criteria as screening commenced.

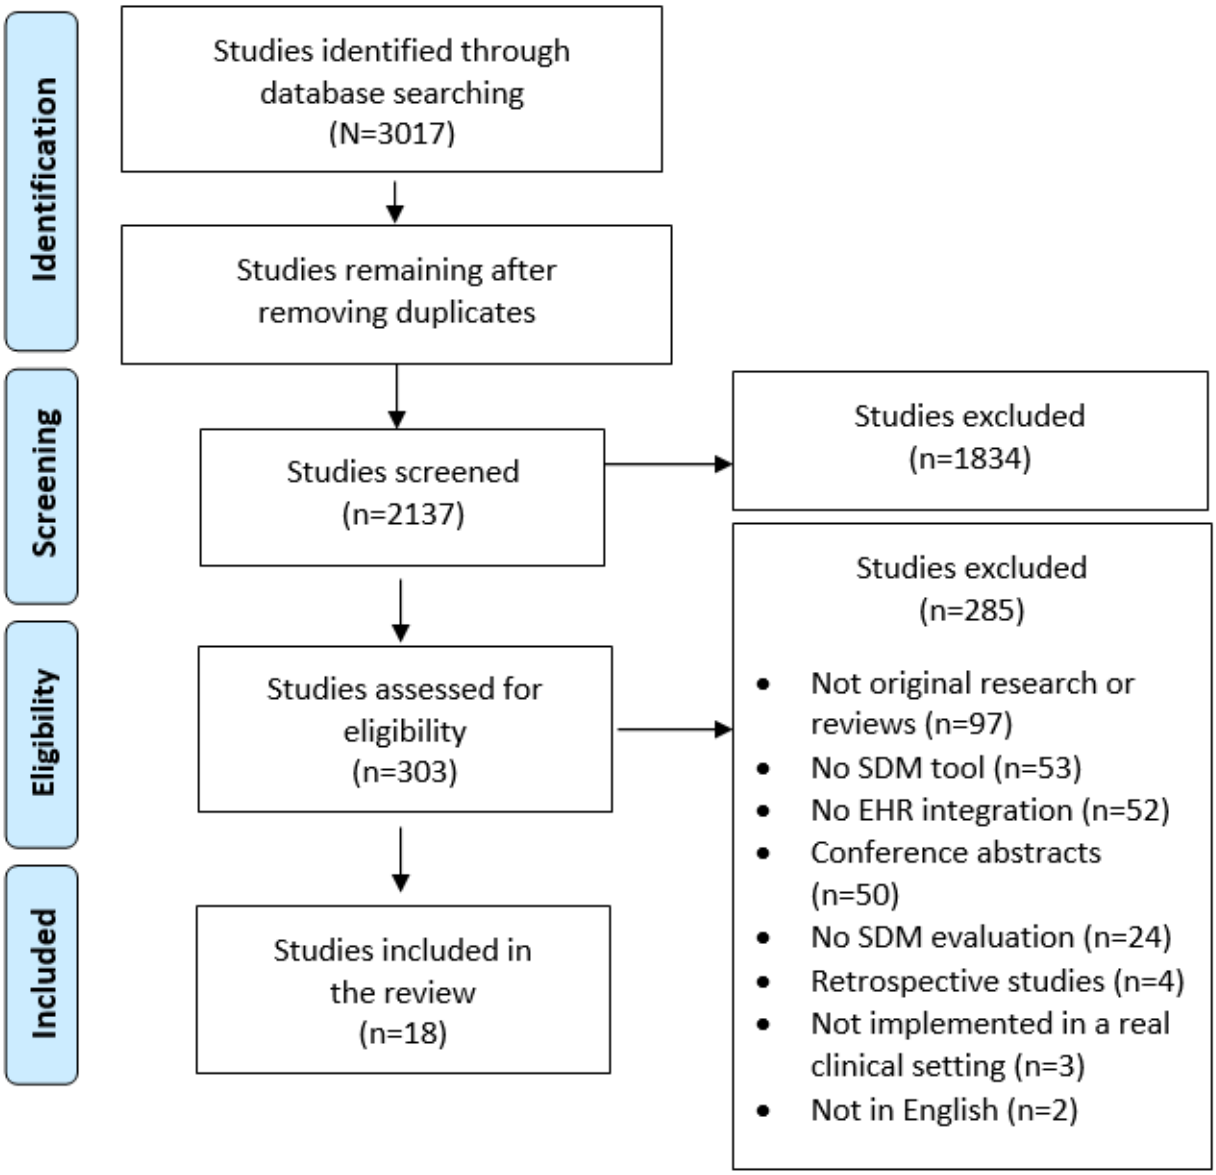
Textbox 1. Expanded scoping review inclusion and exclusion screening criteria.

Inclusion criteria

- Original studies, systematic reviews, and meta-analyses
- Decisions made at the point of care
- Electronic health record–integrated shared decision-making tool
- Intervention implemented into a real clinical setting
- Shared decision-making tool outcomes reported
- Studies written in English

Exclusion criteria

- Retrospective studies
- Conference abstracts
- Limited measures



XSL•FO
RenderX

Eligibility Assessment

A team of 5 researchers, including 2 professors with extensive backgrounds in cognitive and sociotechnical informatics (CW and JMB), 1 informatics researcher experienced in sociotechnical design (TT), an informatics student (JHP), and another informatics student (WR II), met on a weekly basis to discuss inclusion and exclusion criteria and extraction goals for research studies. Initially, each researcher was assigned the same 5 studies to assess for eligibility review. Then, the research team discussed and deliberated on whether each study met the established inclusion criteria until the team achieved consensus. A spreadsheet was created with each evaluation component, including basic study characteristics, integration, and implementation methods. Study characteristics included study type, SDM intervention, clinical domain and conditions, measures, outcomes, integration approaches, and implementation processes. The research team discussed the criteria and achieved consensus for spreadsheet components through discussion, debate, and review. The reviewers then evaluated approximately 10 studies per week as a group, using the spreadsheet to determine criteria for analysis against the study aims. After this, the remaining studies were distributed among the team members for a full review of eligibility. We excluded studies that did not report measurable quantitative outcomes, were not integrated into an EHR system, did not involve a shared decision (with or without a decision aid), and were not in person at the point of care. EHR integration for the purpose of this review ranged from scanned PDFs appended to EHR patient records to full technical integration using semantic interoperability methods.

We identified the studies of tools designed to support SDM that were integrated into the EHR system for evaluation and reported a total of 18 studies, which were included for final review. See PRISMA-ScR Figure 1 and Multimedia Appendix 2.

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) flow diagram. EHR: electronic health record; SDM: shared decision-making.

XSL•FO
RenderX

Review Process

Overview

The research team used the following three-step process to interpret and synthesize the final 18 studies included in the scoping review: (1) data charting, (2) analysis of evidence, and (3) data summary and synthesis. During this process, we performed a detailed review and analysis of the integration methods along with the associated clinical decision support features and then mapped them into a table. Implementation strategies and methods were evaluated and mapped according to the narrative descriptions in the studies.

Data Charting

Data charting was performed according to the methods proposed by Arksey and O'Malley [59] and the JBI, as described by Tricco et al [63], Levac et al [60], and Peters et al [66]. The template was piloted by the researchers and adjusted based on discussion, debate, and deliberation. Data items included the following: (1) study design, (2) aims, (3) measures, (4) outcomes, (5) intervention type, (6) clinical domain, (7) clinical processes, (8) clinical conditions, (9) EHR integration methods, (10) implementation strategies, (11) SDM goals, and (12) SDM model and components.

Analysis of Evidence

The analysis of the data was then performed to understand and map themes and clusters of notable data according to the updated methodological guidance for scoping reviews [67]. To do this, the research team discussed the definition along with examples of each extraction category. Following this, one researcher (WR II) performed a preliminary extraction on categories that were unambiguous. Next, the remaining research team members were assigned manuscripts to extract the more complex categories. The team met for iterative discussions, deliberation, and decision-making to achieve consensus on the final extraction items.

Data Summary and Synthesis

We summarized our findings using narrative synthesis and descriptive statistics to describe the characteristics of SDM tools integrated into the EHR systems [68,69]. For general characteristics, we mapped study types, measures, clinical domains and conditions, and goals of the SDM intervention in a table and calculated frequency counts and percentages [69]. We then categorized each study according to integration methods and features using descriptive content analysis to summarize narrative findings [70]. To do this, we analyzed the various methods used in each of the studies to surface and document SDM tools within the EHR systems. We considered integration to have been achieved so long as the SDM tools surfaced in the clinician's workflow within the EHR systems. We mapped EHR clinical decision support features for each SDM tool according to risk, patient data display, health care provider notification, documentation, and EHR workflow presentation. Then, we analyzed the implementation approaches across studies. To do this, we looked for methods of creating awareness, training programs, and SDM tool buy-in and promotion through clinician leaders. We were then able to organize our results by general characteristics, integration approaches, and implementation methods.

Results

Overview

This scoping review included 18 studies that met the inclusion criteria (Figure 1), including 15 (83%) quantitative and 3 (17%) mixed methods studies. The most commonly used SDM outcome measures are listed in Table 1.

Table 1. Shared decision-making (SDM) outcome measures reported in the included studies (N=18).

SDM outcome measures of included studies	Studies, n (%)
SDM measures	7 (39)
Tool use	7 (39)
Clinical outcomes	5 (28)
Patient satisfaction	4 (22)
Documentation	4 (22)
Clinician satisfaction	2 (11)

Of the 18 studies, 7 (39%) measured SDM components, such as patient empowerment, self-efficacy, self-determination, and goal setting. The 7 (39%) studies measuring use rates reported various levels of use; however, predetermined targeted use rate goals were not noted. We found that at least 3 (17%) of the studies achieved a use rate of >50% of the targeted users. In total, 4 (80%) of the 5 studies using clinical outcome measures reported positive improvements based on the SDM intervention [71,72]. Of the 18 studies, 4 (22%) studies that measured patient satisfaction included elements of communication quality, such as helpfulness, respect for the patient's opinion, understandability, confidence in the health care team, and worry reduction [72-75]. Documentation rates increased for all 4 (22%) studies using documentation as the primary outcome measure [76-79]. A total of 2 (11%) studies that measured clinician satisfaction reported clinician satisfaction at >85% and preference for a systematic approach via a tool at 100% [71,80]. In total, 4 (22%) included studies incorporated patient goals and values in the SDM process [72,78,81,82]. Consistent with previous research, 1 (5%) study reported that obstacles to tool use included a lack of awareness of the tool and low confidence in how to use the tool [83].

XSL•FO
RenderX

Goals of SDM Intervention

We categorized the included studies by macrolevel functional goals to include (1) care planning and goal setting (10/18, 56% studies), (2) prevention and screening (4/18, 22% studies), and (3) medical management and treatment (4/18, 22% studies; Table 2). The largest percentage of the care planning and goal setting category was end-of-life planning [76,77,81,82], followed by communications [72,84]. In total, 75% (3/4) of the prevention and screening studies focused on the detection of cardiovascular disease [71,74,85], and 75% (3/4) of the medication management and treatment decision-making studies focused on diabetes and related pharmacotherapy [80,83,86].

XSL•FO
RenderX

Table 2. Characteristics of the included studies.

Study	Study type	SDM[a] intervention	Clinical domain and conditions	Measures	Study outcomes
Ballard et al [83], 2017	Quantitative	SCDA[b] and DMCDA[c]	• Primary care • Diabetes and hyperlipidemia	• Decision aid tool use rates and barriers and facilitators for use	Log file data indicated that 51% of clinicians used the SCDA, and 9% of the clinicians used the DMCDA. Facilitators of decision aid use included clinicians finding them very useful and their impact on treatment decisions. Both facilitators were reported more frequently by clinicians for the SCDA than for the DMCDA (56% vs 30% and 42% vs 22%, respectively). Barriers to use included lack of knowledge of the EMR[d] link, not finding the decision aids helpful, and time constraints. The use of the tool as intended was low, with many clinicians only discussing decision aid topics that they found relevant.
Bose-Brill et al [76], 2018	Quantitative	A previsit planning tool for patients accessed via a patient portal and EHR[e]-guided point-of-care SDM questions	• Primary care • ACPf	• Documentation of ACP	In total, 19.5% (39/200) of the patients who received previsit planning responded to the framework. The intervention site had an improvement in new ACP documentation rates (P<.01) and quality (P<.01) among all eligible patients. ACP documentation rates increased by 105% (19/39 to 39/39), and quality improved among all patients who engaged in the previsit planning framework (n=39). Among eligible patients aged between 50 and 60 years at the intervention site, ACP documentation rates increased by 37% (27/96 to 37/96). ACP documentation rates increased by 34% among patients who sent >10 messages per year in the EHR (27/67 to 36/67).
Choi et al [77], 2019	Quantitative	EHR reminder to prompt discussions about unintended cardiac defibrillator shocks and deactivation options for EOL[g] care	• Intensive care • Cardiology	• Discussion rates and cardiac defibrillator deactivation rates	After the interventions, the rates of discussions regarding the deactivation of ICD[h] improved from 50% to 93% in patients in comfort care and from 32% to 70% in DNR[i] patients. The rates of deactivated ICDs improved from 45% to 73% in patients in comfort care patients and from 29% to 40% in DNR patients.
Chunchu et al [78], 2012	Mixed methods	PCCP[j] tool to promote self-management planning	• Family medicine	• Self-management plan documented in the EHR • Thematic analysis	More frequent documentation was noted in 8 problem-solving elements within the EHR, and the number of concerns for a visit was twice as high as in the control group.
Coylewright et al [85], 2020	Quantitative	iPDAs[k]	• Multiple specialties, stroke prevention in atrial fibrillation, fracture prevention in osteoarthritis, breast cancer screening, and lung cancer screening	• Clinicians' use of SDM tools and their perceptions of the tool's impact on the quality of discussion and time demands	For the 8-year analysis period, 1209 clinicians used iPDAs, with 57,116 unique patients in 81,728 visits. Of the clinicians, 76% were physicians, 16% were APPs[l], and 8% were other clinicians. There were 2607 unique patient-clinician uses in 2010; 7966 in 2014; and 24,384 in 2017. There was an average increase of 151 new clinicians per year (range 99-302). On average, 82 new clinicians used the iPDAs with at least 1 patient each year (range 56-108), with 657 clinicians for the 8-year period. In total, 54.3% of the clinicians used iPDAs with at least 5 patients.
Crosby and Gutierrez [81], 2019	Quantitative	ACP tool with risk identification for patients with late-stage heart failure	• Ambulatory care and congestive heart failure	• Use of EOL template and clinician survey	In total, 35% use of templates was reported over 3 months, 100% of templates were documented in EHR, 100% of clinic staff reported inconsistent processes for ACP discussion, and 100% of clinic staff preferred a systematic approach to initiating ACP processes.

XSL•FO
RenderX

Study	Study type	SDM[a] intervention	Clinical domain and conditions	Measures	Study outcomes
Denig et al [80], 2014	Quantitative	Diabetes decision aid	• Primary care • Type 2 diabetes	• Patient empowerment, diabetes management, and lipid-regulating prescription changes	Patient empowerment score increases were 0.1 on a 5-point scale, and drug treatment was intensified in 25% of intervention participants with increased cholesterol levels.
Fiks et al [73], 2015	Quantitative	My Asthma clinical decision support tool	• Primary care • Asthma	• My Asthma tool use and number of missed days of school or work	In total, 57% of the parents in the intervention group used My Asthma during at least 5 of the 6 study months. Parents of children with moderate to severe persistent asthma used the portal more often than others; 92% were satisfied with My Asthma. Parents reported that portal use improved their communication with the office.
Fossa et al [84], 2018	Quantitative	OpenNotes patient access for SDM	• Primary care • General practice	• A 3-item Collaborate scale, which measures a patient's experience with SDM	A total of 6913 patients responded (28% response rate). Patients reading ≥4 clinical notes in the past 12 months were 17% more likely to have top Collaborate scores when compared to those who had not read a note in the previous 12 months (response rate: 1.17, 95% CI 1.04-1.32).
Fried et al [87], 2017	Quantitative	TRIM[m]	• Primary care • Pharmacotherapy	• Patient involvement in care, patient-clinician communication, and changes in medications	In total, 29.7% of TRIM participants and 15.6% of control participants provided the highest PACIC[n] ratings; this difference was not significant. TRIM improved communication about medications and the accuracy of documentation.
Huang et al [75], 2020	Quantitative	TEA[o] tool with an annual assessment of key transition skills and setting of transition skill goals	• Pediatrics • Gastroenterology	• Health care providers' TEA tool utility ratings and recommendations to patients	All patients (N=53) performed the transition skills self-assessment and practicum and set transition goals with their health care provider. On a scale of 0 (not helpful at all) to 10 (very helpful), patients reported median (IQR) utility scores of 8 (7-10) for the transition readiness assessment, 9 (7-10) for transition resources provided, and 9 (7-10) for the medical history summary. Most (91%) patients would recommend TEA to other patients.
Jouni et al [74], 2017	Quantitative	CHD[p] genetic risk tool, decision aid for CHD risk estimates, and facilitation of SDM for statin use	• Biobank cardiology data • Genetic heart diseases	• Satisfaction with clinical visits, quality of discussion or participation in decision-making, and physician visit satisfaction	There were no statistically significant differences between the 2 groups in the SDM score, satisfaction with the clinical encounter, and perception of the quality of the discussion or participation in decision-making and physician visit satisfaction scores.
Lafata et al [79], 2014	Quantitative	5A[q] framework–guided discussion during primary care visits for CRC[r]	• Primary care • CRC screening	• Documented CRC screening rates	In total, 93% of patients received a recommendation for screening (advise), and 53% were screened in the following year. The likelihood of screening increased as the number of 5A steps increased: compared to patients whose visit contained none of the 5A steps, those whose visit contained 1 to 2 steps (OR[s] 2.96, 95% CI 1.16-7.53), and ≥3 steps (OR 4.98, 95% CI 1.84-13.44) were significantly more likely to use screening.
Litzelman et al [82], 2017	Mixed methods	GW[t] cards and discussions to identify priorities for advanced care planning	• Geriatrics • EOL care	• ACP conversations completed	A total of 86 patients' data indicated that they had engaged in a preferences-for-care process using GW R cards. The top 3 card choices by patients were attending to spirituality and religious concerns, preparing for EOL, and maintaining personal wholeness.
Plößnig et al [86], 2015	Quantitative	EMPOWER[u] SMP[v] tool to foster self-management of diabetes	• Internal medicine • Type 2 diabetes	• Tool use and empowerment measures: (1) meaningfulness, (2) self-efficacy, (3) impact, and (4) self-determination	Patients used functions for setting goals (65%) or planning activities (71%). More than half of the patients reported using the charts, the calendar, and the journals, while review (29%) and information material (24%) were of little interest. Initial testing showed an overall high level of empowerment. Improvements in self-efficacy, impact, and self-determination were observable in the German users and meaningful in the Turkish users.

XSL•FO
RenderX

Study	Study type	SDM[a] intervention	Clinical domain and conditions	Measures	Study outcomes
Schafer et al [88], 2016	Mixed methods	Pharmacist-led SDM template for medication decisions	• Outpatient • Pharmacy • Mental health	• Feasibility of template, type, and number of DTPsw	On average, 2 DTPs were identified per consultation and were most commonly related to appropriate compliance (30%), appropriate indication (26%), medication effectiveness (23%), and safety (21%).
Sona et al [72], 2020	Quantitative	Family communication tools, including education, decision-making, surrogate decision makers, and advanced directives	• Critical care	• Communication quality, helpfulness of family care conferences, confidence in health care team, impact on patient care, and reduced worry about family members	Excellent communication rating was reported by patients at 69% for RNs[x] and 54% for physicians; 43.5% of patients or families reported liking family care conferences, 52.2% thought family care conferences were helpful, 62.5% had confidence in health care team, 62.5% reported that family communication impacted care of the patient, and 62.5% reported that it reduced worry about family members.
Sperl-Hillen et al [71], 2018	Quantitative	CV Wizard, an SDM tool to reduce cardiovascular risk	• Primary care • Cardiovascular disease	• 10-year cardiovascular risk trajectory and clinician satisfaction rates	Health care provider satisfaction was 85% to 98% for various aspects of the intervention, 10-year cardiovascular risk reduction at 12 months was –2.24%, and use rates were 71% to 77% over the intervention.

[a]SDM: shared decision-making.

[b]SCDA: statin choice decision aid.

[c]DMCDA: diabetes medication choice decision aid.

[d]EMR: electronic medical record.

[e]EHR: electronic health record.

[f]ACP: advanced care planning.

[g]EOL: end of life.

[h]ICD: implantable cardioverter defibrillator.

[i]DNR: do not resuscitate.

[j]PCCP: patient-centered care plan.

[k]iPDA: integrated patient decision aid.

[l]APP: advanced practice provider.

[m]TRIM: tool to reduce inappropriate medication.

[n]PACIC: patient assessment of chronic illness care.

[o]TEA: transition electronic health record activity.

[p]CHD: coronary heart disease.

[q]5A: assess, advise, agree, assist, and arrange.

[r]CRC: colorectal cancer.

[s]OR: odds ratio.

[t]GW: Go Wish.

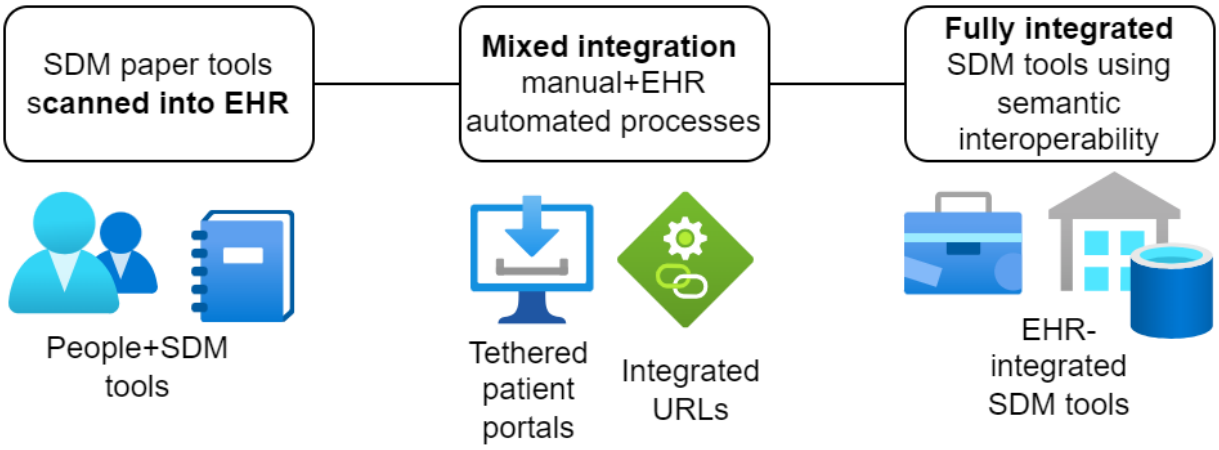
[u]EMPOWER: Support of Patient Empowerment by an intelligent self-management pathway for patients.

[v]SMP: self-management pathway.

[w]DTP: drug therapy problem.

[x]RN: registered nurse.

Tool objectives were generally a direct function of the use of the SDM tool; for example, an end-of-life planning template may have a stated objective to increase documentation rates for communications. Patient satisfaction–related outcomes, such as decision satisfaction because of a shared conversation, were not noted in 11 (61%) of the 18 studies [72,73,75,80-84,86-88].



Promoting SDM Awareness and Adoption

EHR and Workflow Integration

Our study found that workflow integration approaches were highly variable, ranging from scanning paper-based tools into the EHR system to implementing SDM tools with full semantically interoperable data elements surfacing within patient portals and in the clinicians' EHR workflow (Figure 2 and Table 3).

XSL•FO
RenderX

Figure 2. Electronic health record (EHR) integration methods described in the included studies. SDM: shared decision-making.

XSL•FO
RenderX

Table 3. Shared decision-making (SDM) interventions and goals, electronic health record (EHR) integration methods, and implementation approaches (N=18).

Functional goals and studies	Clinical processes	SDM interventions	SDM goals	EHR integration method and implementation approach
Care planning and goal setting (n=10, 56%)				
Bose-Brill et al [76], 2018	ACP[a]	A previsit planning tool for patients accessed via a patient portal and EHR-guided point-of-care SDM questions	To increase the rate of ACP documentation	• An EHR-tethered patient portal presents ACP questions before a visit. The algorithm within the EHR guides the communication between clinician and patient. • Physicians, nurses, and other clinical staff at the intervention clinic were collectively involved in developing this ACP previsit planning algorithm that was rolled out practice wide over a 3-month period.
Choi et al [77], 2019	End-of-life planning	EHR clinician alerts and reminders to prompt discussions regarding unintended cardiac defibrillator shocks and deactivation options during end-of-life care	ICD[b] deactivation discussion	• EHR alerts and decision support tools were integrated into the comfort care order set and DNRc document. • A 10-min training with pre- and postknowledge assessment, posttraining surveys with follow-up education, and special training sessions for various specialties were provided, as needed.
Chunchu et al [78], 2012	PCCP[d]	PCCP tool to promote self-management planning	To increase collaborative self-management planning	• PCCP was developed in EHR with prompts. • Clinician training with video demonstration was provided.
Crosby and Gutierrez [81], 2019	ACP	ACP tool with risk identification for patients with late-stage heart failure	Risk stratification, life expectancy of <3 years, conversations about preferences, and scanning into EHR	• ACP tool was scanned into the EHR. • Readiness to change assessment tool was administered to all clinic staff and internal stakeholders. Education was provided about the ACP tool and project goals. Key stakeholders were involved in tool development and project implementation, workflow assessment, and process development.
Fossa et al [84], 2018	Communication	OpenNotes patient access for SDM	Collaborative decision-making	• OpenNotes access was provided via the patient portal.
Fried et al [87], 2017	Medication reconciliation	TRIM[e]	To facilitate clinician and patient medication communications	• TRIM was fully embedded into the EHR and extracted patient data from the EHR for medication reconciliation.
Huang et al [75], 2020	Transition readiness	TEA[f] tool with annual assessment of key transition skills and setting of transition skill goals	Transition readiness decision-making	• The TEA tool was developed fully in the EHR. • Pilot-testing of the TEA tool was performed at an independent clinic.
Litzelman et al [82], 2017	End-of-life planning or ACP	Go Wish cards and discussions to identify priorities for ACP	ACP conversations	• Go Wish cards+ACP discussion took place with EHR data entry of goals and values. • Training was provided on ACP and Go Wish R cards through workshops, simulation sessions, case conferences, and guidance from the CDSg tool.
Schafer et al [88], 2016	Medication reconciliation	Pharmacist-led SDM template for medication decisions	To promote patient and pharmacist SDM with the use of the Ottawa Personal Decision Guide	• Pharmacy SDM conversation template was integrated into EHR and printed for the patient.
Sona et al [72], 2020	Communication	Family communication tools, including education, decision-making, surrogate decision makers, and advanced directives	To increase the rates of critical care family communications	• The communication bundle document template was developed in the EHR system.
Prevention and screening (n=4, 22%)				
Coylewright et al [85], 2020	Risk assessment and prevention	iPDAs[h]	To promote clinician use of iPDAs with patients for SDM	• A suite of decision aids was integrated into the EHR with use tracking. • A clinician adopter survey was conducted.

[n]DMCDA: diabetes medication choice decision aid.

[o]EMPOWER: Support of Patient Empowerment by an intelligent self-management pathway for patients.

[p]SMP: self-management pathway.

[q]ISO: International Organization for Standardization.

We found that 8 (44%) of the 18 included studies described implementation strategies in sufficient detail to define the approach to operationalizing the SDM processes [71,73,75,77,78,80,82,85]. In 2 (11%) studies, patient portals were leveraged as part of the SDM process [73,84]. One patient portal was described as a tethered patient portal, which referred to SDM processes that were partially embedded into the clinicians' EHR view. This was accomplished by collecting data and then saving them into the patient's record so that a clinician could view the data from their workflow screen [76]. One intervention simply scanned paper documents and uploaded them into the patient record or other sections predefined within the EHR [81].

XSL•FO
RenderX

Some (5/18, 28%) of the studies noted hybrid approaches to EHR integration, such as a combination of manual data collection with EHR documentation of an SDM process (Table 3). Of the 18 studies, 2 (11%) noted the integration of a URL into the EHR that launched a third-party web-based SDM tool [83,85]. Other (12/18, 67%) studies included health care provider alerts that presented patient risk factors to facilitate discussion and decision-making. Health care provider alerts may also help capture documentation of the SDM interaction [74,78].

Determining when to engage a patient in SDM before a clinical encounter is another element of SDM intervention planning. In 1 (6%) study, the engagement interval with patients was extended to previsit preparatory activities [76]. This included SDM processes that initially engaged the patient through preparatory SDM tools or surveys that were delivered via email, patient portals, or web links or delivered in the waiting room immediately before the clinical encounter [73,74,76,79,83-85,87]. Other SDM interventions were designed to be used during the clinical encounter, including EHR-based tools, patient record sharing, communication and conversation guides, patient health plans, and educational printouts for patients [71,72,75,77,78,80-82,86,88]. None of the included studies investigated postclinical encounter SDM tools for ongoing decision affirmation and goal alignment.

Implementation Strategies

A total of 9 (50%) of the 18 included studies described implementation strategies in sufficient detail to define the approach to operationalizing the SDM processes [71,73,75,77,78,80-82,85]. Methods to make clinicians and patients aware of the tools included email notifications and reminders, links in the EHR to an external third-party SDM tool, paper-based posters displayed in common workspaces, educational presentations, and training (Table 3). Trainings were often conducted in person, but some used prerecorded video. Brief trainings focused on how to use the tool; however, longer trainings included skills for engaging in SDM and sometimes involved role-playing these behaviors. In one case, the required implementation workflow caused users to question the “long-term feasibility” of the SDM intervention due to the additional time and resources required to complete the SDM processes, specifically in the case of advanced care and end-of-life planning for patients with heart failure [81].

Clinical adoption was supported by collaboration with physician and nursing leaders for integrating the tools into the clinical workflow, engaging clinicians who initially engaged patients when starting the SDM process, providing feedback at the health care provider or clinic level, and sponsoring lotteries for clinic leadership when tool use achieved a specified level.

Other implementation strategies used to support patient engagement with SDM tools included email reminders to complete surveys, the provision of kiosks in the waiting room to allow patients to access the patient portal, and the provision of paper-based information for patients to read while waiting in the examination room.

We found that there was variance across the targeted users for the SDM tool interaction. In several (7/18, 39%) studies, both patients and clinicians had roles to play within the SDM processes [73,75,76,78,82,84,86]. In most cases, the tool was targeted toward the clinician to activate the process and conduct conversations with the patient [71,72,74,77,79-81,83,85,87,88].

EHR Clinical Decision Support Features

The SDM interventions identified in this review contained several clinical decision support features. Table 4 describes each of these approaches, along with indicating whether the component was delivered manually or automatically within the EHR system. These features include the following: (1) patient risk alerts, which use patient data to compute personalized risk; (2) patient data display through the retrieval of relevant patient information into an informative display; (3) health care provider notification indicating whether a health care provider has to seek out the SDM tool or whether it surfaces within the EHR automatically based on a set of criteria; (4) presented in the EHR, allowing clinicians to access an SDM tool within the EHR (through several different technical approaches), as opposed to an application that is external to the EHR system; and (5) documentation support, including manual, autogenerated, or template-based clinician notes within an EHR to document that an SDM event occurred. One study used an emoji in the EHR to indicate that the SDM conversation had occurred [72].

Discussion

Principal Findings

This review summarizes the findings of 18 studies that investigated approaches to the integration and implementation of SDM tools within EHR systems. Prominent aspects found across studies included functional SDM goals, such as communication, documentation of communication and discussions, and SDM template use. We identified only 4 (22%) randomized controlled trials (RCTs), which may be a reflection of the operational nature of the study measures. In 10 (56%) studies, clinicians were the primary targeted users, whereas 4 (22%) studies targeted patients and 5 (28%) targeted both. Integrating SDM interventions into a clinician's workflow within an EHR system appears to support improved SDM uptake [60,89-91]. Studies reported multiple EHR and workflow integration approaches, which may be an indication that a dynamic model that is scalable could help guide the adoption of SDM tools and processes across different environments. Future research to understand the utility of adjusting SDM model depth and complexity based on the magnitude of the decision,

XSL•FO
RenderX

the complexity of the clinical situation, and the patient preferences is warranted.

Goals of SDM Tools

Most (10/18, 56%) of the included studies focused on SDM tools that were functionally designed to support care planning and goal setting. We also noted 1 (6%) study that used the concept of open medical notes as a precursor to shared care conversations.

Most (4/18, 22%) prevention and screening studies targeted by SDM focused on common conditions, such as the detection of heart disease, colorectal cancer, and other common conditions. Future opportunities for EHR-integrated SDM screening tools include the assessment of social determinants of health for the purpose of supporting individuals with social needs. Furthermore, mental health SDM screening tools offer an important area for prevention and screening to detect anxiety, depression, loneliness, addiction, and suicide risk, as a few examples.

Promoting SDM Awareness and Adoption

Although studies generally lacked sufficient technical detail on the actual integration method into each EHR system, we found considerable variation in how SDM tools are implemented within EHR workflows. The implementation approaches for SDM applications showed varying levels of planning and efforts to promote SDM intervention awareness. For example, 33% (6/18) of the studies did not describe implementation activities for clinicians, whereas other (6/18, 33%) studies described more detailed implementation plans that included training, demonstrations, knowledge queries, and incentives [71,73,77,78,81,82].

In total, 22% (4/18) of the studies included in the review suggested that integrating an SDM intervention into a clinician's EHR workflow may support increased awareness of the intervention [60,72,89,90]. This represents an important step toward supporting clinicians in the adoption and use of SDM tools and processes. Creating awareness, interest, and commitment to SDM tool use is often overlooked and may contribute to waning adoption for otherwise well-designed SDM tools, potentially leading to adoption failure. The implementation plan is a critical component to moving people and the organizational culture toward the adoption of SDM tools. These steps also provide a forum for direct feedback should clinicians lack confidence in the accuracy or efficacy of an SDM tool, as was noted by Ballard et al [83].

This review found that established processes and required patient interactions, such as end-of-life care planning protocols, appear to support greater SDM adoption success because they rely on workflows and processes that are already in practice. Adoption through incremental change, such as an evolutionary approach rather than a revolution, may be more likely to gain momentum over time [85].

Implications for Future Research

Our review found that only a few randomized clinical studies were noted. Future research studies should assess the effect of SDM in multisite pragmatic RCTs.

This review identified a wide range of approaches to how SDM interventions are organized and delivered within the clinical setting. Future research could explore contextually aware tiered levels of intervention. This is important to standardize SDM care processes within specialties in order to support large-scale adoption of validated SDM tools and methods while addressing practical considerations within the constraints of each specialty.

Our review found that 17% (3/18) of the studies attempted to engage patients before a clinical encounter; however, no studies attempted to engage patients in decision-making after a clinical encounter [76,79,84]. Protracted decisions that include a series of small decisions align well with the use of patient portals to begin preparing patients for the SDM process. Another area for future research could be to understand the efficacy of postclinical encounter engagement to address the ongoing maintenance and reinforcement of decisions that have been made in collaboration with the clinician.

We found limited studies that included the identification and measurement of patient values. Thus, patient involvement in establishing their values and alignment of care with those values appear to be areas for additional focus in future research. Involving patients in goal setting is a key element to support patient engagement, which is essential to help patients manage their decisions outside of the clinician encounter [92].

Strengths and Limitations of Approach

Strengths

The review followed rigorous standard scoping review methods set by the JBI, Arksey and O'Malley [59], and others [60,66,93,94]. We carried out a systematic search of multiple databases developed by a medical librarian and independent article screening and data extraction by at least 2 reviewers, with disagreement resolved through consensus. Our research team included investigators from an academic medical setting with extensive research experience in biomedical informatics, cognitive psychology, human factors, and health care.

Limitations

This scoping review may have missed relevant studies that are not indexed by the databases searched. Furthermore, the search retrieved studies published between January 1, 2009, and January 11, 2021; therefore, studies published outside this time frame were not included in our analysis. We did not search the gray literature or unpublished data sources. SDM studies that lacked an SDM tool, EHR implementation, and an actual clinical setting were not included. Implementation details were highly variable in terms of the approach and the level of detail described in the studies. SDM definitions and interpretations were variable, and we found limited references to validated SDM definitions, such as commonly cited definitions by the US National Institutes of Health or other credible sources.

Conclusions

This scoping review revealed a wide range of approaches to the integration and implementation of SDM tools within an EHR workflow. We found that SDM tool integration methods ranged from simple scan and save methods to fully integrated and operable technical integration with an EHR system. Moreover,

XSL•FO
RenderX

implementation approaches were highly variable, ranging from sending an email to clinicians to create awareness to more complete programs involving demonstrations, training, incentives, clinician-led promotion, and feedback sessions. Areas for future research include more RCTs, the development of contextually aware SDM interventions, longitudinal patient engagement with pre- and postvisit interventions, the study of patient-driven goals and values, and the subsequent impact on patient satisfaction levels. Future studies should detail pragmatic and actionable integration and implementation steps to advance the uptake of SDM.

Acknowledgments

The authors would like to acknowledge Hitachi, Ltd (Tokyo, Japan) for partial funding of this project. The funding source played no role in the design, execution, or findings of this study.

During the preparation of this study, the authors used Covidence systematic review software (Veritas Health Innovation) [95] for the screening of studies and EndNote (Clarivate) [96] for management, citation, and storage of references. Following and concurrent with the use of these tools, the authors reviewed, synthesized, and organized the scoping review content. Figure 2 was created using Drawio app (JGraph Ltd) [97].

The views expressed in this paper are those of the authors and do not necessarily represent the position or policy of the US Department of Veterans Affairs or the US government.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

KK, GDF, and CW obtained funding for this project. CW and KK conceptualized the research and recommended the research methodology. JHP led the project administration, with supervision by CW, JMB, and GDF. MMM conducted all data and literature searches. WR II, JHP, CW, JMB, and TT conducted data extraction and synthesis for the final studies. JHP, CW, and TT wrote the original draft of the manuscript. JHP created Figures 1 and 2 and Tables 1-3. CW and JHP created Table 4. All authors reviewed and edited the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Effective shared decision-making between patients and physicians is crucial for enhancing health care quality and reducing medical errors. The literature shows that the absence of effective methods to facilitate shared decision-making can result in poor patient engagement and unfavorable decision outcomes.

Objective: In this paper, we propose a Collaborative Decision Description Language (CoDeL) to model shared decision-making between patients and physicians, offering a theoretical foundation for studying various shared decision scenarios.

Methods: CoDeL is based on an extension of the interaction protocol language of Lightweight Social Calculus. The language utilizes speech acts to represent the attitudes of shared decision-makers toward decision propositions, as well as their semantic relationships within dialogues. It supports interactive argumentation among decision makers by embedding clinical evidence into each segment of decision protocols. Furthermore, CoDeL enables personalized decision-making, allowing for the demonstration of characteristics such as persistence, critical thinking, and openness.

Results: The feasibility of the approach is demonstrated through a case study of shared decision-making in the disease domain of atrial fibrillation. Our experimental results show that integrating the proposed language with GPT can further enhance its capabilities in interactive decision-making, improving interpretability.

Conclusions: The proposed novel CoDeL can enhance doctor-patient shared decision-making in a rational, personalized, and interpretable manner.

Introduction

Shared decision-making (SDM) is a collaborative process between health care providers and patients, designed to incorporate the patient's preferences, values, and the best available evidence to discuss and agree on the most suitable care options [1]. Numerous studies have demonstrated the benefits of SDM, including improved patient engagement in decision-making, enhanced quality of care, and reduced medical costs [2]. In recent years, SDM has emerged as the pinnacle of clinical decision-making, particularly in evidence-based and patient-centered health care settings [3-5].

However, opportunities for active patient participation in medical decision-making remain limited [6], and SDM is predominantly applied in specific health care scenarios [7]. Furthermore, considerable disagreement exists regarding the implementation of SDM, primarily due to the absence of a universally accepted set of steps to guide the process [8,9]. To address these challenges, the Tripartite Dialogue Model was developed as an approach to promote SDM by engaging relevant stakeholders, ensuring continuous updates, and fostering broader

XSL•FO
RenderX

participation [10,11]. However, the practical implementation of similar dialogue models remains largely theoretical, with a lack of detailed guidelines for execution. As a result, understanding the process of joint decision-making and addressing the issue of inadequate consultation—often leading to inefficient utilization of medical resources—has proven challenging [12]. Research indicates that reaching an agreement on a practical model would be a crucial step in promoting its adoption. Currently, there is no existing research specifically focused on doctor-patient codecision-making [7].

Communication among agents, akin to the interaction between a doctor and a patient, is a multifaceted and intricate process. Achieving effective communication and seamless information exchange is crucial for agents to collaborate harmoniously and work toward a shared objective. In the field of linguistic analysis, speech acts have gained prominence for capturing expressions of mental states—such as embarrassment, gratitude, or regret—that convey thoughts or ideas and elicit specific behaviors, such as commands, warnings, or requests, to sustain social interaction [13]. Most research on speech acts has primarily focused on areas such as task assignment, knowledge expression, and identifying intrinsic behavioral patterns in language [14,15]. However, the use of speech acts for regulating interaction behavior remains limited. Among the existing studies that leverage language to describe group behavior, a particularly suitable approach is the Lightweight Coordination Calculus (LCC) language. Initially developed within the framework of the Open Knowledge Project [16], LCC was later extended to the Lightweight Social Calculus (LSC) to support the development of social machines [17]. These languages were not specifically designed to address decision problems and therefore require substantial enhancements to be effectively applied in group decision-making scenarios.

Over the years, various interaction mechanisms for group decision-making have been explored. For example, researchers have developed decentralized group decision consensus mechanisms [18] and introduced personalized feedback mechanisms that provide decision makers with varying levels of consensus alongside tailored feedback suggestions [19,20]. However, in the medical domain, there have been relatively few studies focusing on personalized modeling to describe the group decision-making process. The primary reason is that poor decision-making is often influenced by artificial problems, such as cognitive biases, which may stem from social attributes or certain personality traits [21]. To support group decision-making in health care, some researchers have developed clinical decision support systems [22,23]. These systems aim to create human-computer interactive medical platforms that use data or models to assist doctors and patients in clinical decision-making [24]. However, these systems largely depend on third-party knowledge and fail to adequately consider users' value orientations or preferences.

In medical decision-making, treatment choices are often influenced by physicians' preferences and experience rather than being solely based on medical necessity or scientific evidence, partly due to the lack of evidence-based guidance on the optimal treatment order [25]. To encourage greater patient participation in SDM, patient decision aids (PtDAs) have been developed. These aids provide standardized information about available options and their associated outcomes, helping patients implicitly evaluate the value of these outcomes [26]. However, many existing PtDAs are text-based, include instructions and training for health professionals, and are not aligned with clinical guidelines [27].

With advancements in machine learning and the availability of powerful hardware supporting real-time speech recognition—such as high-quality text-to-speech capabilities and semantic understanding of natural language—health dialogue systems are becoming increasingly popular among patients, hospitals, and universities [28]. These systems enable patients to acquire knowledge and engage in conversations without the direct involvement of health care professionals. Among these systems, ChatGPT, developed by OpenAI, stands out as a prominent language model with significant potential to contribute to public health [29]. Leveraging its extensive knowledge base, it can address patients' inquiries, particularly when dealing with uncertain questions. However, it is important to recognize that, despite its vast database, ChatGPT lacks a deep semantic understanding of the messages it processes [30]. This limitation can undermine trust in its responses, especially in the complex field of medicine, where accuracy and reliability are paramount.

Therefore, by integrating the aforementioned aspects, this paper makes the following key contributions:

- We enhance GPT's explainability by integrating our method with GPT, thereby verifying the feasibility of our approach and enriching our argument.
- We introduce Collaborative Decision Description Language (CoDeL), which includes 4 key elements: (1) a decision-maker interaction process protocol based on LSC; (2) the semantic relationships in the interaction process, defined by combining speech acts; (3) arguments in semantics guided by clinical guidelines; and (4) constraints incorporated for personality modeling. This language provides a more comprehensive description of group decision-making problems and addresses the limitations of LSC.
- We have created some reusable interaction patterns that can be applied in other domains. Specifically, we model the field of atrial fibrillation to validate the feasibility of our method and introduce a novel evaluation approach.

Methods

Overview

We first outlined what our LSC inherited and extended from previous studies (the "LSC-Based Decision-Making Protocol" section). Next, we introduced grammatical semantics within our defined CoDeL (the "Syntactic and Semantics of Collaborative Decision Languages [CoDeL]" section) and demonstrated the interactive relationships of speech acts (the "Constraints of Permissible Speech Acts Pairs" section). Based on the communication model for joint decision-making between doctors and patients, we defined 3 distinct decision-making models (the "An Interactive Model of Shared Decision-Making

XSL•FO
RenderX

Between Doctors and Patients" section). We then used CoDeL to establish the protocol for these decision-making models (the "Protocols Specification Using Collaborative Decision Description Language [CoDeL]" section). Additionally, we briefly discussed the arguments guided by clinical guidelines. Finally, we incorporated the personality model constraint into the protocol (the "The Personality Modeling Included in the Protocol" section).

LSC-Based Decision-Making Protocol

LSC is a protocol language designed to regulate social interactions. It provides a framework for creating social machines that build upon existing social networks, such as X (Twitter), while supporting human interactions through formal role binding, protocol enactment, and result interpretation back to human society [31]. By meeting specific conditions, participants can seamlessly integrate into LSC-based systems, with each condition defining a distinct role and corresponding behavior. In practical applications, the LSC protocol comprehensively defines the agents, roles, messages, computations, and information flows involved, ensuring precise control over complex social interactions and guaranteeing system reliability and efficiency. However, the earlier version of LSC lacked a critical decision-making component, as it did not incorporate clinical guidelines or natural language processing capabilities. Specifically, the original LSC lacked mechanisms for processing natural language and did not support dialogues with argumentation structures grounded in logical reasoning.

To address these gaps, we have extended the earlier version of LSC with a new decision-making component that integrates clinical guidelines and natural language processing capabilities. Our primary objective is to develop an integrated framework that facilitates decision-making in medical settings by leveraging evidence-based recommendations and logical reasoning.

Therefore, we propose a CoDeL to provide health care professionals and patients with a more comprehensive decision support system. Specifically, CoDeL contributes in the ways detailed in Textbox 1.

In contrast to the original LSC, our CoDeL is designed to enable more effective and informed decision-making in medical settings. CoDeL, equipped with natural language processing and evidence-based recommendation capabilities, supports the development of comprehensive decision-support systems tailored to the needs of health care professionals and patients. By addressing this critical gap, we aim to improve patient outcomes, enhance health care quality, and empower clinicians with a cutting-edge tool to support clinical decisions.

Textbox 1. Collaborative Decision Description Language (CoDeL) contributions.

1. Semantically linked to abstract-level speech acts

CoDeL formalizes concrete speech acts into an abstract symbolic format, for example, Rebuttal(surgery1, against_argument)), enabling precise linguistic data transmission and ensuring accuracy in communication.

2. Seamless integration of clinical guidelines

CoDeL incorporates the latest medical guidelines into the decision-making process, providing clinicians with access to up-to-date, evidence-based recommendations. This integration supports informed decision-making through logical reasoning and argumentation structures, ensuring decisions are grounded in empirical evidence.

3. Enhanced patient engagement

CoDeL uses user-friendly natural language formats alongside interactive dialogue mechanisms, enabling patients to participate actively in treatment decision-making. This approach fosters clearer communication, empowering patients to make more informed choices.

Syntactic and Semantics of Collaborative Decision Languages (CoDeL)

Group decision problems involve analyzing individual opinions and preferences to understand how decisions are made. These problems often require cooperation and negotiation among multiple individuals, taking into account factors such as opinions, preferences, rights, and interests. To address these challenges effectively, we propose CoDeL as a framework for describing and solving group decision-making problems. Specifically, to enhance the scientific validity of CoDeL, we define distinct categories of communication processes within the context of doctor-patient SDM in medical scenarios. This approach facilitates improved communication and negotiation among the involved agents, enabling a more robust decision-making process, as outlined in Textbox 2.

It is crucial to emphasize that within the context of our framework, the term *rebuttal* allows for negotiation, discussion, and the presentation of counterarguments. By contrast, *refuse* denotes a definitive and explicit rejection, devoid of any accompanying explanation or reasoning. The concept of *refuse* carries a more forceful connotation, as it involves an outright dismissal of the proposed action or treatment without providing further justification or elaboration.

In this research, we introduce CoDeL, a framework that not only encompasses the aforementioned interaction behaviors but also incorporates a group decision protocol. This protocol defines the roles of agents, specifies the messages to be exchanged, and outlines the information to be utilized during interactions. The protocol can be executed either sequentially or as a committed-choice option, ensuring a systematic and coordinated decision-making process. Within each action, agents follow the protocol associated with their roles and interact with other agents accordingly. Before taking any action, agents evaluate whether they are authorized to perform the action by verifying compliance with the corresponding behavioral rules.

To facilitate a better understanding of the CoDeL syntax, we provide an illustrative example in Figure 1, demonstrating how the framework is applied in practice.

XSL•FO
RenderX

- "a(name(K),N)": Indicates the agent's role name, ID, and intrinsic knowledge of existence.
- "Agenti() ⇒ Agentj()" or "Agenti() ⇐ Agentj()": Indicates that the message is being passed to another agent. A message declaration needs to be specified on the sender side and a rule declaration on the receiver side.
- "then": Indicates that the clause before it must continue the clause after it.
- "or": Indicates that there are alternative decision branches available and only 1 should be selected.
- "←()": Indicates that the constraint satisfaction function must resolve to true in order to execute its associated clause.
- "assert(diseases, surgery1 + surgery2) ⇐ a(doctor(),D)": The patient receives an assertion message sent by the doctor, which includes the name of the disease and the doctor's recommended treatment plan.
- "question(disease, surgery1 + surgery2) ⇒ a(doctor(),D)←interested in(disease, surgery1 + surgery2)": If the patient wishes to acquire more knowledge, they can send a message of inquiry to the doctor and await confirmation from the doctor.

Textbox 2. Decision-making process.

1. Assert

Provide information related to diagnoses, medication instructions, treatment plans, or consultation details.

2. Accept

Agree to follow the proposed action plan, treatment plan, or medical advice.

3. Refuse

Reject the proposed action plan, treatment plan, or medical advice.

4. Question

Seek further clarification due to limited understanding of the information provided in an assertion.

5. Justify

Offer honest answers to questions raised and provide reasonable explanations to support assertions made.

6. Rebuttal

Disagree with an assertion and present reasons for the opposition.

7. Persuade

Attempt to influence the beliefs, attitudes, or behaviors of the opposing party to accept or adopt the assertion made.

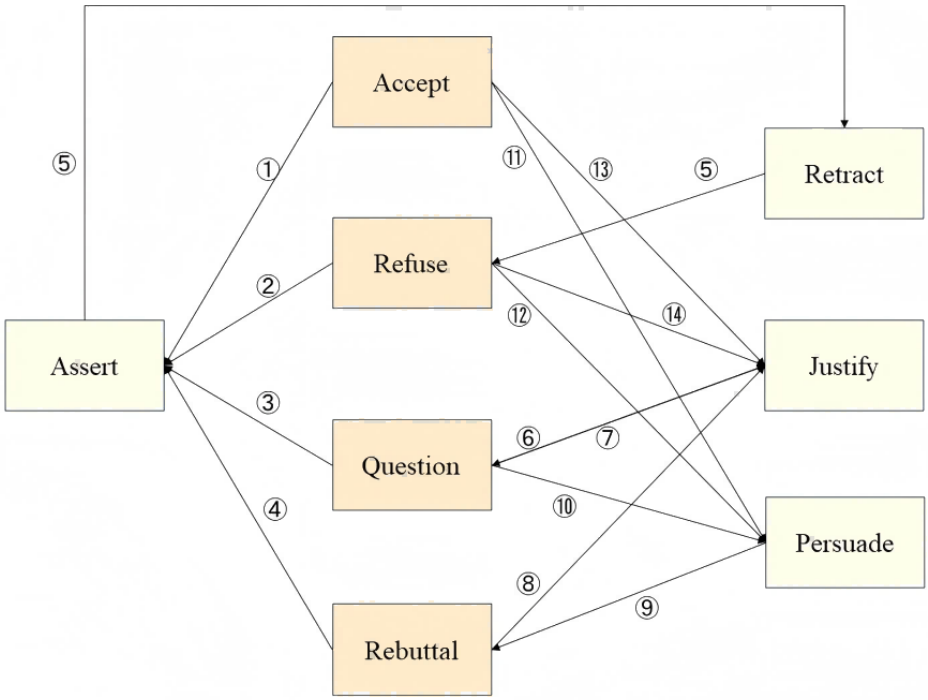
8. Retract

Withdraw the initial assertion due to the discovery of errors or a change in beliefs based on updated information.

Figure 1. An example of doctor-patient communication is LSC. After receiving a message from the doctor, the patient decides whether to send an inquiry message.

```
a(patient(),P)::=
assert(diseases, surgery1+surgery2) ⇐ a(doctor(),D) then
  question(diease, surgery1+surgery2) ⇒ a(doctor(),D) ←interested_in(diease,surgery1+surgery2)
a(patient(),P)
```

Constraints of Permissible Speech Acts Pairs



Speech acts do not exist in isolation; instead, they intersect and influence each other within the dynamic evolution of dialogue, thereby facilitating communication between agents. Figure 2 illustrates the relationships among speech acts, and Table 1 standardizes and explains the speech act interaction pairs applicable to this study.

For instance, when a doctor makes a diagnostic assertion, the patient's response can take various forms, including acceptance, rejection, questioning, or refutation (1-4). If the patient questions the initial assertion, the doctor must provide detailed arguments and validate the rationality of the assertion (6). Based on the doctor's response, the patient may choose whether to continue questioning (7). If the patient rejects the evidence and refutes it (8), the doctor may use persuasive strategies to reinforce their initial position (9), potentially initiating another feedback loop. During this process, the patient may persist with further questions (10), fostering a cycle of in-depth interaction until all concerns are resolved. At the conclusion of the cycle, the patient, influenced by the doctor's persuasion and verification, ultimately makes 1 of 2 decisions: to accept or reject the doctor's assertion (11-14). As the conversation progresses and both parties exchange their perspectives, if the patient persists in rejecting a specific assertion, the doctor may decide to actively retract the previous statement after considering the pros and cons (16).

XSL•FO
RenderX

The doctor can then determine whether to propose a new assertion based on the available alternatives (5). Notably, certain speech act interaction pairs that violate standard behavioral logic are prohibited during agent interactions. For instance, as described above, an agent sending a *refuse* message demonstrates a strong rejection attitude and will not receive any response message. Consequently, the (*refuse-persuade*) interaction pair is logically invalid. Similarly, the (*assert-justify*) interaction pair, where an agent sends an *assert* message to express its opinion and the receiving agent replies with a *justify* message to provide supporting arguments for the other agent's opinion, also violates normal behavioral logic.

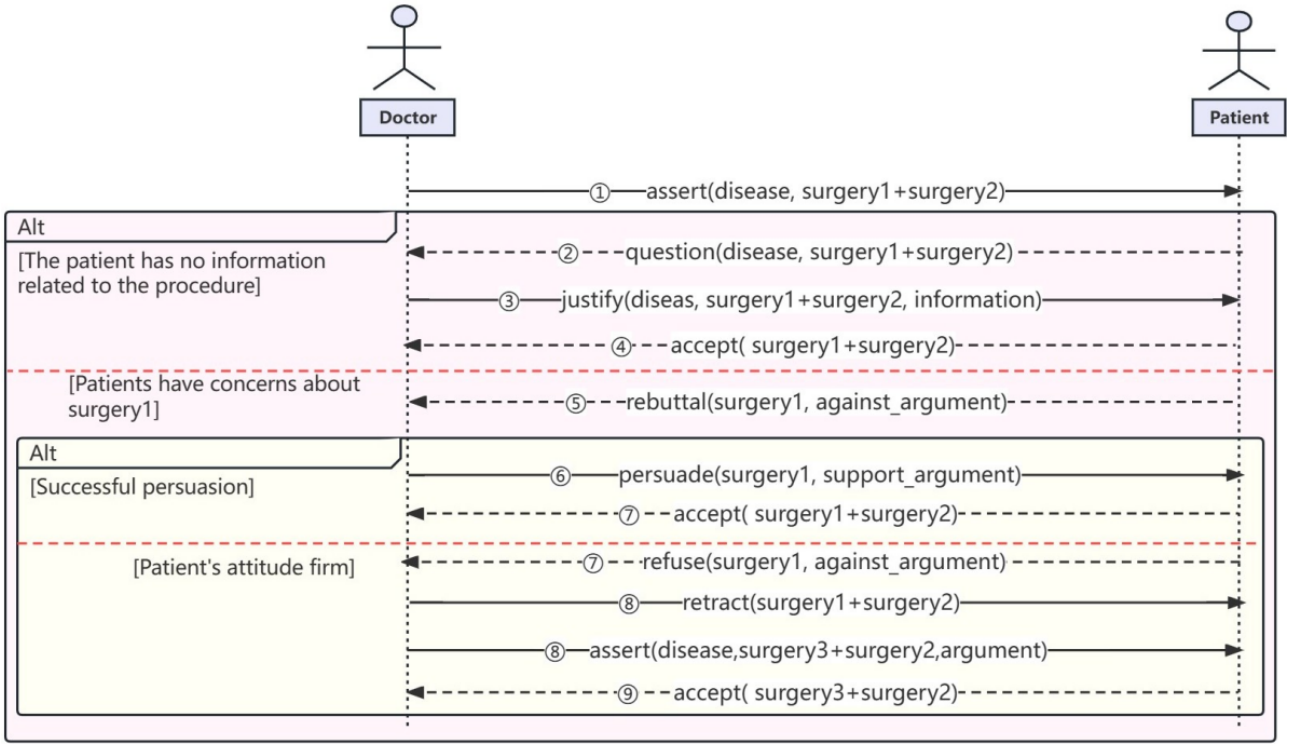
Figure 2. Interaction relationship of speech acts.

XSL•FO
RenderX

Table 1. Legal speech acts interaction pairs that can be constructed and their meanings.

Number	Speech acts interaction	Description
1	*Assert-accept*	The agent that receives the assertion message evaluates that the assertion is reasonable and feasible, and then sends an acceptance message to explicitly express its agreement with the assertion.
2	*Assert-refuse*	When a proxy receives an assertion message, if it cannot accept the assertion result, it sends a rejection message to explicitly indicate that it does not accept the assertion.
3	*Assert-question*	The agent that receives the assertion message further explores the rationality of the assertion by sending a challenge message.
4	*Assert-rebuttal*	The agent that receives the assertion message sends a rebuttal message if it disagrees with the assertion.
5	*Refuse-retract + assert*	An agent that receives a rejection message should withdraw its previous assertion and choose whether to send a new assertion based on the current alternatives.
6	*Question-justify*	An agent that receives a challenge message should send a confirmation message containing supporting arguments to alleviate the agent's challenge.
7	*Justify-question*	When a confirming message is received but doubts remain unresolved, further inquiries or questions can be sent to obtain a more comprehensive understanding.
8	*Justify-rebuttal*	The agent that receives the confirmation message sends a rebuttal message if it disagrees with the supporting information.
9	*Rebuttal-persuade*	The agent that receives the rebuttal message sends a persuasive message to try to change the other party's mind and guide the other party to accept its assertion.
10	*Persuade-question*	When an agent that receives a persuasion message has doubts about the persuasion argument provided, they may send a questioning message.
11	*Persuade-accept*	An agent that receives a persuasion message and believes that the persuasive argument provided is valid will send an acceptance message indicating that it has been persuaded and agrees to accept the assertion issued.
12	*Persuade-refuse*	An agent that receives a persuasion message and deems the provided persuasive argument to be invalid sends a rejection message indicating that it is not persuaded and refuses to accept the assertion issued.
13	*Justify-accept*	After evaluating the received confirmation message and finding no objection, the agent sends an acceptance message to explicitly indicate its agreement with the assertion.
14	*Justify-refuse*	When an agent evaluates a confirmation message and still cannot accept its contents, it will send a rejection message to explicitly convey that it does not accept the assertion.

An Interactive Model of Shared Decision-Making Between Doctors and Patients



Doctor-patient SDM involves collaborative communication and negotiation between health care providers and patients to reach a consensus on the most suitable treatment plan. To establish a standardized framework for their interaction, we introduce a generic interaction model that outlines the specific flow of this process, as shown in Figure 3. This model serves as a valuable tool for understanding and analyzing the dynamics of doctor-patient SDM, supporting the implementation of consistent and effective practices in health care settings.

- Assert(disease, surgery1 + surgery2): The physician sends an assertive message to the patient, outlining the disease and proposed treatment plan.
- Question(disease, surgery1 + surgery2): After receiving the assertive message from the physician, if the patient seeks further clarification, they send a questioning message to the physician.
- Justify(disease, surgery1 + surgery2, information): Upon receiving the questioning message, the physician sends a confirming message with supporting information in response.
- Accept(surgery1 + surgery2): After receiving the confirming message, the patient accepts the physician's proposed treatment plan.
- Rebuttal(surgery1, against argument): If the patient is dissatisfied with a particular surgery, they express their concerns by sending a rebuttal message, outlining the reasons for their opposition.
- Persuade(surgery1, support argument): Upon receiving the patient's rebuttal, the physician engages in persuasion by offering supportive arguments and explanations to address the patient's concerns.
- Accept(surgery1 + surgery2)/Refuse(surgery1 + surgery2): If the persuasion is successful, the patient accepts the physician's assertion and agrees to the proposed treatment plan. However, if the patient remains unconvinced, they may refuse the assertion.
- Retract(surgery1 + surgery2) and Assert(disease, surgery3 + surgery2): If rejected, the physician retracts the previous assertion and sends a new assertive message, offering an alternative treatment plan to address the patient's concerns.
- Accept(surgery3 + surgery2): The patient carefully considers the new treatment plan and ultimately accepts it as the revised course of action.

XSL•FO
RenderX

The determination of a treatment plan is not solely the doctor's decision; the patient is also involved in the decision-making process. After communication and negotiation between the physician and the patient, the most suitable treatment plan is ultimately decided. Based on this process, we have categorized and modeled the different states held by both doctors and patients regarding the same treatment plan, as outlined below.

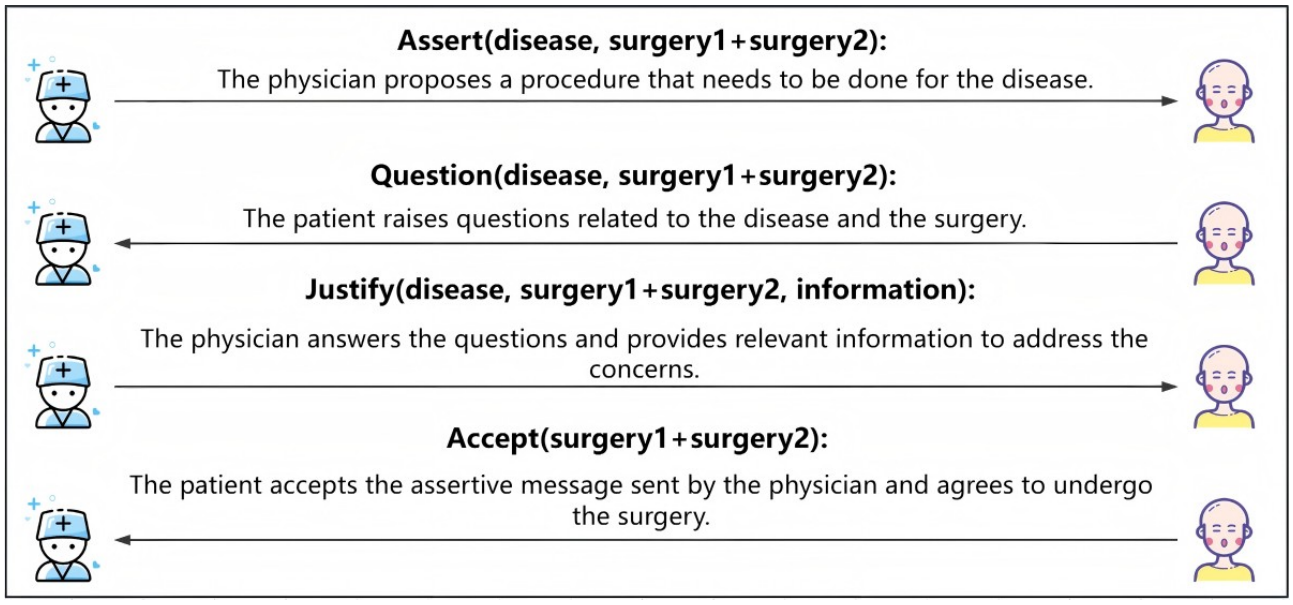


Figure 3. Generic interaction timing diagram for patient-provider shared decision-making.

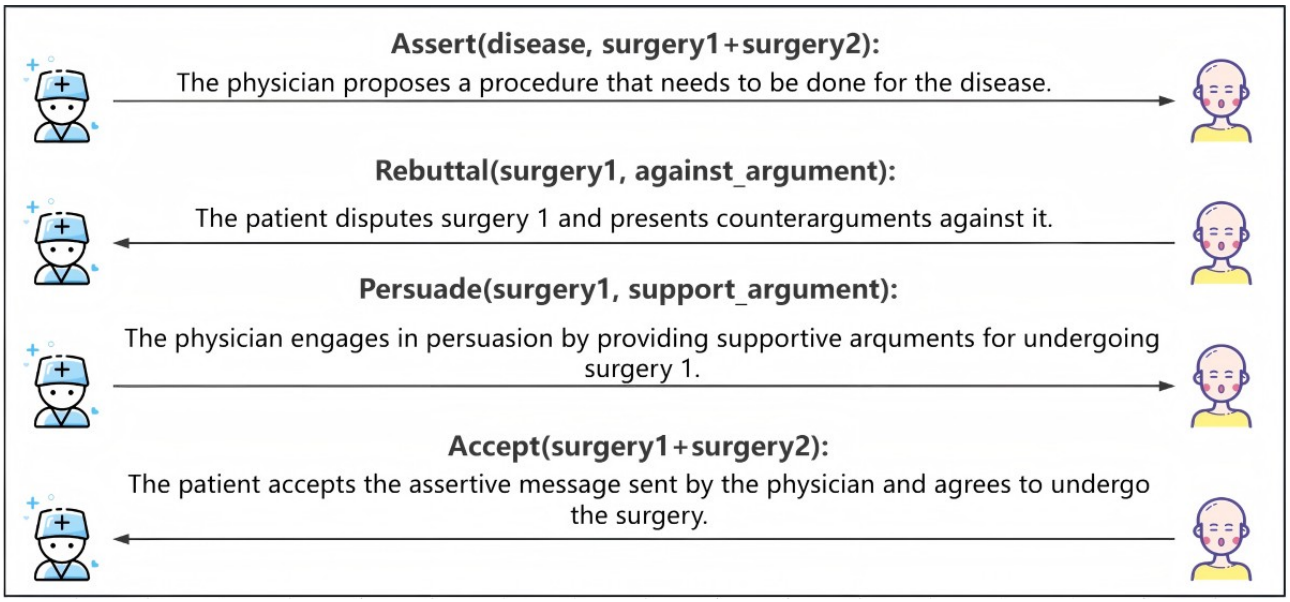
Direct Acceptance Without Consultation

The physician conducts a thorough diagnosis, identifies the specific disease, and proposes a comprehensive treatment plan along with relevant information. After receiving this information, patients who may lack sufficient knowledge about the disease and treatment options may request additional details. As a result, the patient asks a series of questions to seek clarification and further explanation from the physician regarding the information provided. Throughout the communication process, the patient gradually gains a better understanding of the disease and treatment options. Eventually, the patient fully accepts the physician's advice. To describe this process and capture the dynamics of the interaction, we use speech acts to represent the types of messages exchanged during the interaction. As shown in Figure 4, the relevant parameters for each type of interaction and their interpretations are clearly indicated.

Figure 4. Definition of parameters and interaction processes in speech acts.



XSL•FO
RenderX

Patient Has Concerns and Agrees After Consultation

The patient opposes the treatment plan proposed by the physician. When the physician presents the treatment plan, the patient directly refutes it. Upon receiving the patient's objection, the physician, considering the treatment plan as a whole, explains its benefits in an attempt to persuade the patient. Ultimately, after the physician's persuasion, the patient changes their attitude and accepts the proposed treatment plan. The corresponding interaction types and parameter definitions are shown in Figure 5.

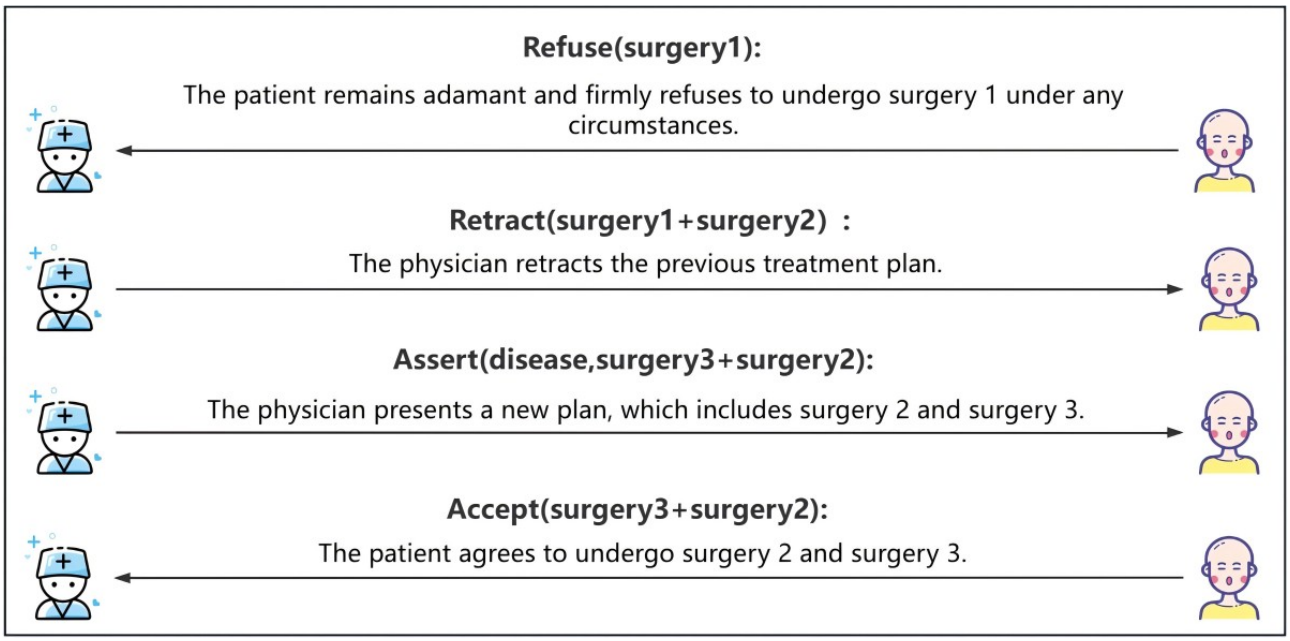


Figure 5. Definition of parameters and interaction processes in speech acts.

Patient Had Concerns and Altered the Treatment Plan After Consultation

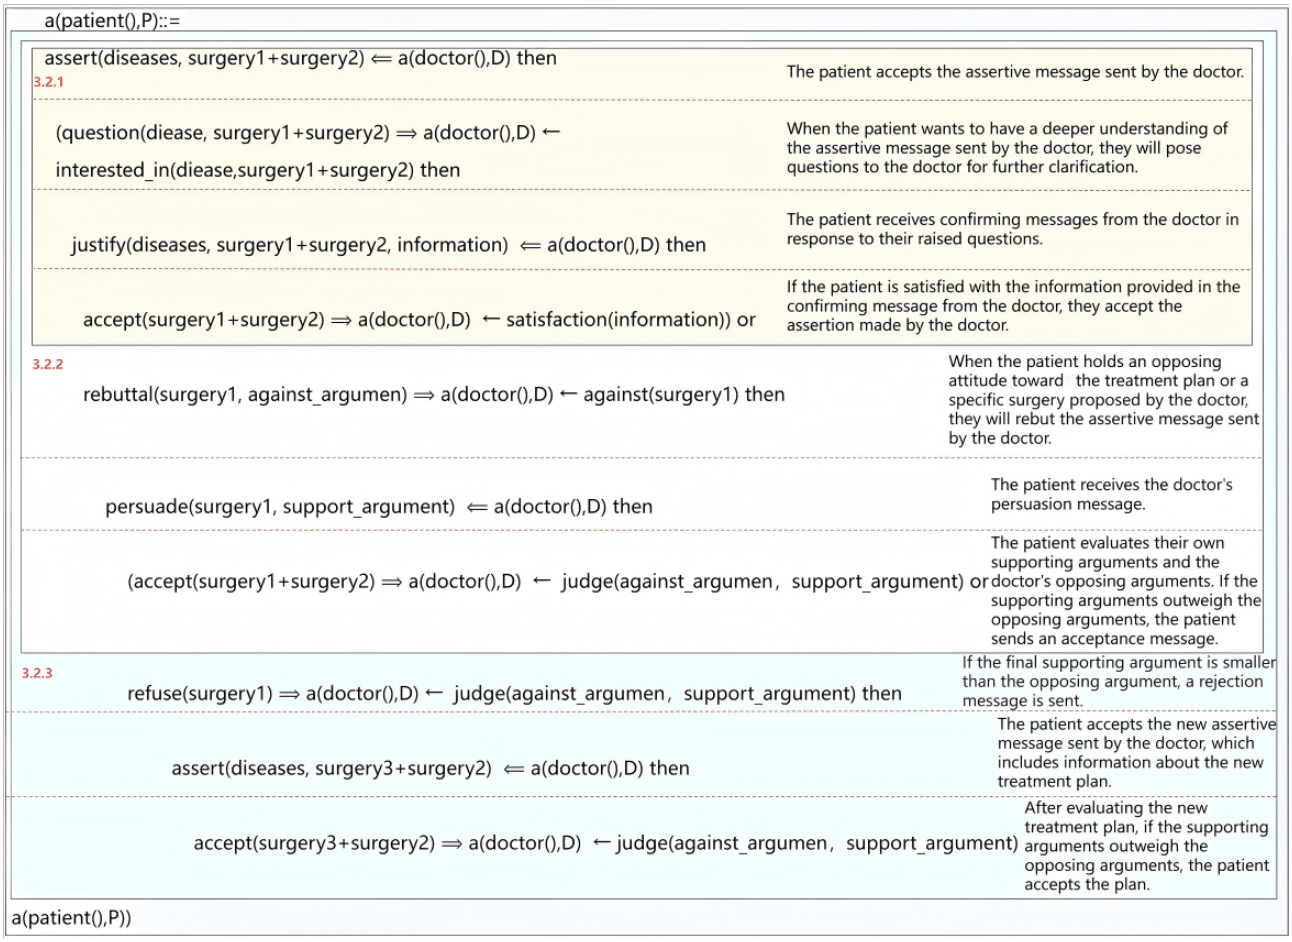
Similar to the previous scenario, the patient expresses opposition to the treatment plan, and the physician attempts to persuade them. However, by contrast, the patient maintains a firm stance, refusing to change their position despite the physician's persuasion. As a result, the physician proposes a new treatment plan, which the patient ultimately accepts. Figure 6 illustrates the interaction definition for the scenario of unsuccessful persuasion, omitting the parts identical to Figure 5 and focusing on the section related to the unsuccessful persuasion.

Figure 6. Definition of parameters and interaction processes in speech acts.

Protocol Specification Using Collaborative Decision Description Language(CoDeL)

By integrating the 3 interaction models for patient-physician SDM, as detailed in the "LSC-Based Decision-Making Protocol" section, we have developed a robust and comprehensive protocol that enhances both interpretability and applicability. The resulting protocols, shown in Figures 7 and 8, define the doctor-patient interaction process, respectively. Within this protocol, there are 2 distinct roles: the "doctor" and the

XSL•FO
RenderX



"patient." These roles are explicitly defined using "a(doctor(), D)" and "a(patient(), P)." To enhance comprehension and maintain consistency, we assign unique identities to each role, represented by the symbols "D" and "P." To provide a comprehensive understanding of the protocol, we carefully explain each sentence, thoroughly examining and clarifying the constraints embedded within it. These constraints, which define the boundaries and requirements of the protocol, are extensively detailed in the "An Interactive Model of Shared Decision-Making Between Doctors and Patients" section of the documentation. To build a comprehensive interaction protocol, we integrate the 3 interaction models defined in the "Syntactic and Semantics of Collaborative Decision Languages (CoDeL)" section, as shown in Figure 8. Each color-coded segment in the figure corresponds to its respective interaction model. By combining these models, we create an overarching framework that encompasses all aspects of the interaction process, facilitating structured and standardized methods of communication and decision-making among the parties involved.

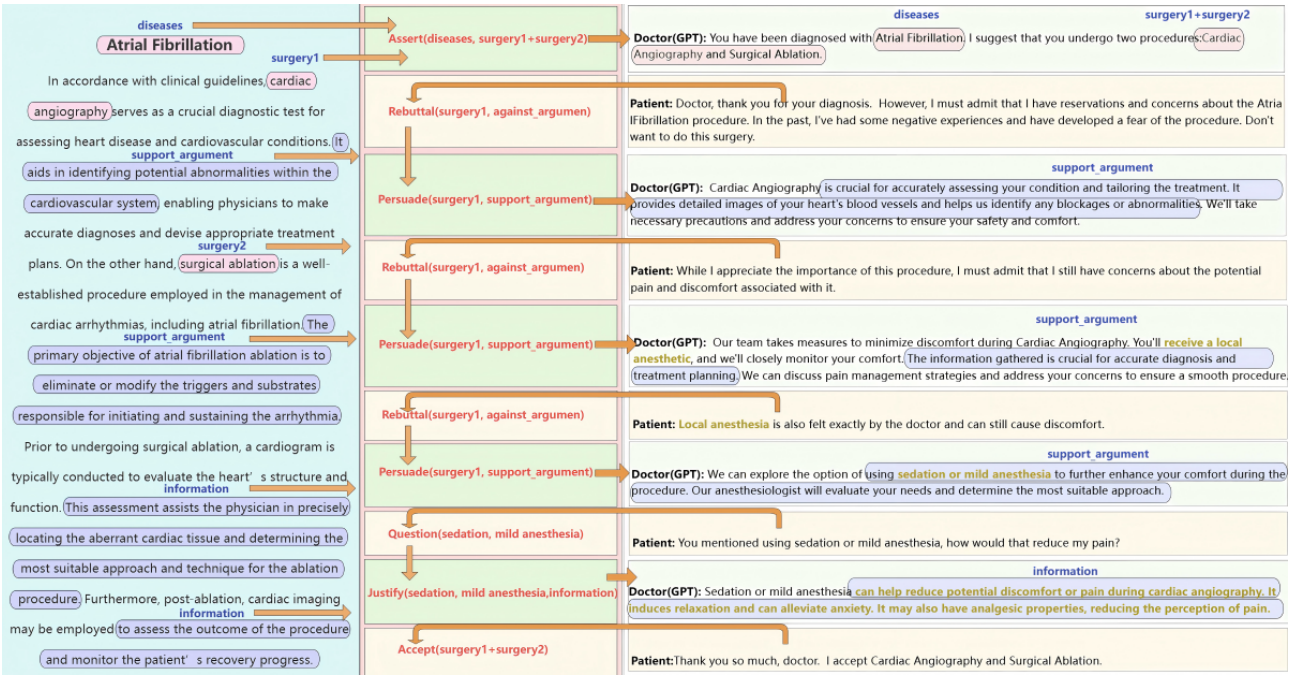
Figure 7. Definition of physician interaction protocol.

a(doctor(),D)::= assert(diseases, surgery1+surgery2) ⟹ a(patient(),P← check(disease) then	Upon meeting the diagnostic criteria for a specific disease, the doctor proceeds to communicate the disease and the treatment plan he has formulated to the patient through an assertion message.
justify(diseases, surgery1+surgery2, information) ⟹ a(patient(),P) ← receive(question(diseases, surgery1+surgery2), a(patient(),P)) then	When the doctor receives a questioning message from the patient, the doctor will respond with a confirming message, providing explanations to address the raised concerns. "Information" is the doctor's confirming evidence in response to the patient's inquiries.
(accept(surgery1+surgery2) ⟸ a(patient(),P) or	Waiting for the patient's acceptance message.
persuade(surgery1, support_argument) ⟹ a(patient(),P) ← receive(rebuttal(surgery1, against_argumen), a(patient(),P))) then	When receiving the patient's rebuttal message, the doctor will engage in persuasion with the patient. "support_argument" refers to the supportive arguments the doctor uses to persuade the patient.
(accept(surgery1+surgery2) ⟸ a(patient(),P) or	Waiting for the patient's acceptance message.
assert(diseases, surgery3+surgery2) ⟹ a(patient(),P) ← receive(refuse(surgery1), a(patient(),P))) then	When receiving the patient's refusal message, the doctor will present a new assertive message. "Surgery3+surgery2" represents the new treatment plan proposed by the doctor.
accept(surgery3+surgery2) ⟸ a(patient(),P) a(doctor(),D)	Waiting for the patient's acceptance message.

XSL•FO
RenderX

Figure 8. Definition of patient interaction protocol.

Argumentation Driven by Clinical Guidelines



The CoDeL framework facilitates dynamic decision-making between doctors and patients through natural language interactions. Throughout this process, the system continuously integrates and updates clinical guidelines and other relevant information to inform its decisions.

To illustrate the operational logic and effects of this pattern, let us consider an example based on clinical guidelines for atrial fibrillation. As shown in Figure 9, the doctor proposes an initial treatment plan (cardiac angiography and surgical ablation) through an assertion to the patient. However, rather than merely presenting a decision, the information exchanged between the doctor and patient includes not only the proposed treatment but also the patient's attitude toward it (eg, acceptance, rejection, or hesitation), along with any concerns or doubts they may have regarding the decision. In the figure, the patient raises a rebuttal, opposing cardiac angiography in the treatment plan. CoDeL will then find supporting arguments for cardiac angiography based on the provided clinical guidelines (eg, "This aids in identifying potential abnormalities..."). The doctor can then use this argument to construct their next dialogue, attaching the corresponding *persuade* speech act semantics to it (eg, "Cardiac Angiography is crucial for accurately assessing...").

As doctors and patients engage in interactive conversations, CoDeL identifies specific decision types and searches for relevant arguments to support or refute these decisions. The system considers not only the proposed decisions but also the dynamic attitudes and concerns of both parties, continuously updating its knowledge base with new information. If persuasion fails, the system offers alternative treatment plans based on prior requests. The conversation is considered complete only when CoDeL determines that the patient's decision type has shifted to acceptance, signaling a mutually agreed-upon treatment plan. Throughout this process, clinical guidelines and other relevant knowledge are dynamically integrated into the joint decision-making model, ensuring that both doctors and patients have access to the most up-to-date information.

XSL•FO
RenderX

Figure 9. CoDeL (Collaborative Decision Description Language) framework driven by clinical guidelines in actual scenarios.

The Personality Modeling Included in the Protocol

To capture the dynamics of decision-making and the influence of individual personalities, we have developed a model that incorporates both arguments and personality factors. This model is represented by the following formula:

In this formula, the decision outcome is determined by the interaction between the arguments presented during the discussion and the unique personality traits of each individual involved. In our model, we define 3 basic personality traits, and by setting parameters for personality modeling, we can explain why patients may exhibit different responses of acceptance or rejection, as outlined in the protocol in the "Constraints of Permissible Speech Acts Pairs" section (Textbox 3).

As depicted in Figure 10, both the doctor and the patient have distinct belief sets, denoted as BDset and BPset, respectively. Each interaction involves a collection of supporting arguments (Arg + set) and opposing arguments (Arg – set). Within the context of their belief sets, individuals encounter both external arguments that challenge their beliefs and supporting arguments that reinforce them. To capture the various manifestations of individuals' cognitive personalities in response to judgment, we represent them in the formula mentioned earlier. The belief sets of both the doctor and the patient have a fixed degree, represented by K. Persistency strengthens the Arg + set, with the degree of persistence determined by K1. The higher the K1, the stronger the persistence, making it less likely to change one's view. The extent to which *openness* enhances the Arg – set is determined by K2, indicating that the greater the willingness to accept opposing views, the more likely it is to change one's own. Critical thinking should be determined based on the current evaluation of the argument. If the evaluation tends to support the argument, it will amplify the effect of the Arg + set, as shown in equations (1) and (3). Conversely, if the evaluation leans toward the opposing view, the impact of the Arg – set will be strengthened, as shown in equations (2) and (4). The exact level of influence is determined by K3. By incorporating these factors into the model, a comprehensive framework is established. Using this model, we can gain a deeper understanding and analysis of the dynamics in doctor-patient interactions, considering the influence of individual personalities and their respective arguments. The calculated values of these factors help to more fully and accurately reflect the decision-making process.

The incorporation of persona modeling constraints is essential to our protocol, as it helps to:

- Capture the differentiation of individual personalities and their impact on decision-making.
- Provide a categorized representation of patient responses to doctor-patient interactions.
- Enhance the overall effectiveness of the protocol by considering the unique characteristics of each individual involved.

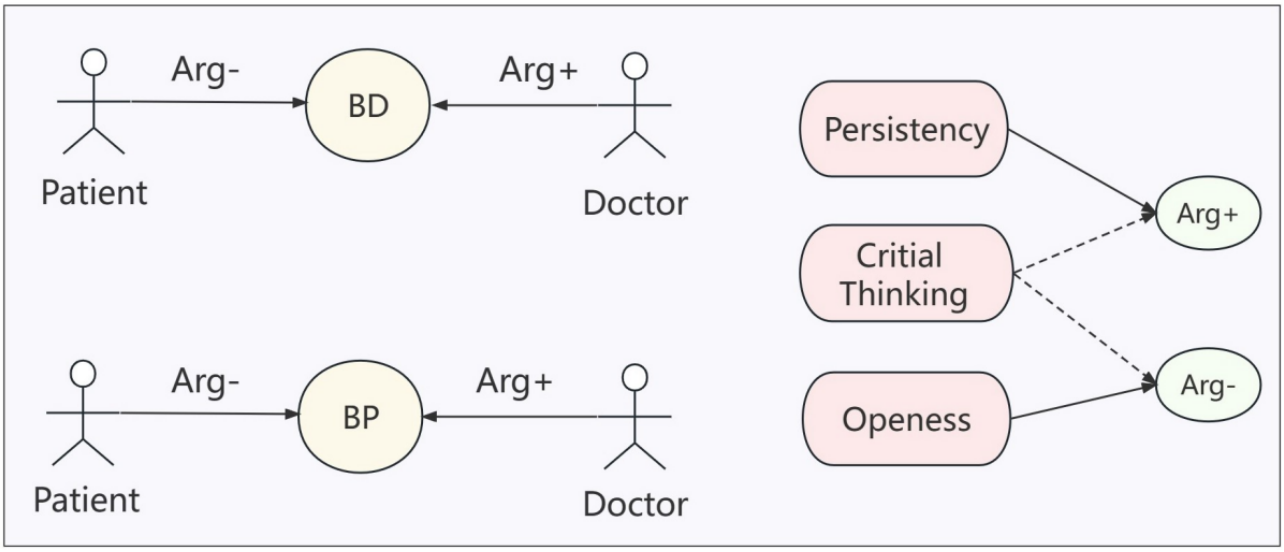
Personality modeling offers a more comprehensive understanding of the decision-making process by incorporating individual personality traits and corresponding arguments. By defining 3 basic personality traits—persistence, critical thinking, and openness—we can capture the dynamics of decision-making and the influence of personality. The model considers the unique traits and corresponding arguments of each individual involved, enabling a deeper understanding of how patients respond to physician persuasion during medical consultations.

XSL•FO
RenderX

Textbox 3. Patient responses.

1. Persistency

Individuals with a persistent personality are characterized by strong beliefs and clear goals. They are determined and resilient, continuing to pursue their objectives despite challenges or obstacles. When confronted with the doctor's persuasion, persistent individuals are less likely to change their beliefs easily and may resist external influence. This persistence often leads them to maintain their original position, resulting in a rejection outcome.



2. Critical thinking

Individuals with a critical thinking personality are adept at evaluating and analyzing information objectively. They approach decision-making with caution and rationality, using logic and reasoning to assess different viewpoints. Critical thinkers actively seek evidence and sound arguments to support their beliefs, and they are vigilant about recognizing biases and errors in the decision-making process. When confronted with persuasion, critical thinkers carefully evaluate the arguments presented, weighing them against their own beliefs. Depending on the strength of the arguments and their alignment with personal reasoning, critical thinkers may either accept or reject the suggestions of others.

3. Openness

Individuals with an open-minded personality are receptive to new ideas and diverse perspectives. They are adaptable and flexible in their beliefs, willing to consider different viewpoints. When faced with persuasion, open individuals are more likely to accept new information and adjust their beliefs accordingly.

Figure 10. The relationship between individual personality and belief.

Ethical Considerations

All procedures performed in this study involving human participants were in accordance with the ethical standards of the institutional and national research committee and with the 1964 Declaration of Helsinki and its later amendments or comparable ethical standards. This study uses the communication process between the knowledgeable person and the doctor as the research support, without any interest relationship, and the informed consent of the other party. Written informed consent has been obtained from participants regarding the release of their individual clinical details.

In accordance with the second provision of Article 32 of the Ethical Review Measures for Life Sciences and Medical Research Involving Humans issued by the National Health Commission of the People's Republic of China, which states that "research using anonymized information data" is exempt from ethical review for non-interventional studies, this study does not require institutional review board approval [32].

Results

This paper aims to explore the medical decision-making process for a patient diagnosed with atrial fibrillation, with the goal of validating the 3 decision models and interaction patterns presented in the "Methods" section (Textbox 4).

To provide a comprehensive understanding of these diagnostic and therapeutic modalities, Table 2 presents a detailed comparison that includes various aspects, such as the alternative of cardiac ultrasound.

In the context of an appeal, the communication between the patient and physician can result in the following possible scenarios:

- David has no further concerns or objections and readily agrees to the proposed solution after fully understanding it. This indicates that the decision-making process was smooth, with no major obstacles or conflicts.
- David expressed reluctance to undergo the cardiac imaging procedure due to the psychological impact of his previous negative experience. However, after effective consultation and discussion with the physician, David was successfully

XSL•FO
RenderX

persuaded and ultimately agreed to proceed with the recommended protocol. This underscores the importance of doctor-patient communication in addressing patients' concerns and alleviating their anxiety to reach a mutual agreement.

- David strongly opposed undergoing cardiac imaging and remained unconvinced despite the physician's attempts to persuade him. In such cases, the physician explores alternative options and proposes a different procedure or diagnosis that aligns with the patient's preferences. This illustrates the flexibility and adaptability of the decision-making process, ensuring the patient's active participation and respect for their autonomy.

To represent these 3 decision-making processes, we apply the generic model outlined in the "LSC-Based Decision-Making Protocol" section, which offers a comprehensive framework for analyzing and understanding the dynamics of SDM between patients and physicians.

Textbox 4. Case description

1. Case

The following case is based on a real-life scenario: David, a 53-year-old individual with a medical history of diabetes and heart disease, has previously undergone cardiac angiography. Recently, he has been experiencing prolonged episodes of heart palpitations, along with temporary episodes of cardiac arrest. To address these issues, he sought medical attention and visited the hospital for a comprehensive examination. Subsequent medical evaluation revealed that David was diagnosed with atrial fibrillation, a common arrhythmia that, if left untreated, can lead to severe complications such as blood clot formation and an increased risk of stroke. As a result, the medical team recommended that David undergo both cardiac angiography and surgical ablation procedures. It is important to note that during his previous treatment, David underwent only a heart angiogram because he was in a city alone without family support. Additionally, he experienced pain during the procedure, which has had a lasting psychological impact on him.

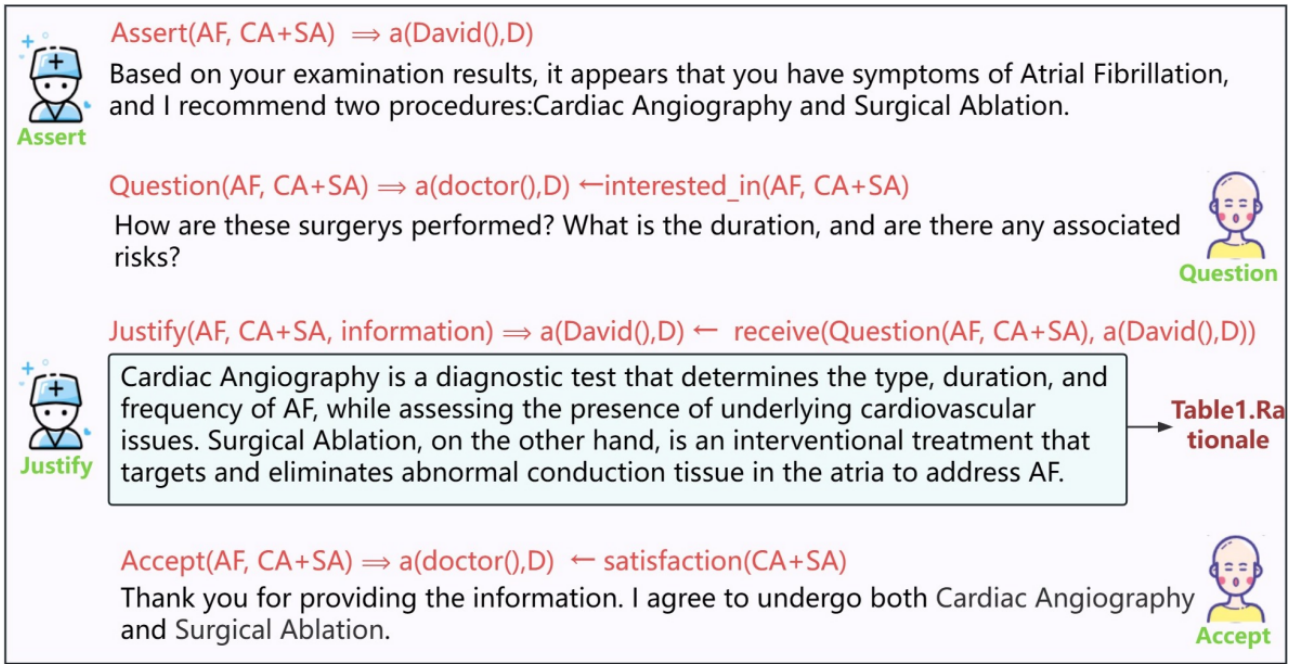
2. Clinical guideline

In accordance with clinical guidelines [33], cardiac angiography is a critical diagnostic tool for evaluating heart disease and other cardiovascular conditions. It helps identify potential abnormalities within the cardiovascular system, allowing physicians to make precise diagnoses and develop appropriate treatment plans. By contrast, surgical ablation is a widely used procedure for managing cardiac arrhythmias, including atrial fibrillation. The main goal of atrial fibrillation ablation is to eliminate or modify the triggers and substrates that initiate and sustain the arrhythmia. Before undergoing surgical ablation, a cardiogram is typically performed to assess the heart's structure and function. This assessment helps the physician accurately identify the abnormal cardiac tissue and determine the most appropriate approach and technique for the ablation procedure. Additionally, after the ablation, cardiac imaging may be used to evaluate the procedure's outcome and monitor the patient's recovery.

Table 2. Information about the surgery involved in the case.

Surgery	Rationale	Support argument (advantages)	Against argument (disadvantages and side effects)
Cardiac angiography	The type, duration, and frequency of atrial fibrillation can be determined, while the presence of potential cardiovascular problems can be assessed.	• Provides detailed information about the structure of the heart. Make an accurate diagnosis. • Helps to plan surgical procedures. • Improves the success rate of surgery and reduces the risk.	• Invasive surgery. • There are potential complications, such as vascular damage, infection, and contrast agent toxicity to the kidney. • Slight pain (which was aggravated by David's last experience). • Vascular injury. • Infection. • Contrast agent toxicity.
Surgical ablation	Interventional therapy to target and eliminate abnormal atrial conduction tissue.	• Effectively restoring normal heart rhythm. • Eliminates arrhythmia symptoms. • Improves the quality of life.	• Invasive surgery. • There is a risk of bleeding, blood clots, and infection. • It may cause pain. • Bleeding and infection.
Cardiac ultrasound	To assess heart structure and function using noninvasive ultrasound imaging.	• Noninvasive procedures. • Provides real-time imaging of the heart. • Helps assess heart function. • Assists in the development of treatment plans.	• Limited ability to visualize certain structures. • It takes expertise to explain it accurately.

David Talked to the Doctor and Accepted the Decision



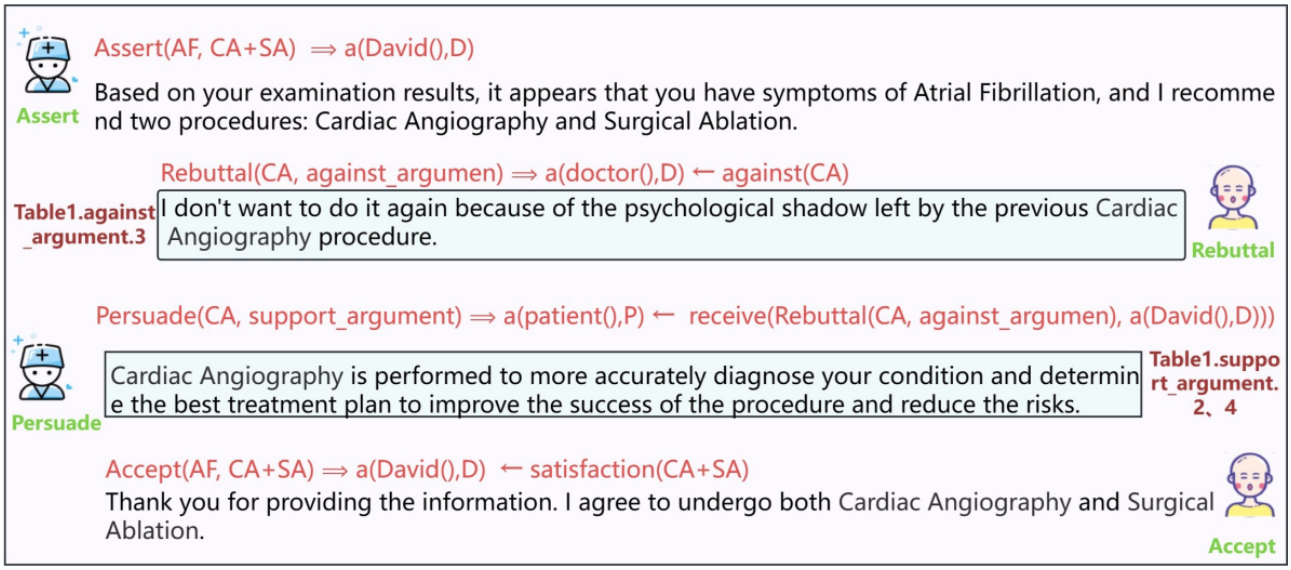
Despite David's previous experience with cardiac angiography and the negative outcome, his determination to address his atrial fibrillation remained strong. To make an informed decision, he actively participated in the communication process outlined in Figure 11. Through effective dialogue with his physician, David sought to gain a comprehensive understanding of the proposed treatment plan. As illustrated in Figure 11, the physician-patient communication followed our defined Collaborative Decision Language (CoDeL), ensuring clear communication and a structured decision-making process.

The doctor initially sends an assertion message recommending a cardiac angiogram and surgical ablation for David's atrial

XSL•FO
RenderX

fibrillation. As David is not familiar with the treatment plan, he responds by asking questions about the 2 procedures. The doctor acknowledges David's questions and provides detailed information, including relevant supporting arguments. After being well-informed, David accepts the doctor's recommendations.

Figure 11. The interaction between the doctor and David and the corresponding CoDeL (Collaborative Decision Description Language).

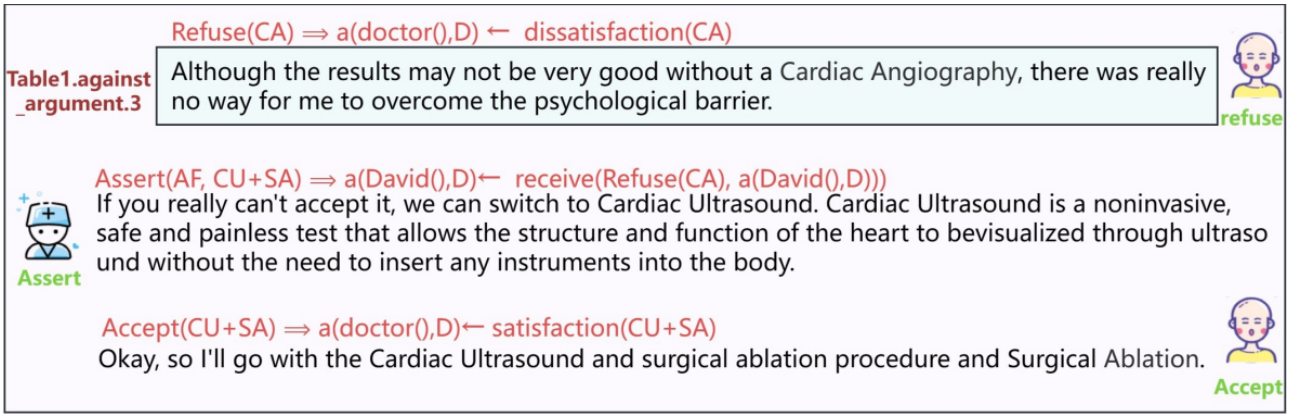


David Has a Concern but Accepts the Decision of the Doctor

Figure 12 presents a concise depiction of the case in which David initially hesitated to undergo the cardiac angiography procedure due to a negative prior experience. However, through the doctor's effective persuasion, David ultimately agreed to proceed with the procedure again.

Initially, the physician delivered an assertive message outlining a comprehensive treatment plan, which included cardiac imaging and surgical ablation for David's atrial fibrillation. Given David's prior experience with cardiac angiography, which had left a lasting impression, he voiced his concerns and objections about the proposed treatment plan. David articulated his reservations, sharing his perspective with the physician. In response to David's rebuttal, the doctor skillfully used persuasive techniques, emphasizing the benefits and advantages of undergoing the cardiac angiography procedure. By carefully explaining the procedure and addressing David's concerns, the doctor successfully persuaded him that the benefits outweighed the potential risks. As a result, David's apprehensions were alleviated, and he ultimately agreed to undergo both cardiac imaging and surgical ablation as part of his treatment plan.

Figure 12. The interaction between the doctor and David and the corresponding CoDeL (Collaborative Decision Description Language).



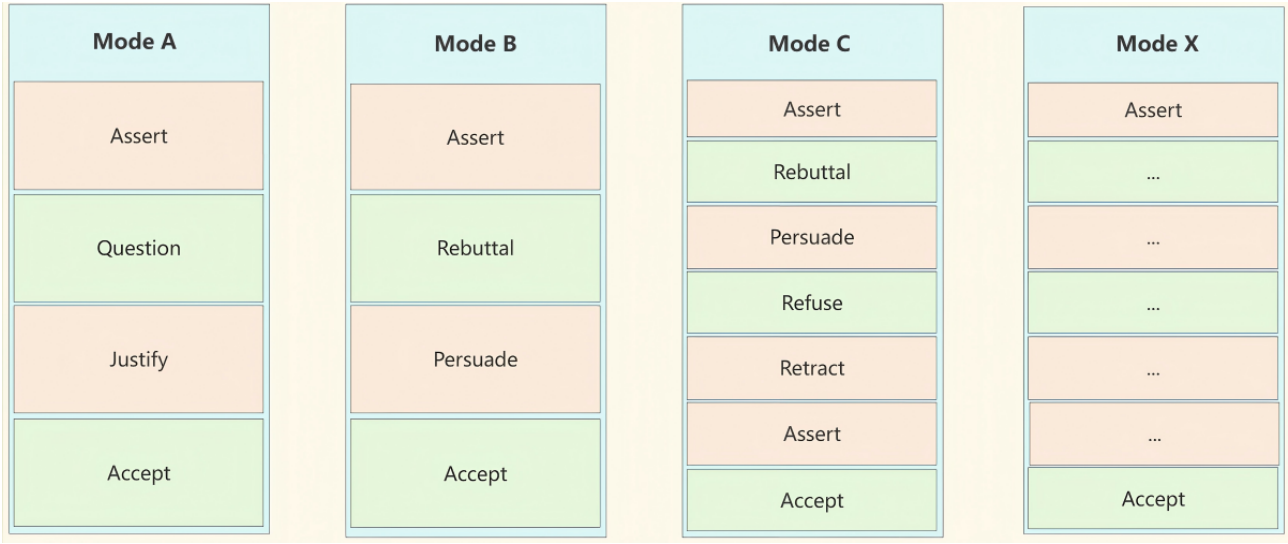
XSL•FO
RenderX

David Had Concerns and the Doctor Accepted His Decision

As described earlier, David expressed a strong aversion to undergoing a cardiac angiogram. However, in this case, despite the doctor's persuasive efforts, David remained resolute and unconvinced, insisting on opposing the procedure. Consequently, the doctor proposed an alternative course of action, suggesting a simultaneous cardiac ultrasound and surgical ablation. Thus, Figure 13 focuses only on the part that was ultimately rejected, which contrasts with the part accepted earlier in Figure 12.

Figure 13. The interaction between the doctor and David and the corresponding CoDeL (Collaborative Decision Description Language).

Findings and Insights From Interactions Between Patients and Physicians With Atrial Fibrillation



In the "David Talked to the Doctor and Accepted the Decision" section, the patient raises questions about the 2 surgical procedures due to insufficient understanding. At this stage, the patient's emotions do not express clear opposition, so the system generates a justification based on the clinical guidelines for these procedures, providing relevant arguments to inform the patient. If the patient accepts the treatment plan, the conversation concludes, and the system generates an acceptance to finalize the decision. This combination of the 4 speech acts can be abstracted and recorded as mode A. However, if the patient opposes the surgery or initially rejects it, as shown in the "David Has a Concern but Accepts the Decision of the Doctor" section, the system will generate a Persuade act, utilizing supporting arguments from the clinical guidelines to advocate for the original treatment plan. If the patient accepts the treatment plan, the conversation concludes and the final decision is established (*accept*). Unlike mode A, we can record these 4 speech acts as mode B. If the patient remains unconvinced by the system and continues to oppose the treatment, the system will replace the opposed treatment plan with an alternative from the clinical guidelines. In the "David Had Concerns and the Doctor Accepted His Decision" section, we observe that the patient repeatedly opposes cardiac angiography, and ultimately, the system replaces it with cardiac ultrasound, generating an *assert* to inquire about the patient's acceptance of the new treatment plan. If the treatment plan is not accepted, the process will repeat until the patient ultimately agrees. This creates a dynamic sequence of multiple speech acts, where the total number of speech acts exceeds those in mode A and mode B. We can categorize this process as mode C.

In essence, a variety of distinct decision modes can be constructed based on the combination of speech acts in dialogues. As shown in Figure 14, each mode is abstracted individually. For example, mode A, which aligns with the decision scenario of addressing patient questions, consists of 4 speech acts: *assert*, *question*, *justify*, and *accept*. Within the CoDeL framework, we can explicitly identify and construct reusable decision modes by dynamically combining different speech acts in specific ways. These modes can be applied to various decision scenarios and adapt to all disease problem domains. This process is flexible and extends beyond the 3 modes identified in this study, referred to as mode X.

In this comprehensive process, our approach emphasizes patient-centered decision-making by adapting to their attitudes and concerns. It devises a treatment plan tailored to their specific worries and needs, ensuring personalized care. Simultaneously, the information and treatment plans provided are guided by clinical guidelines, ensuring transparency and evidence-based reasoning in every interaction. By integrating these elements, our approach ultimately enhances communication between doctors and patients.

XSL•FO
RenderX

Figure 14. Reusable decision modes made up of a various kinds of combination of speech acts.

Validation of the Model for Other Cases

To verify the broad applicability of the CoDeL system, this section will use severe depression as an example to fully demonstrate the medical decision-making process for patients with severe depression (Textbox 5).

Based on the above case information, we will provide a complete demonstration of using the Collaborative Decision Description Language (CoDeL). The communication process is shown in Figure 15. Emily, a patient with major depression, discussed her condition with her doctor. The doctor recommended a treatment plan called CBT + antidepressant, which combines cognitive behavioral therapy (CBT) with antidepressant medication. Emily inquired about the treatment process for CBT and the side effects of the antidepressant medication. The doctor explained the process of CBT and the potential risks of antidepressant medication. However, Emily expressed concerns about the side effects of the medication. The doctor then recommended a selective serotonin reuptake inhibitor, which is generally well-tolerated and considered a safe option. Despite this, Emily remained reluctant to take antidepressants and declined the treatment. As a result, the doctor suggested proceeding with CBT alone, without the addition of antidepressant medication. This cautious choice helps mitigate the potential risks of medication. Ultimately, Emily agreed to the plan, decided to proceed with CBT, and was committed to completing the required homework. This marked a new beginning, with the doctor and Emily working together to address her depression.

Textbox 5. Medical decision-making process for patients with severe depression

1. Case description

Emily, a 28-year-old female, has been experiencing intense sadness and a loss of interest in activities she once enjoyed for the past 6 months. These symptoms have progressively worsened, prompting her to seek medical attention and undergo a comprehensive examination at the hospital. A subsequent psychological evaluation led to a diagnosis of major depressive disorder, a common mental health condition marked by prolonged periods of sadness and disinterest in previously enjoyed activities.

During her hospital visit, Emily expressed feelings of hopelessness and worthlessness. She also reported struggling with sleep issues, including both insomnia and oversleeping. Additionally, she mentioned having difficulty concentrating, remembering things, and making decisions. Emily revealed that she has been isolating herself from friends and family, which has further exacerbated her depression.

2. Clinical guideline

According to clinical guidelines, cognitive behavioral therapy is a type of talking therapy that helps individuals manage problems by changing the way they think and behave. It is most commonly used to treat anxiety and depression, but can also be effective for other mental and physical health issues. By contrast, antidepressants are another treatment option for managing the symptoms of depression. Most people with moderate or severe depression benefit from antidepressants, although not everyone responds the same way. If your general practitioner believes you would benefit from an antidepressant, they will typically prescribe a modern medication known as a selective serotonin reuptake inhibitor. These are as effective as older antidepressants but tend to have fewer side effects, though they can cause nausea, headaches, dry mouth, fatigue, sleep problems, and sexual issues. However, these side effects usually improve over time.

XSL•FO
RenderX

Figure 15. The interaction between the doctor and Emily and the corresponding CoDeL (Collaborative Decision Description Language).

Experiment and Evaluation

By instructing GPT to follow the interaction model when communicating with humans, we assume the role of the patient, while GPT takes on the role of the doctor, simulating a realistic doctor-patient interaction. Figure 16 illustrates the exact content and types of conversations that occur during this communication. In this scenario, patients actively challenge doctors, expressing the need for further information and clarification about treatment plans. In Figure 16, we annotate the parameters generated by GPT according to the interaction pattern we defined. The green-marked font in the figure highlights content that differs from the parameters in the interaction pattern. New concepts in the confirmation messages generated by GPT are introduced, which do not include the disease or the treatment proposed by the doctor. Therefore, we will question GPT and seek confirmation from it.

The patient initially showed an aversion to cardiac angiography surgery, influenced by the psychological impact of past experiences. However, through the doctor's persistence and skillful persuasion, the patient was eventually convinced and agreed to the proposed treatment plan. Throughout the persuasion, the doctor emphasized the numerous benefits of cardiac imaging and offered strategies to alleviate the patient's discomfort during the procedure. It is important to note that in

XSL•FO
RenderX

Figure 17, GPT generates new concepts during the persuasion process, prompting us to question them. In turn, GPT confirms our questions and provides additional information.

As the third situation is similar to the one shown in Figure 17, the main difference is that the patient refuses the doctor's persuasion. Therefore, in the interaction shown in Figure 18, the steps before the rejection are omitted, and the rejection message is presented directly from the beginning. In this conversation, GPT, acting as the doctor, introduced a new alternative option—cardiac computed tomography scan—that we had not previously considered. This novel proposal not only expands the range of available options but also highlights the importance of considering different perspectives in the decision-making process.

In many experiments using only GPT dialogues, we found that without CoDeL language as a dialogue framework, GPT struggled to accurately understand the overall relationship of the patient's intentions within the context. As shown in Figure 19, this is a typical experiment using only GPT dialogues. In the figure, we compare the logical markup in the CoDeL language with the doctor-patient dialogue using only GPT. The upper-right corner of each dialogue shows the logical markup in the CoDeL language, with the logical arguments also circled within the dialogue. At the end of the dialogue, the patient only intended to reject the treatment option of cardiac angiography, but GPT rejected both cardiac angiography and surgical ablation, that is, Assert(diseases, surgery3 + surgery4), and chose other treatment methods. GPT was unable to accurately understand the patient's intentions logically, resulting in output text that lacked coherence and explanatory power.

Discussion

Principal Findings

By engaging in a dialogue with GPT using our approach, we can achieve the following outcomes:

1. Verify the efficacy of our method: The interaction with GPT enables us to test and evaluate the effectiveness of our proposed method in generating meaningful and coherent responses.
2. Enhance the comprehensiveness of our argument: Through dialogue, we can identify gaps or limitations in our argument and address them, thereby improving the overall quality and completeness of our approach.
3. Establish new guidelines for CoDeL: The dialogue with GPT provides an opportunity to propose new agreements or principles for CoDeL (Collaborative Decision Description Language) based on insights gained from the interaction. This contributes to the advancement and refinement of CoDeL as a valuable tool for characterizing collaborative decision-making processes.

By using our method to engage in a dialogue with GPT, we can provide the following benefits for GPT.

1. Enhance interpretability: Through interaction, our method allows GPT to gain a deeper understanding and interpretation of the input text, leading to more accurate and contextually relevant responses. This improves the overall performance and interpretability of GPT.
2. Provide a comprehensive set of interaction modes with personalized capabilities: By utilizing our method, GPT gains access to a diverse range of interaction modes, allowing it to engage in meaningful conversations with users across various scenarios and contexts. This broadens the scope of GPT's capabilities and enhances its versatility as a language model.

Based on the CoDeL method, significant improvements can be observed in the communication between doctors and patients. The actual effects are as follows:

1. Enhanced communication between doctors and patients, supported by the SDM protocol, which includes well-defined speech act semantics and arguments explicitly embedded in the interactive reasoning dialogue processes.
2. More effective elicitation of patient concerns throughout the decision-making process, ensuring the delivery of more personalized decision support and care services. This is particularly evident in the interaction between a patient with atrial fibrillation and their doctor, where CoDeL's implementation encouraged the patient to actively participate in deciding whether to choose cardiac angiography as a treatment plan. This ensured that doctors accurately understood the patient's concerns, preventing errors or unforeseen events caused by insufficient communication.

Conclusions and Future Work

In this study, we explored the semantics of patient-physician collaborative decision-making and the issues of information asymmetry to develop a language framework called CoDeL for describing group decisions. We also defined 3 distinct models of physician-patient decision-making. Both these models and CoDeL are designed to offer a clearer understanding of the communication and decision-making processes between

XSL•FO
RenderX

physicians and patients, ultimately leading to more systematic and standardized methods. The main innovations in this study are found in the following 3 aspects:

- Defined a novel shared clinical decision language that utilizes speech act semantics and arguments to enhance communication between doctors and patients, as well as their interactive reasoning process.
- Demonstrated the applicability of the method using a case study of atrial fibrillation, showing that personalized decision support and care services can be delivered.
- Integrated the shared decision language with GPT to enhance its capabilities in interactive decision-making, allowing GPT-generated arguments to be automatically embedded into the decision protocol instead of being manually extracted from clinical evidence.

