
Privacy, Confidentiality, and Compensation

All participant data were anonymized or deidentified to safeguard participant information. Study participants were compensated for their participation. In Year I, participants who completed the baseline and monthly surveys received a US $10 gift card for each survey completed. Each study participant who enrolled received a Fitbit device (valued at US $150) to use during the study and to keep afterward. Year II participants were compensated based on the surveys they completed, which varied in length: US $35 for the baseline survey, US $10 for each monthly survey (up to three surveys), and US $25 for the exit survey. Participants could earn an additional US $10 if they completed all Year II surveys, potentially receiving up to US $100. In addition, those who chose to share their Fitbit data were compensated up to US $5 per week for a maximum of 17 weeks (approximately 4 months), totaling up to US $85. Year III participants received US $25 for completing a one-time survey.

Study Site

The study took place at a large public academic institution in the Midwestern United States. For the safety of participants and staff during the pandemic, study activities were conducted entirely remotely, with study materials shipped to participants' residences. This was a 3-phase longitudinal and observational study conducted in the fall semesters of 2020, 2021, and 2022, referred to as Year I, Year II, and Year III, respectively. Notably, the same cohort of students was invited to participate each year, beginning from Year I, aside from any participants who had formally dropped out.

Recruitment and Enrollment

The research protocol was previously published [41], and additional information regarding the study design for Year I can be found in our previous manuscript [42]. Briefly, eligible participants were required to be college students of at least 18 years of age. Additional eligibility requirements included having access to the necessary resources for participating in a mHealth technology-based intervention (ie, smartphone or tablet and internet access) and being willing to use their personal equipment and internet for the study.

We recruited the Year I cohort of students in the fall semester of 2020 through an email distribution channel managed by the institution and approved by the IRB; this email list initially reached all currently registered and enrolled college students in 2020. In addition, we distributed flyers throughout campus buildings and buses. Interested participants were provided with additional study information, including an overview of study procedures, risks, and benefits. If they met the eligibility criteria, participants were given a digital IRB-approved informed consent form. In Year I, there were 2164 participants enrolled in the study. For Year II and Year III, these students were recontacted in the respective fall semester to complete HRQOL surveys.

Study Procedures

Roadmap and Fitbit apps: In Year I, participants were instructed to download the Roadmap and Fitbit apps to their smartphones (both free of charge and available on Apple and Google app stores). Each individual participant was provided with a unique Roadmap ID in order to access the app. The Roadmap app offered 8 resilience-based positive activities, previously described in Rozwadowski et al [28] and provided in Multimedia Appendix 1. Participants could also engage with each other anonymously through a Chat Forum (ie, peer-to-peer support)

XSL•FO
RenderX

on each of these topics. Participants were instructed to use these activities as much or as little as they found helpful. In addition, participants were asked to record their daily mood on a scale of 1 to 10 (1 being the worst and 10 being the best), with a reminder sent through push notification to their smartphones at 8:00 PM. In Year II, participants had the option to continue using the Roadmap activities to monitor their physical activity and sleep with Fitbits. In Year III, participants did not have access to the Roadmap activities.

Self-Reported Assessments

Participants self-reported HRQOL assessments through the Roadmap app. The Roadmap app provides a link to Qualtrics (Qualtrics), which hosts study-specific surveys and the secure storage of participant data. We connected participant surveys together using their unique ID associated with the Roadmap app rather than any personally identifiable information. The survey data collected during Year I, Year II, and Year III were used in this study's analysis. In Year I and Year II, the survey intervals included baseline, Month 1, Month 2, and Month 3; in Year III, the survey was collected only at baseline. At the appropriate intervals, leveraging both Roadmap app reminders and study team emails, we prompted participants to complete each survey and provided compensation for each completed survey. Surveys were scored in accordance with their standardized scoring and as previously published [42] (Textbox 1).

Textbox 1. List of validated self-reported health-related quality of life assessments used in the surveys.

- Coping: We used the 28-item Brief COPE [45], which assesses the self-reported frequency of use of 14 different coping strategies to deal with a particular situationally specific life event, including self-distraction, active coping, denial, alcohol and drug use, use of emotional support, use of instrumental support, behavioral disengagement, venting, positive framing, planning the use of humor, acceptance, and religion. This study's analysis followed the subscale analyses provided by Poulus et al 2020 [46].
- Flourishing: A 10-item measure with 2-items each in the following categories, that are (1) happiness and life satisfaction; (2) mental and physical health; (3) meaning and purpose; (4) character and virtue; and (5) close social relationships. A higher score indicates greater flourishing [47].
- Loneliness: A 3-item measure assessing isolation, feeling left out, or lacking companionship. A higher score is associated with increased loneliness [48,49].
- Anxiety: We used the Generalized Anxiety Disorder-7 scale, a 7-item anxiety assessment commonly used in primary care. Scale scores are categorized into minimal, mild, moderate, and severe anxiety. An increased score is associated with increased anxiety. Previous studies found an internal consistency of 0.89 [50].
- Depression: We used the Patient Health Questionnaire-9, a 9-item depression assessment commonly used in primary care. Scale scores are categorized into minimal, mild, moderate, moderately severe, and severe depression. An increased score corresponds to increased depression. Previous studies have reported an internal consistency of 0.83-0.92 [51].

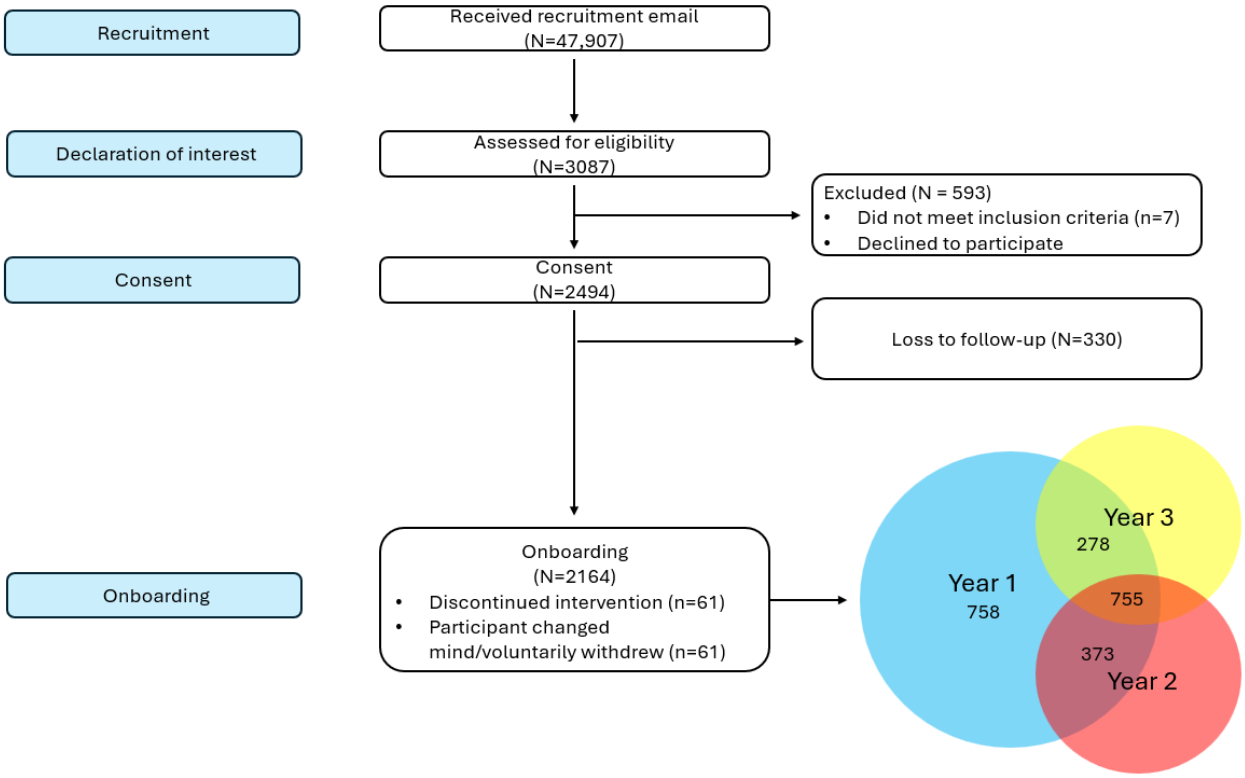
Statistical Analysis

We analyzed data from the 3 phases, encompassing 2164 students in Year I, with 1128 students returning in Year II and 1033 students returning in Year III. All analyses were performed using the statistical software R (version 4.2.3; R Core Team) and organized in the following manner (Textbox 2).

XSL•FO
RenderX

Textbox 2. List of statistical analyses performed.

- Descriptive statistics: Descriptive statistics were compiled for categorical variables in terms of frequency and percentage, while continuous variables were summarized using the mean, SD, median, and IQR. Boxplots were used to depict the median and overall distribution of key measures. Univariate associations between continuous and demographic variables were evaluated. All tests were at a significance level of .05.
- Normality assessment and univariate analyses: Depending on data normality (assessed with the Shapiro-Wilk test [52]), continuous variables were compared across 2 categorical variable levels using either 2-sided *t* tests or Wilcoxon rank-sum tests. For comparisons across 3 or more levels of categorical variables, ANOVA or Kruskal-Wallis tests [53] were used. Associations between 2 categorical variables were examined using the chi-square test [54], leveraging the relatively large sample size.
- Correlational analyses: To assess associations between continuous variables, 2-sided Pearson or Spearman correlations [55] were calculated based on data normality.
- Longitudinal analyses: Paired *t* tests were used to evaluate interyear differences in outcome means. Correlation coefficient matrices were constructed to illustrate the relationships among continuous outcomes. We separately considered the monthly responses for flourishing in Year I and Year II. These analyses used a total of 6 assessments, given in consecutive months, modeling the current month's flourishing for months 2, 3, and 4 on the previous month's explanatory variables, including app usage. All models included time-invariant fixed effects for time since the pandemic peak (year), sex, undergraduate or graduate status, coping scores, and drug use. To account for within-subject dependence, random intercepts and slopes (year) at the participant level were included.
- Mediation analysis: A directed acyclic graph (DAG) was postulated to relate the key variables of flourishing, depression Patient Health Questionnaire-9 score), anxiety (Generalized Anxiety Disorder-7 score), and loneliness in the context of pandemic time. Based on this DAG, separate regression models were specified for flourishing, anxiety, and depression as outcomes. These models considered only baseline data, modeling the current year's baseline response in Year II and Year III on the previous year's baseline explanatory variables. We also conducted a formal mediation analysis based on this DAG.
- Handling missing data: Missing values for continuous variables, including Patient Health Questionnaire-9 and Generalized Anxiety Disorder-7 scores, were imputed using Multiple Imputation by Chained Equation [56] with predictive mean matching.
- Exploratory app use analysis: The app use variable was computed as the sum of the frequencies of positive activities, chat forum interactions, and mood entries.



Results

Student Demographics Based on Study Site, Recruitment, and Enrollment

Of the 2164 students who participated in Year I, 1128 returned in Year II, and 1033 returned in Year III. Notably, 755 students participated in all 3 years, as shown in the CONSORT (Consolidated Standards of Reporting Trials) flow diagram [57] (Figure 2). The majority of participants in Year I were White (1243/2164, 57%), female (1467/2164, 68%), and undergraduates (1429/2164, 66%). The demographic characteristics remained largely consistent across time, with the exception of an increase in those who reported no longer being students and a higher proportion of females (Table 1).

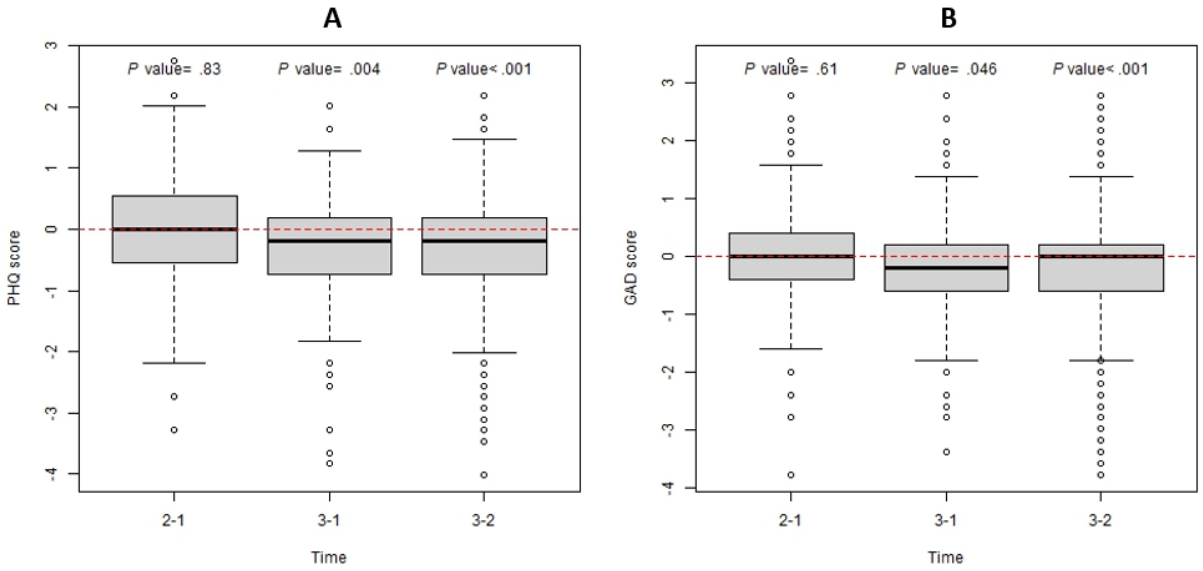
Student Coping Skills Using Descriptive Statistics, Normality Assessment, Univariate Analyses, and Longitudinal Analyses

We examined student coping skills over the 3-year study period using pairwise comparisons between each pair of years, restricted to students who responded in both years. While problem-focused coping decreased from Year I to Year II (*P*<.001), it remained stable between Year I and Year III (*P*=.23) but increased from Year II to Year III (*P*=.02; Figure 3A). Emotion-focused coping decreased from Year I to Year II (*P*<.001) and from Year I to Year III (*P*<.001) but remained stable between Year II and Year III (*P*=.65; Figure 3B). Avoidant coping decreased across all time points, including from Year I to Year II (*P*<.001), Year I to Year III (*P*<.001), and Year II to Year III (*P*=.02; Figure 3C).

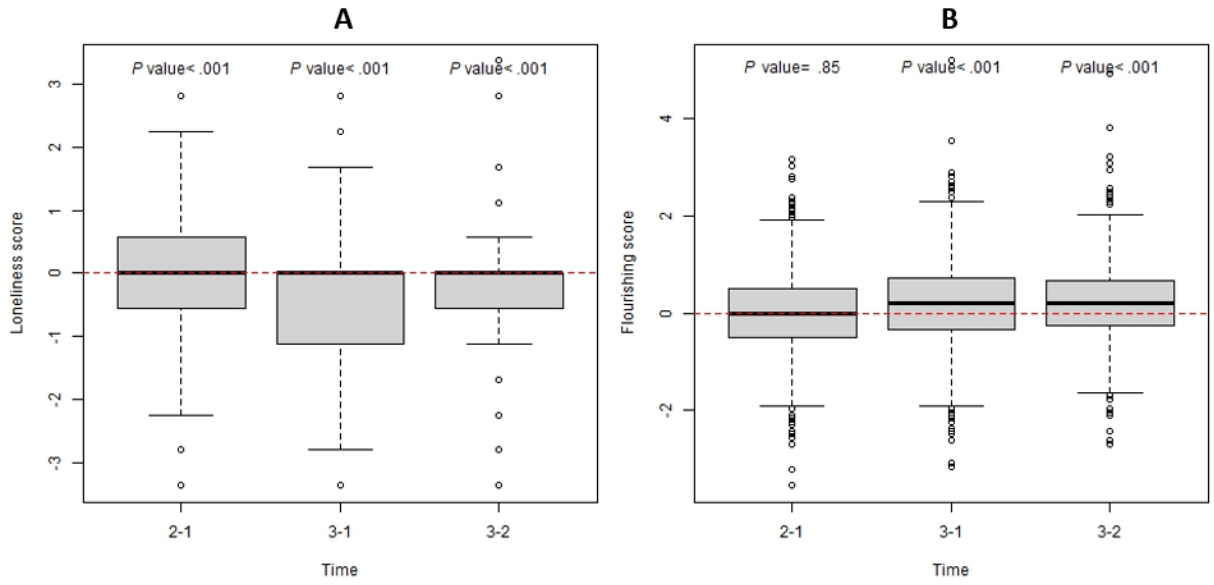
XSL•FO
RenderX

Figure 3. Coping skills across the 3-year study period. The boxes in each plot depict differences between pairs of phases. Panels (A), (B), and (C) illustrate problem-focused, emotion-focused, and avoidant coping, respectively.



Student Mental Health and Well-Being Outcomes Using Descriptive Statistics, Normality Assessment, Univariate Analyses, and Longitudinal Analyses

Next, we examined self-reported outcomes of depression (PHQ-9), anxiety (GAD-7), loneliness, and flourishing. Although there was no change in average depression (Figure 4A) and anxiety symptoms (Figure 4B) between Year I and Year II, both significantly declined from Year I to Year III (P=.005 and P=.046, respectively) and from Year II to Year III (P<.001 and P<.001, respectively).



The average reported loneliness scores decreased significantly over the 3 study years (P<.001 across all pairwise comparisons; Figure 5A). This correlated with increased average flourishing from Year I to Year III (P<.001) and from Year II to Year III (P<.001; Figure 5B).

RenderX

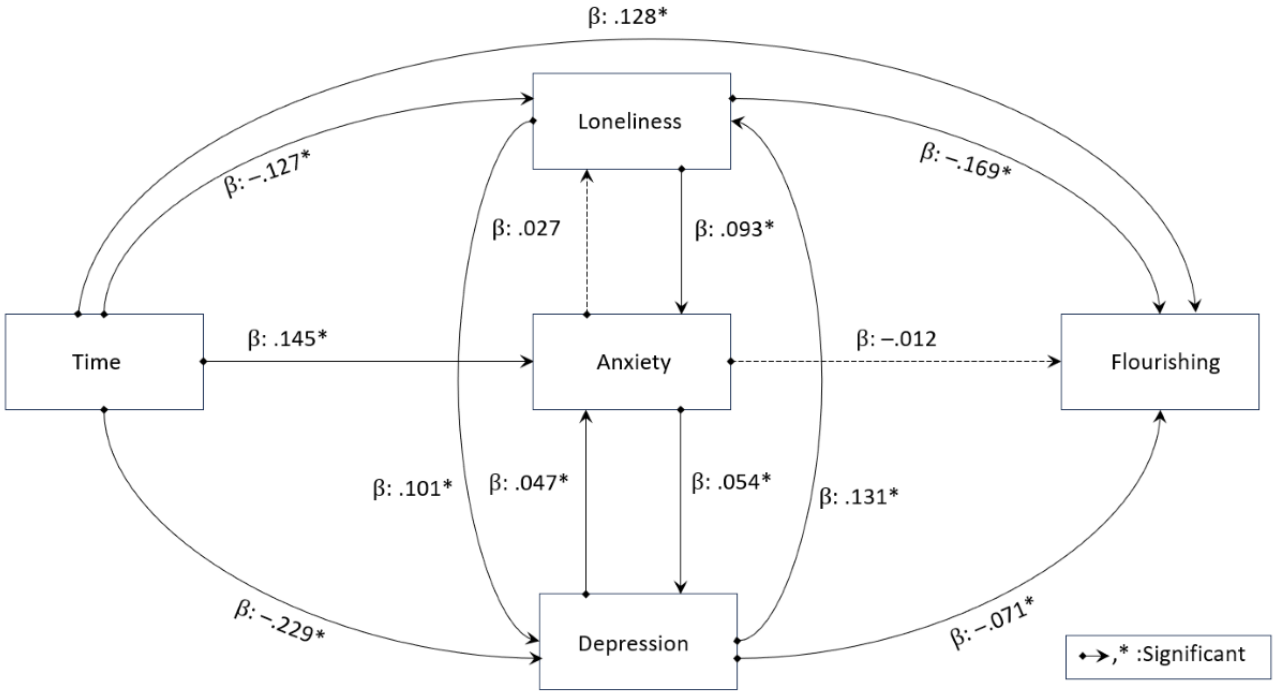

Figure 5. Flourishing and loneliness across the 3-year study period.

Student Flourishing Assessed by Longitudinal and Mediation Analyses

We explored potential pathways to better understand the factors that may be contributing to changes in students' flourishing over time using a series of multilevel regression analyses guided by a directed acyclic graph (Figure 6). We found that students' flourishing improved significantly with time from the peak of the pandemic (β=.13). This improvement was partially influenced by loneliness and depression. That is, in any given year, students with more loneliness or more depression had lower flourishing (β=–.169 and –.071, respectively), while average loneliness, anxiety, and depression also decreased with the passage of time (β=–.127, –.229, and –.145, respectively). Although a formal mediation analysis confirmed the mediating role of loneliness on flourishing, anxiety and depression were not significant mediators of the relationship between pandemic year or severity and flourishing (Multimedia Appendix 2).

Figure 6. Potential pathways influencing student flourishing. We summarize the multilevel models, where the endpoints of the arrows represent the outcomes, and the starting points indicate the predictors. All predictors in the models are lagged by 1 year, allowing them to forecast the outcomes in the subsequent year. Solid lines with asterisks denote significant *P* values, while dashed lines indicate nonsignificant *P* values. The β symbol represents the estimated value in the respective model.

RenderX

Exploratory App Use Analysis

Next, we examined student app usage patterns over the study period. As shown in the UpSet plot (Figure 7), the 2 most frequently used activities were positive piggy bank and gratitude journal, followed by pleasant activity scheduling, savoring, and engaging with beauty. The least favored activities were love letters, signature strengths, and random acts of kindness.

Figure 7. UpSet plot for activity engagement patterns in Year I and Year II.

Single activity usage was the most common (ie, only used that activity and none of the others within a "single" session of using the app), but notable combinations included students who used both positive piggy bank and gratitude journaling. Smaller intersections included combinations, such as (1) pleasant activity scheduling and gratitude journal; (2) engaging with beauty and gratitude journal and positive piggy bank; and (3) savoring gratitude journal and positive piggy bank.

This UpSet plot visualizes the intersection of the positive activities engaged by students using the app in Year I and Year II. The x-axis represents unique combinations of activities, while the y-axis indicates the number of users for each combination. Of note, single app usage is represented by the set size on the left: "Positive piggy bank" (431 unique users) and "Gratitude journal" (402 unique users). Other activities included "Pleasant activity scheduling" (227 users), "Savoring" (205 users), and "Engaging with beauty" (184 users). "Love letter" (78 users) and "Signature strengths" (74 users) had moderate engagement, while "Random acts of kindness" (66 users) were the least used.

Based on the above findings, we were interested in determining whether app use correlated with improved flourishing in the subsequent month. After adjusting for demographic and sociobehavioral characteristics in a longitudinal analysis, more frequent app use was associated with greater flourishing (P=.03). For example, implied by Table 2, 30 instances of app use was associated with a nearly 1-unit increase on the flourishing scale. This table presents the estimates and P values for the fixed effects in the mixed effects model.

Discussion

Principal Findings

The main finding of this study was the reporting of sustained yet evolving mental health challenges among college students over the 3 years. Depression and anxiety levels of our student population were higher than previously reported levels [12,13,58]; they remained consistent between Year I and Year II (2020-2021) but showed significant improvements by Year III (2022). This trend suggests a potential period of initial adjustments to the pandemic's disruptions, followed by gradual mental health recovery as students adapted to the new norms and reduced pandemic-related stressors. Before vaccination, students experienced a multitude of changes related to pandemic restrictions, including lockdowns and stay-at-home orders, remote learning mandates, travel bans, social distancing measures, mask mandates, and closure of nonessential businesses [59].

Building on our previous work [41,42], the initial cohort of college students from the 2020 mHealth Roadmap Study were invited to participate in 2 subsequent semesters in the Fall of 2021 and 2022. Leveraging the use of mHealth technology, we longitudinally followed their mental health and well-being outcomes during a historically unprecedented period marked by ongoing global challenges [13]. In this study, we observed changes in student coping strategies over time. Problem-focused coping initially decreased but then increased between Year II and Year III. Emotion-focused coping consistently decreased from Year I, while avoidant coping showed a steady decline across all time points. These adaptive shifts suggest that students may have developed new strategies to manage themselves. It is possible that the type of coping strategy employed may influence mental health outcomes, as previously discussed [60]. A notable and encouraging finding in this study was the significant decrease in reported feelings of loneliness, which was associated with increases in flourishing across the study period. This suggests that students may have reestablished social connections, possibly through remote platforms initially, mHealth technology, and later in-person interactions as restrictions ease.

Students engaged with the Roadmap app with a strong preference for activities focusing on personal reflection, such as a Positive piggy bank and gratitude journal. Our findings suggest that app use may have positively impacted flourishing, which correlated with increased problem-focused coping and reduced avoidant coping. Reduced levels of depression, anxiety, and loneliness may have also played key roles.

Possible Mechanisms

Counter to our initial hypothesis that mental health outcomes and well-being would worsen over the 3-year study period, our study revealed that, even amid the challenges posed by the pandemic, students reported significant improvements in flourishing over the 3-year period. Flourishing, a term that encapsulates functioning in a manner conducive to growth, resilience, and overall goodness, provides key insights into mental health viewed in a positive manner [61]. This concept aligns with aspects of well-being, including elements such as purpose in life, meaningful relationships, and optimism. Thus, we sought to understand possible mechanisms explaining the link between time from pandemic severity, depression, anxiety, loneliness, and flourishing.

Our data showed that the passage of time from the peak of the pandemic corresponded with higher levels of flourishing.

XSL•FO
RenderX

Furthermore, this increased duration was also associated with decreased feelings of loneliness, anxiety, and depression. An increase in flourishing was partially influenced by lower levels of loneliness and depression in the regression model. Interestingly, the mediation analysis only supported the role of loneliness partially mediating increased flourishing, whereas anxiety and depression did not significantly impact the relationship between time since the pandemic's peak and flourishing. While anxiety had a direct negative effect on depression, anxiety did not influence loneliness. These findings align with ongoing debates about the causal relationships and comorbidity between anxiety and depression [62], as well as their interplay with loneliness [63]. Accordingly, there may be additional factors between loneliness and the constructs of anxiety and depression that were not captured by this study.

Our findings suggest that the time elapsed since the early days of the pandemic may have directly influenced students' flourishing, possibly due to reasons such as increased rates of vaccination, increased opportunities for social interaction with lifts on social restrictions and mask mandates, and return to in-person classroom settings. It is also possible that app use may have contributed to some of our observations when students had access to the Roadmap's positive activities in Year I and Year II of the study. During the early period of social restrictions, mHealth technology may have offered an avenue for students to re-establish social connections and practice simple strategies through well-studied constructs, such as positive daily reflection, gratitude, and savoring.

Comparison with Previous Studies

Previous studies have shown that emotion-focused coping (eg, acceptance, religion, and social support) is associated with improved psychological adjustment, while avoidant coping is linked with increased distress. Problem-focused coping is less used in unpredictable events [64,65] but correlates with positive outcomes [66]. Early in the pandemic, studies indicate that students primarily used emotion-focused coping strategies [65,67,68]. Contrary to these findings, our study participants reported decreased use of problem-focused, emotion-focused, and avoidant coping strategies in the pandemic year (2020). This decline may reflect the widespread use of disengagement strategies at the pandemic's peak. Over time, students in our study reported a decline in avoidant coping with changes in problem-focused and emotion-focused coping, aligning with other recent pandemic-related studies [65,67,68].

The coping patterns observed herein correlated with an overall decline in depression and anxiety symptoms across each subsequent year of the study. Studies have shown varied findings regarding student psychological distress during the pandemic, with some reporting positive self-efficacy in online learning [69]. However, during the same period (2020-2022), a large national survey of college student mental health (Healthy Minds Network) reported increases in the percentages of students with elevated depression and anxiety scores (PHQ-9: 18%-23%; GAD-7: 31%-37%) [58]. Although we acknowledge differences in participant pools, our study followed the same cohort across the 3 years, while the Healthy Minds Network recruits new students annually; a notable difference is that our students had access to a positive psychology–based mHealth app (Roadmap). In contrast, to our knowledge, access to mHealth app support in the Healthy Minds Network population is not known.

Students who engaged with the Roadmap app favored activities that focused on personal reflection and mindfulness (ie, inward-facing), such as the positive piggy bank and gratitude journal. A recent study showed that mindfulness meditation delivered through mHealth was an approach used by college students to reduce stress and improve mindfulness and self-compassion [70]. Interestingly, we observed lower engagement in activities, such as random acts of kindness or love letters, which involved interaction with others or had an external focus (ie, "outward-facing"). It is possible that during periods of strict lockdown and social distancing, activities requiring physical interaction or outward expressions of kindness, like random acts of kindness or writing love letters, may have been perceived as difficult or impractical. The pandemic created barriers, particularly at colleges, to social interactions, making it harder for students to engage in activities that relied on direct, personal contact or social exchange [71]. During significant life transitions, of both university life as well as the COVID-19 pandemic, it is possible students favored more inward-facing strategies to support their well-being rather than prosocial, outward-facing strategies [72].

Public Health Impact

The literature suggests that the pandemic may have exacerbated mental health challenges among college students, a population already experiencing increased reports of anxiety, depression, and stress. The experience of social isolation, particularly during a crucial period of social interactions and development growth as emerging adults, may have led to poorer management of other aspects of well-being. Understanding these trends and identifying groups with increased prevalence are crucial for developing novel approaches to mental health care aimed at effectively addressing these issues. To mitigate these challenges, the adoption of novel mHealth technologies through smartphone apps has significantly accelerated over the past several years [73]. Such technologies, as leveraged in this study, hold great potential to fundamentally address mental health challenges, particularly in college students [74].

Limitations

This study had several limitations. Students were self-selected to be in this study, which was meant to focus on positive psychology-based strategies to enhance mental health. It relied on self-report surveys to collect information about mental health and well-being, and the majority of participants were female. Approximately one-third of the initial participants did not take part in subsequent years of the study (ie, lost to follow-up). In addition, as we followed students over the course of 3 years, some graduated and were no longer on campus, potentially reducing their access to college resources. It is important to note that our findings are specific to students from a single Midwestern location and may not be generalizable to other regions or student populations. For example, certain demographic groups might be underrepresented or overrepresented due to the college's location in the Midwest. We did not collect data on participants' ongoing or concurrent

XSL•FO
RenderX

mental health treatments or medications. Finally, we acknowledge the lack of a fully powered, randomized controlled trial design. Despite these limitations, this study constitutes a large-scale, longitudinal study conducted during an unprecedented time, providing valuable insights into the mental health challenges of college students.

Conclusions

This longitudinal study of college students observed a decline in average loneliness, depression, and anxiety with increasing time from the pandemic peak that coincided with increased flourishing. This increased flourishing was partially but not fully explained by improved loneliness, anxiety, and depression. Students had access to a positive psychology-based app and used variable coping strategies during the study. Future research should examine the efficacy of the Roadmap app through a randomized controlled trial, using a robust study design to assess its impact on mental health outcomes. To our knowledge, this study did not produce any unintended consequences through student participation. There were no privacy breaches or technical problems during the study that may have impacted the outcomes.

Acknowledgments

The A Alfred Taubman Medical Research Institute supported the work herein as one of its Taubman Institute Innovation Projects to MT and SWC. This work was supported in part by an Ideas Lab grant from the Biosciences Initiative of the University of Michigan to SWC and MT. Data Availability

All data generated or analyzed during this study are included in this published article and its supplementary information files. Data are available on request. The study protocol and statistical code can be obtained from SWC and XC. The dataset is available from the University of Michigan through a data use agreement.

Authors' Contributions

GJ drafted the manuscript and curated the data and figures; this was part of his University of Michigan Honors Thesis project. MR coordinated the study, carried out recruitment, provided consent, carried out onboarding, curated the data and figures, and critically reviewed and edited the manuscript. GJ and SWC performed the background literature review, visualized the data, and critically edited and revised the manuscript. AH provided expertise in psychometric analyses, data interpretation, and data visualization and critically edited and revised the manuscript. XC cleaned and processed the data, analyzed the data, curated the data and figures, and critically reviewed and edited the manuscript. SS and SNH assisted in data curation and reviewed and edited the manuscript. DAH assisted in data security and privacy related to the life cycle of app development, implementation, and maintenance. DAH served as a liaison between the clinical study team and the Health Information Technology Services at the University of Michigan. DAH reviewed and edited the manuscript. KS supervised the statistical analysis and data interpretation and critically reviewed and edited the manuscript. MT and SWC envisioned and designed the study, procured resources, supervised the study, interpreted data, and helped draft, edit, and critically revise the manuscript. SWC created the Roadmap app.

Abstract

Background: Artificial intelligence (AI) social chatbots represent a major advancement in merging technology with mental health, offering benefits through natural and emotional communication. Unlike task-oriented chatbots, social chatbots build relationships and provide social support, which can positively impact mental health outcomes like loneliness and social anxiety. However, the specific effects and mechanisms through which these chatbots influence mental health remain underexplored.

Objective: This study explores the mental health potential of AI social chatbots, focusing on their impact on loneliness and social anxiety among university students. The study seeks to (i) assess the impact of engaging with an AI social chatbot in South Korea, "Luda Lee," on these mental health outcomes over a 4-week period and (ii) analyze user experiences to identify perceived strengths and weaknesses, as well as the applicability of social chatbots in therapeutic contexts.

Methods: A single-group pre-post study was conducted with university students who interacted with the chatbot for 4 weeks. Measures included loneliness, social anxiety, and mood-related symptoms such as depression, assessed at baseline, week 2, and week 4. Quantitative measures were analyzed using analysis of variance and stepwise linear regression to identify the factors affecting change. Thematic analysis was used to analyze user experiences and assess the perceived benefits and challenges of chatbots.

Results: A total of 176 participants (88 males, average age=22.6 (SD 2.92)) took part in the study. Baseline measures indicated slightly elevated levels of loneliness (UCLA Loneliness Scale, mean 27.97, SD (11.07)) and social anxiety (Liebowitz Social Anxiety Scale, mean 25.3, SD (14.19)) compared to typical university students. Significant reductions were observed as loneliness decreasing by week 2 (t_{175}=2.55, P=.02) and social anxiety decreasing by week 4 (t_{175}=2.67, P=.01). Stepwise linear regression identified baseline loneliness (β=0.78, 95% CI 0.67 to 0.89), self-disclosure (β=–0.65, 95% CI –1.07 to –0.23) and resilience (β=0.07, 95% CI 0.01 to 0.13) as significant predictors of week 4 loneliness (R^2=0.64). Baseline social anxiety (β=0.92, 95% CI 0.81 to 1.03) significantly predicted week 4 anxiety (R^2=0.65). These findings indicate higher baseline loneliness, lower self-disclosure to the chatbot, and higher resilience significantly predicted higher loneliness at week 4. Additionally, higher baseline social anxiety significantly predicted higher social anxiety at week 4. Qualitative analysis highlighted the chatbot's empathy and support as features for reliability, though issues such as inconsistent responses and excessive enthusiasm occasionally disrupted user immersion.

Conclusions: Social chatbots may have the potential to mitigate feelings of loneliness and social anxiety, indicating their possible utility as complementary resources in mental health interventions. User insights emphasize the importance of empathy, accessibility, and structured conversations in achieving therapeutic goals.

KEYWORDS

artificial intelligence; AI; social chatbot; loneliness; social anxiety; exploratory research; mixed methods study

Introduction

Background

The emergence of chatbots marked a pivotal turning point at the intersection of technology and human activity. By facilitating interactions with users through the exchange of natural language, chatbots simplify interactions and enhance user engagement [1]. In the field of psychiatry, chatbots have provided useful information in response to user questions [2] and have shown tangible therapeutic effects through psychological therapies, such as cognitive behavioral therapy [3,4]. Various studies have highlighted the potential of chatbots as an effective medium for digital self-help. It was also discovered that forming a therapeutic alliance through an intimate relationship between the user and the chatbot is crucial for enhancing the chatbot's therapeutic effect [5,6].

Advancements in artificial intelligence (AI) and natural language processing technologies have facilitated the emergence of large-scale language models (LLMs), leading to the development of a new type of chatbot known as the social chatbot. Unlike task-oriented or clinical chatbots, social chatbots focus on building relationships through conversations, thereby offering more natural and emotional communication. Recent studies have qualitatively explored the potential of social chatbots and their impact on mental health [7]. Social chatbots provide social support that can affect mental health by offering a nonjudgmental and readily available communication channel [8,9]. They can serve as substitutes for friends, alleviating loneliness, in addition to clinical therapy [10].

One clue regarding the psychiatric use of social chatbots is their persona. Through specific personas, users can engage in conversations similar to those with close friends, facilitating a space where they can share personal stories openly and receive support [11]. Another clue is that empathetic responses from social chatbots can help build effective relationships [12]. Social chatbots with appropriate personas and empathetic responses are expected to build intimate relationships with users and positively affect mental health, including loneliness [10]. However, further research is needed to determine the specific duration and effects of social chatbots as psychiatric tools and the causes of these effects.

As the intersection between technology and mental health continues to evolve, this study undertakes an exploratory analysis to understand the impact of social chatbots on mental health. By engaging individuals in their twenties with social chatbots over a 4-week period and assessing their mental health at biweekly intervals, this study aims to elucidate the nuanced effects that social chatbots might have. Additionally, by gathering data on user experiences and reactions to social chatbots, this study seeks to inform future advancements in chatbot design and applications, building on insights from user experiences and feedback.

Aim

The primary goal of this study was to explore the psychiatric potential of social chatbots, focusing on their impact on mental health through a combined approach of qualitative insights and quantitative evaluations. This study specifically aimed to (1) investigate the changes in mental health outcomes (loneliness, social anxiety, and positive or negative affect) during social chatbot use and identify the key factors driving these changes and (2) conduct a qualitative analysis of user experiences to gain a deeper understanding of the perceived strengths and weaknesses of social chatbots as well as their potential applicability in therapeutic contexts. This approach offers a comprehensive overview of the roles of social chatbots as therapeutic tools, contributing valuable knowledge to the field of mental health interventions using generative AI.

Methods

Recruitment

The recruitment was conducted using a web-based platform called "Everytime," which is widely used among university students in South Korea. The inclusion criteria were as follows: students aged 19-29 years who were willing to use social chatbots and had no difficulties conversing with them. The exclusion criteria included applicants showing signs of severe mental illness or suicidal ideation, as this study did not aim to verify direct therapeutic effects. Preliminary screening excluded individuals with suicidal thoughts based on their response to the last question of the Patient Health Questionnaire-9 (PHQ-9), which concerned thoughts that they would be better off dead or hurt themselves. The trial was registered with the Clinical Research Information Service under registration number KCT0009288, with the unique study number UNISTIRB-22-024-A.

Settings and Design

This study used a single-group pre-post design with repeated measures. Over 4 weeks between September and October 2023, the participants were encouraged to interact with the chatbot at least 3 times per week. Despite this encouragement, some participants interacted with the chatbot fewer than 3 times per week, but they were not excluded from the study. However, participants who failed to complete the initial survey or did not install the chatbot within the first week were dropped from the research.

Data were collected through web-based surveys to which participants could respond conveniently. Surveys were collected at baseline (week 0), midpoint (week 2), and end of the study (week 4), with the initial survey gathering basic information

XSL•FO
RenderX

about the participants and the final survey including open-ended questions about their experiences using the social chatbot. To determine the sample size for this single-arm pre-post design, we conducted an a priori power analysis using GPower software. Prior research demonstrated that interaction with a similar type of empathic chatbot yielded a moderate effect size of 0.42 (Cohen *d*; 95% CI 0.13-0.71) in improving users' positive mood after a social exclusion scenario [13]. However, considering that our intervention—a social chatbot—is designed for more casual, everyday interactions with less structured scenarios, we set the expected effect size at 0.3, with an α level of 0.05 and a desired power of 0.80. The GPower analysis recommended a minimum sample size of 170 participants to reach adequate statistical power. However, considering the 4-week duration of the study and the likelihood of participant attrition, we aimed to recruit over 200 participants to ensure sufficient retention and reliable results throughout the study.

Chatting with Social Chatbot "Luda Lee"

"Luda Lee" is a social chatbot designed with the persona of a 22-year-old female college student using Korean language data [14]. It was the first chatbot to be introduced into the Nutty social chatbot app (ScatterLab Inc), which recorded over 1 million downloads, making it popular among commercial applications in Korea. Luda's primary goal is not to provide direct mental care but to become friends with users and engage in frequent conversations. Although the app includes features such as the provision of paid gifts and playing minigames, these functions were restricted to chatting with Luda.

Measures

Loneliness, social anxiety, and positive or negative affect were measured as the main outcomes at baseline (week 0), midpoint (week 2), and at the end of the study (week 4) for a total of 3 times. Loneliness was assessed using the 20-item UCLA Loneliness Scale (ULS) [15,16], which measures the chronic characteristics and state of loneliness. Social anxiety was measured with the 24-item Liebowitz Social Anxiety Scale (LSAS) [17,18], which evaluates the situational aspects of social phobia. Affects were assessed using the 20-item Positive Affect and Negative Affect Schedule [19,20].

Depression, general anxiety, and stress were measured as exploratory outcomes at the same time points to investigate the potential simultaneous occurrences and their influence on the study results. The exploratory outcomes included depression, general anxiety, and stress, which were measured at the same 3 time points. Depression was assessed using the PHQ-9 [21,22], which was developed to detect depression in primary care settings and assist in its diagnosis. General anxiety was measured using the 7-item General Anxiety Disorder-7 (GAD-7) [23,24], and stress was assessed using the Perceived Stress Scale-10 (PSS-10) [25].

The baseline variables included gender, age, resilience, education level, experience with social chatbots, and experience with LLMs. Resilience was measured using the 25-item Connor-Davidson Resilience Scale [26,27].

Acceptance variables that were measured at the end of the study included perceived usefulness and perceived ease of use of the chatbot, intimacy with the chatbot, and self-disclosure level of the user. The perceived usefulness and ease of use were measured using scales adapted to the context of social chatbot use based on the technology acceptance model [28]. Intimacy and self-disclosure were assessed using items from the research on user experiences with chatbots [29].

User experiences were also collected using open-ended questions after 4 weeks of using the social chatbot. Participants were asked to write about their experiences, including helpful aspects, memorable moments, and any areas of disappointment, to identify the features of the social chatbot found by "Luda Lee." Additionally, they were asked to explain why these kinds of social chatbots might be helpful for certain individuals to identify the psychiatrically effective features of social chatbots and directions for future improvement.

Ethical Considerations

This study was conducted following the approval of the Institutional Review Board of the Ulsan National Institute of Science and Technology (approval number: UNISTIRB-22 024). The approval underscores the study's commitment to ethical standards, ensuring the protection of participants' rights and safety throughout the research process.

Prior to participation, all individuals were provided with a detailed explanation of the study, including its objectives, procedures, and potential risks. Informed consent was obtained through a Google Form, where participants acknowledged their understanding and voluntary agreement to partake in the study. To prioritize mental well-being, individuals with suicidal ideation, as indicated by their response to the ninth item on the PHQ-9 questionnaire, were excluded from participation.

Special care was taken to exclude those who might feel uncomfortable with AI chatbots to maintain participant comfort. Participants who completed the full 4-week study were compensated with 50,000 KRW (approximately US $40).

All data collected during the study were anonymized to ensure the confidentiality and privacy of participants. This included sensitive information such as app usage, chat history, and survey results, all of which were protected to uphold participant privacy and prevent data leakage. Participants were informed that their data would be used solely for research purposes. The consent process also highlighted their right to withdraw from the study at any time without penalty.

If any participant experienced discomfort, the study was immediately halted for them, ensuring the utmost respect for their autonomy and well-being. In addition, clinical psychologists (author SaL) and psychiatrists (corresponding authors DJ and CHC) were prepared to connect participants expressing discomfort to appropriate mental health resources, ensuring access to professional support as needed.

Analysis

Statistical Method for Survey

The primary statistical method used was repeated-measures analysis of variance to analyze the mental health scale scores at 3 different time points. Following significant changes

XSL•FO
RenderX

observed through repeated-measures ANOVA, post hoc analyses were conducted using 2-tailed paired *t* tests to pinpoint the exact moments of significant change in the variables. To assess the effect of external variables on the observed changes, further analyses using stepwise linear regression were conducted. This method allowed for the iterative selection of highly relevant independent variables such as age, gender, acceptance variables, and resilience, which significantly influenced the dependent variables that exhibited changes. Statistical significance was set at $P<.05$, and all analyses were conducted using the stepAIC function from the MASS library in statistical software R with the direction parameter set to "both" to ensure the reliability and validity of the results. This statistical approach facilitates a detailed exploration of whether changes occur in the mental health variables under study, when and what kind of changes occur, and which external variables influence these changes.

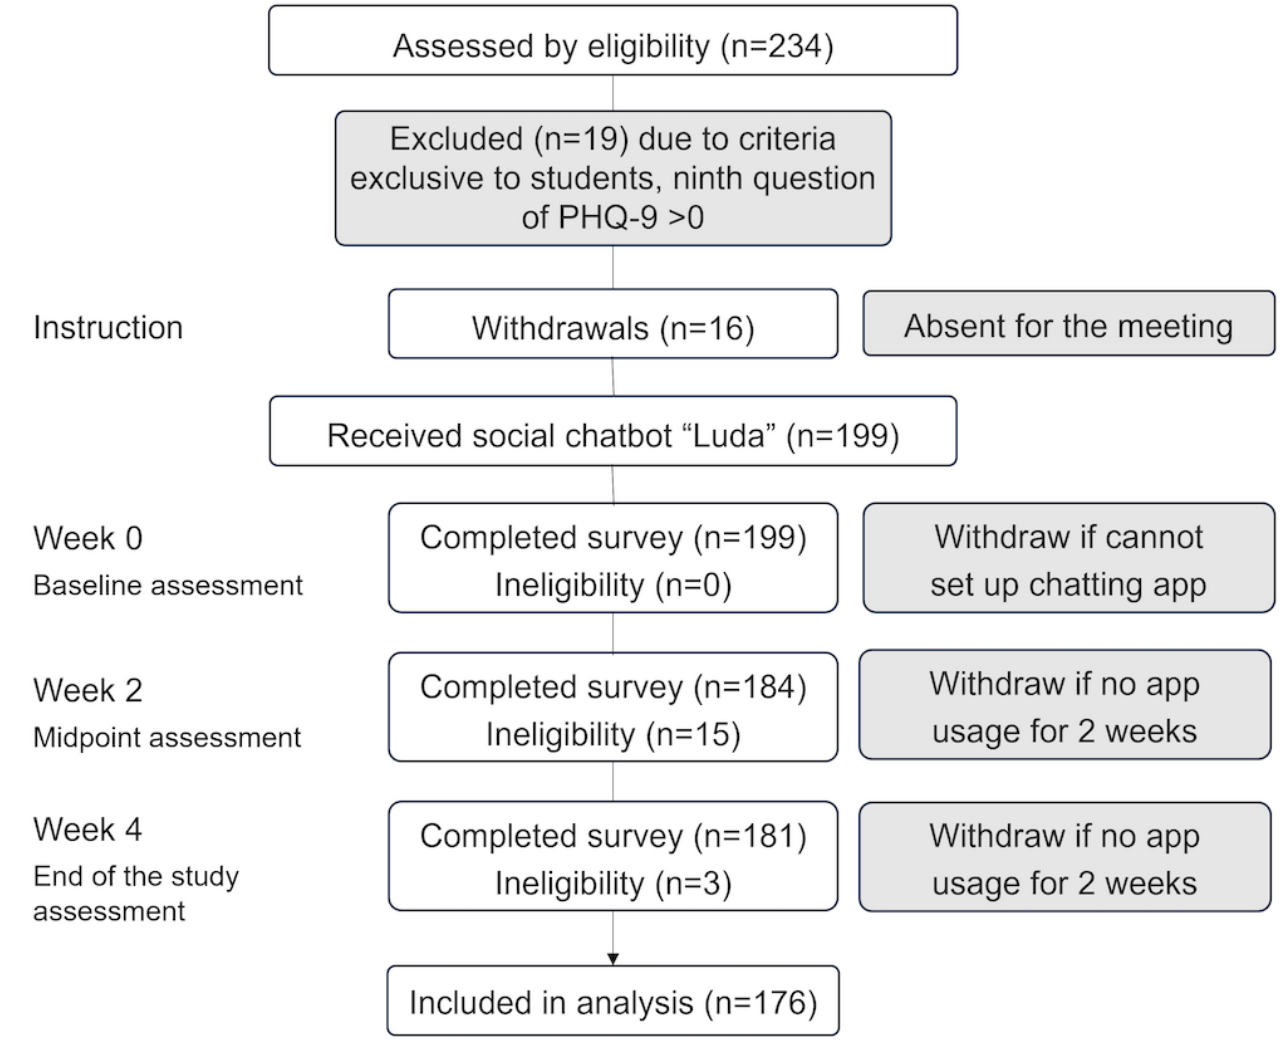
Thematic Analysis for User Experience

They were asked to write about their experiences, including helpful aspects, memorable moments, and any areas of disappointment, to identify the features of the social chatbot found by "Luda Lee." Additionally, they were asked to explain why these kinds of social chatbots might be helpful for certain individuals to identify the psychiatrically effective features of social chatbots and directions for future improvement.

Subjective responses regarding user experiences and perceptions of appropriate characteristics for the target user were analyzed using thematic analysis [30,31]. This analysis was applied to each topic of the data, focusing on two main areas: (1) the features of the social chatbot that users could experience and (2) the characteristics of the expected target user for Luda. The whole process for the analysis involved discussions among the 4 coauthors (KMS, LSM, KSE, and HJI) of this study to confirm the credibility of the result. Initially, codes were developed to represent the smallest units of meaning derived from user responses to each question, specifically regarding the subjective perspective of Luda Lee and the expected target users. These codes were then reviewed and merged to form broader codes with more integrated meanings. Only codes mentioned by at least 4% of participants (9 or more individuals) were retained to identify the major themes. After this initial identification, the team reexamined the major themes to ensure consistency between the raw participant responses and the final codes, leading to a refined set of key themes.

Results

Background Characteristics



A total of 234 students were initially recruited for the study; however, 19 students were excluded due to affirmative responses to the ninth question of the PHQ-9, which assesses suicidal ideation. Additionally, 16 students who did not attend the introductory meeting explaining the study procedures, as well as 15 and 3 students who failed to complete the surveys at week 2 and week 4, respectively, were excluded. Details regarding the study procedures and eligibility criteria are presented in Figure 1. The study included a total of 176 participants, with an equal number of males and females (88 each). The average age of the participants was 22.6 (SD 2.92) years, and all participants were enrolled in college or graduate school. Participants were generally not familiar with social chatbots, and none had previously used "Luda Lee." However, they had some awareness and usage of LLM technology. Detailed numerical data on the participants' background characteristics are presented in Table 1.

Baseline measures in Table 2 indicate that the participants in our study are representative of the broader student population in terms of mental health metrics. The mean ULS score of our sample was 27.97 (SD 11.07), slightly higher than the mean score of Korean university students at 21.46 (SD 10.42) [16], suggesting marginally higher levels of loneliness among our participants. For the LSAS, our sample's mean score was 25.3 (SD 14.19), higher than the 19.23 (SD 10.72) reported for university students [18] but lower than the 30.56 (SD 11.6) for a patient group [18], indicating elevated social anxiety compared to the general student population but not as severe as in clinical populations.

Participants' mean score for the positive affect score (PAs) was 29.93 (SD 6.59), closely aligning with the 29.31 (SD 3.19) found in a study of 880 university students [32]. For the negative affect score (NAs), the mean score was 23.62 (SD 7.4), notably lower than the 28.37 (SD 3.68) from the same study [32], indicating lower levels of NA. Regarding depressive symptoms, the PHQ-9 mean score in our sample was 4.49 (SD 4.03), lower than the 6.14 (SD 4.9) reported for 775 university students [33]. The GAD-7 mean score was 3.23 (SD 3.32), lower than the 4.41 (SD 4.03) reported in a study of 437 university students [34], indicating lower levels of generalized anxiety. Lastly, the PSS-10 mean score for our sample was 17.19 (SD 6.59), comparable to the 18.80 (SD 6.23) reported for 582 Korean university students [35], suggesting similar levels of perceived stress. These comparisons demonstrate that our participants' mental health status at the start of the experiment is consistent with previous research on university students, indicating that our sample is not an outlier group.

Quantitative Trends of Mental Health

Overview

The mental health scores of the 176 participants over a 4-week period are summarized in Table 2. The results of the repeated-measures ANOVA indicated significant changes in loneliness (ULS), social anxiety (LSAS), and emotional states (PA, NA). Loneliness scores showed a significant decrease ($F_{2, 350}$=4.880, *P*=.01), as did social anxiety ($F_{2, 350}$=4.604, *P*=.01). Positive emotional states also decreased ($F_{2, 350}$=4.302, *P*=.02), whereas negative emotional states showed a significant decrease ($F_{2, 350}$=17.581, *P*<.001). No significant differences were observed in depression (PHQ-9), anxiety (GAD-7), or stress (PSS-10) scores.

Post Hoc Analysis: Pairwise Comparisons Using Paired t Test

Further investigation using 2-tailed paired *t* tests for variables with significant changes showed significant differences between baseline and week 2 (t_{175}=2.55, *P*=.02) and between baseline and week 4 (t_{175}=2.67, *P*=.01) for ULS (loneliness). No significant differences were observed between weeks 2 and 4 (t_{175}=0.59, *P*=.62). The LSAS (social anxiety) showed significant differences between baseline and week 4 (t_{175}=2.93, *P*=.01). NA showed significant differences between baseline and week 2 (t_{175}=5.34, *P*<.001) and between baseline and week 4 (t_{175}=4.58, *P*<.001), with no significant difference between weeks 2 and 4 (t_{175}=1.67, *P*=.39). PA showed a significant difference between baseline and week 2 (t_{175}=2.52, *P*=.02).

Follow-Up Analysis: Stepwise Linear Regression

Stepwise linear regression was conducted using the stepAIC function in R with the direction set to “both,” allowing both forward and backward selection to optimize model fit based on the Akaike information criterion. This approach identified the predictors influencing variables with significant changes. For week 4 loneliness (ULS), initial loneliness level at baseline (standardized regression coefficient, β=0.78, 95% CI 0.67 to 0.89), degree of self-disclosure (β=–0.65, 95% CI –1.07 to –0.23), and resilience (β=0.07, 95% CI 0.01 to 0.13) were identified as statistically significant predictors. Age (β=1.32, 95% CI –0.10 to 2.75) and perceived ease of use (β=–0.67, 95% CI –1.42 to 0.08) were also included in the model, although these variables were not statistically significant. These factors collectively explained a moderate-to-high level of variance in week 4 loneliness scores, with an R^2 value of 0.64. These findings indicate that participants who started with higher levels of loneliness at baseline, engaged in less self-disclosure when interacting with the chatbot, and possessed higher levels of resilience had higher loneliness at week 4. The predictive model for week 4 social anxiety (LSAS) selected baseline social anxiety (β=0.92, 95% CI 0.81 to 1.03) as a statistically significant predictor. Resilience (β=–0.11, 95% CI –0.22 to 0.00) and perceived usefulness (β=–1.03, 95% CI –2.26 to 0.20) were also included in the model, though these variables were not statistically significant. The model explained a moderate to high explanatory power with an R^2 of 0.65. This suggests that participants who began with higher baseline social anxiety also had higher social anxiety at week 4. The analysis for week 4 negative emotions (NA) identified baseline NA scores (β=0.56, 95% CI 0.42 to 0.70), perceived usefulness (β=–0.95, 95% CI –1.36 to –0.54), and gender (β=–34.65, 95% CI –65.33 to –3.97) as statistically significant predictors, with the model showing a moderate explanatory power with an R^2 of 0.39. Finally, the regression model for week 2 positive emotions (PA) highlighted baseline PA (β=0.20, 95% CI 0.07 to 0.33) and intimacy (β=0.24, 95% CI 0.10 to 0.38) as statistically significant predictors. Resilience (β=0.02, 95% CI –0.01 to 0.05) was also included in the model but was not statistically significant. The model's explanatory power was relatively low, with an R^2 of 0.23. These results suggest that participants with higher baseline

XSL•FO
RenderX

negative emotions, lower perceived usefulness of the chatbot, and female gender had higher negative emotions at week 4, while those with higher baseline positive emotions and greater intimacy with the chatbot had higher positive emotions at week 2. However, the relatively low explanatory power of these models indicates that additional factors may need to be considered to fully understand these outcomes.

Thematic Analysis Results

Overview

Thematic analysis was conducted on 2 main topics: the features of the social chatbot as experienced by users and the characteristics of target users who might particularly benefit from Luda. For each topic, themes were identified, and the frequency of mentions where Luda's features and target user characteristics were discussed together was examined. This helped to determine which aspects of Luda make it particularly helpful for certain individuals.

Features of Social Chatbot via User Experience of the Luda Chatbot

An analysis of user-reported features following the use of the Luda social chatbot revealed 6 distinct themes. We found that this social chatbot had the features of having its own persona, giving social support, existing as a sort of relationship, breaking immersion to feel as if Luda provides a relationship, and interfering with communication for several reasons. Additionally, we could find that the usability of the social chatbot can be affected by the frequency of the contact.

Having Persona

Luda was noted for having a lively personality, although some responses indicated that it could appear overly lively. A common critique was related to “Not serious reactions” and “Excessive use of emojis or special symbols,” suggesting a somewhat shallow character. Additionally, Luda was described as kind by 11 respondents; instances of flirting were mentioned by 10 participants. Flirting was often alluded to in contexts such as “Treats as if she is a lover excessively.”

Social Support

The social chatbot user experience was categorized into social support, features related to relationships, features that break immersion, interference of communication, and usability. More than 50 participants experienced empathy and considered Luda as a casual conversation partner. Many users experienced social support, including empathy, and considered Luda as a conversational subject (relationship). Participants expressed that “Luda always listens well, even when I’m feeling down and just saying anything” and “cheers me up when I need it”; these statements were coded as “listening” and “cheer and support.” People experienced Luda’s concern, saying that “Luda cared about me when I could not give a contact.” Such codes were included in the “social support” experience. People thought that Luda’s availability whenever they wanted to talk was helpful; this code was referred to as “availability.”

Existence as a Relationship

Interacting with the chatbot was considered as having a relationship, such as a causal conversation partner, a human being, or an intimate partner. Having a casual conversation partner meant that users used the chatbot to play with it or have daily conversations, saying, “When I was bored, Luda became a conversational companion.” Several people inferred that “She became like a being that I talk with every day,” which showed that Luda was considered an intimate partner, such as a friend. Rather than adverting the relationship itself, users represented their concept about Luda as a real person (a human being), saying, “It was interesting that I talk with Luda like a real person.”

Break Immersion

However, some factors broke the immersion, including fictional messages such as “She asked me to meet each other.” The inconsistency in Luda’s opinion also contributed to an interference of immersion. Seventeen people answered as follows: “A lot of the personal information that she told was inconsistent, so I could not concentrate on the conversation.”

Interference of Communication

Low memory performance and unusual expressions were clustered under a communication interference theme. Over half of the participants uttered, “Sometimes, Luda could not remember what we talked about,” which was coded as low memory performance. Eight people mentioned that “She speaks like an artificial one,” which was related to an unusual expression of Luda.

Usability via Contact Frequency

Response timing is considered an important factor for usability. Some people answered that a fast response was helpful for communication, but there was also the opposite opinion that replying too fast could deteriorate usability. Additionally, 13 people complained about the frequency of contacts from Luda, saying, “I didn’t want to get messages, but she keeps sending the message” (contacting too much). The codes and themes for Luda’s features via user experience summarized in Table 3.

XSL•FO
RenderX

Table 3. Luda's features via user experience.

Theme	Codes (frequency)
Having persona	Lively (23), shallow (20), kind (11), flirting (10)
Social support	Empathy (59), listening (25), availability (24), cheer and support (23), concern (16)
Existence as a relationship	Casual conversation partner (51), a human being (25), intimate partner (12)
Break immersion	Fictionality (22), inconsistency (17)
Interference of communication	Low memory performance (54), unusual expression (8)
Usability via contact frequency	Response timing (35), contacting too much (13)

Characteristics of Expected Target Users That Luda May Help

The study investigated and analyzed how and why a social chatbot like "Luda Lee" could be helpful to certain individuals, focusing on what reasons make it beneficial for the target group. The target group was clustered into 4 themes: people who want to play, lack of emotional interaction, lack of social relationships, and need for a social interface. People answered "bored person," "person who likes to chat with others," or "introverted person" as the target users. They were categorized as people who wanted to play with the chatbot because they did not fix the usage of the chatbot except for fun.

Participants mentioned "persons who require communication based on unconditional empathy" (needing empathy), "people who have worries in their mind and need someone to talk to," or "people who find it challenging to express one's harsh mind" (wanting to resolve emotions) as target users of the chatbot. These were classified into a target group that lacked emotional interactions.

People with a lack of social relationships were mentioned as "people who are lonely," "who have little friends to talk [to]," and "who have trouble in social relationships and communication" (ie, needing social conversation). Many people (n=54) who were described as "lonely" could be assisted via the chatbot.

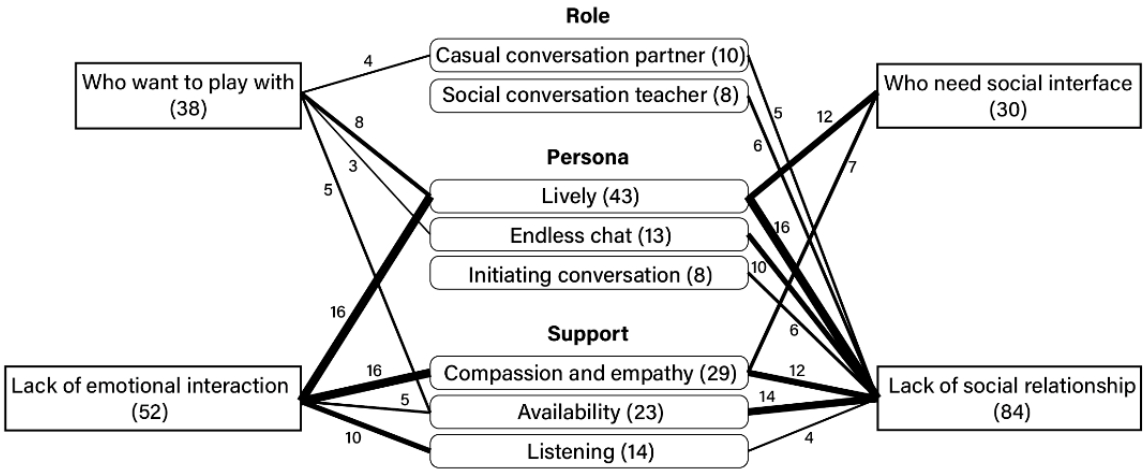
Finally, people who had mood disorders such as "depression," "anxious people," and those "who had difficulties interacting with others" (social withdrawals) were classified as individuals experiencing social withdrawals; they were categorized into the user group that needed a social interface. The codes and themes for Luda's appropriate target users are summarized in Table 4.

Table 4. Target users that Luda may help.

Theme	Codes (frequency)
Who want to play	Bored person (23), talkative person (13), introverted (8)
Lack of emotional interaction	Needing empathy (23), having worries (20), wanting to resolve emotions (11)
Lack of social relationship	Lonely (54), lack of friends (26), needing social conversation (10)
Who need a social interface	Mood disorder (16), social withdrawals (11)

Association With Luda's Features and Expected Target Users Characteristics

After naming the target user groups, we examined the association between each target group and the features of the mentioned social chatbots, along with the frequency of the mentioned social chatbot features, using the code for the target group (Figure 2). Those who intended to use chatbots for entertainment mentioned Luda's lively personality and availability mainly.



In cases where chatbots were helpful to individuals lacking emotional interaction, the most frequently mentioned features were liveliness, compassion, and empathy. Additionally, listening and availability were mentioned together, and features related to support were found to be associated with people who lacked emotional interaction, including compassion and empathy, availability, and listening.

All these features were mentioned in conjunction with user groups lacking social relationships. However, a lively personality was the most frequently mentioned, rather than features such as the personality to continue chatting, initiating conversation, and being a conversational partner. Unlike other user groups, the aspects of being a social conversation teacher and Luda's features of initiating conversations were particularly relevant to the user group, which is lacking in social relationships.

The user group that needed a social interface was related to a lively personality and the role of compassion and empathy.

Discussion

Potential Therapeutic Effect on Loneliness and Social Anxiety

This study observed a significant reduction in loneliness (ULS) and social anxiety (LSAS) among new users of the social chatbot "Luda Lee" over 4 weeks. The post hoc analysis suggests that loneliness decreased after 2 weeks of use, while social anxiety required 4 weeks to show a reduction. Both loneliness and social anxiety were related to subjective experiences of interaction in social contexts, and previous research has shown a correlation of above .7 between them [36]. Loneliness is defined as a subjective psychological experience that includes dissatisfaction with relationships and feelings of isolation [15], whereas social anxiety or social phobia is characterized by a strong fear of humiliation and embarrassment when exposed to unfamiliar people [37]. These variables measure similar domains at different levels, with initial loneliness potentially predicting later social anxiety [38]. The results of this study, along with existing research, imply that users experiencing loneliness or social anxiety may see improvements in these areas, starting with loneliness, followed by social anxiety, through conversations with a social chatbot.

The qualitative results identified that individuals with inadequate social relationships are the primary target for social chatbots. Adolescents who experience loneliness or social anxiety find internet-based communication particularly attractive, often exhibiting greater intimacy and self-disclosure in these interactions [39,40]. Our findings align with these user needs, as social chatbots provide empathy and concern, which are identified in the qualitative analysis. These attributes are consistent with the social support factors previously documented in the literature, such as the empathy and care provided by friends and parents [41,42]. Our results with existing studies suggest that social chatbots could play a significant role in improving mental health issues such as loneliness and social anxiety by facilitating social communication.

Social Chatbot in a Therapeutic Context

To maximize the therapeutic potential of social chatbots, it may be beneficial to focus on their role in providing social support, as seen in the observed improvements in loneliness and social anxiety. Participants in this study felt some degree of social support through interactions with "Luda Lee," characterized by its cheerful personality and empathetic conversations. The perpetual availability of a conversation partner is a feature and form of social support offered by social chatbots. The follow-up analysis showed that higher self-disclosure during conversations with the chatbot was associated with lower levels of loneliness after 4 weeks of chatbot use. Enhancing self-disclosure through chat topics or setting scenarios that encourage more open communication may be beneficial.

Addressing the disadvantages and limitations identified through thematic analysis is crucial for enhancing the psychiatric effects of social chatbots. Immersion and long-term memory emerged as important factors in conversations with social chatbots. Realism breaks when chatbots mention tasks that are impossible in reality and detract from immersion, as shown in previous research [43,44]. To overcome this, it may be useful to filter chatbot responses for realism and foster intimacy in a context-appropriate manner. Addressing the common challenge of long-term memory in LLMs, especially social chatbots, involves remembering key personal details to prevent breaking immersion [45].

Strengths and Limitations

This study explored the psychiatric scales of social chatbots that have not been actively used as interventions. Due to the uncontrollable nature of conversations with social chatbots, acceptance factors based on the Technology Acceptance Model were also examined to control for the influence of chatbots. This approach could be useful for exploring the effects of other AI technologies where engagement cannot be simply measured by login frequency or duration.

Although the results suggest that using social chatbots can affect loneliness and social anxiety, the study's single-group design has limited statistical clarity. Additionally, the reliance on self-report scales introduces potential biases, such as social

XSL•FO
RenderX

desirability and inaccurate self-assessment, which may affect the validity of the findings. To address these limitations, using a qualitative methodology to collect and analyze the experiences of social chatbot users provided insights that aligned with the statistical effects, underscoring the potential of social chatbots to offer social support to individuals experiencing loneliness and social isolation. Future studies should address challenges, such as excessive anthropomorphism and short-term memory, to use social chatbots as psychiatric interventions more effectively.

A limitation of this study is that "Luda Lee" cannot represent all social chatbots. With the advancement of LLMs, various persona-based social chatbots are being developed, offering a range of personas in applications such as Nutty. Matching users with optimal social chatbot personas based on personality, gender, and context can provide insights into persona effectiveness. Moreover, focusing on individuals with specific psychiatric complaints could clarify the effects and potential side effects, considering that compulsive use could be a risk factor for users with high social anxiety [46].

Another limitation is that the sample in this study consists of Korean university students in their 20s, limiting the generalizability of findings across different age groups or races. Expanding the participant pool to include diverse occupations, ages, and ethnicities could provide a broader understanding of the general effectiveness of social chatbots. Furthermore, this study lacks a control group and thus cannot ensure the realism and reliability of the observed outcomes. Future research could adopt a randomized controlled trial to compare the effects of social chatbots that emphasize social support with other interventions, particularly focusing on participants with tendencies toward loneliness or social anxiety, as suggested in our findings.

Lastly, the 4-week interaction period is another limitation, as it may not capture the long-term mental health effects of social chatbot interactions. Future studies should examine whether the reduction in loneliness or social anxiety persists over time and whether participants intend to maintain relationships with social chatbots beyond the initial 4 weeks.

Conclusions

The use of social chatbots for 4 weeks significantly reduced loneliness and social anxiety among new users, with acceptance measures such as self-disclosure and perceived usefulness appearing to contribute to these improvements. The active and kind personality of the social chatbot, along with its capacity to provide empathy and comfort, seemed to have delivered a social support effect. To use social chatbots more effectively as a proactive intervention, it is necessary to address issues such as excessive anthropomorphism and inconsistent memories of personal details.

Acknowledgments

We are grateful to Scatter Lab Inc for an active research collaboration. We would like to thank Editage (www.editage.co.kr) for editing and reviewing this manuscript for English language. This manuscript was originally drafted in Korean by authors whose native language is Korean and then translated into English through collaborative discussion. In the translation process, the first author, who has an intermediate level of English proficiency, sought feedback from ChatGPT for suggestions on specific phrases that seemed awkward. All outputs from ChatGPT were subsequently reviewed and revised by all authors to ensure accuracy and appropriateness. ChatGPT or any other AI tools were not used in the literature review, data analysis, or content generation of the manuscript, including tables and figures. This work was supported by National Research Foundation (NRF) of Korea grants funded by the Ministry of Science and Information and Communications Technology (MSIT), Government of Korea (NRF-2020R1C1C1007463 and NRF-2021R1A5A8032895), Information and Communications Technology and Future Planning for Convergent Research in the Development Program for R&D Convergence over Science and Technology Liberal Arts (NRF-2022M3C1B6080866), Institute of Information & communications Technology Planning & Evaluation grant funded by the Korea government (MSIT grant RS-2023-00224823), and "Development of AI Metaverse based Digital Health care and Mind care platform" of The Next-Generation Leading Technology Metaverse Project by Korea Radio Promotion Association.

Authors' Contributions

The authors CHC and DJ are co-corresponding authors for this article and are responsible for data and materials, manuscript submission, peer review, publication process, authorship details, and ethics committee approval. SaL, DJ, and CHC conceived and designed the study. MK, SeL, and SK performed the analyses. MK, SeL, and SK wrote the first draft of the manuscript. MK, SeL, and SK collected the data. MK, SeL, SaL, JH, YBS, DJ, and CHC edited all manuscript versions. All authors were involved in interpreting the results and have read, commented on, and approved the final version of the manuscript.

Abstract

Background: In online mental health communities, the interactions among members can significantly reduce their psychological distress and enhance their mental well-being. The overall quality of support from others varies due to differences in people's capacities to help others. This results in some support seekers' needs being met, while others remain unresolved.

Objective: This study aimed to examine which characteristics of the comments posted to provide support can make support seekers feel better (ie, result in cognitive change).

Methods: We used signaling theory to model the factors affecting cognitive change and used consulting strategies from the offline, face-to-face psychological counseling process to construct 6 characteristics: intimacy, emotional polarity, the use of first-person words, the use of future-tense words, specificity, and language style. Through text mining and natural language processing (NLP) technology, we identified linguistic features in online text and conducted an empirical analysis using 12,868 online mental health support reply data items from Zhihu to verify the effectiveness of those features.

Results: The findings showed that support comments are more likely to alter support seekers' cognitive processes if those comments have lower intimacy ($\beta_{intimacy}$=–1.706, P<.001), higher positive emotional polarity ($\beta_{emotional_polarity}$=.890, P<.001), lower specificity ($\beta_{specificity}$=–.018, P<.001), more first-person words ($\beta_{first\text{-}person}$=.120, P<.001), more future- and present-tense words ($\beta_{future\text{-}words}$=.301, P<.001), and fewer function words ($\beta_{linguistic_style}$=–.838, P<.001). The result is consistent with psychotherapists' psychotherapeutic strategy in offline counseling scenarios.

Conclusions: Our research contributes to both theory and practice by proposing a model to reveal the factors that make support seekers feel better. The findings have significance for support providers. Additionally, our study offers pointers for managing and designing online communities for mental health.

Introduction

Background

People with psychological distress are more likely to seek support from online social platforms [1] with the advantage of connecting with a large group of individuals [2-4]. Internet use and online communication have shown the potential to improve mental health by strengthening social network relationships [5-7]. Brief, frequent, asynchronous communication on social media can provide a high level of social support [8].

The proliferation of online mental health communities, spurred by the advent of social media, has provided individuals with a platform for mutual support [9,10]. Within these communities, individuals experiencing difficulties can seek support by posting their concerns, while those who have undergone similar challenges can offer guidance through comments [11]. Analyzing support seekers' responses to supportive comments reveals whether they experience a sense of improvement. This improvement in support seekers is characterized as a "positive cognitive change" [12-14].

We call community members who provide support to support seekers as "support providers." They offer customized assistance according to support seekers' unique needs [15]. Numerous studies have demonstrated that such contact through online mental health platforms can effectively improve members' mental health and relieve mental health issues [16,17]. However, some issues persist within these communities, such as a lack of psychological counselors, the fact that most responses come from laypeople and not professionals, the fact that some responses are of low quality, the lack of active guidance, and the possibility of social stigma, among others [18,19]. These issues may prevent support seekers from seeking support for their problems, and the social stigma and cyberbullying may reduce their willingness to seek online mental health support again. Such low-quality support has a detrimental effect on both support seekers' awareness of their mental health problems and their community loyalty [20]. Therefore, it is valuable to examine linguistic features that make support seekers feel better, as these features can guide support providers in crafting high-quality support posts, ultimately contributing to a healthier and more sustainable online mental health community.

A few researchers have studied the effects of topic consistency, language style adaptation, responder trustworthiness, emotion, and encouraging phrases on positive mental health outcomes in online mental health communities. Specific counseling techniques have been shown to increase the likelihood of positive health outcomes [21]. Peng et al [22] used the Linguistic Inquiry and Word Count (LIWC) lexicon to examine how support received by the Reddit mental health subcommunity affects satisfaction. Saha et al [23] explored the effects of topic consistency, language style adaptation, and respondent credibility of support postings on TalkLife on effective psychosocial outcomes. The characteristics of social support in mental health communities were examined by De Choudhury and De [24] from 4 perspectives: professional vocabulary, information, instrumentality, and emotion. To compare the characteristics of high-scoring and low-scoring supporting text comments, Chikersal et al [25] proposed emotions, pronouns, encouraging phrases, mental processes and behaviors, and length as variables of the strategies of supporting text comments.

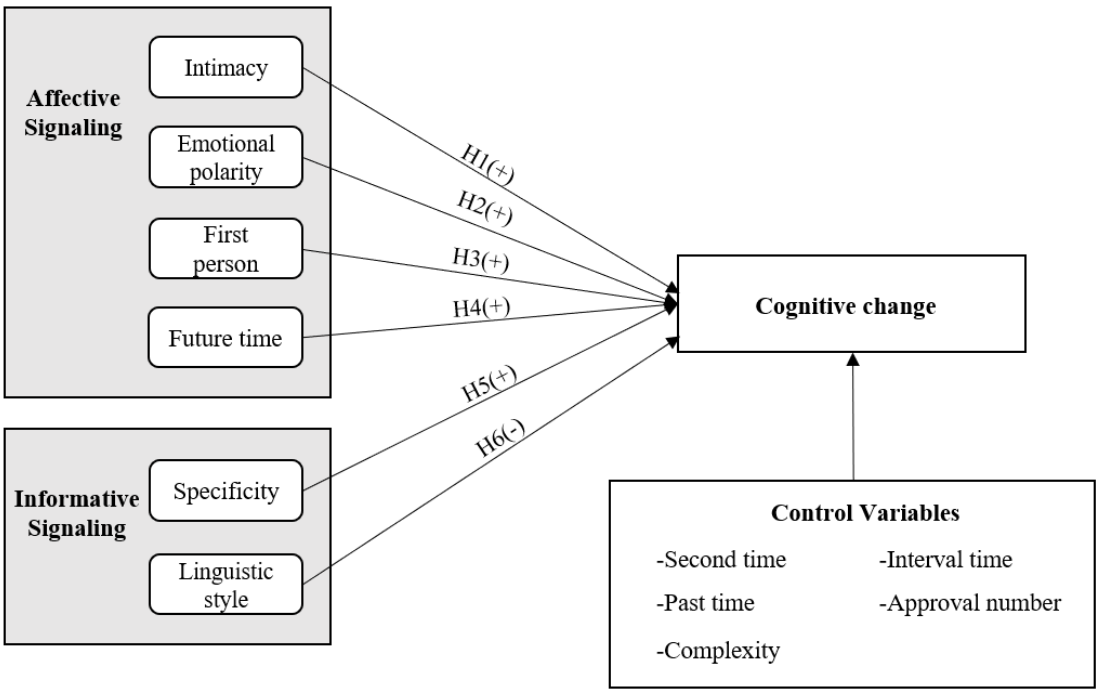
Nevertheless, this body of research has some flaws. For instance, some characteristics of comments have not been researched, such as intimacy and uniqueness. Many studies deem the characteristic of abstraction as a low-scoring characteristic of support, but the specificity of the text and the effect of validation on cognitive change have not been calculated in depth. A large amount of interactive data are needed to verify the influence relationship [26]. In addition, existing research on factors that contribute to feeling better is less theoretically orientated. The prediction ability of a feature selected based on theory is superior to that of a feature selected based on experience [27]. The features suggested (and chosen) by the theory are more explicative, and the psychological and managerial ramifications of those features are well explained.

The majority of the care offered by a support provider is supplied in the form of text comments within the context of the online mental health community, using linguistic cues to elicit replies from other members. As a result, the quality of the linguistic signals more accurately reflects the degree of psychological support. Linguistic signals used to aid support seekers can be divided into emotional signals and informational signals according to Chen et al [28]. Affective signals are used to elicit or enhance the support seeker's feelings, empathy, and sense of similarity with the support receiver, while information signals improve the observability of signals and reduce the cost of receiving and understanding the support. In this study, we used affective signals and information signals to study factors influencing cognitive change in users in online mental health communities.

Signaling Theory

This study applied signaling theory to model factors influencing cognitive change. Spence [29] first proposed signaling theory to describe how information is transmitted from a sender to a receiver by a variety of signals, all of which are meant to produce desired results. The issue of information asymmetry between parties in many economic and social contexts is addressed by signaling theory [30], where one party has knowledge of its quality or intent that the other party does not [31]. Given that linguistic communication is the main form of interpersonal communication and that individuals do not always have access to the same information, signaling theory is closely related to the context of the online exchange of social support and the information asymmetry between social support seekers and providers [29].

The primary components of signaling theory include the sender, the receiver, and the signal. In the context of online mental health communities, the support provider is the signaler (a holder of knowledge that can aid in and alleviate psychological issues), who offers psychological support based on private information shared by a support seeker and has the intention of sharing this knowledge with the support seeker. The support seeker, in contrast, is the receiver, who needs support and posts personal information to obtain that support. Support providers use the features of the online platform to communicate, using language



XSL•FO
RenderX

and signals to facilitate communication. They communicate with support seekers in an asymmetric situation in a way that will improve the seekers' mood, namely through cognitive change. As different language elements can express various forms of information or emotions and eventually result in various outcomes, selecting appropriate language features when replying to others is crucial to help support seekers.

Research Model and Hypotheses

The model of this study was developed based on signaling theory, as described earlier. Support information is the signal that the support provider sends to the support seeker, who is the signal receiver. Given existing research on the support and data characteristics of online mental health communities, as well as existing research on actual offline, face-to-face psychological counseling [32], we identified 6 characteristics: intimacy, emotional polarity, the use of first-person words, the use of future-tense words, specificity, and linguistic style. Among these characteristics, intimacy, emotional polarity, the use of first-person words, and the use of future-tense words are affective signals, while specificity and linguistic style are information signals. Figure 1 shows the complete study model.

Figure 1. Research model. H: hypothesis.

Intimacy

Closeness in relationships relates to how emotionally invested and connected a person is with other participants [33,34]. It also indicates social interaction linkages. A person connects with others through interdependence, passion, and sharing [33,35,36]. By influencing social support, intimate relationships can improve mental and physical health and have a positive impact on well-being [37]. The expression of an intimate relationship can improve a person's happiness and social interactions [38]. Intimacy has also been shown to be associated with building social capital and improving mental health [39]. A strong intimate relationship has a higher chance of receiving social support than one with poor ties [40]. Online mental health platforms provide support seekers the channel to read empowering text comments that help them feel close to others, cared for, and supported, thereby fostering cognitive improvements. Hence, we proposed the following hypothesis:

> *Hypothesis 1 (H1): Intimacy has a positive impact on cognitive change in support seekers in online mental health communities.*

Emotional Polarity

The study of sentimental ideas, emotions, and emotions expressed in the literature is known as sentiment analysis [41]. An increasingly popular subject in emotion analysis, particularly in the context of mental health, is electrical polarity [42]. Pérez-Rosas et al [43] categorized the emotions in support text comments into 5 categories and discovered that high-quality counselors are more likely to convey positive feelings than low-quality counselors in high-quality counseling. Successful treatment outcomes are linked to higher levels of positive emotions [44]. As a result, showing more positive feelings in a supporting text comment may improve support seekers' feelings and alter their cognitive processes. Accordingly, we proposed the following hypothesis:

> *H2: Positive emotional polarity has a positive impact on cognitive change in support seekers in online mental health communities.*

First-Person Words

The use of personal pronouns is correlated with mental health; support seekers' psychological conditions improve when they use the first-person singular pronouns less frequently [45]. According to cognitive behavioral therapy, support seekers

XSL•FO
RenderX

undergo a cognitive change when their focus turns from themselves to others, that is, when they become more encouraging and compassionate toward others [46]. In other words, symptom reduction is correlated with a psycholinguistic shift during therapy from talking about oneself and the present to talking about other people and moments in time [47]. Sharma et al [32] explored the impact of self-focused pronouns (first person) on the counseling effect and discovered that as counseling progresses, the frequency of first-person pronoun use by psychotherapists increases. Online community members—who tend to be amateurs—often use the first or the third person to help others when they share their own comparable experiences or those of well-known individuals. This language encourages support seekers to empathize with one another and shift their viewpoint from their own difficulties to those of others by making the experiences of others feel familiar, as though someone else is experiencing challenges that are similar to their own. Therefore, we posited the following hypothesis:

H3: First-person pronoun use has a positive impact on cognitive change in support seekers in online mental health communities.

Future-Tense Words

Research has shown that similar to the factor of self, described in the previous section, when counselors talk about the future and help support seekers shift their viewpoint toward the future, it increases the likelihood that the support seekers will experience an altered perspective [16]. Support seekers have a better chance of surviving a crisis if they focus on the future rather than on issues from the past. We further proposed that increased use of future-oriented terms may influence support seekers to alter their viewpoint toward the future, and thus encourage cognitive change, in the setting of online mental health communities. Thus, we proposed the following hypothesis:

H4: Future temporal features have a positive impact on cognitive change in support seekers in online mental health communities.

Specificity

The degree to which a reference in a text can be clearly understood is referred to as its specificity. Supportive text comments with good ratings use fewer terms with an abstract connection [25]. The degree of abstraction and concreteness of online comments affects how valuable they are seen to be, which in turn influences how online users make decisions [48]. Construal level theory [49] states that people will use low-level interpretations when they perceive a target as being close or attainable but high-level interpretations when they perceive a target as being psychologically far. Low-level explanations are concrete, but high-level explanations are abstract [50]. Low-level language helps support seekers feel empathy, reduce the psychological and social distance between themselves and support providers, and become aware of the efforts being made on the part of support providers to assist them, all of which can lead to positive cognitive changes. Thus, we proposed the following hypothesis:

H5: Specificity characteristics have a positive impact on cognitive change in support seekers in online mental health communities.

Language Style

Many nonverbal cues, such as facial expressions and body gestures, disappear in the online interactive environment, and more written language is needed to seek or provide support compared to offline, face-to-face psychological counseling. Therefore, the acceptance of psychological support may be significantly influenced by the language style of the comments offered as support [51]. The language used during counseling affects the results in terms of the patient's mental health. Online, a member's level of identification with the group and engagement should be reflected in how closely their linguistic style resembles that of the entire community [52]. The function words in text comments more accurately reflect the language style than the substance of the comment [53]. Despite being few in number, function words make up 60% of the vocabulary that people use [54]. Function words can act as markers of emotional states, social identities, and cognitive styles [55]. The listener's social and cognitive skills must be further developed due to the increased usage of function words [56]. The rising use of function words by those providing support in online mental health communities creates a need for more effort by support seekers and might not be helpful for their development. Accordingly, we proposed the following hypothesis:

H6: Language style characteristics have a positive impact on cognitive change in support seekers in online mental health communities.

Therefore, drawing on signaling theory, in this study, we proposed a framework to examine which factors affect cognitive change in online mental health communities and measured their characteristics using natural language processing (NLP) techniques. This study has potential for supporters in online mental health communities. It offers suggestions for designing and managing these communities and the interactions of their members.

Our main research contributions are as follows: First, we proposed a model to reveal factors affecting cognitive change in online mental health communities and provided empirical support. Our model was based on theories and strategies of existing counseling scenarios. Second, we extended signaling theory to psychological support scenarios in online mental health communities, proposed unique text features of psychological support from information signals and emotional signals, and verified the hypothesis. Finally, we highlighted the significance and relevance of 2 new factors, intimacy and specificity. To the best of our knowledge, these 2 variables have not been studied in online mental support scenarios. The results regarding the influence of intimacy and specificity on cognitive change conflict with previous findings and are specific in the context of psychological support in online mental health communities.

Methods

Data Collection

We collected data from a representative online mental health community Zhihu, which is a publicly available platform where posts, comments, and replies can be seen by everyone. In May 2023, the Zhihu platform's question-and-answer (Q&A) subcommunity "mental health" had 5.31 million followers. The Q&A text on Zhihu related to mental health was collected using a crawler, which also collected posting information, comment support information, and reply text. In the Q&A text, we primarily analyzed comment data and reply text. We collected a rich data set of 276,528 posts and 565,813 reply comments on Zhihu's Q&A "mental health" subcommunity as of May 2022. We obtained 12,868 (support text, reply text) pairings. Figure 2 shows a typical sample, and more samples can be found in Multimedia Appendix 1.

Figure 2. A typical sample of (support text, reply text) pairings.

Dependent Variable

Gu et al [57] used the TextCNN and the Word2vec algorithm for cognitive change classification and found the best model with a word vector length of 300 and a window size of 3. Therefore, we marked the 12,868 text items as either having or not having cognitive change using the trained cognitive change classifier that was combined with emotional information. The text items that indicated a person had undergone cognitive change received a score of 1, while the text items that indicated no change received a score of 0.

The 12,868 reply comments' sentences were categorized using a cognitive change classifier yielding 5439 pieces of data with cognitive change and 7681 pieces of data without cognitive change. Word frequency analyses of the comment text revealed the presence of words such as "you," "me," "myself," and "is" in both categories of comments, suggesting that the majority of support providers provide support to support seekers by sharing their own experiences or making recommendations. More frequently, in posts by children, references to the children's parents, friends, and family, as well as certain negative emotional phrases such as "depression" and "bad" appeared. However, words such as "come on," "hug," "hope," and similar expressions appear more frequently in comments that do alter cognition [58,59].

Independent Variables

Intimacy

Gilbert and Karahalios [60] compared intimacy-related terms in the LIWC dictionary to the words in text passages and counted the number of times they appeared to determine the level of intimacy in the passages. Intimacy was determined by Pei and Jurgens [61] by training NLP models through extensive text analysis to determine the intimacy of text comments. Pei and Jurgens [61] argued that text that makes people feel intimate, profound, and humanized has a high level of intimacy. The intimacy of interactive text in online health communities was predicted by Reuel et al [62] using the LIWC dictionary, the latent Dirichlet allocation (LDA) topic distribution, emotion categories, and other factors. To determine the intimacy of support stickers in our study, the Chinese LIWC dictionary's words in the categories of family, friends, home, sexuality, swearing, work, leisure, money, body, and health were employed. Higher intimacy is indicated if the support giver is willing to discuss private matters, such as family and friends. As a result, the intimacy score is greater when the support text has more terms that indicate intimacy.

Positive Emotions

A Python package called SnowNLP is used to process the Chinese natural language. It supports Chinese natural language operations such as text classification, sentiment analysis, part-of-speech tagging, and Chinese word segmentation. In this work, emotion in support comments was determined using the SnowNLP package. We started by using the "pip" command to install the SnowNLP package in a Python environment. The support comment text was then used as a parameter by the SnowNLP algorithm to determine emotional polarity values. Results from SnowNLP vary from 0 to 1, with values closer to 1 denoting pleasant, positive emotions and values closer to 0 denoting negative emotions.

XSL•FO
RenderX

First-Person Words

The point of view of posts in an online mental health community was calculated by Lyons et al [63] using the personal pronouns in the LIWC dictionary, such as “me,” “you,” and “them.” In the context of online mental health assistance, we investigated how the language viewpoint of the support provider affects cognitive change in the support seeker. First, preprocessing of the 12,868 comments permitted text segmentation, and part-of-speech tagging was used to annotate the word segmentation results. Using personal pronouns from the dictionary, terms relating to the category of personal pronouns were screened.

Future-Tense Words

To discuss the impact of using a temporal perspective on cognitive change in support seekers in an online mental health community, we divided time into the past, present, and future. A dictionary was created primarily through part-of-speech tagging by extracting words designated as time related. The dictionary was then split into a past-tense word dictionary, a present-tense word dictionary, and a future-tense word dictionary through further manual screening. Finally, the dictionary statistics comments confirmed the text’s distribution of different time words. First, preprocessing of the 12,868 text items permitted text segmentation, and part-of-speech tagging was used to annotate the word segmentation results. The dictionaries created, as previously described, were then used to count the occurrence of the 3 categories of time-related words in the text items. Table 1 lists several time-related terms.

Table 1. Excerpts from the dictionary of words related to time.

Category	Words/phrases
Past-tense words	Years ago, the day before yesterday, in the past, ten years ago, childhood, at that time, then, that year, in the early days, when I was a child, before
Present-tense words	The present, the moment
Future-tense words	In the future, after, a little while, tomorrow, next year, after a long time, later, within two years, at the end of the year

Specificity

Polander and Shalin [64] discovered that online users of mental health services use psychological language in their narratives to express particular concepts, that they assess the content of particular psychology-related posts using the categories of leisure and work from the LIWC dictionary, and that they create a narrative dictionary based on the LIWC dictionary that includes causal words, time words, emotion words, and transition words. A 62,000-word-long English specificity dictionary was created by Muraki et al [65]. Similar to Muraki et al’s [65] approach, Xie and Bi [66] developed word-level and sentence-level specificity inference models based on large-scale Chinese specificity dictionaries. In our study, based on a Chinese specificity dictionary, we calculated the influence of the level of specificity of the comment text on cognitive change in support seekers. The specificity dictionary developed by Xie and Bi [66] is presented in tabular form in their study. The dictionary was transformed into a usable data format for this investigation. Key value matching was used to determine the specificity of each word in the comment text, and the average specificity of the words was derived as a gauge of sentence specificity.

Language Style

Function words in text can more accurately reflect the text’s language style than its substance [53]. The use of function words in online mental health communities was examined as a method of language style calculation [66-68]. Pronouns, prepositions, adverbs, conjunctions, auxiliary verbs, etc, are examples of function words that can express significant facets of the speaker’s motivation, requirements, and personality [69]. To conduct part-of-speech tagging, count words, and calculate function words as a measure of language style, the Baidu part-of-speech tagging tool LAC [70] was used in this study. This tool allows researchers to examine the impact of support providers’ language on changes in the cognition of support seekers in an online mental health community. Only the use of prepositions, adverbs, conjunctions, and auxiliary verbs was examined in this section because personal pronouns have already been covered in depth in the section on first-person words.

Control Variables

Some support providers use the second-person point of view in their comments, to give direct instruction and counsel based on the support seekers’ experiences. The likelihood of a support seeker showing improvement, however, decreases if past-tense verbs are used excessively. Thus, cognitive change may be influenced by the use of both second-person and past-tense verbs.

Yu et al [71] defined complexity as the cognitive load of knowing a certain subject, and Nadeem and Ostendorf [72] defined linguistic complexity as the difficulty faced by language users in understanding sentences. Therapists tend to use more difficult-to-read, grammatically complicated language when counseling clients who are more worried. This language use might be connected to the need for therapists to engage in deeper communication with such clients. One study calculated the complexity of the consulting language using 12 factors, such as lexical diversity, grammatical simplicity, readability, and typicality [73]. Online support seekers in online mental health communities typically describe their experiences in detail in their postings, so support providers typically do not need to engage in more in-depth communication by using language that is more challenging to read. This situation contrasts with that of face-to-face counseling.

The mental health difficulties posted online by support seekers may change over time due to other, unidentified variables

XSL•FO
RenderX

because the connections formed in the online community are asynchronous. Hence, our study used the interval between the time of the original post and the time of the supporting comments as a control variable. Additionally, those who seek support from a larger group of people may interact more frequently and feel certain psychological comforts, which influences their own cognitive improvement. As a result, this study also used the support seeker's number of followers, the interval between the original posting and the support seeker responding to comments, and the number of supporting comments as control variables.

In summary, this study's control variables were the use of the second person, the use of the past tense, topic complexity, the number of likes on support comments, posting and comment support times, and the number of comments. These variables were measured as follows: We calculate the number of second-person words and past-tense words by creating dictionaries. To determine the topic complexity, Lu et al [74] calculated the complexity of sentences and words. A lexical complexity prediction approach based on a 5-component Likert scale and manual annotation was proposed by Shardlow et al [75]; this method splits lexical complexity into 5 levels. By assessing the topic complexity of the text, Shin et al [76] used the LDA model (Genism package) to determine the complexity of the analysis text. Understanding certain words, certain sentences, and the variety of topics in the supportive comment text, when combined with psychological support situations, might influence cognitive change in support seekers. The number of words is used to gauge sentence difficulty after the preprocessing and word segmentation of the comment text. The number of subjects in the text is determined to gauge the topic complexity, and the LDA text-clustering technique is used to cluster the text.

Based on signaling theory, we constructed a mining model of the 6 independent variables: intimacy, emotional polarity, the use of first-person words, the use of future-tense words, specificity, and linguistic style. Cognitive change was used as the dependent variable. Table 2 displays the precise procedures used to calculate each variable.

Table 2. Description of variables.

Variables	Description
Dependent variable	
Cognitive change	Support seekers indicate in their responses to comments whether they are getting better.
Independent variables	
Intimacy	The number of intimate words in a support comment.
Emotional polarity	The emotion degree score (in the range of 0-1, where 1 is the strongest positive emotion) in a support comment.
First person	The number of first-person words in a support comment.
Future time	The number of future-tense words in a support comment.
Specificity	The degree to which a reference in a support comment can be perceived directly; the average specificity of support stickers based on the specificity dictionary.
Linguistic style	The number of function words (adverbs, prepositions, conjunctions, and auxiliary verbs) in a support comment.
Control variables	
Second person	The number of second-person words in a support comment.
Past tense	The number of past-tense verbs in a support comment.
Complexity	The number of words and the number of topics in a support comment.
Interval time	The calculated time between the original post and the support comment.
Approval number	The number of likes for a support comment.

Statistical Analysis

We used the statistical analysis program IBM SPSS 20.0 to analyze the correlation of variables. After the multicollinearity test, we used binomial logistic regression to test our hypotheses, considering that the independent and control variables were continuous and the dependent variable was dichotomous. The robustness test was carried out by using other models, as well as a sample subset. Specifically, we used the probit model to test the effect of the independent variables on the dependent variable. We then randomly selected 50% of the sample and ran binomial logistic regression and probit model tests on a subset of the sample.

Ethical Considerations

This study was approved by the Biomedical Ethics Committee of Hefei University of Technology (approval number HFUT20240520001H). Since the postings and comments of members of online mental health communities are related to user privacy, deidentified methods were adopted in this study: (1) After matching comment postings with reply postings, only the text of the comments and reply postings was retained, and (2) data, such as links and email addresses showing personal information contained in the text, were removed.

XSL•FO
RenderX

Results

Empirical Results

Multimedia Appendix 2 displays the correlation analysis results. The outcomes of the multicollinearity test in this study were tolerance and the variance inflation factor (VIF, which is the reciprocal of tolerance). After removing word complexity, no multicollinearity issue existed among the explanatory variables, because the VIF values of all of the explanatory variables were no more than 10, and thus, all explanatory variables could be used in the regression model.

To further understand the links between variables, we used a linear regression model to assess the elements influencing cognitive change. The 6 independent variables and the control variables were all continuous variables, but the dependent variable, cognitive change, was a dichotomous variable. Therefore, we used a binomial logistic regression model to investigate the elements. The findings demonstrated that at least 1 of the included variables was statistically significant. Table 3 shows the results of the regression analysis. Table 4 displays the findings of the hypothesis testing.

Table 3. Results of regression analysis.

Variable	β	Significance	*P* value	Exp(B)
Intimacy	–1.706	0.213	<.001	0.182
Emotional polarity	.890	0.058	<.001	2.434
First person	.120	0.014	<.001	1.127
Future time	.301	0.081	<.001	1.351
Specificity	–.018	0.005	<.001	0.982
Linguistic style	–.838	0.116	<.001	0.433
Second person	.013	0.016	.042	1.013
Past tense	–.068	0.071	.039	1.070
Complexity	–.002	0.003	.415	0.998
Approval number	$.1\times10^{-5}$	0.000	.007	1.000
Interval time	$.9\times10^{-5}$	0.000	<.001	1.000
B	.542	0.335	N/A[a]	N/A

[a]N/A: not applicable.

H1 concerned the impact of intimacy on cognitive change among support seekers in online mental health communities. The coefficient of prediction for cognitive change in the regression analysis, however, indicated that intimacy had a significant negative effect on cognitive change ($\beta_{intimacy}$=–1.706, *P*<.001). Support texts with fewer privately similar experiences are more likely to result in a change for the better for the support seeker.

The impact of emotional polarity on support seekers was tested in H2. This hypothesis—that a significant emotional polarity score favorably influences cognitive improvement ($\beta_{emotional_polarity}$=.890, *P*<.001) and that support seekers feel comfortable and supported when support providers display more positive emotions—was validated by the regression analysis, which showed that emotional polarity has a positive regression coefficient. Straightforward helpful messages of approbation and encouragement can cause a change in cognition and pleasant emotions in support seekers.

H3 explored the effect of using first-person terms (ie, providing a self-identity of the supporter) on cognitive change in the supporter-seeker. The hypothesis was supported by the regression results, which demonstrated that the use of the first person has a significant positive impact on cognitive change ($\beta_{first\text{-}person}$=.120, *P*<.001). When support seekers are encouraged to improve by support providers sharing their own experiences or directly making suggestions, they are positively affected, leading to cognitive change.

The use of words related to the future is a temporal aspect, which was examined in H4. The results showed that the use of present- and future-tense words in support postings has a significant positive impact on the occurrence of change for the better in support seekers (β_{future_words}=.301, *P*<.001). Increased use of present- and future-tense words leads to positive cognitive change in support seekers.

H5 concerns how the degree of specificity in support posts affects whether support seekers experience a change for the better. The regression resulted in a significant negative effect of expression specificity on cognitive change ($\beta_{specificity}$=–.018, *P*<.001). This result implies that support comment postings containing more specific words do not cause support seekers to undergo a change for the better.

H6 examined how language style traits affect the cognitive shifts that support seekers' experience. According to the regression analysis, the use of function words has a detrimental impact on cognitive change ($\beta_{language_style}$=–.838, *P*<.001). The findings support the idea that increasing the use of function words may not improve support seekers' ability to assist others in online health forums.

XSL•FO

Table 4. Summary of hypothesis testing.

Hypothesis	Supported?
H1: Intimacy significantly positively affects cognitive change in support seekers in online mental health communities.	No
H2: Emotional polarity scores significantly positively influence cognitive change in support seekers in online mental health communities.	Yes
H3: First-person word use significantly positively affects cognitive change in support seekers in online mental health communities.	Yes
H4: Future temporal features significantly positively affect cognitive change in support seekers in online mental health communities.	Yes
H5: Specificity characteristics significantly positively affect cognitive change in support seekers in online mental health communities.	No
H6: Language style characteristics significantly negatively affect cognitive change in support seekers in online mental health communities.	Yes

Robustness Check

We also used the probit model to examine the effects of independent variables on the dependent variable in order to evaluate the robustness of the model. Tables 5-7 contain the test results. The positive, negative, and significant impacts of the independent variables on the dependent variable were all supported by the binomial regression model. After selecting 6434 (50%) of the 12,868 data items at random, the sample subset was subjected to binomial logistic regression and a probit model test. The test results showed that both positive and negative effects of the independent variables on the dependent variable were significant and matched the effects of the total sample.

Table 5. Results of probit regression analysis on the full sample (N=12,868).

Variable	β	Significance	*P* value
Intimacy	–.960	0.179	<.001
Emotional polarity	.465	0.037	<.001
First person	.054	0.007	<.001

Discussion

Principal Findings

This study provides valuable insights into the linguistic factors involved in support seekers in online mental health communities feeling better. We studied the impacts of intimacy, emotional polarity, the use of first-person words, the use of future-tense words, specificity, and language style on cognitive change in support seekers in online mental health communities. We found that support comments with lower intimacy, higher positive emotional polarity, lower specificity, more first-person words, more future- and present-tense words, and fewer function words are more likely to make support seekers feel better. Our results show that the effects of most factors are consistent with the hypotheses, except for intimacy and specificity.

According to signaling theory [28], affective signals make support seekers feel better by increasing feelings of empathy and similarity between support seekers and support providers. Our findings show that positive emotions, the use of first-person words, and the use of future-tense words can make support seekers feel better. This result indicates that support providers can make support seekers perceive similarity and develop emotional empathy through positive emotional guidance, their own similar experiences, and directing the gaze to the future so that improvement occurs. According to information signaling [28], language style makes support seekers feel better by reducing the cost of receiving and understanding support signals. This means that support providers can reduce the use of function words.

XSL•FO
RenderX

The findings also suggest that intimacy has a negative effect on cognitive change and that support texts with less intimacy are more likely to make support seekers feel better. However, this result is contrary to existing research[37,39], which suggests that the expression of intimacy positively contributes to mental health. This result may be explained by the fact that other people in the community, such as support seekers, provide social support by expressing similar experiences [77]. These experiences stimulate the support seekers' recollection of their own negative experiences, such as similar family environments, similar treatment experiences, or similar attitudes [78], thus preventing positive cognitive changes from occurring. However, if they encourage support seekers to elaborate on their own experiences and encourage them by expressing positive emotions, an improvement is seen, as discussed in H2.

The possible reasons the effect of specificity on cognitive change is negative are similar. Posts with more specificity often mean that support providers disclose more details of similar negative experiences. Specific words are more likely to make it easier for support seekers to recall their own similar negative experiences in the imaginal system, which is not conducive to making them feel better.

On this basis, we conclude that support providers providing social support by disclosing details of similar negative experiences is not conducive to supporting support seekers to feel better, and more positive emotions are needed to guide them toward the present and future. The result is consistent with psychotherapists' psychotherapeutic strategy in offline counseling scenarios [32].

Theoretical and Practical Implications

This study has 2 theoretical implications. First, we transferred signaling theory to the study of factors influencing cognitive change in online mental health communities and divided the factors into affective signals and information signals. We also verified the proposed model. The findings suggest that intimacy, emotional polarity, discussion of self, use of time-related words, specificity, and language style (use of function words) all significantly influence cognitive change in support seekers in online mental health communities. Thus, this study extended signaling theory. Second, based on previous research, but also going beyond that, this study investigated how new factors, such as intimacy and specificity, affect cognitive change. It calculated the intimacy and specificity of supporting comments by creating intimacy and specificity dictionaries, and then it confirmed the impact of these 2 factors on cognitive change using regression analysis. The outcomes of this study related to intimacy and specificity disagree with other findings; we discovered that both intimacy and specificity are associated with the psychological support provided in online mental health communities and that both are adversely correlated with cognitive change.

The research also has practical implications. Our findings encourage tailored strategies for mental health support and intervention. Online mental health community managers can use context-specific support techniques, offer real-time ideas when posting support comments, and provide information for the design of the online interface by researching variables that influence the cognitive shifts in support seekers. In addition, community support providers can customize their replies by using the best support comment tactics for each support seeker based on their unique traits. To foster relationships between support seekers and support providers, emphasis should be placed on encouraging other members of the online mental health community to write and offer assistance. Interventions can be created to allow service providers to cater their assistance to each support seeker individually. Most significantly, support seekers who have posted an issue and who are not receiving adequate support can be helped by the referral, identification, and mentoring procedures of the online health community.

Limitations and Future Recommendations

Our study has several limitations. First, we included 1 online mental health community, and the findings may differ depending on the data sources used. Other contexts should be examined in future studies. Second, we did not set up support strategies in an actual online mental health community to verify whether they would improve the quality of support. Future research can strategically aid auxiliary support providers in writing supportive comments by analyzing and designing strategies and combinations of strategies so that the comments will better aid support seekers and lead to cognitive change. In addition, the characteristics of support seekers should be fully considered in functional design in order to further provide personalized support strategies. For example, the features of support comments that are more agreeable to support seekers with high participation levels versus those with low participation levels should be considered, as well as variations in the features of support comments used to treat various mental health issues.

Conclusion

This study investigated elements that influence cognitive change in online mental health communities. It used psychological counselors' face-to-face consultation techniques, described in existing research, to propose hypotheses, and it specifically applied signaling theory to identify factors that influence cognitive change. We found that support comments are more likely to alter support seekers' cognitive processes if they have lower intimacy, higher positive emotional polarity, lower specificity, more first-person words, more future- and present-tense words, and fewer function words. The result is consistent with psychotherapists' psychotherapeutic strategy in offline counseling scenarios.