Although the proposed CoDeL language framework and its applications have the potential to enhance communication and decision-making between patients and physicians, we acknowledge several limitations that may still exist.

The study's limitations are as follows:

- Our study relies on simulated data, meaning that the CoDeL framework has not yet been validated in real-world clinical scenarios.
- While CoDeL has shown potential in multiple clinical domains, its applicability may be limited in certain specific contexts.

In our future work, we will focus on optimizing the decision-making negotiation language, emphasizing conciseness to achieve more efficient and intuitive communication methods. This will significantly accelerate the decision-making process and facilitate smoother integration in future applications. Specifically, we will actively apply CoDeL in clinical practice, leveraging external knowledge sources as evidence-based support, and conduct rigorous scientific research to ensure accurate clinical decision-making. We also aim to provide a common interaction model and negotiation language for collaborative decision-making between doctors and patients, to accommodate a wider variety of cases and enhance the efficiency of the group decision-making process.

Authors' Contributions

LX proposed the general research direction, and XRG organized and drew charts and was a major contributor to writing the manuscript. All authors read and approved the final manuscript.

Abstract

Background: The volume of digital drug promotion has grown over time, and social media has become a source of information about prescription drugs for many consumers. Pharmaceutical companies currently present risk information about prescription drugs they promote in a variety of ways within and across social media platforms. There is scarce research on consumers' interactions with prescription drug promotion on social media, particularly on which features may facilitate or inhibit consumers' ability to find, review, and comprehend drug information. This is concerning because it is critical for consumers to know and weigh drug benefits and risks to be able to make informed decisions regarding medical treatment.

Objective: We aimed to develop an understanding of the user interface (UI) and user experience (UX) of social media pages and posts created by pharmaceutical companies to promote drugs and how UI or UX design features impact consumers' interactions with drug information.

Methods: We conducted in-person interviews with 54 consumers segmented into groups by device type (laptop or mobile phone), social media platform (Facebook or Instagram), and age. Interviewers asked participants to navigate to and review a series of 4 pages and 3 posts on their assigned device and platform. Interviewers encouraged participants to "think aloud," as they interacted with the stimuli during a brief observation period. Following each observation period, participants were asked probing questions. An analyst reviewed video recordings of the observation periods to abstract quantitative interaction data on whether a participant clicked on or viewed risk information at each location it appeared on each page. Participants' responses were organized in a metamatrix, which we used to conduct thematic analysis.

Results: Observational data revealed that 59% of participants using Facebook and 70% of participants using Instagram viewed risk information in at least 1 possible location on average across all pages tested during the observation period. There was not a single location across the Facebook pages that participants commonly clicked on to view risk information. However, a video with scrolling risk information attracted more views than other features. On Instagram, at least half of the participants consistently clicked on the highlighted story with risk information across the pages. Although thematic analysis showed that most participants were able to identify the official pages and risk information for each drug, auto-scrolling text and text size posed barriers to identification and comprehensive review for some participants. Participants generally found it more difficult to identify the drugs' indications than risks. Participants using Instagram more frequently reported challenges identifying risks and indications compared to those using Facebook.

Conclusions: UI or UX design features can facilitate or pose barriers to users' identification, review, and comprehension of the risk information provided on prescription drugs' social media pages and posts.

Introduction

Background

Pharmaceutical companies are present and active on social media. Their multipurpose use of social media platforms for corporate identity, community management, and paid promotion of their products achieves varying levels of measured success [1]. The health care and pharmaceutical industry in the United States spends a significant amount of money on social media promotion. Between July and November 2020, this industry spent US $198.3 million on Facebook promotion and US $151.5 million on Instagram posts [2]. The size of these expenditures is particularly noteworthy, given that the cost of digital promotion is considerably lower than other mediums (eg, television).

Consumers can use social media to find information about prescription drugs in a variety of ways, including searching for information from pharmaceutical companies, reading reviews and testimonials, and interacting with other consumers. A nationally representative survey of 1744 US adults found that 26% of respondents had seen a prescription drug advertised on social media in the past 3 months, and 9% had watched a video on the web about a prescription drug on a social networking website [3]. Another survey of 1000 US consumers found that 9% used social media to evaluate new treatment options, and 7% used social media to look for reliable information about medication side effects [4]. A systematic review found that consumers use social media as a complement to a physician's treatment, particularly around social, emotional, esteem, network, and information support [5].

Despite these increases in the volume of digital drug promotion, the amount of research on consumers' use of and trust in prescription drug promotion on social media is scarce, particularly on user interface (UI) and user experience (UX) features associated with accurate understanding of product claims and risks. This lack of evidence is problematic, given that the information shared on these platforms could have a large impact on the treatment decisions of consumers. For example, when this information is shared on television, one study found that exposure to prescription drug promotion for as little as 5 minutes increased consumers' intentions to search for medications on the web or switch medications [6]. Another study found that reading a prescription drug promotion on Twitter was associated with college students obtaining a prescription medication without first obtaining a prescription from a doctor [7].

Prescription drug promotion is regulated by the Food and Drug Administration [8]. According to Food and Drug Administration regulations, when drug benefits are promoted, drug risks must also be described to achieve a "fair balance" [9]. Ensuring "fair balance" on an interactive medium like social media—where there could be character space limitations, targeted newsfeed advertisements, and consumer interaction through comments, shares, and likes—is challenging.

Pharmaceutical companies currently present risk information (often referred to as "safety information" in promotion) about the prescription drugs they promote in a variety of ways across social media platforms. For example, companies may use links to provide access to risk information, such as a link to the drug's external website or a link to a PDF file with the full prescribing and medication guide. Risk information is also sometimes conveyed in a featured text post, a scrolling video post, a risk information pop-up, or a highlighted story.

Many pharmaceutical companies place the risk information in multiple places on their social media pages and posts. However, even when this information is displayed in various locations, UI or UX features of social media platforms may still inhibit consumers' ability to find, review, and comprehend the risk information. This is concerning, given that it is critical for consumers to know and weigh drug benefits and risks to be able to make informed decisions regarding their medical treatment.

Study Purpose and Value

With the increasing use of social media for promotions, understanding the UI or UX design and its impact on how consumers interact with the pages and posts created by pharmaceutical companies to promote drugs is becoming increasingly important. Accordingly, we examined how different approaches to presenting information about the risks of promoted drugs on social media pages and posts influence how consumers engage with the content. Specifically, we assessed how consumers' exposure to and perceptions of risk information was influenced by where and how on the social media pages and posts the information was conveyed. Further, we sought to identify differences in experiences and perceptions by user age as well as the type of device being used to access the pages and posts.

Methods

Study Design

We developed our plan and instruments for conducting in-person, one-on-one interviews with a total of 54 individuals based on our research questions and a review of relevant peer-reviewed literature. As shown in Table 1, study participants were segmented based on three criteria: (1) device type, (2) social media platform, and (3) age. For device type, we segmented participants into reviewing stimuli on either a mobile device (an Apple iPhone 6s running iOS 15.8) or a laptop computer (an Acer Aspire E5-571 laptop with a 15.6-inch screen running Windows 10). For social media platform, we segmented participants to review stimuli on either Facebook or Instagram. For age, participants in the Facebook segment were further segmented into either "adults" (18-61 years of age) or "older adults" (62 years of age or older). Participants in the Instagram segment were further segmented into either "younger adults"

XSL•FO
RenderX

(18-24 years of age) or "adults" (25 years of age or older). The different definitions of "adults" for Instagram versus Facebook reflect that users of Instagram are typically younger [10].

Table 1. Sample segmentation by device type used, social media platform used, and age.

	Device type		Social media platform		Age cohort		
	Mobile	Laptop	Facebook	Instagram	18+ years	18-24 years	62+ years
Group 1 (n=9)	✓		✓		✓		
Group 2 (n=9)		✓	✓		✓		
Group 3 (n=9)	✓			✓	✓		
Group 4 (n=9)	✓			✓		✓	
Group 5 (n=9)	✓		✓				✓
Group 6 (n=9)		✓	✓				✓

Recruitment and Screening Process

To recruit participants, we partnered with a marketing research firm with access to a consumer panel with a national population. This firm emailed adult panelists an invitation to participate. Interested panelists clicked on a hyperlink within the invitation to complete a web-based screener to determine eligibility. If deemed eligible by the web-based screener, participants were contacted by phone to complete a more comprehensive screening process.

To be eligible, participants needed to use either Facebook or Instagram 4 or 5 days per week on a smartphone or laptop or desktop. Participants also had to self-report a type 2 diabetes diagnosis by a medical professional to increase the likelihood that participants would be motivated to learn about some of the products included in the stimuli, which would in turn increase the realism and thus how generalizable our study findings are to the real world and everyday life. We encountered difficulties recruiting persons with type 2 diabetes for the 18- to 24-year age group assigned to view Instagram stimuli on mobile devices (group 4) and removed the diabetes requirement for this one group as a result.

Because the interviews were conducted in person, participants needed to be able to drive or otherwise be transported to the study location (a private meeting room in an office setting) in Raleigh, North Carolina. To reduce the risk of bias, we excluded participants who worked in marketing, in the pharmaceutical industry, or for the US Department of Health and Human Services. Individuals who had participated in a focus group or interview-based research study in the previous 3 months were also ineligible to participate.

Ethical Considerations

This study was determined to be exempt under category 2ii (tests, surveys, interviews, or observation) by RTI International's institutional review board (STUDY00022581) on August 14, 2023. Eligible participants were sent a consent form in advance of the interview providing information about the protection of their privacy and the confidentiality of their data. Additionally, the interviewer reviewed the information presented in the consent form before starting each interview and obtained the participant's verbal consent to participate and have their voice and screen interactions recorded. Participants were informed that neither the transcripts produced based on interview recordings nor any reporting of findings would include identifying information. No potential participants declined to consent or dropped out after consenting. Upon completion of each interview, the participant was sent a US $75 incentive in the form of a digital gift card.

Stimuli

We identified existing social media pages and posts created by pharmaceutical companies for the prescription drugs they manufacture. We focused on Facebook and Instagram pages and posts based on use trends and to limit the number of combinations of variables to be assessed [10].

We selected pages and posts about prescription drugs with a mix of indications, including some that were relevant, and possibly familiar, to many of our participants (ie, drugs indicated to treat diabetes) and some that were not (eg, drugs indicated to treat high cholesterol). To avoid endorsing specific products, we have anonymized the stimuli and referred to the pages and posts by numbers (ie, rather than the promoted drugs' brand names).

We began each interview by asking all participants to review the same "baseline" stimuli page for one of the selected prescription drugs not indicated to treat diabetes (with which they were unlikely to be familiar) with the hope that they would have to explore the content in more depth to learn about the indications, risks, and benefits of a drug that are novel to them.

In total, 3 pages and 3 posts for each of the 2 platforms (ie, Facebook and Instagram) served as the remainder of our stimuli. Key characteristics of these pages and posts are shown in Tables 2 and 3, respectively. Working within the confines of selecting only real-life pages and posts, we sought to achieve the best possible variation in stimuli. For instance, for Facebook pages, we sought pages where engagement policies varied (ie, whether consumers were allowed to comment on or react to posts). For posts, we strove for variation in how risk information was shown, such as whether it appeared in static text or scrolling text in a video.

XSL•FO
RenderX

Table 2. Key characteristics of the study stimuli: prescription drug–focused pages on Facebook and Instagram.

Characteristic	Facebook				Instagram			
	Baseline page	Page #1	Page #2	Page #3	Baseline page	Page #1	Page #2	Page #3[a]
Condition	Multiple autoimmune disorders	Diabetes	Diabetes	High cholesterol	Multiple autoimmune disorders	Diabetes	Diabetes	High cholesterol
Audience engagement allowed on posts	No	Yes	No	No	No	Yes	Yes	Unknown (content removed)
Verified account	Yes	Yes	Yes	Yes	Yes	No	No	Yes

[a]We excluded this page from our analysis because all content (except the risk information pinned post and an external link) was deleted from the page between when we selected it and when we started testing. With limited places to click, all participants who viewed this page clicked on the risk information highlighted story.

Table 3. Key characteristics of the study stimuli: prescription drug–focused posts on Facebook and Instagram.

Characteristic	Facebook			Instagram		
	Post #1	Post #2	Post #3	Post #1	Post #2	Post #3
Type of post	Video	Text only	Video	Video	Photo	Video
Condition	Diabetes	Diabetes	High cholesterol	Diabetes	Diabetes	Diabetes
Risk information is included	Yes	Yes	Yes	Yes	Yes	Yes
Post focuses exclusively on risk information	Yes	Yes	No	No	No	No
Risk information is scrolling	Yes (entire frame scrolls)	No	Yes (bottom one-third of video scrolls)	No	N/A[a]	Yes (some information appears in static text with voice-over; additional information scrolls with no voiceover)
Risk information is shown immediately in the video	Yes	N/A	Yes	No	N/A	Yes (a note advises viewer that safety info appears at the end of the video)
Risk information is shown in caption	No	N/A	Only a hyperlink is shown in caption	No	Yes	Yes
Must click “See more” to view all warnings	N/A	N/A	N/A	No	Yes	Yes
Allows comments on posts	No	Yes	No	Yes	Yes	Yes

Data Collection

We conducted 54 in-depth, in-person interviews using a semistructured interview guide during October and November 2023. Each interview lasted approximately an hour and was conducted by 1 of 3 experienced qualitative researchers (PW, KCG, and RLW) employed by an independent, nonprofit research institute.

Based on the participant’s assigned group, the interviewer asked each participant to use the study mobile phone or laptop to navigate to stimuli on the assigned social media platform. A camera was positioned above the phone screen to record the surface of the phone as well as the fingers of the participants and where they were tapping on the phone. For both devices, the screen was shared, recorded, and livestreamed via Zoom (Zoom Video Communications) to enable the other members of the research team to observe.

First, interviewers directed participants to the baseline drug’s page on Facebook or Instagram (depending on the participant’s assigned segment) via the platform’s search function. Using a think-aloud approach, interviewers encouraged participants to narrate their thoughts and feelings on the social media content as they interacted with the study stimuli [11]. The interviewers allowed participants to explore the page and posts on their own for 3 to 5 minutes, which we called the “observation period.” After the observation period, the interviewers asked probing questions.

Second, participants reviewed the 3 subsequent drugs’ pages. Again, the interviewers allowed an observation period for each page before asking probing questions. After participants had looked at all the pages, the interviewers guided participants to navigate to predetermined posts. The interviewers shuffled the order of the stimuli pages and posts to be reviewed between interviews (with the exception of the baseline stimuli page) so that the sequence was sufficiently random to prevent order effects.

XSL•FO
RenderX

Quantitative Analysis

After data collection was complete, an analyst watched the video recordings of the screenshare to abstract interaction data collected during the observation period. We only abstracted interaction data from the observation period, given that this was the only time participants were able to freely explore the pages on their own.

Because risk information could appear in multiple locations, we identified all locations within each of the stimuli where risk information was displayed or linked before beginning data abstraction. Locations varied greatly across stimuli and included approaches such as links to PDFs, videos that displayed risk information, and posts with static written risk information.

During data abstraction, the analyst recorded whether a participant clicked on or viewed risk information at each location. We calculated the following metrics:

- Ever attentive: For a given drug's social media page, risk information could be shown in multiple locations. "Ever attentive" is the percentage of participants who viewed the risk information for a given drug's page in at least 1 of those locations during the observation period. For example, 10% ever attentive means that 10% of participants viewed risk information in at least 1 location for a given drug's page. This metric helped us determine whether consumers see and engage with information about risks.
- Locations viewed: This metric is more granular and helps us understand the exact locations participants viewed the risk information. "Locations viewed" is the percentage of participants who viewed risk information at a particular location or feature. This could have involved actively clicking on a link or been more passive, such as having the risk information appear upon scrolling down. This metric helped us identify the features or characteristics of the platform associated with consumers' review of risk information.

When abstracting data, we did not code the participant's interactions with social media content for the final page that they reviewed. We opted for this approach because we noticed that most participants learned over the course of the interview that we would be asking them about the drugs' risk information and began proactively seeking this information upon switching to a new stimulus in preparation to answer our questions. Similarly, we did not code participants' interactions with the predetermined posts that participants navigated to after reviewing the final page.

Qualitative Analysis

During each interview, we entered deidentified participant responses into a metamatrix that organized responses by participant ID, interview topic, and segment (ie, device type, platform, and user age). We selected a metamatrix approach because this usability study used interview notes (which were most efficiently captured in Microsoft Excel by notetakers) as our unit of analysis (ie, vs using the transcripts themselves). Unlike the transcripts, the notes captured observational data reflecting what notetakers saw when the user interacted with the pages and posts (eg, the user scrolled past relevant information or clicked around to locate information). The metamatrix enabled us to see multiple participant answers across a single topic and question, which facilitated the identification of themes or consistencies in responses [12].

Following data collection, 3 analysts conducted a thematic analysis to identify commonalities and patterns and to summarize the findings for all pages and posts [13]. Organizing the matrix by segment facilitated the identification of any differences between the segments. Given the sample size and the fact that participant responses were not formally coded using computer software, qualitative themes were not associated with participant counts. A general sense of magnitude is included by describing what portion of participants mentioned each theme (eg, most participants, many participants, and a few participants) [14,15].

Results

Participant Characteristics

The 54 consumers who participated in interviews were reasonably varied with regard to demographic characteristics. Most study participants self-identified as male (n=33, 61%). Of the 36 participants assigned to view Facebook stimuli, 44% (n=16) were in the "adult" segment (18-61 years of age), and 56% (n=20) were considered "older adults" (62 years of age or older). The 18 participants assigned to view Instagram stimuli were evenly split into the "younger adult" (18-24 years of age) and "adult" (25 years of age or older) segments. The mean age for participants viewing Facebook stimuli (60.1, SD 12.16 years) was approximately 22 years older than the mean age for participants viewing Instagram stimuli (38.1, SD 18.05 years). Most of the participants were White (n=39, 72%), and nearly one-fourth (n=13, 24%) were Black or African American. Finally, most participants held an undergraduate or postgraduate degree (n=32, 60%).

Key Quantitative Findings

Results of the analysis of our quantitative, observational data are presented for each of the 2 metrics described in our quantitative analysis methods earlier (ie, ever attentive and locations viewed) and further organized by platform. Differences by device type have been noted as appropriate.

Ever Attentive to Risk Information

Facebook

On average, across all the drugs' pages that we tested on Facebook, 59% of participants were ever attentive to risk information during the observation period (Table 4). Of interest, a higher proportion of the participants using the laptop (72%) were attentive to risk information compared to less than half of the participants using the mobile phone (46%).

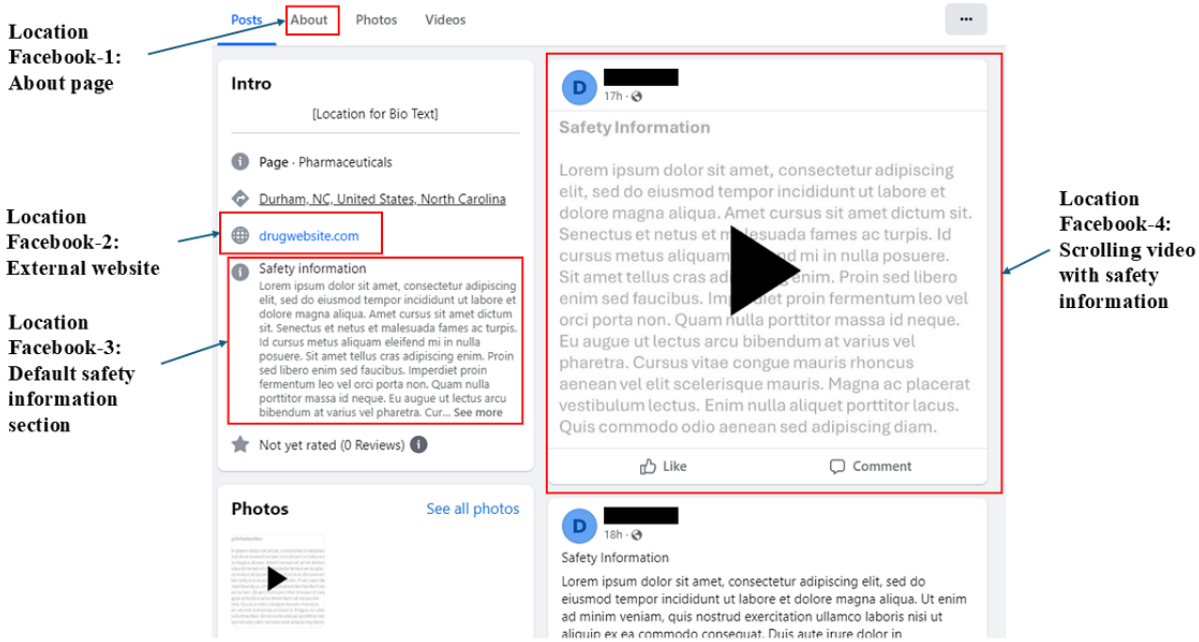
XSL•FO
RenderX

Table 4. Participants who were ever attentive to risk information by platform, device, and prescription drug page.

Platform and device	Baseline page, n (%)	Page #1, n (%)	Page #2, n (%)	Page #3, n (%)	Average (%) (SD)
Facebook					
Overall	18 (50)	15 (71)	19 (63)	11 (55)	59 (3.99)
Laptop	10 (56)	8 (80)	12 (86)	8 (73)	72 (5.62)
Mobile	8 (44)	7 (64)	7 (44)	3 (33)	46 (5.59)
Instagram					
Mobile	18 (67)	14 (79)	15 (67)	N/A[a]	70 (3.27)

[a]N/A: not applicable.

Instagram



On average, across all the drugs' pages that we tested on Instagram, 70% of participants were ever attentive to risk information. Notably, a higher proportion of participants (70%) viewing Instagram pages on a mobile phone were ever attentive to information about risks as compared to Facebook mobile (46%).

Risk Information of Locations Viewed

Facebook

Each Facebook page we tested had nuances in how and where the pharmaceutical company presented risk information, making it difficult to summarize commonalities and differences among them. We did, however, observe 4 common locations where pharmaceutical companies displayed risk information on Facebook (Figure 1).

Figure 1. Common locations of risk information on Facebook pages about prescription drugs (as it appears on a laptop).

- Location Facebook-1: "About" page. This page was accessed by clicking on "About" from the "Posts" page. If a page is set up as a "Pharmaceuticals" page, Facebook automatically gives the page creator the ability to activate a "Safety Information" section on the "About" page. Risk information was frequently placed here, although it is not required by Facebook.
- Location Facebook-2: external website. On the "Posts" page, pharmaceutical companies often included a link to their drug's external website. Companies frequently display risk information at the bottom of their external website landing page.
- Location Facebook-3: default "Safety Information" section in the introduction pane. By default, once a pharmaceutical company adds the "Safety Information" section to the "About" page, Facebook then adds a section entitled "Safety Information" to the introduction pane on the "Posts" page. All text that is added in location Facebook-1 is automatically duplicated here. If a participant clicks "See More," a pop-up will appear with the full text.
- Location Facebook-4: scrolling video. Pharmaceutical companies frequently create videos of scrolling textual risk information.

XSL•FO
RenderX

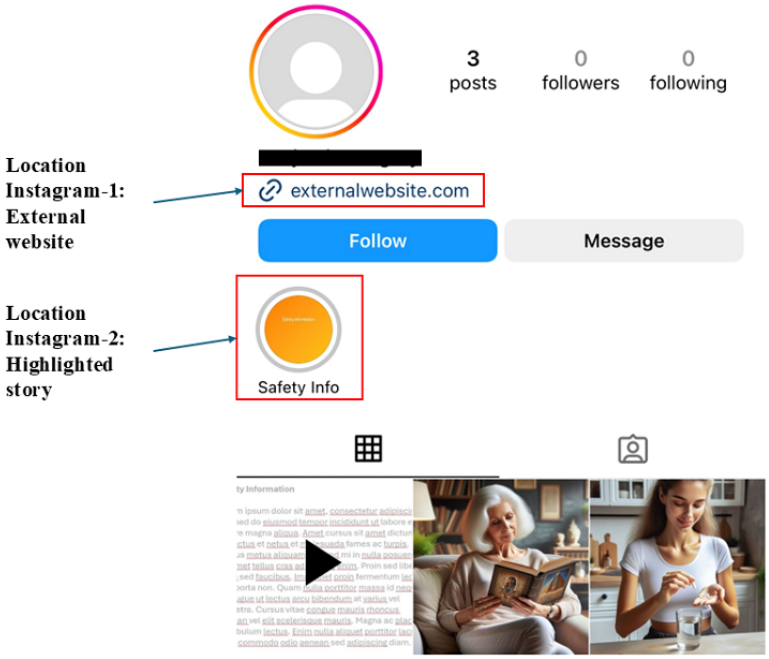
We expected location Facebook-3—the "Safety Information" section in the introduction pane—to have a consistently high level of engagement because it is clearly labeled, but we were surprised to find a wide range in the proportion of participants who viewed it across the drugs (Table 5).

A video with scrolling risk information seemed to be the location most often viewed with risk information. For Facebook on a laptop, at least 40% (n=4) of participants consistently viewed risk information when it was presented in a scrolling video, potentially because the motion caught their attention. On the other hand, the percentage of participants who viewed the scrolling video on the mobile device was lower across the 3 pages using this approach (between n=2, 11% and n=4, 36%).

We found that if 2 or more links to external websites were presented together, participants often only clicked the first link. For example, in situations where links to the full prescribing information and risk information appeared one after another, participants who engaged with either link would always click the first one, but not the second. Furthermore, when the link went to the full prescribing information, participants did not find the risk information or medication guide in the PDF.

Table 5. Participants who viewed risk information on Facebook and Instagram by common location on prescription drug–focused pages.

Location and device	Baseline page, n (%)	Page #1, n (%)	Page #2, n (%)	Page #3, n (%)
Facebook				
Location Facebook-1: "About" page				
Laptop	N/A[a]	2 (20)	3 (25)	0 (0)
Mobile	N/A	2 (18)	1 (6)	1 (11)
Location Facebook-2: external website				
Laptop	2 (11)	0 (0)	3 (25)	5 (45)
Mobile	6 (33)	3 (27)	5 (31)	3 (33)
Location Facebook-3: default "Safety Information" section in the introduction pane of the "Posts" page				
Laptop	N/A	2 (20)	8 (67)	1 (9)
Mobile	N/A	1 (9)	8 (50)	0 (0)
Location Facebook-4: scrolling video				
Laptop	10 (56)	4 (40)	N/A	6 (55)
Mobile	2 (11)	4 (36)	N/A	3 (33)
Instagram				
Location Instagram-1: external website link				
Mobile	9 (50)	4 (27)	8 (57)	N/A
Location Instagram-2: highlighted story with risk information				
Mobile	9 (50)	9 (60)	7 (50)	N/A



[a]N/A: not applicable.

Instagram

Unlike Facebook, Instagram does not have a reserved section dedicated to risk information. This means that pharmaceutical companies must find alternative ways of displaying risk information. There were 2 main locations that pharmaceutical companies used to convey this information on the profile page, which is the main page a person reaches when visiting a drug's Instagram page (Figure 2).

XSL•FO
RenderX

Figure 2. Common locations of risk information on Instagram pages about prescription drugs.

- Location Instagram-1: external website. Instagram allows one or more external links to be included on the profile page.
- Location Instagram-2: highlighted story with risk information. Every drug page on Instagram that we tested created a highlighted story with risk information. A highlighted story is a story that is pinned at the top of the page. These stories can have one or more screens.

Location Instagram-2—highlighted stories—was a common place for participants to view risk information. For all 3 drugs' pages, at least half of the participants consistently clicked on the highlighted story with risk information.

Key Qualitative Findings

Results from our analysis of participants' qualitative interview responses are presented by topic: (1) identification of official pages and verified accounts, (2) ease of locating risk information, (3) factors affecting comprehensiveness of review of risk information, and (4) identification of product risks and indications. Quotations illustrating key themes have been included as appropriate.

Identification of Official Pages and Verified Accounts

Regardless of platform, the majority of participants were able to identify the official page for each drug when searching for it without assistance from the interviewer. Some participants reported that they could tell the page was official because they saw a registered trademark symbol. Participants also reported relying on various other indicators such as the presence of a blue checkmark, the number of followers, the number of posts, and the pharmaceutical company's branding (ie, colors and logos). Participants further mentioned noticing details such as the generic name of the drug, external links to pharmaceutical company websites, and specific medical terms (eg, glucagon and insulin). As one participant said, "It has a Linktree, a lot of followers, and they have 420 posts, which makes me think it's official" [Instagram, mobile, adult]. Finally, another sign participants viewing pages on Facebook noticed was the "Pharmaceuticals" page type in the profile.

When asked about the meaning of the blue checkmark next to the drug's name, participants' responses were mixed. Some participants were unsure about its meaning. Others explained that the blue checkmark meant that the page was real and legitimate or that it confirmed that the page's creator is indeed who they say they are. One participant described their interpretation of the checkmark's implications as: "It's not somebody else with their opinion of it; it's more sort of facts about the drug as the drug company sees it based on the negative reactions that the drug companies had, and they've done their studies" [Facebook, mobile, older adult]. Most participants who reported uncertainty about the meaning of the blue checkmark were older adults viewing Facebook pages.

Participants' responses were also mixed about whether an account being verified influenced their level of trust in the information provided on the page. Some participants reported that account verification has no effect on how much they trust the information. Older adults who viewed Facebook pages were more likely to report that an account being verified influenced their trust of the information compared to adults in the younger age segment. Similarly, none of the young adults who viewed Instagram pages reported that the account being verified affected their trust of the information. One participant viewing Instagram stimuli explained their lack of trust in the blue checkmark: "It doesn't seem like an actual verification since you can pay for it!" [Instagram, mobile, adult].

Ease of Locating Risk Information

As participants finished reviewing each page or post, we asked how difficult it was to locate the risk information for the drug.

XSL•FO
RenderX

Participants commonly reported that it was easy to find the risk information because the information appeared in multiple places or near the top of the page or post. One young adult participant viewing Instagram stimuli explained that it was "not hard, just because it was pinned at the top, and typically things that are pinned are most important" [Instagram, mobile]. However, some participants did find the risk information challenging to locate or at least reported that it took more effort to find information on these drug pages than on other types of pages. We noticed frustration when participants clicked on a link where they expected to find patient safety information but instead found the full prescribing information (ie, information intended for a clinical audience). Furthermore, participants noted at times, especially with third-party multilink services, that they had difficulty finding risk and patient-oriented information.

We asked participants to identify ways this important information could be made easier to find. Participants offered multiple ideas, including changing the formatting of the information by using bold, highlighted, colorful, or larger text; applying section headers or other descriptive labels clearly identifying the topic; using pinned or featured posts; adding risk information as an option in the menu bar (Facebook); and including links in additional places.

Factors Affecting Comprehensiveness of Review of Risk Information

After viewing each of 3 consecutive posts on their assigned platform, participants were asked whether they would normally watch or read the entire post. Participants' responses were mixed across platforms and posts. Participants who reported that they would normally watch or read the entire post commonly clarified that it would depend on whether they were interested in the specific drug highlighted in the post. Some participants who reported that they would not watch or read the entire post indicated that they would just skim it for specific information. Of those who said they would skip the post entirely, a few said they would learn about the drug from an information source other than social media (eg, the drug's website and their physician).

We asked participants who viewed the posts on Facebook whether they were more or less likely to read all the information in the post if it was auto-scrolling and whether they would prefer the post to scroll automatically or not. A few participants reported that they preferred scrolling information (and claimed they would be more likely to read it) or that they did not have any preference about scrolling. However, participants more commonly reported being less likely to fully read scrolling risk information because they prefer to read at their own pace or because they found the speed of scrolling or font size of the scrolling information to be less than ideal. Although most participants knew how to pause a scrolling video, they preferred to avoid the need for pausing or rewinding, especially if they were seeking specific pieces of information. One participant who said that they were less likely to read scrolling information explained, "I don't like the scrolling. I want to go at my speed. If I don't have issues with my gallbladder, I want to skip that information. I don't want to read about gallbladder issues" [Facebook, mobile, adult]. Another participant who reacted negatively to scrolling indicated, "When I saw the scrolling, I saw the pace which I thought was too fast and then I thought, is there something else that could help me? And I saw the links ..." [Facebook, computer, older adult].

After viewing all the Instagram posts and their variety of approaches to showing risk information, participants were asked which they were most and least likely to fully read. Of the posts, 2 presented risk information in static text; participants typically reported one of these 2 posts as being the one they were most likely to read fully. Beyond aversions to scrolling, participants also cited the volume and quality of information as well as how concisely it was written, as factors affecting the likelihood that they would fully review it.

Identification of Product Risks and Indications

After reviewing the baseline drug's page, participants were asked if they felt that they knew the drug's risks and indications. Regardless of whether they viewed the page on Facebook or Instagram, most participants were able to locate the drug's risks without any difficulty. Participants commonly demonstrated that they had successfully found the risks by reading several of them aloud. Some participants clarified that they would need to fully review the risk information to feel like they really "knew" the risks. A few acknowledged that they had not reviewed the page very closely when perusing the drug information.

Similarly, when reviewing the subsequent drugs' pages, nearly all participants indicated that they were able to find the risk information easily and felt that they knew the risks of the drugs. We also asked participants to imagine that they were worried about a specific side effect and to explain whether they would know where to look to find this information. Almost all participants demonstrated that they knew where to find information about the specified side effects.

We asked participants what the risks of a given drug were. Instagram users more frequently reported that they did not know the risks compared to Facebook users. Of the participants who reported that they did not feel that they knew, or could easily identify, the drugs' risks, scrolling and small text size were commonly cited as reasons irrespective of platform. One participant viewing Facebook stimuli remarked, "If I could read this little fine print here, it's probably got it all in there" [Computer, older adult]. Other explanations specific to Instagram included the perception that the drug pages were uninformative and issues with risk information being obscured by other page elements.

Participants were also asked if they felt they knew "what the drug is for" (ie, its indications). Overall, participants generally experienced more difficulty finding this information than they had in finding the risks. However, most participants were ultimately successful in identifying the indications or at least in identifying where they could obtain that information. Participants viewing the baseline drug's page on Facebook were often able to identify information about the drug's indications more quickly and easily than participants viewing it on Instagram. That said, participants viewing the pages on Facebook commonly visited the external website to obtain this

XSL•FO
RenderX

information. Participants viewing Instagram stimuli frequently attempted (and failed) to decipher the indications based on posted images. For example, one participant viewing Instagram stimuli noted that "Just looking at the page, I'd say weight loss and energy ... They look like they're on a road trip or rollercoaster, so maybe it's for the heart or something?" [Mobile, young adult].

In addition to the size of the content, other reasons participants provided for not feeling aware of the drug's risks and indications after their review included the perception that the page's information was not sufficiently comprehensive or credible (ie, that it did not mention all relevant risks). Some participants indicated that they would visit the drug's website for details versus relying solely on the information on any social media page. Several participants (a few on each platform) found scrolling to be a barrier to their efforts to read risk information for understanding. One participant viewing Instagram stimuli explained: "I guess you can also click on the safety story, but I would rather click the link because personally I don't like pausing to stop the scrolling post. I'm sure it's slow enough to read, but just a personal preference" [Mobile, young adult]. All participants viewing Facebook pages who voiced frustration with scrolling risk information were older adults.

Discussion

This unique mixed methods usability study addresses a gap in the literature by enhancing our understanding of consumers' interactions with and perceptions of prescription drug information on social media pages and posts created by pharmaceutical companies, which is a topic of growing importance, given recent, substantial increases in the use of social media for drug promotion.

Key Findings and Implications

Observational data revealed that the majority of participants viewed risk information in at least 1 possible location on average across all pages tested during the observation period. However, there was not a single location across the Facebook pages that participants commonly clicked on to view risk information, likely because of high variability in where risk information was located and how it was labeled. Further, we found that the characteristics of the pages themselves can impede efforts to locate and comprehensively review information. With third-party multilink services or when an external link led participants to the full prescribing information, participants did not find the risk information or medication guide. Furthermore, if 2 or more links to an external website were presented together, participants often only clicked the first link even if they subsequently could not find risk information on that website. More consistency across pages and posts may help consumers find drug information.

Although thematic analysis showed that most participants were able to identify the official pages and risk information for each drug, auto-scrolling text and text size posed barriers to identification and comprehensive review for some participants. Participants sometimes reported that risk information was scrolling at a suboptimal speed or presented in a font size that was too small to be read. Occasionally, part of the text was obscured due to inadequate margins. However, a video with scrolling risk information attracted more views than other features. We found that risk information on Facebook pages was consistently viewed more frequently on a laptop than on a mobile device, suggesting that having more screen real estate may make reviewing risk information easier. On Instagram, at least half of the participants consistently clicked on the highlighted story with risk information across the pages. These findings indicate that the layout and formatting of pages and posts can also affect participants' access to drug information.

Prior research has shown that when consumers do successfully find and read the information on pharmaceutical companies' social media pages, an assortment of other issues can come into play that may impede the use of that information, such as a lack of quality or reliability, information overload, and the inability to correctly apply information found on the web to the users' personal health situation [16]. Along these lines, some participants in our study voiced concerns about the clarity, level of detail, and credibility of the safety information they reviewed during our interviews.

Often social media platforms use a symbol, such as a blue checkmark, to indicate that the account is verified or the page is "official." We found that older adults were less aware of the meaning of the blue checkmark compared to younger participants. This could mean that older adults struggle to locate official drug pages, making them potentially at greater risk of consuming incorrect information from unofficial sources. We also found that older adults generally had a harder time reviewing auto-scrolling risk information and were also less likely than younger participants to know how to pause the scrolling. Part of the reason older adults struggled may be that they are less savvy at navigating social media because they use this information source less than their younger counterparts [16-18]. In summary, our study demonstrates that meaningful barriers remain to consumers' effective use of social media as a source of prescription drug risk information. To maximize the potential of social media to effectively convey information about prescription drugs, it is essential that the information be made as easy as possible to find, read, understand, and use.

Strengths and Limitations

This study had several strengths. First, the study's mixed methods nature enabled us to achieve a comprehensive understanding of users' perspectives by synthesizing quantitative observational data with qualitative data from semistructured discussions, follow-ups, and probes while maximizing reliability and validity. Second, this study's sample was on the larger side for an interview-based usability study, and it included a wide range of age groupings to account for generational differences in digital interactions. Given that the majority of US adults now report using or having used some form of social media [19], a truly representative population for this research should encompass all ages. Finally, we implemented multiple measures to ensure that the stimuli had relevance to the study population and that the interactions were as realistic as possible so that we could assess important differences users may experience, as they navigate this sort of content across different platforms or

XSL•FO
RenderX

with different devices. These measures included assigning participants to use the platform and device they typically use for social media, using actual pages and posts current and live at the time of the interview as stimuli, and including stimuli pertinent to the study's target health condition of diabetes.

This study also had some important limitations. First, the set interview length meant that participants were not able to explore on their own for long periods of time. This likely reduced the opportunity for additional possible insights, especially those concerning discoverability. Second, although our sample included adults of all ages, more research is needed with audiences that vary in terms of other sociodemographic characteristics and levels of health literacy. Third, our use of real-life stimuli means that participants could have had prestudy exposure to promotional content for the selected drugs, either on social media or through some other format, such as television advertisements. Finally, it remains unclear how the findings may be applied to other drugs, medical conditions, and social media platforms beyond the small number included in this study.

Future Research

The exploratory nature of the study provides valuable insights into avenues for further research into the UX of those interacting with prescription drug information on social media. Further exploration with participants who have (or care for those with) other health conditions is likely to provide even more insight into consumer engagement with prescription drug promotion on social media. Since this research tested stimuli only on Facebook and Instagram, supplementary research investigating other widely used platforms could also prove valuable for compiling a well-rounded view of UX with prescription drug promotion in social media.

Additionally, the findings of this study could provide a foundation for developing hypotheses testable by other study types. For instance, experimental stimuli could be developed and tailored to manipulate the way in which the same risk information is presented to enable the quantitative assessment of the level of influence on risk recall and comprehension. Quantitative data such as these could facilitate the development of best practices around UI or UX design features, which could in turn help consumers identify and review important information about drugs on social media more easily. This type of study would circumvent some complexities associated with conducting research in the context of the ever-changing and individualized nature of social media.

Conclusions

This study contributes to existing research by examining how consumers interact with, interpret, and react to prescription drug promotion on social media. Our findings identified UI or UX design features (including where and how drug risk information is presented) that facilitate or pose barriers to users' identification, review, and comprehension of the risk information provided on or via prescription drugs' Facebook and Instagram pages and posts. Based on this study's findings, we have identified future research possibilities to further explore consumer experience regarding prescription drug promotion on social media, as the information shared on these platforms could have a large impact on consumers' treatment decisions.

Acknowledgments

Abstract

Background: Individuals in the United States with limited English proficiency (LEP) experience a disproportionate disease burden. Patient portals provide patient education, outreach, and linkage to preventive health services. While patient portals have been found to be effective in facilitating the use of preventive services, they have predominantly engaged well-educated, English-speaking, White populations. There is limited research investigating experiences and beliefs about patient portals among populations with LEP.

Objective: This study aims to explore perceptions, experiences, and beliefs about patient portals among women with LEP.

Methods: We used a qualitative semistructured interview design and recruited a purposive sample of women through diverse methods. The interview guide covered topics including experiences with patient portals, the perceived feasibility and relevance of patient portals, and perceptions of patient portals targeted toward women with LEP for health promotion. The interviews were audio recorded for verbatim transcription and analysis. Each bilingual interviewer reached data saturation after interviewing 12 (43%), 9 (32%), and 7 (25%) Korean-, Spanish-, and Swahili-speaking women, respectively, yielding a total of 28 women in the study.

Results: We identified 4 main themes that were common across all linguistic groups: perceived benefits of patient portals, perceived facilitators of patient portal use, perceived barriers to patient portal use, and preferred features and suggested improvements. *Perceived benefits of patient portals* had 5 subthemes: easier communication with health care providers and health systems, getting connected and staying connected with health systems, easier and efficient access to one's health records over time, staying informed of and engaged with one's health and health management, and better patient engagement in medical visits. Subthemes for *perceived facilitators of patient portal use* were availability of time, widespread use and availability of smartphones and the internet in the United States, family support, and parenthood. Subthemes for *perceived barriers to patient portal use* were limited digital literacy and limited access to technology, LEP, lack of awareness and knowledge about patient portals, and illiteracy. Finally, subthemes for *preferred features and suggested improvements* were expanded language access to accommodate non-English speakers, improved accessibility to health information using graphics and patient education materials, and user onboarding education and technical support. Of note, while most subthemes were shared across all 3 groups, the widespread use and availability of smartphones and the internet in the United States and illiteracy subthemes were unique to Swahili-speaking women.

Conclusions: Women with LEP recognized multiple benefits of patient portals; however, several barriers were also identified. These included limited digital literacy, restricted access to technology, LEP, and illiteracy. Barriers to patient portal use were closely tied to social determinants of health, which are commonly experienced by women with LEP. To expedite the attainment of health equity, it is important to promote access to health resources such as patient portals.

KEYWORDS

patient portal; limited English proficiency; immigrant; women; mobile phone

Introduction

Background

Racial and ethnic minority individuals in the United States, particularly those with limited English proficiency (LEP) [1], experience significant health disparities; for example, despite high incidence rates of cervical cancer, early detection through regular screening remains low among these populations, especially among women with LEP [2-4]. As a result, racial and ethnic minority women often present with more advanced disease stages than non-Hispanic White women [5]. This is largely due to language and cultural barriers, as well as low health literacy, which hinder their ability to navigate the US health system effectively [1].

One of the innovations in health care is the patient portal. Patient portals offer numerous benefits, including access to diagnosis, treatment information, and other health care resources, which empower patients by enhancing their knowledge and autonomy; for example, a recent systematic review of 10 studies on asynchronous patient–health care provider communication through patient portals found that electronic messaging with health care providers was associated with clinical benefits for patients with breast cancer, including improved screening behaviors [6]. Similarly, another systematic review of 24 patient portal interventions revealed that patient portals are generally effective in improving psychological outcomes (eg, health knowledge, self-efficacy, and decision-making), medication adherence, and the use of preventive services [7]. However, the review also noted that most patient portal interventions have predominantly engaged highly educated, English-speaking, White populations, highlighting a gap in research regarding other demographic groups.

While the use of patient portals has increased over the years, it remains most common among individuals with high literacy, high education levels, and those who are White; for instance, an analysis of the 2011-2015 National Health Interview Survey showed a 36% increase in the use of eHealth services (eg, web-based medical appointments, prescription refills, and email communication with health care providers) among immigrants compared to an increase of 53% among individuals born in the United States [8]. Notably, immigrants with LEP were 81% less likely to use these eHealth services (adjusted odds ratio 0.19, 95% CI 0.09-0.42) than those who spoke English proficiently [8].

Objectives

Despite these disparities, little is known about how individuals with LEP perceive health IT, particularly patient portals, in terms of relevance, feasibility, and impact. To address this gap, the goal of this study was to better understand immigrant women's experiences and perceptions regarding patient portals. Immigrant women face more challenges than immigrant men in accessing respectful and culturally competent health care [9]. By focusing on some of the common languages spoken in households in the United States [10]—Korean, Spanish, and Swahili—this study aimed to (1) explore the perspectives and beliefs about patient portals among women with LEP and (2) describe potential barriers and facilitators to their use in meeting these women's needs.

Methods

Design and Sample

We used a qualitative semistructured interview design to describe the experiences and perspectives of women with LEP in using patient portals for health promotion. This approach allows researchers to assess what respondents describe as aspects of their culture that influence their use of technology for health, in their own words and context, without having constrained categories [11]. This is an extremely valuable approach in cross-cultural work with ethnic minority groups, in that the interviewer is free to pursue topics in greater depth and gain better understanding of cultural values and norms concerning a given phenomenon [12].

Participants were eligible if they (1) self-identified as women with LEP (ie, difficulty using English); (2) spoke Korean, Spanish, or Swahili; and (3) were aged ≥18 years. Participants were excluded if they had an acute or terminal condition (eg, life expectancy of <6 mo or cancer treatment within the past 5 y) or if they had either a psychiatric diagnosis (eg, schizophrenia or cognitive impairment) or other conditions that precluded participation in study activities. The study team reached data saturation after interviewing 12 (43%), 9 (32%), and 7 (25%) Korean-, Spanish-, and Swahili-speaking women, respectively, yielding a total of 28 women with LEP in the study.

Procedures

Given that the study sample involved diverse linguistic and cultural groups of women with LEP, the study team included trained bilingual research staff for each language group, who recruited and interviewed eligible women in their respective languages. Specifically, the research staff distributed study flyers in the 3 target languages through mobile messaging apps, such as WhatsApp (Meta) for Swahili-speaking women, Kakao Talk (Kakao Corporation) for Korean-speaking women, and ResearchMatch (a web-based national registry to connect volunteers to study teams [13]) for Spanish-speaking women, as well as ethnic churches. We also used word of mouth to recruit participants. Once potential participants were identified, bilingual staff sent them a Qualtrics (Qualtrics International Inc) survey link through email or messaging apps and asked them to complete the survey. The Qualtrics survey verified eligibility for participation, and for those who confirmed eligibility, the link provided pertinent consent information followed by a brief survey addressing sociodemographic characteristics and prior use of patient portals. The brief survey

XSL•FO
RenderX

also allowed women to select tentative days and times for the study interview, which was followed up by bilingual staff.

Interviews were conducted via Zoom (Zoom Video Communications, Inc) or in person, based on participant preference. All interviews were conducted in the participant's native language. We developed a semistructured interview guide that covered topics including past experiences with using patient portals for those with prior patient portal use, perceived feasibility and relevance of patient portals among those without prior patient portal use, and perceptions of patient portals targeted toward immigrant women with LEP for health promotion. Sample questions for individuals with prior use of the patient portal included "Tell me about your experience with the patient portal" and "What/who helped you decide to use the patient portal?" Participants were presented with screenshots of patient portal features throughout the interview to facilitate the discussion. Individuals without prior patient portal use were first presented with screenshots of sample patient portal features and informed about its current functionalities. Sample questions for nonusers included "How useful do you think a patient portal would be to meet your needs?" "What device would you likely use to access the patient portal?" (refer to Textbox 1 for example interview questions). Interview guides were originally developed in English and translated into the 3 target languages by the research staff. Each interview lasted 30 to 45 minutes and was audio recorded to facilitate verbatim transcription and analysis. Each bilingual interviewer reached data saturation after interviewing 12 (43%), 9 (32%), and 7 (25%) Korean-, Spanish-, and Swahili-speaking women, respectively, among the 28 participants.

Textbox 1. Example interview questions.

For women with prior patient portal use

- Tell me about your experience with the patient portal.
  - How was it introduced? Has your provider discussed your health conditions or results via patient portal?
  - Was it available in your language? How did you feel about it?
- Tell me about what you gained from using the patient portal.
  - What are some benefits of having health technology like patient portals?
- What did you like least about the patient portal?
  - In making the patient portal better or more useful for you, what should be added, changed, or removed from it?

For women without prior patient portal use

- What would help you decide to use or to not use a patient portal?
  - What or who would help you feel comfortable using it?
- What do you think about the patient portal?
  - How useful do you think a patient portal would be to meet your needs (eg, looking up medication, finding out diagnosis, obtaining laboratory results, and cancer screening)?
  - How would you want to be informed or educated on how to use a patient portal?

Ethical Considerations

The study was approved by the Johns Hopkins Medicine Institutional Review Board (IRB00243015). Verbal informed consent was obtained from all study participants before data collection, either over the telephone or in person. The consent included information on the risks and benefits of participating in the study. Every potential participant was given a chance to ask questions about their involvement in the study before consenting. To maintain participants' confidentiality, the audio-recorded interviews were exported to a secure cloud storage service (Johns Hopkins OneDrive) immediately after the interviews and deleted from the original recording device. Upon interview completion, participants were sent a US $30 gift code for their participation.

Analysis

We used descriptive statistics to summarize sample characteristics collected from a brief sociodemographic survey. The findings from the qualitative interviews were used to identify descriptors and expressions related to the patient portal experiences of women with LEP. The first author and the coders met regularly to discuss the themes and subthemes and resolve any discrepancies.

The bilingual data collectors transcribed the audio-recorded interviews into Microsoft Word documents and individually coded the data in the original languages to minimize the loss of participants' intended meanings of words, phrases, and concepts [14]. We used a deductive coding based on a priori topics used to develop the interview guide and applied an inductive coding approach, allowing the codes to emerge from the data during the coding process [15]. The coders met regularly to discuss the themes and subthemes that emerged from the data. Data

XSL•FO
RenderX

saturation was determined when no new themes emerged from the analysis. The findings from the qualitative interviews were used to identify common themes and subthemes among prior users and nonusers of patient portals. Finally, all themes, subthemes, and quotes were translated into English and merged in a Microsoft Excel spreadsheet.

Results

Sample Characteristics

Table 1 presents the characteristics of the interview participants. Half (14/28, 50%) of the participants were in their 30s and 40s, with the average ages being 37 (SD 12), 42 (SD 11), and 48 (SD 15) years for Korean-, Spanish-, and Swahili-speaking women, respectively. Korean-speaking participants had the longest average length of stay in the United States (15, SD 11 y), followed by Spanish- (12, SD 9 y) and Swahili-speaking (5, SD 2 y) women. All Spanish-speaking participants (9/9, 100%) and most of the Korean-speaking women (11/12, 92%) had received a high school or college education, whereas more than half of the Swahili-speaking participants (4/7, 57%) had only an elementary-level education. All Korean- and Swahili-speaking women identified themselves as non-Hispanic Asian and African American, respectively, whereas 89% (8/9) of the Spanish-speaking women identified themselves as Hispanic. The interview participants originated from Central America (Dominican Republic, Colombia, and Venezuela), South Korea, and sub-Saharan Africa (Democratic Republic of the Congo and Kenya). Prior use of patient portals varied: 58% (7/12) and 44% (4/9) of the Korean- and Spanish-speaking participants, respectively, had prior experience, whereas all Swahili participants (7/7, 100%) had no prior exposure to patient portals.

Table 1. Sample characteristics (N=28).

Characteristics	Korean-speaking women (n=12)	Spanish-speaking women (n=9)	Swahili-speaking women (n=7)
Age (y), mean (SD; range)	37 (12; 23-61)	42 (11; 23-56)	48 (15; 27-70)

Themes and Subthemes

Overview

Multimedia Appendix 1 summarizes the findings on perceptions and experiences with patient portal use, preferred features, and suggested improvements, organized by themes and subthemes with illustrative quotes. We identified 4 main themes that were common across the linguistic groups: perceived benefits of patient portals, perceived facilitators of patient portal use, perceived barriers to patient portal use, and preferred features and suggested improvements. While most subthemes were shared across all 3 groups, some were unique to specific groups, as detailed in the subsections that follow.

XSL•FO
RenderX

Theme 1: Perceived Benefits of Patient Portals

Participants acknowledged and described multiple benefits of using patient portals. Perceived benefits of patient portals included easier communication with health care providers and health systems, getting connected and staying connected with health systems, easier and efficient access to one's health records over time, staying informed of and engaged with one's health and health management, and better patient engagement in medical visits.

Easier Communication With Health Care Providers and Health Systems

Patient portals were perceived as effective and efficient tools for facilitating communication with the health system. Both users and nonusers noted that these portals increase efficiency and reduce unnecessary in-person visits to health care providers. A Swahili-speaking participant in her late 20s perceived that patient portals might be helpful tools for communicating with health care providers, accessing health information, and ultimately reducing the need for frequent in-person hospital visits:

> *It may help you communicate with the health care provider...it makes everything easier; you don't have to frequently go to the hospital to get information concerning your health from the health care provider.* [SIDSW05]

A Korean-speaking participant in her late 40s noted that patient portals enable women with LEP to take as much time as needed to understand health information, including searching for the meanings of terms using translation tools. She pointed out that some terms can easily be missed or misunderstood during conversations:

> *[I]t's better to use the patient portal so that we [people with LEP] can take our own time to dig into the information. We need more time to understand the information because it's challenging to grasp everything during a conversation. By using the patient portal, we can search for terms and use translation tools. I think it's better to use it rather than feeling pressured to understand everything all at once.* [SIDKO01]

Getting Connected and Staying Connected With Health Systems

The health system felt distant to many participants not only due to various barriers but also because of the difficulty in becoming familiar with a health system different from the one they had experienced in their home countries. Many participants expressed that the patient portal made staying connected with the health system and accessing check-ups a smoother process. A Spanish-speaking participant noted that she visits the patient portal at least once a month to schedule or monitor upcoming appointments:

> *At least once a month I would check if I had any upcoming appointments, if I need to schedule a new appointment, if my annual exam is approaching, or if I need to see my gynecologist.* [SIDSP05]

Similarly, a highly educated Korean woman in her early 50s recalled feeling hesitant when she first encountered the patient portal. However, over time, she gained familiarity and appreciation for it. She stated as follows:

> *As I kept using [the patient portal], it became easier to use and...then I realized it doesn't take that much time to get the check-ups [scheduled]...the scope of my medical examination has expanded.* [SIDKO02]

Easier and Efficient Access to One's Health Records Over Time

One of the main benefits highlighted by the participants was that patient portals serve as a convenient way to keep their health records in one place, allowing easy access to their information. Patient portal users shared their positive experiences, contrasting them with past struggles in tracking health information such as immunization records, laboratory results, or medication history. A Korean-speaking participant in her 40s noted that she finds it convenient to have all her health records in one place, readily available whenever she needs to check her test results:

> *It's good that my medical history or information is stored in one place. I can go back to my records and check when I received certain tests.* [SIDKO01]

Efficiency and ease of information access was echoed by a Spanish-speaking participant:

> *A great benefit of patient portals is that I have access to my information immediately...I think the patient portal is very accessible because it lets me see all of my test results.* [SIDSP05]

Staying Informed of and Engaged With One's Health and Health Management

This subtheme, focusing on managing one's health records in one place, contributed to greater awareness of one's health. Having easy access to their records allowed individuals to become knowledgeable about their health status, motivating them to take a more active role in managing their health. As noted by a Spanish-speaking participant, the patient portal gave patients the autonomy to access and stay informed about their records at their convenience:

> *Accessing my medical records [through the patient portal] gives me a lot of independence. I can use [the portal] whenever I want or whenever I can, knowing that I will always have access.* [SIDSP08]

Parallel to this benefit, a Korean-speaking participant emphasized that the patient portal is a valuable tool for looking up one's test results and proactively managing one's health. She stated as follows:

> *I think it's easier to stay informed and reminded of my health status when I can see my own [test] results. By looking at my results, I gain more awareness and can manage my health better.* [SIDKO03]

In addition, a Swahili-speaking participant highlighted the benefits of patient portal access in improving engagement in care:

XSL•FO
RenderX

> *[I]t would be beneficial in communicating with the health care provider; understanding how to get medication, and how to follow up with the health care provider.* [SIDSW04]

Better Patient Engagement in Medical Visits

Participants viewed the patient portal as a valuable tool for accessing health information before and after medical visits. They described experiencing a higher level of stress when communicating in English about vital health matters compared to their experiences in their home countries. The patient portal allowed them to anticipate discussions, prepare questions, and review results at their convenience. A Korean-speaking participant in her 30s mentioned that reviewing her results before her appointment helped facilitate a productive discussion with her health care provider:

> *I can have a better understanding before the appointment. If I go to see the doctor without knowing anything, there might be parts I don't understand. However, if I already know the results in advance, it would be easier for me to comprehend and discuss with the doctor during the appointment.* [SIDKO10]

Along the same lines, Spanish- and Swahili-speaking participants viewed patient portals as a valuable digital tool for following up with health care providers. A Spanish-speaking participant noted that the patient portal is useful for seeking clarification after appointments:

> *There are times during your appointment that you forget to ask [questions], so having the patient portal and being able to go back and check it whenever is a great advantage.* [SIDSP06]

Theme 2: Perceived Facilitators of Patient Portal Use

Participants identified various factors that facilitated their continued use of patient portals, rather than initial adoption. These included availability of time, widespread use and availability of smartphones and the internet in the United States, family support, and parenthood.

Availability of Time

Spanish- and Swahili-speaking participants affirmed that availability of time played a role in facilitating the use of patient portals. Some Swahili-speaking participants also noted that availability of time may be a good motivator for learning how to use patient portals as a source of health information and for seeking care. No relevant quotes were identified for Korean-speaking participants. A Spanish-speaking participant mentioned that availability of time increased the likelihood of using patient portals to view results or schedule appointments:

> *Having the time to make appointments and access your tests results...is a facilitator of patient portal use.* [SIDSP03]

Widespread Use and Availability of Smartphones and the Internet in the United States

Of note, Swahili-speaking participants perceived that the extensive use and availability of smartphones and the internet in the United States enhanced patient portal use. This subtheme was unique to the Swahili-speaking group. A Swahili-speaking participant stated as follows:

> *There is no one in America who does not have a phone, I was even given a computer when I immigrated here, it's just that I don't know how to use it.* [SIDSW07]

Family Support

Participants perceived that support from family members would facilitate their access to and use of patient portals. A Korean-speaking participant disclosed that she would seek help from her son on how to use the patient portal and was confident that she would know how to use it after a few trials:

> *I'll ask my son whenever there's something I don't know, and then once I practice a couple of times, I can use it on my own.* [SIDKO07]

Notably, most of the Korean-speaking participants in their 20s to 40s expressed concerns that their parents would face difficulties accessing the patient portal. Consequently, they expected to provide support to their parents. Similarly, a Swahili-speaking participant who was illiterate shared that either her children or spouse would help her use the patient portal if needed. Consistent with these perceptions, a Spanish-speaking participant in her 50s (a nonuser) reported that she would like a family member to show her how to use a patient portal:

> *It would be more comfortable if someone in my home taught me [how to use the patient portal], like a family member.* [SIDSP03]

Parenthood

Having school-age children acted as a facilitator for patient portal use among Korean- and Spanish-speaking participants with prior portal experience. No relevant quotes were identified for Swahili-speaking participants or for those without prior patient portal use. All 3 Korean-speaking participants who had school-age children emphasized that convenient access to their children's health care records was a key facilitator. While recent immigration could have been a barrier, parenthood seemed to help them quickly adapt to the US culture and health system:

> *With the patient portal, it seems to be an efficient way to connect with their [children's] health care providers, especially for simple questions and check-ups. That's my first impression of it.* [SIDKO1]

Similarly, a Spanish-speaking participant mentioned that, despite difficulties communicating with staff at the physician's office, she was able to schedule her son's medical appointment using the patient portal:

> *Not having the ability to speak English has made everything more difficult. For example, I needed to schedule an appointment for my son to see the doctor. When I called, everyone spoke English, and I didn't understand anything. So, I used my patient portal to open his account, and through there I was able to accomplish it [schedule her son's appointment].* [SIDSP09]

XSL•FO
RenderX

Theme 3: Perceived Barriers to Patient Portal Use

Participants mentioned several barriers to using the patient portal, including limited digital literacy and limited access to technology; LEP; lack of awareness and knowledge about patient portals; and, additionally, for Swahili-speaking participants, illiteracy.

Limited Digital Literacy and Limited Access to Technology

Digital illiteracy, often stemming from limited access to digital devices and the internet, was mentioned as a potential navigational challenge for interested users. Many participants expressed that a lack of knowledge on how to navigate the patient portal would be a key barrier to its use; for example, some Korean-speaking participants shared that their older adult parents or relatives would not use the patient portal:

> *When I think about my aunt, she's not familiar with using smartphones or websites at all. First of all, she forgets her username and password. She dislikes the process of retrieving passwords...Navigating through websites is also difficult for her, whether it's in English or Korean, because there are too many menus. Our portal also has menus, but when you click one, several options pop up. Also, the fonts are small.* [SIDKO12]

LEP Issue

LEP was identified as a profound barrier to patient portal access and use. Women with prior patient portal experience noted that the lack of patient portal access through a language-concordant medical practitioner is a major barrier for many women with LEP. For some, LEP was an even greater challenge than limited digital literacy. A Korean-speaking participant suggested that LEP can undermine self-efficacy in using the patient portal, even among those who are knowledgeable about it and have access to digital devices:

> *If English proficiency is limited, even with well-functioning devices, websites, or apps that are used in English, there is still some fear and uncertainty because of the fixed idea that 'I don't know' or 'I don't understand.' Even if there is knowledge of the existence of such portals, it's still intimidating to try because of the discomfort with English.* [SIDKO05]

Similarly, a Spanish-speaking participant observed that while the patient portal may be accessible in Spanish, the presentation of results in English limits its usability:

> *Honestly, I think the portal is really good because at least it gives you the option to put it in Spanish. That way, it isn't as hard to follow the steps to create your account. However, your tests results are always in English, which always leaves me thinking 'how do I read these?' Even when I try to translate the results, it is not the same [as having it in Spanish]...The doctor could call you and tell you 'Everything is okay,' but that is not enough.* [SIDSP09]

Patient portals are not yet available in other ethnic languages, such as Swahili, which hinders access and use. This concern was highlighted by a Swahili-speaking participant who had no prior experience using a patient portal**:**

> *Patient portal would be more useful if it is written in both English and Swahili, since not everyone understands English.* [SIDSW05]

Lack of Awareness and Knowledge About Patient Portals

Participants noted that, despite the multiple benefits highlighted, patient portals are generally not well known within their communities. They shared that increasing awareness would likely encourage interest and use. A few Korean-speaking participants emphasized that greater awareness could drive adoption:

> *As long as one knows about the patient portal, it's something that would be definitely utilized. But I didn't know...Since I now know, I'm going to use it.* [SIDKO06]

Illiteracy

Illiteracy was identified as a key barrier to patient portal use among Swahili-speaking participants. No other group noted this as a barrier. A Swahili-speaking participant expressed interest in using the portal but cited limited reading ability as a significant obstacle:

> *If patient portal is written in Swahili, I wouldn't know how to read well, I just know a few words, therefore, having information in audio or video formats would be useful since I don't know how to read.* [SIDSW06]

Theme 4: Preferred Features and Suggested Improvements

Participants also shared suggestions to enhance the patient portal user experience, focusing on language accommodation, device access, features, formatting, and specific health information preferences.

Expanded Language Access to Accommodate Non-English Speakers

Most participants emphasized the need for expanded language access to facilitate patient portal use. Across all language groups, they expressed a preference for patient portals available in their preferred languages. A Spanish-speaking participant noted that since LEP is a major barrier to patient portal use, offering access in preferred languages would be ideal:

> *Not knowing the language [English] is the main reason why people can't use the patient portal. Ideally, the portal should be able to be used in different languages depending on the person's preference.* [SIDSP08]

Her sentiments mirrored those of a Korean-speaking participant:

> *I hope these features can be available in Korean. I wish for patient portals to be accessible in Korean so that even those who struggle with new technologies or have difficulty as they age can still have the opportunity to try it in their native language.* [SIDKO07]

XSL•FO
RenderX

In this context, another participant discussed the issue of understanding medical terminology (ie, health literacy) and noted that it would be helpful if information was provided in Korean because medical terms are more difficult to comprehend in English:

> *Since I'm not familiar with medical terms, if something is written only in English, I wouldn't understand. It would be helpful to have more detailed explanations.* [SIDKO09]

In addition, a Swahili-speaking participant affirmed the need for expanded language access:

> *The patient portal will be more useful if it is written in Swahili.* [SIDSW06]

Improved Accessibility to Health Information Using Graphics and Patient Education Materials

Several participants wished for features that would enhance understanding, such as comparisons of laboratory test results, explanations of medications (eg, precautions and contraindications), and detailed interpretations of laboratory results using graphs or charts. A Korean-speaking participant asserted that displaying laboratory values in graphs or charts would be beneficial:

> *It would be much more convenient if there were a chart or graph showing last year's lab values compared to this year's values. For example, if there were red arrows indicating how much they went up or down compared to last year, that would be really helpful.* [SIDKO05]

Likewise, a Spanish-speaking participant stated that the patient portal should be able to provide basic, patient-centered information about health status:

> *[A]t least check my health status. To see if I am allergic to something; if I have any upcoming appointments; if I am taking any medication, and if so what kind, how much of it, and how many times a day...Basic things like that.* [SIDSP05]

In addition, Swahili-speaking participants expressed a desire for the inclusion of pictures and audio-recorded files to improve accessibility to health information on the patient portal:

> *[P]ictures and audios, with texts written in simple English or even Swahili.* [SIDSW03]

User Onboarding Education and Technical Support

Participants' perceived needs for using the patient portal were similar; many suggested that user onboarding education and technical support are necessary improvements for broader adoption. Regarding the format of onboarding education, some participants expressed a preference for audiovisual tools, while others were comfortable receiving links to instructional content. A Korean-speaking participant mentioned that an internet-based demonstration would be sufficient for her understanding:

> *I think [getting instructions] via email and a link to view the video about it would be helpful.* [SIDKO09]

Considering limitations in technology access and use as well as English proficiency, participants noted that printed instructions in their native language or in-person guidance would be helpful for older adults:

> *I would like to be instructed by someone, for instance, after church service.* [SIDSW06]

Finally, recognizing the constraints of physicians' busy schedules, a Korean-speaking participant stated that a brief demonstration during an appointment would be highly beneficial:

> *It's best if the doctor explains how to use the patient portal, but they're busy. If they open my portal during my visit and let me know 'You can see it on this portal,' I'd be more motivated to use it.* [SIDKO05]

Discussion

Principal Findings

Despite the rapid adoption of patient portals in health care settings [7,8], research on the experiences and perspectives of individuals with LEP is scarce. Our sample of women with LEP from 3 cultural and linguistic groups provided valuable insights into their perceptions, experiences, and beliefs regarding patient portals. The findings highlight the benefits, facilitators, and barriers to using patient portals, as well as preferences for specific features and suggestions for improvements.

Participants with LEP strongly associated patient portals with various perceived benefits, including easier communication with health systems and health care providers and better engagement in medical visits. These perceived benefits are similar to those reported in a recent analysis of comments by predominantly non-Hispanic White female patients in their 50s who had used a patient portal in a health system [16]. According to the analysis, most patients highlighted communicating with health care teams and monitoring health status and care activities as beneficial functions of patient portal use. Especially for women with LEP, the ability to review their records and take as much time as needed to understand health information, including searching for the meanings of terms using translation tools, were considered an important benefit of patient portals. Without this option, understanding health information during medical conversations would be challenging. Patient portals are generally considered beneficial to improving patient engagement in health management [17-19]. As patient engagement is increasingly recognized as an essential component of person-centered care [18], our findings suggest that providing women with LEP access to a patient portal could be a viable approach to promote their engagement in health management and care, potentially leading to positive health outcomes [18].

While the subthemes for facilitators of patient portal use (eg, availability of time, widespread use and availability of smartphones and the internet in the United States, family support, and parenthood) varied across groups, family support emerged as a common subtheme across all 3 groups. A cohort study conducted to assess the prevalence of health care portal use before, during, and after the COVID-19 pandemic and involving middle-aged and older adult primary care patients (2019-2022) [20] found that portal log-in activity was higher during the pandemic compared to the 2019 baseline: higher

XSL•FO
RenderX

portal log-in activity was associated with adequate health literacy and multimorbidity, whereas lower portal log-in activity was associated with older age and female sex. Disparities associated with age and sex decreased as the pandemic progressed, but disparities based on health literacy were exacerbated. The subtheme of family support identified in our study highlights how women with LEP navigate limited health literacy related to patient portals by mobilizing resources within their reach, such as children. Evidence points to the unique role of children in immigrant families as language brokers who "translate and mediate between their heritage language/culture and English/US culture" for their parents with LEP [21]. A similar pattern has been reported in the context of digital health where children help their immigrant parents to access web-based health resources [22]. Nevertheless, research in this area is scarce and has primarily relied on qualitative study designs. Future research is warranted to investigate how health literacy develops and is applied to digital health access in immigrant families, as well as the role bilingual children play in obtaining, processing, and understanding web-based health information to support family members, such as parents with LEP.

While patient portals enable women with LEP to communicate effectively with health care providers and health systems, several barriers identified in this study were closely linked to social determinants of health, including limited digital literacy and limited access to technology, LEP, and illiteracy. Similar barriers to patient portal use have been reported; for example, a recent cross-sectional study of 1850 respondents in the United States found that digital health literacy, home internet access, access to technology devices, and English proficiency were among the correlates of patient portal enrollment and intent to use [23]. Similarly, another study using data from the 2017-2018 Health Information National Trends Survey revealed that LEP, along with no health insurance, limited education, and not having a regular doctor, was significantly associated with lower patient portal use [24]. Of note, several reviews reported concerns about privacy and data security as major barriers to patient portal use. However, these concerns did not emerge as subthemes among the women with LEP in this study. One possible explanation is that our study sample included both women with prior patient portal use and those without, whereas previous research often involved patients already engaged with a health system. It would be important to consider how attitudes and perceptions of patient portals in ethical domains (eg, privacy concerns and data security) might hinder or facilitate patient portal adoption and meaningful use among populations with LEP [25].

Key improvements to patient portals suggested by the women with LEP in this study included expanded language access to accommodate non-English speakers, improved accessibility to health information using graphics and patient education materials, and user onboarding education and technical support. An innovative patient portal that transcends critical barriers such as LEP can be an empowering tool, especially for immigrant populations, to obtain health information, manage care, increase knowledge, and take health care ownership. In addition, the suggestions for the use of graphics and educational materials as well as user onboarding education and technical support underscore the need for improved usability, making patient portals more accessible and user-friendly. This also highlights the importance of more active and direct engagement and endorsement by the health system and health care providers [26,27]. Interactions with patient portals have been widely studied; yet, the influence of usability on patients' decision-making remains understudied [28]. Future research should take a comprehensive approach to examining usability and its effect on patient portal use among the growing and increasingly diverse patient population with LEP.

Limitations

This study has some limitations. First, as a qualitative study, the interpretations are inherently subjective, and it is also possible that social desirability bias during the interviews influenced participants' responses. Second, we did not examine participants' type of insurance, which could be associated with immigration status and may present additional barriers to equitable health care access. Insurance coverage seems to play a role in determining whether participants use patient portals [24]. Third, English proficiency was self-reported and may be subject to self-report bias. In addition, our study sample primarily consisted of younger individuals with more than a decade of residence in the United States and high levels of education, except for the Swahili-speaking group, necessitating careful interpretation of the findings. Their experiences were also specific to the US health care context. In addition, part of the recruitment process relied on technology such as WhatsApp, websites, and Zoom, which may have excluded individuals without such access. Future research should strive to include a more diverse sample to capture a broader range of perspectives and experiences. Finally, the study included women without prior patient portal use, primarily Swahili-speaking participants. The interpretability of the findings, particularly among those without prior exposure to patient portals, may be limited.

Conclusions

Women with LEP acknowledged several benefits of patient portals but also identified barriers to their use, including limited digital literacy, restricted access to technology, LEP, and illiteracy. These barriers are closely linked to social determinants of health, which disproportionately affect women with LEP. As digital health continues to evolve, it is critical for health systems to address digital health disparities and foster meaningful use. This study is novel in its inclusion of women with LEP, providing unique insights into their perceptions, beliefs, and experiences with patient portals. One of the Healthy People 2030 goals is to "eliminate health disparities, achieve health equity, and attain health literacy to improve the health and well-being of all" [29]. Our findings suggest that this goal may be supported by promoting accessible health resources, such as patient portals, with several considerations to enhance usability for populations with LEP. Emerging evidence highlights the significance of presentation formats in improving patient satisfaction and usability [30], and our findings could inform future research to promote engagement with patient portals among individuals with LEP.

Abstract

Background: The onset of the COVID-19 pandemic precipitated a rapid shift to virtual care in health care settings, inclusive of mental health care. Understanding clients' perspectives on virtual mental health care quality will be critical to informing future policies and practices.

Objective: This study aimed to outline the process of redesigning and validating the Virtual Client Experience Survey (VCES), which can be used to evaluate client and family experiences of virtual care, specifically virtual mental health and addiction care.

Methods: The VCES was adapted from a previously validated telepsychiatry survey. All items were reviewed and updated, with particular attention to the need to ensure relevance across mental health care sectors and settings. The survey was then revalidated using the 6 domains of health care quality of the Institute of Medicine (IOM) as a guiding framework. These 6 domains include being safe, effective, patient-centered, efficient, timely, and equitable. The VCES was piloted with a convenience sample of clients and family members accessing outpatient care at the Centre for Addiction and Mental Health (CAMH) in Toronto, Ontario, through video or telephone. A confirmatory factor analysis (CFA) was conducted in MPlus and used to test the factorial structures of the VCES, with minor respecification of the model based on modification indices, factor loadings, reliability, and item-total correlation. The respecifications were checked for alignment with the construct definitions and item interpretation. The reliability of the constructs was estimated by the Cronbach α coefficient.

Results: The survey was completed 181 times. The construct reliability was generally high. Timely was the only subscale with an α lower than 0.7; all others were above 0.8. In all cases, the corrected item-total correlation was higher than 0.3. For the CFA, the model was adjusted after multiple imputations with 20 datasets. The mean chi-square value was 437.5, with df=199 (P<.001). The mean root mean square error of approximation (RMSEA) was 0.08 (SD 0.002), the mean confirmatory fit index (CFI) was 0.987 (SD 0.001), the mean Tucker-Lewis Index (TLI) was 0.985 (SD 0.001), and the mean standardized root mean square residual (SRMR) was 0.04 (SD 0.001).

Conclusions: This study describes the validation of the VCES to evaluate client and family experiences of virtual mental health and addictions care. Given the widespread uptake of virtual care, this survey has broad applicability across settings that provide mental health and addiction care. The VCES can be used to guide targeted quality improvement initiatives across health care quality domains. By effectively addressing challenges as they emerge, it is anticipated that we will continue to move toward hybrid modalities of practice that leverage the strengths and benefits of telephone, video, and in-person care to effectively respond to unique client and family needs and circumstances.

Introduction

The onset of the COVID-19 pandemic precipitated a rapid shift to virtual care in health care settings, inclusive of mental health care. Virtual care, often referred to as telehealth or telemedicine, refers to the provision of clinical care using information and communication technologies and can be delivered synchronously (ie, in real-time, at a distance) or asynchronously (ie, separated by time and space) [1,2]. During the early phases of the pandemic, synchronous forms of virtual care, such as video- and telephone-based care, replaced in-person care as the leading modalities of practice in many health care settings [3-6].

Research evaluating virtual mental health care has consistently shown high levels of both client satisfaction [3-7] and provider satisfaction [5,8]. However, recent literature also highlights challenges with virtual care, including inequities in access to and engagement with virtual care [9,10], technology challenges [11], lack of connection between clients and health care providers [4], and concerns regarding privacy and safety [12]. Understanding clients' perspectives on virtual mental health care quality will be critical to inform future policies and practices. In addition, it will be important to understand how these experiences vary across sociodemographic groups, particularly in light of long-standing inequities in health care access and outcomes that risk being reinforced by the widespread uptake of virtual care [10].

To date, there is only 1 known validated measure of client experiences of virtual mental health care, specifically telepsychiatry [6], and there are no known validated measures that can be used to evaluate client experiences across varied types of mental health care. Since the transition to virtual care, a majority of patients across multiple surveys indicate a preference for virtual care to continue to exist as an option [3,4], with many preferring a hybrid approach that combines both in-person and virtual modalities [3]. Validated means to understand client and family experiences of care will be critical to inform evidence-based decision-making regarding virtual care and hybrid modalities of practice moving forward.

This paper outlines the process to redesign and validate the Virtual Client Experience Survey (VCES) that can be used to evaluate client and family experiences of virtual mental health and addictions care.

Methods

Overview

At the outset of the COVID-19 pandemic, the VCES was adapted from a previously validated telepsychiatry survey developed and used within the TeleMental Health program at the Centre for Addiction and Mental Health (CAMH), a mental health and addiction hospital located in Toronto, Ontario [6]. This telepsychiatry survey was updated to respond to the pressing need to evaluate virtual care both within our hospital and externally. Several adaptations were made to extend the use of the tool beyond its original intended use with clients accessing psychiatric consultation and assessment through videoconference [6].

Survey Redesign

The approach to developing and validating the original telepsychiatry survey is outlined in the paper by Serhal et al [6]. Our team of clinicians, researchers, and health care leaders reviewed the telepsychiatry survey and adapted it for use in the current context. All items were reviewed and updated, in particular, with the need to ensure relevance that is accorded with the expansion of virtual care provision beyond physicians and psychiatrists. For example, items on the newly developed VCES ask about the client's experience with the virtual appointment instead of the telepsychiatry appointment. Another item asks whether the health care provider explained the risks and benefits of treatments or interventions rather than the risks and benefits of medications. After consultation with clinicians across multiple programs and services at the hospital, the survey was also updated to ensure applicability not only to clients but to family members as well. This was an important shift given the key role that families play in mental health and addiction care and recovery [13,14] and in supporting access to care through videoconference.

The transition to virtual care during the COVID-19 pandemic also necessitated the examination of virtual care from a digital health equity perspective [10]. Our team consulted with the CAMH Health Equity Office as well as the Provincial System Support Program (PSSP), which administers the Ontario Perception of Care Tool for Mental Health and Addictions (OPOC-MHA) [15], regarding the addition of sociodemographic questions to facilitate health equity analyses. Furthermore, 5 items from the OPOC-MHA were also added to facilitate alignment and comparison between the 2 tools.

The VCES sociodemographic questions ask about gender, age, geographic region, whether the client was born in Canada, racial or ethnic group, illness and disability, and other factors. Clients and families were also asked about their comfort with technology, where they accessed the virtual care appointment from (eg, home, health care organization), the type of device they used to access virtual care (eg, computer, smartphone), and which videoconference platform was used. The telephone was included as an option on the survey, as CAMH, like many health care settings, began providing more services by telephone during the pandemic, particularly for individuals experiencing barriers to video-based care. Finally, as recommended by Serhal et al [6], we added additional survey items to assess access to care, and physical and emotional safety during virtual care appointments. We also added an item about compassionate care, given our research group's interest in compassion as a critical factor in the therapeutic relationship and inpatient and family experience of care [16,17].

XSL•FO
RenderX

The redesigned VCES consists of 22 items to assess the overall quality of care. These items are rated on a 4-point Likert scale (1=strongly disagree, 2=disagree, 3=agree, 4=strongly agree) with additional options including "not applicable" and "prefer not to answer." The final question on the survey is an open-text question to elicit any additional feedback.

Conceptual Framework

Following the adaption of the survey, the survey was revalidated using the 6 domains of health care quality of the Institute of Medicine (IOM) as a guiding framework. These 6 domains include being safe, effective, patient-centered, efficient, timely, and equitable [18]. The IOM domains were selected as a guiding framework to provide a comprehensive evaluation of client satisfaction and experience and to guide targeted quality improvement efforts across the different domains. The heath quality domain definitions [18] have been adapted in Table 1 below for the VCES.

Table 1. Health quality domain definitions.

Health quality domains	Original definition	Adapted definition for the VCES[a] domains
Safe	"Avoiding injuries to patients from the care that is intended to help them [18]."	Virtual care that is physically and psychologically safe and minimizes potential risks.
Effective	"Providing services based on scientific knowledge to all who could benefit and refraining from providing services to those not likely to benefit (avoiding underuse and overuse)" [18]	Effective delivery of virtual care, inclusive of the use of virtual care technologies, to facilitate engagement in virtual care.
Patient-centered	"Providing care that is respectful of and responsive to individual patient preferences, needs, and values and ensuring that patient values guide all clinical decisions" [18]	Virtual care that is collaborative, respectful, and responsive to client and family preferences, needs, and values.
Efficient	"Avoiding waste, in particular, waste of equipment, supplies, ideas, and energy" [18]	Efficiency and ease in accessing virtual care.
Timely	"Reducing waits and sometimes harmful delays for both those who receive and those who give care" [18]	Timely access to virtual care for clients and families, including limited wait times for services.
Equitable	"Providing care that does not vary in quality because of personal characteristics such as gender, ethnicity, geographic location, and socioeconomic status" [18]	Virtual care that does not vary in quality based on personal characteristics and sociodemographic factors.

[a]VCES: Virtual Client Experience Survey.

Question Validation

Survey Dissemination

The VCES was piloted with a convenience sample of clients (16 years of age and older) and family members accessing a wide range of outpatient mental health and addiction services at CAMH through video or telephone. Survey data was collected using Research Electronic Data Capture (REDCap), a web-based application for securely collecting surveys and managing data [19,20]. The electronic survey took approximately 15 minutes to complete. Survey completion was voluntary, and all survey responses were anonymous. Survey data collection took place in 2021.

Information about the VCES and the process for survey administration was shared with clinicians and administrative staff using multiple channels, including the organizational intranet, email, support and sponsorship from clinical program directors, and program-level presentations by the project team. CAMH clinicians and administrative staff were asked to include information about the VCES, including the REDCap survey links, by email to all CAMH clients and families before their virtual care appointment. A template script for email communication to clients was provided, including a reminder that survey completion was voluntary and that all responses were anonymous. Clients and families were asked to complete a survey once per program or service that they participated in. The survey was made available to clients seeing providers across programs at the hospital, which includes multidisciplinary care providers (eg, physicians, nurses, social workers, occupational therapists, psychologists).

Content Validity

The 22 Likert-scale items on the VCES were independently reviewed by a panel of 5 individuals. including clinicians, researchers, and health care leaders, to determine alignment with the following IOM health quality domains: safe, effective, patient-centered, efficient, and timely [18]. Equity, the sixth IOM domain, is assessed through a comparison of survey response options by sociodemographic group. The panel then met through videoconference to discuss discrepancies until a consensus was reached.

Factorial Structure

To test the factorial structure of the VCES, a confirmatory factor analysis (CFA) was adjusted in Mplus (version 8.2; Muthén & Muthén) [21] using the method of weighted least squares with mean and variance adjusted chi-square test (WLSMV), which is recommended for ordinal outcomes [22]. Multiple imputation using the covariance method [23], with 20 imputed datasets, was used to handle missing values, which were present in 45% of the surveys, with 80% of surveys having 3 or fewer items missing. The evaluation of the model relied on the fit indices RMSEA (root means square error of approximation) [24], CFI (comparative fit index) [25], TLI (Tucker-Lewis index) [26],

XSL•FO
RenderX

and SRMR (standardized root mean square residual) [27], as well as the inspection of standardized factor loadings, variance explained, and modification index relative to each item. The initial factorial structure was defined following expert opinion, with minor respecification of the model based on modification indices, factor loadings, reliability, and item-total correlation. The respecifications were checked for alignment with the construct definitions and item interpretation. Cutoffs for fit indices in CFA and reliability are not universally accepted [28]. That said, based on results from Hu and Bentler [29], TLI and CFI higher than 0.95, SRMR lower than 0.08, and RMSEA lower than 0.06 are considered acceptable.

Reliability

The reliability of the constructs was estimated by the Cronbach α coefficient [30], a measure of internal consistency between the items. The corrected item-total correlation (correlation between the item and the total scale score with the item removed) and the α coefficient for the scale with the item removed were also used as sources of information as to how the items fit the factors. A Cronbach α of 0.7 or higher is considered good [28].

Ethical Considerations

Consent to participate was implied. The survey contained an introductory section explaining the purpose of the survey, informing potential respondents that participation was voluntary and anonymous, and informing them that the findings would be presented as grouped or aggregated data for any presentation or publication. There was no compensation offered to clients and families for completing the survey. This project received ethical approval from CAMH Quality Projects Ethics Review (QPER-2021-000).

Results

Descriptive Analysis

In total, the survey was completed 181 times, with 99 surveys completed by clients, 16 by support persons on behalf of clients, and 22 by family members or caregivers. Respondent information is missing on 44 surveys. Sociodemographic characteristics are included in Table 2.

Most respondents used a computer (113/179, 62.4%) or tablet or smartphone (58/179, 32%). Only 5.5% (10/179) reported using a telephone (audio only). The majority of respondents were either comfortable with technology (64/179, 35.8%) or very comfortable (85/179, 47.5%).

[a]CAMH: Centre for Addiction and Mental Health.

Reliability

The construct reliability, as measured by Cronbach α, was generally high. Timely was the only subscale with an α lower than 0.7; all others were above 0.8 (more details in Table 3). In all cases, the corrected item-total correlation was higher than 0.3. Considering the items in the model, item 9 (effective) and items 2 and 10 (timely) had lower corrected item-total correlation, with all the other items having correlations around 0.7 or above. Within the "timely" factor, the low item-total correlation was likely reflective of the small number of items associated with this domain.

[e]Corrected item-total correlation (correlation between the item and the sum score with the item removed).

[f]Item mean (Item values range from 1=strongly disagree to 4=strongly disagree).

[g]Item standard deviation.

[h]Cronbach α (internal consistency).

[i]CAMH is referenced in the survey that was disseminated internally. The external version refers to "this organization."

[j]Items from the Ontario Perception of Care Tool for Mental Health and Addictions (OPOC-MHA) [15].

Confirmatory Factor Analysis

Confirmatory Factor Analysis loadings are shown in Table 3 above. The model was adjusted after multiple imputations with 20 datasets. We show fit statistics using the mean and SD of these 20 datasets. The mean chi-square value was 437.5, with *df*=199 (*P*<.001). The mean RMSEA was 0.08 (SD 0.002), which is considered reasonable. The mean CFI was 0.987 (SD 0.001), the mean TLI was 0.985 (SD 0.001), and the mean SRMR was 0.04 (SD 0.001). These values are considered to be quite good. With the exception of item 9 in the "effective" factor, all the others have standardized loadings higher than 0.7.

The model shown in Table 3 had 2 respecifications: item 19 was moved from "effective" to "patient-centered," and item 18 was moved from "patient-centered" to "safe." These changes were based on the modification index and discussions with the project team; however, they did not meaningfully change the fit measures. While item 9 does not fit as well in the "effective factor," it was maintained as is, as it represented the best conceptual fit.

The sample size for structural equation models is not well defined because of the high number of parameters of interest and broad range of model complexity. Considering our model with 5 factors with an average of 4 indicators per factor and loadings around 0.8, Wolf et al [31] found that a sample size of 120 tends to be sufficient for power above 80%. These results are negatively affected by the presence of missing values; as such, our sample of 181 is expected to have reasonable power for a CFA analysis.

Discussion

Principal Findings

This paper provides a valid and reliable measure to evaluate client and family experiences of virtual mental health and addiction care, focusing on 6 domains of health care quality. This survey has been used internally at CAMH to guide the next steps and recommendations for virtual mental health care and has been shared externally in both English and French to support quality measurement within other organizations. Information about the survey was shared through a webinar, and the survey was subsequently downloaded hundreds of times across Canada and internationally.

Implications for Virtual Mental Health Care

Given the widespread uptake of virtual care, this survey has broad applicability across settings that provide mental health and addiction care. The VCES can be used to guide targeted quality improvement initiatives across the 6 IOM domains of health care quality, including safe, effective, patient-centered, efficient, timely, and equitable care [18]. It also has the potential to be adapted to other health care specialties and contexts.

Considerations for Administering the VCES

From our experience, we found the use of REDCap (Research Electronic Data Capture; Vanderbilt University) to be an effective means to disseminate the survey, collate results, and ensure anonymity. Some training and guidance regarding survey administration processes were required to ensure that the survey was delivered as part of the standard of care. We found it advantageous to delineate a time-limited window for survey dissemination and completion to limit time demands on both clients and clinicians. In terms of interpreting results, we set a cutoff of 3 (agree) and above as a positive result indicating high quality of care. Finally, there was a high degree of interest in receiving feedback on the survey results. We offered aggregated program-level reports once an adequate sample of surveys was completed in order to preserve respondent anonymity; this is particularly important as demographic questions attached to the survey could render individual results identifiable.

Next Steps

While the findings from the VCES provided invaluable and timely feedback, it is important not to limit patient and family feedback to a survey. The open text option on the survey provided a breadth of feedback not necessarily addressed within the existing survey questions. Analysis of this qualitative data may spur future adaptations to the survey and, on a practical level, may steer quality improvement initiatives resulting from survey findings. Furthermore, ongoing patient and family engagement in interpreting survey results and prioritizing and guiding quality improvement will be essential to making meaningful and impactful improvements.

Patient experience of virtual care should also be considered alongside provider experience of virtual care. To complement findings from the VCES and to capture another key perspective within health care, our team has developed and validated the Virtual Provider Experience Survey (VPES). These complementary tools provide key metrics to inform how health care organizations and systems can move toward the "quadruple aim," a well-recognized framework for health care that seeks to improve population health outcomes, reduce health care costs, and improve patient, family, and provider experiences of care [32]. The consistent use of standardized tools across settings is a valuable way to inform policy and program planning with respect to virtual care [33] and to further our advancement toward the quadruple aim. Further practice-based research is also needed to examine the relationship between the experience of care and health outcomes for clients and families who access

XSL•FO
RenderX

virtual mental health and addiction care and the cost-effectiveness of those services.

Limitations

While the VCES was validated with 181 survey responses, it is possible that some clients or family members completed the survey more than once if they were involved in multiple programs or services during the evaluation period. In addition, when administering surveys, there is always the risk of self-selection and response bias. We sought to mitigate this risk by asking clinicians and administrative staff to send the survey link to all clients and families accessing virtual care at CAMH. A response rate can be beneficial to ascertain the extent of potential bias; however, we were unable to determine the response rate, as it is unknown how many clients and families received the link in their email correspondence from clinicians or administrative staff. It is quite likely that those who have a higher degree of familiarity or comfort with virtual care were more likely to complete an online survey sent by email.

Conclusion

We sought to address a notable gap in the literature by redesigning and validating a measure of client and family experiences of virtual mental health care. Client and family perspectives are needed to evaluate the current state of mental health service delivery and highlight areas that need improvement. By effectively addressing challenges as they emerge, it is anticipated that we will continue to move toward hybrid modalities of practice that leverage the strengths and benefits of telephone, video, and in-person care to effectively respond to unique client and family needs and circumstances [11].

Acknowledgments

The authors would like to acknowledge members of the virtual mental health team at CAMH for supporting the development and dissemination of the VCES, as well as CAMH clinicians and administrative staff for their support in sharing the VCES with clients and families. We would also like to acknowledge the clients and families who took the time to share their feedback on their experiences of virtual care. Generative AI was not used for any section of the manuscript. No funds, grants, or other financial support were received for this project.

Abstract

Background: The COVID-19 pandemic has accelerated the digitalization of modern society, extending digital transformation to daily life and psychological evaluation and treatment. However, the development of competencies and literacy in handling digital technology has not kept pace, resulting in a significant disparity among individuals. Existing measurements of digital literacy were developed before widespread information and communications technology device adoption, mainly focusing on one's perceptions of their proficiency and the utility of device operation. In the contemporary landscape, digital transformation is evolving within specialized domains, necessitating a comprehensive evaluation of digital competencies, attitudes, and proficiency in technology application to bridge the digital divide and ensure digital compliance.

Objective: This study was designed to address the shortcomings of existing scales and formulate a digital sensitivity scale tailored to the requirements of today's society.

Methods: Initial items of the Yongin Severance Digital Sensitivity Scale (YI-DSS) were collected through a literature review, and expert opinions were gathered to ensure content validity. An exploratory and confirmatory factor analysis included 986 adult participants evaluating 14 digital literacy items and 6 digital efficacy items. The Cronbach α confirmed internal consistency reliability, and 2-tailed *t* tests, ANOVAs, and post hoc tests analyzed demographic differences in digital literacy and efficacy.

Results: A robust 4-factor digital literacy solution was identified: digital application, digital communication, critical thinking, and digital ethics (Kaiser-Meyer-Olkin=0.891; Bartlett × 2=9829.713; *P*<.001; Cronbach α=0.782-0.947). A 2-factor solution defined digital efficacy: digital confidence and digital anxiety (Kaiser-Meyer-Olkin=0.735; Bartlett × 2=3282.217; *P*<.001; Cronbach α=0.787-0.912). Confirmatory factor analysis was conducted for each model (digital literacy model: χ^2_{71}=676.0, comparative fit index=0.938, Tucker-Lewis index=0.921, standardized root mean square residual=0.73, and root mean square error of approximation=0.093; digital efficacy model: χ^2_8=81.9, comparative fit index=0.977, Tucker-Lewis index=0.958, standardized root mean square residual=0.73, and root mean square error of approximation=0.097), which indicated a good fit. The YI-DSS also showed high correlation with the previously developed Digital Literacy Scale (*r*=0.809; *P*<.001).

Conclusions: The YI-DSS, as a self-assessment tool, has the potential to bridge the generational information gap by promoting acceptance, motivation, and adaptation to digital technology. Furthermore, given the remote nature of digital therapeutics, an individual's familiarity with required technologies and digital communication strongly influences their acceptance of digital treatments and the efficacy thereof. This scale can play a pivotal role in enhancing compliance with digital therapeutics by preemptively assessing individuals' technological literacy and competency.

KEYWORDS

information literacy; health literacy; computer literacy; self-efficacy; attitude; digital divide

Introduction

Background

The COVID-19 pandemic has accelerated digitalization in various sectors, with a notable impact in the field of psychiatry. This shift was essential in maintaining psychological evaluations and treatments during physical distancing, demonstrating the effectiveness of digital approaches in improving mental health care. The incorporation of technology into everyday clinical practice has transitioned from being just a necessity to a vital element of psychiatric services. Despite the successful application of digital therapeutics in treating various conditions such as insomnia, attention-deficit/hyperactivity disorder in children, and substance use disorder [1-4], there are significant barriers that hinder their widespread adoption. In a comprehensive review conducted by van Kessel et al [5], the key factors influencing the assimilation of digital therapeutics into health care systems and their practical application by patients and professionals were examined, identifying digital literacy as the most critical factor according to health care professionals. Specifically, they highlighted a significant concern: if the design of digital therapeutics fails to consider the potential exclusion of individuals with limited digital literacy, it could inadvertently aggravate existing disparities in health care access and outcomes. Therefore, given its pivotal role in the assimilation and practical application of digital therapeutics, digital literacy emerges as a crucial element in the field.

Digital literacy, recognized as a key concept within digital competence, was first introduced by Gilster [6], and its conceptual framework has undergone progressive refinement over time. According to Gilster [6], digital literacy goes beyond the ability to simply operate a computer; it refers to the ability to evaluate and judge digitized information (content evaluation) and combine the collected information with new information to achieve specific personal goals (knowledge), thereby ensuring the proper use of information. This concept has evolved into an essential survival skill essential to the members of modern society, and it is presented as a concept that includes the values of digital citizenship, such as social participation and moral attitude in the digital environment [7-11]. In short, digital literacy is a concept that encompasses the cognitive ability to access and understand digital information and the ability to create new and alternative content, as well as the moral responsibility of communicating in a digital environment and solving problems ethically.

Digital literacy is a comprehensive framework for the complex and integrated subfields of technology, knowledge, ethics, and creative production in a digital network environment. In the *Digital literacy across the curriculum* handbook developed for education workers, Futurelab in the United Kingdom presented eight components of digital literacy: (1) functional skills in information and communications technology (ICT), (2) creativity in developing new content and results, (3) collaboration, (4) effective communication using digital technology, (5) the ability to find and select digital information, (6) critical thinking and evaluation, (7) cultural and social understanding, and (8) e-safety in using digital information without violating laws and ethics [12]. Eshet-Alkalai and Chajut [13] proposed six concepts constituting a framework for digital literacy: (1) photovisual literacy, which refers to the ability to work effectively in interfaces such as graphic communication; (2) reproduction literacy, which refers to the ability to manipulate existing digital information to create meaningful new content; (3) information literacy, which refers to the ability to critically consume information; (4) branching literacy, which refers to the ability to construct knowledge through nonlinear search; (5) socioemotional literacy, which refers to the ability to communicate effectively in online communication spaces; and (6) real-time thinking technique, which refers to the ability to process and evaluate large amounts of information in real time.

According to a report by the Korea Education and Research Information Service (2017), in South Korea, the domains of digital literacy are (1) understanding and using digital technologies, (2) digital consciousness and attitudes, (3) digital thinking skills, and (4) digital practice competence. The study by Kang et al [14] on digital literacy measurement in a smart society suggested that there are 3 domains of diagnostic indexes for digital literacy measurement: technology, application, and mind. The technology domain measured the technological application of ICT, and the application domain measured whether digital technology and knowledge are applied to life. The mind domain in particular measured information ethics awareness and norms required in a smart society, which was different from the finding of previous studies that focused on ICT's instrumental ability and technological proficiency. In his study on digital capabilities in the Fourth Industrial Revolution era, Choi [15] presented the five domains of the framework for digital competence: (1) the understanding of digital society and digital citizenship, (2) communication and collaboration using digital technologies, (3) critical thinking and information literacy, (4) computing thinking and problem-solving, and (5) creative and convergence thinking and content creation.

This proposition was meaningful because it emphasized not only digital citizenship and communication skills and ethics in the digital world, such as the impact of digital technology on society, but also computational thinking, such as programming and modeling. It was also noteworthy that the study used the term "digital competence," emphasizing that "competence" refers to the ability to apply knowledge, expertise, and skills required for effective performance in specific situations. This usage was considered more appropriate than "literacy," which primarily focuses on the encoding and decoding of information [15]. Shin and Lee [16] measured the digital literacy of college students required in a software-oriented society by presenting

XSL•FO
RenderX

four factors: (1) basic competence in ICT, (2) software-oriented social adaptation ability, (3) social networking service (SNS) use and collaboration ability, and (4) basic work use ability, where software-based communication and collaboration capabilities were reflected in addition to competence in ICT use.

Although various previous studies, including the ones mentioned previously, deal with and measure the characteristics and components of digital literacy, they have some limitations. Existing scales simply focus on the operational capability of ICT equipment without incorporating ethical values such as correct information ethics, information use attitude, sound communication, and citizenship [17,18]. Furthermore, many studies were either conducted before the popularization of ICT devices or targeted teachers or students for the purpose of promoting digital literacy education. With the emergence of various digital devices, media, and technologies, there is an increasing need to measure literacy in this new environment.

Meanwhile, studies have suggested 3 stages in the development of digital literacy: digital competence, digital use, and digital transformation [19]. The first stage, digital competence, refers to the confident and critical use of ICT for work, leisure, or communication; it consists of basic knowledge, skills, and attitudes about ICT. Individuals successfully use digital competence for their circumstances and apply it to various situations and contexts to achieve various goals. The second stage, digital use, refers to the application of digital competence to specific situations, including the use of digital tools to solve problems or develop problem-solving methods and to share and learn information within a community of practice. In the final stage, digital transformation, the advances in digital use bring innovation and creativity, effecting significant changes in areas of expertise or knowledge. Although each step may not be performed sequentially, in many cases, skills or knowledge of the digital competence level may be required to achieve innovation at a higher level, such as digital transformation. For this developmental process to occur smoothly, intrinsic factors such as interest and motivation that enable the acceptance and use of digital technologies are necessary [19]. This study intended to present self-efficacy as a personal characteristic that is expected to influence the use of digital technology.

Self-efficacy refers to the belief in one's ability to execute and organize the course of action required to achieve a particular outcome [20]. Individuals' self-efficacy affects their ability to undertake tasks and accept challenges, and it is applicable to various situations [21]. For example, changing the way in which education is delivered—from face-to-face education to non–face-to-face education through computers—may affect students' sense of computer-using self-efficacy [22,23]. Students with previous computer or online training reported a higher level of computer self-efficacy [23,24]. With a high level of computer self-efficacy, the students found it easier to engage in online learning and, thus, participated in online learning for a longer time [25]. In other words, self-efficacy in the digital environment is expected to affect individuals' use of digital technology.

Objectives

This study aimed to develop and present a digital literacy scale suitable for current society while also addressing the limitations of existing scales. In this study, *digital technology literacy* refers to the technical ability to properly handle information and communication equipment (eg, computers, smartphones, and tablets) and the various abilities required to perform tasks in a digital environment. The components of digital technology literacy reconstructed in this study based on the concept of digital literacy presented in previous studies are as follows: (1) the ability to create and reproduce new content based on digital technology, (2) the ability to communicate and collaborate to solve problems using digital technology, (3) the ability to verify the reliability and accuracy of digital information and use it critically, and (4) the ability to comply with ethical guidelines and understand ethical issues that arise from using digital technology. Furthermore, to measure personal factors that may influence the use of digital technology, this study also intended to measure the sense of efficacy in using digital technology. Previous research indicates that self-efficacy levels influence technology use, so this study integrated elements of digital efficacy along with digital literacy. Moreover, to gauge digital literacy across a wide age range, we planned to assess from individuals in their 20s to those aged ≥60 years.

Methods

Preliminary Item Development

For the development of the Yongin Severance Digital Sensitivity Scale (YI-DSS), 6 factors were derived through literature review, with 3 to 4 items being developed for each factor, accounting for a total of 20 items. To check the suitability of the developed items for measuring digital literacy and digital efficacy, the goodness of fit was verified by experts to ensure content validity. The evaluation was conducted by 20 experts, including professors in engineering, psychology, or medicine or experts who had worked in the field for >10 years, and the data collected from 18 experts were used for analysis.

Study Design

This was an observational, cross-sectional study conducted through an online survey. The survey was administered to members of a survey site, and data were collected between May 2023 and July 2023. This study adheres to the Checklist for Reporting Results of Internet E-Surveys guidelines for reporting internet survey results [26].

Participants

An online survey was conducted with 1000 adults aged ≥19 years. Participants eligible for inclusion in the study were adults aged ≥19 years, with quotas set to ensure equal distribution by age and gender and proportional distribution by region. Exclusion criteria included individuals who did not complete the survey or provided responses that appeared insincere based on response patterns. The results were obtained based on the responses of 986 participants, excluding the insincere responses of 14 participants.

XSL•FO
RenderX

Setting

This study recruited a sample from a web panel of individuals registered with Macromill Embrain, a professional survey company specializing in web-based survey and research services. Macromill Embrain maintains a diverse participant pool through continuous recruitment efforts across various demographics (eg, age, gender, and region) and identity verification processes. For this study, participants aged ≥19 years residing in South Korea were selected using quota sampling. Age group and gender were equally allocated, whereas region was proportionally allocated based on the population distribution across the country's 17 major provinces. Participants who completed the consent process were asked to answer screening questions on eligibility and basic demographic information. Those who met the eligibility criteria were invited to participate in the main survey, whereas those who did not qualify or exceeded the required quotas received compensation according to Embrain's policy. Information about this compensation was provided at the bottom of the initial survey screen. Eligible participants were then randomly selected from the assigned quota groups and invited through a link containing a brief description of the study and eligibility criteria.

Participation in the survey was entirely voluntary, and participants could withdraw at any time before submitting their responses without penalty. They were also able to review and change their answers before the final submission, ensuring flexibility. Survey responses were automatically recorded and securely stored in a database. Only completed questionnaires were analyzed.

Sample Size Calculation

According to absolute criteria in factor analysis, a sample size of 100 is considered poor, a sample size of approximately 200 is fair, a sample size of approximately 300 is good, a sample size of approximately 500 is very good, and a sample size of ≥1000 is excellent [27]. In terms of the ratio of sample size to the number of measured variables, various scholars suggest different ratios, but it is generally recommended to have a sample size that is at least 20 times the number of factors to be extracted to obtain stable factors [28]. Considering the aforementioned criteria, the total target number of participants was set at 1000.

Statistical Analysis

The data collected were statistically analyzed using SPSS (version 27.0; IBM Corp) and R (R Foundation for Statistical Computing). First, exploratory factor analysis was performed to extract the factors of the YI-DSS. Items with communality values of <0.4 were considered unsuitable for the factor structure and were removed before conducting the analysis. To examine whether the collected data were suitable for analysis, the Kaiser-Meyer-Olkin (KMO) test for sampling adequacy and Bartlett test of identity matrix were performed. Principal component analysis was performed for exploratory factor analysis, and the varimax rotation was used for factor rotation. Second, confirmatory factor analysis was performed to verify whether the items were properly set in the constructs derived through exploratory factor analysis. Third, the Pearson correlation coefficient was used to identify the concurrent validity of the Digital Literacy Scale developed in the previous study. Fourth, the Cronbach α was obtained to verify the internal consistency reliability of the scale. Finally, the differences in digital literacy and digital efficacy according to demographic characteristics were analyzed using 2-tailed *t* tests and ANOVAs. For cases in which significant differences between groups were found, the Scheffé post hoc analysis was conducted. When heteroscedasticity was identified in the test for homogeneity of variances, the Dunnett T3 test, which accounts for unequal variances, was performed.

Data cleaning, exploratory factor analysis, correlation coefficient analysis, *t* tests, and ANOVAs were conducted using SPSS (version 27.0). Confirmatory factor analysis was performed using the *lavaan* package in R.

Ethical Considerations

This study was approved by the institutional review board of Yongin Severance Hospital (9-2022-0199). Before obtaining consent to participate in the study, the purpose and procedures of the research were explained, including the voluntary nature of participation and the right to withdraw at any time. All personal information provided by participants was anonymized, encrypted, and securely managed. In accordance with the Bioethics and Safety Act, the data will be destroyed 3 years after the conclusion of the study. Monetary incentives were offered to participants upon survey completion to encourage participation.

Measure and Scale

For the development of the YI-DSS, the concepts and components of digital literacy and digital efficacy were defined, as shown in Table 1. For digital literacy, 4 factors—digital application, digital communication, critical thinking, and digital ethics—were defined, and for digital efficacy, 2 factors—digital confidence and digital anxiety—were established.

Preliminary items were created for the development of a scale that reflected the concepts of the components to assess digital literacy and digital efficacy. In total, 3 to 4 items were developed for each construct, and a total of 20 preliminary items were selected. Each item was scored on a 7-point Likert scale, from 1 point for "strongly disagree" to 7 points for "strongly agree"—a higher score indicates higher digital literacy. Table 2 shows the selected items.

XSL•FO
RenderX

Table 1. Components of the scale.

Component	Definition
Digital literacy	It refers to the competence to critically understand digital information using ICT[a] equipment and digital technology and create new content through technology convergence to solve problems cooperatively.
Digital application	The ability to create and reproduce new content based on digital technology
Digital communication	The ability to communicate and collaborate to solve problems using digital technology
Critical thinking	The ability to verify the reliability and accuracy of digital information and use it critically
Digital ethics	The ability to comply with ethical guidelines and understand ethical issues that arise from using digital technology
Digital efficacy	It refers to the sense of having the competence to embrace digital technology and confidently apply it to solve everyday problems.
Digital confidence	The confidence to use digital technology to solve problems
Digital anxiety	Distrust, concern, and anxiety about the use of digital technology

[a]ICT: information and communications technology.

Table 2. Items for the development of the scale.

Construct and item ID	Content
Digital application	
DA1	"I can use digital technologies to create new content."
DA2	"I create my own content to convey information accurately."
DA3	"I am skilled in producing digital content in various formats."
DA4	"Producing content directly using digital technology is not challenging for me."
Digital communication	
DCom1	"When I acquire new information, I share it in online spaces."
DCom2	"I find joy in engaging in online conversations and listening to others."
DCom3	"I actively express my views in online communities through posts, comments, etc., or participate in and signing petitions."
Critical thinking	
CT1	"Before utilizing information I've searched for, I verify its accuracy and reliability."
CT2	"I read information from multiple web sources and cross-check its accuracy before using it."
CT3	"Before using online information, I ensure it is up-to-date."
CT4	"Before utilizing online information, I verify the reliability of the information provider."
Digital ethics	
DE1	"I do not leak personal information about others or upload or download photos or videos of others without their permission."
DE2	"I ethically source information on the web and utilize it directly from its original source."
DE3	"I do not create or share materials online that are harmful to others or illegal."
Digital confidence	
DCon1	"I effectively utilize digital information."
DCon2	"I am confident in utilizing digital technology."
DCon3	"I believe I can solve a problem that arises while using digital technologies myself."
Digital anxiety	
DAnx1	"I feel unsafe using digital technologies as I am concerned about device malfunctions, loss of information, hacking, etc."
DAnx2	"I am hesitant to use digital technologies as I am not confident in using them."
DAnx3	"I am afraid of accidentally losing information while using digital technologies."

XSL•FO
RenderX

The concurrent validity between the YI-DSS developed in this study and the previously developed Digital Literacy Scale was confirmed. The Digital Literacy Scale is a self-report scale developed by Lim et al [29] and consists of a total of 24 questions in 5 factors (using digital information and data, creating and expressing digital content, digital communication and collaboration, information protection and compliance with laws and regulations, and computing thinking). The construct validity of the scale was confirmed through exploratory factor analysis and confirmatory factor analysis, and the internal reliability of the scale was found to be 0.941. The responses are rated on a 5-point Likert-type scale.

Results

Demographics

Table 3 presents data on the gender, age, and educational background of the respondents to the questionnaire used to obtain the study results.

Table 3. Demographics (N=986).

Characteristic	Participants, n (%)
Gender	
Male	499 (50.6)
Female	487 (49.4)
Age (y)	
20-29	159 (16.1)
30-39	164 (16.6)
40-49	200 (20.3)
50-59	210 (21.3)
60-64	103 (10.4)
>65	150 (15.2)
Educational level	
Elementary school graduate	1 (0.1)
Middle school graduate	9 (0.9)
High school graduate	205 (20.8)
Graduate	617 (62.6)
Master's degree	78 (7.9)
Doctorate degree	29 (2.9)

Factor Analysis

Table 4 presents the results of the exploratory factor analysis conducted on the Digital Literacy Scale.

All 20 items met the standard (>0.5) in the measure of communality. The results of the KMO and Bartlett test of sphericity were confirmed. A KMO metric value of ≥0.90 was considered excellent, and a value of ≤0.50 was considered unacceptable. In this analysis, the KMO value of the Digital Literacy Scale was found to be good at 0.891, and the Bartlett sphericity was also statistically significant (χ^2_{91}=9829.7; *P*<.001), indicating that the collected data were suitable for factor analysis.

Regarding each domain, digital application consisted of 4 items, with an eigenvalue of 6.289 and a variance explanatory power of 25.56%. The critical thinking factor consisted of 4 items, with an eigenvalue of 2.552 and a variance explanatory power of 21.02%. The digital ethics factor consisted of 3 items, with an eigenvalue of 1.035 and a variance explanatory power of 15.84%. The digital communication factor consisted of 3 items, with an eigenvalue of 1.013 and a variance explanatory power of 15.363%. Finally, the total variance explanatory power of the 4 factors of digital literacy was confirmed to be 77.782%.

The internal consistency (Cronbach α) of each factor in the Digital Literacy Scale was analyzed. Table 5 shows the results. The Cronbach α was 0.974 for digital application, 0.889 for critical thinking, 0.806 for digital ethics, and 0.782 for digital communication, with the overall Cronbach α for the Digital Literacy Scale being 0.900, indicating a desirable level of reliability for all factors and the scale.

[a]Kaiser-Meyer-Olkin=0.891; Bartlett × 2=9829.713; *P*<.001.

[b]Not applicable.

Table 5. Subfactors of the Digital Literacy Scale and their reliability.

	Item ID	Items, N	Cronbach α
Digital application	DA1, DA2, DA3, and DA4	4	0.974
Critical thinking	CT1, CT2, CT3, and CT4	4	0.889
Digital ethics	DE1, DE2, and DE3	3	0.806
Digital communication	DCom1, DCom2, and DCom3	3	0.782
Digital Literacy Scale: total	—[a]	14	0.900

[a]Not applicable.

A total of 6 preliminary items were selected through literature review and a suitability survey by experts to measure the attitude toward using digital technology in the Digital Efficacy Scale. Each item was scored on a 7-point Likert scale from 1 point for "strongly disagree" to 7 points for "strongly agree." Exploratory factor analysis was performed to extract the factors for the Digital Efficacy Scale. Table 6 shows the results.

In this analysis, the KMO value of the Digital Efficacy Scale was found to be acceptable at 0.734, and the Bartlett sphericity was also statistically significant (χ^2=3389.5; *P*<.001), indicating that the collected data were suitable for factor analysis.

Regarding each domain, the digital confidence factor consisted of 3 items, with an eigenvalue of 2.651 and a variance explanatory power of 44.181%. The digital anxiety factor consisted of 3 items, with an eigenvalue of 2.112 and a variance explanatory power of 35.197%. Finally, the total variance explanatory power of the 2 factors of digital efficacy was confirmed to be 79.378%.

The internal consistency (Cronbach α) of each factor in the Digital Efficacy Scale was analyzed. Table 7 shows the results. The Cronbach α was 0.912 for digital confidence and 0.787 for digital anxiety, with the overall Cronbach α for the Digital Efficacy Scale being 0.720, indicating an acceptable level of reliability for all factors and the scale.

Following the analysis of the exploratory factor analysis results, confirmatory factor analysis of the digital literacy and digital efficacy models was conducted using the *lavaan* package in RStudio (Posit PBC). To evaluate the model fit, several indexes were computed, including the chi-square test, Tucker-Lewis index (TLI), comparative fit index (CFI), standardized root

XSL•FO
RenderX

mean square residual (SRMR), and root mean square error of approximation (RMSEA). TLI and CFI values of >0.90 indicate a good model fit, whereas SRMR values of ≤0.08 and RMSEA values of <0.05 suggest a good fit.

As shown in Table 8, neither the digital literacy nor the digital efficacy models demonstrated good fit based on the chi-square statistic (digital literacy model: χ^2_{71}=676.0 and *P*<.001; digital efficacy model: χ^2_8=81.9 and *P*<.001). However, it is well known that the chi-square statistic is highly sensitive to sample size, so it is important to consider other fit indexes as well. The CFI, TLI, SRMR, and RMSEA values all indicated a good fit, supporting the acceptability of each model's fit.