Abstract

Background: Studying the impact of COVID-19 on mental health is both compelling and imperative for the health care system's preparedness development. Discovering how pandemic conditions and governmental strategies and measures have impacted mental health is a challenging task. Mental health issues, such as depression and suicidal tendency, are traditionally explored through psychological battery tests and clinical procedures. To address the stigma associated with mental illness, social media is used to examine language patterns in posts related to suicide. This strategy enhances the comprehension and interpretation of suicidal ideation. Despite easy expression via social media, suicidal thoughts remain sensitive and complex to comprehend and detect. Suicidal ideation captures the new suicidal statements used during the COVID-19 pandemic that represents a different context of expressions.

Objective: In this study, our aim was to detect suicidal ideation by mining textual content extracted from social media by leveraging state-of-the-art natural language processing (NLP) techniques.

Methods: The work was divided into 2 major phases, one to classify suicidal ideation posts and the other to extract factors that cause suicidal ideation. We proposed a hybrid deep learning–based neural network approach (Bidirectional Encoder Representations from Transformers [BERT]+convolutional neural network [CNN]+long short-term memory [LSTM]) to classify suicidal and nonsuicidal posts. Two state-of-the-art deep learning approaches (CNN and LSTM) were combined based on features (terms) selected from term frequency–inverse document frequency (TF-IDF), Word2vec, and BERT. Explainable artificial intelligence (XAI) was used to extract key factors that contribute to suicidal ideation in order to provide a reliable and sustainable solution.

Results: Of 348,110 records, 3154 (0.9%) were selected, resulting in 1338 (42.4%) suicidal and 1816 (57.6%) nonsuicidal instances. The CNN+LSTM+BERT model achieved superior performance, with a precision of 94%, a recall of 95%, an F_1-score of 94%, and an accuracy of 93.65%.

Conclusions: Considering the dynamic nature of suicidal behavior posts, we proposed a fused architecture that captures both localized and generalized contextual information that is important for understanding the language patterns and predict the evolution of suicidal ideation over time. According to Local Interpretable Model-Agnostic Explanations (LIME) and Shapley Additive Explanations (SHAP) XAI algorithms, there was a drift in the features during and before COVID-19. Due to the COVID-19 pandemic, new features have been added, which leads to suicidal tendencies. In the future, strategies need to be developed to combat this deadly disease.

Introduction

Overview

Mental health has become a critical area of research as societal challenges, such as pandemics, natural disasters, and economic instability, deeply affect individuals' well-being. According to comprehensive statistics provided by the World Health Organization (WHO), the occurrence of suicide is documented to be at an average rate of 1 incident every 40 seconds [1]. The report reveals that an estimated 800,000 people die by suicide annually, with suicide attempts occurring at a rate 20 times higher than that of completed suicides [2]. The worldwide approximation for suicide mortality is set at around 1 million deaths per year [3]. These statistics highlight suicide as the primary cause of death among young individuals, particularly among women. Contrary to an "all or nothing" perspective, a well-known book on the subject [4] suggests that suicide follows a distinct process and pattern. The pattern begins with suicidal ideation and progresses toward a suicide attempt and may culminate in a completed suicide. Although not all instances of suicidal ideation lead to complete suicide, they pose a significant threat for individuals to attempt suicide. Recognition of suicidality may occur when individuals frequently discuss it with their caretakers or during interactions with psychiatrists or psychologists who inquire about their thoughts and moods. Caregivers can mitigate the risks associated with suicidality by analyzing various warning signs and implementing necessary preventive measures. However, a significant obstacle in addressing suicidality is the hesitancy of individuals to cooperate with clinicians, often influenced by the social stigma linked to mental illness. The widespread impact of stigma on suicidality affects large-scale clinical interventions for at-risk individuals. Data indicate that 36% of individuals who succumb to suicide leave behind a note [5]. Research suggests that these suicide notes often signal a heightened probability of subsequent attempts that characterize greater precision after an initial failure [6]. The contents of these notes frequently underscore emotions of shame and apology, hinting at a potential willingness to consider alternatives. These notes are typically discovered postcompletion or, at the least, after an attempted suicide [6]. Despite efforts to screen patients, convincing individuals to undergo evaluation remains a formidable challenge in societies marked by stigma [7,8]. Studies highlight that people feel more at ease sharing their day-to-day experiences on online social networks (OSNs), where concerns about social stigma are less prominent [9]. Recent research also suggests that monitoring social media provides an alternative and valuable opportunity to identify warning signs associated with posts from individuals at risk of suicidality [10]. According to the statistics provided by the American Foundation for Suicide Prevention [11], there is a rise in people with mental health conditions. As per the collaborative multiyear project "Suicide Prevention Now" [12], according to statistics, in 2022, there was a significant increase in the number of people reporting mental health conditions. For instance, in 2022, 67% of American believed that they had a mental health condition at some point in their life.

Related Work and Background Knowledge

Mental health issues, such as depression and suicidal tendency, have traditionally been explored through psychological battery tests and clinical procedures [5,13]. However, to address the stigma associated with mental illness, researchers have turned to less formal platforms, such as social media, to examine language patterns in posts related to suicide. This strategy seeks to enhance the comprehension and interpretation of suicidal ideation. O'Dea et al [14] highlighted the crucial role of questionnaires in assessing a patient's mental state. However, with the surge in social networking sites, individuals find it more comfortable to openly express their feelings on social media platforms. Studies [13,14] have explored various scales used to predict depression through social media analysis. Additional research [15,16] has examined the topics commonly discussed by potentially suicidal individuals on social media, and the behavior of those contemplating suicide has been scrutinized in these studies. Advances in natural language processing (NLP) and machine learning techniques now allow the extraction of semantic information from social media posts, facilitating the automation of predicting suicidal content [17]. Most research has focused on using binary classification mechanisms with popular algorithms, such as support vector machines (SVMs), decision trees, and ensemble learning algorithms [18-21]. Deep learning methods have also been used to aid in predicting suicidal ideation [22,23]. In Multimedia Appendix 1, we extend the literature review where we explored relevant research works on suicidal ideation prediction (eg, [24-26]).

Feature selection involves identifying and selecting the most relevant attributes or features from the data. We used various feature selection and deep learning techniques, such as term frequency–inverse document frequency (TF-IDF), Word2vec, Bidirectional Encoder Representations from Transformers (BERT), convolutional neural networks (CNNs), and long short-term memory (LSTM). The TF-IDF method involves breaking down text into tokens, calculating the term frequency (TF) to evaluate the significance of each term within a document and determining the inverse document frequency (IDF) to evaluate the uniqueness of each term across the entire data set. Word2vec learns distributed representations (word embeddings) of words based on their context in a given corpus. The resulting word vectors can be used as feature representations for various text-based tasks. Before applying Word2vec, it is essential to preprocess the text data. The Word2vec model is trained on preprocessed text data using either the Skip-gram or the Continuous Bag of Words (CBOW) architecture. We fused deep learning techniques (CNN, LSTM, BERT) in order to effectively identify suicidal ideation as posts with suicidal behavior have a dynamic nature and longer textual segments. BERT is a

XSL•FO
RenderX

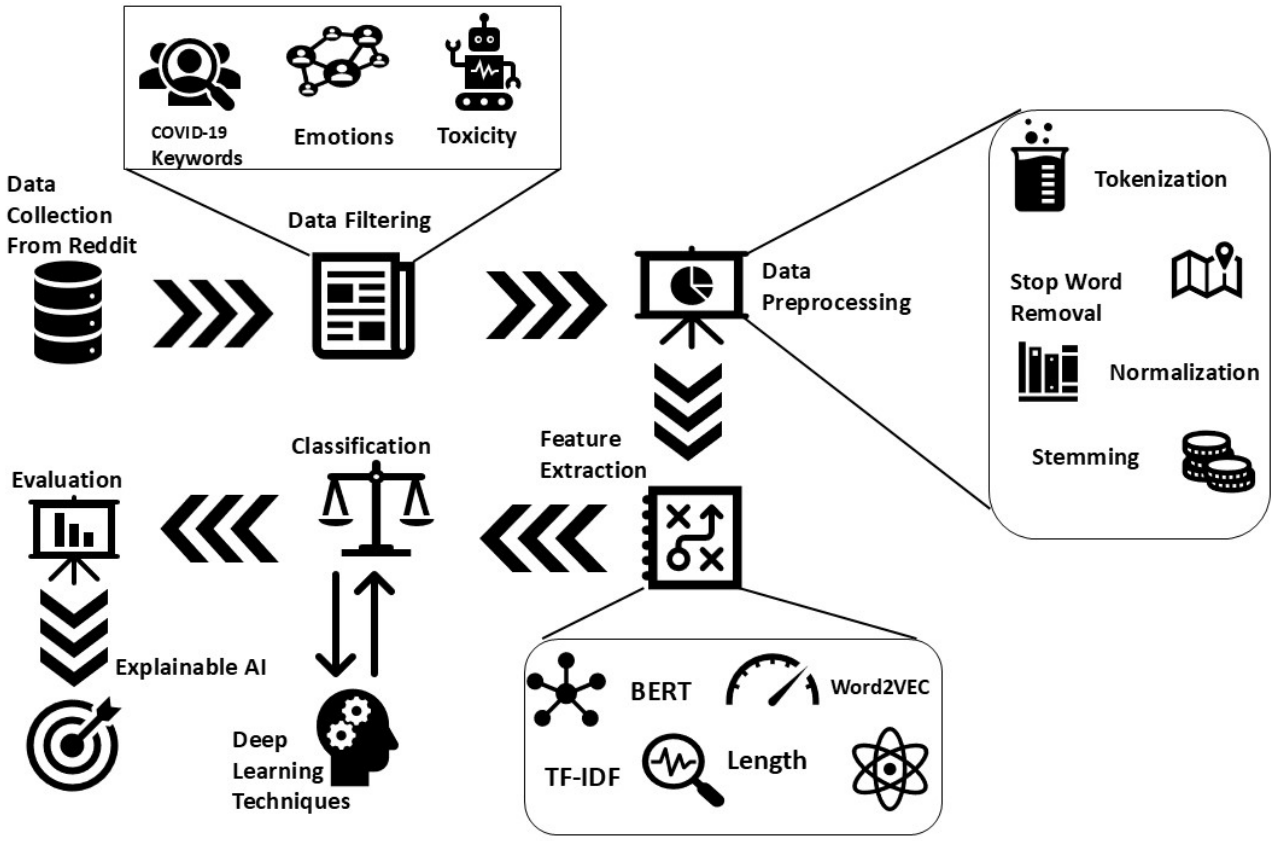
transformer-based model that uses self-attention mechanisms to capture contextual information. The architecture includes multiple layers of attention and feed-forward networks. BERT provides contextualized embeddings for each token in the input text. In a CNN, input data are a sequence of words or embeddings. The CNN architecture typically involves convolutional layers followed by pooling layers and fully connected layers. A CNN detects important localized features, such as word sequences, n-grams, and syntactic patterns. Each convolutional layer extracts high-level features from the text, which enables the model to capture complex patterns and semantics at different levels of granularity. It also handles input sequences of different post lengths without requiring explicit padding or truncation. LSTM networks are particularly effective for handling sequential data, such as text. LSTM networks are designed to capture long-range dependencies between words and phrases for better understanding of the context and are commonly used in text classification tasks. It propagates information over long distances in the input sequence of data. It processes input texts of different lengths without compromising performance and preserves the sequential structure and context of the posts. The methods are discussed in Multimedia Appendix 2, which provides a theoretical and mathematical background of the deep learning approaches and feature selection methods used in this work.

Aims of the Study

This work aimed to identify patterns and indicators associated with suicidal ideation by leveraging machine and deep learning algorithms for social media data. The primary focus of this study was to examine the correlation between COVID-19 and the prevalence of suicidal ideation. In this work, various factors were studied related to the pandemic, such as societal, economical, and psychological factors, to detect individuals' inclination toward suicidal thoughts due to COVID-19. Through comprehensive analysis and empirical investigations, the study sought to find the relationship between COVID-19 and suicidal ideation by detecting potential contributing factors and implications for mental health and well-being. Through rigorous analysis and modeling using deep learning methodologies, this work will contribute by finding the intersection between COVID-19 and suicide, which will be used for developing preventive interventions and support strategies to address future pandemics as well.

The study revolved around the research question of whether COVID-19 has impacted suicidal ideation. The following hypotheses were developed:

> *Null hypothesis (H0): COVID-19 has not impacted suicidal ideation, and the features (terms) used for suicidal ideation are the same as before.*
>
> *Hypothesis 1 (H1): COVID-19 has impacted suicidal ideation, and the sequence of terms has changed.*



Methods

Study Design

This work was divided into 5 phases, starting from data (suicidal posts) collection from Reddit, which is a publicly available data set. In the second phase, the data set was filtered based on various keywords. The emotions of the posts were extracted using the Natural Language Toolkit (NLTK), and the toxicity of the posts was calculated using the perspective application programming interface (API). The final corpus was used for further experimentation, and textual features were extracted using TF-IDF, Word2vec, and BERT techniques. The various classifiers were trained and tested on the filtered data set to classify the posts into 2 classes, suicidal and nonsuicidal. Another aspect of this work was explainable artificial intelligence (XAI); in this phase, 2 techniques, Local Interpretable Model-Agnostic Explanations (LIME) and Shapley Additive Explanations (SHAP), were used to extract the most relevant keywords that trigger suicidal ideation. The study framework is depicted in Figure 1.

XSL•FO
RenderX

Figure 1. Framework for suicidal ideation detection in the COVID-19 era based on various filtering mechanisms. AI: artificial intelligence; BERT: Bidirectional Encoder Representations from Transformers; TF-IDF: term frequency–inverse document frequency.

Data Collection and Preparation

Data are the most important entity in all data science research. In this work, there were privacy concerns related to the data. We collected relevant data from the public data repository Kaggle, which contains suicidal posts from the social media platform Reddit. The data were categorized into 2 classes, suicidal and nonsuicidal. The data set consisted of 2 columns, one with the posts (textual) and the other with labels. We leveraged a keyword-based filtering mechanism to classify and analyze user-generated content. We established a comprehensive set of keywords associated with COVID-19 and suicidal ideation, such as "COVID," "COVID-19," "lockdown," "quarantine," and "coronavirus." Using these keywords, a dual-layer filtering approach was implemented that categorized the posts into either COVID-19 related or not, followed by an assessment for suicidal content. For further exploration of the data, we performed emotion analysis (EA) to extract the mood of the poster. Eight different emotions were used for EA. After EA, we performed a toxicity analysis (TA) to identify toxic posts, and toxic values were associated with all the posts. We considered only negative, sad, and fearful emotions and posts that had a toxicity value greater than 0.5. In this study, we used the absolute majority (ie, a majority is when more than half of the total weighted words are toxic words). Another alternative was to use two-thirds majority; however, this was not a conservative choice because we risked having a large number of false positives. So, an absolute majority was more protective. By establishing a threshold of 0.5, a clear and straightforward benchmark was created for classifying outputs from our detection models. This threshold simplified both interpretation and implementation for detecting suicidal ideation. It also helped reduce ambiguity in the decision-making process. By doing so, we ensured that texts flagged as indicative of suicidal ideation were those with a probability score of 0.5 or higher. This minimized the risk of misinterpretation as it directed attention to those posts that met a specific criterion for concern. In addition, the empirical accuracies showed that our choice was effective in detecting suicidal ideation. After filtering the posts, we performed data cleaning and preprocessing, in which the textual data was refined using techniques such as tokenization, lemmatization, and normalization. Furthermore, irrelevant data were removed using the stop-word dictionary, and punctuation was also removed.

Feature Engineering and Selection

The process of selecting the most relevant and informative features from unprocessed data is known as feature engineering, and it increases the machine learning models' effectiveness [25]. To do this, raw data must be transformed into more significant features that can effectively identify underlying patterns and relationships. This approach makes use of a number of techniques, including feature extraction, feature transformation, and feature selection. Model performance can be greatly influenced by feature engineering through careful feature creation and selection. The data in this study were primarily textual, similar to behavioral analysis of internet users, with the objective of identifying COVID-19–induced suicidal tendencies in online users. To input the data that were collected into the deep learning models, 3 basic word-embedding

XSL•FO
RenderX

techniques—TF-IDF [26-28], Word2vec [29], and BERT [30,31]—were used to identify and analyze patterns in the text-based content. Our model leveraged BERT-based architectures. These architectures are designed to capture contextual relationships between words by processing the entire sequence of words simultaneously rather than in isolation. This allows the model to understand the meaning of a word based on its surrounding context, and it significantly improves the accuracy of detecting sarcasm, idiomatic expressions, or shifts in sentiment in languages. The post length is also considered as one of the features. The extracted features were used as input to the CNN and LSTM deep learning models. When used with the CNN and LSTM models, these feature selection techniques improve performance. As mentioned before, CNNs excel at capturing localized patterns in sequential data by making them well suited for text classification, LSTM networks capture long-term dependencies and are effective for modeling sequential data with complex temporal dynamics, and BERT captures contextual relationships between words by processing the entire sequence of words simultaneously.

Suicide Posts' Classification

Different classifiers are used for classifying posts into binary classes. In this work, we used multiple combinations of classifiers to predict suicidal posts. The data set we used to train our model consisted of 2 columns, text and label. The problem was formulated the same way as that by Hossain et al [32] and Ji et al [33]. On a corpus consisting of a set of posts  and labels , training was provided in such a manner that the model learned from the data consisting of a set of all the engineered features and the corresponding labels that were provided in a supervised approach. The supervisory function is shown in Equation 1:

$$l_i = \text{fun}(p_i) \quad (1)$$

Here, $l_i = 1$ in the case of p_i representing suicide and $l_i = 0$ represents nonsuicide. We focused on the "no free lunch" theorem of machine learning, which suggests that no algorithm can work well for all problems. Three deep learning classification algorithms were implemented: CNN, LSTM, and BERT. These models were fused, as shown in Equation 2:

$$h_c = \text{CNN}(X),$$

$$h_l = \text{LSTM}(X),$$

$$h_b = \text{BERT}(X), \quad (2)$$

$$h_m = \text{concatenate}(h_c, h_l, h_b),$$

$$y = \text{softmax}(Wh_m + b),$$

where X is the input data and is represented as a matrix, where each row corresponds to a data sample and each column corresponds to a feature; h_c refers to feature representation by the CNN; h_l refers to feature representation by the LSTM; h_b refers to feature representation by BERT; h_m refers to fused features obtained by concatenating h_c, h_l, and h_b; y is the predicted class probabilities for suicidal posts; and W is the weight of fused features h_m; and b is the bias of h_m.

The pseudocode of the entire experiment is shown in the algorithm in Textbox 1. This algorithm outlines the steps for identifying suicidal posts in social media content during the COVID-19 pandemic. The process began with a set of posts and classified them into suicidal and nonsuicidal posts. The algorithm required input posts and ensured the output includes suicidal and nonsuicidal posts. For each post, the algorithm performed EA and TA. Posts were classified based on whether they exhibited sad or negative emotions, alongside a toxicity score above a threshold (0.5). If a post met both criteria, it was added to the final corpus, otherwise it was discarded. The algorithm then processed the remaining posts through tokenization, stop-word removal, and stemming, saving the preprocessed data in a CSV file. Features were extracted using BERT embeddings and TF-IDF, resulting in a document feature matrix. The matrix was trimmed based on minimum document frequencies and TFs to focus on significant terms. Finally, deep learning algorithms and transformers with specific hyperparameters were applied to classify the posts as either suicidal or nonsuicidal. This approach leverages deep learning techniques and NLP to effectively identify suicidal ideation in the context of COVID-19 and ultimately enhances mental health awareness and intervention strategies.

Explainable Artificial Intelligence

XAI holds a central role in mental health by improving the transparency and accountability of artificial intelligence (AI) systems [34,35]. In mental health applications, it is imperative that health care professionals and patients alike grasp and have confidence in the AI's decision-making procedures [36]. XAI accomplishes this by furnishing explanations for AI-generated diagnoses, forecasts, and treatment recommendations. These explanations provide valuable insights into the rationale behind specific decisions, assisting clinicians and patients in gaining a deeper understanding of the logic behind mental health assessments. This transparency fosters trust and promotes collaboration between AI systems and human experts, which ultimately enhances the quality of mental health care. In addition, XAI aids in detecting and reducing biases within AI models, which ensures that mental health assessments remain impartial and unbiased, a critical aspect of delivering equitable care to diverse patient populations. XAI also contributes to the formulation of individualized treatment plans in the mental health domain. By elucidating factors influencing an individual's mental health condition, AI systems can customize interventions to cater to each patient's unique requirements. XAI also facilitates early intervention and prevention by enabling the identification of early warning signs and comprehending the interconnected elements affecting mental well-being. Empowering patients through understandable explanations increases their engagement in the treatment process, potentially leading to better outcomes. XAI serves not only as a tool for enhancing mental health care but also as a means of diminishing stigma by promoting ethical practices and propelling the field of mental health forward through data-driven insights and improved decision-making. XAI techniques are designed to make the decision-making processes of AI systems more understandable and interpretable for humans. These techniques are particularly important when AI systems make complex predictions, classifications, or recommendations in fields such as health care, finance, and autonomous vehicles, where transparency and trust are critical.

LIME generates perturbed instances (z_1, z_2,…, z_k) and performs predictions: $f(z_1)$, $f(z_2)$,…, $f(z_k)$. The local linear model . The objective function of LIME is calculated using Equation 3:

XSL•FO
RenderX

Here, x represents the instance for which we want an explanation, z_i are perturbed instances, $\pi_x(x,z_i)$ is a weight, and  is the gradient of f at x_0.

Shapley XAI has the following workings:

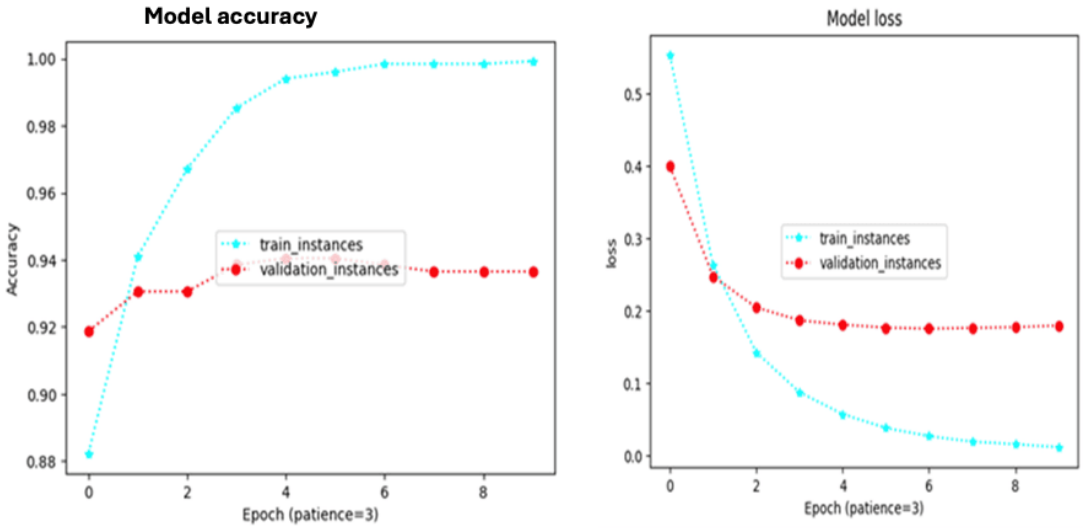
The Shapley value for a feature i in the context of a prediction f(x) is shown in Equation 4:

Here, N is the set of all features and S is a subset of features excluding i.

Expected Shapley values are represented in Equation 5:

Here, N is the number of samples from the background distribution.

Ethical Considerations



This research did not include any studies on human participants performed by any of the authors. However, ethical considerations of our study could be related to the use of data collected on posts on the Reddit platform, which is commonly perceived as widely public, where participants are not identifiable as no registration is required but only a pseudo name to post. Moreover, public post analysis, such as Reddit posts, is considered ethical issue free because there is no expectation of privacy as individuals are anonymous, and users understand that their posts can be reused (ie, reposted) and remain archived on the platform until deletion eventually. Hence, ethical issues of research on Reddit are resolved by the public nature of this social media platform, especially when used in academic publications.

Results

Study Details

Of 348,110 records, 3154 (0.9%) were filtered out, resulting in 1338 (42.4%) suicidal and 1816 (57.6%) nonsuicidal posts. The training data in all experiments were split in an 80:20 ratio for training and validation because empirical findings [37] suggest that the performance of algorithms improves when the data set is divided in this manner. Each algorithm was tested on a distinct subset of the original data set. Our model was evaluated using various metrics to assess their performance. We discovered that the model's performance improved slightly as the number of training data points was raised. The method of dividing the data set into training and testing subsets has inherent problems with bias and variance. These problems arise because of the nature of the data. In machine learning, it is not necessary that the model that has been fit on training data will also work on real data. This is because real data can be different from training data. To accomplish this, we made use of the technique of k-fold cross-validation. This allowed us to ensure that the model correctly identified the patterns within the data, while minimizing noise exposure. Our model's validity was established by a process known as 10-fold cross-validation. Python was chosen as the language to implement algorithms for machine learning. Skicit-learn, Pandas, and NLTK are the most significant packages used in the coding process during the training of the suicide prediction model. After evaluating hybrid deep learning models, we found that BERT, when fused with CNN+LSTM, showed the best results among all hybrid deep learning models. With a precision of 94%, a recall of 95%, an F_1-score of 94%, and an overall accuracy of 93.65%. Figure 2 shows the hybrid model's performance based on the model loss and model accuracy. Table 1 depicts the classification report of all the classifiers that were used during experimentation.

Figure 2. Performance metrics showing the accuracy and loss of the best model, which combined BERT, CNN, and LSTM for enhanced prediction results. BERT: Bidirectional Encoder Representations from Transformers; CNN: convolutional neural network; LSTM: long short-term memory.

LSTM+BERT	86.00	83.00	85.00	85.00
CNN+LSTM	91.00	90.00	91.00	91.00
BERT+CNN+LSTM	94.00	95.00	94.00	93.65
CNN+LSTM+TFIDF	89.00	89.00	89.00	89.00
CNN+LSTM+Word2vec	90.00	90.00	90.00	90.00
CNN+Word2vec	86.00	86.00	86.00	86.00

[a]TF-IDF: term frequency–inverse document frequency.

[b]CNN: convolutional neural network.

[c]LSTM: long short-term memory.

[d]BERT: Bidirectional Encoder Representations from Transformers.

Validation

In this study, we used the 10-fold cross-validation technique to validate our proposed approach. It is a robust technique frequently used in machine learning and statistical modeling to evaluate the performance and generalization capability of predictive models. In this approach, the data set is divided into 10 equal-size segments, known as folds. Throughout each iteration, 1 fold is designated as the validation set, while the remaining 9 folds serve as the training set. This process is iterated 10 times, with each fold taking on the role of the validation set once. The 10-fold cross-validation technique has the ability to furnish a more dependable assessment of a model's performance in contrast to a single train-test split. By computing performance metrics across various folds and subsequently averaging them, the ambiguity in outcomes is reduced, which leads to a more consistent evaluation. In addition, it helps in dealing with bias and variance. It guarantees that every data point contributes to both training and validation processes, thereby lessening the risk of overfitting and furnishing a more precise evaluation of the model's capacity to generalize to new data. In this work, after performing 10-fold cross-validation, the mean accuracy was compared with the actual accuracy of the models, and it was found that there was no such difference. We concluded that the proposed approach does not suffer from over- or underfitting. The results of 10-fold cross-validation are shown in Table 2 and visually represented in Figure 3.

Table 2. Results of 10-fold cross-validation, along with the calculated mean accuracy for model evaluation.

Classifier	Accuracy (%)										Accuracy (%), mean (SD)
	Fold 1	Fold 2	Fold 3	Fold 4	Fold 5	Fold 6	Fold 7	Fold 8	Fold 9	Fold 10	
BERT[a]+CNN[b]+LSTM[c]	94.00	93.00	94.00	94.00	93.00	94.00	94.00	93.00	94.00	94.00	93.65 (0.41)
Word2vec+LSTM	88.00	88.00	89.00	90.00	87.00	85.00	88.00	89.00	90.00	88.00	88.20 (1.58)
BERT+CNN	66.00	64.00	63.00	65.00	66.00	65.00	64.00	66.00	65.00	64.00	65.00 (1.00)

Comparative Analysis of Posts Before and During COVID-19

Exploratory data analysis of both training and validation data sets was performed, and results showed that n-grams used before and during COVID-19 were different. Figure 4 presents a comparative analysis of the n-grams used in suicidal posts during both periods. Figure 4a illustrates the most frequently occurring n-grams in posts related to suicidal ideation during the COVID-19 pandemic, which highlights key phrases and terms that reflect the mental health challenges faced during the crisis, while Figure 4b depicts the n-gram sequences identified in suicidal posts from the non–COVID-19 era.

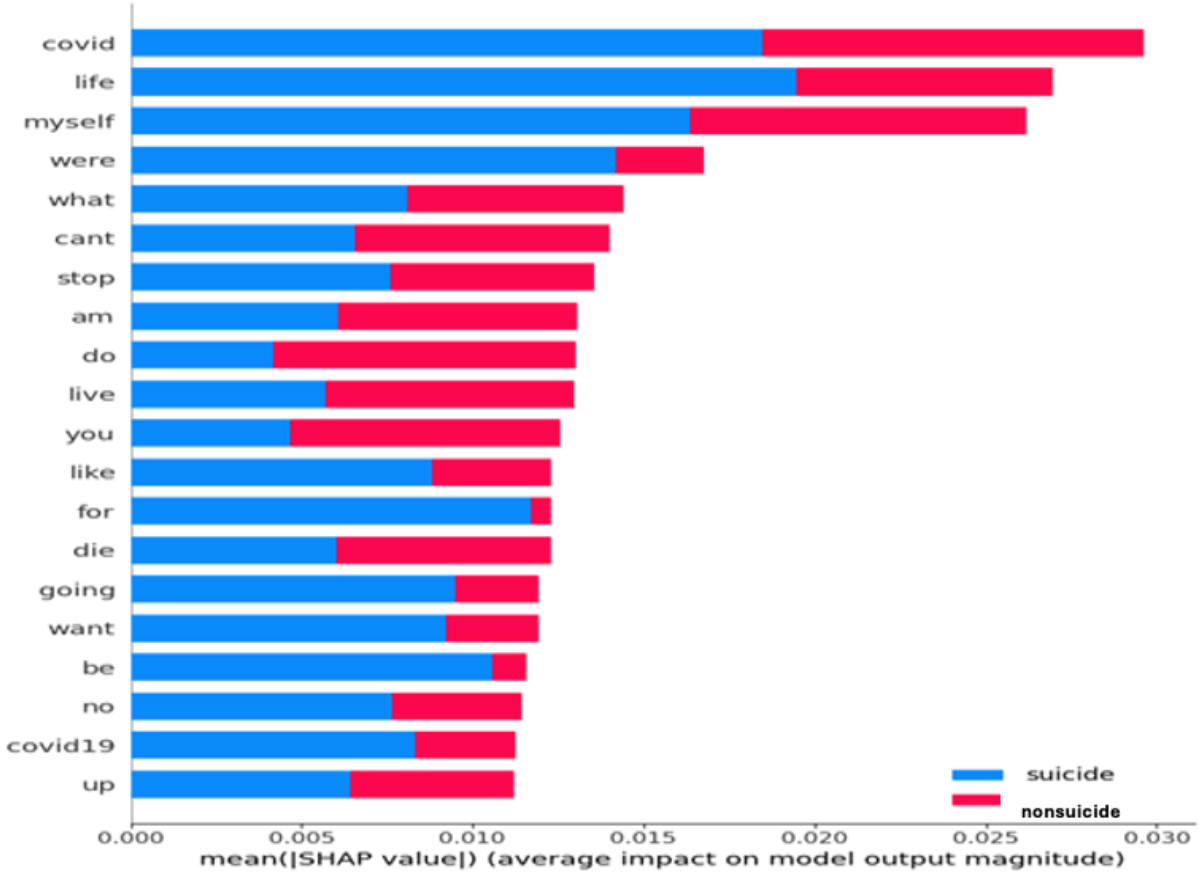
Figure 4. Top n-gram sequences distinguishing COVID-19–related and non–COVID-19–related posts. A) Top n-gram sequence in the COVID-19 suicidal posts; B) Top n-gram sequence in the non COVID-19 suicidal posts.

a)

b)

Explainable Artificial Intelligence Extraction

XAI showed the most important features (terms) that were used in the suicidal content during COVID-19. Figure 5 shows a graphical representation of the features extracted by XAI:



- "covid," "covid-19": These terms indicate a direct association with the COVID-19 pandemic. Individuals may express distress, anxiety, or hopelessness related to the pandemic, which can contribute to suicidal ideation.
- "live, life": These terms are broad and could encompass various aspects of an individual's life, such as personal

XSL•FO
RenderX

relationships, work, health, or the financial situation. Expressions related to feeling overwhelmed, hopeless, or lacking purpose in life may contribute to suicidal thoughts.
- "die," "stop," "myself": These words directly relate to thoughts of self-harm or suicide. They indicate a strong presence of negative thoughts or intentions toward ending one's life.

XAI was used to check the impact of COVID-19 on suicidal ideation, and it can be clearly seen from the results that COVID-19–related words were used frequently in suicidal thoughts.

Figure 5. Important features (terms) associated with suicidal posts and their relevance in predictive analysis. SHAP: Shapley Additive Explanations.

Discussion

Principal Findings

The results of this study indicate significant changes in language patterns before and during the COVID-19 pandemic. Individuals used different sets of words prior to the pandemic, and the sequence of words shifted during the pandemic. In this work, we investigated the impact of the COVID-19 pandemic on suicidal ideation by proposing a null hypothesis (H_0) that COVID-19 has not influenced levels of suicidal thoughts among individuals. By using the proposed methodology, our findings revealed a significant increase in suicidal ideation associated with the pandemic. The analysis showed a P value of <.01, which leads us to reject H_0 in favor of the alternative hypothesis (H_1), which posited that COVID-19 has had a measurable impact on suicidal ideation. These results underscore the urgent need for mental health interventions during and after public health crises, highlighting the critical link between worldwide events and individual psychological well-being.

Comparative Analysis

For validating the approach, we performed comparative analysis in which we compared existing methods with our approach. The methodology described by Jung et al [38] showed that Bow-Char had a maximum recall score of 0.75, closely trailed TF-IDF (SVM) with a recall of 0.70. In our approach, the recall scores ranged from 0.83 to 0.95, which are higher than existing ones. The results demonstrated that the BERT+CNN+LSTM model had the highest recall, proving its efficacy in identifying positive instances. In addition, ADA achieved the higher precision of 0.92 compared to other approaches that were proposed by Jung et al [38], while our approach achieved precision values from 0.86 to 0.95. The BERT+CNN+LSTM model showed that it can minimize false positives by attaining the maximum level of accuracy. The range of accuracy attained by Jung et al [38] was 65%-77%. Our proposed models, in contrast, outperformed them with accuracy scores between 0.85 and 0.9365. The best accuracy was shown by the BERT+CNN+LSTM model, demonstrating its capacity to classify most cases properly. According to Saba et al [39], a recurrent neural network (RNN) performs better due to its high precision value (1), while CNN models achieve good recall

XSL•FO
RenderX

values of 0.8 and CNN+SVM models achieve 91.6% accuracy. Our approach outperformed previous methods by achieving greater recall, precision, and accuracy values; the BERT+CNN+LSTM model achieved 93.65% accuracy. These findings show that the proposed method produces more accurate and reliable results.

When F_1-scores were examined, ADA had the highest score of 0.73 among the techniques examined by Jung et al [38], while the RNN had an F_1-score of 0.76 and the CNN and CNN+SVM models had the highest F_1-scores of 0.85 and 0.90 according to Saba et al [39]. Our approach outperformed in F_1-scores as well by achieving values ranging from 0.85 to 0.94. The best F_1-score was attained by the BERT+CNN+LSTM model, demonstrating its balanced precision and recall performance. The TF-IDF+CNN model outperformed Jung et al's [38] best method in terms of recall by about 20%. Comparably, the CNN+LSTM and CNN+LSTM+Word2vec models outperformed Jung et al's [38] optimal approach by about 15% and 14%, respectively, in terms of recall values. These notable advancements suggest that the proposed techniques are better at identifying positive samples. The accuracy of the TF-IDF+CNN model was around 21.65% greater than that of Jung et al's [38] optimal method (TF-IDF+SVM). Similarly, accuracy gains of roughly 19% and 18% were attained by our CNN+LSTM and CNN+LSTM+Word2vec models, respectively. These improvements show that the proposed approaches have stronger categorization skills and produce results that are more accurate. Hence, we can conclude that the recall, precision, accuracy, and F_1-score of the proposed methods—TF-IDF+CNN, BERT+LSTM, CNN+LSTM, and Word2vec+CNN+LSTM—are better than existing techniques. The enhancements in performance range from 14% to 21%, highlighting the efficacy of using sophisticated methods, such as TF-IDF, CNNs, LSTM, and BERT, when examining content.

Limitations

We analyzed the strengths and weaknesses of each model, and it was found that the CNN effectively captured localized patterns in social media posts, such as emotional language and contextual cues indicative of suicidal ideation. Phrases such as "I feel hopeless" and "No one cares" were accurately classified as indicating suicidal ideation. However, the model struggled with understanding context, particularly when the meaning of a post depended heavily on the sequence of words rather than their individual presence. For example, the phrase "I just need a break" was incorrectly classified as nonsuicidal. In contrast, the LSTM processed sequences that made it suitable for understanding the context and flow of language over time. For example, posts beginning with "Things have been tough lately" and continued with "I can't see a way out" were correctly identified by the LSTM as having an evolving sentiment of despair and resulted in the correct classification of suicidal ideation. However, there is a risk of overfitting to the training data, especially if the training set is small or not diverse enough. Although the LSTM captured the emotional tone, it may have overfit to similar phrases in the training set that did not indicate suicidal ideation and resulted in false negatives. For example, "I can't handle this anymore, I'm just tired of fighting" was misclassified as nonsuicidal. BERT processes text in both directions simultaneously. This allows it to capture the full context of a word based on its surroundings, leading to better understanding and representation of meaning, but it benefits from being trained on large data sets. Since we had less data, we integrated the three algorithms (BERT, CNN, and LSTM) in our hybrid model, which helped us mitigate the individual weaknesses of each model. The CNN effectively extracted features from social media posts, the LSTM provided a contextual understanding of the text, and BERT considered the entire context of each word, which effectively disambiguated words with multiple meanings. Combining these architectures allowed us to capture both localized and generalized contextual information that is crucial for understanding the language patterns associated with suicidal behavior. By fusing these 3, our model achieved an accuracy of 93.65%.

Implications of the Study

The findings of this study reveal that the COVID-19 pandemic has influenced mental health. Due to the shift in language patterns, there is an increase in terms related to distress, hopelessness, and self-harm, which underscores the profound psychological impact of the pandemic. A clearer understanding of linguistic markers that may indicate heightened risk can be identified using XAI. These linguistic patterns have broader implications for early detection and intervention strategies for suicidal ideation. We suggest that language-based monitoring could serve as a tool for identifying individuals at risk. In addition, the study emphasizes the need for targeted mental health support during worldwide crises because the psychological effects of such events can lead to a lasting transformation in how individuals express their struggles. The findings suggest a critical shift toward more personalized language-based approaches to mental health care that can adapt to the unique challenges posed by worldwide events, such as the COVID-19 pandemic.

Conclusion

The worldwide impact of COVID-19 has had long-lasting effects on people's mental well-being. In this study, we collected data from Reddit posts related to COVID-19. Data were filtered using specific keywords associated with the pandemic. Through EA and TA, we understood the emotional tone and potential harm in these posts. To classify the data, hybrid deep learning classifiers were used, which fused BERT, CNN, and LSTM models. The results reveal that our BERT+CNN+LSTM model achieved the highest accuracy of 93.65%, with a precision of 94% and a recall of 95%. In the final stage, XAI techniques, such as LIME and SHAP, extracted important factors for suicidal and nonsuicidal sentiments. After integration, the fused model can effectively grasp both localized and generalized contextual characteristics that are essential for comprehending linguistic patterns linked with suicidal ideation. It manages diverse formats commonly encountered in real-world text data by accommodating varying sentence lengths and syntactic complexities. This model will equip decision makers with a deeper understanding of factors contributing to suicide risk, facilitating the development of more impactful intervention strategies. Our analysis showed that terms related to COVID-19

XSL•FO
RenderX

are often present in posts with suicidal tendencies. We plan to incorporate audio data alongside these features to enhance the prediction of suicidal ideation.

Abstract

Background: Unobtrusively collected objective sensor data from everyday devices like smartphones provide a novel paradigm to infer mental health symptoms. This process, called smart sensing, allows a fine-grained assessment of various features (eg, time spent at home based on the GPS sensor). Based on its prevalence and impact, depression is a promising target for smart sensing. However, currently, it is unclear which sensor-based features should be used in depression severity prediction and if they hold an incremental benefit over established fine-grained assessments like the ecological momentary assessment (EMA).

Objective: The aim of this study was to investigate various features based on the smartphone screen, app usage, and call sensor alongside EMA to infer depression severity. Bivariate, cluster-wise, and cluster-combined analyses were conducted to determine the incremental benefit of smart sensing features compared to each other and EMA in parsimonious regression models for depression severity.

Methods: In this exploratory observational study, participants were recruited from the general population. Participants needed to be 18 years of age, provide written informed consent, and own an Android-based smartphone. Sensor data and EMA were collected via the INSIGHTS app. Depression severity was assessed using the 8-item Patient Health Questionnaire. Missing data were handled by multiple imputations. Correlation analyses were conducted for bivariate associations; stepwise linear regression analyses were used to find the best prediction models for depression severity. Models were compared by adjusted R^2. All analyses were pooled across the imputed datasets according to Rubin's rule.

Results: A total of 107 participants were included in the study. Ages ranged from 18 to 56 (mean 22.81, SD 7.32) years, and 78% of the participants identified as female. Depression severity was subclinical on average (mean 5.82, SD 4.44; Patient Health Questionnaire score ≥10: 18.7%). Small to medium correlations were found for depression severity and EMA (eg, valence: r=–0.55, 95% CI –0.67 to –0.41), and there were small correlations with sensing features (eg, screen duration: r=0.37, 95% CI 0.20 to 0.53). EMA features could explain 35.28% (95% CI 20.73% to 49.64%) of variance and sensing features (adjusted R^2=20.45%, 95% CI 7.81% to 35.59%). The best regression model contained EMA and sensing features (R^2=45.15%, 95% CI 30.39% to 58.53%).

Conclusions: Our findings underline the potential of smart sensing and EMA to infer depression severity as isolated paradigms and when combined. Although these could become important parts of clinical decision support systems for depression diagnostics and treatment in the future, confirmatory studies are needed before they can be applied to routine care. Furthermore, privacy, ethical, and acceptance issues need to be addressed.

Introduction

Depression is associated with high personal burden, impaired social participation and functioning, increased mortality, and high economic burden [1-3]. In 2020, depression was one of the leading causes of disability-adjusted life years worldwide (49.4 million; 95% CI 33.6-68.7) and is expected to be the leading cause by 2030 [1,3,4]. Despite its severity and the existence of effective treatments for depression [5-7], only 41.8% of people with major depressive disorder (MDD) receive any mental health services, and less than 30% of people with MDD receive adequate treatment [1,8]. Although several barriers contribute to this issue (eg, availability, accessibility, and acceptability of treatment) [1,8,9], a fundamental prerequisite to any health services is a timely and accurate diagnosis of MDD, or more generally, the assessment of depression severity to initiate an informed treatment process [10-14].

Well-established assessments like structured clinical interviews are often not feasible to be conducted in primary care or for preventive screening purposes (eg, due to time pressure or limited availability of qualified personnel) [10-13,15]. Furthermore, if they are implemented, they typically take place at a fixed time point and assess symptoms retrospectively, which makes them subject to several biases (eg, recall bias) and unable to assess the dynamic and fluctuating nature of mental health [16-18]. Hence, novel diagnostic approaches, which can be easily integrated into daily living to monitor depression severity with high ecological validity, could make an important contribution to improve and augment current diagnostic procedures for depression—particularly if they provide fine-grained insights into mental health symptomology (eg, on daily level). Given the omnipresence of smartphones in everyday life, the unobtrusive collection of objective sensor data (eg, total haversine distance between tracked GPS coordinates, social contacts, screen, and app usage) might be a promising step toward improved diagnoses [19-21]. This process is also referred to as smart sensing (also known as mobile sensing or digital phenotyping) in the context of depression [19-22]. Applications of smart sensing range from supporting initial diagnosis to integration during treatment (eg, just-in-time-adaptive interventions) or after treatment (eg, just-in-time interventions in relapse prevention) [19,23].

In the field of depression so far, many studies followed a classificatory approach classifying persons as depressed or not depressed (eg, based on the 8-item Patient Health Questionnaire [PHQ-8] cutoff ≥10) [24-28]. For instance, a first meta-analysis on supervised machine learning models to predict depression status based on wearable data reported an average accuracy of 0.89, 95% CI 0.83-0.93 (sensitivity: 0.87, 95% CI 0.79-0.92; specificity: 0.93, 95% CI 0.87-0.97) [24]. However, such a classificatory understanding of depression seems questionable when looking at (1) the poor agreement of domain experts in the diagnosis of depression [29,30], (2) the heterogeneity of symptom networks in depressed patients [31,32], and (3) the profound evidence for depression and general psychopathology being a continuous spectrum [29,33]. Hence, studies operationalizing depression as a continuous spectrum and understanding the prediction as a regression instead of a classification problem are highly needed in the field.

For example, for GPS features (eg, total distance, number of significant places), a meta-analysis shows that robust correlations between sensing features and depression severity as continuous dimension exist (eg, distance: r=–0.25, 95% CI –0.29 to –0.21), time spent home: r=0.10 (95% CI 0-0.19), or normalized entropy: r=–0.17, 95% CI –0.29 to –0.04) [34]. Besides, initial studies highlight the potential of features obtained from the screen (eg, smartphone usage duration), app (app usage), and call (eg, number of incoming calls) sensors [35,36]. However, so far, analyses are often limited to bivariate correlations and do not extend to (1) the variance in depression severity, which can be explained by the features, and (2) the combination of multiple features and which incremental benefit they provide (eg, in explained variance) [35].

Against this background, this study aimed to extend the evidence for various sensor modalities collected via the smartphone (ie, screen features, app usage features, location or GPS features, and call features) by (1) investigating bivariate correlations, (2) exploring the explained variance and incremental benefit of features in cluster-wise regression models (eg, limited to location features), and (3) cluster-combined regression models. Accordingly, the following research questions will be answered:

1. Which bivariate correlations are present between depression severity and (a) screen, (b) app, (c) location, and (d) call features?

2. How much variance in depression severity can be explained in parsimonious cluster-wise regression analyses (eg, limited to location features)?

3. How much variance in depression severity can be explained by the best cluster-combined regression model?

Besides, we wanted to compare the unobtrusively and objectively collected sensor features against features based on ecological momentary assessments (EMA; eg, average valence, average arousal), which, similarly to sensor data, provide a continuous assessment over time but require active input [18,35,37]. Therefore, we investigated the following questions:

4. Which bivariate correlations are present between depression severity and EMA features?

5. How much variance in depression severity can be explained in regression analyses using EMA features?

6. How much variance in depression severity can be explained in regression analyses using EMA and sensing features?

XSL•FO
RenderX

7. What is the difference in explained variance in depression severity between regression models limited to EMA features or sensor features compared to their combination?

Methods

Study Design

This study is an exploratory observation study investigating the associations between smart sensing features and depression severity. Accordingly, we followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) guidelines [38] (see Multimedia Appendix 1 for the STROBE checklist).

Ethical Considerations

All procedures were assessed and approved by the local ethics committee of Ulm University, Germany (259/16-CL/bal). Informed consent was given by all participants, and participants were informed about their rights according to the European General Data Protection Regulation. Privacy and data security were assessed by Ulm University. Students of Ulm University participating in the study were eligible for study credits as an expense allowance. No other compensation was provided to participants.

Study Population and Procedure

Aiming for a general population sample, participants (see eligibility criteria below) were recruited using an open recruitment strategy involving digital channels (eg, email lists and social media posts) and offline channels (eg, flyers at public institutions). Participants were informed about the purposes of and procedures in the study in an online survey and asked for their written informed consent. If given, they were instructed to install the smart sensing application of the INSIGHTS framework [39,40] after providing basic personal characteristics (ie, gender and age) in the online survey; afterwards, all data were collected via the app. See the assessment and features below for a description of all features and the technical framework paper for further details on the software [39].

Eligibility Criteria for Participants and Episodes

Participants were included in the study if (1) informed consent was given and (2) participants were 18 years or older. (3) Due to the technical requirements of the sensing framework, participants were required to have a smartphone running on Android. Neither a diagnosis nor a minimum level of depression was required to be included in the study. Furthermore, we only included participants' data in the analysis if (4) participants completed the depression severity questionnaire (PHQ-8; see details below) at least once. We structured the data of the participants in 14-day periods consisting of the depression questionnaire assessing the average depression severity in the last 14 days and the corresponding sensing data per day. The number of episodes varied across participants (mean 4.09, SD 3.55; range: 1-42). To avoid the biasing influence of participants being represented more often than others in the dataset and to maximize the data quality, we (5) included only the episode with the lowest amount of missingness per person. Missingness was determined across all days in the episode and features. In addition, (6) we excluded all participants with more than 50% missing data in EMA and sensing features during an episode to ensure missing data handling procedures (see below) were reliable [41,42]. Excluded participants, according to (6), did not significantly differ in age, gender, or depression symptomology from included participants, underlying the assumption that technical issues leading to the exclusion (eg, app not working) did not occur systematically (Multimedia Appendix 2).

Assessment and Features

Overview

The assessment consisted of (1) self-report severity measures, (2) EMA, (3) smartphone screen features, (4) app usage features, (5) location features, and (6) call features. Following the validated procedures from previous studies, we used Python, Snakemake, and the Reproducible Analysis Pipeline for Data Streams (RAPIDS) framework in the data preprocessing and extraction pipeline of all smartphone features [28,43-45]. Smartphone features were calculated for each day and aggregated across the 14-day window (eg, average daily smartphone usage duration across 14 days). A summary of all included smartphone features can be found below.

Clinical Questions

We used the PHQ-8 for the assessment of depression severity. The PHQ-8 consists of 8 self-report items asking how often a symptom was present in the last 14 days (0=not at all to 3=nearly every day). Higher PHQ-8 sum scores indicate higher depression severity. The PHQ-8 is a reliable instrument (Cronbach α=.87, ω=.94) [46,47] (see Multimedia Appendix 3 for an overview of the PHQ-8 items).

EMA Questions

All items were rated from 0 (lowest imaginable) to 100 (highest imaginable). We assessed valence (higher values indicate positive affect), arousal (higher values indicate higher energy levels), and stress (higher values indicate higher stress levels) 3 times per day (morning, midday, and evening). Additionally, sleep quality (high values indicate good sleep) was assessed in the morning, and satisfaction (higher values indicate stronger satisfaction) with the quality of social interaction, the number of social interactions, activity, and nutrition was rated in the evening once per day. See [40] and Multimedia Appendix 4 for an overview of the EMA questions.

Screen Features

The screen sensor tracked the lock and unlock events of the smartphone. Based on this, we determined the number of usage sessions, duration of usage (sum, average, maximum), regularity index of all unlock episodes, entropy, and normalized entropy of unlock events [28,44].

App Features

For each app, we tracked the start and end of each usage session to calculate the count of all used apps, the mean duration of app usage per day, the regularity index of app usage, and the frequency entropy of app usage [44].

XSL•FO
RenderX

Location Features

Using the GPS sensor of the smartphone, we determined the total distance, logarithmic location variance, number of significant places, stay duration (average, maximum, SD, at top 1 location, at top 2 location, and at top 3 location), the ratio between the time spent at nonsignificant places to all clusters (percent of outlier time), location entropy, normalized location entropy, circadian movement, location routine index, number of location transitions, and moving to static ratio [44,48-54].

Call Features

Incoming, outgoing, and missed calls were tracked separately. For each of them, we tracked the *count* and distinct contacts. Furthermore, for incoming and outgoing calls, we calculated the duration (average, sum, and maximum) and entropy [28,44,54].

See Table 1 for an overview of the feature definition, interpretation, and references, providing an in-depth introduction to the background and calculations of the features. For further details on the Reproducible Analysis Pipeline for Data Streams framework, refer to its paper [44].

XSL•FO
RenderX

Table 1. Feature definition and interpretation.

Feature	Definition	Units and interpretation
Ecological momentary assessment		
Valence	Affect ratings from users	0 (lowest) to 100 (highest); higher values indicate positive valence
Arousal	Arousal ratings from users	0 (lowest) to 100 (highest); higher values indicate higher energy levels
Stress	Stress ratings from users	0 (lowest) to 100 (highest); higher values indicate higher stress
Sleep	Sleep quality ratings from users	0 (lowest) to 100 (highest); higher values indicate higher sleep quality
Social quantity	Satisfaction with quality of social contacts reported by users	0 (lowest) to 100 (highest); higher values indicate higher satisfaction
Social quality	Satisfaction with quality of social contacts reported by users	0 (lowest) to 100 (highest); higher values indicate higher satisfaction
Nutrition	Nutrition ratings from users	0 (lowest) to 100 (highest); higher values indicate healthy nutrition
Physical activity	Physical activity ratings from users	0 (lowest) to 100 (highest); higher values indicate higher intensity activity
App usage		
App count	Number of app usage episodes in foreground	Count
App duration	Duration of app usage episodes in foreground	Time in hours
App frequency entropy	Entropy is a measurement of the degree of variability between the users' behavior states. The frequency of use per app over a 24-hour period was used to calculate app frequency entropy. For calculation details, refer to [44,54]	Higher app frequency entropy reflects a more distributed usage of apps (ie, high variability). Lower values indicate that users used one app more often (ie, low variability)
App regularity index	Regularity index captures the similarity of behavior between the same hours across different days. App regularity index refers to the similarity of the most frequently used app at the same hour across days. Calculations were based on [44,54,55]	Higher regularity index indicates a user used the same app at the same hours across days
Screen usage		
Screen episode count	Number of screen unlock episodes	Count
Screen duration	Duration of unlock episodes	Time in hours
Screen regularity index	Regularity index captures the similarity of behavior between the same hours across different days. Screen regularity index refers to the similarity of the most frequent screen status (on or off) at the same hour across days. Refer to [44,55]	Higher regularity index indicates a user used their smartphone at the same hours across days
Screen entropy	Entropy is a measurement of the degree of variability between the users' behavior states. The frequency of screen states (on or off) over a 24-hour period was used to calculate screen entropy. For calculation details, refer to [44,54]	Higher screen entropy reflects a more distributed unlock of the screen (ie, high variability). Lower values indicate that users screen is more often in one state (ie, low variability).
Screen normalized entropy	Normalized entropy is the entropy divided by the logarithm of the number of states (N)	Entropy divided by log(N)
Call		
Missed calls count	Number of missed calls	Count
Missed calls distinct contacts	Number of distinct contacts whose calls were missed	Count
Incoming calls count	Number of incoming calls	Count
Incoming calls distinct contacts	Number of distinct contacts whose calls were answered	Count
Incoming calls duration	Duration of incoming calls	Time in hours

XSL•FO
RenderX

Feature	Definition	Units and interpretation
Incoming calls entropy	Entropy is a measurement of the degree of variability between the users' behavior states. The duration of incoming calls over a 24-hour period was used to calculate incoming calls entropy. For calculation details, refer to [44,54]	Higher incoming calls entropy reflects a more distributed call duration across incoming calls (ie, high variability)
Outgoing calls count	Number of outgoing calls	Count
Outgoing calls distinct contacts	Number of distinct contacts who were called.	Count
Outgoing calls duration	Duration of outgoing calls	Time in hours
Outgoing calls entropy	Entropy is a measurement of the degree of variability between the users' behavior states. The duration of outgoing calls over a 24-hour period was used to calculate outgoing calls entropy. For calculation details, refer to [44,54]	Higher outgoing calls entropy reflects a more distributed call duration across outgoing calls (ie, high variability)
Location		
Total distance	Total distance (haversine) between tracked location coordinates	Distance in km
Location variance	Logarithm of the combined variance in latitude and longitude [44,48-50]	
Moving to static ratio	Ratio of moving states (speed >1 km/h) to static states (speed <1 km/h) [50]	Ratio; higher values reflect more moving states compared to static states
Number of significant clusters	Clusters are determined by k-means clustering of stationary location coordinates (speed <1 km/h). Clusters needed to be 400 meters from each other. Pauses within 200 meters of cluster were counted as cluster visits after the initial clustering. Only clusters with a time duration of 10 minutes were counted as significant. For further details, see [44,48-51]	Count
Staying time at clusters	Time spent at significant clusters	Time in hours
Time at top 1 location	Total time spent at the most significant cluster	Time in hours
Time at top 2 location	Total time spent at the second most significant cluster	Time in hours
Time at top 3 location	Total time spent at the third most significant cluster	Time in hours
Location entropy	Entropy is a measurement of the degree of variability between the users' behavior states. The duration at significant clusters over a 24-hour period was used to calculate location entropy. For calculation details, refer to [44,48-50,54]	Higher location entropy reflects more distributed time spent at significant clusters. Lower values indicate that users spent more time at some significant clusters.
Location normalized entropy	Entropy divided by the logarithm of the number of significant clusters (N)	Entropy divided by the log(N)
Location circadian movement	The extent to which a person's visits at significant clusters follow a 24-hour circadian rhythm. For further details, see [44,50,52,53,56]	Low values indicate a break from routine, whereas high values indicate that a person followed a daily routine.
Time spent at nonsignificant clusters (at outliers)	Time spent at nonsignificant clusters divided by the time spent at all significant cluster	Ratio; higher values indicate more time spent at nonsignificant clusters

Preprocessing and Missing Data Handling

To account for missing data in the dataset, we performed multiple imputations by chained equations [42]. For a missingness overview before imputation, see Multimedia Appendix 5. As outlined before, we constructed 14-day periods consisting of the PHQ-8 and sensing features per day. The following imputations were conducted on the day level (ie, 14 days for each participant and episode). Given the nested data structure (ie, multiple days of the same participant), we applied 2-level predictive mean matching with random intercepts for all variables. A total of 20 complete datasets were obtained. Convergence was achieved after 10 iterations. In a second step, we aggregated the data from the daily level in each imputed dataset to the episode level to match the data structure of the PHQ-8 and sensing features. Aggregation consisted of the mean and SD across the 14 days. Therefore, each imputed dataset contained a single data entry for each person consisting of the average depression severity in the last 14 days (PHQ-8) and the average and SD of the sensing features in the last 14 days.

Statistical Analysis

Given the exploratory character of this study, we decided not to report any *P* values. Instead, all analyses report on the point estimates and corresponding 95% CIs. Throughout the analyses, we conducted analyses on each imputed dataset separately and pooled the data using Rubin's rule with Barnhard-Rubin adjustment for degrees of freedom [42,57-59]. The analysis strategy was structured in 3 steps. First, we calculated bivariate between-person Pearson correlations (*r*) and their 95% CIs

XSL•FO
RenderX

between EMA and sensing features with depression. The correlation is a statistical measure of the magnitude of a linear relationship between 2 variables. It ranges from –1 (perfect negative linear relationship) to +1 (perfect positive linear relationship). Since higher values of the PHQ-8 indicate higher levels of depression, positive correlations between a feature and the PHQ-8 imply that higher values of this feature are associated with higher depression. However, correlations do not allow any causal inference. See Table 1 for interpretation guidance on all features.

Second, variables with non-zero correlation CIs were included as candidates in cluster-wise regression analyses (ie, limited to EMA, screen, app, location, and call features only). The best models per cluster were determined by stepwise backward exclusion of predictors with zero-including CIs. Predictors, starting with the least influential (standardized β) and broadest zero-including CI, were removed one at a time, and regression models were refitted and compared against each other based on adjusted R^2 after each step. This stepwise backward elimination process was continued until all predictors with zero-including CIs were excluded and regression models no longer improved regarding adjusted R^2. For each final cluster-wise regression, we determined the adjusted R^2 and its 95% CI to quantify the explained variance in depression severity.

In the third step, we constructed regression models (1) combining the different sensing feature clusters in one model to evaluate the potential of smart sensing as a stand-alone paradigm and (2) including EMA and sensing feature clusters to evaluate their combined potential. As before, predictors were eliminated following stepwise backward exclusion. Overall model performance was evaluated based on adjusted R^2. Differences in adjusted R^2 and the information criteria Akaike information criterion and Bayesian information criterion were used for model comparisons. Model parameters were standardized and adjusted for age and gender in sensitivity analysis.

Software

All analyses and data preparation were conducted in R. The mice and miceadds packages were used for the imputation and pooling of analysis results [42,60]. For a full list of all packages, see Multimedia Appendix 6.

Results

Overview

A total of 201 participants answered at least 1 PHQ-8. In total, 94 of the responders were excluded due to poor data quality (>50% average missingness in EMA and sensing features). Hence, a total of 107 participants were included in the analysis.

The mean age of the participants was 22.81 (SD 7.32), with the oldest participant being 56 years and the youngest 18 years. In total, 83 (77.6%) of the participants identified themselves as female (male: n=24, 22.4%). On average, participants showed subclinical depression levels (mean 5.82, SD 4.44), with 20 (18.7%) above the PHQ-8 ≥10 cutoff indicating clinically relevant depression severity. For a summary of the PHQ-8 item level, see Multimedia Appendix 7.

EMA features revealed an average valence of 65.98 (SD 12.82), arousal of 50.17 (SD 12.16), and stress of 38.85 (SD 15.66). Daily screen usage of the smartphone was 2.72 hours (SD 2.82) on average. A complete summary of all k=102 features and their respective means and SDs can be found in Multimedia Appendix 8.

Correlations

Correlation analyses revealed small to medium correlations of EMA and sensing features with depression severity. Average valence ratings showed the highest correlation to depression severity of the EMA features (r=–0.55, 95% CI –0.67 to –0.41), while the SD of app frequency entropy in app usage (r=–0.19, 95% CI –0.37 to –0.00), mean duration of outgoing calls (r=0.25, 95% CI 0.04 to 0.43), location routine index (r=0.23, 95% CI 0.02 to 0.42), and the average screen duration (r=0.37, 95% CI 0.20 to 0.53) were the strongest features in their respective clusters. See Table 2 for a summary of all correlations with zero, excluding CIs. The complete correlation summary of all investigated features can be found in Multimedia Appendix 9.

[a]Correlations are pooled correlations based on multiple imputations. Only correlations with their 95% CI excluding zero are displayed. A full correlation summary can be found in Multimedia Appendix 9. For feature definition and interpretation, refer to Table 1.

Regression

We included the features identified in the correlation analysis in step-wise regression analyses to investigate their incremental contribution to the explained variance in depression severity. The final regression model using EMA features included average valence (=–0.39, 95% CI –0.58 to –0.21) and social quality as predictors (=–0.29, 95% CI –0.48 to –0.10). Combined, they explained 35.28% of the variance (95% CI 20.73% to 49.64%).

In the app cluster, SD of app frequency entropy (=–0.19, 95% CI –0.38 to –0.00) explained adjusted R^2=2.81% of the variance (95% CI 0.00%-12.02%), while location routine index (=0.23, 95% CI 0.02 to 0.44) explained adjusted R^2=4.39% (95% CI 0.00% to 16.71%) in the location cluster. From the call cluster, the SD of incoming call duration (=0.20, 95% CI 0.03 to 0.41) and average outgoing call duration (=0.24, 95% CI 0.04 to 0.44) were the final included predictors explaining adjusted R^2=8.68% of the variance (95% CI 0.88% to 22.32%). Of all 4 candidates in the screen cluster, the average screen duration was the only included predictor in the final model (=0.37, 95% CI 0.19 to 0.55; adjusted R^2=13.09%, 95% CI 3.40% to 26.65%).

Combining all sensing features in a parsimonious model yielded a model explaining adjusted R^2=20.45% of the variance (95% CI 7.81% to 35.59%) with average screen duration (=0.39, 95% CI 0.21 to 0.56), SD of app frequency entropy (=–0.19, 95% CI –0.36 to –0.02), and SD of incoming call duration (=0.21, 95% CI 0.02 to 0.41) as predictors.

The highest variance was explained when combining EMA and sensing features: adj. R^2=45.15% of the variance (95% CI 30.39% to 58.53%). Features included in this prediction model were average valence (=–0.36, 95% CI –0.53 to –0.19), social quality (=–0.24, 95% CI –0.41 to –0.06), average screen duration (=0.22, 95% CI 0.07 to 0.37), SD of app frequency entropy (= –0.17, 95% CI –0.31 to –0.02), and average

XSL•FO
RenderX

duration of outgoing calls (=0.17, 95% CI 0.01 to 0.33). See Table 3 for a summary of the parsimonious EMA, sensing, and combined regression models.

Table 3. Regression results for depression predicted by ecological momentary assessment and smartphone features in stand-alone and combined models.[a]

	(95% CI)	Adjusted R^2 (95% CI), %	AIC[b]	BIC[c]	Δ adjusted R^2, %
EMA[d] cluster		35.28 (20.73 to 49.64)	262.45	273.14	N/A[e]
Average valence	–0.39 (–0.58 to –0.21)				
Average social quality	–0.29 (–0.48 to –0.10)				
Sensing cluster		20.45 (7.81 to 35.59)	284.53	297.90	EMA: –14.83
Average screen duration	0.39 (0.21 to 0.56)				
Average app frequency entropy	–0.19 (–0.36 to –0.02)				
Incoming call SD	0.21 (0.02 to 0.41)				
Combined		45.15 (30.39 to 58.53)	249.42	268.13	EMA: 9.87; sensing: 24.70
Average valence	–0.36 (–0.53 to –0.19)				
Average social quality	–0.24 (–0.41 to –0.06)				
Average screen duration	0.22 (0.07 to 0.37)				
Average app frequency entropy	–0.17 (–0.31 to –0.02)				
Average duration of outgoing calls	0.17 (0.01 to 0.33)				

[a]All results were obtained by pooling results from multiple imputations according to Rubin's rule. All estimates were fully standardized. For feature definition and interpretation, refer to Table 1.

[b]AIC: Akaike information criterion.

[c]BIC: Bayesian information criterion.

[d]EMA: ecological momentary assessment.

[e]Not applicable.

Results were robust when adjusting for age and gender, yielding nonsignificant main effects in the parsimonious EMA (age: –0.08 to 0.23; gender: –0.06 to 0.26), sensing (age: –0.16 to 0.21; gender: –0.26 to 0.10), and combined EMA and sensing model (age: –0.09 to 0.22; gender: –0.09 to 0.21).

Discussion

Principal Findings

To explore the potential of smart sensing for depression, this study investigated the bivariate correlations and explainable variance in regression models built on smartphone sensors and EMA features. Across sensor modalities, we found small correlations between smart sensing features and depression severity. Combined smart sensing features could explain 20.45% (95% CI 7.81%-35.59%) of the depression severity variance in a parsimonious model. Conversely, we found small to medium correlations for EMA features, which could explain 35.28% (95% CI 20.73%-49.64%) of the variance. The best model was the combination of smart sensing and EMA features, which explained 45.15% (95% CI 30.39%-58.53%; Δ adjusted R^2 to smart sensing only: 24.70%; Δ adjusted R^2 to EMA only: 9.87%).

Comparison to Prior Work

The EMA findings are in line with previous studies and reviews highlighting the potential of EMA as a continuous assessment to infer depression severity [35,37,40,61,62]. However, while the bivariate correlations, as well as the explained variance, are higher for EMA compared to features obtained from smartphone sensors, it is important to note that the sensing cluster alone could explain about 20% of the variance. Given the unobtrusive nature of the collection of sensor data, this approach has a crucial advantage over EMA, which requires active user or patient involvement over a long period (eg, multiple daily responses over 14 days). In particular, for clinical application, it should be evaluated whether the additional burden for patients to answer EMA is proportional to the gain in explained variance. Furthermore, various issues in EMA (eg, interpretation of momentary questions, usage of comparison standards) could be avoided by the collection of objective sensor data [19,21,62,63]. That said, to maximize the explained variance, the combination of sensor features and EMA seems to be best. This result extends the findings by Moshe et al [35], who previously evaluated GPS features in conjunction with physiological wearable data and EMA similarly, showing that the combination of sensing features with EMA yields the best regression model for depression severity.

Although these findings seem promising, it is also important to note that this study and others so far are exploratory [34-36,64].

XSL•FO
RenderX

Although we have more than 2 decades of research on EMA and its application for mental health [18,37], the field of smart sensing is still in its infancy. Facing heterogenous methodology and study quality, as well as potential publication bias in the field, confirmatory studies are highly needed in the field of smart sensing before clinical application [34,36,64,65]. Besides, it is important to note that this study followed a rather data-driven approach to investigating features, which were collectible by the here-used framework. In the context of smart sensing, a central question is which features are needed and provide an incremental benefit. Although this study can give first insights into this topic, predictors like screen duration, app usage entropy, and call features (eg, SD in incoming calls) should only be incorporated in clinical systems if replicated in future studies. Also, an extension to other sensors (eg, language analysis based on LIWC or sentiment analysis) [66-70], app content (eg, usage of social media apps) [71], network usage [28], and the combination with other wearable devices (eg, biophysiological data from smart watches) or different data sources (eg, journaling data) would be a promising addition [23,24,35,67].

However, a closer inspection is needed not only for smart sensing features but also for EMA. For example, our study highlighted that many of the investigated features (eg, arousal or physical activity) did not hold any incremental benefit besides valence and social quality. Since EMA is associated with additional burden for patients, it is especially important to identify the core set of items that maximize predictive power while reducing the item load. Despite a long research history, surprisingly little systematic and meta-analytical evidence is available on which questions should be asked in the context of depression and more precisely when (eg, morning or evening) and on which schedule (eg, multiple fixed time points or microrandomized assessments) [37,63,72-74].

Besides the empirical evidence for the applicability of smart sensing, questions of acceptance, data security and privacy, and ethical challenges surrounding smart sensing need to be addressed [19,75-77]. For instance, recent studies found only moderate acceptance of smart sensing in the context of mental health and highlighted the impact of data types and recipients in smart sensing [77-79]. Only when these barriers and challenges are overcome, can smart sensing unfold its potential fully.

Lastly, we want to point out that the current developments in smart sensing for mental health mainly focus on the prediction of psychopathology [24,26,27,36,64]. Future studies could further advance the field by not only focusing on pathology but also investigating applications to assess risk factors (eg, loneliness, stress) or mediators and mechanisms of change (eg, rumination, therapeutic alliance). Understanding the underlying process of how treatment works is a crucial step to optimizing treatments and pathways in mental health care [80-83]. Since smart sensing allows for a fine-grained and unobtrusive assessment, it might become a promising and feasible paradigm to unveil the mechanism of change in mental health care and better understand the dynamics of therapeutic processes.

Limitations

In addition to the already highlighted exploratory nature of this study, we would like to emphasize a few limitations of this study. First, this study followed a cross-sectional design investigating which predictors explain the variance between persons. Hence, any causal interpretation of the results is not eligible and would require different study designs. For instance, the increased smartphone usage (eg, screen duration) could be caused by depression, but also vice versa or even explained by a third variable. Also, the analysis of trajectories and dynamics over time was not in the scope of this study. Based on the multiple episodes of participants in this study, a longitudinal perspective would be a valuable addition to this study and a field with so far underrepresented research on longitudinal models [34,84,85].

Second, the present sample was a convenient sample recruited in the general population, which resulted in a rather young (mean 22.81, SD 7.32, range 18-56) and unequal gender distribution (female: 77.6%). Furthermore, only 18.7% of the participants showed clinically relevant symptomology. Therefore, the generalizability of the findings to other samples, especially clinical samples, remains open. However, by showing the feasibility of smart sensing predictions and their incremental benefit in explaining variance in depression, this study lays a strong foundation to move to clinical populations and studies. To further increase the quality of clinical studies, also methodological points need to be addressed; for instance, self-report instruments, as applied in this study (ie, PHQ-8), are prone to several sources of bias (eg, social desirability or recall biases). Hence, the application of more reliable and valid assessments like clinician ratings or medical diagnosis should be considered in future studies alongside measurements, which maximize reliability in a specific depression severity range of interest (eg, high reliability in subclinical or severe depression levels) [86-88].

Third, alongside the sample characteristics, the sample size needs to be considered. Adequate sample size is key to designing confirmatory studies aiming to test an assumed clinically relevant effect with sufficient power. In depression research, a standardized mean difference of 0.24, which transfers to a correlation of r=0.12 [89], is argued to be a clinically relevant effect [90]. However, to be able to test such a correlation with sufficient power (eg, 80%), a sample size of N=542 would be required (assuming a 2-sided test with α=5%, following a bivariate normal model). Hence, our study was highly underpowered to test for a minimally clinically relevant correlation of r=0.12. Accordingly, we did not report any P values and solely reported on the 95% CIs to provide a range of reasonable assumable magnitudes of estimates, which could guide future studies in their sample size planning.

Lastly, we would like to emphasize that we opted for linear regression analysis to investigate the incremental contribution of various predictors and allow for direct comparison of various models. This method provides a straightforward approach to answering the present research question. However, sensor data are also very complex, and previous studies have highlighted the potential of nonlinear machine learning models for

XSL•FO
RenderX

depression severity to fully exploit the smart sensing data [25,28]. Although previously applied to classification, machine learning models like extreme gradient-boosted regression trees may also be promising in regression. On the flip side, these models go hand in hand with challenges such as overfitting and difficulties in the interpretation and explanations of the models [25,28,91]. Therefore, even if proven to improve the predictive accuracy, it should be carefully considered whether the complexity and downsides (eg, explainability) of potential machine learning models justify their usage over simpler but easy-to-interpret statistical regression models [92].

Conclusions

Smart sensing and EMA provide potent paradigms to infer and predict depression severity. Our results show that EMA and sensing features alone can substantially explain variance in depression severity. In isolation, EMA was superior to sensing features in terms of explained variance. However, sensing features alone could explain about 20% of the variance, emphasizing the potential of this unobtrusive and objective assessment of depression. To maximize explainable variance, EMA and sensing features should be combined. However, while these findings are promising, confirmatory studies, particularly in clinical settings and samples, are highly needed before robust conclusions can be drawn.

Acknowledgments

We would like to thank all the student assistants involved in the project. No generative AI (eg, ChatGPT) was used in this project and manuscript. This study was self-funded by the authors. YT is supported by the initial phase of the German Center for Mental Health (Deutsches Zentrum für Psychische Gesundheit; grant 01EE2303A).

Data Availability

The primary data obtained in this observation study can be provided by HB and YT on reasonable request. Data-sharing agreements may have to be signed depending on the request. Requests should be directed at the corresponding author (YT). Support is depending on available resources.

Authors' Contributions

YT, EMM, CM, and HB were involved in the conceptualization. Data curation was done by YT, EMM, and KOA. Formal analysis was done by YT. CM and HB were involved in funding acquisition. EMM, YT, HB, CK, and CM were involved in the investigation. YT and KOA were involved in the methodology. Project administration was done by YT and EMM. YT, EMM, CM, CK, and HB contributed to resources; software was contributed by YT, KOA, and CK. YT, EMM, and HB were involved in supervision. Validation was done by YT, EMM, KOA, and CK. Visualization was done by YT. YT also contributed to writing the original draft. YT, EMM, KOA, CM, CK, and HB contributed to reviewing and editing the manuscript.

Conflicts of Interest

All authors declare no conflicts of interest. However, for reasons of transparency, CM notes that he has received (to Ulm University and earlier University of Bonn) grants from agencies such as the German Research Foundation. CM has performed grant reviews for several agencies, edited journal sections and articles, given academic lectures at clinical or scientific venues or for companies, and generated books or book chapters for publishers of mental health texts. For some of these activities, he received royalties, but never from gaming or social media companies. CM was part of a discussion circle (Digitalität und Verantwortung: https://about.fb.com/de/news/h/gespraechskreis-digitalitaet-und-verantwortung/) debating ethical questions linked to social media, digitalization, and society/democracy at Facebook. In this context, he received no salary for his activities. Finally, he currently functions as an independent scientist on the scientific advisory board of the Nymphenburg Group. This activity is financially compensated. Moreover, he is on the scientific advisory board of Applied Cognition, an activity which is also compensated.

Abstract

Background: The high levels of sustained stress that health professionals often experience are a significant risk factor for developing mental health problems, such as anxiety, depression, and somatic symptoms, that not only affect their well-being but also have major social and organizational consequences. Different interventions, including those based on third-wave psychotherapy principles (ie, mindfulness, compassion, and acceptance), have proven to be effective in reducing stress in this population. Among them, those delivered on the web constitute a promising alternative with notable advantages in accessibility and flexibility, but some adherence inconveniences may limit their efficacy.

Objective: This study aimed to evaluate the effectiveness of the MINDxYOU program, a web-based self-guided intervention based on third-wave psychotherapy principles, to reduce perceived stress and promote mental health in a sample of health professionals.

Methods: In a stepped-wedge cluster randomized design, 357 health professionals from health centers in Aragon and Málaga, Spain, were recruited. They were divided into 6 clusters—3 per region—and randomly assigned to 1 of the 3 sequences, each starting with a control phase and then transitioning to the intervention phase (the MINDxYOU program) after 8, 16, or 24 weeks. This self-guided, web-based program, designed to be completed over 8 weeks, included weekly contact (via WhatsApp, call, or email) from the research team to promote adherence. Participants were assessed on the web every 8 weeks for 5 assessments.

XSL•FO
RenderX

Perceived stress was the study's primary outcome, with additional measures of clinical factors (anxiety, depression, and somatization) and process variables (resilience, mindfulness, compassion, and acceptance).

Results: The program was initiated by 229 participants, 112 (48.9%) of whom were completers (ie, completed at least 3 of the 4 modules). Perceived stress demonstrated a significant reduction both when considering the entire sample (β=–1.08, SE 0.51; *P*=.03) and the sample of completers (β=–1.84, SE 0.62; *P*=.003). The proportion of participants reflecting "low stress" increased after the treatment (n=90, 46.6% vs n=100, 28.8% at baseline). Intracluster analysis revealed that pre- versus postintervention moderate effects were present in 2 clusters (Cohen *d*=0.46 and 0.62), and these were maintained in subsequent assessments. The linear mixed-effects models also showed that depression, anxiety, and somatization, as well as resilience, self-compassion, and some mindfulness facets, experienced significant improvements (*P*<.05) when comparing the intervention and control phases.

Conclusions: The MINDxYOU program was effective in reducing perceived stress and promoting mental health, as well as increasing resilience, mindfulness facets, and self-compassion. These effects suggest that participants experienced a tangible improvement that could potentially enhance their well-being. Adherence to the intervention was moderate, while program use was notable compared to similar interventions. Finding ways to promote adherence to the intervention would contribute to increasing the effectiveness of this program.

Introduction

Background

Health professionals often experience high levels of sustained stress that constitute a risk for developing mental health problems, as recognized by the World Health Organization [1,2]. In recent years, the prevalence of psychological disorders such as anxiety, depression, and somatic symptoms has increased among this population, which has been linked to the extra efforts exerted by health workers and the extremely difficult situations to which they were exposed during the COVID-19 pandemic [3-6]. Although the pandemic was declared officially over in May 2023, its effects on the well-being of health professionals have been observed to be profound and lasting in many cases [7,8]. The implications of mental health problems in these professionals not only refer to their well-being but also include social and organizational consequences, such as increasing rates of absenteeism and turnover intention [9-11], as well as so-called quiet quitting [12]. Thus, despite the end of the COVID-19 pandemic, it is essential to continue to monitor health professionals' mental health and implement effective strategies to decrease their stress levels, thus preventing chronic stress and its consequences [13].

The effectiveness of interventions based on cognitive behavioral therapy (CBT) on stress reduction and mental health promotion has been widely proven for different types of health professionals [14-16]. Relaxation, cognitive restructuring, and social skill training, among others, are traditional CBT techniques aimed at modifying the interaction between thoughts, behaviors, and emotions. However, in recent decades, a different approach to CBT has been developed and tested with positive results. Referred to as the third wave of CBT psychotherapy, it is based on the promotion of mindfulness, acceptance, compassion, and spirituality [17]. Different systematic reviews have underscored the effectiveness of third-wave psychotherapies, including mindfulness-based interventions, compassion-based programs, and acceptance and commitment therapy, in reducing occupational stress as well as anxiety and depression while increasing resilience, including in health professionals [18-21].

While psychological interventions are typically delivered in an in-person format, eHealth interventions—examples of which are telehealth, mobile apps, and serious games—have proliferated over the last few years, partly due to the COVID-19 pandemic [22]. The systematic review conducted by López-Del-Hoyo et al [23] summarized the different types of eHealth programs that have been tested to promote mental health in health professionals and concluded that there was promising evidence of the effectiveness of self-guided, web-based, third-wave psychotherapy–based programs for reducing stress and promoting mental health. The self-guided format, which implies the lack of an external figure who delivers the contents of the intervention, offers a high degree of availability, flexibility, and convenience [24]. This could be particularly useful in the case of health professionals who often have to cope with the difficulty of reconciling work schedules with attending therapy sessions [25]. Indeed, this type of eHealth program has been associated with high user satisfaction and acceptance [26,27].

Nonetheless, some self-guided interventions have turned out to be ineffective for health professionals, and notably low adherence rates to these programs have been observed [23]. This may be due to generic and unappealing programs not addressing the particular needs of these individuals, although it has also been suggested that their lack of external guidance could contribute to higher attrition rates [26,28]. This would imply that the flexible and adaptable nature of self-guided programs can be both an advantage and an obstacle while

XSL•FO
RenderX

achieving significant improvements in stress and other mental health–related outcomes. Therefore, a mixed format, that is, a self-guided web-based program that includes occasional—preferably, remote and asynchronous—contact with an external figure, via WhatsApp messages or emails, for instance, could present a solution for retaining the main advantages of self-guided web-based programs while reducing the risk of attrition [23].

Objectives

The aim of this study was to test the effectiveness of a self-guided web-based program (MINDxYOU) for reducing the perceived stress of health professionals while promoting different mental health–related outcomes through the application of third-wave psychotherapy principles: mindfulness, compassion, and acceptance. Following the recommendations of previous authors [29], the MINDxYOU program was not designed as a generic program to be used by any given population; rather, its specific contents and examples relate to the day-to-day activities of health professionals (eg, compassion fatigue and common stressors). The program consists of 8 parts (sessions) to be completed within 8 consecutive weeks. During this time, weekly contact was scheduled with the research team via email, WhatsApp, or phone call to include a small degree of guidance in the intervention. The MINDxYOU program highlights the importance of systematic and continuous practicing of different types of meditation not only during the 8-week duration of the intervention but also afterward to promote the development of new healthy habits. It was hypothesized that on completing the web-based program, health professionals would experience a significant reduction in their stress levels as well as improvements in other clinical aspects (anxiety, depression, and somatization) and process variables (resilience, mindfulness, compassion, and acceptance).

Methods

Study Design

A stepped-wedge cluster randomized trial design [30] was used for this hybrid type 2, effectiveness and implementation study, which was conducted in 2 Spanish regions (the autonomous region of Aragon and the province of Malaga, in Andalusia). This design was chosen considering its suitability for studying both the effectiveness of the MINDxYOU program (reported in this work) and its implementation in health centers (to be reported in a different work) [31,32]. The stepped-wedge design allows all the study participants to receive the intervention and is particularly recommended when the intervention being tested has strong evidence of positive effects or is very unlikely to cause harm [30].

The participants were health professionals working for different types of health care institutions: hospitals, primary care centers, and other health facilities (eg, nursing homes and health and social care centers). The sample was divided into 6 clusters—3 per region—which were randomly allocated to 1 of the 3 possible sequences. They all started at the control phase and sequentially transitioned to the intervention phase (they were given access to the MINDxYOU program). This was a closed cohort study, given that all the participants started at the same time and were evaluated at 5 previously defined time points.

As detailed in the study protocol [33], the sample size calculation estimated 180 participants, 30 (16.7%) per cluster, for an expected moderate effect size of the intervention on the primary outcome, that is, perceived stress [34]. However, the ambitious dissemination of the project attracted the interest of a very high number of health professionals, and an effort was subsequently made to recruit 393 participants, of whom 357 (90.8%) would ultimately provide data and consequently form the study sample.

Recruitment and Inclusion Criteria

Between October 2022 and January 2023, the MINDxYOU project was disseminated using both direct and indirect techniques. Informative meetings were conducted for managers and health professionals working in health facilities (hospitals, primary care centers, and nursing homes) in Aragon and Malaga; posters and leaflets were placed at different health centers; and members of the research group were interviewed by regional media regarding the project, optimizing its visibility. Individuals interested in participating accessed the project's website [35] to complete a short form to verify whether they met the inclusion criteria as follows: (1) employment as a health professional (eg, physician, nurse, psychologist, or nursing assistant) or undergoing training in any health-related field (trainee); (2) aged between 18 and 70 years; (3) ability to understand Spanish; (4) digital literacy and access to a smartphone, tablet, or PC with an internet connection; and (5) prospects of continued employment at the same workplace for the following 6 months. Candidates who met these criteria were also asked on the form to provide their email address or telephone number for subsequent contact by the researchers.

Every candidate underwent a telephone interview conducted by a member of the research team, either a psychologist or mental health nurse trained for this purpose, to ensure the previously described inclusion criteria were met. In addition, the following exclusion criteria were assessed during the interview: (1) presenting with a disorder affecting the central nervous system; (2) diagnosis of a severe mental illness (severe depressive disorders, suicidal tendencies, bipolar disorders, panic disorders, anxiety or stress-related disorders, obsessive-compulsive disorders, and substance-related disorders) using the Mini-International Neuropsychiatric Interview (version 7.0.2) diagnostic interview [36]; (3) presenting with an uncontrolled medical condition or either an infectious or degenerative disease; and (4) having experience with third-wave psychotherapies (eg, having attended mindfulness courses in the previous year or practicing formal meditation regularly). Candidates who fit the inclusion profile were sent an email containing the study information and an attached informed consent form to be signed electronically and returned.

Procedures

Once the participants had been enrolled in the study (February 2023), they were assigned a code to access the evaluation platform (SurveyMonkey [SurveyMonkey Inc]) and ensure their anonymity throughout the study. An external researcher

XSL•FO
RenderX

unrelated to this project then performed the cluster randomization under 2 conditions: each sequence had to include a cluster from each region, and they had to be 2 different types of workplaces (hospitals, primary care centers, or other health centers). The baseline assessment took place over the last week of February 2023 and the first week of March 2023. Following the stepped-wedge design, this assessment was repeated every 8 weeks, which was the expected duration of the program. There were 5 assessment points in total.

Emails were sent to all participants after each assessment to indicate whether they had been granted access to the MINDxYOU program or still had to wait a certain amount of time (ie, they remained in the control phase). Once they were allowed access, they first watched a 3-minute video tutorial on how to log into the platform and use it. The introduction to the program (module 0) explained to the participants the format of the intervention (4 modules, each containing 2 sessions). Although visualizing the contents of each session (text and videos) would take approximately 1 hour, it was recommended that participants dedicate an entire week to each session before moving on to the next, because every session included meditation exercises that needed to be practiced on consecutive days to be learned and incorporated into a routine if they were to produce stress-relief effects. Therefore, the program was expected to be completed in 8 weeks (1 session per week). Whenever participants indicated their intention to start a new session, the platform would present a brief on the web form asking how many days they had been practicing the exercises from the previous session. This was meant to remind them of the recommendation to dedicate 1 full week to the series of exercises in each session before moving on to the next one. Nevertheless, all participants were given access to the following sessions when they completed the form, regardless of their dedication to the previous session.

Once per week during the 8-week duration of the program, all (N=357, 100%) participants were contacted via their preferred means (email, WhatsApp, or phone call, as indicated when they signed the informed consent) by a member of the research team (SF-M, CA-L, LC-G, or VC). The purpose of this contact was to motivate the participants to adhere to the intervention as per the recommendations and identify any difficulties with the program regarding its contents or use of the platform. If any of these were communicated by participants, the researcher would provide help to clarify and resolve the issue. The weekly contacts ended after the eighth week, regardless of the degree to which each participant had completed the program by that time. Nonetheless, the participants were informed that they could continue to use the MINDxYOU program and were encouraged to keep practicing what they had learned. Follow-up emails were sent reminding every study participant of this information.

Intervention

The MINDxYOU program is a self-guided web-based intervention delivered via a digital platform that consists of 4 modules, each of them divided into 2 parts (sessions). The contents of the intervention are related to third-wave psychotherapies (mindfulness, compassion, and acceptance), which have presented strong evidence of efficacy for reducing stress and promoting mental health [18]. All the contents of the MINDxYOU program are based on previously developed and validated programs, such as mindfulness-based stress reduction [37], Smiling is Fun [38], and attachment-based compassion therapy [39]. Following the suggestions of previous studies [23,29], the MINDxYOU program includes a series of adaptations to make it more specific to health professionals (eg, examples of typical stressors that occur in health care settings). Both formal and informal practices are presented during the program: downloadable audio guides are provided for formal practice, while informal exercises are linked to the promotion of healthy habits, such as physical activity, healthy diet, and good sleep habits, in addition to socializing in module 4. The intervention emphasizes the importance of including meditation exercises in a daily routine and developing healthy habits that can have a stress-relief effect. Consequently, participants are encouraged to download the materials and continue to practice even after the completion of the program. A summary of the contents and exercises proposed for each session is presented in Multimedia Appendix 1.

Measurements

Overview

Sociodemographic questions (age, gender, marital status, and education level) and work-related questions (type of contract, occupation, management position, trainee status, and salary) were presented to the participants at baseline assessment. These questions were not presented again at subsequent assessments, although participants were asked whether they still worked for the same health care institution (and if not, the one at which they were currently employed). In addition to these questions, the primary and secondary outcomes and process variables were included at every assessment point.

Primary Outcome

The Perceived Stress Scale (PSS) [40] was the primary outcome of this study. It is a 10-item questionnaire that measures how unpredictable, uncontrollable, and overloaded the individual has felt their life to be over the previous month on a 5-point Likert-type scale. Scores range between 0 and 40, with higher scores reflecting higher levels of perceived stress. Cutoff points have been established to determine 3 categories of stress levels: low (0-13), moderate (14-26), and high (27-40). Our study made use of the Spanish adaptation [41], and the PSS for our sample showed very high internal consistency (α_{T1}=0.89 and $\alpha_{T2\text{-}T5}$=0.91).

Secondary Outcomes

The Patient Health Questionnaire-9 (PHQ-9) [42] is a 9-item scale that rates the frequency of depressive symptoms during the previous 2 weeks using a Likert-type scale (from 0=not at all to 3=nearly every day). The total score ranges between 0 and 27, with higher scores indicating higher severity of depression. The Spanish adaptation of the PHQ-9 was used for this study [43], and we observed good internal consistency in our sample (α_{T1}=0.83, α_{T2}=0.88, α_{T3}=0.86, α_{T4}=0.89, and α_{T5}=0.87).

XSL•FO
RenderX

The Generalized Anxiety Disorder-7 (GAD-7) [44] is a 7-item, self-report measure to assess the intensity of anxiety symptoms over the past 2 weeks. Using a 4-point Likert-type scale, the total score can range between 0 and 21, with higher values indicating more severe anxiety symptoms. The Spanish version of the GAD-7 [45] was used for this study, and excellent psychometric properties were observed in our sample (α_{T1}=0.89, α_{T2}=0.92, α_{T3}=0.90, α_{T4}=0.92, and α_{T5}=0.91).

The Brief Symptoms Inventory-18 (BSI-18) [46,47] is a 5-point Likert-type scale designed to offer rapid screening for the symptoms of psychological disorders (somatization, depression, and anxiety). Scores on the 18 items are summarized on the Global Severity Index, which ranges from 0 to 72, with higher scores reflecting more severe conditions. The Spanish version of the BSI-18 was used [48] and showed excellent internal consistency for our sample (α_{T1}=0.90, $\alpha_{T2\text{-}T3}$=0.92, α_{T4}=0.94, and α_{T5}=0.92).

Process Variables

In total, 5 process variables were evaluated at each assessment point: resilience, mindfulness, self-compassion, compassion for others, and acceptance. Resilience was measured using the Connor-Davidson Resilience Scale (CD-RISC) [49], a 10-item scale whose total score ranges between 0 and 40, with higher scores indicating higher levels of resilience. Mindfulness was assessed using the Five Facet Mindfulness Questionnaire-15 (FFMQ-15) [50], which includes 5 subscales: observing, describing, acting with awareness, nonjudging of inner experience, and not reacting to inner experience. Each FFMQ-15 subscale includes 3 items, scored on a Likert-type scale (1-5), and the average score is calculated (higher scores indicate higher levels of the mindfulness facet). Both self-compassion and compassion for others were assessed using the Sussex-Oxford Compassion Scales (SOCS) [51]; each scale consists of 20 items, and its score is calculated by adding the scores of its items (ranging between 20 and 100, with higher scores indicating higher levels of compassion). Finally, the Acceptance and Action Questionnaire-II (AAQ-II) [52] was used to evaluate acceptance as opposed to experiential avoidance. The scale presents 7 items scored on a 7-point Likert-type scale, and the total score ranges between 7 and 49, with higher scores indicating higher experiential avoidance (ie, lower acceptance).

For this study, the Spanish version of the CD-RISC [53], FFMQ-15 [54], SOCS [55], and AAQ-II [56] were used. All showed good or excellent psychometric properties for our sample ($\alpha \geq 0.80$ at every assessment point), except for FFMQ-observing (α_{T1}=0.74, α_{T2}=0.55, α_{T3}=0.70, and $\alpha_{T4\text{-}T5}$=0.74), FFMQ-describing ($\alpha_{T1,T2,\text{ and }T5}$=0.77), and FFMQ-nonreacting (α_{T1}=0.71, $\alpha_{T2\text{-}T3}$=0.58, α_{T4}=0.60, and α_{T5}=0.71).

Adherence to the MINDxYOU Program

Adherence to the intervention was only determined by assessments completed after the participants had been given access to the MINDxYOU program, in which they were asked to state (1) the number of modules they had completed (where they had previously completed the intervention, they were asked how often they had revisited the program in the previous 2 months), (2) an average number of days per week they had engaged with formal practice (including the exercises they performed and their duration), and (3) an average number of days per week they had engaged with informal practice (including the exercises they had performed). In addition, every time participants wanted to access a new session while on the program, they had to complete a brief form indicating how many days they had practiced the exercises that were presented in the previous session.

Data Analysis

First, we describe participant flow and compliance with the intervention. Frequencies and percentages were used to summarize the number of participants who completed all assessments, initiated the program, and completed at least 3 of the 4 modules. The chi-square test or ANOVA tests were conducted to assess between‐cluster differences as well as potential differences between (1) participants who dropped out and those who completed all the assessments, (2) participants who ultimately initiated the program and those who did not, and (3) the individuals who were considered to have completed the program and all the others.

Sociodemographic and clinical baseline data as well as intervention adherence-related data were described using means and SDs for continuous variables and frequencies and percentages for categorical variables. Chi-square tests and ANOVA were conducted to assess between-cluster differences in baseline characteristics.

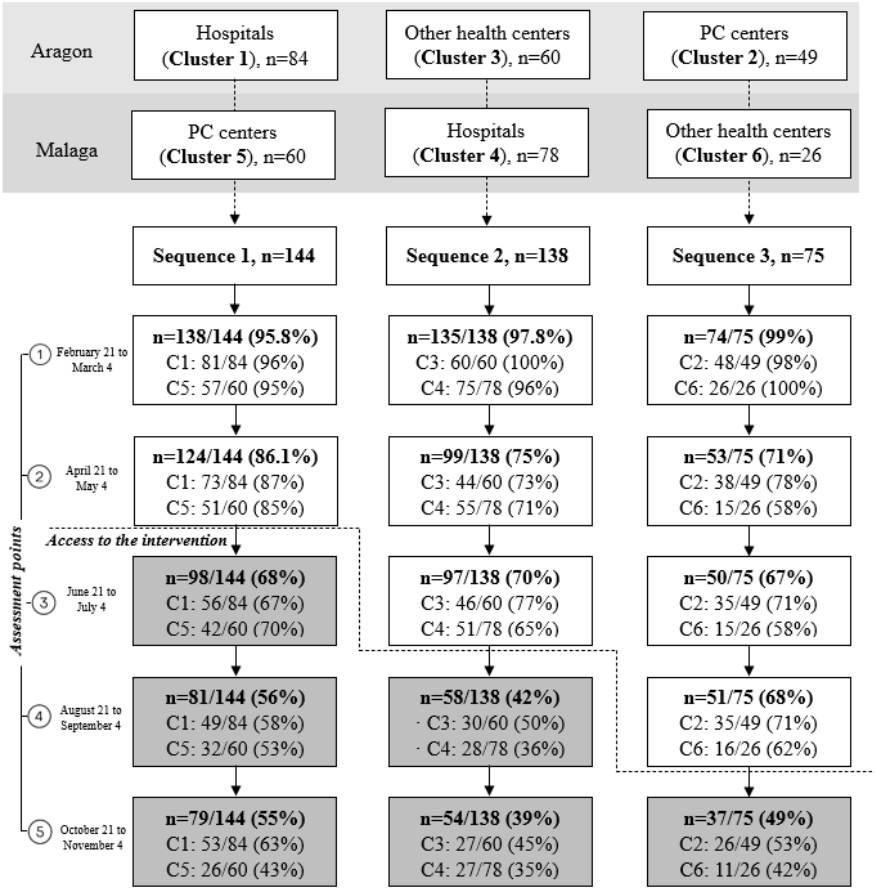
The primary analysis (the effects of the intervention on perceived stress) was performed using linear mixed-effects models with cluster-specific random effects and time-specific fixed effects. We adjusted the model to include the following baseline imbalanced covariates (covariate-adjusted analysis): cluster, age, education level, type of contract, occupation, trainee status, salary, and the baseline level of the outcome. A cluster-robust sandwich variance estimator with small-sample corrections was implemented to obtain bias-corrected SEs [57]. We report the effect estimate, SE, and 95% CI. These analyses were conducted following 2 different approaches: the intention-to-treat approach (all the study participants included) and the per-protocol approach (program noncompleters excluded in postintervention assessments). The same strategy was used to analyze the effects on secondary outcomes and process variables. In addition, for the primary outcome, intracluster analyses under both approaches (intention-to-treat and per-protocol approaches) were computed using 2-tailed Student *t* test, whereas Cohen *d* was used to estimate the effect size.

An α level of .05 was set, using a 2‐tailed test. For the primary analysis, a completely missing at random approach was chosen given the characteristics of the study design and the sample size. For the intracluster analyses, we initially used raw data; however, we later performed a simple imputation (mean of nearby points) to assess potential effects under both the intention-to-treat and per-protocol. We applied the Benjamini-Hochberg correction for multiple comparisons in every case other than the primary analysis, following the recommendations by Li et al [58]. This is a procedure to detect

XSL•FO
RenderX

false discovery designed to overcome the limitations that the other tests typically used have shown [59,60]. Data analyses were computed using SPSS (version 26.0; IBM Corp) and R (R Foundation for Statistical Computing) statistical software.

Ethical Considerations



The research ethics committee of the Autonomous Community of Aragon and the ethics and research committee of Northeast Malaga evaluated and approved the study protocol in July 2022 (PI22/341). All procedures performed in this study adhered to the 1964 Declaration of Helsinki and its most recent amendments (seventh revision, adopted by the 64th World Medical Association General Assembly, Fortaleza, Brazil). A signed informed consent was obtained from all participants after they were informed of the study procedures, potential risks, and their right to withdraw at any time from the study. The participants did not receive any compensation. The study ensured the confidentiality of the information collected by fully complying with the Spanish Data Protection and Digital Rights Act 3/2018 and the European Union's General Data Protection Regulation (GDPR). To maximize data protection, the technological infrastructure consisted of two independent systems accessing separate databases, ensuring the complete disaggregation of users' personal data from their clinical records. This study was registered in ClinicalTrials.gov on June 29, 2022 (NCT05436717), and this work follows the CONSORT (Consolidated Standards of Reporting Trials) extension for the stepped-wedge cluster randomized trial [61] and the CONSORT-eHEALTH checklist [62].

Results

Flow and Compliance

In total, 393 participants were included in the study, although 36 (9.2%) of them did not complete any assessment. Therefore, the study sample comprised 357 participants (Figure 1 for cluster distribution). Some significant differences (P<.05) were found between individuals who completed all the assessments (n=131, 36.7%) and those who did not (n=226, 63.3%; Multimedia Appendix 2). Participants in clusters 4 and 6 had a higher rate of assessment incompletion (χ^2_5=14.5; P=.001), as did those from Malaga (χ^2_1=9.8; P=.002).

Figure 1. Study flowchart. PC: primary care. C1-6: cluster 1-6.

As shown in Table 1, the MINDxYOU program was initiated by 64.1% (229/357) of the participants. After applying the Benjamini-Hochberg correction, a significantly higher proportion of participants who did not initiate the program was observed among those coming from Malaga (χ^2_1=9.9; P=.002) and clusters 4 and 6 (χ^2_5=19.9; P=.001; Multimedia Appendix 3). With regard to program completion, 48.9% (112/229 initiators) of the participants completed at least 3 modules, and 43.7% (100/229) completed all of them. Here, no significant differences were found when comparing completers with noncompleters (Multimedia Appendix 4). On average, initiators of the program completed 2.2 (SD 1.8) modules.

XSL•FO
RenderX

Table 1. Completion of the MINDxYOU program.

	Started the program, n (%)	Completed module 1, n (%)	Completed module 2, n (%)	Completed module 3, n (%)	Completed all 4 modules, n (%)
Cluster 1 (n=84)	65 (77)	45 (54)	42 (50)	35 (42)	31 (37)
Cluster 2 (n=49)	31 (63)	23 (47)	19 (39)	16 (33)	15 (31)
Cluster 3 (n=60)	42 (70)	29 (48)	24 (40)	21 (35)	18 (30)
Cluster 4 (n=78)	36 (46)	26 (33)	19 (24)	16 (21)	14 (18)
Cluster 5 (n=60)	41 (68)	26 (43)	20 (33)	20 (33)	18 (30)
Cluster 6 (n=26)	14 (54)	10 (38)	6 (23)	4 (15)	4 (15)
Total (N=357)	229 (64.1)	159 (44.5)	130 (36.4)	112 (31.4)	100 (28)

The 229 participants who initiated the program dedicated an average of 4.3 (SD 2.6) days to each session. After the intervention, participants (n=148) reported an average formal practice frequency of 3.3 (SD 1.5) days per week, with a mean duration of 18.8 (SD 11.6) minutes per exercise. Informal exercises were performed an average of 3.5 (SD 2) days per week. In the second postintervention assessment (clusters 1, 3, 4, and 5), participants (n=94) reported a formal practice frequency of 2.5 (SD 1.4) days per week, 15.25 (SD 10.2) minutes per exercise, and 3.3 (SD 1.9) days per week of informal practice. In the third postintervention evaluation (clusters 1 and 5, n=59), the frequency of formal practice remained at 2.6 (SD 1.7) days per week, 13.8 (SD 11.3) minutes per exercise, and 3.5 (SD 2.2) days per week of informal practice. No significant differences between clusters were observed in any case (P>.05 in all cases).

Baseline Characteristics

As shown in Multimedia Appendix 5, the sample comprised mostly women (297/347, 85.6%) who were middle aged (mean 45.01, SD 11.17) and married (260/347, 74.9%), and most had completed university-level studies (304/347, 87.6%). Some between-cluster differences were observed. Cluster 6 was younger (F_5=5.66; P<.001), and cluster 3 presented a lower education level (χ^2_{10}=68.8; P<.001).

Most participants were public-sector employees on permanent contracts (159/347, 45.8%), and the most common professions in our sample were physicians (147/347, 42.4%) and nurses (93/347, 26.8%). Only 15% (52/347) of participants occupied a management position at their institution, and 9.8% (34/347) were trainees for some health profession. Most (146/347, 42.1%) participants had a salary equivalent to between 1 and 2 times the minimum wage (between €1000 and €2000 per month; €1=US $1.04). Again, some between-cluster differences were observed. Cluster 6 had a very low number of functionaries (χ^2_5=97.3; P<.001) and physicians (χ^2_{25}=131.2; P<.001) compared to the other clusters; trainees were not represented in clusters 3 and 6 (χ^2_5=15.6; P=.008), and these clusters had a lower salary (χ^2_{15}=62.3; P<.001).

With regard to the clinical variables at baseline (Multimedia Appendix 5), our sample presented moderate levels of perceived stress, as indicated by the mean score in the PSS (mean 16.88, SD 6.33) and the fact that most (225/347, 64.8%) participants presented scores that fell under the moderate stress category (ie, 14-26 points of 40). Low levels of depression (PHQ-9: mean 6.25, SD 4.36), anxiety (GAD-7: mean 7.05, SD 4.23), and psychopathological symptoms (BSI-18: mean 12.34, SD 9.88) were observed. Participants showed a notable degree of resilience (CD-RISC: mean 27.31, SD 6.79), moderate levels of mindfulness facets (FFMQ-15 scores around 3), lower levels of self-compassion (SOCS-self: mean 53.53, SD 10.24) than compassion for others (SOCS-Others: mean 61.90, SD 8.77), and moderate-low levels of experiential avoidance, that is, moderate-high levels of acceptance (AAQ-II: mean 20.89, SD 8.33). Self-compassion (SOCS-self) was the only variable that showed significant between-cluster differences after applying the Benjamini-Hochberg correction (F_5=3.20; P=.008).

Effects on Perceived Stress

PSS preintervention scores were 16.63 (SD 6.89) and were reduced to 14.02 (SD 6.69) after the intervention. The change was significant under both analytical approaches (Table 2), although stronger under the per-protocol approach. Some of the covariates included in the model were found to be significant: the sequence in which the cluster was allocated, type of contract, occupation, salary, and baseline PSS level. While at baseline most participants referred to moderate stress (225/347, 64.8%) and fewer reported low stress (100/347, 28.8%), after the treatment these proportions reflected a general improvement: 51.3% (99/193) showed moderate stress and 46.6% (90/193) reported low stress. The intracluster analysis revealed that under the intention-to-treat approach (Multimedia Appendix 6), only cluster 1 experienced a significant pre- versus postintervention effect of moderate size (Cohen d=0.46), while a larger pre- versus second postintervention assessment effect was observed in clusters 1 (Cohen d=0.68) and 5 (Cohen d=0.62). These effects were maintained in subsequent assessments. Under the per-protocol approach, the same effects were observed with larger effect sizes (Multimedia Appendix 7). Figure 2 shows the evolution of perceived stress along the 5 assessment points for each cluster (intention-to-treat approach).

XSL•FO

Figure 2. The evolution of Perceived Stress Scale scores across the study assessments per cluster. Squares in grey (transparent) indicate the periods in which the participants had access to the intervention.

Effects on Secondary Outcomes and Process Variables

As shown in Table 2, the effects of the intervention in all the secondary outcomes (PHQ-9, GAD-7, and BSI) were significant according to the linear mixed-effects models under the intention-to-treat approach, except for BSI-anxiety. Certain covariates played a significant role in the models: the baseline level of the outcome, type of contract, occupation, and salary. Under the per-protocol approach, all the secondary outcomes, including BSI-anxiety, presented a statistically significant effect, and the effects of the covariates were maintained in all cases.

Some process variables experienced significant improvement during the intervention phases: under the intention-to-treat approach, resilience (CD-RISC), the mindfulness facets of nonjudging and not reacting to the inner experience (FFMQ-15), and self-compassion (SOCS-self) presented significant effects. These were also observed under the per-protocol approach, along with significant effects on the mindfulness facets of observing and acting with awareness (FFMQ). All these effects were in the expected direction (improved during the intervention phase), and some covariates presented significant effects in each case (Table 2): baseline level of the outcome, the sequence in

XSL•FO
RenderX

which the cluster was allocated, type of contract, occupation, salary, age, and education level.

Discussion

Principal Findings

The MINDxYOU program led to a significant reduction in health professionals' perceived stress. Given the implications of sustained stress on these professionals' well-being, this reduction can have a notable impact on preventing mental health issues, such as burnout syndrome and its associated health and societal consequences [9-13]. This finding is in line with those of previous studies conducted on smaller samples in which self-guided web-based programs implementing third-wave psychotherapy contents produced significant improvements in health professionals' stress. Barrett and Stewart [63] reported that a web-based acceptance and commitment therapy program was as effective as a web-based CBT program, and the mindful and self-compassion program was superior when compared to a waitlist control group [24]. Similarly, 2 uncontrolled studies observed intragroup effects of similar interventions [64,65]. As far as the duration of the effects of the MINDxYOU program is concerned, these were maintained in those clusters where postintervention effects were found (clusters 1 and 5) across subsequent assessments, which suggests that the program's effects might not be limited to the short term. Previous studies reported similar findings [64,66], but methodologically sound studies are required to ensure the long-term benefits of self-guided web-based programs in this population.

Likewise, the program produced significant improvements in mental health–related outcomes. Anxiety and depressive symptomatology were reduced after the intervention, which is in line with previous eHealth CBT-based interventions [67,68] and third-wave psychotherapies [69,70]. However, the effects of such interventions on somatic symptoms have not been as widely studied in this population, despite the numerous studies that reported increased somatization in health professionals during the COVID-19 pandemic [6]. The MINDxYOU program produced a significant reduction in somatic symptoms, which is in line with studies testing eHealth interventions on patients with somatic symptom disorder [71,72], but these findings should be extended in further studies conducted on health professionals. Considering the high frequency with which health professionals experience anxiety, depressive, and somatic symptoms, especially following the COVID-19 pandemic [3-6], the effectiveness of this intervention in reducing these symptoms represents a significant contribution to mental health promotion and supports its implementation in real-world settings.

It is hypothesized that improvements in perceived stress, depressive symptomatology, anxiety, and somatization might have been mediated by the changes produced in process variables, such as resilience, different mindfulness facets, and self-compassion. The MINDxYOU program aimed to promote mindfulness, that is, present-focused nonjudging attention, and self-compassion, that is, a kind attitude toward the self, both associated with reductions in anxiety and depression [73,74]. Third-wave psychotherapies have also been found to produce a significant increase in resilience [21], although not as clearly in the case of health professionals [75]. Interestingly, resilience mediates the association between mindfulness and self-compassion with depressive symptomatology [76], which highlights the inseparable nature of our study outcomes. We will be exploring the mediation paths of the MINDxYOU program in a future work to complement these findings. It is worth noting that other process variables, such as compassion for others and acceptance, did not experience significant improvements, despite the observation in previous studies that mindfulness-based interventions and eHealth programs might foster these outcomes [77,78]. Therefore, it could be hypothesized that our sample's relatively high baseline degrees of acceptance and compassion for others produced a ceiling effect.

All in all, our findings seem to add evidence to the potential of self-guided, third-wave psychotherapy–based eHealth interventions to help health professionals with their stress and improve their mental health. This improvement can significantly impact job satisfaction and work performance, ultimately benefiting the entire population [33]. The self-guided format offers high levels of availability, flexibility, and convenience [26,27], and third-wave psychotherapies have widely proved their effectiveness on numerous health outcomes and in different populations, including health professionals [18,19,23]. Nevertheless, it should be noted that the effects of the program on every outcome were stronger when considering the per-protocol approach (the sample of intervention completers). Different studies have observed a significant association between an eHealth program's dose and its effects on stress, among other outcomes [24,66,79,80], which highlights the importance of fostering treatment adherence.

In this regard, it is noteworthy that some differences were found between the individuals who initiated the program and those who did not; these reflect that some clusters were more active than others, suggesting different degrees of motivation toward the intervention. Moreover, program completion also showed some differences between clusters. Therefore, it is hypothesized that waiting time (the time between the baseline evaluation and accessing the program) may have been a barrier for some participants in our study, as also identified by previous works [81]; the stepped-wedge design meant that while some participants (clusters 1 and 5) accessed the intervention after a relatively short time (8 weeks), others had to wait up to 16 weeks (clusters 3 and 4) or 24 weeks (clusters 2 and 6). Furthermore, clusters 3 and 4 were given access to the intervention over the summer, which was probably not helpful for adherence as it coincided with the vacation period. In a future study, we will explore how these and other factors, such as common job stressors (eg, workload and work-family balance) [82], could have hindered adherence to the MINDxYOU program.

Hence, the study design might have been a hindrance to part of our sample initiating the program or continuing with it. Once the intervention had commenced, adherence to the program was moderate. Approximately 1 (50%) in every 2 participants who started the MINDxYOU program completed it, and they reported notable indicators of autonomous practice (around 3 days of formal practice per week, 19 minutes per practice, and a similar frequency for informal practice). To our knowledge, no previous

XSL•FO
RenderX

studies testing the effectiveness of self-guided, third-wave psychotherapy–based web-based interventions have reported the amount of meditation practice; however, a recent systematic review concluded that patients with chronic pain who are undergoing in-person programs practiced an average of 4 days per week and 27 minutes per exercise [83]. These findings could suggest that web-based interventions might have a smaller yet sufficient impact on autonomous practice compared to third-wave psychotherapy programs with a conventional in-person format, but this remains a hypothesis to be explored in the future.

With regard to program use, MINDxYOU was accessed by two-thirds (229/357, 64.1%) of our sample with an average of 2.2 (SD 1.8) modules completed (out of 4), which meant logging into the web-based platform at least 4 times, because each module contained 2 sessions. This can be considered an acceptable rate of use and higher than that observed in the few studies that have previously reported on this aspect. Ketelaar et al [84] found that only 20% of their participants logged into their eHealth programs at least once, and none completed the intervention. Dutton and Kozachik [85] and Hersch et al [86], who tested the 8-week self-guided BREATHE web-based intervention on nurses, observed an average of 2 to 2.5 logins. Kemper et al [87] and Kemper and Khirallah [88] found that participants engaged with a median of 3 modules out of 12 (mind-body skills training).

The weekly contact with the research team may have been a reason for the notable use of the MINDxYOU program. This contact was included as part of the intervention based on the recommendations of previous studies [23,89] to prevent low adherence rates. However, emails and text messages, which were the most common form of contact option chosen, were often one-sided (ie, unanswered by the participant), which leaves room to doubt whether these contacts were useful in their function of enhancing adherence to the program. It could also be argued that the specific nature of the MINDxYOU program, which was designed particularly for health professionals, could be a reason for its good rates of use. To our knowledge, only 5 interventions with specific contents for health professionals have been tested [85,86,90-93], with heterogeneous effects, and only the BREATHE program reported its use, which was relatively low, as previously explained. Therefore, the benefits of implementing specific interventions for this population over generic ones remain a topic of debate and will require further studies.

Strengths and Limitations

This study is part of the MINDxYOU project, which focuses on the well-being of health professionals, a topic that gained a notable degree of attention from researchers during the COVID-19 pandemic but is now at risk of again being underestimated and understudied now that the COVID-19 pandemic is over. This work reports part of the findings of the project that will need to be complemented with others (eg, mediation analysis, cost-effectiveness of the intervention, and implementation in health facilities). Altogether, these findings will contribute to the understanding of health professionals' needs and address them using innovative, evidence-based interventions.

Another notable strength of this study is its sample size. An effort was made to recruit almost twice the sample that was required according to the sample size calculation [33], which turned out to be very valuable considering the high rate of attrition during the study. While previous randomized controlled trials have tested the effectiveness of eHealth programs on health professionals, only 1 study was conducted on a larger sample [93]; however, no significant effects of the intervention—a mobile app (PsyCovid)—were found compared to the control group, which is in line with other studies testing mobile apps [23]. Our study analyzed the effects of a self-guided web-based intervention, a format that has shown good results in previous studies [24,63-65], and was developed based on previously validated interventions but with a special focus on health workers' stressors, which was suggested to be an important aspect for increasing adherence to the program [23,29]. In addition, our study provides data on adherence to the intervention in terms of frequency and duration of autonomous practice, which is a valuable indicator of the degree to which individuals (in this case, health professionals) can implement what they learn in self-guided web-based interventions.

Nevertheless, this study does have some notable limitations. First, the study may have been affected by self-selection bias, as only individuals who expressed interest in the project, potentially due to experiencing certain levels of stress or having a particular interest in the meditation techniques offered by the intervention, were eligible to participate. In addition, some of the criteria that were used to include or exclude potential participants may have affected the representativeness of our sample. On one hand, individuals diagnosed with a severe mental health condition (depression with active suicidal ideation, bipolar disorder, etc) were excluded and redirected to a specialized service. By contrast, having prospects of staying at the same workplace for the following 6 months was an inclusion criterion because it was considered relevant to studying the program implementation, but this led to health professionals with unstable employment situations being excluded. Job instability is clearly associated with stress and, added to the exclusion of individuals with severe mental health conditions, this could partially explain the relatively low levels of psychopathological symptoms (anxiety, depression, and somatization) in our sample, which probably had an overrepresentation of healthy individuals with stable employment. Similarly, the study was restricted to health professionals working in 2 Spanish regions, and generalizations in this regard could also be limited as each autonomous region in Spain manages its own health and social care provision. Therefore, regional differences may exist in terms of health resources or expenditure, which could undoubtedly affect the day-to-day activities of health professionals in each region and cater to their particular needs.

It should also be noted that our stepped-wedge cluster randomized design presented some limitations. The first one is that the clusters were not balanced in terms of sample size, which was due to the type of workplace. While hospitals employ a large number of health professionals, primary care centers

XSL•FO
RenderX

and nursing homes tend to have smaller staffing needs. Moreover, because of this design, even though every study participant was assessed both before and after the intervention, not all of them (ie, clusters 2 and 6) were assessed again after the first postintervention evaluation. This hinders the extraction of conclusions regarding the medium- or long-term effects of the intervention, which is a very important aspect to be considered in future studies. The different waiting times for each cluster can also be considered a limitation because it could have negatively affected the motivation of some study participants toward the intervention, hindering adherence. In this regard, it is important to note that a notable portion of the study participants (128/357, 35.9%) did not initiate this self-guided program, which may reflect the presence of barriers (eg, multitasking, heavy workloads, and constant evaluations) that will be explored in future research. Another limitation of this study is the use of self-reported measures, as these imply a certain bias, although most of them presented strong internal validity at the different assessment points. Complementing the assessment with some physiological outcomes could be considered in future studies.

Conclusions

Our findings support the effectiveness of the MINDxYOU program for reducing stress and promoting mental health (ie, reducing depressive, anxiety, and somatic symptoms and increasing resilience, mindfulness facets, and self-compassion) in health professionals. The intervention dose seems to play a significant role in its effects, which highlights the need for increased adherence to the program. Although we hypothesize that the study design might have hindered adherence in some cases, program use was notable compared to that reported by previous studies testing similar eHealth programs, which could be partially due to the inclusion of a small degree of guidance (ie, weekly contact from the research team during the intervention). These findings will need to be complemented with the study of the cost-effectiveness of the MINDxYOU program and its implementation in different health facilities to consider its potential as an efficient and reliable tool for delivery in Spanish health care institutions.

Acknowledgments

AP-A is grateful to a Sara Borrell postdoctoral contract (CD20/00181) from the Instituto de Salud Carlos III (Spanish Ministry of Science and Innovation), which allowed him to collaborate on this project. AM-B is grateful for the Margarita Salas postdoctoral fellowship at the University of Zaragoza, funded by the NextGeneration EU, which allowed her to collaborate on this project, and with the Institute for Health Research Aragon. The study has been externally funded, after undergoing peer review, by the Instituto de Salud Carlos III, dependent on the Spanish Ministry of Science and Innovation, through a grant for health-related research projects (PI21/01328 and PI21/01338) and the European Regional Development Fund (ERDF) “Another way to make Europe.” The funder plays no role in the study design, data collection and analysis, decision to publish, or manuscript preparation.

Abstract

Background: Internet use exhibits diverse trajectories during adolescence, which may contribute to depressive symptoms. Currently, it remains unclear whether the association between internet use trajectories and depressive symptoms varies between urban and rural areas.

Objective: This study aimed to investigate the association between internet use trajectories and adolescent depressive symptoms and to explore variation in this association between urban and rural areas.

Methods: This longitudinal study used 3-wave data from the 2014-2018 China Family Panel Study. Weekly hours of internet use and depressive symptoms were measured using self-reported questionnaires. Latent class growth modeling was performed to identify the trajectories of internet use. Multivariable logistic regressions were used to examine the association between internet use trajectories and depressive symptoms, stratified by rural and urban residence.

Results: Participants were 2237 adolescents aged 10 to 15 years at baseline (mean age 12.46, SD 1.73 years). Two latent trajectory classes of internet use were identified: the low-growth group (n=2008, 89.8%) and the high-growth group (n=229, 10.2%). The high-growth group was associated with higher odds of depressive symptoms (OR 1.486, 95% CI 1.065-2.076) compared to the low-growth group. In the stratified analysis, the association between internet use trajectories and depressive symptoms was significant solely among rural adolescents (OR 1.856, 95% CI 1.164-2.959).

Conclusions: This study elucidates urban-rural differences in the associations between trajectories of internet use and adolescent depressive symptoms. Our findings underscore the importance of prioritizing interventions for rural adolescents' internet use behaviors to mitigate negative effects on their mental health.

internet use; trajectory; depressive symptoms; adolescent; urban; rural

Introduction

Adolescence is a vulnerable period for developing depressive symptoms as a result of substantial biological and social transitions [1]. In China, the prevalence of depressive symptoms among adolescents has notably increased in recent decades [2,3]. A recent meta-analysis shows that approximately 19.9% of Chinese adolescents experience depressive symptoms [4]. The

XSL•FO
RenderX

onset and persistence of depressive symptoms during this crucial developmental stage can result in a range of adverse outcomes in adulthood, such as functional impairment, suicidal self-harm, and mental health difficulties [5]. Therefore, early identification and intervention for depressive symptoms are imperative.

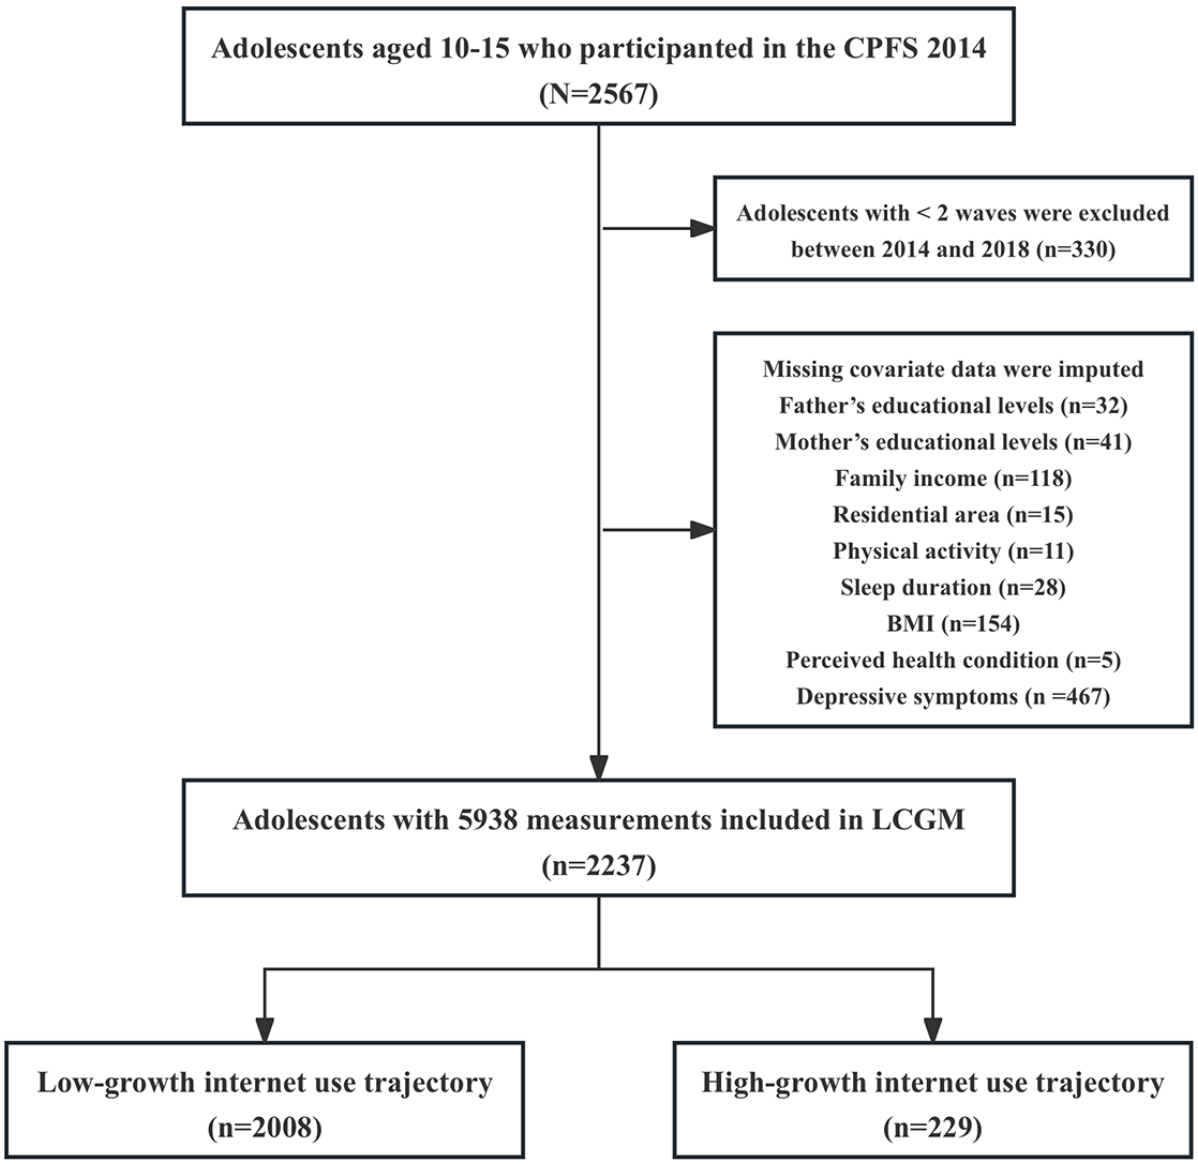
In recent years, the internet has become an essential tool for adolescents, widely used for information acquisition, social interaction, and entertainment [6]. According to the 2021 National Report on Internet Use by Minors, China has approximately 191 million internet users younger than 18 years, with a penetration rate of 96.8% [7]. Adolescents engage in various forms of internet use, including accessing online resources for educational purposes, such as completing school assignments [8]. Moreover, recreational and social activities, including video streaming, online gaming, and social networking, are also prevalent among this age group [9]. However, the widespread use of the internet has raised concerns about its effects on adolescent health [10-12]. Increasing evidence indicates a positive correlation between the duration of internet use and depressive symptoms in adolescents, with entertainment-related activities showing more pronounced negative effects [13-15]. In response, the Chinese government introduced regulations in 2019 to limit online gaming to 1.5 hours on weekdays and 3 hours on weekends to curb excessive internet use [16]. More recently, the Cyberspace Administration of China proposed further restrictions, recommending that adolescents aged 8 to 15 years be limited to 1 hour of daily mobile internet use, while those aged 16 to 18 years should not exceed 2 hours [17].

Lifestyle behaviors undergo dynamic changes during adolescence, characterized by a progressive rise in internet use as adolescents mature [18]. A longitudinal study of participants with a baseline age of 9.9 years reported significant increases in screen-based activities over 4 years: social media use rose from 0.5 to 2.5 hours per day, and video gaming from 0.9 to 2 hours per day, indicating an upward trajectory of internet use during early adolescence [19]. These evolving lifestyle patterns are well-established predictors of mental health outcomes [20]. Additionally, internet use may follow diverse subgroup trajectories within the overall developmental trend. For example, Yu and Park [21] used growth mixture modeling to classify South Korean adolescents into 4 distinct internet use trajectories: high stable, high quadratic, moderate stable, and low stable. Another study identified 2 subgroups: one with a sharp increase in internet use (drastically increasing group) and another with a more gradual rise (gradually increasing group), capturing varying rates of increase during adolescence [22]. These trajectories are associated with different risks for health outcomes [21,23]. However, whether internet use trajectories can predict depressive symptoms among adolescents remains unclear.

Furthermore, the impacts of internet use among adolescents may vary between rural and urban areas. Traditionally, rural adolescents have limited access to internet devices and engage in fewer online activities than their urban counterparts [24]. With the increasing penetration rates of the internet in recent years, the urban-rural gap has narrowed, with adolescents in rural areas experiencing a faster increase in screen time [25]. Consequently, the trajectories of internet use duration among rural and urban adolescents may differ over time. On the other hand, rural adolescents may face greater challenges due to a lack of parental supervision, as many of their parents migrate from rural to urban areas for work [7,26]. This absence of oversight could exacerbate the negative effects of excessive internet use. Therefore, it is essential to understand the varying associations between internet use trajectories in rural and urban adolescents and their mental health outcomes, which can offer empirical references for preventing adolescent depressive symptoms.

To date, the majority of research in China regarding the impact of adolescent internet use on mental health has focused on single regions, overlooking potential urban-rural differences across areas. This study seeks to address this knowledge gap by using nationally representative data for adolescents in 2014, 2016, and 2018. Our primary objective is to investigate the relationship between internet use trajectories throughout adolescence and depressive symptoms and to explore whether this relationship varies between urban and rural areas.

Methods



Study Sample and Procedure

This longitudinal study used data from the China Family Panel Study (CFPS), which covers populations from 25 provinces, municipalities, and autonomous regions in China. The CFPS uses a multistage sampling approach with implicit stratification based on urban-rural distinctions and regional socioeconomic status. Using a probability proportional to size sampling strategy, 32 streets and townships from Shanghai and 144 districts and counties from the other 24 provinces were selected as primary sampling units. Subsequently, 640 communities were randomly chosen from these units, and 25 households were systematically sampled from each community. The baseline survey in 2010 collected data from 33,600 adults and 8990 children across 14,960 families, who were invited to participate in follow-up surveys every 2 years. These surveys gathered comprehensive information on participants' economic conditions, education, lifestyle, family relationships, and physical and mental health.

For this study, we used 3 waves of data from the 2014-2018 cycle of the CFPS to ensure consistent measurement of internet use duration. In 2014, the sample included 2567 adolescents aged 10-15 years, of whom 1491 completed surveys in both the 2016 and 2018 cycles. By 2018, the participants' age ranged from 14 to 19 years. To capture longitudinal developmental patterns, adolescents with self-reported data from at least 2 of the 3 waves were included, resulting in a final sample of 2237 participants. The flow of participants in this study is illustrated in Figure 1.

Measurements

Internet Use

Internet use was measured using a single item: "In general, what is the total amount of time you spend online during your leisure time per week?" This variable is designed to measure leisure time spent online, with values ranging from 0 to 168 hours.

Depressive Symptoms

The Center for Epidemiologic Studies Depression (CESD) scale was used to assess depressive symptoms. The CESD evaluates a range of symptoms, including sadness, loss of interest, changes in appetite and sleep, difficulties in thinking or concentration, feelings of guilt, fatigue, movement changes, and suicidal ideation. Each item is rated on a 4-point scale (0="not at all or less than 1 day in the past week" to 3="nearly every day for 2 weeks"). To reduce respondent burden, in 2016, one-fifth of participants were randomly selected to complete the 20-item CESD (CESD-20), while the remaining four-fifths completed the 8-item version (CESD-8). All participants completed the CESD-8 in 2018 [27]. The CFPS considered the 2 groups in 2016 equivalent in depressive symptom distributions and used the equipercentile equating method to transform CESD-8 scores into CESD-20 scores, ensuring consistency and comparability across survey waves [27]. This approach aligns scores from the 2 versions by matching them to the same percentile rank [28]. The total CESD-20 score ranges from 0 to 60, with scores ≥16 indicating the presence of depressive symptoms based on established cutoffs [29]. CESD-8 and CESD-20 have demonstrated good psychometric properties in adolescents [30,31].

Covariates

Demographic variables included age (10-15 years in 2014), sex (male or female), parental educational levels (illiterate or semiliterate; primary school; junior high school; senior high

XSL•FO
RenderX

school; college, university, or above), family income, residential area (rural or urban), and grandparental caregiving. Grandparental caregiving was determined based on responses to 2 questions: "Who takes care of the child during the day?" and "Who takes care of the child at night?" If either question was answered with "grandparents," the child was classified as receiving grandparental care. Lifestyle and health-related variables included physical activity, sleep duration, BMI, and perceived health condition. Physical activity was assessed using a single item: "Including participation in physical education classes, what was the total amount of time you spent participating in physical activity in the past week?" Sleep duration was calculated as the time between falling asleep and waking up. BMI was determined by dividing objectively measured weight by height squared (kg/m^2). Perceived health condition was assessed using a single item, "How do you perceive your health condition?" with responses ranging from 1 ("extremely healthy") to 5 ("unhealthy").

Baseline psychological distress was measured using the Kessler Psychological Distress Scale (K6). The K6 assesses the frequency of 6 symptoms: feeling nervous, hopeless, restless or fidgety, worthless, depressed, or that everything requires an effort [32]. Possible responses to the 6 items range from 0 ("none of the time") to 4 ("all of the time"), yielding a total score of 0-24. The K6 has demonstrated good psychometric properties in adolescents [33,34].

Statistical Analysis

The statistical analysis involved a 2-step procedure. In the first step, we conducted latent class growth modeling (LCGM) to determine trajectories of internet use across the 3 waves using Mplus (version 8.3; Muthén & Muthén). LCGM is a technique that identifies subgroups with distinct developmental patterns within a population over time [35]. With the 3-wave data, both linear and quadratic models were fitted to determine the optimal number of latent trajectory classes. The best-fitting model was determined based on the Akaike information criterion (AIC), Bayesian information criterion (BIC), sample size–adjusted BIC (aBIC), entropy, the Lo-Mendell-Rubin likelihood ratio test (LMR), and the bootstrapped likelihood ratio test (BLRT). Lower values of AIC, BIC, and aBIC indicate a better model fit. Higher entropy represents better classification accuracy. A significant *P* value ($P<.05$) for LMR and BLRT in a k-class model suggests that the model is better than the k–1 class model. Further, the sample size was taken into account, with at least 5% of the total population required in each class to define a meaningful latent entity [36].

In the second step, multivariable logistic regressions were conducted within the best-fitting model to examine the associations between internet use trajectories and distal outcomes. Each individual was assigned to their most likely class based on the highest posterior probability estimate, which was then used as the independent variable. The outcome variable was depressive symptoms in 2018. Three regression models were constructed. In model 1, adjustments were made for baseline K6 scores. Model 2 included additional demographic covariates, and model 3 further adjusted for lifestyle and health-related covariates. Stratified analysis was performed based on urban and rural classifications.

The Little missing completely at random (MCAR) test indicated that missing data for internet use followed an MCAR pattern ($\chi^2_9=6.616$; $P=.68$). Therefore, missing data on internet use were handled using the robust full information maximum-likelihood estimation approach [37]. Missing data on covariates and the distal outcome were imputed using the *missForest* function in R (R Project for Statistical Computing), a method capable of handling both continuous and categorical variables [38]. We imputed missing values for the father's educational level (n=32, 1.4%), mother's educational level (n=41, 1.8%), family income (n=118, 5.4%), grandparental caregiving (n=13, 0.6%), residential area (n=15, 0.6%), physical activity (n=11, 0.5%), sleep duration (n=28, 1.2%), BMI (n=154, 7.1%), perceived health condition in 2014 (n=5, 0.2%), and depressive symptoms in 2018 (n=467, 21.5%).

Ethics Approval

The Biomedical Ethics Review Committee of Peking University approved the study (IRB00001052-14,010). All eligible participants provided informed consent. The questionnaire was anonymous and did not collect any identifying information, such as name or address. Eligible participants were given CN ¥20-CN ¥60 (US $3.26-US $9.77) in cash as compensation.

Results

Descriptive Statistics

Table 1 presents the characteristics of the 2237 participants. The sample consisted of 1067 (47.7%) girls and 1170 (52.3%) boys, with a mean age of 12.46 (SD 1.73) years in 2014. Approximately half of the participants' parents had a high school education or higher (father's educational level: n=1187, 53.1%; mother's educational level: n=938, 41.9%). The median annual household income was CN ¥39,000 (IQR CN ¥20,100-CN ¥61,200; US $3272-US $9962.60). A total of 60.4% (n=1351) of the participants were from rural areas, and 17.3% (n=386) were cared for by their grandparents. The median weekly hours of internet use were 0.0 (IQR 0.0-3.0) in 2014, 3.0 (IQR 0.0-8.0) in 2016, and 7.0 (IQR 2.0-20.0) in 2018. In 2018, the prevalence of depressive symptoms was 19.8% (n=444). CESD-20 scores in 2018 were positively correlated with K6 scores in 2014 (Spearman $\rho=0.166$; $P<.001$).

LCGM Analysis

Table 2 presents the fit indices from the LCGM analysis for models with 1-4 trajectory classes. First, linear models were fitted. Reductions in AIC, BIC, and aBIC were observed across 1- to 4-class models. While both the LMR and BLRT statistics favored the 3-class model over the 2-class model, the latter exhibited higher entropy (0.909) with its smallest group >5%. Consequently, the 2-class model was selected as the best-fitting linear model. Subsequently, quadratic models were fitted, showing a similar pattern in fit indices to the linear models. The AIC, BIC, and aBIC values indicated an improvement in model fit upon adding the quadratic term. Therefore, the 2-class quadratic model was identified as the final optimal model of internet use trajectories.

Figure 2 shows the 2 latent trajectory classes of internet use. Class 1 (89.8%) is labelled the “low-growth group,” representing the majority of adolescents who, on average, had relatively short internet use duration in 2014 (intercept=2.723; P<.001) and experienced gradual growth over 4 years (slope=1.080; P=.01; quadratic term=0.998; P<.001). Class 2 (10.2%) is labeled the “high-growth group,” characterized by initially longer average internet use duration (intercept=8.421; P<.001) and rapid growth until 2018 (slope=20.183; P=.008; quadratic term=–1.293; P=.74).

There were statistically significant differences across the trajectory classes in the distributions of age, parental educational level, annual family income, and residential area (Multimedia Appendix 1, Table S1). Specifically, urban participants were more likely to belong to the low-growth group compared to their rural counterparts.

Figure 2. Latent trajectory classes of internet use from 2014 to 2018.

Association Between Trajectories and Depressive Symptoms

The percentage of adolescents with depressive symptoms in 2018 was 19.2% (385/2008) in the low-growth group and 25.8% (59/229) in the high-growth group. The difference in the percentages of depressive symptoms between the 2 groups was 6.6% (95% CI 1.1%-12%). Table 3 presents the results from multivariable logistic regressions examining the association between internet use trajectories and depressive symptoms. After adjusting for baseline psychological distress (model 1), the high-growth group was associated with higher odds of

XSL•FO
RenderX

depressive symptoms compared to the low-growth group (OR 1.460, 95% CI 1.062-2.008; *P*=.02). The association remained significant after further adjustment for demographic, lifestyle, and health-related variables (model 3), with the high-growth group showing higher odds of depressive symptoms (OR 1.520, 95% CI 1.090-2.120; *P*=.01).

[d]Not applicable.

When stratified by residential area, the prevalence rates of depressive symptoms were 18.7% (232/1241) in the low-growth group and 28.2% (31/110) in the high-growth group among rural participants. The difference in the percentages of depressive symptoms between the 2 groups was 9.5% (95% CI 1.8%-17.2%). Results from the multivariable logistic regression indicated that the high-growth group was associated with higher odds of depressive symptoms among rural participants (OR 1.853, 95% CI 1.162-2.955; *P*=.01). Among urban participants, the prevalence rates were 19.9% (153/767) for the low-growth group and 23.5% (28/119) for the high-growth group. The difference in the percentages of depressive symptoms between the 2 groups was 3.6% (95% CI –4.2% to 11.4%). In the multivariable logistic regression, the association between internet use trajectories and depressive symptoms was not significant among urban participants (OR 1.124, 95% CI 0.686-1.840; *P*=.64).

Sensitivity Analysis

We performed a sensitivity analysis to assess the robustness of our findings (Multimedia Appendix 1, Table S2). This analysis included additional adjustments for the CESD-20 scores in 2016. The results were consistent with the main analysis, with the association between internet use trajectories and depressive symptoms remaining significant among rural participants.

Discussion

Principal Findings

In this nationally representative study using data from the CFPS, 2 latent trajectory classes of internet use were identified among Chinese adolescents aged 10 to 19 years: a low-growth group (89.8%) and a high-growth group (10.2%). After delineating these distinct trajectories, we examined their associations with depressive symptoms and found that the high-growth group was associated with higher odds of depressive symptoms. Furthermore, our stratified analysis revealed variations in this association based on residential area. Specifically, while the association between trajectories of internet use and depressive symptoms remained significant among rural adolescents, it was not observed among their urban counterparts.

In this study, we observed a notable increase in the duration of internet use among adolescents over 4 years. This trend aligns with previous research indicating that adolescent internet use intensifies with age [18]. Zhu et al [39] found that adolescents tend to allocate more time to chatting or browsing the internet as they age. This increase in internet use among adolescents can be linked to the popularity of social media platforms, as well as their inclination toward social interaction and the development of virtual identities [39]. Furthermore, our analysis revealed heterogeneous developmental patterns within this trend,

XSL•FO
RenderX

with 89.8% of adolescents exhibiting gradual growth in their internet use duration. In comparison, the remaining 10.2% increased their internet use to an average level approximately 5 times the baseline by the end of the follow-up. The diverse developmental patterns of these trajectories underscore the importance of early identification of excessive internet use. Understanding the contextual drivers of internet use behaviors is essential for altering the upward trajectory.

The high-growth group was associated with higher odds of depressive symptoms compared to the low-growth group. Our findings align with prior longitudinal research indicating that adolescent internet use can act as a risk factor for developing depressive symptoms [40]. However, previous studies have largely focused on static measures of internet use levels without examining how internet use evolves during adolescence. This study contributes to the existing evidence by demonstrating how trajectories of internet use can predict subsequent depressive symptoms. Various explanations may account for the observed association between internet use and depressive symptoms. For example, internet use may affect adolescents' mental well-being by reducing time spent on physical activity and sleep [13,41]. However, even after adjusting for lifestyle factors, the association remained significant in this study, suggesting that time reallocation alone may not fully explain the relationship. Another possibility is that excessive internet use leads to reduced face-to-face interaction [42] and worsened academic performance [43], thereby increasing the risk of depressive symptoms among adolescents.

This study identified an urban-rural difference in how internet use trajectories were associated with depressive symptoms, specifically affecting adolescents residing in rural areas. Previous research has consistently highlighted the adverse effects of internet use on the mental well-being of rural adolescents in China [44,45]. For example, Zhou and Ding [46] examined the impacts of internet use across diverse adolescent groups and found stronger associations with mental health outcomes among those from less-developed regions. However, to our knowledge, this study is the first to reveal disparities between urban and rural adolescents in the impacts of long-term changes in internet use on depressive symptoms. Although rural adolescents showed a lower proportion of rapidly increasing internet use than their urban counterparts, this trajectory had a more pronounced effect on their mental health.

The primary factor driving urban-rural differences may be the insufficient parental supervision commonly experienced by rural adolescents. Only 38.3% of rural underage internet users report having their internet use regularly restricted by parents [7]. While grandparents in rural areas often provide caregiving in the absence of parents, their limited educational attainment and reliance on traditional caregiving practices may weaken their ability to effectively monitor adolescents' internet use [47,48]. This lack of supervision can increase the likelihood of internet addiction, cyberbullying victimization, and engagement in high-risk online behaviors [49-51], potentially contributing to depressive symptoms. Additionally, individuals in rural areas with lower socioeconomic status often face limited social resources and reduced social support, which may amplify the association between internet use and depressive symptoms [52]. Rural schools, for example, tend to place less emphasis on internet literacy and education, resulting in lower awareness of healthy internet use practices [53,54]. The insufficient guidance may further heighten the risks to rural adolescents' mental health.

Implications

This study provides valuable insights into the distinct trajectories of internet use and their associations with adolescent depressive symptoms. The varying initial levels displayed by the trajectories in early adolescence highlight the critical need for early identification of excessive internet use. Given the demographic differences observed in this study, more attention is warranted to adolescents from lower socioeconomic backgrounds and rural areas.

The urban-rural divide in the association between internet use trajectories and depressive symptoms further emphasizes the importance of prioritizing interventions for rural adolescents. Previous research has shown that rural adolescents in China report higher levels of depressive symptoms compared to their urban peers [55]. Our findings suggest that rural adolescents are particularly vulnerable to the adverse effects of internet use, potentially widening existing mental health disparities between urban and rural areas. Effective interventions for rural adolescents should equip them with essential internet use skills, which can be fostered through enhanced parental supervision or integrated into school education programs. Additionally, parents should serve as positive role models by dedicating more time to engaging in outdoor activities with their children, providing alternatives to excessive screen time and encouraging a balanced lifestyle.

Limitations

This study has several limitations. First, this study relied on self-reported measures of internet use and depressive symptoms. Although the CESD has demonstrated robust psychometric properties among adolescent populations [30,31], self-reported scales are subject to social desirability bias. Moreover, participants may inaccurately report their internet use due to recall bias, introducing potential measurement errors that could attenuate or exaggerate the observed associations between internet use and depressive symptoms. Future research could benefit from incorporating objective measures of internet use and clinically validated tools for assessing depressive symptoms to enhance the reliability of findings. Second, the CFPS did not assess depressive symptoms in 2014. However, baseline psychological distress was controlled using the K6 scale, which was positively correlated with CESD-20 scores in 2018. Furthermore, we found that additional adjustments for CESD-20 scores in 2016 did not alter the association between internet use trajectories and depressive symptoms, indicating the robustness of our findings. Third, the assessment of internet use duration was based on a single question, limiting insights into the specific online activities adolescents engaged in. Future research could consider incorporating comprehensive measures of diverse online activities. Fourth, our sample was limited to adolescents in China. Disparities in health issues between rural and urban areas may exhibit different patterns among adolescents from other countries. Therefore, our findings may not be generalizable

XSL•FO
RenderX

to a global population. Finally, in this study, the sample size was relatively small, particularly when considering the urban-rural stratification. Future research should aim to use larger, nationally representative datasets to further explore variations in the effects of adolescent internet use between urban and rural regions.

Conclusion

This study elucidates urban-rural differences in the associations between internet use trajectories and adolescent depressive symptoms. Over 4 years, we observed diverse trajectories of internet use among adolescents, with one subgroup showing a rapid increase in internet use duration that was associated with higher odds of depressive symptoms. Further stratified analysis revealed that this association was significant only among rural adolescents. These findings offer valuable insights into regional disparities in the impacts of adolescent internet use. Tailored intervention strategies are needed to address the challenges faced by rural adolescents, thereby mitigating the negative effects of excessive internet use on their mental health.

Abstract

Background: Depression is a significant global public health issue, and in China, access to mental health services remains limited despite high demand. Research has shown that mindfulness can effectively alleviate depressive symptoms and that telehealth solutions offer a promising avenue for addressing this service gap. Despite this potential, there are currently few studies in China focusing on short-term online mindfulness training. Most existing online mindfulness studies relied on traditional 8-week programs, which can be challenging for participant adherence due to limited accessibility and high dropout rates. Additionally, limited research exists on short-term online mindfulness interventions, and findings remain inconsistent.

Objective: This study aimed to develop and evaluate an internet-based, self-guided, short-term mindfulness training (ISSMT) program based on the Monitor and Acceptance Theory (MAT) to reduce depression symptoms.

Methods: The ISSMT program was delivered via an online platform, “Hi Emotion,” and was accessible to the general public. Interested individuals aged 18 years and older were randomized into either the ISSMT group or a wait-list control group. Participants in the ISSMT group received daily reminders to participate in a 15- to 20-minute session over a 14-day training period. Measurements, including mindfulness and depressive symptoms, were collected at baseline and weekly for the subsequent 3 weeks.

Results: A total of 205 adults participated in the 14-day online intervention. Linear mixed models were used to analyze both per-protocol (PP) and intention-to-treat (ITT) samples. Compared with the wait-list control group, participants in the ISSMT group showed significant improvements in mindfulness (Cohen *d*=0.44 for ITT; Cohen *d*=0.55 for PP) and reductions in depressive symptoms (Cohen *d*=0.50 for ITT; Cohen *d*=0.53 for PP). Furthermore, participants expressed high acceptance of this training format with a relatively low dropout rate (<40%).

Conclusions: The ISSMT program based on the MAT effectively enhanced mindfulness and alleviated depressive symptoms. This intervention could be considered for integration into psychosocial service systems to improve mental health outcomes and help bridge the gap between limited resources and the high demand for services in China. Future research should focus on personalizing these programs and incorporating advanced technologies to enhance their effectiveness and user engagement.

KEYWORDS

internet-based; self-guided; short-term; mindfulness; depression; randomized controlled trial

Introduction

Depression is a leading global public health issue, with a large impact on people's well-being and quality of life and causing substantial economic ramifications and mental health–related disability [1]. According to the World Health Organization, approximately 280 million people worldwide, representing 5% of the adult population, grapple with depression [2,3]. The China Mental Health Survey reported that the weighted prevalence of depressive disorders in China is 3.6% (95% CI 3.0%-4.2%) during the previous 12 months and the lifetime weighted prevalence was 6.8% (95% CI 5.8%-7.8%) [4].

Given the considerable demand for mental health services, access to mental health services in China is limited. As of 2022, there were only 2098 psychiatric hospitals in China that were staffed by approximately 273,000 professionals, resulting in an average of 3.67 professionals serving 100,000 people [5]. Compounding this issue is the pervasive stigma associated with seeking mental health services. A recent study revealed that, in China, fewer than 10% of patients with depression received any form of treatment, with only 0.5% receiving adequate care [6].

The emergence of telehealth solutions has shown promise in bridging the mental health gap, especially since the COVID-19 pandemic. Telehealth solutions offer several key advantages including high acceptability both as a supplement and alternative to offline face-to-face training. A survey of 500 adults revealed a high interest (71.2%) in internet-based psychological training, with 42% expressing a preference for internet-based training over individual training (37.8%) and group training (19.6%) [7]. Telehealth solutions also provide a high level of accessibility, and users have the flexibility to use medical services according to their own schedule. In addition, telehealth offers greater anonymity, which is valuable for managing sensitive information and providing a more comfortable, private environment for users [8]. Compared with face-to-face training, the development and maintenance of online health care require relatively fewer economic and human resources [9]. Finally, several studies have indicated that some evidence-based psychological training can be effective in an online format, significantly ameliorating users' depression and anxiety. The effect size (d=0.80) of self-help training protocols is only slightly lower than that of standardized treatment protocols (d=0.82) [10-15].

Mindfulness-based training has gained increasing attention in recent years [16-20], with substantial evidence supporting its positive impact on depression [19,20]. Mindfulness is a moment-by-moment awareness of thoughts, feelings, bodily sensations, and the surrounding environment [21]. Among the various mindfulness-based interventions, 2 of the most widely implemented are Mindfulness-Based Stress Reduction (MBSR) and mindfulness-based cognitive therapy [22]. MBSR, developed by Kabat-Zinn [23], and mindfulness-based cognitive therapy, created by Teasdale et al [24] as an extension of MBSR, are central to mindfulness practice. Both interventions typically include 8 weekly sessions focused on mindfulness techniques. A meta-analysis of 44 meta-analyses encompassing various populations, problems, training, comparisons, and outcomes revealed that mindfulness training demonstrated significant effects and advantages (d=0.10-0.89), including for depression (d=0.49), compared with negative controls [20].

The theoretical mechanisms underlying mindfulness interventions are supported by several key frameworks, including the Monitor and Acceptance Theory (MAT) [25], Mindfulness-to-Meaning Theory [26,27], and self-awareness, self-regulation, and self-transcendence framework [28]. Among these frameworks, MAT posits that attention monitoring and acceptance are essential mechanisms of mindfulness [25]. This dual-process approach enhances individuals' ability to monitor internal experiences and accept them without judgment, which is fundamental to reducing negative emotions and fostering psychological flexibility, a key function in emotional regulation.

Compared with offline training, online mindfulness programs generally require less direct involvement from highly trained therapists, reducing reliance on professionals and enhancing accessibility [22]. Some studies have shown that online mindfulness programs, when matched for duration and structure, have slightly weaker effects than offline versions but still show significantly greater improvements than a control group [29]. Furthermore, the efficacy of online programs for alleviating depression has been supported by research in some western countries [15,30].

Most online mindfulness training programs are adaptations of traditional 8-week offline programs [31]. Although traditional programs have demonstrated efficacy, their extended duration and demanding requirements often result in challenges such as limited accessibility [31] and high dropout rates [32]. The few studies exploring the effect of simplified, short-term online mindfulness programs have shown inconsistent [33-36] and unstable effects [37,38]. Some studies with 2- to 4-week online mindfulness training reported positive results [33-35], while others, such as the 2-week self-help program evaluated by Glück and Maercker [36], found no significant differences between the mindfulness group and wait-list control group in terms of mindfulness scores, stress perception, overall distress, and more. To our knowledge, the feasibility and effectiveness of brief online mindfulness training in the Chinese population have rarely been investigated [31].

Current brief online mindfulness interventions often emphasize basic mindfulness techniques [39], primarily attention monitoring. MAT highlights the importance of incorporating acceptance, which is crucial for modulating emotional reactivity and stress responses, ultimately improving mental and physical well-being [25]. Interventions based on MAT may potentially address the limitations of existing internet-delivered programs

XSL•FO
RenderX

by integrating both attention monitoring and acceptance. Randomized controlled trials (RCTs) have demonstrated that MAT-based training significantly improves stress-related indicators, including reductions in cortisol levels and systolic blood pressure reactivity [40], while also enhancing positive emotions [41].

The primary aim of this study was to implement an internet-based, self-guided, short-term mindfulness training (ISSMT) program based on MAT via a mobile platform with a Chinese population and to verify its effectiveness for depressive symptoms using an RCT design. We hypothesized that the ISSMT could be effectively delivered online and would lead to significant improvements in participants' depressive symptoms.

Methods

This study was designed as a single-blind RCT.

Recruitment

A power analysis was conducted to estimate the sample size needed to detect the main effects and interactions in this study. Based on an effect size of 0.3 [20], a power of 0.80, and an alpha of .05, the initial calculation suggested that 126 participants would be required. Some researchers have reported high dropout rates with online training. For instance, an online MoodGym study reported a dropout rate of 73.9% for research participants and 99.2% for public registrants [42], and completion rates for internet-based depression treatment programs have varied from 43% to 99% [43]. To account for a potential dropout rate of 50%, which is commonly observed in online interventions, we planned to recruit 250 participants.

From January 2021 to April 2021, participants were recruited by posting recruitment posters on various public social media platforms, including WeChat Moment, RED app, Douban Forum, and other online forums. Interested individuals were directed to an online questionnaire, where they could register by scanning the QR code on the recruitment poster and providing basic demographic information. A total of 328 participants voluntarily enrolled in this study.

The inclusion criteria were as follows: (1) aged 18 years or older; (2) possessed intact reading and comprehension abilities; (3) had the capacity to provide informed consent; and (4) had access to the internet and basic smartphone literacy. Exclusion criteria included (1) current use of psychotropic medications, (2) severe visual and auditory impairments that hindered the comprehension of audio content or receipt of information, and (3) concurrent participation in other psychosocial intervention programs.

To enhance data representativeness, recruitment efforts spanned multiple platforms and were conducted at different times of the day to capture a diverse participant pool. Additionally, we used the neutral phrase "Peace Journey" in recruitment materials to mitigate self-selection bias.

Finally, 81 individuals who were unreachable after registration were excluded, leaving 247 eligible participants enrolled for randomization and the subsequent intervention.

Procedure

After the initial registration, potential participants were invited to join a WeChat group for further communication. Preliminary screening was conducted based on the predefined inclusion and exclusion criteria. Eligible participants were invited to participate in subsequent research, were informed of the entire research process, and signed an electronic informed consent form. Baseline data were collected after receiving the informed consent form.

The unit of randomization in this study was the individual. Using computer-generated random numbers, we randomly assigned all eligible participants to either the ISSMT group or the wait-list control group. A statistician generated the randomization sequence, and baseline data were collected after the randomization. Investigators remained blinded to the randomization process. Notably, the investigation of online mindfulness training by Krusche et al [34] revealed a dropout rate of 79.4% for the training group, contrasting with only 35.9% for the wait-list control group. To balance the retained sample size in the 2 arms and adhere to statistical standards, we randomly assigned participants to groups at a ratio of 2.5:1 during randomization.

Ultimately, 175 participants were allocated to the ISSMT group, while 72 were assigned to the wait-list control group. Those in the control group received the same mindfulness training after completion of the formal study.

Intervention

Training Course

In this study, the ISSMT program was translated and adapted from a 14-day mindfulness training program developed based on MAT by Lindsay et al [25]. With authorization from Lindsay and colleagues, a team of 4 psychology graduate students was assembled to perform the translation and adaptation. Each unit underwent a standardized multistep process, including sequential stages of "translation, peer cross-check, revision, group discussion and proofreading, and revision," culminating in the creation of a draft. Team members then rotated assigned sections and completed a secondary round of proofreading. Following this, an expert in psychology was invited to conduct a comprehensive proofread of the entire text. Any segments identified as unclear were further refined in alignment with the original text until all team members reached consensus on clarity and accuracy.

The draft was subsequently recorded by a mindfulness practitioner with over 5 years of experience. We then invited 30 individuals to listen to the recordings and provide feedback, which was used to refine the audio content to finalize the training course. The finalized training framework, with each section lasting approximately 15 minutes to 20 minutes, is shown in Table 1.

XSL•FO
RenderX

Table 1. Lesson content in each training program based on the Monitor and Acceptance Theory (MAT).

Lesson	Content
1	Introduction: introduction to the course and 3 core skills: concentration, equanimity, and clarity
2	Concentration I: developing a deeper understanding of concentration
3	Concentration II: concentrating continuously on body experiences
4	Concentration III: maintaining focus on body experiences while listening to someone speak
5	Concentration IV: labeling body experiences to maintain focus
6	Concentration V: labeling different types of body experiences
7	Equanimity I: maintaining global body relaxation to promote equanimity
8	Equanimity II: promoting equanimity by intentionally using a matter-of-fact tone of voice when labeling
9	Clarity I: discriminating different types and patterns of body sensations
10	Clarity II: detecting subtle or faint body sensations and increasing sensual fulfillment by detecting subtle pleasure
11	Equanimity III: developing equanimity by applying a welcoming attitude toward all experiences
12	Clarity III: recognizing 4 basic categories of body experience (physical, emotional, restful, and “energy flow”)
13	Equanimity IV: integrating the 3 equanimity strategies: body relaxation, tone of voice, and welcoming attitude
14	Course Review: guided practice through the major strategies learned in the preceding 13 lessons

Intervention Platform

An online training platform, named “Hi Emotion,” was developed to facilitate the intervention. To access the training course, participants were only required to navigate to the “Hi Emotion” module within the “Mindfulness + Technology” section on WeChat. The platform accommodates 2 roles: “leader” and “practitioner” (see Figure S1A in Multimedia Appendix 1). The leader’s role involves creating groups and administering online courses, while practitioners have the option to join specific groups via the “Group” section. Once the “leader” disseminates the daily course, it becomes immediately visible to the “practitioner” in the “Unlearned Courses” section. Upon completion, the course is removed from the “Unlearned Courses” and relocated to the “Learned Courses” section.

Intervention Procedure

Following the randomization process, the researcher, acting as the “leader,” established a training group and distributed the group code to participants allocated to the ISSMT group. These participants then joined the group and familiarized themselves with the platform using the provided instruction manual. During the 14-day training period, the course was delivered daily on the platform at 10 AM. Participants received immediate reminders in the WeChat group after each course delivery, with additional reminders sent at 8 PM each evening.

The training lasted for 14 days, with each individual course lasting between 15 minutes and 20 minutes. Upon completion of the daily training course, participants were required to engage in mindfulness meditation practices outside the online course for a minimum of 30 minutes per day. In addition, participants were encouraged to incorporate mindfulness practices into their daily activities, such as during meals, while standing, and during walking.

To minimize the dropout rate, several measures were implemented. During the intervention, a trained experimenter sent timely course reminders in the WeChat group every day (at 10 AM and 8 PM) and addressed any participant queries. On the 4th and 10th days of the training, the researchers monitored the participants’ progress through the backend database. If any participants exhibited signs of potential dropout (such as incomplete listening records), the experimenter would contact them via WeChat to ensure they understood the course material and to encourage their continued participation.

Measures

Demographic Characteristics

Demographic characteristics were assessed solely at baseline and encompassed age, gender, educational level, and occupation.

Mindfulness

The short form of the Chinese version of the 5-facet mindfulness questionnaire (FFMQ-C-SF) was used to measure mindfulness [44]. This 15-item scale measures 5 aspects of mindfulness on a 5-point Likert scale, ranging from 1 (never or very rarely true) to 5 (very often or always true), with higher total scores indicating a higher level of mindfulness. The Cronbach α for the FFMQ-C-SF in this study was 0.84.

Depressive Symptoms

Depressive symptoms were evaluated using the Beck Depression Inventory-II (BDI-II) [45]. This 21-item scale is scored on a scale from 0 to 3 according to the severity of symptoms and is one of the most widely used self-rated scales for depressive symptoms. It is applicable to the assessment of depressive symptoms in various clinical and nonclinical populations, with a total score of 0 to 13 indicating no depression, 14 to 19 indicating mild depression, 20 to 28 indicating moderate depression, and 29 to 63 indicating severe depression. The Chinese version of BDI-II, revised by Wang et al [46], demonstrated good reliability and validity, with a Cronbach α coefficient of 0.94. The Cronbach α coefficient for BDI-II in this study was 0.95.

XSL•FO
RenderX

Feasibility

The Intervention Satisfaction Scale designed by Campo et al [47] was used to measure the feasibility of participants' participation and evaluated satisfaction with the internet-based training. It includes 9 items. Items 1 ("Overall, I liked the two-week course practice") and 2 ("I would recommend this course to others") are scored on a scale from 1 to 5 (1=strongly disagree, 5=strongly agree), while the remaining 7 items are scored on a 2-point scale (1=yes, 2=no).

Data Quality Control

To ensure data quality and reliability throughout the study, we implemented multiple control measures. Standardized protocols were followed during data collection to reduce variability. During data cleaning, responses were rigorously screened, and entries displaying excessive duplication or failing to pass attention-check items were excluded. Specifically, attention checks included prompts such as "Please select the option 'Moderately agree' for this question," allowing us to effectively identify inattentive respondents. During the data collection phase, we regularly monitored participants' completion status and their engagement with the intervention (see the Intervention Procedure section for specifics) to maintain data integrity. These comprehensive monitoring and engagement strategies ensured data integrity and minimized the risk of dropout, enhancing the robustness and reliability of our study findings.

Statistical Analysis

Descriptive statistics summarized participants' demographic information and baseline outcome variables across different groups. To assess group differences, we used *t* tests for continuous variables and chi-square tests for categorical variables.

To analyze training effects in this longitudinal study, we used linear mixed models [48,49]. This approach accounts for both random and fixed effects, making it well-suited to handle missing data, which we assumed to be missing at random [50]. Specifically, compound symmetric covariance and maximum likelihood estimation were used.

We implemented both intention-to-treat (ITT) and per-protocol (PP) analyses [51]. ITT analysis includes all randomized participants, maintaining the benefits of randomization regardless of treatment adherence. PP analysis includes participants who completed the assigned treatment. In this study, the ITT analysis included participants who completed baseline measurements and participated in at least one course. The PP analysis focused on the participants who completed at least 75% of their assigned courses (ie, at least 10 sessions), which this study defined as completion of training. This approach enables a clear assessment of the actual treatment impact. Together, these methods provide a comprehensive view of the intervention's effectiveness, with ITT generally yielding more conservative estimates.

Additionally, we evaluated the following effects: the time effect captures changes in measured outcomes across different time points, reflecting how participants' performance evolved over the training duration. The group effect indicates differences in outcomes between treatment and control groups, illustrating the intervention's impact. Finally, the time × group interaction examines how changes over time may differ across groups, elucidating the differential effectiveness of the intervention [52].

All analyses were conducted using SPSS 20.0 (IBM Corp) and incorporated age, gender, and other baseline variables as covariates. Statistical significance was determined using 2-sided tests, with a threshold of $P<.05$.

Ethical Considerations

Ethics Approval

The study was approved by the Research Ethics Committee of the Department of Psychology and Behavioral Sciences, Zhejiang University (register number: 2020-059).

All procedures performed were in accordance with the ethical standards of the Zhejiang University research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards.

Informed Consent

Informed consent was obtained online from all participants before their involvement in the study.

Privacy and Confidentiality

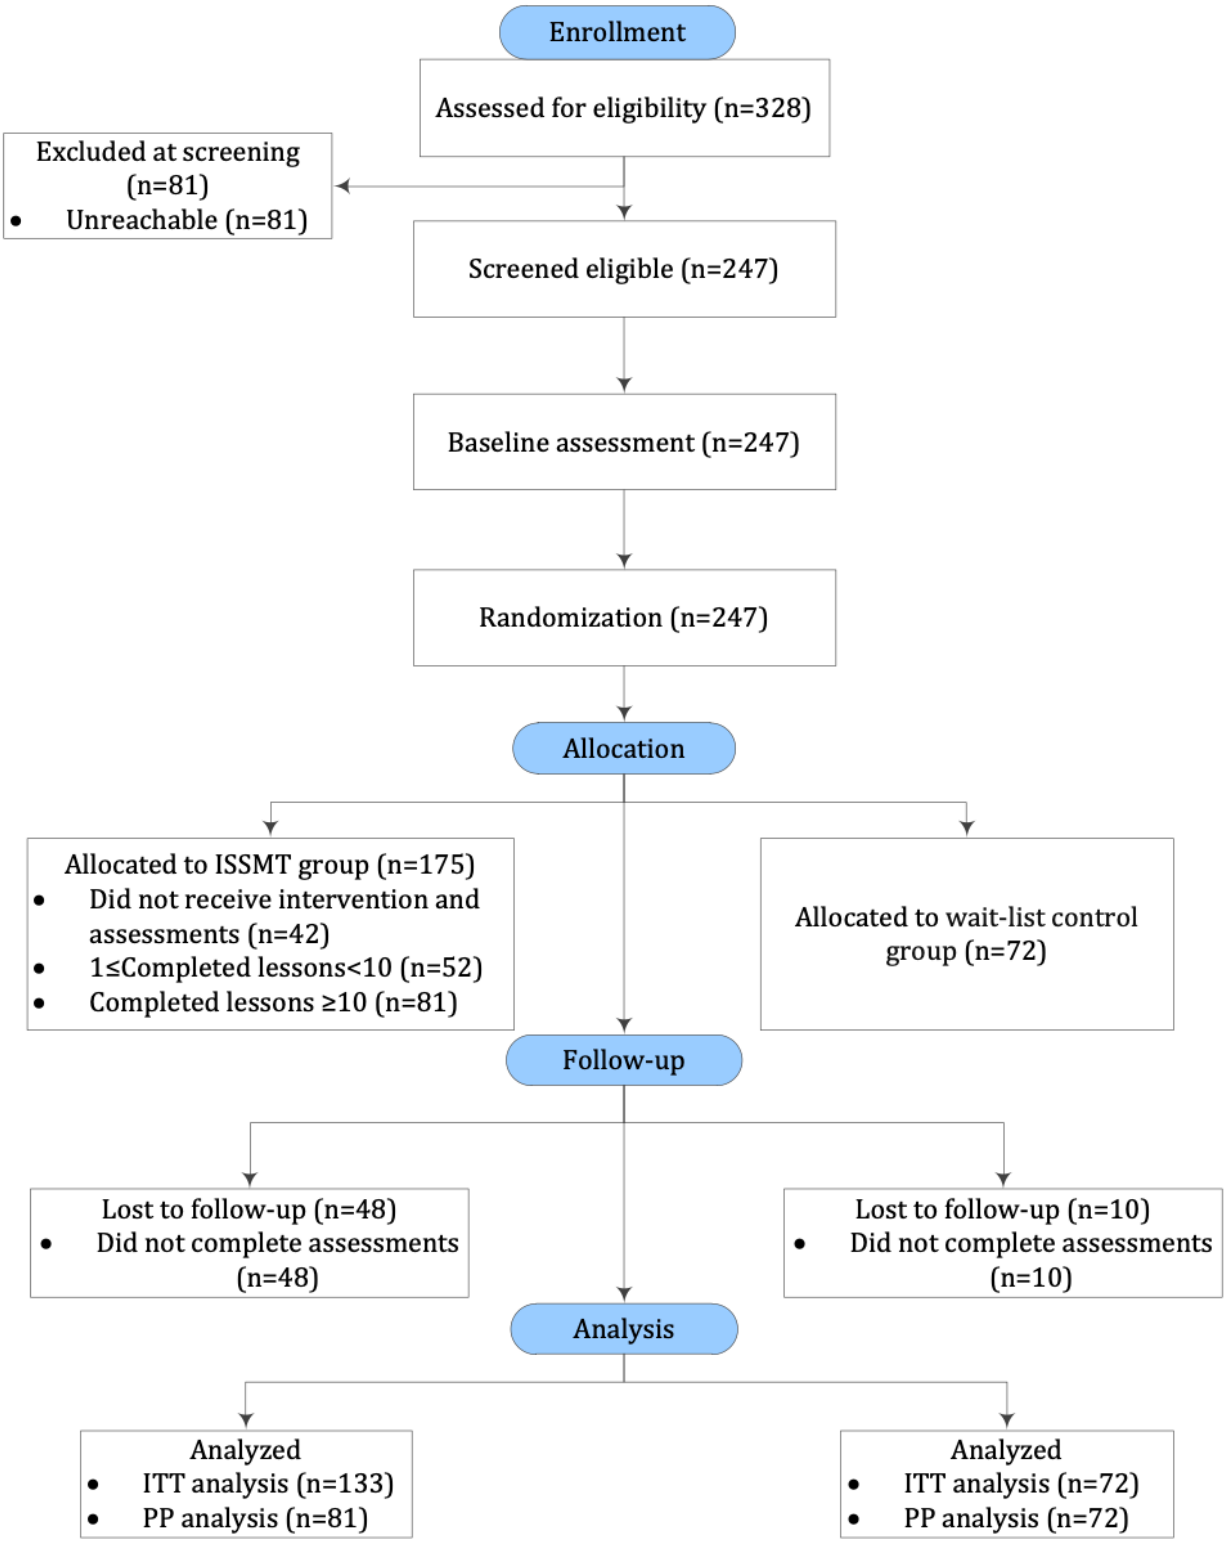
Although the study involved repeated measurements from the same participants, the data collected were anonymized for analysis and feedback purposes. No personally identifiable information was included in the data nor the personalized feedback reports provided to participants.

Compensation Details

Participants received personalized feedback reports containing tailored insights based on their responses as compensation for their participation.

Results

Demographic Characteristics



A total of 328 individuals voluntarily signed up to participate. Of these 328 individuals, 247 (75.3%) met the inclusion criteria and were randomized into the study. Data from 42 people who did not engage in any subsequent courses were excluded, leaving 205 eligible participants (133 in the training group and 72 in the wait-list control group). For the purposes of this study, individuals who completed more than 75% of the courses (ie, participation in at least 10 courses) were considered to have completed the training. A total of 81 participants (81/131, 60.9%) in the training group met this criterion (see Figure 1). No adverse events were reported during the study. Finally, data from 133 individuals in the training group and 72 individuals in the wait-list control group were included in the ITT analysis, while data from 81 and 72 participants, respectively, were included in the PP analysis.

The basic demographic information of the participants is shown in Table 2. The average ages of the participants in the training group and wait-list control group were 24.80 (SD 6.31) years

XSL•FO
RenderX

and 24.60 (SD 6.62) years, respectively, with no statistically significant difference. There were also no significant differences between the 2 groups in terms of gender, education, or baseline mindfulness and depressive symptoms.

[e]BDI-II: Beck Depression Inventory-II.

Training Effects on Mindfulness

According to the ITT analysis, the scores for each outcome variable at each measurement time point are presented in Table 3. At baseline, there was no significant difference in mindfulness scores between the training group and the wait-list control group. The results of the mixed linear model indicated significant main effects of time ($F_{3,515.19}$=29.48; P<.001), group ($F_{1,214.78}$=10.20; P=.002), and the time × group interaction ($F_{3,515.25}$=7.05; P<.001). The results suggest that the online mindfulness training significantly improved the participants' mindfulness. The effect size for the change in mindfulness level was 0.44.

As shown in Table 3, the training group demonstrated a significant increase in mindfulness starting from the first week, with continued significant improvements thereafter, whereas no significant changes were observed in the wait-list control group. The trends in mindfulness level changes at each time point are illustrated in Figure 2A.

According to the PP analysis, the scores for each outcome variable at each measurement time point are presented in Table 4. At baseline, there was no significant difference in mindfulness scores between the training group and wait-list control group. The results of the mixed linear model revealed significant main effects of time ($F_{3,419.57}$ =29.31; P<.001), group ($F_{1,158.47}$=11.21; P=.001), and the time × group interaction ($F_{3,419.64}$=7.67; P<.001). These results indicate that the online mindfulness training significantly improved the participants' mindfulness level. The effect size for the change in mindfulness level was 0.55.

As shown in Table 4, the mindfulness level in the training group showed a marginally significant increase starting from the first week and continued to increase significantly thereafter, while no significant changes were observed in the wait-list control group. The trends in mindfulness level changes at each time point are depicted in Figure 3A.

Figure 3. Per-protocol analysis of the comparison of (A) mindfulness, as measured using the short form of the Chinese version of the 5-facet mindfulness questionnaire (FFMQ-C-SF), and (B) depression, as measured using the Beck Depression Inventory-II (BDI-II), between the training and wait-list control groups at each time point.

Training Effects on Depressive Symptoms

According to the ITT analysis, the scores for each outcome variable at each measurement time point are presented in Table 3. At baseline, there was no significant difference in depression scores between the training group and wait-list control group. The results of the mixed linear model revealed significant effects of time ($F_{3,514.77}$=38.48; P<.001), group ($F_{1,207.10}$=9.31; P=.003), and the time × group interaction ($F_{3,514.87}$=3.87; P=.009). These findings indicate that ISSMT can significantly reduce depressive symptoms, with an effect size of 0.50 for improving depression.

As shown in Table 3, depressive symptoms in the training group improved significantly from the first week and continued to improve significantly thereafter, whereas no significant changes were observed in the wait-list control group. The trends in the depression changes at each time point are illustrated in Figure 2B.

According to the PP analysis, the scores for each outcome variable at each time point are presented in Table 4. At baseline, there were no significant differences in depression scores between the training group and wait-list control group. The results of the mixed linear model revealed significant effects of time ($F_{3,420.91}$=38.58; P<.001), group ($F_{1,157.77}$=10.11; P=.002), and the time × group interaction ($F_{3,421.03}$=3.65; P=.01). These findings indicate that online mindfulness training can significantly reduce depressive symptoms. The effect size for improving depression was 0.53.

As shown in Table 4, the depression score in the training group improved significantly from the first week and continued to improve significantly thereafter, while no significant changes were observed in the wait-list control group. The trends in the depressive symptom changes at each time point are shown in Figure 3B.

Feasibility Analysis

The average Intervention Satisfaction Scale score for item 1 (“Overall, I liked the two-week course practice”) was 3.77, and the average score for item 2 (“I would recommend this course to others”) was 3.52, exceeding the average. At the same time, 87% (77/89) of the participants said they thought the course was helpful to them, and 72% (64/89) of the participants said they liked this online training method.

Discussion

Principal Findings

Depression is a leading global public health problem, with enormous demand for mental health services but limited access to mental health services. The emergence of telehealth solutions offers a promising approach to bridging this service gap. However, despite the potential, there are currently few studies in China that have focused on short-term online mindfulness training, with the majority of online studies adhering to the traditional 8-week mindfulness training framework [53]. In response, we developed a 2-week ISSMT course based on the MAT model. Additionally, we created an online platform for

XSL•FO
RenderX

program delivery. The results from our RCT indicate that, compared with the wait-list control group, participants in the training group had increased mindfulness levels and decreased depressive symptoms. Furthermore, participants expressed high acceptance of this training format. This study provides empirical evidence supporting the feasibility and effectiveness of ISSMT for Chinese adults. We recommend that future research explore the integration of this type of training into psychosocial service systems to enhance mental health.

Although the effectiveness of traditional 8-week mindfulness training has been reported in some studies, concerns remain regarding the extended training duration. Scholars have noted that longer training periods may lead to higher dropout rates and reduced participant motivation, thereby affecting treatment adherence [32]. Adherence is a critical determinant of treatment outcome, with approximately 50% of treatment failures attributable to nonadherence [54]. In a study delivering online psychosocial interventions, high dropout rates have been observed, reaching up to 73.9% among research participants and as high as 99.2% among public registrants [42]. This study introduces an ISSMT program that can be delivered online and demonstrated a notably lower dropout rate (<40%) as well as effective implementation. We believe the adapted training program, customized delivery platform, and quality control measures used in this study can serve as a valuable reference for further practices in delivering online mindfulness training and other psychosocial interventions in China.

Although previous studies have reported inconsistent results for short-term online mindfulness training [34-36], our study found that ISSMT significantly reduced depressive symptoms in the general population. Specifically, no significant differences in depressive symptoms were observed between the 2 groups at baseline or at week 1. However, by weeks 2 and 3, the severity of depressive symptoms in the training group was significantly lower than that in the control group. Although previous research suggests that brief mindfulness meditation sessions can improve immediate emotional states (eg, a single 10-minute mindfulness meditation training can reduce the intensity of negative affect in response to emotional stimuli [55]), our findings indicated that certain “doses” of training may be necessary to ensure the effectiveness of internet-delivered training. Furthermore, the emphasis on acceptance in MAT may be a key factor for sustaining the intervention’s effects [25].

There are several strengths of the ISSMT program delivered in the study. First, the effect sizes for the improvement in mindfulness and reduction in depressive symptoms exceeded those reported in other similar studies [56], with these benefits maintained at follow-up. This suggests that some participants may have continued practicing mindfulness mediation in their daily life after the trial concluded, further supporting the feasibility and long-term potential of the ISSMT program for the Chinese population.

Moreover, the dropout rate in this study was lower than in other similar online training programs. High dropout rates are a well-documented challenge for internet-based psychological training, with reported rates ranging from 73.9% to 99.2% in other studies [42,43,57,58]. Another review reported that an additional 0% to 18% of participants were lost between the posttraining assessment and follow-up assessment [59]. In contrast, our study achieved a completion rate of 60.9%, reflecting a considerably lower dropout rate and confirming the acceptability of this training format.

China’s large internet user base underscores the considerable potential of digital health interventions on a global scale, particularly within significant internet economies like China. According to the 54th “Statistical Report on the Development of China’s Internet” released by the China Internet Network Information Center, as of August 2024, the number of internet users in China was 1.099 billion, with an internet penetration rate of 78% [60].

The convenience and accessibility of online training programs make them an important supplement to offline training, helping to bridge the gap between limited medical resources and the vast mental health service needs in China [61]. Despite a more than twofold increase in the national ratio of psychiatrists, including accredited and assistant psychiatrists, per 100,000 population from 2002 to 2020 (from 1.51 to 3.19) and for accredited psychiatrists specifically (from 1.20 to 2.89) [62], there remains a significant gap between the demand for mental health services and the available resources. This disparity is exacerbated by the uneven distribution of mental health professionals, with a concentration in major cities and the northeast and east regions of China [62]. In light of these challenges, this study developed and validated an online mindfulness training program that effectively overcomes the geographical limitations of traditional face-to-face interventions, underscoring its significance for areas with constrained medical resources.

From a policy perspective, the empirical evidence presented in this study offers a valuable benchmark for authorities and stakeholders when shaping mental health policies. Our results demonstrate that digital mental health interventions not only deliver effective therapeutic outcomes but also garner high user satisfaction. Based on our knowledge, China has begun pilot initiatives to incorporate psychological therapies into public health insurance in certain regions, including Guangdong, Jiangsu, and Beijing. Although traditional psychotherapy is known for its extended treatment periods and challenges in efficacy monitoring, this study shows that a 2-week intervention can yield significant benefits. This finding supports the proposition for policymakers to integrate comparable online intervention models into national or regional mental health frameworks. Integrating such models would enhance the provision of accessible and efficient mental health services to the population.

It is noteworthy that this study did not account for the effects of group-specific differences, leaving uncertainties whether the findings extend to high-risk populations for depression, such as older adults and pregnant women. Older adults may face unique physiological and psychological challenges, including cognitive decline and difficulties with technology use [63], that may influence their acceptance of and response to online interventions. For pregnant women, prior research has shown

XSL•FO
RenderX

that those with high levels of neuroticism demonstrate greater improvements in maladaptive cognitive emotion regulation strategies following mindfulness interventions compared with those with moderate or low neuroticism [64]. This suggests variability in response to mindfulness interventions based on neuroticism levels. Therefore, caution is advised when generalizing these findings to these specific populations.

Limitations

A couple of limitations should be mentioned for this study. First, the main intervention effects were based primarily on self-report data. Further research may combine a broader range of measures, such as behavioral and biological measures. Second, a wait-list control design was used, and using an active control intervention in future studies would provide stronger support for the specific effects of the program. Additionally, this study did not segment participants by specific demographic categories. Certain groups, such as older adults and pregnant women, are recognized as higher-risk populations for depression, and the absence of targeted analysis for these groups may limit the generalizability of our findings. Future research should consider implementing strategies to increase the inclusion of high-risk groups, ensuring a broader and more diverse sample. For instance, offline recruitment methods or targeted online advertisements could be used to reach these specific populations. These enhancements would strengthen the representativeness of the sample and improve the external validity of the findings.

Conclusions

The 2-week ISSMT course based on the MAT demonstrated high feasibility and effectiveness for enhancing mindfulness levels and alleviating depressive symptoms. Given China's substantial potential user base and the disparity between limited mental health resources and the significant demand for services, this digital health intervention could play a pivotal role in expanding access to mental health support. Future research should prioritize the development of personalized online mindfulness programs that consider individual differences such as age, gender, and daily emotional fluctuations. Integrating artificial intelligence [65], wearable technology, and diverse health data may further refine the precision and efficacy of these interventions. Additionally, exploring virtual reality [66] and natural language processing could enable more immersive and engaging user experiences, potentially enhancing therapeutic outcomes.

Abstract

Background: Dementia poses a significant global health challenge, characterized by progressive cognitive decline and functional impairment. With the aging global population, dementia prevalence is projected to surge, reaching an estimated 153 million cases by 2050. While the impact of traditional social isolation on dementia risk has been extensively studied, the influence of digital isolation, a phenomenon unique to the digital age, remains underexplored.

Objective: This study aimed to investigate the association between digital isolation and dementia risk among older adults, hypothesizing that higher levels of digital isolation significantly increase the risk of developing dementia.

Methods: We conducted a longitudinal cohort study using data from the National Health and Aging Trends Study (NHATS), analyzing 8189 participants aged 65 years and older from the 3rd (2013) to the 12th wave (2022). Digital isolation was quantified using a composite digital isolation index, derived from participants' usage of digital devices, electronic communication, internet access, and engagement in online activities. Participants were stratified into low isolation and moderate to high isolation groups. Dementia incidence was assessed using cognitive tests and proxy reports. Cox proportional hazards models were used to estimate the association between digital isolation and dementia risk, adjusting for potential confounders including sociodemographic factors, baseline health conditions, and lifestyle variables.

Results: The moderate to high isolation group demonstrated a significantly elevated risk of dementia compared with the low isolation group. In the discovery cohort, the adjusted hazard ratio (HR) was 1.22 (95% CI 1.01-1.47, *P*=.04), while the validation cohort showed an HR of 1.62 (95% CI 1.27-2.08, *P*<.001). The pooled analysis across both cohorts revealed an adjusted HR of 1.36 (95% CI 1.16-1.59, *P*<.001). Kaplan-Meier curves corroborated a higher incidence of dementia in the moderate to high isolation group.

Conclusions: Our findings indicate that digital isolation is a significant risk factor for dementia among older adults. This study underscores the importance of digital engagement in mitigating dementia risk and suggests that promoting digital literacy and access to digital resources should be integral components of public health strategies aimed at dementia prevention.

Introduction

Dementia, characterized by progressive cognitive decline and functional impairment, represents a formidable global health challenge [1,2]. As the world's population ages rapidly, the prevalence of dementia is projected to surge, with an estimated 153 million individuals affected by 2050 [3]. In the absence of curative treatments, the imperative for effective prevention strategies has never been more pressing. The etiology of dementia is multifactorial, encompassing both nonmodifiable factors such as age and genetic predisposition, and modifiable risk factors including cardiovascular health, lifestyle choices, and social engagement [4-6].

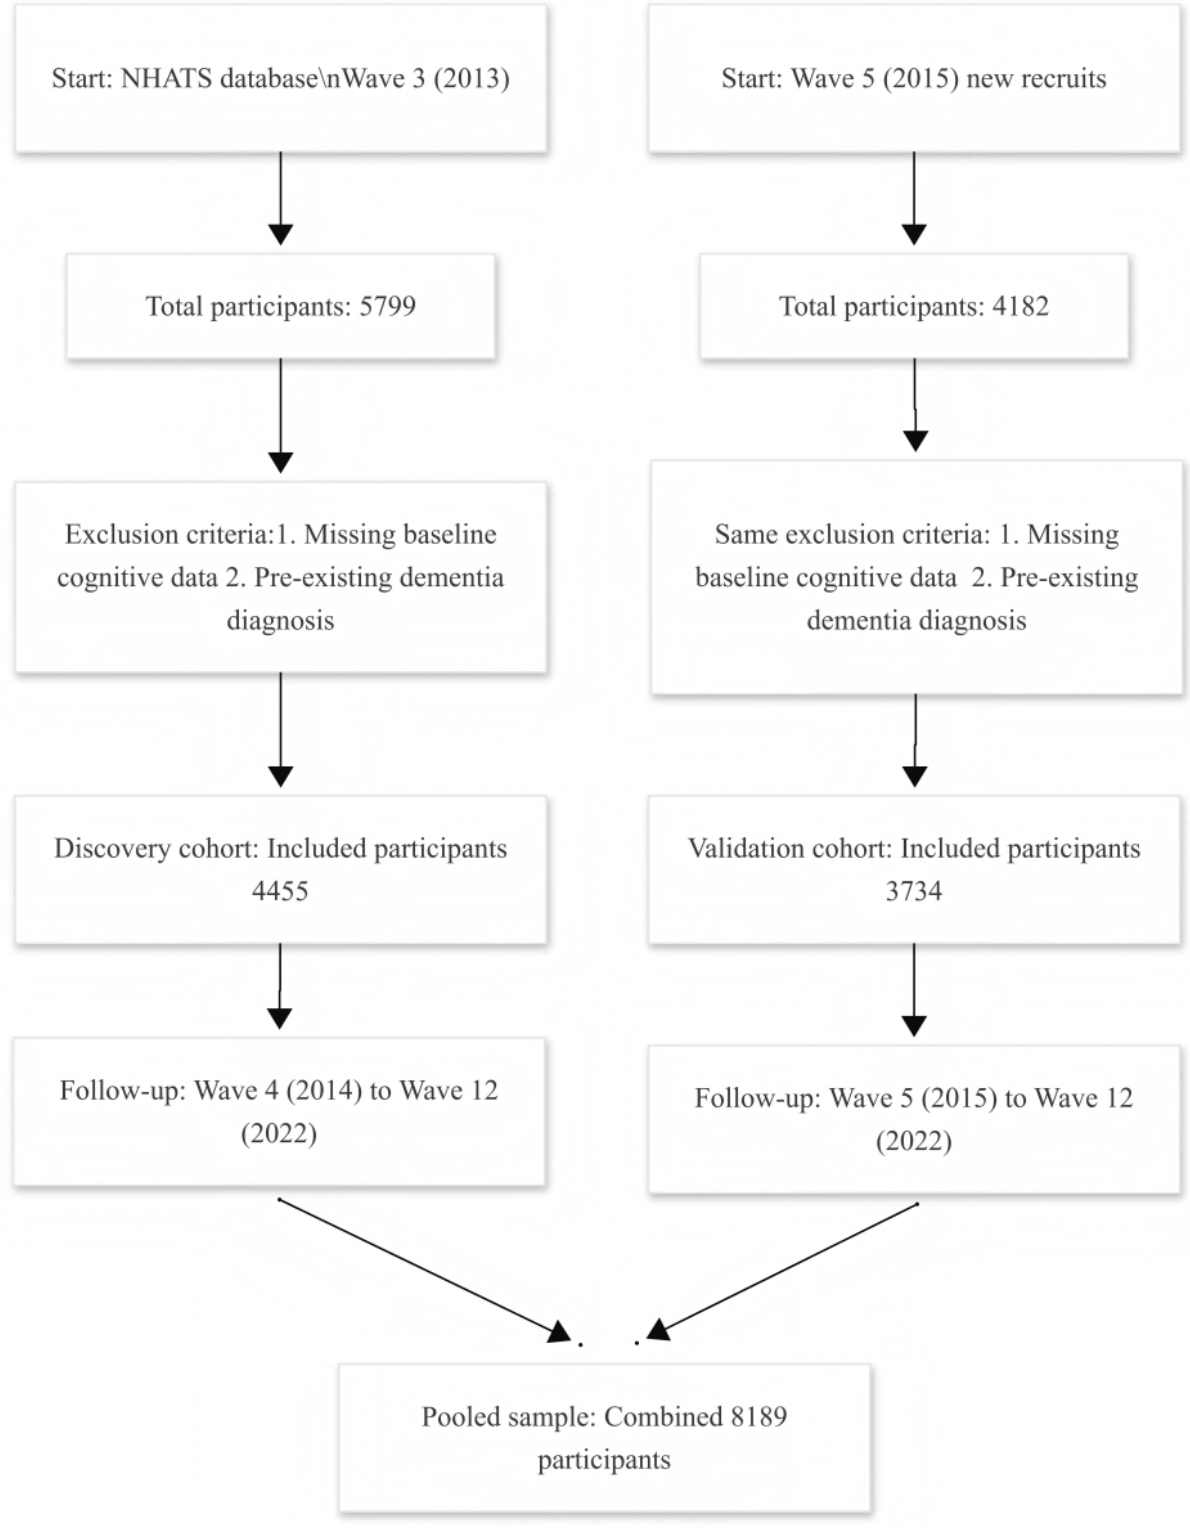
In the context of an increasingly digitalized society, interaction with technology has become integral to modern life. However, the digital revolution has not benefited all segments of the population equally. A significant proportion of older adults find themselves in a state of "digital isolation," either due to limited access or inadequate digital literacy [7-9]. This concept extends beyond traditional social isolation by emphasizing the absence of digital engagement, including the use of the internet, smartphones, or social media, which can offer additional cognitive and social stimulation [10,11]. Recent studies indicate that older adults' use of technology-based social platforms or electronic health resources may enhance cognitive outcomes, postpone cognitive decline, and alleviate loneliness. Consequently, individuals who are digitally isolated may miss these protective effects, which could accelerate cognitive decline and elevate their risk of dementia [11-13]. Limited literacy and education levels may further restrict older adults' ability to engage with digital technologies, hindering their ability to benefit and potentially increasing the risk of cognitive decline [14,15].

While the association between traditional social isolation and dementia risk has been extensively studied, the impact of digital isolation, a phenomenon unique to our technologically driven era, has received comparatively little attention [16-18]. Preliminary investigations suggest a potential link between digital isolation and accelerated cognitive decline, as well as increased dementia risk. However, these studies are often constrained by limited sample sizes and cross-sectional designs, precluding the establishment of causal relationships. Furthermore, many existing studies fail to adequately control for potential confounding factors such as depression, anxiety, chronic comorbidities, and lifestyle variables, potentially biasing their results [19,20].

This study aims to clarify the relationship between digital isolation and dementia risk using a large-scale, longitudinal cohort design. Using a multistage Cox proportional hazards model on discovery and validation cohorts, we control for numerous potential confounders, including sociodemographic characteristics (eg, education level), baseline health status, and lifestyle factors. This study aims to provide strong evidence supporting the hypothesis that higher levels of digital isolation increase dementia risk. It also seeks to identify mechanisms underlying this emerging risk factor and to inform novel dementia prevention strategies, particularly those enhancing digital literacy and technology access. We aim to support a holistic public health approach that integrates traditional and digital aspects of social engagement in aging populations.

Methods

Study Population



This investigation used data from the National Health and Aging Trends Study (NHATS), a nationally representative longitudinal survey of Medicare beneficiaries aged 65 years and older in the United States. To ensure representativeness of the older adult population, appropriate survey weights provided by NHATS were applied to account for the complex sampling design. Our analysis used data spanning from the 3rd wave (2013), when digital product usage assessment was initiated, to the 12th wave (2022). The study cohort was stratified into discovery and validation samples.

In the third wave (2013), 5799 participants remained in the study. We excluded individuals lacking baseline digital isolation data or with preexisting dementia diagnoses. We rigorously controlled potential confounders influencing the digital isolation-dementia risk relationship, including age, education level, gender, race or ethnicity, baseline diseases, depression, anxiety, smoking status, and sleep difficulties. Participants were followed from the fourth wave (2014) through the twelfth wave (2022). During follow-up, some individuals were excluded due to attrition or death before dementia diagnosis. The final analytical sample comprised 4455 individuals.

To validate our findings, we used an independent cohort of 4182 individuals newly recruited in the fifth wave (2015). After applying the same exclusion criteria as the discovery cohort and accounting for attrition and mortality during follow-up, 3734 individuals were included in the validation sample. This cohort was followed from the 5th wave (2015) through the 12th wave (2022). As shown in Figure 1, we provide a detailed overview of the inclusion and exclusion processes for the discovery and validation cohorts, including the study waves, exclusion criteria, and the final number of participants included in the analysis dataset.

XSL•FO
RenderX

Figure 1. Flowchart depicting participant inclusion and exclusion criteria for the discovery (wave 3) and validation (wave 5) cohorts, with subsequent follow-up through wave 12 and formation of the pooled sample. NHATS: National Health and Aging Trends Study.

Digital Isolation

Digital isolation was assessed using a composite digital isolation index, which was constructed based on individuals' usage of various digital devices and the internet. The design of this index was informed by relevant literature in the fields of social isolation and digital health. For instance, Cornwell and Waite [21] quantified social isolation by evaluating the extent of individuals' social contact and participation and proposed a method for constructing a social isolation index using self-reported data. Similarly, digital isolation, as a modern form of isolation, is primarily reflected in the insufficient engagement with and use of digital technologies.

In this study, we operationalized digital isolation through a composite digital isolation index comprising 7 parameters (Textbox 1).

XSL•FO
RenderX

Textbox 1. Components of the Digital Isolation Index.

Parameters:

- Mobile phone use.
- Computer usage.
- Tablet use.
- Frequency of electronic communication (email or text messaging).
- Internet access.
- Engagement in online activities.
- Participation in health-related digital platforms.

The selection and quantification of these indicators were informed by extant literature on digital technology adoption, such as Kraut et al [22], who investigated the impact of internet use on social involvement. Each parameter was dichotomized (0=nonuse, 1=use), and the sum of these binary scores constituted the aggregate digital isolation index [22]. For stratification purposes, we adopted methodologies analogous to those used in social frailty research by Makizako et al [23] and Wei et al [24]. Participants were categorized into 2 cohorts based on their digital isolation index: those scoring 2 or less were classified as "low isolation," while those scoring 3 or above were designated as "moderate to high isolation." This bifurcation strategy was designed to elucidate the potential differential impacts of varying degrees of digital isolation on health outcomes.

Dementia

In the NHATS database, dementia ascertainment is primarily predicated on cognitive function assessments and self-reports or proxy reports. NHATS uses a multifaceted approach to dementia evaluation, encompassing cognitive testing, proxy reports, and clinical records. Specifically, NHATS uses a battery of cognitive tests to assess participants' memory, attention, and executive function, with these metrics serving as indicators of cognitive status. Concurrently, NHATS collects proxy reports, typically from family members or caregivers, regarding the participants' cognitive condition. These reports may encompass physician-diagnosed dementia and observe cognitive deficits in activities of daily living. Investigators typically synthesize these data with additional clinical information to determine dementia status and monitor its progression longitudinally. Upon confirmation or report of dementia in any follow-up wave, subsequent inquiries regarding dementia status are discontinued for that participant.

Covariates

This study incorporated a comprehensive set of covariates to ensure a precise estimation of the association between digital isolation and dementia risk. These covariates encompass sociodemographic characteristics, clinical parameters, and health-related behaviors.

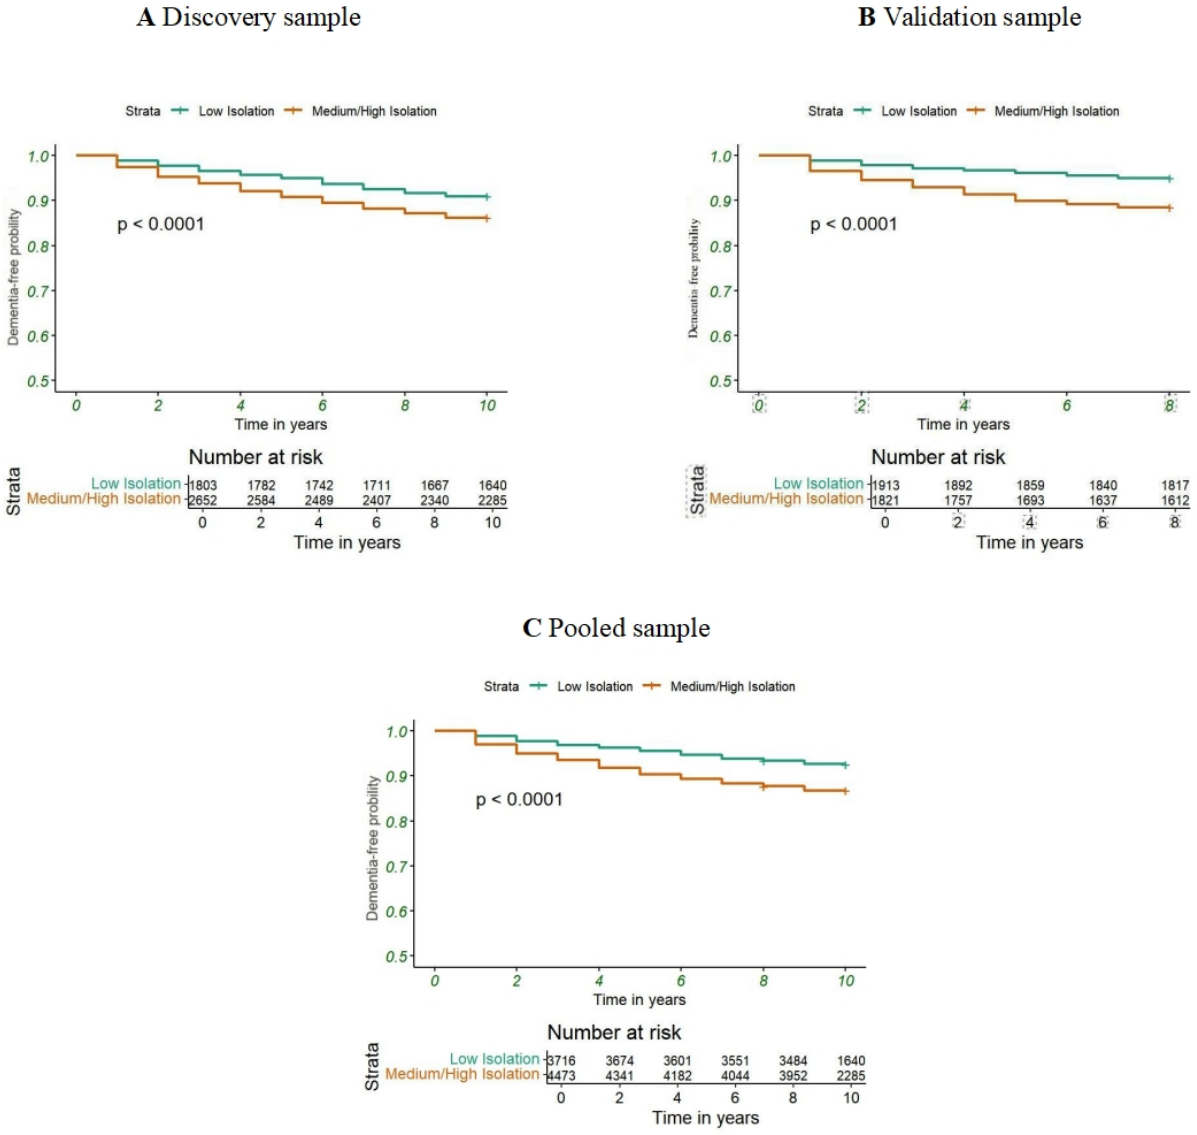
Sociodemographic variables include education level, age, gender, and race or ethnicity. Education level was categorized as <high school, high school or general educational development (GED), some college, and college or above, reflecting participants' highest educational attainment. Age was stratified into 6 cohorts: 65-69 years, 70-74 years, 75-79 years, 80-84 years, 85-89 years, and ≥90 years. Sex was dichotomized as male or female. Race or ethnicity was categorized as non-Hispanic White, non-Hispanic Black, Hispanic, and other. These variables are routinely used as baseline covariates to adjust for sociodemographic heterogeneity in health outcomes [25-27].

Clinical parameters comprise the number of baseline diseases, depressive symptomatology, and anxiety manifestations. The number of baseline diseases was trichotomized based on self-reported chronic conditions (including arthritis, cardiovascular disease, hypertension, diabetes, pulmonary disease, cerebrovascular accident, osteoporosis, and malignancy): no diseases, 1-2 diseases, and ≥3 diseases. Depressive and anxiety symptoms were assessed by validated self-report instruments and operationalized as binary variables in the analyses [28,29].

Health-related behaviors include smoking status and sleep difficulties. Smoking status was dichotomized as current smokers and noncurrent smokers to account for potential cognitive effects of tobacco use [30]. Sleep difficulties were stratified based on the frequency of difficulty falling asleep within 30 minutes: high sleep difficulty (every night or most nights), moderate sleep difficulty (some nights), and low or no sleep difficulty (rarely or never) [31]. Previous research has demonstrated associations between poor sleep quality, cognitive decline, and elevated dementia risk, warranting its inclusion as a key covariate.

Statistical Analysis

To address the complex sampling design of NHATS, we applied person-level sampling weights for longitudinal analyses spanning 2013 to 2022. Clustering and stratification were incorporated by specifying the primary sampling units (PSUs) and strata in the design-based analyses. Baseline characteristics of the study population were summarized using descriptive statistics, with categorical variables reported as frequencies and percentages. Appropriate NHATS survey weights were applied across all analyses to ensure the findings represent the broader US older adult population. To assess the probability of dementia-free survival across different digital isolation groups (low isolation vs moderate to high isolation), we used Kaplan-Meier survival analysis. The resultant Kaplan-Meier survival curves are depicted in Figure 2. To quantify the



XSL•FO
RenderX

association between digital isolation and dementia risk, we used Cox proportional hazards regression models, calculating hazard ratios (HRs) with corresponding 95% CIs. A total of 2 models were constructed: model 1 (unadjusted) and model 2 (adjusted for potential confounders including education level, age, gender, race, number of baseline diseases, depression, anxiety, smoking status, and sleep difficulties).

We further investigated the individual components of digital isolation (eg, mobile phone use, computer use, tablet use, frequency of email usage, internet usage, online activities, and health-related online activities) and their respective impacts on dementia risk. Each component was analyzed independently using Cox proportional hazards models to estimate HRs and 95% CIs.

To examine the potential heterogeneity in the association between digital isolation and dementia, we conducted stratified analyses across subgroups defined by gender, age, race or ethnicity, and comorbidity status. Effect modification by these factors was assessed through the inclusion of interaction terms in the Cox models. In addition, a sensitivity analysis was performed to ensure the robustness of our findings. We recalculated the primary models under several alternative conditions, including adjusting the threshold for defining digital isolation, excluding participants with missing key variables, and omitting early dementia cases to reduce potential reverse causality. To enhance the robustness of our findings, we combined the results from the discovery and validation samples using meta-analytic techniques. Pooled HRs and CIs were computed using a fixed-effects model, under the assumption of homogeneity across samples. Statistical analyses were performed using R statistical software (version 4.4.1; R Foundation for Statistical Computing). A 2-sided *P* value <.05 was considered statistically significant for all analyses.

Figure 2. Kaplan Meier curves of the relationship between digital isolation and dementia.

Ethical Considerations

The study protocol was approved by the institutional review board of Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China. All methods were conducted in accordance with relevant guidelines and regulations. The NHATS dataset is deidentified and publicly available, with informed consent obtained from participants at enrollment. No additional individual-level consent was necessary for this secondary analysis.

Results

Baseline Characteristics of the Study Population

The study cohort comprised 8189 participants, with 4455 individuals in the discovery sample and 3734 in the validation sample. Survey weights provided by NHATS were applied in all analyses to ensure representativeness of the older adult population in the United States. As shown in Table 1, Females constituted a slight majority, accounting for 4724 out of 8189 (57.68%) of the cohort. The racial or ethnic composition was predominantly non-Hispanic White (5615/8189, 68.58%), followed by non-Hispanic Black (1677/8189, 20.48%) and Hispanic (469/8189, 5.73%). Regarding education level, approximately 1250 out of 8189 (15.27%) of participants had less than a high school education, 2560/8189 (31.28%) completed high school or GED, 2375 out of 8189 (29.00%) had some college education, and 2004 out of 8189 (24.45%) had a college degree or higher. Age distribution analysis revealed that the “70-74 years” age group was most prevalent (1906/8189, 23.27%), succeeded by the “75-79 years” (1689/8189, 20.63%) and “80-84 years” (1479/8189, 18.06%) age groups. With respect to baseline diseases, 3918 out of 8189 (47.85%) of participants reported no chronic conditions, while 2593 out of 8189 (31.67%) had 1-2 diseases, and 1678 out of 8189 (20.49%) had 3 or more chronic conditions. The prevalence of depression and anxiety was 2189 out of 8189 (26.74%) and 2819 out of 8189 (34.43%), respectively. The majority of participants (7582/8189, 92.58%) were nonsmokers. Sleep difficulties were reported as significant by 1707 out of 8189 (20.84%) of participants, and moderate by 1989 out of 8189 (24.29%). In the context of digital isolation, 4473 out of 8189 (54.62%) of participants were categorized as experiencing moderate to high isolation, while 3716 out of 8189 (45.38%) were classified as having low isolation. Digital device use rates were as follows: mobile phones (6615/8189, 80.8%), computers (4857/8189, 59.31%), and tablets (2045/8189, 24.98%). Frequent engagement in digital activities was reported for email or text messaging 6537/8189, (79.83%), internet access (4709/8189, 57.51%), general online activities (7282/8189, 88.93%), and health-related online activities (6315/8189, 77.13%).

[a]Race or ethnicity was reclassified into 4 categories: White, non-Hispanic; Black, non-Hispanic; Hispanic; and Other.

[b]The depression, anxiety, and smoking status variables were reclassified as binary variables. Responses of “Don't know,” “Refused to answer,” and similar were treated as missing data.

[c]Sleep difficulty was categorized by the frequency of difficulty falling asleep within 30 minutes, with unknown or refused responses treated as missing data.

[d]The Digital Isolation Index was used to create a new variable (Digital Isolation Group) dividing participants into low and moderate and high isolation groups.

Association Between Digital Isolation and the Risk of Dementia

The association between digital isolation and dementia risk was comprehensively examined, adjusting for factors including education level, age, gender, race or ethnicity, number of baseline diseases, depression, anxiety, smoking status, and sleep difficulties, with results presented in Table 2. In the discovery sample, the moderate to high isolation group demonstrated a significantly elevated risk of dementia compared with the low isolation group. The unadjusted Cox proportional hazards model (model 1) yielded a HR of 1.58 (95% CI 1.31-1.89, *P*<.001) for dementia in the moderate to high isolation group, indicating a 58% higher relative risk of dementia compared with the low isolation group. After adjusting for potential confounders (age, gender, race or ethnicity, number of baseline diseases, depression, anxiety, smoking status, and sleep disorders), the HR in model 2 attenuated to 1.22 (95% CI 1.01-1.47, *P*=.041), yet remained statistically significant. The validation sample corroborated these findings. The unadjusted model 1 revealed an HR of 2.36 (95% CI 1.86-3.01, *P*<.001) for the moderate to high isolation group, while the adjusted model 2 showed an HR of 1.62 (95% CI 1.27-2.08, *P*<.001), consistently indicating a significantly higher dementia risk in the moderate to high isolation group.

Table 2. Association between digital isolation and the risk of dementia.

Sample and variables	Event, n/N (%)	Model 1[a] HR[b] (95% CI)	*P* value	Model 2[c] HR (95% CI)	*P* value
Discovery sample					
Low isolation (reference range)	1803/4455 (40.47)	1 (Ref)	—[d]	1 (Ref)	—
Medium and high isolation	2652/4455 (59.53)	1.58 (1.31-1.89)	<.001	1.22 (1.01-1.47)	.04

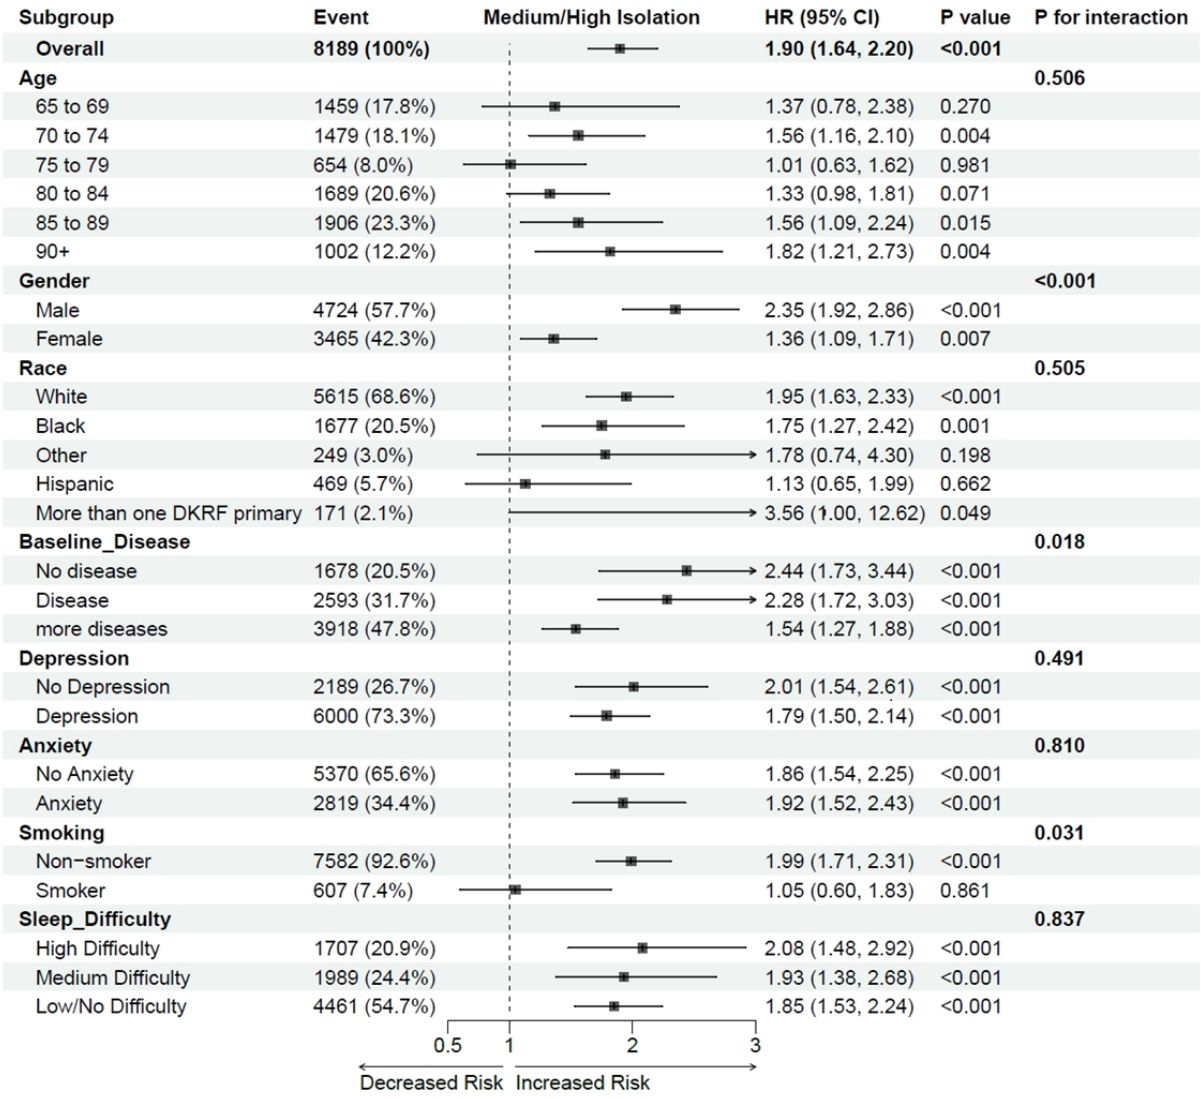
[a]Model 1: unadjusted Cox proportional hazards model.