Table 6. Exploratory factor analysis on the Digital Efficacy Scale (DES)[a].

Item ID	Communality	DES	
		Digital confidence	Digital anxiety
DCon1	0.862	0.926	–0.069
DCon2	0.885	0.937	–0.090
DCon3	0.803	0.894	–0.054
DAnx2	0.653	0.179	0.788

Table 8. Goodness-of-fit indexes for the confirmatory factor analysis models.

Model	Chi-square (*df*)	*P* value	CFI[a]	TLI[b]	SRMR[c]	RMSEA[d]
Digital literacy	676.0 (71)	<.001	0.938	0.921	0.073	0.093
Digital efficacy	81.9 (8)	<.001	0.977	0.958	0.073	0.097

[a]CFI: comparative fit index.

[b]TLI: Tucker-Lewis index.

[c]SRMR: standardized root mean square residual.

[d]RMSEA: root mean square error of approximation.

Covalidation Analysis

Pearson correlation coefficient analysis was conducted to test the covalidation between the YI-DSS and the previously developed Digital Literacy Scale. The total scores on the YI-DSS showed high correlation with the existing Digital Literacy Scale (*r*=0.809; *P*<.001).

Further Analysis

Analysis of digital device use by age group revealed that smartphone use frequency was notably high among all participants (Table 9). Of the 986 participants, 968 (98.2%) reported using a smartphone either "frequently" or "very frequently." Regarding PC use, 78.2% (771/986) of the participants reported frequent use, with approximately 70% of those aged ≥65 years (103/150, 68.7%) also reporting frequent use. In the case of digital communication tools, >73% of the respondents reported frequent use of both SNSs (748/986, 75.9%) and email (720/986, 73%). The use frequency of emerging technologies such as virtual reality, 3D printers (81/986, 8.2%), and voice assistants was low, with <17% (164/986, 16.6%).

XSL•FO
RenderX

An independent-sample *t* test was conducted to examine the difference in digital sensitivity scores by gender (Table 10). The Levene test was used to assess the equality of variances, and the *t* test results were presented based on whether equal variances were assumed. The analysis revealed significant gender differences in both the total digital literacy score and the total digital efficacy score.

In detail, men (mean 66.735, SD 13.008) scored significantly higher than women (mean 62.834, SD 13.775) on total digital literacy (t_{984}=4.574; *P*<.001). Given the significant gender difference in the total digital literacy score, further analysis was conducted on the subfactors. The results indicated significant gender differences across all subfactors. Men scored significantly higher than women in digital application (mean 15.543, SD 5.847 for men vs mean 12.803, SD 6.158 for women; t_{984}=7.167; *P*<.001). Similarly, in the critical thinking factor, men (mean 20.764, SD 4.242) outperformed women (mean 19.762, SD 4.887; t_{984}=–2.658; *P*<.01). The digital communication scores were also significantly higher for men (mean 13.527, SD 3.692) than for women (mean 12.799, SD 3.859; t_{984}=3.029; *P*=.003). Conversely, in the digital ethics factor, women (mean 17.470, SD 3.536) scored significantly higher than men (mean 16.902, SD 3.536; t_{984}=–2.658; *P*=.008).

Regarding digital efficacy, men (mean 25.363, SD 5.152) also scored higher than women (mean 23.895, SD 4.713; t_{984}=4.664; *P*<.001). Analyzing the subfactors, men showed significantly higher scores in digital confidence (mean 14.719, SD 3.656 for men vs mean 12.669, SD 4.153 for women; *P*<.001). However, in the digital anxiety factor, women (mean 11.226, SD 3.543) scored significantly higher than men (mean 10.643, SD 3.997; t_{984}=–2.423; *P*=.02).

To examine whether there were differences in average digital sensitivity across different age groups, a 1-way ANOVA was conducted. A statistically significant difference was found in the total digital literacy score (F_5=18.076; *P*<.001) based on a significance level of .001. Post hoc analysis revealed significant differences in the average total digital literacy scores between individuals in their 20s and 30s and those in their 40s, 50s, and 60s.

The analysis of differences across subfactors by age group is as follows. In the digital application subfactor, individuals in their 20s scored higher than those in their 40s, 50s, and 60s. Individuals in their 30s also scored significantly higher than those in their 50s and 60s, whereas those in their 40s scored higher than those in their 60s. This indicates that individuals in their 60s had the lowest ability to produce information using digital technologies compared to other age groups. In the critical thinking subfactor, individuals in their 20s and 30s scored higher than those in their 50s and 60s, and individuals in their 40s also showed significant differences compared to those in their 50s and 60s. This suggests that individuals in their 60s had a lower ability to critically use digital information compared to other age groups except for those in their 50s. In the digital communication subfactor, individuals in their 20s scored higher than those in their 60s in terms of using digital technologies for communication. Finally, in the digital ethics subfactor, there were no significant differences between age groups.

[c]CT: critical thinking.

[d]DE: digital ethics.

[e]Dcom: digital communication.

[f]DES: Digital Efficacy Scale.

[g]Dconf: digital confidence.

[h]Danx: digital anxiety.

In addition, to examine whether there were differences in average digital efficacy across different age groups, a 1-way ANOVA was conducted (Table 11). The results indicated a statistically significant difference (F=18.592; P<.001) based on a significance level of .001. Post hoc analysis revealed that individuals in their 20s and 30s had higher digital efficacy than those in their 50s and 60s.

When examining the subfactors, it was found that individuals in their 20s and 30s scored higher than those in their 50s and 60s in the digital confidence subfactor. In addition, those in their 40s also showed higher confidence than those in their 50s and 60s. However, in the digital anxiety subfactor, the differences across age groups were not statistically significant.

Discussion

Principal Findings

The detailed study findings are as follows. First, to develop a digital sensitivity scale, basic items were compiled through a literature review, and 20 items were selected after content validity was verified by 18 experts. In total, 4 factors of digital literacy and 2 factors of digital efficacy were identified. The factors of digital literacy were digital application, critical thinking, digital ethics, and digital communication, collectively accounting for 77.782% of the variance. Digital efficacy was divided into 2 factors: digital confidence and digital anxiety, showing an explanatory power of 79.378%.

The following are the specifics of the YI-DSS, which is described in this study. This scale was developed to assess digital literacy, which is known to have a significant impact on digital technology use, as well as digital efficacy, which is expected to affect intrinsic motivation and attitudes toward the use of digital technology. First, as with the Digital Literacy Scale, the domain of digital application was designed to assess the ability to create and reproduce new content based on digital technology. Next, the digital communication domain aimed to evaluate the ability to communicate and collaborate in solving problems through digital technology. The critical thinking domain was intended to assess the ability to verify the reliability and accuracy of digital information and use it critically. Finally, the digital ethics domain was designed to measure the ability to comply with ethical guidelines and understand ethical issues that arise from using digital technology. The Digital Efficacy Scale, on the other hand, was designed to assess users' confidence and competence in using digital technology. In addition, to identify factors that impede the use of digital technologies, concerns and anxiety about the use of digital technologies were measured.

The additional analyses revealed the following findings. First, the analysis by age group confirmed a generational gap in digital literacy. In the past, when the penetration rate of digital devices was not high, the key factor contributing to the digital divide was the ease of access to digital devices. However, as the gap in physical accessibility to digital devices has been bridged, the ability to effectively use digital technology—referred to as digital literacy—has emerged as the primary cause of the digital divide [30-32].

XSL•FO
RenderX

An analysis of the types and frequency of digital device use among the respondents in this study showed that 98.2% (968/986) of the respondents frequently used smartphones. Even considering that this study was conducted through an online survey, the fact that >98% of respondents reported using their devices “frequently” or “very frequently” indicates that digital technology is used daily across all age groups, suggesting a high level of accessibility to digital devices. When analyzing the characteristics of device use by age group, >70% of respondents in their 20s, 30s, 40s, 50s, and early 60s reported frequent use of email or SNSs. Notably, the proportion of respondents in their 20s who reported frequent SNS use approached 93% (149/159, 93.7%). In addition, more than half (748/986, 75.9%) of the respondents in their late 60s reported frequent use of email and SNSs, with approximately 62% frequently using SNSs. These findings indicate that the penetration of digital devices is consistently high across all age groups and that online information activities and interactions actively take place across all ages.

Despite the improved accessibility to digital technology, there remains a clear generational gap in digital literacy and confidence in using these technologies. This finding suggests the need for age-appropriate assessments and interventions in digital sensitivity. The analysis revealed that the gap between those in their 20s and 60s was particularly pronounced. The older age groups demonstrated lower digital literacy, especially in the subfactors of digital application, practical use, and communication. Interestingly, while the frequency of online interactions for relationship building and information acquisition was high across all age groups, the generational gap in digital literacy was still evident. Older adults showed lower capabilities to verify the sources and reliability of information, critically evaluate it, and create new content and communicate on the internet. This aligns with previous research indicating that older adults, due to lower digital literacy, are more susceptible to exposure to misinformation and are at higher risk of accepting it uncritically [33-36]. Therefore, it is essential to educate and support older adults to become more active and critical consumers of information in the digital world.

Moreover, the study found significant differences in digital efficacy across age groups. The disparity in digital efficacy between individuals in their 20s and those in their 60s was particularly notable, with older adults showing lower confidence in using digital technologies. Specifically, the difference was significant in the subfactor of digital competence, indicating that older adults have lower confidence and perceived proficiency in using these technologies. However, there was no significant difference in digital anxiety, which measures concerns or fears about potential mistakes when using digital technologies. According to Bandura [37], self-efficacy increases engagement in exploratory behaviors. Individuals with high self-efficacy are more likely to take on unfamiliar tasks, actively learn and apply new information, and exhibit openness. Previous studies examining the relationship between self-efficacy and digital technology use have also found that individuals with higher self-efficacy perceive technologies as easier to use and show a higher intention to use them [30]. In this study, the analysis of the use of emerging technologies by age group revealed that, among respondents in their 20s, who exhibited the highest digital efficacy, approximately 22% (35/159) frequently used emerging technologies such as voice assistants. In contrast, only 8% (12/150) of respondents in their late 60s, which showed the lowest digital efficacy, reported frequent use of such technologies. This suggests that the level of digital efficacy not only influences the use of currently available digital technologies but also impacts the adoption of extended digital technologies, such as digital therapeutics and emerging technologies. Consequently, measuring and enhancing digital efficacy alongside digital literacy is crucial as it may affect openness to technology and proficiency and contribute to the digital divide.

Third, this study found no significant differences between age groups in ethical attitudes related to digital device use, which is one of the subfactors of digital literacy. This subfactor assesses attitudes to consider when using digital technologies, including online morality. The questions on this factor asked about awareness of clearly unethical practices, such as using illegal online routes and plagiarism, which might have led to socially desirable responses, potentially biasing the results positively. Nevertheless, measuring awareness of moral values and attitudes in digital environments remains important. According to previous research, the main factors influencing awareness of digital communication ethics are the recognition of the importance of ethical norms and individual morality [38].

As living and interacting in the digital world, which transcends the boundaries of time and space, becomes increasingly important, measuring digital ethics can serve as a guideline to help individuals align their general moral awareness, shaped by their values and beliefs, with the unique and unfamiliar environment of the digital world, thereby guiding them in focusing on and considering ethical principles.

In the current trend of digital-based medical care, the importance of digital sensitivity becomes prominent. However, despite society’s rapid digitization, there is a growing gap in the ability to accept and use digital technology.

A gap in understanding and attitude toward things appears unavoidable in a society in which the older generation, which has transitioned from an analogue or paper-based system to a digital system, coexists with the generation of “digital natives” born in a digitalized society and raised with the use of digital technology [39,40]. Therefore, it is critical to assess the extent of the digital divide and assess and improve digital literacy, a key variable that can influence the level of such a gap [39]. Studies have emphasized that successful experiences in acquiring and using ICTs during the early stages of digital literacy development are essential for applying digital technology to various contexts of life. In other words, it is necessary not only to understand how to use digital technology but also to feel competent and effective when doing so. Identifying the factors that contribute to resistance to the use of digital technology will increase digital competence and improve individual digital adaptation by increasing acceptance of and motivation for digital technology in light of such factors.

Strengths and Limitations

In this study, we developed and validated the YI-DSS, an easy-to-use self-report tool designed to assess an individual's digital literacy and efficacy. This study refined the concept by incorporating the latest insights related to digital literacy and included digital efficacy, which is recognized as a crucial component of digital competence. This scale is expected to enable a multidimensional assessment of an individual's digital competence, facilitating the identification of key areas for intervention and helping bridge the information gap between individuals and generations.

The limitations of this study are as follows. First, this study aimed to create a scale to assess understanding of and competence in commonly used digital technologies. Given the rapid development of ICT equipment and digital technology in today's society, the concept of digital literacy will continue to evolve. As a result, it will be necessary to constantly revise and supplement measurement tools to keep up with the pace of technological development.

Second, this study recruited participants and conducted the survey on the web, making it difficult to rule out the possibility that the sample was biased toward users who are more familiar with online platforms and digital devices. Future studies should consider revalidating the findings through offline or face-to-face surveys.

Finally, the survey was conducted as a one-time assessment, so test-retest reliability was not confirmed. Follow-up studies should aim to secure more in-depth reliability by conducting repeated assessments with the same group.

Conclusions

In conclusion, this study developed and validated the YI-DSS to assess digital literacy and efficacy across various age groups. Content-valid items were analyzed using exploratory and confirmatory factor analyses, confirming a robust factor structure. The scale demonstrated strong internal consistency reliability and concurrent validity, confirming its robustness as a tool for evaluating digital literacy and efficacy. This study emphasized the importance of addressing both digital literacy and efficacy to bridge the digital divide and enhance digital adaptation across generations. While this scale provides a comprehensive tool for measuring digital literacy and efficacy, future research should focus on refining it to keep pace with technological advancements and validating the findings with more diverse populations through offline assessments.

Acknowledgments

This study was supported by a Korea Medical Device Development Fund grant funded by the Korean government (the Ministry of Science and Information and Communications Technology; the Ministry of Trade, Industry, and Energy; the Ministry of Health and Welfare; and the Ministry of Food and Drug Safety; project 1711194226 and RS-2020-KD000143) and the Virtual Patient·Virtual Hospital–based medical technology development project through the Korea Health Industry Development Institute funded by the Ministry of Health and Welfare, Republic of Korea (grant HI23C0514).

Authors' Contributions

HIP was responsible for the conceptualization, formal analysis, methodology, data curation, and drafting of the original manuscript, as well as contributing to the review and editing process. MJ contributed to the conceptualization, methodology, and data curation and also participated in the review and editing of the manuscript. JSA was involved in conceptualization and provided significant input during the review and editing of the manuscript. KC contributed to the conceptualization of the study. JYP was responsible for conceptualization, funding acquisition, and overall supervision of the project.

Abstract

Background: In this era of digitalization, eHealth interventions are used to engage patients in health care and help them manage their health. Previous studies showed that this can be particularly interesting for chronic disease self-management and self-care in older adults. Despite older adults becoming increasingly active on the internet, they continue to struggle in using eHealth information due to inadequate eHealth literacy. Thus, assessing and monitoring eHealth literacy is critical to support eHealth interventions.

Objective: This study aimed to describe the translation, adaptation, and validation process of the eHealth Literacy Scale (eHEALS) in Portuguese older adults.

Methods: The cross-cultural adaption followed the steps of forward and blinded backward translations, evaluation of the translations by a committee of judges, pilot-testing, and full psychometric testing. We tested the psychometric properties of the eHEALS by carrying out two studies: general psychometric analysis (study 1) and confirmatory factor analysis (study 2). Study 1 included 80 older adults conveniently selected from a Health Family Unit. Data were collected by in-person questionnaires between May and July 2022. Study 2 included 301 older adults randomly selected from two distinct Health Family Units. Data were collected by in-person questionnaires between May and July 2023.

Results: We tested stability, reliability, construct validity (exploratory and confirmatory factor analyses and known groups), and model fit. Study 1 had 58.8% (47/80) male and 41.3% (33/80) female respondents (mean age 71.20, SD 5.26 years). Study 2 had 56.5% (170/301) male and 43.5% (131/301) female respondents (mean age 71.77, SD 5.15 years). Moderate and strong correlations were identified in the scale items (study 1: $0.42 \leq r \leq 0.91$ and study 2: $0.81 \leq r \leq 0.96$; $P<.001$). The scale showed good internal consistency for study 1 ($\alpha=.92$) and study 2 ($\alpha=.98$), with high correlations between items. The exploratory factor analysis yielded a single-factor structure, explaining 58.3% of the variance in study 1 and 86.4% in study 2. In the confirmatory analysis (study 2), the model fit was mixed ($\chi^2_{20}=265$, $P<.001$; comparative fit index=0.94; Tucker-Lewis Index=0.91; root mean square error of approximation=0.20). Thus, we compared 1-, 2-, and 3-factor structures, deciding on the unidimensional one. In study 1, the eHEALS-PT24 (Portuguese version of the eHealth Literacy Scale for older adults) mean score was 27.25 (SD 5.61), with 43.8% (35/80) and 11.3% (9/80) of participants showing low and high eHealth literacy levels, respectively. In study 2, the eHEALS-PT24 mean score was 23.31 (SD 9.53), with 38.2% (115/301) and 23.6% (71/301) of participants showing low and high eHealth literacy levels, respectively. The known-groups analysis showed statistically significant differences between eHealth literacy and demographic variables ($P<.001$).

Conclusions: The findings suggest that the eHEALS-PT24 is a reliable and valid tool to assess eHealth literacy in Portuguese older adults. Therefore, this instrument can be integrated to support the implementation process of eHealth interventions.

eHealth; health literacy; older adults; psychometric properties; public health

Introduction

Background

Currently, the internet is the main source of health information. According to the survey Flash Eurobarometer 404 [1], 8 (80%) in 10 Europeans used the internet for private matters, with the majority (59%) using it for health information searching purposes. The increasing number of internet users has been influencing health systems globally, leading to investments in the provision of eHealth services. In recent years, there have been great efforts to use eHealth interventions to engage patients in health care and help them manage their health, particularly among older adults with chronic disease self-management and self-care [2-4]. Nevertheless, despite the broad access to the internet and other electronic sources, there continues to be a lack of skills to access valid and reliable health information, as well as to understand, evaluate, and apply it adequately for decision-making purposes [5-7]. Considering this condition, eHealth literacy has emerged as a new concept in health care and a challenge in public health [8].

According to Norman and Skinner [9], eHealth literacy is "the ability to seek, find, understand, and evaluate information from electronic sources and apply it to knowledge gained to address or solve a health problem." Based on this, individuals should be able to perform basic or advanced information retrieval, distinguish documents from reliable sources (eg, authoritative ones or scientific evidence-based), and understand eHealth terminology. Furthermore, this set of skills requires the ability to use information and communication technology (ICT), think critically about their nature, and efficiently navigate different electronic resources to obtain information for health-related decision-making.

Considering that eHealth literacy is not a static set of skills, instead changing over time, Norman and Skinner [9] consider the importance of assessing and monitoring eHealth literacy as critical to supporting eHealth interventions. In recent years, indeed, older adults have become increasingly active on the internet and interested in digital health care services to manage their health; however, limited attention has been given to measuring eHealth literacy in this population. Therefore, we sought to address this gap by translating, culturally adapting, and validating a scale for Portuguese older adults that measure eHealth literacy levels (Multimedia Appendix 1).

The eHealth Literacy Scale

The eHealth Literacy Scale (eHEALS), developed by Norman and Skinner [10], was the most frequently used instrument to measure eHealth literacy worldwide, covering 18 languages, 26 countries, and diverse populations and contexts (ie, adolescents, adults, elderly, patients, healthy people, caregivers, health school professionals, community, and clinical practice) [11]. Since its development, the eHEALS has been widely translated, adapted, and validated in several countries, such as Brazil [12], China [13-16], Ethiopia [17], Germany [18,19], Greece [20], Hungary [21], Indonesia [22], Iran [23,24], Italy [25,26], the Netherlands [27]; Norway [28,29], Poland [30,31], Portugal [32], Serbia [33], South Korea [34-36], Spain [37], and Sweden [38], as well as in countries with English as the main language [39-47].

The scale's development study [10] assessed the eHealth literacy of Canadian adolescents (n=664) aged between 13 and 21 years from 14 secondary schools. Considering the psychometrics test results, the instrument showed a good internal consistency (α=.88), with moderate to strong correlations between items ($0.51 \leq r \leq 0.76$) and a moderate test-retest reliability ($0.40 \leq r \leq 0.68$). In addition, a unidimensional structure was found in exploratory and confirmatory factor analyses, explaining 56% of the total variance.

In Portugal, and similarly to the original study, the eHEALS was translated, adapted, and validated in 2014 in a sample of adolescents (n=1215) attending secondary education. The results showed a good internal consistency (α=.84) and a 2-factor structure in the exploratory factor analysis (EFA; extraction of 2 factors with α=.81 and α=.73), explaining 61% of the total variance. From a subgroup analysis, the authors found statistically significant differences regarding the level of education. For the variables sex and age, no statistically significant differences were found. No further translation, adaptation, and validation studies of eHEALS considering other target populations or contexts in Portugal have been carried out since then [32].

Studies with samples including older adults [24,36,39,43,44,48] showed good internal consistency, with Cronbach α ranging between 0.87 and 0.99. Regarding factor analysis, 3 studies [24,36,39] obtained 1D structures, and 2 other studies obtained 3D ones [43,44].

The questionnaire itself consists of 8 items assessing the person's perception of knowledge, comfort, and ability to find, evaluate, and apply health ICT. Each of the items is scored at 5 points on a Likert scale ranging between "1" (totally disagree) and "5" (totally agree), with a total score from 8 to 40 points. The higher the score, the higher the eHealth literacy levels. Items 1 and 2 are related to awareness, items 3 and 4 are related to demand, items 6 and 7 are related to the evaluation of health resources, and items 5 and 8 are related to the use of health information. The instrument also contains 2 additional items, not adding to the final score, which assesses the participant's perception of using the internet to access health information and make health decisions in terms of its usefulness and importance. The theoretical basis of the eHEALS was the social cognitive theory of Albert Bandura and the Lily Model, which explains multiple components of the constructs based on 6 components of literacies—traditional (literacy and numeracy skills), health, information, scientific, media, and computer [10].

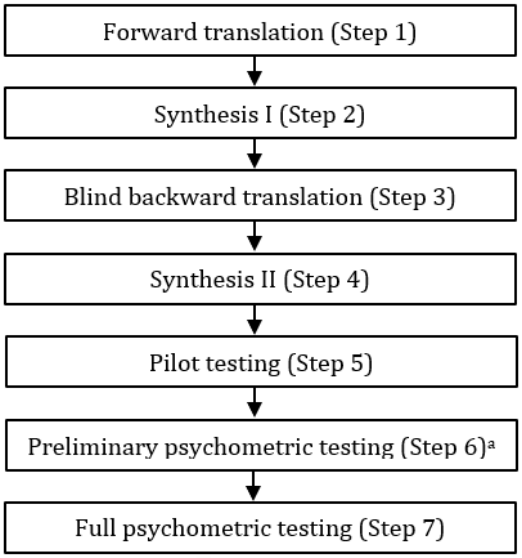
This paper presents and discusses the results of full psychometric testing of the eHEALS-PT24 (Portuguese version of the eHealth Literacy Scale for older adults), which aimed to:



- Translate, culturally adapt, and validate the eHEALS for assessing eHealth literacy in Portuguese older adults.
- Test full psychometric characteristics of the eHEALS to be used in Portuguese older adults.
- Explore associations between eHealth literacy and sociodemographic variables.

Methods

Design

We followed a methodology for translating, adapting, and validating instruments proposed by Sousa and Rojjanasrirat [49]—a 7-step guideline based on the review of existing recommendations in the scientific literature on the process of translation, cultural adaptation, and validation of instruments for use in cross-cultural health care (Figure 1).

Figure 1. Steps of the protocol followed for translating, cultural adapting, and validating the eHealth Literacy Scale (eHEALS). [a]: N/A: not applicable.

The original version of the questionnaire was independently translated to Portuguese by 2 translators with high proficiency in English: a translator with knowledge of the terminology used in health care and another with knowledge of the cultural and linguistic characteristics of the target language (forward translation; step 1). After this, a third translator compared the two translated versions of the instrument and the original one to detect discrepancies. In addition, a first meeting with a committee of experts with different backgrounds and expertise was held to evaluate discrepancies, composed of the 2 bilingual experts from the first step, the third bilingual translator, academia members, and the research team (step 2). These 2 steps generated the preliminary translated version of the instrument for the Portuguese language.

Independent, blinded backward translation to English was carried out by 2 translators whose first language was English as spoken in the United Kingdom: one translator with knowledge of the terminology used in health care and another with knowledge of the cultural and linguistic characteristics of the target language (step 3). This step generated 2 retroverted versions of the original version of the instrument, which were then compared with the original one (in English) to detect discrepancies by the research team. In addition, a second meeting with a committee of experts with different backgrounds and expertise was held to detect discrepancies, composed of all translators involved in the previous three steps, academia members, and the research team (step 4). These 2 steps generated the prefinal version of the translated instrument, which the original authors validated.

The prefinal version of the instrument was then tested in a pilot study in the target language with a monolingual sample (n=15) to evaluate the instructions, items, and response format clarity (ie, to establish whether the instrument could be satisfactorily understood and completed by people from the target population; step 5). As part of this step, a committee of experts (n=8) was also held to further examine the instrument for clarity of the instructions, items, and response format (content equivalence assessment). The fifth step generated some adjustments in the prefinal version of the instrument.

According to the protocol followed, step 6 (preliminary psychometric testing of the prefinal version of the translated instrument with a bilingual sample) is rarely used, except when a bilingual population is accessible, which justified the option of not carrying it out in this validation process.

Full psychometric testing (step 7) involved reviewing and refining the items of the final version of the eHEALS for Portuguese older adults, as well as establishing stability, internal consistency, validity, and model fit. This step encompassed 2 substudies: general psychometric characteristics of the instrument (n=80, study 1) and confirmatory factor analysis (CFA; n=301, study 2). The sample sizes were defined according to the protocol, namely, at least 10 participants per item of the instrument for general psychometric analysis and 300 to 500 participants for CFA.

Participants and Recruitment

Study 1 included 80 older adults from a Health Family Unit (Primary Care) located in Faro. The sampling procedures were based on a convenience sample. Data collection was conducted by in-person questionnaires between May and July 2022. During that time, patients aged 65 years or older who went to the Health Family Unit (Primary Care) for an appointment were invited to participate in the survey.

Study 2 included 301 older adults from 2 distinct Health Family Units (Primary Care), located in Faro and Lisbon. Participants were randomly selected from the total number of patients of the 2 considered Health Family Units and invited by phone to visit the unit and participate in the survey. Data collection was conducted by in-person questionnaires between May and July 2023.

Inclusion criteria were age (aged 65 years or older) and sex (female and male). Difficulty communicating or using the Portuguese language was an exclusion criterion. The questionnaire removal was performed when the questionnaires were not entirely fulfilled.

Data Analysis

The data analysis was conducted in several stages to ensure a comprehensive understanding of the psychometric properties of the eHEALS-PT24. The following steps outline our analytical approach.

Descriptive Statistics

Initially, we performed descriptive statistical analyses to understand the basic features of the data. This included calculating mean, SD, frequencies, and percentages for all the variables, providing a snapshot of the sample characteristics.

Scale and Items Stability

To assess the scale and item stability, we calculated Pearson correlations. We considered the following Pearson correlation ranges: very weak (0.00-0.19), weak (0.20-0.39), moderate (0.40-0.59), strong (0.60 and 0.79), and very strong (0.80-0.99). Also, statistical significance was set at $P<.001$ [50].

Reliability Analysis

To assess the internal consistency, we calculated Cronbach α coefficients. A Cronbach α value of 0.70 or higher was considered indicative of acceptable reliability. The item-total correlation between the items and the total score was considered high, with values above 0.40 [50].

Construct Validity: Factor Analysis

We conducted an EFA to explore the underlying factor structure of the scale. The Kaiser-Meyer-Olkin (KMO) measure and Bartlett test of sphericity were used to assess the suitability of the data for factor analysis. Factors were extracted using principal component analysis, and a varimax rotation was applied to aid interpretability.

Following EFA, a CFA was performed using structural equation modeling to verify the factor structure obtained from EFA. Model fit was evaluated using different indices, including the comparative fit index (CFI), Tucker-Lewis Index (TLI), root mean square error of approximation (RMSEA), and chi-square (*df*) ratio. RMSEA values of 0.00 to 0.05 indicate a closer or good fit, 0.05 to 0.08 a fair fit, 0.08 to 0.10 a mediocre fit, and over 0.10 a poor fit. Other fit indexes that we used were the CFI and TLI, both of which should be close to 0.95 [51].

Construct Validity: Known-Groups Validity

The known-groups validity measures an instrument's ability to distinguish among distinct groups (ie, discriminating groups known to differ on the variable of interest) [50]. To evaluate the known-groups validity, we compared eHEALS-PT24 scores across different sociodemographic groups (ie, age, sex, residence area, and education level) using the independent Student *t* test (2-tailed), ANOVA, or Kruskal-Wallis test, as appropriate.

Statistical Software

All analyses were performed using IBM SPSS and Jamovi (The Jamovi Project). By using this multistep analytical process, we aimed to rigorously evaluate the psychometric properties of the eHEALS-PT24, ensuring its reliability and validity in assessing eHealth literacy among Portuguese older adults.

Ethical Considerations

The ethics review assessments were submitted and approved by Portugal's National Data Protection Authority and Regional Health Administrations (Algarve, Lisbon, and Tagus Valley; (approval 4825/2018). Informed consent was applied to participants, according to the model recommended by the Ethics Committee of the Algarve Regional Health Administration, guaranteeing voluntary participation, the possibility of withdrawing at any time, data anonymity, privacy, confidentiality, and no harm to participants. In addition, an authorization request was made to the original authors of the eHEALS [10], which was accepted.

Results

Pilot Study

Before the full psychometric testing, we carried out a pilot study, which we briefly summarized to support the results presented in this subsection. The sampling procedure for piloting was based on snowball sampling, composed of older people aged 65 years or older (n=15). Data collection was conducted using a web-based questionnaire between July and August 2020. The interrater agreement among the sample was above 80% for all items. As part of this step, a committee of experts (n=8) was also held to further examine the instrument for clarity of the instructions, items, and response format; also, to assess the content equivalence, content validity index at the item level (I-CVI=1) and at the scale level (S-CVI=1), as well as the Fleiss κ coefficient of agreement (κ=0.24; $P<.001$), were calculated.

Participant's Characteristics

Study 1

Out of the 80 participants, the sample comprised 47 male (58.8%) and 33 female (41.3%) participants, with a mean age of 71 (SD 5.26) years, ranging from 65 to 88 years. From the total sample (n=80), most of the participants were married or had civil partners (n=63, 78.8%), living with their spouse (n=65,

XSL•FO
RenderX

81.3%) in urban areas (n=70, 87.5%). In addition, most of the respondents were retired (n=69, 86.3%). Regarding formal education, this was analyzed according to the International Standard Classification of Education (ISCED), showing that the most general education level was upper secondary education—ISCED 3 (n=20, 25%), followed by primary education—ISCED 1 (n=17, 21.3%), and bachelor or equivalent degree—ISCED 6 (n=17, 21.3%). Concerning the current health status, most participants reported a diagnosed chronic condition (n=58, 72.5%), mainly high blood pressure (n=29, 36.3%), diabetes (n=25, 31.2%), and dyslipidemia (n=8, 10%). Regarding prescribed medication, 85% (n=68) of the sample answered that they usually take medicines, with 3 being the average number of medicines per person and 9 being the maximum number. Table 1 presents the sociodemographic data.

Study 2

The sample comprised 170 male (56.5%) and 131 female (43.5%) participants, with a mean age of 72 (SD 5.15) years, ranging from 65 to 88 years. From the total sample (n=301), most of the participants were married or had civil partners (n=215, 71.4%), living with their spouse (n=267, 88.7%) in urban areas (n=267, 88.7%). In addition, most of the respondents were retired (n=271, 90%). Regarding formal education, this was analyzed according to the ISCED, showing that the most general education level was primary education—ISCED 1 (n=116, 38.5%), followed by lower secondary education—ISCED 2 (n=51, 17%) and bachelor or equivalent degree—ISCED 6 (n=37, 12.3%). Concerning the current health status, most participants reported a diagnosed chronic condition (n=252, 83.7%), mainly diabetes (n=179, 59.5%), dyslipidemia (n=45, 15%), and high blood pressure (n=116, 38.5%). Regarding prescribed medication, 92.7% (n=279) of the sample answered that they usually take medicines, with 3 being the average number of medicines per person and 10 being the maximum number. In this study, 19 questionnaires were excluded since they were not entirely fulfilled. Table 1 presents the sociodemographic data of both studies.

Stability

Study 1

From the stability analysis (Pearson correlation coefficient) of the eHEALS-PT24, correlations between all items of the scale were identified, ranging between moderate and strong (except for one very strong correlation), with statistical significance (P<.001). The lowest correlation value (r=0.42) was between items 1 and 8 (moderate correlation). In turn, the highest value (r=0.91) was a very strong correlation between items 2 and 3 (Table 2).

Study 2

From the stability analysis (Pearson correlation coefficient) of the eHEALS-PT24, correlations between all items of the scale were identified, ranging between moderate and strong (except for one very strong correlation), with statistical significance (P<.001). The lowest correlation value (r=0.81) was between items 1 and 8 (strong correlation). In turn, the highest value (r=0.96) was a very strong correlation between items 2 and 3 (Table 3).

Reliability

Study 1

The analysis of the internal consistency of the eHEALS-PT24 showed an adequate Cronbach α coefficient (Cronbach α=0.92). The statistics after excluding 1 of the 8 items did not indicate an increase in reliability: the value of Cronbach α ranged from 0.90 to 0.92. The mean total value in the eHealth literacy for the sample (n=80) was 27.25 (SD 5.61). The average score for each item was 3, ranging between 3.09 (item 8) and 3.55 (item 1). Concerning item-total correlation, coefficients above 0.4 for all items showed that the items were consistent with each other and correlated with the final score (Table 4).

[a]eHEALS-PT24: Portuguese version of the eHealth Literacy Scale for older adults.

[b]All item-to-total correlations were significant as $P<.001$.

[c]Not applicable.

Study 2

The analysis of the internal consistency of the eHEALS-PT24 showed an adequate Cronbach α coefficient (Cronbach α=0.98). The statistics after excluding 1 of the 8 items did not indicate an increase in reliability, with Cronbach α coefficient values remaining stable at 0.98. The mean total value in the eHealth literacy for the sample (n=301) was 23.31 (SD 9.53). The average score for each item was 3, ranging between 2.7 (item 8) and 2.99 (items 1 and 4). Concerning item-total correlation, coefficients above 0.40 for all items showed that the items were consistent with each other and correlated with the final score (Table 4).

Construct Validity: EFA

The Bartlett sphericity test corroborated the factorability of the correlation matrix for both studies (study 1: $\chi^2_{28}=446.87$, $P<.001$; study 2: $\chi^2_{28}=3932.81$, $P<.001$). In addition, the KMO test value demonstrated adequate sampling for both studies (study 1: KMO=0.87; study 2: KMO=0.94). Given the quality of Bartlett and KMO values, the criteria for factor analysis were gathered. By performing the EFA, we considered factors with eigenvalues above 1 for testing the structure of the instrument. In accordance with the original structure of the eHEALS [10], the Jamovi software extracted 1 factor for the structure of the eHEALS-PT24 for both studies (Study 1 and 2).

Study 1

In the EFA of study 1 (n=80), a single factor showed moderate to strong loadings (0.57 to 0.89; Table 5) but poor model fit indicators: RMSEA was high (0.20), TLI was below the threshold (0.79), and there was a significant chi-square test ($\chi^2_{20}=83.7$, $P<.001$). The factor explained 58.3% of the total variance.

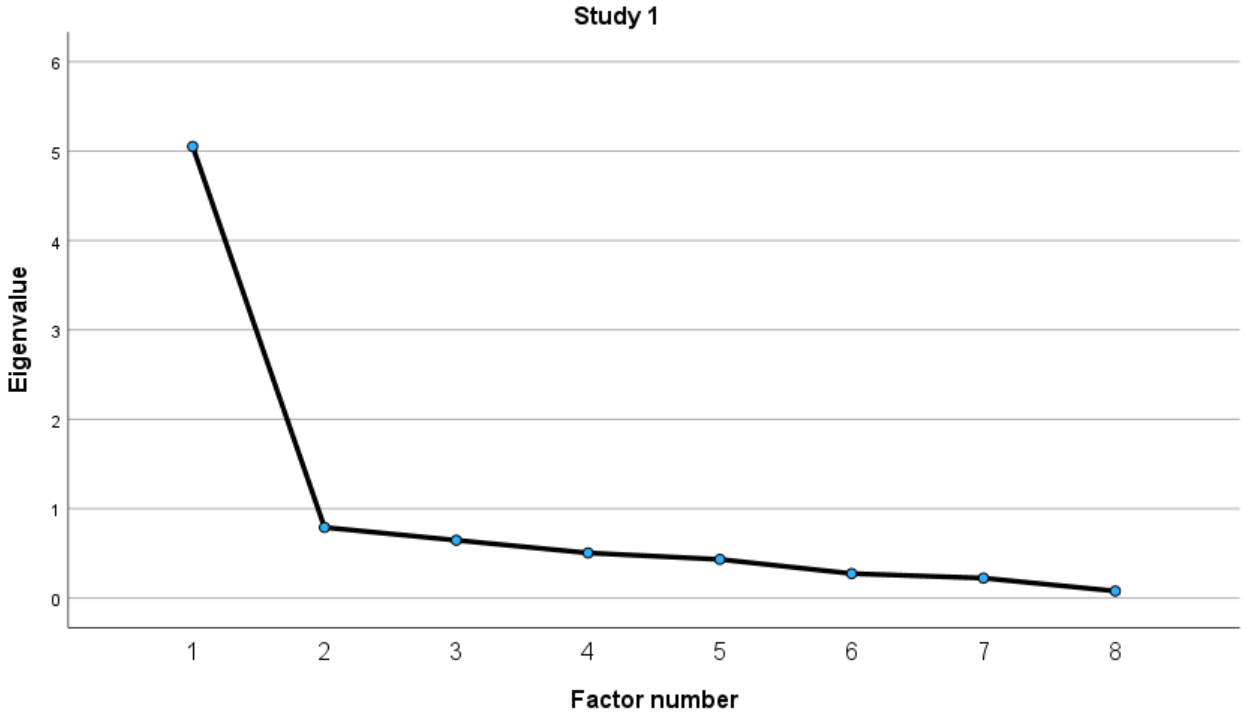
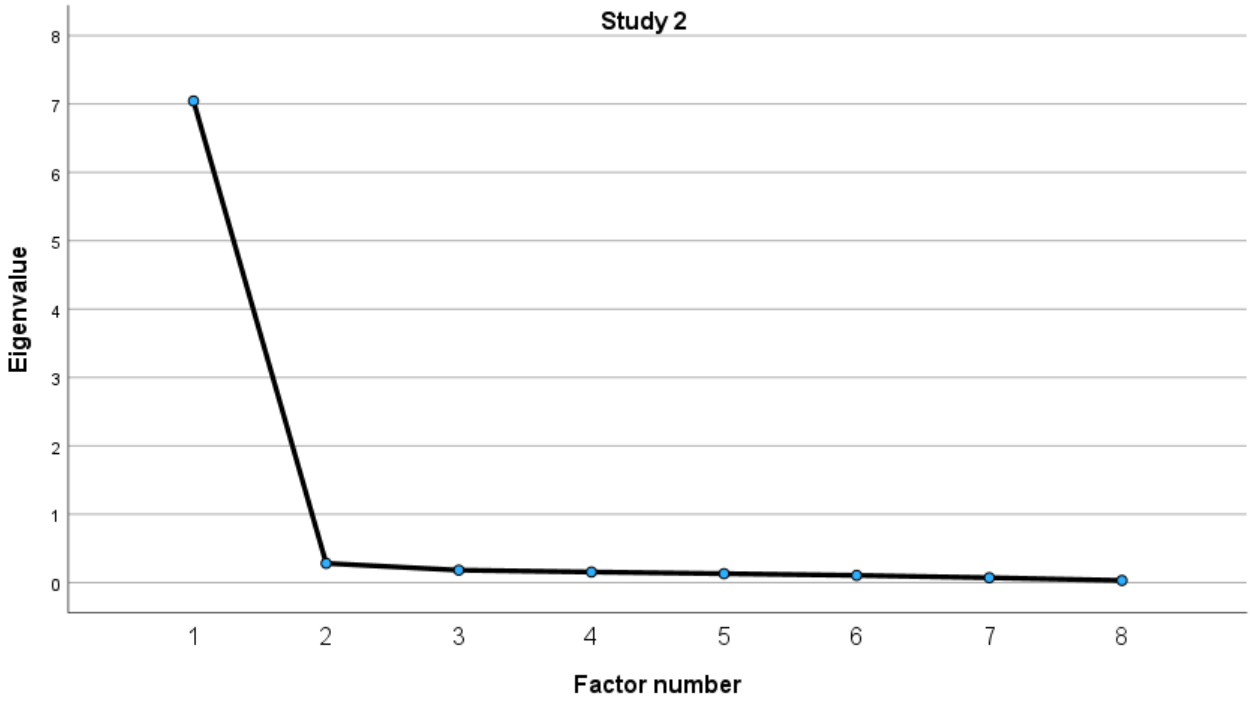
Item 8	0.57	0.89



[a]eHEALS-PT24: Portuguese version of the eHealth Literacy Scale for older adults.

Study 2

In the EFA of study 2 (n=301), a single factor showed moderate to strong loadings (0.89 to 0.95) but poor model fit indicators: RMSEA was high (0.20), TLI was marginally acceptable (0.91), and there was a significant chi-square test (χ^2_{20}=271, P<.001). The factor explained 86.4% of the total variance.



The single-factor structure of eHEALS-PT24 for both studies (studies 1 and 2) was also empirically confirmed on screen plots (Figures 2 and 3).

Figure 2. Screen plot for the eHEALS-PT24 (study 1). eHEALS-PT24: Portuguese version of the eHealth Literacy Scale for older adults.

XSL•FO
RenderX

Figure 3. Screen plot for the eHEALS-PT24 (study 2). eHEALS-PT24: Portuguese version of the eHealth Literacy Scale for older adults.

Construct Validity: CFA

Regarding CFA for study 2 (n=301), a single-factor model demonstrated high item loadings (standardized estimates 0.88 to 0.97; Table 6); however, the model fit was mixed: the chi-square test was significant (χ^2_{20}=265, *P*<.001), CFI was acceptable (0.94), while TLI (0.91) was marginally acceptable, and RMSEA (0.20) indicated a poor fit. Given the RMSEA values for one dimension, and due to the variability of factor structures in the literature, we compared the indexes for 1-, 2-, and 3-factor structures in study 2 (Table 7).

Table 7. Global model fit indices.

Indices	1 Factor	2 Factors	3 Factors
RMSEA[a] (90% CI)	0.20	0.17	0.18
CFI[b]	0.94	0.96	0.96
TLI[c]	0.91	0.94	0.93
Chi-square test, *P* value	<.001	<.001	<.001

[a]RMSEA: root mean square error of approximation.

[b]CFI: comparative fit index.

[c]TLI: Tucker-Lewis Index.

For the 2-factor model, we followed Tomás et al [32], dividing items 1-5 (factor 1) and items 6-8 (factor 2). High item loadings (standardized estimates 0.90 to 0.97) were obtained (Table 6); however, the model fit was mixed: CFI was acceptable (0.96), TLI (0.94) was marginally acceptable, RMSEA (0.17) indicated a poor fit, and the chi-square test was significant (χ^2_{19}=188, *P*<.001; Table 7).

For the 3-factor model, we followed Stellefson et al [43], dividing items 1-2 (factor 1), items 3-5 (factor 2), and items 6-8 (factor 3). High item loadings (standardized estimates 0.90 to 0.98) were obtained (Table 6); however, the model fit was mixed: CFI was acceptable (0.96), TLI (0.93) was marginally acceptable, RMSEA (0.18) indicated a poor fit, and the chi-square test was significant (χ^2_{17}=179, *P*<.001; Table 7).

Interpretation of the eHEALS-PT24 Scores

We used the mean total and SD values to determine high or low eHealth literacy levels. Therefore, participants were divided into 2 groups for each study as follows:

- Study 1: (1) low eHealth literacy levels (≤27 points) and (2) high eHealth literacy levels (>32 points).
- Study 2: (1) low eHealth literacy levels (≤23 points) and (2) high eHealth literacy levels (>31 points).

In study 1 (n=80), 35 (43.8%) participants had low eHealth literacy levels, and 9 (11.3%) had high levels. In study 2 (n=301), 115 (38.2%) participants had low eHealth literacy levels, and 71 (23.6%) had high levels.

Construct Validity: Known-Groups

We performed known-groups validity in study 2, as presented in the following subsections.

Association Between eHealth Literacy and Age (Student t test and Pearson Correlation)

To analyze the association between eHealth literacy and age, participants were distributed into two different groups: (1) 65-79 years and (2) ≥80 years. The first group comprised 269 (89.4%) participants, and the second group comprised 32 (10.6%) participants. The analysis showed differences statistically significant between eHealth literacy levels (total scale value) and age (t_{299}=3.94; *P*<.001). Individuals aged 65-79 years had, on average, 7.0 points higher eHEALS scores than those aged ≥80 years. We also carried out a correlation analysis between both variables (Pearson correlation), which showed that variables are inversely related, which means the greater one variable, the smaller the other (*r*=–0.355, *P*<.001).

Association Between eHealth Literacy and Sex (Student t test)

Female respondents showed an average of 23.68 (SD 9.89) points and male respondents showed an average of 23.03 (SD 9.26) points; however, no statistically significant differences between eHealth literacy levels (total scale value) and sex were found (t_{299}=0.59; *P*=.31).

Association Between eHealth Literacy and Residence Area (Student t test)

Statistically significant differences between eHealth literacy levels (total scale value) and residence area were found (t_{299}=4.19; *P*<.001). Participants living in urban areas showed an average of 24.11 (SD 9.16) points, and those living in rural areas showed an average of 17.03 (SD 10.15) points.

Association Between eHealth Literacy and Education Level (1-Way ANOVA or Kruskal-Wallis Test)

Statistically significant differences between eHealth literacy levels (total scale value) and education level were found (F_8=10.24; *P*<.001), with the highest mean values corresponding to the education levels of doctoral or equivalent level (ISCED 8; mean score of eHealth literacy levels: 31.57, SD 4.20), master's degree or equivalent (ISCED 7; mean 29.17, SD 5.60), and postsecondary but not tertiary education (ISCED 4; mean 27.68, SD 8.52). Since some of the education levels had nonrepresentative samples (ie, ISCEDs 2, 4, 5, 7, and 8), we tested the association between eHealth literacy and education level using Kruskal-Wallis test (H=58.56; *P*<.001). In this analysis, we found statistically significant differences between participants with primary education (ISCED 1) and all other education levels, with an exception for lower secondary education (ISCED 2) and master's degree or equivalent (ISCED 7). No other statistically significant differences were found.

The mean (SD) and significance of eHEALS-PT24 by subgroups (ie, age, sex, residence area, and education level) calculated in study 2 are presented in Table 8.

XSL•FO
RenderX

Discussion

Principal Findings and Comparison With Previous Work

In this paper, we have presented the translation, cultural adaptation, and validation of the eHEALS for Portuguese older adults (eHEALS-PT24) by carrying out a general psychometric analysis in a sample of 80 participants (study 1) and a CFA including 301 participants (study 2). For this discussion, we highlight the findings obtained in study 2 since it represents the final stage of the validation of eHEALS-PT24, according to the followed protocol [49].

Based on scale and items stability and reliability analysis, we concluded that the eHEALS-PT24 is a reliable tool for measuring eHealth literacy. Correlations between all items of the eHEALS-PT24, ranging between moderate and strong ones, with statistical significance, indicated that the questions were related to the instrument with no redundancy. In addition, the instrument showed good internal consistency. All items were considered reliable to assess eHealth literacy levels in older adults, with high correlations between each other. Compared with the original validation study [10], internal consistency was higher (Cronbach α=0.88 vs 0.98), which is comparable with previous studies among older adults [24,36,39,43,44,48]. The only study showing a higher Cronbach α than ours was a validation in older Hispanic participants [48] (Cronbach α=0.99), but the sample was small (n=20), which was pointed out as a limitation by the authors.

Concerning construct validity, the eHEALS was originally developed with a single-factor structure [10], and in our study, the same structure was yielded in EFA, explaining 86.4% of the total variance. This total variance explained was higher compared with the original validation study [10] (56%), as well as to previous studies among older adults [24,36,39,43,44,48], suggesting the model captured a significant portion of the data's variation. Regarding CFA, a single-factor model demonstrated high item loadings; however, the model fit was mixed: the chi-square test was significant (*P*<.001), CFI (0.94) and TLI (0.91) were both acceptable, and RMSEA (0.20) indicated a poor fit. The finding of a unidimensional structure also aligns with previous studies carried out in older adults [24,36,39]; however, it contradicts the results of the 2 other studies conducted among older adults, which indicated a better fit for the 3-factor structure [43,44]. The variability of factor structures in the literature and the RMSEA value obtained led us to compare the indices (ie, chi-square, CFI, TLI, and RMSEA) for 1-, 2-, and 3-factor structures. All indexes fitted well, but RMSEA remained poor (ie, 0.20 for 1 factor, 0.17 for 2 factors,

XSL•FO
RenderX

and 0.18 for 3 factors), suggesting that the model may not fit the data well. These findings are in line with the eHEALS Korean validation study (CFI=0.95; TLI=0.92; and RMSEA=0.12) [36], which followed a unidimensional structure. Considering the original validation study [10], as well as others who used Rasch analysis (or other analyses under modern test theory) [25,40,41], we also decided on the 1-factor structure.

The eHEALS-PT24 mean score was 23.31, with 38.2% (115/301) of participants showing low eHealth literacy levels and 23.6% (71/301) showing high levels. Compared with other validation studies among older adults, the mean score was higher than in Spain (22.35) [48] but lower than in China (30.94) [39] and in the United States (29.05) [43]. As shown by previous studies [12,15,18,30,32], item 8 of the eHEALS-PT24 had the lowest average among all scale items, indicating that people do not feel so confident in using information from the internet to make health-related decisions compared with other eHealth literacy skills.

To further examine construct validity, known-groups validity was assessed, showing statistically significant differences in demographic variables (age, residence area, and education levels), except for sex. While a previous study among older adults [48] found no differences between eHealth literacy levels and age, we concluded that the greater the age, the smaller the eHealth literacy. Those aged 65-79 years had, on average, 7.0 points higher (eHEALS scores) than those aged ≥80 years. Regarding eHealth literacy levels and sex, Aponte and Nokes [48] pointed out significant differences, where mean values of eHEALS scores for men (13.85) were significantly lower than those in women (25.77). In our study, female respondents had, on average, 0.65 points higher eHEALS scores than male respondents; however, no statistically significant differences were found between eHealth literacy levels and sex (P=.31). We also tested the association of eHealth literacy levels and the residence area, finding statistically significant differences (P<.001), where participants living in urban areas had on average 7.08 points higher (eHEALS scores) than those living in rural areas. Regarding education levels, the highest mean values corresponded to doctoral or equivalent level (ISCED 8; 31.57), master's degree or equivalent (ISCED 7; 29.17), and postsecondary but not tertiary education (ISCED 4; 27.68). Since some education-level cases had nonrepresentative samples (n<30), this result should be read with caution. Therefore, we can only infer participants with primary education (ISCED 1) had significant differences in eHealth literacy levels from the participants with other education levels, except for lower secondary education (ISCED 2) and master's degree or equivalent (ISCED 7).

Strengths and Limitations

There are some limitations in this study. First, there was limited geographic representation since the sample did not include older people from all regions of the country (only Faro and Lisbon). If we consider, however, the sample representativeness, we believe it is suitable for providing us with an adequate snapshot of our population of interest. Second, since the web-based questionnaires were only applied in the pilot study, we did not have any rigorous confirmatory process to determine that participants were aged, in fact, aged 65 years or older. Third, similarly to other validation studies [25,27,30-32,43,44,48], test-retest reliability was not conducted. As such, further research could address reliability and responsiveness over time. Fourth, although a more comprehensive psychometric analysis could be conducted to establish the instrument validity, such as investigating correlations with external measures of eHealth literacy or health outcomes, the results of this study are promising and show that the eHEALS-PT24 is a reliable tool for perceived measurement of eHealth literacy. Fifth, the eHEALS instrument measures a narrow scope of eHealth literacy and may not fully capture the complex concept of eHealth literacy nowadays since it was developed before the social media era (Web 2.0). Nevertheless, the benefits of eHEALS (strong psychometric properties, brevity, and usability) outweigh its shortcomings, and the eHEALS arguably serves as a convenient instrument for health professionals.

Conclusions

In conclusion, the eHEALS-PT24 is a reliable and valid instrument for assessing and monitoring the eHealth literacy of Portuguese older adults. This instrument can be useful in identifying older adults who are able to use eHealth resources and participate in eHealth interventions aimed at engaging them in health care and helping them to manage their health and, by extension, assess the effects of eHealth interventions.

Abstract

Background: Short-video dependence (SVD) has become a significant mental health issue around the world. The lack of scientific tools to assess SVD hampers further advancement in this area.

Objective: This study aims to develop and validate a scientific tool to measure SVD levels, ensuring a scientifically determined cutoff point.

Methods: We initially interviewed 115 highly engaged short-video users aged 15 to 63 years. Based on the summary of the interview and references to the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) criteria for behavioral addictions, we proposed the first version of the short-video dependence scale (SVDS). We then screened the items through item analysis (second version) and extracted common factors using exploratory factor analysis (third version) and confirmatory factor analysis (final version). Convergent validity was tested with other scales (Chinese Internet Addiction Scale [CIAS] and DSM-5). Finally, we tested the validity of the final version in 16,038 subjects and set the diagnostic cutoff point through latent profile analysis and receiver operating characteristic curve analysis.

Results: The final version of the SVDS contained 20 items and 4 dimensions, which showed strong structural validity (Kaiser-Meyer-Olkin value=0.94) and internal consistency (Cronbach α=.93), and good convergent validity (r_{CIAS}=0.61 and r_{DSM-5}=0.68), sensitivity (0.77, 0.83, 0.87, and 0.62 for each of the 4 dimensions), and specificity (0.75, 0.87, 0.80, and 0.79 for each of the 4 dimensions). Additionally, an SVDS score of 58 was determined as the best cutoff score, and latent profile analysis identified a 5-class model for SVD.

Conclusions: We developed a tool to measure SVD levels and established a threshold to differentiate dependent users from highly engaged nondependent users. The findings provide opportunities for further research on the impacts of short-video use.

Introduction

Short videos are immensely popular digital content, with platforms like TikTok allowing users to create and share videos ranging from a few seconds to a few minutes [1]. These apps engage users by facilitating viewing, creation, and commenting, changing self-presentation and cultural learning. In 2022, TikTok had 1.2 billion monthly active users, with an average viewing time of 168 minutes per day [2]. Hanaysha [3] noted that during the COVID-19 pandemic, short-video apps became key sources of news and entertainment. These apps have impacted various aspects of the world, such as popular culture, content creation and consumption, and the spread of information on political and social issues.

Short-video apps also raised public concerns about their potential negative consequences, such as distraction, poor time management, and mental health problems [1,4,5]. A number of studies have been conducted in this area. For instance, Domoff et al [6] developed a scale to measure the extent of problematic media use considering the need. However, the lack of reliable and valid tools for assessing the corresponding qualities of short-video usage has hindered the progress of research in this field.

Before developing a scale or questionnaire for short-video dependence (SVD), we need to justify not using the term "addiction," which requires careful consideration to establish standards. First, the latest version (fifth edition) of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) recognizes internet gaming disorder (IGD) as a provisional disorder [7], but not short-video disorder. Second, internet-related disorders are often more about specific online activities than excessive internet use [7,8]. Third, some studies have suggested that short-video users show more "dependence" than "addiction," with behavior being more habitual than pathological [9]. Thus, "dependence" is a more appropriate term in this context.

Some researchers have tried to develop internet-related behavioral disorder scales but have faced limitations pertaining to measuring SVD. Güzeller and Coşguner [10] developed a problematic cell phone use scale for Turkish adolescents considering the need for a measurement tool on problematic cell phone use in this population. In addition, these articles were published early, before TikTok was available, and have less applicability to the present context. Domoff et al [6] developed a tool for assessing screen media addiction in children aged 4 to 11 years. The results of the study indicated that the scale has good psychometric properties in terms of factor structure, reliability, and convergent validity for the measurement of problematic media use in children younger than 12 years. However, the limitations of the study include a lack of methodological constraints in assessing screen time and insufficient racial or ethnic diversity of the sample.

The short-video dependence scale (SVDS) was established based on the IGD diagnostic criteria from the DSM-5, since internet addiction has most convincingly been linked to short-video use [11,12], and research addressing dependence behavior is lacking as compared to research on addiction. The DSM-5 is a widely accepted and used classification system for mental disorders that is used to diagnose and categorize mental health problems. It provides standardized definitions and classifications for a variety of mental disorders, including IGD, gambling disorder, etc. According to the DSM-5, a clinical diagnosis of IGD is indicated if 5 or more of the following 9 criteria are met: preoccupation, withdrawal, tolerance, loss of control, loss of interest, continuation, deception, escape, and jeopardizing. By using the DSM-5 as its developmental framework, the SVDS aims to align with the diagnostic criteria and characteristics of IGD, thereby ensuring the validity and comparability of measurements.

Therefore, the DSM-5 criteria for IGD have some advantages in identifying and assessing SVD, but these are not fully applicable or comprehensive. First, SVD is similar to IGD in many ways, such as excessive use, uncontrollable desire, and interference with daily functioning. However, some criteria may not be suitable or sufficient for short-video addiction, such as tolerance, loss of interest, and jeopardizing. For instance, loss of interest may not encompass the full spectrum of motivational factors that affect short-video addiction, such as social comparison, self-presentation, and peer pressure [1]. Furthermore, users may still be able to carry out their daily activities even after spending an excessive amount of time watching short videos, and thus, jeopardizing may not be as severe or uncommon with regard to SVD. Neglecting or compromising other significant facets of life, like relationships, career, or health, might be a more appropriate criterion. The DSM-5 diagnostic criteria for IGD will be improved and refined by the development of the SVDS, which will include extra items identified through in-depth interviews.

Most importantly, to determine the cutoff point for the SVDS among a large sex-balanced sample of Chinese young adults, latent profile analysis (LPA) was used, which is an epidemiological approach to determine the cutoff point when a clinical interview is not available [13-15]. It allows for the identification of distinct groups of short-video users based on their responses in the SVDS, with the group exhibiting the highest levels of SVD being identified as "dependent short-video users" for determining the optimal cutoff point. To date, numerous studies have applied the LPA approach to derive the optimal cutoff points for measurement tools, such as the Bergen Social Media Addiction Scale [16], Online Social Networking Addiction Scale [13], Dimensional Anhedonia Rating Scale [17], and Smartphone Application-Based Addiction Scale [14].

In summary, the field of SVD lacks standardized definitions and measurements for short-video addiction, which may hinder the comparability and generalizability of the results and further hamper the study of its prevalence, impeding crucial future research in the field of SVD. The evolving internet landscape demands a contemporary scale. This study aims to develop and validate a specific SVDS for SVD, drawing on established frameworks and diagnostic criteria from IGD research. The SVDS provides a standardized tool with a clear diagnostic cutoff point to assess SVD and understand its prevalence, correlates, and consequences.

Methods

Ethical Considerations

The experiment conforms to the Code of Ethics of the World Medical Association (Declaration of Helsinki). The Human Investigations Committee of Hangzhou Normal University approved this research (approval number: 20190505). All participants provided written informed consent before experimentation.

Participants

From October 2022 to December 2023, 4 surveys were conducted online, among which, the first 3 surveys employed 2 data collection platforms in China, namely the TClab platform and NAODAO platform. The last survey involved 16,038 participants from Hangzhou Normal University and Zhejiang University of Water Resources and Electric Power, resulting in a total of 17,266 Chinese participants (Table 1; Multimedia Appendix 1). To clarify, participants were recruited using convenience sampling, and all data collection was conducted virtually.

Table 1. Demographic information of the participants for 4 tests.

Version	Additional scales	Valid sample, N	Age (years), mean (SD)	Age (years), minimum	Age (years), maximum	Female percentage
Pretest	—[a]	457	23.67 (6.84)	16	57	39%

[d]DSM-5: Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition.

Methodological Overview of the Entire Study

Figure 1 shows the complete process of developing the SVDS. There were several stages. First, in the preparation stage, we screened out people with a high degree of SVD through the questionnaire, obtained the dependence symptoms of these people through interviews, and then combined the findings with the DSM-5 to prepare the first version of the SVDS. Second, SVDS 2.0 was created after internal consistency was examined and item analysis was conducted. Third, through exploratory factor analysis (EFA), we removed the unqualified questions and obtained the third version of the SVDS. Fourth, after confirmatory factor analysis (CFA) and another round of screening, the fourth version was established. Finally, we tested the convergent validity, conducted another round of CFA with a massive sample, and confirmed the cutoff points using receiver operating characteristic (ROC) curve analysis and LPA.

In-Depth Interviews

The in-depth interview method is a fundamental psychological research approach that involves face-to-face conversations between interviewers and participants to understand the psychological and behavioral aspects of the participants [18]. The method is applied in various disciplines; in-depth interviews are also conducted in the form of online conversations [19,20]. As a qualitative research method, in-depth interviews are effective in promptly identifying issues and complementing the questionnaire survey method. In this study, the in-depth interview method was used in conjunction with the questionnaire survey. The process of data collection specifically involved preliminary screening of the pretest questionnaire. The screening criteria were as follows: (1) daily viewing of more than 4 hours, (2) significant impact of short-video viewing on daily life, and (3) voluntary acceptance of the interview and recording. Consequently, semistructured interviews were conducted with 15 short-video users of different ages, users from different regions, and users with different usage levels (Multimedia Appendix 2). The interview content was analyzed using the qualitative analysis software NVivo 12 (Lumivero). The key concepts were derived from the interviews [19], and referring to the 9 criteria of the DSM-5, the initial version of the SVDS with 27 items was developed.

The in-depth interview questions in this study were divided into 5 categories: basic questions, short-video platform usage and dependence, in-depth questions, suggestions and countermeasures, and self-assessment questions with ratings (Multimedia Appendix 3). The main aim was to understand the participants' motivations for using short-video platforms and their levels of dependence and to gain a deeper understanding of the specific symptoms of strong dependence. During the interviews, the interviewer focused on the purpose, motivations, experiences, and dependence of short-video platforms in each round of the interviews. Subsequently, the interview content was coded to determine the dimensions and specific items for the first version of the SVDS. In terms of dimensions, small-scale screening was conducted based on the 9 addiction features of the DSM-5, resulting in the identification of 9 dimensions and 27 items for the SVDS. Moreover, to clarify, we used random sampling to recruit participants. The participants were collected through the NAODAO and TClab platforms.

Encoding In-Depth Interview Data According to the Classical Grounded Theory

The grounded theory establishes a close connection between empirical research and theory construction, enabling researchers to develop concepts and construct theories by systematically analyzing and summarizing empirical data [21,22]. The use of in-depth interviews in this study generates a substantial amount of textual data. By applying the grounded theory, specifically open coding, and aligning it with the DSM-5 scale, key conceptual keywords are abstracted, allowing for a direct reflection of the key points covered in the interview content. This process aids in determining the main dimensions upon which the questionnaire design should be based. The sample saturation point was achieved after the completion of the 15th in-depth interview for this study.

Establishment of the First Version of the SVDS

The first version of the SVDS consisted of 27 items (Multimedia Appendix 4). As for the dimensions, the IGD scale from the DSM-5 consisted of 9 dimensions: preoccupation, tolerance, withdrawal, persistence, escape, problems, deception, displacement, and conflict. These 9 dimensions encompassed most of the situations reported by users with a high dependency on short videos, so we used them as a basis for expansion. Meanwhile, items from multiple related scales were collected for the SVDS question bank for further use [7,23-31]. Additionally, we modified the 9 dimensions by considering the actual situation of users who were highly dependent on short videos in the initial screening. Specifically, we counted the frequency of each dimension mentioned in the narratives of highly dependent users of short videos and removed dimensions that were mentioned zero times. Furthermore, a new dimension, "lie detection," was added. As for the items, we developed 3 items for each dimension based on the information coded in the in-depth interviews, which resulted in the first version of the SVDS.

Developing the Second Version of the SVDS After Conducting Item Analysis

Prior to the EFA, we conducted item analysis [32,33] in sample 2 (n=402) and sample 3 (n=369), which is the process of assessing the quality and effectiveness of each item in the scale. Item analysis mainly includes indicators such as item difficulty, item differentiation, and item relevance. Initially, we removed unqualified samples, which were first preprocessed according to the following two steps: (1) removing samples with missing values and manually removing samples where the length of time was shorter than 2 SDs from the mean and all answers were the same and (2) converting the reversed items to numerical values, recording and scoring them accordingly, and assigning new values to the original items. For further information, sample 2 and sample 3 were also recruited using random sampling. They were primarily gathered through the NAODAO and TClab platforms.

We then screened the items according to 2 indicators during item analysis. The first indicator was the correlation between each item's score and the total score. Based on the Pearson correlation coefficient, the deletion criteria were as follows: (1) nonsignificant correlation between the items and the total scale (P>.05) and (2) correlation coefficient (r) between the item score and the total score below 0.45. The other indicator was the reliability coefficient, and the criteria for deletion were as follows: (1) correlation coefficient between the modified item and the total score lower than 0.45 and (2) increase in the internal consistency coefficient (Cronbach α) after item deletion. This resulted in the second version of the SVDS (Multimedia Appendix 5).

Developing the Third Version of the SVDS After Conducting EFA

The suitability of the items of the first version of the SVDS for factor analysis was assessed using the Kaiser-Meyer-Olkin

XSL•FO
RenderX

(KMO) value and Bartlett Test of Sphericity. Additionally, principal component analysis (PCA) with varimax rotation was conducted on the 21 items of the first version of the SVDS. Items that did not meet the established standards and theoretical expectations were removed. The deletion criteria were as follows: (1) measures of sampling adequacy (MSA) below 0.8, (2) typical values below 0.3, (3) factor loading lower than 0.45, (4) items appearing in two or more factors simultaneously, and (5) factors containing only 1-2 items.

The remaining items were subjected to EFA to obtain the new dimensions of the SVDS based on the factor eigenvalues. This resulted in the third version of the SVDS (Multimedia Appendix 6).

Developing the Fourth Version of the SVDS After Conducting CFA

CFA was conducted to assess the goodness of fit between the proposed model and the collected data [34,35]. Based on the factor solution obtained from the EFA, a model diagram was constructed. CFA was then performed using AMOS24, and model fit was evaluated using the comparative fit index (CFI), Tucker-Lewis Index (TLI), normed fit index (NFI), iterative fit index (IFI), root mean square error of approximation (RMSEA), and 90% CI. When dealing with large samples, the CFI and RMSEA are considered informative fit criteria in structural equation modeling [36]. A good fit is indicated when the CFI, TLI, NFI, and IFI are all greater than 0.9 and the RMSEA is less than 0.08 [34,37].

Convergent Validity and Reliability of the Fourth Version of the SVDS

Convergent validity was determined by examining the correlations between the SVDS scores and the frequency of daily short-video platform use, as well as the DSM-5 and Chinese Internet Addiction Scale (CIAS) scores [24,38,39]. The CIAS is a 19-item self-report scale, with each item rated on a scale of 1-4 (1=completely disagree, 2=somewhat disagree, 3=somewhat agree, and 4=completely agree). The total score ranges from 0 to 76. Participants with a score of 53 or above were classified as having internet addiction. The CIAS has been shown to have satisfactory reliability and validity in the Chinese population [39,40]. In the case of good convergent validity, we expected a strong correlation between SVDS and CIAS scores. Additionally, the internal consistency (reliability) of the scales was assessed using Cronbach α in the 2 sample datasets.

Use of Large Samples to Confirm the Reliability and Validity of the Fourth Version

To assess the final version of the SVDS, we applied it to 16,038 subjects, conducted a CFA to test the validity, and tested the reliability using Cronbach α. The test criteria for the indicators were the same as above. For further clarification, participants in sample 4 were drawn from all first-year students at a college in Hangzhou.

Establishment of Cutoff Points for Dependence and Nondependence

To determine the cutoff point for the population and identify individuals with the disorder, we used the DSM-5 criteria. The group of dependent short-video users according to the DSM-5 (getting more than 5 points out of 9) was considered the "gold standard." Furthermore, ROC curve analysis was adopted to determine the optimal clinical cutoff point based on the gold standard for clinical diagnosis. The diagnostic efficacy of the Bergen Social Media Addiction Scale was assessed through the area under the ROC curve (AUC). Sensitivity analysis was adopted to determine the optimal clinical cutoff point for the SVDS. The sensitivity (the proportion of true positives), specificity (the proportion of true negatives), 95% CI, positive prediction rate (PPR; the proportion of correctly diagnosed positive cases), and negative prediction rate (NPR; the proportion of correctly diagnosed negative cases) were calculated.

LPA was then conducted in the community sample to identify the groups of adolescents with a higher risk of being addicted to short videos among dependent short-video users in MedCalc Version 22.01 [13,14]. Models with 2-6 latent profiles were estimated based on the scores of the 20 items of the SVDS. The Akaike information criterion (AIC), Bayesian information criterion (BIC), sample size–adjusted Bayesian information criterion (SSABIC), and entropy of each model were examined. Finally, the Lo-Mendell-Rubin adjusted likelihood ratio test (LMRT) was used to determine the best-class solution. Considering the probabilistic nature of the LPA classes, the Wald chi-square test of mean equality for latent class predictors in mixture modeling was used for these comparisons.

Results

Coding of In-Depth Interview Data to Derive the First Version of the SVDS

In the preliminary survey, we conducted in-depth interviews with 15 participants who were identified as high-dependence users of short videos from a pool of 457 participants. Subsequently, the interview data were subjected to open coding, taking into account the 9 characteristics from the DSM-5 criteria (Multimedia Appendix 7). This process resulted in the identification of 9 dimensions and 27 specific items for the first version of the SVDS (Multimedia Appendix 4). Open coding focuses on assigning relevant concepts to the data, enabling researchers to categorize the information more clearly. In this study, to present the interview content of the participants more coherently, all original data were systematically numbered and sorted. The in-depth interview data, serving as the primary source of information, were labeled as M1, M2, F3, M4, M5, M5, M7, F8, M9, M10, M11, M12, M13, F14, and M15 (Multimedia Appendix 2). While comprehensive open coding was performed on the primary data, other materials were used for supplementary reference. By conducting open coding on the interview data of the 15 participants, the dimensions and specific items for the first version of the SVDS were determined. In the high-dependence group of short-video users, the most frequently occurring feature was "obsession," while the dimension of "conflict" did not appear at all. Therefore, we eliminated the "conflict" dimension. Considering that the DSM-5 scale consists of only 9 items while the SVDS includes 24, we deemed it

XSL•FO
RenderX

necessary to add a dimension related to deception (comprising 3 items) to screen for valid questionnaires.

Item Analysis of the First Version of the SVDS

Before conducting the EFA, a preliminary item analysis [32,33] was performed. First, 402 samples were left after excluding the unqualified samples. Next, after excluding the polygraph item, item analysis was carried out on a total of 24 items. Initially, the correlation between each item's score and the total score was calculated prior to item screening. Based on the Pearson correlation coefficient, the analysis revealed that items 4 (r=0.43; P=.23), 15 (r=0.32; P=.50), 16 (r=0.14; P=.33), and 24 (r=−0.19; P=.55) did not meet the established criteria, resulting in their deletion.

Furthermore, the reliability coefficient was used for item selection. The internal consistency α coefficient of the 24 items was found to be .90, indicating satisfactory internal consistency of the scale. The results indicated that the correlation coefficients of the modified items in items 15 (r=0.34; α=.90), 16 (r=0.16; α=.91), and 24 (r=0.33; α=.90) were all below 0.4. Thus, the 3 items that fulfilled the condition for an increase in the internal consistency coefficient (α) were retained and considered deleted. Consequently, combined with the above item analysis methods, 3 items (15, 16, and 24) were deleted and 24 items were retained, and thus, the second version of the SVDS was obtained (Multimedia Appendix 5).

EFA of the Second Version of the SVDS and the Establishment of 4 Dimensions

The suitability of the items of the second version of the SVDS for factor analysis was assessed using the KMO value (KMO=0.94) and Bartlett Test of Sphericity (χ^2_{325}=7692.17; P<.001). Additionally, the polygraph item analysis showed that higher scores on the items indicated participants' failure to answer the questions honestly [41]. For our study, 402 valid sample groups were retained in the second sample and 369 valid sample groups were retained in the third sample, meeting the minimum requirement for the number of observations per variable [42].

PCA with varimax rotation was conducted on the 21 items of the second version of the SVDS. Items that did not meet the established standards and theoretical expectations (item 4) were removed. Specifically, the factor loading of item 4 was 0.38 (P<.001), which was the lowest among all items and was below 0.4.

After deleting 4 items, 3 items were not needed for lie detection. The remaining 20 items were subjected to EFA, resulting in the emergence of 4 factors with eigenvalues greater than 1, explaining a cumulative variance of 62.5% (Multimedia Appendix 8). All items demonstrated commonalities ranging from 0.50 to 0.70 and factor loadings ranging from 0.48 to 0.78. Factor 1, named "withdrawal and tolerance," consisted of 5 items (5, 3, 2, 6, and 1), which referred to symptoms of maladaptation following cessation of short-video watching and reduced effects due to repeated or prolonged use. Factor 2, named "preoccupation and persistence," comprised 5 items (8, 7, 10, 12, and 11), reflecting persistent thoughts and behaviors related to short-video use. Factor 3, named "damage and hindrance," encompassed 5 items (9, 20, 21, 18, and 17), indicating the negative impact on physical and mental health, which hindered personal growth and development. Factor 4, named "deception and escape," consisted of 5 items (13, 24, 22, 14, and 23), signifying the concealment of short-video use from others and using short videos as a means of avoiding problems. Consequently, the third version of the SVDS comprised 20 retained items (Multimedia Appendix 6).

CFA and the Internal Consistency of the Third Version of the SVDS

CFA was conducted to assess the goodness of fit between the proposed model and the collected data, and model fit indices were employed. In the evaluation of the goodness of fit, CFI, NFI, IFI, and TLI values should exceed 0.90, while RMSEA should be less than 0.08 for a satisfactory model fit [43]. The results of the goodness-of-fit analysis were as follows: χ^2/df=2.366; RMSEA=0.058; CFI=0.943; NFI=0.906; IFI=0.943; and TLI=0.921. All the data met the acceptable fit index criteria. Moreover, the internal consistency α coefficient of the 20 items was found to be .91. Therefore, the fourth version of the SVDS was identical to the third version (Multimedia Appendix 9).

Convergent Validity of the Final (Fourth) Version of the SVDS

To assess the convergent validity, the scores of the respondents in the first version and the final version of the SVDS were correlated with their self-declared SVD and related constructs, such as the frequency of daily short-video platform use, DSM-5 scores, and CIAS scores. The DSM-5 scale refers to the Short Video Addiction Scale, which is a simple adaptation of the Internet Addiction Scale. As shown in Table 2, all correlations were significant at P<.001 and aligned with the expected directions. Both the first version of the SVDS and the final version of the SVDS demonstrated large positive correlations with self-declared SVD (r>0.5), indicating satisfactory convergent validity.

XSL•FO
RenderX

Table 2. Correlations between the short-video dependence scale and validation constructs.

Variable	SVDS[a] 1.0 (n=402)	SVDS 2.0 (n=369)
Self-declared SVD[b]	0.62	0.58
Frequency of daily use	0.72	0.80
DSM-5[c]	0.68	0.73
CIAS[d]	0.53	0.61

[a]SVDS: short-video dependence scale.

[b]SVD: short-video dependence.

[c]DSM-5: Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition.

[d]CIAS: Chinese Internet Addiction Scale.

CFA and Internal Consistency of the Final Version of the SVDS Using a Massive Sample

Similar to the former round of CFA conducted on the third version of the SVDS, a model diagram was constructed using the 20 items and 4 factors. Model fit indices, including RMSEA, CFI, NFI, IFI, and TLI, were employed. Fortunately, the results obtained with the large sample were better than the results of the last CFA. Specifically, the results of the goodness-of-fit analysis were as follows: RMSEA=0.065; CFI=0.928; NFI=0.926; IFI=0.928; and TLI=0.916. All the data met the acceptable fit index criteria. Moreover, the internal consistency α coefficient of the 20 items was .93. The final version of the SVDS is presented in Table 3. The table shows the results after EFA and CFA, with the items rearranged according to the size of factor loading. Factor loading less than 0.4 has not been shown.

Table 3. The final version of the short-video dependence scale.

Index	Item	Dimension
1	Even if advised to watch fewer short videos, I find it difficult to do so.	Preoccupation and persistence
2	In my spare time, I don’t know what to do other than watching short videos.	Preoccupation and persistence
3	If I go without watching short videos for a long time, I fear missing out on popular videos or news.	Preoccupation and persistence
4	Even if I didn’t plan to watch short videos, I would subconsciously open the app.	Preoccupation and persistence
5	While studying or working, I often think about watching short videos.	Preoccupation and persistence
6	I have tried to spend less time watching short videos, but I can’t seem to do it.	Withdrawal and tolerance
7	Compared to last year, I spend more time watching short videos every day.	Withdrawal and tolerance
8	When I try to watch fewer videos, I feel bored or agitated.	Withdrawal and tolerance
9	My life seems uninteresting without short videos.	Withdrawal and tolerance
10	If asked to refrain from watching short videos for a week, I would find it difficult to resist the urge.	Withdrawal and tolerance
11	Watching short videos has had a negative impact on my academic or work performance.	Damage and hindrance
12	It has also negatively affected my physical health, such as eye strain and staying up late.	Damage and hindrance
13	I feel a decreased sense of self-worth due to my inability to control my time spent watching short videos.	Damage and hindrance
14	After watching short videos, I find it harder to focus on self-improvement.	Damage and hindrance
15	Even if I want to go to bed early, I still can’t resist watching short videos.	Damage and hindrance
16	When I watch short videos, it seems as if all of life’s problems disappear.	Deception and escape
17	I have tried to hide the negative effects that watching short videos has had on me from others.	Deception and escape
18	I tend to downplay my short-video viewing time when asked.	Deception and escape
19	After watching short videos, I tend to interact less with family and friends in real life.	Deception and escape
20	The actual amount of time I spend watching short videos is more than I realize.	Deception and escape

Sensitivity and Specificity of the SVDS

The SVDS dimensions were evaluated for sensitivity and specificity. Sensitivity was determined based on positive responses from dependent short-video users in sample 2 (n=107), sample 3 (n=74), and sample 4 (n=16,038), while specificity relied on negative responses from nondependent short-video users in each sample. High sensitivity and specificity are ideal for effective discrimination of false positives and false negatives [44].

XSL•FO
RenderX

Initially, the first SVDS version demonstrated high sensitivity and sufficient specificity in sample 2. Corrected sensitivity and specificity values for each dimension were as follows: preoccupation, 0.87 and 0.45, respectively; tolerance, 0.96 and 0.44, respectively; withdrawal, 0.66 and 0.89, respectively; persistence, 0.88 and 0.61, respectively; escape, 0.98 and 0.32, respectively; problems, 0.85 and 0.84, respectively; deception, 0.68 and 0.85, respectively; and displacement, 0.58 and 0.93, respectively. In sample 4, the final SVDS version showed high sensitivity and sufficient specificity. Sensitivity and specificity values for each dimension were as follows: withdrawal and tolerance, 0.77 and 0.75, respectively; preoccupation and persistence, 0.83 and 0.87, respectively; impairment and hindrance, 0.87 and 0.80, respectively; and deception and escape, 0.62 and 0.79, respectively. Overall, the final SVDS version demonstrated stable sensitivity and specificity, with highly comparable diagnostic accuracy across the samples.

Determination of the Clinical Cutoff Point for the Final Version of the SVDS

According to the SVDS modified based on the IAS in DSM-5, 4693 of the 16,038 participants were identified as dependent short-video users. This clinically diagnosed group was used as the gold standard. The diagnostic efficiency was demonstrated by a high AUC (0.83, 95% CI 0.95-1.00; P<.001).

Table 4 shows the sensitivity, specificity, 95% CI, PPV, and NPV of possible cutoff scores of the SVDS. At a score of 58, the sensitivity was 88.6% and specificity was 96.5%, and the Youden Index achieved its maximum value (85.2%). In this case, the prevalence of dependent short-video users was 4079 out of 16,038 (25.4%). The dependent short-video user group included 53.6% (2188/4079) males and 46.4% (1891/4079) females, while the nondependent short-video user group included 50.1% (5999/11,959) males and 49.8% (5960/11,959) females.

Table 4. Cutoff points for the short-video dependence scale based on clinical diagnostic interviews (N=16,038).

Criterion	Sensitivity[a], value (95% CI)	Specificity[b], value (95% CI)	Youden Index[c]	PPR[d]	NPR[e]
>54	89.58 (87.4-91.5)	86.50 (86.3-87.8)	0.7608	0.79	1.00
>55	89.47 (87.3-91.4)	89.90 (88.5-90.9)	0.7937	0.79	1.00
>56	89.47 (87.3-91.4)	92.68 (91.8-93.0)	0.8215	0.83	1.00
>57	89.47 (87.3-91.4)	95.43 (94.3-96.4)	0.8490	0.86	1.00
>58	88.61 (86.4-90.6)	96.54 (95.5-96.4)	0.8515	0.88	0.99
>59	87.22 (84.9-89.3)	97.41 (96.6-97.4)	0.8463	0.92	0.99
>60	86.40 (84.6-89.0)	97.75 (97.6-98.3)	0.8415	0.93	0.98
>61	85.07 (84.1-88.6)	98.76 (98.5-99.0)	0.8383	0.94	0.94
>62	83.57 (81.0-85.9)	99.03 (99.3-99.7)	0.8260	0.94	0.89

[a]Sensitivity: true negative/true negative and false positive.

[b]Specificity: true positive/true positive and false negative.

[c]Youden index: defined as sensitivity + specificity – 1.

[d]PPR: positive predictive rate (true positive/true positive and false positive).

[e]NPR: negative predictive rate (true negative/true negative and false negative).

LPA Results

The results of the LPA in the last sample are shown in Table 5. The AIC, BIC, and SSABIC values continued to decrease as the number of groups increased. The entropy was adequate for a 2-group solution to a 6-group solution. Despite the small difference in the data, the entropy of 5 classes was the smallest, indicating the highest degree of classification accuracy [45]; therefore, we selected the 5-group solution. The features of the 5 classes are shown in Figure 2. The first class, named “regular users” (6591/16,038, 41.1%), and the second class, named “casual users” (3224/16,038, 20.1%), represent adolescents who generally selected “very rarely” or “rarely” for all 20 items in the final version of the SVDS. The third class, named “low-risk high-engagement users” (2389/16,038, 14.9%), and the fourth class, named “at-risk high-engagement users” (2630/16,038, 16.4%), scored similarly higher on “damage and hindrance” and “deception and escape,” while the third class scored much lower on “preoccupation and persistence” and “withdrawal and tolerance” compared to the fourth class. The fifth class, named “dependent users” (1204/16,038, 7.5%), represents adolescents who generally rated their short-video use as “very often” or “often” for all 20 items in the scale.

Discussion

Principal Findings

This study aimed to develop and validate the SVDS, which is brief, is easy to administer, and has a clear diagnostic cutoff point to differentiate between dependent and highly engaged nondependent short-video users. Through item analysis, EFA, and CFA, the 20-item SVDS with 4 dimensions was established. To establish the diagnostic cutoff point, ROC curve analysis and LPA were conducted. Consequently, the final version of the SVDS with a clear cutoff point demonstrated strong internal consistency and convergent validity, and high sensitivity and specificity.

Development Processes of the SVDS

We initially identified subjects with higher SVD through pretesting and in-depth interviews, extracting key dimensions and items from the raw data. We also used the 9 diagnostic criteria for IGD from the DSM-5 as a reference, which contributed to both the theoretical and conceptual development of the tool. This process led to the identification of 9 dimensions for the first version of the SVDS, each with 3 items. After item analysis, EFA, and CFA, a 20-item scale with 4 dimensions was finalized, resulting in 3 versions of the SVDS. Finally, using a large sample of 16,038 participants, the final version showed strong internal consistency and convergent validity.

Final Version of the SVDS

The final (fourth) version of the SVDS included 4 dimensions: "withdrawal and tolerance," "preoccupation and persistence," "impairment and hindrance," and "deception and escape." Each dimension consisted of 5 items, and SVD was measured. Furthermore, we employed LPA and ROC curve analysis with a large sample of 16,038 people to detect dependent short-video users and define the cutoff point of 58 points. Five more subtypes of users of short videos were retrieved from the LPA.

Final Version of the SVDS Showed Good Reliability and Validity

Our findings demonstrated that the final version of the SVDS is a reliable and valid measure of SVD. The CFA confirmed a good model fit, indicating strong external validity. Moreover, the final version of the SVDS exhibited satisfactory internal consistency (0.93) as well as good convergent validity. These results have important implications for identifying and preventing SVD and its potential negative consequences. Additionally, based on the diagnostic cutoff point of the final version of the SVDS, the prevalence of SVD in the last sample was 25.4% (4073/16,038).

Convergent validity was established by examining the CFA results of the SVDS and its correlations with similar constructs. The CFA results supported a good model fit for the final version of SVDS items, and as expected, there was a strong correlation between SVDS scores and CIAS scores.

Final Version of the SVDS Showed Good Sensitivity and Specificity

Items of the final version of the SVDS exhibited good sensitivity and specificity. This indicates that the scale can accurately identify and differentiate between the presence and absence of social media dependence. Sensitivity refers to situations in which items correctly identify the target characteristic, while specificity refers to situations in which items correctly exclude the absence of the target characteristic. From the first version to the final version of the scale, there were improvements in its sensitivity and specificity, as outlined below.

Confirmation of the Scale's Dimensions

"Withdrawal and tolerance," "preoccupation and persistence," "impairment and hindrance," and "deception and escape" were the 4 dimensions included in the SVDS.

First, withdrawal refers to discomfort when a substance or behavior is reduced or stopped, while tolerance means needing more to achieve the same effect. These are key addiction concepts, so individuals with high scores are closer to an addictive state and more likely to be "at-risk high-engagement users" or "dependent users." Second, "preoccupation and persistence" involve constant thoughts about the activity and continuing despite harm, with higher scores reflecting stronger dependence. Third, "impairment and hindrance" refer to the negative impact on daily life and the reduced ability to resist addictive behavior. High scores suggest significant life problems and difficulty controlling behavior. Lastly, "deception and escape" involve lying or replacing one addictive behavior with another, with elevated scores indicating stronger dependence. The first 2 dimensions are core symptoms of SVD, as they directly impact the individual, while the latter 2 reflect the indirect effects of SVD on daily life.

Establishment of the Diagnostic Cutoff Point

Using DSM-5–diagnosed dependent short-video users as the gold standard, this study suggests a clinically optimal cutoff score of 58 for diagnosing dependent short-video users with the final version of the SVDS. The best balance between sensitivity (88.6%) and specificity (96.5%) was achieved at this cutoff score. The LPA approach has been performed to identify cutoff points in the absence of a gold standard based on clinical interviews. The adequate diagnostic accuracy of the empirical cutoff point based on the LPA suggests that this approach is a reliable method to identify cutoff points.

We compared the SVDS scores of these dependent short-video users and established a SVDS cutoff point of 58, whereby individuals scoring equal to or higher than 58 were considered to be dependent short-video users.

Comparison With Prior Work

Advantages Compared to DSM-5 Items for Behavioral Addictions

The symptoms of SVD are more closely aligned with the SVDS than with the DSM-5. Some of the parameters of the original SVDS indicated weak sensitivity or specificity because they were largely the same as those of the DSM-5. During the SVDS development process, we were able to improve the scale.

For the first version of the SVDS, the dimensions were identical to those of the DSM-5. Additionally, some items showed lower sensitivity and specificity. To start with, the items measuring displacement showed a lower sensitivity in comparison to the other items of the SVDS and the displacement item of the IGD scale [46]. This suggests that a few high short-video dependents lost interest in their previous hobbies and entertainment. This may be because short-video use can coexist with other activities to some extent. Existing studies in the literature have focused on internet addiction and media use, finding that people who are highly dependent on the internet may reduce offline activities and social interactions but do not necessarily lose interest in previous hobbies altogether [6,9,47]. This implies that people who are highly dependent on short videos may strike a certain balance between online and offline activities, rather than completely abandoning their previous hobbies.

XSL•FO
RenderX

Next, the items measuring escape, preoccupation, and tolerance showed a lower specificity in comparison to the other items. This suggests that most short-video users often use short videos to escape from negative feelings, irrespective of whether they are dependent or nondependent short-video users. This may be because short videos are often light-hearted and entertaining in nature, providing a pleasurable and entertaining experience. For low-dependent individuals, watching short videos may be a relaxing and enjoyable way to spend time, rather than an addictive behavior. Short videos also provide a virtual world where people can temporarily escape from real-life problems, stresses, and challenges. Watching short videos can be an escape mechanism that helps people temporarily avoid unpleasant or difficult situations.

Advantages Compared to Other Similar Questionnaires and Scales

We compared the SVDS to related scales (ie, measurement tools that include internet, dependence, addiction, or other similar keywords), such as the CIAS and the Social Media Disorder Scale (SMDS).

The CIAS is a scale used to assess the core symptoms and problems associated with internet addiction in the Chinese population [24,39]. It does not consider the different types or forms of internet addiction, such as social media addiction or short-form video addiction. Furthermore, it appears inappropriate to use a scale created nearly 20 years ago to gauge how dependent modern society is on short films. Therefore, the SVDS with reference to the content of in-depth interviews conducted in 2023 is more relevant to SVD and can provide more accurate results. Most importantly, we provided statistical evidence for a precise diagnostic cutoff point.

The SMDS is a scale used to assess users' motivation to use social media and the degree of addiction [7]. It does not consider users' communication and interaction with other people or groups on social media platforms, such as liking, commenting, etc, and the psychological and social impacts of such communication and interaction on users. Besides, the scale has only 9 dimensions, which may not cover all aspects of social media addiction, such as motivation, frequency, and duration of social media use. As a result, the SVDS, which has more detailed questions and has questions that are pertinent to the features of short-video platforms, is better suited for measuring SVD.

Limitations and Future Directions

While this study provides distinctive insights into the detection of dependent short-video users and the prevalence of SVD among Chinese university students, it is imperative to acknowledge the presence of certain limitations in the research. First, there may be sampling bias as this study recruited subjects on the NAODAO and TClab platforms and focused on universities in one city. As a significant majority of the participants in our sample had at least a college-level education, there was an imbalance concerning age and educational background. Despite previous studies demonstrating measurement invariance of some scales across education and gender [48-50], the imbalance in the number of participants of different genders or education levels may still have affected our results. To further test the SVDS, future research should collect a well-balanced sample. Additionally, since our sample was primarily drawn from Chinese university students, specifically those in Hangzhou, the findings may have limited generalizability to other cultural or demographic contexts. Future studies are needed to validate the scale in diverse cultural settings and populations. Second, according to recent reports from social surveys, a sizable number of short-video consumers are middle-aged and older [51,52]. The SVDS should be administered to this demographic in subsequent investigations. Third, the self-completion scale might have a social desirability effect. Future studies could cross-validate our results using other research methods (eg, field studies). Fourth, future research should focus on examining the relationship between the degree of short-video dependency and individual characteristics such as personality traits, self-esteem, impulsivity, academic performance or work performance, and other relevant factors. Finally, it is important to examine whether there are differences in SVD among different groups, which could help validate the reliability and validity of the current scale.

Conclusions

We followed the pragmatic approach of developing and validating an administration tool to measure SVD, which enables the investigation of trends and developments in the prevalence of SVD during the current period of rapid changes in the short-video landscape. The final version of the SVDS showed high reliability and validity. It could be applied by subsequent researchers in longitudinal studies to investigate the mechanisms of SVD in terms of behavioral, cognitive, and affective influences, as well as to develop effective interventions to deal with the problem of SVD. The development and validation of a questionnaire with a diagnostic cutoff point are essential for understanding and monitoring SVD, facilitating relevant academic investigations, and informing policy development.

Abstract

Background: Artificial intelligence (AI) has potential to transform health care, but its successful implementation depends on the trust and acceptance of consumers and patients. Understanding the factors that influence attitudes toward AI is crucial for effective adoption. Despite AI's growing integration into health care, consumer and patient acceptance remains a critical challenge. Research has largely focused on applications or attitudes, lacking a comprehensive analysis of how factors, such as demographics, personality traits, technology attitudes, and AI knowledge, affect and interact across different health care AI contexts.

Objective: We aimed to investigate people's trust in and acceptance of AI across health care use cases and determine how context and perceived risk affect individuals' propensity to trust and accept AI in specific health care scenarios.

Methods: We collected and analyzed web-based survey data from 1100 Finnish participants, presenting them with 8 AI use cases in health care: 5 (62%) noninvasive applications (eg, activity monitoring and mental health support) and 3 (38%) physical interventions (eg, AI-controlled robotic surgery). Respondents evaluated intention to use, trust, and willingness to trade off personal data for these use cases. Gradient boosted tree regression models were trained to predict responses based on 33 demographic-, personality-, and technology-related variables. To interpret the results of our predictive models, we used the Shapley additive explanations method, a game theory–based approach for explaining the output of machine learning models. It quantifies the contribution of each feature to individual predictions, allowing us to determine the relative importance of various demographic-, personality-, and technology-related factors and their interactions in shaping participants' trust in and acceptance of AI in health care.

Results: Consumer attitudes toward technology, technology use, and personality traits were the primary drivers of trust and intention to use AI in health care. Use cases were ranked by acceptance, with noninvasive monitors being the most preferred. However, the specific use case had less impact in general than expected. Nonlinear dependencies were observed, including an inverted *U*-shaped pattern in positivity toward AI based on self-reported AI knowledge. Certain personality traits, such as being more disorganized and careless, were associated with more positive attitudes toward AI in health care. Women seemed more cautious about AI applications in health care than men.

Conclusions: The findings highlight the complex interplay of factors influencing trust and acceptance of AI in health care. Consumer trust and intention to use AI in health care are driven by technology attitudes and use rather than specific use cases. AI service providers should consider demographic factors, personality traits, and technology attitudes when designing and implementing AI systems in health care. The study demonstrates the potential of using predictive AI models as decision-making tools for implementing and interacting with clients in health care AI applications.

KEYWORDS

artificial intelligence; AI; health care technology; technology adoption; predictive modeling; user trust; user acceptance

Introduction

Background

Artificial intelligence (AI) has shown significant potential in health care and well-being. AI applications play a crucial role in the digital transformation of health care [1]. This includes transformations in areas such as medical data analysis, treatment planning, robotic surgeries, clinical operations support, diagnostics, web-based nursing, and connected health care devices [2]. AI enables new methods for how health diagnoses and treatment recommendations are delivered to patients [3]. In addition, technology adds positive effects to health care such as improving availability, accessibility, and efficiency as well as reducing the cost of health care service delivery [4].

Challenges and the Importance of Trust in AI Adoption

While there are numerous benefits to integrating technology into health care, there are also challenges. Owing to the data-driven and autonomous nature of AI, matters that already posed a concern for health care such as confidentiality (ie, information security and privacy), decision-making, accountability, and responsibility have become more pronounced from a technological perspective. Thus, it is important to examine the ethical and acceptance determinants (including challenges) of AI applications as they are crucial for patient safety and accountability and can significantly boost health consequences [5]. Relating to this, human trust is an *enabler* and a state in which individuals believe that engagement in actions or confidence in others (including objects) will result in a positive outcome [6]. Without assurance that the interests and concerns of humans (patients and professionals) are at the heart of adoption and implementation, human trust—the belief that engagement with a transaction or interaction with the technology will result in positive outcomes [7]—fails to manifest. The current landscape of mass digitalization is rife with scenarios in which individuals are dependent on digitally connected technology without trust (ie, forced digitalization). Trust can be seen as a state of certainty in which the truster believes that the trustee (human, artifact, or service) will act according to promises and expectations [6,8]. Despite the popularity of health care AI scholarship, studies that combine trust with experience of concrete application scenarios are scarce.

Trust can vary dramatically depending on the type of AI system an individual is dealing with, the context, and the level of engagement (ie, queuing for an appointment in a nonemergency situation vs undergoing open-heart surgery). In this domain, human lives and well-being are in question, meaning that the stakes are high for critical AI systems as encountered in medical AI [9]. Trust is closely related to acceptance and intention to use different types of technology, as demonstrated by various studies [10-13]. It is often mediated by perceived usefulness, ease of use, and satisfaction. Applied sociological and economic theories proposed by Pavlou and Gefen [14] revealed that the perceived effectiveness of AI at an institutional level impacted trust at the individual level, both toward the institution and the technology. This perceived effectiveness was based on 2 types of mechanisms—weak (market) and strong (legal). In addition, consideration for behavioral intention based on this perceived effectiveness was incorporated into this study: predicted preference of the technology in the future, the likelihood of using the technology soon, and the intention to use the technology in the future given increased opportunities. Ye et al [15] found that participants with high trust in AI might have high expectations for AI in health care, requiring greater perceived usefulness before engaging with an AI device.

Factors Influencing Trust and Acceptance

Recent studies highlight the influence of various background variables on attitudes toward AI in health care. Khanijahani et al [16] found that the common determinants for the acceptance of AI technologies are *perceived ease of use*, *usefulness*, *performance*, and *expectancy* among health care professionals and patients. However, as we see from the following examples of scholarship, results vary between studies. For instance, Omrani et al [17] found that men and individuals aged >55 years exhibited higher trust in AI. Conversely, Fritsch et al [18] reported that older patients, women, and those with lower education were more cautious regarding AI in health care. Riedl [9] concludes that older people are increasingly concerned by AI systems. The study by Nadarzynski et al [19] on the acceptability of AI-enabled chatbots in health care revealed several emergent themes—understanding: awareness and experience; AI hesitancy: perceived accuracy, premature technology, nonhuman interaction, and cybersecurity; and motivations: anonymity, convenience, and signposting (using words to guide processes). Individuals' opinions toward AI were measured through constructs of *perceived accuracy*, *perceptions of premature technology*, *nonhuman interaction*, *cyber security*, and *accessibility*. The findings highlight hesitancy toward chatbots corresponding with the IT skill levels of participants, as well as dislike for talking to computers. Researchers included multiple demographic factors in their analysis but found no significant association with AI acceptability.

Esmaeilzadeh [20] identified positive effects of gender (man), income, education, employment, technical knowledge, and familiarity with AI on the intention to use AI-based health care tools, while age, race, and general computer skills were not significant. On the other hand, studies such as that by Lambert et al [21] noted no gender effects on AI acceptance among health care professionals. Araujo et al [22] observed that age negatively affected perceived usefulness and positively affected the perceived risk of automated decision-making (ADM) by AI. In this instance, gender was seen to influence perceived usefulness but not risk. A study by Ho et al [23], positioned in a Japanese cultural setting, indicated negative perceptions of emotional AI technology among older adult and male patients. Factors behind these results are attributed to the fear of losing control to AI, while due to its cultural context (Japan), privacy was not a concern as there are high levels of trust regarding the standard

XSL•FO
RenderX

of care in exchange for disclosing medical details. In another cultural setting (Saudi Arabia), Alanzi et al [24] found that individuals in the age group of 43 to 58 years (generation X) were less accepting of AI, mental health, web-based assistants than younger generations, while Park and Woo [25] reported positive associations between age and both emotional and social reactions toward AI. These findings underscore the complexity of factors (cultural background and otherwise) influencing attitudes toward AI in health care, suggesting that demographic variables play significant roles in shaping perceptions and acceptance of AI technologies.

Personality and technical prowess are also relevant factors for attitudes toward AI [9,18,25-27]. Consensus appears that both agreeableness and openness positively affect trust with weaker support for extraversion. High personal technical affinity has a strong positive impact on AI acceptance in health care [18]. In addition, it appears that less-neurotic people exhibit more trust in AI systems [9]. Park and Woo [25] used Big Five personality traits and personal innovativeness in IT (PIIT) trait, which refers to "the willingness of an individual to try out any new information technology." Findings indicated that the Big Five traits and PIIT trait contribute significantly to explaining individuals' attitudes toward AI. For example, those with high extraversion showed rather negative attitudes toward AI, and individuals with high levels of neuroticism displayed more negative emotions toward AI. Those with high agreeableness displayed positive emotions and positive attitudes in the social and functionality dimensions of AI. The PIIT trait had a consistent (positive) effect in predicting all types of attitudes toward AI. For example, those who rated themselves as having poor or moderate IT skills showed lower acceptance of the technology [19]. For patients, higher personal technical affinity increases their perception of AI use in health care [18].

Strategies for AI Adoption in Health Care

Al Badi et al [28] identified 5 main dimensions and 25 subfactors for the main challenges in adopting AI in health care. Their study revealed that accuracy and privacy as well as security criteria are the most important factors toward improving AI adoption in the health care sector. Safety and security were found to be important factors for the acceptance of AI in health care in several other studies [16,21]. The results showed that general knowledge (education) had a positive association with perceptions of ADM usefulness, while domain-specific knowledge (eg, programming and algorithms) had a positive association with perceptions of ADM usefulness and fairness [22]. Characteristics of individuals and medical characteristics of patients also affect AI acceptance and adoption [16]. The use of AI has had negative consequences on trust in data privacy; patient safety; technological maturity (implementing technologies too early in development); and full automation, which has been the result of a rushed transformation from human-human service to human-technology (digital) service [4]. Patients may distrust AI-based data collection methods as part of diagnoses and treatment information [3], which indicates that there might be a difference between AI applications. The lack of available and easily accessible information may operate as a negative factor, slowing down the acceptance of data-driven services in predictive medicine [29].

Previous research has listed several means to increase user acceptance and adoption of AI in health care [4,30,31]. Kwak et al [31] state that to increase nursing students' intent to use AI, promoting performance expectancy, effort expectancy, and self-efficacy are essential interventions. These aid in fostering a positive attitude toward AI. In supporting the adoption of AI in health care, research indicates that focus should be placed more on facilitating early adoption and sustainable implementation in the health system. This particularly applies from the user's perspective [30]. For AI to be successfully adopted in health care, patients and other users must consent to use AI applications [3]. Parvinen et al [29] found that informing potential patients or customers regarding the personal benefits of AI improved their willingness to provide consent to use their genomic data. This shows that a trade-off for benefits would boost the acceptance of using data-driven AI technologies. Positive attitudes toward AI have a substantial impact on the intent to use AI in health care [31]. Positive attitude is decreased by the feeling of losing control to AI systems [23].

Chew and Achananuparp [4] suggest the following improvements to the adoption of AI in health care: enhancing user experience and design, enhancing personalization and customizability, enhancing empathy, and personification of AI-enabled chatbots and education of AI capabilities to the public. Effective governance of AI in health care is a prerequisite to precisely address regulatory, ethical, and trust issues while advancing the acceptance and implementation of AI among patients [5]. Ho et al [23] list the following suggestions that might improve emotional AI perception in patients: explaining how AI tools function (increasing transparency), explaining current legal and ethical safeguards, and describing the role of human professionals in the decision-making process might improve positive attitude. Furthermore, other crucial factors including robust data security, anonymization, and privacy measures as a part of secured data management solutions are crucial for establishing users' acceptance of AI health care applications [32]. In addition, using multimodality and several sensors for health data collection improves the accuracy and trustworthiness of AI applications [33], thus boosting the user acceptance of AI applications in health care.

Frameworks, Ethical AI Models, and Survey Design

Efforts have been made to establish frameworks to create actionable principles that relate to *data management*, *model development*, and *deployment* and *monitoring* [34]. These should exist under the banners of governance (organizational policy) and regulation (legal policy). Such frameworks resonate with the works of Vakkuri et al [35] and Rousi [36]. These can be applied as general guidelines and principles for development, yet context-dependent information must be sought additionally. The priorities and importance of factors affecting acceptance and adoption vary depending on the study. While the previous studies are extensive, we felt that they did not examine the element of trust and the specificities of application context variations to the extent that we are interested in.

For this study, we sought further to find theories and constructs that would enable us to delve deeper and in detail in terms of understanding the varying dynamics of individual perception

XSL•FO
RenderX

of AI in health care according to dimensions and context. We used the ECCOLA model [35] and the Robot Governance Model [36] to establish the ethical AI themes and dimensions under examination. The ECCOLA model was developed on 3 prominent AI ethics studies and guidelines: the systematic mapping of global guidelines by Jobin et al [37], revealing 5 ethical principles (justice and fairness, transparency, responsibility, nonmaleficence, and privacy); Ethically Aligned Design by IEEE Xplore [38]; and the Ethics Guidelines for Trustworthy AI by the European Commission [39]. ECCOLA features 8 themes designed to be practically applicable for increasing ethical awareness in AI development processes. These 8 themes are stakeholder analysis, transparency, data, agency and oversight, safety and security, fairness, well-being, and accountability. The Robot Governance Model adds to this in that it depicts the properties (sense, process, and act) of the AI systems; connects these to specific challenges; and then accounts for layers of governance in relation to accountability and responsibility. In other words, these frameworks were chosen for their thoroughness, multidimensionality, and detail regarding applied settings.

The AI ethics–related themes and dimensions were built-in within the questionnaire in relation to constructs probed that were obtained from studies across the disciplines of human-computer interaction, information systems, and digital health. In this study, themes related to data, privacy, accessibility (fairness), well-being (trust and trade-offs), and safety and security (cybersecurity) are seen as integrated into the questions to *lower* the concepts from high-level principles to actionable propositions. The scenarios were used to tangibly depict the AI applications, while the questions featured were based on the Robot Governance Model, specifically focusing on the "systems and artifacts" layer. The AI acceptability study by Nadarzynski et al [19] was instrumental in formulating the constructs on the propensity to trust AI, also stemming from the foundational work by Pavlou and Gefen [14]. These were also complemented by other constructs obtained from the study by Cheung and To [40] investigating the propensity to trust in-app advertisements.

Using the aforementioned approach with a robust machine learning–based analysis, we established an understanding of the antecedents for trusting and using AI in specific health care use cases. Our main research questions were as follows:

1. How does context affect an individual's willingness to trust and accept AI in health care?
2. How does the perceived level of risk (physical, psychological, and social vulnerability) affect an individual's propensity to trust and accept AI in specific health care settings?

By addressing these questions, we aim to contribute to a deeper understanding of trust dynamics in AI health care applications, ultimately informing strategies for enhancing user acceptance.

Methods

Overview

Our methodological approach aimed to investigate public opinions on AI applications in health care and well-being among consumers. We used a web-based questionnaire and established theoretical frameworks from human-computer interaction, information systems, and digital health. The survey comprised demographic questions, evaluations of 8 AI use cases, and general opinions on AI in health care. After data collection, data preprocessing was conducted to ensure the quality and variability of responses. This was followed by confirmatory factor analysis to identify underlying constructs within the data. For predictive modeling, we used the CatBoost gradient boosted tree regression algorithm to capture nonlinear relationships and complex interactions. We applied the Shapley additive explanations (SHAP) technique to investigate model predictions for each predictor and their interactions. This multifaceted approach enabled us to effectively explore the factors influencing individuals' attitudes toward AI in various health care contexts.

Web-Based Survey Development and Distribution

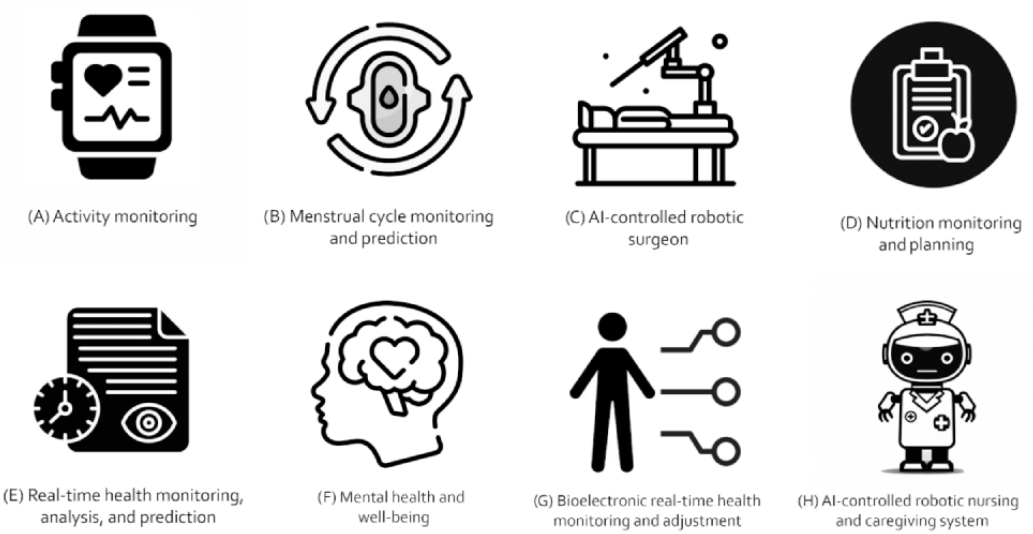
Our web-based survey contained three parts:

1. Demographic and personal information (31 questions)
2. Opinions toward AI in health care and well-being for 8 use cases, from which 5 were randomly selected per participant to avoid waterfall effects (21 questions per use case)
3. General opinions of AI in health care and well-being (31 questions)

Questions in parts 2 and 3 were considered response variables, while questions in part 1 were considered predictor variables. For the development of the questions, we used frameworks developed by Vakkuri et al [35] and Rousi [36]. Our theoretical constructs were drawn from human-computer interaction [40], information systems [14], and digital health [19]. We adapted the work by Pavlou and Gefen [14] on the *propensity to trust* [19], characterized by *ease to trust*, *tendency to trust*, and *willingness to trust* with the assumption that main respondents would not be of expert level in terms of understanding how AI systems operate. For the intention to use AI, we adapted the Unified Theory of Acceptance and Use of Technology model [41], which has been adapted by various authors [10,11,13,20,24]. The question related to exercising habits was adapted from official well-being surveys by the Finnish Institute for Health and Welfare [42]. For personality traits, we applied a 10-question battery by Gosling et al [43]. Education and working fields were based on official categories by the Statistics Finland department. The remaining questions related to interest and knowledge of technology and the state of health were self-developed. Refer to Multimedia Appendix 1 [10,11,13,14,19,20,24,35,36,40,41] for detailed information on questions-related sources and how we combined them into factor constructs (Tables S1 and S2 and Figure S1 in Multimedia Appendix 1).

Overall, each respondent was asked to answer 167 questions, which typically took 15 to 20 minutes. Quantitative questions were numerical, single, and multiple choice as well as Likert type. In addition, respondents were allowed to respond via open-text questions (eg, feedback). The survey was implemented using LimeSurvey (version 6.0; LimeSurvey GmbH). Data were collected between May 12, 2023, and May 23, 2023, using a survey pool. A total of 1125 people responded to the survey,

XSL•FO
RenderX



out of which a smaller subset (1100/1125, 97.78%) finished the survey fully or partially. A printed version of the survey can be found in Multimedia Appendix 2. Data were collected by a third-party service with access to a large pool of Finnish consumers, with each responder receiving a small monetary reward. The survey was offered both in Finnish and English.

We selected 8 AI use cases, which was considered maximum while still keeping the number of questions and response time reasonable. The criteria for choosing those use cases were to obtain a versatile description of the various AI tools in different contexts, ranging from self-care to hospital environments. As stated by Riedl [9], trust can vary strongly depending on what kind of AI system a user is dealing with (critical vs noncritical). On the basis of the variables of the frameworks [35,36], we selected applications that described different use cases where these aspects appeared differently depending on the use contexts. Thus, variables such as the sensitivity of the data being processed and the level of human agency and oversight associated with the AI-generated advice or actions were considered. The 8 AI use cases featured in the survey were as follows (short form in parenthesis):

1. Activity monitoring AI system to support a healthy lifestyle (*activitymonitor*)
2. Menstrual cycle monitoring and prediction AI system (*menstrual*)
3. AI-controlled robotic surgeon (*robotsurgeon*)
4. Nutrition monitoring and planning AI system (*nutrition*)
5. Real-time health monitoring, analysis, and prediction AI system (*healthmonitor*)
6. Mental health and well-being AI system (*mentalmonitor*)
7. Bioelectronic real-time health monitoring and adjustment AI system (*bioelectric*)
8. AI-controlled robotic nursing and caregiving system (*nursing*)

Use cases are illustrated in Figure 1 with detailed descriptions as present in the survey shown in Multimedia Appendix 3.

Figure 1. The 8 use cases from the health care and well-being domain included in the survey. These include both invasive and noninvasive cases that are either already available (eg, activity monitoring), emerging, or futuristic (eg, robotic surgeon and nursing system). AI: artificial intelligence.

Data Preprocessing and Factor Constructs

Response data were converted into a table with rows representing responses from participants. Responses from part 1 of the survey were converted into the following variables in the 3 main groups. Variable abbreviations with descriptions related to basic demographics and personality types are as follows (variables and variable types are provided in parenthesis):

- *age*: age in years (numerical)
- *gender*: gender identity with 3 options (categorical)
- *education_level*: the highest level of education obtained with 5 options (categorical)
- *education_field_* and work_sector_**: field of education and current work sector including education (*education*); commerce, administration, law, or services (*business_services*); science, information and communication technology, or engineering (*science_ICT_engineer*); health and wellness (*health*); and all others (*other*); and all with yes or no options (binary)
- *persona_**: 10 personality dimensions with questions critical or quarrelsome (*critical_quarrelsome*), dependable or self-disciplined (*dependable_selfdisciplined*), anxious or easily upset (*anxious_easilyupset*), open to new experiences or complex (*newexperiences_complex*), reserved or quiet (*reserved_quiet*), sympathetic or warm (*sympathetic_warm*), calm or emotionally stable (*calm_stable*), conventional or uncreative (*conventional_uncreative*), disorganized or careless (*disorganized_careless*), and extraverted or enthusiastic (*extraverted_enthusiastic*), all with 7 Likert-scale options (ordinal)

Variable abbreviations with descriptions related to technology use, knowledge, and attitudes are as follows:

- *IT_skills*: self-evaluated IT skills compared to others with 5 options (ordinal)

XSL•FO
RenderX

- *technology_adoption*: self-evaluated adoption and use of new technology with 3 options (categorical)
- *technology_usage*: frequency of using technology to monitor own health and well-being with 5 options (ordinal)
- *AI_knowledge*: self-evaluated knowledge and experience of AI, a summary construct (numerical)
- *technology_attitude*: attitude toward technology, a factor construct (numerical)

Variable abbreviations with descriptions related to personal health, opinion on health care services, and physical activity are as follows:

- *health_status*: self-evaluated overall health status in the past 12 months with 5 options (ordinal)
- *health_service_usage*: frequency of health services use in the past 12 months with 5 options (ordinal)
- *health care_services*: how does one feel about the current state of health care services (private and public sector in Finland) with 5 options (ordinal)
- *exercise_level*: the amount of exercise and physical straining of oneself in free time with 4 options (categorical)

In addition, the variable *use_case* included 8 options. Detailed variable listings can be found in Table S1 in Multimedia Appendix 4, including a listing of all response options.

During preprocessing, participants who did not proceed to part 2 of the survey were removed. Furthermore, participants whose data lacked variability were excluded based on the assumption that they were mostly motivated by the reward without putting real effort into their responses or showing signs of survey fatigue. The criteria for the variability were evaluated for Likert-type questions, entailing that the minimum allowed SD was 0.15. Furthermore, we excluded participants whose responses were too extreme without using the Likert scale properly. For this, we set a threshold of 90%, and responses surpassing this ratio were excluded. These criteria were applied individually for use cases (part 2) and part 3 of the survey to avoid the removal of too much data. Ordinal categorical responses (eg, Likert type) were converted into numerical integer values using the conversion rules listed in Multimedia Appendix 4. After this initial preprocessing, *Lavaan* (version 0.617) [44] confirmatory factor analysis for R (R Foundation for Statistical Computing) was applied to create factor constructs from the Likert-type question batteries in parts 2 and 3 of the survey, as well as 1 question from part 1. The "*cfa*" function was applied with a maximum likelihood estimation algorithm. The model's reliability was evaluated by calculating the comparative fit index, Tucker-Lewis Index, and root mean squared error. Internal consistency of factors was evaluated by computing the omega, alpha, and average variance explained [45], making sure our factor constructs were reliable and within acceptable limits [46-48]. See Multimedia Appendix 1 for details.

Regression Modeling With Gradient Boosting

A CatBoost gradient boosted tree regression algorithm with multivariate root mean squared error loss was used to train predictive models [49] for parts 2 (model l) and 3 (model 2) of the survey. CatBoost builds an ensemble of decision trees, where each tree learns to improve prediction accuracy by correcting errors made by the previous trees. CatBoost can natively handle multivariate responses with both numerical and categorical predictor variables, as well as missing values. It can also approximate nonlinear relationships and complex, multilevel interactions, which are not feasible with linear models. Gradient boosting has been successfully applied to modeling in various fields, including behavioral [50] and health sciences [51].

For result interpretations and model analysis, we applied the SHAP method [52]. It is a method for interpreting machine learning models by calculating SHAP values, which quantify the contribution of each feature to the model's predictions, such as tree-based gradient boosting methods, including CatBoost. On the basis of game theory, the SHAP algorithm assigns each feature a contribution score that indicates how much it influences a prediction. For tree models, the SHAP algorithm efficiently calculates these contributions by breaking down the model's complex decision processes into simpler, additive components. This approach helps reveal which features have the greatest impact on predictions, allowing us to see not only the individual contributions but also how features interact with each other in determining outcomes. Tree SHAP analysis provides both local (sample level) and global (average) interpretations. Locally, it explains individual predictions, which can help understand individual participants. Globally, by aggregating these explanations across the dataset, the SHAP algorithm enables understanding of broader model behavior and identifying trends or dominant features [52]. In this study, both the main effects of each variable and the interaction of pairs of variables were investigated. While the main effects estimate how individual variables affect the predictions, the interaction effect is the additional combined feature effect after accounting for the main effects, thus giving more nuanced information. Interactions subtract the main effect of the features to obtain the pure interaction effect after accounting for individual effects. We report both mean and mean absolute SHAP values for features defined as follows:

(1)

(2)

where . is a (local) SHAP value of sample *i* of feature *j* and *N* is the number of samples.

The Optuna hyperparameter optimization framework [53] was applied to find optimal CatBoost parameters for the data. Optuna is an automatic hyperparameter optimization software framework, particularly designed for machine learning purposes to optimize parameters that control the learning process. For this, the data were randomly split by setting 15% (165/1100) for testing, 15% (165/1100) for development, and the remaining 70% (770/1100) for training. Each participant was present in only 1 single split to maximize predictive power for new participants. Parameters were optimized via Optuna for the development set, and then a model was fitted using both training and development sets. Optuna was again applied in finding

XSL•FO
RenderX

parameters that maximized and minimized predictions to allow illustrative examples. Finally, trained models were applied to the held-out separate test data. The performance of the model was assessed by computing the root mean squared error of the predictions, comparing that against a constant-only model, and computing Pearson R^2 statistics for test data. We applied a permutation testing procedure to evaluate whether R^2 values were notably different from 0 [54]. In this procedure, data were randomly shuffled multiple times to obtain an empirical distribution of null values that were compared against the original (unshuffled) values to estimate *P* values.

Ethical Considerations

This study followed ethical standards and handled data with care. The research involved secondary analysis of survey data purchased from a Finnish third-party company, which is compliant with Finnish legislation. The data were collected anonymously, with no personal identifiers, so additional ethics review was not required. The third-party company obtained informed consent from participants, who willingly completed the survey after being informed of its purpose and use. Consent included provisions for secondary analysis of anonymized data by the researchers. While the third-party company had access to responder identities to ensure sample coverage, they had no access to survey responses and vice versa for the researchers. This system ensured the anonymity of responses. Potentially sensitive questions, that is, those related to personal health, were optional and skippable for the responders. All participants were compensated for their time per the company guidelines and agreements with panel members. No identifiable information or imagery is included in the manuscript or Multimedia Appendices 1-8.

Results

Measurement Constructs for the Use of AI for Use Cases

The number of valid data points was 5146 with 1100 participants. The confirmatory factor analysis for response variables (21 for each use case) resulted in a model that covered 19 items in 7 constructs. For all fit parameters and items, refer to Multimedia Appendix 1 with descriptive analysis. The 7-factor construct and their interpretations were as follows:

- *Intention* (3 items): intention to use the AI system if offered the chance
- *Trust* (3 items): trust that the AI system can make valid and accurate decisions
- *Predictions* (3 items): the importance of knowing how results were produced
- *Data* (3 items): the importance to know what type and size of training data were used
- *Privacy* (3 items): the importance to know how personal data are stored and used
- *Trade-off* (2 items): willingness to share personal data to improve AI predictions
- *Manufacturer* (2 items): importance to know the company developing the AI system

All factors were coded so that higher values indicate higher agreement, that is, toward the *strongly agree* direction in the Likert scale to aid interpretability. Many constructs for responses were highly correlated, particularly intention and trust (0.808), predictions and data (0.840), manufacturer and data (0.794), and manufacturer and predictions (0.752). All correlations are listed in Table 1.

All 33 predictor variables used in the analysis are listed in Multimedia Appendix 4.

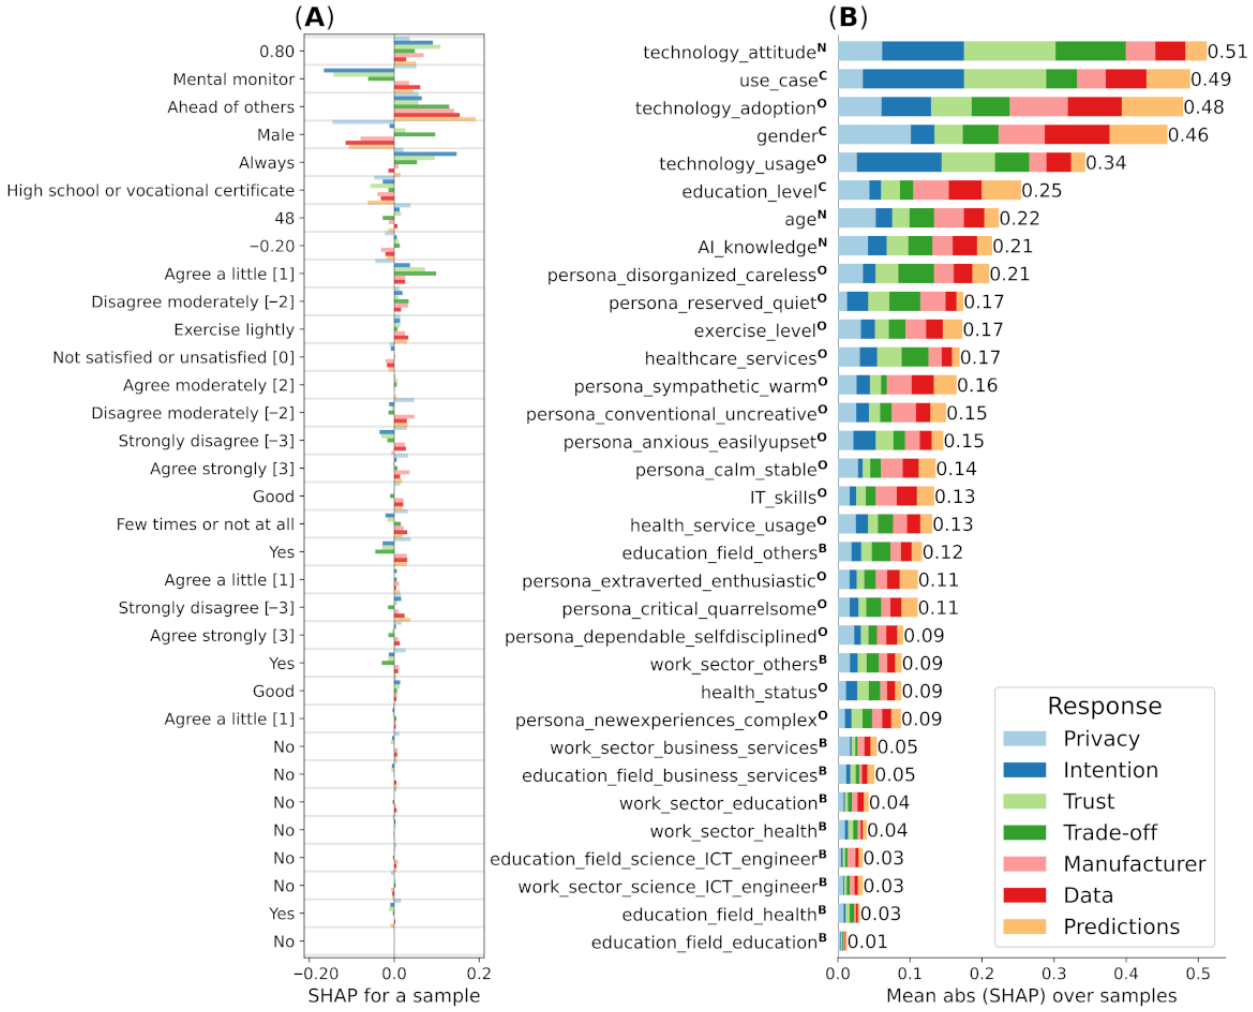
Predictive Modeling With Gradient Boosting

For the predictive model 1 (data from parts 1 and 2 of the survey), we trained a CatBoost model for all 7 response factors. The correlation coefficients for training and testing data were 0.664 and 0.324, corresponding with R^2 values of 0.441 and 0.105. See Table S1 in Multimedia Appendix 5 for detailed information on individual use cases and responses. The difference between training and testing sets indicates some potential overfitting during training. However, our model predicted >10% variance for the testing data and surpassed the chance level ($P<.001$; permutation test with 5000 iterations); thus, we considered it suitable for further analysis. For model 2 (data from parts 1 and 3 of the survey), the procedure was similar. We trained a CatBoost model for intention and trust responses. The final model reached R^2 of 0.225 with 0.235 for intention and 0.220 for trust. See Figures S1-S3 and Table S1 in Multimedia Appendix 6 for full results for model 2.

In the following subsections, SHAP values are reported. The SHAP values were computed using a trained model applied to all available data. First, we investigated the overall importance of features for all 7 responses. Then, we concentrated on intention, trust, and trade-off, for which model 1 reached the best predictive accuracies.



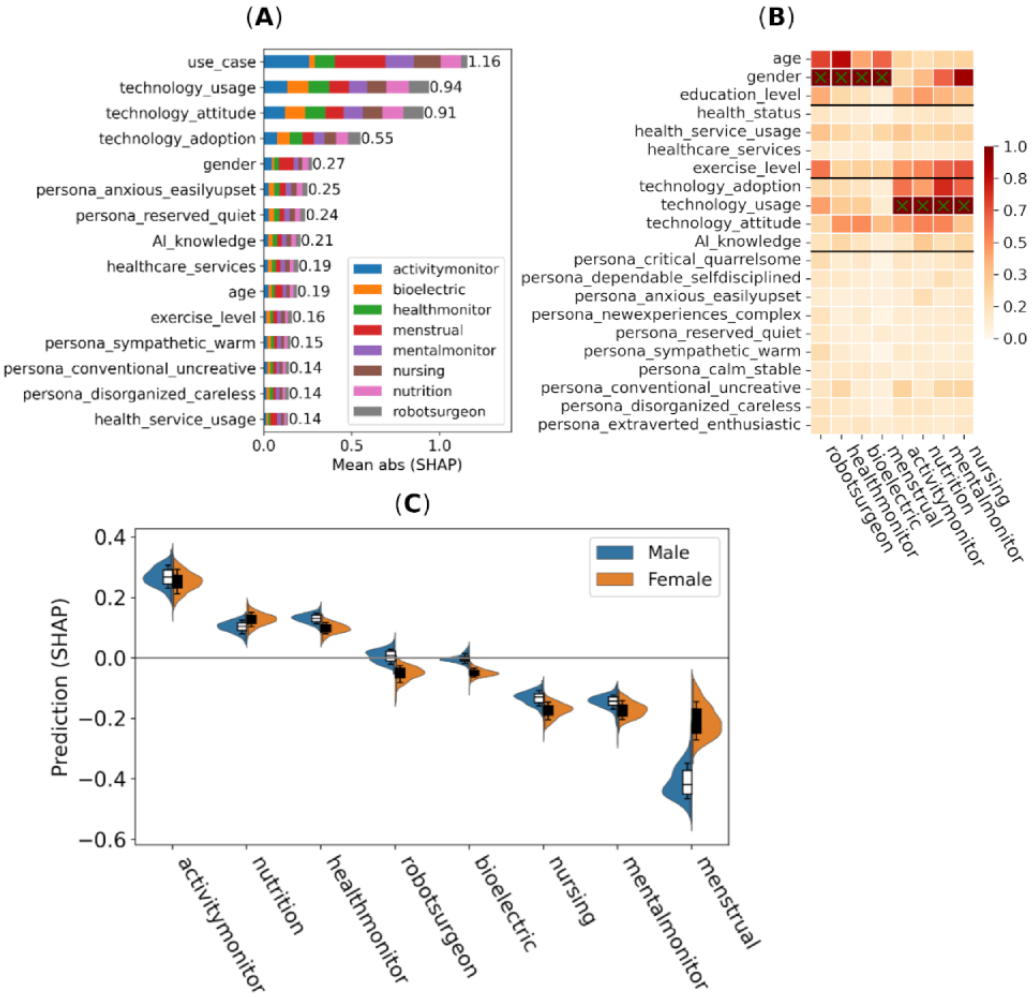
Combined Feature Importance for Use Cases

In Figure 2A, we depict 1 representative sample from the data with its SHAP values computed from the trained model. After combining SHAP values of all samples (n=5146 data points with 1100 participants) by taking their absolute values and means and combining those with all 7 responses, we obtained magnitudes of impact to predictions for all 33 features. This is depicted in Figure 2B, where we have sorted features from the most important (at the top) to the least important (at the bottom) according to mean SHAP magnitudes. The order of features is the same in Figures 2A and 2B. Note that the ranking of features can differ between individual responses; for example, see Figures 3A and 6A for intention and trade-off responses, respectively.

The results indicate that the most important features overall (ranks 1 to 5) were technology_attitude, use_case, technology_adoption, gender, and technology_usage. Other important features covered education_level, age, AI_knowledge, and various personality features. Features related to the education field and work sector were negligible.

XSL•FO
RenderX

Figure 2. Impact of all 33 features on the 7 response variables measured via Shapley additive explanations (SHAP) main effect values. (A) Single representative sample with SHAP values of each feature contributing to the 7 response predictions. Values in parenthesis correspond to numerical Likert encodings. (B) Mean absolute values of SHAP values over all samples (n=5146 data points with 1100 participants) for each response stacked together for all 7 responses. Bars represent the relative impact of each feature for model predictions. B: binary (yes or no); C: categorical; ICT: information and communication technology; N: numerical; O: ordinal categorical.



Feature Importance for Intention to Use of Use Cases

Feature importance for intention (ie, intention to use the AI system if offered the chance) are depicted in Figure 3, including the mean of absolute SHAP values and SHAP values for individual use cases and interaction strength for the most important variables. In Figure 3B, we have sorted columns (use cases) according to the similarity of SHAP values for easier visual comparison.

In Figure 4, SHAP estimates are depicted for technology-related variables technology_attitude, technology_usage, and technology adoption, as well as a responders' view of the status of current health care services (variable health care_services). The shaded regions in subplots in Figures 4A, 4B, and 4D correspond with the 75th percentile of data with the mean value at the center, both computed using a sliding-window approach, while box and whiskers in the subplot in Figure 4C correspond with the 50th and 75th percentile of data. These variables remained highly similar for trust and trade-off; hence, separate plots for those are omitted.

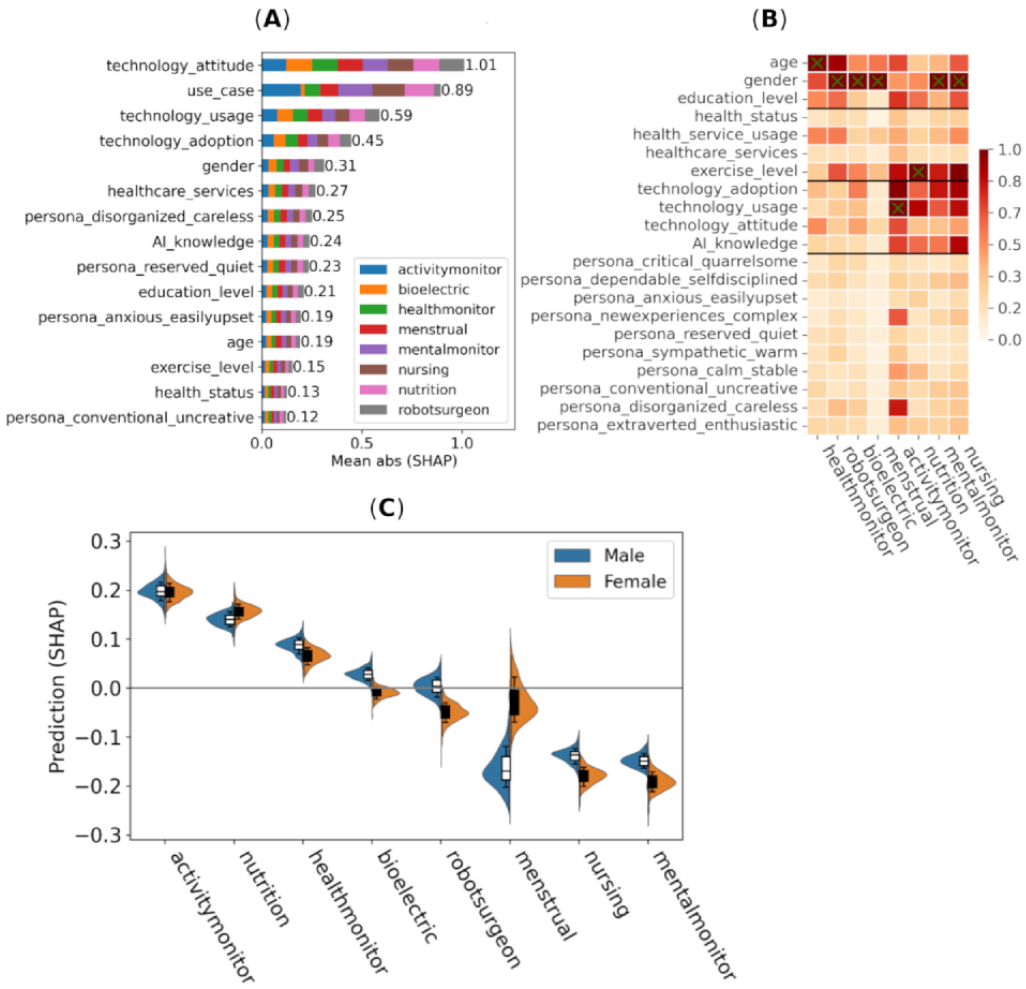
Impact of features on the intention to use the artificial intelligence (AI) system if offered the chance (Intention response) measured via Shapley additive explanation (SHAP) values (all data points; n=5146 data points from 1100 participants). The shaded and boxed regions correspond with the 75th percentile of data. (A) Technology attitude, (B) technology use, (C) technology adoption, and (D) opinion on the status of health care services.



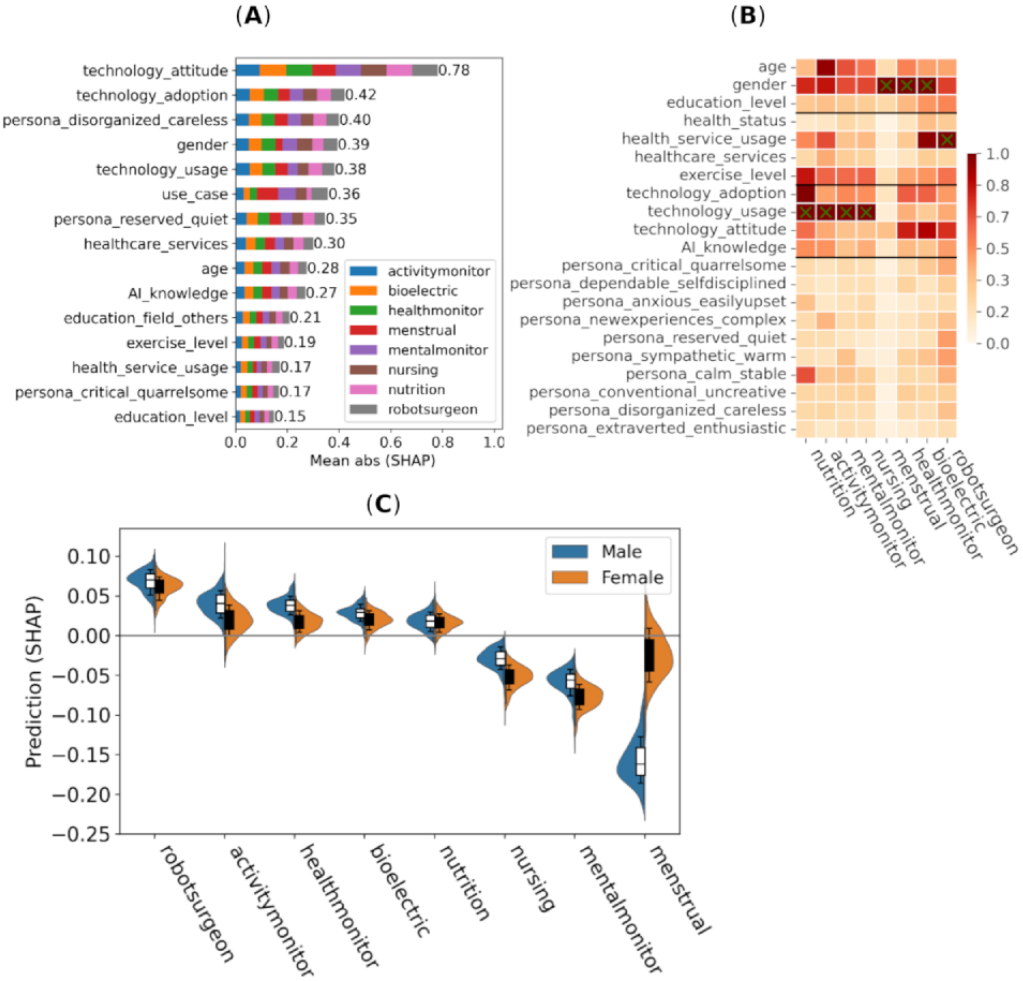
Feature Importance for Trust Toward Use Cases

Feature importance for trust that AI systems can make valid and accurate decisions (trust) are depicted in Figure 5, including the mean of absolute SHAP values and SHAP values for individual use cases and interaction strength for the most important variables.

In distinction from Figure 3B, the importance of the exercise_level variable is elevated for activity and mental monitor, nutrition assistant, and nursing robot, as shown in Figure 5B.

XSL•FO
RenderX

Figure 5. Impact of features on trust that artificial intelligence (AI) systems can make valid and accurate decisions (trust response) measured via Shapley additive explanation (SHAP) values (all data points; n=5146 data points from 1100 participants). (A) Mean absolute SHAP main effect values divided between use cases, (B) mean absolute SHAP interaction values with respect to the use case and selected variables, and (C) Main effect SHAP values for each use case split between male and female (n=1050, 95.45%) participants.



Feature Importance for the Trade-Off Willingness of Use Cases

Feature importance for willingness to share personal data to improve AI predictions (trade-off) is depicted in Figure 6, including the mean of absolute SHAP values and SHAP values for individual use cases and interaction strength for the most important variables.

XSL•FO

(A) Mean absolute SHAP main effect values divided between use cases, (B) mean absolute SHAP interaction values with respect to the use case and selected variables, and (C) main effect SHAP values for each use case split between male and female (n=1050, 95.45%) participants.

Impact of Age, Knowledge of AI, and Personality

Finally, a side-by-side comparison of the other highly important variables, AI knowledge, and age, is depicted in Figure 7. Positive and negative values correspond with increasing and decreasing contributions to the prediction, respectively. Results indicate that those who were least familiar with AI were also less interested in using or trusting AI. Older people were generally more reserved, at least those aged 65 to 70 years. People aged >70 years were most positive toward AI when considering the trade-off measure.

Figure 8 depicts the effect of personality traits. Each colored cell corresponds with the mean of SHAP values over low (Likert values of –3 and –2), neutral (Likert values from –1 to –1), and high (Likert values of 2 and 3) responses. Positive values correspond with increasing contributions to the prediction and vice versa. The strongest patterns by overall importance remain similar between all 3 responses, namely with the positive relationship for *disorganized and careless* and *anxious and easily upset* and negative for *reserved and quiet*.

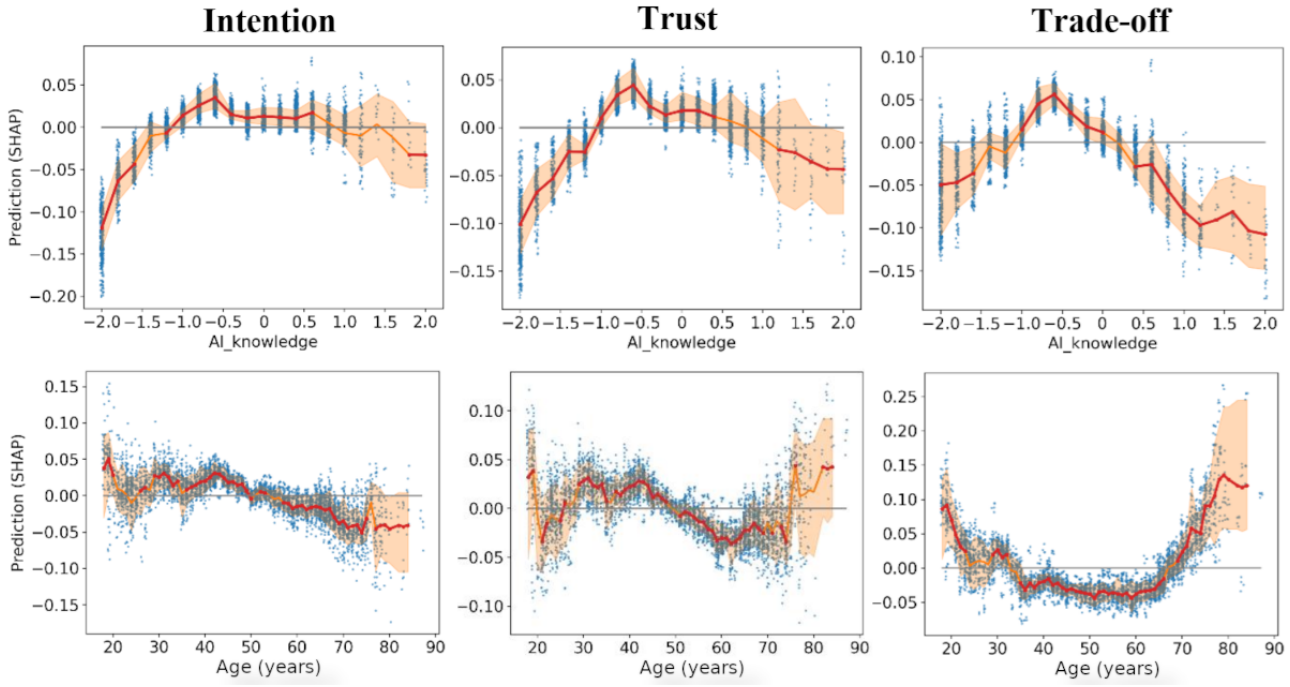
Figure 7. Impact of artificial intelligence (AI) knowledge and age on the intention, trust, and trade-off response measured via Shapley additive explanations (SHAP) main effect values (all data points; n=5146 data points from 1100 participants). The shaded region corresponds with the 75th percentile of data.



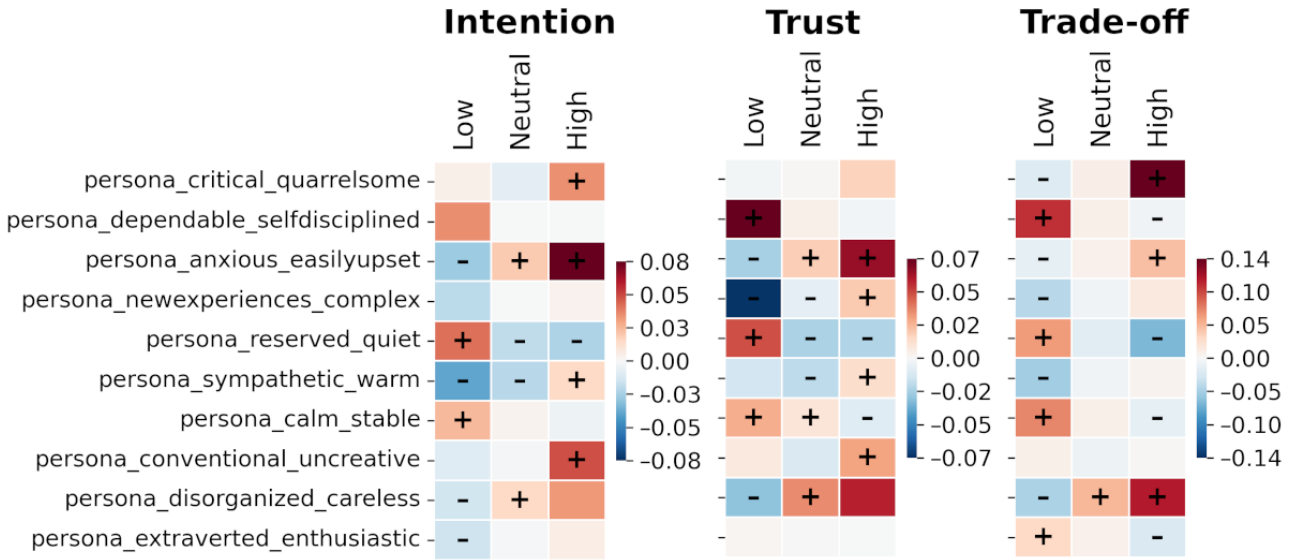


Figure 8. Impact of personality on intention, trust, and trade-off responses measured via Shapley additive explanations (SHAP) main effect mean values (all data points; n=5146 data points from 1100 participants). Plus (+) and minus (–) signs correspond to 75th percentile of SHAP values having positive or negative signs.

Nonlinear Interactions and Example Predictions

SHAP interaction matrices involving variable pairs are depicted in Figures S1 and S2 Multimedia Appendix 7 for both models. Strongest interactions involve variables age, gender, education_level, exercise_level, health care_services, health_status, technology_adoption, technology_attitude, technology_usage, and AI_knowledge. In addition to the use case, gender had strong interactions with education level, technology attitude, health status, and age. Personality had typically weak interactions with other variables, particularly for model 1. The strongest pairwise interactions are illustrated in Figures S3 (model 1) and S4 (model 2) in Multimedia Appendix 7.

We noticed that low and high levels of technology attitude had different effects depending on education level, gender, and AI knowledge. For example, low values of technology attitude in female participants can increase trust toward AI, while the effect was negative for male participants (Figure S3 in Multimedia Appendix 7). The same was noticed for high school or vocational educational backgrounds versus others (Figure S3 in Multimedia Appendix 7). The main effects showed a general positive relationship between opinion on health care services and acceptance of AI (Figure 3D); however, interactions

XSL•FO
RenderX

revealed that age affects this relationship; opinions toward AI were reversed from between those aged <55 years (positive relationship) and those >55 years (negative relationship; Figure S3 in Multimedia Appendix 7). A similar type of "tipping point" effect occurred between technology attitude and AI knowledge (Figure S4 in Multimedia Appendix 7), technology attitude and gender (Figure S4 in Multimedia Appendix 7), and age and disorganized and careless personality (Figure S4 in Multimedia Appendix 7). Additional findings are listed in Multimedia Appendix 7.

Finally, in Multimedia Appendix 8, we depicted illustrative predictions for individual use cases with either very high or low predictions for trust (Figure S1 in Multimedia Appendix 8) and trade-off (Figure S2 in Multimedia Appendix 8) side by side. Predictions were dominated by technological attitude and adoption, but personality traits and gender also had a notable impact.

Discussion

Overview

In this study, the acceptance, trust, intention, and related views of consumers (health and medical care clients and prospective patients) toward the use of AI in the field of health care were evaluated to map the views of individuals, such as prospective patient, consumer, and user, toward AI use cases. The cases ranged from simple health-related applications to more futuristic cases of invasive AI solutions, such as surgical robotics. Using CatBoost and SHAP allowed us to find nonlinear relationships between predictors and responses. Evaluations were collected about the intention to use (intention), trust for AI (trust), model predictions (predictions), training data (data), privacy issues (privacy), willingness to trade-off information for benefits (trade-off), and manufacturer importance (manufacturer) for each use case.

Principal Findings

Correlations between the 7 properties were statistically different from 0 (P<.01; Table 1) for all except intention and manufacturer and trade-off and predictions. Correlations were highest (>0.7) for intention and trust (0.808), predictions and data (0.840), data and manufacturer (0.794), predictions and manufacturer (0.752), and data and privacy (0.708). For negative correlations, the strongest was privacy and trade-off (–0.468), illustrating that people with a higher demand for privacy are not eager to compromise it for benefits. For the overall case, evaluations were analyzed for intention and trust and concerns over accessibility and cybersecurity in AI. For these, the strongest positive correlation was found for intention and trust (0.768) and a negative correlation for trust and cybersecurity (–0.591; Table S1 in Multimedia Appendix 6). The latter confirms that concern regarding security in AI is strongly associated with decreased trust in technology. For intention and trust, our results were at par with existing knowledge of the strong connection between the two [10,11,13].

For the predictive model 1 (with use cases), the single most important variable was technology attitude (rank 1), followed by related variables technology adoption (ranks 2 and 7), technology use (ranks 5 and 2), and AI knowledge (ranks 8 and 4), as depicted in Figure 2 and Figure S1 in Multimedia Appendix 7. Technology attitude was more important than the use case (rank 2). This indicates that general attitude, view, and knowledge of technology are the primary drivers of how consumers evaluate AI applications. This sets the baseline for the individual evaluation of AI that is further adjusted by particular use cases. This is in line with the previous research that showed how attitudes impact the willingness to accept technology, particularly AI in health care [18,19]. Personality had a major impact on all outputs. Although individual personality traits alone were not of the top importance, most of them (6/10, 60%) were considered more important than health status, work sector, or education field (Figure 3). In fact, the pooled importance of all 10 personality traits (a SHAP value of 1.38) came close to the pooled importance of 4 AI attitude, use, and knowledge-related variables (a SHAP value of 1.54). Thus, this study only slightly supports earlier research findings. In addition, as stated earlier, we critiqued the clarity of the earlier research findings. The findings of this study also display a positive link between attitude toward the state of health care services and trust, intention to use, and willingness to trade-off. People with positive and very positive views toward health care services were also positive toward AI (Figure 4).

With regard to trust and intention, our use cases were divided into 3 tiers of popularity (Figures 3C and 5C):

- Tier 1 (ranks 1 to 3): activity monitor, nutrition monitor, and health monitor (noninvasive)
- Tier 2 (ranks 4 to 5): robot surgeon and health monitor (bioelectric)
- Tire 3 (ranks 6 to 8): nursing robot, mental monitor, and menstrual monitor

However, predicted differences were small, around 0.5 on the numerical scale (ie, half step in the Likert scale). As expected, the gender difference was notable for the menstrual monitor (+0.1 for women) and also for the bioelectric health monitor, nursing robot, and robot surgeon (+0.02 for men). A similar finding was reported by Omrani et al [17] with men having higher levels of trust in AI than women. Looking into interaction effects (Figures 3B and 5B) between use cases and selected demographic and personality traits revealed another distinction between the following use cases:

- Group 1: robot surgeon, health monitors (noninvasive and bioelectric), and menstrual monitor
- Group 2: nursing robot, mental monitor, nutrition monitor, and activity monitor

For group 1, the most important features were gender and age. For group 2, the most important features were technology adaptation, exercise level, technology use, and AI knowledge. There was a negligible effect from health status, health service use, technology attitude, or personality traits, which was important only in setting the baseline opinion toward AI. The results for model 2 (without use cases) remained similar to those of model 1 regarding the most important features, which were technology attitude, technology use, and view on health care services (Figure S2 in Multimedia Appendix 6).

XSL•FO
RenderX

In addition to the use case, gender had notable interactions with education level, technology attitude, health status, and age, as measured via SHAP values. We noticed the following: (1) increasing technology attitude decreased trust and use intention for female participants; (2) with "ahead of others" skills in technology adoption, male participants had a higher willingness for trade-off compared to female participants; (3) among those with good health status, female participants had higher trust and use intention compared to male participants; and (4) increased age for female participants also increased trust, use intention, and willingness for trade-off, while the opposite was true for male participants (Multimedia Appendix 7).

Attitude toward technology was by far the most important factor for trade-off (0.78 in SHAP). At the same time, the use case was the sixth most important factor (0.36 in SHAP; Figure 6). The ranking of use cases was similar to above, however, with the robot surgeon now having ranked first (vs fourth and fifth earlier). This indicates that consumers acknowledge the importance of having the most accurate and detailed data about themselves available for invasive operations, such as surgery, and are willing to share sensitive health data. A robot surgeon could be preferred due to its potential accuracy, while a robot nurse would not be preferred due to the absence of social interaction and perhaps empathy with the patient. On the other hand, the same effect was not present for the mental health case (a SHAP value of –0.12 against the robot surgeon). One explanation for this could be that data related to mental health are considered more sensitive than physical data, even regarding health benefits. For interactions, a similar grouping as before was found regarding gender (group 1) and technology use (group 2) being the most important variables for each group.

For personality traits, we found that out of all 10 traits, the most important were *disorganized and careless* (rank 9) and *reserved and quiet* (rank 10 overall). This corresponds with the findings by Park and Woo [25], where extroverts were shown to demonstrate a more negative disposition toward technology than others. However, the contribution seen in this study is that the importance of individual traits varied depending on the output dimension. Covariance with outputs was mostly monotonous with respect to the Likert scale measured via the SHAP algorithm. Relationships in the 7 dimensions were positive for all except for *dependable and self-disciplined*, *reserved and quiet*, and *calm and stable* (Figure 8). It may be summarized that if a person has high levels of disorganized and careless, anxious and easily upset, and critical and quarrelsome traits and low levels of dependable and self-disciplined as well as reserved and quiet traits, they are likely to have higher levels of trust, intention to use, and willingness to do trade-offs for AI. Despite having strong main effects, interaction effects for personality with other variables were generally weak, particularly for model 1 (Multimedia Appendix 7). However, for model 2, some notable interactions were present for disorganized and careless, reserved and quiet, and extraverted and enthusiastic, particularly with AI knowledge. A high disorganized and careless score was associated with an increasing (increasingly positive) relationship with respect to AI knowledge toward trust and intention. The opposite relationship was present with respect to age.

We also found notable nonlinearities for certain features, highlighting the complex interactions underlying the data and the corresponding need for nonlinear modeling to explain them. For model 1, a decreasing (increasingly negative) relationship was seen toward intention, trust, and trade-off that started around the age of 40 years (Figure 7). However, people aged >70 years had a strong positive relationship for trade-off with a lesser degree of trust. This indicates more willingness toward trade-off, as one's health deteriorates with age, particularly so for female participants (Figure S3 in Multimedia Appendix 7). This group recognizes the acute need for health and medical care, yet it has most likely considered or experienced current societal challenges in the underresourcing of the health and medical sectors. Thus, while trust is not high (ie, as seen in a forced digitalization relationship), the recognized need for technological intervention is understood. For model 2 (Figure S3 in Multimedia Appendix 6), three predictive relationships were found: (1) consumers aged <30 years had the lowest intention to use and trust AI, (2) middle-aged consumers aged 35 to 50 years had increased intention to use AI, and (3) the older consumers aged >65 years had the highest levels of trust in AI.

For AI knowledge, a strong inverted *U* shape was found, in which predictions for intention, trust, and trade-off were negative for those with the least and most knowledge about AI according to their own self-evaluations (Figure 7 and Figure S3 in Multimedia Appendix 6). This maintains a resemblance with the Dunning-Kruger effect [55], where people with the least and most knowledge in certain domains have the highest confidence or expectations for potential outcomes. In this study, the effect was inversed, whereby people with the self-evaluated least or most knowledge of AI possessed the most negative expectations. The effect was similar for both models 1 and 2, although for the latter, the dip for the high-end tail was smaller (Figure S3 in Multimedia Appendix 6). For age, the effect varied depending on the model and specific response. For trust and trade-off, we found a positive relationship for older responders (aged >65 years). For intention, young people (aged <30 years) were at the highest (Figure 7) or lowest (Figure S3 in Multimedia Appendix 6), indicating notable context dependency. Park and Woo [25] reported a curvilinear relationship between age and the functionality of the AI dimension, corresponding to a *U*-shaped dependency similar to our findings for trade-off. The effect of age remains diverse and context dependent.

Finally, for trust, intention, and trade-off responses, strong nonlinear interactions were found between age and health care services and technology attitude and AI knowledge (Figure S3 in Multimedia Appendix 7). For the former, an abrupt change could be observed in SHAP predictions for participants aged between 50 and 60 years: people aged >60 years with negative views on health care services (Likert responses <0) demonstrated a positive impact on outcomes. A similar effect of "flipping" of the views was found for AI knowledge concerning technology attitude (Figure S4 in Multimedia Appendix 7).

Theoretical and Practical Contributions

This study contributes to existing knowledge both methodologically and data wise. Previous studies on the subject routinely used simple statistical methods, typically linear

XSL•FO
RenderX

regression (eg, [17,22,23]) or structural equation modeling (eg, [7,20,25]). These can only consider limited numbers of variables and direct impacts without considering nonlinear interactions. Our study included 33 variables, considering all interactions between them, and a large sample of 1100 participants from all consumer groups. The importance of the variables was quantified using the SHAP method, which allows estimation and separation of main and interaction effects.

Attitude, exposure, use, and interest in technology were the main factors determining *baseline* readiness and interest in adopting AI tools in health care. There was a distinction between use cases according to how invasive (physically, socially, and psychologically) AI was perceived in the contexts. However, use cases had less overall importance on the population level than had been hypothesized at the beginning of the study. Regarding the relationship of perceived risk (vulnerability) between people and the AI systems, we assumed that the robot surgeon, mental health monitor, and menstrual monitor would be the most sensitive and least positive (more skeptical) application contexts for AI. Yet, age, gender, education level, and personality were proven to be relevant factors, while education and professional fields had negligible effects. Considering that most previous studies have been conducted on the younger population (average age ≤40 years [9]), our findings for the older population are relevant. Our results for interaction effects demonstrate that age, gender, education level, use, and attitude toward technology, and domain-specific variables (personal health and view of health care services) contribute to AI acceptance. For example, different combinations of age and education can impact female and male participants differently and nonlinearly.

While technological attitude was the major driving factor, the use case was associated with differences between genders and variable interactions. Hence, there was some context dependency. On the basis of literacy, one could assume that the application context within the use cases would significantly impact the ways in which participants evaluated the AI. Ries [27], for instance, proposed a context-dependent Bayesian model of trust, observing that trust is dependent on a number of factors that may either confirm or reject trust, such as conditions (ie, the quality and integrity of a system or object), other actors (host organization or security threats), or the level of risk (potential direct harm or no perceived risk). This stands to reason in perceptive studies as information driven through metaphors (ie, AI, health, type of procedure, or function) are interpreted via context, that is, their relationship to other elements within the perceived scenario [56]. Yet, similar to the recent findings of Stein et al [26], context does not seem to play as great a role in appraising technology as other factors such as personality type and age. The study by Stein et al [26] revealed that the motivation behind engagement (also reliant on personality type) held a strong relationship with attitude toward technology.

Our findings highlight the importance of considering a wide range of factors when determining the antecedents of trust and the use of AI in health care. These factors include the perception of ethical and privacy risks in AI-driven applications. The findings suggest that the health care context may have a more dominant influence on attitudes than specific use cases within health care. Regardless of the microapplication context (use context), the characteristics of AI in health care have an emotional weight. This would mean that all AI-driven applications are *equal*, if they are applied in the same field or overarching context, such as health care. Thus, the use cases can be interpreted rather as domains or sector-specific issues instead of contexts in and of themselves.

The findings related to AI knowledge and its reversed *U*-shape effect emphasize the importance of education and awareness raising of AI. In addition, it gravitates toward the fundamental findings of pragmatic approaches to ethical AI development [35,57], whereby awareness raising and education are critical. The results show that those with very low AI knowledge (novices) and experts are most critically disposed of AI regarding intention to use and trust the technology in health care settings, with novices showing the strongest negative attitudes. On the basis of the findings of the *U*-shaped effect, we conclude that novices and experts are the most critical. We expect experts to be aware of risks and precautions, whereas novices may be hesitant due to unfamiliarity with the technology. Thus, the majority are aware of risks to some extent, but these are not overestimated or underestimated.

Limitations

This work is not without limitations. First, some use cases were still hypothetical (eg, autonomous robot surgeon and nurse), and respondents were required to imagine their experience of these systems based on partial (textual and pictorial) information. No actual user evaluations of these AI applications could be made available. Second, although the data were a representative sample of the Finnish population and consumers regarding age, gender, and education, it was still biased toward people who chose to participate in the survey and were proficient in digital technology, at least enough to respond to web-based surveys. The fact that all participants had access to computers, phones, and the internet may have skewed the sample toward a higher acceptance of technology. Third, participating in the survey was voluntary, which might cause self-selection bias. Fourth, although our fitted models were statistically valid, their predictive power for unseen testing data was generally low (R^2 values of 0.105 and 0.225 for models 1 and 2). This may have resulted from multiple reasons, including the complexity of the survey, survey fatigue, use cases not being engaging, or some relevant predictor variables missing beyond those included. On the other hand, small R^2 values appear common for web-based survey studies and reported by other researchers as well, for example, values of 0.08 to 0.17 [25], 0.03 to 0.14 [22], and 0.02 to 0.18 [25] for linear models without data splitting and 0.11 to 0.30 for boosting models with splitting [50].

Conclusions

This study aimed to understand the willingness to use and trust AI by measuring overall attitudes to various factors in AI in health care in general, as well as dimensions of use case scenarios. The effect of context on individuals' willingness to trust and accept AI in health care proved nuanced. Instead of a use case, the opinion was mainly driven by the individual's attitude toward AI and use of technology. This carries through

XSL•FO
RenderX

to the subquestion of the relationship between perceived risk and the AI application. Noninvasive and less sensitive AI applications, such as activity, nutrition, and health monitors, were considered the most trustworthy and favored, while the nursing robot and the mental health monitor were the least trustworthy and favored. However, when it came to making trade-offs for benefits, a robot surgeon was ranked highest. Mental health monitoring is perceived with more skepticism than general health monitoring and even menstrual monitoring. In addition, we found the following patterns:

1. An inverted, *U*-shaped relationship between AI knowledge and attitudes: both the least and most knowledgeable individuals (by self-evaluation) showed more negative attitudes for intention, trust, and trade-off. This maintains a resemblance to the Dunning-Kruger effect.
2. A clear personality-attitude relationship: positive attitudes toward AI in health care were associated with higher scores in certain traits (disorganized and careless and anxious and easily upset) and lower scores in others (reserved and quiet).
3. A distinct gender effect: women were more cautious than men toward AI in health care, with these differences becoming more pronounced depending on the use case, education level, technology attitude, and age.

These findings have important implications for designing health care–related AI systems. The results indicate that demographic factors influence attitudes toward AI in health care differently across various application settings. Consumer trust and intention to use AI are driven mainly by overall interest and use of technology, as well as personality traits, age, and gender. Training predictive AI models, such as those used in this study, could be used as a tool to adjust and inform on the correct implementation of other AI tools in specific situations. Such AI models could serve as decision-making tools for deploying AI and communicating the systems to clients (ie, explainable AI). Building on these implications, further research is needed into how developing interventions with AI increases trust in AI applications. This includes investigating how educational programs and hands-on experience with AI systems might influence acceptance formation. In addition, researchers should examine how increasing understanding and experiences about the benefits and limitations of AI affect the acceptance of AI and user trust in health care. Longitudinal research tracking how trust in AI evolves over time with increased awareness and exposure would provide valuable insights into health care organizations implementing AI solutions.

Acknowledgments

This research was funded by “AI Driver” (decision number OKM/108/523/2021) and “AI Forum” (decision number OKM/116/523/2020) projects by Finnish Ministry of Education and Culture and “Emotional experience of privacy and ethics in everyday pervasive systems [BUGGED]” (decision number 348391) and “Multifaceted ripple effects and limitations of AI-human interplay at work, business and society [SYNTHETICA]” (decision number 358714) projects by Research Council of Finland.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

JK was involved in the conceptualization, methodology, software, investigation, writing the original draft, formal analysis, data curation, reviewing and editing, visualization, and funding acquisition. RR was involved in conceptualization, methodology, investigation, writing the original draft, visualization, reviewing and editing, and funding acquisition. AA was involved in conceptualization, methodology, investigation, writing the original draft, reviewing and editing, and funding acquisition. All authors reviewed and approved the final version of this manuscript.

Abstract

Background: In China, there is limited research on digital health literacy (DHL) among patients with stroke. This is mainly due to the lack of validated tools, which hinders the precision and sustainability of our country's digital transformation.

Objective: This study aimed to develop and validate a DHL scale specifically for stroke survivors in China.

Methods: We used a sequential, exploratory, mixed methods approach to develop a DHL questionnaire for stroke survivors. This study comprised 418 patients with stroke aged 18 years and older. To evaluate the questionnaire's psychometric qualities, we randomly assigned individuals to 2 groups (subsample 1: n=118, subsample 2: n=300). Construct validity was evaluated through internal consistency analysis, exploratory and confirmatory factor analyses, hypothesis testing for structural validity, measurement invariance assessments using the eHealth Literacy Scale, and Rasch analyses to determine the questionnaire's validity and reliability.

Results: This study underwent 4 stages of systematic development. The initial pool of items contained 25 items, 5 of which were eliminated after content validity testing; 19 items were subsequently retained through cognitive interviews. After an interitem correlation analysis, 2 more items were excluded, leaving 17 items for exploratory factor analysis. Finally, 2 items were excluded by Rasch analysis, resulting in a final version of the questionnaire containing 15 items. The total score range of the scale was 15-75, with higher scores indicating greater DHL competence. Results showed that principal component analysis confirmed the theoretical structure of the questionnaire (69.212% explained variance). The factor model fit was good with χ^2_4=1.669; root mean square error of approximation=0.047; Tucker-Lewis Index=0.973; and Comparative Fit Index=0.977. In addition, hypothesis-testing construct validity with the eHealth Literacy Scale revealed a strong correlation (r=0.853). The internal consistency (Cronbach α) coefficient was 0.937. The retest reliability coefficient was 0.941. Rasch analysis demonstrated the item separation index was 3.81 (reliability 0.94) and the individual separation index was 2.91 (reliability 0.89).

Conclusions: The DHL Questionnaire for Stroke Survivors is a reliable and valid measure to assess DHL among stroke survivors in China.

KEYWORDS

stroke survivors; digital health literacy; validation; reliability; mixed methods study

Introduction

Stroke has become one of the leading causes of death and disability in adults [1]. It is characterized by a high incidence, disability, mortality, and recurrence rate and usually results in physical disability and functional impairment [2]. Approximately 40% of patients experience functional impairment after stroke onset. In particular, more than 85% of patients with stroke experience hemiplegia, which results in impaired upper limb function and decreased motor ability [3]. Many stroke survivors have difficulty accessing outpatient treatment due to mobility issues, transport difficulties, and a lack of necessary support, which in turn affects their outcome and rehabilitation process [4].

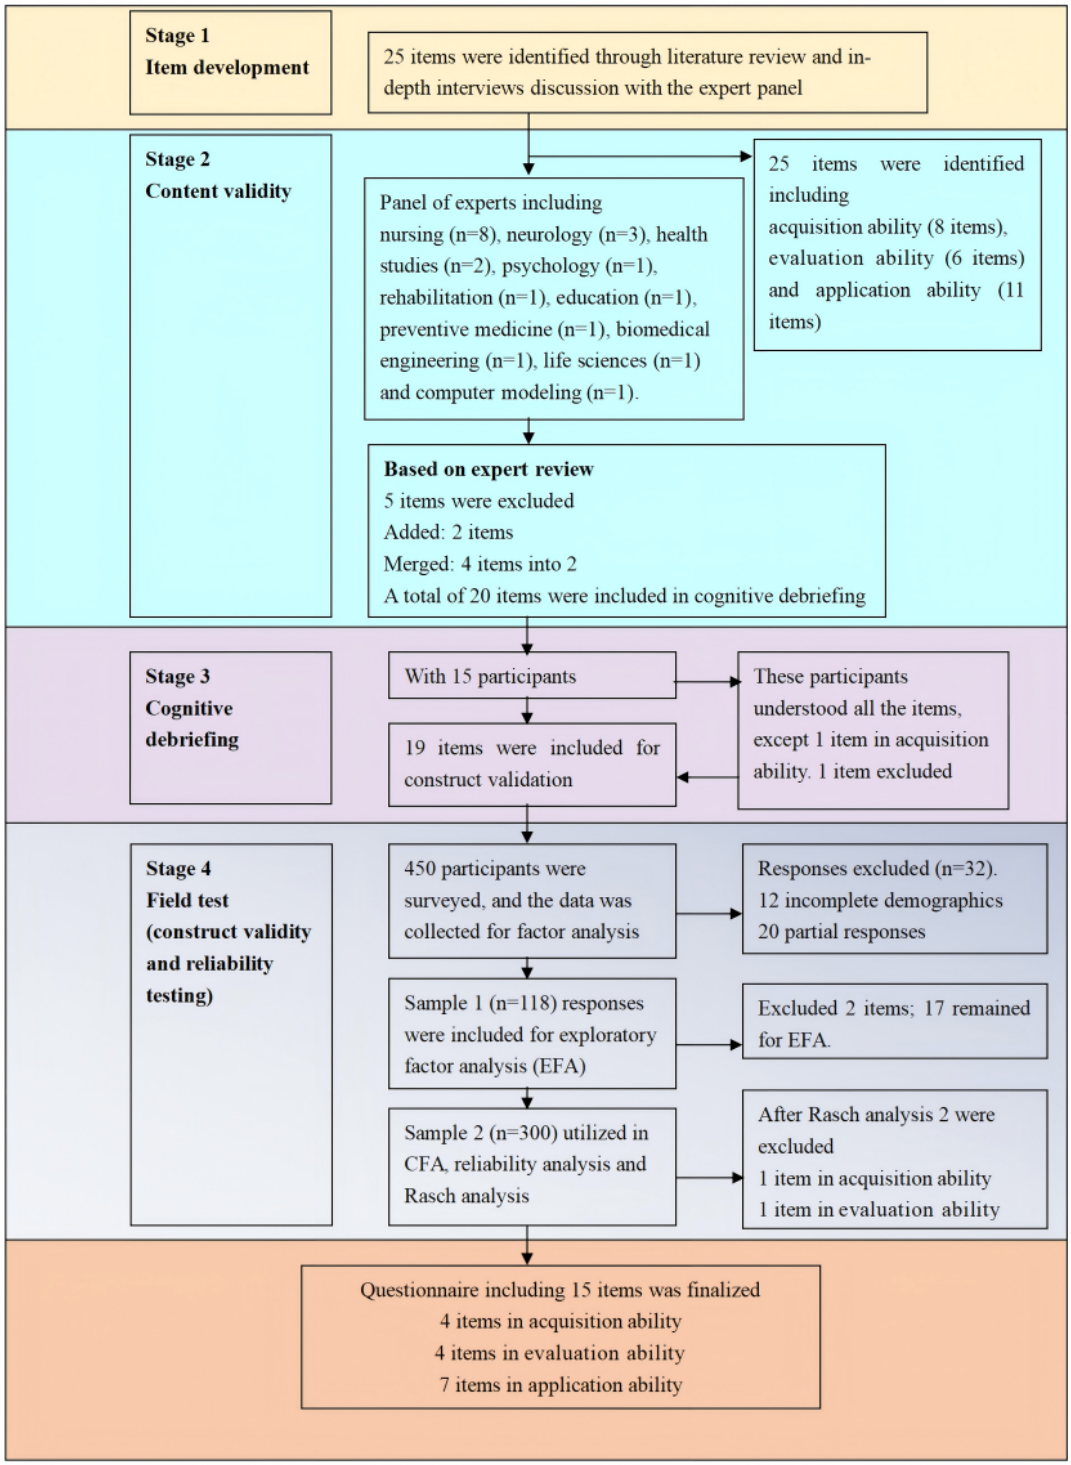
Advances in information technology have provided new opportunities for the management of stroke survivors across time and space [5]. A study has shown that web-based health services, including health information dissemination, patient data monitoring, and remote counseling, effectively manage disease risk factors and lower stroke recurrence rates [6]. Furthermore, the internet enables stroke survivors to exercise independently after being discharged from the hospital, therefore boosting the rehabilitative impact [7]. However, the huge number and varying quality of information on the internet hamper stroke survivors' capacity to properly access and use web-based health resources [8]. Digital health literacy (DHL) refers to an individual's entire capacity to search for, acquire, interpret, and evaluate health information from digital sources and use it to solve health problems [9]. DHL and internet access have lately been identified as "super social determinants of health" because of their influence on broader social determinants of health [10]. DHL is required to effectively participate in the digital age and attain optimal health and well-being [11].

DHL is a process skill that develops with personal, social, and environmental settings and is impacted by personal health concerns, educational level, health state at the time of exposure to digital health resources, information-seeking motivations, and technology used [9,12,13]. DHL, like other forms of literacy, is a discursive practice that aims to uncover meaning-construction processes and essentially structures thought and behavior patterns. Its central goal is to improve the ability of individuals to fully use digital health resources for health decision-making [14].

Several eHealth literacy assessment instruments have been developed over the past 2 decades. The eHealth Literacy Scale (eHEALS) has been widely used for self-reported assessments of individuals' abilities to use the internet [15], but it is recognized that there is a need for more comprehensive tools. The Digital Health Literacy Instrument, developed by van der Vaart and Drossaert [16], offers a broader spectrum of health 1.0 and health 2.0 skills measurement. Additionally, a comparative study by Xie and Mo [17] offered valuable information for evaluating the Digital Health Literacy Instrument and eHEALS in the older adult Chinese population. Generic tools can be used to evaluate a construct (like DHL) across a variety of populations, including healthy populations, populations with and without diseases, and populations with various diseases. The limitation is its potential insensitivity in evaluating the construct within a specific illness population, as key disease characteristics may be inadequately addressed. It is recommended that a patient population use a condition-specific instrument that focuses on content regarding clinical conditions [18].

DHL interventions, an emerging management tool for stroke survivors, have the potential to improve the quality of care provided in resource-limited settings [14]. When delivering digital interventions, clinicians must assess the patient's level of DHL [18]. However, there is no condition-specific instrument that measures DHL specific to stroke. The purpose of this study was to develop and validate a DHL questionnaire specifically for Chinese patients with stroke, with the aim of providing scientific guidance and support for digital health interventions for patients with stroke.

Methods



Study Design

Overview

The DHL Questionnaire for Stroke Survivors was developed using a sequential, exploratory, mixed methods approach (Figure 1), and the study period ran from September 15, 2023, to April 28, 2024. The design involves an initial qualitative phase aimed at generating the item pool and a subsequent second phase aimed at testing items using quantitative techniques (psychometric evaluation).

XSL•FO
RenderX

Figure 1. Item generation and testing process. EFA: exploratory factor analysis.

Participants

We used convenience sampling, and all participants gave informed consent at the beginning. Following the survey, professional researchers conducted in-person examinations with participants. Content validation was conducted among stroke survivors recruited from the Department of Neurology and Department of Neurosurgery at the Fifth Affiliated Hospital of Zunyi Medical University, as well as among experts in the field of neurology. The inclusion criteria were defined as being aged 18 years or older, owning a smartphone, and having the ability to read and understand Chinese. Individuals with mental disorders were excluded from the study.

The field test population included survivors with self-reported strokes. Participants were aged 18 years or older and could self-complete the DHL Questionnaire for Stroke Survivors in Chinese. A minimum sample size of 250 respondents was prespecified for field testing. In Rasch analysis, a sample of

XSL•FO
RenderX

250 respondents provides 99% confidence that item calibrations and person measures are stable within a SD of 0.50 logits [19]. Psychometric procedures were conducted to determine the final items and cutoff scores of the DHL Questionnaire for Stroke Survivors.

In this research, the determination of sample size was guided by principles for conducting exploratory factor analysis (EFA). Academic literature [20] offers various heuristics for sample size estimation in EFA, with absolute minimums ranging from 100 to 250 participants [21]. Some sources suggest larger samples of 300, 500, or more [22,23]. A ratio-based approach is often recommended, where the number of participants (N) to the number of variables (p) ideally should be 5:1, meaning 5 participants for each variable [24].

For both EFA and confirmatory factor analysis (CFA), 2 separate, independent samples are necessary. The minimum required sample size for this study was calculated to be 228 participants, considering a 20% allowance for missing data. It is also noted that a sample size ranging from 30 to 200 is considered sufficient for conducting a Rasch analysis [25].

Conceptual Framework Definition

The lily model, grounded in social cognitive and self-efficacy theories, prioritizes enhancing capabilities and confidence over direct skill measurement to foster behavioral change and skill development [9]. We adopted the lily model to identify 3 key domains of eHealth literacy: information acquisition, evaluation, and application abilities. At its heart are 6 core skills (or literacies): traditional literacy, health literacy, information literacy, scientific literacy, media literacy, and computer literacy. Using the metaphor of a lily, the petals (literacies) feed the pistil (eHealth literacy), and yet the pistil overlaps the petals, tying them together. The lily model of eHealth literacy is used, because it is comprised of multiple literacy types, including an outline of a set of fundamental skills patients require to derive direct benefits from eHealth. A profile of each literacy type with examples of the problems patient-clients might present is provided along with a resource list to aid health practitioners in supporting literacy improvement with their patient-clients across each domain.

Item Generation

For item generation during the development of the new scale, it was important to pool all attributes reflecting the construct being measured. A literature review was used as the source in this study. For the comprehensive literature review, a matrix table was constructed based on the abovementioned DHL conceptualization. The first column on the left of the matrix was dedicated to the posited abilities and skills (acquire, evaluate, and apply). Beginning with the second column, the matrix incorporated specific items. From the third column onward, relevant references were systematically listed.

Content Validation

Content validation was conducted through a web-based expert survey designed to explore the relevance and clarity of the items and to identify items relevant to clinical concerns about DHL. The Item-Level Content Validity Index value for each item was calculated based on the proportion of expert ratings of the item's relevance (modified κ value). Specifically, a modified κ value in the range of 0.4-0.59 indicates fair content validity, 0.60-0.74 indicates good, and ≥0.74 indicates excellent [26]. We relied on the content validity index values of the items to identify those candidates that required further in-depth exploration of their relevance and comprehensibility with stroke survivors.

Cognitive Debriefing

Cognitive debriefing interviews with stroke survivors were conducted face-to-face with the aim of assessing the relevance, comprehensiveness, comprehensibility, and acceptability of the DHL Questionnaire for Stroke Survivors. Verbatim transcripts of the interviews were qualitatively analyzed using thematic analysis. These stroke survivors were also invited to point out other DHL components that may have been omitted from the initial item pool.

Field Testing

A convenience sample of 418 participants was recruited from the Departments of Neurology and Neurosurgery of the Fifth Affiliated Hospital of Zunyi Medical University in China from December 1, 2023, to April 28, 2024.

Test- Retest Reliability

Of the stroke survivors who completed the study survey, 20 were asked to complete the DHL Questionnaire for Stroke Survivors again 2 weeks later.

Measures

The eHEALS, a validated eHealth literacy measure, was used as a comparative tool to evaluate the structural validity of the DHL Questionnaire for Stroke Survivors using a hypothesis-testing method [15]. The eHEALS consists of 10 items scored on a 5-point Likert scale [15]. The eHEALS validation study showed strong internal consistency, with a Cronbach α of .88 and a test-retest dependability intraclass correlation value of 0.49 [15]. Construct validity analysis identified a single component that explained 56% of the variation [15]. The Chinese version of the eHEALS was validated using a sample of 110 high school students [27]. The Cronbach α coefficient was found to be 0.913, indicating excellent internal consistency. Factor analysis revealed loading coefficients ranging from 0.692 to 0.869. In this study, Cronbach α for the instrument was 0.93.

Statistical Analyses

STATA (version 18; StataCorp LLC) was used to clean and prepare the data and for descriptive data analysis. We used SPSS (version 29; IBM Corp) and Amos (version 24.0; IBM Corp) for EFA and CFA. For cross-validation of structural validity, simple random sampling randomly divided the total sample into 2 subsamples. One subsample (subsample 1: n=118) was used for EFA, while the other (subsample 2: n=300) was used for CFA.

In order to determine the applicability of the subsample 1 data to the EFA, the Kaiser-Meyer-Olkin (KMO) test of sample fit and the Bartlett test of sphericity were used to determine the suitability of each category for factor analysis. In EFA, principal

XSL•FO
RenderX

component analysis (PCA) was used to identify common underlying factors. Each factor was identified by eigenvalues greater than 1.0 and rotated orthogonally. A KMO value greater than 0.5 and a Bartlett *P* value less than .05 were used to assess data adequacy. CFA of subsample 2 using diagonally weighted least squares estimation. This study assessed the model fit by root mean square error of approximation<0.08, the Tucker-Lewis Index>0.95, and the Comparative Fit Index>0.95 [28].

Rasch analyses were carried out using Winsteps software (version 3.66.0; WREG). We used standard Rasch analysis procedures. First, we analyzed the fit statistics Then, we deleted items whose response patterns varied from model assumptions. Finally, we re-estimated the item parameters until they were stable.

The Rasch model, a unidimensional measurement framework, was used to assess the likelihood of endorsing items based on their difficulty and the respondents' ability. This model assumes local independence and unidimensionality, meaning that all items are reflections of a single underlying construct [29]. Local independence was confirmed by examining item residual correlations, with correlations below 0.20 supporting the assumption [30]. Infit MnSq statistics should fall within the range of 0.5 to 1.5 for effective measurement [31]. A cutoff of Infit MnSq >1.4 with a standardized z score (Z_{Std}) >2 can be used to identify problematic items [31]. To further evaluate the data, a person-item map was also created. An item separation index of >1.5 was considered indicative of sufficient internal consistency [32].

Measurement reliability was evaluated using person separation indices with defined thresholds: 0.67-0.80 (fair), 0.81-0.90 (good), 0.91-0.94 (very good), and >0.94 (excellent) [33]. The strata were classified as follows: 2 (poor), 2-3 (fair), 3-4 (good), 4-5 (very good), and >5 (magnificent). To confirm model fit, we ran repeated Rasch analyses, modifying items to create new scales and assessing person reliability, separation indices, and scale-to-sample targeting.

Ethical Considerations

The Ethics Committee of Zunyi Medical University's Fifth Affiliated Hospital (2023ZH0084) authorized the study. The study adheres to the principles of the Declaration of Helsinki, and data collection, storage, and analysis are compliant with the European Union General Data Protection Regulation. Informed consent was obtained from all participants, who received a small gift. All images in the manuscript are anonymized to protect participant identities.

Results

Item Development

The literature review extracted an initial pool of 25 attributes that filled the cells of the matrix table constructed in this study (Multimedia Appendix 1).

Content Validation

Content validity indices were calculated for each item based on expert ratings of relevance. The Item-Level Content Validity Index scores for these items ranged from 0.40 to 1, with 20 (80%) of the draft items rated as good or excellent.

The experts' review (n=20) of the item pool informed changes to the wording of items to improve clarity (Multimedia Appendix 2).

Cognitive Debriefing

Cognitive debriefing was established through cognitive debriefing interviews with 15 Chinese stroke survivors aged 18 years or older. The participants' ages ranged from 53 to 72 years, with 7 (46%) participants being male and 8 (53%) participants being older than 65 years. The average monthly income for the participants was between CNY ¥3000 and ¥5000. A total of 7 (47%) participants reported living with a spouse, while 11 (73%) participants had been living with their condition for over a year. In terms of daily activities, 13 (87%) participants demonstrated a mild level of dependence, while 2 (13%) participants were moderately dependent. It is worth noting that 3 (20%) participants were experiencing the illness for the first time.

Thematic analysis was used to classify problems with the relevance, comprehensiveness, clarity, and acceptability of the draft items. The key themes and exemplar quotations from the thematic analysis can be found in Multimedia Appendix 3. The draft DHL Questionnaire for Stroke Survivors consisted of 20 items, organized into 3 domains based on a priori theoretical classification. Each domain was constructed as an independent scale. We used a 5-point Likert scale for assessment (1=strongly disagree, 2=disagree, 3=undecided, 4=agree, and 5=strongly agree). Higher scores indicated a higher level of DHL.

Field Testing

Validation Sample Characteristics

A total of 480 questionnaires were distributed, yielding 450 completed responses, resulting in a response rate of 93.75%. Of these, 32 submissions were deemed incomplete and were therefore excluded from the analyses. Consequently, the final sample comprised 418 complete responses, achieving a completion rate of 100%. The ages of the respondents varied from 33 to 90 years, with a mean age of 65.25 (SD 12.02) years. The sample consisted of 167 female respondents, accounting for 40% of the total. Table 1 provides further details.

[a]Subsample 1: exploratory factor analysis.

[b]Subsample 2: confirmatory and Rasch analysis.

[c]Subsample 3: test-retest reliability.

During the scale refining process, we first used the critical ratio method, sorted scale scores to identify high and low groups, and calculated critical ratio values using *t* tests. Item 19 was eliminated because its critical ratio value fell below the threshold of 3. Furthermore, Spearman rank correlation analysis was performed, resulting in the elimination of item 18 due to a correlation coefficient of less than 0.4. Following these analyses, the scale was simplified to include 17 items.

EFA Examination

Following an EFA on the 17-item subset, the KMO score was 0.901, which was above the acceptable threshold of 0.7, suggesting that the data were appropriate for component analysis. The Bartlett test of sphericity showed significant results (χ^2_{136}=1372.687, P<.001). PCA showed 3 variables with eigenvalues greater than 1, accounting for 69.212% of the variance, showing excellent explanatory power (Table 2). The scree plot confirmed the retention of 3 factors, as the line leveled off after the fourth factor (Multimedia Appendix 4). The scale's construct validity was confirmed by factor loadings over 0.5 and no cross-loadings above 0.5. The items were divided into 3 categories: "acquisition ability," "evaluation ability," and "application ability."

I won’t share my own or others’ health information on social media.	—	—	—

XSL•FO
RenderX

[a]Based on the interitem correlation analysis, items 18 and 19 were considered redundant and were deleted before exploratory factor analysis.

CFA Examination

CFA indicated an excellent model fit, with indices (χ^2_4=1.669; root mean square error of approximation=0.047; Tucker-Lewis Index=0.973; Comparative Fit Index=0.977) aligning with conventional criteria for a good fit. Composite reliability estimates varied from 0.861 to 0.932, and average variance extracted scores were between 0.555 and 0.664, indicating convergent validity. Furthermore, the factor loading values, which are shown in Multimedia Appendix 5, varied from 0.616 to 0.937, supporting convergent validity.

Reliability Testing

The value for Cronbach α, as further evidence of internal consistency reliability, was 0.937. The coefficient of test-retest reliability was 0.941, indicating a high degree of consistency in the measurements over time.

Hypothesis-Testing Construct Validity

The correlation coefficient between the DHL Questionnaire for Stroke Survivors and eHEALS was 0.853 (P<.001).

Rasch Analysis

To evaluate the functionality of the rating scale, we reviewed the Winsteps 3.66.0 output tables and item category probability curves for the 17 items.

After optimization of the response scales, we conducted a Rasch analysis to report the finalized characteristics of the DHL questionnaire for stroke survivors. The DHL Questionnaire for Stroke Survivors consists of 15 items. Multimedia Appendix 6 lists the items included. The Chinese version of the DHL Questionnaire for Stroke Survivors is provided in Multimedia Appendix 7. The scale meets the unidimensional criteria of the Rasch model. The first residual logarithm of the PCA of residuals ranged between 1.4 and 1.8. Item mean squared error values ranged from 0.71 to 1.38 logits, and equipment mean squared error values ranged from 0.67 to 1.75 logits. Items 4 and 7 showed ambiguity in the model. Ultimately, 15 items met the acceptable item fit criteria for the Rasch model.

Four items showed local item dependency, with residual correlation values >0.4 (range 0.44-0.59). In practical terms, a degree of local dependency is always observed in empirical data; therefore, it is necessary to consider the implications for content validity before proceeding with item removal [34]. After a qualitative appraisal of the 4 dependent pairs, we retained all items to ensure a comprehensive assessment of DHL in stroke survivors.

Last, we evaluated item separation, person reliability and separation, and internal consistency reliability. The scale had mean person ability values within a SD of 1.0 logits of mean item difficulty. Person ability ranged from −3.2 to 2.8 logits. Multimedia Appendix 8 shows the item person maps for the DHL Questionnaire for Stroke Survivors. The item separation index was 3.81 (reliability 0.94) and the individual separation index was 2.91 (reliability 0.89).

Discussion

Principal Findings

This study aimed to develop and validate the DHL Questionnaire for Stroke Survivors, comprising of the three components (1) acquisition ability, (2) evaluation ability, (3) and application ability, with a total of 15 items. The validation process included assessing the questionnaire's content validity, construct validity, internal consistency reliability, test-retest reliability, and Rasch analyses. The findings demonstrate the robust psychometric properties of the DHL Questionnaire for Stroke Survivors within the target population in China. Unlike other DHL-related scales [15,16], this study specifically addresses stroke-related competencies in acquisition, evaluation, and application, emphasizing practical applications and interactions with health care providers directly pertinent to stroke management.

The eHEALS developed by Korean scholars for patients with diabetes with comorbid chronic diseases assesses "cognitive behavior" and "digital communication ability," emphasizing the role of "cognition" as a critical component of information health literacy for patients with chronic diseases [18]. Similarly, "accessibility" in this study is closely linked to cognition, as evidenced by behaviors such as tracking stroke news and updates on the internet, searching on the web for in-depth stroke information, and gathering stroke data from various web-based platforms. These actions highlight the cognitive abilities required to identify and filter relevant information, reflecting the mental processes essential for individuals to navigate and process stroke-related information in a digital environment.

In this study, CFA and EFA were performed on 2 separate samples to evaluate the structural validity of the DHL Questionnaire for Stroke Survivors [35]. The CFA results validated the model developed through EFA. Furthermore, the CFA findings demonstrated that each item corresponded to a distinct underlying construct, and the associated item errors were uncorrelated, indicating the reliability of the CFA results [35].

In this study, a χ^2_4<3 was used as the criterion for goodness of fit [36]. The results indicated a χ^2_4=1.669, demonstrating a good model fit. Additionally, the composite reliability of all 3 factors exceeded the criterion of 0.7 [36], ranging from 0.861 to 0.932, which confirmed the good internal consistency of the items within each dimension. Furthermore, the square root of the average variance extracted for factor 1, factor 2, and factor 3 ranged from 0.555 to 0.664, surpassing the correlation values on the nondiagonal line of the discriminant validity scale, thereby further validating the model's discriminant validity. The internal consistency of the final questionnaire was evaluated using Cronbach α, which yielded an overall value of 0.937, demonstrating the reliability and acceptability of the newly developed scale [37]. In terms of overall item performance, the individual reliability was 0.89, and the item reliability was 0.94, reflecting consistency and stability in the results. The person-item separation index was 2.91, indicating a high degree of differentiation between participants' ability levels, while the

XSL•FO
RenderX

item separation index was 3.81, signifying a high degree of difficulty differentiation among the items. The weighted mean square fit statistics (Infit MNSITEM) were 1.06 for persons and 1.07 for items, and the unweighted mean square fit statistics were 1.00 and 1.07, respectively. These values, being close to the ideal value of 1, confirm that the model fits the empirical data well.

The application of the DHL Questionnaire for Stroke Survivors represents a significant advancement in personalized health care by enabling health care providers to tailor interventions according to individual DHL levels. This approach enhances treatment adherence by equipping patients with resources and support that match their digital literacy capabilities. For example, patients with lower literacy may benefit from traditional, face-to-face interactions, whereas those with higher literacy can effectively leverage digital tools and resources [38]. Furthermore, personalized health care facilitated by the DHL Questionnaire for Stroke Survivors fosters patient engagement by ensuring that health information is both accessible and comprehensible, thereby empowering patients to take a more active role in their recovery process [39]. This not only improves the overall efficacy of rehabilitation programs but also optimizes the allocation of health care resources by targeting interventions to meet the specific needs of each patient [40].

Limitations

This study has several limitations. First, the representativeness of the sample is limited, as the respondents were predominantly older individuals with multiple comorbidities. Second, essential items and content for assessing DHL may have been overlooked, given that DHL encompasses a wide range of skills, including complex technology-related health literacy in the digital era. Approaches to DHL have evolved significantly over the past decade and will likely continue to do so. The criterion validity of the DHL Questionnaire for Stroke Survivors was not tested due to the rapidly evolving nature of digital literacy and the absence of a gold standard for assessment. Consequently, the questionnaire should be updated to reflect advancements in this field. Third, the DHL Questionnaire for Stroke Survivors relies on self-reporting, which limits its ability to accurately capture objective proficiency. Future studies should enhance reliability by measuring the temporal stability of individual responses. Finally, the DHL Questionnaire for Stroke Survivors has only been psychometrically tested in Chinese, necessitating cross-national and cross-language validations to confirm its cultural applicability.

Conclusion

With the rapid development of the internet and digital technology, DHL plays an increasingly important role in public health management. For patients with stroke, DHL not only affects their ability to access and understand health information but also directly influences their self-management and quality of life during rehabilitation. Therefore, it is important to develop high-quality measurement tools to assess the level of DHL among patients with stroke in order to better meet the rehabilitation needs of this population. To this end, we developed the DHL Questionnaire for Stroke Survivors. This questionnaire has good psychometric properties and is important for the development of effective health education and interventions.

Acknowledgments

We extend our appreciation to the hospitals that collaborated in the trial, and we are grateful to the entire team involved for their commitment, which was instrumental in the success of this research endeavor. This study was funded by the Implementation Science-Driven Agent Simulation to Develop a Psychological and Behavioral Intervention Protocol for Stroke Survivors Based on a Stepped Wedge Randomized Controlled Trial (82260281); the Science and Technology Fund Project of the Guizhou Provincial Health Commission (gzwkj2023-588); the Scientific Study on the Construction of Shared Medical Model and Optimization Mechanism for Patients with Stroke Depression in Low Resource Area; and Guizhou Science and Technology Plan Project, Guizhou Science and Technology Cooperation (Qiankehe) Foundation (ZK [2024] key Project 069).

Abstract

Background: The COVID-19 pandemic demonstrated the global need for accessible content to rapidly train health care workers during health emergencies. The massive open access online course (MOOC) format is a broadly embraced strategy for widespread dissemination of trainings. Yet, barriers associated with technology access, language, and cultural context limit the use of MOOCs, particularly in lower-resource communities. There is tremendous potential for MOOC developers to increase the global scale and contextualization of learning; however, at present, few studies examine the adaptation and sharing of health MOOCs to address these challenges.

Objective: The World Health Organization's Health Emergencies Programme Learning and Capacity Development Unit and the Stanford Center for Health Education collaborated to survey learners from 4 emergency health MOOCs on the OpenWHO platform to examine differences in course use by World Bank country income classification across three dimensions: (1) how health education MOOCs are used and shared, (2) how health workers adapt MOOC content to meet local training and information needs, and (3) how content adaptations help frontline health workers overcome barriers to using MOOCs.

Methods: This study draws upon two sources of data: (1) course enrollment data collected from the 4 emergency health MOOCs (N=96,395) and (2) survey data collected from learners who participated in at least 1 of the 4 MOOCs (N=926). Descriptive statistics are used to summarize learner characteristics. Differences in enrollment, sharing, and adaptation by country income classification are examined using Pearson chi-square test.

Results: Of the enrollees who indicated their country of residence, half were from lower-middle-income countries (LMICs; 43,168/85,882, 50%) and another 9% (7146/85,882) from low-income countries. The majority of all respondents shared content (819/926, 88%) and used content in official trainings (563/926, 61%). Respondents were more likely to share and use content for trainings in LMICs than in high-income countries (91% vs 81%; *P*=.001). Learners in LMICs also shared content with more people on average compared with high-income country learners although the difference is not statistically significant (9.48 vs 6.73 people; *P*=.084). Compared with learners in high-income countries, learners in LMICs were more likely to adapt materials to distribute via offline formats or technologies, such as WhatsApp or text message (31% vs 8%; *P*<.001); to address cultural, linguistic, or other contextual needs (20% vs 12%; *P*=.076); and to meet local guidelines (20% vs 9%; *P*=.010). Learners in LMICs indicated greater accessibility challenges due to technological and linguistic barriers.

Conclusions: Learners commonly share content from MOOCs about public health emergencies; this is especially true in low-income countries and LMICs. However, content is often adapted and shared via alternative formats. Our findings identify a critical opportunity to improve MOOC design and dramatically scale the impact of MOOCs to better meet diverse global needs.

MOOCs; online learning; global health education; digital health; health worker training; health emergencies; outbreak; COVID-19

Introduction

Overview

First launched in 2017, the World Health Organization's (WHO) Health Emergencies Programme's learning platform, the OpenWHO, uses a massive open access online course (MOOC) format. The platform rapidly expanded during the COVID-19 pandemic, from serving approximately 160,000 learners at the pandemic's start [1] to serving more than 7.5 million learners in 194 countries and 65 languages by the end of 2022, with 46 courses specifically on COVID-19 and more than 85 additional emergency health course topics [1,2]. The MOOCs on the platform are designed to improve equitable access to emergency health topics according to learners' needs and preferred languages [3]. Even with the significant expansion in topics and utilization, technical, cultural, and linguistic barriers limit dissemination of the lifesaving knowledge provided through MOOCs. Preliminary research indicated that local health workers and institutions adapt and share digital content to increase knowledge dissemination [4-6]. This study evaluates how MOOC content on the OpenWHO platform is used, shared, and adapted to better understand the ability of MOOCs to reach frontline health workers during public health emergencies.

Background

Over the past decade, digital education tools have been increasingly incorporated into the training and education of frontline health workers [7-12]. However, the COVID-19 pandemic demonstrated a critical global need to expand easily accessible and trustworthy open-source content for rapid frontline health worker training during health crises. The MOOC format, embraced by the WHO [3,13-16], governments [17,18], and academic institutions worldwide [19,20], is one method for the widespread dissemination of emergency training for frontline health workers.

The MOOC format has been successfully used in public health crises to disseminate information to the public, policy makers, and other stakeholders [21-23] and provide health workers with training and knowledge [15,17,24-30]. While there are different varieties of MOOCs, content is often offered online for learners via readings, wikis, presentation slides, and short videos [31]. MOOCs also typically include learner assessments and interactive components, such as automated quizzes, peer-marked assessments, or online discussion forums, and may be self-paced and asynchronous [31].

While the MOOC format has seen success in public health crises, enrollment in and completion of MOOCs in many low-income and lower-middle-income countries (LICs/LMICs) are disproportionately lower than those in high-income and upper-middle-income countries (HICs/UMICs) [32]. MOOC enrollment and completion vary by region but are substantially lower in countries with limited investment in higher education systems and technology infrastructure [33,34]. Significant technical barriers prevent enrollment and completion of MOOCs in resource-limited and remote settings [6,31-35]. Challenges concerning digital literacy, weak technical support, web access, and broadband cellular coverage persist, limiting the reach and effectiveness of digital health education tools in these regions [27,31,33-38]. Infrastructure barriers can cause challenges when accessing MOOCs, including downloading materials, engaging in interactive elements, and viewing high-resolution videos [31].

There may also be significant cultural and linguistic barriers that prevent MOOC engagement [39-47]. Critics have argued that MOOC content often needs more cultural context for successful curriculum design [31,37,39-48]. Traditional MOOC content has been based on the academic experiences, pedagogical ideas, design concepts, and literature of the Global North [31,39,45,46]. Research has shown that including various learning, assessment, and accreditation activities in MOOC design facilitates learners' progress in one context while inhibiting learners in other contexts [31,40-47]. In particular, Indigenous groups and knowledge have been noted as lacking in MOOC design and research, which has been seen as a limitation in ensuring the relevance of MOOCs for Indigenous populations [47].

In addition to cultural relevance, MOOCs should also be linguistically relevant [3,16] in languages where learners seek out health information [49] and at literacy levels that can be understood by diverse audiences [50,51]. Communities, especially vulnerable communities, have indicated mistrust in digital health materials that are not culturally and linguistically relevant [39,50,52]. Offering MOOCs in multiple languages successfully enables increased access to diverse regional learners with low levels of previous education [2,43], and cultural and linguistic translations can make MOOCs and digital content more relevant for learners [43] and support their ability to learn the material [53].

Culturally and linguistically relevant content has increased positive health beliefs and behaviors [54], which indicates a need for context-specific adaptations for global MOOCs to support learner needs. Yet, initially, most MOOCs were developed in English with more MOOCs now being created in multiple languages [31]. However, research on infectious disease and health MOOCs has found limited resources in languages other than English [20,55,56]. In addition, when MOOCs have been translated from English into other languages, translations include less accessible word choices, especially for low-literacy populations [43,44]. These translations may also reduce the provided health content's complexity [56].

Proponents of open-source digital education have argued that learners can adapt and share well-designed materials to overcome access barriers, leading to what has been termed a "learning multiplier effect" that describes the transformation and sharing of web-based resources into adapted formats to suit learners' needs and local context beyond what can be tracked

XSL•FO
RenderX

by platform analytics [6]. Evidence suggests that during health crises, health workers are motivated to enroll in MOOCs to improve practice [57]. The need for trustworthy information also drives health workers to share MOOC content through personal and professional networks [5,6]. Learners have shared MOOC materials via their networks by downloading materials, providing links to resources, and telling others in their networks about the course and course content [5,57]. They also adapted and integrated MOOC resources into formal training, making MOOCs accessible to even larger audiences [4-6]. Adaptations included efforts to overcome technical barriers, such as downloading or making content available via text message [4-6]. Other adaptations included addressing cultural or local context, such as by adding local health regulations or addressing linguistic relevance with local translations [5,6].

Intervention

The OpenWHO platform is an open access, low-bandwidth requirement online learning platform first launched following the Ebola West Africa outbreak in 2017 [3]. The platform aims to provide lifesaving online knowledge based on the latest WHO technical advice to frontline responders, policy makers, and the public. The platform hosts MOOCs on 33 different infectious diseases in 65 languages aiming to disseminate critical learning materials for any type of health event and outbreak. There are a total of 46 MOOCs related to COVID-19, 5 on Ebola, and a range of courses on different epidemic and pandemic-prone diseases [16].

This study examines 2 MOOCs focused on COVID-19 and 2 on other epidemic and pandemic-prone diseases, Ebola and rabies. These 4 courses were selected because they had large enrollments of health professionals. The 2 COVID-19 courses are “Clinical Management of Patients With COVID-19: General Considerations” and “Clinical Management of Patients With COVID-19: Initial Approach to the Acutely Ill Patient.” The other 2 health emergency courses selected for the study include one of the first courses created for the OpenWHO platform, “Ebola: Clinical Management of Ebola Virus Disease” (developed in response to the 2018 Ebola outbreak in the Équateur Province of the Democratic Republic of the Congo) and a relatively new course, “Rabies and One Health: From Basics to Cross-sectoral Action to Stop Human Rabies Deaths.” The study includes both COVID-19 and other health emergency courses to understand better which course-sharing experiences and adaptations may have been unique to the COVID-19 pandemic context. All of the courses are available in English and 2-4 additional languages. A full description of the MOOCs can be seen in Table 1.

XSL•FO
RenderX

Table 1. Course descriptions.

Course title and description	Languages	Date launched	Course duration	Enrolled learners	Course completion
Clinical Management of Patients With COVID-19: General Considerations: this course gives background on the pandemic, discusses facility operations, and addresses COVID-19 pandemic preparedness at all levels of health care provision, including surge planning, infection prevention and control, palliative care, and transfer of the acutely ill patient. It also discusses ethical issues arising during COVID-19 care.	Albanian, Dutch, English, Indonesian, Kazakh, and Macedonian	October 22, 2020	3 hours	38,941	• Record of achievement: Earning at least 80% of the maximum points from all graded assignments. • Confirmation of participation: Completing at least 80% of the course material.
Clinical Management of Patients With COVID-19: Initial Approach to the Acutely Ill Patient. This course is designed to prepare and support health providers as they provide emergency care to seriously ill COVID-19 patients. The course includes a systematic approach via the WHO/ICRC[a] Basic Emergency Care course content, covering screening and triage, the integrated interagency triage tool, resuscitation area designation, the WHO medical emergency checklist, the ABCDE approach to the acutely ill patient, and the approach to the patient with breathing difficulty, shock, or altered mental status.	English, Portuguese, Russian, Somali, and Spanish	May 5, 2021	6 hours	24,036	• Record of achievement: Earning at least 80% of the maximum points from all graded assignments. • Confirmation of participation: Completing at least 80% of the course material.
Ebola: Clinical Management of Ebola Virus Disease: this comprehensive intermediate-level course is for clinicians caring for patients with suspected or confirmed Ebola virus disease. The course covers screening and triage, infection prevention and control, laboratory diagnostics, organization and clinical care of patients in the Ebola Treatment Centre, and investigational therapeutic agents.	English, French, and Kiswahili	2018	6 hours	23,803	• No certificate available at this time.
Rabies and One Health: From Basics to Cross-Sectoral Action to Stop Human Rabies Deaths: this course provides a general introduction to rabies, and the One Health approach currently taken to prevent it including information on the “Zero by 30” rabies elimination strategy, preventing rabies in people and dogs, awareness and community empowerment, and diagnosis and surveillance. It targets both a general audience and those who would like to learn more about rabies and the pathway to eliminating this disease.	English, French, and Russian	September 2021	3 hours	9615	• Record of achievement: Earning at least 80% of the maximum points from all graded assignments.

[a]WHO/ICRC: World Health Organization/International Committee of the Red Cross.

Objectives

We surveyed the learners from the 4 emergency health MOOCs to understand current trends in sharing and adapting these courses by learners on the OpenWHO platform. This study analyzes the survey responses to examine differences in course use by World Bank country income classification across the following dimensions: (1) how health education MOOCs are being used and shared by learners, (2) how health workers adapt global health education MOOC content to meet local health education training and information needs, and (3) how content adaptations can help frontline health workers overcome the barriers to using health education MOOCs, especially in LICs/LMICs.

Methods

The study leverages 2 sources of data. The first source is course enrollment data collected from the start of each course through the end of March 2022 (N=96,395) from the 4 MOOCs on the

XSL•FO
RenderX

OpenWHO platform. The second data source is surveys of learners who participated in at least 1 of the 4 MOOCs (N=926) during this same time period.

Enrollment Data

The enrollment data describe the demand and the ability to access the 4 MOOCs. The data were collected from learners at the time they registered to enroll in the MOOCs. Enrollment data included information on learners' country of residence, gender, institutional affiliation, age range, primary language, enrollment language, and course completion.

Survey Data

In March 2022, we distributed a survey via email to learners who enrolled in at least 1 of the 4 MOOCs with a link to participate in the survey. The survey was sent in 3 languages: English (all MOOCs had English versions), French (the Ebola and rabies MOOCs had French versions), and Spanish (the COVID-19 "Initial Approach to the Acutely Ill Patient" had a Spanish version).

The 33-question 3-part survey included sections with questions about (1) which MOOCs the learners took and their experiences with the courses, (2) how they shared and adapted course content, and (3) how accessible the learners found course content (see Multimedia Appendix 1 for the full survey). The 7-question section on learners' experiences with the MOOCs asked questions about course completion, timing, and motivation (see survey Section A in Multimedia Appendix 1). The 11-question section on course sharing and adaptation asked questions about course recommendations, sharing modalities, sharing experiences, modification modalities, and modification experiences (see survey Section Bin Multimedia Appendix 1). The 16-question section on accessibility asked questions about learner characteristics and accessibility of course content for professional and patient populations (see survey Section C in Multimedia Appendix 1).

Data Analysis

Enrollment and survey data were summarized using descriptive statistics (mean, SD, and response rates). To understand the generalizability of our survey sample to the overall population of enrollees and course completers, we summarized the learner characteristics of enrollees, course completers, and survey respondents. The learner characteristics we examined include course enrollment, geographic region, country income classification, course language, language preference, professional affiliation, age, and gender. Not all enrollees provided responses to registration questions; we included percentages of those for whom we have data on characteristics.

To investigate the differences in course use across learners globally, we summarized survey data by World Bank country income classifications—HICs, UMICs, LICs, and LMICs. We tested differences in course sharing and adaptation by country income classification using Pearson chi-square test, comparing sharing and adaptation patterns in UMICs, LMICs, and LICs with patterns in HICs.

In an attempt to quantify the course reach that cannot be observed in platform analytics, we calculated a lower-bound estimate of sharing by assuming that each individual shared with the lowest number of people in their respective survey category responses (ie, 0 people, 1-10 people, 11-25 people, 26-50 people, and 50 people). We calculated the lower bound number of recipients reached through sharing, as well as the lower bound number of trainees reached through the use of the course content in official training. We used one-way ANOVA to compare differences in the mean number of recipients and training by country income classification. All statistical analyses were performed using Stata SE version 15.

Ethical Considerations

Informed consent was obtained from all surveyed participants. Approval for this study was obtained from the Stanford University School of Medicine institutional review board (protocol no. 62414). Data were collected anonymously and respondents did not receive compensation.

Results

Enrollment Patterns

A total of 96,395 learners enrolled in the 4 MOOCs from each course's start date until the end of March 2022. Learners could enroll in more than 1 course. Of the enrolled learners who indicated geographic residence when registering for the OpenWHO platform, half indicated that they were from LMICs (43,168/85,882, 50%), and another 9% (7146/85,882) indicated that they were from LICs. For context, roughly 40% of the world's population resides in LMICs, while roughly 9% reside in LICs [58]. More than one-third of enrolled learners indicated that they were from South Asia (29,001/85,882, 34%), with the subsequent largest distribution of learners from Sub-Saharan Africa (14,058/85,882, 16%). Examining enrolled learners' demographics finds that 79% (51,479/64,793) indicated that their preferred language for learning was English, and 88% (84,949/96,395) enrolled in an English language MOOC.

A third of enrolled learners indicated they were students (28,308/87,041, 33%), with the next largest enrolled population being health care professionals (23,773/87,041, 27%). Enrolled learners were generally young, with 85% (50,618/59,896) of learners younger than 40 years. In addition, more than half of the enrolled learners identified as male (35,444/65,430, 54%).

Course Completion Patterns

MOOCs generally have low completion rates, with rates that can be disproportionately lower in LICs/LMICs [31]. These 4 MOOCs have an overall course completion rate of 34% (32,395/96,395), which ranges from 23% (2165/9615) for the Rabies and One Health course to 40% (9376/23,803) for the Ebola: Clinical Management course. Course completion rates were only slightly lower in LICs (2457/7146, 34%) and LMICs (14,942/43,168, 35%) than in UMICs (7207/19,743, 37%) and HICs (6870/15,825, 43%). As shown in Table 2, course completers generally looked similar to the population that enrolled in the MOOCs with few notable differences.

[a]This table compares the characteristics (n [%]) of health workers who completed the focal courses and the follow-up survey. A higher proportion of course enrollees did not specify characteristics compared with survey completers. We show the numbers not specified for each but do not include them in the percentage breakdowns. For course completion, geographic region was identified via course platform analytics; however, we were unable to identify a subset, shown as "not specified" in the table. For survey completion, the geographic region was identified through survey reports and IP addresses and was fully specified across respondents. Percentages are shown for those for whom we have data on characteristics. Other course languages include Armenian, Indonesian, Kazakh, Macedonian, Dutch, Portuguese, Russian, Albanian, Kiswahili, and Somali.

[b]N/A: not applicable.

Survey Respondents

A number of survey respondents enrolled in more than 1 course. Nearly twice as many respondents had enrolled in the COVID-19 courses (COVID-19: General Considerations, N=607; COVID-19: Initial Approach, N=534) as compared with the other emergency health courses (Ebola: Clinical Management, N=354; Rabies and One Health, N=283). As shown in Table 2, the characteristics of the survey respondents generally reflect the characteristics of enrollees and course completers, with a few exceptions. A larger proportion of survey respondents indicated that they were from LICs (171/926, 18%). Differing from the overall enrollment and course-completer data, more than one-third of respondents indicated that they were from Sub-Saharan Africa (332/926, 36%). A larger proportion of survey respondents indicated that they were health care professionals (406/926, 44%) and employed in other health care–related professions (141/926, 15%) compared with the overall enrollee and course-completer population.

Sharing Course Content

Overall, Table 3 shows that the vast majority of survey respondents (819/926, 88%) shared the course content. While sharing is high in all countries, respondents in LMICs (402/441, 91%) were significantly more likely to share course content than those in HICs (92/114, 81%; *P*=.001). The majority of learners who reported sharing course content indicated that they shared with 10 or fewer people (542/926, 59%). On average, learners shared content with a lower bound estimate of 8.16 (SD 14.45) people. Compared with sharing among learners in HICs who shared with an average of 6.73 (SD 12.32) people, the number of people with whom learners shared content was higher in LMICs (mean of 9.48, SD 15.76 people; *P*=.08) although not statistically significant.

26-50 people	49 (5)	6 (5)	11 (6)	.929	25 (6)	.867	7 (4)	.644
>50 people	50 (5)	3 (3)	10 (5)	.313	30 (7)	.094	7 (4)	.513
Lower bound number of trainees, mean (SD)	5.65 (12.54)	3.82 (10.00)	5.39 (12.28)	.247	6.46 (13.65)	.054	5.06 (11.20)	.343

[a]This table shows the rate of informal sharing (as measured by a question asking whether learners had recommended the course or informally shared course content with other individuals) and use in an official training (as measured by a question asking whether learners had shared materials from the course as part of an official training). We also show a lower-bound estimate of sharing and number of trainees, calculated assuming learners shared with the lowest number of people in their indicated survey category response. We show differences by World Bank income classifications: HIC, UMIC, LMIC, and LIC. Tests of comparison in course sharing and adaptation by country income classification were conducted using Pearson chi-square test. We used one-way ANOVA to compare differences in the mean number of sharing recipients and trainees by country classification. We show comparisons of UMICs, LMICs, and LICs with HICs.

[b]HIC: high-income country.

[c]UMIC: upper-middle-income country.

[d]LMIC: lower-middle-income country.

[e]LIC: low-income country.

Course content was commonly used in official trainings (61%, 563/926). Use of the content in official training was significantly higher in LICs (120/171, 70%; *P*<.001), LMICs (284/441, 64%; *P*<.001), and UMICs (113/200, 56%; *P*=.006) than in HICs (46/114, 40%). The majority of the trainings in which course content was shared engaged 10 or fewer people (370/563, 67%). The lower bound estimated number of trainees was, on average, 5.65 (SD 12.54) people. Compared with the mean number of trainees in HICs (mean of 3.82, SD 10.00 people), significantly more were trained on average in LMICs (mean of 6.46, SD 13.65 people; *P*=.054).

Characteristics of Course Sharing, Adaptation, and Accessibility

Learners shared course content widely with many in their personal and professional networks, including most notably colleagues (486/819, 59%) and friends (364/819, 44%). As shown in Table 4, this pattern was generally consistent across income country classifications. Likewise, across all income country classifications, sharing was highest among health care professionals (363/819, 44%) and learners working in other health care–related fields (126/819, 15%).

[a]This table shows the characteristics of course sharing by World Bank income classifications: HIC, UMIC, LMIC, and LIC. Tests of comparison in course sharing and adaptation by country income classification were conducted using Pearson chi-square test. We show comparisons of UMICs, LMICs, and LICs with HICs.

[b]HIC: high-income country.

[c]UMIC: upper-middle-income country.

[d]LMIC: lower-middle-income country.

[e]LIC: low-income country.

[f]N/A: not applicable.

Across income country classifications, learners were most likely to share course content via website links (489/819, 60%), followed by WhatsApp (298/819, 36%), word of mouth (290/819, 35%), and email (242/819, 30%). Sharing course information via WhatsApp was highest in UMICs (67/176, 38%; *P*=.004) and LMICs (165/402, 41%; *P*<.001) and significantly higher than in HICs (19/92, 21%). Learners in LICs were more likely to share course files via offline technology (30/149, 20%; *P*=.009) than those in HICs (7/92, 8%). The course components shared by learners also varied by country income classification. Learners in LICs or LMICs were more likely to share videos (LMICs, *P*=.007; LICs, *P*=.04), slides (LMICs, *P*=.003; LICs, *P*<.001), quizzes (LMICs, *P*=.02; LICs, *P*=.01), transcripts (LMICs, *P*=.01), and downloadable documents (LICs, *P*=.002) than those learners in HICs.

Learners adapted and made modifications to the MOOCs to share their content with others in all countries, with a few notable variations across income country classification. Over a quarter of learners (216/819, 26%) adapted course content to make it easier to distribute via text message or WhatsApp. This type of adaptation was significantly more likely in UMICs (42/176, 24%; *P*=.001), LMICs (125/402, 31%; *P*<.001), and LICs (42/149, 28%; *P*<.001) than in HICs (7/92, 8%). Compared with learners in HICs, learners in LICs or LMICs were also more likely to make adaptations to add cultural or contextual information (LMICs, *P*=.076; LICs, *P*=.079), to adjust content to meet local guidelines and regulations (LMICs, *P*=.010; LICs, *P*=.002), and to address linguistic barriers by translating all or part of the course into a local language (LMICs, *P*=.067; LICs, *P*=.078).

These adaptations may have been made to address accessibility challenges. Internet connectivity was the biggest challenge to accessing and sharing MOOCs for over a quarter of all learners in LMICs (99/402, 25%; *P*<.001) and LICs (43/149, 29%; *P*<.001) and significantly more learners experienced internet connectivity challenges than learners in HICs (7/92, 8%). In addition, nearly a quarter of learners in LICs (34/149, 23%; *P*=.005) expressed that language barriers presented a challenge to accessing and sharing content, which was significantly higher than the proportion expressing this challenge in HICs (8/92, 9%). Even so, a quarter of learners in LICs pointing to language barriers is relatively low considering the levels of literacy of the common course languages (eg, English), suggesting that courses are not reaching a broader audience in LICs.

Across all survey respondents, learners in UMICs, LMICs, and LICs were more likely to express that they found the OpenWHO MOOC content less accessible than learners in HICs (Table 5). The vast majority of learners in HICs (89/114, 78%) expressed that the MOOC content was accessible to most people in their country, compared with just more than half of learners in UMICs (110/200, 55%; *P*<.001) and LMICs (229/441, 52%; *P*<.001). Less than a third of learners in LICs (53/171, 31%; *P*<.001) expressed that MOOC content was accessible to most people in their country. This pattern holds for accessibility among patients, as indicated by health care professionals, with accessibility particularly low in LICs where 38% (54/171) of learners indicated the MOOC content is accessible to only very few people.

Accessible to very few	14 (17)	38 (23)	.225	85 (22)	.285	54 (38)	.001

[a]This table shows responses to questions about the accessibility of OpenWHO courses by World Bank income classifications: HIC, UMIC, LMIC, and LIC. Tests of comparison in course sharing and adaptation by country income classification were conducted using Pearson chi-square test. We show comparisons of UMICs, LMICs, and LICs with HICs.

[b]HIC: high-income country.

[c]UMIC: upper-middle-income country.

[d]LMIC: lower-middle-income country.

[e]LIC: low-income country.

Discussion

Principal Findings

This study is one of the first to examine the sharing and adaptation of health MOOCs globally. The WHO expedites the production of learning materials as soon as evidence-based science becomes available for any disease outbreak to ensure that communities and health workers have resources that are reliable, readily accessible, and language appropriate [3]. Given this diverse scope and the ongoing challenges of accessing web-based platforms and MOOCs in different countries, we sought to understand how these 4 MOOCs are reaching a global audience. Overall, we found that OpenWHO MOOC content is highly shared across all regions of the world, presenting a tremendous opportunity for the dissemination and scaling of health information. However, adaptation (ie, contextualization and localization) is critical to improve reach in LMICs or LICs.

This study demonstrates that in addition to the official course enrollers and completers, the OpenWHO course content is reaching an even larger audience than that which is observable from platform analytics. The majority of survey respondents indicated that they shared course content or used course content in official training. They were most likely to share videos, share content via WhatsApp, and adapt content to share using technologies such as WhatsApp or text message. While respondents across all country classifications shared course content and materials, learners in LMICs were most likely to share course content. On average, they also reached the largest number of people with their sharing.

The variation in the ways MOOCs are being shared and adapted, as well as the reported accessibility challenges in LICs or LMICs, suggests that MOOCs designed purely for an individual learner in an online format will not optimize knowledge and skill dissemination or most effectively reach geographies with the lowest level of resources. To access this content, learners must rely on others with the access, means, and expertise to adapt and translate the MOOCs to overcome technical limitations. Our findings are consistent with previous research on the OpenWHO platform indicating that although the platform is designed for low-bandwidth use, such as providing downloadable materials, technical limitations remain [16]. In LMICs or LICs, we observed a greater level of effort to distribute content in offline ways to address technical difficulties, such as adapting content to distribute via text message and WhatsApp and by sharing course files via offline technology (eg, USB, DVD, and CD). The lower rate of adaptation in HICs may reflect that the content, made by course developers in HICs, requires less modification to share. It may also reflect that there are more widely available alternative

XSL•FO
RenderX

sources of content in HICs. These findings present a tremendous opportunity for course developers to devise new ways of designing and disseminating courses that could have a dramatic scaling effect, particularly in areas with more access challenges.

In addition to addressing technical limitations, we observed that learners in LMICs or LICs were significantly more likely to modify content to address local guidelines, cultural contexts, and languages. Learners in LICs, in particular, expressed that language barriers created an accessibility challenge for content. Our findings reflect the literature that argues that to be relevant, MOOCs need to be adaptable and linguistically and culturally responsive [3,41,46,47]. Successful content adaptations of this nature likewise require substantial time, resources, and particular linguistic and medical expertise, all of which form barriers to individual learners who wish to adapt and share courses in order to spread knowledge and strengthen the local health care response. These findings require that we intentionally design MOOCs that facilitate and support adaptation and sharing by local health professionals to address needs in LMICs or LICs where the content is critical to promoting information equity during public health emergencies.

Limitations and Future Research

Our study findings are limited to the population who responded to our survey. As a result, our findings do not represent the entire population that accessed the OpenWHO platform or enrolled in the MOOCs and shared content but did not respond to the survey. Our survey respondents are learners with email addresses and the time, interest, and capacity to respond to an online survey. Respondents were also those with the inclination and ability to respond to a survey in English, French, or Spanish. That only a quarter of survey respondents in LICs indicated experiencing language barriers—relatively low considering the levels of literacy of the common course languages, (eg, English, French, and Spanish) overall in LICs—could suggest that MOOCs are not reaching a broader audience in LICs but also likely reflects a limitation with the selected survey response. Furthermore, our findings omit feedback from offline learners exposed to course content through the sharing we describe in this study. We hence cannot speak to the quality of the learning experience among such learners, who would be able to shed light on ways to improve the creation of MOOC content to better facilitate alternative content distribution paths.

Future research must illuminate how best to develop tools and provide the additional supports needed for learners and institutions wishing to adapt and share MOOC content. In addition, it is important that we evaluate the impact of shared trainings on “secondary” learners’ knowledge, skills, and behaviors. Such investigations are essential to ensure that shifts toward online and digital educational approaches during health emergencies do not exacerbate global gaps in access to health care and health knowledge.

Conclusions

There exists a strong demand for OpenWHO MOOCs health emergencies trainings as demonstrated by the high rates of sharing materials across countries of all income levels. Local content sharing presents a tremendous opportunity for organizations and governments to exponentially scale the impact of MOOCs. MOOC developers must design courses for easier distribution via commonly identified formats for sharing such as text message and WhatsApp. Learners in LMICs or LICs were more likely to adapt content to meet local cultural, contextual, and linguistic needs but faced increased barriers to adapting and sharing materials. This study advances our understanding of how to design and disseminate educational materials to promote equitable access to critical health information during times of crisis.

Acknowledgments

This study was made possible by contributions from the Stanford Department of Emergency Medicine, the Stanford Center for Health Education’s Digital Medic initiative, and the Learning and Capacity Development Unit, Health Emergencies Programme at the World Health Organization. Generative artificial intelligence tools were used only for grammatical editing and to improve the clarity of writing in the manuscript. We would like to thank all the institutions and learners who directly contributed to this research, especially those who took the MOOCs and shared their experiences with our team.

Data Availability

Some data are available on reasonable request to the corresponding author.

Authors' Contributions

JSJ and NAS led the conceptualization and design of the study and oversaw study implementation, writing, and editing. JSJ led the quantitative analysis and manuscript writing and editing. NN and AT contributed to the data collection design, and AT led the data collection process. EA led data cleaning. NN, AT, EA, HU, and MS contributed to the study’s design, interpretation of findings, and revision of all drafts. All authors have read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Objective structured clinical examinations (OSCEs) are a widely recognized and accepted method to assess clinical competencies but are often resource-intensive.

Objective: This study aimed to evaluate the feasibility and effectiveness of a virtual reality (VR)–based station (VRS) compared with a traditional physical station (PHS) in an already established curricular OSCE.

Methods: Fifth-year medical students participated in an OSCE consisting of 10 stations. One of the stations, emergency medicine, was offered in 2 modalities: VRS and PHS. Students were randomly assigned to 1 of the 2 modalities. We used 2 distinct scenarios to prevent content leakage among participants. Student performance and item characteristics were analyzed, comparing the VRS with PHS as well as with 5 other case-based stations. Student perceptions of the VRS were collected through a quantitative and qualitative postexamination online survey, which included a 5-point Likert scale ranging from 1 (minimum) to 5 (maximum), to evaluate the acceptance and usability of the VR system. Organizational and technical feasibility as well as cost-effectiveness were also evaluated.

Results: Following randomization and exclusions of invalid data sets, 57 and 66 participants were assessed for the VRS and PHS, respectively. The feasibility evaluation demonstrated smooth implementation of both VR scenarios (septic and anaphylactic shock) with 93% (53/57) of students using the VR technology without issues. The difficulty levels of the VRS scenarios (septic shock: P=.67; anaphylactic shock: P=.58) were comparable to the average difficulty of all stations (P=.68) and fell within the reference range (0.4-0.8). In contrast, VRS demonstrated above-average values for item discrimination (septic shock: r'=0.40; anaphylactic shock: r'=0.33; overall r'=0.30; with values >0.3 considered good) and discrimination index (septic shock: D=0.25; anaphylactic shock: D=0.26; overall D=0.16, with 0.2-0.3 considered mediocre and <0.2 considered poor). Apart from some hesitancy toward its broader application in future practical assessments (mean 3.07, SD 1.37 for VRS vs mean 3.65, SD 1.18 for PHS; P=.03), there were no other differences in perceptions between VRS and PHS. Thematic analysis highlighted the realistic portrayal of medical emergencies and fair assessment conditions provided by the VRS. Regarding cost-effectiveness, initial development of the VRS can be offset by long-term savings in recurring expenses like standardized patients and consumables.

Conclusions: Integration of the VRS into the current OSCE framework proved feasible both technically and organizationally, even within the strict constraints of short examination phases and schedules. The VRS was accepted and positively received by students across various levels of technological proficiency, including those with no prior VR experience. Notably, the VRS demonstrated comparable or even superior item characteristics, particularly in terms of discrimination power. Although challenges remain, such as technical reliability and some acceptance concerns, VR remains promising in applications of clinical competence assessment.

Introduction

Objective structured clinical examinations (OSCEs), first described in 1975 [1], have long since been recognized and accepted as a reliable, valid, and objective method to assess clinical competencies in medical education. They are organized in a circuit format and use stations featuring standardized cases and predefined assessment criteria using checklists or global rating scales to objectify the evaluation by the assessor. By breaking down the clinical tasks into multiple subtests, various skills aligned with learning objectives can be evaluated simultaneously [2]. Presently, this examination format is administered using either standardized patients (SPs) or simulators. SPs are trained actors who are provided with specific cases and then present themselves as patients to students [3]. Students using this method can exhibit their proficiency at the third level, “shows how,” of the competency framework by Miller [4]. This surpasses traditional formats such as oral or written examinations, which generally focus on Miller’s second competency level, “knows how,” linked to the application of knowledge. Nevertheless, OSCEs are subject to a number of significant limitations, with one of the primary issues being their resource-intensive nature, both in terms of materials and personnel [2]. The time-intensive training and deployment of SPs also cause significant financial expense. In addition, in terms of content, OSCEs may not comprehensively capture the complexity of emergency scenarios. Using SPs often proves inadequate at accurately simulating the complex pathophysiology found in living organisms. In particular, healthy actors may struggle to depict diseases in all their nuances, and invasive procedures cannot be executed.

Virtual reality (VR) simulation as a supplementary method in medical education has received a high degree of acceptance among learners and shown promising results in terms of learning outcomes [5,6]. Importantly, the use of VR-based scenarios in assessments may potentially overcome the aforementioned limitations: Virtual patients can display symptoms and findings that realistically represent illnesses, and a computed dynamic physiology can replicate appropriate responses to medication or invasive interventions such as endotracheal intubation or administration of catecholamines. Additionally, digitally assisted assessment offers the possibility of relieving examiners through automated and objective recording of the results. Considering these advantages, using VR scenarios of medical emergencies in OSCE stations appears promising, but evidence relating to technical reliability and cost-effectiveness remains limited [7]. Indeed, to ensure smooth examinations, a sufficient level of hardware and software maturity is essential to avoid interruptions resulting from technical issues. Furthermore, the technically available scenarios must align with the learning and assessment objectives of the respective curriculum.

Given these prerequisites, application examples in this domain are limited. A pilot study did showcase the successful use of VR-based training of cardiopulmonary resuscitation in an examination setting [8]. Another study reported that skills assessment using 360° videos delivered via VR head-mounted displays can yield valid outcomes [9]. We also introduced a VR-based simulation training course on complex medical emergencies into the curriculum at our institution in 2020 [10]. It has been continuously refined to meet the aforementioned technical requirements and is now a suitable candidate for use as an examination tool.