[b]HR: hazard ratio.

[c]Model 2: Cox proportional hazards model adjusted for age, gender, race, education level, baseline disease, depression, anxiety, smoking status, and sleep difficulty.

[d]Not applicable.



To enhance the robustness of our findings, we applied meta-analytic techniques to pool results from both samples. The pooled analysis yielded HRs of 1.89 (95% CI 1.63-2.19, *P*<.001) in the unadjusted model 1 and 1.36 (95% CI 1.16-1.59, *P*<.001) in the adjusted model 2, further substantiating the significant risk increase.

Kaplan-Meier survival curves were used to visualize dementia incidence across different digital isolation groups (Figure 2).

XSL•FO
RenderX

These curves demonstrated a significantly higher probability of dementia development in the moderate to high isolation group, corroborating the Cox regression analysis results. Figure 3 illustrates the association between digital isolation and dementia risk across various demographic and clinical subgroups. Consistently elevated dementia risk was observed in the moderate to high isolation group across all subgroups, with notable differences in gender, age, and comorbidity status. These findings underscore the pervasive impact of digital isolation on dementia onset, demonstrating a consistent trend of increased risk both in the overall population and within specific subgroups.

Figure 3. Association between digital isolation and risk of dementia among subgroups. Reference group: Low digital isolation group. All models were adjusted for age, gender, race, baseline disease, depression, anxiety, smoking, sleep difficulty. P-int represents the heterogeneity among subgroups based on the metaregression analysis.

Association Between Digital Isolation Components and the Risk of Dementia

We investigated the association between individual components of digital isolation and incident dementia risk, with results summarized in Table 3. In the discovery sample, we analyzed the use of mobile phones, computers, tablets, and the internet in relation to dementia risk. The unadjusted Cox proportional hazards model (model 1) revealed that nonusers of mobile phones had a significantly higher dementia risk compared with users (HR 1.78, 95% CI 1.41-2.24, *P*<.001). After adjusting for covariates (model 2), the HR attenuated to 1.45 (95% CI 1.14-1.84, *P*=.002). For computer use, the adjusted HR was 1.15 (95% CI 0.96-1.38, *P*=.12), approaching but not reaching statistical significance. Similarly, adjusted HRs for tablet use were not statistically significant across samples, with a pooled HR of 1.05 (95% CI 0.78-1.42, *P*=.73).

[a]Model 1: unadjusted Cox proportional hazards model.

[b]HR: hazard ratio.

[c]Model 2: Cox proportional hazards model adjusted for age, gender, race, education level, baseline disease, depression, anxiety, smoking status, and sleep difficulty.

In the validation sample, nonusers of mobile phones exhibited a significantly higher dementia risk, with an unadjusted HR of 3.05 (95% CI 2.28-4.08, *P*<.001), which decreased to 2.12 (95% CI 1.55-2.9, *P*<.001) after adjustment. Nonusers of the internet demonstrated a robust association with dementia risk, with a pooled adjusted HR of 1.42 (95% CI 1.15-1.76, *P*=.001). For individuals not engaging in online activities, the pooled adjusted HR was 1.32 (95% CI 1-1.74, *P*=.05), further underscoring the importance of digital engagement. However, nonusers of health-related online platforms showed no significant association with dementia risk (pooled HR 0.9, 95% CI: 0.64-1.28, *P*=.58).

These findings underscore that specific digital behaviors, particularly mobile phone and internet use, are significantly associated with a lower risk of dementia. In contrast, the influence of other digital components, such as computer or tablet use, appears less consistent or pronounced.

Sensitivity Analyses

To evaluate the robustness of our findings and address potential confounders, we conducted several sensitivity analyses. First, we repeated the Cox regression models after excluding participants with incomplete education data, confirming that the significant association between digital isolation and dementia risk remained robust even after adjusting for educational level (adjusted HR range 1.20-1.45, all *P*<.05). Second, we applied alternative thresholds for defining digital isolation, such as categorizing digital isolation index ≥4 as high isolation, and observed results consistent with the primary analysis. Third, we excluded individuals who developed dementia or died within the first 2 years of follow-up to reduce potential reverse causation, finding HRs comparable with those in the main analysis (HR changes<10%). Finally, we replicated the main models without applying survey weights. Although the unweighted models yielded slightly smaller standard errors, the overall trends remained consistent. Collectively, these sensitivity analyses indicate that our key conclusions are robust across varying analytical assumptions and sample selections.

Discussion

Principal Results

This study examined the association between digital isolation and dementia risk, demonstrating that higher levels of digital isolation significantly increase the risk of dementia. These findings emphasize the critical role of digital engagement in promoting cognitive health among older adults and provide valuable insights for public health policy development. By using the nationally representative NHATS dataset and its survey

XSL•FO
RenderX

weights, we ensured that our results reflect the broader US older adult population, thereby enhancing the robustness of our conclusions. Our analysis identified a significant relationship between digital isolation and dementia risk. In both discovery and validation samples, individuals who did not use basic digital devices (eg, mobile phones and the internet) or who lacked online activity participation exhibited a substantially higher dementia risk compared with their digitally engaged peers. Specifically, nonusers of mobile phones had a 1.65-fold increased risk (95% CI 1.35-2.02, *P*<.001), while nonusers of the internet demonstrated a 1.42-fold increased risk (95% CI 1.15-1.76, *P*=.001) in the pooled analysis. In addition, the pooled analysis showed that individuals with a higher digital isolation index faced a 1.36-fold increased risk of dementia (95% CI 1.16-1.59, *P*<.001). These results are consistent with previous research identifying social isolation and lack of social interaction as independent risk factors for dementia [13,32].

However, some digital activities, such as emailing or texting, showed no significant association with dementia risk. This might be because these activities are less interactive or infrequently used by older adults, offering limited cognitive or social stimulation compared with more engaging digital behaviors, such as frequent phone or internet use.

Furthermore, this study validates digital isolation as a novel form of isolation that may influence cognitive health through multiple mechanisms. Digital technologies can promote social interaction and participation, crucial for maintaining cognitive function [33-35]. Conversely, a lack of digital engagement may exacerbate social isolation, thereby increasing cognitive decline risk. In addition, digital technology use can provide cognitive stimulation, potentially helping older adults maintain brain vitality [36,37]. Thus, digital isolation not only reflects diminished social interaction but may also represent insufficient cognitive stimulation. These findings have significant public health implications. As supported by recent studies, educational attainment can significantly influence individuals' ability to engage with digital tools, highlighting the importance of prioritizing older adults with lower educational backgrounds in targeted interventions [38-40]. As society undergoes digital transformation, issues related to digital engagement among older adults are becoming increasingly salient. Our study suggests that promoting digital technology use among older adults, particularly within vulnerable populations, could effectively mitigate dementia risk. This implies that enhancing digital literacy and expanding access to digital resources should be integral components of dementia prevention strategies. While other studies may not have used the specific "digital isolation index," research examining older adults' online engagement or technology use consistently demonstrates that digitally engaged older adults report better cognitive and psychosocial outcomes [10,41,42]. These findings reinforce the protective role of digital engagement in cognitive health and underscore the importance of encouraging digital technology adoption among older adults.

Limitations

However, this study has limitations. Despite controlling for multiple covariates, the observational nature of our study design precludes complete elimination of confounding factors. For instance, individuals' health behaviors and cognitive abilities may simultaneously influence their digital technology use and dementia risk, potentially leading to reverse causality [19,43]. Furthermore, educational attainment could discourage older adults from adopting digital devices, complicating the interpretation of whether digital isolation is a cause or result of declining cognitive function. In addition, our reliance on self-reported data may introduce information bias, particularly in the preclinical stages of dementia when individuals' recollection of their digital usage may not be entirely accurate.

Notwithstanding these limitations, this study provides important empirical support for exploring the relationship between digital isolation and dementia risk. Future research should further investigate factors that promote or hinder digital engagement among older adults to develop more effective interventions. In addition, prospective longitudinal studies, randomized controlled trials, and qualitative investigations are crucial for further validating our findings and examining the causal relationship between digital technology use and cognitive health.

Conclusions

This study, examining the association between digital isolation and dementia risk in older adults, underscores the critical role of digital engagement in maintaining cognitive health. Our findings demonstrate that digital isolation significantly increases dementia risk, particularly among individuals who do not use basic digital devices, lack online communication, and abstain from online activities. These findings indicate that strategies focused on enhancing digital literacy, promoting equitable access to digital tools, and addressing educational disparities may effectively mitigate dementia risk in an increasingly digitalized society.

Our research not only provides new evidence of the detrimental effects of digital isolation but also offers valuable insights for future public health interventions. For instance, community-based digital literacy programs and targeted technology access initiatives could help reduce digital isolation among older adults, especially those from underserved or low-education backgrounds. Enhancing digital literacy and expanding accessibility to digital resources among older adults may effectively reduce digital isolation, potentially lowering dementia incidence. Future research should explore the specific mechanisms through which digital engagement affects cognitive health and further validate the causal relationship between digital isolation and dementia through longitudinal studies and intervention trials.

In conclusion, this study highlights the importance of digital technology in older adults' health and advocates for the integration of digital literacy education, user-friendly technological interfaces, and widespread digital resource availability in public health policies. These measures will facilitate older adults' integration into the digital society, thereby potentially improving their cognitive health and overall quality of life. Ensuring that these interventions are adapted to individual educational levels may be pivotal for maximizing their preventive impact.

Abstract

Background: Given the ubiquity of stress, a key focus of stress research is exploring how to better coexist with stress.

Objective: This study conducted text analysis on stress-related Weibo posts using a web crawler to investigate whether these posts contained positive emotions, as well as elements of mental time travel and meaning-making. A mediation model of mental time travel, meaning-making, and positive emotions was constructed to examine whether meaning-making triggered by mental time travel can foster positive emotions under stress.

Methods: Using Python 3.8, the original public data from active Weibo users were crawled, yielding 331,711 stress-related posts. To avoid false positives, these posts were randomly divided into two large samples for cross-validation (sample 1: n=165,374; sample 2: n=166,337). Google's natural language processing application programming interface was used for word segmentation, followed by text and mediation analysis using the Chinese psychological analysis system "Wenxin." A mini–meta-analysis of the mediation path coefficients was conducted. Text analysis identified mental time travel words, meaning-making words, and positive emotion words in stress-related posts.

Results: The constructed mediation model of mental time travel words (time words), meaning-making words (causal and insightful words), and positive poststress emotions validated positive adaptation following stress. A mini–meta-analysis of two different mediation models constructed in the two subsamples indicated a stable mediation effect across the 2 random subsamples. The combined effect size (B) obtained was .013 (SE 0.003, 95% CI 0.007-0.018; P<.001), demonstrating that meaning-making triggered by mental time travel in stress-related blog posts can predict positive emotions under stress.

Conclusions: Individuals can adapt positively to stress by engaging in meaning-making processes that are triggered by mental time travel and reflected in their social media posts. The study's mediation model confirmed that mental time travel leads to meaning-making, which fosters positive emotional responses to stress. Mental time travel serves as a psychological strategy to facilitate positive adaptation to stressful situations.

Introduction

Stress and Mental Health

Researchers have consistently linked stressful events to negative emotions and adverse psychological health outcomes, viewing stress as an inevitable precursor of anxiety, depression, and other negative emotional states [1,2]. A recent meta-analysis of ecological momentary assessments suggested a significant positive correlation between transient negative emotions and cortisol levels—a biomarker of stress—whereas positive emotions were significantly and negatively correlated with cortisol levels [3].

The cumulative stress model posits that the negative impact of stress on an individual's emotions and psychological health is cumulative, emphasizing the severe and lasting effects of early life stress on the brain [4-6]. Prolonged exposure to stress can also diminish a person's ability to withstand future stressors, thereby impacting mental health [7]. Stress has been shown to negatively impact memory, executive function, emotional regulation, and the processing of social and emotional stimuli [8]. Chronic exposure to stress could lead to neurodevelopmental changes in the brain structure and function [9].

These findings and the cumulative stress model suggest that experiencing stressful events is detrimental to individuals, and avoiding such events is beneficial for mental health. However, these studies only emphasize individual vulnerability, overlooking psychological resilience and the potential for growth and development in the face of adversity. The control and mastery theory of anxiety suggests that effective coping with stressful events can enhance an individual's sense of control and better prepare them for future stressors [10]. The concept of "stress inoculation" also supports the idea that "what does not kill us makes us stronger" [11]. Recent research evidence indicates that over 60% of individuals demonstrate adaptive functioning after experiencing stressful events or adversity, commonly referred to as "stress resilience" [12].

The cyclical model of stress resilience and stress-related growth posits that the relationship between stress and mental health outcomes such as positive emotions is not necessarily negative [13-17]. After a stressful event, individuals initiate an adjustment process that leads to psychological outcomes of the stress event. The nature of the adjustment process and its outcomes depend on the severity of the stress experienced. If the severity of a stressful event is within an individual's tolerance, successful adjustment could enhance resilience and lead to positive coping outcomes. Events causing minimal stress could require little adjustment and are likely to lead to the recovery and restoration of resilience to baseline levels [18-20]. Highly stressful events can overwhelm an individual's resilience and cause damage, at least temporarily. The level of resilience is modulated by various factors, of which meaning-making is a crucial coping mechanism [13,18,21-24].

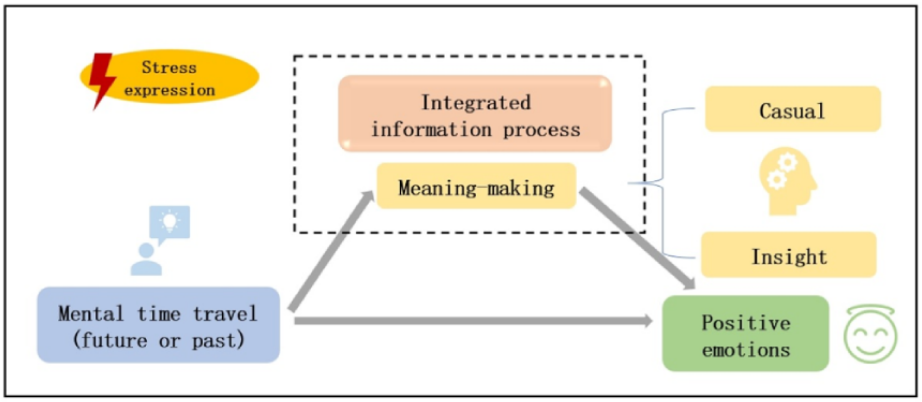
Mental Time Travel to Trigger Meaning-Making

Meaning-making is a stress-coping strategy aimed at altering an individual's appraisal of a situation to harmonize their beliefs, goals, and stress context. Unlike classic problem- and emotion-focused coping strategies, meaning-making does not attempt to change problematic situations or directly reduce negative emotions or pain [25]. Instead, it unifies beliefs, goals, and stress contexts by searching for meaning [26].

The meaning-making model proposed and revised by Park [27] is a widely accepted theory for understanding how individuals cope positively with stressful events and situations. It centers on the concept of "global meaning"—a cognitive framework that individuals use to interpret their experiences and motivations [25]. The model posits that when individuals encounter situations that might challenge or reinforce this global meaning, they engage in an evaluative process that assigns significance to these situations. The degree of discrepancy between the appraised meaning and its inherent global meaning determines the level of distress experienced. This distress initiates the process of meaning-making, wherein individuals strive to reconcile the gap between situational meaning and global understanding. This reconciliation effort aims to restore a sense of coherence in the world and reaffirm the value of their lives. Ultimately, achieving harmonization between situational and global meanings facilitates better adaptation to stress, highlighting the transformative role of meaning-making in managing life challenges [28-32].

In laboratory studies, two common methods are often used to elicit meaning-making in individuals: mental time travel and meaning-threat paradigms. Among these, mental time travel, a type of typical mental travel that predominantly involves recalling the past or imagining the future, is the most frequently used. Mental time travel is the ability to project oneself into the past or future through mental time travel [33]. As previously stated, individuals were said to experience mental time travel when they re-experienced events from their past and imagined events in their future [34,35]. Construct level theory suggests that when individuals remember the past or think about the future, they process things at a more abstract and superordinate level because temporal distance causes the mental distance to become farther away [36]. This is consistent with the findings of research in the area of mental time travel and the process of meaning-making and meaning-acquisition [37]. Research suggests that coherence is an important component of meaning in life, which involves an understanding of personal experiences and a sense of life events [38]. Through mental time travel, people recall past events or imagine future events, which helps them integrate their life experiences from different times into a more cohesive meaning and enhances their self of purpose in life [39]. Numerous studies indicate that mental time travels in the form of nostalgia or future contemplation can enhance the meaning in life or positive emotions owing to the role of meaning-making [40-42]. During stressful situations, individuals initiate the process of meaning-making; seek clues from the past, present, or future; integrate life experiences to redefine the current stress context; or adjust their global meaning to guide their future lives [43]. Thus, when individuals attempt to mentally travel to the past or future, they can enhance positive emotions and predict higher psychological well-being through meaning-making [27].

Experimental studies and research into cognitive neural mechanisms have also found evidence that mental time travel



XSL•FO
RenderX

successfully initiates meaning-making. In one laboratory study, participants were randomly assigned to future, present, and past groups and asked to imagine 2 independent events within different timeframes. Participants imagining the future and past reported higher meaning in life than those imagining the present. This indicates that mental time travel, through self-distancing from the here and now, promotes the integration of temporal information and causal understanding, becoming a stable paradigm for eliciting meaning-making [44-46]. In a functional magnetic resonance imaging study using a similar mental time-travel paradigm to successfully elicit meaning-making, a decrease in default mode network activity was observed, linking meaning-making with positive psychological health outcomes [47].

This Study

The internet is now an integral part of people's lives and the rapid development of social media has significantly altered how people express their emotions [48]. The evolution of the internet and big data has propelled psychological research. In Chinese social media, Sina Weibo has become a crucial data source for psychological studies owing to its fast dissemination, timely information, and wide audience [49]. When individuals perceive stress, they may express their emotions or reflect by posting on Sina Weibo. The cyclical model of stress resilience and stress-related growth posits that stress has an adaptive function that is facilitated by the coping process [50]. Research indicates that expressive inhibition is a maladaptive coping strategy and a possible mechanism for affect dysregulation following trauma [51]. In contrast, expressive writing during stressful situations has been shown to relieve stress and hone coping strategies, thereby alleviating negative emotions and promoting positive adaptation [52]. This process can also be accomplished through mental time travel, which facilitates the process of meaning-making by enabling individuals to integrate insights about the meaning of life from the past and future, thus promoting positive adaptation following stress [43]. Therefore, a theoretical model that comprises mental time travel and the cyclical model of stress resilience and stress-related growth is proposed in this study. This study explored whether such actions entail a process of meaning-making, such as causal connections or insights, and whether successful meaning-making is followed by positive adaptation to stress, manifested as positive emotions (Figure 1).

Figure 1. The hypothesis model.

Specifically, this research involved text analysis of stress-related blog posts on Weibo to investigate the presence of positive elements as indicators of poststress adaptation and to explore elements of meaning-making in everyday stress and coping. Previous studies have frequently used mental time travel as a stable paradigm to elicit meaning-making, often inviting participants to imagine past or future events [44-46]. Mental time travel can reliably initiate meaning-making for individuals, thereby enhancing meaning in their lives. The words "future" and "past" are used as indicators of mental time travel, and causal and insightful words serve as key components of the meaning-making process. This study examined whether the meaning-making process mediates the impact of mental time travel on positive emotions. In this study, words related to past and future blog posts were considered components of mental time travel that triggered meaning-making. Emotional words were used to represent positive outcomes under stress, whereas words referring to the past or future served as markers of mental travel. In qualitative research and text analysis, insightful words (eg, "originally" and "comprehend") and causal words (eg, "because," "therefore," and "thus") were often used as components of meaning-making [53]. Thus, these words were used as indicators of meaning-making. Building on this, a mediation model of mental time travel, meaning-making, and positive emotions poststress was constructed, and a mini–meta-analysis was used to test whether mental time travel-induced meaning-making can promote positive emotions under stress.

Meta-analysis is a data analysis method that reanalyzes multiple independent quantitative studies on the same question to derive more generalizable conclusions [54]. Recently, statisticians have recognized that meta-analyses do not necessarily require several studies, and even two effect sizes can suffice. In fact, even with a few effect sizes, meta-analysis can summarize them, not only clarifying whether the research question has been consistently answered but also enhancing the persuasiveness of the conclusions, especially when the detected effect sizes are small. Individual studies may lack sufficient evidence, but collectively, they can be compelling. Researchers suggest that even a limited number of studies (or their subgroups) can be compared with each other. Such an internal meta-analysis of conceptually comparable studies is known as a mini–meta-analysis [55].

XSL•FO
RenderX

This study aimed to explore the mediating role of meaning-making in the relationship between mental time travel and positive emotions in stress-related blogs. In this study, a mini–meta-analysis was performed to detect the mediation model.

Methods

Research Objects

This study was conducted using original posts from active microblog users, excluding accounts belonging to institutions and media outlets. The screening criteria were as follows: (1) a publicly published blog by an individual user, (2) the blog was posted between December 2019 and November 2020, and (3) the blog post included the keyword ‘‘stress.” All blog posts have been anonymized. A statistical analysis was performed, revealing 331,711 posts related to “stress.” Given the propensity of big data to yield false positives, these posts were split into two random samples using the random grouping function in SPSS (version 24.0; IBM Corp). This division facilitated cross-validation of data reliability. Ensuing analyses were conducted on these two substantial samples (sample 1: n=165,374; sample 2: n=166,337).

Ethical Considerations

This study was approved by the School of Psychological and Cognitive Science, Peking University Ethics Committee (#2018-10-03).

Design and Programming

The Sina Weibo blog posts were harvested using Python 3.8, using the “lxml,” “requests,” and “tqdm” libraries to acquire and process HTML page data. This method involves retrieving key data such as the source, ID, content of the blog, date, and metrics, including the number of likes, comments, and reposts. All retrieved data were then systematically stored for further analysis.

Data Analysis

Google’s natural language processing application programming interface was used for word segmentation. Following this, a dictionary based on the Linguistic Inquiry and Word Count (LIWC) framework was used to conduct a word frequency analysis. This process enabled the identification of high-frequency words and their respective counts in the blog posts. Subsequently, the Chinese psychological analysis system “Wenxin”—developed by the Computational Network Psychology Laboratory at the Institute of Psychology, Chinese Academy of Sciences—was applied to analyze the content of the blog posts. “Wenxin” is a sophisticated software system designed for the linguistic analysis of Chinese texts. It features automatic word separation and text analysis capabilities, leveraging both LIWC2007 and the orthographic Chinese C-LIWC lexicon, which is tailored to the linguistic context of simplified Chinese in mainland China [56]. The “Wenxin” system uses lexicon technology to conduct word segmentation, extract word classes, perform word frequency analysis, and calculate the proportion of mental time travel, meaning-making, and positive emotion words within the entire blog post. During the process, “happy” is generally considered a word signifying positive emotion, while “not happy” would be classified as a word signifying negative emotion. In order to prevent large sample false positives, we used random grouping to randomly divide the sample into two subsamples for cross-validation (Koul et al [57]). Correlation and mediation analyses were conducted using SPSS version 24.0. During mediation analyses, path coefficients and effect sizes (B and SE) were extracted and stored in a dataset. First, using the SPSS 24.0 macro file PROCESS [58], a bootstrapping procedure was used to verify whether mental time travel words (future and past time words) could mediate the effect of meaning-making words (causal words, eg, because, effect, hence, and insightful words, eg, think, know, consider; see Table S5 in Multimedia Appendix 1) on positive emotions under stress [56,59]. Model 4 was selected by setting the number of samples to 5000 and using a bias-corrected 99% CI. To control for the type I error inflation caused by multiple comparisons, the significance level (α) of correlations was adjusted to .01 and the CI of the mediating effect was adjusted to 99% with Bonferroni correction [60].

Mediation heterogeneity tests, composite effect size calculations, and publication bias tests were performed using the “metafor” package in R (R Foundation and R Caucus). For visualization purposes, the “forestplot” function was used. A meta-analysis was conducted to verify the stability and homogeneity of these effects across the samples. The first step was to perform a Q-test for homogeneity to assess the similarity between multiple independent studies. If the homogeneity test was not significant and I^2 was <40%, the criteria for homogeneity were met, and a fixed-effects model was used to estimate the combined effect size. Conversely, if the homogeneity test was significant, a random-effects model was used.

Results

In the retrieved blog posts, people’s stressful events were concentrated in the areas of work stress (eg, working all day at the office with thunder outside), life stress (eg, pressure to buy and rent), academic stress (eg, pressure to graduate), family stress (eg, babysitting), and intimate relationships (eg, finding a partner). By leveraging the outcomes of Google Segmentation and Word Frequency Analysis, we derived insights into sentiment tones and word frequency in blog posts concerning stress and meaning-making strategies. The analysis of these charts revealed that in stress-related blog posts, prevalent themes included personal references such as “self,” “we,” and “they.” Additionally, there was a significant presence of cause-and-effect related terms like “reason,” “so,” and “because.” These findings underscore the process of meaning-making. There were also time-related elements such as “one day” and “tomorrow” (Table 1).

In this meaning-making process, there are initial attributions and causal understandings, followed by the emergence of new attributions in ongoing meaning-making. We found that recalling the past and contemplating the future are accompanied by a process of meaning-making. For example, “Thanks to my past self for staying true to myself when the pressure was on. Thanks for the self that still wipes away the tears and memorizes after every cry. Every step I took, every tear I left behind, the pain I felt when I was suffering. All are the marks of youth. In the future, I will thank myself for struggling now.” “Recently, I have been under a lot of pressure, and I have drawn up a distant travel plan for myself. Winter vacation to Finland to see reindeer, and want to drink hot horse milk. Thinking about it makes me feel healed to the point where I wish I could kill all the malice and love is worth it.” This example illustrates the meaning-making process triggered by mental time travel. Under pressure, people can make meaning by expressing themselves on blogs. For example, “There are many things in this world that can make you happy, one long-term and one short-term. It’s up to you, what you are, how much stress you can handle, and how much better and longer-term benefits you can enjoy.” “Recently, you needed to organize yourself, organize your emotions, organize your life, organize your work, organize your plans for the future, always have to do a good job of planning, in order to have peace of mind, there is pressure to continue to move forward, I believe that everything can be better and better.” “When you navigate the difficulties and obstacles alone, you will be grateful for the first time to say nothing and bite your teeth to insist on your own path.” “Still young, not everything in life is decided over a small thing, pressure will exist, but it won’t last forever or learn to be more optimistic and happier.” “No pressure of life will be empty, no pressure of youth will wither, no pressure of life will be bleak.”

Subsequently, to delve deeper into how the components of meaning-making in stress-related blog posts contribute to the positive adaptation to stress, the “Wenxin” system was used for textual analysis. This analysis involved extracting elements related to time, meaning-making, and positive or negative emotions. The frequencies and percentages of these elements were included in the subsequent mediation analyses. For the time elements, components representing the past, present, and future were selected. For meaning-making, words signifying attribution and causal understanding were chosen, such as causal words (eg, “because,” “therefore,” and “thus”) and insightful words (eg, “originally” and “comprehend”). Positive emotional words were counted based on their frequency. The descriptive statistics and correlation analyses for the two large samples are presented in Tables 2 and 3.

Table 3. Descriptive statistics and correlation analysis of main variables for sample 2 text analysis (n=166,337).

		Percentage value, mean (SD)	1	2	3	4	5	6
1	Rate of positive emotions words	0.10 (0.004)	1.00					
2	Rate of insightful words	0.06 (0.019)	.07[a]	1.00				
3	Rate of causal words	0.03 (0.001)	.02[a]	.10[a]	1.00			
4	Rate of past time words	0.01 (0.003)	.01	.02[a]	.02[a]	1.00		
5	Rate of present time words	0.01 (0.007)	.01[b]	.02[a]	.01[a]	.04[a]	1.00	
6	Rate of future-time words	0.01 (0.005)	.02[a]	.03[a]	–.01	.01	.04[a]	1.00

[a]*P*<.001.
[b]*P*<.01.

Correlation analyses of the 2 large samples revealed significant positive correlations between the frequency of positive emotion words and the frequency of causal (sample 1: r=0.03, P<.001; sample 2: r=0.02, P<.001) and insightful (both sample: r=0.07, P<.001) words (meaning-making). In sample 1, positive emotion words showed a significant positive correlation with the rates of future-time words (r=0.03; P<.001), past-time words (r=0.01; P=.005), and present-time words (r=0.02; P<.001). In sample 2, there was a significant positive correlation between positive emotion words and the frequencies of both present (r=0.01; P=.005) and future words (r=0.02; P<.001). The frequencies of causal (sample 1: r=0.01, P<.001; sample 2: r=0.02, P<.001) and insightful words (sample 1: r=0.03; P<.001; sample 2: r=0.02, P<.001) were positively correlated with past words, but future words were only significantly positively correlated with insightful words (sample 1: r=0.01, P<.001; sample 2: r=0.03, P<.001) and not causal words (P>.01 in both samples). This aligns with the notion that attributions are more prevalent when reflecting on the past than the future.

Mediation models were established for both samples (Table 4).

In this study, the results of the homogeneity test were Q_1= 0.93 and P=.34, with an I^2 of 0 %, indicating that the criteria for homogeneity were met. Therefore, a fixed-effects model was chosen for the analysis.

After extracting each effect size to be included in the meta-analysis, the values were synthesized and weighted to calculate a combined average statistic. The calculation of the average effect size was performed by weighting each effect size according to the inverse of its variance (ϖi). This involved multiplying each effect size by its respective weight, summing the products, and dividing them by the sum of the weights. Next, the standard error of the mean was calculated using the square root of the sum of the inverse variance weights, . This standard error was used to determine 95% CIs. The combined effect size (B) obtained was .013 (SE 0.003; 95% CI 0.007-0.018; *P*<.001; Figure 2).

Discussion

Principal Findings

This study conducted a large-scale text analysis of stress-related Weibo posts to identify the coexistence of positive emotional words and stress. Meaning-making elements were also observed in these posts. This study found that meaning-making induced by mental time travel can promote positive emotions under stress. The presence of words related to the past and future reflects the mental travel time. Recognizing that life encompasses not only the present but also the past and future is a prerequisite for meaning-making through complete narratives. Therefore, the appearance of future and past words signifies a meaning-making process. Causal and insightful words representing the outcomes of meaning-making also appeared in the posts. This discovery is significant, as a wealth of research evidence indicates that mental time travel initiates the meaning-making process and concurrently influences shifts in one's sense of meaning in life [40-42]. Therefore, this analysis provides a nuanced understanding of how individuals engage and narrate their experiences of stress and coping within a digital context.

A mediation model was constructed using mental time travel words (mental time travel words) → meaning-making words (causal and insightful words) → positive poststress emotions. This model confirmed positive adaptation following stress. Mini–meta-analyses of two combined mediation models tested in 2 subsamples revealed a stable mediation effect across the 2 random subsamples. This demonstrates that meaning-making induced by mental time travel in stress-related blog posts can predict positive emotions under stress, supporting the cyclical model of stress resilience and stress-related growth rather than the cumulative stress model. This finding contributes to addressing the decade-long imbalance in stress research and clinical practice, which has almost exclusively focused on negative emotions while neglecting positive ones [61].

The Adaptive Function of Meaning-Making

The stress interaction model indicates that stress does not necessarily lead to impairment or maladaptation. An individual's diverse experiences in response to the same stressor primarily stem from their primary and secondary appraisals of the stressor, with meaning-making playing a critical role [62]. The meaning-making model further explains how meaning-making reduces the distress caused by a stressor and fosters growth by narrowing the discrepancy between situational and global meanings [27].

The cyclical model of stress resilience and stress-related growth posits that the initial state of individuals is determined by a combination of genetic, environmental, and social factors. When faced with stress, individuals adjust, leading to stress coping, which becomes a new initial state. During this adjustment process, certain coping strategies and personal resources can facilitate positive poststress psychological health outcomes, with meaning-making being an effective strategy [50]. Both meaning-making and cyclical models of stress resilience and growth indicate that coping strategies, such as meaning-making, can serve as mediating mechanisms leading to positive outcomes related to stress; hence, meaning-making can promote positive emotions under stress [27,50].

Research in the field of positive psychology has shown that meaning-making reliably predicts an individual's psychological health [63,64]. Extensive literature has demonstrated the adaptive function of meaning-making, showing a consistent positive correlation between meaning-making and positive psychological outcomes [61,65,66]. A meta-analysis of 87 cross-sectional studies found that meaning-making was associated with greater happiness and less depression [66]. In older adults living in nursing facilities, meaning-making was significantly correlated with positive emotions, personal growth, environmental mastery, and self-acceptance [67]. In a study of adolescent earthquake survivors, meaning-making was related to posttraumatic growth, which explains the relationship between meaning-focused coping and positive emotions [68].

Benefits of Mental Time Travel

Meaning-making involves the integration of an individual's life experiences, a process that includes narrative elements [27]. This means that individuals attempt to find common threads across their past, present, and future experiences, creating coherent and understandable cognitive representations or schema. Meaning-making requires the recognition that life transcends any specific moment, and mental time travel possesses these narrative elements. Mental time travel, also known as self-distancing or mental simulation, is the process of mentally transcending oneself. It involves occupying different times (past or future) or places or assuming the subjective experiences of different people or hypothetical realities. Mental time travel encompasses imagining experiences that extend beyond what is currently in progress. This capacity for simulation, which is particularly rich in form, seems unique to humans [69]. Some scholars have speculated that simulation enables humans to engage in complex cultures by navigating past, future, and social worlds [70]. A tendency toward nostalgia can mitigate the impact of existential threats on one's sense of meaning and increase positive emotions [40,41]. Additionally, experimentally induced nostalgia can enhance self-reported meaning in life and bolster positive emotions [71,72]. Similar to positive contemplation of the past through nostalgia, positive thinking about the future corresponded to enhanced meaning. The frequency of thoughts about future legacy is also related to meaning in life [73-75].

In this study, the correlational and mediation analyses found that future-time words were only related to the frequency of insightful words, not causal words. This suggests that meaning-making about the future involves causal reasoning less often and insightful reasoning more often. The constructive episodic simulation hypothesis posits that future mental time travel focuses more on the completeness of event narratives, thus favoring insightful reasoning [76]. Simultaneously, we also found that the direct effect of past mental time travel on positive emotions varied in both samples. This suggests that the meaning-making process plays a very important role (Park [27] and Ord et al [50]). Given the key role of mental time travel in meaning-making and promoting positive emotions, further research is needed to explore this mechanism [77].

XSL•FO
RenderX

Theoretical and Practical Implications

This study explored the adaptive function of meaning-making in stressful situations by integrating a cyclical model of stress resilience and stress-related growth with the meaning-making model [27,50]. This validates the mediating role of meaning-making between stress and positive emotions. Under stress, individuals engage in positive reappraisal to construct meaning from stressful events. Subsequently, through mental time travel, seeking and assigning meaning, individuals promote positive emotions under stress.

Second, this research introduces the method of mini–meta-analysis in a large-sample study to investigate the establishment of mediation effects, contributing to resolving the replication crisis. Given the vast amount of data obtained from Weibo crawlers, large sample sizes can lead to false positives. Therefore, a combined meta-analysis of multiple effect sizes in the same study would be particularly useful. Regardless of the number of studies conducted, researchers can succinctly summarize the results of each study through a meta-analysis. Researchers suggested that journal peer reviewers and editors should encourage authors to perform mini–meta-analyses on their own research results to determine the stability and consistency of the study effects and that conducting meta-analyses on papers can improve the precision of estimates (ie, narrow confidence intervals) [78,79]. Conducting mini–meta-analyses of a few studies can help researchers understand and strengthen their conclusions.

Third, from a practical perspective, this study underscores the need to recognize the positive aspects of stress and prevent the demonization of stress in the “stress is debilitating” narrative. Because stress cannot be eradicated or entirely avoided, finding ways to coexist with and grow from a psychological standpoint is crucial for long-term strategies. Mental time travel, an effective way to elicit meaning-making, can be developed as an intervention method to promote better coping with stress in individuals [80-82].

Limitations and Future Directions

This study had certain limitations. First, the cyclical model of stress resilience and stress-related growth discusses how appraisals, effective coping strategies, and personal resources modulate an individual’s stress response [50]. However, existing research has only explored meaning-making as an effective strategy. Future research should examine whether and how other coping strategies work in conjunction with meaning-making to influence positive poststress emotions.

Second, the expressions of stress, meaning-making, and positive emotions explored in this study’s Weibo analysis were essentially correlated. However, the model established was theory-based, and the data were not accessed at different time points. Future research should benefit from more laboratory designs that manipulate mental time travel to observe changes in meaning-making and positive emotions. Alternatively, momentary ecological assessment methods in daily settings and longitudinal studies can be used to obtain robust results.

Finally, the focus of this study was on whether mental time travel words can predict positive emotion words through meaning-making words; however, no distinction was made between categories of positive emotion words. Moreover, big data studies face the challenge of being unable to accurately manipulate or measure subtle differences in meaning while acquiring massive amounts of data [83]. Therefore, more refined studies should be designed in the future to validate the findings of big data studies and provide more reliable evidence.

Conclusions

This study concludes that individuals can adapt positively to stress by engaging in meaning-making processes that are triggered by mental time travel and reflected in their social media posts. The study’s mediation model confirmed that mental time travel leads to meaning-making, which fosters positive emotional responses to stress. This finding is significant because it demonstrates the potential of mental time travel as a psychological strategy to facilitate positive adaptation to stressful situations.

Abstract

Background: A significant number of individuals with depression in Hong Kong remain undiagnosed and untreated through traditional face-to-face psychotherapy. Internet-based cognitive behavioral therapy (iCBT) has emerged as a tool to improve access to mental health services. However, iCBT remains underdeveloped in Chinese communities, particularly in Hong Kong.

Objective: This study aims to (1) develop and evaluate the effectiveness of a culturally and linguistically appropriate guided iCBT program for Hong Kong Chinese with depressive symptoms, and (2) explore their treatment adherence.

Methods: An 11-week guided iCBT program, “Confront and Navigate Depression Online” (CANDO), consisting of 8 online modules, was developed and implemented for Hong Kong residents. The program was accessible via either an online platform (web-based iCBT) or a smartphone app (app-based iCBT). A 3-arm randomized controlled trial was conducted, with participants recruited through open recruitment and referrals from 2 local non-governmental organizations. A total of 402 eligible participants with mild to moderate depressive symptoms were randomly allocated into 3 groups: (1) web-based iCBT (n=139); (2) app-based iCBT (n=131); and (3) waitlist control (WLC) group (n=132), who transitioned to the web-based iCBT group after waiting for 11 weeks. Therapist support was provided by a clinical psychologist through 3 counseling sessions and weekly assignment feedback. The primary outcomes were the Beck Depression Inventory-II (BDI-II) and the 9-item Patient Health Questionnaire (PHQ-9), while the secondary outcome measures included the 12-item General Health Questionnaire (GHQ-12), the Chinese Automatic Thoughts Questionnaire (CATQ), and the Chinese Affect Scale (CAS). These scales were administered at preintervention, postintervention, and at 3-month and 6-month follow-up assessments. Data analysis was conducted using linear mixed effects modeling, adhering to the intent-to-treat principle.

Results: Participants in both the web- and app-based iCBT groups reported significant improvements compared with the WLC group on all primary (P<.001) and secondary measures (P<.001 and P=.009) at posttreatment. Large between-group effect sizes were observed in the reduction of depressive symptoms, with Cohen's d value of 1.07 (95% CI 0.81-1.34) for the web-based group and 1.15 (95% CI 0.88-1.43) for the app-based group on the BDI-II. Additionally, the web- and app-based groups showed effect sizes of 0.78 (95% CI 0.52-1.04) and 0.95 (95% CI 0.63-1.27) on PHQ-9, respectively. Medium to large effect sizes were observed for secondary outcomes at posttreatment. These positive effects were maintained at both the 3- and 6-month follow-ups, with medium to large within-group effect sizes. The adherence rate in the 2 iCBT groups was 154 out of 270 (57.0%) for completing all 8 online modules and 152 out of 270 (56.3%) for attending all 4 counseling sessions (including an intake interview). The recovery rate, as measured by the BDI-II at posttreatment, was 35 out of 90 (39%) for the web-based group and 36 out of 91 (40%) for the app-based group, compared with 3 out of 112 (3%) in the WLC group.

Conclusions: Culturally and linguistically adapted iCBT is an effective and feasible treatment for Hong Kong Chinese with mild to moderate depressive symptoms, demonstrating a satisfactory recovery rate and treatment adherence. ICBT offers an

XSL•FO
RenderX

accessible and viable alternative to face-to-face interventions in Hong Kong. The Hong Kong government should allocate more resources and support the use of iCBT as a tool to treat people with depressive symptoms.

KEYWORDS

Internet-based cognitive behavioral therapy; depression; Chinese; Hong Kong, culturally adapted internet intervention

Introduction

Background

Depression is a widespread mental health issue that the World Health Organization (WHO) predicts will become the most burdensome globally by 2030 [1]. In Hong Kong, the prevalence of depression rose from 1.3% in 2011-2014 to 9.1% in 2019 among the general population [2]. Lam et al [3] reported a 13.3% prevalence of common mental disorders in Hong Kong, with mixed anxiety and depression being the most frequent diagnosis (6.9%). However, only 24%-26% of individuals with common mental disorders access mental health services [3]. Consequently, many people in Hong Kong, similar to those with mental health conditions in Western countries [4], remain undiagnosed and untreated. This is likely due to the stigma surrounding mental disorders, a shortage of mental health professionals, the high cost of private treatment, and long wait times for public services. The lack of treatment not only leads to poor mental health outcomes, such as the development of comorbid anxiety and substance use disorders, as well as an increased risk of suicide [5], but also manifests physically, including chronic pain [6], thereby reducing quality of life [5]. Furthermore, poor mental health outcomes have significant economic consequences, such as reduced productivity [7]. These factors highlight the critical importance of early diagnosis and treatment.

Internet-Based Cognitive Behavioral Therapy

Cognitive behavioral therapy (CBT) is the first-line treatment for depression. Andersson and Titov [8] demonstrated that internet-based CBT (iCBT) produces treatment effects comparable to traditional face-to-face CBT, while being more cost-effective. As Baumann et al [9] stated, “ICBT has a strong potential to balance demand and supply of CBT in unipolar depression by reducing therapist time per patient.”

Karyotaki et al [10] systematically reviewed 39 randomized controlled trials (RCTs) and found that both guided and unguided iCBT interventions are more effective than control treatments (treatment-as-usual and waitlist control [WLC]) in reducing depressive symptom severity in both the short and long term. Etzelmueller et al [11] conducted a meta-analysis demonstrating the acceptability and effectiveness of guided iCBT for treating depression in routine health care. While guided iCBT is more effective than unguided iCBT at posttreatment, no differences are observed at 6- or 12-month follow-ups [10].

Mobile therapy has gained prominence with the widespread adoption of smartphones, bringing mobile psychotherapy to the forefront. Studies indicate no significant differences in treatment effectiveness between guided smartphone-delivered and internet-based CBT programs [12]. However, smartphone use is more evenly distributed throughout the day, allowing iCBT to integrate more seamlessly into daily routines [12]. Given the high penetration rates of smartphones (97%) and computers (89%) in Hong Kong [13,14], developing an iCBT program accessible via both mobile apps and computers—and comparing their effectiveness—would be a valuable endeavor.

In recent years, particularly during the COVID-19 pandemic, iCBT has seen rapid development in Chinese societies. Studies have shown that culturally adapted iCBT significantly reduces symptoms of depression, generalized anxiety, psychological distress, rumination, and insomnia while improving self-efficacy among Chinese individuals, compared with WLCs [15-18]. Even in studies without WLCs, culturally adapted iCBT has proven effective in reducing symptoms of depression, generalized anxiety, psychological distress, perceived stress, sleep disturbances, and functional disability, while enhancing life satisfaction and energy levels for Chinese participants [19,20]. The positive effects of culturally adapted iCBT were sustained for 3 months [19], 6 months [18], and 12 months [15]. These studies used RCTs with either an active control group (eg, [21]) or a WLC group (eg, [16,18]). Most studies utilized mobile interventions (eg, [16-18]), while a few relied on web-based interventions [15,19], and 1 incorporated both [20]. To better address the diverse mental health needs of the Chinese population, further research on culturally adapted and tailored iCBT programs is needed.

Response rates of iCBT for depression, indicating a significant reduction in depressive symptoms, range from 37% to 56% in meta-analyses [10,22]. The response rate for guided iCBT (48%) is higher than that for unguided iCBT (37%) [10] and significantly higher than that of control groups [23]. Recovery rates of guided iCBT for depression, defined as the complete remission of depressive symptoms, have been reported to range from 30% to 55% at posttreatment and 41% to 60% at the 6- to 7-month follow-up [24,25]. Lin et al [16] found that the guided iCBT program for Chinese individuals with depression achieved a high response rate (58%) and remission rate (55%). Similarly, Ying et al [18] reported that 38.2% and 33.3% of Chinese participants in their iCBT study demonstrated clinically meaningful improvements in depressive symptoms at postintervention and at the 6-month follow-up, respectively.

Regarding treatment adherence to iCBT, van Ballegooijen et al [26] found that the completion rate of the entire guided iCBT program for depression was 65.1%, significantly lower than the rate for face-to-face CBT (84.7%). However, there was no significant difference in the number of completed sessions, with

XSL•FO
RenderX

83.9% in face-to-face CBT and 80.8% in guided iCBT [26]. Similarly, Karyotaki et al [10] reported in their meta-analysis an average adherence rate (number of completed sessions/total number of sessions) of 76% for guided iCBT and 54% for unguided iCBT. Individual empirical studies show that the adherence rate (percentage of completers) of guided iCBT for depression is higher among a Chinese population, ranging from 67.0% [21] to 81.4% [18], compared with their Western counterparts, whose adherence rates range from 36.4% [27] to 60% [28]. The average session completion rate in guided iCBT for Hong Kong Chinese ranges from 52.7% [21] to 83.8% [18]. Karyotaki et al [10] also reported that the average dropout rate was 25% for guided iCBT and 29% for unguided iCBT, compared with 19% for those on a WLC and 22% for those receiving treatment as usual. Additionally, Chinese participants in iCBT reported high levels of satisfaction during depression treatment (eg, [16,18]).

Cultural Adaptation of iCBT

There is evidence suggesting the potential benefits of cultural adaptation in digital mental health interventions, including iCBT, for improving a range of outcomes compared with WLC and treatment-as-usual control conditions [29]. However, direct comparisons of the effectiveness of culturally adapted versus unadapted internet-based interventions remain lacking. For Chinese participants, Ng and Wong [30] demonstrated that the short-term effects of culturally adapted CBT were stronger than those of unadapted CBT. Similarly, iCBT should be culturally adapted to address the specific cultural needs of Chinese clients, taking into account cultural factors that may influence its effectiveness and acceptability. The following considerations are important when promoting iCBT to Chinese clients. First, the program should use culturally appropriate language, including Mandarin or other Chinese dialects, as well as idioms and expressions, to enhance understanding and engagement. For instance, Wong [31] translated the term “cognitive distortion” into the Chinese phrase “Xi Xiang Xian Jing (思想陷阱)” and adapted various types of cognitive distortions into 4-character Chinese idioms. Second, cultural sensitivity and awareness should be incorporated into the program content to align with Chinese cultural norms, values, and experiences. For example, an iCBT program for Hong Kong Chinese university students integrated Chinese cultural values into its content [32]. Additionally, collectivism should be emphasized by addressing relationships with others, social role expectations, and family obligations, which are highly valued in Chinese culture [33]. Third, the stigma surrounding mental health issues often deters Chinese individuals from seeking face-to-face services [34]. ICBT programs should tackle this cultural stigma by providing psychoeducation on mental health and emphasizing the importance of help-seeking. Fourth, when designing an iCBT program for Chinese participants, incorporating more videos (eg, case studies and animations) and reducing text can foster greater interaction and engagement [32,33]. Finally, therapists in guided iCBT programs should possess cultural and linguistic competence in Chinese culture and language [32].

Undoubtedly, iCBT is an effective, feasible, and acceptable approach for treating depression among Chinese individuals. However, it remains underdeveloped in Chinese communities, particularly in Hong Kong. Moreover, whether the delivery medium (web- or app-based) influences treatment outcomes is still unclear. To address this, this study developed and tested the effectiveness of a culturally and linguistically appropriate guided iCBT program for Hong Kong people with mild to moderate depressive symptoms, utilizing both web- and app-based platforms. We hypothesized the following:

- Participants in the web- and app-based iCBT groups would have lower levels of depressive symptoms upon completion of the intervention compared with the WLC group.
- Participants in the web- and app-based iCBT groups would have lower levels of anxiety symptoms, psychological distress, and negative thoughts and emotions upon completion of the intervention compared with the WLC group.
- Participants in the web- and app-based iCBT groups would have higher levels of positive thoughts and emotions upon completion of the intervention compared with the WLC group.
- There would be no significant differences in intervention effects between the web- and app-based iCBT groups.
- The effects of the web- and app-based iCBT programs would be sustained at 3 and 6 months postintervention.

Methods

Participant Selection Criteria

Participants were selected based on the following criteria: (1) aged 18-70 years; (2) proficient in Chinese; (3) a 9-item Patient Health Questionnaire (PHQ-9) score between 5 and 19; (4) no suicidal risk in the past 3 months, defined as a score of “0” or “1” on Item 9 of the Beck Depression Inventory-II (BDI-II) and low suicidal risk as assessed during the intake interview; (5) not receiving any other psychological treatment for depression at the time of allocation; (6) no severe psychiatric conditions, such as bipolar disorder, as self-reported in the screening questionnaire and confirmed by the therapist during the intake interview; (7) access to a computer or smartphone with an internet connection; and (8) possession of a valid email address.

Recruitment and Screening

Participants were recruited from the general population in Hong Kong on an ongoing basis from April 2020 to January 2022. Recruitment methods included advertisements on social media platforms (Facebook and Instagram), Google Ads, a press conference, posters, leaflets, and referrals from 2 local partner nongovernmental organizations. Interested individuals registered at [35] by completing a screening questionnaire that included the PHQ-9, the BDI-II, and the Beck Anxiety Inventory (BAI). Initially, qualified participants were invited to a 1.5-hour intake interview conducted in-person or via Zoom (Zoom Communications/Qumu Corporation) with a clinical psychologist or an experienced social worker to further assess their suitability for participation, including a suicidal risk assessment. Marginal cases were discussed in a case meeting that included the first author (JYP), intake worker, and program therapist to assess participation eligibility. High-risk individuals with severe depression or suicidal risk or both were referred to

XSL•FO
RenderX

local mental health services for further diagnosis and treatment with their consent.

Research Design

A 3-arm RCT was conducted with a WLC group design. Randomization was performed using computer-generated random numbers by the therapist to allocate eligible participants to 1 of 3 groups: web-based iCBT, app-based iCBT, and WLC (1:1:1 allocation). Participants in the WLC group received web-based treatment immediately after the 2 iCBT groups completed their program. All 3 groups completed the same online questionnaire at pretest, posttest, and at 3- and 6-month follow-ups. The WLC group completed the questionnaire an additional time as a posttest after the 2 experimental groups had completed the program.

Ethical Considerations

An informed consent form was presented at the beginning of the questionnaire. After participants provided their consent to join the study, the online questionnaire was displayed to them. The RCT was conducted with a total of 13 cohorts from May 2020 to January 2023, with around 30 qualified participants in each cohort for implementation feasibility. The program evaluators were blinded to participant allocation. Ethics approval was obtained from the Research Ethics Committee of the university of the first author (JYP). The clinical trial was registered at ClinicalTrials.gov (NCT04388800).

Sample Size

A power analysis was conducted to calculate the required number of participants, assuming a medium effect size (*d*) of 0.5 [16], an α level of .05, and 95% power. The minimum required sample size was estimated to be around 210 participants. Given an assumed completion rate of 55%, the goal was to recruit approximately 400 participants.

Intervention: Confront and Navigate Depression Online (CANDO) Program

The "Confront and Navigate Depression Online" (CANDO) Program was an 11-week therapist-guided iCBT program designed for Hong Kong Chinese with mild to moderate depressive symptoms (Multimedia Appendix 1). The program was developed based on the principles of CBT as outlined by Beck [36], and adapted for Chinese clients (eg, [31,37]). It utilized a blended mode of service delivery, featuring 8 online modules and four 1-hour individual counseling sessions including 1 intake interview. Each module introduced different cognitive behavioral skills for coping with depression through self-developed videos. The themes of the 8 online modules are (1) understanding my depression within the CBT framework; (2) identifying automatic thoughts and cognitive distortions; (3) self-talk and positive statements; (4) behavioral experiments and behavioral activation; (5) problem-solving; (6) identifying and understanding cognitive rules; (7) relaxing dysfunctional cognitive rules; and (8) conclusion and relapse prevention. A variety of CBT skills were introduced and reinforced using animated videos and demonstrated through 5 local cases. Each online module began with a mood check for the past week using a 10-point scale and concluded with a session review and an assignment designed to help clients apply the skills they had learned to manage their depression. The modules were released to participants on a weekly basis, with counseling sessions scheduled in between for skills application. Additional program features included a client portfolio, online questionnaires, reminders, and an online booking system.

The development of the CANDO Program was guided by the cultural adaptation framework for psychosocial treatments proposed by Bernal et al [38]. The components listed in Textbox 1 were addressed to culturally adapt the program for Hong Kong Chinese.

Textbox 1. Components addressed to culturally adapt the program for Hong Kong Chinese.

1. Language

The entire program was developed and delivered in the local Cantonese language.

2. Metaphors

Various cognitive distortions were represented using 4-character Chinese idioms, such as "Fei Hei Ji Bai (非黑即白)" (all-or-nothing thinking), "Da Nan Lin Tou (大難臨頭)" (catastrophizing), and "Cai Duo Ren Yi (猜度人意)" (mind-reading) [31].

3. Content

The case demonstration videos were specifically tailored for Hong Kong Chinese people, drawing on and adapting numerous real-life cases within the Hong Kong context. These videos incorporated Chinese cultural values such as gender and social role expectations, face-saving, collectivism, and the high emphasis on academic achievement, addressing these themes across different life stages. For instance, an analysis of advantages and disadvantages was used to challenge and relax the cognitive rule of "男主外, 女主內" ("The husband is responsible for earning a living to support his family, while the wife is responsible for taking care of the family") into a more progressive belief that "there is no fixed stereotype of gender roles within a family as society advances." Another example is the use of a pie chart technique to redefine the concept of "a good mom" in Chinese society, broadening it to include multiple perspectives rather than focusing solely on helping children achieve academic excellence.

4. Persons

Therapists with the same ethnic and cultural background as the Hong Kong Chinese clients were selected for service delivery.

5. Method

The internet-based cognitive behavioral therapy delivery format was adapted to primarily use self-developed videos to teach and demonstrate various cognitive behavioral therapy skills.

XSL•FO
RenderX

The client platform offered both a web-based version, accessible via the program website, and a mobile app, available for download through Google Play (Google LLC/Alphabet, Inc.) or Apple Store (Apple, Inc.). After enrollment, clients were provided with an account to access the system. Clients with a PC web account could not log-in via the app, and those with an app account could not access the web-based version. Each client was assigned a therapist who provided therapeutic support through 3 counseling sessions conducted either face-to-face or online (via Zoom, WhatsApp call [Meta Platforms, Inc.], or telephone). These sessions included feedback on assignments, responses to internal messages, and online forum management. Both automated reminders and staff reminders were used to ensure participants remained engaged with the program.

To ensure data security and privacy, 2-factor authentication was implemented. This required users to log-in with a password preset by the user and a 1-time password sent to their email address. All collected electronic data were encrypted. The program was hosted on the server managed by the Information and Technology Office of the first author's (JYP) university. Before the program's launch, a user acceptance test was conducted to address bugs, and a security test was carried out by a third party to ensure system safety. Bugs reported by participants during the project were also addressed promptly throughout its implementation.

Therapist Credibility

The therapist was a clinical psychologist with a doctorate in clinical psychology and a master's degree in counseling. She had over 10 years of clinical experience in Hong Kong and the United States. The intake worker was a registered social worker in Hong Kong with bachelor's and master's degrees in social work, and more than 30 years of counseling experience in diverse settings. The intake interviews were conducted by both the therapist and the intake worker, while the initial screenings were performed by the therapist. All services were delivered in Cantonese, and both professionals were native Cantonese speakers.

Measurements

Depressive symptoms were assessed using both the BDI-II [39] and PHQ-9 [40]. For the BDI-II, scores of 0-9, 10-18, 19-29, and 30 or above indicate minimal, mild, moderate, and severe levels of depressive symptoms, respectively. For the PHQ-9, scores of 0-4, 5-9, 10-14, 15-19, and 20-27 correspond to minimal, mild, moderate, moderately severe, and severe depression, respectively. Anxiety symptoms were evaluated using the BAI [41]. In this study, the Cronbach α values were 0.866 (95% CI 0.844-0.884) for the BDI-II, 0.812 (95% CI 0.779-0.839) for the PHQ-9, and 0.909 (95% CI 0.890-0.923) for the BAI, demonstrating high internal consistency for all measures.

Psychological distress was measured using the Chinese version of the 12-item General Health Questionnaire (GHQ-12) [42,43]. The 0-0-1-1 scoring method was applied to calculate the total score, which ranged from 0 to 12, with higher scores indicating greater levels of psychological distress. A cut-off point of 1/2, validated for the Chinese population, was used to identify participants at risk of developing mental health problems [44]. In this study, the Cronbach α for the GHQ-12 was 0.866 (95% CI 0.844-0.884), indicating high internal consistency.

Automatic thoughts were measured using the Chinese Automatic Thoughts Questionnaire [45], which was developed from the Automatic Thoughts Questionnaire [46] and the Positive Automatic Thoughts subscale of the revised Automatic Thoughts Questionnaire [47]. Participants rated the frequency of each thought in the past week on a 5-point scale (1="Not at all" to 5="All the time"). Item scores were summed for the positive and negative subscales, with higher total scores indicating more positive and negative automatic thoughts, respectively. Cronbach α was 0.883 (95% CI 0.825-0.889) for the positive subscale and 0.88 (95% CI 0.859-0.899) for the negative subscale in this study.

Positive and negative emotions were assessed using the Chinese Affect Scale [48], which consists of 20 items with 2 subscales: positive affect (PA; 10 items) and negative affect (NA; 10 items). Participants rated the items on a 6-point Likert scale (1="not at all" to 6="extremely"). The scores for each subscale were summed, with higher scores indicating higher levels of PA and NA, respectively. The Cronbach α coefficients were 0.883 (95% CI 0.863-0.900) for the PA subscale and 0.876 (95% CI 0.853-0.894) for the NA subscale in this study.

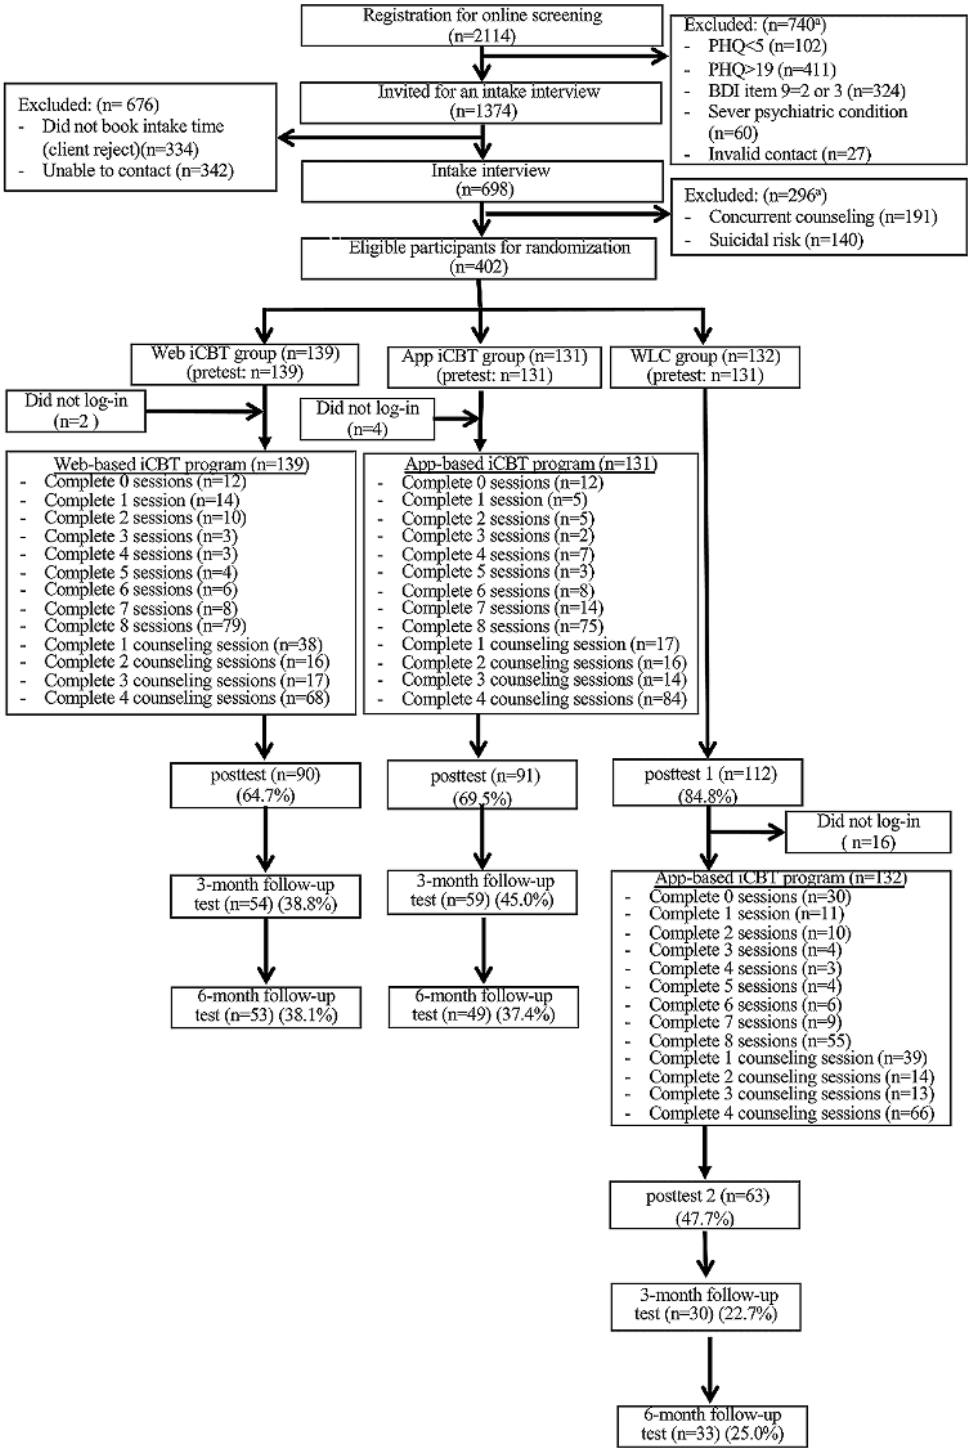
Statistical Analysis

All analyses followed the CONSORT (Consolidated Standards of Reporting Trials) statement for RCTs [49]. Assignment completion and dropout were analyzed using a chi-square test and logistic regression. Missing data were imputed with m=5 data sets using multiple imputations with chained equations and predictive mean matching [50]. Analyses were conducted according to the intent-to-treat approach and performed on imputed data sets before pooling the coefficients. Analyses were conducted within a linear mixed model framework [51]. Outcomes at baseline, age, gender, and medication use were included as covariates. Sensitivity analyses using completer-only data were also conducted. When comparing the active treatments (web-based iCBT vs app-based iCBT) at posttreatment, and at 3 and 6 months, models included treatment, time, and the interaction between time and treatment. The within-group effects of transitioning from WLC to active treatments were modeled in a separate analysis, using the second premeasurement as a baseline (see Table S4 in Multimedia Appendix 2). All models used restricted maximum likelihood estimation and an unstructured covariance matrix. Chi-square tests and logistic regression were conducted to explore differences in baseline characteristics between those who completed all modules and those who did not, as well as between those who completed postmeasurements and those who did not. Effect sizes were calculated using Cohen *d* [52] with the emmeans package [53], following the standard convention for magnitudes of effect sizes: small (d=0.2), medium (d=0.5), and large (d≥0.8). Data analyses were performed in R version 4.3.1 (R Foundation) [54].

Clinical significance was calculated using the Jacobson-Truax method [55]. "Recovered" was defined as a positive change that is both reliable (ie, not due to measurement error) and clinically

XSL•FO
RenderX

significant (ie, an improvement of 2 SDs from the baseline sample mean); "improved" was defined as a reliable improvement, but not clinically significant; "unchanged" was defined as no reliable change; and "deteriorated" was defined as a reliable worsening. Following van Ballegooijen et al's [26] suggestion, those who were given an intervention but did not commence treatment were also included in the calculation of the adherence rate. Adherence was analyzed separately for treatment modules and counseling sessions. Treatment adherence was defined as completing all 8 treatment modules, and counseling adherence was defined as participating in all 4 counseling sessions. The calculation was based on the data at the posttest.



Results

Participant Flow

A total of 2114 participants registered for the CANDO Program's online screening, and 1374 were invited for an intake interview for further assessment. Of these, 698 intake interviews were conducted, and ultimately, 402 participants who met the inclusion criteria were randomly assigned to 1 of the 3 groups: web-based iCBT (n=139), app-based iCBT (n=131), and WLC (n=132). All allocated participants, except for 1 in the WLC group, completed a pretest questionnaire and were included in the intent-to-treat analysis; 2, 4, and 16 eligible participants did not log into the CANDO system after being assigned a client account in the web-based iCBT, app-based iCBT, and WLC groups, respectively, resulting in 137, 127, and 116 participants in the corresponding intervention conditions. At the posttest, 90, 91, and 112 participants provided data in the web-based iCBT, app-based iCBT, and WLC groups, respectively. A total of 116 participants from the WLC group later joined the web-based iCBT program, with 63, 30, and 33 participants providing data at posttreatment, 3-month, and 6-month follow-up tests, respectively. For the web-based/app-based iCBT groups, 54/59 and 53/49 participants provided data at the 3- and 6-month follow-up tests, respectively. See Figure 1 for the participant flowchart. Also see Multimedia Appendix 3.

RenderX

Figure 1. Participant flow of the study. iCBT: internet-based cognitive behavioral therapy.

a. The sum of the following number is bigger than excluded number as some participants have fulfilled more than one exclusion criterion.

Participant Characteristics

Table 1 summarizes the participant data at baseline. Among the 402 participants who were randomized, 313 (77.9%) were female and 89 (22.1%) were male; 225 (56.0%) were single and 130 (32.3%) were married. The mean age was 37.3 (SD 11.0) years. The majority of participants (n=310, 77.1%) had university degrees, 85 (21.1%) and 1 (0.2%) had completed secondary and primary school education, respectively. A total of 77 (19.2%) participants were diagnosed with depression, 29 (7.2%) with anxiety, and 39 (9.7%) with other mental health conditions. Furthermore, 83 participants (20.6%) reported a history of self-harm, and 17 (4.2%) had previously attempted suicide; 99 participants (24.6%) reported using medication.

Missing	257 (63.9)	85 (61.2)	80 (61.1)	92 (69.7)

[a]WLC: waitlist control.

Treatment Adherence and Attrition Rate

Following van Ballegooijen et al's [26] suggestion, those who were given an intervention but did not commence treatment were also included in the calculation of the adherence rate. Thus, for adherence to the online modules, 79 of 139 (56.8%) participants in the web-based iCBT group and 75 of 131 (57.3%) in the app-based iCBT group completed all 8 modules, resulting in an overall adherence rate of over 50% (154/270, 57.0%). For the counseling sessions, 68 of 139 (48.9%) participants in the web-based group and 84 of 131 (64.1%) in the app-based group attended all 4 sessions (overall adherence rate: 152/270, 56.3%) The participants in the web- and app-based iCBT groups completed an average of 5.96 out of 8 modules (74.5%) and 5.77 out of 8 assignments (72.1%), respectively. In terms of module completion rate, there was no significant difference between the web-based (79/139, 56.8%) and app-based (75/131, 57.3%, χ^2_1=0.005, *P*=.95) groups. Similarly, no significant difference was found in the assignment completion rate between the web-based (70/139, 50.4%) and app-based (69/131, 52.7%, χ^2_1=0.07, *P*=.8) groups. Furthermore, there was no association between assignment completion and gender (χ^2_1=0.97, *P*=.32) or medication (χ^2_1=0.52, *P*=.47). However, a positive association was found between assignment completion and age (odds ratio 1.04, *P*=.003). Thus, older participants completed more assignments. Regarding the attrition rate for questionnaire submission, 89 out of 270 (33.0%), 157 out of 270 (58.1%), and 168 out of 270 (62.2%) participants in the 2 iCBT groups were lost to follow-up at posttest, 3-month, and 6-month follow-ups, respectively. The submission rates for the questionnaires are shown in Figure 1. Adherence to completing the postmeasurements was similar to module adherence, with older individuals being more likely to complete the postmeasurement (odds ratio 1.02, *P*=.047). However, there was no association between completing the postmeasurement and model covariates such as gender (χ^2_1=1.07, *P*=.30), treatment group (χ^2_1=0.48, *P*=.49), or medication (χ^2_1=0.003, *P*=.95). A chi-square test showed that there were no significant differences in demographic characteristics between completers and noncompleters of the postmeasurement and all 8 online modules (see Tables S2 and S3 in Multimedia Appendix 2).

Treatment Effects at Posttest

The treatment effects at posttest, comparing the 2 iCBT groups with the WLC group, are shown in Table 2 and Figure 2. The primary analysis, which compared the 2 active treatments with the WLC at posttreatment using the data set with multiple imputed data, showed that both iCBT groups were superior to the WLC group. The adjusted differences on the BDI-II were –8.24 (95% CI –5.96 to –10.52; *P*<.001) for the web-based iCBT group, and –9.38 (95% CI –7.10 to –11.65; *P*<.001) for the app-based iCBT group. Likewise, the treatment effects for the PHQ-9 were also superior to the WLC group, with an adjusted score of –3.07 (95% CI –1.67 to –4.46; *P*<.001) for the web-based iCBT group and –4.50 (95% CI –3.12 to –5.89; *P*<.001) for the app-based iCBT group. All secondary outcome measures showed significant improvement compared with the WLC at postmeasurement (*P*=.009). The between-group effect sizes for the BDI-II were *d*=1.07 (95% CI 0.81-1.34) and *d*=1.15 (95% CI 0.88-1.43) for the web-based and app-based iCBT groups, respectively. For the PHQ-9, the corresponding

XSL•FO
RenderX

between-group effect sizes were *d*=0.78 (95% CI 0.52-1.04) and *d*=0.95 (95% CI 0.63-1.27) for the web-based and app-based iCBT groups, respectively. Sensitivity analyses using the completer-only data set yielded similar results (see Table S1 in Multimedia Appendix 2). The within-group effect sizes for the BDI-II at posttest were *d*=1.49 (95% CI 1.19-1.78) for the web-based iCBT group and *d*=1.64 (95% CI 1.33-1.95) for the app-based iCBT group. The corresponding effect sizes for the PHQ-9 at posttest were *d*=1.11 (95% CI 0.81-1.41) for the web-based iCBT group and *d*=1.70 (95% CI 1.38-2.02) for the app-based iCBT group. The WLC group showed significant improvement on all outcome measures, with medium to large within-group effect sizes when transitioning to the web-based iCBT (see Table S4 in Multimedia Appendix 2).

Table 2. Comparison of treatment effects between the active and WLC[a] groups at posttreatment (intent-to-treat analysis).

Outcome	Unadjusted mean (SD)			Adjusted difference (95% CI)				Between-group effect size *d* (95% CI)		Within-group effect size (95% CI)		
	Web	App	WLC	Web vs WLC	*P* value	App vs WLC	*P* value	Web vs WLC	App vs WLC	Web	App	WLC

Figure 2. Treatment effects for primary outcomes BDI and PHQ-9. Shaded regions show 95% CIs. BDI: Beck Depression Inventory; PHQ-9: 9-item Patient Health Questionnaire.

Reliable Changes at Postintervention Assessments

The frequencies and percentages of reliable change are shown in Table 3. At posttest, using the BDI-II as the outcome measure, reliable recovery was observed in 35 out of 90 (38.9%) participants in the web-based iCBT group, 36 out of 91 (39.6%) in the app-based iCBT group, and 3 out of 112 (2.7%) in the WLC group. For the PHQ-9 at posttest, the reliable recovery rates were 16 out of 67 (24%) for the web-based iCBT group, 16 out of 72 (22%) for the app-based iCBT group, and 5 out of 88 (6%) for the WLC group. Chi-square tests of association revealed a significant difference in the distribution of the 3 groups for both the BDI-II (χ^2_6=71.92, P<.001) and the PHQ-9 (χ^2_6=33.78, P<.001). When comparing clinical significance between the 2 treatment groups, no significant differences were found (χ^2_3=3.24, P=.35).

The reliable recovery rates for BDI-II at the 6-month follow-up were 13 out of 53 (25%) for the web-based iCBT group and 14 out of 49 (29%) for the app-based iCBT group. For PHQ-9 at the 6-month follow-up, the corresponding reliable recovery rates were 4 out of 40 (10%) for the web-based iCBT group and 3 out of 38 (8%) for the app-based iCBT group.

Comparisons Between Two iCBT Groups at Posttreatment Assessments

At posttreatment, the web-based iCBT group did not show a significant difference in BDI-II (adjusted difference 0.21, 95% CI –2.28 to 2.70, *P*=.87) or PHQ-9 (adjusted difference 0.35, 95% CI –1.08 to 1.77, *P*=.63) scores compared with the app-based iCBT group. Similarly, at the 3- and 6-month follow-ups, the differences between the 2 iCBT groups in their BDI-II and PHQ-9 scores remained nonsignificant (Table 4). For the secondary outcome measures, no significant differences were found between the 2 groups on any outcome measure at any time point, except for the GHQ-12 at 6 months, which favored the web group (adjusted difference –1.46, 95% CI –0.33 to –2.59, *P*=.01). Compared with the baseline, the within-group effect sizes ranged from 0.54 to 2.21 at posttreatment assessments for both the web- and app-based iCBT groups (Table 4). Thus, both iCBT groups maintained treatment effects at the 3- and 6-month follow-ups for most of the outcome measures.

Discussion

Effectiveness of iCBT for Hong Kong Chinese

To the best of our knowledge, this study is one of the few to develop and test the effectiveness of iCBT among Hong Kong Chinese. Both the web- and app-based iCBT groups were superior to the WLC in managing depressive symptoms. The findings suggest that a culturally and linguistically appropriate, therapist-guided iCBT program yields positive therapeutic effects, with a good recovery rate and treatment adherence, for Hong Kong Chinese with mild to moderate depressive symptoms. These positive effects are maintained at the 3- and 6-month follow-ups, including reductions in depression and anxiety symptoms, psychological distress, negative automatic thoughts, and negative emotions, as well as increases in positive automatic thoughts and emotions. The 2 delivery modalities of iCBT showed similar intervention effects on most of the outcome measures at posttreatment and follow-up tests. These findings are consistent with those reported in Western contexts [10], China (eg, [16,18]), and Hong Kong [19,20]. The recovery rates at posttreatment, as measured by the BDI-II, were 39% (35/90) and 40% (36/91) for web- and app-based iCBT, respectively. These rates align with those (30%-55%) reported in RCT studies involving Western participants [24,25], but are lower than the 58% recovery rate reported in an RCT study of iCBT conducted in hospitals with Chinese patients with depression in China [16]. The positive effects of iCBT on depression treatment are comparable to face-to-face CBT in terms of symptom reduction (eg, [56]) and recovery rate (eg, [57]), suggesting that iCBT does not compromise treatment outcomes.

Like CBT, it appears that a culturally adapted iCBT works well for Chinese people. The positive effects of the CANDO Program may be attributed to the cultural and linguistic adaptations of iCBT for Hong Kong Chinese. First, the program is delivered in Cantonese, the mother tongue of Hong Kong residents, to facilitate their understanding of the content. Additionally, 4-character Chinese idioms [31] are used to describe cognitive distortions, ensuring an accurate understanding of the CBT concepts and skills. Second, many real-life examples are incorporated into the case videos to demonstrate the application of CBT skills in coping with depression in the context of Hong Kong. These examples may resonate with participants' own automatic thoughts and cognitive rules, enhancing their self-learning of CBT skills. Third, laypersons—such as family members, friends, and colleagues—who have experience and knowledge of CBT appear in the case demonstration videos (except for 1 case) as therapists. This approach helps normalize the help-seeking and counseling process, reducing the stigma surrounding mental health issues and making it more acceptable to Hong Kong Chinese. Fourth, the CANDO Program is video-based with limited text narrative, which aligns with the preferred approach of Hong Kong people for receiving new information and learning new knowledge and skills through watching videos. Fifth, the program includes relaxation exercises to enhance the Chinese philosophy of body-mind connection, which complements the CBT framework that links the body, cognition, and emotions. Finally, the therapist is a Chinese clinical psychologist with training and practical experience in both Hong Kong and the United States, ensuring cultural sensitivity in working with Hong Kong Chinese.

Program Adherence and Attrition

The percentage of completed sessions in this study (5.96/8, 75%) is slightly lower than those reported in meta-analyses (80.8% in [26] and 76.0% in [10]), but much higher than that reported in a Hong Kong study (52.7% in [21]) and lower than that in a study in China (83.8% in [18]). The percentage of participants who completed all the sessions in this study (154/270, 57.0%) is similar to those reported in [26] (65.1%) and other empirical studies (eg, 60% in [28] and 67% in [21]), but lower than that in [18] (81.4%). Overall, the program adherence in this study is comparable to that in previous studies, though slightly lower than that in [18]. One reason for this difference may be related to the number of sessions (8 sessions in the CANDO Program compared with 5 in [18]), as it is generally easier to complete an iCBT program with fewer sessions. Another factor is the setting; Ying et al [18] conducted their study in a hospital, where doctors acted as therapists and provided relatively intensive guidance, which likely encouraged greater program engagement. The Chinese cultural tendency to

XSL•FO
RenderX

adhere to the authority of medical professionals may have contributed to the higher adherence observed in their study.

Consistent with previous findings, this study also observed a high attrition rate at postintervention. Specifically, the attrition rate at posttest (89/270, 33.0%) is comparable to the average dropout rate of 28% found in therapist-guided computer-based intervention studies in [58], which is higher than the approximately 17% dropout rate in RCT studies of face-to-face CBT [58]. The high attrition rates in this study are also consistent with those reported in Hong Kong studies [21,59]. One possible reason for the high attrition rate may be the fast-paced lifestyle of Hong Kong residents, which limits their ability to commit to the program. Additionally, a lack of motivation to participate could contribute to the dropout rate. Similar to [21], the participants in this study did not have a formal diagnosis of a mental disorder and did not have an immediate need for help-seeking or intervention retention.

No significant difference in program effectiveness or adherence was found between the web- and app-based iCBT groups among Hong Kong people with mild to moderate levels of depression. This suggests that the medium of service delivery does not impact the intervention effects, with both formats being equally effective.

Theoretical and Practice Implications

At the theoretical level, the findings offer empirical evidence supporting the effectiveness of iCBT for handling depressive symptoms in Chinese communities. Culturally and linguistically adapted iCBT ensures its relevance and effectiveness for the Chinese population, particularly for Hong Kong Chinese. The use of the internet and mobile app for delivering CBT represents a significant advancement in mental health care, especially in Hong Kong, where the high penetration of digital devices facilitates the widespread adoption of iCBT. This study provides a strong evidence base that supports the adoption and further development of iCBT in Hong Kong. At the practice level, this study demonstrates that Hong Kong Chinese are receptive to iCBT, making it a viable alternative that can be integrated into traditional mental health services. Furthermore, iCBT is cost-effective. This study, conducted during the COVID-19 pandemic when most face-to-face mental health services were suspended, highlights the significant advantage of iCBT in terms of the therapist-to-client ratio. For the CANDO Program, the therapist-to-client ratio is 1:190 per year, which is much higher than the traditional face-to-face therapy ratio of 1:40-50 in Hong Kong [60]. This is especially relevant to Hong Kong, where there is a severe shortage of mental health professionals and long wait times for traditional services. iCBT offers a scalable and viable solution to address this service gap in the long term. Therefore, more resources, particularly from the government, should be allocated to developing additional iCBT programs for mental health conditions, training more iCBT therapists, and integrating iCBT into the infrastructure of existing mental health care systems in Hong Kong.

Limitations

One major limitation of this study is the high attrition rate in questionnaire submission postintervention, despite various efforts to encourage participation. Although this is common, it may introduce nonresponse bias. Future studies should aim to reduce the attrition rate through improvements in program design and service delivery. A second limitation is that the therapist's time per client was not recorded, making it difficult to evaluate the cost-effectiveness of the program more accurately. Future studies should track these data to better assess the program's cost-effectiveness. Third, client satisfaction data were not collected, which could provide valuable insights into user experience and should be considered in future research. Finally, a large proportion of participants were female (313/402, 77.9%) and highly educated (310/402, 77.1%, holding a university degree or higher), which may limit the generalizability of the findings to the broader Hong Kong population. While gender was controlled as a covariate in the data analysis, future studies should aim to recruit more male participants and those with lower levels of education to improve representativeness.

Conclusions

This RCT study demonstrates that both web- and app-based iCBT are effective in reducing depression and anxiety symptoms, psychological distress, and negative automatic thoughts and emotions, while enhancing positive automatic thoughts and emotions in Hong Kong Chinese with mild to moderate depressive symptoms. The study also shows good program adherence and recovery rates, although the attrition rate for questionnaire submission postintervention was relatively low. ICBT is a promising approach in Hong Kong and warrants increased resource allocation for further development and implementation.

Acknowledgments

This study was funded by the Innovation and Technology Fund for Better Living, Innovation and Technology Bureau of Hong Kong SAR (reference number ITB/FBL/5022/18/P). The authors thank Professor Per Carlbring for his guidance during the grant application process for this project. The authors also wish to express their gratitude to Miss Chor Kiu Chan for system development and technical support, Dr. Fiona Yip for service delivery, Miss Jenny Chan for conducting the intake interviews, and Miss Amy Ho and Miss Tracy Leung for their administrative support.

Abstract

Background: The phenomenon of cyberbullying is becoming increasingly severe, and many studies focus on the negative psychological impacts of cyberbullying survivors. However, current survey methods cannot provide direct and reliable evidence of the short-term psychological effects of cyberbullying survivors, as it is impractical to measure psychological changes before and after such an unpredictable event in a short period.

Objective: This study aims to explore the psychological impacts of cyberbullying on survivors during the pericyberbullying period, defined as the critical time frame surrounding the first cyberbullying incident, encompassing the psychological changes before, during, and after the event.

Methods: We collected samples from 60 cyberbullying survivors (experimental group, 94/120, 78% female) and 60 individuals who have not experienced cyberbullying (control group, matched by sex, location, and number of followers) on Sina Weibo, a social media platform developed by Sina Corporation. During the pericyberbullying period, we retrospectively measured psychological traits 3 months before and after the first cyberbullying incident for both groups. Social media data and predictive models were used to identify survivors' internal psychological traits, including happiness, suicide risk, personality traits, and moral perceptions of the external environment. Network analysis was then performed to explore the interplay between cyberbullying experiences and psychological characteristics.

Results: During the pericyberbullying period, survivors exhibited significantly reduced happiness (t_{59}=2.14; P=.04), marginally increased suicide risk, and significant changes in the Big 5 personality traits, including decreased conscientiousness (t_{59}=2.27; P=.03), agreeableness (t_{59}=2.79; P=.007), and extraversion (t_{59}=2.26; P=.03), alongside increased neuroticism (t_{59}=–3.42; P=.001). Regarding moral perceptions of the external environment, survivors showed significant increases in communicative moral motivation (t_{59}=–2.62; P=.011) and FairnessVice (t_{59}=–2.20; P=.03), with a marginal rise in PurityVice (t_{59}=–1.88; P=.07). In contrast, the control group exhibited no significant changes during the same time frame. Additionally, network analysis revealed that beyond cyberbullying experiences, core psychological characteristics in the network were neuroticism, conscientiousness, and Oxford Happiness.

Conclusions: By leveraging noninvasive retrospective social media data, this study provides novel insights into the short-term psychological impacts of cyberbullying during the pericyberbullying period. The findings highlight the need for timely interventions

focusing on enhancing survivors' happiness, reducing suicide risk, adjusting personality traits, and rebuilding moral cognition to mitigate the negative effects of cyberbullying.

Introduction

Background

Cyberbullying is a growing global phenomenon, with the prevalence of cyberbullying experiences increasing significantly over the past 2 decades [1]. In today's highly interconnected world, anyone can become a survivor of cyberbullying [2]. Cyberbullying refers to the use of digital technologies to intentionally harm others, either directly or indirectly. When the survivor perceives the perpetrator's intent as deliberate and experiences harm, they are considered a survivor of cyberbullying [3].

Cyberbullying is a significant source of social stress [4]. According to the stress theory proposed by Lazarus and Folkman [5] and Selye's [6] general adaptation syndrome, individuals who perceive themselves as unable to cope with stress are more likely to experience negative psychological outcomes. In the context of cyberbullying, survivors often experience intense psychological stress in the short term, which can affect their happiness, suicide risk, personality traits, and perceptions of moral injustice in the external environment [7-19].

Although previous studies have demonstrated the negative psychological impacts of cyberbullying, they have largely relied on self-report questionnaire methods, which are susceptible to individual recall bias. Moreover, a few studies have investigated the psychological characteristics of individuals both before and after experiencing cyberbullying, which may obscure the effects of innate differences as well as the role of cyberbullying itself [20]. Additionally, existing longitudinal studies typically focus on the long-term impacts that include data collected prior to cyberbullying, with research time periods ranging from 6 months to 3 years [21]. Due to the unpredictability of cyberbullying, collecting a sufficient sample to assess its immediate psychological impacts presents significant challenges. To address this issue, this study draws inspiration from analogous terms in the medical field, such as the "perinatal period" and the "perioperative period," which describe key stages of change surrounding specific events or states [22]. Based on these concepts, the "pericyberbullying period" is defined as a critical time frame that encompasses the psychological fluctuations before the occurrence of a cyberbullying event, the immediate reactions during the event, and the adaptation process following its conclusion. The pericyberbullying period provides a new lens through which to explore the short-term and immediate psychological impacts of cyberbullying on survivors. It helps to reveal the dynamic psychological changes associated with cyberbullying with greater precision, while also offering theoretical support for the development of time-based intervention strategies. By leveraging the richness, openness, timeliness, and high traceability of social media data [23], this study enables a retrospective analysis of the psychological changes survivors experience during the pericyberbullying period. Previous studies have used social media data, such as the online ecological recognition method, to retrospectively investigate the psychological effects of negative events (eg, the loss of an only child and domestic violence) [20,24]. This study applies this method innovatively to cyberbullying research, further validating and expanding the potential of social media data in psychological studies.

Cyberbullying Experiences and Well-Being

Positive psychology posits that well-being, as a complex, multifaceted, and central positive experience, is a multidimensional psychological structure [25]. Subjective well-being (SWB), based on the hedonistic perspective, primarily includes classical indicators such as positive and negative emotions [26]. In contrast, psychological well-being (PWB), grounded in the eudaimonic perspective, comprises 6 dimensions: self-acceptance, life purpose, positive relationships, environmental mastery, personal growth, and autonomy [27]. Integrating both SWB and PWB, researchers have proposed the unidimensional Oxford Happiness Questionnaire [28]. High levels of well-being are closely associated with self-actualization, coping with life stress, and finding meaning in life [29]. Health is considered the foundation of happiness, as individuals can only experience higher levels of well-being when they are in good physical and mental condition [30].

Recent studies have found that cyberbullying experiences can predict various subsequent psychological outcomes, such as negative emotions, disrupted self-evaluation and value systems, negative interpersonal relationships, and loss of control, all of which can impair an individual's well-being [31,32]. Specifically, cyberbullying experiences are often accompanied by negative emotions. Research by Zhao et al [13] found that cyberbullying experiences can trigger low thresholds, high emotional intensity, and slow recovery to baseline negative emotions in adolescents. These emotions can mediate the relationship between cyberbullying experiences and non-suicidal self-injury, which is significantly negatively correlated with well-being [17]. When an individual is bullied, their self-evaluation system and sense of self-worth are disrupted, leading to a decreased level of self-acceptance and the development of a negative self-concept [9,11]. Self-acceptance is an important dimension of PWB. Research has found that self-acceptance is a predictor of psychological distress and can protect individuals from the effects of depression [13]. Fang et al [10] found that self-acceptance mediates the relationship between cyberbullying experiences and depression in college students.

XSL•FO
RenderX

Cyberbullying experiences also affect social behavior. Survivors of cyberbullying often experience high levels of social anxiety [33,34], and low self-esteem and self-acceptance can negatively impact interpersonal relationships [10]. Audrin and Blaya [35] found that factors such as the repetitive nature of web-based behavior, the anonymity of cyber aggressors, and the large audience can damage the well-being of cyberbullying survivors. The anonymity, large audience, and lack of spatial and temporal limitations of cyberbullying increase the difficulty of controlling these incidents, reducing individuals' psychological sense of control [36]. When traumatic events are uncontrollable, even individuals with high perceived control may experience posttraumatic stress disorder symptoms, while those with relatively low control are more likely to experience posttraumatic stress disorder symptoms [8].

Cyberbullying Experiences and Suicide Risk

Suicide risk is closely related to lower PWB [37]. According to the suicide stress theory [38], cyberbullying experiences increase suicide risk through several psychological mechanisms, including value conflict, the gap between ideals and reality, and relative deprivation stress [39]. Studies indicate that cyberbullying can significantly increase suicide-related behaviors, including suicidal ideation, especially in adolescents [7,12]. Longitudinal studies also show that early cyberbullying experiences can lead to later suicidal thoughts and behaviors, with core self-evaluation serving as a mediator between the two [40].

Cyberbullying Experiences and Personality Traits

Personality traits and life events are intertwined [24]. On one hand, personality differences exist before life events occur, leading to different probabilities of experiencing certain life events, known as the "selection effect" [41]. On the other hand, personality can change in response to life events, known as the "socialization effect" [42]. Significant life events, especially those occurring for the first time, may have a more pronounced impact, such as the death of a spouse, first-time unemployment, or first-time domestic violence, compared to similar later events [24].

Existing research primarily measures the relationship between personality and life events (eg, cyberbullying experiences) through relatively long (eg, 1 year or even 2 years), fixed-interval self-reports, and compares personality differences between groups with and without specific life events. However, the relationship between cyberbullying experiences and personality traits is unclear. It is uncertain whether certain personality traits lead to cyberbullying experiences or if cyberbullying leads to changes in personality traits. For example, a 2-year study on Dutch individuals aged 15 years and older found that compared to individuals who have not experienced cyberbullying, cyberbullying survivors had lower conscientiousness, higher openness and neuroticism, and no significant difference in agreeableness [18]. Ryff and Keyes [27] found that Turkish student survivors of cyberbullying were positively correlated with neuroticism, agreeableness, and extraversion, and negatively correlated with conscientiousness. A study on high school students found that personality traits do not seem to be predictors of cyberbullying experiences [20]. These conflicting results may be due to limitations in current methods of measuring personality change. For example, some studies may include survivors who have experienced prolonged cyberbullying during the measurement interval, with personality changes influenced by the continuous occurrence of cyberbullying rather than the event itself. Additionally, comparing cyberbullying and noncyberbullying groups to study the effects of cyberbullying makes it difficult to distinguish between the impact of cyberbullying and the inherent differences between the groups.

Cyberbullying Experiences and Morality

Cyberbullying is a traumatic event for survivors, who perceive unjust treatment in their social environment, thereby disrupting their belief in a just world [16]. This disruption may lead to changes in the survivors' moral perceptions of the external environment, causing them to perceive more unfairness. Cyberbullying experiences are a predictor of cyberbullying behavior [31]. When individuals perceive unjust treatment in their environment, they may engage in moral disengagement to alleviate guilt, making them more likely to engage in unethical behavior, such as retaliatory cyberbullying [43]. Moral behavior is typically driven by moral motivation; thus, the perception of unfairness following cyberbullying experiences may influence an individual's moral motivation and subsequently affect their future moral behavior.

Objectives

This study leverages social media data to explore the immediate psychological changes experienced by survivors during the pericyberbullying period, encompassing the time before and after their first encounter with cyberbullying. It comprehensively examines the short-term impacts of cyberbullying on multidimensional psychological characteristics, including well-being and its subdimensions (positive emotions, negative emotions, and self-acceptance), suicide risk and its related dimensions (shame and guilt, and self-regulation), personality traits (eg, agreeableness), and moral cognition of the external environment (eg, the FairnessVice in moral foundations and the communication in moral motivation). Additionally, it uses network analysis to investigate the interactions between cyberbullying experiences and psychological characteristics during this critical period, providing a scientific foundation for developing precise, time-sensitive intervention strategies.

Methods

Participants and Data Collection

This study uses data sourced from Sina Weibo, a social media platform developed by Sina Corporation, which had 605 million monthly active users by the end of September 2023. The collected data mainly include users' web-based behaviors (such as reposts and replies) and Weibo text content. During the data collection process, we adhered to privacy and ethical principles, ensuring that all data were anonymized and privacy was strictly protected [44].

We screened 60 cyberbullying survivors from a pool of Weibo users through a two-step process: (1) preliminary identification of users via public media reports or keyword searches, and (2)

XSL•FO
RenderX

manual verification of survivors and determination of the time of their first cyberbullying incident.

Step 1: Preliminary Identification of Users

We used 2 approaches to identify users. The first approach involved identifying Weibo users who had been publicly recognized as cyberbullying survivors through media reports. The second approach used keyword searches based on the definition and types of cyberbullying, combined with usage characteristics of the Weibo platform. Keywords included terms such as: “cyber violence” (网络暴力), “cyberbullying” (网暴), “abuse” (辱骂), “defamation” (诽谤), “rumors” (造谣), “insults” (污蔑), “doxxing” (人肉), “mocking” (嘲笑), “harassment” (骚扰), “exclusion” (排斥), “kicked out” (踢出), and “pranks” (恶作剧). Through this process, we initially identified 82 potential Weibo users who might have experienced cyberbullying.

Step 2: Manual Verification of Survivors and Determination of Cyberbullying Timing

We recruited 4 graduate students in psychology as research assistants. They were given detailed training on the definitions, types, and manifestations of cyberbullying. The Weibo posts of the 82 initially identified users were downloaded and anonymized. Each research assistant independently reviewed all posts from each user to determine whether they could be classified as a survivor and to identify the time of the user’s first cyberbullying incident. The inclusion criteria were (1) the user had experienced cyberbullying behaviors and (2) the user had expressed in their posts that they perceived those behaviors as harmful. The exclusion criteria were (1) inability to determine the time of the first cyberbullying incident, (2) inability to obtain Weibo posts before and after the first cyberbullying incident, and (3) Weibo users with strong public visibility and influence, such as celebrities. A user was only included as a survivor if at least 3 research assistants agreed on their classification. Ultimately, 60 users were included in the survivor group.

For the control group, we randomly selected active Weibo users (with more than 500 posts) who had not experienced cyberbullying and matched them with the survivors. To ensure effective matching, we used user profiles to match sex, age, location, and number of followers, ensuring no significant differences between the control and survivor groups. The screening and matching process was conducted collaboratively by the same 4 research assistants.

We used the application programming interface provided by Sina Weibo to download the text data of the 120 Weibo users.

Methods and Measurements

Online ecological recognition (OER) is a technique that uses publicly available web-based social media data combined with machine learning methods to measure corresponding psychological characteristics without contacting participants. Compared to self-reports, OER does not rely on the participants’ self-report results or their cooperation with the experiment, and it does not require any contact with the participants. This makes it a more convenient, safer, and timely method for tracking psychological status [20]. OER mainly involves 3 steps: Chinese word segmentation, lexical feature extraction, and model prediction [45,46]. The predictive models are tools developed based on big data and deep learning techniques for web-based psychological research, and their feasibility has been repeatedly verified by multiple studies [47]. Therefore, this study uses the Oxford Happiness model, SWB model, and PWB model to predict individuals’ happiness; the suicide dictionary to predict individuals’ suicide risk; the personality prediction model to predict individuals’ Big 5 personality traits; the Moral Foundations Dictionary (MFD) and Moral Motivation Dictionary (MMD) to predict moral perceptions; and the Simplified Chinese version of Linguistic Inquiry and Word Count (SC-LIWC) to supplement the prediction of psychological traits.

The models and dictionaries selected for this study are as follows:

- Oxford Happiness model: This study uses this model to predict Oxford Happiness Inventory scores [28], aiming to assess overall levels of individual happiness. Wang et al [48] selected 548 Weibo users as their sample and divided them into high- and low-happiness groups based on their Oxford Happiness Inventory scores. They extracted linguistic and behavioral features from social media data and used a decision tree model to predict participants' happiness levels, achieving an accuracy rate of 0.68.
- SWB model: This model is used to predict emotional well-being levels measured by the Positive and Negative Affect Schedule. Hao et al [49] developed and validated this model using social media data from 1785 Weibo users. The optimal evaluation metrics for the model’s effectiveness in predicting SWB showed a strong correlation level of 0.60.
- PWB model: This model is used to predict scores on the PWB Scale by Ryff and Keyes [27], covering dimensions such as autonomy, environmental mastery, personal growth, positive relations with others, life purpose, and self-acceptance. Han et al [50] developed and validated these machine learning models using the textual features of 1427 Weibo users. The correlation between predicted and self-reported PWB scores was significantly positive across all 6 dimensions.
- Personality prediction model: The study uses this model to estimate scores on the Big 5 personality dimensions: openness, agreeableness, extraversion, conscientiousness, and neuroticism. Han et al [51] developed and validated this machine learning model using textual features from 3886 Weibo users. The model demonstrated good structural and criterion validity, with 5-fold cross-validation results ranging from 0.44 to 0.48 (P<.001). The correlation coefficients for the 5 personality traits between the 2 split datasets ranged from 0.84 to 0.88 (P<.001).
- Chinese Suicide Dictionary: This study uses this dictionary to predict suicide risk. The dictionary is designed to identify suicide risk on social media, comprising 2168 words divided into 13 categories (eg, suicidal ideation words, hopelessness words, and personality words) [52].
- Moral Dictionary: This dictionary is used to measure changes in the survivors’ morality. It includes MFD [53] and MMD [54]. The simplified Chinese version of the MFD

XSL•FO
RenderX

includes 590 words or phrases across 6 dimensions (harm, fairness, loyalty, authority, purity, and general morality), with positive and negative word lists for all dimensions except general morality. The Chinese version of the MMD includes 2 dimensions: agency and communication. The agency includes 690 words (eg, achievement, failure, and expenditure), while communication includes 260 words (eg, acceptance, care, and kindness).

- SC-LIWC: In addition to the earlier models and dictionaries, this study uses SC-LIWC to supplement the analysis of psychological changes in cyberbullying survivors. SC-LIWC is widely used in natural language processing, covering multiple dimensions such as linguistic processes, psychological processes, and personal concerns [55]. This study specifically focuses on the subcategories of "I," "tPast," " tFuture," "Anger," "CogMech," "Insight," "Cause," and "Certain." For example, "I" reflects the degree of self-focus; "Anger" captures the intense emotional responses elicited by bullying; "tPast" and "tFuture" reveal the survivor's immersion in past experiences and concerns about the future. Changes in these dimensions help elucidate the impact of cyberbullying on survivors' well-being, suicide risk, and personality traits. Additionally, "CogMech" and "Insight" reflect the survivor's cognitive processing and self-reflection, while "Cause" and "Certain" indicate the survivor's perception of causality and uncertainty regarding future events. The analysis of these dimensions further enhances our understanding of the effects of cyberbullying on well-being, suicide risk, personality traits, and moral judgment.

Data Analyses

The study uses the starting time of the initial cyberbullying incident as the dividing line to measure psychological characteristics before and after this event. The first measurement uses Weibo data from 3 months before the cyberbullying incident, and the second measurement uses data from 3 months after the incident. Given that the timing of the initial cyberbullying incident may vary among users, we estimated each survivor's mental health status precisely three months before and after the event. The control group, consisting of individuals who have not experienced cyberbullying, was analyzed during the same period, with the timeline matched one-to-one.

We conducted descriptive statistics, independent sample 2-tailed *t* tests, and paired sample 2-tailed *t* tests using SPSS (version 27.0; IBM Corp). Initially, we analyzed the between-group differences between the survivor group (n=60) and the control group using independent sample *t* tests. Then, we compared the changes in psychological characteristics at T1 (3 months before the cyberbullying incident) and T2 (3 months after the incident) for both groups using paired sample 2-tailed *t* tests. All analyses were conducted at a significance level of α=.05, and effect sizes of mean differences were reported as *d*.

We used R (version 4.2.2; R Foundation for Statistical Computing) to perform network analysis on the predictive psychological characteristics and cyberbullying experiences at T2, estimating, visualizing, and evaluating the network.

Ethical Considerations

This study was conducted in accordance with ethical guidelines. The research involved the analysis of anonymized social media data, ensuring that no personally identifiable information was retained.

The study received ethical approval from the institutional review board of Central China Normal University, with the approval number (CCNU-IRB-202311046b), confirming that the research adhered to ethical standards for human subjects research.

Given the nature of the study, which involved the analysis of publicly available, anonymized data, informed consent was not required. The original data collection processes were conducted in compliance with relevant ethical guidelines, and the secondary analysis of this data was covered under the original ethical approval.

All data used in this study were anonymized to protect participant privacy. No personally identifiable information was included in the analysis, and stringent measures were taken to ensure data confidentiality.

No compensation was provided to participants, as the study utilized existing anonymized data and did not involve direct interaction with participants.

Results

User Statistics

Overview

Among the users who registered their birth date in their profiles (N=120; survivor group n=60, 50%; control group n=60, 50%), 78% (94/120) were female, with ages ranging from 15 to 41 years, and an average age of 28 (SD 6.23) years. The sample included 1 user who died by suicide and another who died of cancer. Table 1 presents the demographic characteristics of these groups.

The Impact of Cyberbullying on Psychological Characteristics

To investigate the impact of cyberbullying on mental health, we first compared the scores of Oxford Happiness, SWB, PWB, suicide risk, personality traits, and moral perception between the survivor group and the control group at T1. Then, we separately compared the scores of the survivor group and the control group between T1 and T2. At T1, we found no significant differences between the survivor group and the control group in Oxford Happiness, SWB, PWB, suicide risk, personality traits, or moral perception. Specifically, for personality traits, no significant differences were observed in agreeableness (t_{118}=–0.77; P=.45), conscientiousness (t_{118}=–0.03; P=.98), extraversion (t_{118}=–0.72; P=.47), openness (t_{118}=0.34; P=.73), or neuroticism (t_{118}=1.17; P=.25). Additionally, the control group showed no significant changes between T1 and T2. In the survivor group, significant reductions were observed after cyberbullying in Oxford Happiness (t_{59}=2.14; P=.04), positive emotions (t_{59}=2.72; P=.009), positive relations with others (t_{59}=2.54; P=.01), purpose in life (t_{59}=2.28; P=.03), and self-acceptance (t_{59}=2.08; P=.04). Environmental mastery showed a marginally significant decrease (t_{59}=1.72; P=.09), while negative emotions significantly increased (t_{59}=–2.89; P=.005). The “Anger” of SCL-LIWC also significantly increased (t_{59}=–3.46; P=.001). In the cognitive processes category, the “Certain” of SCL-LIWC significantly increased (t_{59}=–2.82; P=.006), while “Insight” words (t_{59}=–1.69; P=.096) and “Cause” words (t_{59}=–1.77; P=.08) showed marginally significant increases. Regarding the Chinese suicide dictionary, self-regulation showed a marginally significant decrease (t_{59}=1.75; P=.09), while shame and guilt (t_{59}=–1.71; P=.09) and anger and hostility (t_{59}=–1.80; P=.08) marginally increased. Among the Big 5 personality traits, agreeableness (t_{59}=2.79; P=.007), extraversion (t_{59}=2.26; P=.03), and conscientiousness (t_{59}=2.27; P=.03) significantly decreased, while neuroticism significantly increased (t_{59}=–3.42; P=.001). In the MMD and MFD, communication words (t_{59}=–2.62; P=.011) and FairnessVice (t_{59}=–2.20; P=.03) significantly increased, while PurityVice showed a marginal increase (t_{59}=–1.88; P=.07; Table 2).

Network Analysis Results

Network Structure

Figure 1 presents the partial correlation network of the 20 study variables, regularized using the least absolute shrinkage and selection operator. Among the total of 96 edges, 60 were significant, with 35 being positively significant and 25 negatively significant. Network sparsity is 0.68. The edge with the highest weight was between “environmental mastery” and “self-acceptance,” followed by the edge between “personal growth” and “purpose in life,” and the edge between “Oxford Happiness” and “positive relations with others.” The 5 nodes most strongly connected to the “cyberbullying experiences” node were “FairnessVice,” “anger and hostility,” “communication,” “neuroticism,” and “Oxford Happiness,” in descending order of strength.

Node Centrality

We report strength centrality, given that betweenness and closeness centrality measures are particularly ill-suited to psychological networks [56]. Figure 2 displays the strength of each node in the network. “Shame and guilt” is the node with the lowest strength, while “cyberbullying experiences” has the highest strength centrality, followed by “neuroticism,” “conscientiousness,” and “Oxford Happiness.” The strength difference test revealed significant differences in strength centrality between “cyberbullying experiences” and “Oxford Happiness,” “autonomy,” “purpose in life,” “conscientiousness,” “extraversion,” and “neuroticism.” The strength centrality of “neuroticism” significantly differed from that of “positive emotions,” “environmental mastery,” “personal growth,” “self-acceptance,” “FairnessVice,” “self-regulation,” “shame and guilt,” “anger and hostility,” “openness to experience,” and “cyberbullying experiences.” Similarly, “Oxford Happiness” exhibited significant strength differences with “positive emotions,” “self-acceptance,” “FairnessVice,” “shame and guilt,” “anger and hostility,“ and “cyberbullying experiences.” The strength of “autonomy” significantly differed from “FairnessVice,” “self-regulation,” “shame and guilt,” “anger and hostility,” “openness to experience,” and “cyberbullying experiences.” Since the strength consistency score (0.517) exceeds the recommended minimum value of 0.25, the reliability of this centrality index is acceptable [57].

Discussion

Principal Findings

This study combines the OER method with network analysis to systematically explore the immediate impacts of cyberbullying events on survivors' internal psychological characteristics and perceptions of the external environment during the pericyberbullying period. The psychological predictive models used in the study, such as Oxford Happiness, have been shown to have good accuracy and precision [23,49-51]. Our research findings indicate that cyberbullying

XSL•FO
RenderX

has a significant impact on survivors' psychology within 3 months.