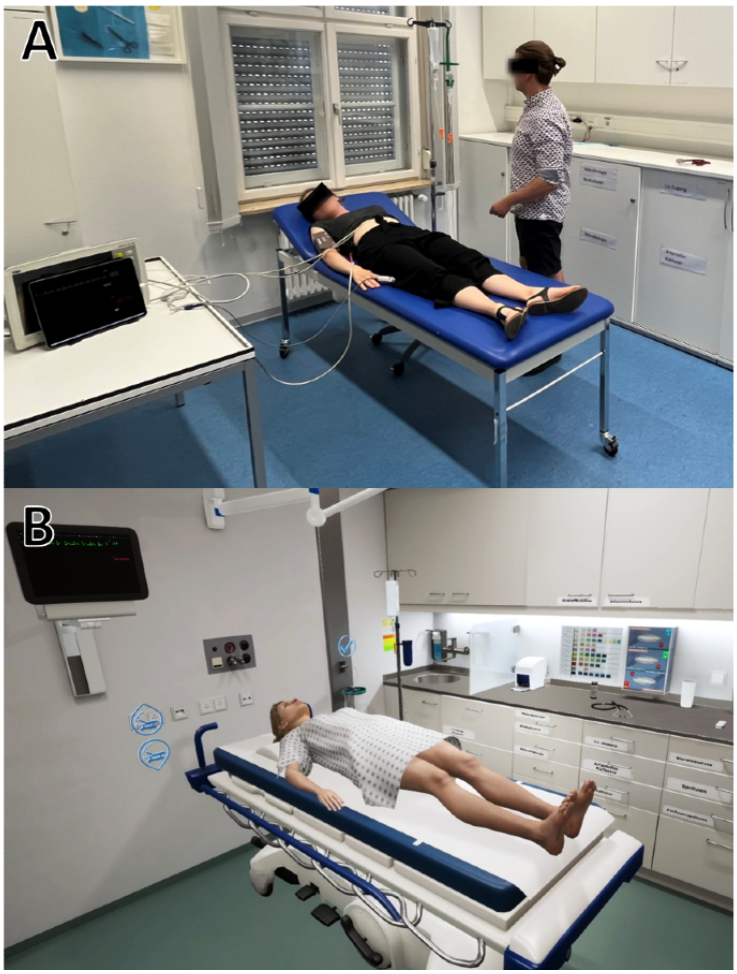
Although VR holds promise for medical assessment, research into large-scale OSCEs and technical feasibility is limited. Additionally, only a few studies address the didactic requirements, such as test quality and consistency of results. In this study, we aimed to determine whether the theoretical benefits of VR are realized within the tight schedule of an already established routine OSCE in the curriculum with a full cohort of students.

On this basis, we aimed to address the following: (1) whether it is both organizationally and technically feasible to integrate VR-based stations focused on emergencies within an existing curricular OSCE framework, (2) whether VR-based stations display item characteristics (such as item difficulty, item discrimination, discrimination index) comparable to their physical counterparts that test identical content, and (3) how students perceive and to what extent they accept the VR-based stations.

Methods

VR-Based Simulation Training

STEP-VR (version 0.13b; ThreeDee GmbH) was used as the VR-based simulation of complex emergencies together with the hardware setup and head-mounted displays essentially as described previously [10].



Study Design

The study was conducted at a medical school in Germany (University of Würzburg) at the end of the fifth year of study toward the degree of medicine. The already established curricular OSCE was designed traditionally as a circuit with 10 stations, with 2 circuits running parallel to each other to increase throughput and reduce the total examination duration to 2 days. Of the 10 stations, 5 were case-based focusing on a number of specialties, and 4 were skills-based. Central to the study was the tenth station, the medical emergencies station. This station was the only one available in 2 separate modes: either a VR-based or a real-world mode, which we designated as a VR-based station (VRS) or physical station (PHS), respectively. The VRS and PHS were designed to be visually and functionally as similar as possible, including the case description and task assignment for the students, case dynamics during simulation (expressed through changes in vital parameters), and functionality of the emergency room environment (Figure 1).

XSL•FO
RenderX

At each station, students were given 1 minute to read the case description and task, followed by 9 minutes to complete the examination. To mitigate the consequences of students potentially sharing information, scenarios in all stations were switched at differing intervals.

Figure 1. Representative scenes from the (A) virtual reality–based station (VRS) and (B) the physical station (PHS) counterpart.

Throughout the semester, students received comprehensive preparation for the OSCE, with particular emphasis on its implementation of emergencies in VR. They were given a script detailing the acute treatment of different types of shock. Additionally, a tutorial video was made available to familiarize students with the VR equipment and software. All students participated in STEP-VR as part of mandatory 3-hour small group sessions. However, during these sessions not all students were active in the VR; some were observing through a screen displaying the first-person perspective. Furthermore, each student had the opportunity to practice using the system beforehand in a voluntary training session.

In the VRS and PHS on day 1, students encountered a patient with an initial diagnosis of fistulizing Crohn disease leading to septic shock. The assessment focused on the managing measures of the “One Hour Bundle” (ie, actions to treat sepsis to be executed within 1 hour) and the decision-making process for either interventional or surgical abscess drainage. On day 2, students faced the challenge of stabilizing a patient experiencing anaphylactic shock triggered by the painkiller metamizole. In addition to managing the associated respiratory distress, they were required to advise the patient on measures to prevent recurrence. All medical content was based on established guidelines and reviewed by experienced faculty members. At the outset of the OSCE, participants were randomly assigned to 1 of the 2 parallel and simultaneous circuits. Ultimately, each student had to undertake 1 of the 2 scenarios either within the VRS or the PHS. A backup VR setup was always on hand to address any technical issues.

In both the VRS and PHS, students were provided with all the essential information for the case in the task description (as a sign on the door prior to entering the station). This encompassed medical history, physical examination, and diagnostic test results. The subject and goal of the examination were focused on acute treatment (taking immediate actions) and making decisions for the next steps (correct indication for intervention or surgery or providing recommendations). Students were provided with assistance when donning the head-mounted display and controllers. The first-person perspective of the students was transmitted to a screen, allowing assessors to view the students’ actions. The performance was rated with standardized candidate assessment forms.

For students assigned to the VRS but who chose not to use VR technology owing to reservations (such as past instances of simulation sickness), a tutor took over the operation of the headset and controllers. The student could observe the scenario

XSL•FO
RenderX

on the screen and had to guide the tutor with the appropriate actions and measures through verbal commands. However, data from these students were not included in the study.

The 5 case-based stations (internal medicine, surgery, family medicine, pediatrics, gynecology) were comparable to the VRS and PHS. In the case-based stations, the scenarios were changed every half day, so that 4 different scenarios were used for each specialty. These also assessed students' management and clinical decision-making, especially with regard to diagnostic and therapeutic measures. The other 4 stations, which focused on procedural competence in highly standardized scenarios (eg, postoperative blood transfusion), were incomparable with the other stations and thus excluded from subsequent analysis in this study.

Randomization

Randomization was performed using computer-generated random numbers. The block size was set to 18 for each session to divide participants into 2 different circuits (including VRS and PHS). The randomization sequence was created prior to the study, and all OSCE stations were conducted within the randomized group allocation.

Blinding

VRS and PHS were substantially different, so that both participants and assessors were aware of the group allocation. Thus, blinding was not possible in this study.

Sample Size Calculation

As the number of participants was constrained by the total number of students available in the semester, sample size was not determined through a specific power analysis. Instead, a full census was conducted, including all available students at the end of their fifth academic year.

Feasibility Evaluation

Throughout the implementation process, various measures of organizational and technical feasibility [11] were evaluated. Building on extensive data from our group and others on the integration of VR scenarios in medical training, along with promising results from pilot studies on partially immersive VR-based assessments (eg, using 360° videos, as mentioned in the Introduction section), we opted to trial the approach with an entire cohort of students. Feasibility outcomes were documented across key areas, including acceptability, demand, implementation, practicality, adaptation, integration, expansion, and limited efficacy. Additionally, a cost comparison between the VRS and PHS modalities was conducted.

Collection of Performance and Evaluation Data

Assessment of Student Performance

To assess students in both the VRS and PHS as equally as possible, identical candidate assessment forms were used. They consisted of 10 items (septic shock) and 13 items (anaphylactic shock) from the categories of (1) additional monitoring and diagnostics, (2) treatment and definitive diagnosis, and (3) subsequent actions and advice. Scoring for each item was either binary (criteria met or not met, corresponding to 1 or 0 points) or ternary (criteria fully met, partially met, or not met, corresponding to 2, 1, or 0 points). When calculating the total sum, all items were equally weighted and normalized to a maximum of 1 point. The candidate assessment forms are outlined in Tables S1 and S2 in Multimedia Appendix 1.

Online Survey for Evaluation and Feedback From Students

Right after the OSCE, students were invited to participate in an online survey accessible via a QR code to be scanned and performed following the examination. The survey encompassed demographic parameters such as age and prior experience with VR technology. It also featured a total of 18 items divided into various topics: stress experience (3 items), usability (2 items), preparation (2 items), acceptance (5 items), subjective performance (3 items), and general rating (3 items to share views on the OSCE's value, its personal relevance, and its future inclusion). Items were rated on a 5-point Likert scale from "strongly agree" (5 points) to "strongly disagree" (1 point). Students could also provide qualitative feedback via 2 open-ended questions.

Analysis of Item Characteristics

The OSCE's item characteristics for both the VRS and PHS across the 2 scenarios as well as for the other 5 case-based stations, each comprising 4 distinct scenarios, were detailed. Parameters, such as difficulty P (average participant score at the station), discrimination r' (correlation of station scores with overall scores excluding that station), and discrimination index D (difference in difficulty between high and low performers based on the top and bottom 33rd percentiles) were computed for all OSCE stations, as suggested by Möltner et al [12]. Regarding item difficulty (P), values between 0.4 and 0.8 were considered ideal [12]. For item discrimination (r'), values above 0.3 were considered good, values between 0.2 and 0.3 were considered acceptable, and values below 0.2 were considered insufficient [12]. For the discrimination index (D), values above 0.4 were considered excellent, values between 0.3 and 0.4 were considered good, values between 0.2 and 0.3 were considered mediocre, and values below 0.2 were considered insufficient [12].

The computation of item statistics was carried out using R 4.3.1 [13]. For the sake of clear presentation, the average was provided for each of the other 5 case-based stations. Reporting was primarily conducted in accordance with the CONSORT-EHEALTH recommendations [14]. The corresponding checklist is provided in Multimedia Appendix 2.

Analysis of Survey Data

Student responses from the VRS and PHS were analyzed using descriptive statistics such as counts (both absolute and percentages), means, and SDs. Nominally scaled variables were compared using the chi-square test. For continuous survey data, such as aggregated Likert data, the Shapiro-Wilk test was initially used to assess normality. Since the assumption of normality was violated for most items, the Wilcoxon rank-sum test was used for comparisons between the groups (VRS vs PHS).

XSL•FO
RenderX

A "thematic analysis" approach was used to summarize the anonymous open-ended responses from VRS participants, following the method outlined in [15]. The free-text comments were reviewed by 2 independent researchers, who identified overarching categories through a consensus process. The comments were then categorized and quantified, with a representative example selected for each category.

Ethical Considerations

Human Subject Ethics Review Approval

The local institutional review and ethics board (Medical Ethics Committee at the University of Würzburg) judged the project as not representing medical or epidemiological research on human subjects and as such adopted a simplified assessment protocol. The project was approved without any reservation under the proposal number 20230323-03.

Informed Consent

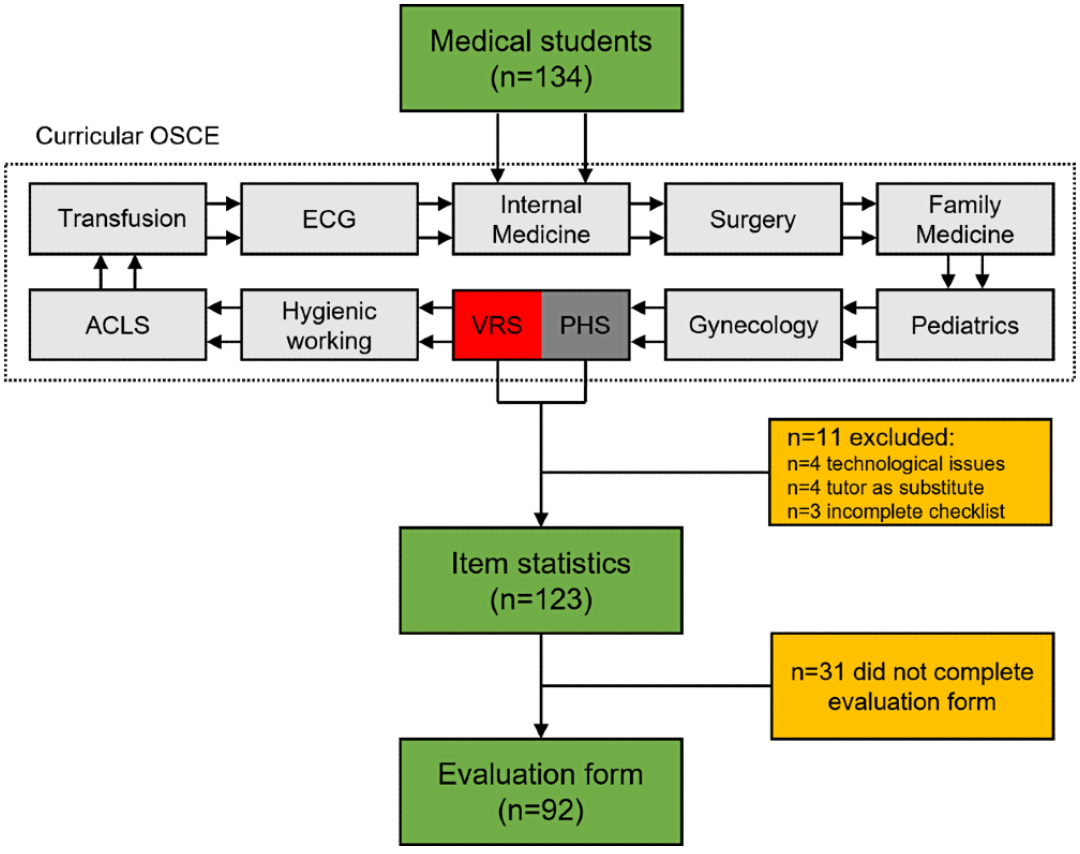
Students were informed about the study, and their participation was voluntary. Written informed consent was obtained from all participants, who were also provided with information on data processing for the analysis and the publication of results. Contact details were supplied for participants wishing to withdraw their consent to data processing. The decision to participate or not had no consequences on the students' academic progress.

Privacy and Confidentiality

Survey data from the questionnaires were collected anonymously using the EvaSys platform (Evasys GmbH, Lüneburg, Germany). Data were processed and stored in accordance with local data protection laws.

Compensation Details

No compensation was provided to the participants.



Results

Student Participation and Feasibility Evaluation

In total, 134 students participated in the OSCE examination. We excluded 11 students from the final analysis for various reasons: technical problems with the VR equipment (n=4), VR procedures executed by a tutor instead of the student (n=4), and incomplete assessment forms (n=3). Thus, 123 participants completed either the VRS (n=57) or PHS (n = 66; Figure 2).

The feasibility evaluation (Multimedia Appendix 3) confirmed that the implementation of the VRS proceeded smoothly, without major organizational challenges. From a technical perspective, 53 of 57 students (93%) were able to use the VR technology without any issues. The transition to VR did not negatively impact the overall process nor performance of the OSCE, and the modular design of the OSCE stations facilitated seamless integration of the VRS. Regarding the cost comparison, approximately €750 (US $776.42) per semester was saved with the VRS than with the PHS, primarily due to lower expenses for SPs and consumables. However, these savings must be considered in light of the total development costs, which amounted to approximately €25,000 (US $25,880.50) for the 2 VR scenarios used.

Figure 2. Layout of the objective structured clinical examination (OSCE) and data collection methods (green) used in the study from both the virtual reality–based station (VRS) and physical station (PHS). The number of participants, along with those excluded (yellow), is indicated. ACLS: advanced cardiac life support; ECG: electrocardiogram.

XSL•FO
RenderX

Performance Data and Item Characteristics

The characteristics of items across all stations are presented in Table 1. The overall average item difficulty P was 0.68. In VRS, septic shock and anaphylactic shock exhibited similar item difficulties at 0.67 and 0.58, respectively, which were comparable to the same scenarios in PHS (0.71 and 0.64, respectively). Additionally, the mean item difficulty for scenarios from the other 5 case-based stations consistently aligned at 0.71. Concerning item discrimination, the overall average was r'=0.30. The VRS scenarios proved to be above average with values of 0.40 (septic shock) and 0.33 (anaphylactic shock), in contrast to the PHS scenarios, for which below-average values of 0.12 and 0.25, respectively, were determined. The scenarios from surgery, pediatrics, and gynecology demonstrated values that were comparable or even better than those for the VRS, while others (internal medicine, family medicine) had significantly lower values. When calculating the discrimination index D, an average of 0.16 was observed across all stations. The VRS scenarios outperformed all other stations, achieving the highest values of 0.25 and 0.26. Conversely, the PHS scenarios fell below this average, with values of 0.10 and 0.12. The other case-based scenarios presented a diverse range of values, mirroring the subject-specific trends seen in item discrimination, with an average of around 0.15.

Table 1. Item characteristics of the objective structured clinical examination (OSCE) stations for the virtual reality–based station (VRS) and physical station (PHS) in the specific scenarios, as well as the other 5 case-based stations—each comprising 4 scenarios.

Scenarios	Item difficulty (P)	Item discrimination (r')	Discrimination index (D)
VRS			
Sepsis (n=32)	0.67	0.40	0.25
Anaphylaxis (n=25)	0.58	0.33	0.26
PHS			
Sepsis (n=31)	0.71	0.12	0.10
Anaphylaxis (n=35)	0.64	0.25	0.12
Internal medicine (n=134)	0.68	0.18	0.09
Surgery (n=134)	0.72	0.49	0.22
Family medicine (n=134)	0.78	0.12	0.08
Pediatrics (n=133)	0.67	0.44	0.18
Gynecology (n=134)	0.70	0.40	0.17
All stations	0.68[a]	0.30[a]	0.16[a]

[a]Mean value shown.

Quantitative and Qualitative Results of Survey Data

The online survey was completed by 92 participants following the OSCE, resulting in a 74.8% (92/123) response rate. Table 2 depicts the gender distribution of the participants, as well as their previous experience with emergency medicine and VR. No notable disparities were identified between the VRS and PHS groups.

Students rated their perceptions and attitudes toward the VRS or PHS (Table 3). Moderate scores were recorded for the perception of stress, with no significant difference between the VRS and PHS. Usability was scored favorably, and both formats were viewed as effective in demonstrating acquired skills. Students felt they only had a moderate level of preparation from the general curriculum for the station they completed. However, the specific materials provided enhanced their readiness. Students from both the VRS and PHS groups found their respective scenario to be a realistic portrayal of medical emergencies and clinically relevant. They rated the scenarios as manageable within the given time. Students believed that the station allowed them to demonstrate their skills and felt they handled the station well. Overall, students found the OSCE worthwhile as an examination format in medical school. They perceived the type of examination station they completed as meaningful. Notably, compared with the VRS, there was a significant preference among students for increased use of the PHS in future assessments.

Table 3. Students' perceptions and attitudes toward the 2 specific objective structured clinical examination (OSCE) modalities (virtual reality–based station [VRS] and physical station [PHS]).

Theme and items[a]	VRS (n=43), mean (SD)	PHS (n=49), mean (SD)	*P* value[b]
Stress			
1. I felt stressed because many aspects of the scenario were beyond my control.	2.28 (1.26)	2.51 (1.19)	.30
2. I felt stressed because I lacked sufficient medical knowledge to handle the case.	2.56 (1.14)	2.39 (1.06)	.61
3. The presence of the examination staff put pressure on me.	1.61 (0.98)	1.71 (1.17)	.87
Usability			
4. The equipment worked without any issues.	3.63 (1.18)	3.74 (1.17)	.75
5. I was able to perform the medical procedures as I had envisioned.	3.40 (1.20)	3.37 (1.24)	.92
Preparation			
6. I felt adequately prepared for the station through the curriculum lectures and courses.	2.67 (1.06)	2.69 (1.23)	.87
7. I felt adequately prepared for the station through the preparation materials.	3.23 (1.09)	3.61 (1.27)	.06
Acceptance			
8. The scenario felt realistic.	3.21 (1.32)	3.25 (1.32)	.89
9. I found the scenario manageable within the given time.	3.88 (1.12)	4.08 (0.89)	.54
10. The content of the scenario was clinically relevant.	4.47 (0.59)	4.45 (0.82)	.68
11. This type of station should be used more frequently as an examination format.	3.07 (1.20)	3.57 (1.40)	.04
12. Overall, I would rate the station as:[c]	3.58 (1.10)	3.78 (1.10)	.32
Performance			
13. The station provided me with an opportunity to demonstrate my learned skills.	3.61 (0.90)	3.61 (1.22)	.70
14. I was able to handle the examination station well.	3.40 (0.88)	3.53 (1.00)	.35
15. I would rate my performance on this station as:[c]	3.44 (0.80)	3.57 (0.84)	.40
General rating			
16. I believe OSCE examinations in medical school are generally worthwhile.	3.49 (1.32)	3.55 (1.21)	.92
17. I find the type of examination station I completed to be meaningful.	3.05 (1.27)	3.53 (1.24)	.07
18. This type of station should continue to be a part of the OSCE examination.	3.07 (1.37)	3.65 (1.18)	.03

[a]Rated on a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree).

[b]Comparison between the VRS and PHS groups using the Wilcoxon rank-sum test.

[c]Rated on a 5-point Likert scale ranging from 1 (very poor) to 5 (very good).

We subsequently performed thematic analysis on the answers to the open-ended questions from the VRS participants to provide some context for the quantitative findings and to gain deeper insights into students' perspectives on using VR technology in examinations. From the open-ended responses, we identified both positive and negative themes (Table 4) encompassing usability, difficulty or fairness, preparation, practical relevance, and general feedback. Of note, there were nearly twice as many positive (n=58) as negative comments (n=30). Students predominantly praised the realism and fairness of the examination, with approximately 35% (20/58) and 30% (17/58), respectively, of the positive comments focused on these aspects. These themes also emerged less frequently in a negative context, often from students who faced challenges with time constraints or found some interactions in VR as abstract. Difficulties with the technology were identified by 8 participants, who experienced minor issues or challenges. Other notable positive feedback included a generally positive outlook toward the VRS and a strong appreciation for the relevance of the medical content.

Table 4. Summary of positive and negative feedback on the virtual reality–based station (VRS) from the open-ended questions.

Theme	Responses, n (%)[a]	Example quote
Positive themes (n=58)		
Realism	20 (34)	"The setting was realistic and provided ample room for action."
Fairness	17 (29)	"The station was manageable within the time frame. There was [technical] assistance available when needed."
General	7 (12)	"I had fun during the examination."
Relevance	6 (10)	"Responding in an emergency situation is a highly relevant content."
Usability	5 (9)	"The operation was reliable and intuitive."
Preparation	3 (5)	"The preparation served as good practice."
Negative themes (n=30)		
Realism	9 (30)	"The medications and procedures could be made somewhat more realistic."
Fairness	9 (30)	"I would have needed more time and more support."
General	2 (7)	"The VR[b] station should not be part of a graded examination."
Relevance	0	N/A[c]
Usability	8 (27)	"The handling could be optimized. Additionally, I experienced technical disruptions, which could also be addressed."
Preparation	2 (7)	"Better preparation through teaching is needed for medical emergencies."

[a]Multiple responses were allowed. The percentages refer to responses given in each specific category (positive or negative) and not to the total number of respondents.

[b]VR: virtual reality.

[c]N/A: not applicable.

Discussion

Principal Findings

In our study, we integrated a VRS featuring 2 complex emergency scenarios into the established OSCE for advanced medical students at our institution. We found that the VRS presented a comparable level of difficulty to the traditional PHS stations. Notably, the VRS was more effective in distinguishing between high and low-performing students, as demonstrated by higher item discrimination and discrimination index values. Many students, including first-time VR users, praised the VRS for its realistic portrayal of medical emergencies and the fair assessment conditions provided. However, some expressed hesitancy about the broader application of VR in future practical assessments.

The integration of the VRS into the existing OSCE framework proved feasible both technically and organizationally. This is evidenced by successful participation of 134 students in the OSCE, with 53 students (or their tutor representatives) completing the tasks on the VRS without substantial issues. Our feasibility evaluation suggests that VRS can be implemented both practically and efficiently, even within the constraints of tight examination schedules. Since this is the first description of a VRS being included in a curriculum-based OSCE for a full cohort, it is difficult to compare costs more broadly. A recent review discussed the expenses related to VR-based training, including scenario development costs [16]. Consistent with our findings and those of others [17], these initial development costs can be offset by substantial long-term savings in recurring expenses such as SPs and consumables. Furthermore, once developed, the VR scenarios can be reused in various contexts without additional costs.

Analysis of performance data revealed that the item statistics for the VRS were not only comparable to, but in some cases even superior to, those of the PHS and the physical case-based scenarios from the 5 medical disciplines. Such good item characteristics and high discrimination values align well with observations from other studies. Recently, the efficacy of VR-mediated 360° videos in differentiating various skill levels during assessments was highlighted [9]. Studies of telemedicine examinations during the COVID-19 era also suggest that the validity and reliability of digital examination tools can be strong [18,19]. Of note, the discrimination r' and discrimination index D of the VRS were superior to those of the PHS, despite the randomization of participants and rotation of examiners at the stations. One possible explanation for these findings is the more uniform setting offered by VR. This environment minimizes or even eliminates the variability [20] that might be introduced unintentionally by SPs, which can occur even when SPs are well-trained and experienced in their roles. Furthermore, the possibility exists that operating the VRS itself may constitute an additional task that high-performing students are more adept at handling, which could lead to greater differentiation in performance at these stations. In other words, there might be confounding variables (eg, spatial ability) related to achievement in VR environments [21], which could potentially enhance performance outcomes. This hypothesis warrants further investigation, such as examining the correlation between VR handling skills and overall academic performance. Such insights

XSL•FO
RenderX

could prove valuable in the design of more complex digital examinations and case-based assessments.

The study clearly demonstrates that students generally responded positively to the VRS, indicating a favorable attitude and willingness to engage with and benefit from VR technology. The realism and content relevance of the VR scenarios received above-average ratings and were frequently commended in the qualitative feedback. Fair assessment conditions were emphasized, and even stress experienced during the examinations was considered manageable. This aligns with the findings of recent studies indicating that students exhibit a positive attitude [22] toward VR-based teaching and assessment. Furthermore, they perceive VR as engaging and immersive, affecting learning outcomes positively [9].

Presumably, owing to the lower level of technical refinement in its implementation, another study discovered that students were still more likely to accept VR in classroom settings as opposed to its use in practical assessments [23,24]. Of note, the VRS here was accepted by students across various levels of technological proficiency, including those with no prior VR experience. Interestingly, a substantial majority (64/92, 70%) of the students chose not to use the offers of extra preparation toward the VR examination. Moreover, for 25% (23/92) of the participants, this was their first ever experience with a VR application. These findings highlight the viability of VR as an examination tool, accommodating students with a wide range of familiarity with technology. This study did not concentrate on the viewpoint of assessors; another study has explored the feasibility and benefits of using specific VR scenarios in OSCEs, receiving positive evaluation from assessors [18].

Nevertheless, a degree of hesitancy among participants was recorded regarding whether VRS should be used in future examinations: Agreement with this statement was clearly less than that for the PHS. This aligns with findings from another study, which indicated that students' reservations were primarily due to their lack of experience with VR technology [25]. The referenced study concluded that practical examinations using VR should only be considered once the technology is firmly established and has demonstrated reliability in educational contexts. Notably, some open-ended comments in our study expressed concerns regarding the potential increase in replacing human assessors and SPs with technology, aligning with findings from prior research [26]. A strategy to counteract this could involve clear communication that VR simulation is intended merely as an additional option to complement, not merely replace, existing examination formats. Reservation and reliance on technology during the early stages of implementation were also reasons why we still opted for manual recording during data collection, regardless of the fact that the VR software provided the capability of automated performance evaluation through a checklist. Nonetheless, the potential to use such automated features in the future to aid assessors in their demanding role is promising. This approach could represent a significant advancement in the efficiency and objectivity of future assessments, including approaches for formative feedback [27].

Strengths of the Study

One advantage of the study is the use of hardware and software that have been undergoing continuous evaluation in learning contexts since 2018, providing a high level of realism with minimal simulation sickness. Students were provided enough practice opportunities in the VR environment beforehand to minimalize operational issues (as demonstrated by good usability results). Nevertheless, the technology needs further rigorous development and enhancement to avoid issues in the examination context. Another strength of this study is the relatively large number of participants drawn from an entire semester cohort, which should generally be viewed as representative of the entire medical student population, including those with critical perspectives. The study's greatest strength, however, lies in the comparison of item statistics and questionnaires directly between the VRS and PHS. This approach allows for the separation of effects related to scenario content and those related to the modality, which can influence the overall acceptance of and performance within the examination. Additionally, comparing results with other medical disciplines in the same examination aids in assessing the overall performance of the students.

Limitations of the Study

One clear limitation is the restriction to a single institutional site and medical discipline. This is especially relevant to practical training, for which curricula can vary greatly across different faculties, thus limiting study generalizability. Another weakness is the absence of inferential statistical analysis that would correlate performance data with survey results. This was a consequence of the voluntary and anonymous nature of the questionnaires. Making participation in the survey mandatory may have overwhelmed the students and potentially affected acceptance of the VRS. Nevertheless, this analysis should be conducted in the future to identify students facing specific challenges with the VRS.

Conclusions

Our study successfully demonstrated that complex VR-based assessment scenarios can be integrated into an established OSCE. Compared with the similar PHS, the VRS exhibited a similar level of difficulty but showed more favorable discrimination metrics. Student acceptance was high, with no major significant differences between VR-based and physical OSCE stations. Consequently, we encountered no systematic issues that would hinder the broader adoption of VR in assessing clinical competence.

Data Availability

The data sets generated during and analyzed during this study are available in Multimedia Appendix 4 and Multimedia Appendix 5.

Authors' Contributions

TM was responsible for the conceptualization of the study, acquiring funding, supervising the execution, analyzing the survey data, and writing the original draft. VS contributed to the conceptualization, conducted the investigation, and performed analysis of survey data. MA handled the curation of performance data, supervised the overall execution of the objective structured clinical examination (OSCE), and conducted the formal analysis. TL was involved in performance data curation; formal analysis; and the writing, review, and editing of the manuscript. SK also contributed to study conceptualization; performed formal analysis; and participated in writing, review, and editing of the manuscript.

Conflicts of Interest

TM was involved in the software development process for STEP-VR. All other authors have no conflicts of interest to declare.

Abstract

Background: In recent years, the use of digital technology in the education of health care professionals has surged, partly driven by the COVID-19 pandemic. However, there is still a need for focused research to establish evidence of its effectiveness.

Objective: This study aimed to define the gaps in the evidence for the efficacy of digital education and to identify priority areas where future research has the potential to contribute to our understanding and use of digital education.

Methods: We used a 2-stage approach to identify research priorities. First, an umbrella review of the recent literature (published between 2020 and 2023) was performed to identify and build on existing work. Second, expert consensus on the priority research questions was obtained using a modified Delphi method.

Results: A total of 8857 potentially relevant papers were identified. Using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) methodology, we included 217 papers for full review. All papers were either systematic reviews or meta-analyses. A total of 151 research recommendations were extracted from the 217 papers. These were analyzed, recategorized, and consolidated to create a final list of 63 questions. From these, a modified Delphi process with 42 experts was used to produce the top-five rated research priorities: (1) How do we measure the learning transfer from digital education into the clinical setting? (2) How can we optimize the use of artificial intelligence, machine learning, and deep learning to facilitate education and training? (3) What are the methodological requirements for high-quality rigorous studies assessing the outcomes of digital health education? (4) How does the design of digital education interventions (eg, format and modality) in health professionals' education and training curriculum affect learning outcomes? and (5) How should learning outcomes in the field of health professions' digital education be defined and standardized?

Conclusions: This review provides a prioritized list of research gaps in digital education in health care, which will be of use to researchers, educators, education providers, and funding agencies. Additional proposals are discussed regarding the next steps needed to advance this agenda, aiming to promote meaningful and practical research on the use of digital technologies and drive excellence in health care education.

KEYWORDS

digital education; health professions education; research priorities; umbrella review; Delphi; artificial intelligence; AI

Introduction

In just over two decades, the use of digital technology for delivering education and learning has increased globally [1]. The growth of digital education in health care has seen a similar trajectory internationally [2].

The adoption of digital technologies in health care education forms part of a global strategy to invest in the health workforce [3] and support the United Nations 2023 Agenda for Sustainable Development [4]. This agenda is echoed within the United Kingdom's National Health Service (NHS) Long Term Workforce Plan [5]. In its plan to address projected workforce shortages, the NHS has undertaken to expand health care education and training over the next 15 years. Informed by the Topol Review [6], the Long Term Workforce Plan acknowledges the need to embrace a wide range of learning methods to achieve the scale of education delivery that will be required [5]. These methods include the use of web-based learning, blended learning, hybrid learning, and simulation and immersive technologies. In addition, it is clear that easily accessible and usable artificial intelligence (AI) will have an increasing role in education [5].

The COVID-19 pandemic saw a surge in the use of digital technologies for health care education. Consequently, several bibliometric analyses illustrate how research activity across a variety of digital technologies significantly increased internationally [2,7-13]. Since 2020, research activity has shifted from rapid development during the early stages of the COVID-19 pandemic to a focus on quality improvement and opportunities for sustained use in the postpandemic period [8]. Zhang et al [8] state that the data project a trend of continued growth in digital education in health care globally, including increased application of advanced technologies. In the United Kingdom, the Council of Deans of Health highlighted in their report "Post-Pandemic Progress: Lessons Learnt in Healthcare Education" [14] that attitudes of educators and students toward the use of digital modalities have shifted. Universities UK [15] echoes this sentiment, recommending increased investment and further expansion of digital technologies in health professions education.

To successfully leverage the full potential of existing technologies for education delivery and understand the opportunities presented by advanced technologies, there is a requirement to ensure that learning needs are being effectively met [16] and that there is proven return on the investment needed to deploy these technologies. The Immersive Healthcare Collaboration [17] emphasized the importance of rigorous evaluation when adopting new technologies and highlighted the need for continued investment in digital education research. However, currently it is not clear where these research efforts and resources should be focused.

Recent studies on research priorities in health care digital education have mostly focused on surgery [18-25]. However, a recent literature review by Tudor Car et al [26] explored evidence across all health care disciplines and across multiple digital education modalities. The authors sought to broaden the scope of their inquiry beyond evidence of effectiveness and to identify where gaps in the evidence lay around other factors such as context, infrastructure, education, and learners [26]. In doing so, they constructed an evidence map, a contextual framework, and a potential research agenda. They offered a list of research questions that, at that time, were still to be fully addressed by the scientific literature [26]. While this work is both comprehensive and informative, it was conducted before or early in the COVID-19 pandemic era; all the reviewed papers were published between January 2014 and July 2020. With the massive increase in the use of digital education in response to the COVID-19 pandemic, the authors of this study felt that this work warranted revisiting and updating to uncover additional evidence gaps and new areas of inquiry that may have emerged since 2020.

Therefore, this study aimed to build on work by Tudor Car et al [26] and identify, within the conceptual framework, any new research priorities in health care digital education that have emerged since 2020. Identifying these research priorities would help shape future global research in digital education and guide the determination of priorities for activity and resource allocation within NHS England.

Methods

Overview

To identify research priorities in health care digital education, a 2-stage approach was used. First, an umbrella review was conducted to build on previous work, and second, experts were invited to reach consensus on the relevant research questions using a modified Delphi method. This 2-stage approach was used to ensure a balance between the published literature and test its applicability through expert opinion. Details of each stage are described in the following sections.

Umbrella Review

As a first step to identifying any additional research questions since the study by Tudor Car et al [26], an umbrella review (a review of systematic reviews) of the literature was conducted based on the method used by Tudor Car et al [26]. The systematic review and research syntheses checklist has been used to self-appraise the process on completion (Multimedia Appendix 1) [27].

Inclusion and Exclusion Criteria

Studies eligible for inclusion were peer-reviewed systematic reviews or meta-analyses with a clear focus on digital education for health professions education, which were published between 2020 and 2023 and written in English. The list of digital education technologies as described by Tudor Car et al [26] was used to guide eligibility screening. For convenience, definitions have been shared in Multimedia Appendix 2 (Textbox 1).

XSL•FO
RenderX

Textbox 1. Eligibility criteria.

Included (studies involving one or more of the following digital education technologies)

- Online digital education
- Massive open web-based course
- Mobile education
- Serious gaming and gamification
- Virtual reality
- Virtual patients
- High-fidelity manikins
- Blended education
- Augmented reality
- Extended reality

Excluded

- 3D printing (after considerable discussion, it was decided that 3D printing should not be considered a digital educational intervention because this intervention leads to an analogue product and is used as such)
- Primary research
- Conference abstracts
- Non-English language papers

To further assess eligibility for inclusion, all the following questions had to be answered in the affirmative:

1. Are the participants in the intervention preservice (ie, students) or in-service professionals (ie, after degree completion, including postgraduate trainees and those in independent practice)?
2. Are the participants from disciplines such as medicine, dentistry, nursing and midwifery, medical diagnostic and treatment technology, physiotherapy and rehabilitation, and pharmacy? (practitioners of traditional, alternative, and complementary medicine were excluded)
3. Is the educational intervention using digital technology?

Information Sources

A knowledge specialist (EW) searched the following major bibliographic databases for review papers meeting the inclusion criteria and published between July 2020 and April 2023: MEDLINE (Ovid), Embase (Ovid), CINAHL (EBSCO), and the Cochrane Library. In addition, the knowledge specialist (EW) searched ERIC, Google Scholar, and Research Gate using the following search terms: *systematic review, digital education, eLearning, health professionals*, and *health professions education.* All searches were conducted on April 21, 2023.

Search Strategy

The MEDLINE (Ovid) search strategy was identical to that used by Tudor Car et al [26] (Multimedia Appendix 3). Minor modifications were needed to convert the strategy for CINAHL (EBSCO) and the Cochrane Library.

Study Selection

The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) methodology was used to identify studies for inclusion. The search results were captured in RefWorks [28], and duplicates were removed. Pairs of independent reviewers screened the title and abstract of each paper against the eligibility criteria and predefined question set for inclusion. The full-text papers meeting the inclusion criteria were then retrieved and reviewed by pairs of independent reviewers. At both stages of screening, any discrepancy between reviewer pairs was resolved by a third independent reviewer.

Data Extraction

A data capture tool was developed in Jisc Online Surveys [29] and piloted by 8 reviewers (AP, CM, EH, SK, ION, EN and 2 volunteers from the NHS England technology enhanced learning team) using a sample paper, with refinements made to the tool before data extraction from all papers included in the review.

Data extracted were study characteristics and future research recommendations as set out by the authors. Future research recommendations were mapped to the conceptual domain framework devised by Tudor Car et al [26] and any previously identified research questions, where possible. If there was insufficient alignment with existing research questions, a new one was created. All papers with future research recommendations were reviewed a second time, with any discrepancies resolved by a third independent reviewer.

Analysis

AP and EW consolidated the extracted research questions by mapping them to existing questions, removing duplicates, and rephrasing those with similar meanings. New questions were then grouped and categorized by CM into overarching research questions. CM and AP discussed and reached a consensus on the final set of questions.

XSL•FO
RenderX

Delphi Consensus

Overview

A 4-round modified Delphi was conducted through January to March 2024 to arrive at 5 final research questions. The method consisted of a desktop exercise to formulate the Delphi survey from the results of the umbrella review (round 1), assessment (round 2), prioritization (round 3), and ranking (round 4). Each survey was created by AP and tested by members of the research team.

Round 1: Umbrella Review and Preparation of the Survey

The results of the umbrella review provided the material to compile a web-based survey of research questions for consideration by experts in later rounds. Research questions, previously identified in the umbrella review, meeting the inclusion criteria formed the basis of a web-based survey in round 2.

Inclusion criteria were as follows:

- The median number of papers identified and mapped to an existing research question in the study by Tudor Car et al [26] was 7.5, and this was used as an inclusion threshold.
- Following consolidation, all newly identified questions were included in the survey.

Round 2: Assessment Against Criteria

A total of 42 participants were recruited, including digital education professionals and simulation faculty, clinical educators, health and care workforce development and transformation leads, academics, and health care students, using the set criteria (Textbox 2). Recruitment was advertised via the Association for Learning Technologies' weekly news digest and a nationwide digital education mailing list for health professionals maintained by NHS England (Multimedia Appendix 4).

A web-based survey, created in JISC Online Surveys and comprising all research questions from round 1, was distributed to the expert panel.

Using an adapted set of criteria from the Delphi process used by Schneider et al [30], participants were invited to anonymously score each research question against 5 criteria (Table 1).

Research questions that met the consensus threshold formed the basis for round 3.

The consensus thresholds for Round 2 were as follows:

- Inclusion: >75% of respondents provide a positive result (3) on a 3-point Likert scale for all criteria.
- Exclusion: >75% of respondents provide a negative result (2) on a 3-point Likert scale for all criteria.
- Nonconsensus: when the proposed priority research question has met neither the inclusion nor the exclusion consensus thresholds.

Questions that met the inclusion criteria and those with nonconsensus were carried forward into round 3.

Textbox 2. Participant recruitment criteria per expert group.

Stakeholder group and inclusion criteria for expertise

- Technology enhanced learning (TEL) professional and simulation faculty: substantial experience working in TEL or simulation in the National Health Service or academia
- Educator: anyone in clinical practice who trains health care professionals (such as consultant or nurse educator)
- Workforce development and transformation lead: experience or knowledge of TEL in health and care education within their geography or domain
- Academic: working in academia, with at least 1 first or senior author paper in the field of TEL
- Learner: health care student, either final-year undergraduate or postgraduate student or trainee

Table 1. Scoring options for each research question in round 2.

Criteria	Scoring options		
Scientific merit	1=unable to respond	2=disagree	3=agree
Significance for workforce development	1=unable to respond	2=disagree	3=agree
Innovation	1=unable to respond	2=disagree	3=agree
Relevance to the LTWP[a]	1=unable to respond	2=disagree	3=agree
Feasibility for further study	1=unable to respond	2=disagree	3=agree

[a]LTWP: Long Term Workforce Plan.

Round 3: Prioritization

Participants' voting in this round was informed by knowledge of the consensus outcomes for each research question from round 2. A web-based survey was shared with participants, consisting of 2 sections: one with research questions that met the inclusion criteria for round 2 (including the percentage consensus agreement for each question) and another with questions from round 2 that did not reach consensus.

XSL•FO
RenderX

Participants were invited to score each research question again, but this time based on priority, with 1 score assigned to each question. The scoring options were as follows: 1=not to be studied, 2=low priority, 3=medium priority, and 4=high priority.

The consensus thresholds for Round 3 were as follows:

- Inclusion: ≥80% of respondents scored the research question as a 3 or 4
- Exclusion: 100% of respondents scored the research question as a 1 (not to be studied)
- Nonconsensus: when the proposed priority research question met neither the inclusion nor the exclusion consensus thresholds

Those meeting the inclusion criteria were taken forward for ranking in round 4.

Round 4: Ranking

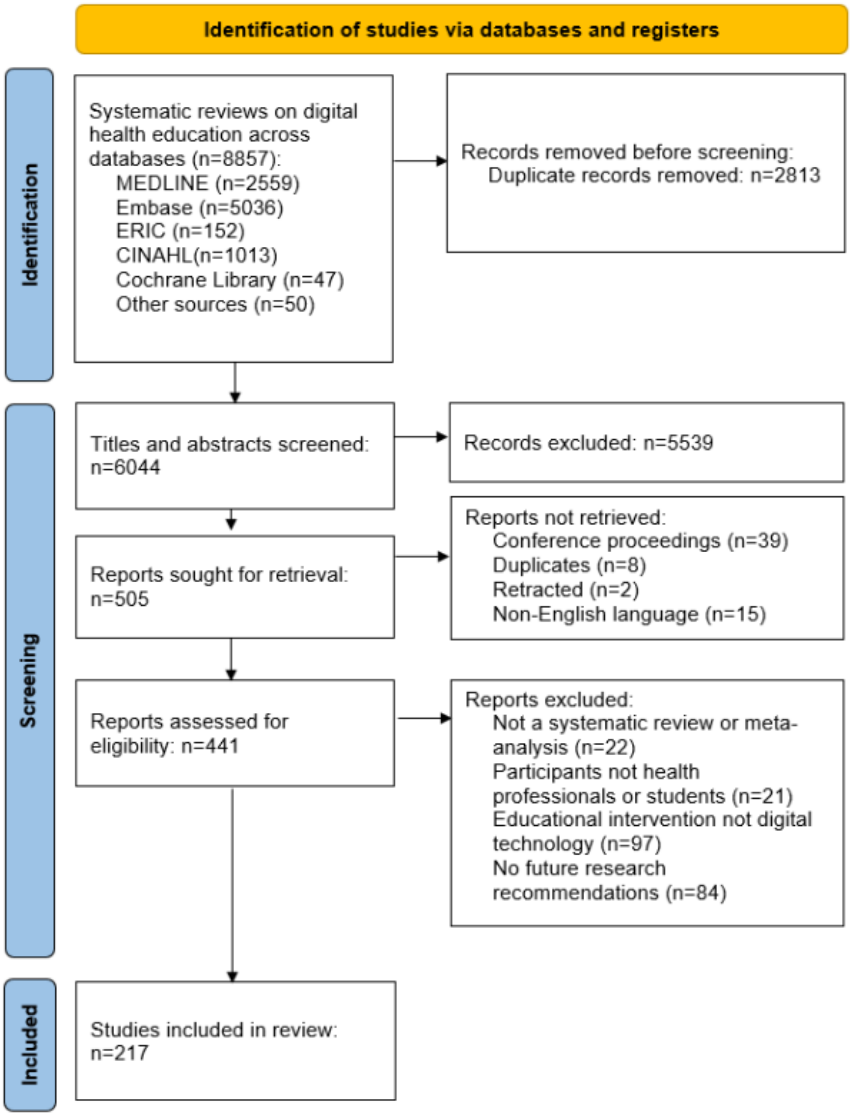
A web-based meeting was conducted with participants, facilitated by CM and AP. Participants were sent results of the previous round in advance (Multimedia Appendix 5). The meeting offered the opportunity to discuss results from round 3 in small groups. Finally, participants were asked to select and rank their top 5 research questions independently via a web-based survey constructed in Slido [31], a web-based audience interaction tool that offers in-meeting and between-meeting polling and surveying. Participants unable to attend the meeting were invited to complete this exercise within 1 week of the meeting date. After this time, for each ranked question, points were assigned in a descending order, where higher ranks received more points, for example, a question ranked first place received 5 points, and each subsequent rank received 1 point less, down to 1 point for a question ranked fifth. The 5 research questions with the highest mean formed the final set of research priorities.

Finally, a narrative synthesis approach was chosen to summarize the diverse range of selected studies in a structured manner.

Ethical Considerations

The NHS Research Ethics screening tool was completed, and approval was not required for this study. However, key ethical requirements were considered when designing and conducting the Delphi. The NHS England Data Protection Impact Assessment was completed. Delphi participant recruitment was voluntary, with opt out being possible. Compensation was not provided. A participant information sheet outlining the purpose of the study, key contacts, their potential involvement with anticipated time commitment, and how data would be handled and stored and by whom was shared. Personal data were stored in a spreadsheet hosted on an organizational SharePoint and were only accessible to relevant members of the research team. Participants were not asked for any personal details in the Delphi surveys; instead, they were assigned a code number. This code number allowed the research team to keep track of response rates and to administrate any follow up.

Results



Umbrella Review

Study Selection

A total of 8857 potentially relevant papers were identified across all information sources. Following removal of duplicates, of the 8857 papers, 6044 (68.24%) were screened by title and abstract. Of these 6044 papers, 441 (7.3%) were assessed for eligibility via full-text review, leading to 217 (3.6%) papers being included in this review (Figure 1). Refer to Multimedia Appendix 6 for a complete list of key study characteristics for all included studies.

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram charting identification of studies.

Study Characteristics

All included papers were systematic reviews or meta-analyses. Of the included studies across all the systematic reviews, high-income settings were predominant, with 23% (50/217) exclusively consisting of high-income countries and 33.6% (73/217) including a mix of high- and middle-income countries. In total, 14.3% (31/217) covered high-, middle-, and low-income countries, with only 0.9% (2/217) identifying middle- and low-income countries. The remaining 28.1% (61/217) of systematic reviews did not report the economic setting of their included studies.

In total, 29% (63/217) of the systematic reviews were focused on preservice alone. Of these, 11% (24/217) were nursing students, 5.1% (11/217) were medical students, and 7.8% (17/217) were mixed student populations. The least common population groups to be studied in the included reviews were pharmacy students (4/217, 1.8%), dentistry students (4/217, 1.8%), physiotherapy students (2/217, 1.8%), and health sciences students (1/217, 0.5%). This reflects the number of publications from these disciplines.

Reviews exploring the use of interventions with in-service professionals (44/217, 20.3%) are divided into fewer, less distinct categories: 13.8% (30/217) physicians, 6.5% (14/217) mixed health care professionals, and 0.5% (1/217) health care workers.

Of the systematic reviews comprising studies for both pre- and in-service professionals (110/217, 50.7%), 22.1% (48/217) focused on medical students and physicians, 17.5% (38/217) focused on mixed students and health care professionals, and 6% (14/217) focused on nursing students and nurses. Reviews comprising studies on dentistry, pharmacy, and physiotherapy were less common: 1.4% (3/217) dentistry students and dentists, 0.9% (2/217) pharmacy students and pharmacists, and 0.5% (1/217) physiotherapy students and physiotherapists.

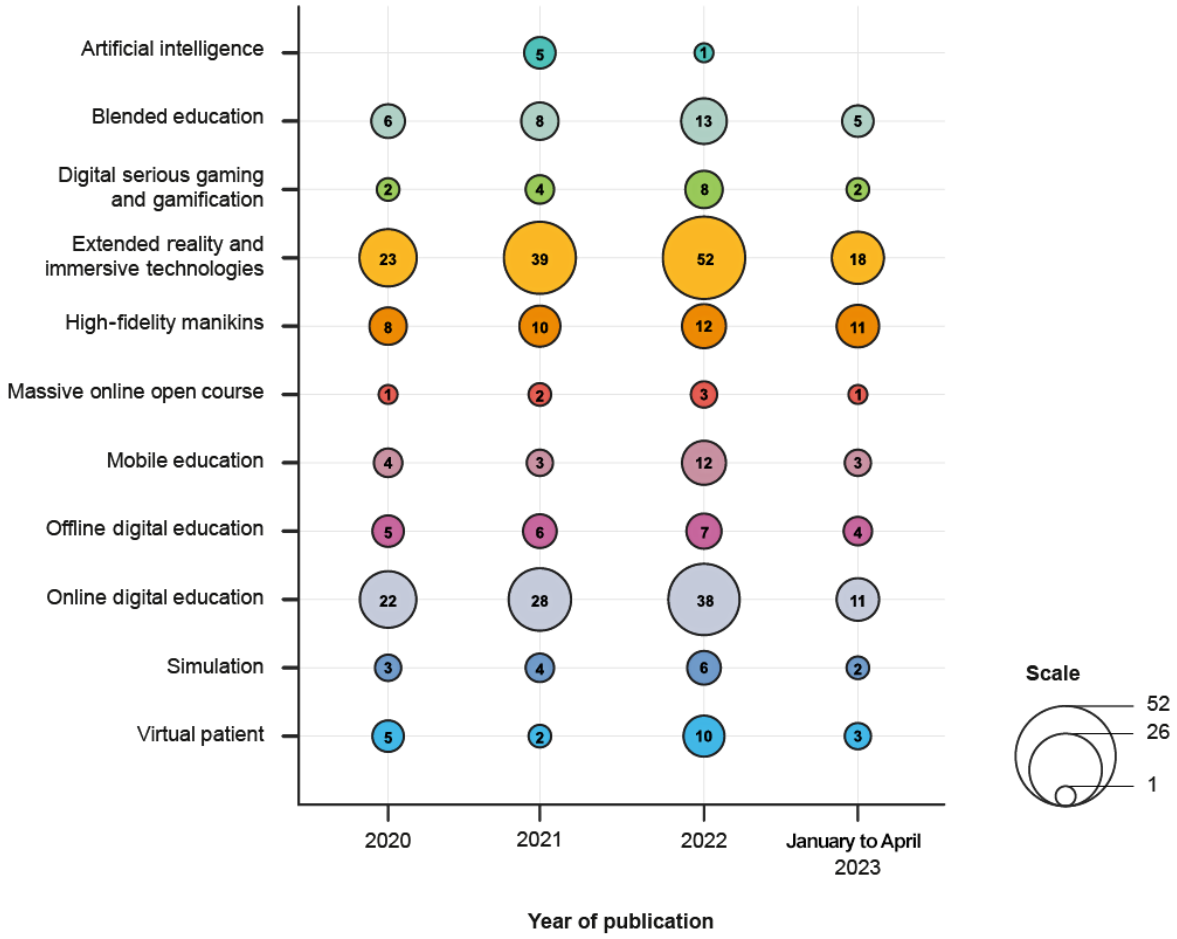
The included reviews investigated digital education interventions for learners at a variety of stages in their career: 45.2% (98/217) were created for both students and graduates, 29.5% (64/217) for students only, 10.1% (22/217) for practicing postgraduate health care professionals, 7.8% (17/217) for a mix of trainees and postgraduate health care professionals, and 7.4% (16/217) for graduate trainees.

XSL•FO
RenderX

Figure 2 displays a chart showing the number of systematic reviews published for each digital modality, organized by publication year. Several additional digital modalities were identified in the systematic reviews over and above the modalities included in the study by Tudor Car et al [26]. These were consolidated into three new categories:

1. AI: this category includes traditional AI and generative AI, as well as novel AI-driven education modalities such as personalized learning, adaptive learning, AI-enabled extended reality (XR), chatbots, and virtual learning coaches. It also covers AI as an enabling technology, for example, when it helps educators produce content or generates data-driven insights.
2. XR and immersive technologies: this category includes augmented reality, XR, mixed reality, and haptic technology. Virtual reality was also reclassified to fall within this definition.
3. Simulation: this category includes high-fidelity simulators and robotic simulation.

Refer to Multimedia Appendix 2 for a full list of definitions.



Most systematic reviews focused on XR and immersive technologies (132/217, 60.8%) and online digital education (99/217, 45.6%). The least focus was given to serious gaming and gamification (16/217, 7.4%), simulation (15/217, 6.9%), massive online open courses (7/217, 3.2%), and AI (6/217, 2.8%).

Publication numbers were highest in 2022, although the annual totals between January 2020 and April 2023 (Figure 2) exceed those published in the original study by Tudor Car et al [26].

Mapped against the conceptual framework of digital health education for health care professionals [26], most systematic reviews were focused on education modality (170/217, 78.3%) and instructional design (99/217, 45.6%). Very few reviews focused on human resource requirements (7/217, 3.2%) and regulatory factors (6/217, 2.8%) in relation to digital education infrastructure, with only 0.9% (2/217) of reviews concerned with quality assurance of digital health education in the setting.

The majority of studies emphasized reporting educational outcomes related to skills (161/571, 28.1%) and knowledge (133/571, 23.3%), followed by studies focusing on satisfaction (77/571, 13.5%), attitude (54/571, 9.5%), and behavior (38/571, 6.7%). Few studies (29/571, 5.1%) reported patient outcomes.

Figure 2. Number of systematic reviews published per year up to April 2023 for each digital modality.

Future Research Recommendations

A total of 151 future research recommendations were extracted from the 217 systematic reviews. These were analyzed, recategorized, and consolidated by 3 authors (AP, CM, and EW) to create a final list of 63 updated research questions. Refer to Tables 2 and 3 for the complete lists.

XSL•FO
RenderX

Across the questions, online digital education (299/1257, 23.7%) and XR and immersive technologies (266/1257, 21.1%) were the most predominant digital modalities requiring further research. Most questions suggest further inquiry within the following domains of education: modality (21 questions), instructional design (16 questions), and assessment (14 questions).

The least predominant modalities are massive online open courses (20/1257, 1.59%) and AI (18/1257, 1.43%).

Table 2. New research questions identified from the included papers.

New research questions identified from the included papers	Evidence source references
Can the positive outcomes observed in studies at levels 2B and 3 of the Kirkpatrick model be further validated through studies at level 4, and what are the potential organizational and participant-level changes that may result from implementing these techniques?	[32]
How do immersive technologies impact learning outcomes?	[32-40]
How do we measure the learning transfer from digital education to the clinical setting?	[41-45]
How does research and evidence inform education commissioning and selection of digital technologies?	[46]
How does the design of VPS[a] impact learning outcomes in health professions education and training curriculum?	[47,48]
How does the use of social media as a pedagogical tool contribute to learner efficacy?	[49,50]
How effective is blended learning in different disciplines, age groups, and learning environments for nursing students?	[51]
How can digital health education be used to offer an inclusive learning experience for staff and students?	[52-55]
How can we optimize the use of AI[b], machine learning, and deep learning to facilitate education and training?	[56,57]
What are health care students' learning needs, and can they be met by the use of digital gamification?	[58-64]
What are the advantages and disadvantages of the recognized standard setting methods in simulation-based training?	[58,65-67]
What are the challenges of setting up digital simulation education in primary care?	[68]
What are the experiences and attitudes of teachers and trainers toward developing and implementing digital learning designs in health care education?	[69-71]
What are the outcomes and implications of high-quality randomized controlled trials evaluating the impact of virtual reality and augmented reality simulators on the entire robotic surgery learning curve?	[37,72]
What are the specific effects of video as a learning delivery method?	[73]
What automated performance metrics might prove effective in remote proctoring and assessment? For example, eye tracking	[61]
What is the comparative efficacy of various e-learning platforms in teaching specific subtopics when standardized guidelines for information delivery and assessment are used?	[74,75]
What is the effectiveness of digital health education on long-term retention of skills and knowledge?	[70,74,76-80]
What is the effectiveness of high-fidelity simulation compared with other forms of simulation training?	[81-84]
What is the effectiveness of immersive technologies compared with other forms of simulation training?	[67,80,85]
What is the effectiveness of synchronous digital education compared with asynchronous digital education to deliver health professions education?	[86-88]
What is the impact of digital health education on clinical outcomes in the short and long term?	[89-93]
What is the long-term impact of the COVID-19 pandemic on the educational gaps of health care learners?	[94-97]
What is the validity of using AI, machine learning, and deep learning to generate automated feedback for procedural skills training?	[98,99]

[a]VPS: virtual patient simulation.

[b]AI: artificial intelligence.

Table 3. Research questions identified from the included papers and mapped to questions originating from the study by Tudor Car et al [26].

Research questions identified from the included papers	Evidence source references
What are the instructional design barriers and facilitators that affect the continued adoption of digital tools in health professions education?	[63,69,88,100-104]
How does the frequency and duration of digital simulation–based psychomotor skills training affect health professionals' skills transfer to the clinical setting?	[105-111]
How does the interactivity of digital education programs affect the learning and clinical outcomes of health professionals?	[89,91,105,112-117]
What are the technical resources needed to deliver digital education to health care professionals?	[36,80,105,107,118-122]
Is spacing digital simulation–based training more or as effective as traditional education in clinical psychomotor skills development?	[41,80,105-109,111,117,123,124]
What are learners' acceptability of digital education with different levels of interactivity?	[87,91,105,107,115,122,125-129]
What is the differential impact of digital education on the clinical performance of trainee or expert surgeons?	[107,120,124-126,130-133]
Can digital education be used to overcome challenges in delivering content-specific topics for health professions education (eg, surgical training in rare pathologic states)?	[33,75,105,107,109,121,125,128,134-137]
Which components of digital health education (eg, interactivity and feedback) contribute to enhanced learning outcomes?	[55,58,61,80,89,115,125,128,129,138-140]
Can digital simulation–based training be used to train nontechnical skills in health professionals?	[32,85,97,111,123,126,128,131,136,141-143]
Is health professions' digital education more time efficient than traditional education?	[95,105,107,115,123-126,144-149]
Which learning theories can be used to inform the development of effective digital health professions education?	[62,63,69,74,81,87,126,150-157]
Does digital simulation–based psychomotor skills training provide any benefit to medical trainees?	[37,107,115,120,123-125,145,147,158-163]
How does health professions' digital education affect individual and health services outcomes and organizational practice?	[87,95,105,107,112,123,124,133,134,146,147,158,164-167]
What is the effectiveness of using digital education to train and assess nontechnical skills in health care professionals?	[42,82,84,88,95,111,117,128,131,143,168-170]
How do cost and cost-related outcomes influence the adoption of digital technology in health professions education?	[36,65,107,115,117,123,135,145,167,171-175]
Which features of digital education (eg, technical features, fidelity, safety, and adaptability) affect the learning outcomes of health professions education?	[36,82,104,105,112,122,124-126,129,130,134,139,142,145,171,176,177]
Is mastery learning via digital education more or as effective as traditional education in terms of clinical psychomotor skills improvement?	[34,35,80,105,108,109,115,123,124,134,147,155,158,178-181]
What are health professionals' attitudes toward digital delivery of education and training programs?	[55,69,70,87,89,91,105,107,112,115,122,125,126,128,146,148,174,182,183]
What are the challenges of digital education for health professionals training in different socioeconomic settings?	[32,68,122,140,171,172,175,184-186]
Can digital education be designed to achieve learning outcomes denoted in the Kirkpatrick model?	[32,40,74,87,107,112,117,124,128,133,134,140,141,147,155,156,164,187,188]
What are health care professionals' learning needs and can they be met using digital simulation training?	[88,104,105,107,115,117,120,122,123,125,126,128,129,138,146,148,158,162,164,183,189,190]
What type of instructional design is used in the effective digital education of health professions education?	[33,42,80,82,87,104,117,119,125,126,128,129,135,137,139,156,162,190-194]
What is the optimal duration, frequency, and intensity of digital health professions education programs to improve the learning and clinical outcomes for health care professionals?	[41,69,80,82,102,106-108,110,111,114,124,127,141,161,175,184,186,195]

Research questions identified from the included papers	Evidence source references
What is the long-term cost-effectiveness of digital education compared with traditional education for health professionals?	[35-37,48,78,81,85,91,95,105,107,115,120,123,148,159,167,169,173-175,196,197]
How does providing access to digital education improve the learning outcomes of health professionals?	[36,87,89,105,107,109,112,113,115,122-126,129,133,134,138,142,145,147,149,162,164,167,174,187]
How should learning outcomes in the field of health professions' digital education be defined and standardized?	[41,45,66,81,87,98,103,104,107,120,121,125,128,129,133,134,141,145,147,149,156,164,165,174,198-202]
What pedagogy should be used in the digital education of health professionals to improve their knowledge and skills?	[74,78,81-83,87,88,95,102,106,114,117,122,126,150,154-156,165,170,191,192,201-204]
Can digital education complement (ie, blended) or substitute traditional education for health professionals?	[34,41,43,56,61,64,80,87,91,95,96,104,115,119,124,126,128,140,145,154,156,187,205-209]
How can digital technology be incorporated into the current health professions education and training curriculum to improve learning outcomes?	[41,80,95,99,105,107,111,112,121,123-127,129,133,134,147,165,168,198,208,210-214]
What is the ideal approach to assessing health professionals' knowledge, skills, attitudes, satisfaction, and clinical outcomes from digital technology–based education and training programs?	[32,51,61,83,87,102-104,117,120,123,128,129,133,140,149,156,164,165,176,178,184,192,193,196,200,201,215-224]
How should studies on digital health professions education be reported?	[37,38,45,46,74,79,82,87,89,91,101,102,104,105,107,114,123,125,126,128,129,134,140,147,148,153,176,178,184,188,201,202,204,211,223,225-227]
Is digital education effective in improving health professionals' knowledge and skills performance in the clinical setting?	[36,44,62,87,95,104,105,107,109,113-115,117,123-126,131,133,134,144,145,147,149,154,158,162,164,176,187,190,192,194,196,209-211,213,215,228]
Which performance metrics or measurement instrument should be used to assess health professionals' knowledge, skills, attitudes, satisfaction, and clinical outcomes from digital technology–based training programs?	[33,41,46,51,58,61,66,82,87,98,102,104,107,109,120,123,124,128,129,133,140,141,145,147,153,156,164,166,169,170,178,179,191,199-201,211,215,220,222,229]
How does the design of digital education interventions (eg, format and modality) in health professions education and training curriculum affect learning outcomes?	[33,37,40-42,47,48,54-56,61,63,64,73,80-82,87,95,96,101-103,112,113,119,126,128,130,131,133,138,142,152,154,196,210,213,230-233]
How should studies of digital health professions education be designed to ensure the generalizability of their findings across different settings?	[38,51,52,62,76,79,80,87,91,92,102,104,105,107,114,115,120,123-126,128,129,133,134,138,140,141,144,145,147-149,164,170,172,176,184,200-202,205,207,211,223,225-227,234-238]
What is the impact of digital simulation–based training on clinical outcomes in the short and long term?	[35,37,40,48,68,70,76,81,87,93,106,108,112,117,123,124,128,131-134,140,143,146,147,155,164,165,174,179,181,185,186,188,196,197,201,218,227,228,236,239-241]
What is the effectiveness of digital education (mixed or single modality) compared with nondigital education to deliver health professions education?	[33,34,36,43,53,56,64,68,75,85,87,89,91,95-97,104,115,119,123,124,126,128,129,131,134,136,138,140,145,147,149,154,159,161-164,181,192,196,198,205-207,209,225,230,242,243]
What are the methodological requirements for high-quality, rigorous studies assessing the outcomes of digital health education?	[35,37-39,42,46,47,51,52,57,60,62,63,70,72,74,79-83,86,87,91,100,102,104,105,107,113-115,123-126,128,129,133,134,140,141,144,145,147-149,152,153,168,176,179,184,185,188-190,195,199,201-204,214,218,222,223,225-227,234,236,238,241,244-247]

Delphi Consensus

A total of 42 experts were enrolled to participate in the Delphi consensus activity. Of these, there were 11 academics, 18 clinical educators, 14 simulation faculty, 6 immersive technology professionals, 6 workforce and transformation professionals, 1 learner, and 13 TEL professionals.

In round 1, a total of 151 research questions identified from the literature review were consolidated into 63 questions. These 63 questions were then used to form the web-based survey for round 2.

In round 2, experts assessed each question against the set criteria (scientific merit, significance on workforce development, innovation, relevance to the Long Term Workforce Plan, and feasibility for further study). Two participants chose to withdraw from the Delphi process after reviewing the survey. There was a 78% (31/40) response rate, with nonconsensus thresholds across all questions. Therefore, all 63 questions went through to the next round.

In round 3, in total, 53% (21/40) experts responded to the survey to determine the priority with which each question ought to be pursued with further research. A total of 18 research questions met the consensus threshold for the final round.

In the fourth and final round, the response rate was 55% (22/40), and consensus was reached on the 5 research questions (Table 4) that the expert group identified as the most important and likely to impact the future delivery of digital education.

How should learning outcomes in the field of health professions' digital education be defined and standardized?	30

[a]AI: artificial intelligence.

Discussion

Principal Findings

This study presents findings from 217 systematic reviews on digital education in health care, published between 2020 and 2023. The findings expand upon previous research conducted by Tudor Car et al [26] and define current gaps in the evidence for the efficacy of digital education. After analysis and consolidation, this study identified 63 future research questions: 24 new questions derived from the umbrella review and 39 from the original study by Tudor Car et al [26]. Most reviews focused on XR and immersive technologies as well as web-based digital education, targeting a mixed audience of students and in-service health care professionals. This was also the case for studies with the least commonly represented population groups (dentistry, pharmacy, and physiotherapy).

The 63 research questions were then prioritized through a consensus process with 40 experts from health care and academia, resulting in 5 key research questions (Table 4). These questions span several domains outlined in the conceptual framework [26]: assessment, engagement, learner, level of education, modality, and research.

The 5 Top-Rated Research Questions

Each of the top-rated questions is supported by a wealth of recommendations for conducting research in digital education. A high-level summary of this evidence is provided for each question.

Question 1: How Do We Measure the Learning Transfer from Digital Education to the Clinical Setting?

The evidence behind this research question points to several related yet distinct avenues of inquiry. A common theme among them is the need for further research to demonstrate how learning outcomes translate into real-world contexts, both for technical and nontechnical skills, particularly in nursing and medical fields [42-44]. One study specifically recommends further research to ensure that the competence and confidence in clinical practice skills demonstrated in a learning environment are maintained when applied in the clinical setting, where additional external factors may come into play [44]. Ensuring that the learning experience is relevant and closely mirrors real-world situations is a key consideration when designing instruction to facilitate effective transfer of knowledge and skills [248].

Furthermore, studies should track and evaluate the effectiveness of learning throughout a health care professional's career [41], using clinical outcomes and patient-reported outcome measures to assess the transfer of learning [45].

Question 2: How Can We Optimize the Use of AI, Machine Learning, and Deep Learning to Facilitate Education and Training?

The use of AI to optimize health education is a rapidly developing field. Current evidence proposes further research on the potential of this technology to elevate and shift performance assessment from benchtop and simulated environments to real-world context, offering more precise and scalable feedback mechanisms for both trainees and practitioners. For instance, machine learning has already shown promise in surgical skills training, where it could provide automated, objective assessments of technical skills, provided that more reliable assessment data were available [57]. Besides enhancing existing approaches to learning and assessment, AI also enables new modalities, such as personalized learning, which can enable more self-directed learning and may also support learner motivation by connecting data-driven insights to learning experiences, and adaptive learning [249]. AI integrated into personalized or adaptive learning could help students practice clinical decision-making by simulating different patient cases customized to their knowledge gaps based on previous performance. Furthermore, AI could generate dialogue, actions, and complex situations that replicate clinical settings, further enabling students to develop critical skills with reduced risk [56]. However, while AI offers substantial benefits, its implementation must be carefully considered to mitigate against potential challenges such as ethical concerns, bias from training data, and over-reliance on technology [249]. To safely and effectively adopt AI into health care education, a careful approach could integrate AI in a way that complements existing strategies that emphasize critical thinking and adaptability as well as technical proficiency.

Question 3: What Are the Methodological Requirements for High-Quality, Rigorous Studies Assessing the Outcomes of Digital Health Education?

Across the spectrum of digital education modalities, several studies highlighted the need for research to adopt appropriate study designs to determine learning gains [35, 63, 80, 87, 102,123,128,129,179,199,203,226]. Designs need to be larger in scale [39,60,105,107,113,124,134,140,188,214,218,246], multicentered [45,134,227,245], and carry out longer-term

XSL•FO
RenderX

follow-up [37,62,81,105,107,128,133,140,149,195,223,241] to ensure retention and transfer of learning. Many of the included studies recommended more randomized controlled trials [37,38,62,81,100,105,115,124,140,188,195,214,222,236,241], although one paper supports the suggestion provided by Tudor Car et al [211] that quasi-experimental designs may be better suited to educational research [144] and another study, in relation to cultural competency, suggests that observational studies and other designs may be preferred [52].

Question 4: How Does the Design of Digital Education Interventions (eg, Format and Modality) Used in Health Professions Education and Training Curriculum Affect Learning Outcomes?

Key recommendations from the data sources that derive this research question are primarily concerned with the integration and sequencing of pedagogical devices (ranging from flipped classrooms, timing of simulation briefing, e-learning, and active vs didactic approaches) in health education training and curricula as well as the quality of the approach used [41,42,82,95,102,119,133,142]. Some studies suggest delving further by closely comparing and evaluating the impact of nuanced difference in the design elements of an intervention or specific educational technology [37,63,82,101,130].

Stepping back from this detail within the intervention design itself, studies also reinforce the need to define educational needs, the context, and the setting to select suitable, appropriate, and effective modalities for specific learner groups [40,80,103,126,232].

Looking to the future, some studies highlight several novel technologies and suggest exploring their potential for designing more advanced educational interventions, such as AI [56], adaptive learning [87], wearable technology [213], eye tracking for assessment [55,61], and gamification to increase learner motivation [61].

While many still recommend further comparison studies between digital and nondigital interventions [33,48,119], others support the recommendation by Tudor Car et al [26] that comparisons between digital-to-digital interventions are now needed and necessary [142,231].

Question 5: How Should Learning Outcomes in the Field of Health Professions Digital Education Be Defined and Standardized?

Principally, the foundations of this research question lie within a body of evidence that urges a more standardized approach to outcome measurement, using validated measurement tools [81,98,120,141,165]. Beyond this, there is little guidance on how to achieve this, although 1 study (specific to surgical skills training) suggests that machine learning could help identify which metrics accurately assess skills [201].

In many ways, each of these research priorities are connected and interdependent. For example, to be able to measure learning transfer, learning outcomes need to be defined from the beginning and integrated into the learning design. This, in turn, will influence the research methodology used.

Comparison With Prior Work

This study builds upon and extends research by Tudor Car et al [26]. By doing so, the study not only updates their findings to include data up to 2023 but also extends them by prioritizing 5 research questions through Delphi consensus, thereby addressing a limitation previously identified by Tudor Car et al [26].

In comparison to the 6-year period covered by Tudor Car et al [26], the 3-year timeframe (2020 to 2023) in this study shows a dramatic increase in the number of publications on digital education in health care (from 77 to 217). This surge of activity is reflective of the rise in uptake of digital education in response to the COVID-19 pandemic.

Research with medical students and physicians has seen the greatest increase (from 12% to 22% of studies) and accounts for the largest portion of studies included in this review. In contrast, most earlier studies were more heterogeneous, with a combination of students and health professionals spanning several professions and specialties [26]. Dentistry staff and students remain one of the least represented groups in the literature, along with pharmacy and physiotherapy. The digital education modalities studied align with the broader outcomes of this study (namely, virtual reality, augmented reality, and web-based digital education), and their recommendations for future research mainly focus on the benefits, effectiveness, and perceptions of these modalities.

This study sees the addition of 3 new modalities: AI (in the form of personalized learning, adaptive learning, AI-enabled XR avatars, chatbots, and virtual learning coaches), XR and immersive technologies, and high-fidelity simulation. There has been an explosion of research around the use of XR technologies (132/217, 60.8% of included studies) as well as the emergence of AI (6/217, 3% of included studies). Aside from virtual reality, these technologies were not present in the earlier study.

There was a slight increase (from 5% to 14%) in the number of studies from high-, medium-, and low-income countries [26]. This could be indicative of greater collaborative relationships during the COVID-19 pandemic, as digital education was used globally to overcome the challenges of social distancing in health education delivery. Although evidence relating to digital education research in low-income countries continues to be sparce, the data from this study suggest that future research should focus more closely on learner audiences and intercultural differences to better understand what works across various socioeconomic settings [175,237].

While there have been noticeable shifts in the research populations and the education technologies studies since the findings shared by Tudor Car et al [26], some aspects remain unchanged. Studies comparing digital education interventions with traditional education remain popular, with a continued emphasis on the randomized control trial study design. Comparison studies between digital and nondigital approaches have made significant progress in recent years. Researchers are now encouraged to focus more on comparisons between digital methods in future studies to further advance digital education

XSL•FO
RenderX

research. However, despite a move toward research focusing on the context of the learner since the study by Tudor Car et al [26], this review has shown that there continues to be a lack of studies relating to quality assurance, human resources, and regulatory aspects of digital education infrastructure.

Strengths and Limitations

The findings of this extensive umbrella review replicated a robust methodology used by Tudor Car et al [26] and expanded it to identify the most pressing research questions currently needing attention in digital education within UK health care. Furthermore, these findings were strengthened by consultation with 40 stakeholders across health care and academia to arrive at consensus for the 5 research questions.

By replicating the methodology used by Tudor Car et al [26], this study was constrained by many of the same limitations set out in their study, particularly the exclusion of original research outside of systematic reviews. In addition, this study excluded conference abstracts and non-English papers. However, the impact of excluding non-English papers is considered minimal on the overall outcome [250], and while there may be advantages in including conference abstracts in a systematic review [251], they did not provide the level of information required for data extraction in this study.

There was very low representation from the learner stakeholder group on the Delphi expert panel. Initially, there was uncertainty among the research team members about whether learners would be classed as "experts" for a Delphi panel, which delayed promotion to this group. According to Nasa et al [252], an "expert can be defined as someone with knowledge and experience on a particular subject matter." In addition, there were similarities drawn with the concept of "experts by experience" [253]. While there are significant differences between being a patient, carer, or service user and a student or learner, the principles of "experts by experience" were considered to be similar. This approach involves gathering the views of people receiving the interventions, in this case, their views and expertise regarding their experience with education. Therefore, a heterogeneous group of stakeholders including final-year undergraduate health care students and postgraduate students or trainees, including doctors in training, was considered applicable to the aims of this study.

Next Steps

Having defined 5 high-level, key research priorities, it remains to determine what the next steps should be. Stefanidis et al [19] observed that, in the field of surgical simulation, little actual research evidence has been generated despite numerous papers attempting to define priorities. To avoid repeating this shortcoming, the next stage should be to identify specific research questions that have the greatest potential to have significant and practical impact across the system. As proposed by Stefanidis et al [19], establishing a number of expert working groups to devise specific, high-impact and feasible research proposals based on these 5 priorities is suggested. These ideas will subsequently be developed into formal research projects including research questions, collaborators, project design, and required resources. It is anticipated that successful completion of these projects will answer important questions about the practice of digital education in health care.

Conclusions

This review provides a list of current research gaps in digital education in health care, presenting them as a set of research questions along with the sources from which they are derived.

While the ongoing focus of digital education research on medical trainees and professionals is acknowledged, there is a need for more research involving nursing and allied health professions. It also highlights that there continues to be a need to address the quality assurance, human resources, and regulatory aspects of digital education infrastructure through research.

The prioritized set of 5 research questions, developed with input from expert representatives across health care and academia, is expected to serve as a valuable guide for researchers, funding agencies, and educators. For researchers, these questions offer a helpful starting point for addressing some of the existing gaps in knowledge. For funding agencies, they provide a framework for allocating resources to the areas identified as top priorities for the health care system. Finally, for educators and education providers, these questions can inform decision-making regarding implementation, curriculum design, and quality.

Acknowledgments

The authors would like to thank their volunteers (Angela Holmes, Claire Beattie, Harbie Rathore-Khatkar, Chris Jacobs, Ian Blacklock, Eleni Keogh, Sarah Gray, and Matt O'Brien) for their time and commitment throughout the process. The authors would also like to thank Nick Peres, Patricia Howe, and Faisal Mushtaq for their valuable advice and for helping to refine the methodological approach. The authors also thank the experts who participated in the Delphi process.

Conflicts of Interest

NR is the Deputy Director of Technology Enhanced Learning at NHS England. This team delivers digital learning services and products directly to the National Health Service (NHS) as well as providing system leadership and transformation programs.

Abstract

Background: To address gaps in global understanding of cultural and social variations, this study used a high-performance machine learning (ML) model to predict adolescent substance use across three national datasets.

Objective: This study aims to develop a generalizable predictive model for adolescent substance use using multinational datasets and ML.

Methods: The study used the Korea Youth Risk Behavior Web-Based Survey (KYRBS) from South Korea (n=1,098,641) to train ML models. For external validation, we used the Youth Risk Behavior Survey (YRBS) from the United States (n=2,511,916) and Norwegian nationwide Ungdata surveys (Ungdata) from Norway (n=700,660). After developing various ML models, we evaluated the final model's performance using multiple metrics. We also assessed feature importance using traditional methods and further analyzed variable contributions through SHapley Additive exPlanation values.

Results: The study used nationwide adolescent datasets for ML model development and validation, analyzing data from 1,098,641 KYRBS adolescents, 2,511,916 YRBS participants, and 700,660 from Ungdata. The XGBoost model was the top performer on the KYRBS, achieving an area under receiver operating characteristic curve (AUROC) score of 80.61% (95% CI 79.63-81.59)

XSL•FO
RenderX

and precision of 30.42 (95% CI 28.65-32.16) with detailed analysis on sensitivity of 31.30 (95% CI 29.47-33.20), specificity of 99.16 (95% CI 99.12-99.20), accuracy of 98.36 (95% CI 98.31-98.42), balanced accuracy of 65.23 (95% CI 64.31-66.17), F_1-score of 30.85 (95% CI 29.25-32.51), and area under precision-recall curve of 32.14 (95% CI 30.34-33.95). The model achieved an AUROC score of 79.30% and a precision of 68.37% on the YRBS dataset, while in external validation using the Ungdata dataset, it recorded an AUROC score of 76.39% and a precision of 12.74%. Feature importance and SHapley Additive exPlanation value analyses identified smoking status, BMI, suicidal ideation, alcohol consumption, and feelings of sadness and despair as key contributors to the risk of substance use, with smoking status emerging as the most influential factor.

Conclusions: Based on multinational datasets from South Korea, the United States, and Norway, this study shows the potential of ML models, particularly the XGBoost model, in predicting adolescent substance use. These findings provide a solid basis for future research exploring additional influencing factors or developing targeted intervention strategies.

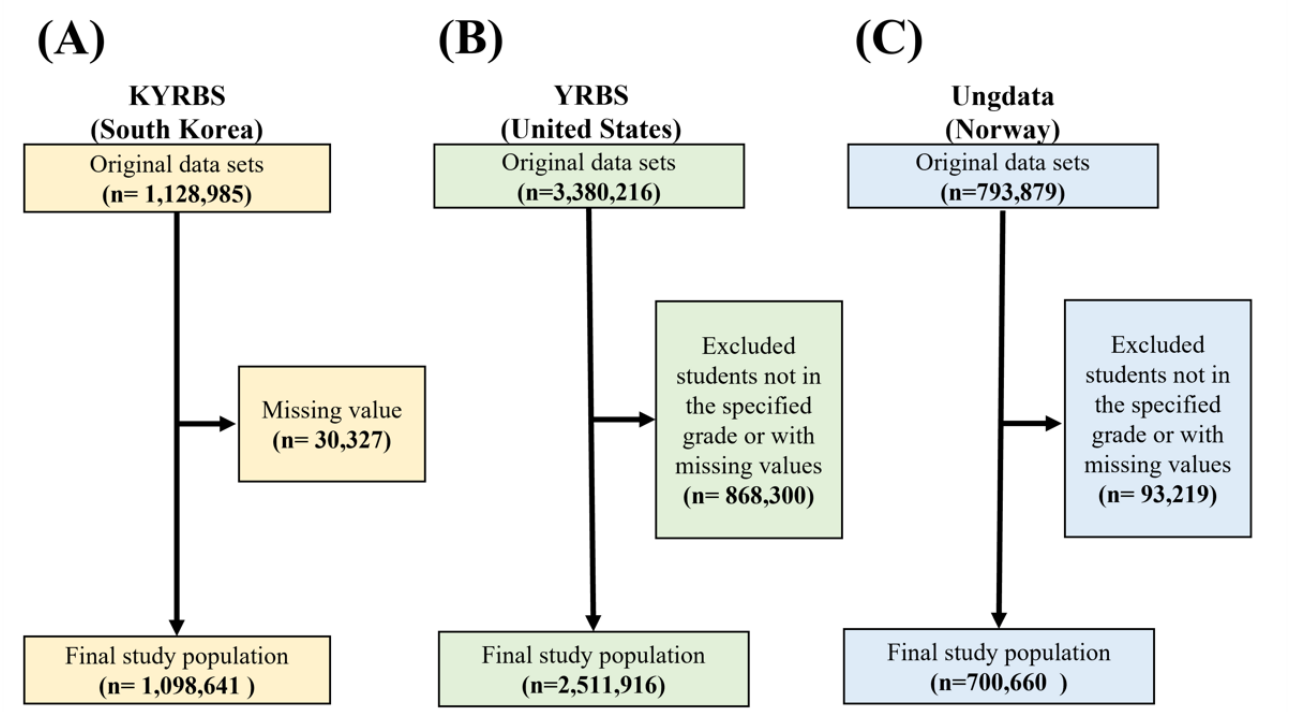
Introduction

Substance use among adolescents remains a global concern, often leading to both immediate and long-term health challenges, such as mental health disorders and addiction [1]. When initiated at an early age, these behaviors can escalate to more serious health conditions, including chronic substance dependence and comorbid mental health issues [2]. As globalization and cultural integration continue to expand, substance use patterns vary significantly across regions, making it paramount to understand these patterns across a diverse cultural landscape [3]. Conventional statistical methods have long been used to examine the predictors and outcomes of adolescent substance use [4]. However, these approaches often fall short in capturing complex, nonlinear relationships between variables. Therefore, with recent advancements, machine learning (ML) has introduced powerful tools capable of identifying complex patterns and relationships, offering a deeper understanding of adolescent substance use [5].

Existing studies provide insights into the epidemiology and sociocultural factors associated with adolescent substance use in various contexts, but few have used ML techniques with multinational datasets [4,6]. Such approaches have the potential to yield more precise and globally relevant insights [5,7]. By identifying key predictors of adolescent substance use that remain consistent across diverse cultural contexts, this study aims to develop a prediction model adaptable to global public health initiatives. To validate its generalizability, the model was tested using datasets from two additional countries, highlighting its adaptability to diverse sociocultural environments [8].

This study developed an ML-based prediction model for adolescent substance use, using comprehensive datasets from South Korea, and extended our validation process by using datasets from the United States and Norway [9]. This validation process and refinement process ensured the model's accuracy and applicability across diverse cultural and national contexts. By integrating these global datasets, we developed a predictive model that reflects our collaborative international research. Our novel approach equips stakeholders with a sophisticated tool informed by global data. This helps address and preempt adolescent substance use effectively across different national contexts.

Methods



Study Design and Participants

Adolescents enrolled in middle and high school who completed their respective surveys were included. In the context of educational systems, adolescents are more appropriately categorized by grade level rather than age. To ensure consistency across the three countries, participants were limited to students from middle school (7th grade) to high school (12th grade). This study was primarily designed to develop an ML model for substance use prediction among adolescents using three distinct nationwide datasets: Korea Youth Risk Behavior Web-Based Survey (KYRBS) from South Korea [10], Youth Risk Behavior Survey (YRBS) from the United States [6,11], and Norwegian nationwide Ungdata surveys (Ungdata) from Norway [12]. KYRBS was initially used to train the ML model, followed by the external validation process using the YRBS and Ungdata.

The discovery dataset, KYRBS, was conducted annually by the Korean Disease Control and Prevention Agency (KDCA) from 2008 to 2022, to assess health behaviors among Korean middle and high school students. It began with 1,128,985 participants and ended up with 1,098,641 after exclusions from the missing values in BMI [13], primarily representing a demographic largely comprised of East Asians (Figure 1A). The KYRBS dataset can be accessed through the official website of the KDCA.

XSL•FO
RenderX

Figure 1. Study population. KYRBS: Korea Youth Risk Behavior Web-Based Survey; Ungdata: Norwegian nationwide Ungdata surveys; YRBS: Youth Risk Behavior Survey.

The YRBS, which was conducted by the US Centers for Disease Control and Prevention (CDC), along with state and local education and health agencies, began with 3,380,216 participants, was narrowed down to 2,511,916 after excluding students not enrolled in middle or high school and those with missing data (Figure 1B**)**. YRBS encompasses a diverse racial spectrum of American adolescents. YRBS data are downloaded and available through the US CDC's official website.

Similarly, from the initial count of 793,879 in the Ungdata, a cross-sectional survey conducted by the social research institute, Norwegian Social Research Institute (NOVA), at Oslo Metropolitan University consists of a questionnaire for school pupils throughout, only 700,660 participants were selected after data processing (Figure 1C). Ungdata is offered to all local and county councils in Norway, who administer the questionnaire in collaboration with NOVA and regional centers for substance use rehabilitation. The dataset can be accessed via the official Ungdata website. During the data processing phase, individual missing values in the KYRBS and YRBS datasets were imputed using a random forest regression–based imputation method [14]. For the extravalidation cohorts, YRBS and Ungdata, variables that were entirely absent were imputed using the median values derived from the discovery dataset, KYRBS.

In order to evaluate the generalizability of our model across diverse cultural groups, we used a phased validation approach. The validation process used the YRBS dataset, which includes participants from diverse ethnic backgrounds, as well as the Ung dataset from Norway, representing a markedly different cultural context. By using validation datasets encompassing a wide range of cultural groups, we conducted a rigorous assessment of the model's robustness and versatility across diverse populations [15].

Our primary outcome, substance use, was derived from the question "Have you ever consumed illicit substances at least once in your lifetime." We distinguished smoking and alcohol from other substances in our analysis, recognizing their unique consumption patterns, sociocultural implications, and health effects [16]. Substances other than smoking and alcohol are distinguished primarily due to concerns regarding their potential for misuse and health risks [17]. This decision was made to ensure that our model captures nuances specific to each substance, thereby enhancing the specificity and relevance of our predictions. Integral covariates under consideration spanned across factors including grade, sex, region, BMI, academic achievement, household income, smoking status, alcoholic consumption, stress status, sadness and despair, suicidal thinking, and suicide attempts [13].

Model Development and Validation

Using the KYRBS, we developed a predictive model to extrapolate the behavioral patterns of Korean adolescents regarding substance use. Due to rigorous substance regulations and law enforcement measures in South Korea, accessibility and consumption of substances are notably limited [18]. Consequently, the number of instances representing substance use within the KYRBS was sparse (n=12,803, 1.17%).

Given the intricate nature of the data, we used a comprehensive approach to model development, leveraging 10-fold cross-validation to divide the KYRBS dataset into training and testing subsets. Various tree-based and statistical models, including LightGBM, CatBoost, AdaBoost, random forest, and XGBoost, were evaluated in comparison with logistic regression, a widely used baseline model, to determine the most effective algorithm for predicting substance use [19,20].

XSL•FO
RenderX

After model development using the KYRBS, external validation was conducted with datasets from diverse cultural contexts (YRBS and Ungdata) to evaluate the generalizability of the predictive model. This step ensured the applicability of the modeling approach across heterogeneous adolescent populations [21].

To further strengthen the validity of our results, hyperparameter tuning was performed for each algorithm using GridSearchCV, focusing on maximizing performance metrics such as the area under the receiver operating characteristic curve (AUROC) and precision. The hyperparameter values for the selected model are detailed in Table S1 in Multimedia Appendix 1. The sensitivity and specificity of the model were determined based on a classification threshold of 0.5. Various metrics, including AUROC score, accuracy, sensitivity, specificity, balanced accuracy, precision, F_1-score (ie, the harmonic mean of the precision and recall), and the area under precision-recall curve (AUPRC) were used to evaluate the model's performance across datasets [13].

Performance Assessment

The tools and techniques we used for assessment were consistent. Our evaluation metrics comprised AUROC, accuracy, sensitivity, specificity, balanced accuracy, precision, F_1-score, and AUPRC. These metrics were collectively considered to comprehensively evaluate and compare model performance. To provide a visual representation of the model efficacy, we used visualization techniques, notably the ROC curve [19,20,22-24].

SHapley Additive ExPlanation Value Analysis

To interpret and better understand the model's predictions, we calculated the SHapley Additive explanation (SHAP) values based on the summary model [25]. SHAP is a widely used method for providing local explanations of ML model predictions. Proposed by Lundberg and Lee, SHAP offers a unified framework for explaining the output of any ML model [25]. This technique visualizes the contribution of each feature to the model's prediction for a specific instance, illustrating how each feature shifts the model's output from the base value.

Software and Libraries

All computations, model training, validation, and evaluation processes were executed using Python (version 3.12.4; Python Software Foundation). Key libraries from our toolbox included Scikit-learn (version 1.5.2; Scikit-learn development team), NumPy (version 1.26.4; Python Software Foundation), and Pandas (version 2.2.0; Python Software Foundation) for ML tasks and data wrangling. Visualization was facilitated using Matplotlib (version 3.8.4; Python Software Foundation) and Seaborn (version 0.13.2; Python Software Foundation).

Ethical Considerations

The study protocol was approved by the institutional review board of the KDCA (2014-06EXP-02-P-A), US CDC (#1969.0), and NOVA (18778329) [12], and all participants provided written informed consent. This research followed the guidelines outlined in the TRIPOD (Transparent Reporting of a multivariable prediction model for Individual Prognosis or Diagnosis) statement [26].

Results

Demographic Characteristics

This research used a detailed exploration using nationwide adolescent datasets from South Korea, aiming to design and validate an ML model to predict substance use tendencies among adolescents. The primary demographic consisted of middle (7th grade) to high school (12th grade) students (Figure 1).

We collected data from the KYBS, the YRBS, and the Ungdata, and subsequently standardized the covariates for the ML predictive modeling process. Within the primary cohort from the KYRBS to develop the prediction model, the sex distribution was as follows: male (n=566,437, 51.56%) and female (n=532,204, 48.44%). For the initial external validation cohorts of an external validation process, the YRBS features a sex distribution of: male (n=1,233,846, 49.12%) and female (n=1,278,070, 50.88%). In the second validation step, the Ungdata has the following sex distribution: male (n=345,428, 49.30%) and female (n=355,232, 50.70%; Table 1).

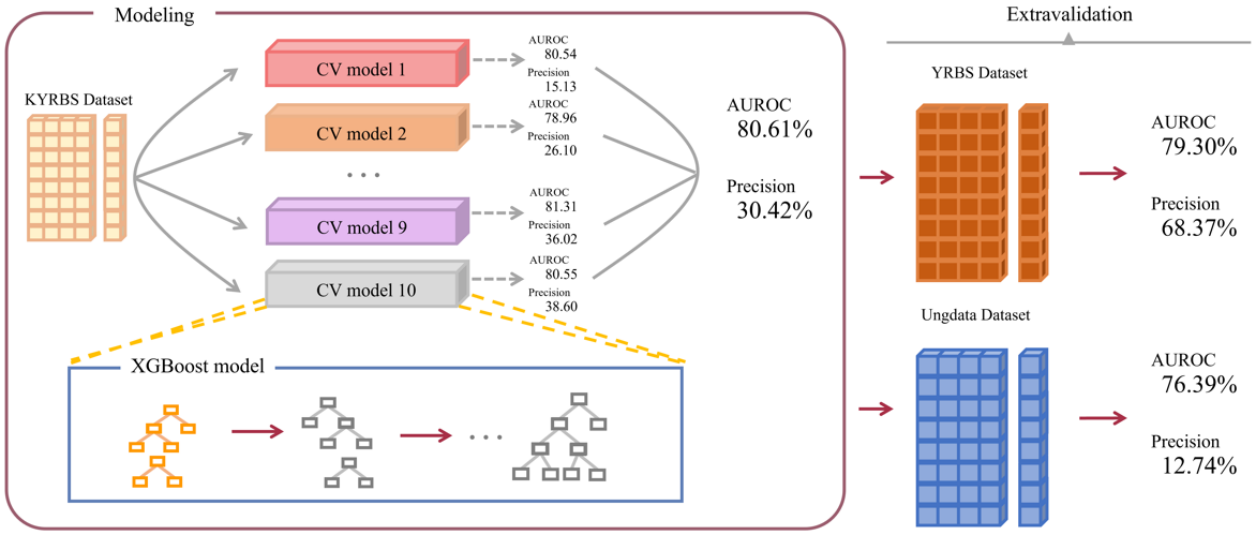
[a]KYRBS: Korea Youth Risk Behavior Web-Based Survey.

[b]YRBS: Youth Risk Behavior Survey.

[c]N/A: not applicable.

[d]BMI was divided into four groups according to the 2017 Korean National Growth Charts: underweight (0-4 percentile), normal (5-84 percentile), overweight (85-94 percentile), and obese (95-100 percentile).

[e]Stress was defined by the receipt of mental health counseling owing to stress.



We compared the distributions of key variables across the three cohorts (KYRBS, YRBS, and Ungdata), as presented in Table 1. Notable similarities and differences were identified. For instance, the proportion of smokers differed significantly between KYRBS (228,734, 20.82%) and YRBS (n=1,332,839, 53.06%), while the Ungdata cohort exhibited a much lower smoking prevalence (n=138,542, 19.77%). Similarly, alcohol consumption rates were higher in the Ungdata cohort (n=394,450, 56.30%) compared to KYRBS (n=517,296, 47.09%) and YRBS (n=1,175,954, 46.82%). These differences likely reflect cultural and policy variations influencing substance accessibility and behavioral norms in each country. Furthermore, visual comparisons of key baseline characteristics, such as smoking and alcohol consumption, are provided in Figure S1 in Multimedia Appendix 1 to offer additional insights.

ML Model Results

Extensive model evaluations, considering both AUROC and precision, revealed that the XGBoost model was the optimal model for predicting substance use among adolescents (Figures 2 and 3). The primary model, sourced from the KYRBS and assessed disclosed that the XGBoost model notched an AUROC score of 80.61% (95% CI 79.63-81.59) and precision of 30.42 (95% CI 28.65-32.16) with detailed analysis on a sensitivity of 31.30 (95% CI 29.47-33.20), specificity of 99.16 (95% CI 99.12-99.20), accuracy of 98.36 (95% CI 98.31-98.42), balanced accuracy of 65.23 (95% CI 64.31-66.17), F_1-score of 30.85 (95% CI 29.25-32.51), and AUPRC of 32.14 (95% CI 30.34-33.95). Other models exhibited the following AUROC scores: random forest at 81.45 (95% CI 80.51-82.37), LightGBM at 80.35 (95% CI 79.35-81.33), AdaBoost at 80.32 (95% CI 79.29-81.31), CatBoost at 77.84 (95% CI 76.84-78.84), and Logistic 77.38 (95% CI 76.39-78.40). Precision scores were as follows: LightGBM at 35.58 (95% CI 33.63-37.58), AdaBoost at 8.94 (95% CI 8.43-9.45), random forest at 4.61 (95% CI 4.39-4.83), Logistic at 3.07 (95% CI 2.92-3.21), and CatBoost at 2.34 (95% CI 2.23-2.44).

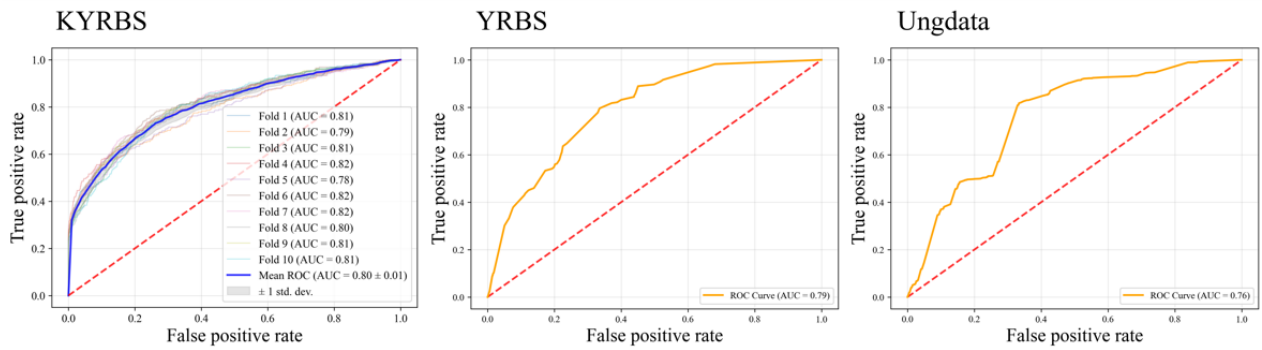

Figure 2. Model architecture. The original KYRBS was partitioned into the original data set for model development, with performance assessed using the AUROC score. Selected high-performing models were further validated. The external validations were generated using YRBS and Ungdata. AUROC: area under the receiver operating characteristic curve; KYRBS: Korea Youth Risk Behavior Web-Based Survey; YRBS: Youth Risk Behavior Survey.

For the initial external validation, the independent YRBS dataset was used. The XGBoost displayed an AUROC score of 79.30%, followed by a precision of 68.37%, sensitivity of 77.77%, specificity of 67%, accuracy of 72.15%, and balanced accuracy of 72.38%, F_1-score of 72.77%, and AUPRC of 74.79%. In the subsequent external validation using the Ung dataset, the XGBoost model yielded an AUROC score of 76.39%, coupled with a precision of 12.74%, sensitivity of 83.02%, specificity of 63.93%, accuracy of 64.34%, balanced accuracy of 73.48%, F_1-score of 2.18, and AUPRC of 7.25 (Figure 3).

Figure 3. The assessment of five different machine learning algorithms using AUROC score and ROC curve for initial model construction with the KYRBS, and external validation with the YRBS and Ungdata. AUROC: area under the receiver operating characteristic curve; KYRBS: Korea Youth Risk Behavior Web-Based Survey; LightGBM: light gradient boosting model; ROC: receiver operating characteristic; XGBoost: extreme Gradient Boosting model; YRBS: Youth Risk Behavior Survey.

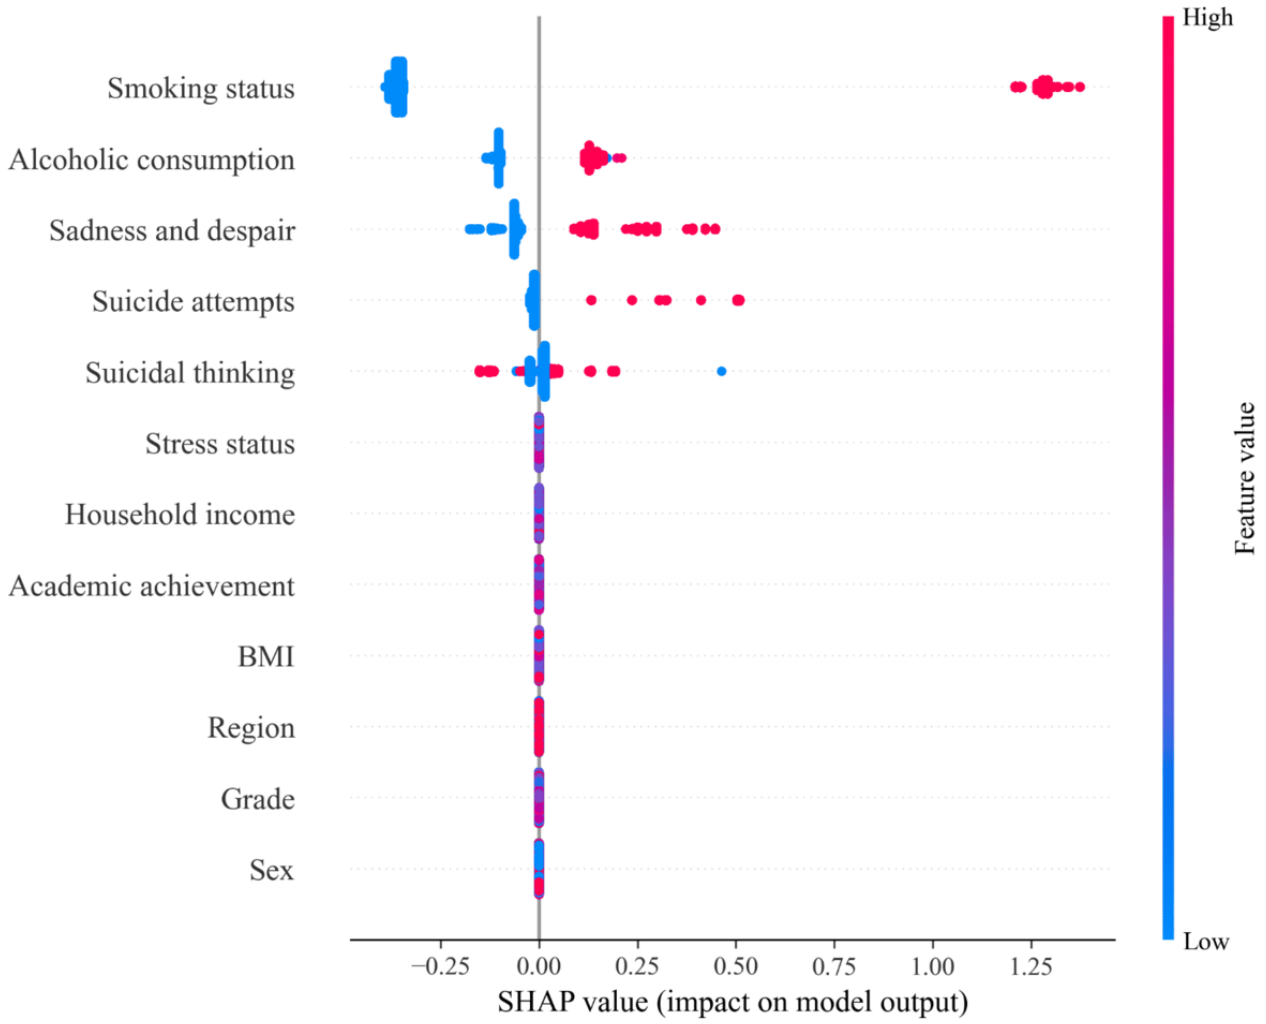
XSL•FO
RenderX

Across all evaluations, both internal and external, the XGBoost model consistently exhibited a predominant performance, particularly in terms of the AUROC score and precision, cementing its adoption for the study objective.

Feature Importance

Table 2 illustrates the importance of various features as determined by the XGBoost model in predicting substance use among adolescents. Specifically, smoking status was identified as the most significant predictor, accounting for 16.62% importance. This was closely followed by BMI with 13.45%, and suicidal thinking at 12.58%. Other notable features include suicide attempts (9.88%), grade (9.83%), stress status (8.99%), academic achievement (7.51%), household income (7.45%), sadness and despair (6.84%), alcoholic consumption (3.78%), sex (2.76%), and region (0.32%).

Table 2. Feature importance of the XGBoost model.



Feature	Importance (%)
Smoking status	16.62
BMI	13.45
Suicidal thinking	12.58
Suicide attempts	9.88
Grade	9.83
Stress status	8.99
Academic achievement	7.51
Household income	7.45
Sadness and despair	6.84
Alcoholic consumption	3.78
Sex	2.76
Region	0.32

SHAP Values

Figure 4 presents the SHAP analysis results for the substance use prediction model, illustrating the contribution of each variable to predicting the likelihood of substance use [25]. The analysis identified smoking status as the most influential variable, with higher smoking levels strongly associated with an increased likelihood of substance use. Similarly, alcoholic consumption and sadness and despair were identified as key factors; alcohol consumption consistently increased the likelihood of substance use, while emotional states such as sadness exhibited both positive and negative effects depending on their levels.

XSL•FO
RenderX

Figure 4. SHAP value of the XGBoost model. SHAP: SHapley Additive exPlanation.

Suicidal thinking and suicide attempts also showed distinct and significant impacts, with higher values substantially increasing the likelihood of substance use. In contrast, variables such as BMI, grade, and sex had relatively minimal contributions, indicating that the model is more sensitive to psychological and behavioral factors than to demographic characteristics. These findings offer critical insights into the primary predictors of substance use and their complex interactions.

Code Availability

Based on the results of the ML model, we established a web-based application for policy implementation or health system management to support their decision-making process for cases involving substance use in adolescents [27]. An example of a web interface and the results are shown in Figure S2 in Multimedia Appendix 1. Custom code for the website is available on the web [28].

Discussion

Key Findings

This study stands out as one of the first comprehensive ML-based approaches to predict adolescent substance use on an international scale. One of our critical insights revolves around the influence of cultural diversity on substance use, drawing datasets from South Korea, the United States, and Norway [21]. Moreover, the outcome revealed that the XGBoost model proves to be commendable. It displayed predictive capabilities with an AUROC score of 80.61% (95% CI 79.63-81.59) and a precision of 30.42% (95% CI 28.65-32.16) in the discovery dataset. Our model consistently exhibited robust performance across external validation sets, achieving AUROC scores of 79.30% and 76.39% and precision of 68.37% and 12.74 in each respective dataset. Upon closer inspection, we discerned pivotal features influencing adolescent substance use predictions. Smoking status emerged as the predominant predictor for substance use, followed by BMI and suicidal thinking. Furthermore, the SHAP value analysis confirmed smoking status as a critical variable, with alcoholic consumption and sadness and despair identified as additional influential factors. To apply our findings to real-world scenarios, we devised a cutting-edge web-based platform. We believe that this tool will serve as an insightful methodology for the public to navigate potential substance-related challenges.

Plausible Mechanism

The influence of smoking status and alcohol consumption on adolescent substance use is noteworthy and warrants consideration. Neurobiological evidence indicates that nicotine, especially when introduced during formative years, can alter

XSL•FO
RenderX

the brain reward pathways, making other substances more appealing [29]. Similarly, alcohol can modify neurotransmitter levels during these formative years, making the brain more susceptible to effects from other substances [30,31]. Smoking and drinking during adolescence often signal risk-taking behaviors [32], leading to further experimentation with other substances.

Both smoking and alcoholic consumption align closely with societal expectations and peer pressures. Societal dynamics and peer interactions, which may normalize or even perceive smoking and drinking as socially acceptable, could act as influential factors in encouraging adolescents to engage in these behaviors [33,34]. In many cultures, both behaviors are viewed as rites of passage that expose adolescents to other available illicit substances [35].

Psychological factors also play a role. Many adolescents resort to smoking or drinking as coping mechanisms for stress or emotional turmoil [36,37]. These initial coping behaviors may prompt adolescents to seek stronger stimuli for more intense experiences, potentially resulting in substance addiction or misuse [38].

This study further emphasized the relationship between BMI and substance use, as another predictor of adolescent substance use. From a physiological perspective, substances can modulate metabolic rates and appetite. Adolescents engaged in substance use might experience weight changes, either due to the direct effects of the substance or inconsistent dietary habits [39]. Additionally, the role of BMI extends beyond mere physiological changes. Adolescents with “nonstandard” BMIs often face societal challenges such as weight-centric bullying and entrenched societal ideals regarding body standards. The prevailing societal standards of an ideal body may influence some adolescents toward substance use, either as a means to conform to societal expectations or to address the associated mental distress [40].

Another noteworthy observation was the understated importance of academic achievement and stress status. Although stress is traditionally considered influential in adolescent behaviors [41,42], its limited representation in this study may be attributed to data constraints. These variables were absent in our extravalidation dataset, and we resorted to imputing these values using the median from our primary training cohort. This modification might have contributed to its reduced importance in our results.

Clinical and Policy Implications

The results of this study offer significant insights into both clinical and political implications. We underscore the vital role of factors such as smoking status, BMI, and alcoholic consumption in predicting substance use among adolescents. These critical determinants enable clinicians to identify and monitor at-risk adolescents more effectively, assisting in their decision-making process [43]. Following further refinement, this model has potential commercial viability [44], especially when combined with a streamlined self-report questionnaire. The existence of multiple models assessing substance use further attests to the commercial potential of our model [45]. Emphasizing characteristics predictive of substance use is essential, suggesting the need for systems to alert parents about potential risks their children might face. Since parental intervention has proven to be effective in preventing adolescent substance use [46], establishing an early detection system becomes paramount.

Strengths and Limitations

Findings from this study must be interpreted in light of several limitations. The external validation datasets contained numerous missing values, which could have impacted the predictive accuracy of the model. Specifically, we were unable to find corresponding data for variables like BMI (due to the absence of height and weight) and academic achievement in external cohorts such as Ungdata. Moreover, stress status, suicidal thinking, and suicide attempts were also missing or unmatched in datasets like YRBS and Ungdata, leading to gaps in these key areas. To address this gap, we applied imputation methods, including median imputation based on the KYRBS dataset for entirely missing variables [47]. While this approach mitigated the issue of missing data, it may have introduced biases, highlighting the need for more harmonized and comprehensive data collection protocols in future studies to enhance model generalizability and robustness. Additionally, this study used a discovery dataset derived from adolescents in South Korea. This biased discovery dataset could unexpectedly reflect the specific racial and cultural features unique to Korean adolescents. While our model underwent external validation from a diverse cultural and demographical landscape, we also acknowledge that it may reduce sample diversity and potentially cause overfitting issues [48]. Furthermore, this study did not pinpoint a definitive causal link between the significant risk factors and adolescent substance use. In other words, it remains unclear whether substance use influences other factors or if those factors stimulate substance use. Thus, further comprehensive studies are needed to elucidate this intricate cause-and-effect relationship. Another limitation of our study is the potential variability in feature importance rankings across different ML algorithms. Different algorithms may prioritize predictors differently due to their inherent characteristics and methods of handling data. This variability suggests that the identified predictors, such as smoking status, BMI, and alcohol consumption, should not be generalized as the sole determinants of adolescent substance use. Instead, these results should be interpreted with caution, and further studies are needed to validate the findings across diverse models and datasets. Finally, this study identifies factors associated with current and past substance use rather than explicitly predicting future trends. While the model provides valuable insights into risk factors and enables early intervention strategies, its predictive performance may be limited by the imbalanced nature of the dataset and the lack of longitudinal data. Future studies should address these limitations by incorporating balanced datasets and temporal data to enhance predictive accuracy and generalizability.

Despite these limitations, this study offers significant contributions. By using extensive datasets from South Korea, the United States, and Norway, our ML model boasts enhanced prediction accuracy, highlighting its global relevance and robustness [49]. Our strategic phased validation approach,

XSL•FO
RenderX

beginning with the YRBS and progressing to the distinct Ungdata from Norway, underlines the model's versatility across diverse sociocultural backgrounds. This phased validation not only ensures consistent model evaluation but also establishes its capability in different cultural contexts [45,50,51]. Moreover, the features incorporated into the model are derived from simple questionnaires. The primary advantage of our model-based platform is its exceptional accessibility, allowing users to gather insights through straightforward surveys. This ease enables swift evaluations and widens its scope of use, equipping both clinicians and individuals with valuable insights conveniently. Our findings provide the relative importance of numerous factors. These results can guide the decision-making process by identifying key areas for the prevention of substance use among adolescents.

Conclusions

This study introduced an ML model using data from three distinct national cohorts to predict adolescent substance use. Among six unique predictive models, the XGBoost model consistently revealed a notable performance (AUROC: KYRBS, 80.61% [discovery]; YRBS, 79.30% [extravalidation]; and Ungdata, 76.39% [extravalidation], and precision: KYRBS, 30.42% [discovery]; YRBS, 68.37% [extravalidation]; and Ungdata, 12.74% [extravalidation]). Feature importance analysis identified smoking status, BMI, and suicidal thinking as significant contributors to the risk of substance use. Further insights into the influence of these variables were derived from SHAP value analysis, which identified smoking status, alcoholic consumption, and sadness and despair as the most impactful factors, in that order. The findings of this study indicate the potential of ML-driven predictive models to swiftly predict the likelihood of substance use among adolescents using a simplistic survey. It is anticipated that with further refinement and development, these models could be broadly used as efficient tools for preventing adolescent substance use.

Abstract

Background: Virtual patients (VPs) are computer-based simulations of clinical scenarios used in health professions education to address various learning outcomes, including clinical reasoning (CR). CR is a crucial skill for health care practitioners, and its inadequacy can compromise patient safety. Recent advancements in large language models (LLMs) and social robots have introduced new possibilities for enhancing VP interactivity and realism. However, their application in VP simulations has been limited, and no studies have investigated the effectiveness of combining LLMs with social robots for CR training.

Objective: The aim of the study is to explore the potential added value of a social robotic VP platform combined with an LLM compared to a conventional computer-based VP modality for CR training of medical students.

Methods: A Swedish explorative proof-of-concept study was conducted between May and July 2023, combining quantitative and qualitative methodology. In total, 15 medical students from Karolinska Institutet and an international exchange program completed a VP case in a social robotic platform and a computer-based semilinear platform. Students' self-perceived VP experience focusing on CR training was assessed using a previously developed index, and paired 2-tailed *t* test was used to compare mean scores (scales from 1 to 5) between the platforms. Moreover, in-depth interviews were conducted with 8 medical students.

Results: The social robotic platform was perceived as more authentic (mean 4.5, SD 0.7 vs mean 3.9, SD 0.5; odds ratio [OR] 2.9, 95% CI 0.0-1.0; *P*=.04) and provided a beneficial overall learning effect (mean 4.4, SD 0.6 versus mean 4.1, SD 0.6; OR 3.7, 95% CI 0.1-0.5; *P*=.01) compared with the computer-based platform. Qualitative analysis revealed 4 themes, wherein students experienced the social robot as superior to the computer-based platform in training CR, communication, and emotional skills. Limitations related to technical and user-related aspects were identified, and suggestions for improvements included enhanced facial expressions and VP cases simulating multiple personalities.