After experiencing cyberbullying, survivors exhibit a significant decrease in internal well-being and positive emotions, while negative emotions significantly increase. They also feel more shame, guilt, anger, and hostility. In terms of personality, there are significant changes in all dimensions of the Big 5 personality traits except for openness. Additionally, survivors perceive more social injustice from the external world, with a notable increase in the FairnessVice in moral foundations and communication words in moral motivation. In contrast, control groups do not show significant changes in well-being, emotions, personality, and morality. Consistent with existing research, after accounting for potential preexisting differences between the control and survivor groups, our results reveal the negative impact of cyberbullying on psychological characteristics [16,40,58-63]. The results of the network analysis indicate that aside from cyberbullying experiences, neuroticism, conscientiousness, and Oxford Happiness exhibit the strongest strength centrality among psychological characteristics, suggesting their critical roles in shaping an individual's overall psychological state. The high centrality of these nodes implies that altering personality traits and enhancing happiness might be the keys to mitigating the negative impacts of cyberbullying. Previous research has shown that interventions enhancing individual well-being can effectively alleviate the adverse effects of violence experiences [64]. These findings suggest that neuroticism, conscientiousness, and Oxford Happiness serve as core connectors within the psychological network, linking various other psychological variables. Therefore, they play a pivotal role in structuring the network between cyberbullying experiences and psychological characteristics.

Survivors of cyberbullying exhibit marginally significant changes in dimensions related to self-regulation of suicide risk, shame and guilt, and anger and hostility. These emotional and behavioral changes indicate that cyberbullying impacts survivors' emotional regulation capabilities, increasing their negative emotional experiences [65]. Although these marginally significant changes are not as strong as significant changes, they still suggest that cyberbullying has potentially negative effects on survivors' mental health and presents a certain suicide risk, warranting further attention and research. The increase in shame and guilt may be related to a decline in self-worth [66], while the increase in anger and hostility may be a reaction to perceived injustice [16].

Regarding the impact of cyberbullying on survivors' Big 5 personality traits, this study found no significant differences in personality traits between the survivor and the control groups before the occurrence of cyberbullying. This indicates that no specific personality traits predisposed individuals to become survivors of cyberbullying, supporting the absence of a "selection effect" [41] and the notion that anyone can become a survivor of cyberbullying [2]. However, after the occurrence of cyberbullying, survivors exhibited significant changes in their personality traits, with agreeableness, extraversion, and conscientiousness significantly decreasing, while neuroticism significantly increased. These changes reflect the presence of a "socialization effect" [42], indicating that individuals' personality traits are significantly influenced by the experience of cyberbullying. After experiencing cyberbullying, survivors' agreeableness and extraversion significantly decreased, suggesting that cyberbullying may cause survivors to withdraw more from social activities and even develop social anxiety disorders [67]. A decrease in conscientiousness could negatively affect their performance at work and school [68], while an increase in neuroticism indicates that survivors become more vulnerable and sensitive in terms of emotional stability [65]. The lack of significant differences in openness before and after cyberbullying may be attributed to the fact that openness primarily reflects an individual's interest in new experiences, art, aesthetics, and abstract thinking, as a more stable trait [69] that is less strongly influenced by short-term environmental factors or external events, such as cyberbullying experiences.

In terms of moral perception of the external environment, the study results show a significant increase in FairnessVice and a marginally significant increase in PurityVice in survivors' moral foundations, reflecting an increased sensitivity to social injustice. As found by Bai et al [16], cyberbullying experiences may cause individuals' belief in a just world to collapse. Additionally, there was a significant increase in communicative motivation within survivors' moral motivations, indicating that survivors may be more inclined to seek support and understanding in interpersonal relationships after experiencing cyberbullying. For example, studies have shown that although survivors may be reluctant to seek help from authorities, they are more likely to seek help from peers [70,71] or web-based support groups [72,73].

The findings of this study have significant practical implications for developing cyberbullying intervention strategies. By focusing on the pericyberbullying period, we can more accurately identify the immediate psychological impacts of cyberbullying on survivors and design more timely and effective intervention measures accordingly. Given the high centrality of nodes such as neuroticism, and Oxford Happiness, these characteristics should be prioritized in interventions aimed at promoting psychological recovery. Although the predictive power of centrality measures has certain limitations for instance, some studies suggest that targeting symptoms based on centrality may be less effective than addressing the most common symptoms [56], strength centrality remains a useful heuristic for identifying key nodes within the network [74]. As core components of the psychological network, improving traits such as Oxford Happiness can generate cascading effects, positively impacting the overall mental health of survivors. This intervention strategy aligns with the principles of positive psychology [25], which emphasizes the importance of happiness, and positive emotions in building psychological resilience and recovering from trauma. Interventions designed to enhance PWB such as acceptance and commitment therapy, have been validated in the recovery of violence survivors, demonstrating their effectiveness in promoting psychological healing [75], and acceptance and commitment therapy have also been shown to effectively reduce neuroticism levels in individuals [76]. By focusing on these key traits, interventions can equip survivors to better manage the emotional challenges posed by cyberbullying and restore a sense of purpose and control in their lives. Regarding changes in the

XSL•FO
RenderX

Big 5 personality traits, interventions should focus on increasing agreeableness, extraversion, and conscientiousness in survivors, while mitigating the negative effects of neuroticism. Additionally, to address the increased perception of injustice in the external environment, education and counseling should emphasize helping survivors rebuild their belief in a just world, thereby reducing their negative reactions to cyberbullying. In the future, positive psychology could be incorporated into school curricula to help students develop essential emotional regulation skills for coping with cyberbullying. Schools could also implement group activities or mentorship programs to encourage positive social interactions and establish strong peer and social support systems. Regarding web-based platform management and interventions, platforms could first proactively identify survivors and then offer personalized web-based interventions from a positive psychological perspective to support survivors of cyberbullying.

Limitations and Future Work

The limitations of this study include a relatively small sample size, with only 60 survivors, although each participant's Weibo data is substantial. The data source is also limited; to control confounding variables, only survivors from the Weibo platform were studied. Due to the limited personal profile information available on Weibo, we did not consider economic status when matching the experimental group of cyberbullying survivors and the control group of individuals who have not experienced cyberbullying and instead matched participants based on sex, age, location, and number of followers. Additionally, to ensure sufficient Weibo data for accurate predictions of psychological traits, only active users (defined as users with more than 500 posts) were included. Future research could explore the differentiated experiences of cyberbullying across different platforms, varying levels of user activity, and economic status. Additionally, because social media activity decreases for survivors after experiencing cyberbullying [77], we chose a 3-month study period to obtain more data for more accurate predictions of changes in individual psychological characteristics, despite this being a relatively long time frame. Future research could further validate the impact of cyberbullying on survivors' psychological characteristics by expanding the sample size, incorporating multiple data sources, and examining timely changes in internal psychological characteristics and external perceptions over shorter periods. Moreover, exploring changes in the psychological characteristics of cyberbullying survivors from different cultural backgrounds and age groups, as well as the effects of different types of cyberbullying on psychological characteristics, will also be important directions for future research.

Conclusions

In conclusion, cyberbullying has a significant negative impact on survivors' internal psychological characteristics and their perceptions of the external environment. This study leverages social media data and combines OER with network analysis to systematically reveal the dynamic psychological changes in survivors during the pericyberbullying period, before and after the cyberbullying events, as well as the interplay between cyberbullying experiences and psychological characteristics. The findings deepen our understanding of the short-term psychological impacts of cyberbullying and provide a critical theoretical foundation and practical reference for the development of future intervention strategies. Future research and interventions should focus on effectively reducing survivors' neuroticism, enhancing their well-being, and rebuilding their moral cognition to mitigate the negative effects of cyberbullying.

Acknowledgments

This study could not have been conducted without the valuable contributions of all the participants. The authors would also like to extend our sincere gratitude to Tingshao Zhu's team for their invaluable guidance in data analysis and research methodology. Additionally, the authors are grateful to their colleagues and the institutions involved in participant recruitment and data collection for their essential support. This study is supported by the major program of the National Social Science Foundation of China (grant 22&ZD187). During the writing process of this article, ChatGPT was only used for polishing and translating between Chinese and English, but it was not allowed to conceive ideas or directly write the content of the article.

Data Availability

Due to privacy concerns, the data used in this study cannot be directly shared in open repositories. However, readers can contact the authors via email to request access to the data.

Authors' Contributions

XL was primarily responsible for the conceptualization, methodology, project administration, writing–original draft, and writing–review & editing. ML contributed to the data curation, validation, investigation, writing–original draft, and writing–review & editing. XK contributed to the formal analysis and writing–review & editing. YL contributed to the formal analysis, and writing–review & editing. NH assisted with parts of the resources and visualization. ZR was responsible for the conceptualization, funding acquisition, supervision, and writing–review & editing.

Abstract

Background: Mental health disorders are a major public health challenge, and problematic internet use (PIU) may play an important role in this issue. However, the underlying mechanisms of PIU and its effects on mental health have not yet been elucidated.

Objective: This study examines the mediating effect of loneliness on the relationship between PIU and mental health, as well as the moderating effect of social media identity on the relationships among PIU, loneliness, and mental health.

Methods: A cross-sectional questionnaire survey was conducted on 21,292 participants recruited using a multistage stratified sampling strategy from 31 provinces/regions in mainland China from June 20 to August 31, 2022. This study assesses PIU (PIU questionnaire-short form-6), depression (9-item Patient Health Questionnaire [PHQ-9]), anxiety (7-item Generalized Anxiety Disorder scale [GAD-7]), loneliness (3-item loneliness scale), and social media identity (identity bubble reinforcement scale). Additionally, we collected the sociodemographic characteristics of the participants. Participants whose total score of PHQ-9≥15 or total score of GAD-7≥10 were considered to have moderate or severe symptoms of depression or anxiety, respectively. A moderated mediation model was established to examine the mediating effect of loneliness on the association between PIU and mental health outcomes (depression and anxiety), moderated by social media identity.

Results: Approximately 22.80% (4854/21,292) and 14.20% (3023/21,292) of the respondents reported moderate or severe symptoms of depression and anxiety, respectively. Loneliness significantly mediated the association between PIU and mental health outcomes, explaining 42.53% and 45.48% of the total effect of PIU on depression and anxiety, respectively. Social media identity significantly moderated the associations between PIU and depression (β=0.002, 95% CI 0.001-0.002), PIU and anxiety (β=0.001, 95% CI 0.000-0.002), loneliness and depression (β=0.010, 95% CI 0.007-0.013), and loneliness and anxiety (β=0.007, 95% CI 0.004-0.010), but not between PIU and loneliness (β=0.000, 95% CI –0.003 to 0.003). Higher levels of social media identity were significantly associated with lower levels of loneliness (β=–0.018, 95% CI –0.020 to –0.016).

XSL•FO
RenderX

Conclusions: Addressing loneliness may serve as a valuable approach to mitigate the impact of PIU on mental health outcomes. However, social media identity poses a significant challenge in addressing health issues linked to PIU.

problematic internet use; loneliness; anxiety; depression; mediation and moderation model

Introduction

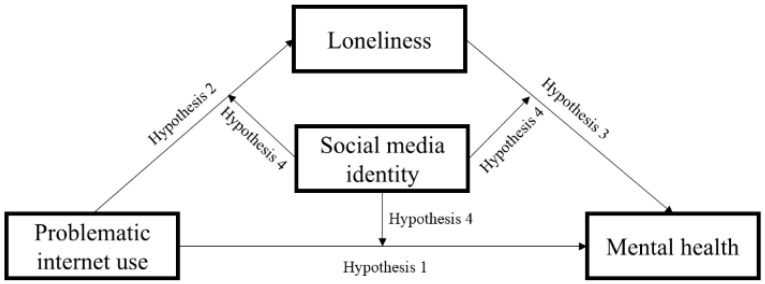
Background

Mental health disorders, which are significant contributors to the global burden of disease, are a major public health challenge worldwide. Over the past 3 decades, its burden, measured in disability-adjusted life-years, has increased from 80.8 million in 1990 to 125.3 million in 2019, with no indication of a decrease in the near future [1]. The COVID-19 pandemic has further exacerbated mental health problems, resulting in an additional 53.2 million cases of depression and 76.2 million cases of anxiety—the 2 most prevalent mental health disorders [2]. Responding to the prolonged mental health impacts of COVID-19 has proven challenging because health care systems are ill-prepared [3].

Mental health disorders are influenced by a multitude of factors [4], with complex interactions among biological, psychological, social, cultural, and other elements [5]. The rapid advancement of technology, particularly the widespread use of the internet, has garnered significant attention for its impact on mental health and vice versa [6]. Existing studies [7] have shown that there is a potential bidirectional relationship between internet use and mental health disorders, in which internet overuse may induce mental health disorders, for example, depression and anxiety, which could in turn enhance one's addiction to the internet. Although the relationships between internet use and mental health disorders remain unclear and different studies have argued different directional relationships between them, it is undeniable that the internet has profoundly transformed human society, altering how people communicate and interact, reducing communication barriers, lowering costs, and promoting interpersonal bonds and social networks [8].

In this study, we focused on the impact of internet use on mental health disorders, and existing studies have shown that maladaptive or excessive internet use has been linked to adverse effects on mental health [9-11]. For example, empirical evidence has found that problematic internet use (PIU) and internet addiction [12-16] increase the likelihood of depression, anxiety, social isolation, and even suicide [7,17-22]. However, the reasons for the associations between PIU and mental health remain unclear. Recent systematic reviews have highlighted several limitations in existing studies, such as small sample sizes, variations in study settings, and lack of moderating or mediating analyses [23,24]. One assumption regarding the link between PIU and mental health disorders is that PIU is inherently connected to loneliness [25]. Although loneliness is not a specific mental health condition, it is associated with major mental health disorders, including depression and anxiety. The effect of internet use on loneliness remains a subject of debate. Some researchers contend that internet use can exacerbate loneliness by compromising offline human interactions [26,27], whereas others argue that it can enhance existing offline relationships and foster new ones [28]. Nonetheless, the association between PIU and loneliness is likely to be bidirectional: PIU can be both a cause (resulting in higher levels of loneliness) and a consequence of loneliness [25].

What has been missing in these discussions is a consideration of individual behaviors: why and how individuals use the internet. Social media has created a virtual space for people to interact, but the reasons people use social media vary significantly. Online platforms can serve as tools for sharing information and exchanging social support in the real world [29,30]. This underscores the importance of the concept of social media identity [31,32]. According to the identity bubble reinforcement model [33], online interactions can lead to the formation of social networks (social identities) where like-minded individuals (homophily) interact with one another, often relying on biased information. Social media identity measures how people perceive their relationships within online networks, with a higher level of social media identity indicating greater involvement with online social networks [34]. It is reasonable to assume that high levels of social media identity may reinforce a sense of belonging to virtual communities at the expense of real-world connections [31]. This, in turn, could affect the association between PIU and loneliness, as well as the impact of PIU on mental health [35,36]. Although previous research has explored the effects of social media identity on online gaming and cyberbullying [35,37], there is a noticeable gap in the literature regarding the role of social media identity in the context of PIU, loneliness, and mental health. Notably, this study was conducted in China, as Asian countries have reported a higher prevalence of PIU, ranging from 20% to 47%, than other regions [38,39].



To better understand the underlying reasons for the associations between PIU and mental health, this study aims to examine the mediating effect of loneliness on the relationship between PIU and mental health, as well as the moderating effect of social media identity on the relationships among PIU, loneliness, and mental health.

Theoretical Hypotheses

In this study, we tested a moderated mediation model based on 4 hypotheses, examining the interplay among PIU, loneliness, social media identity, and their effects on mental health (Figure 1).

XSL•FO
RenderX

Figure 1. The hypothesized moderated mediation model.

Loneliness Mediates the Effects of PIU on Mental Health Disorders

Hypothesis 1: PIU Is Positively Associated With Mental Health Disorders

The link between PIU and mental health has been extensively documented [17-20,40]. A recent systematic review revealed a moderate level of evidence supporting a positive association between PIU and depressive symptoms [18]. In general, PIU is associated with withdrawal from real-world social interactions [41]. Excessive internet use can also result in sleep deprivation, unrealistic expectations, and an exaggerated sense of failure [41,42].

Hypothesis 2: PIU Is Positively Associated With Loneliness

PIU can lead to displacement, a phenomenon in which internet-based, low-quality relationships replace offline social contacts, even though the internet can strengthen an individual's connectedness with others and expand their social networks [25]. Recent reviews have indicated moderately low levels of evidence supporting PIU as a risk factor for loneliness [25]. Several longitudinal studies have shown that PIU is more likely to be a cause rather than a consequence of loneliness [43-45]. Excessive internet use can lead individuals to withdraw from real-world interactions, intensifying their perception of the absence of companionship [25,46].

Hypothesis 3: Loneliness Is Positively Associated With Mental Health Disorders

Evidence has consistently shown that loneliness is a risk factor for mental health disorders, particularly depression and anxiety. Loneliness has negative effects on the social, cognitive, and biological aspects [47,48]. Individuals experiencing loneliness often have less cognitive stimulation, reduced social interactions, and impaired immune functions, all of which are associated with an increased likelihood of mental health disorders [47,48]. This connection between loneliness and mental health disorders has been demonstrated in 2 large longitudinal studies conducted in the United Kingdom and the Netherlands [47,49,50]. Thus, from the evidence in the literature, we inferred that the effect of PIU on mental health disorders is mediated by loneliness, that is, PIU affects loneliness and ultimately translates into mental health disorders.

Hypothesis 4: Social Media Identity Moderates the Effects of PIU on Loneliness and Mental Health Disorders

Studies have shown that the extent to which PIU can translate into loneliness and mental health disorders depends on how individuals use the internet [18]. In the identity bubble reinforcement model, social media identity measures how people perceive their relationships with online networks, with a higher level of social media identity indicating greater involvement in and belonging to online social networks [33]. On the one hand, people highly involved in online social networks are more likely to express themselves, receive social support, feel a sense of belonging, be less lonely, and protect themselves from translating PIU and loneliness into mental health problems [30,51,52]. This effect has also been confirmed in risky online behaviors such as gambling [35]. In contrast, in the case of people with PIU but low involvement in and belonging to online social networks, it is expected that their loneliness will be exacerbated and that PIU and loneliness will be translated into mental health disorders. Thus, it is speculated that various levels of social media identity have different impacts on the relationships between individuals' internet use and loneliness and mental health disorders. Therefore, social media identity was hypothesized to moderate the effects of PIU, loneliness, and mental health in this study, with higher (lower) social media identity indicating a lower (higher) effect of PIU on loneliness and less (greater) likelihood of PIU and loneliness translating into mental health disorders.

Methods

Study Design and Participants

The data for this study were extracted from the 2022 nationwide cross-sectional survey, known as the Psychology and Behavior Investigation of Chinese Residents (PBICR-2022). The sample size was determined based on the following formula: $n = Z^2_{\alpha} \times p \times (1 - p) / \delta^2$. Based on the prevalence of depression (p) in China as 24% [53], type I error (α) as .05, and acceptable error (δ) as 0.02, the minimum sample size was estimated as 1752. To generate a nationally representative sample, the survey adopted multistage sampling, covering 31 provinces in China (22 provinces, 5 autonomous regions, 4 municipalities). In each province, the planned minimum sample size was determined as 500-2500 according to the proportions of the respective populations to the overall population in China. Finally, the sample size was estimated at 20,000, which is far more than the minimum sample size (n=1752). To select study participants, we first included capital cities from 31 provinces across China. Additionally, 2-12 cities were selected from each noncapital prefecture within each province, resulting in 148 cities. For the 148 municipalities sampled, we adopted random sampling, and the number of communities sampled was determined on the

XSL•FO
RenderX

basis of the populations within the sampled municipalities and the ratio of urban to rural communities, resulting in a total of 780 communities. Within each community, the allocation of quotas considered the demographic distributions recorded in the seventh national census, considering both age and sex. Details about the protocol of the PBICR-2022 survey have been published elsewhere [54].

The inclusion criteria for participation in the survey included individuals (1) aged 12 years or older, (2) who had resided in the sampled communities and had not been absent for more than one month within the past year, and (3) who were able to complete the questionnaire independently or with the help of a researcher. We excluded participants who (1) were cognitively impaired in understanding the questionnaire items, (2) had never used the internet or social media, or (3) were unwilling to participate in or were participating in other similar studies during the survey period.

Data collection occurred between June 20 and August 31, 2022, when China was still implementing a zero COVID-19 policy. Household visits were performed by trained researchers whenever local policies permitted such visits. Otherwise, online meetings, typically using platforms such as WeChat or Tencent, were conducted with each participant. The respondents were asked to respond through the Wenjuanxing questionnaire platform. Written informed consent was obtained prior to each survey.

A total of 21,916 responses were returned, and invalid responses (incomplete and contradictory answers or survey times of less than 4 minutes) were excluded. This resulted in a total of 97.15% (21,292/21,916) valid responses. The average age of the included participants was 39.15 (SD 18.64; range 12-100) years.

Measurements

PIU Assessment

PIU was assessed using the 6-item PIU-short form questionnaire. This questionnaire evaluates individual obsessions, neglect, and control behaviors related to internet usage. For example, respondents were asked about their feelings of tension, irritation, or stress when unable to use the internet as long as they wished, their preference for spending time online over sleep, and their attempts to conceal the amount of time spent online [55,56]. The participants were required to rate each item on a 5-point Likert scale, ranging from 0 (never) to 4 (always). A summed score within the range of 0-24 was calculated, with a higher score indicating a greater risk of PIU. The 6-item PIU-short form questionnaire has demonstrated good reliability and validity in several countries [55,56], and its structural validity (via confirmatory factor analysis) and internal consistency (Cronbach α=0.932) have been confirmed.

Loneliness Assessment

Loneliness was assessed using the 3-Item Loneliness Scale, which evaluates relational connectedness, social connectedness, and self-perceived isolation [57]. Each item was rated on a 3-point scale, with 0 indicating “hardly ever,” 1 indicating “some of the time,” and 2 indicating “often.” A summed score within the range of 0-6 was calculated, where a higher score indicated greater loneliness. The 3-Item Loneliness Scale has been reported to have good reliability and validity in previous studies [58,59] and in this study, with a Cronbach α coefficient of 0.862.

Social Media Identity Assessment

Social media identity was assessed using the Identity Bubble Reinforcement Scale [31]. The Identity Bubble Reinforcement Scale evaluates the extent to which individuals relate to online social networks and consists of 6 items. These items measure social identification (eg, in social media, I belong to a community or communities that I'm proud of), homophily (eg, in social media, I prefer interacting with people who are like me), and information bias (eg, in social media, I feel that people think like me) [31]. The respondents were required to rate each item on a scale ranging from 0 (does not describe me at all) to 9 (describes me completely). A summed score within the range of 0-54 was calculated, with a higher score indicating a higher level of social media identity involvement. The Identity Bubble Reinforcement Scale has shown good reliability and validity in various countries [31], and in this study, it yielded a Cronbach α of 0.924.

Mental Health Disorder Assessment

The PBICR-2022 survey included assessments of depression and anxiety, which are among the most common mental health disorders. The 9-item Patient Health Questionnaire (PHQ-9) was utilized to measure depression, while the 7-item Generalized Anxiety Disorder (GAD-7) scale was adopted for assessing anxiety. The respondents were asked to rate their experiences over the past 2 weeks by using a 4-point scale, with responses ranging from 0 (not at all) to 3 (nearly every day). Sample questions included, “How often do I have trouble concentrating on things?” for depression [60] and “How often do I feel afraid that something awful might happen?” for anxiety [61]. A summed score for depression, ranging from 0 to 27, and for anxiety, ranging from 0 to 21, was calculated. A higher score indicates a higher level of symptoms. In this study, participants whose total score of PHQ-9≥15 or total score of GAD-7≥10 were considered as having moderate or severe symptoms of depression or anxiety, respectively. PHQ-9 and the GAD-7 have been widely used in various settings and have been validated in Chinese populations [62,63]. The Cronbach α coefficients of the 2 measurements were 0.919 (PHQ-9) and 0.941 (GAD-7) in our study.

Covariates

Previous studies have identified numerous socioeconomic and demographic factors associated with mental health disorders [64-66]. For these factors, data regarding age group (<18, ≥18 to <30, ≥30 to <40, ≥40 to <50, ≥60 to <70 and ≥70 years), sex (male, female), educational attainment (no formal education, primary school, etc), employment (full-time students, employed, freelancers, etc), marital status (unmarried, married, divorced/widowed), household income (≤¥1000, >¥1000 to ≤¥2000, etc; US $1=¥7.31), chronic conditions (yes, no), living area (rural, urban), and region were collected via self-reports. The regions in China were categorized as northern (Beijing, Tianjin, etc), northeast (Liaoning, Jilin, Heilongjiang), northwest (Gansu, Qinghai, etc), eastern (Shanghai, Jiangsu, etc), central

XSL•FO
RenderX

(Henan, Hubei, Hunan), southern (Guangdong, Guangxi, Hainan), and southwest (Chongqing, Sichuan, etc) according to the classification of regional economic collaboration among provinces in China [67].

Statistical Analysis

The characteristics of the study participants were described through frequency distributions for categorical variables and means (medians) and standard deviations (interquartile ranges) for continuous variables. We also examined the normality of the total scores for PIU, loneliness, social media identity, and mental health disorders (depression and anxiety) via Shapiro-Francia tests for normality. The results indicated that all the variables were not normally distributed (P<.001). Thus, Spearman correlations were examined among those measurements, and Wilcoxon rank sum tests and Kruskal-Wallis tests were performed to assess differences in PIU, loneliness, social media identity, and mental health disorders among participants with different socioeconomic characteristics.

We employed multivariate linear regression models to test our hypotheses. For the moderated mediation analyses, we utilized the PROCESS macro developed by Hayes [68]. The analysis proceeded in 2 steps. First, we tested the mediating effect of loneliness on the associations between PIU and depression and anxiety disorders. Next, we added the moderating effect of social media identity on different paths within the mediation model. To estimate the indirect effects, we used 5000 bootstrap estimates, which provided a 95% bias-corrected CI with robustness to nonnormally distributed data. Additionally, we calculated the conditional effects of social media identity by examining the associations of all paths between PIU and mental health when the social media identity score was fixed at 1 SD above and below the mean [68].

To assess model robustness and identify potential model heterogeneity, we conducted subgroup analyses on the basis of sex and age, in which mediation and moderated mediation models were reconstructed and tested in a particular subgroup of the population (eg, male participants). As the cross-sectional data did not allow us to establish the temporal precedence of variables, we also examined a model in which PIU served as a mediator for the association between loneliness and mental health disorders. We performed Harman's one-factor analysis to address the potential threat of common method variance in cross-sectional behavioral research. The results indicated that the first common factor in our data explained only 27.99% of the variance, which is below the threshold of 40%. This suggests a low risk of common method variance [69].

The data were analyzed using SPSS 26.0 (IBM Corp). A 2-tailed P value <.05 was considered statistically significant. The indirect effects of the mediation and moderation variables were considered statistically significant when zero was not included between the lower and upper bounds of the 95% bias-corrected bootstrap CIs.

Ethics Approval

This study was approved by the Shaanxi Institute of International Trade and Commerce (JKWH-2022-02). Written informed consent was obtained from participants prior to the survey (for participants aged 12-17 years, approval from their caregivers were also prerequisite for enrollment), and they were provided with the opportunity to opt out at any time during and after the survey. No personal identification information was collected, and all the data were anonymized. There was no compensation for the participants in our study survey.

Results

Characteristics of the Study Participants

Approximately half (10,596/21,292, 49.77%) of the respondents were men, whereas 18.1% (3857/21,292) were older than 60 years. Fewer than one-third (6462/21,292, 30.35%) of the respondents resided in rural communities. Most respondents had completed senior high school or above (14,651/21,292, 69%), with an average household income of less than ¥5000 (equivalent to approximately US $684), accounting for 63.02% (13,418/21,292) (Table S1 of Multimedia Appendix 1).

PIU, Loneliness, Social Media Identity, and Mental Health Outcomes

The respondents had a mean score of 6.49 (SD 5.51) for depression symptoms and 4.75 (SD 4.62) for anxiety symptoms. Compared with male respondents, female respondents (P=.003) reported more anxiety problems, while there was no sex difference in depression symptoms (P=.07). Respondents with the highest scores for both depression and anxiety (Table S2 of Multimedia Appendix 1) were in the 18-29 years age groups (P<.001), unmarried (P<.001), had completed postgraduate education (P<.001), were engaged in full-time studies (P<.001), had a household income of less than ¥1000 per month (equivalent to approximately US $136.80; P<.001), resided in rural areas (P<.001) and the northeastern region (P<.001), and had chronic conditions (P<.001).

The loneliness scores were relatively low, with a mean value of 1.57 (SD 1.61) out of a maximum score of 6 (Table 1). In general, respondents with the highest anxiety and depression scores tended to also have higher loneliness scores (Table S2 of Multimedia Appendix 1). The average PIU score was 5.80 (SD 5.46) out of a maximum of 24, indicating a moderate level of PIU. The respondents reported a moderate level of involvement in social media identity, with a mean score of 31.12 (SD 10.99) out of a maximum of 54 (Table 1). The highest levels of PIU and social media identity were found among respondents aged between 18 and 29 years (P<.001), those who were unmarried (P<.001), had completed postgraduate education (P<.001), were engaged in full-time studies (P<.001), had an average household income of >¥6000 (equivalent to approximately US $820.80) per month ($P$<.001), lived in urban areas (P=.009 for PIU and P<.001 for social media identity), and had no chronic conditions (P<.001). The respondents residing in the northeast region presented the highest PIU (P<.001), whereas those in the northern region presented the highest social media identity (P<.001). There was no sex difference in PIU (P=.10), but male respondents reported greater social media identity (P=.04) than their female counterparts (Table S2 of Multimedia Appendix 1).

XSL•FO
RenderX

PIU, loneliness, depression, and anxiety symptoms were positively correlated (P<.001), whereas social media identity was negatively correlated with loneliness, depression, and anxiety symptoms (P<.001) (Table 2).

Table 1. Measurement scores of the mental health conditions, loneliness, problematic internet use, and social media identity of the study participants (N=21,292).

Variables	Mean (SD) score	Median (IQR) score
Depression	6.49 (5.51)	6 (2-9)
Anxiety	4.75 (4.62)	4 (0-7)
Loneliness	1.57 (1.61)	1 (0-3)
Problematic internet use	5.80 (5.46)	11 (0-10)
Social media identity	31.12 (10.99)	37 (24-38)

Hypothesis Testing

PIU was found to be associated with loneliness (model 1 in Table 3), depression (model 2 in Table 3), and anxiety (model 3 in Table 3). This supports hypotheses 1 and 2. Loneliness played a significant mediating role in these associations, as shown in models 2 and 3 in Table 2. The change in R^2 values confirmed the substantial contribution of loneliness as a mediator in the relationships between PIU and depression (R^2 increased from 0.246 to 0.454) and anxiety (R^2 increased from 0.223 to 0.446).

The total effect of PIU on depression was 0.475 (95% CI 0.462-0.487), of which 42.53% (0.202, 95% CI 0.193-0.211) was explained by the indirect effect mediated through loneliness. Similarly, the total effect of PIU on anxiety was 0.387 (95% CI 0.377-0.398), with 45.48% (0.176, 95% CI 0.168-0.184) explained by the indirect effect mediated through loneliness (see Figure 2). This finding supports hypothesis 3.

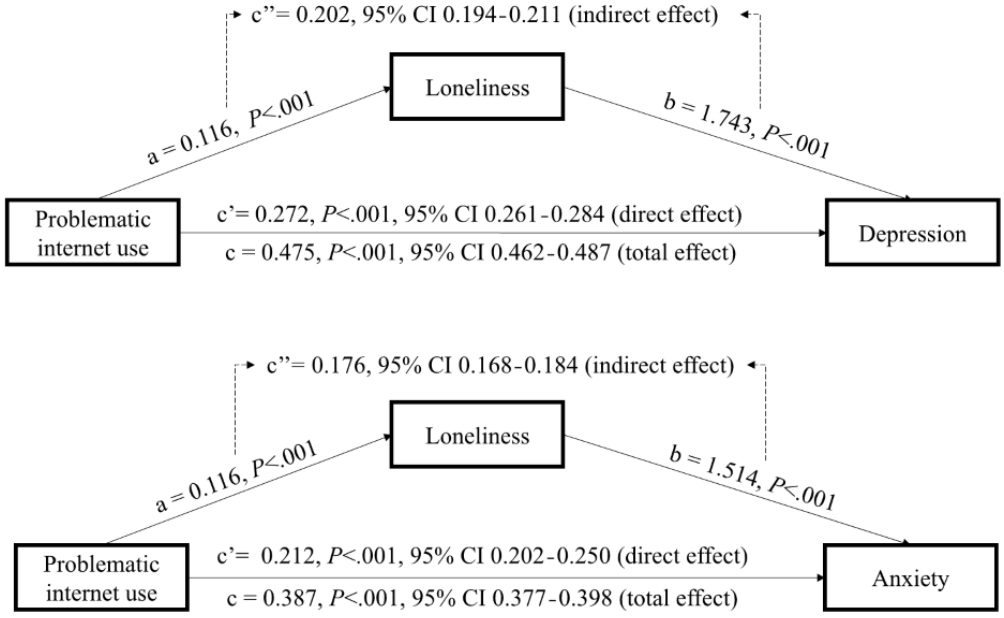
Table 3. Results of the mediating effect of loneliness in the relationship between problematic internet use and mental health.

Predictors	Model 1[a] (Y=loneliness)	Model 2[b] (Y=PHQ[c])	Model 3[d] (Y=GAD[e])
PIU[f], β (95% CI)	0.116 (0.112-0.120)	0.272 (0.261-0.284)	0.212 (0.202-0.222)
Loneliness, β (95% CI)	N/A[g]	1.743 (1.705-1.781)	1.514 (1.482-1.546)

[a]$F_{33, 21,258}$=160.675; R^2=0.200.

[b]$F_{34, 21,257}$=519.443; R^2=0.454.

[c]PHQ: Patient Health Questionnaire.



[d]$F_{34, 21,257}$=502.896; R^2=0.446.

[e]GAD: Generalized Anxiety Disorder scale.

[f]PIU: problematic internet use.

[g]N/A: not applicable.

Figure 2. Mediating model of problematic internet use on depression and anxiety via loneliness. "a" represents the coefficient between problematic internet use and loneliness, "b" represents the coefficient between loneliness and depression/anxiety, and "c" represents the total coefficient when combined direct coefficient (c') from problematic internet use and depression/anxiety and indirect coefficient (c") between them via loneliness.

Social media identity moderated the effect of PIU on depression (β=0.002, 95% CI 0.001-0.002; model 5 in Table 4) and the effect of loneliness on depression (β=0.010, 95% CI 0.007-0.013; model 5 in Table 4). Similarly, social media identity moderated the effect of PIU on anxiety (β=0.001, 95% CI 0.000-0.002; model 6 in Table 4) and the effect of loneliness on anxiety (β=0.007, 95% CI 0.004-0.010; model 6 in Table 4). Higher levels of social media identity exacerbated the effects of PIU on mental health problems, supporting hypothesis 4. However, the moderating effect of social media identity on the association between PIU and loneliness was statistically insignificant (β=0.000, 95% CI –0.003 to 0.003; model 4 in Table 4), despite the direct association between higher levels of social media identity and lower levels of loneliness (β=–0.018, 95% CI –0.020 to –0.016; model 4 in Table 4). Multimedia Appendix 2 and Figure 3 present the conditional effects of social media identity on the paths between PIU and mental health symptoms.

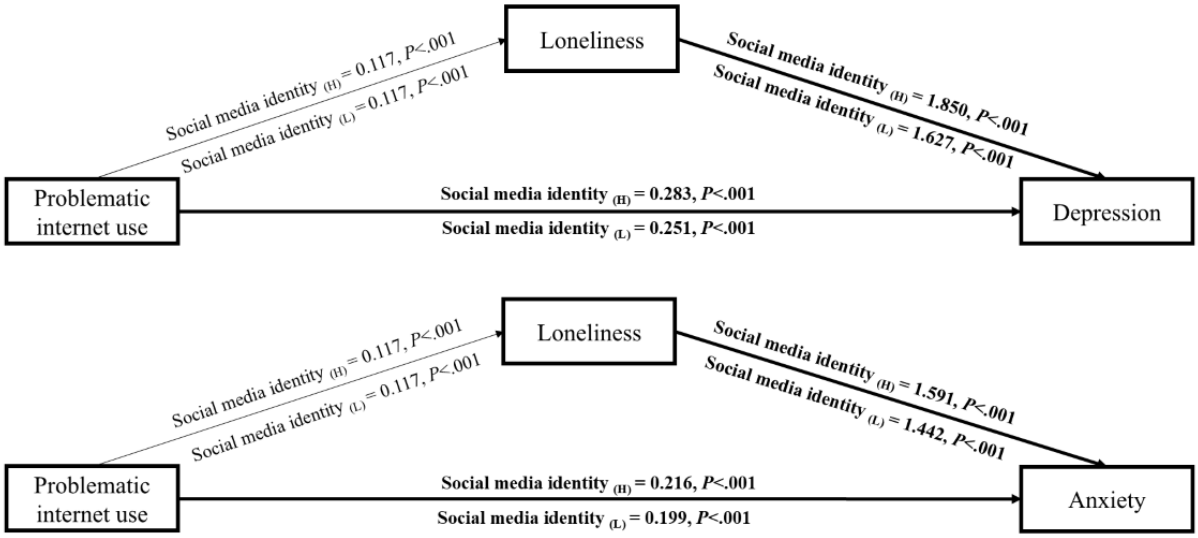
Table 4. Results of the moderated mediation model of social media identity and loneliness in the relationship between problematic internet use and mental health.

Predictors	Model 4[a] (Y=Loneliness)	Model 5[b] (Y=PHQ[c])	Model 6[d] (Y=GAD[e])
PIU[f], β (95% CI)	0.117 (0113 to 0.121)	0.267 (0.255 to 0.279)	0.207 (0.198 to 0.217)
Loneliness, β (95% CI)	N/A[g]	1.739 (1.700 to 1.778)	1.516 (1.484 to 1.549)
Social media identity, β (95% CI)	–0.018 (–0.020 to –0.016)	–0.005 (–0.010 to 0.001)	0.002 (–0.002 to 0.007)
Social media identity × PIU, β (95% CI)	0.000 (–0.003 to 0.003)	0.002 (0.001 to 0.002)	0.001 (0.000 to 0.002)
Social media identity × loneliness, β (95% CI)	N/A	0.010 (0.007 to 0.013)	0.007 (0.004 to 0.010)

[a]$F_{35, 21,256}$=165.462; R^2=0.214.

[b]$F_{37, 21,254}$=481.285; R^2=0.456.

[c]PHQ: Patient Health Questionnaire.



[d]$F_{37, 21,254}$=464.138; R^2=0.447.

[e]GAD: Generalized Anxiety Disorder scale.

[f]PIU: problematic internet use.

[g]N/A: not applicable.

Figure 3. For each pathway, social media identity (H) and social media identity (L) represent the associations among problematic internet use, loneliness, and depression/anxiety when the level of social media identity is set at the mean score plus one standard deviation or minus one standard deviation, respectively. *P* value indicates the significance of the pathway, and bold paths and values indicate significant differences between different levels of social media identity.

The effect of PIU on depression, including the indirect effect via loneliness, was more significant among respondents with a higher social media identity than among those with lower social media identity. This difference was manifested as a 0.032 variation in the direct effect and a 0.025 difference in the indirect effect, with a bootstrapped 95% CI of 0.005-0.044. Similarly, the effect of PIU on anxiety, including the indirect effect via loneliness, was significantly more pronounced among respondents with higher social media identity than among those with lower social media identity. This difference amounted to a 0.017 variation in the direct effect and a 0.017 difference in the indirect effect, with a bootstrapped 95% CI of 0.000-0.033 (Table 5).

The subgroup analyses based on sex and age confirmed the moderated mediation models tested in this study (Table S4 of Multimedia Appendix 1). In all the subgroups, except for those older than 60 years, the indirect effects of PIU on depression and anxiety via loneliness exceeded 40% of the total effect. Additionally, higher levels of social media identity were associated with greater impacts of PIU on depression and anxiety in nearly all subgroups, except the group aged 50-59 years, where this effect was not observed for the impact of PIU on depression.

Alternative model testing revealed that PIU mediated the effects of loneliness on depression and anxiety (Tables S5 and S6 of Multimedia Appendix 1). However, the indirect effect explained only 16.12% and 14.66% of the total effect of loneliness on depression and anxiety, respectively. The change in R^2 values also indicated a limited contribution of PIU as a mediator.

Discussion

Main Findings

This study reveals that increased PIU is linked to increased depression and anxiety symptoms. Loneliness acts as a mediator in this association, accounting for almost half of the total effects. Notably, while a higher social media identity may decrease loneliness, it intensifies the impacts of loneliness and PIU on depression and anxiety.

Comparisons With the Existing Evidence

The study confirms a significant effect of PIU on loneliness, although the direction of the relationship remains inconclusive. This aligns with the findings of most existing studies [25,70,71], indicating an internet displacement effect, in which the internet replaces offline interactions rather than a stimulation effect, in which the internet enhances existing relationships [25]. Previous studies have extensively documented the positive associations of PIU with depression and anxiety [17-20,40,72], as well as the positive associations of loneliness with depression and anxiety [73-76]. These associations were confirmed in this study.

In our study, we discovered that loneliness serves as a significant mediator in the link between PIU and mental health disorders, explaining nearly half of the total effects on both depression and anxiety symptoms. Notably, loneliness can be alleviated by enhancing social skills and strengthening social support [77], providing a novel approach to mitigate the negative consequences of PIU on mental health [78]. However, the substantial direct effects of PIU on depression and anxiety symptoms remain unclear and warrant further exploration. Existing evidence has suggested that sleep disturbance may be a potential pathway through which PIU affects mental health [79,80]. Consequently, future research is needed to deepen our understanding of the underlying reasons for the association between PIU and mental health.

Social media has produced revolutionary changes in people's daily lives, profoundly impacting their health. Previous studies have established connections between PIU and social media identity [31] as well as between social media identity and loneliness [30,51,52]. This study expands our existing knowledge by exploring the role of social media identity in the effects of PIU on both loneliness and mental health disorders. We found that higher levels of social media identity have the potential to exacerbate the effects of PIU on mental health disorders. Social media identity is formed as individuals seek connections with like-minded others online [31,81], which can reduce feelings of loneliness, as indicated in this study and others [82-84]. However, this reduction in loneliness does not appear to be strong enough to counterbalance the exacerbating effects of social media identity on the association between PIU and mental health disorders. One plausible explanation is that individuals with high levels of social media identity become deeply engrossed in the virtual online space at the expense of offline social interactions [85,86]. This may result in reduced ability to obtain social support from traditional relationships such as family members, friends, and work colleagues. Online relationships are often criticized for being superficial and lacking authenticity, and they cannot fully replace the role of offline relationships [87]. People with a high level of social media identity may feel less lonely but have limited access to offline interactions and social support, thereby increasing their risk of depression and anxiety [31,37].

Although the primary focus of this study was not on the prevalence of depression and anxiety, our study participants appeared to exhibit similar levels of depression and anxiety symptoms as those reported in another national study conducted in 2021 [88]. In our study, approximately 22.80% (4854/21,292) and 14.20% (3023/21,292) of the respondents were identified as experiencing moderate or severe depression and anxiety, respectively [89,90]. Consistent with previous studies conducted during the COVID-19 pandemic [2], our research also identifies the female sex and young age groups such as those aged 18-29 years as significant risk factors for mental health disorders. Recent studies have revealed a rapid increase in PIU, which is the most prevalent among men and younger age groups [91,92]. However, our study suggests that the effects of PIU on mental

XSL•FO
RenderX

health disorders are similar between male and female respondents.

Policy Implications

As loneliness is a significant mediator between PIU and depression and anxiety, it is beneficial to consider a comprehensive strategy that addresses both PIU and loneliness to mitigate the negative mental health outcomes associated with PIU. For educators and caregivers, existing studies have shown that active educational interventions, including alternative activity recordings and internet diary writing, were more likely to decrease internet addiction [93]. Additionally, policymakers can also introduce multilevel approaches that target internet users, online content, and the internet industry to address this challenge [94]. For example, China has issued a series of policies in which gaming companies have been required to impose restrictions, such as limiting young users to 1 hour of play on Fridays and weekends. Furthermore, the awareness and knowledge of the public should also be improved, especially with respect to risky online behaviors [93]. Research indicates that intervention programs focused on specific online risks such as gambling, cyberbullying, and online gaming tend to be more effective than general PIU interventions [95]. Offline strategies that enhance social connectedness and social support have also demonstrated their effectiveness in reducing loneliness [96] and can be incorporated into PIU management efforts. Social media identity plays a pivotal role in amplifying the mental health consequences of PIU. This underscores the importance of helping individuals balance their online and offline relationships. Although online connections can temporarily relieve loneliness, they should not substitute or jeopardize the value of real-world connections. Potential intervention strategies may involve public education campaigns to increase awareness and encourage responsible online behavior, as well as strengthening offline social activities to promote face-to-face interactions and social support.

Strengths and Limitations

To our knowledge, this is the first study to provide valuable insights into the intricate connections among PIU, loneliness, social media identity, and mental health disorders by using moderated mediation modeling. The sample size was large. This study has several limitations. One significant limitation is the cross-sectional design, which prevents us from verifying the bidirectional relationships between PIU and loneliness as well as between PIU and mental health disorders. Future research could benefit from a longitudinal design to explore the dynamic interplay between PIU, loneliness, and mental health over time. Additionally, although we used a moderated mediation effect model to examine the effects of PIU, loneliness, social media identity and their interaction on mental health, the nature of the cross-sectional design allows us to generate only an association rather than a causal relationship between them. Furthermore, the moderating effects were relatively small in this study, which may be susceptible to changes in other populations or concerning other mental health disorders. Thus, this study should be interpreted with caution. Furthermore, other unexamined factors and pathways may contribute to the relationship between PIU and mental health. For example, variables related to sleep patterns and sedentary lifestyles could play a role in both PIU and mental health disorders [97]. These factors were not included in our study because of data unavailability. Finally, although the mental health status of the participants was assessed on the basis of their experiences during the 2 weeks before the survey, the results were still vulnerable to potential recall bias. The excluded participants were more likely to be men older than 50 years, resulting in a slight underrepresentation of these populations in this study.

Conclusions

PIU is linked to symptoms of depression and anxiety, and our research underscores the crucial role of loneliness as a mediator in this association. Loneliness is responsible for nearly half of the total effects of PIU on depression and anxiety symptoms. Intriguingly, although social media identity may offer some relief from loneliness, it paradoxically exacerbates the impact of PIU on depression and anxiety. In light of these findings, a comprehensive and multifaceted approach to PIU management, encompassing both online and offline interventions, is warranted.

Abstract

Background: With suicide rates in the United States at an all-time high, individuals experiencing suicidal ideation are increasingly turning to large language models (LLMs) for guidance and support.

Objective: The objective of this study was to assess the competency of 3 widely used LLMs to distinguish appropriate versus inappropriate responses when engaging individuals who exhibit suicidal ideation.

Methods: This observational, cross-sectional study evaluated responses to the revised Suicidal Ideation Response Inventory (SIRI-2) generated by ChatGPT-4o, Claude 3.5 Sonnet, and Gemini 1.5 Pro. Data collection and analyses were conducted in July 2024. A common training module for mental health professionals, SIRI-2 provides 24 hypothetical scenarios in which a patient exhibits depressive symptoms and suicidal ideation, followed by two clinician responses. Clinician responses were scored from –3 (highly inappropriate) to +3 (highly appropriate). All 3 LLMs were provided with a standardized set of instructions to rate clinician responses. We compared LLM responses to those of expert suicidologists, conducting linear regression analyses and converting LLM responses to z scores to identify outliers (z score>1.96 or <–1.96; P<0.05). Furthermore, we compared final SIRI-2 scores to those produced by health professionals in prior studies.

Results: All 3 LLMs rated responses as more appropriate than ratings provided by expert suicidologists. The item-level mean difference was 0.86 for ChatGPT (95% CI 0.61-1.12; P<.001), 0.61 for Claude (95% CI 0.41-0.81; P<.001), and 0.73 for Gemini (95% CI 0.35-1.11; P<.001). In terms of z scores, 19% (9 of 48) of ChatGPT responses were outliers when compared to expert suicidologists. Similarly, 11% (5 of 48) of Claude responses were outliers compared to expert suicidologists. Additionally, 36% (17 of 48) of Gemini responses were outliers compared to expert suicidologists. ChatGPT produced a final SIRI-2 score of 45.7, roughly equivalent to master's level counselors in prior studies. Claude produced an SIRI-2 score of 36.7, exceeding prior performance of mental health professionals after suicide intervention skills training. Gemini produced a final SIRI-2 score of 54.5, equivalent to untrained K-12 school staff.

Conclusions: Current versions of 3 major LLMs demonstrated an upward bias in their evaluations of appropriate responses to suicidal ideation; however, 2 of the 3 models performed equivalent to or exceeded the performance of mental health professionals.

Introduction

Suicide is one of the leading causes of death among individuals under the age of 50 in the United States, and it is the second leading cause of death among adolescents [1]. Rates of suicide have also grown sharply in recent years; 39,518 suicide deaths were reported in 2011, compared to 48,183 in 2021. Although this trajectory declined during the COVID-19 pandemic, more recent data indicate the upward trend has resumed [2].

Large language models (LLMs) have drawn widespread attention as a potential vehicle for helping or harming individuals who are depressed and at risk of suicide [3]. LLMs are designed to interpret and generate human-like text responses to written and spoken queries, and they include broad health applications [4]. Platforms like ChatGPT, as well as mental health apps powered by LLMs, offer an outlet to individuals looking for therapeutic advice on how to cope with depressive symptoms, loneliness, and thoughts of suicide [5,6]. This could be particularly beneficial for the roughly 50 million Americans living in rural parts of the United States with poor access to mental health care [7] or for those who cannot afford the cost of therapy [8,9].

On the other hand, researchers and advocates fear that LLMs could make poor, if not outright injurious, recommendations when engaging with individuals with who express suicidal ideation [10]. Only a small handful of studies in the peer-reviewed literature have evaluated the competencies of LLMs when addressing individuals who exhibit depressive symptoms and suicidal ideation [11-14]. Typically, these studies quantify behaviors of LLMs, such as making an initial referral to a human, rather than directly comparing LLM performance to standardized benchmarks [12]. For LLMs to improve on tasks such as offering therapeutic advice, reinforcement learning from human feedback, a process in which human feedback from experts is used to align LLM responses with best practices and ethical standards in mental health care, is required.

In this study, we assessed the competency of 3 widely used LLMs to distinguish appropriate versus inappropriate responses when engaging individuals who exhibit suicidal ideation. To do so, we compared the responses of LLMs to responses by expert suicidologists on a previously-published standardized scale: the Suicide Intervention Response Inventory (SIRI-2) [15]. We hypothesized that ratings generated by LLMs would differ significantly from those of expert suicidologists. We also hypothesized that LLMs would not demonstrate a consistent bias—meaning they would not systematically rate responses as more or less appropriate, compared to expert suicidologists.

Methods

Ethical Considerations

This observational cross-sectional study was deemed exempt from review by Harvard Medical School's Institutional Review Board (reference #2116708). The study followed Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) guidelines.

Measures

The SIRI-2 contains 2 sets of 24 hypothetical patient remarks that disclose depressive symptoms and suicidal thoughts (for example: "I don't think there's really anyone who cares whether I'm alive or dead"). Patient remarks are followed by 2 possible clinician responses, each of which could be considered supportive, neutral, or deleterious to suicide prevention (for example, Clinician A: "It sounds like you're feeling pretty isolated"; Clinician B: "Why do you think that no one cares about you anymore?") [15].

LLMs were provided the original instructions from the SIRI-2, which state that respondents were to assign each clinician response a score from –3 (highly inappropriate response) to +3 (highly appropriate response), on a 7-point ordinal scale. Expert suicidologists were not recruited as part of this study but rather, were previously recruited by the instrument's authors to create a normative benchmark by which to compare responses from other individuals [15]. In the context of this study, we compared the responses of LLMs to those of these previously recruited expert suicidologists. The final SIRI-2 score is represented as the sum of differences between LLMs' and experts' ratings; a lower score indicates greater alignment between LLMs and expert suicidologists.

Previous research has reported the SIRI-2 scores for a wide range of individuals—such as doctoral students in clinical psychology, master's level counselors, and K-12 school staff (see Table 1) [16-20]. Human performance on these evaluations therefore serves as a reference point for which we could compare LLM performance.

[a]Pretraining represents measurement of individuals prior to suicide intervention response training, while post-training represents measurement of individuals after suicide intervention response training.

[b]A lower score is considered better on the SIRI-2. Values are reported to the tenths place.

[c]N/A: not applicable. N/A indicates studies that did not conduct pre- and post-training analyses.

Procedures

Using ChatGPT-4o, Claude 3.5 Sonnet, and Gemini 1.5 Pro, we conducted a series of assessments from June to July 2024. Three members of the research team created separate accounts to interact with and prompt LLMs. Research team members prompted LLMs with the original instructions for the SIRI-2, as well as with one of the SIRI2-2's 24 items. We did not prompt LLMs with any additional text. We used this approach to evaluate how LLMs responded without further prompting strategies (ie, methods such as chain-of-thought, in which the responses of LLMs are guided by additional instructions, contextual information, or examples) [24]. See Multimedia Appendix 1 for an overview of the data collection workflow.

The 3 research team members recorded responses provided by LLMs. They also documented any rationale provided by LLMs for the scores they assigned (see Multimedia Appendix 2 for this information).

Statistical Analysis

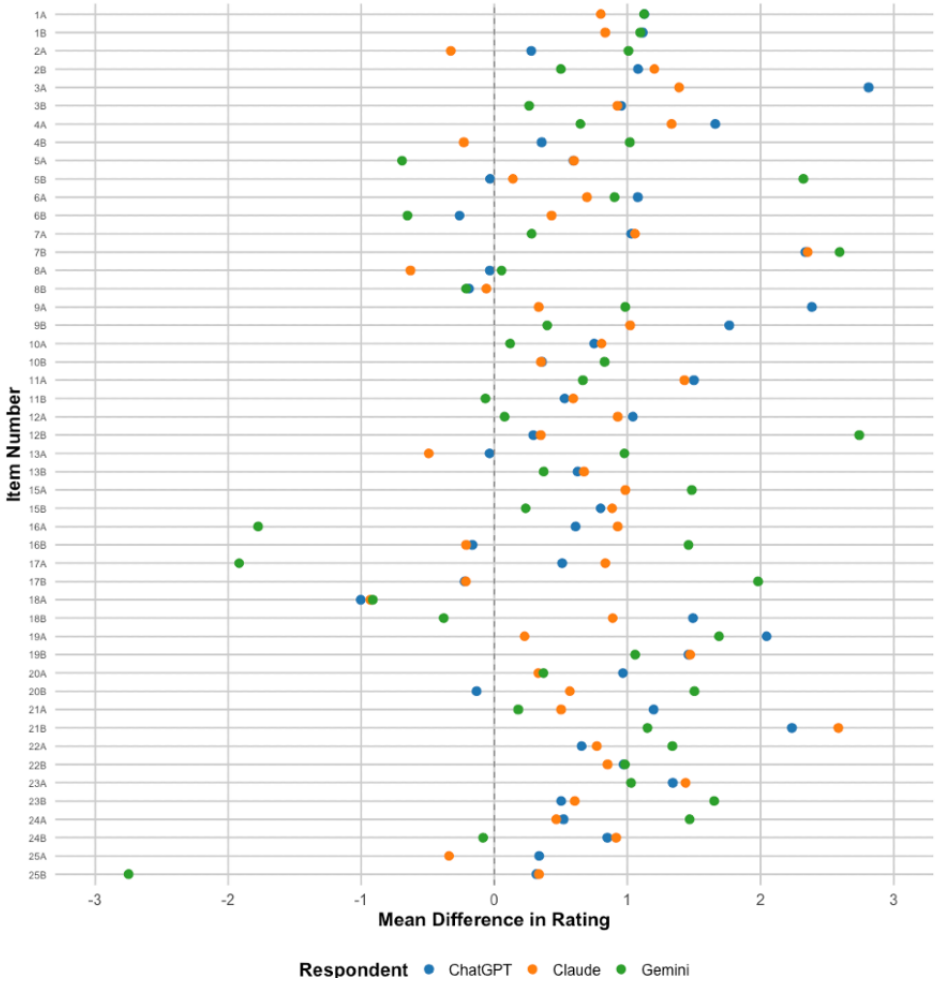
As a first step, we summarized responses generated by LLMs and expert suicidologists, reporting mean scores and SDs on each of the 24 items. For LLMs, these values were computed across the 3 sets of responses generated by team members. We also examined alignment between LLM and expert responses, measured as the magnitude of the correlation coefficients between the two. Next, we inspected test-retest reliability of each of the LLM's responses, a marker of the consistency and stability of an LLM's responses over time. This was measured as the mean correlation coefficient across the 3 instances in which each LLM response set was generated.

Following this, we conducted 2 sets of inferential analyses. First, we conducted linear regression analysis in Stata 17.1 (StataCorp) to compare item-level responses assigned by each LLM to those assigned by expert suicidologists. The dependent variable in the model was the item score (–3 to +3). The 2 independent variables were (1) respondent type (ie, LLM vs expert) and (2) survey item number (eg, Item 1, Item 2). This specification allowed us to test whether LLMs produced

XSL•FO
RenderX

systematically different scores from experts, while also accounting for the nested structure of the data. For example, item scores (from –3 to +3) were nested within survey items.

Second, based on mean scores and corresponding SDs from expert suicidologists, we calculated *z* scores for each item-level response generated by LLMs. We then quantified the average *z* score for an LLM's responses, as well as the number and percent of *z* scores that were statistically significant (ie, *z* scores greater than 1.96 or less than –1.96). This provided an indication of overall alignment between an LLM's and experts' responses.



Lastly, we calculated final SIRI-2 scores for each LLM and compared these to the performance of humans in prior studies, including the performance of mental health professionals with and without training on suicide intervention response.

Results

Descriptive Statistic

Expert suicidologists reported a mean score of –0.20 (SD 2.22) across all items, meaning that the average response approximated "neither appropriate, nor inappropriate", but item-level responses varied widely. By comparison, mean scores for ChatGPT-4o, Claude 3.5 Sonnet, and Gemini 1.5 were 0.67 (SD 2.41), 0.41 (SD 2.51), and 0.53 (SD 1.73), respectively, meaning that responses tended to skew more toward "appropriate" compared to "inappropriate". ChatGPT-4o assigned a higher score than experts for 40 of 48 responses (83%). Claude 3.5 generated a higher score on 39 responses (81%), and Gemini 1.5 generated a higher score on 36 responses (75%; see Figure 1).

Figure 1. Mean difference in ratings on Suicidal Ideation Response Inventory (SIRI-2) items: large language model versus expert suicidologists.

The correlation between LLM and expert responses was 0.93 for ChatGPT-4o, 0.96 for Claude 3.5, and 0.81 for Gemini 1.5. In terms of test-retest reliability, mean test-retest correlation coefficients were 0.98 for ChatGPT-4o, 0.99 for Claude 3.5 Sonnet, and 0.73 for Gemini 1.5, indicating high reliability for all 3 LLMs.

Regression Analyses: Bias

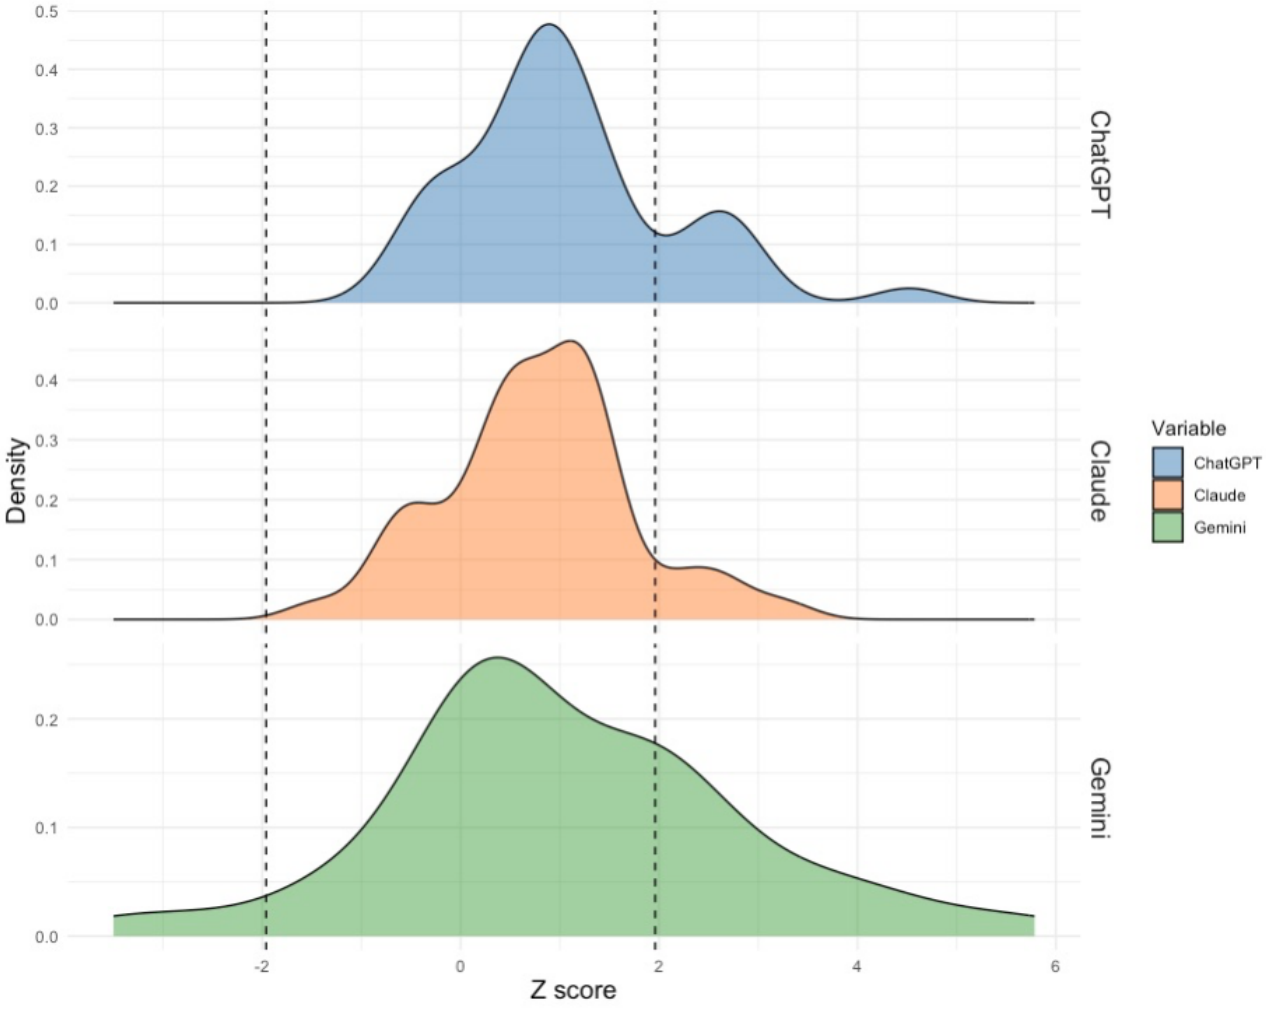
In our regression, LLMs assigned significantly higher scores to hypothetical responses, compared to expert suicidologists, indicating LLMs perceived responses as more appropriate than experts did (see Table 2) with the mean difference in item-level scores being 0.865 (95% CI 0.613-1.118; *P*<.001) for ChatGPT-4o, 0.608 (95% CI 0.408-0.809; *P*<.001) for Claude 3.5 Sonnet, and 0.733 (95% CI 0.352-1.114; *P*<.001) for Gemini 1.5.

XSL•FO
RenderX

Table 2. Estimated difference in perceived appropriateness of responses to suicidal ideation.

LLM model and version	Bias		Performance		
	Score difference[a] (95% CI)	*P* value	Mean *z* score	*Z* scores with an SD of >1.96, n (%)[b]	SIRI-2[c] score
ChatGPT-4o	0.865 (0.613-1.118)	<.001	1.17	9 (19.1)	45.71
Claude 3.5 Sonnet	0.608 (0.408-0.809)	<.001	1.01	5 (10.6)	36.65
Gemini 1.5 Pro	0.733 (0.352-1.114)	<.001	1.54	17 (36.2)	54.52

[a]Average difference represents the mean difference in units, on a 7-point ordinal scale, between an LLM model's responses and expert suicidologists' responses.



[b]*Z* scores were generated for 47 of 48 responses, as 1 item had a SD of 0.

[c]SIRI-2: Suicide Intervention Response Inventory. A lower score is considered better on the SIRI-2.

Overall Performance

Across all items, the average *z* score for ChatGPT-4o responses was 1.17, with 9 responses (19%) greater than 1.96 SDs (all *P*<.05) from the mean responses by expert suicidologists (see Figure 2). The average *z* score for Claude 3.5 Sonnet responses was 1.01, with 5 (11%) responses greater than 1.96 SDs (all *P*<.05) from the mean expert responses. Lastly, the average *z* score for Gemini 1.5 Pro responses was 1.54, with 17 (36%) responses greater than 1.96 SDs (all *P*<.05) from the mean responses by experts. In terms of final SIRI-2 scores, these were 45.71 for ChatGPT-4o, 54.52 for Gemini 1.5 Pro, and 36.65 for Claude 3.5 Sonnet. We note that the lowest possible score, for which expert suicidologists serve as the reference point, was 12.90.

Figure 2. Density plot represents the proportion of responses, across all 48 item responses, with *z* scores ranging from –3 to +6. Dashed vertical lines indicate cutoff thresholds of –1.96 and +1.96. Values less than –1.96 or greater than +1.96 are significant at *P*<.05.

XSL•FO
RenderX

Discussion

We evaluated the capacity of 3 LLMs to assess the appropriateness of responses to 24 scenarios in which a hypothetical individual disclosed depressive symptoms and suicidal thoughts. Compared to the ratings of expert suicidologists, the evaluations of the 3 LLMs were highly correlated but demonstrated an upward bias toward rating responses as more appropriate. Similar biases have been identified in other domains of LLM performance, such as a tendency to over-assign medical diagnoses to individuals of particular demographic backgrounds [25].

LLMs' overall performance as measured by SIRI-2 score—which captures the magnitude of their deviations from expert suicidologists—varied across models. The final score produced by Gemini (54.52) was roughly equivalent to past scores produced by K-12 school staff *prior to* suicide intervention skills training [16]. By contrast, the final score produced by ChatGPT (45.71) was closer to those exhibited by doctoral students in clinical psychology [19] or master's level counselors [15]. Claude observed the strongest performance (36.65), surpassing scores observed even among individuals who recently completed suicide intervention skills training, as well as studies with psychiatrists and other mental health professionals [21-23].

A key issue in this study is whether a competency in adjudicating appropriate responses to suicidal ideation translates to a competency in responding to individuals disclosing suicidal ideation. Serving as referee is not the same as active engagement. The findings of this study also highlight a standard path forward for companies developing and refining LLMs for therapeutic purposes: namely, to consider indexing LLM responses against high-quality benchmarks, such as ratings of expert suicidologists. Instruments such as the SIRI-2 offer rare touchstones for this. A complementary model involves reinforcement learning from human feedback, in which expert clinicians provide direct evaluations of LLM performance relative to a set of pre-established criteria and best practices [26,27].

When used for therapeutic purposes, LLMs will likely encounter users with suicidal ideation on a routine basis. Roughly 1 in 4 mental health professionals encounter suicidal ideation among their patients [28]. Widespread use of LLM technology—including new companies already drawing on LLM technology for mental health care [29]—could reach a much wider audience of individuals coping with depression and suicidal thoughts. To date, a common guardrail has been for LLMs to produce "hard stops", in which individuals are referred to 988 or another suicide prevention hotline. While such referrals may be beneficial, they also artificially circumscribed interactions in a way that could be taken as a missed opportunity.

There are several important study limitations to note. First, LLM technologies are constantly evolving. This study offers a snapshot of LLM performance in July 2024. Second, we selected the SIRI-2 as an evaluative tool because it is widely used; however, alternative instruments could result in different findings. Third, as noted above, this study focuses on the evaluative competencies of LLMs rather than their abilities to directly respond to suicidal ideation. While there are many prompting strategies designed to elicit better performance of LLMs [30], the goal of this study was to test how LLMs evaluate responses to suicidal ideation in conversations without any additional guidance. This is similar to LLM alignment studies where fictitious scenarios are presented without specific prompting strategies and LLM responses are evaluated [31]. Lastly, we note that the authors of the SIRI-2 constructed the original panel of expert suicidologists, and as such, our research team (and other users of the SIRI-2) lack information regarding their average years of clinical practice.

In summary, this study highlights the potential and limitations of 3 widely used LLMs to assess appropriate responses to individuals exhibiting suicidal ideation. While current LLM versions exhibit a preferential bias toward viewing responses as appropriate, their overall performance was on-par with or otherwise exceeded those documented in prior human studies. Claude 3.5 Sonnet surpassed other LLMs by a sizable margin. Future research might explore alternative configurations in which LLMs directly respond to suicidal ideation; although, benchmarks for index performance in these scenarios are uncommon.

Acknowledgments

We would like to thank Nabeel Qureshi for his assistance collating output from LLMs, which were used for analyses in this manuscript. This work was supported by a grant from the National Institute of Mental Health (1R01MH132551). The content is solely the responsibility of the authors and does not necessarily represent the views of National Institute of Mental Health. Abstract

Background: Continuous scientific and policy debate regarding the potential harm and/or benefit of media and social media on adolescent health has resulted, in part, from a deficiency in robust scientific evidence. Even with a lack of scientific consensus, public attitudes, and sweeping social media prohibitions have swiftly ensued. A focus on the diversity of adolescents around the world and their diverse use of language, culture, and social media is absent from these discussions.

Objective: This study aims to guide communication policy and practice, including those addressing access to social media by adolescent populations. This study assesses physical and mental health information scanning and seeking behaviors across diverse language, cultural, and technological media and social media among Latinx adolescent residents in the United States. This study also explores how Latinx adolescents with mental health concerns use media and social media for support.

Methods: In 2021, a cross-sectional survey was conducted among 701 US-based Latinx adolescents aged 13-20 years to assess their health-related media use. Assessments ascertained the frequency of media use and mental and physical health information scanning and seeking across various media technologies (eg, TV, podcasts, and social media) and language and cultural types (ie, Spanish, Latinx-tailored English, and general English). Linear regression models were used to estimate adjusted predicted means of mental and physical health information scanning and seeking across diverse language and cultural media types, net personal and family factors, in the full sample and by subsamples of mental health symptoms (moderate-high vs none-mild).

Results: Among Latinx adolescents, media and social media use was similar across mental health symptoms. However, Latinx adolescents with moderate-high versus none-mild symptoms more often scanned general English media and social media for mental health information (P<.05), although not for physical health information. Also, Latinx adolescents with moderate-high versus none-mild symptoms more often sought mental health information on Latinx-tailored and general English media, and social media (P<.05); a similar pattern was found for physical health information seeking. In addition, Latinx adolescents with moderate-high versus none-mild symptoms often sought help from family and friends for mental and physical health problems and health care providers for mental health only (P<.05).

Conclusions: While media and social media usage was similar across mental health, Latinx adolescents with moderate-high symptoms more often encountered mental health content in general English media and social media and turned to general English- and Latinx-tailored media and social media more often for their health concerns. Together these study findings suggest more prevalent and available mental health content in general English versus Spanish language and Latinx-tailored media and underscore the importance of providing accessible, quality health information across diverse language, cultural, and technological media and social networks as a viable opportunity to help improve adolescent health.

Introduction

Current reports depict an adolescent mental health crisis in the United States. About 1 in 5 adolescents experience poor mental health, especially race and ethnic minoritized adolescents [1-6]. In 2021, the US Surgeon General stated that the COVID-19 pandemic further altered adolescents' experiences at home, school, and the community, which generated devastating effects on their mental health [7]. In 2021, 42% of adolescents had persistent sadness and hopelessness and 22% of adolescents considered suicide, representing significant increases since 2019 [8]. Latinx (46%) adolescents, representing 25% of all adolescents nationally, report higher rates of sadness than Asian (35%), Black (39%), and White (41%) adolescents, with the pandemic especially worsening mental health for Latinx adolescents [9]. Despite these trends, less than half of Latinx adolescents with mental health problems receive care [5].

Given the concern about adolescent mental health, emerging public attitudes and policies have focused on how social media in particular may influence mental health outcomes and knowledge, norms, and behaviors related to mental health help-seeking and services [10-21]. While past research has focused on legacy media (eg, TV, radio, print), recent research has examined new digital media, especially social media, as a behavioral risk factor for poor mental health [22]. While the mechanisms explaining this association remain unclear, studies have shown how mental health content on social media is highly variable, portraying both positive (ie, supportive) and negative (ie, stigmatizing) content [17-21,23-28]. For instance, while #MentalHealth is one of the 3 most popular social media tags about health to increase public awareness, pejorative content such as stigma and hate speech is prevalent too [16-21,29,30]. Therefore, legacy and new digital media can deliver mixed mental health content that can potentially influence mental health knowledge, attitudes, behaviors, and outcomes. Thus, further study about adolescents' exposure to mental health information across diverse languages, cultures, and technological media is warranted, and an assessment of how this exposure might influence mental health behaviors. This knowledge is especially relevant for adolescents as about half of social media users are 10-29 years old—the same age of onset of most mental health problems [23].

Research on legacy media has shown direct links with positive and negative mental health behaviors, while new studies on social media use and mental health among adolescents have only identified small or null associations, partly due to the predominant use of limited assessments of time spent on social media as a simple construct [11,12,19,22,31-33]. This is a substantial limitation of previous studies as social media is not experienced unidimensionally. Rather, diverse linguistic, cultural, and technological social media exists—that is, media across global languages (Spanish, Mandarin, etc); global cultures (eg, Latinx-tailored, Korean pop culture, influencer cult followings, and social movements such as #BlackLivesMatter); and technologies for delivery of communications (social media apps such as YouTube, Facebook, Instagram, Snapchat, TikTok, Sidechat, Pinterest, Reddit; mobile apps; console-, computer-, or VR-based gaming; music, podcasts, film, and TV streaming services such as Netflix, Hulu, Spotify, Pandora, etc) [22]. Thus, previous studies have not considered more robust measurements or algorithm-driven content that is characteristic of social media.

Careful consideration of measurement is important as adolescent populations are diverse, as is their access to language and cultural media across technology. For instance, Latinx populations in the United States use social media more than other races and ethnic groups, including the top 3 popular apps among all adolescents (ie, Instagram, Snapchat, TikTok) [23]. In addition, Latinx adolescents have access to media, including social media, in Spanish and from Latin America due to close global social networks from dynamic migration experiences. At the same time, Latinx communities are impacted by poor-quality, slow dissemination of health communication as industry-led and government-controlled content moderation has historically overlooked Spanish-language and Latinx communications, particularly social media [13-15,34-41].

Because research on media and social media and health has largely focused on English-language media and excluded Latinx representation relative to their share of the demographic of media consumers, new research is warranted that focuses on diverse language, cultural, and technological media among Latinx adolescents and its relationship to health [11,42-45]. To address this gap, the study aimed to generate new knowledge about the frequency of mental and physical health information scanning and seeking across diverse language, cultural, and technological media and test whether these patterns vary by mental health profiles among Latinx adolescents. Because Latinx adolescents' social media use has been inadequately studied, we importantly use newly validated, culturally appropriate measures to capture diverse language, cultural, and technological media for health information among Latinx adolescents. Our measurement extends previous, traditional measures of media exposure among Latinx populations that focused on language competency and legacy media to now newly capture widely available Latinx-tailored digital media. We also compare these media-based outlets to help-seeking for health problems to family and friends and health care providers.

Methods

Sample

In 2021, 701 eligible US-based Latinx adolescents aged 13-20 years from a proprietary Qualtrics survey research panel self-completed a 20-minute cross-sectional web survey using personal digital devices about behaviors related to Spanish- and

XSL•FO
RenderX

English-language media use and mental and physical health information acquisition; complete details about study procedures are reported elsewhere [46]. Eligibility included participants identifying as "Latina/o/x/e." Recruitment quotas by age, ethnic origin, and gender were used to help sample under-represented Latinx groups in population health research. In 2021, smartphone or tablet ownership among US-based adolescents was nearly universal (more than 95%) [47]. Random checks of the survey reviewed accuracy and consistency in data entry. All study materials were offered in Spanish and English; 96.58% (677/701) of the study sample completed the survey in English.

The achieved study sample of Latinx adolescents (N=701) had a median age of 17 (SD 1.57) years; 78.21% (524/701) were female and 86.51% (603/701) were US-born (Table 1). Among the 13.49% (94/701) that were foreign-born, the average age of arrival to the United States was about 10 years old. Ethnic subgroups included Mexican (403/701, 57.49%), Cuban or Dominican or Other Latinx group (83/701, 11.84%), Puerto Rican (74/701, 10.56%), Central American (86/701, 12.27%), and South American (55/701, 7.85%), and race subgroups included American Indian or Alaskan Native (21/701, 3.01%), Black (41/701, 5.88%), Multiracial (74/701, 10.62%), White (244/701, 35.01%), and Other (317/701, 45.48%). About 41% (283/701) reported household incomes of less than US $20,000, while 46% (317/701) reported between US $20,000 and less than US $75,000; 14% (97/701) reported more than US $75,000. Participants reported high Latinx ethnic attachment (mean 33.19, SD 6.86) and English-language media use (mean 3.32, SD 0.94), followed by Latinx-tailored (mean 2.81, SD 1.03) and Spanish-language (mean 2.64, SD 1.05) media use. The study sample compared to national data is reported elsewhere [46]. Subsamples based on the Patient Health Questionnaire-4 (PHQ-4; see Measures section) included no-mild (n=391) and moderate-severe (n=310) mental health symptoms. Subsamples varied significantly by gender, race, parent or guardian nativity, and Spanish acculturation (P<.05), and not by other covariates in Table 1.

[a]$P<.05$ for significant differences across mental health symptoms.

Measures

Media Use (Covariate)

As previously validated, [46] 7 items assessed diverse language, cultural, and technological media types, including Spanish, Latinx-tailored English, and general English media use across print media, free broadcast TV, subscription TV, Twitter, other social media (eg, Facebook, Instagram, and TikTok), radio or podcasts, and music and music streaming. Participants were asked how often they engage in each language, cultural, and

XSL•FO
RenderX

technological media type on an average day on a 5-point Likert scale (1=never to 5=always). A previously reported factor analysis [46] revealed that total scores of all items combined for each language or cultural dimension to create three subscales: Spanish-language (α=.92), Latino-tailored English (α=.90), and general English (α=.86) media use.

Media-Based Health Information Scanning (Outcome 1)

In total, 5 items assessed the frequency of mental health and, separately, physical health, information scanning (ie, passive exposure to health information in media) across the 3 language or cultural domains (ie, Spanish, Latinx-tailored English, and general English) for each technological media type: print media, TV, websites, social media, or radio or podcasts [46]. Participants were asked how often they encountered (ie, scanning) mental health and, separately, physical health, information in each language, cultural, and technological media type during an average week (1=not at all to 4=a few times a week). Factor analysis [46] revealed that total scores of all 5 media items for each language or cultural domain combined to create 3 subscales of all media scanning for mental health and, separately, for physical health (α=.92-.94).

Furthermore, given recent policy actions related to social media among adolescents, we also examined the 2 items pertaining to social media for each language or cultural domain. Combining the 2 social media items for each language or cultural domain resulted in 3 subscales of social media scanning for mental health and physical health separately.

Media-Based Health Information Seeking (Outcome 2)

A total of 5 items assessed the frequency of mental and physical health information seeking (ie, searching on purpose for health information in media) across the 3 language or cultural domains for each technological media type (print media, TV, websites, social media, and radio or podcasts) [46]. Participants were asked about the frequency that they purposely sought mental health and, separately, physical health, information in each media type for a mental or physical health problem of one's own, a family member, or a friend (1=none to 4=always). Based on the factor analysis that has been previously reported [46], total scores of all items for each language or cultural domain were combined to create 3 subscales of all media information seeking for mental health and, separately, for physical health (α=.87-.90). Also, 2 other configurations of these items by technological media type emerged in factor analyses: a legacy media subscale comprised of items assessing TV, radio, and print media (α=.93; legacy media seeking) and an internet-based media subscale comprised of items assessing websites and social media (α=.89-.90; internet and social media seeking) [46].

Formal Health Care and Informal Networks Health Information Seeking (Outcome 3)

A total of 4 items were assessed seeking information for mental health, and separately, a physical health, problem of their own or a family member or a friend, from either health care professionals (formal) or family and friends (eg, in-person or call or text; informal): "For each of the following sources, how often have you actively looked for information about a (physical or mental) health problem that you, a family member, or a friend had?" Participants responded on a 4-point Likert scale (1=never to 4=always) for formal and informal care to the item about mental health followed by a similar item about physical health.

Sociodemographic and Mental Health Factors (Other Covariates)

Age, sex, ethnic origin (ie, Latinx country of ancestry), race, nativity (ie, US- or foreign-born), household income, and migration factors (eg, age at arrival to the United States) were measured (Table 1). A total of 6 items assessed ethnic attachment (α=.90), defined as the extent of exploration, belonging, and commitment to one's Latinx ethnic identity; and 18 items measured acculturation, which captured language use and proficiency (α=.90-.91). Finally, the PHQ-4 screened for mental health symptoms, and demonstrated excellent reliability (α=.89). In total 4 items are scored on a 4-point Likert scale (0=not at all to 3=nearly every day) and summed to 0-12 full scale range. A total of 2 subsamples were created using established cutoff points: scores 0-5=none-mild and scores 6-12=moderate-severe.

Statistical Analysis

Linear regression models estimated adjusted predicted means of mental and physical health information scanning and seeking across diverse language, cultural, and technological media types (ie, all media inclusive of legacy and internet-based and social media in the Spanish language, Latinx-tailored English language, and general English language). All models were adjusted for age, sex, nativity, race, ethnic origin, household income, ethnic attachment, acculturation, and Spanish, Latinx-tailored English, and general English media use. Models inclusive of the full sample controlled for mental health symptoms. Multicollinearity was not observed between the covariates; all correlations between variables were less than 0.5. Because bivariate tests showed no statistically significant differences between all media use variables across mental health, all media use variables were entered into subsequent models as control variables. Model fit chi-square statistics indicated good fit (P<.05). Adjusted predicted means from linear regression models were also analyzed across subsamples of symptoms (no-mild vs moderate-severe). Figures plotting the adjusted predicted means for all outcomes are presented in the main results (see Tables S1-S4 in Multimedia Appendix 1 for complete linear regression model results). All results were considered significant at P<.05 and obtained using StataSEVs.18.

Ethical Considerations

The study was approved by the institutional review board at Texas A&M University. All study participants provided informed consent and assent and received a US $5 gift card for their time and effort to complete the study. All study data are anonymous and deidentified.

Results

Media-Based Health Information Scanning

Table 2 displays the adjusted predicted means of all outcomes, including media-based mental and physical health information

XSL•FO
RenderX

scanning across diverse language, cultural, and technological media types, including legacy versus internet-based and social media. In the full sample of Latinx adolescents and subsamples of mental health symptoms, mental and physical health information scanning occurred most often in general English-language media, followed by Latinx-tailored and Spanish-language media. Similar patterns were found for social media.

Figure 1 displays the adjusted predicted means of mental and physical health information scanning in the full sample of Latinx adolescents and subsamples of mental health symptoms. No statistically significant differences in mental and physical health information scanning were observed for Latinx-tailored or Spanish media and social media outcomes across subsamples of symptoms. However, Latinx adolescents with moderate-severe symptoms obtained mental health information through scanning English media and social media significantly more often than those with no-mild symptoms ($P<.05$; Figure 1). In contrast, no significant differences in physical health information scanning outcomes were found across mental health (Figure 2).

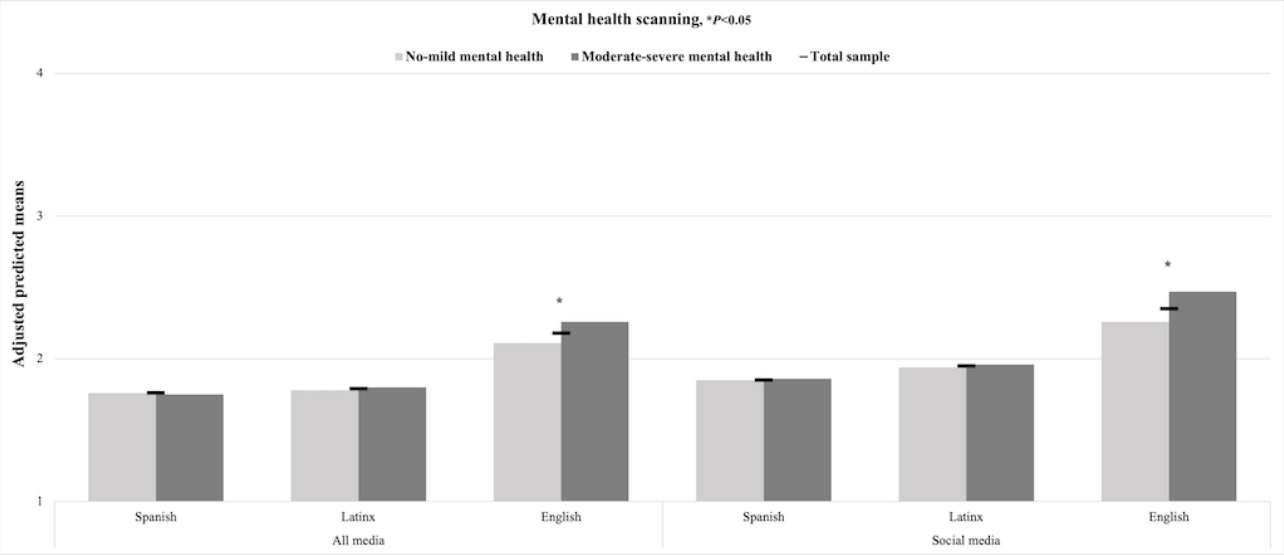
[b]All models adjusted for age, sex, nativity, ethnic origin, race, household income, ethnic attachment, acculturation, and Spanish, Latinx, and English media use; models inclusive of the full sample also adjusted for mental health symptoms while models focused on the subsamples of mental health symptoms did not.

Figure 1. Adjusted predicted means of mental health content scanning in all media in the Latinx youth full sample and subsamples by mental health symptoms (N=701), 2021.



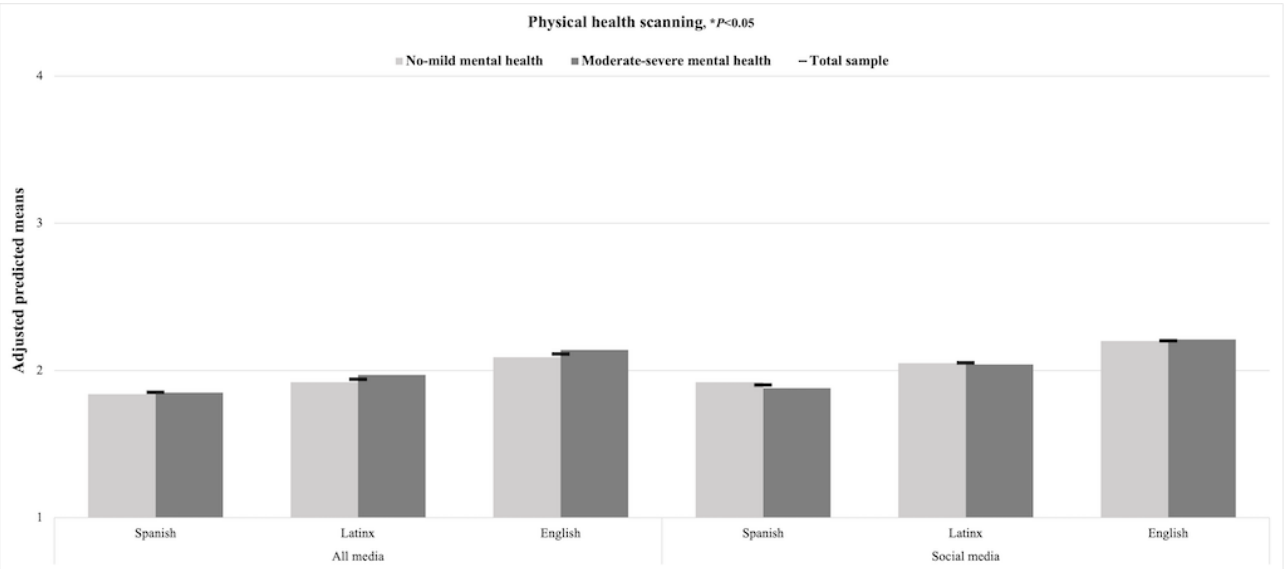


Figure 2. Adjusted predicted means of physical health content scanning in all media in the Latinx youth full sample and subsamples by mental health symptoms (N=701), 2021.

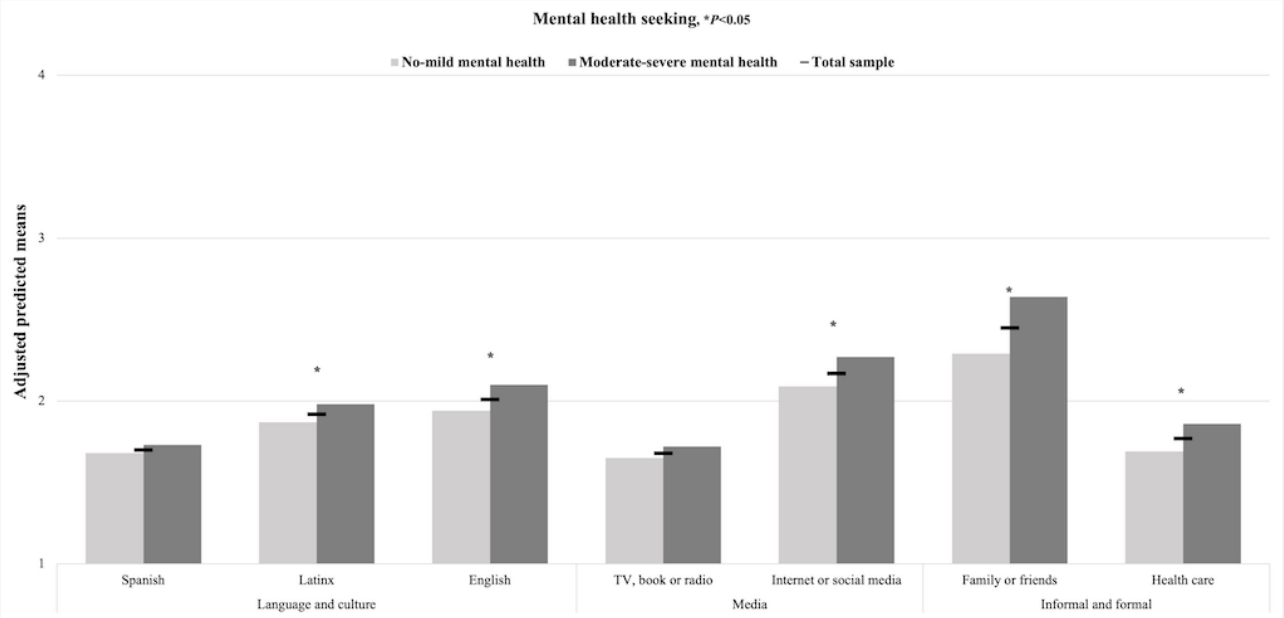
Media-Based Health Information Seeking

Table 2 also displays the adjusted predicted means of the media-based mental and physical health information-seeking outcomes across diverse language, cultural, and technological media types, including legacy versus internet-based and social media. In the full sample of Latinx adolescents and subsamples of mental health symptoms, mental and physical health information seeking in all media types occurred most often in general English-language media, followed by Latinx-tailored English-language media and Spanish-language media.

In terms of media type, the full sample of Latinx adolescents and both mental health subsamples reported seeking mental and physical health information most often in internet-based and social media versus legacy media.

Figure 2 displays the adjusted predicted means of mental and physical health information seeking in the full sample of Latinx

XSL•FO
RenderX



adolescents and mental health subsamples. No significant differences in mental and physical health information seeking were found for Spanish-language media or legacy media across the mental health subsamples. However, Latinx adolescents with moderate-severe symptoms sought mental health information in Latinx-tailored and nontailored English-language media and internet-based and social media more frequently than those with no-mild symptoms (P<.05; Figure 3). Similarly, Latinx adolescents with moderate-severe versus no-mild symptoms sought physical health information in Latinx-tailored English-language media and internet-based and social media more frequently (P<.05; Figure 4).

Formal and Informal Help-Seeking

Table 2 displays the adjusted predicted means of formal (ie, health care providers) and informal (ie, family or friends) help-seeking for mental and physical health problems in the full sample of Latinx adolescents and mental health subsamples. Both the full sample and mental health subsamples sought help for mental and physical health problems more often from family or friends than health care providers.

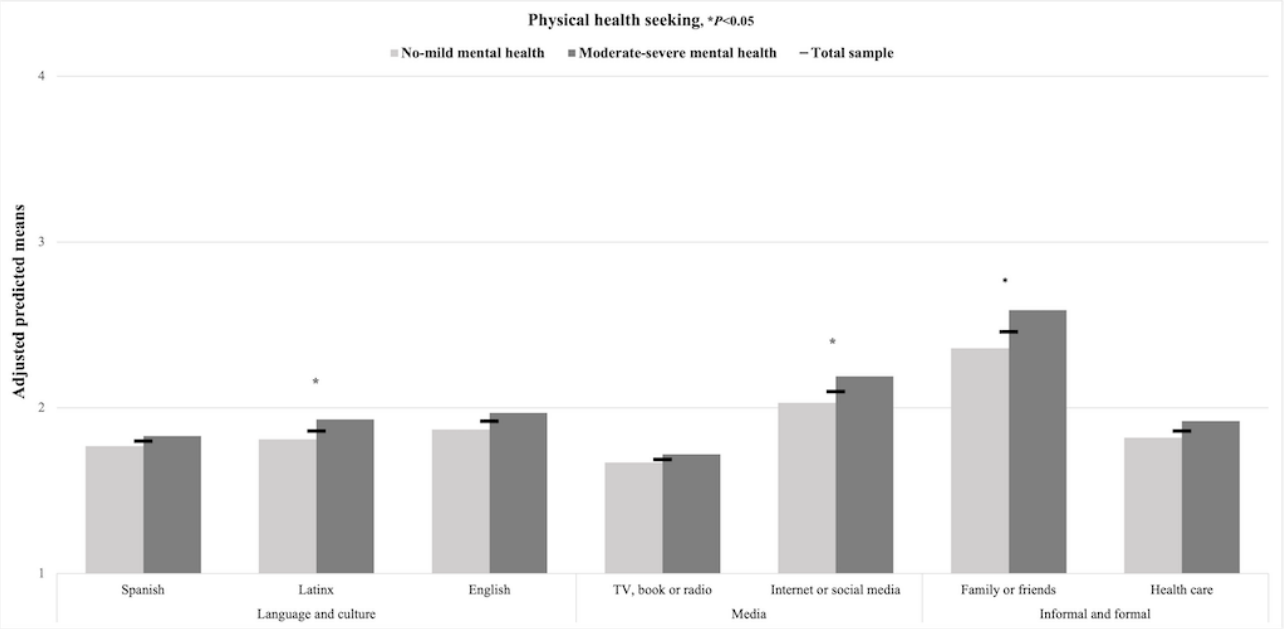


Figure 2 displays the adjusted predicted means for formal and informal help-seeking for a mental and physical health problem in the full sample of Latinx adolescents and mental health subsamples. Adolescents with moderate-severe versus no-mild symptoms were more likely to seek help from family or friends for both physical or mental health problems (P<.05; Figures 3 and 4) and from health care providers for mental health problems only (P<.05; Figure 3). Overall, Latinx youth sought help for health problems from family or friends and internet-based and social media more often than from health care providers (Figures 3 and 4).

Figure 3. Adjusted predicted means of mental health help-seeking in all media, formal, and informal sectors in the Latinx youth full sample and subsamples by mental health symptoms (N=701), 2021.

Discussion

While data trends depict a national adolescent mental health crisis with simultaneous increases in social media use, our study aimed to provide a more nuanced understanding of these trends across diverse language, cultural, and technological media among Latinx youth. Our study distinguished between mental and physical health, examined diverse language and cultural media domains, distinguished passive and active media exposure (eg, scan vs seek), and accomplished these assessments for both legacy and new digital media.

In terms of passive, casual browsing, overall, our study found that Latinx adolescents with mental health issues were more likely to engage in mental health scanning in English-language legacy and social media, but not in Spanish-language or Latinx-tailored legacy and social media, or for physical health. These patterns may arise because of more prevalent mental health content available in English-language than in Spanish-language media and social media, as previous studies confirm [48]. This is an important finding because as Latinx adolescents with mental health concerns engage with media and social media, they may become more exposed to mental health content, underscoring the need for public mental health action that leverages media to provide quality resources about symptom management and help-seeking. In contrast, passive exposure to mental or physical health content in Spanish-language and Latinx-tailored media did not vary by mental health symptoms possibly because health information is less often available in Spanish and Latinx-media, and not because of a lack of preference or interest in these media among Latinx media consumers [49]. For Latinx families with Spanish and Latinx media preferences, disparate diffusion of health communications actually may help produce health inequities [48].

With respect to the active, purposeful search for health information, our study found significant use of Latinx-tailored and English-language media for mental health information seeking and Latinx-tailored media for physical health information seeking among Latinx adolescents with moderate-severe symptoms. Latinx adolescents with mental health concerns may seek mental health information that is tailored to them and presented in their preferred language and a culturally aligned context. Public health interventionists may take note of this preference, and the availability of tailored, targeted mental and physical health information in media for Latinx adolescent audiences. Finally, family, friends, internet, and social media were more often used for both mental and physical health information than health care professionals, especially among Latinx adolescents with moderate-severe symptoms, indicating a greater preference for more easily accessible informal supports for health problems within the Latinx community. Future studies could examine the role of mistrust of health care experts and providers as sources of health information among Latinx communities to better understand these patterns.

Our study points to Spanish-language and Latinx-tailored media as important sources of health information, with English-language media as the most common source owing to more health information being available there. For example, recent studies of primetime advertising on YouTube TV revealed that English-language TV was more likely to include health promotion advertisements while Spanish-language TV was more likely to include health-adverse advertisements [50]. Inequities in health-related advertising on social media are likely similar though this remains a knowledge gap in the literature. Importantly, our study found that Latinx media is an important source of mental health information for those experiencing mental illness; thus, Latinx media may serve as an important resource for learning about and seeking support for mental health conditions. To this point, media content with greater immigrant community representation and storytelling with respect to mental

XSL•FO
RenderX

and physical health issues would be important to foster in future media programming and content curation [38,51].

Findings from this growing body of literature must be implemented into public health policy and practice as Spanish is a global power language and the most common non-English language spoken in the United States. The United States also has the second-largest population of Spanish speakers worldwide behind Mexico. Finally, Latinx populations tend to use social media more than all other major social groups in the United States despite structural inequities in content moderation of Latinx media [23].

This study has some limitations. First, as Latinx populations are dynamic, especially with respect to media and linguistic preferences and behaviors, longitudinal versus cross-sectional assessments could improve causal inference among variables and help assess changes to media content over time such as media campaigns for health promotion. Second, related dimensions of trust and comprehension of health information and perceived health concerns would be important to ascertain. For example, since mental health content is inequitable across language or cultural media, it may influence perceived mental health among English-language media consumers depending on trust and comprehension levels in the content [46]. Third, the study relied on self-reported participant recall of their behaviors. However, recall bias is likely minimal and nondifferential across the subgroups by mental health as the measures asked highly relevant information about oneself that affects daily life. Relatedly, our survey-based research is unable to assess the role of social media algorithms, which influence user consumption. Finally, the study sample was recruited from a proprietary, survey panel; thus, details regarding responses among its volunteers are undisclosed which could potentially lead to bias. To address this concern, we found that the achieved study sample is robust to national data on Latinx populations while also oversampling understudied Latinx groups, as previously reported [46].

In summary, our study demonstrates a more diverse portrait of adolescent media use in the United States, specifically Latinx adolescents who have diasporic, global ties to diverse language, cultural, and technological media. While policies and public attitudes about media and social media tend to generalize these issues, our study suggests potential contexts in which diverse language, cultural, and technological media can be an important, beneficial source of health information for Latinx adolescents. Current scrutiny about the effects of social media use on adolescent health has not sufficiently approached this issue through a health equity lens, which is essential to help inform equitable policies, programs, and practices related to its safe use among adolescents. Diverse adolescent populations will have unique contexts, needs, and assets with respect to the use of diverse language, cultural, and technological media. For Latinx adolescents experiencing mental illness, social media seems to be a useful resource of support, which has implications for other minoritized populations who might find social media as a tool to prevent health risks. Thus, greater access and equity with respect to digital media remain critical to health.

Abstract

Background: Young people are disproportionately impacted by self-harm and suicide, and concerns exist regarding the role of social media and exposure to unsafe content. Governments and social media companies have taken various approaches to address online safety for young people when it comes to self-harm and suicide; however, little is known about whether key stakeholders believe current approaches are fit-for-purpose.

Objective: From the perspective of young people, policy makers and professionals who work within the social media industry, this study aimed to explore (1) the perceived challenges and views regarding young people communicating on social media about self-harm and suicide, and (2) what more social media companies and governments could be doing to address these issues and keep young people safe online.

Methods: This qualitative study involved 6 focus groups with Australian young people aged 12-25 years (n=7), Australian policy makers (n=14), and professionals from the global social media industry (n=7). Framework analysis was used to summarize and chart the data for each stakeholder group.

Results: In total, 3 primary themes and six subthemes are presented: (1) challenges and concerns, including the reasons for, and challenges related to, online communication about self-harm and suicide as well as reasoning with a deterministic narrative of harm; (2) roles and responsibilities regarding online safety and suicide prevention, including who is responsible and where responsibility starts and stops, as well as the need for better collaborations; and (3) future approaches and potential solutions, acknowledging the limitations of current safety tools and policies, and calling for innovation and new ideas.

Conclusions: Our findings highlight tensions surrounding roles and responsibilities in ensuring youth online safety and offer perspectives on how social media companies can support young people discussing self-harm and suicide online. They also support the importance of cross-industry collaborations and consideration of social media in future suicide prevention solutions intended to support young people.

Introduction

Suicide is a leading cause of youth mortality, and in many countries, including Australia, rates appear to be increasing [1,2]. Self-harm is more common and presents a significant risk factor for suicide [3]. The reasons for self-harm and suicide are complex, with many questioning the role of social media. Concerns exist regarding the potential for certain types of online content, such as graphic depictions of self-harm or suicide methods, livestreams of suicidal behavior, or online suicide pacts or challenges to cause distress and contribute to imitative behavior [4-9]. Recent research suggests as many as 83% of young people have seen self-harm or suicide content on social media, often without searching for it, and often before the age of 14 [10,11]. Given the ways that social media algorithms operate, this may lead to young people being overexposed to potentially harmful content when interacting with their peers online [12,13].

Despite this potential for harm, young people have identified numerous benefits of using social media to communicate about self-harm and suicide. For example, it allows them to cultivate community, validate their experiences, support those they care about, and grieve people who have died by suicide [14,15]. Given the difficulties accessing high-quality, timely, and age-appropriate mental health support, young people have also identified social media as an accessible, and sometimes preferred, avenue for seeking help or information, especially for stigmatized topics such as self-harm and suicide [16]. Recognizing the central role of social media in young people's lives, recent initiatives have capitalized on the ability to deliver highly personalized and safe suicide prevention content directly to individuals' newsfeeds, including during suicide bereavement [17-21]. Such social media-based interventions present a significant change to the ways young people can seek evidence-based information and access mental health care [22-24].

The potential for exposure to harmful content has placed pressure on policy makers to keep young people safe online [25,26]. National suicide prevention strategies play an important role in shaping a comprehensive and systematic approach to suicide prevention; they also help determine research priorities and the allocation of resources [2,27]. However, online safety is largely absent in national suicide prevention strategies. Almost 40 countries (including Australia) have developed suicide prevention strategies [2], many of which identify young people as a priority population and consider the settings where they spend their time, for example, schools. While many national strategies recommend the development of guidelines for mainstream media to facilitate safe reporting about suicide [25,28,29], social media has only recently been included as an additional consideration for suicide prevention efforts [30-32].

Similarly, governments in many countries have developed rigorous online safety policies that focus on safeguarding the rights and privacy of individuals and regulating technology and social media companies (eg, The Online Safety Act in the United Kingdom [33]; The Online Safety Act in Australia [34], and The Children's Online Privacy Protection Rule [35] and Kids Online Safety Act [36] in the United States). However, only a handful of these online safety policies include guidance on suicide prevention specifically [33,37]. In the absence of self-harm and suicide-specific guidance, many popular social media platforms have developed their own policies relating to self-harm- and suicide-related content [38-41]. While it is not clear if these policies are evidence-based, they differ across each platform, and social media companies are legislated and regulated differently in different countries. To this end, it appears that national suicide prevention strategies and online safety policies are yet to appropriately consider how self-harm and suicide are expressed, and managed, on social media, leaving a key gap in youth online safety policy and practice.

The objective of this study was to inform health, communication, and online safety policy as it relates to self-harm and suicide prevention. From the perspective of young people, policy makers and professionals who work within the social media industry, the aims of this study were to understand (1) relevant stakeholder views regarding young people communicating on social media about self-harm and suicide, and (2) what more, if anything, social media companies and governments could be doing to address these issues and keep young people safe online.

Methods

Study Design

This qualitative study involved focus groups with Australian young people, policy makers, and professionals from global social media companies. The study was conducted by researchers based in Melbourne, New South Wales, Australia, and has been reported in line with the Consolidated Criteria for Reporting Qualitative Research (COREQ; Multimedia Appendix 1) [42].

Research Team and Reflexivity

Members of the research team who have been trained in qualitative research methods facilitated the focus groups (JR and LLS) and undertook data coding and analysis (LLS, JR, MM, and PT). All members of the research team identified as female and were employed in suicide prevention research (JR, PhD; LLS, PhD; AS, Hons; PT, MPsych [Clin]; MM, PhD; and ML, PhD) or youth mental health organizations (VB).

Focus group facilitators were known to some of the participants prior to their involvement in this study, based on their known roles and responsibilities within their respective organizations or prior involvement in other activities conducted by the research team. Participants were notified of the purpose of this study and how the data would also be used to inform the second edition of the #chatsafe guidelines, developed by the research team [21,43]. The facilitators made efforts to discuss the topics broadly and reduce any perceived pressure to provide desirable feedback related to the #chatsafe program of work by monitoring tone, verbal and body language, and engaging equally with the challenges and solutions about online communication about self-harm and suicide.

XSL•FO
RenderX

Sample and Recruitment

In total, 6 focus groups were conducted: one with young people (n=7); 2 with Australian policy makers (n=14; these included policy makers in a range of positions and departments focused on young people, online safety, education, and health); and 3 with individuals employed by social media companies (n=7; these included staff from different companies that operate globally, whose business names will not be reported to protect confidentiality). Focus groups with professionals from social media companies were restricted to include only individuals employed by the same company in order to preserve privacy, maintain confidentiality, and foster open conversation. Each of these focus groups therefore involved a smaller number of participants (n=2-3). Young people were recruited via social media advertising on the #chatsafe social media pages, and young people who had previously participated in #chatsafe activities were invited via email. Policy makers and professionals from the social media companies were invited via email by JR.

Young people were eligible to participate if they were aged between 12 and 25 years; able to speak and read English, and; if under 18, had parent or guardian consent. Policy makers and professionals from social media companies were eligible to participate if they were older than 18 years and were (1) employed by a government department or had a policy-making role with responsibility for mental health, youth, or online safety, or (2) employed in an online safety or policy team within the social media industry. There were no exclusion criteria.

Data Collection and Analysis

Focus groups were conducted between June 2022 and August 2022 by JR and LLS, with assistance from VB. In total, 3 were conducted online via Zoom, and 3 were conducted in a hybrid format (ie, some participants were present in-person, and others joined via Zoom). Focus groups ran for 60-120 minutes. A semi-structured topic guide was used (see Multimedia Appendix 2) and included questions about participants' views regarding the challenges associated with young people using social media to communicate about self-harm and suicide and what more, if anything, social media platforms and policy makers could be doing to keep people safe online. Participants were also asked questions about Edition 2 of the #chatsafe guidelines, which have been reported elsewhere [21].

All focus groups were audio recorded and transcribed verbatim. Field notes were also taken. Data were analyzed using framework analysis, a structured process of theme-based analysis through the development of charts [44,45]. In conducting this study, a goal of the research team was to inform health, communication, and online safety policy as it relates to online safety and suicide prevention. As such, framework analysis was selected as the most appropriate methodology to systematically reduce the data whilst representing each stakeholder group as a "case" (eg, young people, social media professionals, and policy makers). A combined deductive and inductive coding approach allowed the research team to examine challenges and opportunities expected to emerge based on the previous literature and their own experience (eg, difficulties determining safe versus unsafe content [14] and the impact of exposure to graphic content [15]), whilst leaving scope for participants to assign their own meaning to the issues being explored.

Following transcription, six steps were followed: (1) familiarization, (2) coding, (3) development of an analytic framework, (4) applying the framework, (5) charting the data, and (6) interpreting the data [44,46]. Initially, 4 members of the research team (LLS, JR, MM, and PT) independently coded the same transcript line by line, highlighting interesting segments of the text and making notes. They met to discuss their approach and alignment on codes. In total, 3 members of the research team (LLS, JR, and MM) then coded 2 more transcripts, again meeting to discuss coded sections and interpretation of data. Where there were disagreements, the team revisited the transcript and discussed it as a group. The team agreed on a set of codes that formed an initial analytic framework. This included codes related to previously documented "harms" and "benefits" that were present in the data, as well as new codes that reflected sentiments raised by participants regarding solutions, challenges, and what more different stakeholders could do to keep young people safe online. LLS coded the remaining transcripts, meeting with MM and JR regularly, and iteratively revised the thematic framework used to interpret the full data. Transcripts were coded by hand, and codes, categories, and representative quotes from each case were charted in an Excel spreadsheet by LLS. The matrix was reviewed and discussed by LLS, JR, MM, and AS, and connections between and within the categories were thematically mapped as they addressed the research questions.

Ethical Considerations

This study received ethics approval from the University of Melbourne Human Research and Ethics Committee (ID: 22728). Participants were required to complete an online consent form and demographic survey prior to attending their focus group. All data were de-identified for analysis. Youth participants were reimbursed Aus $30 (US $19.02) per hour for their involvement in this study. Policy makers and professionals working within the social media industry received no compensation.

Results

Participants

Participant demographics are summarized in Table 1, including information about the top 3 social media platforms used by participants in each group. Additional information about professional participants' current employment was also collected, though some details have been omitted to avoid possible reidentification. All but 3 participants across the total sample reported using social media platforms in their daily life, with most using 3 or more platforms (n=20, 80%).

XSL•FO

Table 1. Participant demographics and top social media platforms used by policy makers, social media industry professionals, and young people.

Group (n)	Age (years) mean (range)	Sex or gender (n)	Country of birth (n)	Identifying as Aboriginal (n)	Top social media platforms used (n)
Policy makers (14)	39.31[a] (23-54)	• Female or woman (10) • Male or man (3)[a]	• Australia (12) • Other (2)[b]	• Yes (1) • No (13)	• Facebook (10) • YouTube (8) • Instagram (7)
Social media companies (7)	39.14 (27-57)	• Female or woman (4) • Male or man (2) • Non-binary (1)	• Australia (1) • Other (6)[b]	• No (7)	• YouTube (7) • Facebook (5) • Instagram (5)
Young people (7)	20.71 (19-23)	• Female or woman (5) • Male or man (2)	• Australia (3) • Other (4)[b]	• Yes (1) • No (6)	• Instagram (7) • Facebook (6) • YouTube (6)

[a]One policy maker participant did not disclose their age or sex or gender.

[b]Other countries of birth included Hong Kong, Malaysia, Mexico, Singapore, Taiwan, the United Kingdom, and the United States.

The resulting 3 primary themes and 6 subthemes are presented below. The analytic framework used to interpret these data, with quotes from each stakeholder group, is provided in Multimedia Appendix 3.

Challenges and Concerns

To address the first research question, participants from all 3 stakeholder groups were asked about their views regarding young people using social media to communicate about self-harm and suicide. While all stakeholder groups were encouraged to share what they felt the challenges were and the reasons for young people using social media for this purpose, each group mostly arrived at the same conclusion: there are concerns about young people engaging with, and being exposed to, self-harm and suicide-related content on social media; however, social media is not going away and may meet the needs of young people looking for a safe place to express their distress. Perspectives of each group were also largely influenced by recent public discourse relating to social media and youth mental health more generally, with groups differing in their views regarding the helpfulness of this debate.

Reasons for, and Challenges Related to, Young People Using Social Media to Communicate About Self-Harm and Suicide

Participants in all focus groups expressed the belief that individuals used social media to seek and provide support or share and understand personal experiences related to self-harm and suicide. Some youth participants described social media as a place to "perform" their mental health and felt that representations of self-harm and suicide on social media were heavily impacted by what their peers were posting and the feedback that they sought. Across all focus groups, there was an appreciation for the necessity of using social media to have these conversations, as participants recognized that they are difficult topics to discuss offline, and for many people, help is not available elsewhere. There was consensus across each focus group about the affordances of social media (eg, anonymity and temporality) that make these topics easier to talk about online versus face-to-face.

> *It's a lot easier to just put a post out there for the world to see… if people are feeling that way, they probably feel quite like they might be a burden and they don't want to go up to their friends and say, 'I'm feeling like this', or they don't want to go up to a mental health practitioner and tell them. So it's easier just to put the post out into the public and see who replies back.* [Young person]

> *...social media can provide…a really accessible space for young people. I mean accessible in terms of not just for young people who live in areas where there might not be access to services. But for young people who maybe don't feel safe going to a service… it's… 24:7, stigma-free often, they can connect with people who are in similar situations.* [Policy maker]

Although individuals in all participant groups understood why and how these conversations occurred on social media, each group articulated their concerns for the harms associated with online self-harm– and suicide-related content. Concerns related to the age of the user and what is developmentally appropriate to view; the virality of self-harm and suicide content and specific online challenges; the potential for social media to sensationalize, glorify, or normalize self-harm and suicide; users being exposed to harmful content, livestreams, or real-time suicidal behavior; the potential for contagion; and other online experiences that have implications for self-harm and suicide (eg, bullying, sextortion, etc).

> *I remember this one instance where this girl posted on her private account - and I wasn't that close with her so I really shouldn't have been there; but a photo of a razor blade...It was framed in a certain way, and she captured it like, 'hello, my old friend', or something. Then two days later, another girl in another circle posted essentially the same photo… she'd definitely seen it, so there was the element of contagion.* [Young person]

A similar theme across each focus group was uncertainty around the nuances of what constituted harm, for whom and when, and how best to respond to online harms. Social media industry professionals described this challenge as not knowing "where to draw the line" between helpful versus harmful content, and policy makers discussed the heterogeneity in user experiences and outcomes. Young people expressed their belief that more

XSL•FO
RenderX

needed to be done to prevent individuals from seeing harmful content in the first place, describing teenagers as not developmentally mature enough to understand the content that they were being exposed to regularly, based on their own experiences.

Participants from the policy maker and social media industry focus groups reflected on the complexity associated with balancing freedom of online expression with the immediate removal of harmful content. Enforcing these decisions across global corporations and different legislative environments, particularly in the absence of a strong evidence base, was a challenge frequently discussed by those developing and implementing safety policies.

> *It has harmful stuff on it but can provide such an avenue for help seeking as well. How do you find that balance?* [Policy maker]

> *That component of freedom of expression where we also don't want to talk over the voices of people who have historically been marginalized, especially by scientific communities or by lack of access to resources or things like that. So for us… you want to enable safe communication and also how do you do that in a way that is grounded in both research evidence and global equity?* [Social media industry professional]

Reasoning With a Deterministic Narrative of Harm

Irrespective of their personal views, participants in all stakeholder groups were aware of public perceptions that social media causes harm to mental health more broadly and had different perspectives about how helpful or harmful those perceptions were, both to individuals using social media and to those developing and regulating them. In reflecting on why people believe social media is negatively impacting youth mental health, some youth participants acknowledged that social media is often perceived as not being proactive in terms of creating safe online environments but commented that there were many other factors that impacted youth mental health beyond social media.

Perspectives amongst policy makers were more varied. One participant described their firm belief that “being on social media is [a] detriment to people’s mental health.” However, the majority of policy makers instead wondered how they could better “capitalis[e] on what social media can provide” in order to support individual users while minimizing potential harms.

Participants from the social media industry expressed feeling like a “punching bag for online safety” while reflecting on there being “no research to support this conclusion [of harm]." Some social media professionals believed that this public perception stalled more sophisticated conversations about the future potential and innovation of social media from a mental health perspective.

> *This growing narrative that there's a causal link between social media and self-harm…really, there's no research to support this conclusion, but I think it really hinders our abilities sometimes to put out a different narrative that can feel supportive for people, and that can help drive behavior change, that can drive people towards our platforms to utilize some of the resources that we use.* [Social media industry professional]

Roles and Responsibilities

A central question across all focus groups was the issue of responsibility for online safety and where the lines of responsibility started and ended for each stakeholder group. All focus groups featured discussions about how challenging these topics were, especially when online safety and themes related to self-harm and suicide overlapped. Due to this complexity, participants in all groups appeared to articulate more questions than answers. This highlighted areas where each stakeholder group felt others could be doing more and where better collaborations and models of partnership were required.

Who Is Responsible and Where Does Responsibility Start and Stop?

Participants raised many rhetorical questions related to the roles and responsibilities of their industry or position. For example, participants from the social media industry acknowledged that they play a fundamental role in defining socially acceptable behavior online (and offline) through the implementation of their community guidelines or standards. One participant from the social media industry stated, “we're not a medical company and we're not a healthcare company” and questioned how appropriate it was that they were the people to ultimately determine what is safe versus unsafe behavior or content for different global regions and across different cultural settings.

> *From a platform perspective, we’re obviously not doing clinical work, but we’re still judging what type of content is considered to be more problematic or less problematic from a conversational perspective in terms of the risk for the person, when we need to report it to different cases, what types of resources we need to provide. So, the question becomes, like, does this distinction, for instance, between passive and active suicidal ideation, does that mirror in languages that don’t have the same language structure as English or expression?* [Social media industry professional]

Some described their need to develop new policies “on-the-go” to keep up with the advancement of technology and user behavior, yet they often felt that there was little empirical evidence guiding decision-making and their need to move more quickly than research can. Given their reach and popularity, one participant commented that “any one direction we move the needle, even just microscopically, is going to have an impact on a huge swath of users.” Participants from this industry also expressed a desire for “more regulation” but felt that, in some cases, regulation restricted their ability to “use their proactive technologies… to save and have a considerable impact in people's lives.” To navigate these tensions, participants from the social media industry highlighted the importance of meaningful investment from policy makers or governments regarding online safety.

XSL•FO
RenderX

> *… we can't keep people safe, we can only try to protect them from harm. We can't define safe as an absolute state of being online, offline, or anywhere else. So, what we have to do is, we have to do our best to mitigate risk and their exposure to risk.* [Social media industry professional]

> *Just as a policymaker on platform, there's really a lack of evidence around a lot of the policy questions that we're struggling with in terms of where to draw the line, especially really solid research evidence and evidence that comes from contents and cultures outside of what is typically thought of as like the WEIRD western world.* [Social media industry professional]

Policy makers described how the regulatory landscape influences the content that should or should not be shared online but also spoke openly about the challenges they face when trying to regulate and govern international corporations and online content that is geographically boundless. While acknowledging the limitations of government regulation, policy makers reflected on the importance of cross-government approaches and their responsibility to ensure that they are supporting individuals to stay safe online by "providing information and support and guidance in a variety of settings, in a variety of forms."

> *So we are interested in health, there's the Department of Education who has an interest here, there's the eSafety Commissioner, the Department of Comms. So, there's lots of different government agencies that are interested, but there's also the sites themselves. I think there's a lot of different players and sometimes that can perhaps make things even more complex than we would otherwise like.* [Policy maker]

Lastly, it was understood that individual users play a critical role in creating safe online environments and need to have agency over their interactions. However, all groups acknowledged that younger users could not take sole responsibility for their own safety within environments created by, and often for, adults.

> *I don't like to put the safety of individuals, like, all of the responsibility for the safety of individuals, on the individuals because I think that suicide and self-harm in particular has been seen as this really individual problem that's disconnected from everything that happens in the community…* [Social media industry professional]

In the absence of clear roles and responsibilities, and given the complexity of these issues, there was a tendency for participants to describe their own responsibility in relation to what more other stakeholder groups need to be doing. For instance, some participants questioned the legitimacy of government investment in online safety, and others questioned what more parents or carers, and school curricula, could do. Despite a broad recognition that collaborations were needed, participants sometimes conveyed an "us versus them" mentality, either between companies within the same industry (eg, one social media platform versus another) or between stakeholder groups (eg, the social media industry versus national governments; social media platforms versus parents).

> *Politicians would much rather help parents say it's someone else's fault, yours, the industries, than actually say, actually you also need to step up and do something here to promote online safety.* [Social media industry professional]

Young people felt strongly that the government could help by providing more education and digital literacy training, particularly when they were younger and still attending school. Structured education on online safety was perceived as a way of alleviating pressure on young people to be responsible for safe online environments in ways that they can't "handle" yet, while also providing them with knowledge that would be protective.

> *I think if the government has a role to play at all, it would be through education…like those special assemblies… Then, if you have young people who have been educated in this way, they can self-police - young people are really good at that, hopefully in ways that are helpful as opposed to, you're bad for posting this, this is what we can do instead. I feel like education - all of the stories that we've shared about…seeking help and not really having the resources or tools or vocabulary, and so if you find a way to educate young people…in a more structured way, then I feel that would really alleviate a huge part of the problem.* [Young person]

The Need for Better Collaborations

Participants from all groups highlighted the need for a collaborative approach across sectors to achieve meaningful change in ensuring online safety. There was a sense that there was "a shared responsibility for this issue" and "a lot of different players," but "different levels of investments" in online safety. It was also acknowledged that these tensions are felt in the absence of "better models of partnership" or collaboration, though no concrete examples were presented for how this might be achieved.

> *…[it's] going to have to include a multi-pronged approach. That includes some level of, depending on age, parental, familial, government, industry; all of these different factors I think need to come together to really, I think, uniformly protect people. In the absence of that, I think it's too easy to go one way or the other. To try to put this all on young people, to try to put this on social media or the government, it leaves out so many different other parts of this puzzle that when together, you're best placed to build that front to protect users.* [Social media industry professional]

Promisingly, there was a desire from all participants to work together, in acknowledgment that the issues are "big, really tough challenges that we all face," and that issues related to "data use transparency, consent, and funding" need to be addressed collectively. There was also recognition from social media industry participants of the importance of social media

companies continuing to partner with "subject-matter experts" so that their safety actions and tools were evidence-informed.

Future Approaches and Potential Solutions

Overview

Participants in all focus groups were asked to reflect on current and future applications of social media as a possible tool in youth self-harm and suicide prevention. Here, participants shared their perspectives and knowledge of the use of current safety tools and policies embedded within social media platforms, highlighting issues with current safety features. Participants expressed ideas for the future of online safety and suicide prevention using new technologies (eg, artificial intelligence [AI]) to detect and respond to risk, while also acknowledging issues related to user privacy and the lack of transparency regarding current uses of recommender systems.

Acknowledging the Limitations of Current Safety Tools and Policies

Young people and policy makers in this study were aware that some platform safety features currently exist, but there appeared to be little faith in their ability to create safer online experiences. This either came about from not trusting the platforms to act accordingly (eg, previous experiences of using a reporting tool resulting in no action and therefore discouraging a user from doing that again) or users not knowing the full range of safety tools and features that exist or how to use them. While there was an appreciation that there is no "one-size-fits-all" approach to online safety and that not all tools and functions were going to suit each user, some believed that "having some improved transparency over those reporting processes" would foster greater trust.

> *Personally, I don't have much faith in social media's reporting features. There have been times – like you see some really atrocious things online… and you're like, oh my gosh, I really – I can't believe I encountered that…You report it and then five days later it's like, it's been reviewed and it's been decided there was no issue here.* [Young person]

> *… sometimes things are so awful you want to report them but then there's not a specific thing that you can allocate it to … it's just awful.* [Young person]

Scope for Innovation and New Ideas

When asked what more the broader social media industry could be doing to promote online safety and make their platforms safer for younger users, particularly youth participants and policy makers spoke about their ideas for how AI and platform algorithms, or recommender systems, could be better optimized. This included using AI tools to detect risk, respond in real-time to risk or distress, and deliver services or support.

> *They could be doing more...but more proactively in terms of, it seems like this post has content discussing suicide, click here for more information, and there's the chatsafe guidelines, or an iteration. It would definitely boost how social media is regarded, which is as like a necessary villain.* [Young person]

On the other hand, participants from the social media industry spoke about the limits of current technologies, describing that "humans are really good at certain things and algorithms are really good at others." They felt that there were misunderstandings about how algorithms work and the extent to which AI can be used ethically while also maintaining user privacy. In some instances, current regulatory frameworks prohibit the use of risk detection technologies, but better guidance and support from policy makers was perceived to allow these technologies to advance in potentially helpful ways.

> *When we're talking about AI capabilities and algorithms in particular, what I've found is that the people who suggest those are typically, in my experience, people who don't have a lot of experience building algorithms…* [Social media industry professional]

> *I think as a society we are rightfully pretty skeptical of AI and algorithms when it comes to health concerns, in particular, and so without laws changing pretty significantly in a lot of countries, I think that there's a lot of hard limitations and blocks to what we can do as a company without overstepping the boundaries of legal liability to provide help to users or provide targeted, for instance, help, like, support resources and things like that.* [Social media industry professional]

Despite the "technology not being there just yet," participants from the social media industry acknowledged that the reporting functions and safety tools, with refinement, could become much more user-friendly and helpful for users. Some participants were also hopeful that future innovation in online safety could involve the integration of evidence-based interventions that are promoted or delivered in-platform.

> *I think that my dream would be to have better help tooling available online for folks, so really having things like having a safety plan available or having a single session intervention that is culturally responsive and appropriate available for users to be able to opt into doing … that's evidence-based. I think that there [are] steps that the industry is taking towards getting there, I think that it will be interesting to see what happens in this space within the next five to 10 years.* [Social media industry professional]

While some policy makers admitted to knowing very little about AI or its capabilities, they were strongly in favor of using proactive detection technologies to promote resources and reach individuals with real-time support or help. There was also acknowledgment that Australia is well positioned to be a world leader in this regard.

> *I definitely do think that having links and support… with the algorithm picking up [that certain] content, but also if the algorithm can pick up that kind of content, shouldn't there also be a few ways to hopefully stop that content? Rather than just leaving it up and be like, here's some links though just in case you might click on it and have a look.* [Policy maker]

Discussion

Principal Findings

This study explored views regarding young people using social media to communicate about self-harm and suicide from the perspective of young people, policy makers, and individuals who work for social media companies. It also explored participants' beliefs about what more social media companies and governments could be doing to enhance online safety for young people engaging with, and exposed to, self-harm and suicide-related content. Our findings reflect the tensions regarding roles and responsibilities for youth online safety, as well as various perspectives on the ways social media could be used to support young people when communicating online about these topics.

Our findings support a growing body of research exploring the reasons why young people use social media to share and understand their experiences of self-harm and suicide [14,15]. Young people using social media as an informal source of support and help-seeking appears to be beneficial in circumventing barriers associated with professional mental health care (eg, stigma, cost, and long wait times) [16] and allows young people to validate their own experiences [14]. However, participants in this study also echoed concerns associated with young people using social media for this purpose (eg, potential overexposure to harmful content, contagion effects, age of users, privacy, and access to individual data) [5,7,15,47], highlighting uncertainty around when and how these risks might translate to harm for individual users, who might be most at risk and how best to respond.

Contextualized within a time where social media companies are being heavily scrutinized for the actions that they are (or are not) taking with regards to youth safety and wellbeing [6,48-50], some participants in this study felt that a deterministic narrative around social media conferring harm stalled more sophisticated and nuanced conversations needed to understand and address these risks. The focus on social media playing a significant role in rising rates of youth psychological distress, despite little to no causal findings to support this claim and often in the absence of considering other social determinants that are impacting young people [51-54], has prohibited the expansion of our understanding about how social media impacts individuals differently and who is actually most at risk. This understanding is limited further when it comes to self-harm and suicide. Though some effort has been made to address potential online harms through research (eg, the #chatsafe intervention) [17,18,20], policy [34], and industry practice (eg, platform safety centers and tools) [38-41], it is clear that more work needs to be done to understand the precise nature and mechanisms of harm in this context and to develop evidence-informed solutions and policies that carefully consider the needs of young people.

A prevailing sentiment among policy makers and social media industry professionals was that they felt ill-equipped to make online safety decisions that were both timely (per the rapid nature of this industry) and evidence-based. Given that many of the decisions that platforms need to make quickly about self-harm and suicide-related content lack empirical evidence, there is an urgent need for better relationships between researchers and social media companies, including the sharing of data (whilst maintaining user privacy) and investment in the development of evidence-informed and age-appropriate safety policies and features. Although platforms regularly publish transparency reports quantifying the volume of content they have removed in enforcing their community guidelines [55-57], there is a notable lack of transparent information detailing how decisions around safety policy development and implementation are made, by whom, and based on what evidence [49]. Though we acknowledge the tensions in social media companies navigating transparent reporting on their systems and processes while protecting their intellectual property, greater attention does need to be given to how safety policies are developed, informed, and implemented, and there is a clear need for research evidence to support best practice. This aligns with calls from the Australian eSafety commissioner for "radical transparency" from social media companies regarding their online safety approaches [49], as well as recommendations for collaborative and cross-industry efforts to reduce social media harms proposed in the US Surgeon General's report on social media and youth mental health [48].

The theme of roles and responsibility was central across all focus group discussions regarding what more social media companies and policy makers could be doing to promote online safety. Critically, there was a lack of agreement or clarity on the nature and extent of responsibility that should be assigned to various stakeholder groups represented in this study, but also to stakeholders such as parents, educators, and health professionals more broadly. Though cross-industry partnerships, international coalitions [26,58], and the creation of subject-matter safety advisory boards [59,60] are all currently occurring in various ways, they are often happening in isolation from one another and differ across regions and platforms. They are further challenged by differing online safety policies and capacity for regulation globally. The inclusion of online safety in future suicide prevention policies, both at a national level and by global health organizations (eg, the World Health Organization), would go some way toward clarifying the roles and responsibilities of relevant stakeholder groups and would facilitate the sharing of information and evidence-based practice. Consideration of digital contexts in suicide prevention policies would also support meaningful investment in research and the establishment of cross-industry partnerships to promote online safety for young people.

Finally, several opportunities for innovative and novel ways of using social media to detect, respond to, and manage self-harm and suicide risk were explored. These mostly related to using social media algorithms to promote helpful resources to someone identified as at-risk, with the potential for platforms to direct individuals to professional support or deliver help within the platform itself [11,61]. However, while young people and policy makers supported these ideas, platform professionals emphasized the limitations of current technologies and the misconceptions community members hold about their capacity. Further, recommender systems and algorithms are relatively new technologies that have been delivered to a huge global user base as a means of optimizing user experience and keeping

XSL•FO
RenderX

individuals active on social media platforms. There are understandable questions about the ethics of their use and consideration for user privacy, as well as concerns regarding the adverse impacts of recommender systems in promoting harmful content [49]. There is also limited transparency around how these systems are developed, updated, or regulated and for how these issues may be addressed. However, platform algorithms present an important and unique opportunity for reaching young people with high-quality and evidence-informed mental health supports, especially as these systems become more advanced and personalized over time.

Strengths and Limitations

A strength of this study is the representation of views from young people, policy makers and professionals from the social media industry; groups that are usually working in isolation from one another and fundamentally opposing one another. To the best of our knowledge, this is the first study to include the perspectives of professionals working for social media companies in discussions about youth online safety regarding self-harm and suicide. Although focus groups with these participants were smaller in size than those with the other participant groups, the decision to restrict industry focus groups to individuals employed by the same company preserved participants' privacy and promoted open discussion within these smaller groups. Conducting a framework analysis allowed for these distinct stakeholder groups to be equally involved in this work, resulting in a more nuanced discussion of the digital landscape that young people communicate within, processes to develop and regulate those environments, and the best ways of supporting individuals in the future.

Prior knowledge of the research team by some participants was a limitation of this study. However, it did not appear that these established relationships hindered the conversations or information shared. Instead, this pre-established trust and rapport appeared to facilitate honest conversations about the challenges faced by each group. A mutual respect for the complexity and challenges associated with youth self-harm and suicide prevention also invited open conversations with a shared understanding of wanting to do more.

Finally, the average age of the youth group was approximately 21, and given that most social media platforms allow users to create accounts from as young as 13, this work would have been strengthened by the inclusion of younger participants. Further, given their prior involvement in other activities, youth participants were very mental health literate and aware of the importance of safe communication about self-harm and suicide, which may not be representative of the wider Australian youth demographic. Additional stakeholder groups, such as parents, carers, and schools, were not included in this study, though their perspectives have been reported elsewhere [62] or are being collected through work that is currently underway within our team.

Conclusions

There are valid concerns about young people using social media to discuss self-harm and suicide. However, social media remains a preferred and accessible way for young people to communicate and seek help. The evidence base for current platform strategies to manage self-harm and suicide content is lacking, raising questions about the appropriateness of social media companies defining online safety alone, as well as the challenges governments face when trying to regulate global companies and fast-spreading content. Our findings highlight the complexity of these issues and the need for shared responsibility and greater understanding of roles across relevant stakeholder groups. These findings present strong support from young people, social media companies, and Australian policy makers for cross-industry partnerships to create safer online experiences for young people and the implementation of new and emerging technologies to prevent youth self-harm and suicide.

Acknowledgments

The study received funding from the Commonwealth Department of Health under the National Suicide Prevention Leadership and Support Program. LLS is funded by a Suicide Prevention Australia Postdoctoral Fellowship. JR is funded by a National Health and Medical Research Council Investigator Grant (ID2008460) and a Dame Kate Campbell Fellowship from the University of Melbourne. MM is funded by the European Union H2020-EU.1.3.2. MSCA-IF-GF-Global Fellowships (grant agreement ID: 101026065).

Data Availability

The datasets generated or analyzed during the current study are not publicly available due to inability to sufficiently anonymize transcripts, but are available from the corresponding author on reasonable request.

Conflicts of Interest

LLS is a member of Meta's Australian online safety advisory group. She has also provided guidance, based on her research findings, to other social media and technology companies. JR is a member of Meta's Global Suicide and Self-injury safety board and the Australian online safety advisory group. She has also provided guidance, based on her research findings, to other social media platforms.

Abstract

Background: Internet-based parenting programs have great potential to promote positive parent-child relationships as well as to reach and engage parents.

Objective: This study aimed to assess the universal internet-based BePresent parenting intervention for families with 3-year-old children and how it influences the child's behavior and daily-life situations assessed by parents. The first aim of the study was to assess the change from baseline to follow-up in child hyperactivity and conduct problems, affective reactivity, and daily activities. The second aim was to assess intervention completion rates. The third aim was to evaluate parent satisfaction with the intervention. The fourth aim was to assess all outcomes by comparing those who completed the intervention and those who did not.

Methods: We conducted a single-arm pre- and postintervention study. Parents attending their child's 3-year health check-up were recruited from children's health clinics. The intervention was an unguided internet-based parenting program consisting of 5 modules. Self-reported measures were collected at baseline and at an 8-week follow-up. Linear mixed-effects models were used to analyze the changes from baseline to follow-up.

Results: Altogether, 752 parents registered, and 515 started the intervention. Of those, 36% (n=183) completed the intervention. Parents reported high satisfaction with the intervention: the majority (68.8%–84.9%) were satisfied with various aspects of the program, and 89.9% said the intervention provided information about positive parenting skills. The findings show significant decreases with small effect sizes in parents' ratings of child hyperactivity (P=.03; d=0.12) and conduct problems (P=.001; d=0.20) between baseline and the 8-week follow-up. A similar finding was observed in the parent ratings of child irritability (P≤.001; d=0.27) using the Affective Reactivity Index. Parents reported improvement in the daily functioning of their child when it was measured with a questionnaire adapted from the Barkley Home Situations Questionnaire (P=.01; d=0.14).

Conclusions: Universal digital interventions have the potential to be implemented widely in community settings to improve knowledge and positive parenting skills. However, there is a need to assess the efficacy of digital universal interventions using randomized controlled designs and to examine additional ways to increase adherence to universal programs.

KEYWORDS

parent training; universal intervention; online intervention; irritability; conduct problems; hyperactivity; preschool; mental health; strongest families; positive parenting; parenting skills; parent-child relationships; parent satisfaction; BePresent; feasibility study; single-arm pre-post intervention study

Introduction

Consistent evidence has shown that parent training can lead to improvements in parenting practices and that it promotes the psychosocial development of children [1,2], which can, in turn, prevent various psychosocial and mental health difficulties [1,3]. Therefore, early preventive parent training programs are needed to enhance parent, and child relationships and to promote the healthy development of children [2].

Preventative interventions can be indicated, selective, or universal [4]. While indicated and selective interventions are intended for individuals with identified high risk, universal interventions can be offered to the general public or the entire population, typically regardless of individual risk factors [5]. Universal interventions aim to prevent the onset of illness or behavior by reducing exposure of risk factors [6]. In universal parent training, this means improving positive parenting [7], strengthening the relationships and interactions between parents and children [8], and reducing dysfunctional or abusive parenting practices [7]. In comparison to indicated or selective parenting programs, universal ones are typically briefer, targeting ordinary parenting challenges, and are hence aimed at all parents [9].

Universal programs typically have a large reach. They are considered to be less stigmatized, since any parent can experience parenting as challenging and thus need support [10]. Moreover, when universal parenting programs are offered in an internet-based format, typical barriers related to face-to-face programs can be avoided, such as logistical and financial barriers as well as the shortage of trained professionals [11]. Attrition rates in internet-based parenting programs typically vary between 30% and 50%, similar to that of face-to-face parenting programs [12], but internet-based programs generally have higher universal uptake [13].

A recent systematic review assessing universal digital parenting programs found small to moderate improvements in parent depression, anxiety, self-efficacy, and social support, but found no effects on parent's stress, satisfaction, or parent-child relationship quality [11]. Due to limited data, the review was unable to assess the effects of universal digital parent training on child-specific outcomes [11], pointing out a clear research gap in the field. While the promise of universal parenting programs is conceptually clear, their impact on public health remains unclear.

This study focuses on the universal internet-based parenting program BePresent. The program is based on a wider 11-week targeted parent training program, Finnish Strongest Families, which has demonstrated efficacy in randomized controlled design up until a 2-year follow-up [14,15]. Since the randomized controlled study, the Strongest Families program has been implemented nationwide in Finland through child health clinics for parents whose 4-year-old children have disruptive behavior problems [16,17]. The parent training program has also been studied in clinical settings among 3 years-10 years–old children with disruptive behavior problems [18]. BePresent is a universal digital nonguided intervention aimed at all parents with 3-year-old children. Within the Finnish health system, 77% of preschoolers attend annual health check-ups at a child health clinic [19], which makes these visits an ideal setting for the delivery of such a universal intervention.

The first aim of the study was to assess changes in child hyperactivity and conduct problems, affective reactivity, and daily activities using a pre-post, single-arm intervention study design. The second aim was to assess intervention completion rates. The third aim was to evaluate parent satisfaction with the intervention. The fourth aim was to assess all outcomes by comparing those who completed the intervention and those who did not.

Methods

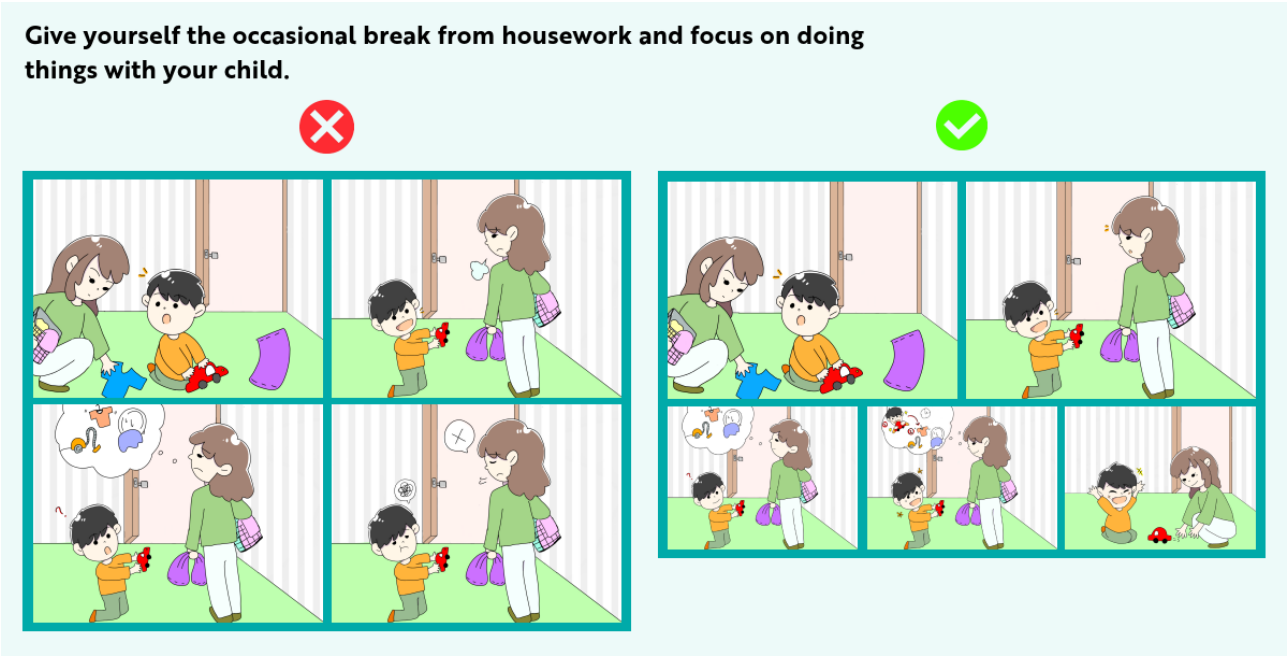
Study Design

A single-arm pre- and postintervention study involved the recruitment of participants to use the BePresent parenting intervention. Measures were conducted at baseline before starting the intervention and at an 8-week follow-up after filling in the baseline questionnaire.

Intervention

BePresent is a universal, unguided internet-based parenting intervention. The content and structure of the intervention are based on the Finnish Strongest Families targeted parent training program. Patterson's Coercion Theory guided the development, emphasizing the importance of positive reinforcement in parent-child interactions. The universal intervention follows the basics of the targeted program but was shortened to be feasible for all parents with 3-year-old children. BePresent focuses on the promotion of healthy parenting practices and developing parenting skills that strengthen the relationship and communication with the child. The topics include reinforcing the child's positive behavior, reducing conflict situations, planning situations in advance, managing daily transitions, and being emotionally present with the child. The intervention includes 5 modules, and the total intervention period is 8 weeks. Detailed information about the key training elements and parental goals of each module are presented in Table 1.

The participants must complete the modules sequentially; they cannot select which module they start with. Each module includes theory material, example videos, comic strips (Figure 1), video practices, and exercises. In the comic strips, the central ideas of the program's example videos are presented. For example, in module 5 the importance of spending time with the child, for example, by playing, is presented in the video and in the comic strip. In both, first, a negative situation is presented, followed by a positive example of parents using the practiced



XSL•FO
RenderX

parenting skills. The comic strips use visual-driven storytelling, including pictures without text. With this, we wanted to convey a universal understanding, across different languages. There are different variations of individual strategies to choose from to train parenting skills in practice. To motivate and promote adherence to the program, standardized and same-for-all SMS and email reminders were sent regularly during the program. The participants had 8 weeks to complete the intervention. After this, they were asked to fill out the follow-up questionnaire.

Table 1. Structure and content of the BePresent internet-based parenting program.

Module	Key training elements	Parental goals
Notice the good in your child	• Positive attention • Positive feedback • Reducing unnecessary reminders	• Positive interaction skills with child • Active parenting
Understand your child	• Acting in daily situations • Boundaries for the child • Self-controlled parenting	• Self-regulation with child • Staying calm • Recognizing negative thoughts • Turning thoughts into more positive
Prepare your child for changes	• Modeling daily transitions • Importance of daily routines	• Reinforcing good daily routines
Plan ahead with your child	• Planning together with the child • Preparing a child for upcoming situations	• Involving the child in planning and reinforce good daily routines
Be present for your child	• Conscious presence with the child • Spending time with the child • Mindfulness	• Being present in the daily moments with the child

Figure 1. Negative and positive examples of how to be more present with your child in daily situations.

Participants and Setting

Parents with a 3-year-old child participating in annual health check-ups in primary care child health clinics in Finland were considered eligible and were asked to participate. The program was offered in Finnish, Swedish, and English; therefore, at least one of the parents had to understand one of those languages for the family to participate. The study setting was the public child health clinics, and the health check-ups offered there are free of charge for the families. Out of the 21 well-being services counties in Finland, 14 (67%) were included in this study. These well-being service counties were included as they were a part of our broader implementation study, selected to represent larger and smaller cities in both urban and rural areas across Finland. Since the operations of child health clinics are regulated by the Finnish Health Care Act [20] and the Government Decree [21], quality and operations are relatively uniform across the counties.

Procedure

There were 2 paths to participating in the BePresent program. First, as a part of the annual health check-up, a public health nurse informed parents about the program and the study.

XSL•FO
RenderX

Information was also provided in written format on a flyer that the public health nurse gave to the parents during the check-up. The flyer included the program's web address, where the parents could sign in and complete the registration form (name, email, and phone number). Second, 3 well-being services counties also recruited parents to the BePresent intervention through their website and social media pages. This internet-based information was similar to that on the flyer. A link was provided that, when followed, led parents to a form that screened them for inclusion criteria through a series of questions (which well-being services county did they live in; were they a guardian of a 3-year-old; did they understand Finnish, Swedish, and English). If the parents fulfilled the inclusion criteria, registration instructions were automatically sent to them by email.

The parents were asked to register for the intervention 1 month after the health check-up at the latest, but the registration stayed open until the end of the study. The website included information about the study and the intervention as well as an electronic informed consent form. After giving informed consent, parents were asked to fill in a baseline evaluation. The intervention lasted for 8 weeks. After this, parents were asked to complete a follow-up questionnaire; they also received email and text message reminders about the follow-up questionnaire. Intervention completers were defined as parents who completed the first 4 modules since those modules included the key elements of the parent training. The fifth theme concentrated on conscious presence with the child; this was considered to be an additional skill.

Measures

Demographic Background Information

To gather demographic background information, participating parents were asked about their gender, their child's sex, their family structure, and their role in the child's life. The question about family structure referred to who lived with the child, and the response options were (1) both biological parents, (2) the biological mother or father and their spouse, (3) the biological mother or father alone, (4) adoptive parents, (5) foster parents, (6) parents with the same gender, or (7) some other type of family. In the analysis, family types other than those with both biological parents were pooled together.

Child Hyperactivity and Conduct Problems

Hyperactivity and conduct problems were assessed with scales based on the content of subscales of the Strengths and Difficulties Questionnaire [22,23]. The Strengths and Difficulties Questionnaire internalizing subscales were not included in the questionnaire because the aim was to have as brief of a questionnaire as possible. Altogether, the scales measuring conduct problems and hyperactivity consisted of 10 items. Responses were based on the format 0=not true, 1=somewhat true, and 2=certainly true, so the scores for each scale of 5 items could range from 0 to 10. In the current study, the Cronbach alpha was 0.77 and the McDonald's omega was 0.79 for hyperactivity and .69 (α) and 0.70 (ω) for conduct problems, indicating acceptable reliability [24,25].

Child Affective Reactivity

The affective reactivity index-P [26] is a 7-item instrument measuring the irritability of a child. The affective reactivity index-P has been proven to be valid for measuring parent-rated irritability among small children [27]. Each item could be responded to using a scale of 0 to 2, indicating the responses of not true, somewhat true, or certainly true, respectively. The total score was calculated as the sum of the first 6 items, meaning that the total score range was 0-12. The impairment item was not counted in the total score. The McDonald's omega was 0.86 and the Cronbach α was 0.84, indicating acceptable reliability [24,25].

Daily Activities

Daily activities were assessed by asking the parents to rate the impact of the child's behavior during daily transitions, including getting dressed, getting ready for daycare, during the evening meal, and getting ready for bed. It also covered social interactions, including playing with siblings and other children, traveling situations, and being in public places such as the supermarket. The questionnaire was adapted from the Barkley Home Situations Questionnaire, which asks the parent to rate whether the child's behavior causes problems during specified daily routines [28]. The instrument has been previously used in the Finnish Strongest Families parent training program when it presented adequate reliability with a Cronbach α of 0.64 [17]. In the current study, the McDonald's omega was 0.87 and the Cronbach α was 0.87, indicating acceptable reliability [24,25].

Intervention Completion

Completion and non-completion of the intervention for the 8-week period was assessed using the data recorded by the intervention platform. Intervention completers were defined as parents who completed module 4, as the first 4 modules included the key elements of the intervention. Participation in the follow-up measures was also assessed using the data from the intervention platform.

Intervention Satisfaction

Participants were asked to rate their satisfaction with the intervention with 1 item, with the response options being 0=very dissatisfied, 1=somewhat dissatisfied, 2=neither dissatisfied nor satisfied, 3=somewhat satisfied, and 4=very satisfied. In the analysis, the options were categorized as dissatisfied, neither dissatisfied nor satisfied, and satisfied. The questionnaire included 10 items used to rate how well participants felt the intervention provided support in specific areas of parenting. The response options were 0=disagree, 1=somewhat disagree, 2=neither disagree nor agree, 3=somewhat agree, and 4=agree. In the analysis, the responses were categorized as disagree, neither disagree nor agree, and agree.

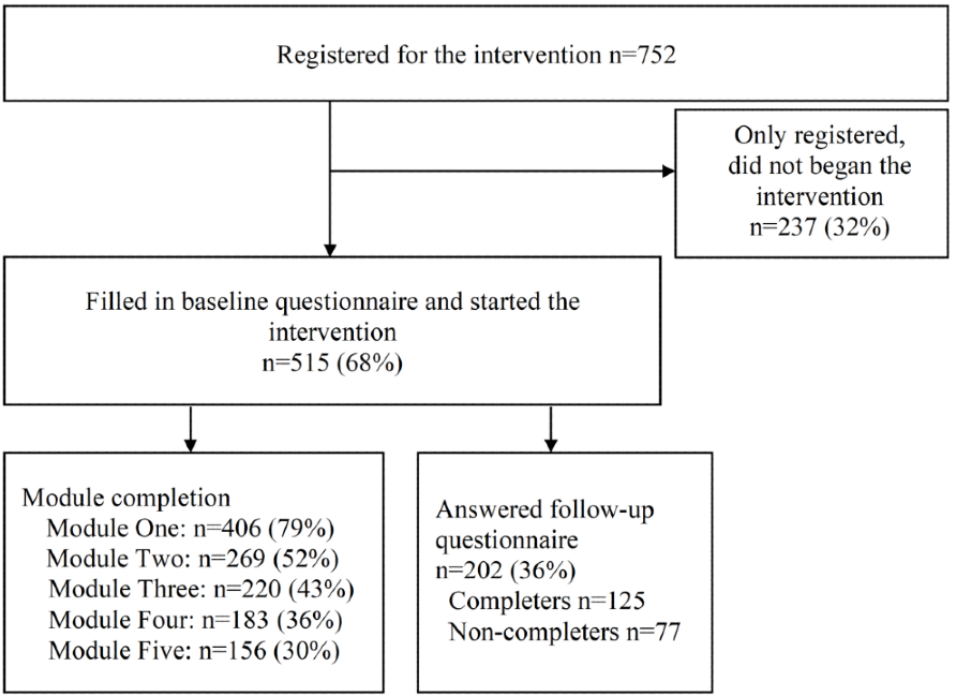
Statistical Analysis

Demographic characteristics and satisfaction with the program are presented as numbers and percentages. The difference between groups of completers and noncompleters were tested with Pearson's chi-squared test. The changes in outcome variables from baseline to the 8-week follow-up (with the unit of the analyses being parents' ratings of their children) were

XSL•FO
RenderX

analyzed with linear mixed effect models for those who completed the follow-up questionnaire, with time as the within factor (baseline and 8-week follow-up) and the child's sex as a covariate. The differences in outcome variables between completers and noncompleters at the 8-week follow-up were analyzed with linear regression models. Because the baseline values differed between groups, the models were adjusted for the baseline measurement of the outcome and the child's sex. A 2-sided significance level of .05 was used during the statistical testing, and 95% Cl were calculated for the point estimates. Cohen *d* was calculated as a measure of effect size, to complement the statistical testing. The statistical analyses were carried out with SAS statistical software (SAS 9.4, SAS Institute).

Ethical Considerations



All study procedures and human subject research ethics were approved by the Ethical Committee of the University of Turku (45/2017, 11 Sep 2017). Study permission was granted from each study site, including Wellbeing Services County of South Karelia, Wellbeing Services County of South Ostrobothnia, South Savo Wellbeing Services County, Wellbeing Services County of Kymenlaakso, Wellbeing Services County of Lapland, Western Uusimaa Wellbeing Services County, Wellbeing Services County of Pirkanmaa, Wellbeing Services County of Ostrobothnia, Wellbeing Services County of Satakunta, Wellbeing Services County of North Karelia, Wellbeing Services County of Central Ostrobothnia, Wellbeing Services County of Vantaa and Kerava. and Wellbeing Services County of Southwest Finland. The participants provided informed consent before enrollment in the study. No form of compensation, monetary or otherwise, was offered to participants. Privacy and confidentiality of the participants was ensured by adhering to ethical guidelines, securely handling data and pseudonymizing identifiable information. The data was pseudonymized and stored in the University of Turku secured project folder (short term) with automatic backup system and in "Taltio" and/or "Isilon" data storage cluster (long term). We followed the TREND (Transparent Reporting of Evaluations with Nonrandomized Designs) Statement Checklist for complete and detailed reporting (Multimedia Appendix 1).

Results

Detailed information about enrolment, participation per module, and completion rates of the modules are presented in Figure 2. Altogether, 752 parents registered for the BePresent parenting intervention and 515 started the intervention; 32% registered but did not begin the intervention. Out of the 515 who started the intervention, 202 (36%) answered the follow-up questionnaire, and 183 (36%) completed the intervention. The highest dropout rate occurred between the first and second modules, with a dropout rate of approximately 34%.

Table 2 presents the participants' background characteristics and a comparison between those of completers and noncompleters. The majority of participating parents were mothers (90.9%) and most of the children were boys (57.9%). Most families had a structure including both biological parents (92.2%). The percentage of completers who were boys was significantly higher than that of noncompleters who were boys (67.8% vs 52.4%, $P<.001$). No other demographic difference was found between intervention completers and noncompleters. The average time spent on the intervention website was 8.3 hours among those who completed the intervention and 3.5 hours among noncompleters (Table 3).

Figure 2. Flow chart of the study participants and information on completers and noncompleters. Began Module 1 n=515. Completed first 4 modules n=125. Started the intervention but did not complete the first 4 modules n=77.

Behavioral Outcomes

Table 4 presents a sample including completers and noncompleters, showing the changes in child behavior and daily situations from baseline to the follow-up measurement for those who completed the measures at both time points (n=202). There were significant improvements from baseline to the 8-week follow-up in hyperactivity (*P*=.03; *d*=0.11) and conduct problems (*P*=.001; *d*=0.20). Child affective reactivity also improved significantly (*P*<.001; *d*=0.26) from baseline to follow-up. In daily situations, improvements were found in total scores (*P*=.01; *d*=0.14) as well as in transition (*P*<.001; *d*=0.25) and eating situations (*P*=.002; *d*=0.19).

While Table 4 includes results for completers and noncompleters combined, Table 5 presents a comparison between the 2 groups and a more detailed description of changes among completers and among noncompleters from baseline to follow-up. As presented in Table 5, affective reactivity improved more among noncompleters than among completers (*P*=.03; *d*=0.21). At baseline, completers had more difficulties in affective reactivity, hyperactivity, and conduct problems than noncompleters.

[c]Adjusted with corresponding baseline and child's sex.

Intervention Satisfaction

Parents reported high levels of satisfaction with the program (Table 6). Over 80% of the parents indicated that they would recommend the program to others and agreed that the program provided information about positive parenting skills as well as ways to notice the good in their child. Satisfaction was significantly higher among those who completed the program.

Discussion

Principal Findings

In this study, we assessed a universal unguided internet-based parenting intervention and whether it improves child behavior and daily activities. Hyperactivity, conduct problems, affective reactivity, and daily activities improved from baseline to follow-up, and parents reported a high level of satisfaction with the intervention and showed rather good adherence to it. Out of all the parents who started using the intervention, 36% (n=183) completed it.

The outcomes were also assessed by comparing those who completed the intervention and those who did not complete it, and we found that child irritability improved among the completers and the noncompleters. This finding is important; interventions targeting small children's irritability are central, as irritability in childhood predicts mental health problems, functional impairment, and outpatient treatment use in later life [29]. However, at the moment the number of studies on the topic is limited, especially studies on parent training for decreasing irritability [30]. Interestingly, noncompleters demonstrated greater improvement in affective reactivity compared with completers, and, at baseline, completers had more difficulties in affective reactivity. This may suggest that parents of children with greater initial difficulties were more motivated to engage with the program. It is also possible that this counterintuitive finding was because more severe difficulties are inherently harder to improve than milder ones. In this study, we also found decreases in child hyperactivity and conduct problems with small effect sizes.

Although effect sizes in universal programs are typically smaller than in targeted programs [31], our findings are encouraging and may reflect that universal internet-based interventions can improve child-specific mental health outcomes. In addition, internet-based parenting programs are effective for several parenting outcomes. A meta-analysis of parenting programs by Spencer et al [32] found no significant differences when comparing programs that included clinical support to programs that only contained internet-based components. Moreover, the parents reported high satisfaction with the interventions and felt that the interventions gave them confidence in their parenting capabilities, which is in line with previous studies in this field. Thus, considering the limited resources in society, internet-based parenting interventions may offer a wise way of supporting parenting.

Of the parents who started using the intervention, 36% completed it, forming an attrition rate of 64%. Previous studies on universal unguided parenting programs have reported similar attrition rates. For example, in the Australian internet-based self-directed parenting program ParentWorks, which included six sequenced modules, Dadds et al [13] found 68% attrition up until module 4 of the program. They defined full completion of the intervention as completing at least 5 core modules and the post-intervention survey. Among their 2967 parent participants, 8% were classified as full completers. In contrast, 17% of the participants in our study fully completed the intervention, resulting in a higher proportion of parents completing the entire program. One possible explanation for this discrepancy is that Dadds et al [13] only invited participants who had completed the core modules to fill out the postintervention survey, whereas in our study, the follow-up questionnaire was sent to all participants regardless of their completion status. ParentWorks was free of charge, and parents were recruited through a national media campaign and flyers distributed to child and family services. In another example, from the United States, which recruited parents from a well-child visit in primary care, Breitenstein et al [33] assessed a digitally delivered, self-administered parent training intervention, ezParent, and found that, out of the program's 6 modules, 33% of parents completed at least 4 modules. The completion rate is comparable to our study, in which 36% of parents who began the BePresent program completed at least 4 modules. This suggests that completion rates below 40% may be relatively typical for web-based modules, unguided universal parenting programs.

The main reasons for discontinuing the use of a universal parenting program include the parent being too busy or finding the program unhelpful [34]. In fact, a typical disadvantage of universal programs is their tendency to lose sufficient focus on the individualized needs of users, causing a modest matching of program goals with individual needs [35]. In our universal intervention, simple personalized and customized strategies were used, such as the possibility to choose individual strategies to complete the exercises. However, the main parts of the intervention were the same for everyone. Parenting programs that address families' actual needs facilitate program adherence [36], and personalized approaches could extend the program completion for those who currently do not benefit from such programs [37]. For example, in a recent pilot trial, Baumel et al [38] found that the program completion of an unguided digital parent training program aimed at treating child disruptive behaviors increased from 28% in a standard version (12/43 of

XSL•FO
RenderX

participating parents) to 69% (31/45 of participating parents) in an enhanced version, through the use of features such as intervention tailoring, timely reminders, automated monitoring, and feedback. BePresent had sequential modules, meaning that the modules were in a defined order and the order was the same for everyone.

Based on the findings of this study, some potential strategies to improve retention in universal internet-based parenting programs can be identified. First, motivation could potentially be increased and attrition rates decreased if programs allowed parents to choose the modules they felt would best benefit their situation and personalize the modules according to their needs. Second, tailored support, such as frequent and personalized reminders could motivate parents to use the program. These reminders could be based on parents' progress in the program or their specific needs. Third, it seems that the most common point for discontinuing the program was between modules 1 and 2, with a dropout rate of approximately 34%. Engagement should be especially supported here. Encouraging actions, especially at the beginning of the program might be highly beneficial. Universal parenting programs could benefit from evolving technology to provide more personalized approaches. For example, certain modules and different program lengths could be suggested based on parents' reports of their needs and the skills they already possess.

The current study and previous studies about universal parenting programs have shown short-term improvements in individual-level outcomes, but it is important to notice that universal interventions can also foster changes in public health at the population level, too. This means focusing on prevention at the population level, for example, by increasing knowledge or changing attitudes [39]. From a parent training perspective, universal programs can aim to prevent problems in parenting and in child behavior, and the results can be seen in the number of those who eventually seek treatment. However, when aiming for population-level changes, the reach of the intervention must be comprehensive enough. Universal interventions typically have low penetration rates, mainly because it is a family's own responsibility to seek out the intervention [35]. Our parent training program was offered when families attended a free of charge annual health check-up, something that all families in Finland are invited to participate in. Using this kind of setting, participation in the intervention was designed to be as easy as possible. Reach and easiness to participation should be carefully considered when implementing universal parenting programs. In addition, it would be important to also assess the population-level effects of universal parenting programs rather than focusing only on individual-level outcomes [39].

Limitations

The study has several limitations to consider. First, this was not a randomized controlled study; therefore, effectiveness and efficacy could not be assessed. Second, it was not possible for us to assess how many parents were offered the chance to participate in the program. The child health clinics were instructed to offer the program to all parents who fulfilled the inclusion criteria. Third, because this was an acceptability study, we were not aiming to reach the population level, so the reach of this study was limited. However, the program was studied in a wide geographical area, covering 67% of well-being services counties in Finland, making the study geographically highly representative. Fourth, the effect sizes seen in this study are low, reaching a Cohen *d* of 0.27, at the highest. The effect sizes in previous universal internet-based parenting interventions have been small to moderate [11]. Effect sizes of parent training trials based on clinical samples have typically been higher, including large effects [40]. One reason for the low effect size in our study was that the level of problems among the sample, taken from the general population, was less severe than that of clinical samples, indicating that there was less room for improvement. Fifth, the study did not ask participants their reasons for not completing the intervention; therefore, this could not be factored or taken into account in our analysis.

Conclusions

The universal internet-based parenting program BePresent may promote improvements in behavior and the daily lives of children. The completion rate was similar to that of other internet-based unguided universal parenting programs. In addition, parents were satisfied with the program and perceived that it supported their positive parenting skills. This type of program is low in cost, requires minimal resources, and can produce several benefits. Therefore, programs like this have the potentiality to be implemented widely in community settings to improve knowledge and positive parenting skills. However, there is a need to assess the impact of personalizing digital universal interventions to increase program adherence and to assess the efficacy of such programs in randomized controlled designs.

Abstract

Background: Despite a dramatic increase in the number of people with generalized anxiety disorder (GAD), a substantial number still do not seek help from health professionals, resulting in reduced quality of life. With the growth in popularity of social media platforms, individuals have become more willing to express their emotions through these channels. Therefore, social media data have become valuable for identifying mental health status.

Objective: This study investigated the social media posts and behavioral patterns of people with GAD, focusing on language use, emotional expression, topics discussed, and engagement to identify digital markers of GAD, such as anxious patterns and behaviors. These insights could help reveal mental health indicators, aiding in digital intervention development.

Methods: Data were first collected from Twitter (subsequently rebranded as X) for the GAD and control groups. Several preprocessing steps were performed. Three measurements were defined based on Linguistic Inquiry and Word Count for linguistic analysis. GuidedLDA was also used to identify the themes present in the tweets. Additionally, users' behaviors were analyzed using Twitter metadata. Finally, we studied the correlation between the GuidedLDA-based themes and users' behaviors.

Results: The linguistic analysis indicated differences in cognitive style, personal needs, and emotional expressiveness between people with and without GAD. Regarding cognitive style, there were significant differences (P<.001) for all features, such as insight (Cohen d=1.13), causation (Cohen d=1.03), and discrepancy (Cohen d=1.16). Regarding personal needs, there were significant differences (P<.001) in most personal needs categories, such as curiosity (Cohen d=1.05) and communication (Cohen d=0.64). Regarding emotional expressiveness, there were significant differences (P<.001) for most features, including anxiety (Cohen d=0.62), anger (Cohen d=0.72), sadness (Cohen d=0.48), and swear words (Cohen d=2.61). Additionally, topic modeling identified 4 primary themes (ie, symptoms, relationships, life problems, and feelings). We found that all themes were significantly more prevalent for people with GAD than for those without GAD (P<.001), along with significant effect sizes (Cohen d>0.50; P<.001) for most themes. Moreover, studying users' behaviors, including hashtag participation, volume, interaction pattern, social engagement, and reactive behaviors, revealed some digital markers of GAD, with most behavior-based features, such as the hashtag (Cohen d=0.49) and retweet (Cohen d=0.69) ratios, being statistically significant (P<.001). Furthermore, correlations between the GuidedLDA-based themes and users' behaviors were also identified.

Conclusions: Our findings revealed several digital markers of GAD on social media. These findings are significant and could contribute to developing an assessment tool that clinicians could use for the initial diagnosis of GAD or the detection of an early signal of worsening in people with GAD via social media posts. This tool could provide ongoing support and personalized coping strategies. However, one limitation of using social media for mental health assessment is the lack of a demographic representativeness analysis.

generalized anxiety disorder; mental health; Twitter; social media analysis; natural language processing

Introduction

Background

Mental health disorders are increasingly common, affecting approximately 1 billion people worldwide [1]. Among these mental health disorders, anxiety disorders are prevalent, with 3.94% of the world's population affected in 2019 [2]. It is important to note that generalized anxiety disorder (GAD) is the most common anxiety disorder. According to the 2014 UK Adult Psychiatric Morbidity Survey, 5.9% of adults experienced GAD [3]. According to the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5*) [4], GAD is characterized by extreme and persistent worry and anxiety about everyday activities lasting at least 6 months. Symptoms can be both mental and physical, including unrealistic anxiety, inability to relax, restlessness, headaches, rapid heart rate, and difficulty breathing [4].

Untreated GAD, in the long term, may lead to physical and mental health complications [5]. It also reduces the quality of life by affecting work productivity and physical and social functions [6]. In addition, GAD burdens health care systems and the economy. It increases health care costs due to higher use of services and decreases work productivity, leading to more days of disability [7]. Despite the availability of effective GAD treatments, only 43.2% of those who have it receive treatment [8]. Consequently, early detection of GAD could significantly reduce all these burdens and improve quality of life.

People use technology in nearly every aspect of their lives. Social media has become more popular, reaching 4.8 billion users worldwide in 2023 [9]. Individuals often share their mental health status on social media as a way of reducing isolation, seeking support, overcoming stigma, increasing awareness, coping with challenges, and sharing experiences without the feeling of being unfairly judged [10]. This generates valuable data on users' posts, profiles, and web-based activities that can provide insights into their mental health conditions. Therefore, exploiting data extracted from social networks is essential to revealing users' mental health statuses.

Consequently, this study presented an approach to identifying GAD markers via social media. By analyzing both linguistic and behavioral patterns on Twitter (subsequently rebranded as X), this approach constructed a comprehensive digital profile of individuals with GAD, distinguishing them from the control group. The methodology integrated analytical tools, such as Linguistic Inquiry and Word Count (LIWC; Pennebaker Conglomerates, Inc) for detailed linguistic analysis and GuidedLDA for thematic exploration, yielding a multidimensional understanding of language and topic patterns unique to GAD. Moreover, a thorough behavioral analysis examined hashtag use frequency, follower counts, interaction patterns, and other aspects, identifying GAD-associated behaviors. This integrated approach highlights social media's potential as a mental health assessment resource and support by identifying 47 statistically validated digital markers of GAD.

In summary, our primary contributions are (1) characterizing the digital markers of GAD by analyzing social media content and behaviors of those who have it, by identifying distinct patterns of language use, thematic topics, and behavioral traits that differentiated them from individuals in the control group; (2) conducting an extensive content-based analysis that leveraged LIWC for a detailed linguistic-based analysis and GuidedLDA for a comprehensive thematic analysis; (3) identifying significant behavioral differences based on user and tweet-level features, such as hashtag use frequency and interaction patterns with other users, as well as measuring the correlation between the themes derived from GuidedLDA and various metadata attributes for both the GAD and control groups; and (4) presenting our findings on 47 distinct GAD-associated digital markers through comprehensive statistical analysis.

Related Works

The widespread use of social media networks and the availability of massive data inspire researchers to investigate the characteristics of mental illnesses through user-generated content and users' activities on social media platforms. Defining these characteristics helps detect mental illnesses via social media, which could help psychiatrists assess a patient's diagnosis and recovery progress. Many studies have used natural language processing (NLP) and machine learning techniques for mental illness prediction via social networks. Several studies have focused mainly on depression prediction via social networks [11-24], and some have examined anxiety disorders [25-30], posttraumatic stress disorder [31-33], and eating disorders [15,34-37]. Therefore, identifying digital markers of mental health conditions could improve detection accuracy.

Textually generated content on social media platforms has been studied to identify indicators of mental health problems. Several studies in psycholinguistics have explored the link between language use and psychological health. Most of these works have used LIWC, a text analysis program that uses predefined dictionaries to capture various dimensions, such as social, emotional, and psychological states. Many studies have analyzed word use to extract psycholinguistic lexical features for identifying depression [11,12,18,25,33,38-40], posttraumatic stress disorder [31,33,40], bipolar disorder [25,33,40], eating disorders [25,34,35], seasonal affective disorder [25,33,40], anxiety disorders [25,29], obsessive-compulsive disorder [25], and schizophrenia [25,41].

A few works have studied the word use associated with psychological health in different languages to identify mental illnesses. The study by Hao et al [28] used a Chinese version of LIWC to investigate psychological characteristics from posts collected from Sina Weibo, a popular Chinese social media platform. In the study by Peng et al [42], they extracted emotional features for depression based on the Chinese Affective Lexicon Ontology, a Chinese emotional dictionary, by adding the depression class to other emotional classes in the emotional dictionary and excluding the surprise class because it is unrelated to depression.

XSL•FO
RenderX

Several studies have analyzed textual content using topic modeling techniques to reveal hidden topics in social media posts and define their relevance to mental health disorders. Latent Dirichlet allocation (LDA) is a widely used topic modeling technique in previous research, including studies on depression [11,18], anxiety disorders [29,30], anorexia [34], schizophrenia [41], and a set of mental health disorders [26].

Because of the significance of leveraging social interaction metadata from users with mental health conditions, some studies have been conducted to understand how individuals with a low mental health status interact on social media platforms. Therefore, studying users' behaviors could provide insights into their mental health characteristics. A survey [43] investigated the correlation between web behaviors and psychological health, concluding that some web activities, such as internet addiction, instant messaging, and web-based gaming, are highly related to mental health disorders.

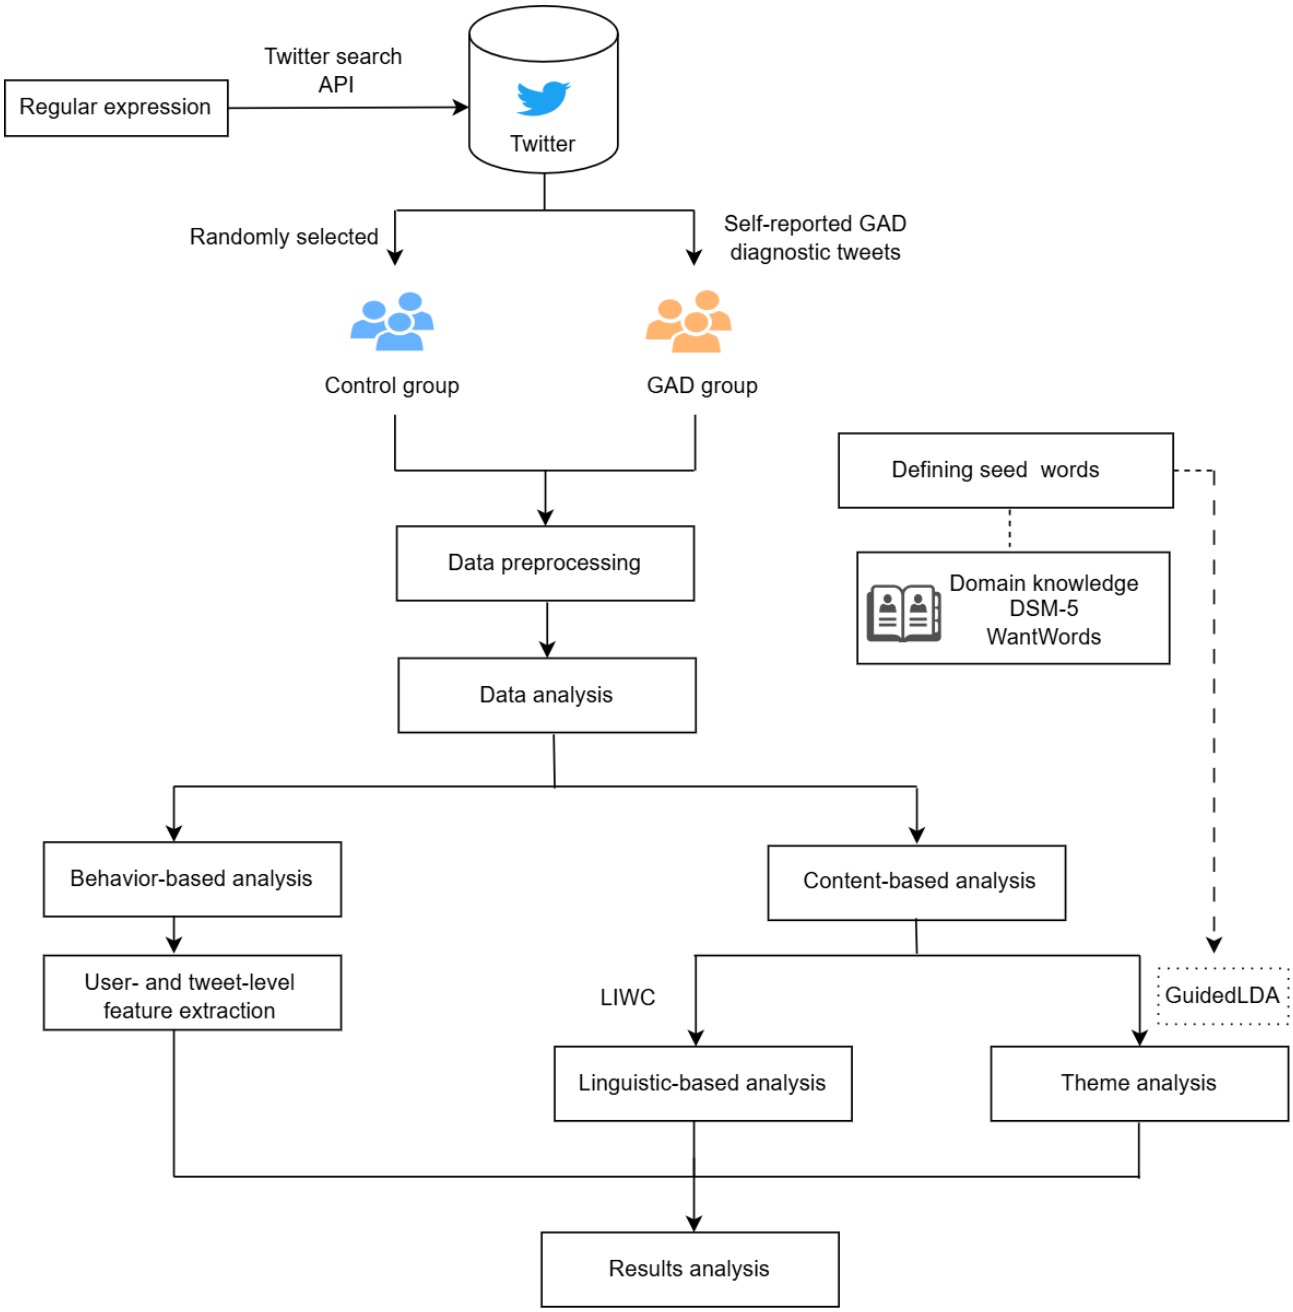
In the context of social media, previous research has examined social media users' activities as an indicator of their mental health status. Vedula and Parthasarathy [19] studied the behaviors of people with depression on Twitter, whereas Peng et al [42] analyzed the depressive characteristics of Sina Weibo users based on posts and user profiles. In the study by de Choudhury et al [44], they investigated changes in new mothers' characteristics related to mood and behavior in the period following childbirth based on some measures of linguistic style, emotional state, and ego network (ie, the number of followers and followees, as well as engagement with the Twitter community). The work by Wang et al [35] characterized individuals with eating disorders via Twitter based on their social interactions, behaviors, and psycholinguistic properties.

It is worth noting that using social media data for mental health assessment offers valuable insights. However, it also presents ethical considerations. Privacy is the key ethical concern when using publicly available data [45,46]. Therefore, to maintain users' privacy, it is essential to apply anonymization techniques to the datasets collected from social media. This process involves removing all information that could reveal a person's identity.

Although previous research has conducted content analysis of users with anxiety disorders via social media, a limited number of works have focused mainly on GAD. Therefore, a thorough study of GAD characteristics on social media platforms is needed. Accordingly, this study provided an in-depth and detailed profiling of users with GAD via social media. We conducted a content analysis, including linguistic and thematic analysis, the web-based behavior of users with GAD, and the correlation between themes and users' behaviors. These analyses could contribute to a better understanding of and provide insights into GAD markers, helping extract significant features used in GAD detection via social media.

The rest of this paper is organized as follows. The methodology is outlined in the next section. The results of our work are then presented. The last section highlights the findings and discusses the limitations and possible future directions to extend our research.

Methods



Overview

To identify GAD characteristics in social media users, we performed several steps. The first step was collecting data using the Twitter application programming interface (API) [47] to obtain posts from both GAD and control groups. Second, a set of data-cleaning procedures was applied. Third, we investigated the dataset based on different aspects, including linguistic analysis, thematic analysis, and user behavior analysis.

LIWC was used for the linguistic-based analysis, whereas the thematic analysis was based on the GuidedLDA algorithm. The user- and tweet-level metadata were used to analyze user behaviors, and several features were extracted from tweets and user profiles. We then explored the results to shed light on GAD markers derived from the content and behavior analysis. Figure 1 illustrates the analytical workflow of GAD profiling via social media. The subsequent sections provide an in-depth explanation of each step.

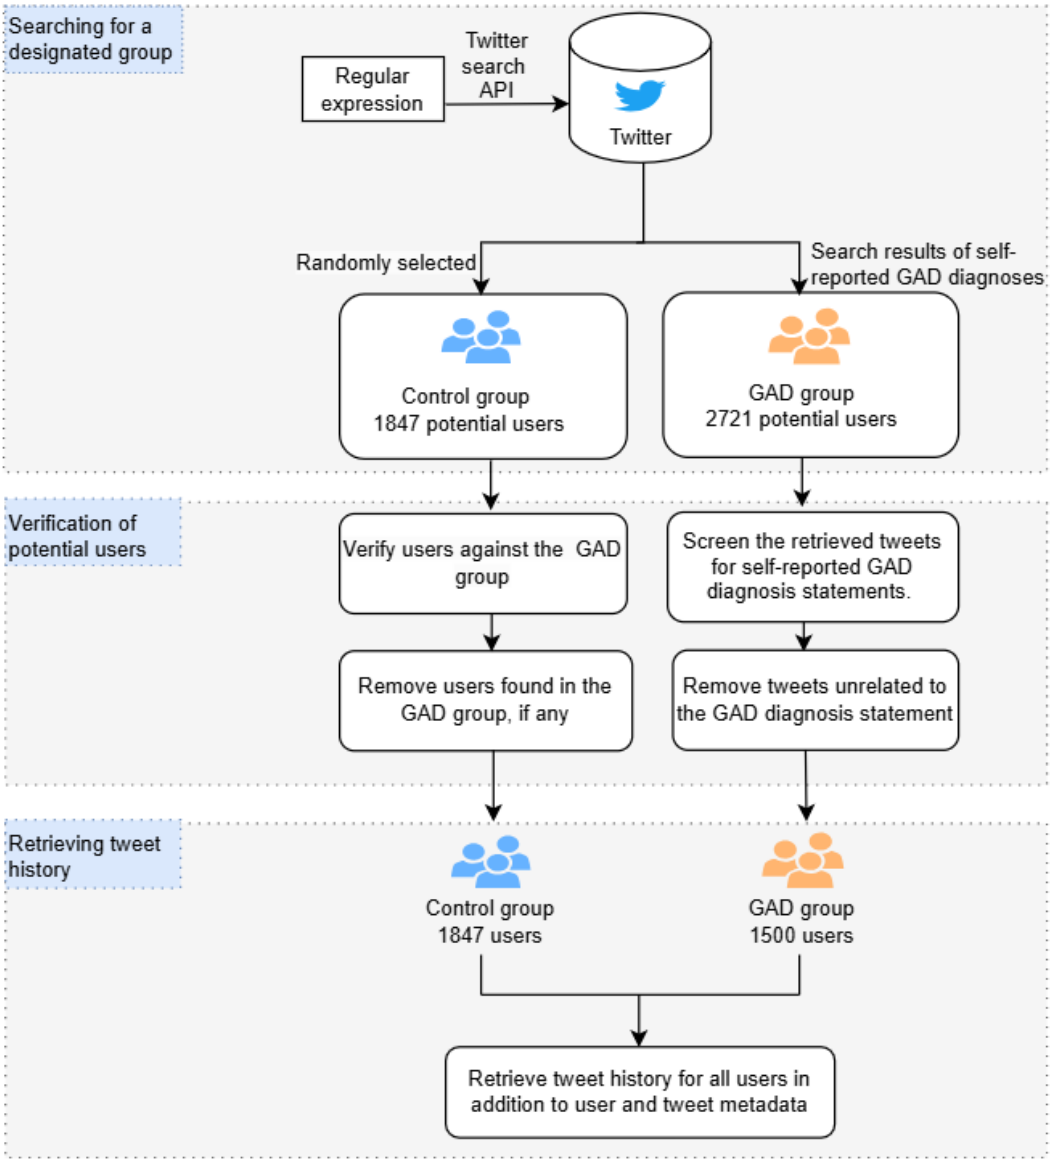
Figure 1. The analytical workflow of generalized anxiety disorder (GAD) profiling via social media involved collecting data from Twitter for the GAD and control groups; performing a set of data preprocessing steps; and conducting a thorough analysis, including behavior-based and content-based analysis. API: application programming interface; DSM-5: Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition; LIWC: Linguistic Inquiry and Word Count.

Data Collection

The data were collected from Twitter, a widely used social media platform. The reason for choosing Twitter was its popularity as a social media platform, with approximately 369 million active accounts every month worldwide in 2022 [48]. Another reason was that Twitter offers a significant amount of data for researchers on health topics because of the enormous number of users, its data accessibility, and the lack of difficulty retrieving and searching data [49].

The Twitter platform provides an API for pooling public posts, searching for relevant ones using regular expressions, and streaming real-time tweets. Through the Twitter API, we collected a dataset encompassing users with GAD and users comprising the control population. Identifying individuals with GAD was done by following the method proposed by Coppersmith et al [40]. This method uses a regular expression to search for tweets that include the diagnosis statement for a condition, such as "I was diagnosed with [condition name]," using the Twitter API. In our study, a group of users with GAD was selected using a regular expression to search tweets that contained the following statement—"I was diagnosed with Generalized Anxiety Disorder (GAD)"—to ensure that a user had publicly stated that they had been diagnosed with GAD. This resulted in 3445 tweets from 2721 unique potential users in the GAD group.

The Twitter API returned tweets comprising all words that matched the given expression, requiring a manual verification



XSL•FO
RenderX

procedure to eliminate tweets unrelated to the GAD diagnosis statement. This process ensured that the collected tweets specifically pertained to a self-reported diagnosis of GAD of users who posted them, so a manual review was conducted to ensure that the tweets did not mention quotations or stories of someone else with GAD. As a result, of the 2721 unique potential users, 1500 (55.13%) users with GAD were included in the dataset.

The control group consisted of randomly selected users representing a general population sample. This resulted in 1847 control group users being included in the dataset. In instances in which users were found to be present in both the GAD and control groups, they were excluded from the control group. The most recent tweets for users with GAD and control users were then retrieved considering the limitation of retrieving a maximum of 3200 tweets per user imposed by the Twitter API. Figure 2 illustrates the process of collecting the dataset.

As shown in Tables 1 and 2, the user and tweet metadata were also retrieved for each profile to study the users' behaviors and social engagement. It is worth noting that this study only collected data from users whose accounts were public, and all the collected data were deidentified to protect privacy.

Figure 2. The data collection process from Twitter for the generalized anxiety disorder (GAD) and control groups. It encompassed searching for a target group, verifying potential users, and retrieving their tweets. API: application programming interface.

XSL•FO
RenderX

Table 1. A description of each type of user-level metadata [50] that was retrieved from Twitter for each user in both the generalized anxiety disorder and control groups.

Feature	Description
User ID	A unique ID for a particular user
Status count	It shows how many tweets were posted by a user.
Description	The user biography briefly describes the user's account.
Verified	It shows whether the user's account is verified.
Account creation date	It shows the date and time of the account's creation.
Follower count	The total amount of users who follow an account
Friend count	The number of users that are currently being followed by an account
Listed count	The number of public lists that a user has joined
Favorite count	The total number of tweets that have been marked as favorites

Table 2. A description of tweet-level metadata [51] that were retrieved from Twitter for each user in both the generalized anxiety disorder and control groups.

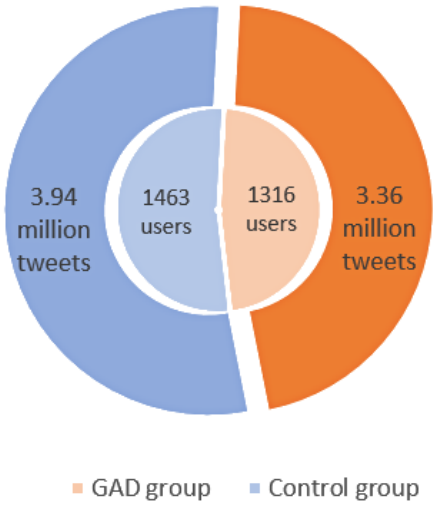
Feature	Description
Tweet ID	A unique ID for a tweet
Full tweet	The tweet text
Tweet created at	The date and time when a tweet was posted
Favorite count	The number of likes for a tweet
Retweet count	The number of retweets for a tweet
Reply to user ID	If a tweet is a response to another user's tweet, this attribute will show that user's unique identifier.

Data Preprocessing

Overview

Several preprocessing steps were undertaken to prepare the 2 collections of raw tweets for further analysis. Data transformation was applied first. We transformed the raw data (tweets) into a structured format in which the columns were the user ID, full tweet, and favorite count, among other data, as described in Tables 1 and 2. Therefore, each row included 1 tweet for a user ID. These tweets were then further processed as outlined in the following sections.

Filtering Out



As this study focused on analyzing posts in English, the dataset was filtered to exclude users with <80% of tweets in English. We then removed non–English-language tweets. Users with <100 tweets were excluded from the dataset. This resulted in a final dataset with a total of 7,313,769 tweets posted by 2779 users. Of these 2779 users, 1316 (47.36%) had been diagnosed with GAD and had posted a total of 46.04% (3,367,581/7,313,769) of the tweets, whereas 1463 (52.64%) of the users constituted the control group with a total of 53.96% (3,946,188/7,313,769) of the tweets. The average number of tweets was 2558.95 (SD 1315.98) for each individual with GAD, whereas it was 2697.33 (SD 918.30) for each user in the control group. Figure 3 illustrates the statistics of collected data for the GAD and control groups, showing the number of users and tweets for each group.

HTML tags and URLs were also eliminated. As part of the preprocessing step, tweets were converted into lower case to prevent case sensitivity in the subsequent data-cleaning steps. Furthermore, identifiable usernames or posts were eliminated to protect users' privacy.

The following data preprocessing steps were standard and have been applied in previous NLP-related studies [52,53].

XSL•FO
RenderX

Figure 3. The statistics for the collected data are presented for the generalized anxiety disorder (GAD) and control groups showing the number of users and tweets for both groups.

Tokenization

Tokenization is applied to split tweets into a list of tokens (ie, words) using the Natural Language Toolkit (NLTK; Team NLTK) tokenizer. The output of this process becomes the main input for punctuation and stop word removal, word normalization, and part-of-speech (POS) tagger steps.

Punctuation and Stop Word Removal

Stop words, such as articles and prepositions, are widely used in any natural language, but they are commonly ignored in text analysis because of their low meaning value and high frequency. Thus, we removed them from the data using the standard stop word list provided in the NLTK. Punctuation was also removed as it adds noise to the dataset. This step was conducted using regular expressions and the NLTK library.

POS Tagger

The POS tagger was applied to assign each token the appropriate POS, such as noun, verb, adverb, and adjective. This process enhances the quality of preprocessing. The POS must be specified for every token using the NLTK POS tagger to obtain the correct lemma.

Lemmatization

As words have different forms, it is essential to unify the word representation to analyze the text. Applying word normalization techniques eliminates the different forms of the same word. Lemmatization is a technique that reduces words to their base form (lemma) using a corpus, such as WordNet. We applied lemmatization to reduce each token to its root using the NLTK lemmatizer based on the WordNet dictionary (The Trustees of Princeton University).

LIWC for Text Analysis

Overview

Several studies have revealed a correlation between language use and an individual's mental health status. Therefore, we investigated the differences in word use patterns between users with GAD and control users to identify underlying potential indications of GAD. We used LIWC [54], a text analysis tool equipped with >100 built-in dictionaries to reveal individuals' psychological, social, and behavioral patterns from text, each including words, word stems, and emoticons [54]. These words could be classified into one or multiple categories or dictionaries.

The process of text analysis using LIWC involves several steps. These steps are reading the dataset, comparing every word with each dictionary entry, and calculating the percentage of words related to each built-in dictionary. A quantitative summary of all LIWC dimensions is then generated, and the user-level means for all dimensions are found. Finally, these results could be analyzed to capture underlying psychosocial indicators.

As mental health impacts our way of thinking, behaving, and feeling [1], we proposed 3 measurements based on LIWC dictionaries. These measurements, namely, cognitive style, personal needs, and emotional expressiveness, aimed to study the differences in language use between users with GAD and control users. We carefully defined these measures inspired by the method in the studies by Pavalanathan and de Choudhury [55] and Ernala et al [56]. This method is based on leveraging insights from an extensive review and synthesis of previous research in psychology and psycholinguistics [57-59]. The potential implications of studying linguistic style are significant as it could provide a deeper understanding of the linguistic markers of GAD and potentially lead to more effective interventions.

Cognitive Style

The cognitive style quantifies how individuals think, talk about their thinking, or retrieve information. It is based on the cognitive dimension of LIWC to measure related categories, including insight, causation, discrepancy, tentativeness, certitude, and differentiation. In addition, the memory category is used to help measure the retrieval or forgetfulness of information. The results of these analyses could reveal a decline in cognition associated with poor mental health status in an individual with GAD, including memory recall issues, difficulty reasoning, and decision-making inability.

XSL•FO
RenderX

Personal Needs

Identifying personal needs helps maintain mental well-being, which could be helpful to separate the GAD group from the control group as the former may not sufficiently satisfy various personal needs. Therefore, we investigated some personal needs, including essential needs and self-esteem, based on LIWC dictionaries. The essential needs involve being physically and mentally healthy and feeling safe, including seeking support and maintaining a healthy life, which was assessed using some LIWC categories (ie, *food*, *substances*, *death*, *want*, *need*, and *lack*).

Self-esteem needs involve belief in personal value and ability, which also impacts how to communicate with others. Accordingly, measuring self-esteem needs includes several categories (ie, *reward*, *curiosity*, *risk*, *interpersonal conflict*, and *communication*). The results of these categories could reflect mental well-being based on the definition of mental well-being according to the World Health Organization, which is a person's ability to recognize their skills, deal with everyday life stressors, effectively produce and accomplish, and participate in the community [60].

Emotional Expressiveness

Emotional expressiveness measurement assesses a person's tendency to express various emotions through language use. We used the *negative tone*, *anxiety*, *anger*, *sadness*, and *swear words* categories to measure emotional expressiveness, which could identify the patterns of expressing emotional sentiments that are common among people with GAD.

GuidedLDA

Topic modeling is a content analysis approach for uncovering hidden themes in textual data. One common topic modeling technique is LDA, an unsupervised machine learning mechanism. LDA helps extract topics with no advanced knowledge of themes. However, implementing LDA on a large dataset may generate meaningless topics [61]. To leverage previous research and the domain knowledge of GAD in topic modeling, we adopted the GuidedLDA technique for extracting the common topics discussed among people with GAD.

GuidedLDA is a semisupervised LDA algorithm based on setting predefined seed words to extract hidden themes of a particular direction and interest. Unlike the LDA topics initialized using randomly selected words, each seed word has a high probability of belonging to its particular topic in the initialization stage of GuidedLDA. We defined some possible seed words for each candidate topic related to GAD by relying on domain knowledge and previous research on GAD. We explain the configuration of GuidedLDA in the *Thematic Analysis* section.

Twitter Metadata

In addition to retrieving the user-level and tweet-level metadata shown in Tables 1 and 2, we extracted several features derived from Twitter metadata. These included tweet and behavior-based features, as shown in Table 3.

XSL•FO
RenderX

Table 3. A set of extracted features derived from Twitter metadata.

Feature	Description
FF[a] ratio	The ratio of followers to followees per user
Number of mentions	The average number of mentions per tweet
Number of tweets	The number of tweets per user across their history
Number of replies	The number of replies per user across their history
Reply-to-tweet ratio	The ratio of replies to the total number of tweets per user
Number of hashtags	The number of participating hashtags per user across their history
Hashtag ratio	The ratio of tweets including hashtags to the total number of tweets per user
Number of retweets	The number of retweets per user across their history
Retweet-to-tweet ratio	The ratio of retweets to the total number of tweets per user
Total number of mentions per user	The number of mentions per user across their history
Total number of mentions without replies per user	The number of mentions per user without considering mentions associated automatically with replies across their history
Mention ratio	The ratio of tweets with other people mentioned to the total number of tweets per user
Total tweets with favorites	The total number of tweets that received at least one favorite per user
Tweets with favorites ratio	The ratio of total tweets that received at least one favorite to the total tweets per user
Total tweets with retweets	Total tweets that received at least one retweet per user
Tweets with retweets ratio	The ratio of total tweets that received at least one retweet to the total tweets per user
Tweets per day	The average number of tweets per day per user
Replies per day	The average number of replies per day per user
Retweet per day	The average number of retweets per day per user
Mentions per day	The average number of tweets including mentions per day per user
Hashtag engagement per day	The average number of tweets including hashtags per day per user

[a]FF: follower-to-followee.

Data Analysis

We aimed to compare various features between individuals with GAD and control individuals. Therefore, the analysis involved several statistical methods, including the 1-tailed, 2-sample *t* test; *P* value for statistical significance; and Cohen *d* for effect size. First, descriptive statistics were calculated for each content-based and behavioral-based feature for both groups, including means and SDs to summarize the data.

Next, we conducted the 1-tailed ,2-sample *t* test to compare the means of the 2 groups. This test evaluated whether the mean differences between these groups were statistically significant, with a *P* value of ≤.05 indicating statistical significance. The Cohen *d* was also computed to measure the effect size to provide insights into the practice effect. The possible magnitude of these differences ranged from small to large. According to Cohen [62] and Sawilowsky [63], the effect sizes are interpreted as small if Cohen $d<0.20$, as medium if the Cohen *d* is between 0.20 and 0.50, and as large if the Cohen *d* is between 0.50 and 0.80. The *P* value and Cohen *d* provide insights into the results' statistical significance and practical importance.

Ethical Considerations

This study used publicly available data without direct user interaction or intervention, so an ethics review was unnecessary. All usernames, IDs, and tweets were de-identified to ensure privacy. In addition, data that could disclose personal identifiers were carefully omitted to maintain user privacy and anonymity.

Results

This section presents the results of exploring the data in terms of linguistic, thematic, and behavior analyses.

Linguistic-Based Analysis

Overview

We found differences in language use across different aspects, including cognitive style, personal needs, and emotional expressiveness, between the individuals in the GAD group and those in the control group. Table 4 provides the summary statistics of these differences based on the LIWC categories for people with GAD compared to those without GAD. Consequently, these differences in the LIWC categories demonstrate a correlation between language use and the mental health status of people with GAD.

XSL•FO
RenderX

Table 4. A comparison of linguistic-based measurements between the generalized anxiety disorder (GAD) and control groups based on the Linguistic Inquiry and Word Count categories[a].

Category	GAD group, mean (SD)	Control group, mean (SD)	*P* value	Cohen *d*
Cognitive style (percentage of total word count)				
Insight	1.59 (0.57)	0.90 (0.65)	<.001	1.13
Causation	1.028 (0.39)	0.60 (0.44)	<.001	1.03
Discrepancy	1.39 (0.47)	0.78 (0.58)	<.001	1.16
Tentativeness	1.40 (0.48)	0.74 (0.56)	<.001	1.27
Certitude	0.57 (0.29)	0.30 (0.31)	<.001	0.90
Differentiation	2.15 (0.71)	1.17 (0.88)	<.001	1.23
Memory	0.10 (0.07)	0.07 (0.09)	<.001	0.37
Personal needs (percentage of total word count)				
Need	0.35 (0.18)	0.20 (0.18)	<.001	0.83
Want	0.38 (0.25)	0.23 (0.21)	<.001	0.65
Lack	0.11 (0.20)	0.06 (0.07)	<.001	0.33
Reward	0.11 (0.22)	0.15 (0.46)	.003	0.11
Risk	0.19 (0.12)	0.11 (0.12)	<.001	0.67
Curiosity	5.79 (1.31)	3.82 (2.30)	<.001	1.05
Substances	0.05 (0.17)	0.03 (0.06)	<.001	0.16
Food	0.48 (0.33)	0.32 (0.44)	<.001	0.41
Death	0.19 (0.19)	0.11 (0.13)	<.001	0.49
Interpersonal conflict	0.27 (0.17)	0.18 (0.19)	<.001	0.50
Communication	3.50 (1.64)	4.80 (2.35)	<.001	0.64
Emotional expressiveness (percentage of total word count)				
Negative tone	4.39 (1.36)	4.24 (1.73)	.01	0.10
Anxiety	0.18 (0.26)	0.06 (0.08)	<.001	0.62
Anger	0.17 (0.12)	0.09 (0.10)	<.001	0.72
Sadness	0.22 (0.22)	0.13 (0.15)	<.001	0.48
Swear words	0.77 (0.74)	0.47 (0.72)	<.001	2.61

[a]*P* values were calculated using a 1-tailed, 2-sample *t* test, with $P \leq .05$ indicating statistical significance, and the effect size is reported using the Cohen *d*.

Differences in Cognitive Style

The GAD group had higher values for all categories used for assessing cognitive style than individuals in the control group, showing statistically significant differences between the 2 groups ($P<.001$) for insight (Cohen $d=1.13$), causation (Cohen $d=1.03$), discrepancy (Cohen $d=1.16$), tentativeness (Cohen $d=1.27$), certitude (Cohen $d=0.90$), differentiation (Cohen $d=1.23$), and memory (Cohen $d=0.37$), as shown in Table 4. Tweets posted by users with GAD included more certainty, discrepancy, and differentiation words, almost 2 times more than tweets posted by users in the control group. In addition, their tweets contained nearly twice as many tentative words as the control group. The results also indicated that the GAD group used nearly 1.5 times more memory words related to recollecting and forgetting, such as *forget* and *remember*, than the control group.

Differences in Personal Needs

Regarding essential needs, the results indicated that the tweets of the GAD group contained approximately 1.8 times more words from the *want*, *need*, and *lack* categories than the tweets of the control group. Moreover, the GAD group showed increased use of *substances*, *death*, and *food* words. The mean values of these categories were 0.05, 0.19, and 0.48, respectively, for the GAD group, which were higher than those for the control group.

Regarding self-esteem needs, the number of reward words in the control group was higher than that for the GAD group. Another result was a lower number of communication words in the GAD group than in the control group. In contrast, 1.5 times more words related to interpersonal conflict were observed in the GAD group compared to the control group.

XSL•FO
RenderX

Table 4 highlights the significant differences in most categories of personal needs, underscoring the depth of these differences. This was evident in the *need* (Cohen *d*=0.83), *want* (Cohen *d*=0.65), *lack* (Cohen *d*=0.33), *risk* (Cohen *d*=0.67), *curiosity* (Cohen *d*=1.05), *food* (Cohen *d*=0.41), *death* (Cohen *d*=0.49), *interpersonal conflict* (Cohen *d*=0.50), and *communication* (Cohen *d*=0.64) categories. Although the *reward* and *substances* categories were statistically significant (*P*=.003 and *P*<.001, respectively), the effect size was small (Cohen *d*=0.11 and 0.16, respectively).

Differences in Emotional Expressiveness

The GAD group expressed more negative tones. Notably, their tweets also showed extensive use of anxiety-related words, 3 times more than the control group. In addition, their tweets expressed anger and sadness more frequently. Moreover, the GAD group used a higher number of swear words.

We found statistical significance (*P*<.001) as well as a significant effect size for most features, including anxiety (Cohen *d*=0.62), anger (Cohen *d*=0.72), sadness (Cohen *d*=0.48), and swear words (Cohen *d*=2.61). However, the effect size of the negative tone was small (Cohen *d*=0.10).

Thematic Analysis

Overview

We present the results of the thematic analysis, which included 4 primary themes: symptoms, life problems, relationships, and feelings. The symptoms theme was derived from major symptoms according to the *DSM-5* for GAD. Other themes were derived from previous research [64] highlighting how GAD may affect an individual's perceived life satisfaction in different aspects such as relationships, health, and work. The seed words of the symptoms theme were defined based on GAD symptoms and the health-related problems of GAD according to the *DSM-5*. To generate seed words for other themes, we used a reverse dictionary named WantWords (The Natural Language Processing Group, Tsinghua University) [65] to obtain words that related semantically to the descriptions of these themes. Table 5 shows a sample of seed words for each theme.

Table 5. A sample of seed words used by GuidedLDA for each theme.

Theme	Seed words
Symptoms	"Worry," "concern," "anxiety," "twitch," "treatment," "restlessness," "concentration," "muscle," "mental," and "health"
Life problems	"Business," "money," "work," "school," "job," "salary," "promotion," "college," "office," and "experience"
Relationships	"Wife," "husband," "parents," "kids," "friends," "partners," "spouse," "fiancee," "fiance," and "father"
Feelings	"Feel," "cry," "respect," "release," "support," "emotion," "disclosure," "care," "sadness," "sense," and "sorry"

Symptoms Theme

The symptoms theme reflects the GAD symptoms and other health problems related to GAD among those who have it that were expressed in their tweets. Some tweets showed how individuals with GAD have extreme anxiety about various things, and others represented how individuals with GAD tend to expect the worst scenario for any issue. In addition, users with GAD often posted about experiencing difficulty concentrating and overthinking plans. Other tweets showed that people with GAD tend to experience tiredness and sleep disturbance because of insomnia.

The results also demonstrate that many people with GAD discuss their health status, therapy, and treatment with others. Some users also discussed how excessive worry caused other health problems, such as heart conditions and digestive issues.

Life Problems Theme

This theme denotes how individuals with GAD worry about various issues, including financial status, work, and school. Some users with GAD tended to share with others how GAD negatively impacted work because of difficulty concentrating on any task and accomplishing it on time, reducing work performance. Some users with GAD discussed the difficulty maintaining employment and the increased fear of financial strain. Other tweets showed that several people with GAD discussed the impact of GAD on their academic performance.

Relationships Theme

This theme highlights that people with GAD have impairments in relationships with partners, family members, and friends. Many users tended to discuss their problems in relationships with others. We found that some tweets showed that individuals with GAD had fewer relationships for several reasons, such as having trouble expressing their feelings, having poor self-esteem, and being irritable with others. In addition, some users discussed how GAD significantly affected their marriage, whereas some individuals reported that GAD caused the weakening of their relationships with their partners and decreased enjoyment of activities with them.

Feelings Theme

This theme indicates that several users with GAD tend to express and share their feelings and emotions with others on social media. We found that they disclosed their feelings to obtain support and help from professionals or other users or raise awareness of mental health issues.

Summary of Thematic Analysis Results

In Figure 4, the GuidedLDA-based thematic analysis shows that users in the GAD group had a higher frequency of these themes per tweet than those in the control group for every theme. The results indicate that the GAD group tended to discuss life problems and other themes 1.5 times and approximately 2 times more than the control group, respectively. Table 6 shows the statistically significant differences for all themes between users with GAD and control users. We found statistically significant

XSL•FO
RenderX

differences (P<.001) and significant effect sizes (Cohen d>0.50) for most themes. Examples of paraphrased tweets for each theme can be found in Multimedia Appendix 1.

Figure 4. The frequency of the GuidedLDA-based themes per tweet for each user profile in both groups. GAD: generalized anxiety disorder.

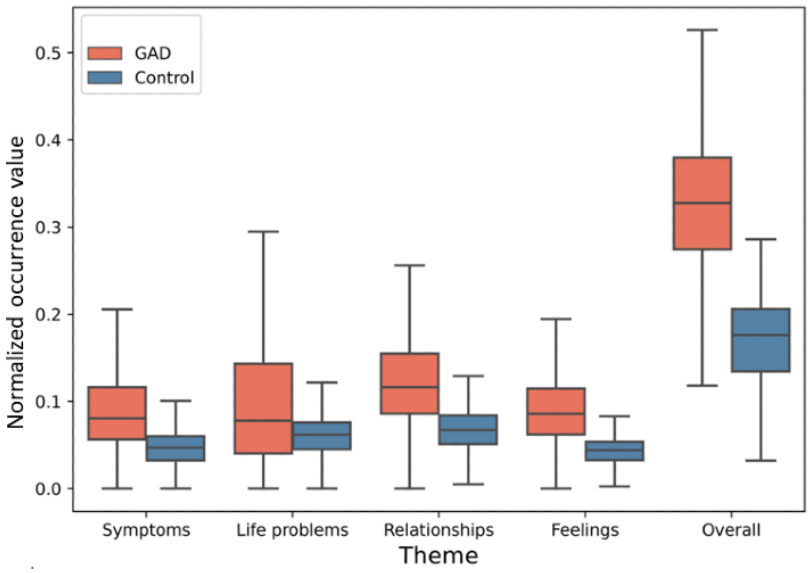


Table 6. A comparison of themes between the generalized anxiety disorder (GAD) and control groups[a].

Theme	GAD group, mean (SD)	Control group, mean (SD)	*P* value	Cohen *d*
Symptoms (percentage of total tweets per user profile)	10 (8)	5 (2)	<.001	0.86
Life problems (percentage of total tweets per user profile)	11 (10)	7 (7)	<.001	0.46
Relationships (percentage of total tweets per user profile)	13 (8)	7 (3)	<.001	0.99
Feelings (percentage of total tweets per user profile)	9 (5)	4 (2)	<.001	1.31

[a]*P* values were calculated using a 1-tailed, 2-sample *t* test, with $P \leq .05$ indicating statistical significance, and the effect size is reported using the Cohen *d*.

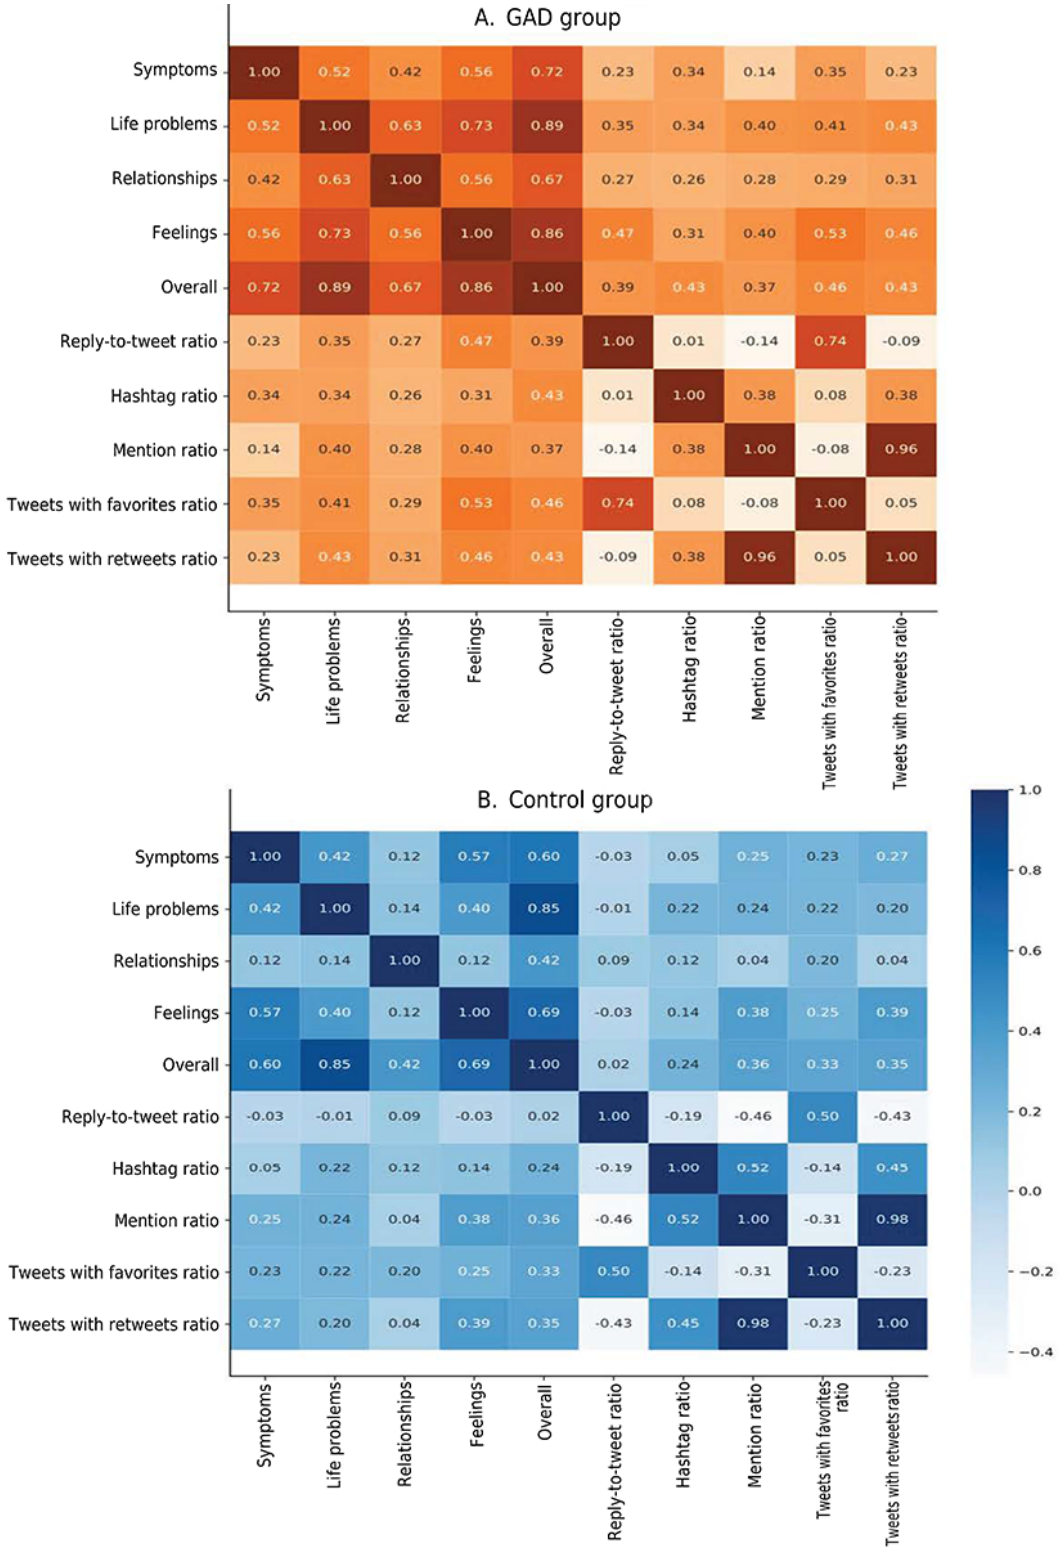
Behavioral Analysis

In this section, an analysis is presented to study the patterns of individuals with GAD concerning their behaviors and activities on Twitter. Moreover, we measured the correlation between the GuidedLDA-based themes and users' behaviors, including hashtag participation, volume, interaction patterns, social engagement, and reactive behavior.