Conclusions: A social robotic platform enhanced by an LLM may provide an authentic and engaging learning experience for medical students in the context of VP simulations for training CR. Beyond its limitations, several aspects of potential improvement

XSL•FO
RenderX

were identified for the social robotic platform, lending promise for this technology as a means toward the attainment of learning outcomes within medical education curricula.

Introduction

Virtual patients (VPs) are computed interactive simulations of clinical scenarios for educational or learning purposes [1]. These tools are used to address several learning outcomes in health professions education (HPE) curricula [2]. VP platforms can be designed in a linear fashion, where medical information and treatment options are gathered in a fixed order without consequences, or with a branched design, where interactions also impact the outcome of the case [3]. VPs have been proposed as an effective educational tool for practicing clinical reasoning (CR) in undergraduate medical education [4] while also ensuring that medical students encounter representative patient cases, which might not always be possible to encounter during clinical rotations [5-7]. CR is an essential skill for health care practitioners, and its inadequacy may threaten patient safety, making it a key goal in HPE [8-10]. An essential aspect of VP simulation is the interface, which allows the user to interact with the VP in multiple ways. A common feature of VP platforms is that they can facilitate the obtainment of medical history, the conduct of physical examinations, and referral for laboratory tests and the provision of their findings to culminate in a reasonable diagnosis and management plan [11].

Previous research shows that medical students perceive VP simulation as a satisfactory educational activity for training CR while they acknowledge the lack of complexity and level of interactivity compared with authentic patient encounters [12]. Interestingly, students have been shown to perform better at examinations after exposure to VP simulations compared to other educational activities with similar learning outcomes, but the positive effect of VPs on CR training is still unclear [2,13].

Recent technological developments have enabled the integration of dialogue systems with natural language processing capabilities, embodied conversational agents [14], and social robots [15] to enhance the interactivity and realism of VP interactions. The emergence of large language models (LLMs) and their application in dialogue systems and social robots have introduced novel possibilities within this field [16,17]. However, their use for VPs has been limited to preliminary endeavors [18-21]. To the best of our knowledge, no prior studies have used LLMs in conjunction with a social robot for VP simulation and evaluated their effectiveness in facilitating CR training.

We hypothesized that the integration of an LLM in a social robotic modality for the presentation of VPs would involve several advantages. More specifically, we hypothesized that the physical presence of a social robot, combined with its nonverbal communication capabilities, would enhance engagement and immersion in the learning experience. This integration of visual and social cues, along with advanced verbal interactions, could facilitate a more comprehensive information-gathering process during the VP encounter until a diagnosis has been made and a management plan has been proposed compared with using only LLMs for VP presentation or conventional computer-based platforms.

While VPs can be valuable across many medical disciplines, this study focuses on their application in rheumatology education. Rheumatic diseases affect a substantial proportion of the population and are considered a significant public health concern [22-24]. These conditions often present complex diagnostic challenges that make them particularly suitable for CR training through VP simulations. To ensure that patients with rheumatic diseases receive appropriate care, it is crucial to provide evidence-based training in CR for medical students [25]. The aim of this study was to explore the potential added value of and potential limitations with a social robot combined with an LLM in comparison to a conventional, computer-based, semilinear VP platform presenting rheumatic conditions for medical students' CR training.

Methods

An interventional, explorative, proof-of-concept study was conducted between May and July 2023. We combined quantitative and qualitative methodology to assess medical students' self-perceived CR training using a previously developed index for VP design evaluation [26] as well as in-depth interviews.

Participants

In total, 15 medical students from Karolinska Institutet (KI) were recruited in the study either from a 5-week elective course for third-year students or a 4-week exchange program for international students, both pertaining to inflammation within internal medicine, including rheumatology, gastroenterology, dermatology, nephrology, and infectious diseases. All students had completed the sixth term of their medical education. More specifically, prior to the course, students from KI had completed 2 full years of preclinical medical education (eg, anatomy, physiology, and pathophysiology) and 1 year of clinical rotations in internal medicine. International students had also completed the preclinical phase of their medical education and had varying clinical backgrounds, with at least 1 full year of clinical rotations in internal medicine. While all students had prior experience with patient encounters and were fluent in English, none were native English speakers, and their previous experience of communicating with patients in English varied. In total, 8 students also agreed to participate in in-depth interviews, scrutinizing their experience with the social robotic platform

XSL•FO
RenderX

compared with the conventional computer-based VP platform with regard to CR training.

Ethical Considerations

The study protocol was reviewed and approved by the Swedish Ethical Review Authority (registration 2022-04437-01). Written informed consent was obtained from all study participants prior to enrollment. Participants had the ability to opt out at any time. All data were deidentified prior to analysis. No compensation was provided for participation in this study.

Development and Implementation of VP Cases

A VP case illustrating a common rheumatic disease (ie, polymyalgia rheumatica) was developed for presentation in a social robotic platform from Furhat robotics [27] and a conventional semilinear computer-based platform (ie, the virtual interactive case simulator [VIC]) [28]. The case development in both platforms adhered to distinct principles for VP case development proposed by Posel et al [29].

First, we identified the content of the VP case and selected the design. Between a linear and an explorative design, we anticipated advantages in using an explorative design, as it more closely resembles real-life clinical situations. We then organized the VP content by clarifying the purpose of each step within the VP cases. Next, we tailored the delivery of the VP case by adjusting the level of difficulty to align with the medical students' prior knowledge of rheumatic diseases. The VP cases were continuously evaluated through feedback from students and peers before, during, and after development. Integrity and confidentiality were maintained by creating typical case scenarios without using any information from real patients.

The students were tasked to perform the VP case individually in both platforms to facilitate paired comparisons. The case was considered within a particular situational context to be a primary care encounter. The students were assigned the role of an attending physician. The case was completed when the students had obtained sufficient information to make a diagnosis and suggest a management plan for the patient.

After interaction with each VP platform, students immediately filled out a questionnaire evaluating the VP design with an emphasis on CR training and provided optional free-text evaluation within seven themes: (1) authenticity of patient encounter, (2) professional approach in the consultation, (3) coaching during consultation, (4) learning effect of consultation, (5) overall judgment of case work-up, (6) special strengths of the case, and (7) special weaknesses of the case [26]. The questionnaire consisted of 14 questions, of which the first 12 questions (corresponding to themes 1 to 5) were graded using a 5-point scale, where 1=strong disagreement and 5=strong agreement, whereas responses to the last 2 questions (corresponding to themes 6 and 7) were only provided in the form of free text. This questionnaire was specifically developed for evaluating the design of VP platforms with an emphasis on CR training. Its development combined a theoretical framework for CR training along with the involvement of an international team of VP experts, supporting its content validity [26]. The questionnaire is provided in Figure S1 in Multimedia Appendix 1.

Social Robotic Platform

The social robot serving as the embodiment for the novel VP platform features an animated face back-projected onto a translucent mask and a neck with 3 degrees of freedom, allowing for natural head movements. The social robot consists of a built-in speaker to convey dialogue and a microphone to perceive spoken phrases that are later interpreted using a speech-to-text synthesis. Moreover, the social robot uses computer vision to track multiple users in real time, performing facial expression analysis, head pose estimation, and user distance measurement. It includes a face detection system, multiuser tracking, depth estimation, spatial modeling, and a deep neural network–based face recognition for tracking users over time [27]. The animated face expresses subtle emotions through facial expressions and gaze behavior, crucial for conveying a patient's internal state [30].

The platform combines the robot-steering software development kit FurhatSDK [27] and the LLM OpenAI's GPT-3.5-turbo chat completion model [31]. To maintain authenticity and avoid responses sounding like an assistant, we used a single user message containing the required information to generate a VP response. This prompt included a patient case description, the last 10 dialogue turns, and instructions to generate the next dialogue line. A shortened example of a prompt is provided in Figure S2 in Multimedia Appendix 1.

We also used the LLM to generate facial expressions, essential for reflecting the patient's emotional states during interactions, similar to the methods described by Irfan et al [16]. At the beginning of each utterance, anchor points were inserted at phrase boundaries within the text. The LLM was next prompted to incorporate suitable facial expressions at each anchor point, selecting from the FurhatSDK's available expressions, for example, sad, happy, or surprised facial expressions, illustrating a variety of nonverbal expressions adapted to the context of the conversation.

The LLM calls for generating dialogue responses and facial expressions were separate. First, the dialogue response was generated, and the response was translated using a text-to-speech synthesis. While the response was being synthesized, a second call was made to the LLM to generate the list of facial expressions related to each anchor point. While the robot was speaking, the system kept track of when each word had been spoken, so that the relevant facial expression could be projected.

Using LLMs can cause response delays, complicating turn-taking, as users might not realize that the robot is generating a reply [16]. This issue is worsened when there is no provision for barge-in. To address this, various approaches can be adopted, such as the use of a turn-holding cue to indicate that the robot is actively "thinking" about a response [32]. We adopted a gaze aversion technique [33] combined with LED lights at the base of the robot to communicate its turn-taking status, indicating whether it is speaking or listening.

Virtual Interactive Case Simulator

In VIC, a semilinear approach is used, ensuring a consistent beginning and end for each case while allowing users to explore the case environment in their preferred order [3]. Every case

XSL•FO
RenderX

starts with a brief patient summary and finishes with a diagnostic verdict and management approach, presented in a multiple-choice structure. This interface allows the user to investigate, for example, the patient's medical history, administer a physical examination, and retrieve laboratory test results. Interaction with this platform is facilitated entirely using prewritten clickable options, with no reliance on natural language processing methodologies.

Interviews

We carried out one-on-one, semistructured interviews with medical students following the completion of the VP case sessions using both platforms. This was performed on the same day, immediately after having completed the VP cases in both platforms. We developed an interview guide that consisted of questions concerning the participants' experiences with the VP platforms as tools for learning and CR training as well as their views on potential applications and integration of these platforms within medical curricula. The interview guide is provided in Figure S3 in Multimedia Appendix 1.

Interviews were held at Karolinska University Hospital during clinical placements as described earlier and lasted from 20 to 30 minutes each. The interview data were stored in dedicated spaces at the Department of Medicine Solna, KI. The recorded audio files were transcribed verbatim, and the transcripts were pseudonymized, ensuring the removal of any sensitive or personal identifiable information.

Analysis

To compare responses to the quantitative part of the questionnaire (themes 1 to 5) relating to the robotic platform versus VIC, the paired 2-tailed *t* test was used to compare mean scores between the platforms. This analysis included both separate questions and summary scores within themes. Results from paired 2-tailed *t* tests are presented as the mean score (SD), 95% CI, odds ratio (OR), and *P* value. The statistical analysis was performed using the R statistical software (version 4.2.1; R Foundation for Statistical Computing). Differences generating *P* values <.05 were considered statistically significant.

Interview data were analyzed systematically for the identification of key themes. The thematic analysis was carried out following the approach described by Braun and Clarke [34]. First, the verbatim transcripts of the interviews were reviewed multiple times to ensure familiarity with the content. The interviews were analyzed individually as a first step, and then horizontally, that is, across interviews. International recommendations for integrating CR training into HPE curricula [10] were used as a guideline when coding words and phrases related to CR training. This coding process was iterative, with the researchers collaborating to identify, interpret, and refine the codes until the final themes emerged. The initial stages of the analysis and theme development were undertaken by 2 investigators (AB and BJ), while a third investigator (IP) supervised the process and contributed to the final selection of the themes.

All authors contributed to the interpretation of the results, bringing diverse perspectives to the analysis. AB was at the time of writing a medical intern and PhD student within medical pedagogy, CG was a nurse specialized in intensive care, BJ was a medical student during the fourth year of the KI medical program, VH was a resident physician in rheumatology, KW was a consultant rheumatologist, MR was a consultant endocrinologist, SE was a senior lecturer and associate professor in medical pedagogy, GS was a professor in speech technology, one of the founders of the social robot used in the project, and chief scientist at Furhat Robotics. IP was a senior consultant rheumatologist, associate professor of rheumatology, and educator within the KI medical program. This multidisciplinary team contributed complemental approaches and views during different stages of the analysis, substantially enhancing the overall interpretation of the data.

Results

Questionnaire

In total, 6 (40%) of the 15 medical students were women, and 9 (60%) were men. A total of 11 (73%) students declared no previous experience with VP platforms. The mean age of the students was 23.9 (SD 4.8) years. Response frequencies to all quantitative themes (1 to 5) are provided in Tables S1-S5 in Multimedia Appendix 2.

The students perceived the social robotic platform as more authentic compared with VIC with regard to decision-making (mean 4.4, SD 0.6 vs mean 3.9, SD 0.9; OR 3.2, 95% CI 0.1-1.2; *P*=.03) as well as beneficial regarding the preparation of taking care of a real-life patient with the same complaint (mean 4.4, SD 0.6 vs mean 4.0, SD 0.7; OR 4.2, 95% CI 0.1-0.7; *P*=.009). We documented a numerical difference in favor of the social robotic platform with regard to the appropriateness of the VP case's level of difficulty (mean 4.7, SD 0.5 vs mean 4.3, SD 1.0; OR 2.4, 95% CI –0.1 to 0.9; *P*=.08); however, this difference did not reach statistical significance. Detailed results are shown in Table 1 and Figure 1.

Figure 1. Violin plots illustrating distributions of scores from students' responses to questions within quantitative themes (1 to 5) with regard to the social robotic platform versus VIC. Lines within violin plots denote median values and IQRs. Numbers at the bottom of the plots refer to mean values. Statistically significant *P* values are in italics format. Q: question; VIC: virtual interactive case simulator.

Summary scores within themes demonstrated superiority of the social robotic platform compared with VIC both regarding authenticity (mean 4.5, SD 0.7 vs mean 3.9, SD 0.5; OR 2.9, 95% CI 0.0-1.0; *P*=.04) and learning effect of the consultation by feeling more prepared to care for a real-life patient with a similar complaint (mean 4.4, SD 0.6 vs mean 4.1, SD 0.6; OR 3.7, 95% CI 0.1-0.5; *P*=.01), as illustrated in Figure 2 and Table 2.

Open-ended themes (6 and 7) highlighted the special strengths and limitations with both platforms. Students perceived the social robotic platform as a good way to simulating realistic patient conversations and providing an interactive and engaging experience. Limitations of the social robot included the lack of laboratory results and the lack of modality for training physical examination, as well as that conversations sometimes felt mechanical due to their turn-based structure and due to the fact that students were interrupted by the robot if their verbal pause was too long since this pause was perceived as the end of turn.

By contrast, students perceived the VPs presented through VIC as a good tool for structured learning and revision of the case. VIC provided useful feedback and information regarding various clinical investigations. However, the fixed question format in VIC was a limiting factor, as was the lack of the possibility to ask the VP follow-up questions. Some students noted that VIC did not provide a feeling that resembled a real patient encounter to the same extent as the social robot. Detailed responses are shown in Tables S6 and S7 in Multimedia Appendix 2.

Interviews

Overview

A total of 8 medical students participated in in-depth interviews. In total, 5 (63%) students were women, and 3 (37%) students were men. The students' mean age was 21.5 (SD 1.9) years. Thematic analysis resulted in four themes: (1) realism and immersion, (2) skill acquisition and development, (3) procedural limitations, and (4) potential for improvement (Table S8 in Multimedia Appendix 2).

Realism and Immersion

The theme "realism and immersion" was divided into two subthemes: (1) authenticity and (2) interactivity and engagement. Students perceived the experience with the LLM-empowered robotic platform as a realistic and authentic patient encounter, outperforming the computer-based platform in these aspects. Within the subtheme "authenticity," students described that the realistic impression conferred from the social robotic platform made them feel like being the treating physician in a real-life scenario, with responsibilities toward the presented patient. Relevant quotes are presented in Textbox 1.

XSL•FO
RenderX

Textbox 1. Relevant quotes by theme "realism and immersion" and subthemes from in-depth interviews.

Subtheme: authenticity

- "It felt close, like if I were with a real patient" [Male student, 22 years].
- "[...] you are asking the questions and in real time there is a response, and it is like a real conversation. [...] I definitely felt like the treating physician with the robot, knowing that it is up to me to ask the questions and to take in what the patient is saying" [Female student, 22 years].
- "Because the patient was expressing how he was in pain, and how, you know, the pain was bothering him. [...] So yeah, it felt quite intimate at that time. And it felt like I was a physician taking care of a patient" [Male student, 25 years].

Subtheme: interactivity and engagement

- "The robot is more interactive compared to the computer. The computer [...] is of course very helpful. But with the robot, it is more fun because you see this robot talking to you and answering your questions in real time" [Female student, 20 years].
- "[...] the computer platform is more passive. You don't have to be so productive" [Male student, 25 years].
- "I think the computer-clicking, the computer platform, is less demanding. I would say it is on a lower level of interactivity than the robot" [Male student, 22 years].

The social robotic platform facilitated a highly interactive and engaging experience, which was described to be superior to VIC. Within the subtheme "interactivity and engagement," students expressed that the robot required active participation, which was experienced as more engaging and immersive than passively clicking through the computer-based case. The face projection of the robot added to the feeling of interactivity (Textbox 1).

Skill Acquisition and Development

The theme "skill acquisition and development" consisted of three subthemes: (1) CR skills, (2) communication skills, and (3) emotional skills. Within the subtheme "CR skills," students perceived the robot as an effective tool for acquirement of CR skills by engaging in an active dialogue, practicing the obtainment of medical history, reasoning across different explorative approaches, and planning for various treatment strategies. Students believed that this was due to them actively having to think about the patient's symptoms and ask relevant questions based on the responses they were given. They acknowledged that the computer-based case was more informative, but in the latter, they lacked the ability to ask follow-up questions, which was possible with the LLM-empowered social robot (Textbox 2).

Students experienced that the robotic platform helped them practice "communication skills," especially by facilitating active communication, engaging them in thinking about which questions to ask and how to phrase them in real time (Textbox 2). While the social robotic platform allowed students to feel closer to VPs compared with the computer-based platform, students perceived that the practice of "emotional skills," such as empathy, was inferior with both platforms compared to real-life patient encounters (Textbox 2).

Textbox 2. Relevant quotes by theme "skill acquisition and development" and subthemes from in-depth interviews.

Subtheme: clinical reasoning skills

- "To direct your questions. Patients often come with something very diffuse, like pain. And then you have to think, 'pain, duration, onset [...]' to quickly orient yourself in the patient's problem and then direct your questions afterwards. It's a great tool for practicing that" [Male student, 25 years].
- "The computer case, I would say, is very comprehensive. It gave us the data on pretty much everything, the lab tests, the patient's history. It has data on everything" [Female student, 20 years].
- "I remember asking 'does it get better with a certain medication?' or 'how long does it last?,' 'when was the last time you had it?' [...] And I felt like that's something I couldn't have found in the computer-based case. It didn't give me that information" [Female student, 21 years].

Subtheme: communication skills

- "With the robot, I felt I got to use my skills of how to speak to a patient. [...] you really have to use your medical knowledge to ask [the right] questions and get answers" [Female student, 21 years].

Subtheme: emotional skills

- "Because you have to not only ask about the medical stuff, but also you have to have a dialogue [...] as you do with a human being. So, yeah, you feel closer [to the patient] with the robot compared with the computer" [Female student, 22 years].
- "[...] Just like having that [...] empathy or when you're just talking to a human, looking them into the eyes and saying, 'oh, I'm very sorry for you that you have had these headaches.' You don't really see the pain in someone through a robot" [Female student, 21 years].
- "Maybe what it lacked is [...] emotions. Not like patients whom you need to reassure" [Female student, 19 years].

XSL•FO
RenderX

Procedural Limitations

The theme "procedural limitations" consisted of two subthemes: (1) technical limitations and (2) user-related challenges. Within the subtheme "technical limitations," students expressed technical problems such as being interrupted by the robot during conversational pauses that were conceived as the end of a spoken sentence. This resulted in the perception of a time constraint while responding to the platform, which sometimes hindered the flow of the interaction (Textbox 3). The subtheme "user-related challenges" sheds light on challenges relating to language barriers as well as a need for adapting to the conversational style of the social robot (Textbox 3).

Textbox 3. Relevant quotes by theme "procedural limitations" and subthemes from in-depth interviews.

Subtheme: technical limitations

- "Well, you have a time when you can talk and another time when you can't talk. Apart from the clinical reasoning, you have to pay attention to when [you should talk]. It can be disturbing" [Male student, 22 years].
- "[...] you have to complete your sentence, or else it might cut you off in the middle and start giving you responses" [Female student, 22 years].

Subtheme: user-related challenges

- "It was a bit difficult. Partly because you're not used to speaking English with patients. But also because of how [the robot's] artificial pauses could disturb" [Female student, 23 years].
- "I guess for some people, who are limited by [...] language barriers in English, it might be difficult for them" [Female student, 20 years].

Potential for Improvement

Within the theme "potential for improvement," students expressed how specific technological aspects could be improved in the social robotic platform. Students envisioned the potential of more realistic facial expressions and a multitude of patient personalities, which both could enhance the degree of interactivity and perception of realism, presumably contributing to increased engagement and increased chance of achieving the intended learning outcomes. This potential was limited to the social robotic platform (Textbox 4).

Textbox 4. Relevant quotes by theme "potential for improvement" from in-depth interviews.

- "Maybe [improvements] on the face. To work with the voice. And to broaden the responses. So that it might be more complex" [Male student, 20 years].
- "Like in real life, all patients won't give you the same amount of information. So, I think it can be interesting, apart from [presenting] different diseases, also present different types of personalities" [Male student, 22 years].
- "[...] various personalities and patients who are not cooperative or might need many questions to receive certain responses need different ways of being handled; one patient is not another alike. I think you have to adapt to whichever type of patient you have in front of you" [Female student, 21 years].

Discussion

Principal Findings

We developed a novel social robotic VP platform in conjunction with an LLM and present herein results from a proof-of-concept study that explored the self-perceived usefulness and effectiveness of this new pedagogical modality for CR training of medical students compared with a conventional, computer-based, semilinear VP platform. The study included a quantitative comparison between the 2 platforms and qualitative in-depth interviews. Results indicated that VP exercise with the social robotic platform was perceived as more authentic and immersive as well as conferring a self-perceived benefit regarding the learning effect compared with the computer-based platform. Overall, students experienced that the social robot could promote training of CR, communication, and emotional skills. Students highlighted the limitations of the social robot relating to technical and user-related aspects and provided suggestions for potential improvements within the context of CR training.

Medical students perceived the social robotic platform as more authentic compared to the computer-based platform, as demonstrated by significantly higher scores in the authenticity theme of the questionnaire. The qualitative analysis of the interviews further supported these findings, with students describing the social robotic platform as providing a realistic and immersive experience that closely resembled a real patient encounter. These results are consistent with previous studies that highlight the role of interactivity and complexity within VP platforms in enhancing learning toward defined outcomes [3,12,35]. It was based on this premise that we designed and developed the social robotic VP platform for enhanced interactivity, integrating an LLM for enhanced complexity.

The quantitative analysis revealed that students perceived the social robotic platform as preferable to the computer-based platform in terms of the learning effect of the consultation, particularly regarding the perceived transferability of skills to real-life clinical scenarios. The qualitative analysis of the interviews provided further insights into the specific skills that students believed they acquired through interaction with the robotic platform. Students reported that the robotic platform facilitated the development of CR skills by engaging them in

XSL•FO
RenderX

active dialogue, requiring them to think critically about the patient's symptoms, and allowing them to ask relevant follow-up questions. Additionally, students experienced that the robotic platform helped them practice communication skills by encouraging them to actively engage in conversation and think about how to phrase their questions, which has previously been highlighted as an important aspect for CR training using VPs [29].

The qualitative analysis of the interviews revealed several limitations and challenges associated with the social robotic platform. Students reported technical limitations, such as being interrupted by the robot during conversational pauses, which sometimes made the conversation feel mechanical and hindered the flow of the interaction. This could negatively affect the perceived authenticity of the social robotic platform, highlighting the need for technical improvements in this area as a priority for future development.

Students also reported the benefits of the computer-based platform compared with the social robot, noting it as more informative. Another advantage, though not directly compared in this study, is that the computer-based platform VIC is more accessible, as students can access these cases on their personal computers, whereas the social robot is only available when students are physically present with the modality.

User-related challenges, such as language barriers and the need to adapt to the conversational style of the robot, were also identified. These findings highlight the importance of addressing technical limitations and providing adequate support to users to ensure a smooth and effective learning experience. Despite these limitations, students also expressed that the social robot introduced potential for additional improvements that cannot be facilitated by a conventional computer-based platform, such as more realistic facial expressions and the incorporation of various patient personalities, which can be anticipated to further enhance interactivity and realism.

Limitations and Strengths

This study has several limitations. First, the sample size was small, which limits the generalizability of the findings. Second, the study was conducted in a single center, and the results may not be representative of the experience of medical students in other settings. Third, CR is a complex skill, and how its training is facilitated cannot be comprehensively assessed by a single questionnaire, whose validation may not encompass all its aspects. The questionnaire used in this study was specifically designed to evaluate VP design with a particular focus on CR, but it did not directly assess the acquisition of CR skills; this aspect was instead explored in the qualitative part of the study through in-depth interviews. Our study also has several strengths. The use of a mixed quantitative and qualitative methodological approach allowed for a comprehensive evaluation of students' perceptions and experiences with the VP platforms. Importantly, the study compared a novel social robotic platform in conjunction with an LLM, to our knowledge the first of its kind for medical pedagogy, with a conventional computer-based platform, providing valuable insights into the added value of social robots and artificial intelligence in VP simulations for CR training in HPE curricula.

Implications

Overall, the social robotic VP platform shows promise for enhancing CR training by bridging theoretical learning and clinical practice. Its heightened authenticity and interactivity bring it closer to real-life patient interactions, enabling medical students to practice CR in a realistic environment before engaging with actual patients. However, further evaluation and comparisons with other LLM-driven modalities are needed to assess the unique benefits of using a physical robot versus an LLM alone for VP simulation. Given current accessibility limitations, the platform may be most effective as part of a hybrid approach, combining traditional computer-based VPs for broader access with scheduled sessions using social robotic VPs to deepen skill development. This approach could optimize educational impact while managing practical resource constraints across various medical education settings.

Conclusions

This study demonstrates that a social robotic platform enhanced by an LLM could provide an authentic and engaging learning experience for medical students in the context of VP simulations for training CR. The social robotic platform was perceived as beneficial compared to a conventional computer-based platform in terms of authenticity and overall learning effect, and students reported that it facilitated training of CR, communication, and emotional skills. Despite the limitations and challenges identified, the potential for improvement in the social robotic platform lends promise for this technology in future medical education. Importantly, however, costs and logistics may constitute limitations for the implementation of this technology. Finally, it is worth noting that this was a proof-of-concept study, and further research with larger sample sizes and in diverse educational settings is warranted to fully understand the value of social robotic VPs in facilitating the attainment of learning outcomes within medical education curricula.

Acknowledgments

The authors would like to thank the medical students who participated in the study as well as the medical staff at the Division of Rheumatology at the Karolinska University Hospital, Stockholm, Sweden.

Data Availability

The data generated or analyzed during this study can be provided by the corresponding author upon reasonable request.

Authors' Contributions

AB, CG, MR, SE, GS, and IP conceived the study and designed the work. AB, BJ, VH, KW, and IP contributed to the acquisition of data. AB, BJ, GS, and IP contributed to the statistical analysis. AB, BJ, and IP contributed to the interpretation of the data. AB and IP wrote the original draft of the manuscript. All authors reviewed and approved the final version of the manuscript prior to submission and agreed to be accountable for all aspects of the work.

Conflicts of Interest

IP has received research funding or honoraria from Amgen, AstraZeneca, Aurinia, BMS, Elli Lilly, Gilead, GSK, Janssen, Novartis, Otsuka, and Roche. GS is a cofounder of and chief scientist at Furhat Robotics; due to this conflict of interest, GS was involved in the technical implementation of the social robotic VP platform but not the acquisition or interpretation of data. The other authors declare that they have no conflicts of interest.

Abstract

Background: Stroke treatment has significantly improved over the last decades, but the complexity of stroke cases requires specialized care through dedicated teams with specific knowledge and training. The National Institutes of Health Stroke Scale (NIHSS), widely used to assess neurological deficits and make treatment decisions, is reliable but requires specific training and certification. The traditional didactic training method, based on a video, may not adequately address certain NIHSS intricacies nor engage health care professionals (HCPs) in continuous learning, leading to suboptimal proficiency. In the context of time-constrained clinical settings, highly interactive e-learning could be a promising alternative for NIHSS knowledge acquisition and retention.

Objective: This study aimed to assess the efficacy of a highly interactive e-learning module compared with a traditional didactic video in improving NIHSS knowledge among previously trained HCPs. Furthermore, its impact on knowledge retention was also assessed.

Methods: A prospective, multicentric, triple-blind, and web-based randomized controlled trial was conducted in 3 Swiss university hospitals, involving HCPs previously trained in NIHSS. Invitations were sent through email, and participants were randomized to either the e-learning or traditional didactic video group through a fully automated process upon self-registration on the website. A 50-question quiz was administered before and after exposure to the training method, and scores were compared to assess knowledge acquisition. The quiz was repeated after 1 month to evaluate retention. Subjective assessments of learning methods that is, user satisfaction, probability of recommendation, perceived difficulty, and perception of duration, were also

XSL•FO
RenderX

collected through a Likert-scale questionnaire. A sample size of 72 participants were deemed necessary to have an 80% chance of detecting a difference of 2 points in the postcourse quiz between groups at the 5% significance level.

Results: Invitations to participate were sent through email to an estimated 325 HCPs. 174 HCPs enrolled in the study, of which 97 completed the study course. Both learning methods significantly improved NIHSS knowledge, with an improvement of 3.2 (range 2.0-4.3) points in the e-learning group and of 2.1 (1.2-3.1) points in the video group. However, the e-learning group performed better, with higher scores in knowledge acquisition (median score 39.0, IQR 36.0-41.0 vs 37, IQR 34.0-39.0; *P*=.03) and in knowledge retention (mean score 38.2, 95% CI 36.7-39.7 vs 35.8, 95% CI 34.8-36.8; *P*=.007). Participants in the e-learning group were more likely to recommend the learning method (77% vs 49%, *P*=.02), while no significant difference was found for satisfaction (*P*=.17), perceived duration (*P*=.17), and difficulty (*P*=.32).

Conclusions: A highly interactive e-learning module was found to be an effective asynchronous method for NIHSS knowledge acquisition and retention in previously NIHSS-trained HCPs, and may now be considered for inclusion in NIHSS training programs for HCPs.

Introduction

Background

Despite the decline in stroke incidence and mortality since 1990, the absolute number of stroke cases are increasing due to the steep growth in the global population, along with an aging demographic and a greater burden of risk factors across many parts of the world [1]. Hence, stroke remains a major public health issue due to its high morbidity rates [2]. Acute reperfusion therapies, such as intravenous thrombolysis and thrombectomy, improve functional and survival prognosis after stroke [3,4]. However, patients must be carefully screened and selected, and these procedures must be performed within a limited timeframe, due to risks and complications associated with the treatment [3].

The National Institutes of Health Stroke Scale (NIHSS) is widely used around the world to triage, select treatment strategies, monitor and follow-up stroke patients [3,5]. First described in the late 1980s, it gained popularity after the publication of the first successful acute stroke treatment study [5,6]. The reliability of the NIHSS has been demonstrated across diverse populations of health care professionals (HCPs) [7,8]. However, prior training and certification are required [9-14] as it is a complex scale with numerous subtleties. In Switzerland, national stroke center and stroke unit certification procedures specify that all personnel must be appropriately trained. In the French-speaking part of Switzerland, all HCPs working in stroke units should be familiar with NIHSS. However, the training program, usually comprised of formal teaching sessions with a senior neurologist and bedside clinical training, is non standardized and center-specific [15-17].

Constraints of working in these 24-hour acute care units, such as unexpected inflow of patients, and weekend and night shift patterns, can limit HCPs exposure to regular clinical training sessions. The absence of time constraints and the self-paced nature of asynchronous digital learning methods such as electronic learning (e-learning) modules have contributed to their popularity in medical education [18], and have been extensively used during the COVID-19 pandemic [19,20]. Hence, a highly interactive e-learning module was created to teach the NIHSS [21]. Its use has been shown to improve user satisfaction, knowledge acquisition as well as dissemination in NIHSS-naive populations, when compared with the traditional didactic video alone [22,23].

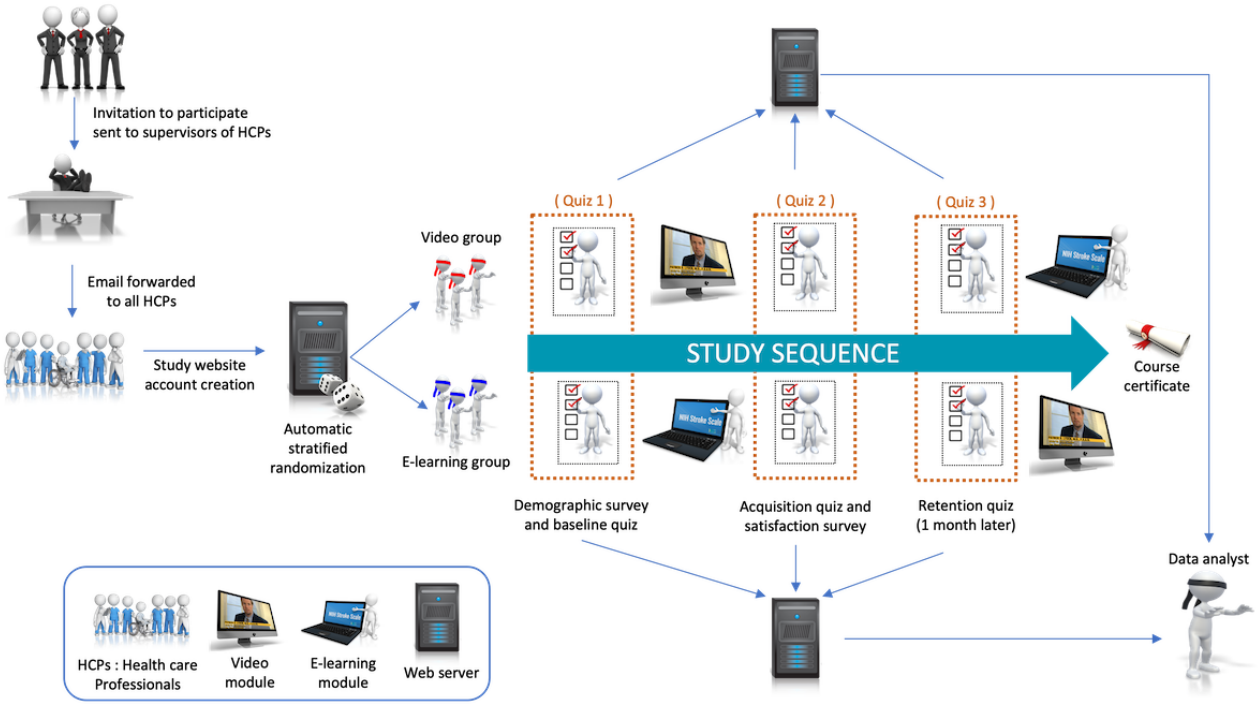
Despite widespread usage of the NIHSS, little literature exists on the actual performance of HCPs using it on a regular basis. Over time, with routine practice and bedside training, some key aspects of NIHSS scoring may be overlooked, improperly practiced, or forgotten. Therefore, we hypothesized that even previously trained HCPs may have suboptimal NIHSS knowledge and that a refresher course using an e-learning module could be more effective than the traditional didactic video at improving their NIHSS proficiency. Further, we also hypothesized that knowledge retention at 1 month would be higher after following this interactive module than after reviewing the standard didactic video.

Given the heterogeneity of training described above, all HCPs authorized by their employers to care for neurological patients on a regular basis were considered eligible to participate in this study.

Objectives

Our primary objective was to assess whether NIHSS-trained HCPs would significantly improve their NIHSS knowledge after completing a highly interactive e-learning module than after following the traditional didactic video. The secondary objective was to determine whether following either training material allowed better retention of knowledge at one month.

Methods



Study Design and Setting

This was a prospective, multicentric, web-based, triple-blind (participants, investigators, and data analyst) randomized

XSL•FO
RenderX

controlled trial. Its main aim was to compare scores to a 50-question quiz, taken before and after exposure to the randomly assigned learning method, to assess the impact on knowledge acquisition. The same quiz was repeated 1 month later to assess the impact on knowledge retention. Figure 1 provides a detailed infographic of the study design.

Figure 1. Study design.

This study was initially designed to include HCPs from the stroke units and neurology wards of 2 university hospitals in the French-speaking part of Switzerland, namely the Geneva University Hospitals and the Lausanne University Hospital. A third center, the Cantonal Hospital of Fribourg, joined the study a few weeks before its launch. Cantonal Hospital of Fribourg supervisors also extended the study invitation to all their personnel who potentially used the NIHSS on a regular basis, which included intensive care unit HCPs and emergency ward nurses.

The medical and nursing supervisors of all 3 centers forwarded an invitation email to their teams, containing a summary of the main points of the study and a link to the online platform. It is estimated that approximately 185 nurses and 140 physicians received this email. One author (L Suppan) sent weekly email updates to the supervisors of each center summarizing the number of participants in each hospital, stratified by profession. This email also detailed the number of participants at each stage of the study, thus enabling supervisors to monitor participation. Reminder emails regarding enrolment were left to the discretion of the supervisors. Automatic reminders were sent to participants who had registered on the platform but had not completed the required and appropriate study steps.

The initial invitation email was sent in July 2022. Enrollment and registration of new participants was disabled on March 31, 2023, and ongoing participants were invited to complete all steps by May 31, 2023. While the study platform remained accessible for scientific purposes such as further data extraction, users were no longer able to log in.

The study protocol has been previously published [24] and protocol deviations are reported in Multimedia Appendix 1.

CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) guidelines [25] and checklist (Multimedia Appendix 2) were followed, integrating relevant elements from the CHERRIES (Checklist for Reporting Results of Internet E-Survey) [26] and iCHECK-DH (Guidelines and Checklist for Reporting on Digital Health Implementations) guidelines [27].

The RCT was not prospectively registered because registration is not necessary for studies evaluating the effect of interventions on providers rather than patients [28].

Online Platform

The internet-based online study platform, compliant with General Data Protection Regulation, was created using the Joomla 3.10 content management system (Open Source Matters). Participants were assigned to specific user groups according to their progression using Joomla's Access Control List. Custom PHP code was embedded using Sourcerer 9 (Regular Labs) to manage user group assignments.

The self-enrolment process was entirely automated. The first page of the website contained all necessary information regarding the study, and the consent information form was downloadable. Participants were explicitly informed that completing the registration process implied consent to participate in the study. Those who wished to enroll had to click on the logo of their hospital before acknowledging their profession (doctor or nurse) by clicking on a captioned image. This procedure invisibly randomized them either to the video or to

XSL•FO
RenderX

the e-learning group using Gegabyte's Random Article module 2.3. A 1:1 allocation was not possible due to the stratification by profession and center, and an unknown total number of participants. Participants were then asked to self-evaluate their current NIHSS knowledge (limited, moderate, or extended). The Membership Pro 3 component (Joomdonation) was then used to show a simple registration form that only asked for an email address and a secure password.

First Questionnaire

After completing the registration process, participants were asked to fill in a first questionnaire (Multimedia Appendix 3) designed to collect demographic data, administered using the Community Surveys 5.6 component (Shondalai) [29]. A detailed description of the first questionnaire can be found in the study protocol [24].

Participants then completed a 50-question quiz (Multimedia Appendix 4) designed to assess their baseline knowledge (quiz 1). Each question, worth 1 point, pertained to 1 of the 15 NIHSS items. All possible scores for that item were displayed and the participant had to choose the appropriate score. The quiz comprised a full NIHSS evaluation of 3 patients, for a total of 45 points. A total of 5 additional questions pertained to the general principles of NIHSS and certain subtleties, bringing the total to 50 points. All questions were mandatory, with multiple-choice answers to choose from.

Completion of this first quiz granted access to the allocated learning material as per randomization.

Learning Material and Second Questionnaire

The video group was given access to the original video created by Professor Lyden, of a duration of 53:07 minutes. The French subtitled version used for this study is freely available online under a Creative Commons license [30].

The e-learning group was given access to version 21c of the interactive e-learning module created under Storyline 3 (Articulate Global), also available freely online under a Creative Commons license [21]. This web-based module, which contains 184 slides, is divided into chapters following the NIHSS structure. Subtitled excerpts of Professor Lyden's original video are embedded into the different chapters to illustrate clinical testing. This e-learning module has been extensively described in previous publications as well as in the protocol of this study [22-24].

Participants had full control of the allocated learning material, could go back and forth as often as needed, and pause, resume, restart, and review chapters, all without constraints or time limitations. Upon completion of the learning material, participants were then taken through the same 50-question quiz to assess knowledge acquisition (quiz 2).

This quiz was followed by a short satisfaction survey collecting subjective outcomes (ie, satisfaction, difficulty, duration, and likelihood of recommendation) using a 5-point Likert scale (Multimedia Appendix 5).

Knowledge Retention

Four weeks after completion of the satisfaction survey, participants were invited through email to complete the final quiz. They were asked to answer the 50-question quiz a third time to assess knowledge retention (quiz 3). At the end of this quiz, a certificate of participation was automatically generated that could be downloaded and printed. Only the email ID used for registration appeared automatically on the certificate, and participants were asked to write their names down after printing it. Each certificate was embedded with a unique barcode that could be scanned for verification of authenticity.

Outcomes

The primary outcome was knowledge acquisition, assessed by the score on the second quiz, taken after completing the learning material.

Secondary outcomes were knowledge retention, assessed by the score on the third quiz undertaken at least 1 month after completion of the learning material, and subjective assessments of the followed learning method, namely user satisfaction, user perception of the duration, perceived difficulty, and the likelihood of recommending the learning material to a colleague.

Participants and Sample Size

A total of 72 participants were required to have 80% chance of detecting a difference of 2 points in the postcourse 50-question quiz between groups at the 5% significance level. Considering a 40% attrition rate, we aimed to recruit 120 participants. A higher number of participants were accepted as participation did not entail any risk.

Data Curation and Statistical Analysis

Data curation and statistical analysis were carried out using Stata (version 15.1; StataCorp). Data curation was done by 1 author (L Suppan), who assigned neutral names to the e-learning group and the video group. Another author (L Stuby) was then given this curated and blinded DTA file for data analysis. Continuous variables were first graphically described to look for the shape of the distribution. In case of doubtful normality, the Shapiro-Wilk test was applied. Then, depending on the variable's distribution, either the Student *t* test or the Mann-Whitney *U* test were used. Results are reported either using mean (95% CI) or median (IQR).

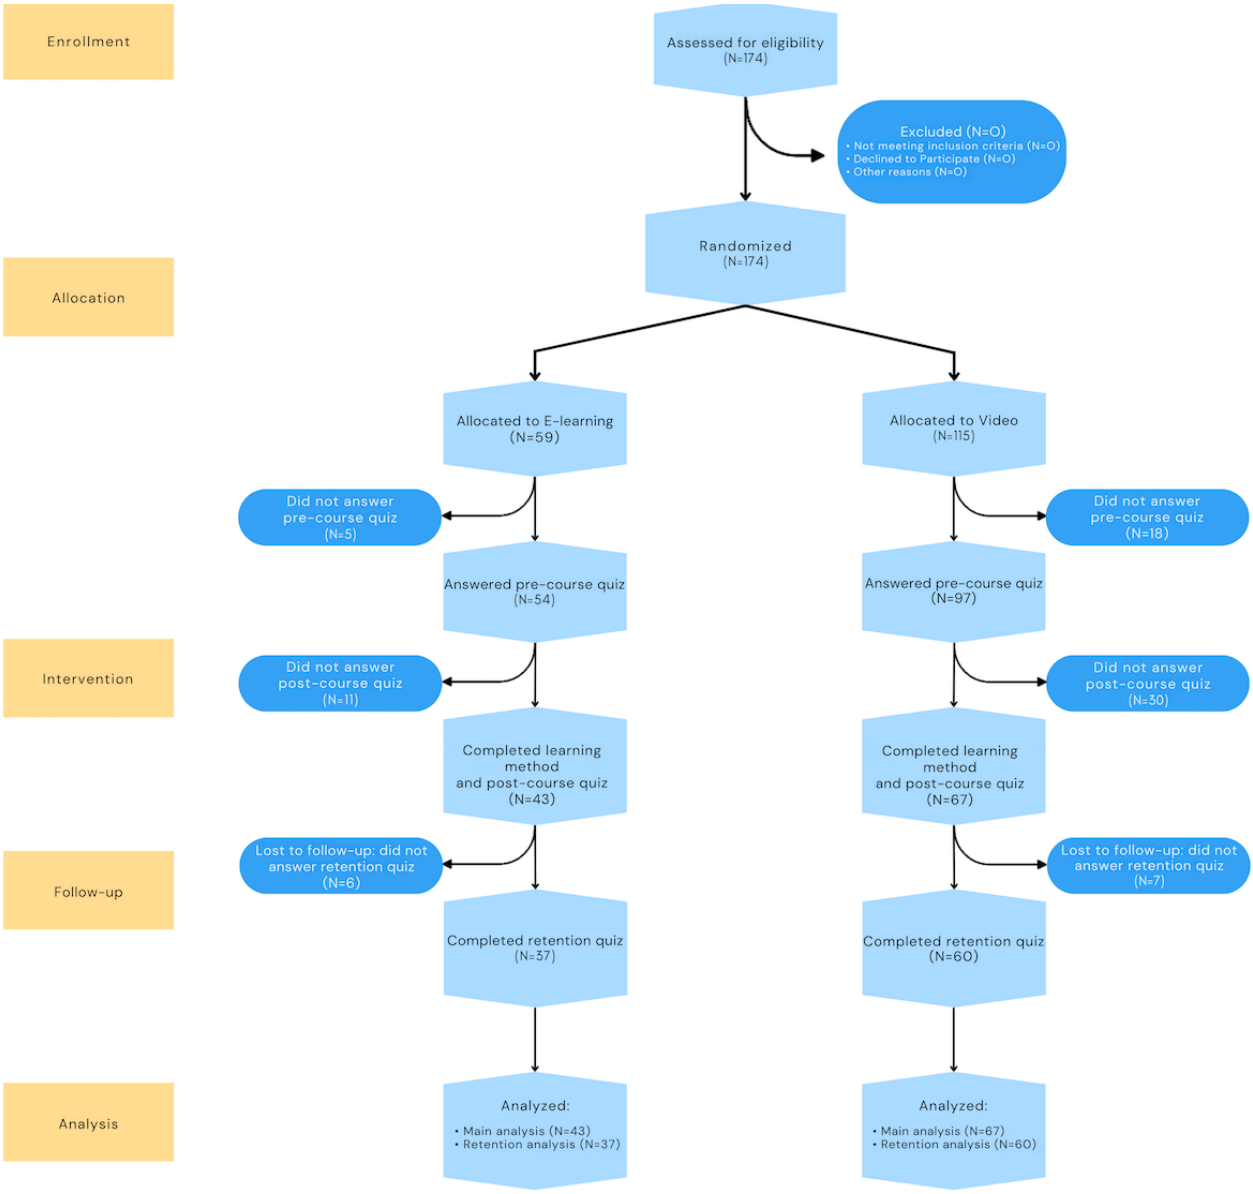
A sensitivity analysis was performed by excluding those who had previously followed either the e-learning module, the original video from Patrick Lyden [20], or any other official NIHSS training. Categorical variables (eg, Likert scales) were first analyzed graphically, and then by Fisher exact test.

The time interval between the end of quiz 2 and the start of quiz 3 was also analyzed to ensure that the time elapsed before assessing retention was not lower than required as per the original protocol.

Ethical Considerations

The regional ethics committee issued a "Declaration of no objection" in response to a jurisdictional query that we submitted (Req-2021-00543), as this study does not involve patients and falls outside the scope of the Swiss legislation regulating

XSL•FO
RenderX



research on human subjects. Potential participants were provided with a detailed 4-page study information document, downloadable through a link on the study web page. Some of the key points noted in the document were that participation was on a voluntary basis, without any financial compensation, and data was fully anonymized before analysis. Furthermore, the document, and the study page, clearly indicated that registering for the study by creating an account was considered as acceptance to participate in the study. A screenshot of the study web page, and the consent information document, are annexed (Multimedia Appendices 6 and 7).

Results

Participants Characteristics

A total of 174 participants enrolled in the study. The fully automated randomization process attributed 59 participants to the e-learning group, and 115 participants to the video group (Figure 2). Characteristics of participants having completed the study path are described in Table 1. Given the high attrition rates, the characteristics of the participants who dropped out were also extracted and are displayed in Multimedia Appendix 8.

Figure 2. Study flowchart as per CONSORT guidelines. CONSORT: Consolidated Standards of Reporting Trials.

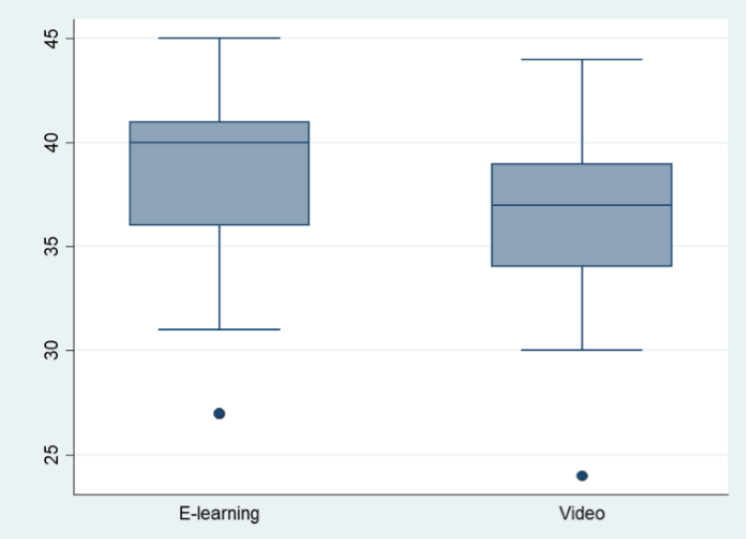
Participation According to Group Allocation



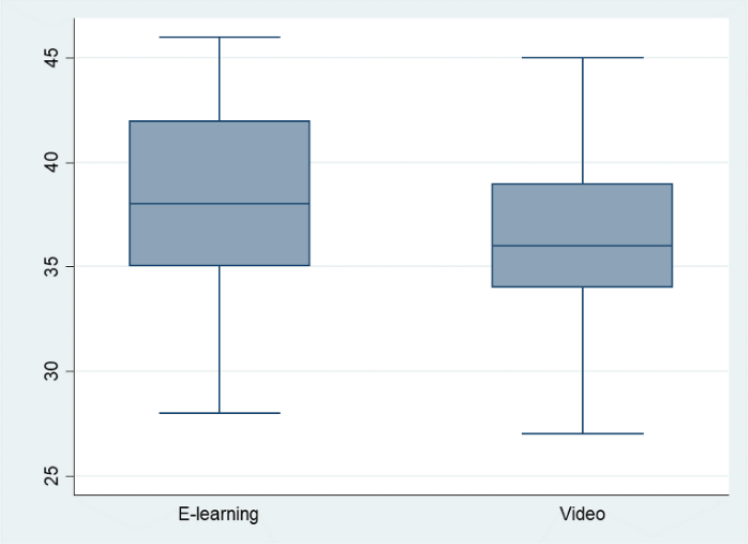
A difference of 10.5% in the participation rate was found, with 37/59 (62.7%) participants completing the study course in the e-learning group versus 60/115 (52.2%) in the video group.

Knowledge Acquisition

Both learning methods had a positive impact on knowledge acquisition as both groups improved their scores. The improvement in the e-learning group was a mean of 3.2 points (range 2.0-4.3) and of 2.1 points (range 1.2-3.1) in the video group.

Participants who followed the e-learning method performed better in the acquisition quiz than the participants in the video group (median score of 39, IQR 36-41 vs 37, IQR 34-39; *P*=.03; Figure 3).

Figure 3. NIHSS knowledge acquisition scores (quiz 2) among groups. NIHSS: National Institutes of Health Stroke Scale.



XSL•FO
RenderX

Knowledge Retention

The participants who followed the e-learning module had significantly higher scores on the retention quiz (38.2, 95% CI 36.7-39.7 vs 35.8, 95% CI 34.8-36.8; *P*=.007; Figure 4).

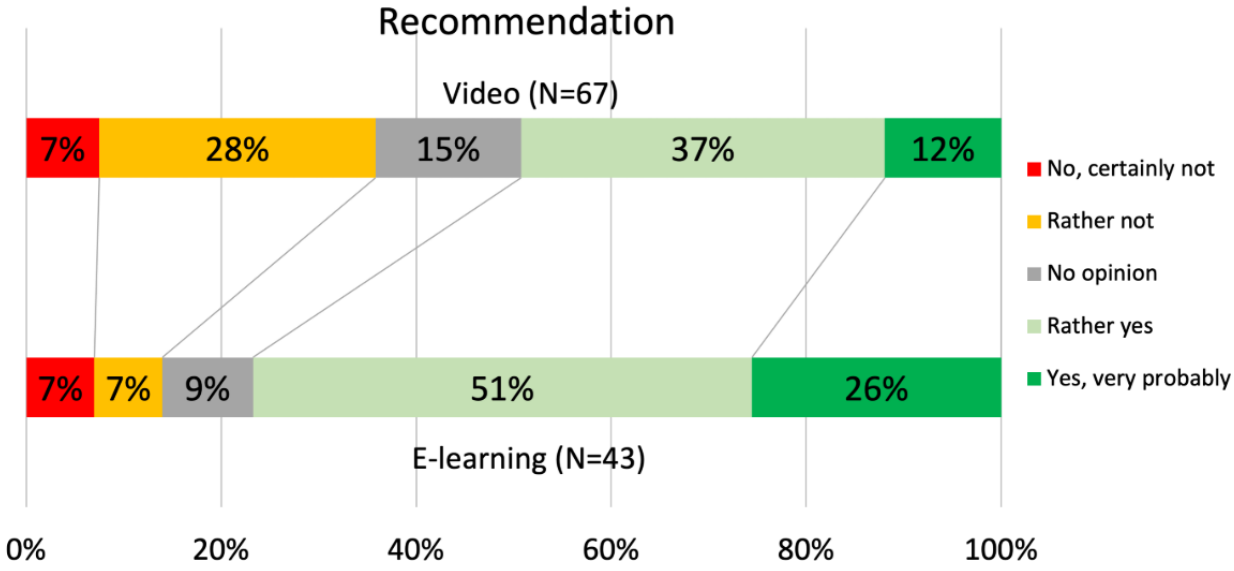


Figure 4. NIHSS knowledge retention scores (quiz 3) among groups. NIHSS: National Institutes of Health Stroke Scale.

Subjective Assessments

All participants who completed the learning method answered the subjective questionnaire. The likelihood of recommending the learning method was statistically higher in the e-learning group, with 33/43 (77%) participants in the e-learning group and 33/67 (49%) participants in the video group (*P*=.02; Figure 5). There was no significant difference regarding satisfaction (*P*=.17), perceived duration (*P*=.17), and difficulty (*P*=.32) (Multimedia Appendices 9-11).

Figure 5. Likelihood of recommending the learning method to a colleague.

Sensitivity Analysis

The prespecified sensitivity analysis (ie, excluding those who had previously followed either learning method or any official NIHSS training) did not change the results (Table 2).

Table 2. Sensitivity analyses.

	e-Learning	Video	*P* value
Sensitivity analysis of primary outcome (knowledge acquisition), median (IQR), n	39 (37-41), 40	36 (34-39), 59	.02
Sensitivity analysis of knowledge retention, mean (95% CI), n	38.2 (36.6-39.7), 33	35.6 (34.5-36.7), 52	.007

XSL•FO
RenderX

Time Interval Analysis

Time interval analysis confirmed that about a month had elapsed between the start of quiz 2 and the start of quiz 3 in both groups (e-learning versus video median of 36.0, IQR 27.4-49.0 versus 35.3, IQR 28.3-58.9 days).

Discussion

Principal Findings

This study shows that when compared with the traditional didactic video, a highly interactive e-learning module improves NIHSS knowledge acquisition and retention in HCPs caring for patients with stroke.

Decline in knowledge retention has been shown to be nonlinear, with a high percentage of decline measurable after only 4 weeks of acquisition [31]. The higher scores at quiz 3, undertaken at least 4 weeks after quiz 2, demonstrate that this interactive e-learning module also has a significant impact on knowledge retention.

Although both learning methods were considered equally difficult, participants of the e-learning group expressed a higher likelihood of recommending the learning method to colleagues, and thus would probably facilitate knowledge dissemination. Further, it is worth noting that the number of participants who completed the learning process was higher in the e-learning group by more than 10%, also hinting toward higher satisfaction in this group.

Comparison to Previous Work

Previous studies have shown a positive impact of the e-learning module on knowledge acquisition among paramedics and medical students not familiar with the NIHSS [22,23]. However, this is the first study to show similar results in HCPs with prior NIHSS knowledge. This is also the first study to test for impact on knowledge retention as mentioned above.

Strengths and Limitations

Several limitations must be acknowledged. First, attrition rates, as anticipated, were high in both groups. This is probably related to the fact that the entire study path takes a long time, requiring 4 to 5 hours to be completed and that there is currently a very high rate of fatigue among HCPs, with high turnover rates [32]. The study was conducted over a prolonged period of 11 months and participants were allowed to pause and resume the study at any time to try to minimize this issue.

Second, participants were informed that the study was to be completed individually and without any visual support such as a NIHSS form during the quiz. However, given the web-based asynchronous design of the study, we are unable to verify compliance to these points. The randomization however mitigates this issue, should it hold true.

Third, there is no certainty that multiple participants following different learning methods did not collaborate during this study, creating a potential contamination in the learning process. While a cluster-based randomization, with each center being an individual cluster, could have mitigated this risk, the large sample size required for such a design would have seriously impacted the feasibility of this study. In addition, based on their teaching experience with the study participants, the authors and supervisors strongly believe that the risk of such contamination is very low.

Fourth, the improvement of the score at each repetition could be partly induced by a priming effect. However, this effect would be similar across both groups and therefore should not induce any bias in data interpretation when comparing both groups.

Finally, trying to determine NIHSS knowledge by using a 50-question quiz cannot be considered fully representative of the skills in the clinical application of the score. However, this method has been used for the previous 2 decades to test NIHSS competency [11,14,33]. Its usage can therefore be considered valid to compare multiple learning methods.

This study also has some strong points, which are mentioned here. To our knowledge, this is the first paper that assesses the impact of an e-learning method on a population of previously trained HCPs, in terms of knowledge acquisition and retention. The protocol was published before starting this study, and deviations from the protocol have been thoroughly detailed in this paper (Multimedia Appendix 1). The randomization process was fully automated enabling us to guarantee the concealment of allocation, and data blinding was accomplished at the highest standard. The elapsed time between the second and third quizzes was assessed to ensure that the interval was indeed more than 1 month, thus ensuring compliance with the protocol.

Because language proficiency could have an impact on learning performance, participants were asked about their levels of English and French in the initial demographic questionnaire. Although randomization was intended to guarantee an equal balance of these elements in each group, the comparison allowed us to ascertain it.

The e-learning module itself also has certain advantages. Access to the official NIHSS training and certification could be limited by financial constraints and linguistic barriers, as most participating HCPs are French-speaking. This e-learning module is freely available online, its asynchronous learning design is particularly adapted to HCPs constraints, and it can easily be translated into different languages. The intrinsic design of the platform also enables quick updates of individual chapters if needed in the future. All these points allow easier dissemination of NIHSS knowledge and skills through e-learning than with the traditional didactic English video alone.

Future Directions

Compared with previous studies in populations not familiar with the NIHSS [22,23], the overall scores are slightly higher. However, these scores are lower than could be expected given the specific study population of HCPs with previous NIHSS knowledge using the scale on a regular basis. Several hypotheses could explain this finding. First, baseline data analysis shows that 15% of participants declare themselves uncomfortable with the application of NIHSS, 26% consider themselves as having limited NIHSS knowledge, and only 7 participants have followed the official NIHSS training and certification. Furthermore, only about half the HCPs participating in this

XSL•FO
RenderX

study declare having been through the internal training program of their institution. These low numbers could partly be explained by a high turnover currently seen in HCPs in general since the COVID-19 pandemic [34,35], with many new staff members who might have recently started working in these units as reflected by the low number of years the participants have been in their service. Moreover, some of the participants, such as Intensive care unit HCPs and emergency ward nurses, may have less exposure to NIHSS usage in their daily practice. Further studies should investigate the association between self-assessed level of NIHSS expertise, and frequency of exposition to the score, with the actual NIHSS knowledge.

The videos used for the quiz could also have an impact on the overall scores. A previous study [23], using the first edition of the e-learning module, had shown that the lack of video extracts, or graphic examples of neurological deficits, decreased the performance of candidates for certain chapters. An updated version integrating the missing video extracts showed that the performance of the same chapters improved [22]. However, feedback from previous study participants and discussions with experts correlate to say that some of the video excerpts in the e-learning or in the quiz could contain some ambiguity and leave room for some interpretation, for example, due to camera angles. We believe that this could in part explain some incorrect scoring and thus reduce the overall scores, and that replacing the videos with animated models demonstrating the neurological deficits more clearly could improve overall performance at testing.

Conclusion

A highly interactive e-learning module was found to be an effective asynchronous method to improve NIHSS knowledge acquisition and retention, notably in previously NIHSS-trained HCPs. It may now be considered for inclusion in NIHSS training programs for HCPs.

Acknowledgments

The authors would like to thank all participants for their valuable time, and the numerous supervisors for facilitating this study.

Further, the authors would also like to thank the University of Geneva for sponsoring publication fees, as per institutional guidelines.

Data Availability

The datasets generated during and/or analyzed during this study are available in the Yareta repository [36].

Authors' Contributions

L Suppan, MS, EC, PM, L Stuby and AK contributed to conceptualization and methodology. MS, L Suppan, L Stuby, and AK handled software and project administration. L Suppan contributed to supervision. AK, L Suppan, MS, FM, TS, FR, EC, NMP, PM, and L Stuby conducted investigations. L Suppan and MS handled data curation. L Stuby performed formal analysis. AK, L Suppan, and L Stuby contributed to writing-original draft preparation. All the authors performed writing-review and editing.

Abstract

Background: Digital gaming has become increasingly popular among older adults, potentially offering cognitive, social, and physical benefits. However, its broader impact on health and well-being, particularly in real-world settings, remains unclear.

Objective: This study aimed to evaluate the multidimensional effects of digital gaming on health and well-being among older adults, using data from the Japan Gerontological Evaluation Study conducted in Matsudo City, Chiba, Japan.

Methods: Data were drawn from 3 survey waves (2020 prebaseline, 2021 baseline, and 2022 follow-up) of the Japan Gerontological Evaluation Study, which targets functionally independent older adults. The exposure variable, digital gaming, was defined as regular video game play and was assessed in 2021. In total, 18 outcomes across 6 domains were evaluated in 2022; domain 1—happiness and life satisfaction, domain 2—physical and mental health, domain 3—meaning and purpose, domain 4—character and virtue, domain 5—close social relationships, and domain 6—health behavior. Furthermore, 10 items from the Human Flourishing Index were included in domains 1-5, with 2 items for each domain. Overall flourishing was defined as the average of the means across these 5 domains. In addition, 7 items related to domains 2, 5, and 6 were assessed. The final sample consisted of 2504 participants aged 65 years or older, with questionnaires containing the Human Flourishing Index randomly distributed to approximately half of the respondents (submodule: n=1243). Consequently, we used 2 datasets for analysis. We applied targeted maximum likelihood estimation to estimate the population average treatment effects, with Bonferroni correction used to adjust for multiple testing.

Results: Digital gaming was not significantly associated with overall flourishing or with any of the 5 domains from the Human Flourishing Index. Although initial analyses indicated associations between digital gaming and participation in hobby groups (mean difference=0.12, *P*=.005) as well as meeting with friends (mean difference=0.076, *P*=.02), these associations did not remain significant after applying the Bonferroni correction for multiple testing. In addition, digital gaming was not associated with increased sedentary behavior or reduced outdoor activities.

Conclusions: This study provides valuable insights into the impact of digital gaming on the health and well-being of older adults in a real-world context. Although digital gaming did not show a significant association with improvements in flourishing or in the individual items across the 5 domains, it was also not associated with increased sedentary behavior or reduced outdoor activities. These findings suggest that digital gaming can be part of a balanced lifestyle for older adults, offering opportunities for social engagement, particularly through hobby groups. Considering the solitary nature of gaming, promoting social gaming opportunities may be a promising approach to enhance the positive effects of digital gaming on well-being.

Introduction

Digital Gaming for Health

Digital gaming has become increasingly common among older adults. In 2021, 10.7% of people aged 65 years or older in Japan played digital games for hobbies and entertainment [1]. This trend illustrates the growing appeal of digital gaming among older adults, which holds the potential for promoting both physical and cognitive health [2,3]. A systematic review, for example, has demonstrated that video game–based interventions, such as exergames, can support physical health in older adults by improving balance, mobility, strength, physical fitness, and walking performance [3]. In addition, there is a growing body of evidence that computer games with and without physical components may have positive changes in cognitive function including enhanced executive function, memory, and focused attention [4-6]. Such evidence suggests that digital gaming could serve as a valuable tool for supporting active aging and helping older adults maintain physical and cognitive vitality while providing an enjoyable and engaging activity.

Limitations of Current Evidence

While existing research has provided valuable insights into the health impacts of digital gaming, several limitations remain. First, although digital games can enhance the lives of older adults in various ways [7], current evidence is largely focused on physical and cognitive health outcomes [3-6,8,9]. The World Health Organization defines health as “a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity” [10]. This definition highlights the complexity and breadth of health beyond the absence of illness. In recent years, there has been growing recognition of the multidimensional nature of health, leading to increased attention on the concept of human flourishing. Human flourishing refers to “a state in which all aspects of a person’s life are good” and includes five core domains, which are (1) happiness and life satisfaction, (2) physical and mental health, (3) meaning and purpose, (4) character and virtue, and (5) close social relationships [11]. Growing evidence suggests that games can facilitate engaging conversations and serve as a shared activity, helping to promote bridging social capital, foster civic participation, and enhance satisfaction [12,13]. However, the broader social and psychological impacts of digital gaming among older adults remain underexplored [14-16].

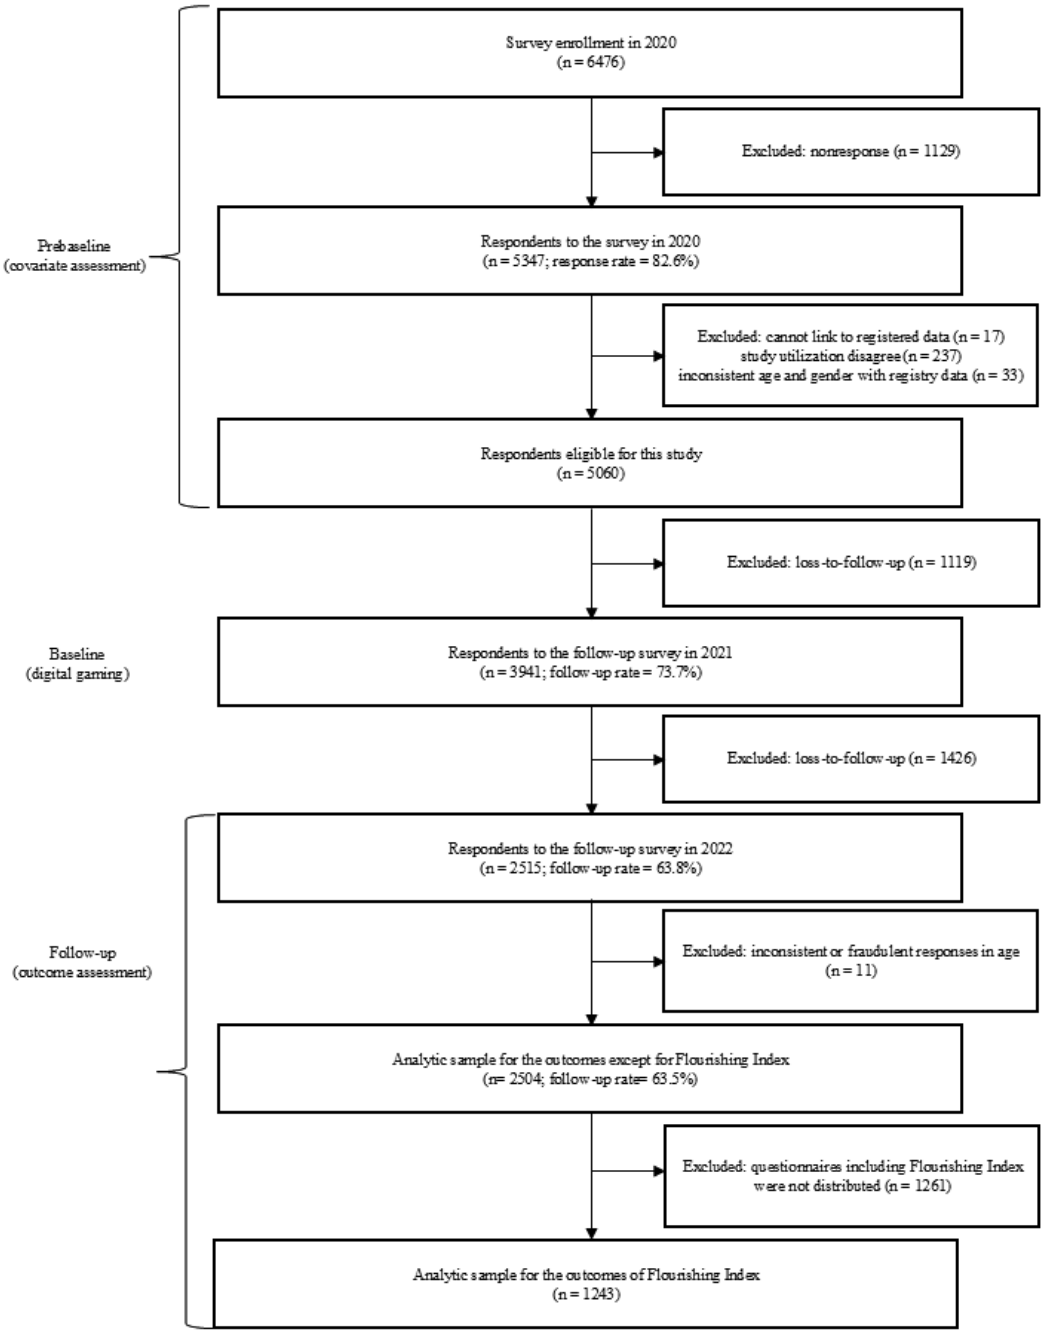
Second, much of the existing evidence comes from studies that examine a single or limited number of outcomes, making it difficult to fully understand the range of digital gaming’s effects. The impact of gaming on older adults is inherently multidimensional—potentially beneficial for some outcomes but less so for others. For example, while certain games may encourage physical activity, gaming could also contribute to a more sedentary lifestyle if it predominantly occurs indoors. To gain a holistic understanding of digital gaming’s effects, comprehensive, large-scale studies that assess a wide range of health and well-being outcomes simultaneously are needed.

Third, many previous studies have been conducted in controlled settings, such as short-term exergame interventions lasting 3 months. While these studies provide valuable evidence about the effects of specific gaming interventions, they do not capture the long-term impact of daily gaming activities on health and well-being. To address this gap, studies using well-powered real-world data from community-dwelling older adults are necessary. Such research can offer deeper insights into how regular, everyday digital gaming interacts with the long-term health trajectories of older adults.

The Aim of This Study

This study aimed to expand the current body of evidence on the multidimensional impact of digital gaming on the human flourishing of older adults. As digital gaming represents a novel and increasingly popular activity among older adults, understanding its associations with holistic health outcomes—including human flourishing—can provide valuable insights into how such activities contribute to their overall well-being and support active aging. We used an outcome-wide analytic approach to simultaneously examine the longitudinal associations between digital gaming and 18 subsequent health and well-being outcomes among Japanese older adults. We examined outcomes across domains of happiness and life satisfaction, physical and mental health, meaning and purpose, character and virtue, social well-being, and health behaviors [17].

Methods



Data Sources

We used data from the 2020 (prebaseline), 2021 (baseline), and 2022 (follow-up) waves of the Japan Gerontological Evaluation Study (JAGES), a nationwide survey of adults aged 65 years or older who were not receiving public long-term care insurance benefits in Japan [18]. Our analysis focused on data from participants from one of the JAGES study sites—Matsudo City, as the questionnaire on digital gaming was included only there. Matsudo City is located in Chiba Prefecture, Japan, just northeast of Tokyo. It serves as a suburban area within the Greater Tokyo Area, with a population of around 500,000. Self-administered questionnaires were distributed in 15 districts through random sampling. The study included respondents aged 65 years or older in 2020 who completed the 2020 survey (n=5347; response rate 82.6%). Respondents with inconsistently reported age or gender, as well as those with implausible height (<100 cm or >200 cm) or weight (<30 kg or >100 kg) values, were excluded. Of the 2020 respondents, 73.7% (3941/5060) responded to the 2021 survey. Of the 2021 respondents, 63.8% (2515/3941) responded to the 2022 survey. After excluding 11 participants with inconsistently reported ages, the analytic sample consisted of 2504 participants. For the assessment of human flourishing, the questionnaire version that included the Human Flourishing Index was distributed only to randomly selected half of the respondents (submodule: n=1243). Thus, we used 2 analytic samples—the submodule respondents for flourishing assessments (n=1243) and the full analytic sample for all other outcomes (n=2504). Figure 1 and Figure S1 in Multimedia Appendix 1 provide a detailed flowchart of the data linkage and sample selection process. The participants of the JAGES were informed that their participation was voluntary,

XSL•FO
RenderX

and returning the questionnaire implied their consent to participate in the study.

Figure 1. Flowchart of study participants.

Measures

We measured the covariates, exposures, and outcomes in a temporal sequence using the 3-wave panel structure of the data (2020, 2021, and 2022). This structure allowed us to account for pre-exposure covariates, including previous values of the outcomes before exposure to digital gaming, which helps mitigate the risks of confounding and reverse causality without the need to adjust for potential mediators [17].

Exposure Variable

The exposure variable, digital gaming, was obtained from the 2021 survey. Participants were asked, “Have you played video games with a PC, cell phones, smartphones, tablets, or consoles in the last five years?” The response options included “Playing regularly,” “Have played,” “Know video games, but have not played,” and “Do not know video games.” For analysis, we created a binary variable, where participants who answered “Playing regularly” were coded as 1, indicating regular digital gaming, while all other responses were coded as 0.

Outcomes

We examined 18 outcomes in 2022 across 6 domains of health and well-being, following VanderWeele’s human flourishing framework and a previous outcome-wide study using the JAGES data [11,19]. We first assessed human flourishing based on the Human Flourishing Index. Human flourishing refers to “a state in which all aspects of a person’s life are good,” and the Human

XSL•FO
RenderX

Flourishing Index is a comprehensive measure designed to capture multidimensional aspects of health and well-being, encompassing several domains [11]. This index consists of 10 self-reported items measuring human well-being outcomes across 5 domains (ie, 2 items per domain). Domain 1 consists of happiness and life satisfaction, domain 2 consists of physical and mental health, domain 3 consists of meaning and purpose, domain 4 consists of character and virtue, and domain 5 consists of close relationships. For each domain, we calculated the mean of the responses to 2 domain-specific items, and overall flourishing was defined as the average of these means across the 5 domains.

In addition to these outcomes, we also examined other outcomes based on items available in the JAGES survey. For domain 2, we assessed instrumental activities of daily living (IADL), forgetfulness, and depressive symptoms using the Geriatric Depression Scale. IADL refers to tasks that enable an individual to live independently within their community, such as managing finances, preparing meals, and handling transportation. For domain 3, we assessed ikigai, broadly defined as "what makes life worth living," a well-accepted psychological concept in Japanese culture [20]. For domain 5, we assessed participation in hobby groups, participation in sports groups, meeting with friends, and the number of friends. We also examined several health behaviors as outcomes (domain 6: health behavior), including a sedentary lifestyle, smoking, drinking, and frequency of going out. Detailed information on the definitions and measures of these outcomes is shown in Table S1 in Multimedia Appendix 1.

Covariates

All covariates were obtained from the 2020 survey, conducted a year before the wave in which the exposure levels were assessed.

As confounders in this study, we included several sociodemographic factors, such as age, gender (men or women), years of education (6-9 years vs 10 or more years), self-rated deprivation, marital status (married or not), living arrangement (living alone or not), and employment status (employed or not).

To minimize the potential for reverse causation, we adjusted for previous values of outcomes wherever available. These included pre-exposure levels of happiness, life satisfaction (as a binary variable), self-rated health, IADL, forgetfulness, Geriatric Depression Scale, participation in hobby groups, participation in sports groups, meeting with friends, number of friends, sedentary behavior, smoking, alcohol consumption, and frequency of going out.

Statistical Analysis

This study adopted an outcome-wide analytic approach, which explores the associations between a single exposure and multiple outcomes simultaneously [17,21]. This method allows for a comprehensive assessment of the impact of exposure across a wide range of outcomes. In addition, this approach offers methodological advantages, such as being less susceptible to *P*-hacking and publication bias. It is particularly beneficial for studying the impact of digital gaming, as it captures the multidimensional effects across various domains of health and well-being, providing a holistic understanding of its potential benefits and risks. By examining multiple outcomes within the same framework, this method helps identify patterns and trade-offs that may not be evident when focusing on individual outcomes.

We estimated the population average treatment effects of video gaming on each of the 18 outcomes across the 6 domains, using the doubly robust targeted maximum likelihood estimation. The "doubly robust" method is a statistical approach that combines 2 models—one for the exposure (eg, gaming behavior) and one for the outcome (eg, health or well-being measure). It is termed "doubly robust" because it provides consistent estimates of the average treatment effect as long as at least 1 of these 2 models is correctly specified when the causal identification assumptions are met. Thus, this method is useful as it enhances the robustness of effect estimation by reducing potential biases from model misspecification, compared with methods that rely on a single model (eg, outcome regression and propensity score weighting). To further mitigate the potential bias due to model misspecification, both the exposure and outcome models were fitted data-adaptively using the SuperLearner, an ensemble method that combines weighted estimates from multiple candidate algorithms, including generalized linear models, gradient-boosting machines, and neural networks [22]. The "Super Learner" algorithm is a machine learning technique that data-adaptively selects the optimal weighted combination of estimators from a set of candidate algorithms to improve predictive accuracy. By synthesizing estimates from multiple algorithms, it further reduces the risk of bias due to model misspecification. The targeted maximum likelihood estimation and Super Learning procedures were performed using the ltmle and SuperLearner packages in R (R Foundation for Statistical Computing). For continuous variables, we estimated the difference in the mean levels of the outcomes. All continuous outcomes were standardized (mean 0, SD 1) to ensure that the effect estimates could be interpreted as SD changes in the mean outcomes. For binary outcomes, we estimated risk ratios. To address the issue of multiple testing, we applied the Bonferroni correction that used a highly conservative *P* value threshold for statistical significance of P=.00278 (.05/18).

As a sensitivity analysis, we calculated the e-values for each exposure-outcome association to assess the robustness of the estimated associations against unmeasured confounding [23]. E-values quantify the minimum strength of association, on the risk ratio scale, that an unmeasured confounder would need to have with both the exposure and outcome, conditional on the adjusted covariates, for the confounding bias to account for the observed associations.

To address potential bias due to missing data, we used random forest imputation via the R package "missRanger" to impute missing values. All analyses were performed using R (version 4.3.1).

Ethical Considerations

Ethical approval for the study was obtained from the Ethics Committee at Chiba University (approval M10460). The participants of the JAGES were informed that their participation

XSL•FO
RenderX

was voluntary and returning the questionnaire implied their consent to participate in the study.

Results

Table 1 shows the prebaseline characteristics of the submodule sample by the baseline digital gaming. Among the 1243 respondents, 192 (15.45%) and 380 (15.18%) played digital games, respectively. Individuals who played digital games tended to be younger men, have higher educational attainment, experience less deprivation, be married, live with others, and be employed. These trends were consistent between the submodule sample and the full analytic sample (Table S2 in Multimedia Appendix 1; n=2504).

Table 2 shows the estimated effects of digital gaming on overall flourishing and each of its 5 domains based on the Human Flourishing Index. We found no evidence of the association between digital gaming and these outcomes.

Table 3 shows the estimated effects of digital gaming on other outcomes related to human flourishing and health behaviors. Digital gaming was associated with more frequent participation in hobby groups (mean difference=0.124, *P*=.005) and meeting friends (mean difference=0.076, *P*=.02). However, these associations were above the α=.05 cutoff after applying the Bonferroni correction for multiple testing.

Tables S3 and S4 in Multimedia Appendix 1 present E-values, which indicate the robustness of the observed associations between digital gaming and subsequent health and well-being outcomes against potential unmeasured confounders. For example, in the association between digital gaming and participation in hobby groups, an unmeasured confounder would need to have a risk ratio of at least 1.48 with both the exposure and the outcome, conditional on the measured covariates, to fully account for the observed association. In addition, a risk ratio of 1.22 would be required to shift the CI to include the null value.

Discussion

Principal Findings

The main findings of this study were threefold. First, video gaming was associated with more frequent participation in hobby groups and meeting with friends, although these results should be interpreted with caution as they may be false positive findings due to multiple testing. Second, video gaming was not associated with lower levels of physical activity, as indicated by measures of sedentary lifestyle and frequency of going out. Third, video gaming did not appear to be associated with the flourishing outcomes across the 5 domains, including psychological well-being.

XSL•FO
RenderX

Our findings highlight the potential of digital gaming to positively impact the social well-being of older adults, contributing to meaningful social interactions and engagement. Previous studies have shown that older adults who play digital games experience social benefits, such as reduced loneliness and improved social functioning [15,24]. However, these studies often relied on smaller samples or qualitative methods, limiting the generalizability of their findings. In contrast, our study, based on a larger sample size, provides more robust evidence to support the social benefits of digital gaming.

Digital gaming may enhance social well-being by fostering participation in hobby groups, where gaming can act as a shared interest and a catalyst for engaging conversations. These interactions create opportunities for older adults to build and strengthen social connections, thereby promoting a sense of belonging and community. This underscores the role of digital gaming as not only a recreational activity but also a potential tool for enhancing social engagement and overall well-being among older adults.

Digital gaming, particularly nonphysical types, may reduce physical activity levels among older adults by promoting sedentary behavior, as players often remain seated for extended periods. This sedentary time could potentially replace activities like walking or outdoor socializing. In contrast, exergames—digital games that require physical movement—have been shown to promote physical activity by improving mobility, balance, and fitness levels [2]. Despite concerns about sedentary behavior, our study found no evidence in a real-world context that digital gaming was associated with increased sedentary behavior or decreased outdoor activities among older adults in Japan. This finding suggests that, for many older adults, digital gaming can integrate into a balanced lifestyle without negatively affecting physical activity levels.

Digital gaming may also enhance psychological well-being among older adults by providing relaxation and social interaction [24,25], although we did not find evidence of such improvements in our study. Research indicates that the social aspects of gaming, such as playing together or discussing games with family and friends, are crucial for translating digital gaming experiences into positive well-being outcomes [15,26]. However, many older adults tend to play digital games alone, which can limit the potential social benefits that gaming might otherwise offer. This highlights the need for targeted initiatives to promote and encourage more social forms of digital gaming among older. Facilitating environments where digital games are played together, such as community centers or online platforms designed for older users, could help harness the social benefits of gaming and, in turn, improve their overall well-being.

This study has several limitations. First, the broad definition of gaming behavior used in this study may not adequately reflect the specific characteristics and impacts of individual games. The diversity of digital games, including their types, purposes, and contexts, means that our analysis may have attenuated potential associations. In addition, whether participants played alone or with others could significantly alter the associations. Future research should adopt a more nuanced approach by categorizing gaming behavior to better capture the specific effects of different game types.

Second, the generalizability of our findings is limited, as our data were derived from a single city in Japan. Results may differ in other regions or countries with different cultural contexts and gaming habits.

Third, due to the observational nature of this study, the possibility of unmeasured confounding and reverse causation cannot be completely ruled out. However, to mitigate this issue, we adjusted for numerous covariates, including confounders and prebaseline outcomes, as recommended in the outcome-wide approach [17,21]. Fourth, while our study is larger than previous studies, it is still likely underpowered (eg, n=1243 with an exposure prevalence of approximately 15%). Future studies with larger sample sizes are warranted to provide more robust conclusions.

Fifth, the outcome-wide analytic approach used in this study was designed to provide a comprehensive overview of associations across multiple outcomes; however, it does indeed sacrifice depth for breadth due to the word count limit. The traditional design focusing on a single or a narrow set of outcomes has other limitations (eg, not providing holistic evidence on gaming-health associations, *P*-hacking, and publication bias), which the outcome-wide design seeks to address, at least to some extent. We think this is a trade-off, and the outcome-wide design (which contains more breadth) and traditional study design (which contains more in-depth discussion) are both complementary and play different roles in the advancement of science. Future research on specific outcomes with more detailed analysis (eg, effect heterogeneity across subgroups) is needed.

Finally, our study did not account for the potential overlap between digital gaming and social media usage. Gamers are more likely to use social media, and the impacts of gaming may overlap with those of social media usage. This overlap is particularly relevant as many digital games include social interaction features that resemble social media functions, such as in-game chats or multiplayer platforms. Consequently, some observed associations may reflect the combined effects of gaming and social media rather than gaming alone. Future studies should measure and differentiate these activities to clarify their unique and overlapping impacts on health and well-being.

Conclusion

While digital gaming did not show a significant association with improvements in flourishing or its subdomains, our results indicate that digital gaming could lead to greater social engagement without increasing sedentary behavior and reducing outdoor activities. These results suggest that digital gaming can be integrated into a balanced lifestyle, offering a potential tool for enhancing social well-being in older adults. Furthermore, integrating digital gaming into community and health care settings presents novel opportunities for fostering social connections and supporting healthy aging in this population.

Abstract

Background: Although commercially developed automated insulin delivery (AID) systems have recently been approved and become available in a limited number of countries, they are not universally available, accessible, or affordable. Therefore, open-source AID systems, cocreated by an online community of people with diabetes and their families behind the hashtag #WeAreNotWaiting, have become increasingly popular.

Objective: This study focused on examining the lived experiences, physical and emotional health implications of people with diabetes following the initiation of open-source AID systems, their perceived challenges, and their sources of support, which have not been explored in the existing literature.

Methods: We collected data from 383 participants across 29 countries through 2 sets of open-ended questions in a web-based survey on their experience of building and using open-source AID systems. Narratives were thematically analyzed, and a coding framework was identified through iterative alignment.

XSL•FO
RenderX

Results: Participants consistently reported improvements in glycemia, physical health, sleep quality, emotional impact on everyday life, and quality of life. Knowledge of open-source AID systems was largely obtained through the #WeAreNotWaiting community, which was also the primary source of practical and emotional support. The acquisition of the components to build an open-source AID system and the technical setup were sometimes problematic.

Conclusions: The #WeAreNotWaiting movement represents a primary example of how informed and connected patients proactively address their unmet needs, provide peer support to each other, and obtain results through impactful, user-driven solutions. Alongside providing evidence on the safety and efficacy of open-source AID systems, this qualitative analysis helps in understanding how patients' experiences and benefits range from psychosocial improvements to a reduction in the burden of managing diabetes.

Introduction

Overview

In recent years, much attention has been given to the beneficial impacts that online peer support has on people living with chronic health conditions, yet the exact nature of these impacts may still appear to be somewhat intangible [1]. Through our findings, we provide an example of peer support in which the focus of the interaction is very tangible and where the impacts are profound and wide-ranging. The case in point being type 1 diabetes (T1D), where, in recent years, patients have been taking on the role of innovators in the design and development of technology used for their treatment. People with T1D who have developed and disseminated open-source automated insulin delivery (AID) systems exemplify a potential within online peer-to-peer communities that is only just beginning to be realized, particularly among people with chronic health conditions. To better understand how developments have reached the cutting edge in T1D treatment, we first provide some background about the challenges of everyday diabetes management and how open-source AID technology holds promise to alleviate them.

Background and Challenges in T1D Management

T1D is a lifelong condition caused by the autoimmune-induced loss of insulin-producing cells in the pancreas. Until the discovery of insulin by Banting et al [2] a century ago, T1D inevitably resulted in death by ketoacidosis within months. This changed once pharmaceutically procured insulin was available. Yet, while developments of the last 100 years in pharmaceuticals and technology have improved the physical health and life expectancy of people with T1D from a biomedical perspective, the burden of managing the condition remains a challenge. Life with T1D exists in the center of a continuous data feedback loop, where dosing of exogenous insulin via subcutaneous injections or insulin pumps must be frequently adjusted in accord with glucose levels and predicted trends, carbohydrate intake, physical activity, individual physiology, and behavior, among a variety of other factors.

The #WeAreNotWaiting Movement

Given the complexity of diabetes management, the everyday experience of managing the condition may lead to frustration, a feeling that was also a key driver in the emergence of the movement that has subsequently become known as #WeAreNotWaiting [3]. Initially, this frustration was related to issues with the accessibility of data from continuous glucose monitors (CGMs) in real time. Taking matters into their own hands, individuals reverse engineered commercially available devices to enable uploading of device data to the cloud in real time. In a model of diffusion that has characterized subsequent developments, the source code was published as open-source software, freely available to anyone and linked by the social media hashtag #WeAreNotWaiting. Eventually, a large, global community has united under this banner.

One of the most significant innovations to emerge from the #WeAreNotWaiting movement are open-source AID systems—sometimes referred to as do-it-yourself artificial pancreas systems—such as OpenAPS [4], AndroidAPS [5], iAPS [6], and Loop [7]. These systems link CGM sensors and insulin pumps with predictive control algorithms running on smartphones or microcontrollers. Insulin dosing is automatically adjusted according to predictions based on real-time data from CGMs, individual settings, and user inputs such as meal information. This technology emerged well in advance of the recent availability of commercial AID systems in select countries [8].

Current Evidence and User Perspectives

Evidence from randomized controlled trials and observational studies has demonstrated the safety and efficacy of commercial AID systems [9], as well as a positive impact on the users' lived experience and quality of life [10]. Given the lengthy, complex development and approval processes, only few systems are currently licensed, and their functionality is limited due to regulatory constraints. Even in countries with market availability of commercial AID systems, they are not universally accessible to the user, with reimbursement policies for devices varying considerably between countries [11].

XSL•FO
RenderX

Open-source AID systems work much like commercial AID systems at a basic level, connecting devices and automatically adjusting insulin dosing via predictive algorithms. They differ from commercial systems in terms of device choice, interoperability, transparency, access, customization, and usability. While commercial systems traditionally include manufacturer-designed education for clinicians and users, open-source AID user support and education initially took place via peer support outside of clinical settings [12]. The source code for open-source AID systems is freely available from online portals. In addition, these communities have also created documentation that has been translated into many different languages. Peer support is freely available to help with the setup and use of these systems.

It is estimated that >10,000 individuals worldwide are currently using open-source AID systems, and the uptake continues to increase globally. Evidence from a recent randomized controlled trial [13] and real-world studies based on self- and caregiver-reported outcomes [14,15], in silico [16], user-provided data [17], and observational studies [18-20] point to the safety and effectiveness of these systems, with improvements in clinical parameters such as glycated hemoglobin (HbA_{1c}), time in range, occurrence of hypoglycemia, and glycemic variability. However, until recently, the perspective of the user and their reported outcomes has only been touched upon [21-25], and there remains much to learn about how open-source AID systems impact the lives of those who use them.

Study Objectives

The focus of this study was to establish the physiological, cognitive, and emotional impact of open-source AID system use. We further aimed to identify sources of support and challenges associated with setup, regular use, and maintenance of open-source AID systems. This study was designed and conducted by the OPEN (Outcomes of Patient's Evidence with Novel, Do-it-Yourself Artificial Pancreas Technology) consortium [26], an international, interdisciplinary team of patient innovators, clinicians, and scientists, many of whom also live with T1D and use open-source AID systems.

Methods

The research data were obtained from responses to open-ended questions included in a cross-sectional, web-based survey examining the use of open-source AID systems. The survey, titled DIWHY, was conducted between November 2018 and March 2019 [26].

Survey Design

The survey (Multimedia Appendix 1) was created by the OPEN consortium in collaboration with further open-source AID system users and was piloted with a small group of them before final release. The Checklist for Reporting Results of Internet E-Surveys was used to guide survey development [27]. The survey comprised 39 items in total with 2 sets of open-ended questions, which sought to capture lived experiences with open-source AID systems in the form of narratives. For these questions, participants could provide a free-text response with a maximum length of 1000 words each. The first set of questions assessed sources of information, support, and emotions associated with the preparation and setup process. The second question set addressed the impact of open-source AID system use on everyday life, associated changes, and challenges with respect to the transition to open-source AID systems.

Participants and Recruitment

Participants included in this study were adults (aged >18 y) who are living with diabetes (type 1, type 2, or other) and are current users of open-source AID systems. There were no restrictions in time since diagnosis or commencement of open-source AID systems. In this study, participants were exclusively recruited from the global diabetes online community, leveraging the outreach of the #WeAreNotWaiting movement. This approach enabled us to tap into a highly empowered and informed population of people with diabetes and particularly target those who were users of open-source AID systems. We used several social media channels, including the Facebook (Meta Platforms) groups Looped (with >6000 members) and AndroidAPS users (with >1800 members as of November 2018) and regional subgroups, and posted publicly on Twitter using the hashtags #WeAreNotWaiting and #DIYAPS to engage with the wider diabetes online community. Participation was further promoted through announcements on the OPEN project website. There were no paid promotions or targeted advertising on any platform. Participants were able to choose between 2 language options (English and German).

Data Collection and Analysis

Data were collected and managed using REDCap (Research Electronic Data Capture; Vanderbilt University) [28], and the qualitative analysis of the narratives was performed using NVivo (version 12; Lumivero, 2018). The narratives were analyzed with an approach applying the principles of template analysis [29], in which a hierarchical coding structure is recommended to allow researchers to capture the diversity of meaning within broader overarching themes. This approach was deemed necessary due to the framing of the open-ended questions, in which respondents were prompted to reflect on specific aspects of their open-source AID system use experience. Therefore, the initial template and coding were deductively driven, with physical impact, emotional impact, sources of support, and challenges established as the overarching themes. In the subsequent stage of coding, the deductively coded data were analyzed inductively to identify subthemes within the overarching framework. Initially, 3 coders worked (BC, YC, and MW) on a small sample of the deductive data and presented putative inductive themes for evaluation within the author group. These were discussed and refined to ensure that there was equivalence in relation to the levels of abstraction and thus in the hierarchical organization of the template. On the basis of this initial inductive coding, it was agreed that only 1 level of abstraction was necessary and that the overarching themes could be articulated sufficiently by 1 level of subthemes. The resulting comprehensive codebook, which included both deductively and inductively developed codes, descriptions, example quotes, and thematic categories, are detailed in Tables 1-4. All the data were then coded deductively in accordance with the full template by

XSL•FO
RenderX

BC and YC, although emergent themes not established in the initial inductive analysis were also proposed. Finally, 2 coders (HB and DC) reviewed the coding template to assess the external validity of the coding process. Where clarity or consistency was questioned, further group discussions were held until all issues were resolved.

Table 1. Comprehensive codebook detailing thematic analysis of open-source automated insulin delivery system user narratives collected from a multinational cohort of 383 participants. This table presents findings related to the physical health benefits and quality of life impact of using open-source automated insulin delivery systems, such as improvements in glycemic control, time in range, and reduced hypoglycemia.

Theme	Description	Example quotes
(A) Physical impact and quality of life impact		
Glycemic outcome improvement (A1)	Refers to improved time in range and HbA_{1c}[a] levels, less glucose variability	• "I purchased the Miaomiao brand Bluetooth transmitter to send my blood glucose levels to my phone, thereby having access to alerts that have undoubtedly saved my life." • "My biggest hope was to control my blood sugar peaks due to gastroparesis and this works 95% of the of time very well. Thanks to this technology, I am a big step closer to my goal." • "He's not T1, but was concerned about my time in range and felt the DIY Loop system was better than approved FDA methods." • "Looping has dramatically improved time in range and how I feel. After 5 weeks Looping, my A_{1C} lowered from 6.8 to 6.3."
Hypo- and hyperglycemia (A2)	Refers to fewer hypo- and hyperglycemia and reduced complications associated	• "Overall, my blood sugar adjustment has improved tremendously. Hypoglycaemia is extremely rare. Times above the limit occur but are limited in duration." • "My values have become immensely better. Hypos with unconsciousness did not occur anymore." • "I've always had problems with hypos. The Freestyle showed me in the morning that I was hypoglycemic, nevertheless, I spent the night—retrospectively—in hypoglycemia. Or even a whole night with levels over 250 mg/dl."
Sleep quality (A3)	Denotes all aspects of improved sleep quality for either caregivers or children, such as increased sleep duration, fewer sleep interruptions, and feeling better rested in the morning	• "Thereby having access to alerts that have undoubtedly saved my life, both while sleeping and while alone in public transportation, among others." • "Only looping for about 2-3 weeks. So far, better quality sleep for my husband and me (no nocturnal hypos which would happen regularly prelooping)." • "I sleep so much better. I no longer fear lows. I understand my body's needs much better." • "It was hard to convince my wife that I was going to turn over control of my diabetes to open source code that I downloaded from the internet. It actually got to a point where I explained to her that I was doing it with or without her approval. When she realized how passionate I was about it, we sat down together and I explained the ins and outs of everything. She sleeps so much better now knowing I'm healthier overall and more safe overnight."
Exercise management (A4)	Refers to the improvements in physical exercise since the use of DIYAPS[b]	• "Better sleep and exercise management, AAPS has very good objectives to work through. Diabetes management is now less hassle and lower risk." • "Exercising and working out is a lot more easier since I no longer have that many low BGs. I overall feel physically and mentally much better since my time in range has increased by 30%."
Quality of life (A5)	Refers to the mentioned improvements in quality of life and describes the degree to which an individual is healthy, comfortable, and able to participate in or enjoy life events	• "But today, at 44, I have a system that already reduces a lot, and ensures very good values and thus a better quality of life." • "Help with stress situations both high and low, preworkout and postworkouts are less drastic, overall better mental health since I don't need to make so many decisions throughout the day about BGs and knowing that I have the ability to have more time in range and a better A_{1C} while still living a pretty normal life." • "A DIY system gives me this flexibility and adaptability. A huge weight has been lifted off my shoulders knowing that I will be safe during the night, and won't be doing undue damage to my organs during stressful situations like exams or during panic episodes." • "Since then, every night was like that and every day I feel more active and fitter...that's what I call Quality of Life."

[a]HbA_{1c}: glycated hemoglobin.

Table 2. Comprehensive codebook detailing thematic analysis of open-source automated insulin delivery (AID) system user narratives collected from a multinational cohort of 383 participants. This table summarizes user-reported experiences regarding the positive and negative emotional effects of open-source AID systems.

Theme	Description	Example quotes
(B) Emotional impact		
Positive (B1): describes positive emotions of participants related to the experience with open-source AID in daily use, including anticipation, enjoyment, excitement, relief, freedom, and inspiration.		
Anticipation	Describes hopeful emotional states of anticipation and great expectations of participants that lie on the open-source AID system for improved diabetes management and hope for improved quality of life	• "Looking forward to next steps: predicting algorithms." • "I had high hopes that everything would be different from now and I do not have to do anything for my diabetes anymore, and that the loop regulates everything on its own." • "Hope and impatience since I was looking for an atomization almost for 20 years."
Enjoyment	Describes that participants enjoy using the open-source AID system or enjoy the satisfied outcomes brought by open-source AID system use	• "Now I enjoy quiet nights and hope for a future without long term complications." • "I am doing well and I am happy to use the loop." • "My CGM alarms are all turned off now and I love the silence." • "In terms of expectations, I had a vague feeling that closed looping could be a solution to my lack of control during the night but I did not have very clear or measurable expectations. I just wanted to try it, I was curious to see what it was going to bring me. And now, of course, soooooooo glad that I did that!" • "Just awesome. By far the biggest impact has been the reduction in time spent "doing" diabetes. I am rarely woken at night even after intense exercise and little tweaks which previously interrupted my day have largely disappeared. It is a revelation."
Excitement	Describes exciting emotions of participants related to the experience with open-source AID systems in daily use, including excitement, happiness, and satisfaction with AID system use and associated results	• "I was just so excited to learn about DIY closed looping, and ordered gear immediately." • "I have been looping for only 4 months now and I am really grateful to all the people that have worked so hard to developed this amazing technology." • "I was very excited learning about how the system worked. I saw it as a challenge to understand and build it. Understanding the algorithm and building it myself gave me a great understanding of the system and mitigated any fears that I might have had about it's functioning." • "To me, loop is a miracle—I can hardly believe it after 35 years to finally have normal blood glucose levels." • "Just awesome. By far the biggest impact has been the reduction in time spent "doing" diabetes. I am rarely woken at night even after intense exercise and little tweaks which previously interrupted my day have largely disappeared. It is a revelation!" • "[I am] able to read the blood sugar over a watch and no longer have to perform finger pricks, should become true! I still remember the exact moment, I immediately had tears in my eyes."
Relief	Describes that participants feel relieved since their diabetes-related complications alleviated and quality of life improved after using open-source AID systems	• "I felt well and relieved, within a few days there was a clear improvement in my control." • "It's the reduction in disease burden, reduction in lows and highs and the overall improvement in time in range that has changed things so much for me." • "Since the change, I feel safer and simply more comfortable." • "My diabetes does not bother me any more, I can accept it and even like it."
Freedom	Describes the feeling of freedom since participants gained more control of their diabetes by using open-source AID systems	• "The essential feeling of freedom and the feeling of being in control of diabetes." • "I feel free for the first time in years!"
Inspiration	Describes that participants were encouraged and motivated during their journey of building open-source AID systems	• "No special 'key events' other than reading many stories of a diverse group of T1's who all seemed to overcome all the I-am-new-to-software-building challenges and reading how happy they now we're that they took this effort. Also, reading questions of people and seeing that they were answered fast and elaborately by more experienced and knowledgeable users made a great impression on me." • "I was immediately thrilled and the hints that the whole thing wouldn't be completely legal somehow motivated me even more." • "I knew that other people could do it so I was convinced I should be able to do it myself as well. I expected to run into issues in the building process, but I wasn't held back as I knew I would also run into solutions."

Theme	Description	Example quotes
Negative (B2): describes negative emotions, such as fear, frustration, worry and anxiety of users, mainly due to the concern of not being able to build and maintain open-source AID systems and difficulties encountered.		
Caution	Describes participants' concerns in regard to building and maintaining open-source AID systems	• "I was quite worried about trying it, there were many things I didn't quite understand and found technically challenging" • "I am still a bit afraid to close the loop." • "I have other fears: will my OTG cable have a loose connection again tonight? will I get to an old replacement pump (combo)? We integrate the Dexcom G6 with xdrip or disassembled xdrip the battery - how was it read today? Will the pharmaceutical industry put more obstacles in our way?" • "I have had some fears of system failure, but i do not have them anymore"
Frustration	Describes participants' frustration when experiencing difficulties in sourcing, building, or maintaining open-source AID systems	• "Unfortunately, I first failed because of the technology (availability of the accessories, order from the USA). It was a bit frustrating, but I did not want to give up." • "I also experienced a sadness for how long I had struggled (43years) with inadequate tools to manage my condition." • "My biggest challenge has been the isolation of it all. Online support is always present very timely, but not the same as having someone to be present to help troubleshoot when loop stops. I live in very rural area and sometimes I feel like I'm stranded on an island. Frustrating at times, but I would not trade my cure for anything!!"
Worry and anxiety	Describes that participants worry about the problems that may arise from the use of open-source AID systems	• "as I have no idea what the programme is doing and every time I keep my fingers crossed that I won't see any screen other than in the tutorial because I have no idea how to fix that." • "The biggest hurdle was I was not confident I could build the loop app on my own." • "And I have concerns about the dependence on Bluetooth/Wifi/Internet/ servers." • "I had heard things about DIY closed loop systems in the various cgm related Facebook groups, but had always thought I wouldn't be able to build & maintain one." • "It was something that I considered at the time, but never thought I would be able to do it as I'm not very good with coding/tech." • "suddenly relying on the phone instead of your own mind is a little strange, I often did not trust the loop and delivered boluses on my own or ignored the TBR suggestions." • "A defective libre sensor the other day (already on the 2nd or 3rd day) has given me a lot of restlessness and effort, because the measurements were incorrect every now and then. I was Worried every now and then a single component of the overall system will fail and cause high adjustment effort."

Table 3. Comprehensive codebook detailing thematic analysis of open-source automated insulin delivery (AID) system user narratives collected from a multinational cohort of 383 participants. This table outlines the challenges users face during setup, regular use, and maintenance of open-source AID systems, including technical difficulties and knowledge gaps.

Theme	Description	Example quotes
(C) Challenges		
Accessibility (C1): describes the challenges encountered by the participants regarding accessing the open-source AID systems device, including sourcing hardware, cost, and understanding of the open-source AID systems rationale.		
Sourcing hardware	Describes the problem of sourcing hardware that is compatible with open-source AID systems	• "My main struggle was with losing access to my favorite pump (OmniPod). I switched back to a tube based pump I'm favor of this system, while hoping that the pods are cracked soon. I followed the OpenOmni efforts." • "but then I was unlikely to do it as I didn't have the right pump anymore" • "And my health insurance was vague about the info they needed to get the pump and supplies reimbursed. Denied my request several times. Took a lot of communication between health care providers, myself, insurance which was a frustrating process for me." • "My health care providers initially didn't want to prescribe the (loopable) pump."
Cost	Describes the issue of costs associated with building open-source AID systems	• "The main challenge has been self-funding the CGM which is expensive in New Zealand." • "I started with the pump therapy just before loopin. The health insurance did not supply me with a pump at the time, so I was on my own without diabetic care." • "The Dana RS pump has the one huge advantage of the open interface to control, otherwise the pump looks like a product from the penultimate decade, compared to other systems. The needles are not great either and the counterclockwise luer lock should be replaced. The should be a standard for pump connections to avoid manufacturer tie-ins and make cost reductions possible (the equipment is still too expensive)."
Understanding	Describes problems with understanding the rationale provided by the instructions for open-source AID system setup	• "My initial feeling of starting to build my loop was that it is poorly documented and difficult to diagnose setup issues." • "Understanding the system was both challenging and frustrating. The documentation is poorly explained and the system has its limitations but it is the best we have." • "In the meantime there is a ton of information about closed loops, which was an intensive learning and reading phase in both the medical literature and the posts and documentation of the community. Since at the beginning the overview was missing, this was also a bit confusing because the meaning of individual components was not yet estimable for the own implementation when reading. What is a Wixel, can it be eaten, and if so, how many carbs do I have to expect?. It had to burst a lot of knots until it was clear which software components to make the (actually quite simple) beginning. But maybe that's just too complicated for me, a certain tendency is not to be denied." • "In the lead up to building, I felt overwhelmed by all info." • "Apart from the setup difficulties and my lack of English skills I had no difficulties."
Setting up (C2): describes the difficulties encountered by the participants when maintaining the use of open-source AID systems, including adjusting and fine-tuning, consumption of time and effort, inconvenience in everyday life and technical issues.		
Adjusting and fine-tuning	Describes the process of determining the factors and further adjusting and fine-tuning	• "Determining the factors with decimal place accuracy, calculating the sensitivity factor was/is in first place effortful." • "The only difficulty in the change of therapy (apart from the unfamiliar handling of the technique in general) was to adjust the loop for different types of sports, depending on the time of day and physical condition." • "disillusionment followed immediately - even the updated nightscout / set up is very complicated to operate for non-nerds. It's often not clear what happens and what is shown on night scout."
Time and effort	Describes the amount of time and effort required for open-source AID system setup	• "It takes a lot of time and attention to begin with" • "It has been a tricky process, as we have been learning by doing" • "With the technical implementation, it was an uphill battle. It took a while to work but was worth the effort...I do not want to be without loop..."

XSL•FO
RenderX

Theme		Description	Example quotes
	Everyday life	Describes inconvenience with using open-source AID systems in daily life regarding exercise and diet, etc	• "I had to reduce the overall carb intake in order to achieve better time in Range, and this had a major impact on my and my family lifestyle" • "The regulation of sports is still a bit difficult" • "I discovered Loop app was terrific, but the phone was too bulky. So I purchased a new pump outright and started AAPS with a tiny phone. I am actually about to try AAPS on a stand-alone watch. The bulk of the gear is super important to me, as I can't be carrying a lot of excess stuff at work" • "I always think about if I need to charge anything (with Enlite it's just a bit more complicated than with other systems.) I have to keep reminding myself not to go out of the house without my new hand bag - and not without a smartwatch" • "Social judgment from part of the DT1 Community which [accused] me of obsession with the disease."
	Technical challenges	Describes technical issues with the equipment, such as battery charging	• "The issues I've had have been of a minor technical issue only, like accidentally shorting out my Miao Miao charger, and having difficulty ordering another. So I changed to Dexcom G5, and have learned to rebattery my transmitters, making it actually cheaper than using Libre. I have also had some troubles with my phone updating it's OS and becoming useless. I also have some battery issues with my new pump." • "Biggest challenge was building the app in Android studio, as I have no idea what the programme is doing and every time I keep my fingers crossed that I won't see any screen other than in the tutorial because I have no idea how to fix that." • "The only difficulties that I am sometimes experiencing are technical problems such as connectivity issues between the Riley link and the pump, and blood sugar fluctuations once the insulin sensitivity changes, which are more noticeable now with a tighter BG management than before, where every day with diabetes was just chaos."

XSL•FO

Table 4. Comprehensive codebook detailing thematic analysis of open-source automated insulin delivery system user narratives collected from a multinational cohort of 383 participants. This table highlights the role of peer support, online communities, and other resources in facilitating the adoption and use of open-source AID systems, emphasizing the sense of community and shared expertise.

Theme	Description	Example quotes
(D) Support		
Family and friends (D1)	Describes that the participants received support from their family or friends	• "My husband supported and encouraged me, which helped but I'd have gone ahead even without that support." • "Friend who had acquired the components and assisted [me] in building. He was already using [AndroidAPS]."
Online support (D2)	Describes the types of support that participants seek on the web, such as social media, blogs, forums, and other people with diabetes	• "First, I found information about AAPS in Freestyle Libre Forum." • "I felt the whole process was very simple with very comprehensive instructions and support through Facebook." • "March 2017 was the first time I started looking for treatment improvements. I acquired all the information and knowledge in through own research on the internet." • "In our area there is a Whatsapp diabetes group that meets in person now and then. A PwD there works in IT and was contacted about 1,5 years ago. With his technical support I have closed my loop." • "I set up a Nightscout server and the AndroidSeries600Upload app for his Medtronic pump in the hospital - and read a lot - and at first set up OpenAPS for myself. As a technophile I was of course immediately on fire, but I still took 2 months to read about the topic online intensively, trawling through forums, Facebook etc., and my anticipation and enthusiasm grew steadily."
DIY[a] community (D3)	Describes that the participants received support from the DIY community, such as help from author DL	• "I got support from the DIY community via face to face meetings and via the online community." • "When I could connect the technical side (IT) with my diabetes, it all started. Then I met Adrian and Dana [authors AT and DL] in person."
Conference and meeting (D4)	Describes the support that the participants received from conferences or meetings	• "However, due to the great help from the looper.de group and the looper meeting, I already wanted much more at this time and have been able to implement this with a lot of reading and informing and with still some technical problems"
Medical professionals (D5)	Describes that the participants received support from medical professionals, such as doctors, nurses, diabetes educators, endocrinologists, etc	• "I actually first heard about DIY options from my doctor, who referred me to another patient who was already using one."
Self-support (D6)	Describes that the participants learn to build DIYAPS[b] all by themselves, with no direct support from others	• "I like the user manual, which it written clearly step by step." • "[N]o direct support or advice from third parties."

[a]DIY: do-it-yourself.

[b]DIYAPS: do-it-yourself artificial pancreas systems.

Ethical Considerations

This study was performed in line with the principles of the Declaration of Helsinki. Approval was granted by the Ethics Committee of Charité–Universitätsmedizin Berlin (EA2/140/18). Informed consent was obtained electronically from all individual participants included in the study. The deidentified datasets are available from the corresponding author upon request. Participation was anonymous and voluntary. No financial or other compensation was provided.

Results

Participant Characteristics

In total, 383 participants (N=722, 53% of participants of the DIWHY survey) responded to the open-ended questions in the survey, and there were a combined 645 responses to the 2 open-ended items. Characteristics and clinical features of the cohort are shown in Table 5.

Template Analysis

Emotional and Quality of Life Impact

"Anticipation" and "curiosity" were emotions mentioned by participants in relation to their first encounter with open-source AID technology. This highlights the intuitive appeal of this solution for diabetes management—"I had envisioned this type of solution for many years and was looking out for the emergence of suitable technology" (Man, age 59 years, United Kingdom)—and why, for many people, initial reservations were quelled by the potential improvements offered by AID systems—"One is a little uncertain, but the curiosity for the improvement of control has won!" (Gender unspecified, age 49 years, Germany).

However, as this sentiment indicates, anxiety and caution were also a part of the emotional responses experienced by our participants. This could be as they confronted the prospect of developing their own system—"I was quite worried about trying it, there were many things I didn't quite understand and found technically challenging" (Woman, age 69 years, United Kingdom)—but was also apparent even once the system had been successfully built—"Originally it felt like a big step to let the algorithm make changes" (Woman, age 42 years, Australia).

Thus, both the challenges—real and anticipated—in setting up the system and the prospect of allowing an algorithm to undertake a life-critical role could have a negative emotional impact.

XSL•FO
RenderX

However, for the most part, initial concerns about the complexity of the technology and ceding control to an algorithm were replaced by a sense of "pride" and "relief"—"I feel very good and proud I did it because it was technically difficult to build it with my pump and CGM" (Man, age 50 years, Germany).

The sense of relief experienced by our participants was 2-fold; relief that the system was built and functioning but also a sense of being partially released from the burden of everyday diabetes management—"The most impressive thing is how little diabetes suddenly plays a role, how simple everything has become, how rarely one suddenly has to wonder about metabolic fluctuations, how well one can sleep, knowing that blood sugar stays in range" (Woman, age 49 years, Germany).

Twisting the concern with automation, some participants also noted that it was precisely because control was given over to an algorithm that improved outcomes could be achieved—"I was happy to hand over control to something which makes fewer irrational decisions and is less emotionally involved in the process" (Woman, age 35 years, United Kingdom).

The relief they experienced did not come without considerable effort and "frustration," and this was also a common emotion in the narratives. Part of this frustration was related to the reliability of technology:

> *While the burden of what to do in reaction to blood glucose has gone down, the tech troubleshooting and figuring out how to fine-tune has increased greatly. Traded one problem for another.* [Woman, age 62 years, United States]

As can be inferred from this comment, frustration was also driven by an expectation that the level of automation would be greater: "A few months into closed looping I am starting to see results, though I was expecting [it] to be easier and thought it was going to handle much more the ups and downs by itself" (Man, age 41 years, Netherlands).