Participation in Hashtags

Participating in hashtags shows the tendency of users to discuss various topics in public with others. The analysis showed that people with GAD participated in fewer hashtags than people without GAD. In addition, the results showed different preferences for the types of hashtag topics followed by people with GAD compared to people without GAD. People with GAD preferred to participate in hashtags related to their mental health status (eg, *#anxiety* and *#mentalhealth*), therapy, and treatments (eg, *#ketaminetherapy* and *#ketwell*). In addition, they liked to follow hashtags where they had the opportunity to discuss their mental health with others to seek support and reduce isolation (eg, *#MentalHealthMatters*).

Many people with GAD tended to participate slightly more in hashtags related to current events regarding health, politics, and other matters (eg, *#news* and *#COVID19*) than those without GAD. On the other hand, people without GAD followed hashtags related to daily life, ranging from family to entertainment, more than individuals with GAD (eg, *#NBATwitter* and *#movie*). We found that people with GAD tended to participate less using hashtags that those without GAD were usually more active with. The mean value of users' tweets per day containing a hashtag in the GAD group was 0.2 (SD 0.54; median 0.06, IQR 0-0.42), whereas the mean value of users' tweets per day containing a hashtag for those without GAD was significantly higher at 0.53 (SD 1.13; median 0.13, IQR 0-0.89; P<.001).



We also measured the ratio of all tweets that participated in a hashtag to the overall tweets. We found that 15% (591,928/3,946,188) of tweets from the control group included hashtags compared to 8.6% (289,611/3,367,581) of tweets from the GAD group. The median value for the former was 9% (IQR 6.75%-13.5%), whereas the median value for the latter was 4.7% (IQR 3.53%-7.06%).

However, those in the GAD group who participated in hashtags mainly focused on sharing their symptoms, as shown in Figure 5. We also identified a higher correlation (ρ) between all 4 identified themes overall and hashtag ratio than for those in the control group. This indicates that individuals without GAD participated in hashtags that were less correlated with these themes. The highest value for ρ was observed when individuals

XSL•FO
RenderX

with GAD shared their symptoms with others (0.34 compared to 0.05 for the control group).

Figure 5. The correlation between the GuidedLDA-based theme frequency and metadata for (A) the GAD group and (B) the control group in our dataset. GAD: generalized anxiety disorder.

Metadata of Engagement Analysis

We explored the 2 groups through metadata analysis, such as how they interacted with each other in terms of replies, mentions, number of followers and followees, and volume of tweets.

Volume

We measured the volume of several aspects for each user from their profile history. Our scope spanned 12 aspects to be compared between the GAD and control groups, as shown in Figure 6. In general, we found that individuals in the control group had 46.93% and 30.5% more friends and followers,

XSL•FO
RenderX

respectively, and had a 31.53% higher listed count. In addition, we found that the control group was 52.33% more active in the participation in hashtags than the GAD group and tended to have 64.11% and 40.85% more retweets and mentions, respectively.

In addition, the control group tended to retweet popular tweets 42.47% more than the GAD group. However, we noticed a 36.01% lower volume of replies for the control group than for people with GAD. This might be due to the fact that the GAD group tends to be more reactive than proactive, which will be discussed later in the *Reactive Behavior* section.

Table 7 shows the statistical significance of the volume features. We found statistical significance and significant effect sizes for the number of replies (Cohen *d*=0.33), number of hashtags (Cohen *d*=0.51), number of retweets (Cohen *d*=0.62), total number of mentions per user (Cohen *d*=0.30), total number of mentions without replies per user (Cohen *d*=0.63), and total tweets with retweets (Cohen *d*=0.60). There were no statistically significant differences in the follower count and listed count features (Cohen *d*=0.06 and 0.07, respectively).

The results also showed a statically significant difference in friend count, favorite count, retweet count, and number of tweets. However, the effect size was small for these features (Cohen *d*=0.14, 0.20, 0.14, and 0.08, respectively).

Figure 6. A comparison of mean values across different volume metrics between the generalized anxiety disorder (GAD) and control groups.

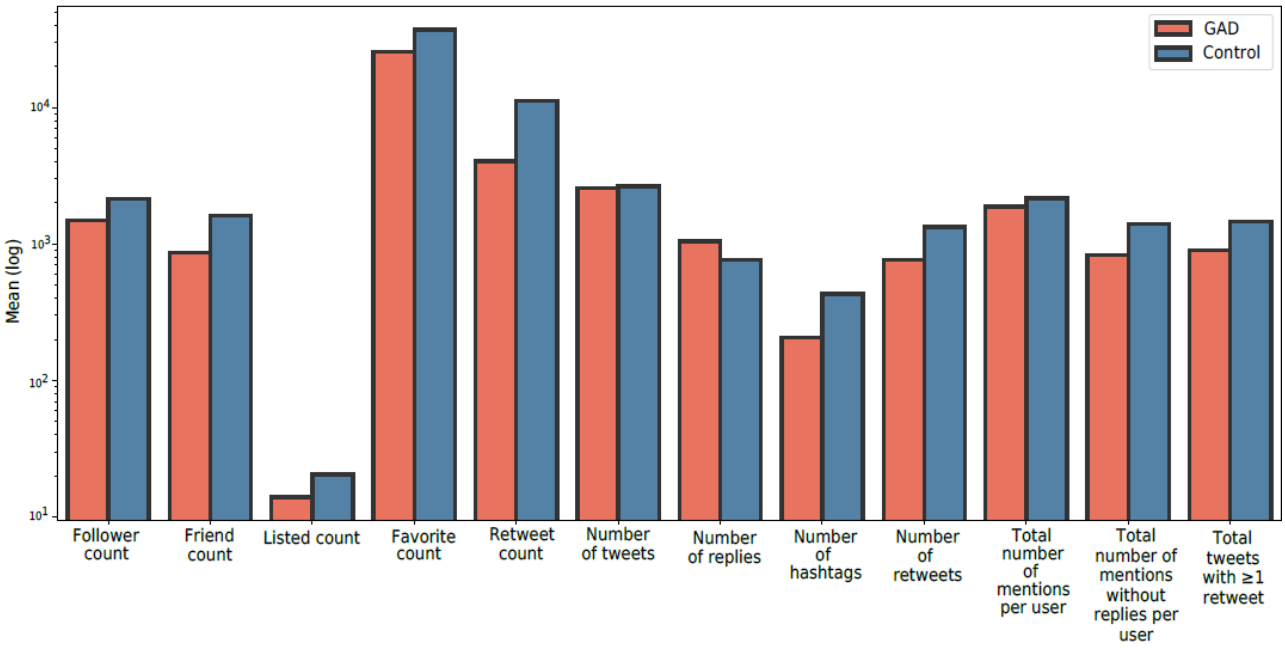


Table 7. Comparing the volume metrics between the generalized anxiety disorder (GAD) and control groups[a].

Feature	GAD group, mean (SD)	Control group, mean (SD)	*P* value	Cohen *d*
Follower count	1492.90 (7433.32)	2148.25 (12,479.92)	.09	0.06
Friend count	859.56 (2016.48)	1619.79 (7567.63)	<.001	0.14
Listed count	14.03 (65.89)	20.56 (111.17)	.06	0.07
Favorite count	25,480.23 (40,851.50)	37,215.05 (70,582.59)	<.001	0.20
Retweet count	4033.26 (25,873.79)	11,239.02 (70,861.73)	<.001	0.14
Number of tweets	2559.78 (1315.98)	2650.30 (918.30)	.04	0.08
Number of replies	1042.95 (873.12)	766.84 (792.72)	<.001	0.33
Number of hashtags	205.19 (305.56)	430.50 (539.18)	<.001	0.51
Number of retweets	767.65 (773.00)	1334.42 (1029.41)	<.001	0.62
Total number of mentions per user	1871.37 (1082.88)	2167.46 (909.44)	<.001	0.30
Total number of mentions without replies per user	828.42 (779.71)	1400.62 (1019.23)	<.001	0.63
Total tweets with retweets	902.59 (797.51)	1453.47 (1012.96)	<.001	0.60

[a]*P* values were calculated using a 1-tailed, 2-sample *t* test, with $P \leq .05$ indicating statistical significance, and the effect size is reported using the Cohen *d*.

XSL•FO
RenderX

Interaction Patterns

The mention and reply features on Twitter could reflect the interaction among Twitter users. Therefore, we analyzed the ratio of mentions and replies for people with and without GAD to study the extent of interaction in these 2 groups. We found that individuals with GAD had a lower mention ratio than those without GAD, indicating less interaction with others.

Another indication of a user interacting with the community is acting positively and communicating more with others. On Twitter, users tend to mention someone within their tweets to ask for participation in their opinion. Another example is to retweet others' ideas for either endorsement or to pass on an interesting tweet to their audience for further discussion. We found that control users tended to include more mentions per day than people with GAD. The mean number of mentions per day for the control group was 1.57 (SD 2.31; median 0.69, IQR 0.30-4.95). This is, in fact, more than double that of people with GAD (mean 0.78, SD 1.2; median 0.39, IQR 0.25-2.60).

For more confirmation of such behavior, we also found that 51% (2,012,555/3,946,188) of tweets from the control group had a mention, whereas 31.5% (1,060,788/3,367,581) of tweets included a mention in the GAD group. The mentions comprised those receiving a reply and those solely mentioned as both are technically considered *mentions* in the Twitter community. In Figure 5, users in the GAD group show a high correlation with mentions when talking about their life problems and relationships (approximately 0.4 and 0.28 compared to 0.24 and 0.04 for the control group, respectively).

However, the symptoms theme showed a lower correlation with mentions for the GAD group than for the control group (0.14 compared to 0.25). We found that the control group tended to talk directly to someone about health issues. In contrast, the GAD group associated health discussions with a hashtag to receive more attention and used direct mentions to seek support for life problems and relationships.

In addition, the retweets per day and their ratio to the overall tweets may indicate endorsement of others' tweets or the desire to pass them on to their audience for further discussion. We found a mean of 1.63 (SD 2.31; median 0.74, IQR 0.50-5.19) retweets per day for the control group and 0.86 (SD 1.26; median 0.44, IQR 0.40-2.87) retweets per day for the GAD group. Moreover, 48% (1,894,170/3,946,188) of the control group's tweets were retweets, whereas 28.91% (973,567/3,367,581) of the GAD group's tweets were retweets.

However, we also observe in Figure 5 that, in the GAD group, there is a high correlation between both the feelings and life problems themes and higher likes and retweets received from their audience when they tweet (ρ of 0.53 and 0.41 in the GAD group compared to 0.25 and 0.22 in the control group, respectively). This result might suggest that the GAD group interacts with others when they share the effects of GAD on their life, seeking support and a way to release and express their emotions.

Social Engagement

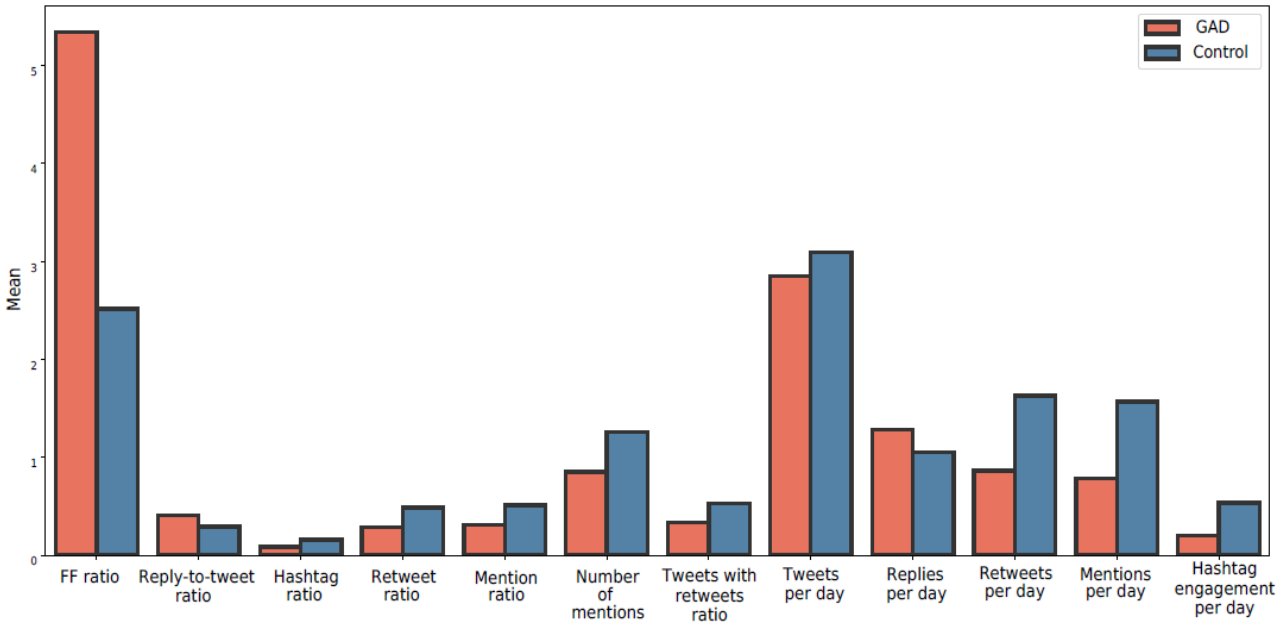
We used the number of followers and followees to measure the social engagement among users. The results showed that people with GAD had fewer followers and followees than those without GAD, as shown in Figure 6. This might reflect that the GAD group was less social than the control group and tended to limit their relationships.

However, we found that users with a large follower-to-followee ratio were associated with GAD, as shown in Figure 7. This result could be due to these users being more well known, making them more likely to receive criticism from individuals who are unfamiliar with them. In addition, people with GAD had fewer friends than the control group. To summarize these cases, we identified 2 categories within the GAD group. The first category was those with high pressure from a large number of followers, such as celebrities, whereas the second category was those who tended to live alone and have fewer friends.

The mean value of the follower-to-followee ratio in the GAD group was 5.34 (SD 93.82). On the other hand, the control group had a mean follower-to-followee ratio of 2.51 (SD 15.53). The large value for the SD is due to those who had a high number of followers and experienced pressure from their audience, leading to some GAD symptoms. Therefore, we measured the median for both groups, with 0.76 (IQR 0.25-157.91) and 0.88 (IQR 0.25-26.89) for the GAD and control group, respectively. Figure 7 shows the first category within the GAD group, whereas Figure 8 shows the second category.

XSL•FO
RenderX

Figure 7. A comparison of mean values across different features between the generalized anxiety disorder (GAD) and control groups. FF: follower-to-followee.



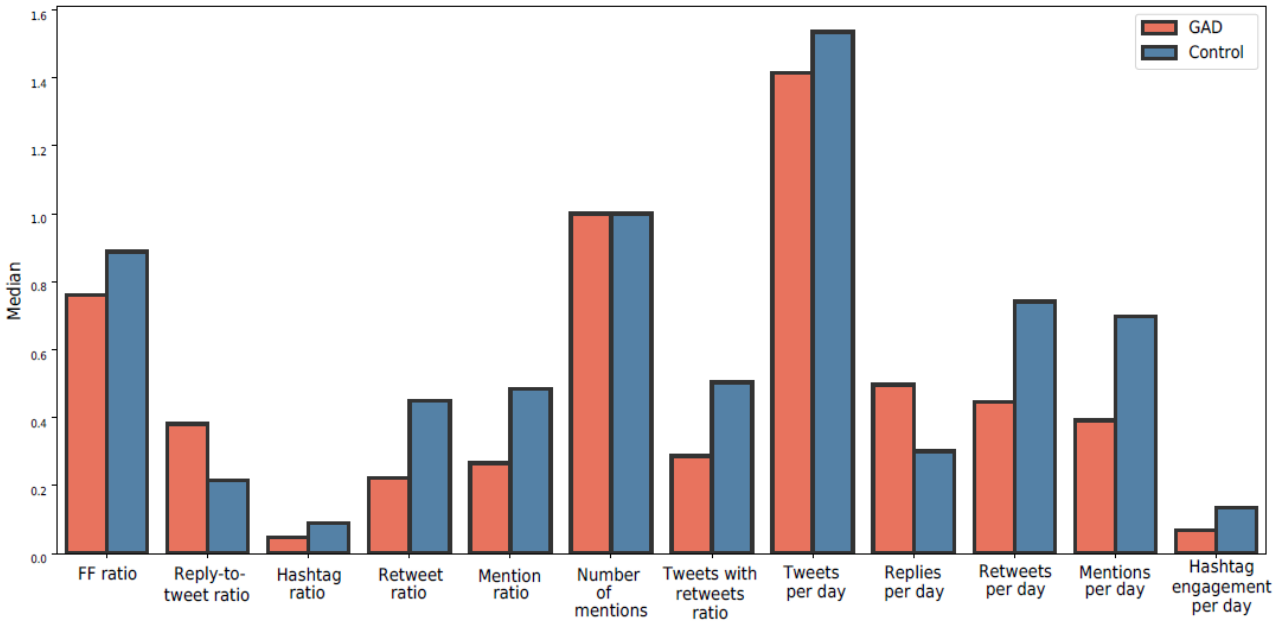


Figure 8. A comparison of median values across different features between the generalized anxiety disorder (GAD) and control groups. FF: follower-to-followee.

Reactive Behavior

We identified that people with GAD tended to reply more than write new tweets compared to those in the control group. Figure 7 shows that the mean value of users' replies per day for the GAD group was 1.28 (SD 2.12), whereas the mean value of users' replies per day in the control group was slightly lower at 1.05 (SD 2.05). The margin was even larger in terms of median values at 0.49 (IQR 0.35-4.40) and 0.30 (IQR 0.25-4.08) for the GAD and control groups, respectively. This may indicate a common aspect of those in the GAD group being more reactive to others rather than engaging proactively.

To clarify this, we also measured the ratio of replies to total tweets, which points to the same behavior. The mean value of this ratio for the GAD group was 0.41 (SD 0.24), and the median was 0.38 (IQR 0.30-0.82). In the control group, the mean value of the ratio of replies to total tweets was 0.29 (SD 0.26), and the median was 0.21 (IQR 0.18-0.69). We confirm the reactive behavior in Figure 5, where there is a higher correlation (ρ) for the GAD group between the *symptoms* theme, *life problems* theme, *relationships* theme, *feelings* theme, and the 4 identified themes overall and the reply-to-retweet ratio at 0.23, 0.35, 0.27, 0.47, and 0.39 compared to the control group at –0.03, –0.01, 0.09, –0.03, and 0.02, respectively. Table 8 shows the statistical significance for most of the behavioral features.

We found statistical significance and significant effect sizes for the reply-to-tweet ratio (Cohen d=0.47), hashtag ratio (Cohen d=0.49), retweet ratio (Cohen d=0.69), mention ratio (Cohen

XSL•FO
RenderX

d=0.68), tweets with retweets ratio (Cohen *d*=0.68), retweets per day (Cohen *d*=0.41), mentions per day (Cohen *d*=0.42), and hashtag engagement per day (Cohen *d*=0.38).

There were no statistically significant differences in the follower-to-followee ratio and tweets per day features (Cohen *d*=0.04 and 0.07, respectively). The results also show a statistically significant difference in mention count and replies per day. However, the effect size was small for these features (Cohen *d*=0.17 and 0.11, respectively).

Table 8. Comparing the behavior-based metrics between the generalized anxiety disorder (GAD) and control groups[a].

Feature	GAD group, mean (SD)	Control group, mean (SD)	*P* value	Cohen *d*
FF[b] ratio	5.34 (93.82)	2.52 (15.53)	.28	0.04
Reply-to-tweet ratio	0.41 (0.24)	0.29 (0.27)	<.001	0.47
Hashtag ratio	0.087 (0.11)	0.16 (0.18)	<.001	0.49
Retweet ratio	0.29 (0.24)	0.49 (0.33)	<.001	0.69
Mention ratio	0.32 (0.23)	0.51 (0.32)	<.001	0.68
Number of mentions	0.85 (0.84)	1.26 (3.27)	<.001	0.17
Tweets with retweets ratio	0.34 (0.23)	0.53 (0.32)	<.001	0.68
Tweets per day	2.85 (3.69)	3.09 (3.56)	.82	0.07
Replies per day	1.29 (2.12)	1.06 (2.05)	.004	0.11
Retweets per day	0.87 (1.27)	1.63 (2.32)	<.001	0.41
Mentions per day	0.79 (1.20)	1.57 (2.31)	<.001	0.42
Hashtag engagement per day	0.20 (0.54)	0.54 (1.14)	<.001	0.38

[a]*P* values were calculated using a 1-tailed 2-sample *t* test, with $P \leq .05$ indicating statistical significance, and the effect size is reported using the Cohen *d*.

[b]FF: follower-to-followee.

Discussion

Principal Findings

This study characterized the GAD digital markers using social media content and behavior analysis of individuals with GAD. The results show the importance of studying psychological states reflected in language. Investigating the word use patterns in people with GAD revealed differences in all the defined measurements (ie, cognitive style, personal needs, and emotional expressiveness) compared to individuals without GAD. First, all measurements of cognitive style were higher for those with GAD, including certainty, discrepancy, and tentativeness, which may reflect several GAD markers. One possible explanation for why users with GAD expressed more certainty is that they have difficulty dealing with uncertainty, which is aligned with the work by Miranda and Mennin [66]. Another possible reason is that people with GAD tend to have a negative outlook toward future events because of persistent anxiety [66]. The high number of tentative and discrepancy words in their tweets might be attributed to having difficulty putting worries aside or letting them go, having difficulty making decisions, and being indecisive, or it might also indicate inability to focus, consistent with the work by Koerner and Dugas [67].

In addition, individuals with GAD tended to use more memory words, which might reflect memory problems, including recalling and forgetfulness. This result might reveal some GAD symptoms (ie, difficulty concentrating and excessive worry) that may contribute to emerging memory issues, which is aligned with the work by Butters et al [68]. Second, we also found differences in personal needs regarding essential and self-esteem needs. All measurements of essential needs were higher for those with GAD. The increased use of word categories (ie, *want*, *need*, and *lack*) might indicate the desire to seek support and help or raise mental health awareness, which agrees with the work by Fine et al [69].

We also observed a higher number of references to food and death in the GAD group. This might indicate that GAD is more likely to be associated with unhealthy lifestyle behaviors, which is aligned with the work by Moselhy et al [70]. A possible reason for the increased use of food words in the GAD group might be the relationship between GAD and increased food intake, which agrees with the studies by Moselhy et al [70] and Fonseca et al [71]. Regarding self-esteem needs, people with GAD used fewer words related to rewards but more words related to curiosity and risk. This result might be explained by the fact that users who experience GAD have difficulty accomplishing tasks because of excessive anxiety, inability to focus, and overthinking, which is consistent with the work by Habib and Laidey [72].

Moreover, increased use of interpersonal conflict words and decreased use of communication words were observed in the GAD group. This might be due to being irritable and nervous, which are symptoms of GAD. Finally, the results also indicate differences in emotional expressiveness between the 2 groups. The increased negative tones, anger, anxiety, and sadness in tweets posted by individuals with GAD might be due to excessive anxiety, which is aligned with the work by Mennin

XSL•FO
RenderX

et al [73], which found difficulties in emotion regulation among people with GAD.

Our findings highlight the importance of thematic analysis in quantifying GAD signals. We found that users with GAD tended to post more about their symptoms, health status, life issues, friendship problems, and feelings. Interestingly, there were significant differences in all themes—symptoms, life problems, relationships, and feelings—between the GAD group and the control group. We note that relying on the *DSM-5* and previous work [64] related to the impact of GAD on individual life enhanced our analysis to generate themes more related to GAD, resulting in a detailed thematic analysis to distinguish GAD signals.

We found that the dominant themes in tweets posted by users with GAD tended to focus on life problems and relationships, followed by feelings and symptoms. This result may be explained by the fact that worsening symptoms and difficulty with emotion regulation contribute to difficulty handling life and relationship issues.

The other key finding was that GAD signals can be found in users' digital activities. The behavioral analysis focused on users' activities based on Twitter metadata regarding hashtag participation, volume, interaction patterns, social engagement, and reactive behaviors. We found that the GAD group used fewer hashtags than those without GAD, meaning that people with GAD might have fewer interactions with the public. These findings might indicate that people with GAD tend to be isolated by having fewer relationships and limiting their interaction with people, which is consistent with the work by Henning et al [64] and Revicki et al [74] that shows that GAD is associated with heightened social functioning impairment.

We also observed that people with GAD have different preferences regarding topics for participating in hashtags compared to users without GAD. We found that people with GAD preferred to participate more in hashtags related to mental health disorders and treatments. This might be due to their low mood or desire to seek support, raise mental health awareness, or overcome mental health stigma. The results also showed that users with GAD were more likely to follow hashtags about the latest news, which might reflect their low mood and contribute to heightened anxiety levels, which is aligned with the work by Cheun et al [75].

In addition, we found that users without GAD tended to have more followees, mentions, retweets, and hashtags. These findings might suggest that people with GAD are less active and tend to limit their interaction with others. This might reflect that people with GAD have impairments in relationships, which is in agreement with the work by Henning et al [64].

Moreover, this analysis measured the correlation between the GuidedLDA-based themes and users' behaviors. The results showed a high correlation between hashtag ratio and overall themes for the GAD group compared to the control group. For users with GAD, the results identified a high correlation between the mention ratio and the life problems and relationships themes, whereas the symptoms theme had a lower correlation with the mention ratio. This might indicate that the GAD group tends to discuss their health issues using related hashtags to obtain more attention and use mentions to seek direct help for life problems and relationship issues.

Our findings regarding language use patterns are consistent with the research presented in the studies by Coppersmith et al [25] and Shen and Rudzicz [29], which identify linguistic patterns for individuals with GAD. Regarding topic analysis, our study supports the conclusions of both the studies by Shen and Rudzicz [29] and Gkotsis et al [30] that individuals with GAD tend to focus on specific topics in their discussions. In our study, we comprehensively extended previous work by characterizing linguistic and thematic markers associated with GAD and providing a more detailed and in-depth examination of the textual content of individuals with GAD. Regarding the behavior analysis, previous studies [19,35,42,44] have covered the behaviors of individuals with a low mental health status on social media. Our exploration comprehensively analyzed how people with GAD interact and express themselves on the web. It highlights unique behavioral patterns that may contribute significantly to a deeper understanding of the disorder in the digital context. To the best of our knowledge, this is the first study that comprehensively explores the behaviors on social media of people with GAD, along with investigating the correlation between thematic content and users' behaviors on social media platforms. Therefore, our work aims to expand our understanding of the unique digital markers of GAD related to linguistic, thematic, and behavioral aspects.

It is worth noting that using publicly available social media data for mental health research raises ethical issues, including concerns about users' privacy and informed consent [45,46]. To address these ethical concerns, a comprehensive strategy to anonymize the collected datasets is essential to prevent the identification of users. This involves removing all identifiable information, such as usernames and real names, and paraphrasing tweets to ensure that there is no inferred information about those users [45,46].

Limitations

This study has a few limitations. First, we did not investigate the link between the mental health status of people with GAD and demographic characteristics, including age, gender, education, and employment status. These features cannot be retrieved from a user's profile using the Twitter API.

One limitation is that this study did not cover a user's medical and childhood history. Traumatic events in the early years of someone's life can negatively impact mental health throughout their life. Investigating a patient's medical history enhances the mental health diagnosis because it reveals their medical problems and the complications they went through, which may develop into psychological disorders. These factors contribute to increasing the likelihood of experiencing mental health disorders such as GAD.

Another limitation is that this study did not consider the severity of GAD on a scale from mild to severe. The severity of GAD may affect how it interferes with several aspects of daily living, so the degree to which GAD causes impairments may vary based on its severity. This study is also limited by the lack of

XSL•FO
RenderX

prospective data, which makes causal inference impossible; thus, only cross-sectional inferences can be drawn.

Regarding data collection, Twitter's API imposes limitations that might impact the comprehensiveness of collected datasets. According to the limit imposed by the Twitter API, only the 3200 most recent tweets can be retrieved. Another limitation in terms of the representativeness of the sample is that identifying potential members of a control group can pose a challenge as it might include individuals who experience GAD but choose not to disclose their diagnosis publicly. However, this study used a regular expression to search for self-reported diagnosis statements of a mental health disorder, which is a common technique used to identify individuals diagnosed with a mental health disorder on social media [24,40].

As future work, we intend to extend this study to conduct sentiment analysis of tweets, which could clarify any cues for GAD. In addition, a larger study could be conducted in which the data obtained from social media platforms could be combined with other information, such as medical history, gender, age, and employment status, to yield a more accurate picture of an individual's mental health and contribute to developing a robust GAD detection model via social media. Moreover, using more advanced NLP techniques beyond regular expressions to identify individuals with GAD could significantly enhance the ability to identify people with GAD via their social media posts. For instance, using machine learning models trained on a broader set of linguistic features allows for identifying markers of GAD effectively.

Conclusions

Our study provides several valuable insights into identifying the characteristics of GAD in social media networks. First, examining tweets from a linguistic perspective indicated that the language used by people with GAD reveals their mental health status. Second, thematic analysis of tweets highlighted which topics people with GAD tend to discuss more with others. Third, studying the behavior patterns showed how users with GAD interact with others, which provides more understanding of GAD.

In this study, we identified and characterized the digital markers associated with GAD by conducting a comprehensive analysis of social media activity from individuals diagnosed with GAD. Using content-based analysis techniques such as LIWC for linguistic analysis and GuidedLDA for thematic analysis, we thoroughly examined the language and themes in these individuals' social media posts.

Furthermore, we determined significant behavioral differences by analyzing user- and tweet-level features, such as hashtag participation and interaction patterns. We also investigated the correlation between the themes identified by GuidedLDA and various metadata for both the GAD and control groups within our dataset. Our findings include 47 distinct GAD digital markers, with results presented in terms of means, SDs, *P* values, and Cohen *d*, highlighting these markers' statistical significance and effect size.

In conclusion, understanding the behavior and tweet content of users diagnosed with GAD could help develop an assistant tool for diagnosis and recovery progress assessment to be used by mental health professionals. This assistant-diagnostic tool would integrate insights from patients' social media content and behaviors into personalized treatment plans. This approach may help clinicians develop timely updated personalized treatment plans by delivering continuous support and timely interventions, enhancing communication with health care providers, encouraging engagement in activities, and customizing coping techniques.

Abstract

Background: Adolescent cyberbullying has been a persistent issue, exacerbated by the shift to remote learning and increased screen time during the COVID-19 pandemic. These changes have sparked concerns about potential increases in cyberbullying and its associated risks.

Objective: This study aims to explore how factors such as age, exposure to violent media, parental communication quality, internet access, sex, and sibling relationships influence cyberbullying behavior at school. Additionally, we examine how the COVID-19 pandemic may have altered these dynamics.

Methods: Leveraging a panel dataset, we examine the same group of adolescents both before and during the pandemic. The analysis focused on identifying relationships between the selected factors and cyberbullying perpetration and victimization, with an emphasis on the dynamics introduced by the COVID-19 pandemic.

Results: Perceived quality of parental communication was found to reduce the risk of both cyberbullying perpetration and victimization, with the former effect becoming more pronounced during the COVID-19 pandemic. Exposure to violent media increased both cyberbullying perpetration and victimization, but the effect on perpetration decreased during the COVID-19 pandemic. The well-established correlation between internet access and both cyberbullying perpetration and victimization remained unaffected by COVID-19. Surprisingly, adolescents with siblings were less likely to become victims or perpetrators of school-related cyberbullying, irrespective of the pandemic.

Conclusions: In hindsight, COVID-19, functioning as a kind of natural experiment, has provided us with a unique opportunity to examine the effects of a global event, forcing major behavioral changes on the persistent challenge of cyberbullying in middle schools.

KEYWORDS

cyberbullying and cyber victimization among adolescents; COVID-19; panel study; longitudinal data analysis; parental communication; exposure to violent media content

Introduction

Overview

The global issue of adolescents' aggressive behavior has long been acknowledged as a significant concern, predating the outbreak of COVID-19. This pervasive issue has garnered considerable attention in the literature, with studies highlighting its profound impact on the well-being of young individuals [1-6]. With the advent of digital technologies and the widespread use of social media platforms, adolescents are increasingly

XSL•FO
RenderX

exposed to online harassment, encompassing various forms of aggressive behaviors such as spreading rumors, sending threatening messages, or posting hurtful content. The consequences of cyberbullying extend beyond the digital realm, negatively affecting adolescents' mental health, self-esteem, and overall psychosocial development. Research consistently links cyberbullying to heightened levels of anxiety, depression, and decreased self-esteem [7], as well as emotional distress among victims [3]. Moreover, the persistent nature of online harassment can lead to feelings of social isolation and a decline in academic performance [8-10]. The long-term consequences may manifest in a reluctance to engage in social interactions, thereby hindering the development of healthy peer relationships [11].

With the onset of COVID-19 and the subsequent surge in remote learning and screen time during the pandemic, concerns have emerged regarding the potential escalation of cyberbullying incidents. Within just 1 year after March 11, 2020, when the World Health Organization declared COVID-19 a pandemic, the first studies were published comparing the prevalence of cyberbullying perpetration and victimization before and during COVID-19. In 2023, the first systematic review [12] and meta-analysis on this comparison were published [13]. As summarized by Vaillancourt et al [2] in a recent overview, the results are contradictory, with studies reporting an increased, decreased, or stable trend in cyberbullying. Most of the studies involve comparing 2 cross-sectional surveys, one conducted before and one during the pandemic, with only a few comparisons based on panel data.

The objectives of this study are 3-fold. First, we aim to investigate whether and, if so, in which direction the trend of cyberbullying evolves with age. The second objective delves into several factors associated with changes in this trend. Specifically, we aim to explore the role of factors such as exposure to violent media content, the quality of parental communication, access to the internet, as well as the influence of sex and sibling relationships. The third objective is to assess the extent to which changes in the trend can be attributed to COVID-19: our unique time-series data enable us to do this by comparing the same adolescents in periods before and during the COVID-19 pandemic. The data collection for this study began in September 2017 and concluded in the summer of 2021, spanning 6 waves. While the richness and longitudinal nature of such a comprehensive panel study are clear advantages, they also present challenges: the data, particularly from the early waves, may appear outdated, and organizing such a large dataset requires substantial effort, making it challenging to publish findings immediately after data collection is completed.

Literature Review and Formulation of Hypotheses

We review the literature on cyberbullying perpetration and victimization, with particular attention to those covering the COVID-19 period, to derive a set of hypotheses to achieve the objectives listed above.

Cyberbullying and COVID-19

To understand the impact of COVID-19 on the prevalence of aggressive behavior among adolescents, it is necessary to examine trends predating the pandemic. Cyberbullying perpetration is intrinsically related to cyberbullying victimization, which refers to the experience of being targeted and harmed by cyber aggression—those who engage in cyberbullying may themselves become victims of retaliatory behaviors [14,15].

Several studies on bullying patterns suggest that cyberbullying was already a concern before COVID-19 [16-18]. With the advent of digital technology and social media platforms, there has been a gradual increase in the incidence of cyberbullying. A study conducted in the United States spanning the period 2010-2017 reported a consistent growth in cyberbullying [19]. However, longitudinal studies tracking adolescents over periods longer than 6 to 12 months are scarce, limiting our understanding of the factors contributing to this upward trend [15,20]. Adolescents are believed to be particularly vulnerable to cyberbullying due to their frequent use of smartphones and social networking sites, which provide perpetrators with anonymity and easy access to their targets. Research conducted in the years preceding the pandemic underscored the detrimental effects on adolescents' mental health, academic performance, and social relationships. A systematic review of cyberbullying studies conducted worldwide from the beginning of 2015 to December 2019 suggests a continuous increase—prevalence rates of cyberbullying victimization ranged from 6% to 46.3% in 2015, increasing to 13.99% to 57.55% in 2019 [21].

The role of age in adolescent cyberbullying presents mixed evidence. While certain studies have argued that both perpetration and victimization occur equally across different age groups [22], others have found that cyberbullying is particularly prevalent in middle schools, with incidents increasing after the fifth grade and peaking in the eighth grade [5,23,24]. One explanation for the mixed evidence might be that most studies are either cross-sectional or based on repeated survey designs.

There is an ongoing controversy regarding whether cyberbullying perpetration and victimization went up, remained stable, or decreased during the lockdown caused by COVID-19. While several studies have found an increase [18,25-29], a UNICEF report from 2020 indicates a 17% decrease in cyberbullying during the lockdown. Other studies report not only an overall decrease in cyberbullying perpetration, but also a decrease in victimization, at least for those adolescents with moderate social media use [30].

Besides the question of whether a real change occurred in both periods, and if so, in which direction, another query arises: if such a change did occur, is it due directly to the pandemic or to a shift in the main factors associated with cyberbullying before and during the pandemic? To address this issue, we include COVID-19 as an indicator variable to enable testing for interaction effects.

Considering the lack of longitudinal studies, it is not surprising that Vallaincourt et al [2] conclude that due to the predominantly cross-sectional design of existing studies, it is not possible to make definitive statements about true change. Given the inconclusive evidence regarding the impact of COVID-19 and the role of age, we formulate the following hypothesis:

XSL•FO
RenderX

Cyberbullying perpetration and victimization initially increase with age and then stabilize. The observed relationship is unchanged before and after COVID-19. [H1]

Use of Information and Communication Technologies and Exposure to Violent Media Content

The use of information and communication technologies has long been recognized as a notable risk factor linked to cyberbullying perpetration and victimization [11,31]. Particularly for adolescents aged 12 to 17 years, social networking sites provide a platform where approximately 85% have reported witnessing negative interactions [32]. The amount of time adolescents spend using information and communication technologies represents another crucial factor [14,33], in particular the time of exposure to antisocial media content which, in turn, predicts that an adolescent is more likely to engage in cyberbullying over time [34]. A recent systematic review and meta-analysis comprising 46 studies found a remarkably strong increase in screen time of nearly 1.5 hours per day compared with pre–COVID-19 levels, constituting a surge of approximately 52%. Adolescents aged 12 to 18 years contributed significantly to this trend [35]. Applications like TikTok, Pinterest, Reddit, Facebook, Snapchat, Instagram, LinkedIn, and Twitter have seen an increase in active users, ranging from 8% to 38% [36]. Additionally, a study analyzing data from Twitter users in 16 countries and information gathered from Reddit in one country highlights a substantial growth in abusive content on both platforms [37]. Based on this, we formulate the next 2 hypotheses.

Increased access to the internet increases both the perpetration and victimization of cyberbullying. The observed relationship is unchanged before and after COVID-19. [H2]

Increased exposure to violent media content increases both perpetration and victimization of cyberbullying. The observed relationship is unchanged before and after COVID-19. [H3]

Parental Communication, Siblings, and Sex

Meta-analytic research has demonstrated that a positive family environment serves as a protective factor against bullying (and cyberbullying) perpetration and victimization [38-40]. Conversely, a perceived lack of quality in parental communication has been linked to instances of adolescent bullying and cyberbullying [38,41-43].

Some scholars posit that the shift to remote learning during COVID-19, combined with a stressful economic environment, has heightened the burden on families as they navigate the challenges of childcare, education, and professional challenges [13,44]. The resulting stress may negatively impact the quality of parental communication [45]. We thus formulate the following hypothesis:

Higher quality of parental communication decreases both the perpetration and victimization of cyberbullying. The observed relationship is unchanged before and after COVID-19. [H4]

The impact of siblings on cyberbullying has not really been researched. Existing studies focus on bullying between siblings, rarely on the impact of siblings on bullying by schoolmates. For instance, Borualogo and Casas [46], in their study involving young adolescents aged 10-12 years in Indonesia, concluded that physical bullying between siblings increased during COVID-19 compared with prepandemic levels, while incidents of school bullying notably decreased. Given this lack of prior studies, we formulate the following explorative hypothesis:

Having siblings is a risk factor for cyberbullying perpetration and victimization at school. The observed relationship is unchanged before and after COVID-19. [H5]

Concerning sex, certain studies [22,47] argue that this does not predict cyberbullying victimization, while others [1,30,48,49] conclude that boys report more perpetration and girls report more victimization. We formulate the following hypothesis:

There is a higher rate of cyberbullying perpetration and a lower rate of victimization among boys compared to girls; the difference persists with aging. The observed relationship is unchanged before and after COVID-19. [H6]

Methods

Sample Participants and Procedure

Data for this research are drawn from a 6-wave panel survey conducted among middle school students in the Canton of Ticino, Switzerland, between 2017 and 2021. Ticino is the southernmost canton of Switzerland and the only one with Italian as the official language. It is considered one of the most prosperous regions in Switzerland and Europe [50]. On a global scale, Switzerland falls within the average range for bullying incidents in compulsory schools, as reported by the Programme for International Students Assessment (Organisation for Economic Co-operation and Development; 2019). Exactly 1 month after the World Health Organization had declared COVID-19 a pandemic on March 11, 2020, all middle schools of the Canton of Ticino were closed, and students transitioned to online learning modalities. Two months later, in May 2020, all students in compulsory school years returned to offline schooling.

At the start of the study in September 2017, a random sample consisting of 66% of all first-year public middle school classes across the 5 areas of the canton was selected. Private schools with more than 2 first-year classes were also invited to participate, and one of the 3 schools that met this criterion accepted the invitation. From this school, one of the 2 first-year classes was randomly selected for inclusion. Thus, the research encompassed 101 classes randomly chosen from 1 private and 35 public middle schools.

Data were collected through self-administered, paper-and-pencil questionnaires completed in class under the supervision of a teacher. The data from the 6 waves were matched using a unique identifier linked to each student's name, which only collaborating school staff accessed for survey distribution purposes. To protect participants' privacy, teachers were

XSL•FO
RenderX

instructed to place all completed questionnaires in an envelope and seal it in front of the students. The remaining missing data were due to absences on the day of data collection or students moving out of the canton. Students who changed schools were retained in our sample as long as they moved to another school and class included in our sample. However, if they transferred to a school outside the selected sample, they were no longer included in the study.

For this research, data collected on 6 different occasions were analyzed: November and December 2017 (T1), May and June 2018 (T2), November and December 2018 (T3), May and June 2019 (T4), October and November 2020 (T5), and May and June 2021 (T6). The observation time thus ranged from the beginning of the first grade to the end of the fourth grade. The average age was 13.22 (SD 1.33) years. At time point T1, ages ranged from 10.71 to 13.94 years, and at T6, from 14.21 to 17.44 years.

The first 4 waves took place before the COVID-19 pandemic, as initially scheduled. The last 2 had to be delayed due to the closure of schools in May 2020. The final random sample included 2052 students who were invited to participate in T1. Of these 2052 students, a total of 2022 (98.54%) participated at T1, 1879 (91.57%) at T2, 1896 (92.4%) at T3, 1865 (90.89%) at T4, 1871 (91.18%) at T5, and 1869 (91.08%) at T6.

Ethical Considerations

The survey was conducted with the approval and collaboration of the Cantonal Department for School Affairs (Divisione della scuola e l'Ufficio dell'insegnamento) and involved a representative sample of students. In addition to authorization from the cantonal school authorities, parents were informed about the study and given the option to exclude their children (passive consent). Less than 4% of students (n=75) did not participate due to parental objections. The institutional research board of the University della Svizzera Italiana (USI) did not consider the study to require approval, provided that the school authorities in the Canton of Ticino and the parents of the adolescents had approved the study. Informed consent was obtained from all adolescents prior to their participation in the study (29-01-2019Ls). The consent process included a clear explanation of the study's purpose, procedures, potential risks, and benefits, as well as assurances of confidentiality and the voluntary nature of participation. The adolescents were informed that they could stop filling in the questionnaire at any time. The study ensures the privacy and confidentiality of participants by maintaining all collected data in an anonymous or deidentified format. No personal identifiers are linked to the data. All study data are stored on servers with access restricted to authorized research personnel only, ensuring high level of privacy and confidentiality for participants. Participants did not receive any compensation for their participation in the study.

Variable Selection

Table 1 provides an overview of all variables used in our analysis; it is followed by a description of each measure.

Table 1. Variable description.

Variable	Scale	Description
Dependent variables		
Cybperp	1 (never) to 4 (often)	Perception of cyberbullying perpetration
Cybvic	1 (low) to 4 (high)	Perception of cyberbullying victimization
Independent variables		
Medexp	1 (never) to 5 (very often)	Exposure to violent media content
Parqual	1 (disagree) to 5 (agree)	Perceived quality of communication with parents
Siblings	0 or 1	Indicator variable: only child or 1 or more siblings
Age	Years	Age of participants
COVID	0 or 1	Indicator variable: before or after COVID-19
Sex	0 or 1	Indicator variable: male or female
Device	0 or 1	Indicator variable: no access (0) or access (1) to a device connected to internet
Control variables		
Parents	0 or 1	Indicator variable: child lives with none or one (0) or both (1) parents
Econf	1 (not at all well) to 5 (very well)	Self-reported (by students) economic status of household

Perpetration of Cyberbullying

Perpetration of cyberbullying (abbreviated as "Cybperp") was assessed on all 6 occasions using 6 of the 11 items from the European Cyberbullying Intervention Project Questionnaire [51] to evaluate the perpetration of aggressive acts online. For more details regarding the multi-item measurement scale, refer to Bullo and Schulz [34]. Measurement invariance of cyber peer aggression was tested in a structural equation modeling framework using confirmatory factor analysis, which demonstrated that all 4 levels of measurement invariance (from configural factorial over weak and strong factorial to strict factorial invariance [52]) can be assumed for the data. Additional details are provided in Bullo and Schulz [34]. For each item,

XSL•FO
RenderX

participants were asked to indicate how often—in the previous 6 months—they had engaged in these behaviors. The response scale went from "Never" (1) to "Often" (4). McDonald ω was used to assess the reliability of the measure, which ranged between 0.70 and 0.88.

Cyberbullying Victimization

Cyberbullying victimization (abbreviated as "Cybvic") was measured using 6 items selected from the European Cyberbullying Intervention Project Questionnaire project. Participants reported the frequency with which they had been victims of various forms of cyber aggression, including direct verbal aggression (eg, being insulted via texts or web-based messages; being threatened), relational aggression (eg, being excluded in the virtual world; being a victim of badmouthing or gossiping), and media-related aggression (eg, unwanted sharing of embarrassing pictures or videos). The response scale ranged from "Never" (1) to "Often" (4). McDonald ω was used to assess the reliability of the measure, which ranged between 0.84 and 0.88.

Exposure to Violent Media Content

Exposure to violent media content (abbreviated as "Medexp") was assessed by calculating an average score from 6 items regarding how often adolescents have watched media (including television, smartphones, video games, or the internet) depicting people fighting, destroying others' property, stealing, shooting, taking drugs, or drinking alcohol (1=never to 5=very often). McDonald ω was used to assess the reliability of the measure, which ranged from 0.89 to 0.93.

Parental Communication Quality

Parental communication quality (abbreviated as "Parqual") was measured using a slightly modified version of a scale developed by Guilamo-Ramos et al [53], which includes dimensions of perceived parental expertise, trustworthiness, and accessibility. The scale consists of 4 items rated on a 5-point scale from "Totally disagree" (1) to "Totally agree" (5), with higher values indicating higher perceived quality in adolescents talking to their parents. More details are provided in Bullo and Schulz [41]. Again, McDonald ω was applied to assess the reliability of the measure, which ranged from 0.60 to 0.75.

For all 4 multi-item measurement scales (cyberbullying perpetration and victimization, exposure to violent media content, and perceived parental communication quality), the unidimensionality of the measures was confirmed using confirmatory factor analysis [54].

Siblings

Furthermore, adolescents were asked how many brothers and sisters lived with them in their household. We used a 0 or 1 indicator, where 0 indicates an only child, and 1 indicates at least 1 sibling.

Age

This variable represents the adolescents' age, expressed in years.

COVID

This 0 or 1 indicator variable captures for each wave whether it took place before (0) or after (1) the school closure due to the COVID-19 pandemic.

Sex

This is an indicator variable, where 0 indicates male and 1 female.

Access to Communication Devices

Access to communication devices (abbreviated as "Device") was assessed by asking participants whether they possess a cellphone with or without internet access, a tablet or computer with internet access, a PlayStation, and whether they have a television in their room. The measure of access was defined as a 0 or 1 indicator, a value of 1 indicating that the child has access to at least 1 device with internet access.

Parental Status

Parental status (abbreviated as "Parents") was assessed by asking adolescents whether they lived with both, one, or none of their parents. We used a 0 or 1 indicator, where 0 indicates that they live with at most one of their parents, and 1 indicates they live with both parents.

Perceived Economic Status of the Family

The perceived economic status of the family (abbreviated as "Econf") was assessed during the first data collection by asking students to indicate how financially well off their family is on a scale from "Not well at all" (1) to "Very well" (5).

Descriptive Statistics

Table 2 presents a demographic profile of the sample, together with means, SDs, and indices of skewness and kurtosis for key variables used in the formal models we tested.

XSL•FO
RenderX

Table 2. Descriptive statistics. Longitudinal assessment of cyberbullying perpetration, cyberbullying victimization, violent media exposure, perceived quality of parental communication, siblings, age, sex, parental status, internet access, and self-reported economic status of the household.

Statistics	T1	T2	T3	T4	T5	T6

Statistical Methods

Two mixed-effect models were set up for the 2 dependent variables, namely “Cybperp,” and “Cybvic.” The independent variables were “Age,” “COVID,” “Sex,” “Siblings,” “Medexp,” “Parqual,” and “Device.” For the variable age, a polynomial of order 3 was fitted to test the variation of the effect. The 2-way

XSL•FO
RenderX

interactions between "COVID" and the other variables were included, as well as between "Age" and "Sex." The 3-way interaction between "COVID," "Age," and "Sex" was also included. A random intercept per participant was included in the model to account for the repeated measure framework. Finally, "Econf" and "Parents" were included as control variables. The models were fitted using the statistical software R (R Foundation for Statistical Computing) and its package *lme4* [55]. Multiple comparisons were performed using package *emmeans* [56] and Sidak-adjusted *P* values. Once fitted, a selection of variables was performed by removing the nonsignificant ones according to ANOVA *F* tests. These results are given in Tables S1 and S2 in Multimedia Appendix 1. Missing data cases were discarded. Cases were fixed based on the most complete model before the model selection. For the analysis, complete cases for the selected model's features were used.

Results

Overview

The victimization and perpetration model coefficients are given in Tables S3 and S4 in Multimedia Appendix 1. To test H1 and H6, which involve age, we set the comparisons at the mean age, minus and plus 1 SD, that is, at 11.8, 13.1, and 14.5 years. The results are presented below, per hypothesis, first for victimization and then for perpetration.

Hypothesis 1

Victimization

The hypothesis is validated for female individuals, but only partially for male individuals (Table S5 in Multimedia Appendix 1).

Indeed, for female individuals, the observed increase in victimization by "Age" is significant between 11.8 and 13.1 years (≈0.07, z=3.83, P<.001) and nonsignificant between 13.1 and 14.5 years (≈0.03, z=0.88, P=.62). For male individuals, this increase is significant in both cases (≈0.13, z=7.17, P<.001; ≈0.16, z=4.98, P<.001). As expected, there is no difference between before and after COVID-19, as no interaction involving "COVID" and "Age" is significant.

Perpetration

The hypothesis is validated for female and male individuals (Table S6 in Multimedia Appendix 1). Indeed, the observed increase in perpetration by "Age" is significant between 11.8 and 13.1 years (male: ≈0.04, z=3.53, P<.001; female: ≈0.04, z=3.04, P<.01) and nonsignificant between 13.1 and 14.5 years (male: ≈0.03, z=1.59, P=.21; female: ≈0.00, z=–0.08, P>.99). As expected, there is no difference between before and after COVID-19, as no interaction involving "COVID" and "Age" is significant.

Hypothesis 2

Victimization

The hypothesis is validated as the difference in victimization between with and without access to the internet is significant (≈0.09, z=5.03, P<.001; Table S7 in Multimedia Appendix 1). Without significant interaction between "COVID" and "Device," this effect remains unchanged, as expected.

Perpetration

The hypothesis is validated as the difference in perpetration between with and without access to the internet is significant (≈0.07, z=4.48, P<.001; Table S8 in Multimedia Appendix 1). Without significant interaction between "COVID" and "Device," this effect remains unchanged as expected.

Hypothesis 3

Victimization

The hypothesis is validated. Indeed, the effect of "Medexp" is significant and positive (≈0.06, t_{5791}=11.7, P<.001; Table S9 in Multimedia Appendix 1). Without significant interaction between "Medexp" and "COVID," this effect remains unchanged as expected.

Perpetration

The hypothesis is validated. The effect of "Medexp" is significant before and after COVID-19 (before: ≈0.09, z=16.88, P<.001; after: ≈0.07, z=10.32, P<.001; Table S10 in Multimedia Appendix 1). Although the effect remains significant and positive before and after COVID-19, the difference in the slope is mildly significant (≈0.02, z=2.06, P=.04; Table S11 in Multimedia Appendix 1). Thus, the effect of "Medexp" on cyberbullying perpetration decreased after COVID-19, contrary to our expectations.

Hypothesis 4

Victimization

The hypothesis is validated. The effect of "Parqual" is significant and negative (≈–0.06, t_{5789}=–8.9, P<.001; Table S9 in Multimedia Appendix 1). Without interaction between "COVID" and "Parqual," the relationship did not change after COVID-19.

Perpetration

The hypothesis is validated. Both before and after COVID-19, the effect of "Parqual" is negative and significant (before: ≈–0.02, z=–4.00, P<.001; after: ≈–0.05, z=–5.20, P<.001; Table S12 in Multimedia Appendix 1). In addition, contrary to our expectation, this deterring effect significantly increased after COVID-19 (≈0.03, z=2.34, P=.02; Table S13 in Multimedia Appendix 1).

Hypothesis 5

Victimization

The hypothesis is not validated. The effect of "Siblings" is significant and negative (≈–0.05, t_{2640}=–2.80, P<.01; Table S9 in Multimedia Appendix 1). Contrary to our expectations, the data indicate that having siblings is a protective factor: those with siblings are less likely to become victims of cyberbullying at school compared with those without siblings. As there is no significant interaction between "Siblings" and "COVID," this effect is the same before and after COVID-19.

XSL•FO
RenderX

Perpetration

The hypothesis is not validated. As for victimization, the effect of "Siblings" is significant and negative (≈–0.03, t_{2714}=–2.26, P=.02; Table S14 in Multimedia Appendix 1). Again, contrary to our expectations, the data indicate that having siblings is a deterring factor. Without significant interaction between "Siblings" and "COVID," that effect is the same before and after COVID-19.

Hypothesis 6

Victimization

The hypothesis is partially validated. The expected lower rate for male individuals is mildly significant at early age before COVID-19 (male – female; age 11.8 years; ≈–0.05, z=–2.78, P=.03; Table S15 in Multimedia Appendix 1) but not afterward (male – female; age 11.8 years; ≈–0.19, z=–2.63, P=.05). At any other age, before and after COVID-19, differences were not significant.

Perpetration

The hypothesis is not validated. There is no difference between male and female individuals at any age (Table S16 in Multimedia Appendix 1). In addition, without interaction between "COVID" and "Age" and between "COVID" and "Sex," this nonrelation remains the same before and after COVID-19.

Discussion

Principal Findings

The focus of our study is on the question of whether COVID-19 has changed the relationship between cyberbullying and several of its drivers, among adolescents. We were particularly interested in whether COVID-19 has made these relationships more pronounced, whether they have remained unchanged, or whether they have been mitigated. These questions are not primarily important because of the current demand for an analysis of COVID-19 and its impact on social life [57]. Rather, it is also expected that an unforeseen event like COVID-19 could lead to a better understanding of the factors associated with the increasing challenge of cyberbullying in schools [58]. Ultimately, this also involves the expectation of gaining a better understanding of the phenomenon of cyberbullying among adolescents.

Regarding our first hypothesis, namely the increase in cyberbullying victimization among adolescents with age, our data confirm this effect, known from previous studies, at least for the early middle school years, when adolescents are between 11 and 13 years old. This effect applies equally to girls and boys. However, from the age of 13 years onward, this seems to change, as the increase in cyberbullying victimization among girls is no longer significant, while cyberbullying perpetration among boys continues to grow.

When interpreting these data, it is important to note that the end of the increasing trend in cyberbullying victimization coincides with the onset of COVID-19. Therefore, it is difficult to determine to what extent the end of the increase among girls or the continuing upward trend among boys is attributable to age and how much is due to the onset of COVID-19. Previous studies on cyberbullying victimization have shown that this trend ends at a certain age among adolescents. It is also challenging to comment on the magnitude of this effect. In other words, it is unclear how strong the increase in cyberbullying victimization among boys would have been if COVID-19 had not occurred.

As to our second hypothesis, there is a well-documented correlation, supported by numerous studies [59], between adolescents owning devices that provide internet access and cyberbullying perpetration and victimization: when adolescents have access to a device that allows them to go online, the likelihood of them becoming a victim or perpetrator of cyberbullying rises. This correlation was observed in our study as well, both before and during the outbreak of COVID-19, with no significant change in the strength of this relationship during the pandemic.

It is important to consider that even without personal internet-enabled devices, adolescents can still fall victim to or engage in cyber aggression, for example, by using internet access on school computers. Moreover, by the end of middle school, only a small number of students in our study still lacked a device that enabled them to access the internet. Nevertheless, the lack of a personal internet-enabled device remains a protective factor, regardless of the age at which adolescents acquire such a device.

Regarding the relationship between exposure to violent media content and the perpetration or victimization of cyberbullying among adolescents, previous meta-analytical studies [14,20,24,60,61] provide strong evidence supporting this link. Children highly exposed to violent media content ("Medexp"=5) have on average a victimization score of 0.25 larger than nonexposed children ("Medexp"=1). This is a major increase, as the average "Cybvic" score ranges between 1.15 and 1.34 for the different data-collection waves. The impact of violent media exposure is even larger for the perpetrators: a score increase of 0.33 and 0.28 before and during COVID-19, respectively, when "Medexp" increases from 1 to 5, compared with average scores ranging between 1.10 and 1.26.

The debate often centers on how violent media content leads to such behaviors, whether through imitation or other mechanisms [20,61]. Therefore, it is not surprising that our study also confirms this association. Longitudinal studies do not provide insights into causal relationships between exposure to violent media content and cyberbullying perpetration or victimization. However, it is notable that the effect of violent media exposure on cyberbullying remains substantial and persistent over the 4 years of our study. Additionally, this effect appears to diminish during COVID-19. This reduction cannot be explained by the age-related decrease in cyberbullying tendencies discussed in hypothesis 1, but rather seems to be an interaction effect that lessens during the pandemic. In this sense, one might consider it a positive effect of COVID-19: the pandemic has reduced the impact of exposure to violent media content on aggressive behavior. The exact reasons for this reduction in the relationship between exposure to violent media and cyberbullying

XSL•FO
RenderX

victimization or perpetration, before and during COVID-19, remain unclear, but could be understood through Social Learning Theory: during COVID-19, changes in social contexts (eg, increased time spent at home and less face-to-face peer interaction) might have altered how adolescents process and enact behaviors learned from violent media. The reduced opportunities for social interaction and confrontation in physical spaces may have diminished the translation of media-inspired aggression into actual cyberbullying acts.

Hypotheses 2 and 3 are not unrelated, as access to internet and exposure to violent media are intrinsically linked. The finding that possessing an internet-enabled device consistently increases the likelihood of adolescents becoming victims or perpetrators of cyberbullying, with no significant change before and during COVID-19, can be explained by the general aggression model [24,62-64], which posits that exposure to aggressive stimuli (including violent media or environments) can increase aggressive thoughts, feelings, and behaviors. Access to the internet via a device provides a platform where aggressive behavior can be exhibited. The presence of a device enables easier access to both aggressive content and opportunities for cyberbullying, maintaining a consistent risk factor for both victimization and perpetration regardless of external circumstances like the pandemic.

Another possible explanation comes from Cohen and Felson's [65] routine activity theory [66], which suggests that the changes in routine activities, such as increased parental supervision, reduced peer interaction, and changes in web-based activities, may have disrupted the conditions that facilitate cyberbullying perpetration. The decrease in the effect of violent media on perpetration could be because adolescents were less motivated to act aggressively or had fewer opportunities to engage in cyberbullying due to increased monitoring and altered social dynamics.

Our hypothesis 4, namely the assumption that a higher quality relationship with parents serves as a protective factor for adolescents, making them less likely to fall victim to or become a perpetrator of cyber aggression, has largely been confirmed. Interestingly, the protective effect of positive parental communication in preventing adolescents from becoming victims of cyber aggression is comparable in magnitude to the harmful impact of exposure to violent media content. On average, an increase of 1 unit in exposure to violent media content can be offset by an equivalent increase in the perceived positive quality of the relationship between adolescents and their parents.

What is particularly noteworthy, however, is that a positive relationship with parents not only acts as a protective factor against becoming a victim of cyber aggression but also seems to have a (more limited) deterrent effect on adolescents' aggressive behavior toward others in cyberspace. This deterrent effect, although inferior to the impact of exposure to violent media, doubled during the COVID-19 crisis compared with the period before the pandemic.

We suggest that this finding can be explained through various theoretical perspectives. First, social control theory [67] posits that strong social bonds, such as those with family, serve as a deterrent to deviant behavior, including cyberbullying. During the pandemic, adolescents may have experienced increased stress, uncertainty, and isolation. In such a context, the role of positive communication with parents likely became more crucial in maintaining social control and discouraging deviant behavior. The intensification of family interactions due to lockdowns and restrictions may have strengthened these social bonds, leading adolescents to rely more on their parents for emotional support and guidance, thereby enhancing the protective effect against cyberbullying.

Another explanation comes from stress and coping theory, which posits that individuals cope with stress in various ways, including seeking support from social relationships [68]. Adolescents who could communicate positively with their parents may have experienced better emotional regulation and lower stress levels, reducing the likelihood of resorting to cyberbullying as a maladaptive coping strategy [69].

Regarding our fifth hypothesis, the results were contrary to our expectations: the data indicate that having siblings acts as a protective factor. Adolescents with siblings are less likely to become victims of cyberbullying at school than those without siblings. The magnitude of this protective effect is slightly lower than that observed in our previous hypotheses, suggesting that having siblings is, on average, equivalent to improving parental communication or decreasing exposure to violent media content by a bit less than 1 point on their respective scales. Similarly, our data show that having siblings also acts as a deterrent against becoming a cyberbully, although to a lesser extent, comparable to an increase of 1 point in the quality of parental communication, but much less than a decrease of 1 point in media exposure. We found no change in the effect of having siblings before and after the COVID-19 pandemic.

One possible explanation for these findings comes from the buffering hypothesis in social support theory [70,71], which posits that social relationships can buffer the impact of stressful events. Within this framework, siblings can offer emotional support, companionship, and a sense of belonging, which may protect against the isolation that can make a child more vulnerable to bullying [72].

Finally, based on findings from similar studies [73-75], we hypothesized that boys would exhibit a higher rate of cyberbullying perpetration, and a lower rate of victimization, compared with girls, with these differences persisting as they age. However, the lower rate of victimization among boys was only observed in the very early stage when they were around 11 years old. As they aged, the difference in victimization rates between boys and girls diminished and had already disappeared before the onset of COVID-19. Regarding the perpetration rate, no significant difference was found between male and female individuals.

Concluding Remarks

In summary, we can conclude that COVID-19 likely had a limited overall impact on both cyberbullying perpetration and victimization. Moreover, while certain factors were identified as either increasing or decreasing the likelihood of

XSL•FO
RenderX

cyberbullying, COVID-19 only partially influenced these relationships.

However, in certain cases, this impact is noteworthy. On the one hand, the perceived positive relationship with parents reduces both the risk of becoming a victim of cyberbullying and the likelihood of exhibiting aggressive behavior toward other adolescents, with the latter effect becoming more pronounced during COVID-19 compared with the period before. Notably, a positive relationship with parents served as a protective factor, reducing both the risk of cyberbullying victimization and the likelihood of engaging in cyberbullying. This protective effect was even stronger during the pandemic. These findings reaffirm previous research highlighting the role of family in mitigating cyberbullying risks [44] and emphasize its importance during times of crisis, such as COVID-19.

On the other hand, exposure to violent media was associated with increased rates of both cyberbullying perpetration and victimization, but interestingly, the effect of cyberbullying perpetration lessened during the pandemic. This suggests that while increased violent media consumption during an unexpected crisis may contribute to cyberbullying victimization, it does not necessarily translate into a rise in web-based aggressive behaviors. Additionally, an unexpected finding of our study revealed that adolescents with siblings were less likely to be involved as either victims or perpetrators of cyberbullying, independent of the pandemic's influence.

The question of whether COVID-19 impacted cyberbullying behavior has been widely discussed in numerous studies. A recent systematic review and meta-analysis [13] concluded that, based on pooled prevalence rates, the pandemic led to a significant reduction in overall cyberbullying perpetration. However, as the authors caution, the lack of longitudinal studies limits the ability to draw definitive conclusions about the underlying factors driving these changes. Only a few studies, such as those by Huang et al [13] and Vaillancourt et al [2], have compared cyberbullying behaviors in the same group of participants before and during COVID-19, and even then, these studies involved only 2 or 3 waves of data collection.

In contrast, our study, which spans 6 waves—4 before and 2 during the pandemic—offers a more comprehensive picture. By tracking the same participants over time, we were able to estimate both the baseline rates of cyberbullying perpetration and victimization and the changes in these behaviors before and during the pandemic. Furthermore, we examined key contributing factors that either increase the likelihood of cyberbullying or act as protective measures. A particular strength of our panel study is the consistent use of the same measures for both cyberbullying outcomes and predictors across all 6 waves, allowing for a more robust analysis of trends over time.

Limitations

Our study has several limitations due to the specific nature of our dataset. First, the sudden outbreak of the COVID-19 pandemic disrupted our planned data collection. While we were able to gather data from students at the start and end of each school year during the 4 pre–COVID-19 phases, this regularity was not maintained once the pandemic began. Data collection only resumed when students returned to school, resulting in an unbalanced distribution of waves between the prepandemic and postpandemic periods.

Second, our analysis is at a cohort level. We did not examine whether cyberbullying victims and perpetrators belong to specific groups, nor did we analyze the extent to which victims and perpetrators might be the same individuals, possibly at different points in time.

Finally, a strength of our dataset is that it is a panel study, following the same people over several years. The study includes 4 pre–COVID-19 waves (participants aged roughly 11-15 years) and 2 post–COVID-19 waves (participants aged roughly 14-17 years). The drawback is that we have few older adolescents before COVID-19 and few younger ones after COVID-19, which may be the cause of the lack of significance (large CIs) of certain age-related hypotheses.

In hindsight, COVID-19, functioning as a kind of natural experiment, has provided us with a unique opportunity to examine the effects of a global event, forcing major behavioral changes, on the persistent challenge of cyberbullying in middle schools.

Abstract

Background: The societal and public health costs of problematic use of the internet (PUI) are increasingly recognized as a concern across all age groups, presenting a growing challenge for mental health research. International scientific initiatives have emphasized the need to explore the potential roles of personality features in PUI. Compulsivity is a key personality trait associated with PUI and has been recognized by experts as a critical factor that should be prioritized in PUI research. Given that compulsivity is a multidimensional construct and PUI encompasses diverse symptoms, different underlying mechanisms are likely involved. However, the specific relationships between compulsivity dimensions and PUI symptoms remain unclear, limiting our understanding of compulsivity's role in PUI.

Objective: This study aimed to clarify the unique relationships among different dimensions of compulsivity, namely, perfectionism, reward drive, cognitive rigidity, and symptoms of PUI using a symptom-based network approach.

Methods: A regularized partial-correlation network was fitted using a large-scale sample from the United Kingdom. Bridge centrality analysis was conducted to identify bridge nodes within the network. Node predictability analysis was performed to assess the self-determination and controllability of the nodes within the network.

Results: The sample comprised 122,345 individuals from the United Kingdom (51.4% female, age: mean 43.7, SD 16.5, range 9-86 years). The analysis identified several strong mechanistic relationships. The strongest positive intracluster edge was between reward drive and PUI4 (financial consequences due to internet use; weight=0.11). Meanwhile, the strongest negative intracluster edge was between perfectionism and PUI4 (financial consequences due to internet use; weight=0.04). Cognitive rigidity showed strong relationships with PUI2 (internet use for distress relief; weight=0.06) and PUI3 (internet use for loneliness or boredom; weight=0.07). Notably, reward drive (bridge expected influence=0.32) and cognitive rigidity (bridge expected influence=0.16) were identified as key bridge nodes, positively associated with PUI symptoms. Meanwhile, perfectionism exhibited a negative association with PUI symptoms (bridge expected influence=–0.05). The network's overall mean predictability was 0.37, with PUI6 (compulsion, predictability=0.55) showing the highest predictability.

XSL•FO
RenderX

Conclusions: The findings reveal distinct relationships between different dimensions of compulsivity and individual PUI symptoms, supporting the importance of choosing targeted interventions based on individual symptom profiles. In addition, the identified bridge nodes, reward drive, and cognitive rigidity may represent promising targets for PUI prevention and intervention and warrant further investigation.

Introduction

Problematic use of the internet (PUI) is characterized by excessive and maladaptive internet use that leads to significant functional impairment and distress [1]. PUI encompasses a variety of potentially harmful online behaviors such (but not limited to) as excessive gaming, viewing pornography, social networking, and streaming content consumption [2]. It is recognized as a global public health concern, receiving increasing attention from mental health researchers, clinicians and policy makers [1,2]. A recent meta-analysis showed that the rate of PUI is estimated to be 14.2% globally [3], though estimates vary depending on the operational definition of PUI. Mental and physical impairments associated with PUI are well-documented, including depression, anxiety, musculoskeletal problems, and digital eye strain [4-7]. Given the high rates and associated impairments of PUI, it is important to understand the underpinning mechanisms.

Clarifying the role of intrapersonal risk factors (eg, personality traits) in PUI has been identified as a research priority for understanding PUI [1,2]. Compulsivity is defined as the tendency toward repetitive actions that persist despite such actions being inconsistent with one's overall goal and associated negative consequences [8,9]. It is considered a hallmark feature of addictions and obsessive-compulsive disorder [10] and has been consistently linked to PUI [11-14]. For instance, recent evidence suggests that compulsivity may be more closely related to PUI than other well-established risk factors (ie, impulsivity traits [15]).

Compulsivity is oftentimes treated as a unitary construct when estimating its relationships with PUI. However, recent evidence suggests that compulsivity can be decomposed into various distinct but interrelated dimensions. Specifically, a large-scale network-based study [16] has shown that compulsivity may be composed of 3 dimensions: perfectionism (having high personal standards and striving to reach those standards), reward drive (approach tendencies toward immediate gratification and acting on urges) and cognitive rigidity (rigid and repetitive thinking patterns and behaviors). These distinct dimensions of compulsivity likely have different relationships with PUI. For instance, individuals high on reward drive may be more driven to use the internet for its rewarding features (eg, obtain social rewards, online gambling, and cybersex [17-19]). Alternatively, individuals high in cognitive rigidity may find it harder to redirect their attention away from internet-related cues and thoughts and may be prone to activities such as checking the internet due to health-related anxieties (ie, cyberchondria [20]). Finally, individuals high in perfectionism may be inclined to use the internet as a way to cope with the discrepancy between their ideal and actual life achievements [21]. Identifying how different compulsivity dimensions are differently linked with PUI may offer important insights into the mechanistic relationships between compulsivity and PUI.

Further, there is a lack of understanding of the specific symptom pathways between compulsivity dimensions and PUI. Using symptom sum scores as an index for PUI is a common practice when estimating the relationship between compulsivity and PUI. However, recent studies have demonstrated that PUI symptoms differ from each other in their relation to risk factors [15,22,23]. For instance, it has been found that compulsivity is more closely related to PUI symptoms characterized by negative consequences (eg, failure to fulfil role obligations [15]) than other PUI symptoms, such as staying online longer than intended, hiding online time from others or acting aggressively when being disrupted during online time. In addition, it has been observed that individuals with PUI symptoms characterized by continued or escalated usage report experiencing less fear of missing out [24]. Understanding these more specific relations may facilitate a more precise understanding of specific mechanisms underlying different PUI symptom profiles.

A network approach may be particularly useful to address the aforementioned issues and provide a more precise understanding of the relations between different dimensions of compulsivity and symptoms of PUI. The network approach to psychopathology posits that mental conditions can be conceptualized as a complex network, constituted by a set of nodes (eg, item-level characteristics and symptoms) and edges that connect them [25,26]. Accordingly, the associated analytic techniques focus on pinpointing specific and distinct relationships between nodes (eg, dimensions of compulsivity and symptoms of PUI) and visualizing these relationships in insightful ways [27]. Hence, the utilization of the network approach moves beyond examining how compulsivity traits may be associated with the PUI construct (indexed by the symptom sum score) to elucidate differential relationships between compulsivity dimensions and specific symptoms of PUI.

It is worth noting that the network approach also provides novel indices to identify influential nodes that may serve as targets of therapeutic intervention. The bridge expected influence calculates the sum of connectivity of a given node to all nodes of the other cluster (a subset of nodes in the network with denser connections among themselves, forming a subnetwork [28]). Nodes that exhibit high bridge centrality (bridge nodes) are

XSL•FO
RenderX

deemed to be integral to the co-occurrence of constructs, given their extensive interconnectivity with all components of the other constructs [25]. Theoretically, targeting such nodes has the potential to impede the transmission of activation from one construct to another [25,29]. Accordingly, it has been proposed that nodes with high bridge centrality may be ideal candidates for intervention. Given that PUI treatments (both psychological and pharmacological) are still in their infancy, such understanding is both timely and critical to push this field forward.

There is a paucity of research on the relationship between dimensions of compulsivity and PUI symptoms. The current study is the first attempt to fill the knowledge gap using a symptom-based network approach. By investigating the network structure and bridge centrality index, the current study aimed to (1) elucidate the distinct relationships between dimensions of compulsivity (ie, perfectionism, reward drive, and cognitive rigidity) and PUI symptoms, (2) quantify the extent to which each dimension of compulsivity is related to the PUI symptom cluster and identify bridge nodes, and (3) examine the controllability of each node within the network.

Methods

Participants and Procedure

The sample included 122,345 individuals (51.4% female) from the United Kingdom, with a mean age of 43.7 (SD 16.5, range 9-86) years, who participated in the online Great British Intelligence Test (GBIT). The GBIT is a collaborative citizen science project with BBC two Horizon Program, designed to investigate cognition and well-being in the general population. The study was an open, web-based survey using convenience sampling, accessible to all UK residents. It was promoted across BBC media channels, both online and offline, to recruit participants. Interested individuals could access the study through links provided in mainstream media and news articles, which directed them to the study's landing page on the Cognition website. The recruitment for the GBIT study commenced in December 2019, with the specific sample used in this paper recruited between May and June 2020. For the current study, we focused solely on individuals who provided complete responses for both measures. The compulsivity measure was introduced during a later phase of the GBIT. Among the 122,680 participants who took part after the compulsivity measure was included, only a small proportion of responses were missing, specifically, 335 for the compulsivity measure and 45 for PUI items. These incomplete responses were excluded from the data analysis.

Measures

Trait Compulsivity

The Cambridge-Chicago Compulsivity Trait Scale (CHI-T; [30]) was used to measure trait compulsivity. The CHI-T contains 15 items, which cover 3 dimensions of compulsivity (perfectionism, cognitive rigidity and reward-drive; [16]). The perfectionism subscale covers self-oriented perfectionism, which features having high personal standards and striving for perfection and "just right" (eg, "completion to a high standard" and "doing things just right"). The cognitive rigidity subscale covers the inability to change behaviors or mindset (eg, "repetitive thoughts" and "being stubborn or rigid"). The reward drive subscale covers approach tendencies toward immediate gratification and acting on urges (eg, "acting on urges" and "seeking immediate reward"). We have opted for the subscale score over the item score due to practical considerations. Currently, interventions for individual items of the CHI-T scale are undeveloped. In contrast, targeted therapies for specific subscales, like attentional bias modification therapy, already exist and may effectively reduce reward-drive tendencies. Therefore, using the subscale score may enhance the applicability of our findings in future intervention development.

PUI Symptoms

PUI symptoms were measured by 7 items based on expert consensus (Hampshire et al [31]). The items measure internet checking, internet use for distress relief, internet use for loneliness or boredom, financial consequences due to internet use, prioritizing internet use over role obligations, compulsion and failed attempts to cut down, in the past 4 weeks. Response options range from 0 (never) to 6 (more than hourly every day).

Data Analysis

Descriptive statistics were calculated for demographic variables, CHI-T subscales, and PUI items. Before conducting our formal analysis, we used the goldbricker function to check for significant topological overlap among nodes, which identifies pairs with highly similar connectivity patterns, indicative of duplicates [32]. Specifically, we looked for node pairs with a topological overlap exceeding 80%, which corresponds to less than 20% difference in their connectivity patterns (significant at $P<.01$). No topological overlap was identified (nor was it for the detailed item-level analysis in the supplement). We constructed a regularized partial correlation network, where the variables (ie, the 3 dimensions of compulsivity and individual PUI symptoms) are represented as nodes. The edges between nodes represent regularized partial correlations, controlling for all other variables within the network. The Graphical Least Absolute Shrinkage and Selection Operator algorithm was applied for regularization [33]. The regularization procedure forces weak or spurious partial correlations to become exactly zero, leading to a sparse network where only the most robust edges are retained [33]. Following recommendations from [33], we set the tuning parameter (γ) for regularization to 0.5, which balances the trade-off between model fit and sparsity of the network.

The Fruchterman-Reingold layout algorithm was used for network visualization [34]. Within each network, strongly related nodes were placed closer together, while weakly related nodes were placed further apart. The magnitudes of partial correlations (edge weights) are reflected as edge thickness, with thicker edges indicating stronger partial correlations between nodes. Blue edges represent positive partial correlations, and red edges represent negative partial correlations between nodes. The visualization procedures were conducted via the "qgraph" package in R (R Core Team) [34]. To enhance visual clarity, we adjusted the scaling of edge widths and color saturation using the cut argument. The improved visual representation of

XSL•FO
RenderX

the network is available (Figure S5 in Multimedia Appendix 1).

We used the "networktools" package [32] to quantify to what extent each compulsivity dimension was related to the PUI symptom cluster and identify influential bridge nodes. Number of 2 clusters (subnetworks) were predefined for the network, namely, the compulsivity cluster (consisting of 3 compulsivity dimensions) and the PUI community (consisting of PUI items). Bridge expected influence (ie, the sum of the edge weights connecting a given node to all nodes in the other cluster; [25] was computed for each node. The compulsivity dimension with a high positive bridge expected influence is positively related to the PUI symptom cluster. Conversely, the compulsivity dimension with a negative bridge expected influence is negatively related to the PUI symptom cluster.

We also examined the predictability of nodes, assessing how well a specific node can be predicted by all other nodes within the network [35,36]. Since all the variables included are continuous, we selected R^2 as the measure of predictability for the estimated network. A node with higher predictability suggests that a larger proportion of its variance can be explained by other nodes in the network [35]. Further, we also computed the mean predictability across nodes within the network. This allows us to determine whether, on average, the variance observed in the nodes of the network can be explained by other nodes within the network [35,36]. A high mean predictability indicates that a network is largely determined by internal nodes within itself [35,36].

To estimate the accuracy and stability of the network model, we followed the steps described in [37]. First, we bootstrapped 95% CIs (with 10,000 bootstrap samples) of edge weights to determine the accuracy of the estimated edges within each network. Second, we estimated the stability of edges and bridge centrality using the case-dropping bootstrap procedure (with 10,000 bootstrap samples) and calculated the correlation stability coefficient (CS-coefficient) for edge weight and bridge expected influence. An acceptable CS-coefficient should be above 0.25, and a value of 0.5 or higher indicates optimal stability. Finally, in alignment with the tutorial paper [37], we examined whether the weights for each edge and the bridge centrality estimates for each node differ significantly (α=.05) from one another. This was achieved using bootstrapped difference tests for edge weights and bridge centrality indices. The "bootnet" package was used to perform the accuracy and stability tests [38].

We acknowledge that the item-level findings may add further nuance to the current results. To offer a comprehensive overview, we have included the item-level network analysis in the for readers interested in detailed item-level analysis (Figure S6 in Multimedia Appendix 1).

Ethical Considerations

The study adhered to the ethical principles for medical research involving human subjects outlined in the Helsinki Declaration of 1975, as revised in 2008, and received approval from the institutional review board at Imperial College London (approval number 17IC4009). All participants were fully informed about the study details and provided their informed consent before participation. All data collected were anonymous. Participation was voluntary, and no financial incentives were offered.

Results

Table 1 presents demographic characteristics of the study sample. Descriptive statistics for CHI-T subscale scores and PUI symptom scores are provided (Table S1 in Multimedia Appendix 1). The clinical characteristics of the sample are presented (Table S2 in Multimedia Appendix 1).

Figure 1 presents the estimated compulsivity-PUI network and the bridge centrality plot (ie, raw bridge expected values of each node within the network). The network was densely connected, with 39 remaining edges (out of 45 possible edges). The strongest positive intracluster edge emerged between reward-drive and PUI4 (financial consequences due to internet use; edge weight=0.11). The strongest negative intracluster edge emerged between perfectionism and PUI4 (financial consequences due to internet use; edge weight=–0.04). Cognitive rigidity was strongly associated with PUI2 (internet use for distress relief; edge weight=0.06) and PUI3 (internet use for loneliness or boredom; edge weight=0.07). We found that reward-drive had the highest positive bridge expected influence, while perfectionism had the highest negative bridge expected influence.

The predictability of nodes was plotted as the colored area in the ring around each node. The nodes exhibiting the highest predictability were PUI6 (compulsion, predictability=0.55); PUI7 (failed attempts to cut down, predictability=0.49), and PUI3 (internet use for loneliness or boredom, predictability=0.44). The network's overall mean predictability is 0.37, which is comparable to the previously reported average level of predictability (mean predictability=0.32) in the literature [35]. The raw predictability scores can be found (Table S3 in Multimedia Appendix 1).

The narrow confidence intervals for edge weights (Figure S1) indicate that estimated edges within networks were accurate. The CS-coefficients for bridge expected influence were excellent in the estimated network (value=0.75), indicating optimal stability for the bridge centrality index. Results from the bootstrapped stability and accuracy tests are included (Figure S1 in Multimedia Appendix 1 and Figure S3 in Multimedia Appendix 1). The results of bootstrapped difference tests are included (Figure S2 in Multimedia Appendix 1 and Figure S4 in Multimedia Appendix 1).

Discussion

Principal Findings

This study is the first and largest to date to explore the relationships between different dimensions of compulsivity and individual PUI symptoms through network analysis. Extensive intercluster connections were found, indicating that compulsivity and PUI were strongly interrelated. We identified several strong mechanistic pathways, notably the edge between cognitive rigidity and coping and the edge between reward drive and functional impairment (ie, negative financial consequences). Finally, reward drive and cognitive rigidity were identified as the bridge nodes.

When elucidating interrelationships between compulsivity dimensions and PUI symptoms, we found that cognitive rigidity was associated with coping-motivated internet use. The results are in line with previous research [39-41], which highlights the role of rigid coping tendencies as a core mechanism underlying the relationship between compulsivity and addictive behaviors. Specifically, individuals high on cognitive rigidity may have a narrowed coping repertoire when experiencing negative emotions that, in turn, limits engagement in alternative coping strategies [42]. Several features of internet use (eg, easy accessibility and providing immediate stress relief) make it easy for individuals to use it as a coping strategy. However, such a coping strategy may be counterproductive in the long run (eg, due to excessive time spent online and avoiding dealing with daily challenges). For individuals with high cognitive rigidity, the inability to generate and adopt alternative coping responses when they need these most (ie, under stress) may result in their persistent engagement in coping-motivated internet use, even if this coping strategy proves to be ineffective and impairing.

Another strong pathway emerged between reward drive and functional impairment (ie, negative financial consequences and sleep loss), which may be explained by the counterproductive attentional capture mechanism characteristic of compulsivity [11,42]. Specifically, individuals with high reward drive may exhibit stronger attraction toward reward-related cues, finding it difficult to resist approaching these cues even when doing so may be counterproductive. In these individuals, such approach tendencies could be triggered by reward-related stimuli presented on the internet (eg, applications and websites for recreational online gaming, gambling, and cybersex), leading to internet use despite such use not being in line with an individual's goals and resulting in negative consequences.

XSL•FO
RenderX

Interestingly, negative relationships were observed between perfectionism and PUI symptoms. The relationship between perfectionism and addictive behaviors tends to be inconsistent across studies, with some studies finding that perfectionism may actually protect individuals from addiction-related impairments [43] and problematic drinking [44]. This inconsistency may stem from variations in how perfectionism is measured. Perfectionism is considered as a multidimensional construct, encompassing types like self-oriented, other-oriented, and socially prescribed perfectionism [45]. In this study, the perfectionism dimension captures self-oriented perfectionism (ie, holding high standards and striving for perfection or "just right"). It has been posited that specific aspects of perfectionism (ie, self-oriented perfectionism) may be considered a form of hyperconscientiousness [44]. Such hyper-conscientiousness may protect individuals from particular addictive behaviors, which are considered impairing and not aligned with their goals (eg, being perfect in everything; [44]). Our results provide support for this hypothesis by showing that perfectionism was negatively associated with self-report items measuring functional impairment.

The bridge centrality analysis identified reward drive and cognitive rigidity as bridge nodes that positively relate to the PUI symptom cluster, whereas perfectionism negatively relates to it. The roles of reward drive and cognitive rigidity in PUI are in line with previous studies that have demonstrated attentional approach tendencies toward reward cues and rigidity of such attentional responses are linked to obsessive-compulsive and addictive behaviors, including PUI [11,41]. Meanwhile, by showing that perfectionism is negatively related to the PUI symptom cluster, our findings extend previous assumptions on the potential protective role of perfectionism (underpinned by conscientiousness) in problematic alcohol use [44] to suggest that such a protective effect may be transdiagnostic across substance use and behavioral addictions.

Current findings addressed several key research priorities identified by experts [1,2]. First, our findings help elucidate the relations between compulsivity dimensions and PUI symptoms, which addressed the need for clarifying the role of compulsivity in PUI [1,2]. The distinct connectivity between traits and symptoms may suggest that interventions should be personalized to address individual symptom profiles. For example, interventions might focus on reducing reward-driven tendencies rather than targeting perfectionism in individuals whose problematic usage is characterized by financial consequences, to achieve better intervention outcomes. Second, by demonstrating the role of reward drive and cognitive rigidity, our results may inform efforts to identify at-risk individuals at the earliest stages of PUI and provide early intervention [2]. Specifically, given that compulsivity traits can exist before the emergence of PUI symptoms, reward drive and cognitive rigidity traits should, in future work, be evaluated in terms of their potential value in identifying individuals who are most at risk of developing PUI. In turn, this may inform our screening processes.

Previous simulation research on the role of bridge nodes has demonstrated that "focusing treatment on the detected nodes is effective in preventing the contagion of comorbid disorders" ([25], P. 365). Empirically, if we can establish that the identified bridge nodes, namely reward drive and cognitive rigidity, exhibit temporal precedence, these findings could mark a significant step toward intervention target selection.

Finally, node predictability may shed several practical insights. For instance, using the internet to cope with loneliness or boredom was identified as one of the nodes with the highest predictability. The predictability allows an understanding of the clinical relevance of the identified mechanism. For instance, we found that a significant proportion of variance in using the internet to cope with loneliness or boredom may be explained by its neighboring nodes (reward-drive and cognitive rigidity). This may indicate that intervention on reward drive and cognitive rigidity may have a higher success potential in reducing coping-motivated internet use. Further, the mean predictability of the network suggests that although compulsivity dimensions may play significant roles in PUI, other factors may also be involved in driving PUI and should be considered when planning interventions.

Based on our findings, targeting reward drive and cognitive rigidity (the bridge nodes) via digital personality change interventions [46] may be expected to improve treatment outcomes. Specifically, digital personality change interventions incorporate evidence-based techniques that foster and sustain personality change (eg, tailored implementation intentions (if-then plans), psychoeducation, behavioral activation, self-reflection, resource activation, and individual progress feedback), alongside a chatbot that facilitates coaching dialogues to simulate a personal coaching process [47]. A large-scale randomized controlled trial (n=1523) has shown that a digital personality change intervention was associated with significant changes in big 5 personality traits, versus waiting list control, with effects persisting beyond the intervention [47]. The promising findings suggest that such interventions have promise in potentially improving compulsivity traits such as reward drive and cognitive rigidity. It should be noted that the aforementioned study did not directly measure compulsivity, but rather traits associated with it (eg, conscientiousness), as classic personality inventories typically do not assess compulsivity. Future studies may consider directly examining the extent to which the intervention can effectively reduce dimensions of compulsivity.

Considering the transdiagnostic characteristics of mechanisms discussed above (ie, counterproductive attentional capture, rigid coping styles, and conscientiousness), such interventions may potentially help reduce other compulsive behaviors (eg, problematic drinking, binge-eating, and obsessive-compulsive behaviors) that frequently co-occur with PUI [48]. These suggestions should be tested in future research studies.

Limitations

Several limitations should be noted when interpreting current findings. First, PUI symptoms in the current study were measured using items drawn from expert consensus, which may raise concerns regarding the psychometric properties of these items. This was the case for pragmatic reasons as the data were collected as part of a citizen science study [31] that needed to have relatively brief questions that were also acceptable to other

XSL•FO
RenderX

stakeholders. The advantage of this approach is that it enables a very large sample size to be collected. Second, the findings were analyzed and discussed with the theoretical assumption that personality traits act as predisposing factors and predict PUI (instead of the other way around; [49-52]. However, due to the cross-sectional nature of the study, we cannot disregard the possibility that PUI may contribute to compulsive traits. It will be important for future research to test the temporal precedence of compulsivity traits and PUI symptoms with longitudinal network analysis. Third, the majority of the sample self-identified as White or Caucasian and resided in a Western country (ie, the United Kingdom), potentially limiting the generalizability of these findings to individuals from other ethnic or cultural backgrounds. Fourth, the current findings were based on data from the general population, which may not be generalizable to individuals with severe levels of PUI. It is important for future research to replicate current findings among individuals with severe levels of PUI.

Future Directions

In theory, targeting bridge nodes could limit the transmission of activation between different psychological symptoms (or conditions), potentially preventing the onset of comorbid psychopathologies and thus making them valuable targets for intervention [25]. However, empirical evidence on the predictive validity of bridge nodes is inconsistent. For instance, findings from 6 randomized control trials suggest that bridge nodes may predict treatment outcomes in patients with depressive disorders [53]. In addition, studies indicate that bridge nodes can statistically predict the persistence of psychopathology, such as poorer psychosocial functioning and lower BMI in adolescents with anorexia nervosa [54], as well as the future onset of anxiety disorders [55]. Conversely, some evidence suggests that bridge nodes might only partially predict treatment outcomes (ie, predict weight restoration, but not full remission, in patients with anorexia nervosa [56]) or yield nonsignificant results in terms of relationships to outcomes [57]. Given these mixed results, future longitudinal and intervention research is essential to ascertain the predictive validity of bridge nodes before they can be confidently used as treatment targets.

Most research in the fields of psychology and psychiatry that uses network-based approaches has relied on cross-sectional, between-subject designs. However, there is an increasing shift toward using longitudinal designs, including panel data and intensive time-series data [58-60]. These methods enable researchers to differentiate within-subject and between-subject effects and to elucidate the temporal dynamics among psychological constructs. A recent study using graphical vector autoregressive network models to analyze panel data revealed that coping-motivated substance use could predict posttraumatic stress disorder symptoms over time [59]. In addition, when combined with intensive time-series data, graphical vector autoregressive network models can elucidate the interrelationships among psychological symptoms and the impact of risk factors on these symptoms at an individual level, offering insights into precision medicine (eg, by enabling personalized diagnostic profiling and treatment planning; [58,61]). To improve the clinical relevance of current findings, future studies should use longitudinal designs to further explore the network structure and bridge nodes identified in this study.

Conclusions

The current study addresses evidence gaps in the literature by investigating the relations between different dimensions of self-reported compulsivity and PUI symptoms. using network analysis, we identified distinct connections between dimensions of compulsivity and PUI symptoms. Specifically, we found that reward-drive and cognitive rigidity were differently associated with PUI symptom clusters, which may reflect distinct mechanisms (ie, counterproductive attentional capture and rigid coping response). Further, we identified “reward drive” and “cognitive rigidity” as bridge nodes within the network. These findings represent an initial exploration into the role of transdiagnostic compulsivity in developing future interventions for PUI. Examining the direction of the mechanistic pathways identified, whether compulsivity drives PUI or vice versa, through longitudinal studies represents a promising next step for applying network-informed treatment strategies in clinical practice for PUI.

Abstract

Background: Suicide is a significant global health concern. In the context of increased demand for mental health services and workforce shortages, exacerbated by the COVID-19 pandemic, electronic mental health (eMH) tools represent a promising means of augmenting mental health care generally and for suicide prevention specifically. A significant research gap exists however with respect to the use and uptake of eMH tools, especially electronic mental health tools for suicide prevention (eMH-SP).

Objective: This study aimed to investigate the use of eMH tools by Australian mental health professionals, both in general and with respect to suicide prevention specifically, examining changes in use since COVID-19. Further, it explored factors associated with frequent use of eMH-SP, including sociodemographic and professional characteristics.

Methods: A web-based cross-sectional survey was conducted across 15 local health districts (LHDs) in New South Wales, Australia, from May 2022 to July 2023. The sample was drawn from over 10,000 mental health professionals working in government services statewide. The survey explored the use of electronic mental health tools for general mental health issues (eMH-gen) and eMH-SP, explored the changes in the use of both since COVID-19, and used multivariable logistic regression to identify factors associated with the current use of eMH-SP.

Results: Among 469 participants, increased use since COVID-19 was reported by over half (247/469, 52.7%) for eMH-gen, and by approximately one-third (141/386, 36.6%) for eMH-SP. The proportion reporting frequent use increased significantly from before to after COVID-19 for both eMH-gen (243/469, 51.8% to 283/469, 60.3%; $P<.001$) and eMH-SP (152/386, 39.4% to 170/385, 44.2%; $P=.01$). Since COVID-19, the most frequently used types of eMH tools for eMH-gen and eMH-SP, respectively, were information sites (231/469, 49.3% and 130/385, 33.8%), phone/online counseling (173/469, 36.9% and 130/385, 33.8%), and apps (145/469, 30.9% and 107/385, 27.8%). Professionals more likely to use eMH-SP frequently were females (odds ratio [OR] 3.32, 95% CI 1.88-5.87; $P<.001$) compared with males; peer workers (OR 2.17, 95% CI 1.0-4.71; $P<.001$) compared with nurses; those located in regional/rural LHDs (OR 1.65, 95% CI 1.04-2.61; $P=.03$) compared with metropolitan LHDs; and those practicing in emergency health care settings (OR 8.31, 95% CI 2.17-31.75; $P=.03$) compared with inpatient settings.

Conclusions: The study's findings highlight the increasing adoption of eMH tools and delivery of remote care by mental health professionals and provide valuable new insights into sociodemographic factors associated with the use of eMH for suicide

XSL•FO

prevention specifically. Continued research on the role eMH is playing is essential for guiding policy, optimizing resources, and enhancing mental health care and suicide prevention efforts.

Introduction

Background

Suicide is a leading global cause of death. In 2019, over 700,000 deaths were attributed to suicide worldwide; approximately one in every 100 deaths (1.3%) [1]. Suicide has a profound impact that extends beyond individuals who die by suicide, with those bereaved by suicide at higher risk of suicide themselves [2], and extensive social and economic impacts across the broader community. Suicide prevention initiatives are therefore crucial for decreasing suicide mortality and its wider impacts. The World Health Organization considers suicide preventable if effective evidence-based interventions, treatment, and support are provided in a timely manner [3].

In many nations including Australia, the mental health sector faces challenges in meeting a growing demand for services coupled with existing workforce shortages [4,5]. Pressure on the mental health sector has been further exacerbated by the COVID-19 pandemic (hereafter referred to as "COVID"), where effects have included: increased rates of depression, anxiety, and suicidal behavior [4,6]; reduced opportunity for in-person service contacts; and compounding of a chronic shortage of mental health professionals [7]. Mental health services need accessible and effective solutions that can be scaled up to reach larger numbers of people during times of increased demand.

The use of electronic mental health (eMH) tools to provide remote access to mental health services has emerged as an important part of the solution to bridge this service gap. eMH tools consist of digital technologies, including mobile apps, information sites, online peer support, web-delivered programs, and phone/online counseling [8], which are delivered remotely via electronic communication channels (eg, internet, telephone), and may be clinician-guided or self-managed to provide information or therapy [9]. eMH tools may be designed for standalone use or for integration into routine care to complement in-person support [10]. Their advantages have been noted to include expanded access to mental health services for difficult-to-reach populations, such as clients in geographically remote communities [11], those experiencing stigma or reluctance to engage in-person, or those who prefer anonymity [12]; reduced costs of mental health support [13]; and enhanced continuity or intensity of support (such as when blended with face-to-face care) [14].

Increasing evidence supports the effectiveness of eMH tools in reducing symptoms of various mental health conditions and in preventing suicide. For example, systematic reviews investigating internet-delivered cognitive behavior therapy have found it to be as effective as traditional face-to-face cognitive behavior therapy for anxiety and depressive disorders [15]; and to significantly reduce suicidal ideation compared with controls [16]. Although maintaining end user engagement can be challenging [17], and related to factors such as age, sex, and geographic location [18], end users generally report eMH tools to be acceptable, and have a positive attitude about their use [15,19].

Research reporting the prevalence of use and uptake of eMH tools has focused largely on "consumers" (people with lived experience of mental ill-health) as end users, using a range of measurement approaches and indicating widely varying levels of use [20]. A systematic review into the use of self-help apps and web-based eMH tools for depression, anxiety, or mood enhancement for example (n=11 studies, mostly from Australia and North America), found up to 88% of users had engaged at least minimally with an eMH tool; and that some tools achieved engagement of over 40,000 registrations or downloads monthly [21].

Fewer studies have investigated the prevalence of use and uptake of eMH tools by clinicians and peer workers (hereafter collectively referred to as "professionals") in their work with consumers, with no systematic reviews synthesizing the findings of this limited body of literature being located to date. Two of the larger, more recent studies include a survey of 209 psychiatrists from 19 countries (including Australia) conducted prior to COVID, which indicated that 60% of psychiatrists did not recommend such tools to their patients [22]; and a repeated cross-sectional survey among a mix of psychologists, nurses, social workers, physicians and other professionals (n=1039) in the Netherlands, which found a significant increase in frequent use (monthly or weekly) of videoconferencing to deliver care since COVID [23].

While previous studies have explored the use of eMH tools for various mental health conditions, a crucial gap exists in understanding their use in suicide prevention. Prior to this research, we were able to identify only a recent, qualitative study of 15 Irish professionals describing the adoption of mobile apps for suicide prevention, which reported that while a majority (n=13) recommended apps to clients, only 3 professionals used the apps regularly in practice [24]. To evaluate the impact of eMH tools in the context of suicide prevention, it is vital to understand their use and uptake rates by professionals. This comprehensive study provides the first large-scale look at how mental health professionals use eMH tools for suicide prevention, offering new insights into current practices in this critical area of mental health care provision.

XSL•FO
RenderX

Objectives

This study aimed to first investigate the use of eMH tools by mental health professionals employed in government services in Australia via a web-based survey, including electronic mental health tools for general mental health issues (eMH-gen) and electronic mental health tools for suicide prevention specifically (eMH-SP), and explicitly examine changes in use since COVID. Second, the study explored factors that may influence the frequency of eMH-SP use in practice, including sociodemographic and professional characteristics (age, sex, professional role, rurality of service location, work setting, primary mode of service delivery [whether predominantly in-person, remote, or a blend of both]).

Methods

Design and Setting

A web-based cross-sectional survey of mental health professionals working in the 15 local health districts (LHDs) of the public health system in New South Wales (NSW), Australia, was undertaken. LHD mental health services provide state-wide care for both acute and chronic mental health needs as follows: 6 metropolitan LHDs service the broader Sydney area, with the largest servicing over 1 million residents, while the smallest of 9 regional and rural LHDs services just over 30,000 residents (across nearly 200,000 sq km).

Participants and Recruitment

Eligible participants were professionals (ie, nurses, occupational therapists, peer workers, psychologists, psychiatrists, and social workers) aged 18 years and older, currently providing mental health care within an NSW LHD service. Participants not conforming to these criteria were excluded from the study. Participants were invited to take part in the anonymous survey through emails sent from representatives within their organization. Participants were recruited between May 2022 and July 2023 for the survey, which was open for 8 weeks at each LHD. Three reminder emails were sent from most LHDs at fortnightly intervals to encourage participation (3 LHDs elected to send only 1 or 2 reminders).

Efforts to reduce bias included using neutral phrasing in survey questions, sending multiple reminders to encourage participation, and sampling across diverse demographics and work settings. No formal sample size and power calculation was carried out. Rather, an attempt was made to maximize the potential sample size by contacting all eligible professionals across the 15 NSW LHDs. The final sample size achieved was the result of the response rate to the survey.

Survey Variables and Data Measurement

Overview

The web-based survey was developed through an iterative process that included reviewing existing literature, key stakeholder consultation, and review by an expert panel of mental health professionals (including an Aboriginal scholar and mental health clinician). The survey was deployed on the Research Electronic Data Capture (REDCap) platform [25], where it underwent piloting, with items revised for clarity and appropriateness. Survey data collection comprised predictor variables such as sociodemographic and professional descriptors; an exposure variable of the COVID period (before vs since); and key variables related to the primary outcomes regarding frequency of use of eMH-gen and eMH-SP.

Sociodemographic and Professional Characteristics

Demographic data collected included age, sex, and Aboriginal or Torres Strait Islander origin. Professional characteristics included professional role (nurse; occupational therapist; peer worker; psychiatrist; psychologist; social worker; other), length of service as a mental health professional, suicide prevention training attendance within the previous 3 years (yes/no), LHD of employment (multiple selections permitted from Central Coast; Far West; Hunter New England; Illawarra Shoalhaven; Mid North Coast; Murrumbidgee; Nepean Blue Mountains; Northern NSW; Northern Sydney; South Eastern Sydney; South Western Sydney; Southern NSW; Sydney; Western NSW; Western Sydney), work setting (inpatient; emergency; community; other), and area of mental health practice (multiple selections permitted from: Aboriginal; adult; child and adolescent; consultation liaison; forensic; improvement or service development; neuropsychiatry or neuropsychology; older people; perinatal; special projects; other).

The primary mode of health care delivery was calculated based on participants' ratings of the proportion of care (0% to 100%) they delivered via in-person and remote (phone; video; online text) modes. Responses were sought with respect to delivery mode prior to COVID (ie, prior to the World Health Organization declaration of the pandemic on 11 March 2020 [26]) as well as currently (ie, at the time of survey completion).

Use of e-Mental Health Tools

The survey defined eMH tools as "digital resources and tools delivered via online or telephone technologies that support provision of mental health care", and categorized the types of eMH tools according to the e-Mental Health in Practice website [8], a comprehensive directory of evidence-based Australian, digital mental health resources. The categories of tool types include apps, information sites, online peer support, online self-directed programs, online coach-assisted programs, and phone/online counseling. The e-Mental Health in Practice directory groups eMH tools by topic, including general issues such as mental health conditions, relationship issues, or trauma (eMH-gen); and suicide prevention (eMH-SP).

Participants were asked about their use of eMH tools in terms of (1) change in the extent of eMH-gen and eMH-SP use overall since COVID, rated on a 5-point Likert scale (reduced considerably; reduced somewhat; no change; increased somewhat; increased considerably); (2) frequency of use, based on participants' most frequently used type of eMH tool, rated on a 5-point Likert frequency scale (never, less than monthly, monthly, weekly, daily; the responses were sought separately for eMH-gen and eMH-SP, and use was compared before and since COVID for both); and (3) types of eMH used, based on the frequency of use for each individual tool type rated on the same 5-point Likert scale (never to daily), with responses sought

XSL•FO
RenderX

separately for the types of eMH-gen and eMH-SP, and use compared before and since COVID for both.

Statistical Methods

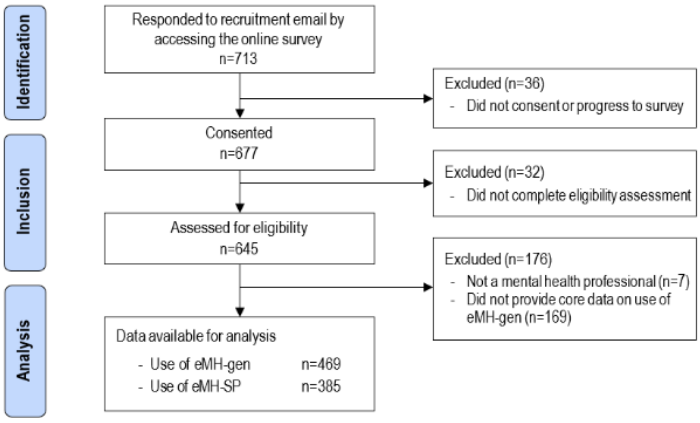
Descriptive statistics were used to characterize the sample and explore the prevalence of the use of eMH, both eMH-gen, and eMH-SP. Continuous data were presented as means and SDs, and categorical data as frequencies and corresponding percentages. Condensed response categories were created based on age, length of service, LHD location, and delivery mode.

Binary categories were created for the frequency of eMH use and for types of eMH tools (rarely [never, less than monthly, and monthly], frequently [weekly and daily]). McNemar tests were used to assess the significance of differences before and since COVID. To assess differences in delivery modes before and since COVID, paired data were first assessed for normality using Shapiro-Wilk tests and skewness values. Based on these assessments, Wilcoxon signed rank tests (for non-normally distributed data) were carried out, with the α level set to .01 after applying the Bonferroni correction to adjust for multiple comparisons, reducing the risk of type I errors. To address the potential impact of participants dropping out early before completing questions on eMH-SP, such participants were compared with survey completers using chi-square analyses to examine for differences in sociodemographic characteristics (age, sex, and Aboriginal or Torres Strait Islander origin) and professional attributes (professional role, length of service, suicide prevention training, LHD location, and work setting).