Yet, most participants declared themselves happy to invest the effort when the reward was so tangible and transformative for overall quality of life:

> *...it doesn't just fix everything and that there are still settings to adjust and check, but once these were okay then I've had very few issues. It has allowed me to take a back seat with my diabetes care...It has taken huge amounts of the diabetes burden away from me!* [Woman, age 25 years, United Kingdom]

In fact, the work also served as a source of inspiration, with many participants gaining new insights into important factors influencing glucose fluctuations:

> *Looping has provided me much detailed insight into the inner-workings of my endocrine system and diabetes management. I've learned that my insulin ratios and [basal rates] needed to be greatly adjusted. As I've learned, two bad settings can mask each other and end up appearing to be correct. The learning curve is steep, but very rewarding.* [Woman, age 24 years, France]

Overall, participants indicated that the net gains of open-source AID were extensive and profound. Often, a sense of gratitude was expressed:

> *The community has helped me so much. I can't express my gratitude to all developers, helpers and people in my local community as well who freely give their time and skills to make this possible.* [Woman, age 65 years, Australia]

Source of Support

The community mentioned earlier highlights the particular model of diffusion that has fostered the use of open-source AID systems. To echo a common refrain in this context, *do-it-yourself* does not mean *do-it-alone* [15], so while each user is ultimately responsible for building their own system, the support that they can obtain in doing so is potentially extensive.

For those without preexisting skills in IT, support was at hand, for some, among one's established social network, for example, family and friends:

> *I was very intimidated at first as I have extremely limited coding knowledge. After following along in the group for a while, I began to get more comfortable. My boyfriend also encouraged me and offered to help set it up since he has a bit more tech knowledge.* [Woman, age 22 years, Canada]

Both technical and medical expertise within the individual's network was an important antecedent to the uptake of open-source AID systems:

> *My partner immediately supported me because, as a doctor, it was very clear to him that it had a much better metabolic effect...The support of the Facebook group especially for small logistic things was very important to me.* [Woman, age 37 years, Germany]

This participant's comments also highlighted that direct support from health care professionals (HCPs) may be lacking:

> *The support by my social environment has increased, the support by doctors and the diabetologist's office are completely lost, I consider this to be a risk, I am waiting for the moment when our diabetologists will not only be "not forbidden" but required to inform about the Closed Loop as the gold standard of therapy.* [Woman, age 37 years, Germany]

This is not to say that HCPs were not supportive or positive about AID outcomes, but the support they could provide was more often informal and emotional rather than practical:

> *My two diabetologists know about the loop and are amazed/enthusiastic about my [glucose] levels, but unfortunately cannot support me for legal reasons.* [Woman, age 55 years, Germany]

While an individual's social relations could profoundly impact the building and maintaining an open-source AID system, support was still available even without direct expertise in one's personal network—"I've found the technology almost impossibly difficult to deal with and have had a considerable

XSL•FO
RenderX

amount of personal help from other users" (Woman, age 62 years, United Kingdom).

For some users, this occurred at face-to-face meetings (eg, "build events"), where expert users could guide them, but, for the majority, such support was obtained via online forums—"The biggest (and for me only) help with technical problems or 'fine-tuning' the settings is provided by the Looper online community" (Woman, age 27 years, Germany).

The #WeAreNotWaiting community was the main source of support cited by our participants, and this was multifaceted. In its most basic form, the online documentation developed by users for users was an essential resource and frequently praised for its clarity. Beyond this, in the various social media–based groups connected with open-source AID systems, there was also a wealth of information from reading existing threads and others' posts, where frequently asked questions and troubleshooting topics could guide through challenging aspects of the process. Finally, the online forums also served as a real-time support network, where users could expect rapid and reliable responses to whatever issue they might reach out for:

> *I don't want to finish without mentioning the importance that the support groups are having to me. Both in helping understand and setting the system and managing the everyday life... It is completely amazing being able to be connected to so many people who are also looping and give and get support.* [Woman, age 40 years, Spain]

Also notable was how the encounter with this community and its essentially altruistic spirit could inspire new users to be willing to participate and serve within this support network:

> *What one cannot do, the many can manage. The group has helped me. I'm getting involved as well and spread the knowledge so others can benefit from it.* [Man, age 54 years, Germany]

Challenges

Principally, the challenges reported included (1) accessibility and (2) technical setup and maintenance. There were 3 prevailing issues regarding accessibility. The first one was cost, since essential hardware was not readily available via health care services or insurers:

> *CGM is prohibitively expensive in my country. I only started using it two months before looping as part of preparing to loop. I am trying to hang in there paying for it because of the fantastic benefits but it is a big drain on family income.* [Woman, age 51 years, Australia]

In addition, even in circumstances where hardware was potentially available to users via public health care or insurance, access could still be problematic if potential users were not eligible according to insurers, or HCPs had reservations about recommending devices that could be used for open-source AID systems:

> *My healthcare providers initially didn't want to prescribe the (loopable) pump. And my health insurance was vague about the info they needed to get the pump and supplies reimbursed. Denied my request several times. Took a lot of communication between health care providers, myself, insurance which was a frustrating process for me.* [Woman, age 33 years, country of residence undisclosed]

The final aspect of accessibility was the anticipated complexity of the process and the documentation to be followed to set up an open-source AID system—"I had heard things about DIY closed-loop systems in the various CGM-related Facebook groups, but had always thought I wouldn't be able to build & maintain one" [Woman, age 47 years, United Kingdom].

Thus, the obstacle was sometimes more about expectation than experience, with people deterred from the attempt by the expectation that they would not be able to solve technical issues.

However, for others, it was as much the experience as the expectation that could provide an obstacle to access—"There was a lot to learn. I often sat crying in front of the computer" (Woman, age 35 years, Germany).

Technical challenges associated with building open-source AID systems were prevalent in the narratives, with only a handful indicating that the process was straightforward:

> *I tried about a year before I actually started to build a system and it proved too difficult. After a year of being burned out and things not being any better, I tried again and succeeded.* [Woman, age 36 years, United States]

Participants conveyed difficulties with both hardware and software components, for example, with connectivity loss.

Even with all components fully functioning and connected, other technical challenges remained, though these were more related to the technicalities of diabetes management than technology per se. Users of open-source AID systems take on the role of diabetes experts as much as programmers and are required to fine-tune the settings on their devices in accordance with a selection of parameters:

> *[The] first weeks of looping were a bit hard because my ratios were off and it was hard to understand why Loop is making some decisions. Or, what's even more important, which parameter should be tweaked in order to make it behave better.* [Man, age 32 years, Poland]

Determination of these settings is generally undertaken by HCPs in the context of prescribed, commercial devices, ideally in collaboration with the user, but it may remain more or less opaque to the individual with diabetes. So, although many users were highly engaged with diabetes management previously, there was a learning curve involved for most, not least because the level of control for different parameters allowed by open-source AID systems extends significantly beyond those in commercial systems:

> *So I have to work more on my settings. Nothing is (fully) automatic and runs all by itself. For me, as a technician who believes in the possibilities of self-regulating automation, there is still a lot to be done.* [Man, age 51 years, Germany]

XSL•FO
RenderX

The combination of the different challenges involved in building an open-source AID system evoked another issue for some, inasmuch that considerable time was required to resolve the issues emerging from building and maintaining the system—"My husband has suggested several times that I was doing more work with the system than without, because of the frustration & time (whole weekends) involved in getting my loop back up & running" [Woman, age 51 years, United States].

Yet, while time was undoubtedly a factor to be dealt with, the extent to which it was perceived as a challenge, impinging on everyday life, was often weighed against the time spent "doing diabetes" before transitioning to open-source AID systems:

> *My own personal tight control prior to looping was very time-consuming. Post APS I save more than 1hr every day. Imagine my experience of living 1/24th longer life for the rest of my life because of APS.* [Man, age 46 years, New Zealand]

Physical Impact

For the most part, participants reported marked improvements in physical health in accordance with the measures traditionally used to gauge this in T1D, such as HbA_{1c} and time in range, as reported elsewhere [15]. For some, these improvements occurred soon after their switch to open-source AID systems:

> *Benefits from the first 8 weeks: 80-90% of the time-in-range without changing my lifestyle! Previously that value was 40-45%.* [Man, age 37 years, Germany]

The time regarding changes in HbA_{1c} was longer but still commented upon, often as levels within a reference range for people without diabetes:

> *I knew some that tuning was needed but I was patient. Now I have used a DIY system 24/7 approx 23 months for almost two years! Hba_{1C} is 5.2%, I'm happy.* [Man, age 44 years, Finland]

In addition to these clinical outcome improvements, participants also reported changes in their health based on more immediate, everyday experiences. The experience of hypoglycemia was something alluded to extensively—"The blood glucose fluctuations and the hypos have become much less, I feel much safer and I am doing things again that I used to avoid" (Woman, age 45 years, Germany).

The sense of safety can have a profound effect on an individual's life. Both hyper- and hypoglycemia in their moderate expression can induce physical symptoms that are unpleasant and disruptive but, in their extreme extent, are potentially fatal. Ameliorating the risk of highs and lows, open-source AID systems served to diminish the unpleasant symptoms and, at the same time, reduce the anxiety attached to what might happen in worst-case scenarios. This, aside from its direct benefits, also had follow-on effects on other health-related aspects. Many participants noted benefits of open-source AID systems related to physical activity—"I'm much less afraid of unplanned physical activity because the loop usually regulates it with a few extra carbs" (Woman, age 55 years, Germany).

Again, the point here is not only that glucose levels are within range during exercise but also that the potential fear around exercising was lessened. Fear of exercise and its unpredictable impact on glucose levels represents a clear obstacle removed by open-source AID systems, with potential general health benefits—"I have recently started exercising again after years of sedentary living" (Woman, age 31 years, Australia).

By far, the most frequently mentioned quality of life improvement among our participants was sleep duration and quality:

> *I can sleep and have no alarms from the CGM at night. In the morning I wake up with a value that I do not have to correct. This has a positive effect on the blood sugar during the day.* [Woman, age 38 years, Germany]

Persistently disturbed sleep is by any reckoning something that one would expect to impact health and overall quality of life, but for people living with T1D, it is a given:

> *I SLEEP. That's the most brilliant, life-changing thing. I'd been sleep-deprived for so long I didn't even realize what a difference it would make.* [Woman, age 49 years, United States]

In a similar vein to exercise, open-source AID systems had a dual impact in relation to sleep. It served to alleviate symptoms of hypo- and hyperglycemia that could disturb sleep directly or trigger alarms on devices waking people up. Simultaneously, it helped reduce the fear of nocturnal hypoglycemia, which could result in sleep difficulties due to anxiety and adverse aversion strategies, such as intentionally aiming for higher glucose levels before sleep:

> *I have no anxiety about sleeping alone when my wife is working away from home. I actually sleep through the night. Eating out is no longer a major stress since I know that even if I underestimate carbs [it] will fix my errors overnight and I will wake mostly in range.* [Man, age 42 years, United Kingdom]

As might be expected, improved sleep was also associated with further physical and mental health benefits:

> *Waking up that first morning in a normal range, and every morning thereafter was amazing. It's incredible how much more you can get done in a day when you wake up in a normal blood glucose range.* [Man, age 39 years, United States]

Part of this is obviously about having more energy because of being well-rested. Beyond that, there is the important difference of waking up with glucose in target range and how this resonates through the rest of the day:

> *The almost fully automatic delivery of needed insulin has made life a lot easier and once the factors are set correctly, it is almost possible to live like a 'healthy' person. It's also much easier to start a new day, starting at a value of 90 mg/dl and not 180-200 as before! Working days are much easier than before!* [Man, age 47 years, Germany]

XSL•FO
RenderX

Rather than using considerable time, energy, and resources attempting to reestablish balance in one's glucose levels, open-source AID systems allowed people to concentrate more on the business of the day. So, whereas previously a working day may have felt more like "running the gauntlet," a different experience and outlook on life could be fostered:

> *Since I've used [open-source AID], I was upgraded on my job, I'm mentally faster and sleep like a baby without alarms. I've started several personal projects and [I'm] currently on professional certification. I have plenty of quality time now without hypo or hyper and finally happy.* [Woman, age 40 years, Spain]

Discussion

Principal Findings and Their Implications

The findings we present here concerning the impact of open-source AID systems highlight their immense benefits from the perspective of the user, simultaneously setting the extremely challenging nature of diabetes and the ways it may compromise quality of life into relief. This is the first study to analyze narratives and to examine the emotional and physical health impact of open-source AID systems in adult users. Our findings are in line with our analysis of children and adolescents using open-source AID systems, including their caregivers [30], although there were age-specific findings, for example, navigating diabetes throughout puberty and remote monitoring and control by caregivers that only applied to the child cohort. Our results also align with other, smaller cohort studies examining the user experience with open-source AID systems [22,24,31] with the literature pointing to the importance of setting expectations for both onboarding and the ongoing use of AID systems [32,33]. Studies of users of commercial AID systems found similar results [34,35]. Furthermore, the sense of community and empowerment, often referred to as "paying it forward," was almost exclusively described in open-source AID system users.

In our approach to analyzing the data, we opted to use 4 categories as the basic framework for our template. This was necessary, first and foremost, because these topics were already framed in the wording of the questions. That said, the findings also underline the somewhat fluid nature of the categories, especially with respect to the physical and emotional impact that open-source AID systems can have. So, while we have sought to tease emotional and physical impacts apart for the purposes of our analysis, our findings ultimately serve to highlight how inexorably bound up they are. This is most intuitively illustrated through the example of sleep, where poor quality sleep inevitably impacts emotional well-being, which may, in turn, also impact glucose levels, both directly and indirectly [36].

Peer Support as a Driver of Innovation and Empowerment

Although there is not the same level of symbiosis between the categories "challenges" and "support," the findings did point to a strong link between the two in the sense that many of the challenges associated with initiating and maintaining the use of an open-source AID system were resolved via support from a wider community of users. The sense of community underpinning the development and diffusion of open-source AID systems and peer support as a key resource for practical but also emotional support were predominant topics in other qualitative studies on the lived experience with open-source AID systems [22,31]. For many, the discovery of a peer group that one could identify and engage with was as important and meaningful as building their AID system.

As has previously been noted [37], digital platforms can provide opportunities for peer support and the exchange of experiential knowledge about living with illness. The importance of peer support for people with diabetes in the context of online communities has been clearly highlighted elsewhere [12,22,23,38,39]. Moreover, engagement in these communities has been shown to positively impact HbA_{1c} levels [23,40]; reduce diabetes-related distress [41]; and foster support and connection, advocacy, self-expression, information and education, technical support, and humor as a coping strategy [38,42].

However, it is also evident that the type of peer support upon which the dissemination of open-source AID systems has been based is of a somewhat different order. In part, this reflects something of the nature of T1D, where the prevailing model of care, inasmuch as it requires individuals to be actively engaged in their care, may potentially foster the growth and dissemination of expertise [43]. In this situation, the delineation of expertise into "professional" and "laypeople" seems outmoded and evokes the well-known Shavian aphorism that the former serves the purpose of conspiring against the latter [44].

As AID algorithms are being constantly developed further and new features will be introduced (eg, fully closed-loop systems without bolusing for meals), future research should address the lived experiences of people with diabetes associated with their use in addition to the analysis of clinical outcomes. Their full health impact can only be evaluated if real-world user experiences are included.

Looking back at how innovations in diabetes treatment were perceived by HCPs and the scientific community over the last century, increased autonomy and empowerment of people with diabetes have continuously been regarded with skepticism. Similarly, it was debated if people with diabetes were capable of blood glucose self-monitoring in the 1970s [45], calculating their insulin doses by themselves, or understanding real-time readings of their CGM device [46]—all aspects that are standard of care today. In the IT age, people with diabetes creating their own technological tools might be just another iteration of patient empowerment but accompanied by similar controversy. The "lesson learned" from these controversies should be the urgency to foster collaboration with patients and involve them early as stakeholders—whether in research and development of medical devices or the development of care concepts that will ultimately affect them.

This study is the first large-scale qualitative study assessing the lived experiences of adult open-source AID system users. Moreover, it is a study with a truly multinational scope, and in

XSL•FO
RenderX

its stakeholder engagement via the involvement of the #WeAreNotWaiting community, it strives to remain true to the values of the phenomenon it is investigating.

Of course it should be noted that the survey was undertaken in 2019, and thus the participants can be considered early adopters of open-source AID systems. At one level, this means that the size of our sample represents what, at that time, was a significant proportion of all users of open-source AID systems. However, by the same token, given the subsequent dynamic technical development and rapid expansion of open-source AID system users since that time, the experiences captured in our study may not be reflective of later experiences and current use of open-source AID systems. In addition, many position papers and an international consensus paper have been published to provide guidance to HCPs who wish to support people using open-source AID systems, which may have contributed to increased knowledge and a change of attitudes [47,48]. A selection bias may be present with the survey only being available in German and English.

Conclusions

The efforts of the #WeAreNotWaiting community are changing the landscape of available treatment options and the way we look at the role of patients as initiators rather than as passive recipients of a health care product or service. The online communities that support this movement have not only transformed diabetes care with its technology but have also eased the individual burden for those involved due to the tools and peer support it has fostered. The extensive testimony from users of open-source AID systems acquired in this study provides new insights, highlighting factors inspiring people to adopt such solutions, user experiences in transitioning to open-source AID systems, and the transformative impact of AID systems on the everyday life of people with diabetes. These results may contribute to a better understanding of their unmet needs; the impact of AID systems on physical and emotional health; and some of the current challenges to the uptake of AID technology in terms of access, availability, and usability.

Acknowledgments

This study is part of the OPEN project. OPEN is funded by the European Commission's Horizon 2020 Research and Innovation Program under the Marie Skłodowska-Curie Action Research and Innovation Staff Exchange (grant 823902), the Deutsche Forschungsgemeinschaft (DFG)-funded Digital Clinician Scientist Program of the Berlin Institute of Health, and the SPOKES Wellcome Trust Translational Partnership Program.

Data Availability

The datasets generated and analyzed during this study are available from the OPEN project on request. Researchers interested in working with the OPEN data are encouraged to submit inquiries for data access to the project coordinator (SO) via email. The authors welcome the opportunity to collaborate and accommodate research needs where possible.

Authors' Contributions

BC, KB, SO, AT, KR, DL, and TS designed the study. KB and KR were responsible for administration and ethics approval. KB collected the data. KB, MW, and TS processed the data. BC, YC, MW, HB, DC, and SO analyzed the data. BC, YC, and KB drafted the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Early maladaptive schemas (EMSs) are pervasive, self-defeating patterns of thoughts and emotions underlying most mental health problems and are central in schema therapy. However, the characteristics of EMSs vary across demographics, and despite the growing use of online mental health communities (OMHCs), how EMSs manifest in these online support-seeking environments remains unclear. Understanding these characteristics could inform the design of more effective interventions powered by artificial intelligence to address online support seekers' unique therapeutic needs.

Objective: We aimed to uncover associations between EMSs and mental health problems within OMHCs and examine features of EMSs as they are reflected in OMHCs.

Methods: We curated a dataset of 29,329 posts from widely accessed OMHCs, labeling each with relevant schemas and mental health problems. To identify associations, we conducted chi-square tests of independence and calculated odds ratios (ORs) with the dataset. In addition, we developed a novel group-level case conceptualization technique, leveraging GPT-4 to extract features of EMSs from OMHC texts across key schema therapy dimensions, such as *schema triggers* and *coping responses*.

Results: Several associations were identified between EMSs and mental health problems, reflecting how EMSs manifest in online support-seeking contexts. Anxiety-related problems typically highlighted *vulnerability to harm or illness* (OR 5.64, 95% CI 5.34-5.96; *P*<.001), while depression-related problems emphasized unmet interpersonal needs, such as *social isolation* (OR 3.18, 95% CI 3.02-3.34; *P*<.001). Conversely, problems with eating disorders mostly exemplified negative self-perception and *emotional inhibition* (OR 1.89, 95% CI 1.45-2.46; *P*<.001). Personality disorders reflected themes of *subjugation* (OR 2.51, 95% CI 1.86-3.39; *P*<.001), while posttraumatic stress disorder problems involved distressing experiences and *mistrust* (OR 5.04, 95% CI 4.49-5.66; *P*<.001). Substance use disorder problems reflected negative self-perception of *failure to achieve* (OR 1.83, 95% CI 1.35-2.49; *P*<.001). Depression, personality disorders, and posttraumatic stress disorder were also associated with 12, 9, and 7 EMSs, respectively, emphasizing their complexities and the need for more comprehensive interventions. In contrast, anxiety, eating disorder, and substance use disorder were related to only 2 to 3 EMSs, suggesting that these problems are better addressed through targeted interventions. In addition, the EMS features extracted from our dataset averaged 13.27 (SD 3.05) negative features per schema, with 2.65 (SD 1.07) features per dimension, as supported by existing literature.

Conclusions: We uncovered various associations between EMSs and mental health problems among online support seekers, highlighting the prominence of specific EMSs in each problem and the unique complexities of each problem in terms of EMSs. We also identified EMS features as expressed by support seekers in OMHCs, reinforcing the relevance of EMSs in these online support-seeking contexts. These insights are valuable for understanding how EMS are characterized in OMHCs and can inform the development of more effective artificial intelligence–powered tools to enhance support on these platforms.

Introduction

Background

Over recent years, mental health problems have become increasingly prevalent worldwide [1-3]. However, access to professional therapy remains limited for many individuals due to high treatment costs and a shortage of trained mental health professionals [4-6]. As a result, a growing number of individuals are seeking support for their problems through online mental health communities (OMHCs) [7-9]. These communities provide a more accessible alternative to professional therapy [10,11], allowing individuals to share their distressing experiences and receive peer support to help them cope [11,12]. These problems, typically shared through posts within OMHCs, not only reveal support seekers' struggles but also reflect the underlying dysfunctional beliefs contributing to their distress. These insights are crucial in shaping more personalized and effective online interventions for support seekers [13,14].

A set of dysfunctional beliefs commonly present in OMHC posts is early maladaptive schemas (EMSs) [15,16]. Central to schema therapy (ST), EMSs are pervasive, self-defeating beliefs formed in childhood and often persist into adulthood. Young et al [15] identified 18 distinct types of EMSs (Table 1) that distort worldviews and are typically associated with mental health problems, such as anxiety [17-21]. Understanding these associations provides a more reliable method for anticipating potential schemas based on a mental health diagnosis, enabling proactive and targeted therapeutic interventions [15,22,23]. Similarly, recognizing the unique features of each schema (eg, "I'm incompetent when it comes to achievement," corresponding to the *failure to achieve* schema) helps inform targeted interventions (eg, setting small, realistic goals to foster a sense of accomplishment). By addressing these schemas, these interventions can enhance therapy effectiveness and improve treatment outcomes.

However, the characteristics of these EMSs can vary across demographic groups. For example, Cámara and Calvete [18] identified a strong association between the *failure* schema and depression in Spanish university students. However, Wright et al [24] did not report such an association in their study of a US cohort. Similarly, Balsamo et al [25] did not observe a relationship between the *failure* schema and depression among young adults in Italy. Likewise, OMHCs likely present a demographically distinct population of online support seekers reflecting unique EMS characteristics [18,24-26]. Gaining a clearer understanding of these characteristics could provide valuable insights for policy making and the design of more effective digital therapeutic tools for this online support-seeking population. However, how EMSs are reflected in these communities remains largely unexplored, despite their growing importance in mental health support.

This research gap largely stems from the lack of tools for accurately identifying EMSs in the asynchronous, text-based environments of OMHCs. In professional practice, therapists use the Young Schema Questionnaire (YSQ) [27] to assess patients' EMSs through clinically validated statements of dysfunctional beliefs, which patients rate on a scale from 1 ("completely untrue of me") to 6 ("describes me perfectly"). Replicating this structured assessment in OMHCs is challenging due to the unstructured nature of online support-seeking interactions [15,28,29]. Overcoming this challenge requires interpreting EMSs directly from the text, which necessitates specialized natural language processing techniques to identify EMSs in OMHC posts. Recent advancements in large language models (LLMs) have demonstrated remarkable performance in complex language tasks, such as text classification, retrieval, and generation, which require nuanced interpretation of unstructured texts [30-32]. These models can capture subtle meanings in textual discourse, such as recognizing that the phrase "dark tunnel" in "I just feel like I'm stuck in a dark tunnel, and there's no way out" metaphorically conveys despair, isolation, and hopelessness [33]. LLMs have also been used to predict mental health problems, such as depression, from online conversations [34-38] and have recently been applied to predict EMSs in OMHC posts [16].

XSL•FO
RenderX

Table 1. The taxonomy proposed by Young et al [15] of 18 early maladaptive schemas (EMSs) with representative examples from the Young Schema Questionnaire (YSQ) [27]. EMSs represent cognitive and emotional patterns that shape perception and behavior, often contributing to mental health problems.

EMS	Description	Examples from YSQ
Abandonment/instability	The perception that others will not be reliable enough to provide emotional support or connection, leading to a sense of instability and insecurity	"I worry that people I feel close to will leave me or abandon me."
Approval seeking/recognition-seeking	A constant desire for approval, recognition, or acceptance from others to the extent that one compromises their authentic self	"Unless I get a lot of attention from others, I feel less important."
Defectiveness/shame	A deep-seated belief that one is flawed, unlovable, or inferior, leading to feelings of shame and inadequacy	"I cannot understand how anyone could love me."
Dependence/incompetence	A belief in one's inability to handle daily responsibilities or make appropriate decisions independently	"I feel that I need someone I can rely on to give me advice about practical issues."
Emotional deprivation	The belief that one's emotional needs will not be adequately met by others	"For much of my life, I haven't felt that I am special to someone."
Emotional inhibition	The suppression or inhibition of emotions, often due to a fear of losing control or being overwhelmed by intense feelings	"People see me as uptight emotionally."
Enmeshment/undeveloped self	An overly intense emotional attachment and proximity to one or more important individuals (typically parents), which hinders the process of becoming an independent individual and impedes normal social development	"I often found myself constantly turning to my parents for approval in every decision I made."
Entitlement/grandiosity	An exaggerated sense of self-importance and a belief that one deserves special treatment	"I get very irritated when people won't do what I ask of them."
Failure to achieve	The belief that one has failed or will inevitably fail in achieving personal and practitioner goals, leading to a sense of underachievement	"I am humiliated by my failures and inadequacies in the work (or school) sphere."
Insufficient self-control/self-discipline	An inability to control impulses, leading to difficulty in achieving long-term goals.	"I often do things impulsively that I later regret."
Mistrust/abuse	A belief that others are likely to deceive, take advantage of, or harm the person emotionally or physically	"I have been physically, emotionally, or sexually abused by important people in my life."
Negativity/pessimism	A pervasive focus on the negative aspects of life while neglecting the positive aspects	"People close to me consider me a worrier."
Punitiveness	The belief that harsh punishment is deserved for perceived mistakes or failures	"I am a bad person who deserves to be punished."
Self-sacrifice	The belief that one must meet the needs of others at the expense of one's own needs and desires	"No matter how much I give, I feel it is never enough."
Social isolation/alienation	The belief that one is different from others, leading to a sense of isolation and difficulty connecting with others	"I always feel on the outside of groups."
Subjugation	A tendency to prioritize others' needs and desires over one's own because one feels coerced	"I let other people have their way, because I fear the consequences."
Unrelenting standards/hypercriticalness	The belief that one must meet high standards of performance, usually to avoid criticism	"I can't let myself off the hook easily or make excuses for my mistakes."
Vulnerability to harm or illness	The belief that catastrophic events are imminent, leading to excessive worry and anxiety about potential harm or illness	"I feel that the world is a dangerous place."

Objectives

Using the EMS classifiers from the recent study on EMS prediction [16] and leveraging recent LLMs, we can identify EMS labels within large volumes of unstructured OMHC texts. This enables us to (1) uncover associations between EMSs and mental health problems within OMHCs and (2) examine how features of EMSs are reflected in online support-seeking populations. These insights will guide the development of online interventions powered by artificial intelligence (AI) and grounded in ST, tailored to meet the unique therapeutic needs of online support seekers [15].

RenderX

Methods

Curating the Dataset and Identifying EMSs

We curated posts shared by support seekers in 3 highly frequented OMHCs, namely 7-Cups [39], Beyond-Blue [40], and Patient [41], from 2013 to November 2023. Using a custom Python-based web crawler developed for this study, we collected posts from subcommunities focusing on anxiety, depression, posttraumatic stress disorder (PTSD), personality disorders (PDs), eating disorders (EDs), and substance use disorders (SUDs). These mental health problems are prevalent among adults [42,43] and are often treated with ST [15].

To identify EMSs in OMHC posts, we used the entailment-based prediction model (EPM) from a recent study [16]. EPM predicts EMSs from a post by leveraging textual entailment, a sentence-level inference technique from natural language processing [16]. In textual entailment, a statement entails a hypothesis *h* if a human reader would infer that *h* is likely true based on *t* [44]. EPM computes the entailment between sentences in a post and statements from the YSQ. When a sentence entails a YSQ statement, the latter serves as an "explanation" for assigning the corresponding EMS label. For instance, the sentence "Since then I either try to find excuses not to ride or when I do try to ride, I have to push myself and have massive panic attacks." entails the YSQ statement "I often feel that I'm going to have an anxiety attack." This YSQ statement corresponds to the *vulnerability to harm or illness* schema, and the EPM labels the post with this schema. We used the Text-To-Text Transfer Transformer (Google; T5-LLM [45]) in EPM to compute entailment and assign EMS labels to each post.

The 18 EMSs in Table 1 are each represented as a binary categorical variable, where a value *1* indicates the relevance of a schema to an OMHC post, and *0* indicates nonrelevance. In a similar way, we labeled each post with 6 binary categorical variables, each corresponding to one of the mental health problems examined in this study.

Uncovering Associations Between EMSs and Mental Health Problems

Using these categorical variables, we constructed 2×2 contingency tables (Table S1 in Multimedia Appendix 1) and calculated the expected frequency, E_{ij} (equation S1 in Multimedia Appendix 1), and the χ^2 statistic (equation S2 in Multimedia Appendix 1) for each pair of schema and mental health problem [46]. Each χ^2 value was compared to the critical value from the χ^2 distribution table with 1 *df* and a significance level of 0.05. For each χ^2 value that exceeded the critical value, we rejected the null hypothesis to indicate a statistically significant association between a schema and mental health problem. To quantify the strength of association for each statistically significant pair, we calculated the odds ratio (OR), OR_{ems_mhp} (equation S3 in Multimedia Appendix 1), and its 95% CI, $OR_{ems_mhp_95\%CI}$ (equation S4 in Multimedia Appendix 1) [47,48]. Following established guidelines for interpreting ORs [48], we considered an association inconclusive if the 95% CI of the OR included the null value of 1.

Examining Features of EMSs With Group-Level Case Conceptualization

We further examined how online support seekers express their schemas by analyzing specific features reflected in their online posts. For this purpose, we used the case conceptualization technique, which is commonly used by therapists to identify key features related to patients' beliefs and mental health problems, thus facilitating personalized therapeutic interventions. In ST, case conceptualization focuses on several dimensions, including *schema triggers* (situations that activate the schema), *emotions* (associated feelings), *negative thoughts* (irrational beliefs), *coping responses* (behaviors and reactions), and *bodily sensations* (physical and physiological experiences) [15].

We adapted this case conceptualization to our dataset using a data-driven AI approach, which we refer to as group-level case conceptualization. First, we prepared the data by using the EPM to identify sentences from OMHC posts that entailed specific YSQ statements, as outlined in the Curating the Dataset and Identifying EMSs section. These sentences reflected the dysfunctional beliefs and respective schemas established in the YSQ. We grouped these sentences according to their schema, resulting in a distribution of sentence counts by EMSs, which ranged from 8494 for *social isolation* to 98 for *subjugation*. To derive group-level features for each schema, we randomly sampled 10% of the sentences (in Multimedia Appendix 2, we demonstrate that the similarity scores between features extracted from different groups of randomly sampled sentences consistently average 0.79 (SD 0.09), which indicates substantial overlap in the features generated across groups. This validates the approach of conducting in-depth analysis on a single group of randomly sampled sentences for each schema and instructed GPT-4 (OpenAI; we used the model gpt-4-1106-preview for GPT-4) [32] through a custom prompt (Textbox 1) to extract common features among the sentences and categorize them along the dimensions of case conceptualization.

XSL•FO
RenderX

Textbox 1. Prompt used to instruct GPT-4 to extract common features from groups of randomly sampled sentences for each schema.

Identify every common features exhibited from the given sentences. The features should belong to one of the following dimension (a) Schema Triggers (What are the situations that trigger the emotions, negative thoughts, coping responses, and bodily sensations?) (feature should start with: Situation where...), (b) Emotions (What are the feelings involved?) (feature should start with: Feeling...), (c) Negative thoughts (What irrational thoughts are going through the mind?) (feature should start with: Thinking that...), (d) Coping Responses (What are the behaviors and reactions?) (feature should start with: Responding by...), (e) Bodily Sensations (What are the physical and physiological experiences with the body?) (feature should start with: Experiencing...). Provide more than 1 relevant samples from the given sentences for each feature.

If a dimension has feature(s), the output should be in the format as this example:

(d) Coping Responses:

** Destructive or impulsive actions when upset.

• "When I'm angry or frustrated, I sometimes lose control of my emotions and destroy things."

• "Im 22, and I have this problem when I get angry I can't control myself I yell hit stuff around me and often I hurt myself."

If a dimension does not have any feature, the output should be in the format as this example:

(d) Coping Responses:

**NO_FEATURES.

Given sentences:

Ethical Considerations

This study aligns with NUS-IRB Review Not Required guidelines by analyzing nonindividually identifiable data from OMHCs to explore the characteristics of EMSs. Specifically, we used textual content that was already anonymized through usernames and we further decoupled these pseudonyms and other identifying information from the data. In addition, the analysis focused exclusively on examining publicly available data, with no interactions with support seekers. This approach minimized the risks of introducing harmful or unsupportive content while also adhering to ethical guidelines and the responsible use of these online platforms [49,50].

Results

Dataset Statistics

Our dataset comprised 29,329 online posts in which support seekers shared their experiences with various mental health problems. Anxiety was the most frequently mentioned problem, appearing in 51.56% (15,149/20,329) of the posts, followed by depression, which appeared in 33.98% (9966/20,329) of the posts. PTSD, SUDs, PDs, and EDs correspondingly represented 8.75% (2565/20,329), 1.96% (576/20,329), 1.87% (548/20,329), and 1.79% (525/20,329) of the dataset. This distribution aligned with general sociodemographic trends in the prevalence of mental health problems. For example, anxiety is typically more prevalent than depression, while both are more common than PTSD, PDs, and EDs [42,51]. This suggests that the mental health problems discussed in OMHCs may reflect their real-world prevalence, suggesting that policies based on these trends could be effectively applied to online settings.

Regarding post length, the median sentence count was 10 (IQR 5-16). Word count showed similar variability, with a median of 214 words (IQR 124-356). This variability likely reflected the open nature of online support forums, where individuals can express themselves freely, unconstrained by the structured environments of in-person therapy. Unlike therapy sessions, where therapists guide conversations and encourage concise, focused responses, OMHCs allow support seekers to share their experiences through detailed, unfiltered narratives. Consequently, the dataset included both succinct and elaborate descriptions of mental distress.

As illustrated in Table 2, the distribution of EMSs, as predicted by EPM [16], was nonuniform across the dataset. Posts more frequently involved schemas related to *social isolation* and *vulnerability to harm or illness* than schemas such as *approval seeking* and *subjugation*. We hypothesize that this skewed distribution resulted from a combination of societal, environmental, biological, and psychological factors. For instance, modern societal pressures, pervasive social media use, and global crises, such as the COVID-19 pandemic, may amplify feelings of isolation and vulnerability [52,53]. In contrast, schemas such as *approval seeking* and *subjugation* may be less common due to cultural factors, including the emphasis on individualism and self-reliance in many societies [54].

XSL•FO
RenderX

Table 2. Distribution of early maladaptive schemas (EMSs) in posts on mental health problems shared by support seekers on 7-Cups, Beyond-Blue, and Patient, between 2013 and 2023 (N=29,329). The distribution is uneven, with certain schemas being more prevalent, reflecting the diverse emotional and cognitive patterns of individuals seeking support in online mental health communities.

EMSs	Posts with EMSs, n (%)
Social isolation/alienation	12820 (43.71)
Vulnerability to harm or illness	10191 (34.75)
Dependence/incompetence	5414 (18.46)
Abandonment/instability	3736 (12.74)
Enmeshment/undeveloped self	2942 (10.03)
Negativity/pessimism	2777 (9.47)
Defectiveness/shame	2451 (8.36)
Emotional inhibition	2006 (6.84)
Emotional deprivation	1916 (6.53)
Mistrust/abuse	1641 (5.6)
Insufficient self-control/self-discipline	1578 (5.38)
Self-sacrifice	1530 (5.22)
Failure to achieve	1316 (4.49)
Unrelenting standards/hypercriticalness	1301 (4.44)
Punitiveness	839 (2.86)
Entitlement/grandiosity	487 (1.66)
Approval seeking/recognition seeking	475 (1.62)
Subjugation	276 (0.94)

Associations Between EMSs and Mental Health Problems

Among all mental health problems, depression had the highest number of statistically significant associations with 12 out of the 18 EMSs (refer to Table S1 in Multimedia Appendix 3 for specific *P* values, ORs, and 95% CI of these associations). This was followed by PDs and PTSD, which had 9 and 7 associations, respectively. In contrast, anxiety, EDs, and SUDs showed fewer associations, with only 2 to 3 EMSs associated with these problems.

In Table S1 in Multimedia Appendix 3, we present the strength of the association between specific schemas and particular mental health problems using ORs. Consistent with previous works [55,56], we used OR<1.5 to indicate small effect sizes (weak associations), OR<2.5 to indicate moderate effect sizes (moderate associations), OR<4.0 to indicate large effect sizes (strong associations), and OR>4.0 to indicate very large effect sizes (very strong associations). Higher ORs suggest stronger associations, indicating that certain EMSs are relatively more likely to be present in specific mental health problems observed in OMHCs compared to others.

For anxiety, the strongest association was observed with the *vulnerability to harm or illness* schema, reflecting a very large effect size. In contrast, *insufficient self-control* and *emotional inhibition* schemas exhibited weak associations with anxiety.

In the case of depression, schemas with strong associations included *social isolation*, *approval-seeking*, and *emotional deprivation*. Moderate associations were observed for *abandonment*, *defectiveness*, *dependence*, *failure to achieve*, and *negativity*. Meanwhile, *unrelenting standards*, *entitlement*, *punitiveness*, and *self-sacrifice* schemas showed weak associations.

For EDs, moderate associations were observed with the *emotional inhibition*, *defectiveness*, and *self-sacrifice* schemas.

In PDs, the *subjugation* schema exhibited a very strong association, followed by moderate associations for the *abandonment*, *entitlement*, *enmeshment*, *defectiveness*, *punitiveness*, and *mistrust* schemas. Weak associations were observed for *emotional deprivation* and *social isolation*.

PTSD showed a very strong association with the *mistrust* schema and strong associations with *punitiveness* and *subjugation*. The *emotional deprivation* schema demonstrated a moderate association with PTSD, while weak associations were observed for *enmeshment*, *self-sacrifice*, and *abandonment*.

For SUDs, a moderate association was observed with the *failure to achieve* schema, while the *dependence* schema exhibited a weak association.

Features of EMSs Extracted From Group-Level Case Conceptualization

Features of each schema were identified using GPT-4, as detailed in Multimedia Appendix 4. On average, our group-level case conceptualization approach identified approximately 13 features per schema across the 5 dimensions of case conceptualization. *Schema triggers*, *emotions*, and *negative*

XSL•FO
RenderX

thoughts each comprised approximately 3 features, followed by *coping responses* with about 2 features, and *bodily sensations* with 1 feature. Most features conveyed negative connotations. For instance, individuals with the *abandonment* schema often perceived themselves as burdens to others and frequently reported feelings of loneliness, anxiety, and emptiness.

These features also highlighted the unique characteristics of each schema. For instance, the *punitiveness* schema, which centers on self-blame, involved features, such as "situations where there is a fear of repeating past mistakes or events," "feelings of guilt or shame over past actions or events," "thinking that one cannot forgive oneself or others for past wrongdoings," and "responding with self-harm or destructive behavior." These features are elaborated on in the Discussion section.

Discussion

Principal Findings

Associations With EMSs Reflect Varying Complexities Among Mental Health Problems

The associations identified in this study highlight the varying complexities of mental health problems among online support-seeking populations. Depression exhibited numerous associations with EMSs, suggesting a considerable overlap with depression symptomatology. This indicates that EMSs may provide a valuable framework for understanding the diverse factors influencing the experience of depression, underscoring its multifaceted nature [57-60]. Similarly, the large number of associations between EMSs and either PDs or PTSD highlight the heterogeneous and complex nature of these mental health problems, emphasizing the need for personalized and comprehensive therapeutic approaches.

In contrast, fewer associations were observed between EMS and anxiety, EDs, and SUDs, respectively. This suggests more uniform schema-related underpinnings for these problems, suggesting that individuals with anxiety, EDs, or SUDs may present a more consistent and predictable symptomatology. Consequently, treatment strategies for these conditions could focus on targeting specific schema patterns rather than adopting broader, more comprehensive approaches.

The Prominence of "Vulnerability to Harm or Illness" in Anxiety Problems

The association observed between anxiety and *vulnerability to harm or illness* schema aligns with findings from previous studies, which have identified this schema in groups with higher anxiety levels, such as individuals affected by COVID-19 and college students [17,18,24,61,62]. The very strong association found in this study suggests that individuals seeking support for anxiety in OMHCs are very likely to experience and express heightened feelings of vulnerability. This observation aligns with the core purpose of OMHCs: creating a supportive safe space for individuals to share their challenges and vulnerabilities.

In contrast, associations between anxiety and the *insufficient self-control* and *emotional inhibition* schemas, though consistent with previous offline studies [62-69], were weak in OMHCs. One possible explanation is that individuals participating in OMHCs may exhibit greater self-discipline, as their active participation reflects motivation for change and growth [70]. In addition, the anonymity of OMHCs likely encourages more open disclosure, mitigating tendencies for emotional inhibition [12].

Overall, these findings suggest that anxiety-related problems discussed in OMHCs are prominently characterized by perceptions of vulnerability to harm and danger rather than deficits in self-control or emotional inhibition. This highlights the central role of vulnerability in the experiences of online support seekers with anxiety and underscores the importance of addressing these feelings in the development of online peer support interventions.

The Prominence of "Prolonged Unmet Interpersonal Needs" in Depression Problems

The associations between depression and schemas of *social isolation*, *approval seeking*, and *emotional deprivation* are consistent with previous research, suggesting that individuals with depression often experience social exclusion, seek external validation, and report unmet emotional needs [71-75]. These schemas showed strong associations in OMHCs, suggesting these schemas are more likely to appear and are central concerns for individuals seeking support for depression-related problems.

In contrast, schemas such as *abandonment*, *defectiveness*, *dependence*, *failure to achieve*, and *negativity* exhibited moderate associations, consistent with studies relating depression to struggles with fears of abandonment, low self-worth, reliance on others for emotional support, and pervasive pessimism [71,76-79]. These schemas are likely to appear in OMHC discussions on depression but may not dominate the discourse to the same extent as those with strong associations.

In contrast, schemas such as *unrelenting standards*, *entitlement*, *punitiveness*, and *self-sacrifice* demonstrated weak associations. These schemas are less likely to emerge in OMHC discourse on depression, although these schemas have been identified as relevant to depression in previous studies [74,77,79].

The varying strengths of association between these schemas indicate a focus on prolonged unmet interpersonal needs in depression-related discourse. Strongly associated schemas, such as *social isolation*, *approval seeking*, and *emotional deprivation*, highlight long-term difficulties in forming social and emotional connections. In addition, the *abandonment*, *defectiveness*, *dependence*, *failure to achieve*, and *negativity* schemas reflect interpersonal aspects, although seemingly primarily on the implications of unmet interpersonal needs. Indeed, depression is known to exacerbate interpersonal challenges, further intensifying fears of rejection, lowered self-esteem, interpersonal dependency, and dissatisfaction with both self and life [80-82]. In contrast, weakly associated schemas, such as *unrelenting standards* and *entitlement*, are less focused on unmet interpersonal needs and seem more related to self-directed or situational aspects of depression.

XSL•FO
RenderX

The Prominence of "Self-Neglect and Negative Self-Perception" in ED Problems

The association between the *emotional inhibition* schema and EDs aligns with previous research suggesting that individuals with disordered eating behaviors often use these behaviors to avoid confronting distressing emotions [83-85]. This avoidance hinders healthy emotional processing and could contribute to neglecting psychological well-being.

The *defectiveness* schema reflects deep-seated feelings of inadequacy and self-criticism, which are particularly prevalent in individuals with binge eating behaviors. These individuals often resort to binge eating as a coping mechanism to manage pervasive feelings of shame, self-criticism, and low self-worth [86-88].

The *self-sacrifice* schema reflects a tendency to prioritize others' needs over one's own well-being. This behavior is closely related to pathological altruism, which involves irrational behaviors aimed at promoting the welfare of others but with negative consequences for the individual [89]. In the context of EDs, previous studies have found that individuals engage in self-sacrifice driven by pathological altruism to cope with negative self-perception of inadequacy and defectiveness, often stemming from their maladaptive eating behaviors [90-93].

These schemas demonstrated moderate associations with EDs in OMHCs, suggesting that themes of self-neglect and negative self-perception are likely to emerge from the distress experienced by individuals seeking support for their EDs within these communities.

The Prominence of "Subjugation" in PD Problems

The strong association between the *subjugation* schema and PDs observed in this study aligns with findings from previous research on avoidant PD and borderline PD (BPD) [19,94,95]. This association suggests that individuals discussing PD-related challenges in OMHCs are more likely to articulate struggles related to feeling oppressed by others. These struggles are often accompanied by fears of retaliation, humiliation, or rejection when expressing their true feelings and needs [15]. These fears can hinder their ability to assert themselves, establish boundaries, and manage conflicts effectively.

Moderate associations were uncovered between PDs and schemas such as *abandonment*, *entitlement*, *defectiveness*, *mistrust*, *enmeshment*, and *punitiveness*. While these schemas likely appear in discussions about PDs, they are less prominent compared to the *subjugation* schema. The *abandonment*, *mistrust*, *defectiveness*, and *enmeshment* schemas are frequently observed in individuals with BPD [19,96-98], whereas *entitlement* is more frequently seen in individuals with narcissistic PD [99], and *punitiveness* is associated with both BPD and avoidant PD [19,96].

This study also found weak associations between PDs and schemas such as *emotional deprivation* and *social isolation*. While consistent with earlier studies on BPD [19,21,100], these findings suggest that these schemas are less emphasized in discussions about PDs within OMHCs.

Overall, themes of *subjugation* emerge as a central focus in PD problems discussed in OMHCs. These themes highlight patterns rooted in power dynamics, emotional oppression, and interpersonal dependency. They appear to overlap with other schemas, such as *abandonment*, *defectiveness*, *entitlement*, *mistrust*, *enmeshment*, and *punitiveness*. For instance, individuals who feel subjugated may develop a fear of abandonment if they challenge others' expectations [15]. In contrast, schemas such as *emotional deprivation* and *social isolation* might be less prominent because they focus more on internal emotional states (eg, feelings of neglect or alienation) and less on the relational and power dynamics that are central to subjugation.

The Prominence of "Traumatizing Experiences" in PTSD Problems

The association between PTSD and the *mistrust* schema in OMHCs is consistent with research showing that individuals typically develop chronic mistrust following traumatic experiences involving betrayal, attachment disruptions, or abuse [101-106]. The very strong association suggests that mistrust is very likely to emerge from OMHC discussions on PTSD.

Similarly, the association between PTSD and the *punitiveness* schema highlights the prominent role of self-blame, which is frequently observed in individuals with PTSD [105,107-109]. The association with the *subjugation* schema indicates that individuals may express feelings of being controlled or oppressed, with the anonymity afforded by these online platforms likely encouraging the disclosure of such sensitive experiences [105,106,110,111]. These strong associations suggest that these schemas are more likely to appear in OMHC posts about PTSD.

The association between PTSD and the *emotional deprivation* schema aligns with findings from previous research on traumatized populations, such as veterans and survivors of interpersonal trauma [105,112]. The moderate association observed in this study suggests that emotional neglect is likely to be reflected in OMHC discussions on PTSD.

Consistent with previous studies that identified relationships between PTSD and schemas such as *enmeshment*, *self-sacrifice*, and *abandonment* [105,106], this study identified similar associations. However, the associations observed in OMHCs are comparatively weak, suggesting that these schemas are less central to PTSD experiences shared within these online platforms.

Overall, the findings suggest that individuals seeking PTSD support in OMHCs are more likely to describe acute traumatizing experiences, reflecting schemas such as *mistrust*, *punitiveness*, *subjugation*, and *emotional deprivation*. In contrast, schemas such as *enmeshment*, *self-sacrifice*, and *abandonment* play a lesser role in these discussions.

The Prominence of "Perceived Failure" in SUD Problems

The association between SUDs and the *failure to achieve* schema is consistent with previous research, suggesting that individuals who perceive themselves as underachievers are more susceptible

XSL•FO
RenderX

to substance misuse, and vice versa [20,113-117]. The moderate association observed in OMHCs indicates that themes of inadequacy and failure are likely to emerge in posts related to SUDs.

In contrast, the weak association between the *dependence* schema and SUDs in OMHCs challenges the traditional understanding of the disorder, which often emphasizes a high degree of helplessness and complete reliance on others for daily functioning [118-122]. The weak association suggests that individuals with SUD seeking support in OMHCs may still retain some autonomy and self-sufficiency despite their struggles.

Extracted Features Reflect Known Characteristics of EMSs

The EMS features (features extracted by GPT-4 for each schema are as listed in Multimedia Appendix 4; the features referenced in this section are enclosed in quotes.) identified in OMHCs reflect the core characteristics of each schema and align with previous research. Notable examples are presented subsequently.

Several features of the *vulnerability to harm or illness* schema suggest that it is triggered when an individual "anticipates or experiences a panic attack," "fears a negative health outcome," "encounters social interactions or public places," and "perceives everything is falling apart." These are consistent with the findings of Young et al [15], who noted that this schema is often activated by fears of uncontrollable external events. Similarly, McGinn et al [123] found that heightened anxiety about bodily symptoms and low perceived control significantly increase vulnerability to panic. The looming vulnerability model by Riskind [124] provides additional support for this, proposing that perceived vulnerability amplifies anxiety, manifesting in hypervigilance and beliefs such as "something bad is going to happen" and "one's health is in serious danger." In addition, Faustino et al [17] related this schema to COVID-19–related anxiety, emphasizing how individuals with heightened vulnerability often interpret health concerns as severe. Dean et al [125] observed that social exclusion intensifies vulnerability, perceived harm, and avoidant behaviors, aligning with the feature of "avoiding situations or places." In addition, features related to somatic symptoms, such as "physical discomfort or pain related to anxiety" and "heavy breathing or heart palpitations," were identified, consistent with the findings of McGinn et al [123] on somatic responses to low perceived control and vulnerability. Another notable feature of this schema is "seeking reassurance or help." Groves et al [126] found that patients awaiting medical diagnoses often sought reassurance from nurses, alleviating feelings of vulnerability and fostering greater optimism about medical outcomes.

Features of the *social isolation* schema indicate an increased sensitivity to "potential rejection," often leading individuals to "self-isolate" and "avoid social interactions or places." This behavior aligns with the findings of Watson and Nesdale [127] on how social rejection exacerbates isolation tendencies. Individuals with this schema often view themselves as "unworthy or unlovable," believe "others are better off without them," and believe they are "fundamentally different and unable to connect with others." These beliefs mirror the low self-esteem associated with social isolation and exclusion, as highlighted by Stanley and Arora [128] and Verkuyten and Thijs [129]. Emotional struggles, such as feelings of "hopelessness or helplessness," and at times, "fear or anxiety," are also prevalent. Johari et al [130] reported similar themes among homeless youth in Iran, who frequently experienced loneliness, abandonment, and fears of social harassment. Despite these challenges, some individuals with this schema expressed a "desire for connection," which is consistent with the observation by Cacioppo and Cacioppo [131] that loneliness, while heightening sensitivity to social threats, can also drive efforts to seek and rebuild social bonds.

The *emotional inhibition* schema is characterized by a persistent fear of having "personal issues or emotions disclosed," particularly in "social interaction" settings. This is consistent with findings by Young et al [15] and Coggins and Fox [68], who noted that individuals with this schema often suppress emotions out of concern that "others will judge or misunderstand them." As a result, they frequently experience feelings of being "overwhelmed by anxiety and worry," "scared or fearful," and at times, "helpless or hopeless." This schema is commonly triggered in situations where "negative outcomes are anticipated," as observed by Iwamitsu et al [132], who found that patients with breast tumor reported higher emotional distress when suppressing emotions after receiving their diagnosis. In addition, individuals with this schema often "avoid discussing personal issues" and "internalize feelings without seeking help." These tendencies mirror the inhibition and withdrawal behaviors observed by Denollet and Duijndam [133] in adults who had been socially inhibited, highlighting an aversion to open emotional expression and a reluctance to seek support from others.

Individuals with the *mistrust* schema often exhibit behaviors such as being "untrusting or suspicious" and perceiving others as "deceitful or have malicious intent," particularly when their "personal safety or well-being feels threatened." This aligns with the findings by Young et al [15], who observed that individuals with this schema commonly view others as potential threats, making them feel vulnerable if they lower their guard. Similarly, LaMotte et al [104] found that mistrust plays a role in the relationship between betrayal in romantic relationships and subsequent experiences of intimate partner violence. Individuals with this schema often believe they "will always be a targeted or wronged," aligning with the concept of victim sensitivity [134-136], which involves a heightened expectation of untrustworthy motives in others and intense reactions to perceived injustices. Pilkington et al [137] further highlighted the link between "mistrust" and accounts of violence, particularly in cases of domestic violence. Furthermore, those with this schema often "push others away" and prefer being "isolated or alone." Smith and Rosen [138] observed similar patterns among older clients receiving methadone treatment, who tended to self-isolate because of their mistrust. This self-isolation undermines the development of healthy relationships that are essential for recovery.

The *failure to achieve* schema reflects a persistent belief that one is "not good enough" and has "ruined everything," leading to cycles of "self-criticism." Young et al [15] similarly noted

XSL•FO
RenderX

that individuals with this schema often feel doomed to failure in both present and future endeavors. Wood et al [139] found that such individuals frequently engage in social comparison, seeking reassurance by comparing themselves to others they perceive as less successful. This aligns with the observation that individuals often "compare themselves to peers or societal standards." However, comparisons with those perceived as more successful can often intensify feelings of "jealousy," "disappointment in themselves," and "helplessness," sometimes causing them to "give up trying" to improve their circumstances. Leahy [140] observed that unfavorable comparisons in competitive environments can lead to envy, humiliation, helplessness, and withdrawal. This withdrawal reinforces feelings of failure, perpetuating the belief in one's inability to succeed and deepening cycles of self-criticism.

Limitations

This study focused exclusively on 3 widely accessed OMHCs that use English as the primary mode of communication. To broaden the cultural and linguistic diversity of the sample, future research could explore OMHCs that use other languages and compare the findings of this study with subsequent research to verify whether our results extend to OMHCs in different sociolinguistic and cultural contexts, where schema expression may vary. In addition, while the anonymity of these platforms encourages openness, it limits access to sociodemographic data (eg, age, gender, and socioeconomic status), which might be important in shaping mental health perspectives and schema characteristics. Future studies could explore methods that allow for the ethical anonymous collection of demographic data or use validated techniques to infer demographic characteristics while maintaining user privacy, which is of utmost importance. These suggestions are essential for assessing the generalizability of the EMS characteristics uncovered in this study. Expanding the demographic and cultural scope in future research would help validate and deepen these findings, contributing to a more comprehensive understanding of EMSs in online support-seeking environments.

Conclusions

In this study, we examined the characteristics of EMSs within OMHCs, situating our findings within the existing literature. By analyzing a large dataset of posts from widely accessed OMHCs, annotated with EMS labels using a state-of-the-art EMS classifier, we identified key EMS features and various associations between EMSs and mental health problems. Notably, we found that depression, PDs, and PTSD were associated with a wide range of EMSs, highlighting the complexity of these multifaceted problems. These findings suggest that interventions for these problems could benefit from addressing multiple EMSs simultaneously. In contrast, mental health problems with fewer EMS associations, such as anxiety, may respond more effectively to more targeted interventions focused on specific schemas. In addition, we identified EMSs as more prominently associated with certain mental health problems in OMHCs. For example, anxiety-related posts typically center around vulnerability to harm, while depression-related posts reflect prolonged unmet interpersonal needs. Negative self-perception and self-neglect are prevalent in posts about EDs, while posts about PDs involve themes of subjugation. Posts about PTSD often describe traumatic experiences, and those concerning SUD are marked by themes of personal failure. A key contribution of this study is the novel group-level case conceptualization technique, which uses recent advanced LLMs and prompt engineering techniques to extract EMS features from OMHC posts. This approach provides valuable insights into how EMSs are expressed in online support-seeking environments and has the potential to inform personalized, ST-focused interventions. Overall, this study provides a foundational understanding of EMS characteristics in online support-seeking contexts and their role in shaping mental health experiences. Our findings highlight the potential for tailored, ST-based interventions in online peer support settings, which could enhance therapeutic outcomes and promote the mental well-being of individuals seeking support in these online communities.

Abstract

Background: Online health communities (OHCs) enable people with long-term conditions (LTCs) to exchange peer self-management experiential information, advice, and support. Engagement of "superusers," that is, highly active users, plays a key role in holding together the community and ensuring an effective exchange of support and information. Further studies are needed to explore regular users' interactions with superusers, their sentiments during interactions, and their ultimate impact on the self-management of LTCs.

Objective: This study aims to gain a better understanding of sentiment distribution and the dynamic of sentiment of posts from 2 respiratory OHCs, focusing on regular users' interaction with superusers.

Methods: We conducted sentiment analysis on anonymized data from 2 UK respiratory OHCs hosted by Asthma UK (AUK), and the British Lung Foundation (BLF) charities between 2006-2016 and 2012-2016, respectively, using the Bio-Bidirectional Encoder Representation from Transformers (BioBERT), a pretrained language representation model. Given the scarcity of health-related labeled datasets, BioBERT was fine-tuned on the COVID-19 Twitter Dataset. Positive, neutral, and negative sentiments were categorized as 1, 0, and –1, respectively. The average sentiment of aggregated posts by regular users and superusers was then calculated. Superusers were identified based on a definition already used in our previous work (ie, "the 1% users with the largest number of posts over the observation period") and VoteRank, (ie, users with the best spreading ability). Sentiment analyses of posts by superusers defined with both approaches were conducted for correlation.

Results: The fine-tuned BioBERT model achieved an accuracy of 0.96. The sentiment of posts was predominantly positive (60% and 65% of overall posts in AUK and BLF, respectively), remaining stable over the years. Furthermore, there was a tendency for sentiment to become more positive over time. Overall, superusers tended to write shorter posts characterized by positive sentiment (63% and 67% of all posts in AUK and BLF, respectively). Superusers defined by posting activity or VoteRank largely overlapped (61% in AUK and 79% in BLF), showing that users who posted the most were also spreaders. Threads initiated by superusers typically encouraged regular users to reply with positive sentiments. Superusers tended to write positive replies in threads started by regular users whatever the type of sentiment of the starting post (ie, positive, neutral, or negative), compared to the replies by other regular users (62%, 51%, 61% versus 55%, 45%, 50% in AUK; 71%, 62%, 64% versus 65%, 56%, 57% in BLF, respectively; $P<.001$, except for neutral sentiment in AUK, where $P=.36$).

XSL•FO
RenderX

Conclusions: Network and sentiment analyses provide insight into the key sustaining role of superusers in respiratory OHCs, showing they tend to write and trigger regular users' posts characterized by positive sentiment.

Introduction

Background

Online health communities (OHCs) have been increasingly explored in recent years as a means of enabling people with long-term conditions (LTCs) to exchange peer self-management support [1-3]. Such communities offer an easily accessible and cost-effective means of sharing experiences, exchanging information, and providing mutual support to one another [4,5]. Participation in OHCs for individuals living with LTCs could address part of the health care service demand and indirectly improve access to health care [6]. The analysis of the role of OHCs in health promotion and management of LTCs indicates that there might be a positive effect on patients' perception of social support, health literacy, clinical outcomes, and behavior change [7,8]. Furthermore, the involvement of patients in these OHCs can improve their engagement with respect to their care and their ability to self-manage, their mental health outcomes [9], and contribute to health equity [3]. However, despite the growing popularity of OHCs, there is still much we do not know about how these communities function [10]. Moreover, the specific nature of regular users' interaction with the so-called superusers—that is, individuals who frequently engage with the community—and the extent to which it supports self-management remains largely unknown [7].

Recent social network analysis performed on 2 active respiratory OHCs has suggested that superusers play a critical role in holding together the community and ensuring timely exchange of support and information [5,10]. These superusers have been shown to contribute more content to the community, initiate more interactions, and respond more often to other users' queries than regular members [8,9]. From a topological point of view, their characteristics are similar to those of hubs, that is, nodes with a disproportionally large number of connections compared to other nodes in the network.

Across a variety of empirical domains, it has been documented that hubs are valuable resources that help facilitate the spread of information widely and amplify information cascades [11], for example, help design effective vaccination campaigns and selective immunization strategies against disease diffusion and epidemics [12,13] and help improve the system's robustness and vulnerability to random failures [14]. However, some hub identification approaches can be very time-consuming and suffer from the possibility that spreaders are so close together that they overlap the sphere of influence. In this context, VoteRank is a simple iterative method to identify a set of decentralized spreaders with the best spreading ability [15]. In this approach, all nodes vote in a spreader in each turn, and the voting ability of neighbors of the elected spreader will be decreased in the subsequent turn. It is, therefore, an effective solution for identifying possible nonoverlapping superusers.

However, the analysis of the network topology alone is not sufficient to fully understand the interactions between regular users and superusers and their impact on the whole community. For this reason, it is necessary to analyze the content of posts and what relationships (if any) exist between the 2 groups with respect to how they react to each other's content. Sentiment analysis (SA), that is, a subfield of natural language processing provides an understanding of the sentiment of posts and whether there is a cause-and-effect relationship between posts in a thread. This approach consists of analyzing digital text to determine its polarity, that is if the emotional tone of the message is positive, negative, or neutral. SA can create structured and actionable knowledge from unstructured text for decision makers [16] in different fields, from marketing to politics and health [17]. In particular, with respect to the health domain, a variety of works have used SA techniques (both lexicon-based and semantic-based) [18] in recent years for different health conditions, for example, assessing the degree of psychological distress linked to COVID-19 [19,20], evaluate the risk of alcoholism in particular categories of users [21], analyze the emotional state of users with diabetes [22], or the role digital platforms in mediating health-related support with respect to specific cancer drugs [23]. In most of these works, a distinction is not made between categories of users, their interactions, and their role in OHCs.

This work is part of a research program that will eventually test whether promoting engagement in OHC improves self-management and clinical outcomes [24]. The primary motivation of this study is to investigate the engagement patterns of different user types, particularly superusers and regular users, and how their interactions influence the overall sentiment of posts. Our hypothesis is that superusers play a pivotal role in community cohesion, offering immediate access to a support network for self-management, as well as emotional and illness-related support. By doing so they foster positive sentiment among regular users, which subsequently may mediate improvements in self-management behaviors [25,26]. By understanding these dynamics, we aim to provide insights that can enhance the effectiveness of OHCs.

Using a semantic approach, this study aims to explore the sentiment of posts in 2 dynamic and active respiratory OHCs; in doing this, regular user interactions with superusers are assessed, in order to shed light on the impact of such interactions on users' sentiment and which may ultimately impact on the self-management of their LTCs. Specifically, we investigate the sentiments of both regular users and superusers expressed in these interactions as well as their patterns over time.

XSL•FO
RenderX

Additionally, we aim to compare the sentiment of superusers' posts, with superusers defined in 2 different ways, one with emphasis on high-posting activity and the other on high-spreading ability, to verify whether they display similar characteristics or represent indeed the same population.

By shedding light on these critical aspects, this study contributes to understanding the mechanisms underlying the effectiveness of OHCs as a tool to facilitate self-management and provides insights into how respiratory OHCs may meet the needs of their users.

Data

As described in our previous work [10], data were collected by HealthUnlocked [27], the platform provider of the Asthma UK (AUK) and British Lung Foundation (BLF) communities. In both communities, registered users can choose to either write posts publicly or send private posts to one another. In the latter case, posts are shared between 2 users only, whereas when posts are written publicly, other users can become connected through threads of posts. For this study, only posts that were shared publicly were considered. Our datasets were stored and analyzed in a Safe Haven space, that is, a secured database held by Queen Mary University. Anonymized user IDs were provided by HealthUnlocked, and no demographic information was available. The datasets included posts and their metadata including the date of posting, the hierarchical level of the post within the corresponding thread, and the dates in which the users joined and left the community. No data were collected on participants' characteristics, though only people declaring themselves to be older than 16 years of age were permitted to create an account and take part in OHCs.

Six different types of data associated with the corresponding user actions were collected for each user including (1) posts followed, (2) users followed, (3) likes, (4) level-0 posts (ie, posts starting new threads), (5) level-1 replies (ie, replies to the level-0 posts), and (6) level-2+ replies (ie, replies to other replies beyond level 2). The original datasets consisted of 32,780 data items associated with 3345 users from 2006 to 2016 for AUK, and 875,151 data items associated with 19,837 users from 2012 to 2016 for BLF. Since in this study, we are interested in analyzing only the textual content associated with posts, and some of them turned out to be without any content, they were removed from the datasets. The final datasets, therefore, contained 12,413 and 369,224 posts for AUK and BLF, respectively. In 2015, HealthUnlocked took over the AUK forum, leading to substantial increases in posting activity and volume of users. Further details are provided in the posting activity section of our previous work [10].

Methods

Study Design

Superusers were first identified using two different methodological approaches: (1) their posting activity and (2) their spreading ability. Next, SA was applied first to all posts and then to interactions between superusers and regular users.

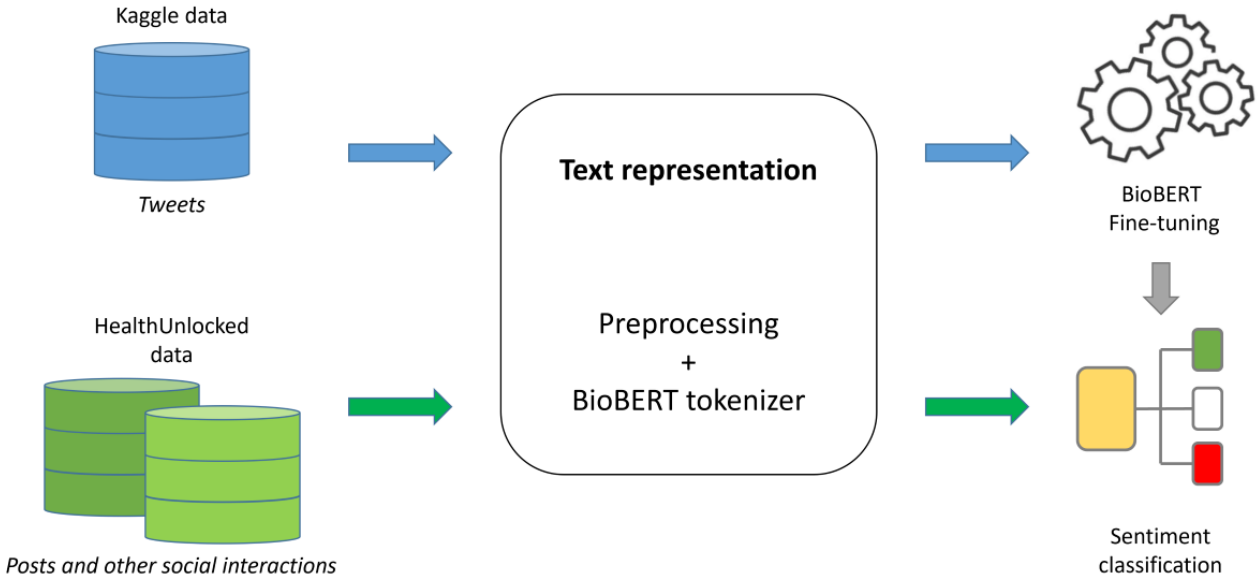
Identification of Superusers

Two ways of identifying superusers were considered. The first method was based on identifying the "top 1% of users characterized by the largest number of posts written in the community over the entire observation period," as previously described in a study by Joglekar et al [10]. The second method approximates being a "spreader" to being a superuser, according to the VoteRank algorithm [15]. This algorithm is implemented in Python (Python Software Foundation) in the *NewtworkX* package [28]. The VoteRank algorithm finds the top-ranked nodes as spreaders according to an influence ranking. The idea behind VoteRank's rank is to choose a set of spreaders one by one according to the voting scores of nodes obtained from the neighbors. The node that gets the most votes in each turn is selected as the most influential node. It is an iterative method where at the beginning all nodes take part in ranking their neighbors. However, when a node is identified as a spreader, it will no longer take part in subsequent iterations and neighboring nodes will have a penalty, so that nodes that are not significant in the transmission of information but exploit proximity to the influencing nodes are not considered as spreaders. To make a fair comparison, we identified and compared the same number of superusers according to the 2 definitions. This was achieved by picking the k top-ranked spreaders by VoteRank, where k is the number of superusers according to the "top 1%" definition.

Sentiment Analysis

SA was carried out by means of a semantic approach based on bidirectional encoder representations from transformers (BERT). BERT is a contextualized word representation pretrained language model [29,30]. Its architecture is a multilayer bidirectional transformer encoder based on the original transformer implementation. Vaswani et al [31] shows further details about the transformer architecture.

BERT is built in 2 steps: pretraining and fine-tuning. The model is trained first on unlabeled data over different pretraining tasks. Later, the model with the pretrained parameters is fine-tuned using labeled data from downstream tasks. Every task has a separate fine-tuned model. However, a unique characteristic of BERT is that it has a unified architecture across different tasks, so the difference between pretrained architecture and the final downstream is small. We used BioBERT (Bio-Bidirectional Encoder Representation from Transformers), which is a pretrained language representation model for the biomedical domain [32].



Fine-Tuning BioBERT for SA

BioBERT was fine-tuned using a COVID-19 Twitter Dataset [33] taken from Kaggle [34]. The choice was opportunistic as there were few open datasets related to health. The COVID-19 Twitter Dataset has a total of 143,903 usable records, with labels associated with neutral, positive, and negative posts. Numeric values have then been associated with sentiment: 0 for neutral, 1 for positive, and –1 for negative posts. Examples of posts with sentiment labels are given in the Multimedia Appendix 1. Normalization and stop-words removal were performed on both datasets.

XSL•FO
RenderX

The considered SA workflow performed on AUK and BLF is illustrated in Figure 1. The BioBERT model was initialized by using the standard configurations and weights from the Hugging Face repository [35]. As a first step, we converted the data to sequences, adding the tags to indicate where the sentence starts and its separator. Then, we tokenized the resulting sequences with the BioBERT tokenizer creating a tensor dataframe of 128 characters. The dataset was then split into training and validation sets, with 85% observations for training and 15% observations for validation. The Adam function was used as an optimizer [36], the sparse categorical cross-entropy as loss function [37], and the sparse categorical accuracy as a metric for training [38]. The training was performed on just 2 epochs with a batch size of 32. Google Colab Pro was used to fine-tune BioBERT [32]. After the fine-tuning, weights, and result configuration files were stored.

Figure 1. Sentiment analysis workflow. BioBert: Bio-Bidirectional Encoder Representation from Transformers.

SA on AUK and BLF

By using the earlier fine-tuned model, we performed SA on AUK and BLF data, including all posts (it is important to note that in this paper when we talk about posts, we also generally include replies; when we consider only replies, we refer to them directly). We performed the following analyses.

Average Sentiment

Average sentiment scores (AVSs) for both regular users' and superusers' posts have been computed separately. As sentiment labels are associated with numeric values (ie, 0 to neutral, 1 to positive, and –1 to negative), the average values of the sentiment of a set of posts can be computed and used to capture the general sentiment expressed in those posts. Specifically, the AVSs range in the [–1, 1] interval, where positive values and getting closer to 1 indicate increasing positive sentiment, while negative values and getting closer to –1 indicate increasing negative sentiment. We considered different aggregations of content types as follows: (1) , the AVS of all posts of a set of users in *v*; that is, either regular users (*U*) or superusers (*S*); (2) , the AVS of level-0 posts of users in *v*; (3) , the AVS of all replies given by users in *v*; (4) , the AVS of level-1 replies given by users in *v*; and (5) , the AVS of level-2+ replies given by users in *v*.

Along with the AVSs, we also computed the percentage of posts with different sentiments to show the distribution of sentiment expressed in users' posts. To investigate the trend of the average sentiment over time, we sorted all posts based on their publication time and regrouped them into 15 bins with an equal volume, for which we computed AVSs. We did not aggregate posts based on the month and year of publication because the number of available data was too small in AUK before 2015 (when HealthUnlocked took over the forum), and because the period of analysis in the 2 communities was different. 2-tailed *t* tests were used for statistical significance when comparing 2 AVSs of different users.

User-Superuser Interaction Sentiment

These analyses investigated the interactions between regular users and superusers. We addressed the following.

- Regular users' and superusers' sentiments when replying to each other: To do this, we first identified threads started by regular users and superusers, denoted as TU and TS, and calculated the AVS of replies written by the other group of users. Specifically, we computed , which denotes the average sentiment of regular users in reply to superusers' initiated threads; and , which denotes the average sentiment of superusers in reply to regular users' initiated threads.
- Regular users' sentiments when replying to other regular users and superusers: Here, we focused on regular users' replies only and checked whether they acted differently when replying to other regular users or superusers. Specifically, we compared with respect to which

XSL•FO
RenderX

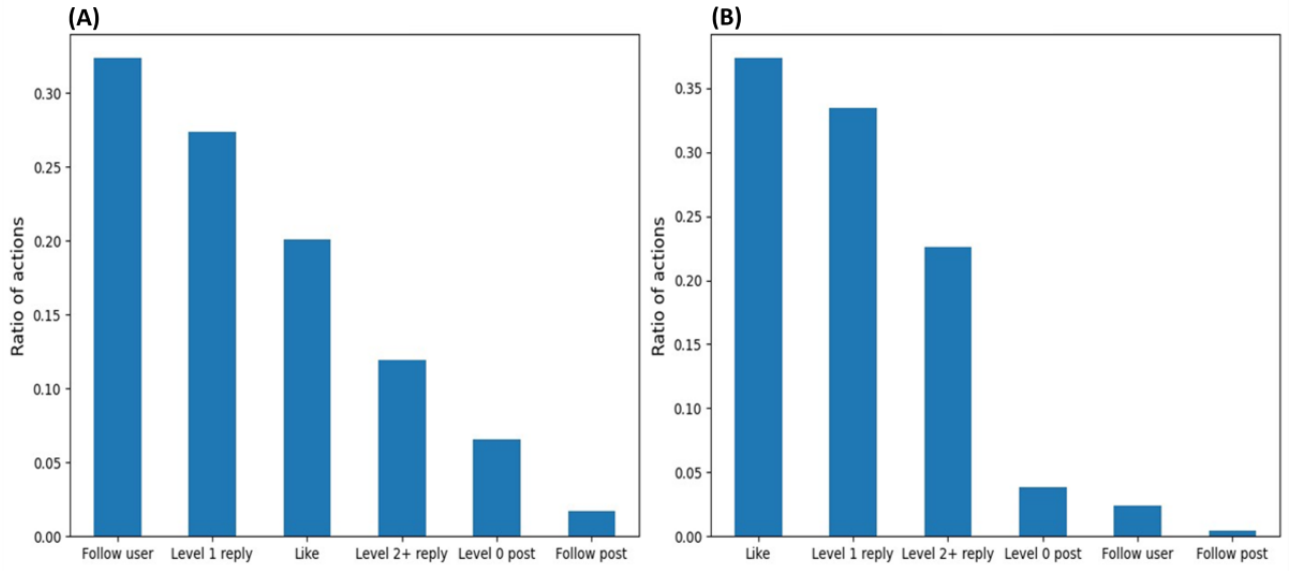
denotes the average sentiment of regular users in replying to other regular users' threads. A similar approach to that introduced earlier was used to analyze the trend in the value of  over time.

- Superusers' sentiments when replying to regular users: In this case, we only took into consideration the sentiment of the replies superusers give to regular users. Note that superusers also interact with each other, but the study of these interactions is beyond our research questions and is not shown here. We investigate the sentiment of superusers in reply to positive, negative, and neutral level-0 posts of regular users. To do this, we computed , which denotes the average sentiment of superusers in replying to regular users' positive level-0 posts; , which denotes the average sentiment of superusers in replying to regular users' negative level-0 posts; and , which denotes the average sentiment of superusers in replying to regular users' neutral level-0 posts.

Regular users' replies to other regular users' level-0 posts are used as a baseline and compared with AVSs of superusers. This analysis assesses in more detail the superusers' tendency to act as help-givers [10], especially when regular users express negative sentiments. Along with the AVSs, we also computed the percentages of posts with different sentiments to show the distribution of sentiment expressed in users' posts. The 2-sample *z* tests for proportions were used for statistical significance when comparing 2 percentages of different users.

A similar approach to that introduced earlier was used to analyze the trend in these percentages over time.

Ethical Considerations



The study was approved by the Queen Mary University Research Ethics Committee (QMERC 22.279). The research team did not have access to personally identifiable information. The data was anonymized to ensure user privacy, and no demographic information was included in the analysis. The posts analyzed were publicly available, with the users having consented to their use for analytical purposes by choosing to share them publicly. In addition, the research protocol was examined and permission to undertake the research was obtained by AUK and BLF charities, and as well as HealthUnlocked. To further protect the privacy of the users, no posts are directly quoted.

Results

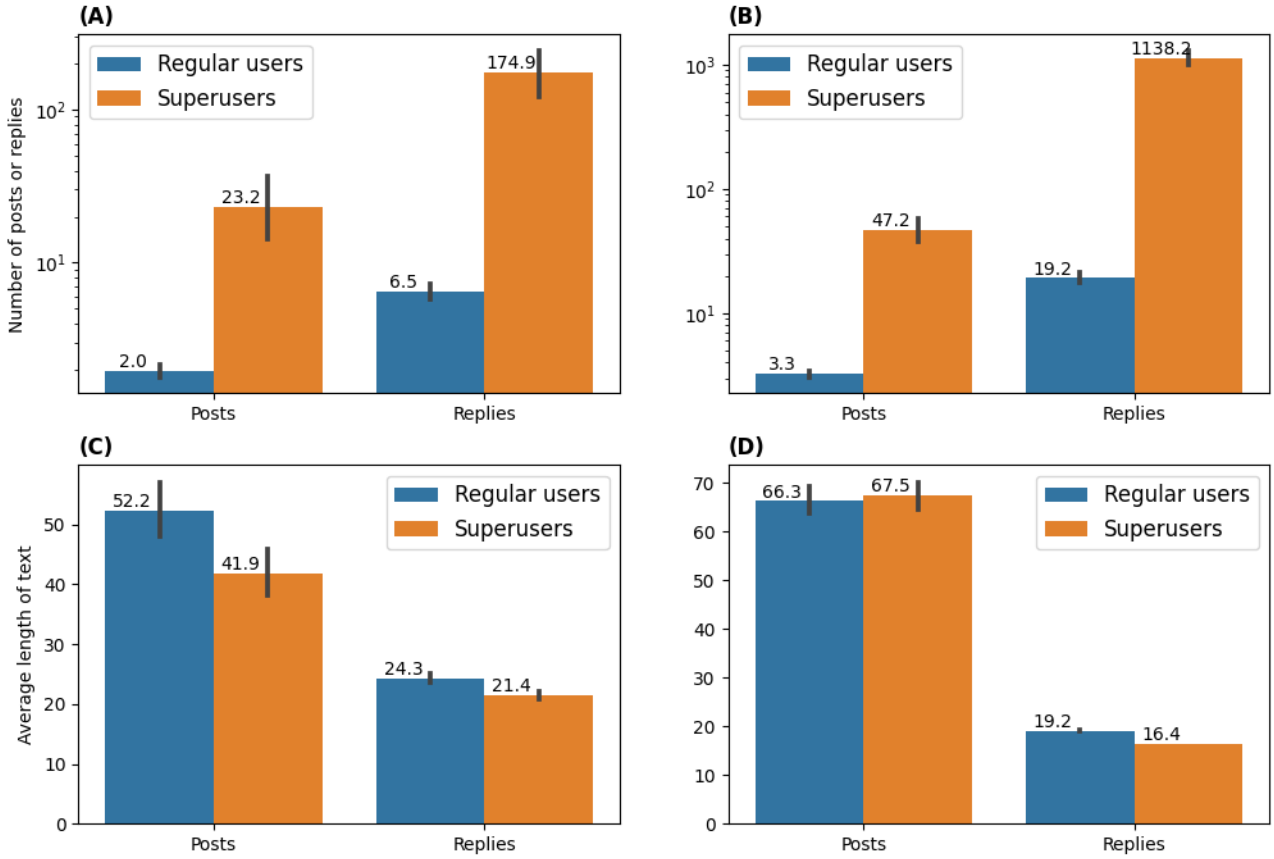
Overview

The ratio of distinct actions over all actions performed with respect to both OHCs is shown in Figure 2. In AUK, the most common action was to "follow" users, while for BLF was to "like" posts or replies. In both communities, the action of generating level-0 posts, that is, starting a new thread, was smaller than generating both level-1 and level-2+ replies, showing that users mostly communicated through replies.

Figure 2. Distribution of different actions in distinct communities. (A) Asthma UK (AUK); (B) British Lung Foundation (BLF).

Identification of Superusers

Using the definition of superusers as the "top 1% of users characterized by the largest number of posts written in the community over the entire observation period" yielded 33 and 198 superusers in the AUK and BLF communities, respectively. A detailed description of users' posting activity can be found in our previous work [10].



Then, we used the second definition of superusers with VoteRank to identify the same numbers of superusers. The ratio of overlap of superusers according to the 2 definitions was greater than 60% (20/33 in AUK and 156/198 in BLF), showing that users who posted the most (1% definition) were largely overlapping with the spreaders (VoteRank definition). As the results observed from both definitions were consistent in this study, we only show in the following the results obtained by using the 1% definition and have moved those obtained with the VoteRank definition to Multimedia Appendix 2. In both communities, 60%-70% of registered users never wrote any

XSL•FO
RenderX

posts, which shows that the majority of regular users were passive (ie, the so-called lurkers).

Figure 3 compares the number of posts as well as the length of text written by both categories of users. Specifically, Figures 3A and 3B show that superusers tended to reply more often than starting new posts, as described in our previous work [10]. Figures 3C and 3D show that both superusers and regular users tended to write longer level-0 posts than replies. In addition, we can observe that superusers' level-0 posts and replies are significantly shorter than regular users' ones in AUK, while they are of similar length in BLF.

Figure 3. Comparisons of the number and length of posts written by superusers and regular users. (A,C) Asthma UK (AUK); (B,D) British Lung Foundation (BLF).

Sentiment Analysis

The fine-tuned BioBERT-based SA with the COVID-19 Twitter Dataset achieved an accuracy of 96% on the validation set.

Average Sentiment

In both communities, most posts were associated with positive sentiment, as illustrated in Figure 4. Figures 4C and 4D show the percentage of posts with positive, negative, and neutral sentiments, across the 15 bins, related in Figures 4A and 4B to sentiment versus total number of posts. In both communities, posts with positive sentiment were always the ones with higher frequency.

Table 1 shows the percentages of sentiment across all posts, along with the overall average sentiment. The average sentiment of superusers' posts was consistently higher than the one for regular users. Both superusers and regular users tended to be significantly more positive in replies compared to their level-0 posts (P<.001).

Figure 5 illustrates the average sentiment in level-0 posts, level-1 replies, and level-2+ replies. Although the patterns of superusers' sentiment were different in the two communities, regular users tended to be the most positive in level-2+ replies and least positive in level-0 posts. This result further confirms that regular users tended to be more positive when having in-depth communications with others in the community.

Figure 6 shows the trend of regular users' and superusers' sentiments over time. There is a trend toward positive sentiment for all users, with superusers being consistently more positive than regular users.

User-Superuser Interaction Sentiment

Regular Users' and Superusers' Sentiments When Replying to Each Other

We first analyzed how regular users reacted to superusers' posts. We specifically identified the threads started by superusers and investigated the sentiments as well as the lengths of replies written by regular users in those threads (Table 2). We compared them with the replies written by superusers in threads started by regular users (Table 2). We showed the number of threads started by different groups of users, the number of threads with replies from the other group of users, AVS, and the average length of text ( ). We calculated the AVS and of (1) posts written by the focal group with replies from the other group, and (2) replies written by the other group of users.

We can observe that, in both communities, superusers started more than a third of all threads (ie, 626/1680 in the AUK and 7831/20,756 in the BLF communities). Regarding the sentiment in posts and replies, the average sentiment of starting posts written by superusers with replies written by superusers at the start of a thread was much more positive than those written by regular users (ie, 0.395 vs –0.004 in AUK and 0.25 vs 0.137 in BLF). Superusers tended to reply in a way that was much more positive than the sentiment expressed in the level-0 posts of regular users. Most interestingly, the sentiment of regular users in reply to superusers' threads was as positive (0.489 vs 0.470 in BLF) or even more positive than superusers' sentiment when replying to regular users (0.447 vs 0.352 in AUK).

In terms of the length of texts, similar to what we found in Figure 3, replies of both superusers and regular users tended to be shorter than level-0 posts. However, superusers tended to write longer texts when replying to regular users than regular users replying to them. This is opposite to what we found in Figure 3, where we show the overall length of superusers' replies tended to be shorter than regular users. This observation suggests that superusers were willing to provide more information as help-givers when replying to regular users.

[d][x]: average length of text.

Regular Users' Sentiments When Replying to Other Regular Users and Superusers

To explore how regular users reacted toward superusers' threads, we investigated superusers' posts with different sentiments separately. Table 3 represents the number of posts written by superusers, the percentage of posts with regular users' replies, and the average sentiment and length of text in those replies. In both communities, the sentiment in regular users' replies was largely affected by the sentiment of superusers in their posts. Regular users tended to be less positive and write longer texts when replying to superusers' posts with negative sentiments.

To investigate how regular users' sentiments in replies to superusers' posts change over time and whether they behaved differently when replying to superusers, we show the trend of regular users' sentiments in threads started by superusers and regular users in Figure 7. In both communities, the sentiment of regular users when replying to superusers' threads was becoming more positive while their sentiment in replying to regular users' threads was relatively stable. The results suggest that superusers were somehow instrumental in the trend toward more positive sentiment from regular users over time.

Table 3. Summary of superusers' threads and how regular users replied to them. [x], [x], and [x] are computed for AVS[a] in corresponding columns.

	Sentiment of superusers (AUK[b])			Sentiment of superusers (BLF[c])		
	Negative	Neutral	Positive	Negative	Neutral	Positive
Posts	189	31	406	2421	866	4544
Replies, %	51.32	61.29	58.13	81.91	69.40	77.11
AVS of replies	0.230	0.508	0.495	0.364	0.435	0.503
[x][d] of replies	24.11	19.41	19.14	19.84	14.11	16.76

Figure 7. Sentiment trend in interactions between superusers and regular users. Average sentiment of regular users when replying to threads started by other regular users and superusers are calculated separately in each bin. (A) Regular users' sentiments Asthma UK (AUK); (B) Regular users' sentiments British Lung Foundation (BLF).

Superusers' Sentiments When Replying to Regular Users

In Table 4, we compared the sentiments of superusers and regular users when replying to threads started by regular users with different sentiments expressed in their level-0 posts. From the sentiment in regular users' replies, we found that regular users' sentiment was largely affected by the sentiment expressed in the level-0 posts. On the other hand, superusers tended to write positive replies in threads started by regular users, whatever the type of sentiment of the starting post, positive, neutral, or negative, compared to regular users (62%, 51%, and 61% vs 55%, 45%, and 50% in AUK and 71%, 62%, and 64% vs 65%, 56%, and 57% in BLF, respectively). $P<.001$ for all pairs except for that in neutral threads in AUK, where $P=.36$. The result suggests superusers replied to regular users in a positive way as help-givers.

In Figure 8, we show the percentage of superusers' replies against the sentiments of the users' posts with different sentiments over time. The percentage of superusers' positive replies only marginally changed over time, and the majority of superusers' replies were consistently associated with positive sentiments, whatever the users' posts' sentiment.

Table 4. Percentage of replies with different sentiments and average sentiments based on the sentiment in the level-0 post in each thread written by regular users. , , and are computed for AVS[a] in corresponding columns. Regular users' replies to other regular users' level-0 posts are used as a baseline and compared with AVSs of superusers.

	Sentiment of regular users (AUK[b])			Sentiment of regular users (BLF[c])		
	Negative	Neutral	Positive	Negative	Neutral	Positive
Regular users' replies						
Negative, %	39.83	21.15	31.93	31.03	22.58	20.80
Neutral, %	9.87	33.65	12.09	11.82	20.48	14.07
Positive, %	50.30	45.19	55.98	57.15	56.94	65.13

Discussion

Principal Results

This study shed novel light on regular users' and superusers' engagement in OHCs and on the impact of their interaction on the sentiment of communication (ie, posts). First, we showed that superusers who posted the most were largely overlapping with the "spreaders" of information and support. Then we found that superusers had a key role in promoting positive sentiment in OHCs, which could represent one of the mechanisms underlying their OHC "sustaining" role. In both OHCs, the great majority of posts were characterized by positive sentiment. This trend did not change over time. The average sentiment of superusers' posts was consistently higher than that of regular users. Both superusers and regular users tended to be significantly more positive in their replies, especially at level 2+ replies compared to their sentiments in level-0 posts. Although this was likely due to the first posts of threads including a request for help presented within the context of a personal story, this could also be interpreted as regular users becoming more positive as a result of the engagement with the community and interaction with superusers. Indeed, the majority of superusers' replies were consistently characterized by positive sentiments, whatever the users' sentiment (negative, neutral, or positive) at the start of threads. Superusers wrote longer posts when replying to regular users, despite their overall tendency to write short posts. This suggests that superusers were willing

XSL•FO
RenderX

to dedicate more time to providing information in replies to regular users compared to other regular users themselves. Moreover, we found evidence of regular users' change toward a more positive sentiment after interaction with superusers. In fact, there was a trend toward more positive sentiment by regular users when replying to threads started by superusers, while their sentiment in replying to threads started by regular users was relatively stable. These results suggest that the active participation of superusers with consistently positive sentiment can not only enhance community cohesiveness but also foster an encouraging environment conducive to positive interactions and ensure the effective spread of informational and emotional support [4-9].

These findings have significant implications for both researchers and policy makers. Superusers in OHCs may represent a scalable and cost-effective health care workforce, providing a means for health and social care integration [6]. Their significant contributions have the potential to alleviate pressure on formal health services by promoting self-management and enhancing community-based care. As current health care challenges emphasize self-care and local service expansion [10], superusers could provide vital support by increasing the confidence of individuals in managing their conditions, reducing the demand on general practices, emergency care, and hospitals, and ultimately saving money within health care systems and across society.

By understanding the mechanisms of community sustainability and the impact of superuser involvement, policy makers and researchers can leverage these individuals as part of a broader health care team to develop and test more effective interventions. Future research is needed to explore how superusers might be formally recognized as contributors to health care, functioning as allied professionals within digital communities. This approach addresses the need for accessible and effective self-management interventions that integrate peer support into health care systems.

Strengths and Limitations

A key strength of this work is the use of previously characterized datasets from 2 established active and dynamic respiratory OHCs [10]. The paper analyzes extensive data from the 2 significant OHCs with activities of more than 20,000 users in total. Based on SA, this work has started elucidating crucial mechanisms underlying the potential of superusers to affect the sentiment of OHC users. Besides, the paper shows the consistency in results with 2 different definitions of superusers, providing a robust basis for its findings.

A limitation of this study is the lack of a domain-specific labeled dataset for the fine-tuning of BioBERT. The choice to use this dataset for fine-tuning BioBERT was opportunistic as there are few open datasets related to health in social networks, and most are about COVID-19. In our study, BioBERT was fine-tuned on a COVID-19 Twitter Dataset. The brevity of Twitter posts, constrained by character limits, might restrict the richness of health discussions compared to longer, more detailed posts found in OHCs. Additionally, the intense emotional tone surrounding the COVID-19 pandemic may skew SA results toward more extreme expressions of sentiment. This could result in a bias toward stronger sentiment expressions in our model's predictions, potentially differing from sentiment trends in other health-related datasets that are not solely concerned about global health crises. A further limitation is the lack of demographic and clinical information of participants as well as verification and validation of the information shared in the OHCs. In this study, the contents of some posts were analyzed for the validity of our sentiment model, however, findings were not validated through a comprehensive semantic analysis of most posts.

Comparison With Prior Work

The results of this study are consistent with previous work and help illuminate the dynamics within OHCs [10]. These results are also in keeping with previous research on emotional contagion [29], which has shown that one person's mood might fleetingly determine the mood of others. Previous work in social networks suggests that happiness is a network phenomenon, clustering in groups of people that extend up to three degrees of separation [30]. Methodologically, users' sentiment was extracted with semantic-based techniques, which is a common approach used in previous research [19-21]. In most of these works, a distinction is not made between categories of users, their interactions, and their role in OHCs. By investigating the sentiments of regular users and superusers as well as during their interactions, this study provides novel insights into the essential role played by superusers. In agreement with previous research, superusers tended to reply to other users' posts [10] with concise posts in general. In addition, when replying to regular users, they tended to provide more information by writing longer texts. Besides, they contribute more content to the community and respond more often to other users' queries than regular members [8,9]. Comprehending the dynamics of superuser interactions can help us understand more about what effective peer moderation could look like (ie, moderation by superusers). It also helps design strategies for better moderation and engagement in OHCs, potentially improving the support and information exchange in these communities.

Conclusions and Future Research

SA provides insight into the key sustaining role of superusers in respiratory OHCs, showing they tend to write and respond with posts with positive sentiment. Future research is needed to develop an approach able to understand the sequence of responses in a discussion thread within the OHC datasets to understand whether a superuser's response was successful in changing the user's sentiment in the case of negativity. Moreover, the existence of groups of users writing posts with negative sentiments could be explored, whether these users form "echo chambers" [39], therefore reinforcing beliefs and reducing exposure to users with alternative views on the topic of discussion. The evolution of such echo chambers over time could also be characterized. Another interesting development could be topic modeling analysis, in order to test the existence of subcommunities based on topics of discussion, but also to investigate the correlation between topics and sentiment types, and user characteristics associated with different sentiments concerning different topics. In addition, it would be interesting to analyze sentiment associated with topics of discussion, for example, symptoms and treatment, to inform the moderation process and provide tailored information or support. The

XSL•FO
RenderX

ultimate aim would be to develop strategies for better OHC moderation, enhanced effectiveness of engagement, and improved OHC users' safety so that engagement in OHCs could be integrated within health care services for patients with chronic conditions.

Acknowledgments

The authors would like to thank AUK, BLF, and HealthUnlocked for granting them permission to conduct the study. The study was partly funded by the National Institute for Health and Care Research Program Grant for Applied Research (reference 202037; effectiveness and cost-effectiveness of a digital social intervention for people with troublesome asthma promoted by primary care clinicians). The views expressed are those of the author or authors and not necessarily those of the National Health Service, National Institute for Health and Care Research, or the Department of Health and Social Care.

The contributors associated with the AD HOC group are as follows: Pietro Panzarasa, School of Business and Management, Queen Mary University of London, London, UK; Georgios Karampatakis, Helen E Wood, and Chris J Griffiths, Wolfson Institute of Population Health, Asthma UK Centre for Applied Research, Queen Mary University of London, London, UK.

Data Availability

Data sharing is not applicable to this article as no datasets were generated during this study.

Authors' Contributions

XL and EV conceptualized the study, with both taking on leading roles. XL led the data curation, formal analysis, investigation, methodology, project administration, and visualization, while EV contributed equally to data curation and supported the formal analysis and visualization. ADS played a leading role in funding acquisition and shared equal responsibility with MV in resource, supervision, and validation. ADS and MV contributed equally to methodology and project administration. GP supported the methodology and supervision. The writing of the original draft was led by XL, with support from ADS and MV, while the review and editing involved all authors as well as the AD HOC group, in which Pietro Panzarasa contributed to the validation and review of the final manuscript; and Georgios Karampatakis, Helen E Wood, and Chris J Griffiths contributed to the review of the final manuscript.

XL and EV share first authorship, while ADS and MV share last authorship.

Conflicts of Interest

None declared.

Abstract

Background: Kidney diseases encompass a variety of conditions, including chronic kidney disease, acute kidney injury, glomerulonephritis, and polycystic kidney disease. These diseases significantly impact patients' quality of life and health care costs, often necessitating substantial lifestyle changes, especially regarding dietary management. However, patients frequently receive ambiguous or conflicting dietary advice from health care providers, leading them to seek information and support from online health communities.

Objective: This study aimed to analyze social media data to better understand the experiences, challenges, and concerns of patients with kidney disease and their caregivers in South Korea. Specifically, it explored how online communities assist in disease management and examined the sentiment surrounding dietary management.

Methods: Data were collected from *KidneyCafe*, a prominent South Korean online community for patients with kidney disease hosted on the Naver platform. A total of 124,211 posts from 10 disease-specific boards were analyzed using latent Dirichlet allocation for topic modeling and Bidirectional Encoder Representations From Transformers–based sentiment analysis. In addition, Efficiently Learning an Encoder That Classifies Token Replacements Accurately–based classification was used to further analyze posts related to disease management.

Results: The analysis identified 6 main topics within the community: *family health and support*, *medication and side effects*, *examination and diagnosis*, *disease management*, *surgery for dialysis*, and *costs and insurance*. Sentiment analysis revealed that posts related to the *medication and side effects* and *surgery for dialysis* topics predominantly expressed negative sentiments. Both significant negative sentiments concerning worries about kidney transplantation among family members and positive sentiments regarding physical improvements after transplantation were expressed in posts about family health and support. For *disease management*, 7 key subtopics were identified, with inquiries about dietary management being the leading subtopic.

Conclusions: The findings highlight the critical role of online communities in providing support and information for patients with kidney disease and their caregivers. The insights gained from this study can inform health care providers, policy makers,

XSL•FO
RenderX

and support organizations to better address the needs of patients with kidney disease, particularly in areas related to dietary management and emotional support.

KEYWORDS

kidney diseases; online health communities; topic modeling; sentiment analysis; disease management; patient support

Introduction

Background

Kidney diseases primarily manifest in 2 main forms: chronic kidney disease (CKD) and acute kidney injury (AKI), which are 2 significant kidney conditions [1,2]. CKD is characterized by a progressive decline in kidney function lasting >3 months, whereas AKI refers to a sudden decrease in kidney function that occurs over a period of hours to days [1,2]. Both conditions can arise from various underlying causes, including primary glomerular diseases (eg, glomerulonephritis), inherited disorders (eg, polycystic kidney disease), and secondary complications of systemic conditions such as diabetes and hypertension [2,3]. These conditions collectively affect a significant proportion of the global population, with CKD alone estimated to affect 13.4% of people worldwide [4]. Both CKD and AKI, regardless of their underlying etiology, increase the risk of other medical complications and significantly impact patients' quality of life and health care costs [2,5]. Managing these conditions can require substantial lifestyle changes, particularly in dietary habits, which can be challenging for patients [6]. However, maintaining a healthy lifestyle can reduce the risk of kidney disease progression and lower mortality rates [7].

Despite the critical role of lifestyle modifications in managing kidney diseases, patients often report receiving ambiguous or conflicting information from health care providers, leading to confusion and a sense of disempowerment [8]. Time constraints in clinical settings further limit the extent of guidance that health care providers can offer, leading many patients to turn to online health communities for information and support.

The use of web-based platforms for health-related information has become increasingly prevalent, with approximately 80% of patients using the internet to exchange information and over one-third of adults using social media for health information and social support [9,10]. Unlike traditional research methods such as surveys or interviews, social media analysis provides access to authentic, unprompted patient discussions, offering unique insights into their daily challenges and evolving needs [9,10]. This approach has been widely used to understand patient experiences within chronic disease communities. For example, studies have used social media analysis to capture patient narratives about cancer [11] and examine the social media behaviors of patients and health care providers across various conditions, including asthma, mental health disorders, diabetes, and gout [12,13].

While topic modeling has been widely used to extract health-related topics from social media, studies specifically examining public discourse on kidney diseases are scarce, particularly in South Korea. Despite the country's high internet penetration and active online health communities, research that systematically analyzes patient experiences with kidney disease through social media remains limited. Successful applications of social media analysis in South Korea include studies on diabetes-related communication on social networking services [14], evaluations of physician-created thyroid cancer content on YouTube [15], the use of topic modeling for pancreatic cancer information [16], and investigations into cross-cultural perceptions of urological conditions [17]. However, comprehensive studies of kidney disease communities are notably absent. These communities often reflect unique cultural challenges and interactions with the health care system that are specific to South Korean patients.

Recent advances in natural language processing (NLP) have transformed how researchers analyze and interpret unstructured health-related text data. Deep learning approaches in NLP have shown significant success in processing various types of health care text, including clinical narratives, electronic health records, and social media content [18,19]. These computational methods are particularly effective in uncovering patterns and insights that are not readily apparent through traditional analytical methods. Applications of NLP in health care range from extracting medical entities and relationships from clinical texts to analyzing patient sentiments, behaviors, and experiences shared in online health communities. Such approaches are instrumental in bridging the gap between raw data and actionable insights in health care research.

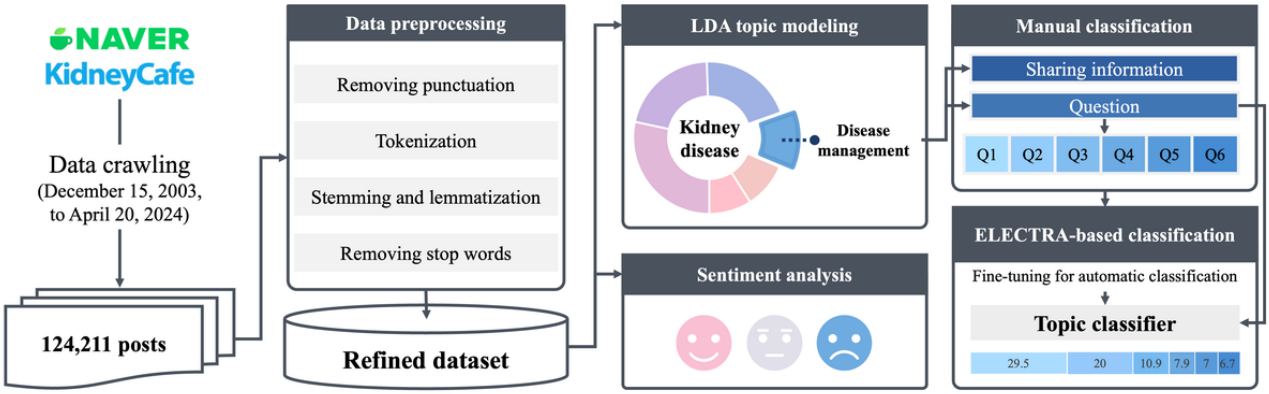
While topic modeling allows for quantitative analysis of discussed topics, it does not fully capture the emotional and experiential dimensions of patients' lives. To address this limitation, our study combined topic modeling with sentiment analysis, using advanced NLP techniques to provide both quantitative insights and a qualitative understanding of patients' emotional challenges. This dual approach bridges the gap between unstructured patient narratives and actionable health care insights. By focusing on the experiences of South Korean patients with kidney disease, our findings can inform the development of culturally appropriate, patient-centered interventions, enabling health care providers to address patient concerns more effectively, design impactful educational materials, and enhance support systems tailored to these patients' unique needs.

Objectives

The main objectives of this study were to (1) analyze social media data using topic modeling to better understand the experiences, challenges, and concerns of patients living with various kidney diseases and their caregivers in South Korea; (2) explore the ways in which online communities can provide assistance, specifically in relation to disease management for

XSL•FO
RenderX

different kidney conditions; and (3) examine the sentiment surrounding disease management among individuals with kidney diseases.



By achieving these objectives, this study aimed to provide valuable insights that can inform health care providers, policy makers, and support organizations in better addressing the needs of patients with a spectrum of kidney diseases and renal conditions.

Methods

Overview

The goals of this study were to identify the challenges faced by patients and determine the key topics related to kidney disease management. We used topic modeling for quantitative analysis and sentiment analysis for qualitative analysis to achieve this. Relevant posts were gathered from online communities discussing kidney disease, preprocessing was conducted, and the topics and sentiments were analyzed. Figure 1 provides an overview of the research methodology.

Figure 1. Overall procedures used in the study. The workflow included data crawling from the Naver KidneyCafe, data preprocessing, latent Dirichlet allocation (LDA) topic modeling, sentiment analysis of the total posts, and manual and Efficiently Learning an Encoder That Classifies Token Replacements Accurately (ELECTRA)–based classification related to the disease management topic. Q1: the safety of specific foods; Q2: dietary management strategies; Q3: dietary recommendations; Q4: water intake management; Q5: weight management; Q6: exercise management.

Data Collection and Preprocessing

We collected data from *KidneyCafe*, a prominent South Korean online community for patients with kidney disease and caregivers hosted on the Naver platform [20]. This community has approximately 183,545 members and facilitates discussions across various themed boards, each concentrating on specific kidney-related topics. For our analysis, we focused on the disease-specific boards within the *Member Participation* section, which is dedicated to active discussions among engaged community members. These boards address topics such as kidney transplantation, dialysis, and related medical conditions, enabling us to capture in-depth conversations pertinent to a wide array of kidney disease experiences and management strategies.

The Selenium WebDriver was used to extract 124,211 posts from 10 disease-specific boards, dating from the community's inception on December 15, 2003, to the date of data collection (April 20, 2024). The collected data included post titles and content.

Data preprocessing was conducted using Python (Python Software Foundation), with the *KoNLPy* library used for Korean NLP [21]. This step involved removing punctuation and noninformative words as well as extracting nouns from the text to prepare for subsequent analysis. To handle informal language patterns in user-generated content, we used a custom-built stop word list to exclude frequently appearing, noninformative terms that do not contribute to semantic analysis. This stop word list was created by reviewing existing lists from similar Korean health-related studies [22] and further customizing it to focus on discussions surrounding kidney disease. These preprocessing steps were essential in ensuring the robustness of our analysis and the interpretability of the results.

Topic Analysis Using Latent Dirichlet Allocation

We used latent Dirichlet allocation (LDA) topic modeling [23], an unsupervised machine learning model, to uncover latent topics in the collected posts. Topic modeling is a technique widely used in NLP for discovering topics and extracting meaning from large, unstructured documents. LDA is the most popular topic modeling method and is based on statistical probability inference. It assumes that each document can be represented by a probabilistic distribution over latent topics, and each topic is characterized by a probabilistic distribution over the words [24].

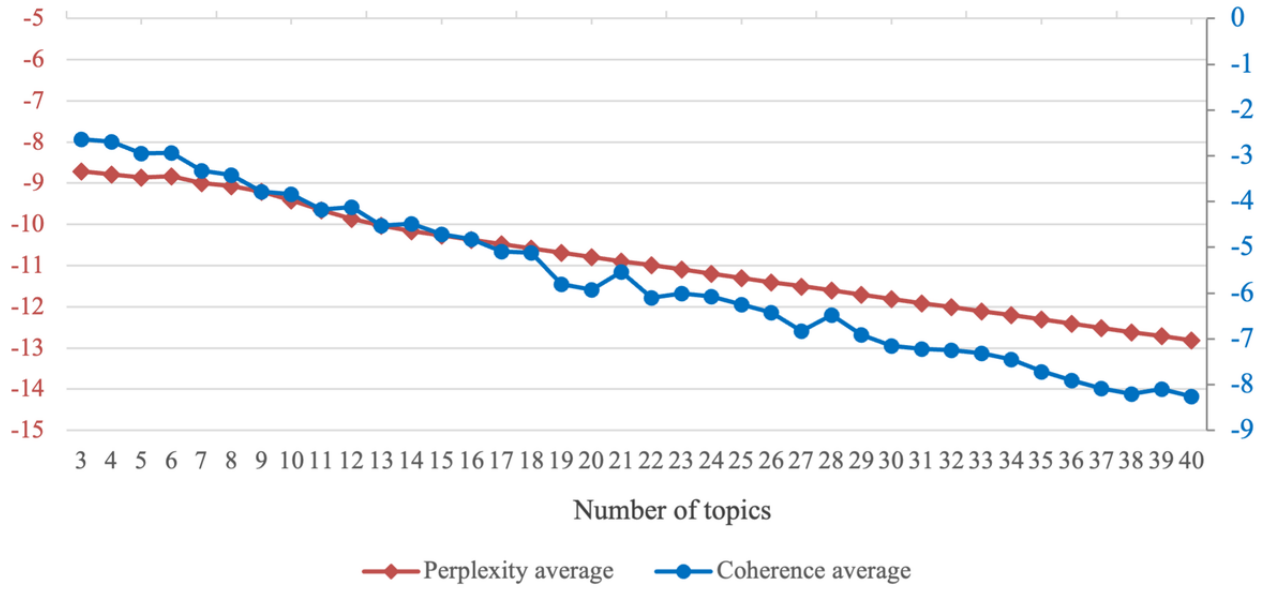
We imported LDA models from the *Gensim* library for this study. When analyzing topics using LDA, the number of topics is typically determined using coherence scores such as U_mass and perplexity [25,26]. The U_mass coherence score, which is based on word co-occurrence statistics within documents, has been validated to closely correspond with human labeling results [27,28]. This score has been effectively used in analyzing health-related social media topics, including obesity, COVID-19, and vaccines [27-30]. Similarly, perplexity has proven to be a valuable metric in recent topic modeling studies [31,32]. While a higher coherence score typically indicates better topic quality and interpretability, recent research shows that statistical optimization alone may not guarantee optimal interpretability of topics [32-34]. To tackle this issue, several studies have

XSL•FO
RenderX

adopted validation methods that integrate statistical metrics with qualitative assessments. For instance, Min et al [31] combined perplexity and coherence metrics with qualitative evaluations in their analysis of occupational accidents, whereas Lyu et al [33] and Li et al [32] emphasized the significance of semantic coherence alongside statistical validation.

Following established approaches [32-34], we first calculated perplexity and U_mass coherence scores across a range of topics (3-40) using 10-fold cross-validation. As shown in Figure 2, both metrics demonstrated better performance with fewer topics, leading us to concentrate on the range of 3 to 10 topics. Within this range, we conducted 10 iterations of the model to ensure consistency and, ultimately, selected 6 topics. This decision was based on a combination of qualitative assessments of topic interpretability and the high U_mass coherence scores observed at both 3 and 6 topics (Figure 3).

Figure 2. Perplexity and U_mass coherence scores across different numbers of topics. This figure shows the perplexity and U_mass coherence scores as the number of topics varies from 3 to 40 using 10-fold cross-validation. Both metrics indicate better performance with a lower number of topics.



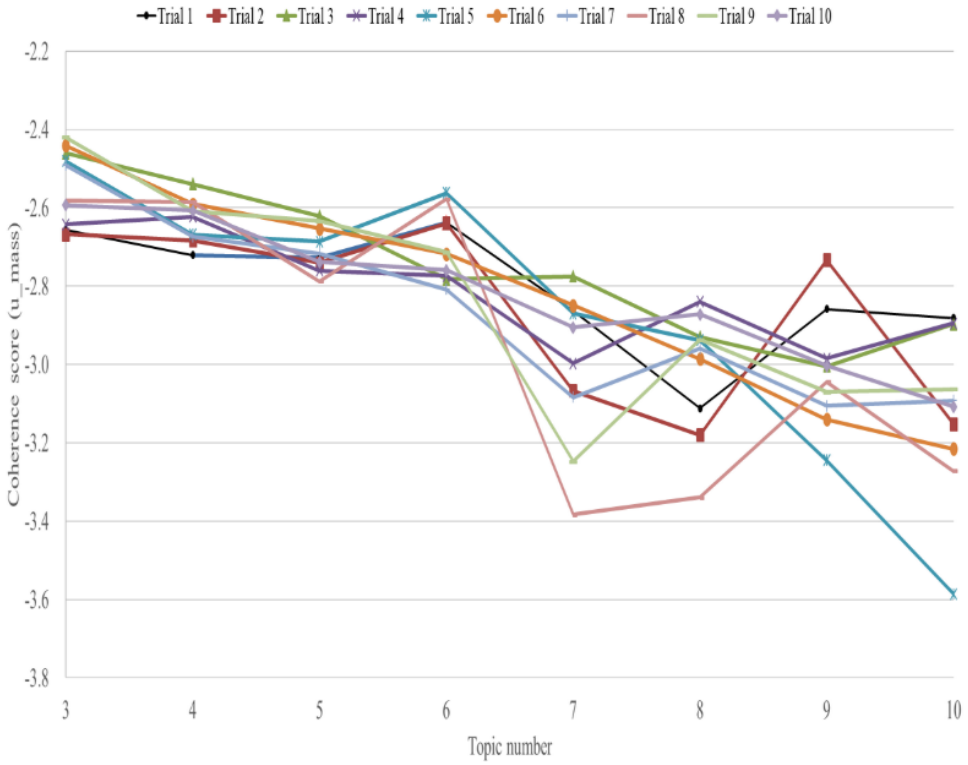


Figure 3. U_mass coherence scores for 3 to 10 topic clusters across 10 trials. This figure shows the U_mass coherence scores as the number of topic clusters increases from 3 to 10 across 10 separate trials. The highest coherence score is observed when there are 3 and 6 topic clusters.

XSL•FO
RenderX

Using the optimal cluster size, we ran the LDA model to obtain lists of representative words for each cluster. The topic-labeling process involved 4 researchers, each with diverse expertise in nutrition and food science, who collaboratively reviewed and interpreted the word lists. We followed established methodologies in social media analysis [33,35,36] using an iterative, discussion-based approach. Initially, each researcher independently analyzed the word lists generated by the topic modeling algorithm, focusing on the most significant terms and their relative weights within each topic to identify potential themes. Next, they reviewed representative posts selected for their strong association with each topic to contextualize the keywords and understand their relevance to the experiences and concerns of patients with kidney disease. This independent review enabled researchers to form initial interpretations and propose tentative labels for further discussion.

After the independent review, the researchers gathered to compare their initial interpretations and collaboratively refine the proposed labels through discussion. When differing interpretations emerged, the team reviewed additional example posts from the topic clusters to gain more context. This process included examining word clouds and representative posts that distinctly exemplified each topic while also considering the specific experiences and information-seeking behaviors of patients with kidney disease. Final topic labels were assigned once all 4 researchers reached a consensus through comprehensive discussion and contextual analysis.

The contribution of each word to a cluster was evaluated using the probability metric derived from the model results. Representative example sentences for each cluster were identified based on the probability that each post belonged to the topic.

Sentiment Analysis

The Bidirectional Encoder Representations From Transformers (BERT) method, a machine learning technique for NLP, was used to identify the sentiment of posts about dietary management—positive, negative, and neutral—to uncover which aspects of dietary management were the most challenging. While word embeddings can be derived from large and unannotated corpora using word co-occurrence statistics, they do not consider the context when creating word vectors [37]. However, BERT is context dependent; it produces dynamic and context-specific representations of the word by accounting for neighboring words, which helps interpret the semantics along with the grammatical structure [38].

The sentiment analysis in this study used the Naver CLOVA Sentiment platform, which uses a pretrained BERT model specifically adapted for analyzing Korean-language texts. This adaptation enables the model to effectively capture context-specific nuances, particularly in the informal and colloquial language common in social media discussions. While the specific parameters and fine-tuning details of the application programming interfaces are proprietary to Naver and cannot be disclosed, the effectiveness of this methodology for Korean sentiment analysis has been validated through several academic studies [39-41]. The platform provides sentiment classification results (ie, which sentiment—positive, negative, or neutral—is best represented in the texts), along with the expected probability of each sentiment.

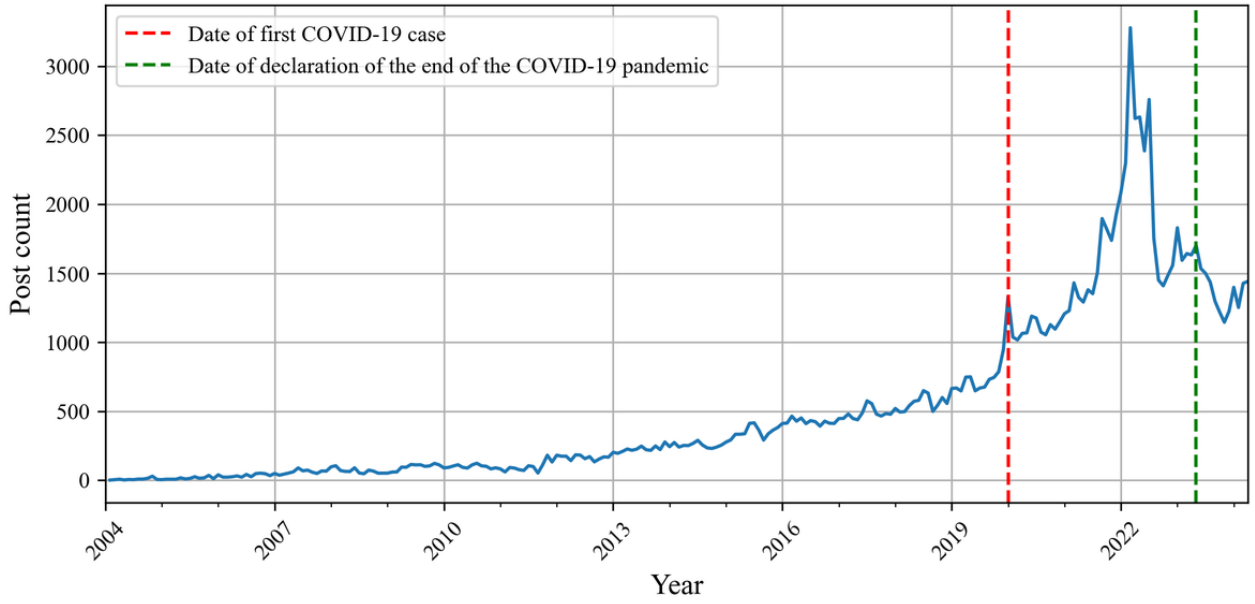
Analysis of the Disease Management Topic Using Efficiently Learning an Encoder That Classifies Token Replacements Accurately

The *disease management* topic was investigated by conducting a detailed analysis. One author manually classified the posts categorized under *disease management* by the LDA results into questions and nonquestions. In total, 3 additional authors independently annotated a subset of 300 posts to establish the annotation rules. The posts were reviewed for seven key sentiments: (1) general dietary management methods, (2) food recommendations, (3) inquiries about the safety of consuming specific foods, (4) requests for dietary evaluations, (5) water management, (6) exercise management, and (7) weight management. After discussion, the annotators agreed on a finalized set of annotation rules and guidelines.

Next, 2 independent annotators labeled a random set of 1000 posts from the overall dataset. The Cohen κ coefficient for interrater reliability was 0.77, indicating substantial agreement. These annotated data were used for transfer learning. We fine-tuned the Efficiently Learning an Encoder That Classifies Token Replacements Accurately (ELECTRA) model, a pretrained language model that has demonstrated state-of-the-art performance across various Korean-language tasks [42]. Compared to BERT and the A Robustly Optimized BERT Pretraining Approach model, ELECTRA offers both computational efficiency and improved performance on downstream classification tasks [43], making it particularly suitable for handling large-scale datasets such as ours. In addition, ELECTRA's generator-discriminator training mechanism has been shown to outperform masked language models in tasks that require nuanced contextual understanding, as validated in previous Korean NLP studies [42]. We used 1000 manually annotated posts split into training and test sets at a ratio of 80:20. The evaluation metrics on the test set yielded an F_1-score of 0.85, indicating high performance. This fine-tuned ELECTRA model was then used to annotate the question posts related to the topic of *disease management*.

Ethical Considerations

This study used preexisting publicly accessible data with no identifiable information and therefore does not require institutional review board review per Federal Regulations for the Protection of Human Research Subjects (45CFR 46.104(d)(4)) or patient consent [44]. In compliance with these guidelines and established research practices, all identifying information, such as usernames and specific identifiers, was anonymized or removed before analysis. This approach is consistent with methodologies used in similar international studies using publicly accessible data [33,45,46], as well as previous research analyzing public Naver Cafe posts [47-49].



XSL•FO
RenderX

Results

Community Overview

We gathered a comprehensive dataset that included 124,211 posts from various discussion boards in the KidneyCafe community to better understand the experiences, challenges, and concerns of patients living with kidney disease and their caregivers in South Korea. These posts were written by 34,472 unique users, indicating a highly engaged community. Of these users, 34.92% (12,039/34,472) wrote multiple posts, with an average of 3.6 (SD 7.3) posts per user. This high level of repeated engagement suggests that many users found ongoing value and support within the community. Figure 4 illustrates the monthly distribution of posts, showing a significant increase during the beginning of the COVID-19 pandemic in South Korea.

Figure 4. Timeline of the number of posts per month. The red line indicates the first confirmed COVID-19 case in South Korea, whereas the green line marks the World Health Organization's declaration of the end of the COVID-19 emergency. Monthly post counts were aggregated.

One of the notable advantages of this community is the categorization of discussion boards according to specific diseases. An examination of the number of posts collected per board (Table 1) showed that the highest number of posts was related to kidney transplantation (39,221/124,211, 31.58%), followed by kidney dialysis (27,692/124,211, 22.29%).

Table 1. Number of posts per board (N=124,211).

Board[a]	Crawled posts, n (%)
Hypertension & Diabetes	1422 (1.14)
Pediatric Kidney Disease	3271 (2.63)
Others	3969 (3.2)
Polycystic & Cysts & Lumps	4011 (3.23)
Kidney Cancer	6097 (4.91)
Chronic Kidney Failure	8216 (6.61)
Proteinuria & Hematuria	10,113 (8.14)
Nephrotic Syndrome & Glomerulonephritis	20,199 (16.26)
Hemodialysis & Peritoneal Dialysis	27,692 (22.29)
Kidney Transplant	39,221 (31.58)

[a]KidneyCafe organizes posts into boards according to specific health conditions.

Main Topics Within the KidneyCafe Community

Overview

We used LDA for topic modeling to identify the common topics discussed by patients with kidney disease in KidneyCafe. Our analysis revealed 6 distinct topic clusters that represented important discussions within the community. Each cluster was labeled based on the main keywords, as shown in Table 2. The distribution of discussion topics across the community was as follows: 28.36% (35,226/124,211) *family health and support*,

XSL•FO
RenderX

21.11% (26,221/124,211) *medication and side effects*, 20.12% (24,991/124,211) *examination and diagnosis*, 11.67% (14,495/124,211) *disease management*, 9.71% (12,061/124,211) *surgery for dialysis*, and 9.03% (11,216/124,211) *costs and insurance*.

Table 2. Keywords representative of the 6 discussion clusters in KidneyCafe.

Topic label	Keywords[a]
Family health and support	"Mother," "father," "discharge," "mind," "preparation," "husband," "start," "family," "groom," "tomorrow," "sibling," "call," "nurse," "life," and "body"
Medication and side effects	"Intake," "immunosuppressant," "symptoms," "side effects," "steroids," "prescription," "cold," "treatment," "morning," "rejection reaction," "dose," "injection," "face," "yesterday," and "head"
Examination and diagnosis	"Blood pressure," "tissue examination," "normal," "creatinine," "blood test," "management," "creatinine levels," "outpatient," "professor," "maintenance," "hematuria," "figures," "current," "diagnosis," and "function"
Disease management	"Exercise," "water," "weight," "food," "rice," "meal," "blood sugar," "potassium," "daily," "diet," "eat," "urine volume," "control," "diabetes," and "snack"
Surgery for dialysis	"Blood vessels," "peritoneal dialysis," "removal," "pain," "recommendation," "procedure," "surgical site," "hemodialysis," "anesthesia," "surgery," "peritoneum," "machine," "arteriovenous fistula," "Seoul," and "endoscopy"
Costs and insurance	"Application," "price," "registration," "antibodies," "usage," "insurance," "error," "Korea," "disease," "occurrence," "brain death transplant," "cross-reaction," "benefits," "treatment," and "donation"

[a]The keywords represent the top 15 terms for each topic ranked by their relevance score from the latent Dirichlet allocation results, making them the most representative words for each topic.

Topic 1: Family Health and Support

Topic 1, which accounted for 28.36% (35,226/124,211) of the discussions, mainly focused on family members with kidney disease and concerns regarding their health. The key terms included words related to familial relationships, such as "mother," "father," "husband," "family," "groom," and "sibling." These terms appeared frequently in discussions about kidney transplantation within the family context.

The following is an example of those posts:

> *It seems like my father will donate a kidney to my mother, but I'm worried.*

In addition, concerns and emotions surrounding posttransplant discharge and care were prevalent, with terms such as "discharge," "mind," and "preparation" appearing frequently in the posts, as shown as follows:

> *I work full-time, so how should I take care of my husband after he is discharged?*
>
> *My sibling offered to donate a kidney, but my mind is very uneasy about it.*

Topic 2: Medication and Side Effects

Topic 2 comprised 21.11% (26,221/124,211) of the discussions and included posts about the correct use, precautions, and dosages of medications. Key terms such as "intake," "immunosuppressant," "prescription," "treatment," "morning," and "dose" were frequently mentioned, highlighting discussions on the proper way to take specific prescription medications. The following are examples of those posts:

> *I was prescribed Solondo. Can Solondo and immunosuppressants be taken together?*
>
> *Should immunosuppressants be taken on an empty stomach in the morning?*

The community also engaged in discussions on various side effects and their causes, with terms such as "symptoms," "side effects," "steroids," "injections," and "rejection reaction" being commonly mentioned. The following is an example of such posts:

> *I was prescribed steroid injections and am experiencing side effects.*

Topic 3: Examination and Diagnosis

Topic 3, accounting for 20.12% (24,991/124,211) of the discussions, focused on kidney disease tests and diagnostic content. Terms related to specific test items, such as "blood pressure," "creatinine," and "hematuria," as well as test methods such as "tissue examination" and "blood test," were particularly frequent.

The following are examples of posts using those keywords:

> *My blood pressure was too low during a blood test.*
>
> *Which is more important, creatinine levels or the glomerular filtration rate?*

In addition, discussions often included receiving a diagnosis from a physician based on test results, with terms such as "normal," "management," "outpatient," "doctor," "maintenance," and "current" appearing frequently. Examples of those posts are shown as follows:

> *I came for an outpatient consultation to review my test results.*
>
> *The doctor said that, as of now, my test results showed normal creatinine levels and glomerular filtration rate, but ongoing management will be necessary for maintenance.*

Topic 4: Disease Management

Topic 4, accounting for 11.67% (14,495/124,211) of the discussions, focused on the management of kidney diseases,

XSL•FO
RenderX

including exercise, water intake, and dietary management. Major keywords such as "exercise" and "weight" were prevalent in exercise management discussions such as the following:

> *What exercises should I do to lose weight?*

Keywords such as "water" and "urine volume" were commonly observed in posts related to water intake management, such as "How much *water* do dialysis patients typically consume?"

Keywords such as "food," "snack," "meal," "diet," "eat," "potassium," and "control" were identified in the context of dietary management. Examples of those posts are shown as follows:

> *What are some high-calorie foods or snacks that don't strain the kidneys?*
>
> *Is it okay to eat snacks after dialysis?*
>
> *I'm following a low-protein, low-potassium diet. What should I be cautious of when planning my meals?*

Topic 5: Surgery for Dialysis

Topic 5, which accounted for 9.71% (12,061/124,211) of the posts, focused on dialysis and predialysis procedures. Major keywords such as "hemodialysis," "peritoneal dialysis," "recommendation," and "pain" were prevalent, with many posters seeking advice on the reasons for selecting and transitioning between the 2 types of dialysis. Examples of those posts are shown as follows:

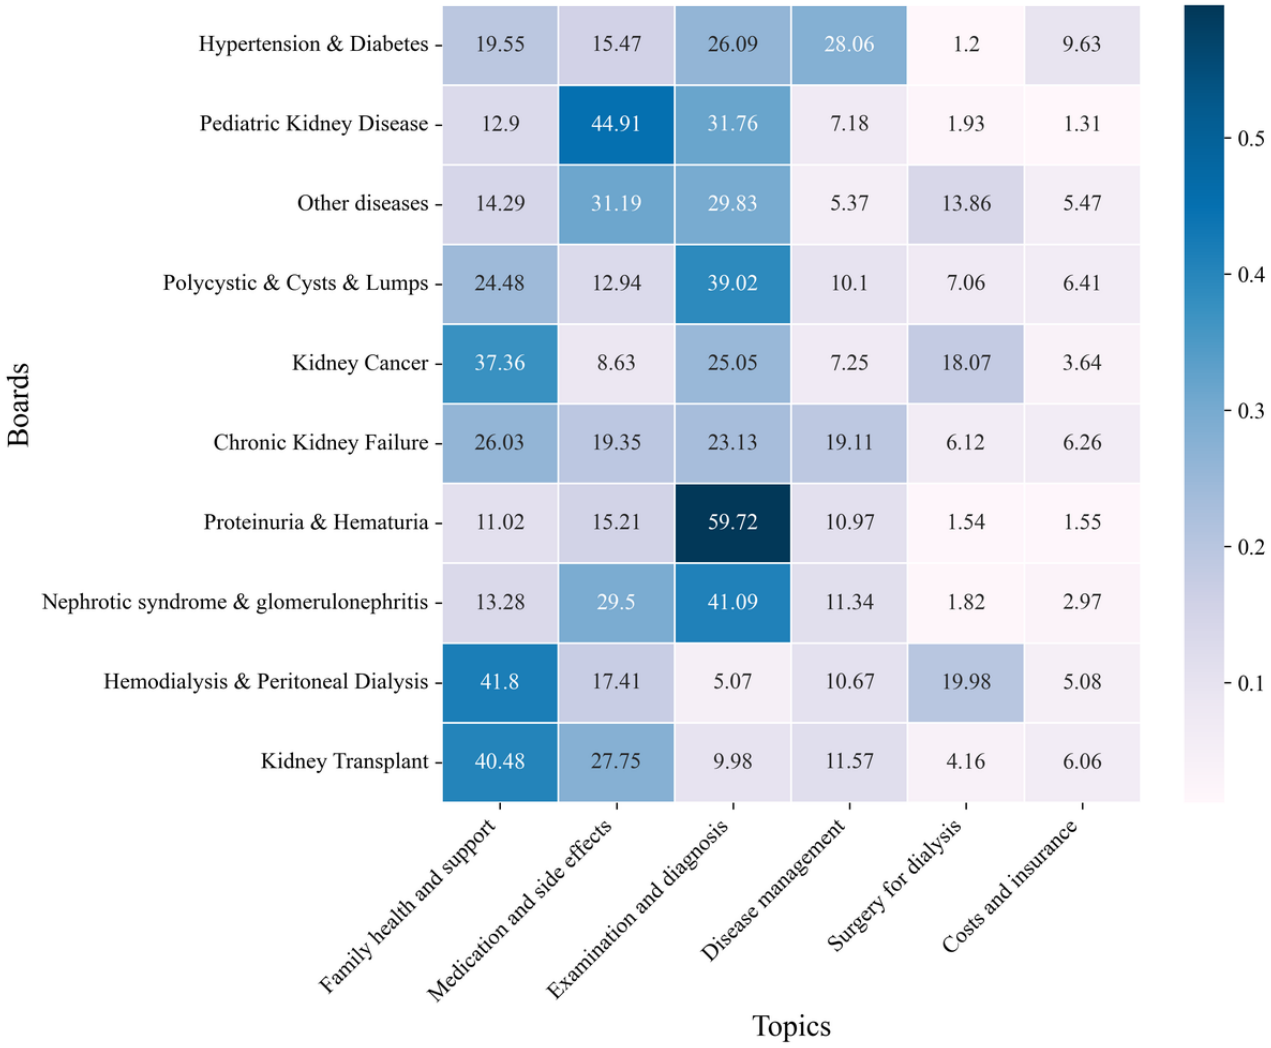
> *Give me a recommendation on whether I should choose hemodialysis or peritoneal dialysis.*
>
> *While undergoing hemodialysis, I experienced pain as the pressure increased.*

In addition, keywords such as "blood vessels," "procedure," "surgical site," "anesthesia," "surgery," "arteriovenous fistula," and "Seoul" frequently appeared in posts related to predialysis surgery, including arteriovenous fistula creation or placement surgery and peritoneal dialysis catheter insertion. The following are some examples:

> *Can you recommend a good hospital in Seoul for arteriovenous fistula surgery?*
>
> *After an arteriovenous fistula surgery, my blood vessel feels enlarged, and the surgical site is swollen. Is it normal for the vessel to enlarge after the procedure?*

Topic 6: Costs and Insurance

In topic 6, accounting for 9.03% (11,216/124,211) of the posts, the users expressed significant concerns regarding financial and insurance-related issues with respect to managing their health conditions. The major keywords were "application," "price," "registration," "insurance," and "benefits." They appeared in sentences such as the following:



> *What documents do I need to prepare for an insurance application and reimbursement for costs?*
>
> *How much compensation do patients undergoing dialysis receive?*
>
> *I am a kidney donor and have registered for insurance. Can I claim insurance benefits?*

Distribution of Topics Across the Boards

We analyzed the distribution of topics across different boards to gain insights into the specific focus areas in each board (Figure 5). Our analysis revealed that the Kidney Transplant board had the highest concentration of posts related to the *family health and support* topic and also showed a significant focus on the *medication and side effects* topic. Of note was that the Hemodialysis & Peritoneal Dialysis board had a higher proportion of transplant-related posts than of dialysis-specific ones. The Nephrotic Syndrome & Glomerulonephritis and Proteinuria & Hematuria boards showed a high concentration of posts related to the *examination and diagnosis* topic. The Pediatric Kidney Disease board notably focused on the *medication and side effects* topic, whereas the *disease management* topic was particularly prominent in the Hypertension & Diabetes board.

XSL•FO
RenderX

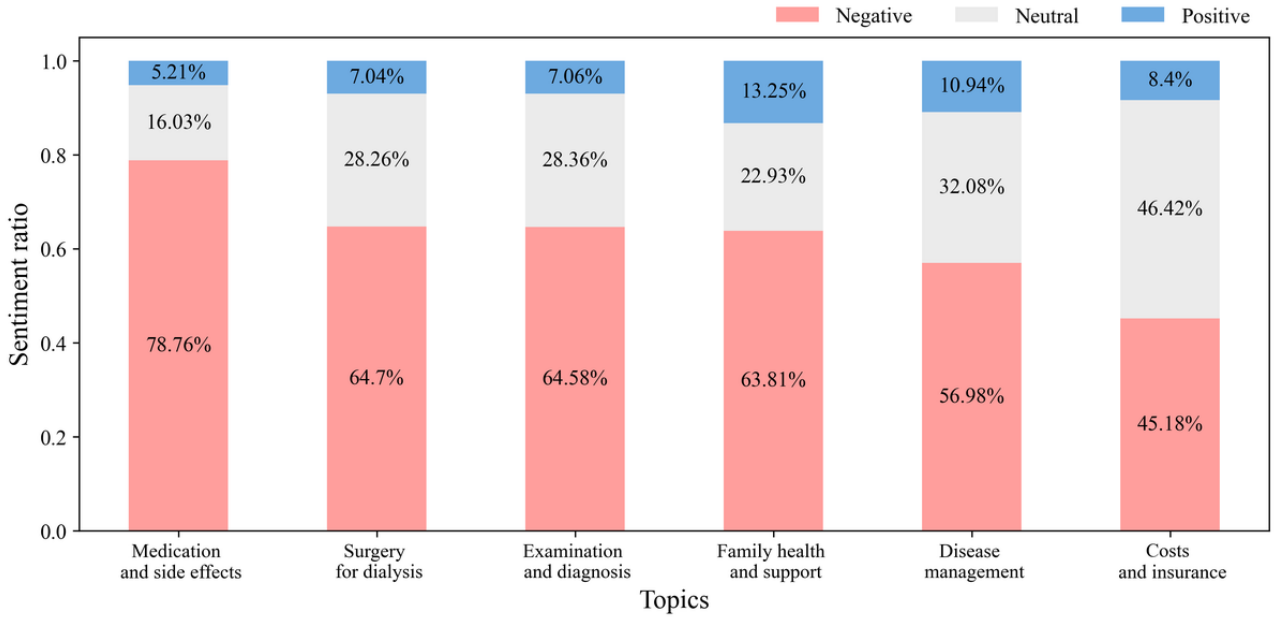
Figure 5. Topic distribution per board. The intensity of the colors represents the frequency of a particular topic on a board, with darker shades indicating a higher concentration of posts related to that topic. The topics are ordered from left to right in descending order of overall prevalence across all boards. The boards are arranged from bottom to top in descending order of total post count.

Sentiment Analysis of the Kidney Disease Topics

Posts on each topic cluster were analyzed to determine their sentiment, which was then categorized as positive, neutral, or negative. The results indicated that posts on the *medication and side effects* topic contained the highest proportion of negative sentiments (Figure 6). This cluster often included discussions about adverse reactions to prescribed medications, concerns about the impact of other drugs on kidney health, and general anxiety about the side effects of medications used to manage kidney disease. The following are a few posts from the community expressing these sentiments:

> *Since starting steroids, my eyes feel very dry, and my legs feel heavy. Is this normal?*
>
> *As a polycystic kidney patient, is it safe to be prescribed medication for severe itching from a dermatologist?*

While many posts described challenges, some shared positive experiences, such as temporary relief from side effects:



> *It was incredibly itchy and kept spreading, so I tried applying various remedies. However, the neem oil I bought from Homeplus yesterday had an immediate effect on the itching.*

Similarly, the *surgery for dialysis* and *examination and diagnosis* topics mainly comprised posts with negative sentiments. These posts often discussed difficulties with dialysis, dissatisfaction with diagnostic outcomes related to kidney disease, and other related issues. The following are some examples from each topic:

> *I'm currently in my third year of peritoneal dialysis. I'm not anemic, but I feel extremely dizzy. Does anyone have any advice?*
>
> *Last year, I was diagnosed with stage 4 polycystic kidney disease, which was tough. Now, finding out that my son has also inherited it makes it even harder.*

XSL•FO
RenderX

Figure 6. Sentiment analysis by topic—the distribution of positive, neutral, and negative sentiments across the 6 topics, demonstrating the varied emotional responses within the community discussions.

Positive sentiments were observed when participants shared their favorable test results:

> *Last December's blood test was normal, and today's urine test also came back clean. I'm relieved but daunted by the thought of restarting my diet management.*

The *family health and support* topic also comprised posts with many negative sentiments, primarily expressing worries regarding kidney transplantation among family members:

> *My sister is insisting on donating immediately, but I'm too worried about her health.*

However, alongside these concerns, high proportions of posts about physical improvements after transplantation were also notable among the positive sentiments:

> *It's been three years since my simultaneous pancreas-kidney transplant. I just tried a urine test kit, and the results are good, which makes me happy.*
>
> *I'm so happy to receive such warm hearts from everyone who left comments. I sincerely thank both the patient-commenters and the patient-readers.*

While the *disease management* topic also had significant negative sentiments, they were relatively fewer compared to the negative sentiments in other topics. Negative posters often expressed frustration with managing the disease or feeling overwhelmed by uncertainties in disease management:

> *Managing my diet is the hardest part.*
>
> *I really want to drink lots of water, but it's sad that I can't.*

In contrast, many posts inquiring about disease management strategies were classified as expressing neutral sentiments:

> *Is it okay to eat wild mango jelly?*
>
> *Does curry have a lot of potassium?*
>
> *For lunch, I had boiled squid and shiitake mushrooms fried with egg whites, enhanced by the flavorful addition of perilla oil.*

In the *costs and insurance* topic, negative and neutral sentiments were expressed in similar proportions. Negative posts often focused on concerns regarding delays or cost issues in insurance paperwork, such as the following:

> *I applied for reimbursement of my cancer diagnosis fee, but the review process is taking too long.*
>
> *I currently have workplace group supplemental insurance, but I'm worried about what will happen after retirement.*

Satisfaction with the health care system was occasionally noted:

> *Korea's health insurance is exceptional, covering both residential treatment and transplant surgery costs.*

In contrast, neutral posts mainly shared information regarding the handling of costs or insurance, such as the following:

> *Today, when I visited the local district office, they provided me with an informational leaflet regarding the required documents for registering as a person with kidney disease.*
>

In-Depth Analysis of the Disease Management Topic

Given the complexity and importance of self-management for patients with kidney disease, we conducted an extensive analysis of the *disease management* topic. We carefully sorted the posts in this category into 2 main groups: information sharing and questions, as shown in Figure 7. We used an ELECTRA-based model to further categorize the questions into 6 specific subtopics. This process allowed us to qualitatively examine which issues were being actively discussed. We also analyzed

XSL•FO
RenderX

the sentiments associated with each specific subtopic, which was important for determining which subtopics were causing more difficulties for the patients (Figure 8).

Figure 7. Subtopics in the disease management topic.

The number of posts under the *questions* category was >4 times higher than that of posts under *information sharing* (Figures 7 and 8). The *information sharing* category included valuable resources such as *Recommended information for post-transplant patients* and *Nephrotic syndrome management methods extracted from the Korean Dietetic Association*. Most posts in the *questions* category were related to dietary management (Figure 7), and these subtopics also comprised posts with more negative sentiments (Figure 8). Specifically, 29.5% (4276/14,495) of the inquiries were about the safety of specific foods, 20% (2899/14,495) sought guidance on dietary management strategies, and 10.9% (1580/14,495) requested dietary recommendations. Examples of inquiries about the safety of specific foods included the following:

Can I eat ginger if I have diabetes or kidney disease?

Are low-sodium salt and low-sodium soy sauce sold in stores okay?

Examples of inquiries seeking guidance on dietary management strategies included the following:

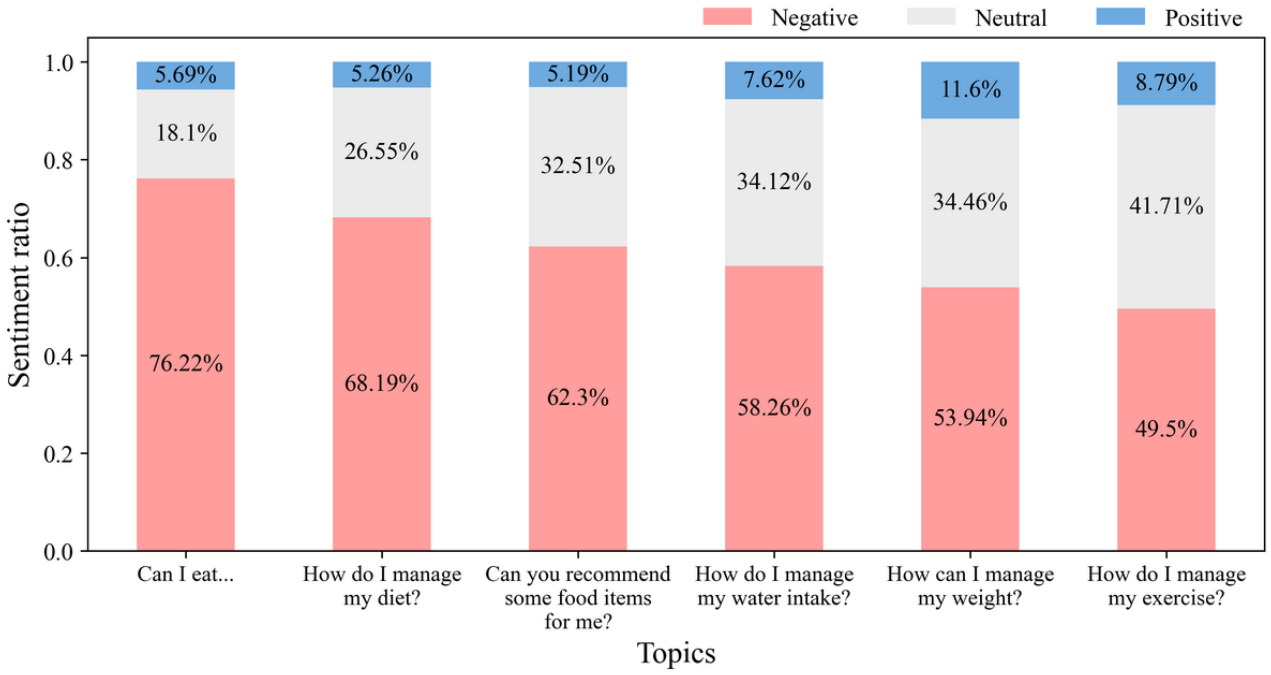
How should a single working person manage their weekday diet?

How should I manage my diet for proteinuria?

Examples of inquiries requesting dietary recommendations included the following:

Can you recommend low-potassium foods?

Other popular subtopics included water intake management (1145/14,495, 9%), weight management (1015/14,495, 7%), and exercise management (971/14,495, 6.7%). Examples of these questions included the following:



Is it okay to do high-intensity exercises like CrossFit if I have polycystic kidney disease?

What should I do if my weight keeps dropping?

How many liters of water do you drink per day?

Figure 8. Sentiment analysis by disease management subtopic—the distribution of positive, neutral, and negative sentiments across the 6 subtopics, demonstrating the varied emotional responses within the disease management topic.

Discussion

Principal Findings

Our study findings provide valuable insights into the concerns and challenges faced by patients with different kidney diseases and conditions. The analysis of online community discussions revealed several key points with important implications for patient care, education, and support.

Impact of the COVID-19 Pandemic

The analysis revealed a significant increase in community activity during the COVID-19 pandemic. This observed increase underscores the heightened health concerns and information needs of patients with CKD during this period. This finding aligns with research highlighting the increased vulnerability of patients with CKD to COVID-19 complications [50-52] and emphasizes the importance of online communities as sources of support and information during health crises.

Topic Distribution and Varied Information Needs Across Disease Stages

Our analysis identified six main discussion topics in the kidney disease community: (1) *family health and support*, focusing on concerns surrounding kidney donation among family members and posttransplantation management; (2) *medication and side effects*, where conversations centered on medication administration methods and the associated side effects; (3) *tests and diagnostics*, where results of blood tests and tissue examinations were predominantly discussed; (4) *disease management*, which involved advice and shared experiences related to exercise, diet, and fluid intake; (5) *surgery for dialysis*, which addressed dialysis methods and surgical procedures; and (6) *costs and insurance*, covering financial burdens related to managing kidney disease and insurance issues.

Our findings demonstrate distinct differences in patient concerns and priorities across various stages of kidney disease. Early-stage patients, as evidenced by discussions on the Nephrotic Syndrome & Glomerulonephritis and Proteinuria & Hematuria boards, primarily focused on examinations and diagnoses. These discussions often included inquiries about test results, such as creatinine levels and glomerular filtration rates, as well as clarifications on diagnostic procedures. This reflects a strong emphasis on understanding their condition and its implications. This aligns with prior work that emphasizes the importance of initial diagnostic understanding in shaping early-stage patient behaviors [53,54].

As the disease progresses, the focus shifts to managing daily life with kidney disease. On the Chronic Kidney Failure board, discussions centered on dietary restrictions, medication adherence, and emotional coping strategies. These findings align with qualitative studies that highlight the barriers to and facilitators of self-management, emphasizing that managing diet, medication regimens, and psychological well-being are critical yet challenging [55,56].

In the later stages of kidney disease, particularly for patients undergoing dialysis, discussions about transplantation became more prominent. On the Hemodialysis & Peritoneal Dialysis board, many patients compared dialysis methods and sought advice on the transplantation process. These findings underscore the transitional nature of this stage as patients undergoing dialysis often consider or prepare for transplantation. Previous research has similarly highlighted the psychological and logistical complexities associated with the transition from dialysis to transplantation [56].

For recipients of transplants, the focus shifted to challenges unique to posttransplantation life. Posts on the Kidney Transplant board were dominated by topics related to *family*

XSL•FO
RenderX

health and support as well as *medication and side effects*. These discussions reflect the complex challenges faced by recipients of transplants, including adherence to strict medication regimens, management of side effects, and navigation of relationships with family members who may have been donors. This aligns with previous qualitative research highlighting the importance of social support, effective communication, and self-management strategies in facilitating successful posttransplant adaptation [56]. Posts also revealed emotional and relational challenges as recipients of transplants grappled with their roles within family dynamics and the impact of their health on loved ones.

In addition to these stage-specific concerns, our analysis highlighted challenges faced by patients with comorbidities and special populations. The Hypertension & Diabetes board prominently featured the *disease management* topic, underscoring the added complexity of simultaneously managing multiple chronic conditions. The findings emphasize the need for integrated care approaches that address the interplay between kidney disease and common comorbidities [57,58]. The Pediatric Kidney Disease board's notable focus on the *medication and side effects* topic reflected the heightened concern about treatment impacts on children. This underscores the importance of providing tailored support and education to meet the specific needs of these populations.

By examining shifts in patient priorities and concerns, our analysis offers valuable insights into the evolving challenges faced by patients with kidney disease at different stages of their journey. These findings underscore the importance of stage-specific, patient-centered approaches in clinical care and support services.

Emotional Challenges and Support

The sentiment analysis revealed that discussions about medication side effects elicited the most negative emotions. The results identified particularly high levels of negative emotions in the topics of *medication and side effects* and *surgery for dialysis*. This underscores the difficulties that patients with kidney disease face regarding pain management as pain is a significant issue for these patients and significantly impacts their quality of life. Pharmacological changes associated with kidney disease increase the risk of side effects from pain medications, complicating pain management [59,60]. Specifically, >58% of patients undergoing dialysis experience pain, with 49% rating it as moderate to severe [61]. Medications typically need to be taken in the long term, causing ongoing concerns about side effects, which can lead to heightened negative emotions. Similarly, posts on the *surgery for dialysis* topic expressed negative emotions as patients began an indefinite period of dialysis.

The *family health and support* topic showed a mix of negative sentiments. Negative sentiments regarding kidney transplants and their impact on families were also prevalent, consistent with studies showing that both recipients of transplants and their families experience significant stress and concerns [62]. However, successful kidney transplants are associated with improved health outcomes and increased life satisfaction, as indicated by the relatively higher proportion of positive sentiments in posts on this subtopic [63,64]. Thus, kidney transplantation, meaning the end of long-term dialysis and dietary restrictions, which can allow patients to return to a more normal lifestyle, can increase positive sentiments.

Financial Concerns

The emergence of *costs and insurance* as a significant topic indicates that financial burden is a major concern for patients with kidney disease. This finding is consistent with previous research highlighting the economic challenges faced by patients with kidney disease and their families, especially those with limited financial resources [65]. The economic strain of managing CKD encompasses expenses for medical supplies, specialized diets, and transportation to medical appointments. These challenges are exacerbated by various factors, including increased costs during hospital stays for transplantation; additional expenses due to delayed graft function, which can cost an additional average of US $18,000 [66]; and the need for multiple dialysis sessions. The severity of the kidney condition typically correlates with the magnitude of the financial impact [65-67].

The prolonged nature of kidney disease often makes it challenging for patients to maintain stable employment, further contributing to their financial difficulties. The strain of managing a long-term illness can lead to interruptions in careers, thereby increasing economic hardships for both patients and their families. Many patients and caregivers report reduced work hours or job loss, leading to further financial strain [68,69]. The financial burden varies between different countries due to differences in local health care systems, yet the impact on work hours and productivity is universally challenging [70].

Disease Management Challenges

Consistent with previous research highlighting the role of online communities in providing a platform for individuals to share information, experiences, and support regarding health issues [71-73], our study found significant engagement in the *disease management* topic. Posts related to disease management often included sharing daily experiences and asking for advice, particularly about dietary management, which appeared more frequently compared to exercise, fluid intake, and weight management. Previous studies [58,73-75] have identified dietary management as one of the most challenging self-care tasks for patients with kidney disease. The dietary regimen for patients with kidney disease is complex and varies based on the stage of kidney disease or remaining kidney function, necessitating comprehensive management. Individual differences in taste, including a preference for salty food, pose another challenge for managing the disease.

Patients with comorbid conditions such as obesity or diabetes experience additional challenges in disease management [57,58]. Because dietary management is different for different kidney diseases, the question of whether a food item is acceptable for their condition was the most popular among the dietary management questions. This highlights the need for precise and tailored patient education regarding disease management from health care providers.

XSL•FO
RenderX

Comparison With Prior Work

Despite the active discussions in kidney disease communities, a notable paucity of research analyzing these communities exists. To our knowledge, the only study that has previously analyzed a kidney disease community focused on the National Kidney Foundation's online community for CKD [73]. However, this study only qualitatively analyzed approximately 20,000 posts without using topic modeling techniques. In contrast, our study used text mining methods to analyze a larger dataset, capturing more comprehensive insights into the perspectives prevalent in kidney disease communities. Another key advantage of our study was the ability to analyze posts based on disease state, which was not possible in the National Kidney Foundation's online community due to the lack of separate boards for different disease states. The previous study did not conduct a sentiment analysis either.

Other studies exploring the challenges faced by patients with kidney disease have relied on surveys or interviews [67,76]. Analyzing online communities offers practical and voluntary insights into consumer sentiment [77], as highlighted by previous studies [78,79]. Our approach captured a more mainstream perspective due to the vast amount of user-generated content available on the web over extended periods [79]. Traditional survey methods are limited by resource constraints in analyzing data within specific spatial and temporal boundaries. In contrast, diverse individuals contribute extensive posts on web-based platforms, making text mining particularly valuable for the qualitative analysis of such large datasets.

Our findings resonate with the themes identified in previous studies. For instance, previous studies [73,76] have highlighted themes related to *managing CKD and symptoms*, *medical tests and results*, and *navigating health care and clinical needs*, which translated to *medication and side effects*, *tests and diagnostics*, and *disease management* in our study. In addition, *family health and support* and *dialysis surgery* have been similarly categorized as themes such as *considering dialysis* and *family and transplantation*, reflecting the dynamics of CKD status. *Support on the forum*, a significant theme in previous research [73], was classified in our study as *sharing information* within *disease management*, emphasizing the role of information exchange and communication in disease management.

Limitations

While our study provides valuable insights into the discussions and challenges in online kidney disease communities, it is not without limitations.

First, the data were limited to posts from the KidneyCafe community, which may not represent all patients with kidney disease. Individuals who do not actively participate in online communities—due to factors such as digital literacy, access to technology, or personal preferences—were likely underrepresented. This limitation may particularly affect perspectives from older adults and individuals in socioeconomically disadvantaged groups. In addition, the specific context of Korean patients with kidney disease, such as differences in race, lifestyle, economic status, diet, and health care systems, may not be fully generalizable to other countries. These factors play a crucial role in shaping patient experiences and discussions. Conducting comparative analyses that use data from various web-based platforms and formal health care databases can offer a more thorough understanding of how health care systems and societal attitudes affect patient conversations. Furthermore, cross-platform comparisons would help validate our findings and reveal any potential biases specific to certain platforms in patient narratives. Expanding future studies to encompass diverse communities and geographical regions would improve the generalizability and comprehensiveness of our findings, providing deeper insights into the experiences and needs of patients with kidney disease worldwide.

Second, while the topic modeling method (LDA) was effective in extracting main topics, it does not inherently determine the optimal number of topics and may not fully capture semantic relationships between topics. The ELECTRA model, while efficient for our classification tasks, could benefit from domain-specific pretraining on medical corpora to enhance its performance on health-related text. These methodological constraints may limit the depth and precision of the topic modeling and classification results.

Third, the manual annotation process for classifying question posts related to disease management achieved substantial interrater agreement (Cohen κ coefficient of 0.77). However, the potential for bias cannot be entirely ruled out. To mitigate this, clear and detailed annotation guidelines were developed and thoroughly discussed by all annotators before the process began. Regular discussions were held to resolve disagreements and ensure consistency in interpretations, considering additional context from posts when necessary to reach consensus. While these measures contributed to the high interrater reliability observed, the limited number of annotators may have introduced some residual bias.

Fourth, the Naver CLOVA Sentiment platform's BERT-based analysis provides significant advantages for Korean text analysis, particularly its ability to accurately interpret nuanced, context-dependent expressions in kidney disease discussions. However, this approach also has its limitations. Domain-specific lexicon-based methods, widely used in English-language sentiment analysis, provide greater transparency by enabling researchers to trace sentiment classifications back to specific words or phrases [80-82]. These methods have demonstrated effectiveness and explainability in both medical [80,81] and public health research [82], achieving meaningful results. However, their application to Korean-language analysis is constrained by the limited scale and domain-specific coverage of existing Korean sentiment lexicons [83]. This limitation highlights the trade-offs inherent in our methodology—while the BERT-based approach effectively captures contextual nuances, it is less interpretable compared to lexicon-based methods. In addition, the Naver CLOVA Sentiment platform's computational intensity and token limit constraints may restrict its ability to process longer posts comprehensively. These choices reflect our decision to prioritize accuracy in contextual understanding, which was crucial for analyzing complex and nuanced patient discussions in Korean medical contexts.

XSL•FO
RenderX

Future research could address these limitations by incorporating data from multiple online communities, formal health care databases, and private discussions through surveys or interviews. Combining qualitative and quantitative methods, such as incorporating expert review processes or using correlated topic models, could further refine topic selection and analysis. Expanding the scope to include diverse communities from different countries would provide broader perspectives, enhancing the comprehensiveness and generalizability of the findings. These efforts would contribute to a deeper understanding of the experiences and needs of patients with kidney disease across varied contexts.

Clinical Practice Implications

The findings of this study have important implications for clinical practice, emphasizing the crucial role that health care providers play in addressing the emotional concerns and information needs of patients with kidney disease, as is prominently reflected in web-based discussions [84].

The high prevalence of negative sentiments in posts about medication side effects and dialysis surgery underscores the need for health care providers to proactively address patients' fears and anxieties. Strategies may include providing detailed explanations of what to expect during treatments, offering practical coping mechanisms, and regularly monitoring patients' emotional well-being. Research indicates that such proactive support can enhance treatment adherence and improve overall clinical outcomes [85].

Our findings underscore the necessity for clearer and more consistent dietary recommendations as diet-related inquiries dominated the *disease management* topic. Dietary adherence is particularly challenging for patients with kidney disease due to the complexity of nutritional restrictions and their impact on daily life [86]. Patients often express confusion and frustration with conflicting or vague dietary advice, which hinders effective disease management. Health care providers should prioritize offering patient-specific, practical, and easy-to-understand dietary recommendations tailored to the disease stage, comorbidities, and individual preferences. Personalized dietary counseling has been shown to improve adherence and clinical outcomes [87]. Regular follow-up consultations are essential for adjusting these recommendations based on patients' experiences and evolving health needs.

In addition, posts expressing frustration, confusion, or anxiety underscore the importance of empathetic communication and psychosocial support from health care providers. Integrating emotional support into routine care can effectively address these concerns. By fostering empathetic patient-provider relationships and offering clear, actionable guidance on disease management—especially regarding diet—health care providers can empower patients to actively participate in their care, ultimately improving their quality of life.

Conclusions

Our study offers an in-depth analysis of web-based discussions among patients with kidney disease, highlighting key concerns and informational needs. The findings underscore the importance of online communities in providing support and education to patients and caregivers. These insights can inform health care providers and policy makers when developing targeted interventions to address the specific needs of patients with kidney disease. Precise and tailored patient education regarding disease management from health care providers is clearly needed and can be significantly enhanced through the insights gathered from online community discussions.

Abstract

Background: Stigma surrounding women's sexual and reproductive health (SRH) often prevents them from seeking essential care. In South Korea, unmarried women face strong cultural taboos, increasing their risk for conditions such as pelvic inflammatory disease, infertility, and cervical cancer. While many unmarried women turn to web-based communities for support, these spaces frequently expose them to microaggressions, further discouraging their access to health care and worsening their health risks.

Objective: We aimed to encourage a safe space for seeking support on the culturally taboo topic of SRH by counteracting and reducing web-based microaggressions. We sought to make these last-resort safe spaces supportive by reducing and preventing microaggressions, fostering coping strategies, and educating rather than solely punishing perpetrators.

Methods: We conducted co-design sessions with 14 unmarried Korean women. In the first co-design session, we introduced the term microaggression and collaborated with participants to create base design components aimed at countering and preventing microaggressions. In the second co-design session, participants initially viewed examples of microaggression comments, then designed using the provided base design templates inspired by their suggestions from the first session and finally designed for a scenario where they would be seeking support. We analyzed co-design session transcripts using inductive and deductive methods.

Results: Our analysis revealed 6 goals addressing coping strategies, educational approaches, and cultural characteristics shaping participants' designs. Reflective coping strategies were supported through designs that numerically indicate positive support and provide holistic views of diverse perspectives, helping participants reassess provocative situations with cognitive clarity. Suppressive coping strategies were fostered by encouraging less-emotional responses, empowering participants to address microaggressions logically without self-blame. Educational approaches emphasized fostering shared awareness of microaggressions and providing respectful education for perpetrators about the harm their words can cause. Participants suggested counterspeech mechanisms, including rephrasing suggestions and public educational resources, to balance education with freedom of expression. They also proposed that forum-approved experts guide discussions to ensure accurate, empathetic responses and support users in addressing nuanced situations effectively. Cultural characteristics heavily influenced these goals. Participants noted the nebulous nature of microaggressions, their reluctance to burden their social support network, and societal perceptions of women as overly emotional—all of which shaped their desire for designs that enhance logical justification. For example, participants preferred tools such as expert-led discussions and comprehensive perspectives to rationalize their experiences while reducing stigma.

Conclusions: Our work advocates for prioritizing educational and explanatory approaches over punitive detection and deletion measures to create supportive web-based spaces for individuals discussing stigmatized SRH. By integrating culturally informed coping strategies, counter speech mechanisms, and educational designs, these tools empower microaggression targets and allies while fostering reflection and behavior change among perpetrators. Our work provides a first step toward counteracting microaggressions and ultimately encouraging women to seek the needed SRH care.

Introduction

Background

In many cultures, including South Korea (hereafter referred to as Korea), unmarried women grapple with the stigma surrounding sexual and reproductive health (SRH), often opting to suffer in silence rather than seek necessary care [1-6]. Conversations about SRH topics—such as contraception, menstruation, sexual discomfort, or sexual pleasure—remain taboo, hindering access to essential services, such as screening and prevention of sexually transmitted infections (STIs) [3,7]. This reluctance to seek care poses substantial health risks, including pelvic inflammatory disease, ectopic pregnancy, and infertility [8]. Despite efforts to challenge traditional beliefs and decouple female sexuality from marriage [8,9], many women remain reticent to openly discuss SRH or seek related care, such as cervical cancer screening and prevention [6]. The consequences of this stigma can be dire. For example, Korean women who face many microaggressions regarding SRH [10] also experience disproportionately high rates of cervical cancer, with both native and immigrant populations being affected [6]. Despite the availability of preventive measures such as the human papillomavirus vaccine, the persisting stigma surrounding SRH care hampers efforts to address these health disparities [10]. Stigmatized SRH refers to topics considered taboo for unmarried women, such as STIs, sexual pleasure or discomfort, pregnancy, and contraception. However, the stigma also extends beyond these issues, limiting access to care for non-STI or pregnancy-related concerns, such as cervical cancer, and underscoring the broader barriers unmarried women face in SRH care.

For such stigmatized health topics, many people turn to web-based communities for support [11,12], but those web-based spaces also often contain microaggressions—communications that put down, insult, or invalidate them. These microaggressions not only harm people's physical and psychological health [13-17] but also discourage people from seeking necessary health care [10,18,19]. This problem is particularly salient for women seeking SRH care, as it is a taboo topic in many cultures [1,20,21]. The perpetrators of web-based microaggressions include users who intentionally or unintentionally harm support seekers, including within-group perpetrators [10,15,22]. In this study, we focused on the web-based microaggressions that South Korean women face, often from other women, when seeking support for the recommended SRH care.

To jointly imagine designs that could help counteract web-based microaggressions, we co-designed with unmarried women—the targets of these microaggressions—who grew up in Korea and have used web-based forums to seek SRH care. In this study, we define the term *used* as not solely the active use of posting or commenting but also the passive use of viewing posts and comments of the web-based forum user's interest. In addition, we define "targets" as the women who experience microaggressions related to their SRH. This definition aligns with the concept of *targets* in microaggression literature by Sue et al [23], which describes individuals who are subjected to prejudice and discrimination. While the study by Sue et al [23] focused on racial microaggressions, we expanded the term to include gender-based prejudice and discrimination.

In this study, we focused on designing solutions to counteract web-based microaggressions to cultivate a resilient and safe space for support on stigmatized SRH. We sought to make these last-resort safe spaces truly supportive by reducing the negative effects of microaggressions on the targets and allies' health and well-being and educating rather than solely punishing perpetrators. We refer to allies as individuals who challenge bias within their own communities and actively support others, even within marginalized groups [24,25]. Examples include anonymous women users in web-based health communities, as well as friends who, while also facing stigma related to SRH, work to counteract the microaggressions they experience or witness others experiencing.

Our work focuses on presenting the findings from 2 co-design sessions with unmarried Korean women. We identified 6 goals participants had for counteracting web-based microaggressions to create a resilient and safe space for seeking and providing support on stigmatized SRH. On the basis of these 6 goals, we uncovered that, unlike most web-based content-moderation approaches that focus on detecting and deleting offensive content, most women would prefer systems that help them cope with web-based microaggressions and help perpetrators reflect on the ramifications of their words. In this paper, we have contributed designs that support these goals and preferences.

Related Work

In this section, we connect with 3 bodies of work related to our research: rethinking content moderation, supporting vulnerable users' coping, and designing without compromising vulnerable users' agency.

Rethinking Content Moderation: The Shortcomings of Detection and Deletion Approaches

The predominant content-moderation strategy on platforms such as Facebook and Twitter (subsequently rebranded X) heavily relies on detection and deletion of harmful content [26-28]. These methods focus on removing content after it has been flagged, which makes them predominantly reactive. This approach can leave users feeling unsupported and frustrated, especially when it comes to content that falls into a "gray area," such as microaggressions, that may not explicitly violate platform policies but still causes harm [29,30].

Ma et al [30] highlight this gap, noting that the current detection and deletion model fosters an adversarial relationship between

XSL•FO
RenderX

users and platforms, where moderation feels punitive rather than supportive. Myers West [31] also emphasizes the need for more nuanced moderation practices, particularly in ambiguous cases where platform guidelines are unclear, stressing the importance of building a culture of responsible web-based citizenship that goes beyond mere content removal. Similarly, Sharevski et al [29] demonstrate the ineffectiveness of warning tags and labels, which often fail to engage users meaningfully or prevent the harm caused by problematic content. These limitations underscore the weaknesses of the detection-first approach.

Despite advancements in moderation technologies, the focus remains on swiftly identifying and removing harmful content [32-35]. This method overlooks deeper issues of user discontent, as Jhaver et al [32] report, where users express frustration over content removal without clear explanations or guidance, often feeling that their content was unjustly deleted. These issues demonstrate that the current detection and deletion approach may exacerbate tension rather than address the root causes of harmful behavior [36-38].

In this study, we aim to address these gaps by exploring alternatives to detection and deletion, focusing on strategies that offer more nuanced, supportive solutions to handling harmful content—particularly in complex cases such as microaggressions.

Supporting Vulnerable Users' Coping

The current narrow focus on detection and deletion often results in harm to the very communities that we are trying to support or protect [39,40]. For instance, Thach et al [39] demonstrate how the invisible process of web-based content moderation makes marginalized social media users face disproportionate content moderation and removal (eg, computational model could flag a person of color's post about racial justice or racist experience as hate speech). They state that the content removal or banning of the poster from the web-based community would bring further marginalization of the already marginalized users. Thus, in an attempt to better support and protect marginalized social media users, researchers from the University of Michigan School of Information developed Online Identity Health Center—a website that helps marginalized users (1) understand different social media platforms' policies and rules about content takedowns and (2) provide easy-to-understand resources on different social media guidelines and what to do if your content is taken down [41].

In support of alternative approaches that extend the web-based content-moderation task beyond detection and permanent removal, studies on dealing with the negative consequences of microaggressions [14,33-36] have also emphasized the importance of coping in reframing web-based content moderation to better support marginalized users. Coping with negative emotions and stress induced by microaggressions is crucial to reducing the negative effects on the targets' health and well-being [14]. Microaggressions are perpetrated and experienced subtly and often unconsciously; the target often questions the reality of the oppression [42,43]. Thus, targets of microaggressions frequently blame themselves for being overly sensitive and dismiss, if not excuse, the behavior of the perpetrators. Targets of microaggressions also show a pattern of quietly shouldering the impact of such behavior, sometimes out of fear of retaliation from the perpetrator or others involved. They also worry about reinforcing negative stereotypes (eg, women are emotionally needy and overly sensitive) if they choose to confront the perpetrator [44]. Targets of microaggressions often experience negative impacts on their well-being (eg, feelings of guilt, embarrassment, shame, regret, and remorse) after unconfronted microaggressions. Furthermore, internalizing these feelings has long-lasting effects on the target's self-confidence and mental and physical health [45,46].

In contrast, if targets or allies choose confrontation, they must take on additional risks for themselves. Targets frequently need to circumvent fears of either being further invalidated or reinforcing negative stereotypes about their group if they were to confront microaggressions. Empirical evidence supports this notion; targets report that using confrontation opened them up to further microaggressions (eg, being further invalidated and being called "oversensitive" and "paranoid") [47,48]. Thus, coping is essential for targets and allies in dealing with microaggressions.

Coping can be carried out through 2 emotion regulation strategies: cognitive reappraisal and expressive suppression [49,50]. Cognitive reappraisal refers to re-evaluating the meaning of a given situation to reduce its emotional impact [49,50], whereas expressive suppression refers to inhibiting an emotional response [49,51]. Although suppression may help a person avoid undesirable interpersonal consequences that can follow from expressing negative emotions, it has generally been found to be ineffective in reducing the negative emotions themselves [52-55]. Thus, Juang et al [51] suggested combining the use of both emotion regulation strategies when people encounter microaggressions. With the combined use, they indicated that expressive suppression will help in avoiding further negative interpersonal interactions, and cognitive reappraisal will help ease the emotional burden of denigration. This combined use is further corroborated by the study of Hernández and Villodas [56], where the sole use of reactive and suppressive coping was discouraged. Only reflective coping (ie, which relates to cognitive reappraisal) was associated with more positive mental health, whereas reactive and suppressive coping (ie, which relates to expressive suppression) were associated with poorer mental health after experiencing microaggressions [56]. Thus, in this study, we aimed to design features that help counteract microaggressions and do not merely detect and delete content but rather support people in reflective coping.

Designing Without Compromising Vulnerable Users' Agency

The population we are designing for are microaggression targets within an oppressive social structure, where support for SRH care is difficult to find [10]. Thus, understanding how to design within oppressive social structures without compromising the agency of vulnerable users was pivotal to our work. Sultana et al [24] conducted a study on designing within a patriarchal society and investigated the economic, social, and cultural challenges faced by rural Bangladeshi women. They then

XSL•FO
RenderX

presented 2 user-centered strategies for design to empower the vulnerable users. The first strategy was to try to empower women within the structures of their society, instead of trying to destroy those structures [24]. This strategy was also supported by Alsheikh et al [57] who suggested designing for openness, which supports Islamic feminist values that posit women as having agency but also operating under a set of Islamic cultural assumptions. They defined supporting agency as allowing women in Arabic culture to enact particular cultural roles in the context of their relationships rather than designing for Western feminist values (eg, demanding equality) or the patriarchal values underlying the Arabic sociocultural context.

The second strategy was to shift focus from the problems that women face to the tactics they already use to cope and look for opportunities to support these tactics [24]. Rabaan et al [58] resonated with this strategy and emphasized the importance of understanding the interwoven complexity of the sociocultural dimensions of the problem, considering historical developments, and accepting and respecting the different choices people make while understanding why they make them. With an in-depth understanding of the scarce structural support in protecting Saudi women from domestic abuse, they uncovered that resiliency was a valuable strategy for these women to sustain moving forward and even to take action to end the violence. To design for a customized interactive system that supports resiliency, Rabaan et al [58] suggested designing a screening tool to measure where a woman is at in her options, resources, needs, and concerns and what she perceives as expected or abusive.

In this study, we incorporated the 2 strategies into our design considerations. First, we designed within existing structures using the web-based forums that unmarried Korean women often use to not only seek SRH care support but also reflect the oppressive social structure in Korea [10]. Second, we focused on the tactics that unmarried Korean women already use to cope and looked for opportunities to support those tactics.

Methods

In this section, we describe our study's ethical considerations; co-design process, which includes co-design session 1—the creation of a base design template for improvisational enactment and co-imagination of new ideas—and co-design session 2; and co-design session analysis process.

Ethical Considerations

This study received an exempt status from the University of Washington Human Subjects Division under Category 2, as it involves only interviews with data recorded in a manner that either does not allow for participant identification or poses no risk of harm if disclosed. The institutional review board ID is STUDY0013885. This co-design study received institutional review board approval from the University of Washington. Informed consent was obtained from all participants before their involvement in this study. Participants were provided with detailed information about the study's purpose, procedures, potential risks, and benefits, as well as their rights to confidentiality and the option to withdraw from the study at any time without penalty. In addition, participants were given the opportunity to ask questions and receive clarification before providing their consent. All study data were deidentified, with participants referred to by their ID (eg, P [participant ID number]) in co-design transcripts and session designs. Personal information, such as names and ages, was stored in a separate file. Participants were compensated with a US $25 Amazon gift card for each co-design session, totaling US $50 for their participation. To protect participants' privacy, we ensured that no personal identifiers were linked to any images included in the manuscript.

Co-Design Process

Overview

Co-design, defined by Sanders and Stappers [59] and Kleinsmann and Valkenburg [60], involves collective creativity and shared knowledge among participants, leading to a comprehensive understanding of design content and process [59-61]. This process, also known as joint inquiry and imagination, encourages ethical engagement and starts with abduction, suggesting potential solutions [61,62]. Our study used a modified approach for remote co-design sessions, aiming to stimulate creativity and facilitate discussions on sensitive topics such as SRH care [10,63]. In the following sections, we describe our participants, details for each of the co-design procedures, and our analysis approach.

Participant Recruitment and Consent

We recruited unmarried Korean women between the ages of 18 and 29 years, a demographic most susceptible to microaggressions around SRH care due to the assumption that they are unmarried. These younger women often seek support on the web for SRH care, and we wanted to capture a holistic understanding of the challenges they face. Among the participants, only 7 had sought clinical SRH care (eg, obstetrics and gynecology office, women's health clinic, and public health office), while others solely relied on web-based forums. Despite these differences, both groups used web-based spaces to navigate SRH care support, so we interviewed both to inform designs that address microaggressions targeting unmarried Korean women.

Participants were required to have received 9 to 12 years of compulsory education in Korea and to be currently unmarried. Those who had received foreign curriculum–based education during their compulsory education (eg, US curriculum–based schools) were excluded from the study. Recruitment was conducted through university board flyers at Yonsei University in Korea, web-based SRH support communities for Korean women such as women-only forums in Nate Pann, and snowball sampling.

Participants for this study were recruited using a multistep process designed to ensure their informed and voluntary participation. Potential participants initially expressed interest by completing a screening questionnaire. This questionnaire was used to verify eligibility based on the study's inclusion and exclusion criteria.

XSL•FO
RenderX

Once eligibility was confirmed, participants received a consent form via email, which provided comprehensive details about the study. The consent form outlined the study's purpose, the inclusion and exclusion criteria, the procedures involved in participation, the potential benefits and risks, the compensation offered, and the measures taken to protect participant confidentiality and privacy. Participants were encouraged to review the consent form independently, and a minimum of 48 hours was provided for this review to ensure they had adequate time to make an informed decision.

Following this review period, we scheduled individual calls with each participant to discuss the consent form further. During these calls, participants had the opportunity to ask questions, seek clarification about the study, and address any concerns they might have. After ensuring that participants fully understood the consent form and its implications, we proceeded with obtaining their signatures. Once consent was obtained, we scheduled the first co-design session with each participant.

Co-Design Session 1 Procedure

We conducted co-design session 1 as contextual research to provide the necessary background for co-design session 2 (ie, support the creation of the base design components for the co-design sessions). Co-design session 1 was conducted in a web-based setting, and each session lasted approximately 50 to 60 minutes. In co-design session 1, we asked questions about who should be responsible for counteracting microaggressions and how technology could support them. As the topic of gynecological care is taboo, we told participants that they could answer for themselves or someone they know. We first asked participants about their SRH care support–seeking experiences. Then, we explained to them what microaggressions are and showed them examples of microaggressions derived from the study by Ryu and Pratt [10]. Afterward, we asked them to think of microaggression counteraction or prevention design ideas based on their web-based SRH care support–seeking experiences.

After we received participant-generated design suggestions without specific design scenarios, we asked them about specific features (eg, flagging comments, blocking content, and content alerts) derived from currently implemented measures of major social media platforms such as Facebook [26,28] and Twitter [27,28]. Furthermore, we asked them about specific situations that social media platforms have not been able to resolve, such as "gray area" cases of moderation [30]—instances where the removed content was not wildly in violation of explicit guidelines and required some interpretation [31] (eg, when the perpetrator or target is unaware of the harm caused by microaggressions). During co-design session 1, we told participants to ignore current technological or financial limitations when ideating their designs.

Co-Design Session 2 Procedure

On the basis of co-design session 1, we created a base design template that we showed to the participants during co-design session 2. We made a post comment sample using a hypothetical scenario with a post topic commonly seen in the web-based forums that unmarried Korean women seek SRH care support on. The hypothetical scenario focused on vaginitis and clinical visit concerns (Figure 1) because it is one of the most common concerns shared by women in web-based forums [10]. On the basis of our reviews of existing forum posts, we included comments that reflect those that showed genuine support or microaggressions from other users. We also included the ally's response to the microaggressions and showed the microaggression perpetrators attacking the ally to reflect the current state of web-based support and microaggressions [10,42,44,64]. For the format and features (eg, post and comment like and dislike functions with the number of likes and dislikes displayed and comment filter options), we made the post comment sample reflect those of web-based forums that unmarried Korean women typically seek support from. To provide an initial design that participants could react to and provide feedback on, we presented templates for each participant-suggested design found in co-design session 1 next to the post comment sample.

XSL•FO
RenderX

Figure 1. Design session sample scenario. It mimics the format and features of forums that unmarried Korean women currently go to seek sexual and reproductive health care support. The features that the design session sample scenario reflects from the original forum are the (1) post structure (ie, title, author ID, date, post views, post content, and number of post recommendations and oppositions); (2) comment structure (ie, comment filtering options and replier name, reply date, number likes and dislikes, and a comment flagging button for each comment or replies to head comment); and (3) reply and comment posting structure (ie, reply writing box and reply posting button).

Co-design session 2 was divided into three sections: (1) viewing only the post comment sample (Figure 1) without the base design template; (2) designing after viewing the base design template, which were reenactments of the participant-suggested designs; and (3) designing for a situation where the participant themself would be the support-seeking post author. Each design session was held with each participant individually using Lucidchart software (Lucid Software Inc) as the co-design tool and lasted approximately 50 to 60 minutes. Lucidchart is a design tool that facilitates remote, synchronous, and collaborative design. As our participants took part in the co-design sessions remotely, we used Lucidchart to build, replicate, and share post comment samples and design templates developed during co-design session 1. In co-design session 2, participants used Lucidchart to design web-based microaggression counteraction strategies collaboratively and synchronously.

XSL•FO
RenderX

We used the same group of participants from the initial design needs interviews because we wanted to empower them by actualizing their own designs and reflecting on not only their own but also others' designs to counteract microaggressions. Participants received US $25 for participating in co-design session 2. We audio-recorded the interviews and used a professional transcription service to have the recordings transcribed verbatim.

We wanted to learn about the participants' design ideas when they saw the post comment sample, so we first asked the participants to review only the post comment sample and tell us about their thoughts on how they would design the forum to counteract web-based microaggressions. Then, we asked them the same question after showing the base design template for counteracting web-based microaggressions and prototyped each design and their suggested use. We encouraged them to talk aloud as they created their designs and prompted them to explain why they wanted the microaggression counteraction feature to be designed a certain way. We asked the participants to make edits on their own but assisted them when they were experiencing difficulties.

Before and during co-design session 2, we explained that they did not have to use the design in its suggested form or at all if they did not want to use the feature. Also, we emphasized that they could alter the design to better reflect their intended use of the design (eg, adding and removing options and changing the phrases). At the end of the session, we reviewed the designed web-based microaggression tool together to check if there had been any misinterpretations and to give them the opportunity to edit their designs.

Finally, to understand how the web-based microaggression counteraction design would change if they had designed it only for themselves, we asked the participants if they would change anything if they were the ones writing the posts and receiving the microaggressions.

Co-Design Session Analysis

A total of 2 authors participated in the analysis. The first author acknowledges her standpoint as an educated, unmarried Korean woman. She is a native Korean who received primary education in Korea and received additional intensive English language education in middle and high school. Although she is not an avid participant in the comment sections of the web-based spaces where unmarried Korean women seek support, she has investigated numerous interactions of other users, advocated for safe web-based spaces free of microaggressions, and is intrigued by the use of language to mark and protect microaggression targets. She acknowledges that her positionality influenced this study to some extent but also helped her interpret the participants' design ideas and influences from the Korean sociocultural context. The second author is from the United States and has done extensive research on web-based health communities as well as design research with people from marginalized communities. Her cultural background has made her much more aware of microaggressions and their negative effects on her life over decades, which has helped to complement the first author's more recent exposure to the concept of microaggressions. This complementary background also helps them consider the broader implications of this work. Because much of the second author's research portrays the benefits of web-based health communities, she may perceive more positive possibilities for web-based health communities in this study.

The first author completed the analysis of both co-design sessions 1 and 2, with support from the second author using the ATLAS.ti analysis software (Lumivero). We analyzed 28 transcripts in total, consisting of 14 (100%) transcripts from co-design session 1 and 14 (100%) transcripts from co-design session 2. Both co-design sessions were analyzed using the same procedure. The first author cycled between field notes kept during the co-design sessions and the co-design session transcripts in an approach meant to build on themes in real time. To begin, the first author coded 5 co-design session transcripts using an open coding approach [65], labeling what she saw in the data. Then, she discussed the codes with the second author, refined these into a revised codebook, and finished coding all the remaining transcripts. Following another round of discussion and clarification, the authors finalized the codebook. As open coding was completed, the first author conducted a round of deductive coding that focused on sentences about each microaggression counteraction feature. The 2 authors then discussed interpretations and addressed any discrepancies in the application of the code set of features to counteract microaggressions and adjusted their coded data as needed. We reached saturation after coding 6 (42%) co-design session 1 transcripts and 8 (57%) co-design session 2 transcripts.

Results

Overview

First, we report on the participant information and participant-suggested designs and how they envisioned their designs to be enacted from co-design session 1. We further show how the designs were enacted as a design template for them to use during co-design session 2. Second, we discuss 6 goals that participants had for creating a safe and resilient web-based community that would allow them to seek support for the culturally taboo topic of SRH.

Participants

As the co-design participants were asked to share their experiences that are not frequently or overtly discussed and are considered a sensitive topic in the culture, we used snowball sampling to recruit a total of 14 participants (Table 1); the mean age was 24 (SD 2.73) years.

P14	27	Yes	Yes	No	Yes

[a]SRH: sexual and reproductive health.

[b]For example, obstetrics and gynecology clinic, women's health clinic, and public health office.

All participants had physical and financial access to SRH clinical services, but the women who reported "no" to seeking SRH in various clinical settings stated that they did not seek SRH care due to stigma. We explored whether there were differences in results between participants who had sought SRH clinical care and those who had not, but we found no noteworthy differences in the designs they created.

Participants who had no knowledge of microaggressions before this study elucidated that they had not heard of microaggressions, so even if they had experienced microaggressions, they were unable to name what they were experiencing. We explored whether having prior knowledge of microaggressions influenced the designs participants put forth, but we found no notable differences between those with and without prior knowledge. Participants who had prior knowledge of microaggressions had only a basic understanding, primarily from skimming social media posts. All participants noted that they would not be able to categorize microaggression types or provide a clear definition.

Initial Design Results

In co-design session 1, we identified the features participants wanted and whom they intended the features to be used by (Table 2).

Table 2. Participant-suggested features from co-design session 1.

Feature	Actor using feature
Labeling type of support	Woman seeking support[a]
Choosing percentage of microaggression to view	Woman seeking support
Alerting about microaggression content with extra step of consent to view content	Woman seeking support
Microaggression comment rephrasing suggestions	Potential microaggression perpetrator or ally[b]
Microaggression flagging explanations	Woman seeking support
Messages to microaggression perpetrators or targets	Woman seeking support and potential microaggression perpetrator or ally
Professional certification badge	Woman seeking support

[a]Post authors.

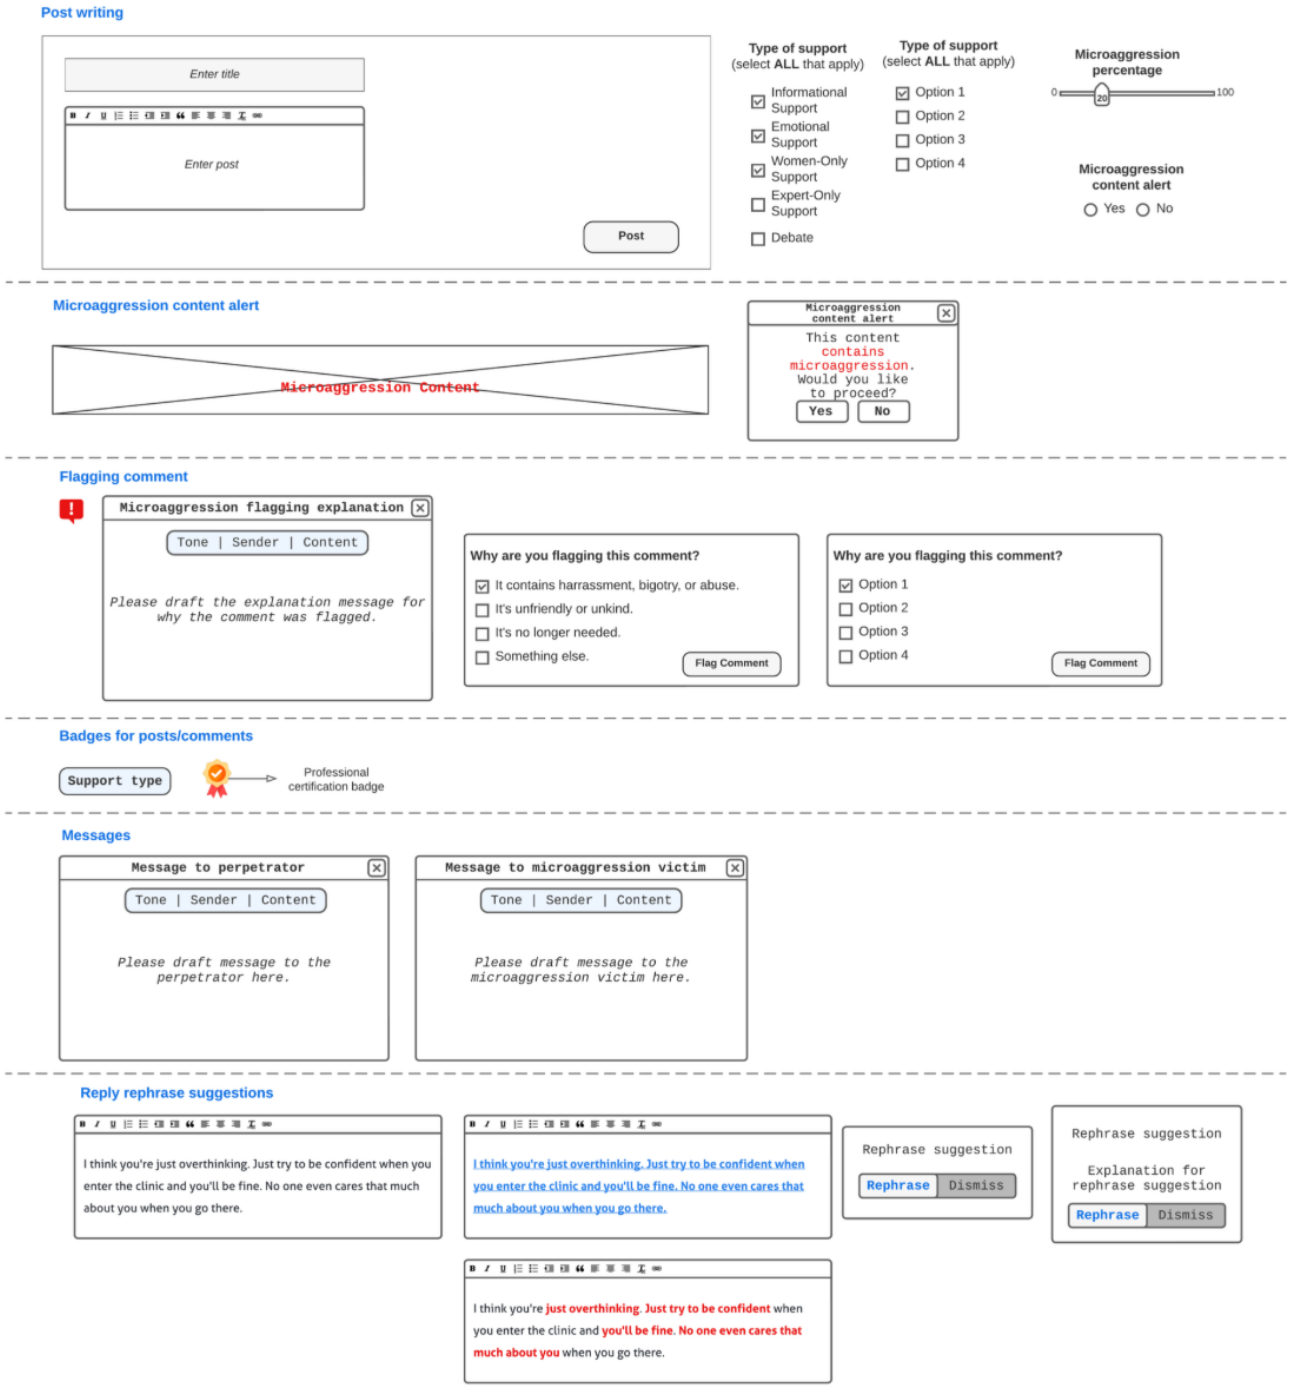
[b]Commenters.

First, to ensure that post authors receive the type of support they want, participants suggested 3 design features or functionalities that could be used while people are writing their posts. The first feature would allow post authors to label their posts with the type of support sought. Participants identified five types of support: (1) emotional support, (2) informational support, (3) women-only support, (4) expert-only support, and (5) debate. Second, participants suggested choosing the percentage of

XSL•FO
RenderX

comments with microaggressions post authors were willing to view. Participants suggested the inclusion of viewing all microaggression comments (100%) and no microaggression comments (0%) as options. Finally, inspired by the idea of content blocking on Instagram, participants wanted a microaggression content alert to initially block comments with microaggressions but allow people to view the comment if they click the button to view the comment.

To reduce the microaggressions received and to educate people writing comments, participants wanted support for people while they were writing comments. Participants envisioned features that would suggest rephrasing a microaggression with explanations for the suggestions. They either wanted the whole comment or specific parts of the comment to be highlighted. For the highlighted parts, participants wanted features that would provide rephrasing suggestions that could be applied with a click of a button. Some participants also wanted features that would provide the comment writer with explanations for why the rephrasing suggestion would make their comment not a microaggression. Other participants did not want a feature with rephrasing suggestions because they wanted to protect comment writers' freedom of speech.



Participants suggested three types of features to identify microaggressions in comments for the original poster, commenters, and readers after a comment has been posted. First, participants wanted to be able to flag comments that contain microaggressions along with an explanation for why it was a microaggression. Participants explained that the current social media platforms allow them to report or flag comments but that their choices for indicating why a comment should be flagged are too general to help commenters understand why their comments contained microaggressions. In particular, participants wanted the flagged reason to be shown in the public explanations for each flagged comment, which would help the community and the commenter learn about microaggressions. Second, participants wanted features that would send messages to the microaggression perpetrators or the targets of the microaggressions—who could be either the original poster or another commenter. To provide reassurance and validation of the targeted person's thoughts and feelings, participants wanted to send messages letting them know that the microaggressions were noticed. For the perpetrators of the microaggressions, participants thought that perpetrators might continue to write microaggressions if they were merely given warnings that their comments had been flagged. However, participants were uncertain about the exact content they would include in such messages or the flagging explanation, and the interviews did not include time for them to think through and compose a sample. Thus, in the design session, we provided an opportunity for participants to compose their explanations or messages if they wished to.

As a justification for their final post comment design suggestion, participants wanted health professionals to have more accountability for their words because the participants placed higher trust and reliance on these professionals. Participants suggested a feature that would flag comments from health professionals. Participants wanted health professionals to make their status as a health professional public, thus putting their status and reputation on the line and making them more responsible for what they say. Participants wanted to create a professional certification badge based on the badges stamped next to the professionals' replies in Naver Jisikin—a widely used question-and-answer forum in Korea.

With the participant-suggested designs and their descriptions of how they should be envisioned, we made templates for each design (Figure 2). These designs allowed participants to experience their designs' enactment in co-design session 2.

XSL•FO
RenderX

Figure 2. Co-design session 2 base design template. It shows the set of participant-suggested designs found in co-design session 1. For support during post writing, participants had the option to design with labeling the type of support post authors needed (a-1) which would be shown with the support type badge on the post (a-2), microaggression percentage (b), and microaggression content alert (c-1) which would be shown on the comments as (c-2). For during comment writing support, participants were able to design reply rephrase suggestions by highlighting the rephrase needed parts (g-1) and offering the rephrase suggestions with or without explanations (g-2). For support after a comment has been posted, participants could choose to implement the professional certification badge (e) and design the flagging options (d-1), flagging explanation messages (d-2), and messages to microaggression targets and perpetrators (f).

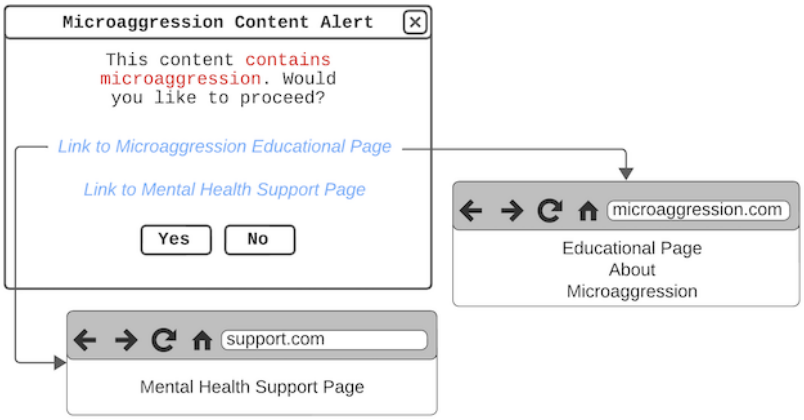
Design Goals

Overview

Through the analysis of the co-design sessions, we found that participants had 6 goals in counteracting web-based microaggressions to create a safe and resilient web-based community for seeking support on the stigmatized SRH. These goals arose in co-design session 1 but were further expanded upon in co-design session 2 after they had learned more about microaggressions and were able to tangibly interact with their envisioned designs. We first describe each of the goals and participants' design ideas for achieving these 6 goals. The figures of the design ideas shared in this paper were created by the participants using Lucidchart software.

- Goal 1: having shared knowledge of microaggressions among all users.

XSL•FO
RenderX



- Goal 2: indicating positive support numerically.
- Goal 3: responding with less emotion to microaggressions.
- Goal 4: having forum-approved experts guide the discussions.
- Goal 5: respecting perpetrators' freedom of speech while educating them to understand their words' negative impact.
- Goal 6: knowing the "reality."

Furthermore, we describe how the 6 goals were affected by 3 cultural characteristics: the nebulous nature of microaggressions, reluctance to burden their social support network, and questioning the validity of their own thoughts due to the social perception that women are too emotional.

Goal 1: Having Shared Knowledge of Microaggressions Among All Users

Participants advocated for providing people with educational resources about microaggressions and supporting people harmed by microaggressions. They wanted unmarried Korean women post authors to be more informed about microaggressions by adding links to microaggression-related educational resources and support groups under the microaggression content alert option (Figure 3):

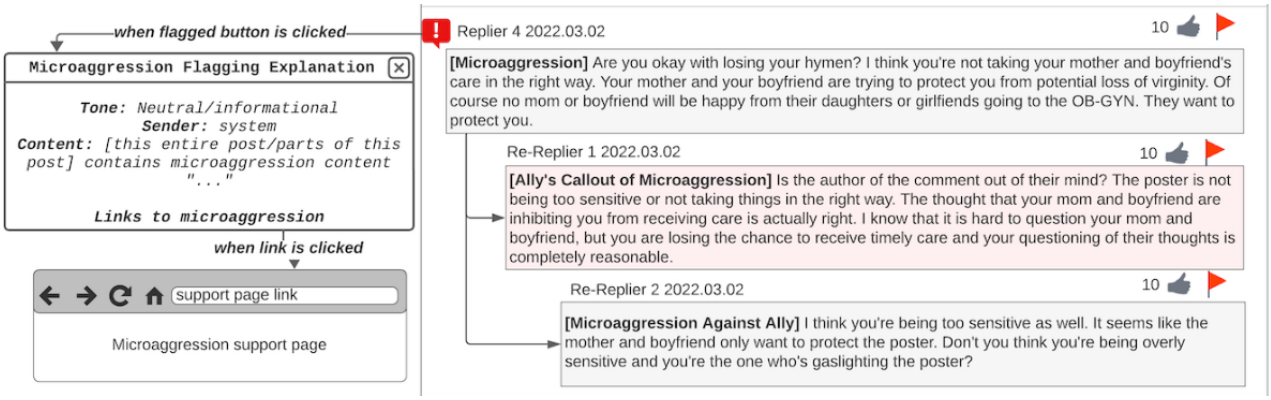


Figure 3. Microaggression content alert design by P6. On the microaggression content alert, links to a mental health support page and an educational page about microaggression are added.

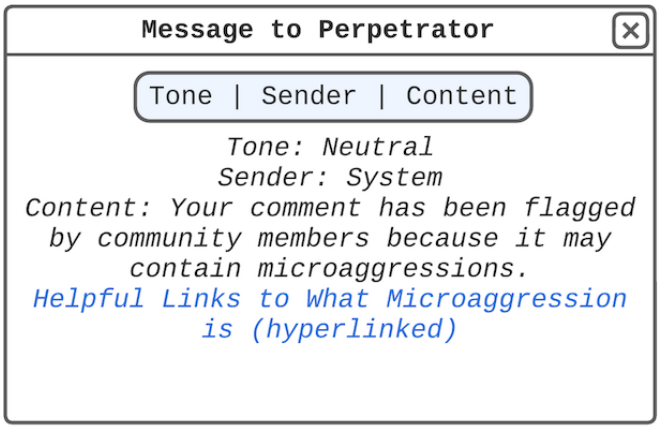
> *First of all, we have to understand that there's a lack of shared knowledge here. People don't know what microaggressions are. How are we supposed to defend ourselves without knowing what to defend ourselves from? When we see the [microaggression] content alert, we need to have additional resources or groups we can access to get support or a better understanding of microaggressions.* [P3]

Beyond the post authors, participants also wanted other web-based forum users to learn about microaggressions and their impacts. Thus, participants suggested adding microaggression educational resources to explanations next to flagged comments (Figure 4):

Figure 4. Educational flagged reason explanation design by P11. When the flagged button next to a flagged comment is clicked, the user can see a message that the comment contains microaggression content and links to microaggression support pages.

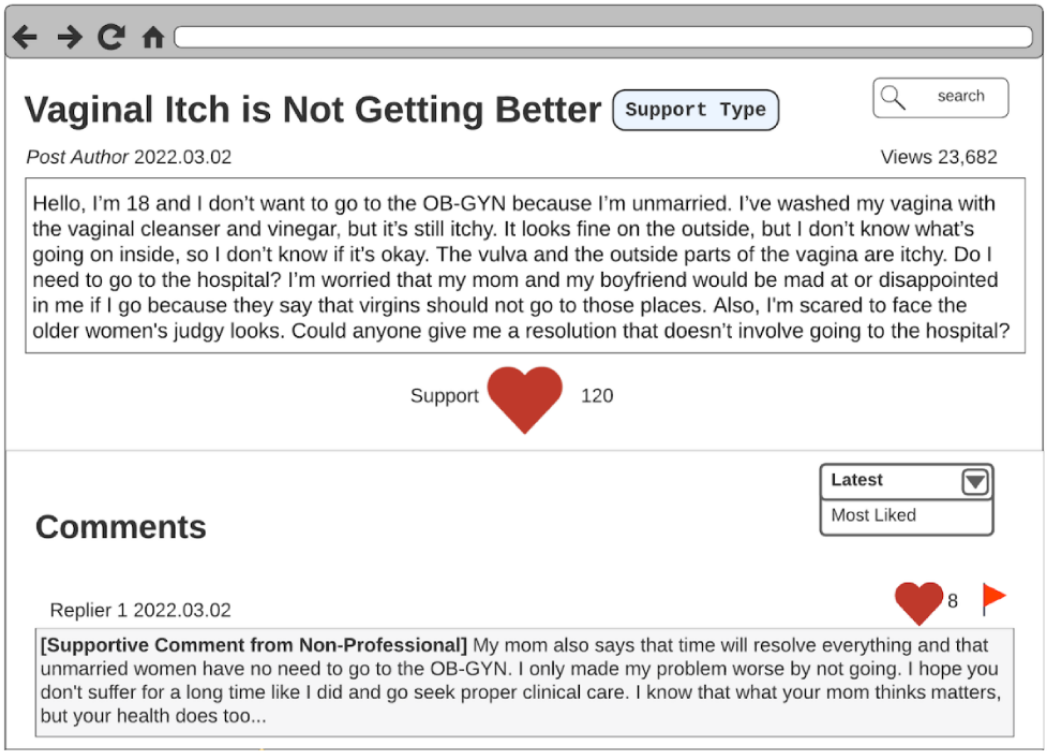


> *It's not just people who post on the [online] forums that need to know about microaggressions. Other people using the [online] forums also do too. I think the best way to do that is to have information [about microaggressions] or [website] links to microaggression information right next to the comments, the ones that are flagged, so everyone can see it.* [P11]

Furthermore, they wanted to ensure that perpetrators were educated on microaggressions by sending them a private message with additional microaggression educational resources attached to the explanation of why the comment was flagged (Figure 5):

XSL•FO
RenderX

Figure 5. Message to perpetrator design by P8. The message to the microaggression perpetrator is designed to have a neutral tone and shows the message that the perpetrator's comment has been flagged because it may contain microaggressions. The message also has links to help the perpetrator understand what microaggressions are.



*I don't want the so-called perpetrators to be confused and be like what the f***? when they get a message after writing something that they think in their head is supportive. I don't want them [perpetrators] to be mad. I want them to understand. Having the message [sent to microaggression perpetrators privately] would point them to the right direction of understanding their "unintentional" wrongdoing.* [P4]

Goal 2: Indicating Positive Support Numerically

Participants advocated for emphasizing positive support through numerical indicators and deleting negative support indicators, such as thumbs-down or dislike options for posts and comments. They suggested transforming the like button into more supportive options (eg, text forms: helpful supportive; icon form: heart; Figure 6):

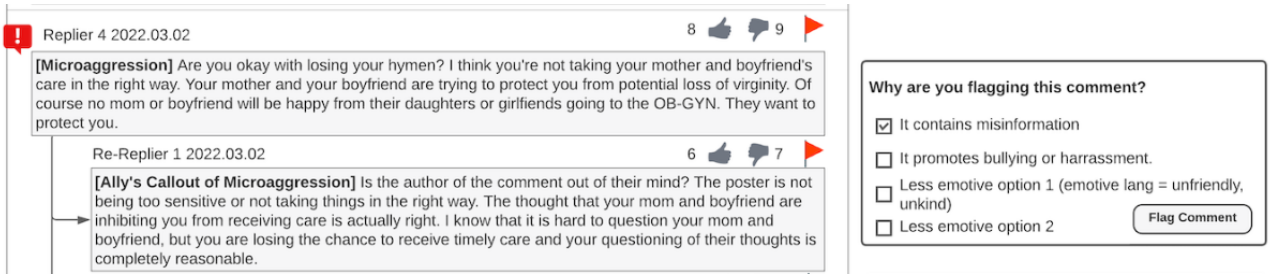
Figure 6. Support button design by P13. Instead of the like and dislike button, only the support button was made available with a heart icon to indicate support. The number of people who pressed the support button was displayed next to the support button.

Why does the like button have to be a thumbs-up button? I think it could be words like "supportive". It shows more of why people clicked the button. People have to put in another layer of thought before pressing the button. They would have to think like "Oh was this actually supportive?" [P8]

All participants except one suggested the number of clicks on the transformed like button to be displayed next to each post or comment (Figure 6). With the number of likes, participants stated that they could organically find the comments most people found most supportive, which they would also likely find helpful:

XSL•FO
RenderX

> *Numbers are produced naturally. That sounds weird saying it out loud but it's something you can't refute. The more numbers, the more support (for the comment).* [P6]



As participants perceived that the numerical indicators would be helpful in finding truly supportive comments, many of the participants did not choose to send the messages to post authors who have faced microaggressions in the comment sections. Participants thought that sending the messages to post authors would be "unnecessarily coddling" [P6] when they could be given the agency to learn how to sort out truly supportive comments on their own with the help of numerical indicators:

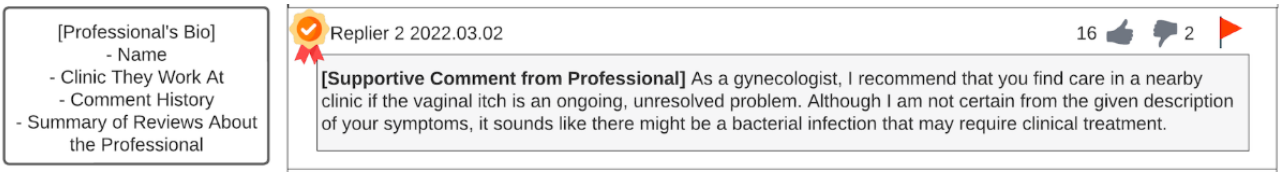
> *I want to give women the strength to defend and sort out helpful information on their own. I don't know if I would describe the internet as a jungle, but it sometimes is. You got to know what's poison and what's not. Like the color of mushrooms, the brighter they are, the more poisonous they are. The numbers [of support] next to a comment is the color [of mushrooms].* [P1]

Goal 3: Responding With Less Emotion to Microaggressions

After evaluating widely used flagging options in social media, participants perceived the currently used flagging options to be too emotional. Participants stated that emotive language, such as unfriendly or unkind, is too subjective and suggested changing it to less-emotive words (eg, it contains misinformation and it promotes bullying or harassment; Figure 7):

Figure 7. Less-emotive flagging option design by P2. Less-emotive flagging options (eg, it contains misinformation and it promotes bullying or harassment) were used to replace the more emotive current flagging options (eg, it is unfriendly and it is unkind).

> *Words like unfriendly, unkind are too whatever you make of it. Microaggressions are already subjective or at least in how I understood it [microaggressions are subjective]. I think it amplifies that subjectiveness in the flagging explanation if we continue with the emotive language. We need to be less emotive using phrases like "It promotes bullying or harassment."* [P5]



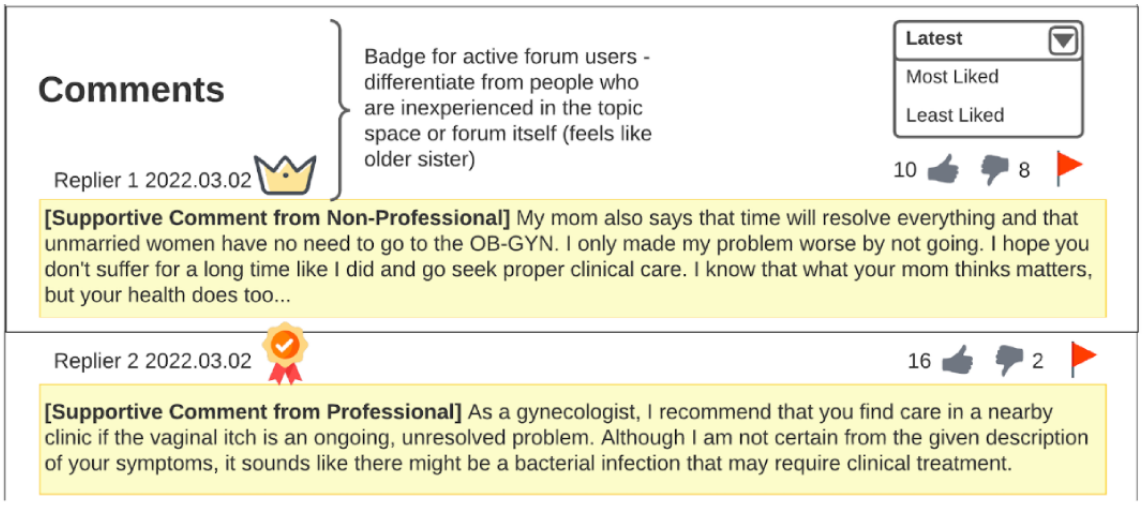
Participants who wanted private messages to be sent to microaggression perpetrators thought that using a neutral tone stating why the comment was flagged would be sufficient. Participants did not think a more threatening or emotionally intense response would be needed. They stated that guiding microaggression perpetrators to the microaggression-related educational resources and providing opportunities for microaggression perpetrators to learn the impacts of their microaggression comments on their own would be more valuable than penalizing them:

> *Neutral [tone for the private messages sent to microaggression perpetrators] is good. We don't want to threaten them. What if they retaliate? I don't want them to keep causing harm. We want them on our side. In that case, opening their eyes to what they are not seeing is better. Make them learn more and realize on their own.* [P14]

Goal 4: Having Forum-Approved Experts to Guide the Discussions

Participants wanted experts to help provide guidance in sorting out helpful comments since they expected the forum-approved experts only to post helpful and truthful comments. To ensure that the forum-approved experts were posting only helpful and truthful comments, participants requested web-based forums to include the process of professional certification in the forum description page. In addition, they requested more information about the forum-approved professionals, such as their names, the clinics they work at, their comment histories, and a summary of the reviews about the professionals on their user page (Figure 8). With this information, participants wanted forum-approved experts to help guide users to disregard comments with microaggression as well as comments containing misinformation:

Figure 8. Professional certification badge and information page about professional design by P4. Professionals who are certified by the forum would have a badge next to their names when they post a comment. When other users click on the professional's ID, they would be able to see a hovering information page with information about the professional's name, the clinic they work at, comment history, and a summary of reviews about the professional.



XSL•FO
RenderX

> *People can lie about being professionals and go around spreading misinformation, so for people who are seeking support, the badge would be helpful to differentiate between certified and non-certified professionals.* [P2]

Participants also requested certifications and badges for active forum users (Figure 9). Participants wanted the active forum users to be differentiated from people who were inexperienced about the topic or new to the forum. They wanted the active forum users to act as the "older sister" [P9] role by guiding the discussion in the right way for topics they were more knowledgeable about. With both types of certified experts, participants thought that microaggression comments that are disrespectful and contain misinformation could be weeded out and counteracted:

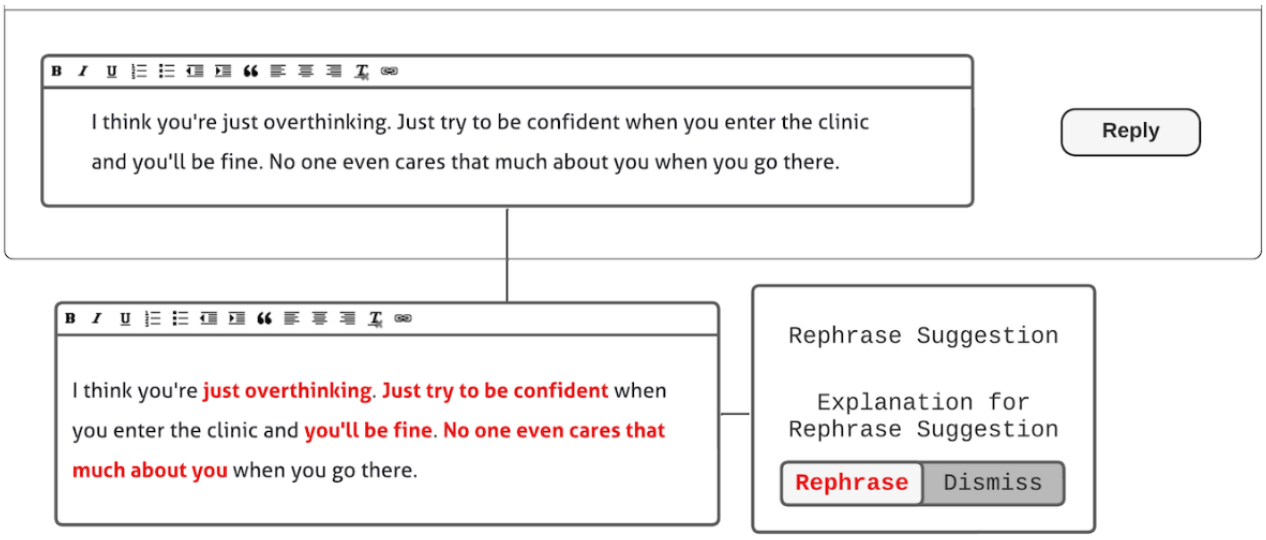
Figure 9. Active or experienced user badge design by P9. Active or more experienced users who could act as the older sister guide for less experienced users were identified by the forum with a crown badge.

> *Kind, emphasis on the kind, experienced, or more knowledgeable users should be differentiated from people who are inexperienced in the topic space or forum itself. They know how to deal with people who are acting disrespectfully and fend them off, you know like an older sister protecting her younger sister at a playground.* [P9]

Goal 5: Respecting Perpetrators' Freedom of Speech While Educating Them to Understand Their Words' Negative Impact

Most participants did not think that microaggression perpetrators would be willing to change their microaggression comments when given a choice. Thus, they chose not to implement the microaggression comment rephrase suggestions:

> *It's rarely incidental when people are writing microaggressions. Deep down in their hearts, they probably do really know that they are causing harm or at least that what they're posting could be harmful. These people know what they are doing, so rephrasing suggestions or explanations for them is only helpful if they want to know.* [P2]



However, participants also wanted to respect the perpetrators' and potential allies' freedom of speech rather than add a burden on people who were merely offering help or support. They wanted microaggression perpetrators who had the potential to become allies to be less burdened by this "big brother monitoring" [P9]:

> *I like the idea of a little fixing [of microaggressions] but having it still be optional. Something just doesn't sit well with me if I am forcing the person writing the comment to change it before they even post it. I hope that they are smart enough to make the right decision and I want to believe that they could change the parts they want and make it less harmful on their own.* [P7]

Although the microaggression comment rephrasing feature was considered an unnecessary burden by most participants, the few who wanted to provide potential microaggression perpetrators or allies the option to rephrase their comments saw potential in it. The few participants who wanted to implement the microaggression comment rephrasing feature suggested providing both the rephrasing suggestions and explanations of why the suggestions would make the comment genuinely supportive (Figure 10). These participants firmly believed that potential allies "have a good heart" [P12] and would see the value of choosing to rephrase with the rephrasing suggestion when they see the explanation attached to the suggestion:

XSL•FO
RenderX

Figure 10. Microaggression comment rephrase suggestion and explanation design by P10. While writing the comment, the user is notified which parts of the comment contain microaggression. Then, the user receives a rephrase suggestion and an explanation for why the rephrase suggestion would make the current comment genuinely supportive. The user could choose to rephrase the comment by clicking on the "Rephrase" button or choose to not rephrase by clicking on the "Dismiss" button.

Commenters may not have had any intention to cause microaggressions, so to further decrease microaggressions that were not intentional, having explanations [for why their comments are microaggressive and how the suggested changes make them less microaggressive] would be helpful. They don't know the why, and people need to know the why, if there was no ill-heartedness behind their actions, to make changes to them. [P4]

Goal 6: Knowing the "Reality"

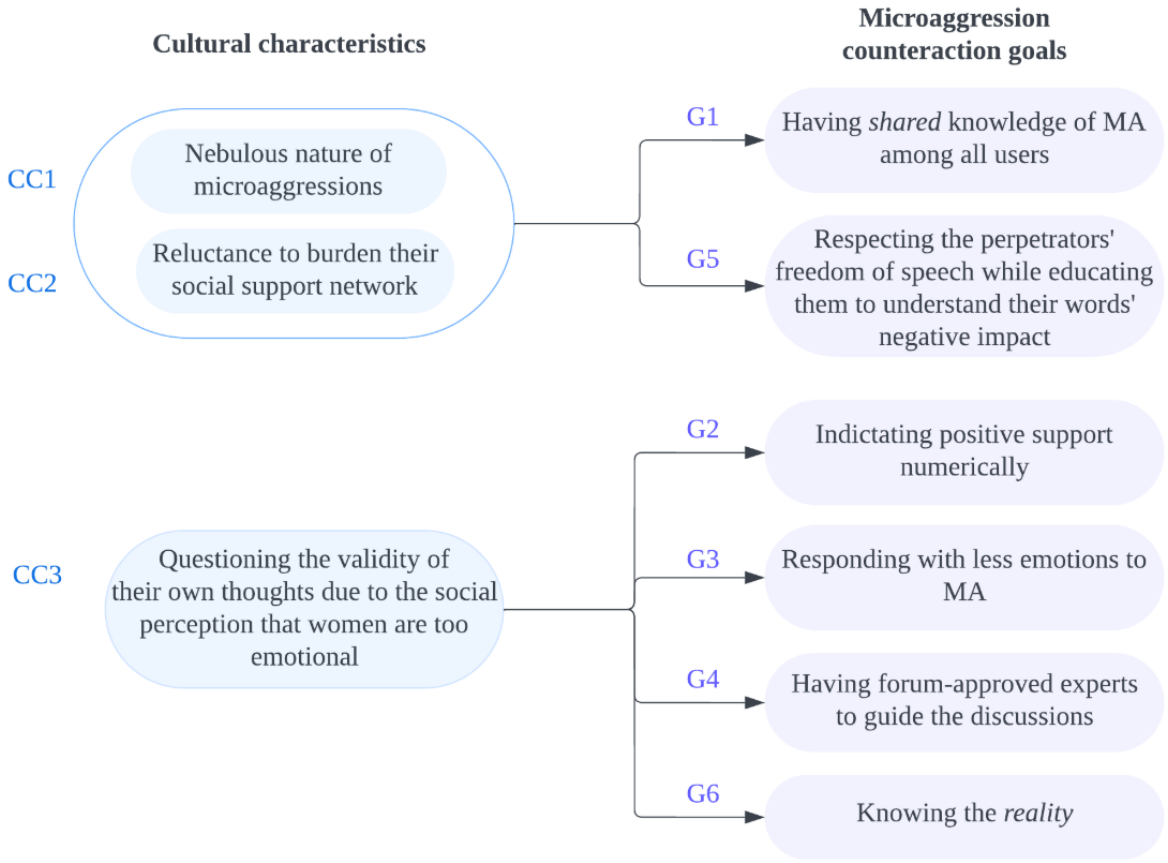
This section is not about findings on microaggression counteraction, but rather the byproduct of participants' evaluation of the effects of counteracting or blocking all microaggressions. During co-design session 1 ideation and at the beginning of co-design session 2, participants were focused on finding ways to counteract and combat microaggressions, as shown in the earlier subsections. However, near the end of the co-design session 2, when they were asked if there was anything they would like to change if they were the sole users of the web-based community and the microaggression counteraction features, participants stated that they had the right to know the truth or reality they were facing, even if it meant that they had to directly interact with microaggressions. Participants were concerned that showing a rosy environment where "everything is unicorn and rainbows" [P2] is deceptive and thought that users should be aware of the reality. Thus, they suggested the implementation of the debate and seeking opinions option for the support type labels and controversiality as a comment sorting option when they were designing microaggression counteraction measures for solely themselves (Figure 11):

XSL•FO
RenderX

Figure 11. Support type label and comment sorting option design by P2. The "Debate" option was added as a type of support that post authors could indicate on their posts. In the comment sorting options, the "Controversial" option was added to see comments that had the most controversy among users.

> *I can honestly handle whatever it is because I want to get the whole picture – both sides, not just one cuddly side. I want to be able to face reality. It would be even better to not only have the true opinions accessible, but also easier to access. Maybe by sorting the comments here [the comment sorting button] with a controversiality sorting.* [P3]

The change in design for themselves showed that the participants found value in incorporating all opinions, even negative, discriminatory, and disheartening ones, to help them make a decision about their SRH care with the information gathered. However, they still wanted to have other microaggression counteraction measures put into effect, which showed that even with the features suggested to know the reality, microaggression counteraction was still deemed by the participants as pivotal and necessary:



> *I still want everything else [the other microaggression counteraction features P2 applied to the design for other unmarried Korean women users] there. I still want to be protected. I just also want to know the controversial opinions to make sure that I have all the information I need to make the most right? I'm not sure if that's the right word, but you know what I mean. The most optimal decision.* [P2]

Cultural Characteristics Affecting Microaggression Counteraction Goals

We uncovered cultural characteristics that affected the 6 microaggression counteraction goals and participants' designs and ideas to support those goals. First, microaggressions are nebulous in nature, particularly in the South Korean culture, where the language does not even have a term for microaggression. Second, participants rejected approaches that would burden their social support network. Third, participants questioned the validity of their own thoughts due to the social perception that women are too emotional and sensitive. The first 2 cultural characteristics jointly influenced goals 1 (ie, having "shared" knowledge of microaggressions among all users) and 5 (ie, respecting the perpetrators' freedom of speech while educating them to understand their words' negative impact). The third cultural characteristic influenced goals 2 (ie, indicating positive support numerically), 3 (ie, responding with less emotion to microaggressions), 4 (ie, having forum-approved experts guide the discussions), and 6 (ie, knowing the "reality"; Figure 12).

XSL•FO
RenderX

Figure 12. Cultural characteristics (CC) affecting microaggression (MA) counteraction goals (G). CC1 is that the microaggressions are nebulous in nature, particularly in the South Korean culture, where the language does not even have a term for microaggression. CC2 is that participants rejected approaches that would burden their social support network. CC3 is that participants questioned the validity of their own thoughts due to the social perception that women are too emotional and sensitive. CC1 and CC2 jointly influenced G1 and G5. CC3 influenced G2, G3, G4, and G6.

During the discussions for goal 1 (ie, having "shared" knowledge of microaggressions among all users), participants brought up that they did not want to burden their social support network, but due to the nebulous and subtle nature of microaggressions, they were inclined to have a shared knowledge of microaggressions among all users:

> *You might not know if you have just said already harmful words in your daily life, so I don't think it's a very terrible thing. Maybe it depends, but I don't think it should be taken that seriously. So it's okay to give some experience and time for people to get through the flags and learn through all the comments that they said that are harmful without removing them. Support the women who could be supporters!* [P7]

Participants were concerned that acquiring the knowledge of what microaggressions are and how they affect the targets would be cumbersome for male perpetrators who were not interested in putting in the time and effort to see from the target's perspective:

> *I would give all of them [male microaggression perpetrators] vaginas and uteruses and have them go get a pap smear done or understand the process of seeking SRH care so they can become more empathetic towards the situations and experiences that women go through every day.* [P6]

However, they thought that in the long term, it would help their social support network (ie, fellow female users who have the intent to help them) be less burdened to provide the support they were trying to offer:

> *This microaggression thing is hard to pinpoint and I just don't want to make everyone who is trying to help feel like it's too hard to help. I think that having a communal sense of knowledge would be better. I know that it's going to burden women who are only trying to help at first, so I'm kind of iffy about the idea, but I think in the long term, it would help much more [to counteract microaggressions].* [P7]

While ideating the design ideas to support goal 5 (ie, respecting the perpetrators' freedom of speech while educating them to understand their words' negative impact), participants further reflected on how making judgments about users with supportive intentions based on microaggressions which are so subtle in nature would encumber users who were merely trying to be supportive. They elucidated that in the Korean culture, support is sometimes provided in the form of hard-hearted advice rather than a warm and sympathetic embracement, which would often be associated with microaggressions. Although most participants

XSL•FO
RenderX

did not know what microaggressions were before this study, they acknowledged that the current delivery of support is not ideal and could be ameliorated:

> *You know how we [Koreans] can be. Words of affirmation are definitely not our [culture's] love language. We [Koreans] give it to you straight and don't want to just tell you things that will make you feel better at the moment. Although it might sound uncaring, giving you that push to snap out of it and solve your problems is our way of showing that we care. Though I agree that it doesn't always make things better. It sometimes just hurts, and it could be [delivered] better.* [P6]

During the discussions for goals 2, 3, 4, and 6, participants constantly stated that sociocultural context shaped them to question their own thoughts and depend on others' judgments to determine what is right for them. However, the same design-influencing cultural characteristic affected the designs of each goal-supporting features in different ways. For goal 3 (ie, responding with less emotion to microaggressions) supporters, the need to respond with less emotion to microaggressions stemmed from them wanting to be treated less as an emotional or sensitive person and their want to be treated as a person who can justify their opinions or decisions with logic:

> *[Unmarried Korean] women are just framed to be these emotional beings who are just too da** sensitive. In our society, whenever women bring up discomforts or problems, we're told that we're being sensitive and somewhat irrational, even by other women. I think we need the preset options for why a comment is a microaggression to be as coherent and rational as possible to help our case.* [P13]

Similarly, goal 2 (ie, indicating positive support numerically) and goal 6 (ie, knowing the "reality") advocates indicated unmarried Korean women users need to be more logical in their justifications of their thoughts. However, goal 2 and goal 6 supporters had different opinions on what was required for logical justifications. Goal 6 proponents claimed that to provide a logical rationale, they needed to comprehend the diverse perspectives that other users hold to better defend themselves:

> *I need to know what I'm dealing with as a whole to better understand how I should be taking something. Without the whole picture, how do I know that I am making a sensible judgment of what I am reading and the people who are writing what I am reading? After I see the complete picture, I will know who I agree with more and who I agree with less.* [P9]

On the other hand, goal 2 supporters argued that logical rationales for one's own thoughts could be supported by the number of support that a comment or claim has. Participants who advocated for goal 2 claimed that showing the number of negative responses to a comment would only make the questioning of their own thoughts worse rather than help them get the evidence they need to make themselves not be seen as overly emotional people:

> *I am uncomfortable with the idea of just having two options (thumbs-up button and thumbs-down button). Well, I'm more uncomfortable with the thumbs-down button. Seeing the number of thumbs-downs would just make me feel uneasy when I'm trying to make sure that what I'm thinking is right. It would just make me question my decisions when I don't have to. I shouldn't have to [question my decisions], but it's making me do that.* [P8]

In contrast to goals 2, 3, and 6 advocates, goal 4 (ie, having forum-approved experts guide the discussions) proponents expanded the process of finding logical justification for their own thoughts to include the opinions of verified experts. Goal 4 proponents' proposed ideas should not be evaluated as ideas that comply with the social perception that women are too emotional. Instead, they should be regarded as expanding the sources of knowledge they could use in strengthening their logical justifications, as shown in the following quote:

> *We just cannot do it all - not be sensitive or emotional and find all the medical, factual, and experiential knowledge. We need help, and that's where experts, of course those who are certified, could help.* [P12]

Discussion

Overview

In this section, we elucidate how the goals identified from the participants' co-design could be leveraged to build a more resilient and safe web-based space to discuss and seek support on SRH care issues. In the first part of our discussion, we describe how the goals that we identified from participants' co-design activities would also support known psychological strategies for coping with microaggressions. In the second part of the discussion, we detail how participants' goals support educational and explanatory approaches to counteracting microaggressions.

Coping Strategies for Web-Based Microaggressions

The combined use of reflective coping (ie, re-evaluating the meaning of a given situation to reduce its emotional impact [50]) and suppressive coping (ie, inhibiting of an emotional response [51]) have been proven to be effective in coping with microaggressions [50,51,56]. Participants' goals uncovered in the co-design sessions show how to achieve reflective and suppressive coping strategies in web-based microaggression counteraction measures.

Goals 2 (ie, indicating positive support numerically) and 6 (ie, knowing the "reality") supported the microaggression targets to achieve reflective coping. Individuals using reflective coping styles examine causal relationships, reflect, and engage in behaviors that are intended to produce changes in their affective states and cognitive processes [66-68]. Indicating positive support numerically and seeing the whole picture by understanding both sides was suggested by participants to help them reassess the given situation with an objective standard, which is pivotal to cognitive reappraisal or picturing the provocative situation from a third-person perspective [48,50]. By understanding how many people explicitly support an

XSL•FO
RenderX

opinion or argument, participants thought that they would be able to evaluate whose opinions they should trust. In addition, by seeing the whole picture and not just the positive support numerical indicators, they thought that they would not be making a judgment based on viewing only one side and be able to change their affective states and cognitive processes with a holistic understanding of the provocative situation [67,68].

For suppressive coping, participants suggested goal 3 (ie, responding with less emotion to microaggressions) with an added level of agency. In a notable study that investigated strategies to counteract web-based ableist microaggressions, the coping mechanisms for ableist microaggressions were found to align with traditional suppressive coping mechanisms (eg, deleting comments and letting it go, blocking rather than reporting, and taking a break from social media) [69]. However, in this study, we found that responding with less emotion to microaggressions did not necessarily mean to "avoid" dealing with microaggressions. Rather, suppressive coping was transformed into active responses to microaggressions but with less-emotive words. By using less emotion in response to microaggressions, either in private messages or through flagging options, participants thought their claims that a comment contained microaggression would be less subjective. Making their claim seem less subjective was pivotal because microaggression targets tend to blame themselves for being overly sensitive and worry about reinforcing negative stereotypes [10,42,44,47,48].

Thus, with tools to support the stated goals, we hope to expand the ways to incorporate reflective and suppressive coping mechanisms for the targets of web-based microaggressions. However, we advise designers to implement the participant-suggested designs with caution, especially for reflective coping–supporting designs. The goals that were identified to support reflective coping—goals 2 (ie, indicating positive support numerically) and 6 (ie, knowing the "reality")—were influenced by the cultural characteristic that unmarried Korean women are often exposed to situations where they question their own thoughts and value the public's account of their opinions because they are socially perceived to be overly emotional and sensitive. Thus, the implementation of tools to support reflective coping would need to be provided with constant exposure to microaffirmations: subtle verbal remarks and storytelling microaggression targets engage to affirm each other's dignity, integrity, and shared humanity [70]. Jones and Rolon-Dow [38] support the notion that constant exposure to microaffirmations helps targets understand what microaggressions and microaffirmations are, how they are perpetuated, and how they impact the target. With the benefits of repeated listening to microaffirmations, women would be able to achieve deeper reflective coping [38,70,71]. Targets of these microaggressions would be able to better construct a narrative about the microaggressions they experienced and develop more effective action plans to change their affective states and cognitive processes [38,71].

Educational and Explanatory Approaches to Counteracting Microaggressions to Increase Awareness of Microaggressions Among All Users