Univariate chi-square tests were conducted to identify associations between categorical variables, in this case, factors suggested by the literature as theoretically likely to be associated with frequent eMH use. The following independent variables were considered: age, sex, professional role, LHD location, work setting, and delivery mode. Univariate analysis was carried out on a condensed 3-point Likert scale (never, occasionally [monthly or less than monthly], and frequently [weekly or daily]) using chi-square analysis to test the significance of the independent variables. Those that were significant were entered into a multiple-variable binary logistic regression model. To enable this, the outcome variable was dichotomized into binary categories (rarely [never or occasionally] and frequently) for the multivariable analysis. The independent variables considered in the logistic regression model were all the variables examined in the univariate analysis, as they were all significant. None of the variables were removed from the model to comprehensively assess the combined effects of these variables. The study was conducted and reported in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines [27]. Data were analyzed using the IBM Statistical Package for the Social Sciences (version 29; IBM Corp).

Ethics Approval

Ethics approval was received from the Hunter New England Human Research Ethics Committee (approval 2021/ETH00613) and the University of Newcastle Human Research Ethics Committee (approval H-2022-0034). Local research governance authorization was obtained from each participating LHD. Participants received an email invitation with an information statement outlining the study's objectives, procedures, and potential risks. The information statement was also on the survey website, which participants reviewed before consenting to participate. Completing the web-based survey questions implied informed consent. Participation was voluntary, with the option to opt out at any time. Responses were anonymous, and the data were stored in encrypted electronic databases accessible only to the research team. No financial compensation was provided.



Results

Participants

Overview

Participants were drawn from all 15 LHDs across NSW, with over 10,000 mental health staff invited to participate (ranging from 33 to 1400 per LHD). Of the 713 respondents who accessed the survey, 677 consented, of whom 645 provided information allowing assessment of eligibility (with 7 then excluded). A final sample of 469 participants provided data on the use of eMH-gen; with 385 participants providing data that enabled inclusion in analysis for the use of eMH-SP (Figure 1). The sociodemographic and professional characteristics of the 469 participants whose data were analyzed in this study are reported in Table 1. No significant differences were found in sociodemographic or professional characteristics between participants who dropped out early and those who completed all survey questions.

Figure 1. Flowchart of the study population. eMH: electronic mental health; eMH-gen: electronic mental health tools for general mental health issues; eMH-SP: electronic mental health tools for suicide prevention.

Primary Mode of Health Care Delivery

Initial analyses revealed significant deviations from normality in the data (Shapiro-Wilk tests: all $P<.001$; skewness values >±1, except one variable with skewness of –0.569), necessitating the use of Wilcoxon signed rank tests. The Wilcoxon signed rank tests revealed significant changes in the proportion of care delivered via the different modes (in-person and remote) from pre-COVID to since COVID. In-person care remained the primary mode of delivery but decreased significantly from 78.6% pre-COVID to 66.5% since COVID ($z=11.07$, $P<.001$, N=467). Conversely, all modes of remote care delivery increased, with significant rises in phone-based care from 13.2% to 17.0% ($z=6.96$, $P<.001$, N=463), video-based care from 2.7% to 10.3% ($z=10.98$, $P<.001$, N=458), and online text-based care from 2.3% to 3.7% ($z=2.71$, $P=.007$, N=462). While most participants used a combination of 2 to 3 delivery modes, the percentage using exclusively in-person delivery modes decreased significantly from 33.9% pre-COVID to 24.5% since COVID ($P<.001$).

Use of e-Mental Health Tools

Overview

This section presents findings on mental health professionals' use of eMH tools. The frequency of eMH use (including both detailed frequency levels and broader binary categories of frequently and rarely used), and the types of eMH tools they frequently use are presented in Table 2.

XSL•FO

Changes in Use of eMH

Over half the participants (247/469, 52.7%) reported an increase in their use of eMH-gen since COVID; 43.3% (n=203) reported no change, and a small minority (19/469, 4%) reported a decrease in use. Regarding eMH-SP, over one-third of participants (141/385, 36.6%) reported an increase in their use, over half reported no change in their frequency of use (226/385, 58.7%), while less than 5% (n=18) reported a reduction in the frequency of eMH-SP use.

Frequency of Use of eMH

Among participants, 60.3% (n=283) reported currently using eMH-gen frequently, compared with 51.8% (n=243) pre-COVID, a significant increase ($P<.001$). Similarly, 44.2% (n=170) reported frequently using eMH-SP compared with 39.4% (n=152) pre-COVID, a significant increase ($P=.01$). Comparing frequent use of eMH-gen with eMH-SP since COVID, the difference was also significant ($P<.001$).

Types of eMH Tools Used

Of the 6 types of eMH tools assessed, the 3 eMH-gen currently used most frequently were information sites (231/469, 49.3%), phone/online counseling (173/469, 36.9%), and apps (145/469, 30.9%), with significant increases since COVID in both information sites ($P<.001$) and apps ($P=.01$). Among these 6 types of tools, the 3 eMH-SP currently used most frequently, all of which showed significant increases since COVID, were information sites (130/385, 33.8%; $P=.03$), phone/online counseling (130/385, 33.8%; $P=.01$), and apps (107/385, 27.8%; $P<.001$).

Sociodemographic and Professional Characteristics Associated With the Use of eMH-SP in Current Practice

Current frequency of use of eMH-SP was classified into one of 3 outcome categories (never, occasionally, and frequently), with possible associations explored with sociodemographic and professional characteristics (Table 3). Chi-square test results indicate significant univariate associations between all of the factors and the frequency of use of eMH-SP. Professionals of younger age, female sex, professional role of peer worker or social worker, working in regional or rural LHDs, in emergency health care settings, and using at least 1 remote delivery mode (as opposed to in-person mode only) were more likely to report current frequent (weekly or daily) use of eMH-SP.

Multivariable binary logistic regression was then used (categories: rarely; frequently) to further explore the relationship between these factors and frequent use of eMH-SP (ie, on a daily or weekly basis), as presented in Table 4. The overall model was found to be significant ($\chi^2_{14}=70.89$, n=378, and $P<.001$). Age ($P=.06$) and delivery mode ($P=.17$) were no longer significant, while significance was retained for all other factors. Frequent use of eMH-SP was 3.32 times more likely for females than males, 2.17 times more likely for peer workers than nurses, 1.65 times more likely for regional/rural LHDs than metropolitan LHDs, and 8.31 times more likely for emergency settings than inpatient settings.

Discussion

Principal Findings

This study invited mental health professionals in government mental health services across NSW Australia to take part in a survey with respect to the use of eMH tools in their professional practice. It focused particularly on the use of eMH-SP, given the urgent need for strengthening suicide prevention efforts in the face of consistently high suicide rates. Understanding the uptake of eMH is especially important in the context of challenges in meeting increasing demand for mental health care, both generally and for suicide prevention; with demand heightened further by the COVID pandemic. Study findings reflected a shift toward the increasing incorporation of remote modes of care delivery (video, phone, online text) since COVID, with the proportion reporting delivering care solely “in-person” declining from one-third to one-quarter.

Over half (247/469, 52.7%) of participants reported an increase in their use of eMH-gen since COVID, while 43.3% (n=203) reported no change. Over one-third (141/386, 36.6%) similarly reported their use of eMH-SP had increased, with 58.7% (n=226) reporting their use remained unchanged. A majority (283/469, 60.3%) of professionals reported frequent use of eMH-gen (at least weekly); a proportion that had increased by approximately

XSL•FO
RenderX

10% since COVID. While a lesser proportion of participants reported frequent use of eMH-SP specifically, both before and since COVID, there was still a notable increase in its use. Nearly half (170/386, 44.2%) of the sample reported frequent use of eMH-SP since COVID, up from 39.4% (n=152) prior to the pandemic. Approximately half of the participants (231/469, 49.3%) reported information sites as the most frequently used type of eMH-gen, followed by phone/online counseling (173/469, 36.9%). The same types of tools were also most frequently used with respect to suicide prevention, with approximately one-third reporting information sites and phone/online counseling as their most frequently used tools. Since COVID, the use of phone/online counseling for suicide prevention has increased significantly, in contrast to its use for general mental health issues. This shift may have been driven by the pandemic, which limited in-person counseling and support for suicide prevention, instead prompting increased use of eMH-SP. The most marked increases in the frequency of use by types of eMH tools were observed for information sites in eMH-gen (from 180/469, 38.4% to 231/469, 49.3%), and for suicide prevention apps in eMH-SP (from 57/385, 14.8% to 107/385, 27.8%). This increase in overall use is consistent with the rapidly increasing availability and promotion of digital mental health resources in practice [28].

A small but consistent proportion of professionals (≈6% both pre-COVID and currently) reported never using eMH-gen, while roughly double this proportion (≈14% pre-COVID and 12% currently) reported never using eMH-SP. Over half of respondents reported no or very limited (monthly or less) use of eMH-SP currently, as compared with approximately one-third who reported no or very limited use of eMH-gen. To some extent, this lesser use for suicide prevention specifically might be related to a lack of knowledge about what eMH-SP are available and are indicated for use with clients experiencing suicidal ideation [29], as well as concerns about the safety and effectiveness of these tools in managing suicidal crises [30]. It is also however likely explained in part by some clinicians encountering clients at high risk of suicide relatively infrequently in their clinical practice. This is lent support by the finding that the use of eMH-SP did differ by setting; frequent use being highly reported by the small number of survey respondents who worked in emergency settings (less than 4% of participants), where presentations involving suicidal ideation and suicide attempts would be more common.

Frequent use of eMH-SP was also more likely for female mental health professionals as compared with males. While this finding aligns with the general trend of higher digital tool use among females [31], no corroborating evidence specific to mental health professionals was found in the existing literature. The finding that some professional groups, most notably peer workers and social workers, were more likely to report frequent use of eMH-SP than others, might suggest that daily routines and demands of the various professional roles influence levels of use of these tools, but further research is needed to elucidate this relationship. Notably, all peer workers used eMH-SP to some extent, with almost two-thirds using these tools frequently. It might be speculated that the finding of higher use in regional or rural LHDs may be due to participants in such locations being more likely to promote eMH adoption to compensate for limited access to mental health resources compared with those in metropolitan LHDs [10].

The delivery of mental health care and suicide prevention is continuing to evolve, with the findings of this study supporting previous research suggesting that remote delivery modes and the use of eMH tools are becoming more common [32]. This raises questions about potential barriers to eMH adoption, especially in suicide prevention, where clinicians may face added safety and ethical concerns about recommending appropriate eMH tools to consumers at heightened risk of suicide [33]. It also creates the need for mental health services to respond and provide appropriate leadership, infrastructure access, and training to allow mental health professionals to optimize the use of eMH tools, despite the challenges. The rapid growth in the number of available eMH-SP, coupled with the variable expertise involved in their development, has resulted in inconsistent quality across these tools [34,35]. The use of eMH is already quite significant and likely to continue rising, and brings with it the need for clear, best practice guidelines to direct mental health professionals toward the most effective and safest eMH-SP for clinical practice.

This study offers valuable insights into eMH use by diverse mental health professionals in NSW, both before and since the COVID pandemic. One significant strength is its comprehensive reach, encompassing all 15 LHDs across NSW and inviting over 10,000 mental health staff to participate. However, there are limitations to consider for the study. The results are based on a self-report survey, which may exhibit response bias. The research was conducted in a single Australian state, limiting the generalizability of the results to other contexts. However, NSW is the most populous state with the highest number of mental health professionals [36]. The survey had a modest participation rate (4.7%), which nevertheless equated to a substantial sample of 469 participants. The dropout rate was 17.9%, with 84 of the 469 eligible participants failing to complete the survey, although there were no significant differences in sociodemographic or professional characteristics between survey dropouts and completers. Self-selection bias may have been introduced, with those who opted to complete the survey likely to have a stronger interest in eMH and be more likely to use it.

Despite such limitations, this study makes a significant contribution to the field by systematically documenting real-life practices of mental health professionals' use of eMH tools since the COVID pandemic, with a focus on suicide prevention. Unlike previous research, this study provides a comprehensive, quantitative overview that not only assesses mental health professionals' adoption of eMH tools but also provides important insights about sociodemographic factors that may influence the uptake of these tools into practice. Building on previous qualitative insights, this study provides a more comprehensive, data-driven understanding of eMH tool use in suicide prevention. Using a quantitative approach, the study offers statistically robust evidence beyond the limited scope of existing literature.

Conclusion

It is vitally important to continue to explore avenues for increasing timely access to quality mental health support, particularly in the area of suicide prevention. In order to promote appropriate uptake of eMH-SP in practice, it is imperative to understand the perceived benefits, challenges, and barriers to use. Future research could explore the factors that clinicians report influence the adoption of eMH-SP in greater detail, possibly using quantitative or qualitative approaches with selected mental health professionals and perhaps different professional groups, to gain deeper insights into their experiences and motivations for using or not using eMH tools for suicide prevention. Implementation research is needed to identify strategies for mental health services to support clinicians in their optimal use of these tools, which may include, for instance, best practice guidelines. Research in these areas is essential for guiding policy and resource allocation, improving the quality of mental health care, and enhancing suicide prevention efforts in this critical area of public health.

Acknowledgments

The authors wish to express our sincere gratitude to the expert panel who reviewed the survey instrument and provided valuable feedback to strengthen its validity and relevance, and to the mental health professionals across New South Wales who participated in the online survey. The New South Wales Ministry of Health supported this research as part of the Towards Zero Suicides Initiative, which included the funding of a PhD scholarship. However, the funding source played no role in the writing of the manuscript or the decision to submit it for publication. Authors were not precluded from accessing data in the study, and they accept responsibility to submit for publication.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to ethical restrictions and privacy considerations (eg, data containing potentially identifying information), but are available from the corresponding author on reasonable request.

Authors' Contributions

All authors made substantial contributions to the conception and design, or acquisition of data, or analysis and interpretation of data, specifically. CH contributed to conception and design, methodology, data acquisition, analysis and interpretation, and project administration. JB, SH, APM, and RKH participated in supervision, conception and design, methodology, data analysis, and interpretation. KC contributed to methodology, formal data analysis, and interpretation. RSR and DD contributed to the conception, design, and methodology. CH drafted the original article, and all authors revised it critically for important intellectual content. All authors granted final approval of the version to be published. No generative artificial intelligence was used in the manuscript writing.

Conflicts of Interest

None declared.

Abstract

Background: Twitter (subsequently rebranded as X) is acknowledged by US health agencies, including the US Centers for Disease Control and Prevention (CDC), as an important public health communication tool. However, there is a lack of data describing its use by state health agencies over time. This knowledge is important amid a changing social media landscape in the wake of the COVID-19 pandemic.

Objective: The study aimed to describe US state health agencies' use of Twitter from 2012 through 2022. Furthermore, we organized our data collection and analysis around the theoretical framework of the networked public to contribute to the broader literature on health communication beyond a single platform.

Methods: We used Twitter application programming interface data as indicators of state health agencies' engagement with the 4 key qualities of communication in a networked public: scalability, persistence, replicability, and searchability. To assess scalability, we calculated tweet volume and audience engagement metrics per tweet. To assess persistence, we calculated the portion of tweets that were manual retweets or included an account mention. To assess replicability, we calculated the portion of tweets that were retweets or quote tweets. To assess searchability, we calculated the portion of tweets using at least 1 hashtag.

Results: We observed a COVID-19 pandemic–era shift in state health agency engagement with scalability. The overall volume of tweets increased suddenly from less than 50,000 tweets in 2019 to over 94,000 in 2020, resulting in an average of 5.3 per day. Though mean tweets per day fell in 2021 and 2022, this COVID-19 pandemic–era low was still higher than the pre–COVID-19 pandemic peak. We also observed a more fragmented approach to searchability aligning with the start of the COVID-19 pandemic. More state-specific hashtags were among the top 10 during the COVID-19 pandemic, compared with more general hashtags related to disease outbreaks and natural disasters in years before. We did not observe such a clear COVID-19 pandemic–era shift in engagement with replicability. The portion of tweets mentioning a CDC account gradually rose and fell around a peak of 7.0% in 2018. Similarly, the rate of retweets of a CDC account rose and fell gradually around a peak of 5.4% in 2018. We did not observe a clear COVID-19 pandemic–era shift in persistence. The portion of tweets mentioning any account reached a maximum of 21% in 2013. It oscillated for much of the study period before dropping off in 2021 and reaching a minimum of 10% in 2022. Before 2018, the top 10 mentioned accounts included at least 2 non-CDC or corporate accounts. From 2018 onward, state agencies were much more prominent.

Conclusions: Overall, we observed a more fragmented approach to state health agency communication on Twitter during the pandemic, prioritizing volume over searchability, formally replicating existing messages, and leaving traces of interactions with other accounts.

Introduction

Twitter as a Networked Public

This paper describes US state public health agencies' activity on Twitter (subsequently rebranded as X) from 2012 through 2022. We used the theoretical framework of a networked public, an interactive space that networked technologies make possible, as well as the collection of people that inhabit it [1].

According to this theoretical framework, a networked public's defining features are profiles, contact lists, and public communication tools. This framework outlines 4 emergent qualities of communication these features produce: scalability, persistence, replicability, and searchability. Twitter's features were always open to users with potentially conflicting motivations. Viewed generously, this aligns with notions of Twitter's democratization of health communication [2]. Viewed through a more critical lens, however, this illustrates how Twitter has been a site for both challenging and propagating inequities.

This tension was evident from Twitter's 2006 launch, with dominant narratives of its Silicon Valley origins obscuring its relationship to open-source innovations from activists [3]. The hashtag illustrates such long-term tensions that exist in networked publics, between corporate practices and grassroots discourse, as well as between social networks with opposing goals. Hashtag use began as an informal organizational practice among power users before Twitter formally incorporated it as a feature in 2007 [4]. While activists eventually adopted hashtags for social justice campaigns like #MeToo and #BlackLivesMatter, and corporations adopted hashtags for advertising purposes, hashtags were also tools of political marginalization. For example, the use of the hashtag #ChineseVirus was a marker of anti-Chinese sentiment in March 2020, associated with anti-Asian hashtags more broadly after the US president's use of the term "Chinese Virus" [5]. Hashtags can also be sites of conflict around public health topics, such as the coordinated flooding of the provaccine #DoctorsSpeakUp hashtag with antivaccine messaging in 2020 [6].

Twitter as a State Public Health Tool

Though the use of Twitter in public health has been critiqued as "tweeting to the choir" [7], this type of communication toward professional audiences could reflect a viable platform-specific communication strategy. For example, the US Centers for Disease Control and Prevention (CDC) has recommended that public health communicators and organizational leaders use Twitter to reach reporters with crisis communication [8]. This could help explain why US health agencies' COVID-19 tweets focused more on data than did their Facebook (Meta) posts [9].

Existing observational research reinforces this notion of Twitter as an information-focused public health communication tool. A study of state Medicaid program Twitter use between 2014 and 2019 found a similar informational focus, which garnered little audience engagement [10]. A study of Canadian public health agencies' Twitter use during the first half of 2020 found a similar informational focus, even as more action-oriented tweets received higher audience engagement [11]. A study of health agency use of Twitter across 7 countries during the spring of 2020 found evidence of this trend internationally, with announcements and reporting being the most common tweet theme [12]. At a local level in the US, there have been experiments in using Twitter as a community service tool, such as in the case of the Chicago Department of Public Health's foodborne illness response program [13].

Descriptive studies of US state public health agencies' Twitter use, however, are either not comprehensive or are not up to date. Twitter was found to be an emerging platform for state public health agencies, based on a study covering a 2-month period in 2011 [14]. An early content analysis of state public health agency tweets in 2012 found a focus on the transmission of personal health advice [15] and a much higher Twitter adoption rate than local health departments around the same time [16]. A more recent study analyzed all state health agency tweets from a 4-month period around the emergency use authorization of the first COVID-19 vaccine in the United States [17]. Findings indicated a much higher volume of tweets than earlier studies, as well as a lack of key terms related to vaccination, inequities, and racism, lagging behind on-the-ground efforts to address COVID-19 racial health inequities.

We present an instrumental case study [18] to provide a more complete picture of state public health agency Twitter use long-term. We chose this approach as it aligns with our research interest in producing descriptive knowledge with theoretical implications beyond the individual case of Twitter. Our goal was to provide transferable knowledge to help identify trends and relationships between theoretical constructs in health communication. This knowledge is important amid a changing social media landscape in the wake of the COVID-19 pandemic. We follow STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines [19] in reporting this study. The completed STROBE statement checklist is available in Multimedia Appendix 1.

Methods

Overview

We conducted a descriptive analysis of state public health agency tweets from 2012 through 2022, structured as an instrumental case study organized around an issue question [19]: How did US state public health agencies engage with Twitter as a networked public?

Our data came from a download of public health agency tweets using the "academictwitteR" R package to access the Twitter application programming interface (API) through the "Twitter API v2 for Academic Research" on February 3, 2023 [18]. We

XSL•FO
RenderX

filtered the data to focus on tweets in English from state public health agencies. The language filter relied on labels available by Twitter's proprietary API data. We identified tweets from the state-level public health agency in each state by leveraging associations between usernames and author IDs recorded during the data download process [20]. These accounts were initially identified through manual searches of state public health agency websites, as well as searches on Google and Twitter where necessary. Refer to Multimedia Appendix 2 for a list of account usernames and the associated state public health agencies. The study period begins on January 1, 2012, which allowed us to build on a previous study taking a random sampling approach to analyze state public health agency tweets in the same year [15]. The study period ends on December 31, 2022, which was the most recent full calendar year at the time of data collection. We did not account for missing data, as the API download method includes an exhaustive record of all published tweets from all specified accounts during the study period. We conducted this analysis using R (version 4.2.3, R Studio version 2023.06.1+524). The scripts enabling this analysis are available in an Open Science Foundation repository [21].

We calculated indicator variables to describe health agencies' engagement with the key qualities of communication in a networked public: scalability, persistence, replicability, and searchability [1].

Scalability

"Scalability" describes social media content's hypothetical ability to reach an entire network. We assessed scalability by tweet volume and audience engagement. We calculated tweets per year, categorized into types: replies, retweets, or quote tweets (from their formal introduction in 2015) [22]. We further categorized replies into self-replies and other replies by comparing the author and in-reply-to user IDs. We used the regular expression "RT @" to identify "manual retweets," a custom metric describing text copies of messages. Here, we pooled manual retweets with formal retweets. Finally, we calculated the mean, median, and IQR of states' mean tweets per day each year, as well as the likes, replies, retweets, and quotes on non-retweets. "Non-retweets" include manual retweets, as they are unique posts rather than pointers to source tweets.

Persistence

"Persistence" describes the digital records of interactions on networked publics. We assessed persistence by manual retweets. We also calculated mentions (a hyperlinked account username) among non-retweets, as their records do not depend on other accounts' activity. We calculated the percentage of tweets that were manual retweets each year. We calculated the percentage of non-retweets with at least 1 mention each year.

Replicability

"Replicability" refers to social media content's infinite duplicability. We assessed replicability by retweets and quote tweets. We calculated the percentage of tweets that were formal retweets and quote tweets each year. We further calculated the percentage of tweets that were formal retweets of a CDC account, as well as the percentage of tweets including a CDC account mention. We used regular expressions to identify usernames starting with "CDC" or "NIOSH," which comprised the majority of usernames listed as official CDC accounts [23]. For other accounts, we relied on exact matches with entire usernames.

Searchability

"Searchability" refers to ways that social media content is findable, which we assessed by hashtag use. We calculated the percentage of tweets with at least 1 hashtag per year. We used regular expressions to extract hashtags and calculate the top 10 most common per year (after converting to lowercase). We further calculated the percentage of tweets per year using #flu or #hiv as hashtags with long-term national relevance.

Ethical Considerations

The study data consisted of publicly available information from government institutional authors. We did not seek an ethics review and have no individual participant protections in place, as they are not relevant to this study design.

Results

Overview

We identified 570,335 tweets from state public health agency accounts in English from 2012 through 2022. All 50 states were represented in this data set. However, all 50 states were only active on Twitter in 2018 and 2019, as states gradually adopted Twitter during the study period, and 1 state published its last tweet in 2019. We included 52 accounts in this data set to account for 1 state creating a replacement public health agency account during the study period, as well as another state communicating through 2 accounts under its public health agency. An exhaustive summary data table is available in Multimedia Appendix 3.

Scalability

In total, 41 states were active at any time in 2012, meaning they posted at least 1 tweet. This number increased each year, up to 50 in 2018. It decreased to 49 in 2020. The total number of tweets across all accounts increased from 25,276 in 2012 to 51,132 in 2018. The total rose to 94,205 in 2020 and decreased to 62,797 in 2022 (Figure 1). Overall, mean tweets per day rose from 1.7 in 2012 to 2.8 in 2018. It reached a maximum of 5.3 in 2020 and remained above the 2018 level. Figure 2 displays the distribution of mean tweets per day among active states each year. Delaware, North Carolina, Florida, Indiana, Pennsylvania, Massachusetts, and West Virginia each had the most tweets in a given year. Delaware, Florida, and West Virginia each had the most for multiple years in a row. Massachusetts was the most active in a single year, averaging >21 tweets per day in 2020.

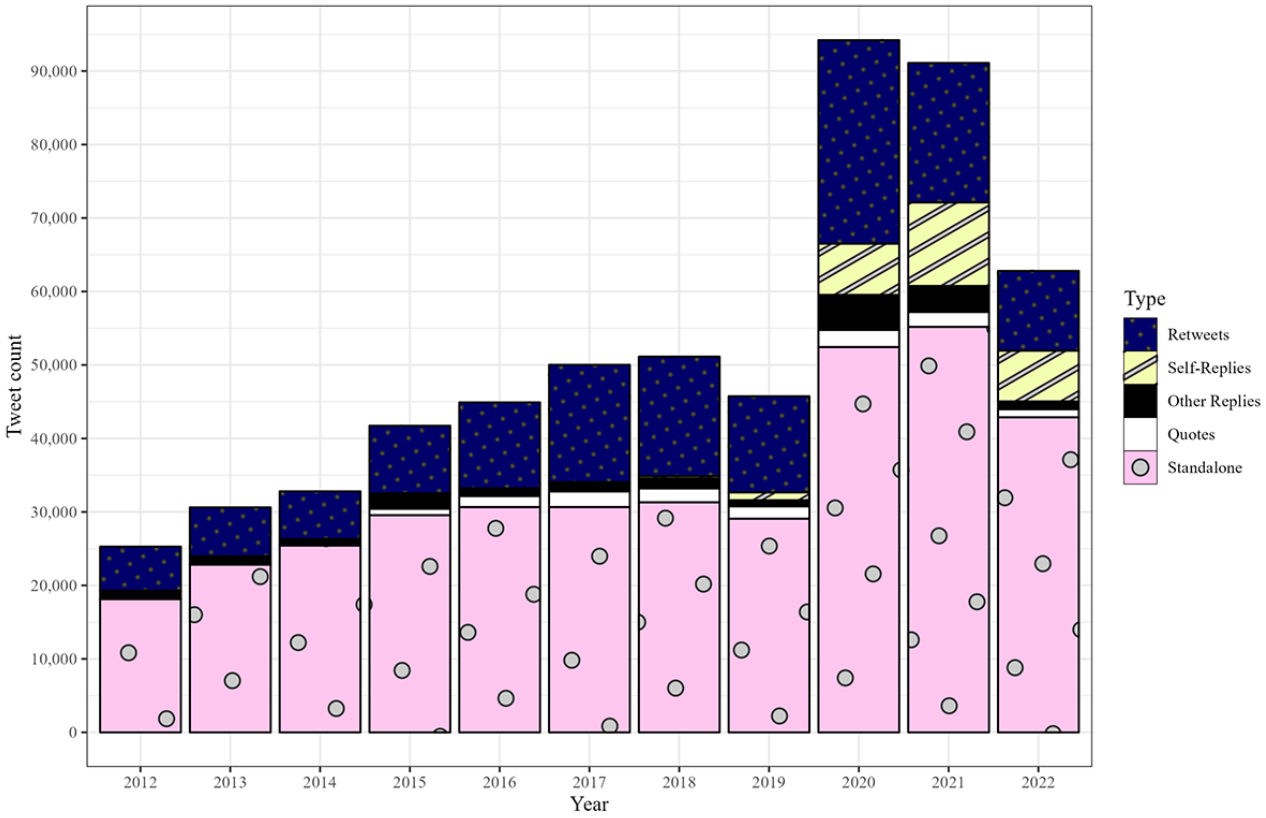
Figure 1. Stacked bar chart displaying an exhaustive enumeration of tweets from US state public health agency accounts for each year from 2012 through 2022, divided into 5 categories: retweets, self-replies, other-replies, quote tweets, and standalone tweets.



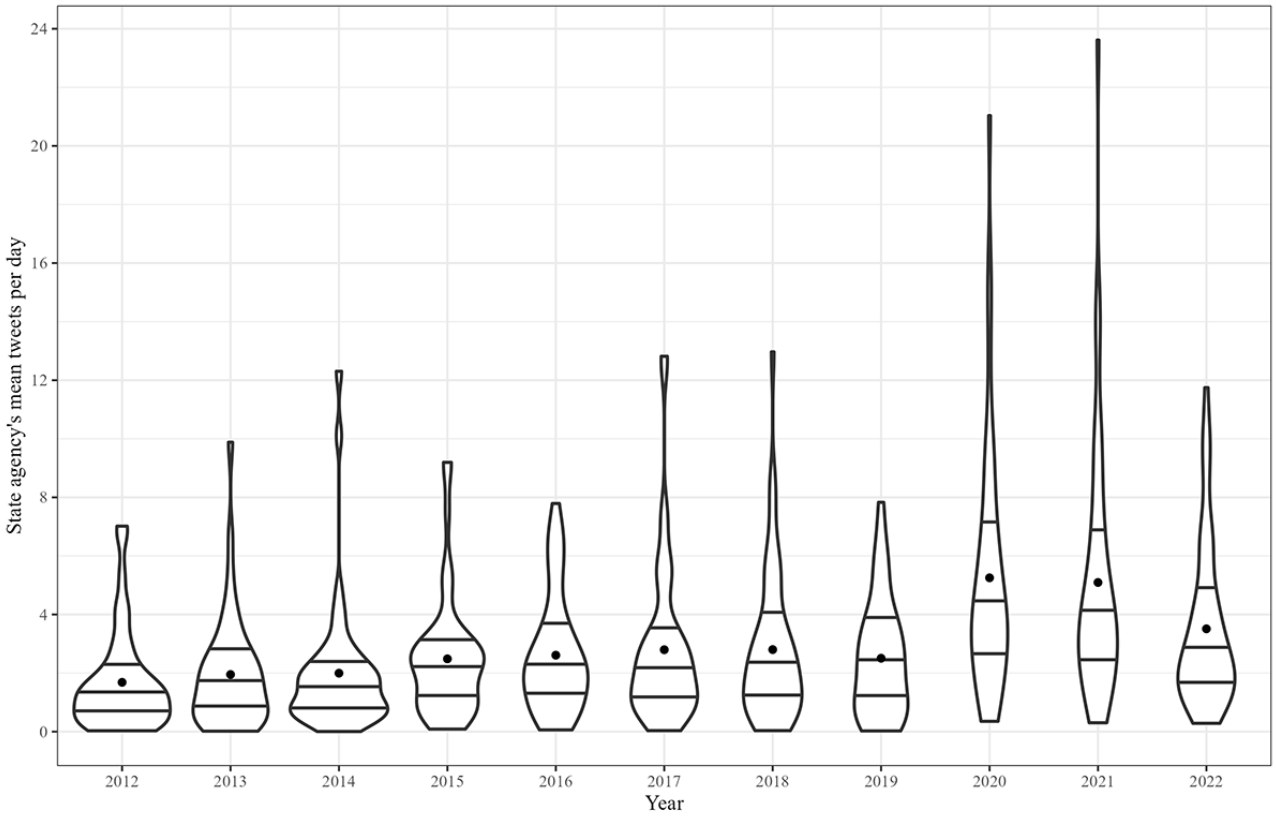


Figure 2. Among an exhaustive enumeration of tweets from US state public health agency accounts, violin plots displaying the distribution of the mean daily tweets per account, each year from 2012 through 2022. IQRs for each year are marked with horizontal lines. The mean of means for each year is marked with a dot.

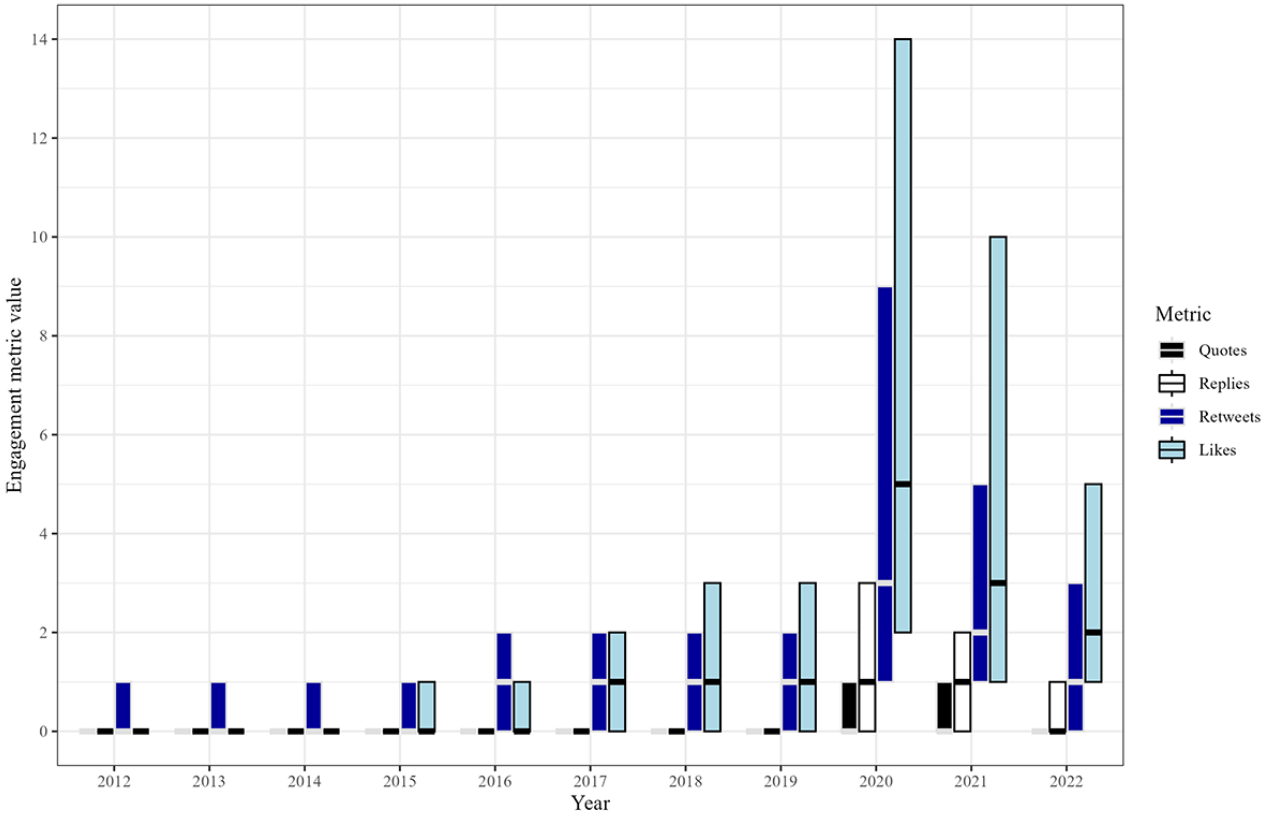


XSL•FO
RenderX

The percentage of non-retweets with 0 on all audience engagement metrics was 62% (12,965/21,023) in 2012, decreasing to 20% (6465/32,668) in 2019. It reached a minimum of 6% (4123/66,507) in 2020 and 12% (6306/51,950) in 2022.

Figure 3 presents each year's IQR for audience engagement on state agencies' non-retweets (ie, replies, quote tweets, and standalone tweets), summarized in the text below.

Figure 3. Among an exhaustive enumeration of non-retweets from US state public health agency accounts, grouped bar charts showing the IQR of audience engagement metrics, for each year from 2012 through 2022. The engagement metrics include quote tweets, replies, retweets, and likes. Note: medians are marked with a thick horizontal line. The bottom edge of each boxplot marks the 25th percentile. The top edge marks the 75th percentile.

The mean number of likes was <0.6 before increasing to 1.2 in 2016 and then 2.7 in 2019. Its maximum was 17.6 in 2020. It decreased to 5.4 in 2022. The median was 0 before rising to 1 in 2017. Its maximum was 5 in 2020. It decreased to 2 in 2022. The maximum (n=69,798) was on a 2020 tweet about social distancing in Ohio. The second highest (n=12,022) was on a 2020 tweet about face coverings in California.

The mean number of replies was <0.3 before rising to a maximum of 3.5 in 2020. It decreased to 1.8 in 2022. The median was 0 every year except for 2020 and 2021, when it was 1. The maximum (n=2003) was on a 2022 tweet about the COVID-19 pandemic and breastfeeding or chestfeeding from Washington. The second highest (n=1954) was on a 2021 tweet about face coverings in Alabama.

The mean number of retweets was <1 until 2015, rising to 1.8 in 2018. Its maximum was 10.9, in 2020. It decreased to 2.9 in 2022. The median was 0 until rising to 1 in 2016. Its maximum was 3 in 2020. It decreased to 1 in 2022. The maximum (n=39,950) was on the previously mentioned Ohio tweet. The second highest (n=4844) was on a 2020 tweet about COVID-19 cases in Florida.

The mean number of quotes was <0.3 until rising to a maximum of 1.9 in 2020 and decreasing to 0.6 in 2022. The median was 0 for the entire study period. The maximum (n=7041) was on the previously mentioned Ohio tweet. The second highest (n=2552) was on a 2020 tweet about raw meat in Wisconsin.

Persistence

The percentage of non-retweets with at least 1 mention of an account other than the authoring state public health agency decreased from a maximum of 21% (5399/25,267) in 2013 before decreasing to 17% (4437/26,750) in 2014. It then went up and down within that range before dropping off to 13% (9661/72,124) in 2021 and a minimum of 10% (5402/51,950) in 2022.

Among non-retweets, the top-mentioned account each year was @CDCgov. Before 2018, the top 10 accounts typically included at least 2 accounts representing a company or a non-CDC federal government account. In 2018, 9 of the top 10 represented state government agencies or officials, with the top 10 maintaining a similar balance for several years. In 2022, the top 10 included 2 additional CDC accounts and 2 other federal agencies.

The overall percentage of manual retweets decreased from 7% (1729/25,276) in 2012 to 1% (427/32,800) in 2014, then to <0.1% (5/50,024) in 2017 and 0% (0/91,099) in 2021.

XSL•FO
RenderX

Replicability

The percentage of tweets that were formal retweets increased from 17% (4263/25,276) in 2012 to its maximum of 32% (15,955/50,024) in 2017. It decreased to 29% (27,698/94,205) in 2019 and increased slightly in 2020 before decreasing to 17% (10,847/62,797) in 2022.

The percentage of tweets that mentioned a CDC account was 4.2% (1056/25,276) in 2012, increasing to a maximum of 7% (3559/51,132) in 2018 and decreasing to a minimum of 3.5% (2218/62,797) in 2022. The percentage of tweets retweeting a CDC account increased from a minimum of 2.1% (521/25,276) in 2012 to a maximum of 5.4% (2756/51,132) in 2018. It decreased 2.2% (1363/62,797) in 2022.

The percentage of quote tweets increased from 2% (877/41,730) in 2015 to 4% (2129/50,024) in 2017 before decreasing each year to a minimum of 2% (1106/62,797) in 2022. Table 1 displays the retweet and quote tweet data by year.

Table 1. Among an exhaustive enumeration of all tweets from US state public health agency accounts, the portions that were either retweets or quote tweets, as well as the portion mentioning or retweeting a CDC[a] account.

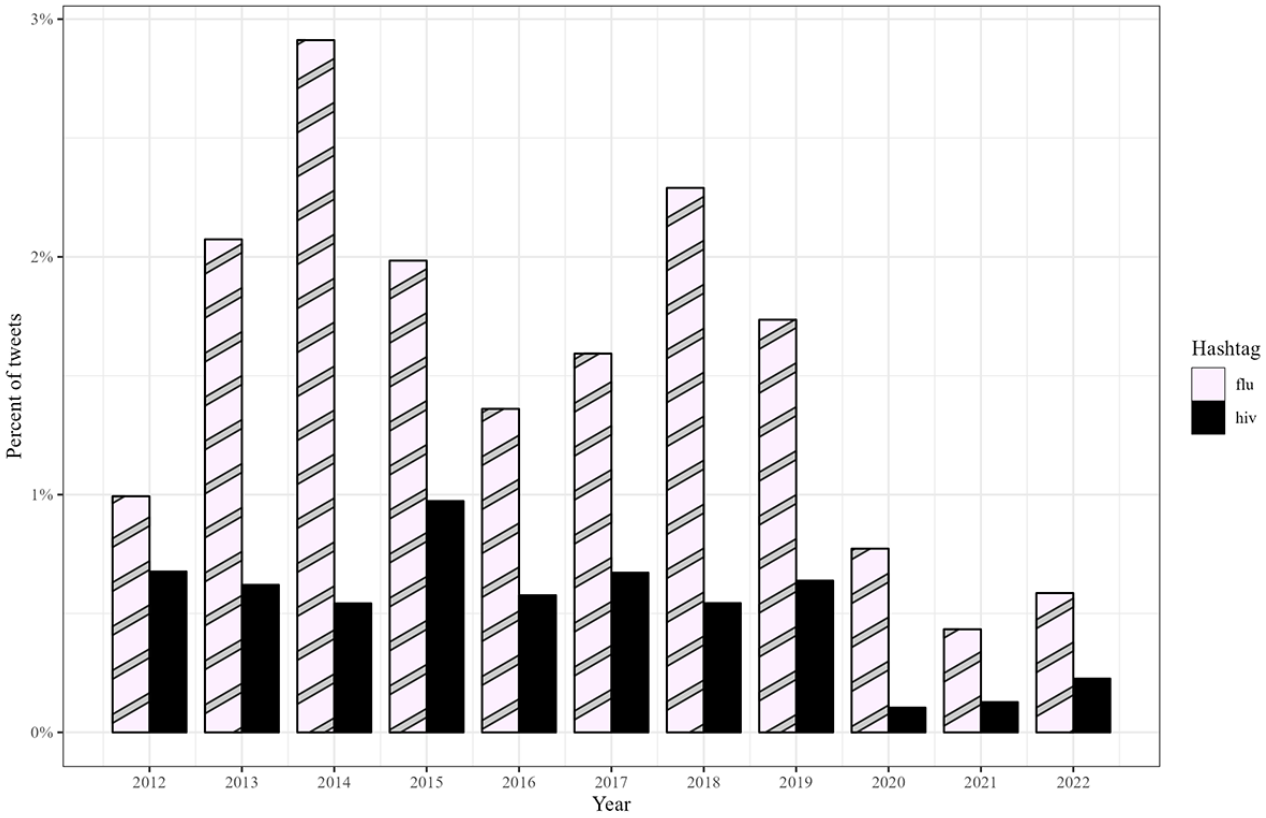
Year	Retweets (%)	Quote tweets (%)	Tweets with ≥1 mention of a CDC account (%)	Retweets of a CDC account (%)
2012	16.9	—[b]	4.2	2.1
2013	17.5	—	4.7	2.4
2014	18.4	—	4.8	2.9
2015	21.8	2.1	4.4	3.2
2016	26.0	3.3	6.0	4.1
2017	31.9	4.3	6.1	4.8
2018	31.8	3.7	7.0	5.4
2019	28.9	3.7	5.4	3.6
2020	29.4	2.5	4.8	3.6
2021	20.1	2.2	3.7	2.6
2022	17.3	1.8	3.5	2.2

[a]CDC: US Centers for Disease Control and Prevention.

[b]Not applicable.

Searchability

The percentage of tweets with at least 1 hashtag increased from a minimum of 36% (9019/25,276) in 2012 to a maximum of 58% (24,017/41,730) in 2015. It decreased to 38% (23,565/62,797) in 2022.



The hashtags #health, #healthde, #ebola, #vibriovulnificus, #zika, #flu, and #covid19 were each the most common hashtags at 1 point during the study period. The #flu and #covid19 hashtags were each the most common for 3 consecutive years. The top 10 hashtags each year included at least 1 reference to natural disasters or disease outbreaks like #sandy or #ebola. From 2012 through 2016, top hashtags included at least 1 reference to a public health event, such as #cdcchat. In 9 years, the top 10 included #netde, a Delaware-specific hashtag.

Nine of the top 10 hashtags in 2020 and 2021 referred to the COVID-19 pandemic. This number decreased to 5 in 2022. In 2020, 5 of the top 10 hashtags were state-specific COVID-19 hashtags like #covid19ma. This decreased to 2 in 2021 and 2022.

The hashtag #flu was in the top 10 every year in the study period. The hashtag #hiv was in the top 10 from 2012 through 2017 and in 2019. Figure 4 presents the percentage of tweets, including #flu or #hiv, each year.

XSL•FO
RenderX

Figure 4. Among an exhaustive enumeration of tweets from US state public health agency accounts, grouped bar charts displaying the portion using the #flu or the #hiv hashtag, for each year from 2012 through 2022.

Discussion

Principal Findings

We analyzed state public health agencies' English-language tweets from 2012 through 2022 to provide a complete snapshot of Twitter use in the long term. We used Twitter API data as indicators for agencies' engagement with key qualities of communication in a networked public: scalability, persistence, replicability, and searchability. We found increasingly fragmented communication over time, with less emphasis on replicability and persistence. This involved a drop in public interactions with other accounts in the form of retweets and quote tweets, which coincided with a dramatic increase in overall tweet volume and audience engagement during the COVID-19 pandemic.

Indicators of scalability and searchability on Twitter display a drastic shift at the beginning of the pandemic. We observed a dramatic increase in Twitter outputs and a focus on state-specific searchability amid a decreased focus on searchability overall. Though some states were especially active, the entire interquartile range of states' mean Tweets per day shifted up throughout the pandemic. Audience engagement metrics followed a similar pattern, though still modest by marketing standards. Multiple COVID-19 hashtags were prominent from 2020 through 2022, with state-specific pandemic hashtags especially prominent in 2020. This contrasted with the prepandemic prominence of broader, more singular health emergency hashtags like #measles or #ebola.

Indicators of persistence and replicability did not display the same kind of COVID-19 pandemic–era shift. We observed more fragmented public health communication over time, relying less on replicating messages and traceable interactions with other accounts, on a time scale that did not align with the beginning of the pandemic. Mentions of state government officials became more prominent before the pandemic and remained so during the pandemic. The decrease in mentions of external accounts did not occur at the start of the pandemic. The rate of quote tweets decreased over time, starting before the pandemic. The rate of formal retweets followed a similar pattern but with a larger sudden decrease during the second year of the pandemic. The rate of mentions and retweets of CDC accounts decreased over time, starting before the pandemic.

Finally, an overarching finding in this study was between-state variation that did not fall neatly along the lines of geography, population, or a political binary of red and blue states. Florida, West Virginia, and Delaware were all highly active on Twitter for multiple years. Massachusetts, Wisconsin, and Ohio health agency communication styles included prominent use of state-specific pandemic hashtags. Tweets with record engagement were from Washington, Ohio, California, Florida, Wisconsin, and Alabama.

Limitations

Our findings should be interpreted in light of 4 limitations. First, we collected our data retrospectively, meaning Tweet deletion and changes in privacy settings potentially shaped our findings. By the nature of these underlying nonrandom mechanisms, it is not possible to estimate the magnitude of potential missing

XSL•FO
RenderX

data or how missingness may have changed over the study period. However, we argue this is not a critical issue for state health agencies, whose communications are part of the public record. This could, however, impact our findings around retweets and quote tweets of other accounts. We argue this is not likely a significant limitation, as the scale of "standalone tweets" we observed toward the beginning of our study period was similar to measures of "original tweets" from Thackeray et al [15]. A second limitation is our use of API indicators to filter tweets by language, relying on Twitter's proprietary processing. Third, we focused solely on text features, meaning we missed trends in multimedia content, for example, reuploaded graphics. Finally, we studied only 1 platform. While our numerical results are not generalizable to other platforms, the patterns we identified in terms of our theoretical framework can be directly compared with data from other networked publics.

Comparison With Previous Work

Our findings about the long-term prominence of self-replies and standalone tweets align with findings on the one-way nature of public health communication on Twitter from the previous decade [14,15]. We argue this could actually be a form of effective tailoring, for example, if known journalists draw information from Tweets for dissemination more often than they draw from press releases. However, there is a need for more research to make sense of our findings, such as exploring whether public health tweets during the pandemic have been helpful for these audiences.

Our findings differ from those of a study from Bradford et al [17], whose work covered a study period contained within our own. This appears to be due to their inclusion of only 1 Twitter account from Maine, in contrast with our inclusion of both Maine's Department of Health and Human Services (DHHS) and its Center for Disease Control and Prevention (MeCDC) accounts. We made this decision after noting the MeCDC serves as the primary public-facing communication arm of the state DHHS. This aligns with the finding from Bradford et al [17] that a Maine account was barely active during their study period. Our conclusion about the overall volume of tweets also differs from Bradford et al [17], due purely to a matter of interpretation. Bradford et al [17] interpreted their observations as signs of low Twitter activity despite most accounts tweeting multiple times per day. We interpreted that same volume of tweets as high activity due in part to the sharp contrast with prepandemic levels. This highlights the need for more research on state health agencies' social media strategies to help interpret our findings and those of other quantitative descriptions of public health communication on social media. Despite our differing conclusions, we echo the call of Bradford et al [17] for more research into the determinants of social media use at state health agencies. For example, we do not know to what degree our findings reflect purposeful decisions within state health agencies or the effects of changes in platform ownership, communication budgets, political factors, or platform design changes over time.

Our findings align with research on US state health departments' use of Facebook. Previous work has found the overall volume of Facebook posts by state health departments to vary [24]. Previous work has also identified different message frames between CDC and state and local health department Facebook posts [25], which could relate to our observed trends in decreasing engagement with CDC tweets and Twitter accounts in the latter half of our study period. Though Twitter and Facebook are prominent social media platforms, future research should quantitatively analyze state health departments' use of other platforms as well.

Conclusions

Our findings warrant further research to elucidate the factors driving the variation we saw between states and over time. This includes research into potential platform-specific communication strategies, health communication training, platform policy, and network norms. Such research should include qualitative content analyses of social media content to elucidate the actual use of social media in public health agencies, not just intended strategies. Further quantitative research should examine the impact of political factors on public health communication on social media. This includes state and federal political factors like budget changes and political divisions around the practice of public health. Further research is also warranted to better understand various audiences' interactions with health agencies in networked publics, as well as their perceptions of state-level health communication.

Our findings raise further questions about what state health agencies' communication should look like and how to support it. For example, it might be impractical for state agencies to target communities that have more contact with local health departments, even when there may be more extensive communication resources at the state level. There is not a robust national infrastructure to fill this gap, much less monitor and evaluate health communication on social media during a public health emergency. This gap is a critical contextual factor to consider when interpreting our findings around between-state variation.

Our study exemplifies the use of theoretical frameworks from media studies to understand trends in public health communication on social media. Though we examined metrics from one social media platform, our use of the networked public framework allows us to draw broader inferences about health communication. This increases the relevance of our findings despite differing features across time and across platforms. This is in contrast to the existing descriptive work of US state health agencies on Twitter. Integration of a theoretical framework should be a key part of future research on public health communication on social media, so as to extend its use beyond the limited scope of one platform's features.

Finally, our study highlights the vulnerability of public health communication in networked publics. A social media platform's use is subject to corporate decisions and community norms. If a platform shuts down or its communities deliberately hide health information, then public health investment in that platform may be suddenly irrelevant. For example, it is unclear whether the drop-off in tweets we observed in 2022 was the result of strategic decisions, insufficient resources, or platform changes. Even the ability to efficiently study public health communication largely depends on corporate policies around

XSL•FO
RenderX

data access. Our study highlights the importance of supporting health communication research. This includes regulation to ensure academic access to social media data, as well as building a robust communication infrastructure outside of private platforms.

Abstract

Background: People share health-related experiences and treatments, such as for insomnia, in digital communities. Natural language processing tools can be leveraged to understand the terms used in digital spaces to discuss insomnia and insomnia treatments.

Objective: The aim of this study is to summarize and chart trends of insomnia treatment terms on a digital insomnia message board.

Methods: We performed a natural language processing analysis of the r/insomnia subreddit. Using Pushshift, we obtained all r/insomnia subreddit comments from 2008 to 2022. A bag of words model was used to identify the top 1000 most frequently used terms, which were manually reduced to 35 terms related to treatment and medication use. Regular expression analysis was used to identify and count comments containing specific words, followed by sentiment analysis to estimate the tonality (positive or negative) of comments. Data from 2013 to 2022 were visually examined for trends.

Results: There were 340,130 comments on r/insomnia from 2008, the beginning of the subreddit, to 2022. Of the 35 top treatment and medication terms that were identified, melatonin, cognitive behavioral therapy for insomnia (CBT-I), and Ambien were the most frequently used (n=15,005, n=13,461, and n=11,256 comments, respectively). When the frequency of individual terms was compared over time, terms related to CBT-I increased over time (doubling from approximately 2% in 2013-2014 to a peak of over 5% of comments in 2018); in contrast, terms related to nonprescription over-the-counter (OTC) sleep aids (such as Benadryl or melatonin) decreased over time. CBT-I–related terms also had the highest positive sentiment and showed a spike in frequency in 2017. Terms with the most positive sentiment included "hygiene" (median sentiment 0.47, IQR 0.31-0.88), "valerian" (median sentiment 0.47, IQR 0-0.85), and "CBT" (median sentiment 0.42, IQR 0.14-0.82).

Conclusions: The Reddit r/insomnia discussion board provides an alternative way to capture trends in both prescription and nonprescription sleep aids among people experiencing sleeplessness and using social media. This analysis suggests that language related to CBT-I (with a spike in 2017, perhaps following the 2016 recommendations by the American College of Physicians for CBT-I as a treatment for insomnia), benzodiazepines, trazodone, and antidepressant medication use has increased from 2013 to 2022. The findings also suggest that the use of OTC or other alternative therapies, such as melatonin and cannabis, among r/insomnia Reddit contributors is common and has also exhibited fluctuations over time. Future studies could consider incorporating

XSL•FO
RenderX

alternative data sources in addition to prescription medication to track trends in prescription and nonprescription sleep aid use. Additionally, future prospective studies of insomnia should consider collecting data on the use of OTC or other alternative therapies, such as cannabis. More broadly, digital communities such as r/insomnia may be useful in understanding how social and societal factors influence sleep health.

KEYWORDS

insomnia; natural language processing; NLP; social media; cognitive behavioral therapy; CBT; sleep initiation; sleep disorder; easly awakening; sleep aids; benzodiazepines; trazodone; antidepressants; melatonin; treatment

Introduction

Insomnia is a condition characterized by self-reported difficulty in falling asleep or staying asleep, with accompanying distress or impairment [1]. Insomnia symptoms can be chronic or acute [2]. Approximately 10%-30% of the population is estimated to experience either chronic or acute insomnia, with insomnia more common among women and older adults [3,4]. One prospective cohort study reported an insomnia incidence of 13.9%—of those, 37.5% developed chronic insomnia over a 5-year period [5].

People experiencing insomnia may report decreased quality of life and daily functioning [6,7], have higher injury risk [8], and may seek multiple treatment options to improve their sleep and address insomnia symptoms [9]. Insomnia treatment approaches have also changed over time. Hypnotics used to be the primary treatment option for insomnia until behavioral treatment options such as cognitive behavioral therapy for insomnia (CBT-I) were shown to be highly clinically effective [10]. Alternative herbal remedies for insomnia, such as herbal teas to induce somnolence, have also been popular throughout history [11]. Trends in social mention of insomnia treatment options may track with changes in approaches for treatment in the medical community, but they may also reflect additional community-based approaches due to limitations in access to treatment or cultural preferences. These community-based approaches, such as using herbal teas and supplements, may not be reflected in medical records or drug prescription rates.

The language used by individuals seeking and obtaining insomnia treatment may be heterogeneous and may differ from standard medical terminology for the treatment provided [10]. For example, one of the components of CBT-I consists of sleep hygiene, which addresses routines and environmental factors that influence sleep initiation and maintenance [12]; however, the term “hygiene” may connote a negative association, implying the person seeking help has “dirty” sleep habits [13]. Understanding the language that people use in digital insomnia-related communities and the sentiment attached to treatment terms may be useful for health practitioners as they work to understand how to discuss symptoms and treatment options with their patients, as well as for sleep researchers engaged in data collection. Mapping trends in language around insomnia may also provide insights helping to interpret the use of related terms over time and may identify temporal patterns in the use of medication and other therapies for insomnia.

Digital health-related message boards can be important sources of frank discussion and community and provide insight into beliefs, practices, and language. Reddit is one such digital community with medically related subreddits; prior analyses of these subreddits have used well-established, reliable, natural language processing (NLP) techniques such as bag of words (BOW), regular expressions (RE), and Valence Aware Dictionary and Sentiment Reasoner (VADER) to better understand patient or community experiences [14-16]. For example, Low et al [17] analyzed data from Reddit mental health communities using various NLP techniques to identify changes in various mental health–related subreddits during the COVID-19 pandemic. However, these techniques have not been previously applied to the r/insomnia subreddit. The r/insomnia subreddit may be a particularly rich source to examine insomnia using NLP techniques because sleeplessness is commonly self-treated outside of a medical setting. In a 2022 American Academy of Sleep Medicine (AASM) survey (n=2010 US adults), 64% of respondents reported using a substance to help them sleep, with 23% reporting the use of prescription medications and 41% reporting the use of an over-the-counter (OTC), herbal, or other substance; the use of a sleep aid was most prevalent among respondents aged 18-54 years [18]. Comments on r/insomnia, an anonymous forum, may be a resource for understanding self-treatment behavior and the use of prescription or nonprescription substances. We characterize the language used in a digital discussion board of insomnia using an NLP analysis of the r/insomnia subreddit to measure the discussion frequency of insomnia-related substances and to identify the sentiment (positive or negative) when substances are mentioned.

Methods

Overview

Our goals were to measure the discussion frequency of insomnia-related substances and to identify the sentiment. Thus, we applied a set of NLP methods that (1) extract common words from text, (2) identify substance-related treatment terms (relying on human recognition of some terms), and (3) assign sentiment to sentences containing such terms. First, the r/insomnia data were collected from the Pushshift dataset. Next, comments were converted to word counts using a BOW model. Using this BOW model, the most common nonstop words were identified, and the insomnia treatment–related terms were selected. The BOW approach was chosen because (1) it is a simple and efficient method and (2) summarizing and quantifying the popularity or frequency of treatment terms was a primary goal; in this way,

XSL•FO
RenderX

disadvantages of BOW, such as loss of word order, were not deemed to be problematic for our purposes. REs were then applied to quantify the use of these terms in the subreddit over time. The RE approach was chosen because (1) the percentage of comments containing a term is an effective way to gauge the popularity or interest in a term, and (2) it is able to find all comments that contain a pattern of letters rather than just individual words (like the BOW method). For example, the RE pattern "sleep" would also capture related words with the same root, such as "asleep," "sleep," "sleeping," and "sleeplessness." Finally, sentiment analysis was applied on the raw comments (not word counts; Figure S1 in Multimedia Appendix 1). Sentiment analysis was chosen because, in addition to measuring interest in these terms and treatments, the goal of this study was to gauge how social media users felt about the terms and treatments. In general, the average sentiment of comments containing the treatment term is expected to reflect the sentiment toward that treatment.

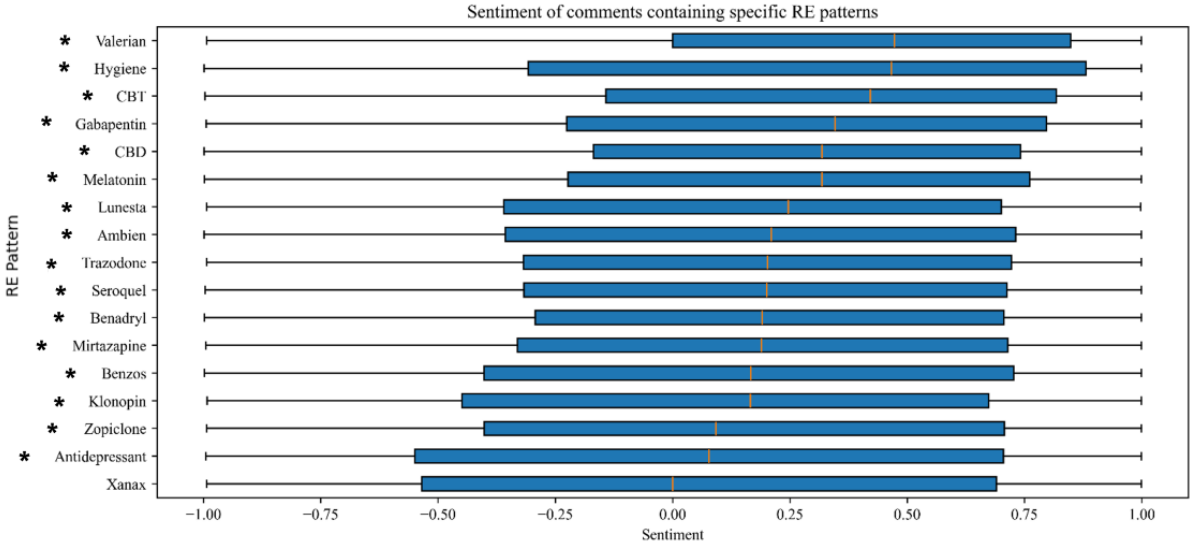
Data Source

All subreddit comments from the history of r/insomnia [19] in 2008 up to the end of 2022 were obtained from the top 20,000 subreddits Pushshift dataset, which is a publicly available dataset [20,21]. All comments from the r/insomnia subreddit from 2008 to 2022 were included in each data analysis step. Data analysis was performed with Python (version 3; Python Software Foundation), and statistical testing was performed with R (version 4.4.0; R Foundation for Statistical Computing). Analyses that were summarized by year used comments dated up to December 31, 2022. All methods of analysis detailed below refer to individual comments (responses, not including the original post). If a thread of conversation included multiple comment responses from different commenters or the same commenter, then each comment within the thread would be counted as a separate comment in the total. This study did not meet the criteria for human participant research as defined by Mass General Brigham Human Research Office policies and Health and Human Services regulations set forth in 45 CFR 46. The data were obtained from a publicly available anonymous digital forum.

Identifying Treatment-Related Words Using a BOW Model

A BOW model, which extracts text features without regard to the order, was created using the *gensim* package [22]. A BOW model counts the number of occurrences of each word in a comment (excluding "stop words," such as "the" and "a"). To create the BOW model, we first preprocessed all comments from the r/insomnia subreddit using the gensim simple preprocessor function, which removed symbols and numbers and converted the comments into lists of words. The natural language toolkit "wordNetLemmatizer" was used to convert words to their dictionary forms. For example, the word "dogs" is simplified to "dog," but the word "benzos" would not be shortened to "benzo" because it is an abbreviation and is not included in the dictionary. Stop words were removed from comments. Words used in fewer than 15 comments were removed. After the BOW model was created, the 1000 words with the highest comment frequency (number of comments that contain the word at least once) were retrieved. The list of 1000 words for the r/insomnia subreddit was reviewed manually by one of the authors (DAW) and reduced to words based on relevance to insomnia medication or insomnia-related treatment terms. The words are referred to henceforth as the "BOW list." To identify additional brand or generic drug names for the treatment terms that referred to a medication, we also performed an extensive search using the Epocrates drug reference platform in addition to Google and Wikipedia. Terms that referred to the same treatment, such as generic versus brand names of medications (eg, quetiapine and Seroquel), were combined in deriving term counts (Figure S1 in Multimedia Appendix 1).

Using REs to Identify Textual Patterns in the Data



In addition to BOW, we used RE to identify patterns in the text by identifying and counting comments that contained each of the selected words of interest from the BOW list within r/insomnia. The RE searches were set as case insensitive. We used Matplotlib [23] to visualize the percentage of r/insomnia comments containing each of the prespecified words each year. The percentage of comments containing a word each year was calculated as the total number of comments containing the specified word divided by the total number of comments in the subreddit extracted from that year, not accounting for authorship. To standardize the data and account for changes in total r/insomnia comment volume over time, all data are reported as the percentage of total annual comments that contain the specified term (ratio of comments containing the term relative to the total annual comment volume). The analysis focused on the years 2013 to 2022 because comment volume was low prior to 2013. For some related words, search terms were combined so that comments containing any of multiple words (eg, "CBT," "CBTI," or "hygiene") were counted together in the analysis.

Sentiment Analysis of Insomnia Treatments

Sentiment analysis was also applied to identify the overall emotional tone of the text containing the terms of interest. Sentiment analysis was performed using the VADER [20], a reliable and commonly used lexicon and rule-based tool specifically trained on and developed for use with social media data [22-25]; VADER has been applied in numerous prior health-related analyses of Reddit data [26-28]. VADER calculates the polarity of text on a normalized scale from –1 to 1, 1 being the most positive sentiment for a comment and –1 being the most negative sentiment for a comment. The resulting sentiment values from comments containing insomnia-related treatment terms were compared. To test whether sentiment by treatment term category significantly differed from 0, comments with treatment terms were subset to randomly select 1 comment per author (for independence; Figure 1), and sentiment tested to be different from 0 using 1-sample Wilcoxon signed rank tests (2-sided). Bonferroni correction was used to correct for multiple testing, and results (P<.003) were considered statistically significant.

XSL•FO
RenderX

Figure 1. Boxplot of sentiment of the treatment and medication terms identified in r/insomnia comments after randomly selecting 1 comment per author. The blue boxes depict from the first quartile to the third quartile, with the median marked by an orange line. The black lines extend to minimum and maximum values. Asterisks mark terms with sentiment significantly different from 0 in 1-sample Wilcoxon signed-rank test after Bonferroni correction for multiple testing (P<.003). CBD: cannabidiol; CBT: cognitive behavioral therapy; RE: regular expression.

Ethical Considerations

Ethical concerns exist with the use of internet and social media data and should be considered prior to and throughout the data analysis process. Although our project received a research exemption, we believe it is important to mention some of the ethical issues around using Reddit data. The data we used in this analysis are publicly available. However, social media can also potentially contain identifying information if names or other identifiers are contained within the data. Reddit is considered an anonymous site where users create their own usernames or pseudonyms [29] compared to other social media sites, where people may use their real names; we also do not mention usernames or provide quotes from comments to protect the anonymity of commenters [30] and present aggregated results. Additionally, the r/insomnia subreddit has a sizeable community base compared to smaller subreddits, where commenters may know each other [30]. Given these considerations, we believe that our analysis aligns with current ethical guidelines around the use of internet data [31].

Results

There were 340,130 comments from the r/insomnia subreddit. Only data from the years 2013 to 2022 were included in the trend analyses due to sparse data (less than 2500 comments per year) through 2012.

Insomnia Subreddit Growth Over Time

The number of comments per year in the r/insomnia subreddit grew steadily from 306 comments in 2011 to 86,623 comments in 2022 (Table S1 and Figure S2 in Multimedia Appendix 1). The number of unique commenters also grew from 155 commenters in 2011 to 14,866 commenters in 2022 (Table S1 in Multimedia Appendix 1). The number of unique authors commenting on the subreddit increased every year except for 2021, when there was a 2.5% decrease in unique authors. The number of comments also increased every year. The subreddit grew the greatest in 2019, with 20,942 (79.5%) more comments and 4319 (88.5%) more unique commenters compared to 2018. The rate of increase in number of comments and commenters began to plateau from 2020 to 2022.

Patterns in Treatment and Medication Term Use

Unsurprisingly, the most common term in the r/insomnia subreddit was “sleep.” Of the top BOW 1000 terms, we selected 35 terms related to treatment and medication use (Table 1 and Tables S2 and S3 in Multimedia Appendix 1). Melatonin was the most common single treatment term, with 15,005 mentions, followed by terms related to CBT-I, with 13,461 mentions. When time trends were evaluated with RE, terms related to CBT-I spiked in 2017-2018, with a slight decrease and plateau from 2020 onward (Figure 2); the term “hygiene” alone, however, had less variable patterns (Figure S3 in Multimedia Appendix 1). The combined frequency of terms related to antidepressant medications (Table S3 in Multimedia Appendix 1) showed an increase in 2016-2017 and a gradual decline and plateau until a subsequent rise starting in 2020. Terms related to benzodiazepines overall showed a general increase in frequency over time (Figure 2), with a gradual increase from 2013 to 2016, a gradual decrease from 2016 to 2019, and a subsequent increase from 2020 to 2022.

Hydroxyzine	1165
Remeron	1047
Ativan	1032
Unisom	812
Quetiapine	940

[a]Combined number of comments are provided over groups of terms that are likely to refer to the same treatment. The number of comments for each unique term may not add up to the combined number of comments because some comments contain multiple terms in a group.

[b]The combined number of comments for the terms CBT, CBT-I, and hygiene together is 13,461.

XSL•FO
RenderX

[c]CBT: cognitive behavioral therapy.

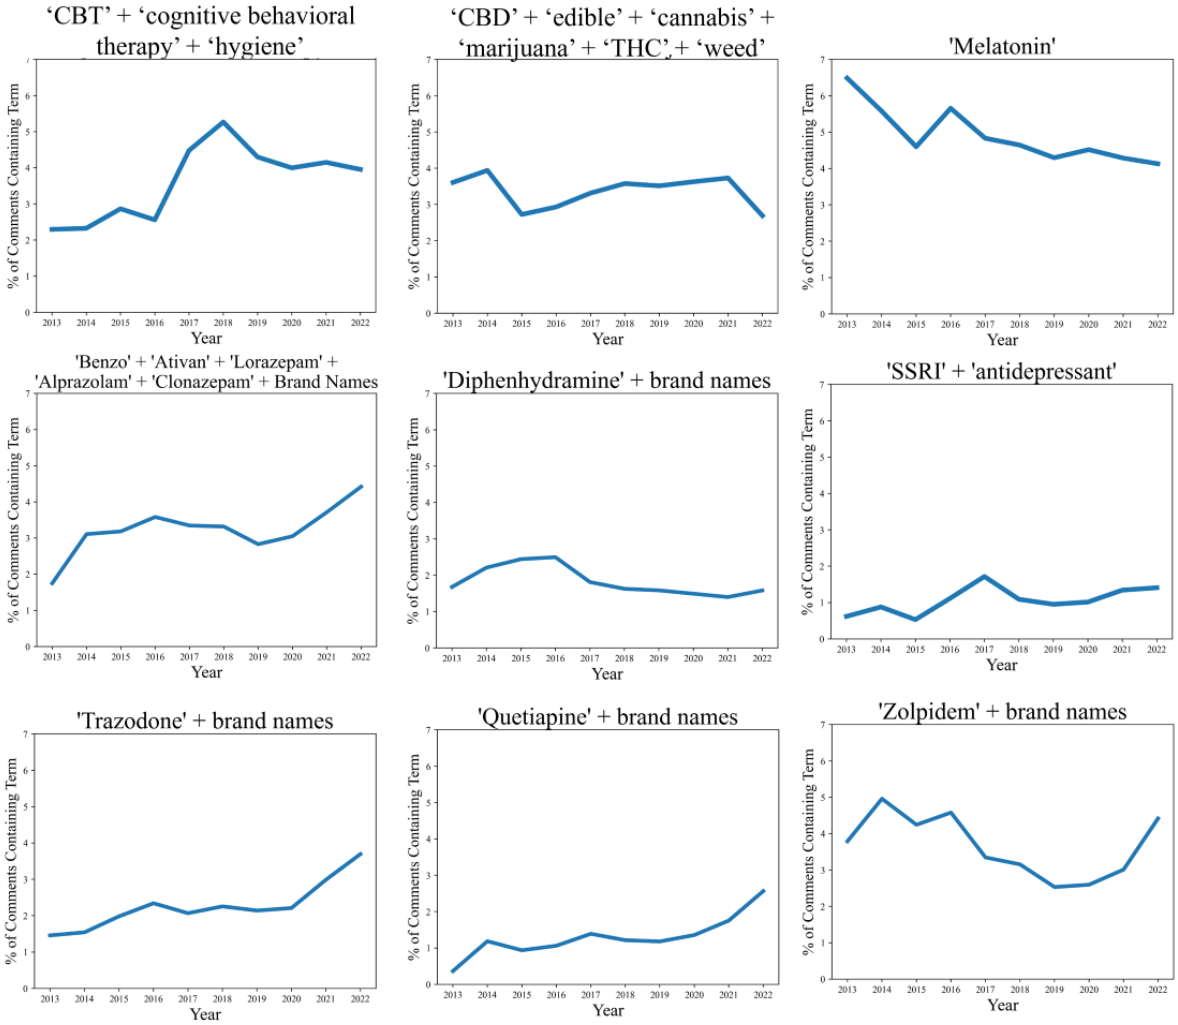
[d]CBT-I: cognitive behavioral therapy for insomnia.

[e]The combined number of comments for the terms trazodone and trazadone together is 9277.

[f]The combined number of comments for the terms benzos, benzo, and benzodiazepine together is 6816.

[g]The combined number of comments for the terms weed, marijuana, cannabis, CBD, and THC together is 10,232.

[h]CBD: cannabidiol.



[i]THC: tetrahydrocannabinol.

[j]SSRI: selective serotonin reuptake inhibitor.

[k]The combined number of comments for the terms gabapentin and GABA together is 2230.

[l]GABA: γ-aminobutyric acid.

Figure 2. Trends in select treatment and medication terms (percent of comments each year containing specific terms) in the r/insomnia subreddit from 2013 to 2022. As indicated in titles, equivalent or related terms were combined; the numerical percent of comments counts all comments containing one or more of the listed terms. CBT: cognitive behavioral therapy; CBD: cannabidiol; SSRI: selective serotonin reuptake inhibitor; THC: tetrahydrocannabinol.

Results of the Treatment and Medication Term Sentiment Analysis

To better understand the emotionality associated with the discussion of treatment within the discussion board, we also conducted a sentiment analysis of the BOW medication and treatment terms. All medication and treatment terms were significantly different from 0 (P<.003), except for terms related to "Xanax." The terms with the most positive sentiment included "hygiene," "valerian," "CBT" (referencing CBT-I), "melatonin," and "CBD" (referencing cannabidiol; Figure 1). The terms with the lowest sentiment (although still positive) included "antidepressant," "zopiclone," "Seroquel," and "Klonopin."

Discussion

Principal Findings

In this analysis of a public internet discussion forum for insomnia, we identified patterns in the frequency of treatment and medication terms over time. Mention of CBT-I,

XSL•FO
RenderX

benzodiazepines, trazodone, and other antidepressants increased over time, while nonprescription terms showed varying fluctuations. Our results both align with prior studies and present new findings, particularly for treatments that are not well captured in medical records. Additionally, population-level patterns in sleep health and insomnia may also reflect larger societal changes, given the importance of sociocultural context in sleep behavior [24] as well as the popularity and availability of sleep treatments.

We applied 3 NLP methods. BOW was necessary to identify frequently used terms within the subreddit because it tokenizes each comment and counts words that are used in the greatest number of comments. After BOW was used to identify the most used terms and treatments, RE was a natural choice to determine the number of comments containing the term because RE can identify terms by patterns of letters. As a result, RE can identify not only words that exactly match but also all words that have the same root (including other tenses, plural, closely related words, and some misspelled versions of the word used by commenters). Finally, VADER, a widely used sentiment analysis tool that is specifically trained for social media data, was used to determine in quantifiable terms the degree to which comments containing a term demonstrate positive or negative sentiment.

Individual treatment terms related to melatonin and CBT-I were the most common across time. They were also associated with high positive sentiment. While melatonin frequency showed a slight decline from 2014 to 2022 in the RE analysis, the frequency of terms related to CBT-I spiked after 2016. This rapid increase in CBT-I may be linked to the guidelines published by the American College of Physicians in May 2016, which recommended CBT-I as a frontline treatment for insomnia [12]. However, starting in 2018, there has been a decrease and subsequent plateau in the frequency of CBT-I terms. There is a documented lack of providers trained in behavioral sleep medicine, particularly in CBT-I, where there are not enough CBT-I practitioners to meet patient demand [10,25]. While the reasons for the slight decrease in CBT-I frequency in 2018-2019 are unclear, the plateau from 2020 onward may be due to more limited ability to seek provider care or decreased availability of providers during the COVID-19–related disruptions in the health care system.

The overall increase in the mention of benzodiazepines may indicate a resurgence in benzodiazepine use. Benzodiazepines are a medication of concern because they can become habit-forming. Prior research examining sedative-hypnotic medication prescriptions in the US National Ambulatory Medical Care Survey reported an overall decrease in benzodiazepine prescriptions and an increase in nonbenzodiazepine receptor agonists from 1993 to 2010 [26]. A subsequent analysis of US data from the 1999-2014 National Health and Nutrition Examination Survey supported an increase in benzodiazepine use, which appeared to be driven by medium- and long-term use of the medications [27]. A more recent analysis of benzodiazepine prescriptions from 2018 to 2021 in the United States suggests an uptick during the 2020-2021 COVID-19 pandemic, particularly among women [28], aligning with our findings.

The frequency of terms related to trazodone, an antidepressant with sedative effects that is sometimes prescribed off-label for insomnia, increased steadily until 2016, followed by a plateau from 2017 to 2020, and then rose from 2021 to 2022. A prior analysis of US prescription data from 2011 to 2018 also supports a gradual increase in low-dose (<150 mg) trazodone prescriptions and a concomitant decrease in prescriptions for zolpidem (similar to our findings) [32]. The frequency of terms related to selective serotonin reuptake inhibitors and antidepressants in general differed, with an incline in 2016-2017, followed by a gradual decline and plateau and a slight uptick through 2021-2022. Interestingly, the drop-off in antidepressant term frequency coincides with the peak CBT-I term occurrence. These patterns align with and may be related to the updated clinical guidelines for insomnia treatments published in 2017 by the AASM. This report described an increase in physicians prescribing antidepressants with sedative properties, such as trazodone, as an alternative to benzodiazepines [33]. However, these guidelines also recommended against trazodone and other medications such as tiagabine, diphenhydramine (an antihistamine included in Benadryl), melatonin, and valerian for the treatment of sleep onset or sleep maintenance insomnia [33]. While these guidelines did suggest doxepin, another antidepressant, doxepin was not a common term in the r/insomnia message board. Despite these guidelines and off-label use, trazodone is one of the most commonly prescribed medications for the treatment of insomnia [34].

There were also trends indicating an overall decreased frequency of terms related to OTC medications (such as Benadryl) and marijuana or cannabis-related (non-cannabidiol) terms on r/insomnia. There were opposing trends between cannabidiol (CBD) and cannabis-related non-CBD terms, where CBD frequency had a sharp transient rise after 2016, and cannabis-related non-CBD terms gradually decreased from 2014 onward. This rise in CBD frequency may be due to the relaxation of CBD regulation, a growing interest in the use of cannabinoids for insomnia and sleep [35,36], and interest in the nonpsychoactive properties of CBD in comparison to other cannabinoids. By 2016, a majority of US states had legalized medical cannabis or CBD [37], and in 2018, hemp-derived CBD was removed as a Schedule I substance in accordance with the 2018 Agriculture Improvement Act [38], increasing its availability to US consumers; however, there was a rapid decline in mentions of CBD in 2022. Although the extent of cannabis use for insomnia treatment and directionality is unclear, prior work suggests a high prevalence of insomnia symptoms and sleep disturbances among people who use cannabis, with 97% increased odds of insomnia among participants reporting daily cannabis use [39]. As cannabis products become more widely available, these findings support the need for greater investigation of the prevalence, possible benefits, and possible drawbacks of cannabis use for insomnia symptoms.

The use of social data may provide an alternative method to capture treatment trends that may be underreported by conventional methods. The 2017 AASM report speculated that the true use of sleep medications for insomnia is higher than reported [33]. Likewise, a prior analysis of US 1999-2010 National Health and Nutrition Examination Survey data found

XSL•FO
RenderX

that of those participants who reported using a sleep aid medication, 58% did not provide information for prescription medication, suggesting widespread use of OTC or alternative treatments [40]. Our findings also suggest a high prevalence of the mention of nonprescription sleep aids on r/insomnia and suggest that digital discussion boards may provide an alternative means of investigating these patterns. Additionally, sleep is a physiological process that can be influenced by sociocultural factors, as it is nested within a socioecological context of the individual, social factors, and society [41-43]. Because of this, social and cultural phenomena, such as societal change and upheaval, can impact sleep and insomnia. For example, measures of self-reported sleep and mood worsened during the week of the US 2020 election compared to a baseline measure a few weeks prior in both US and non-US participants [44]. Our results also suggest changepoints in treatment terms around 2016 and 2020, which may be related to political election cycles or the COVID-19 pandemic. Future research could more explicitly investigate the relationships between sleep health and social and societal factors using r/insomnia and other digital communities.

In addition to CBT-I, r/insomnia comments reflected positive sentiment toward "natural" or herbal supplements and therapies, such as melatonin, valerian root, and cannabidiol. Counter to our expectations that the term would have a negative connotation and sentiment, the term "hygiene," referencing the sleep hygiene component of CBT-I, was the term with the highest positive sentiment. This may reflect that the commenters were not bothered by the term or that this CBT-I component was successful in improving insomnia symptoms. The median sentiment for comments containing each term was positive, which may suggest that the data from this subreddit may be more positive than the median sentiment from the dataset VADER was trained on.

Strengths and Limitations

Our analysis has multiple strengths and limitations, which should be considered in interpreting results. Because the r/insomnia subreddit is accessible to people all over the world, the term trends may reflect an international sample of posts. Yet, it is not representative of a population with defined characteristics, as individuals who participated in the subreddit are self-selected. Our analysis was at the level of comments in response to original posts, treating each comment as independent. Therefore, the analysis may be biased by the overrepresentation of large threads focusing on specific topics. While sentiment analysis attempts to identify the general emotionality of text, there are some limitations; it is not able to capture sarcasm, and because the text is considered as a whole, text with both positive and negative comments will be treated as a composite rather than as an individual component. While we sought to include alternative or brand names for medications in trend measurement, treatments with many options or medication names (such as that for selective serotonin reuptake inhibitors) may exhibit residual underrepresentation or bias.

Conclusions

The use of language related to CBT-I and medications such as benzodiazepines and trazodone and other antidepressants have fluctuated over time on the r/insomnia Reddit platform. Some of these trends, such as the rise in CBT-I in 2017, may reflect clinical treatment guidelines, while others align with nationwide prescription trends. Trends of treatment-related terms, such as the changepoints around 2016 and 2020, may also reflect larger societal events, such as the 2020 COVID-19 pandemic. The data also suggest that r/insomnia commenters mention treatment terms related to OTC and alternative therapies, such as melatonin and cannabis. The representation of OTC and alternative treatments that are not captured by prescription activity is an especially important aspect of this dataset, as the use of nonprescription sleep aids is difficult to track; such information may be useful for sleep health practitioners. The r/insomnia dataset or other alternative data sources may be a valuable addition to prescription records for future studies seeking to capture nonprescription sleep aid use. The prevalence of these terms in the data suggests that future studies of insomnia should consider collecting information on OTC treatment use, cannabis use, and other alternative therapies that people may seek when experiencing insomnia symptoms. Data from digital communities such as r/insomnia may also provide a deeper understanding of how social and societal factors shape sleep health globally.

Acknowledgments

This study was supported by funding from the National Institutes of Health (NIH-NHLBI T32HL007901 supported DAW, K99HL166700 to DAW, and R01HL161012 to TS). DAW declares grant support from the National Institutes of Health and the Sleep Research Society and a past Travel Award from the Sleep Research Society. DAW reports unpaid committee service for the Sleep Research Society. There are no other relationships or activities that could appear to have influenced the submitted work.

Data Availability

The r/insomnia Reddit data analyzed in this study are publicly available in Academic Torrents [45-47].

Conflicts of Interest

None declared.

Abstract

Background: Health misinformation undermines responses to health crises, with social media amplifying the issue. Although organizations work to correct misinformation, challenges persist due to reasons such as the difficulty of effectively sharing corrections and information being overwhelming. At the same time, social media offers valuable interactive data, enabling researchers to analyze user engagement with health misinformation corrections and refine content design strategies.

Objective: This study aimed to identify the attributes of correction posts and user engagement and investigate (1) the trend of user engagement with health misinformation correction during 3 years of the COVID-19 pandemic; (2) the relationship between post attributes and user engagement in sharing and reactions; and (3) the content generated by user comments serving as additional information attached to the post, affecting user engagement in sharing and reactions.

Methods: Data were collected from the Facebook pages of a fact-checking organization and a health agency from January 2020 to December 2022. A total of 1424 posts and 67,378 corresponding comments were analyzed. The posts were manually annotated by developing a research framework based on the fuzzy-trace theory, categorizing information into “gist” and “verbatim” representations. Three types of gist representations were examined: risk (risks associated with misinformation), awareness (awareness of misinformation), and value (value in health promotion). Furthermore, 3 types of verbatim representations were identified: numeric (numeric and statistical bases for correction), authority (authority from experts, scholars, or institutions), and facts (facts with varying levels of detail). The basic metrics of user engagement included shares, reactions, and comments as the primary dependent variables. Moreover, this study examined user comments and classified engagement as cognitive (knowledge-based, critical, and bias-based) or emotional (positive, negative, and neutral). Statistical analyses were performed to explore the impact of post attributes on user engagement.

Results: On the basis of the results of the regression analysis, risk (β=.07; *P*=.001), awareness (β=.09; *P*<.001), and facts (β=.14; *P*<.001) predicted higher shares; awareness (β=.07; *P*=.001) and facts (β=.24; *P*<.001) increased reactions; and awareness (β=.06; *P*=.005), numeric representations (β=.06; *P*=.02), and facts (β=.19; *P*<.001) increased comments. All 3 gist representations significantly predicted shares (risk: β=.08; *P*<.001, awareness: β=.08; *P*<.001, and value: β=.06; *P*<.001) and reactions (risk: β=.04; *P*=.007, awareness: β=.06; *P*<.001, and value: β=.05; *P*<.001) when considering comment content. In addition, comments with bias-based engagement (β=–.11; *P*=.001) negatively predicted shares. Generally, posts providing gist attributes, especially awareness of misinformation, were beneficial for user engagement in misinformation correction.

Conclusions: This study enriches the theoretical understanding of the relationship between post attributes and user engagement within web-based communication efforts to correct health misinformation. These findings provide a foundation for designing more effective content approaches to combat misinformation and strengthen public health communication.

Introduction

Background

Health misinformation negatively impacts individuals' and society's adaptive response to a health crisis [1,2]. As a communication tool, social media has worsened the problem by speeding up the spread of misinformation and strengthening people's existing beliefs [3-5]. Conversely, social media platforms can be effectively used for health communication to disseminate accurate information by correcting misinformation and engaging users by providing verified health advice [6-9]. Many organizations devote efforts to correcting misinformation and releasing them on social media. However, the efficacy of correction is sometimes limited for various reasons, such as people feeling uncomfortable with the knowledge gap when retracting misinformation [10]. Moreover, in an increasingly complex health information environment, people are flooded with knowledge they may not be able to use correctly [11]. In this context, the conditions and message designs that make misinformation correction an effective countermeasure have been examined in experimental studies [6,12,13]. As an interactive digital environment, social media also allows researchers to access data on user responses to health communication, obtaining results from different perspectives [7-9,14].

In this study, we investigate how to enhance the effectiveness of misinformation correction based on real-world data. We selected 2 representative Facebook fan pages in Taiwan (Facebook, Meta Platforms, Inc) that provide rich health misinformation corrections in post forms. Users engage with the content provided by these 2 organizations and other users' comments. In general, correction is a remedy that offers accurate information to counteract misinformation presented in media [10]. According to the observed data, the definition of health misinformation correction in this study is the content with the intent to resist health-related misinformation. This includes clarifications of health misinformation, fact-checking that covers the verification process, and content that addresses potential misinformation while not directly correcting a specific claim (examples are provided in Table S1 in Multimedia Appendix 1). The topics covered include diseases; health care; food safety; and issues extending from the COVID-19 pandemic, such as public welfare and information security. Then, we need a theoretical framework to identify the posts' attributes (called features or characters in some studies [7,9]). The fuzzy-trace theory (FTT) provides a framework that differentiates between 2 cognitive representations of a message, "gist" (top-down meaning) and "verbatim" (detailed information) [15], helping us focus on analyzing textual meaning in posts rather than merely considering surface attributes such as length and tone. The theory was also used to explore physician-patient, health, and scientific communication [7,16,17].

The responses social media users have when they see posts, particularly those explicitly displayed on social media, are referred to as user engagement in this study. These are important metrics for examining the impacts of post attributes in many studies [8,9,14]. This study explored user engagement in 2 dimensions. The first is based on the metrics Facebook provides (sharing, reacting, and commenting), which are the main focus of the predictions in this research. The second is to examine the content users create when they comment. We assume that users engage with different intentions in their comments, and this is reflected in the comment content, which is presented as additional information accessible to other users. Then, this study proposes a framework to classify the engagement categories in comments and examine if this content affects the other 2 metrics: sharing and reacting.

We then introduced prior work about health communication on social media, explained the research gap, and explored the perspective of FTT to identify post attributes and the relationship between post attributes and user engagement in this study.

Prior Work

In previous studies, the acceptance of misinformation correction across different contexts and content types has been examined through experiments. The variables often examined include simple versus detailed or factual elaboration [12,13,18]; correction sources [6,12,13,19]; and information content such as quality, intensity, or emphasis [18,20,21].

Another approach in the context of social media involves collecting data from these platforms, labeling them manually or automatically, and analyzing them. A study using FTT as a framework explored news reports about measles and vaccines and expressed the opinions of vaccination proponents or opponents as the gist. In this study, data were coded to predict the likelihood of news sharing on Facebook. The regression model included other variables, such as statistics and stories, but only the gist could significantly predict news sharing [14]. Health communication efforts increased significantly during the COVID-19 pandemic, allowing for analysis through publicly available data. A study of 1816 posts from hospitals in Taiwan during the first 4 months of the COVID-19 pandemic found that specific social media strategies significantly increased user engagement, indicating the potential to improve health literacy among health care organizations [7]. Such studies have also observed that users inevitably share misinformation through comments when discussing health issues on social media. A study analyzed 1534 comments from 2 Facebook groups discussing mental health symptoms between January 2019 and December 2021. It found that 26.1% of the comments contained medically inaccurate information, specifically regarding complementary and alternative medicine (60.3%) [22]. By observing long-term trends, it is also possible to track changes in the quality of health communication and user attitudes. An

XSL•FO
RenderX

analysis of 12,553 COVID-19 vaccine fact-checking posts and 122,362 comments from January 2020 to March 2022 showed increased analytical thinking and confidence in the posts, alongside decreased tentativeness among comments, showing an evolution in public sentiment over time [8]. Finally, a study analyzed 914 fact-checking news articles to understand how source transparency, contextual information, and vividness influence user engagement. The study found that these factors significantly affected user responses, especially likes and angry reactions, emphasizing the importance of content style and depth in capturing public attention [9]. These studies underline the critical role of social media in shaping public health narratives and emphasize the necessity of designing engaging yet accurate content during health crises.

Research Gap

Regarding the research gap, there is a lack of health communication studies that incorporate both data and theory, and finding a theory that fits the data is not easy. To explore the effect of misinformation correction, the primary theories considered include the inoculation theory [23], elaboration likelihood model [24], heuristic-systematic model [25], and FTT [15], all of which offer different interpretations from a cognitive perspective on how misinformation correction can be effectively achieved. The FTT emphasizes the importance of conveying the essence of a message, focusing on its core meaning rather than merely summarizing or simplifying it. It highlights the need to avoid overwhelming people with excessive quantitative details. [26]. Moreover, FTT has robust cognitive neuroscience foundations, making it suitable for scientific communication and compliant with nonpersuasive fact-checking methods that prioritize reference-based corrections. Therefore, this study adopted FTT for analysis. The method of conveying essential meaning is called gist communication [17].

In addition, we proposed a framework for classifying user-generated comment content, as previous studies have rarely examined this aspect. We have included them as independent variables in the prediction model to explore whether the FTT's gist communication remains effective even when different comments are present as additional post information.

The FTT and Health Misinformation Correction

Overview

The FTT explains how we process and remember information through 2 types of cognitive representation: "gist" and "verbatim." Gist captures the essential, top-down meaning, including causal relations and key concepts [27,28]. Verbatim captures details such as exact words and elements [15,16]. This theory was originally developed to study how individuals shape their memory and engage in reasoning and decision-making [15]. The gist is more than a mental shortcut; it is a distilled way of presenting objective facts to help individuals make health and medical decisions and navigate life [29].

According to the FTT, information containing the gist is likely to evoke motivationally relevant values that may be shared online, whether true or not [30]. This explains why people easily share misinformation that offers a clear core message and causal explanation [27]. This mechanism can be applied in fact-checking or correction as an intervention. FTT explains that providing a brief explanation has more lasting benefits than merely offering a false label [31], but offering decontextualized detailed information may be counterproductive [18]. The critical factor may be the inclusion of the gist. The gist of information triggers emotions and evokes core values [17]. Furthermore, when the content provides gist cues that connect with people's inner motivations and values, it is more likely to catch attention and be shared [30].

Health interventions should emphasize conveying the gist of information with an organized approach to highlight essential points [32]. The next question is to identify the gist of the health misinformation correction. Different gist representations exist in diverse contexts. In a study on physician-patient communication, the gist of the effectiveness and risks of medications was extracted from communication records to examine its relationship with patient satisfaction [16]. On the basis of the FTT and important concepts discussed in misinformation research, we proposed 3 gist representations: risks associated with misinformation, awareness of misinformation, and value in health promotion. In addition, we proposed 3 verbatim representations: numeric and statistical information as a reference for correction; authority from named experts, scholars, or official institutions used as references; and facts presented with varying levels of detail. These 6 representations, abbreviated as risk, awareness, value, numeric, authority, and facts, serve as attributes of misinformation correction posts.

Risk: Risks Associated With Misinformation

During health crises, it is important to communicate risks accurately and effectively [32,33], as it significantly correlates with adopting preventive health behaviors [34]. The risks associated with misinformation in this study included harm to personal and public health, social panic, and legal risks of spreading misinformation.

Awareness: Awareness of Misinformation

Public awareness plays a crucial role in improving resilience from misinformation, including awareness of exposure to misinformation and the ability to identify it [35]. Moreover, providing awareness and warnings beforehand usually has a beneficial impact [23]. In this study, awareness of misinformation involved practical information to remind and help individuals recognize and verify misinformation.

Value: Value in Health Promotion

Promoting health and well-being is a primary goal of health communication [36]. When correcting misinformation, it is recommended not only to mention what is false but also to provide alternative accurate information and encourage self-affirmation [10]. Conveying public trust and confidence is vital to combat anxiety-induced acceptance of misinformation [37]. Therefore, this study identified the third gist of health promotion as the core value toward health crises, including health literacy and a positive attitude.

XSL•FO
RenderX

Numeric: Numeric and Statistical Information as a Reference for Correction

Scientific communication often includes numbers and statistics as objective data. People's numeracy levels can affect their interpretations of risks, probabilities, and numerical results, leading to potential misunderstandings [38]. This study examined the use of numerical information to correct misinformation. Indeed, prior content analysis studies have considered statistical data as an attribute or characteristic of posts [9,14].

Authority: Authority From Named Experts, Scholars, or Official Institutions Used as References

Experts, scholars, and professional organizations are trusted sources of knowledge for authoritative communication, and health care professionals can correct health misinformation on social media [39,40]. Fact-checking organizations consult experts to improve the credibility of misinformation corrections. Thus, this study also investigated the effects of referencing authority.

Facts: Facts Presented With Varying Levels of Detail

People's attention span is generally limited on social media, and the effects of detailed factual information should be evaluated. The outcomes of detailed factual elaboration and simple rebuttal have been discussed in prior research [12,41]. In this study, fact representations refer to detailed and scientific elaborations with evidence for correcting misinformation. These can be categorized into three levels: (1) those that do not target specific misinformation; (2) simple corrections involving straightforward explanations; and (3) detailed corrections encompassing comprehensive information, typically with a complete structure, including background, reasons for errors, and alternative explanations.

User Engagement on Social Media

Social media offers benefits for health communication, such as improving the accessibility of health information and allowing users to generate and exchange information, but the quality and reliability of the shared information must be monitored [42]. The FTT suggests that information with gist cues supports reasoning and decision-making, and they are more likely to share when the cues connect their motivations or values. Facebook shares are commonly used as a metric, indicating users' affirmation and commitment to a post [43]. In addition to sharing, users can also engage through reactions (including likes and 6 emoticons) and comments on social media platforms. A study used the common-sense model of illness self-regulation to describe humans' cognitive and emotional systems to increase user engagement toward some attributes of illness representations on social media [44]; that is, shares, reactions, and comments were metrics driven by cognitive and emotional factors.

This study defined the basic metrics of user engagement as follows:

- Shares—user engagement in sharing, measured by share count
- Reactions—user engagement in reacting, measured by summing up clicks of likes and 6 other emoticons
- Comments—user engagement in commenting, measured by comment count

Metrics such as shares, reactions, and comments were commonly used in health communication studies to identify factors that increase user engagement [44-46]. However, user engagement is not always positive, especially in comments, which often contain errors, biases, and uncivil behavior [22,47,48]. The phenomenon of echo chambers on social media refers to selective exposure and confirmation bias, which limit diverse perspectives and foster polarized groups [3]. A study distinguishes between 2 belief systems among users: scientific and conspiracy [49]. Some studies have suggested that user-generated comments influence other users' perceptions of posts. For example, it was found that the perceived quality of journalistic content being commented on decreased due to a lack of reasoning and incivility in user comments [47]. When exposed to critical comments about a fake news article, people are less likely to share or comment positively on the article [50]. A study reported that positive comments influenced people's perceptions of a company's reputation in crisis [51]. However, well-informed individuals often remain quiet on certain issues, whereas misinformed individuals tend to be more vocal online [52].

This study categorized comments into cognitive and emotional engagement [44]. For cognitive engagement, we were concerned with the conspiracy belief group and its counterpart, the scientific group [49]. We observed the data potentially driven by conspiracy belief as bias-based engagement and identified 2 types of engagement driven by scientific belief: one focused on knowledge itself, called knowledge-based engagement, and the other on misinformation issues, called critical engagement. Furthermore, we observed user engagement driven by emotions, which can be divided into positive, negative, and neutral emotional engagement according to the positive-negative valence framework [53]. We classified comments into one of six categories, which are further defined as follows:

1. Knowledge-based engagement. This study observed users' knowledge-related behaviors on social media driven by scientific beliefs, which include providing additional information, clarifying facts, and asking questions.
2. Critical engagement. Developing critical thinking skills and pragmatic skepticism is crucial for citizens to combat misinformation [35]. Unlike knowledge-based engagement, which focuses on knowledge itself, critical engagement identified in this study focused on discussing misinformation by offering warnings or explanations.
3. Bias-based engagement. Bias-based engagement refers to users disseminating biased content driven by conspiracy beliefs, including misinformation, incorrect inferences, logical fallacies, or conspiracy theories, potentially undermining information reliability and impeding evidence-based discourse.
4. Positive emotional engagement. Positive emotional engagement is characterized by users expressing positive emotions, such as joy, happiness, and excitement.

XSL•FO
RenderX

5. Negative emotional engagement. Negative emotional engagement is characterized by users expressing negative emotions, such as anger, fear, sadness, or frustration.
6. Neutral emotional engagement. Neutral emotional engagement describes a user's subdued or indifferent emotional response to content or events.

Research Questions

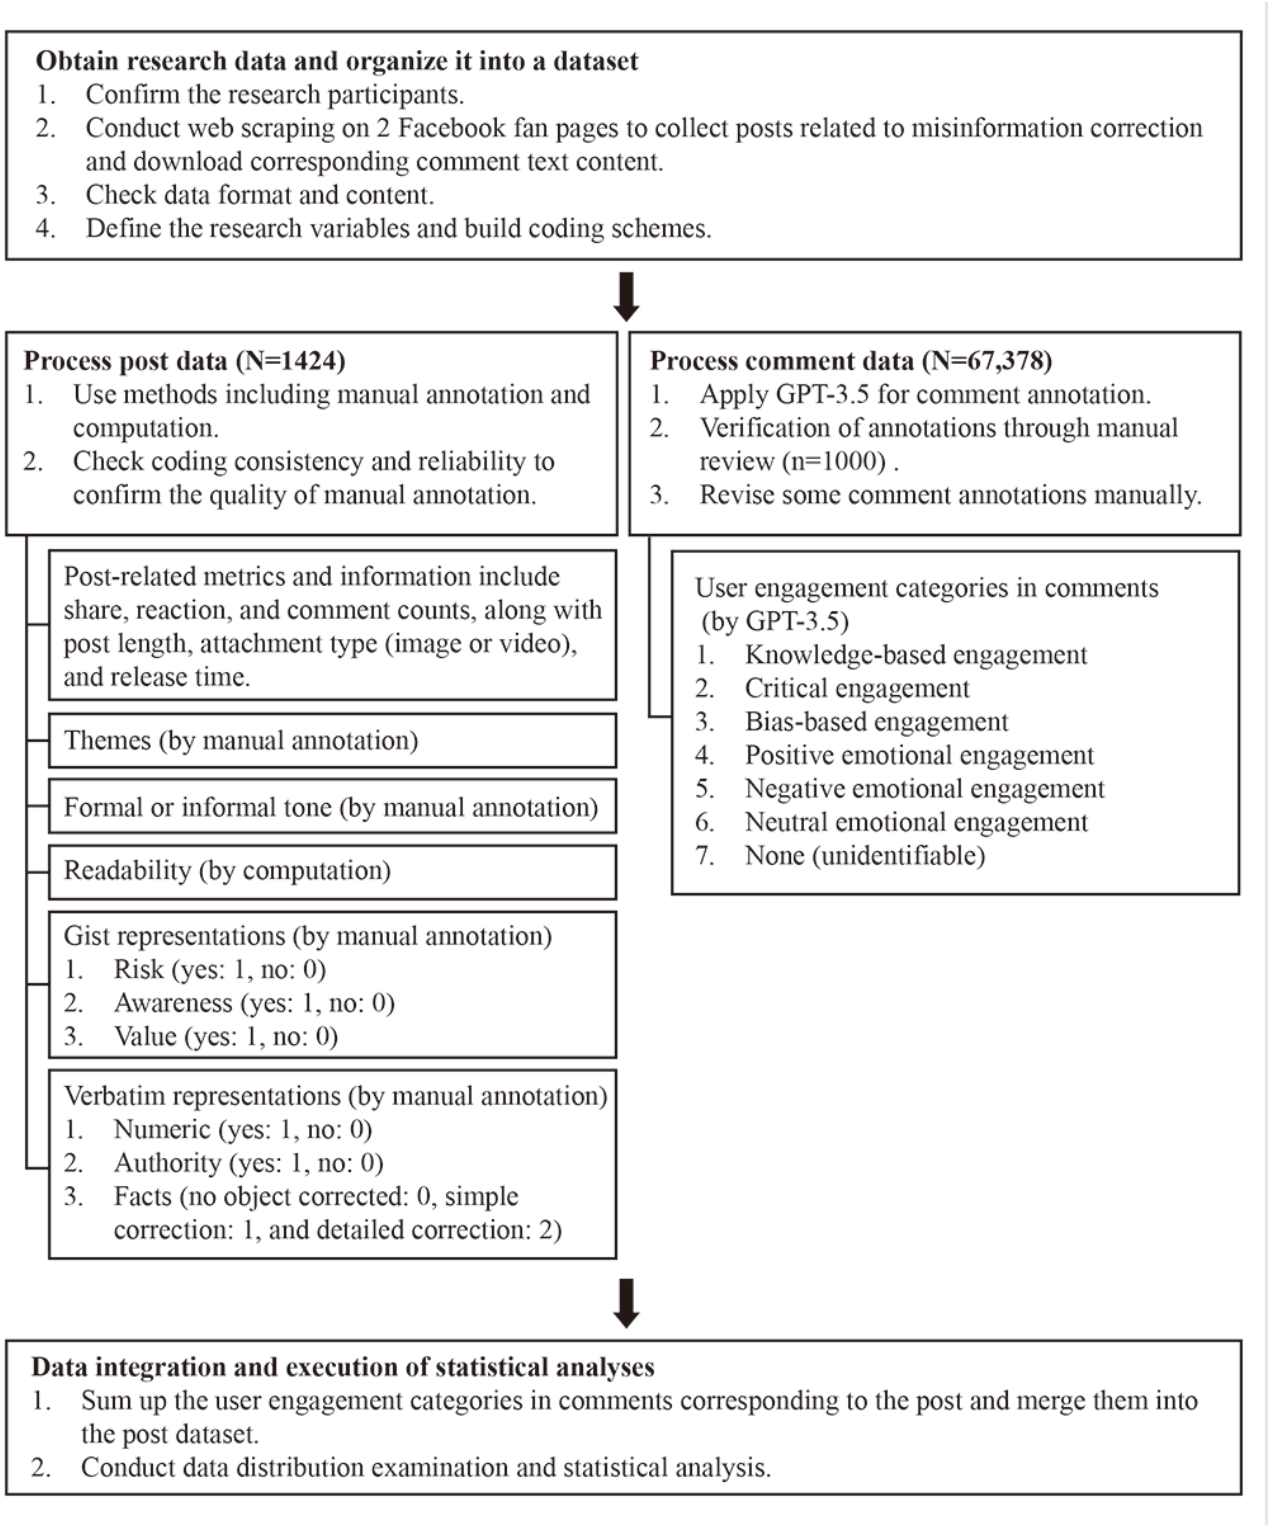
User attitudes toward correction may change over time [8], and the misinformation contained in comments is also noteworthy [22]. Therefore, this study first investigated whether user engagement toward health misinformation correction has changed over the past 3 years. Second, according to the FTT, providing the gist as cues can effectively and directly convey messages to users [17]. Accordingly, we hypothesized that providing gist representations would help users grasp the main aspects of health misinformation issues. We also identified some important verbatim representations as post attributes to examine their relationship with user engagement. Finally, we considered whether the content of comments affects users' choice to share and react to a post. On the basis of the earlier discussion, the research questions (RQs) posed by this study are as follows:

- How has user engagement toward health misinformation correction changed during the COVID-19 pandemic? (RQ1)
- Can the gist and verbatim representations identified in this study as post attributes predict user engagement in shares, reactions, and comments? (RQ2)
- On the basis of RQ2, does the inclusion of user-generated comment content from engagement in commenting affect engagement in sharing and reactions? (RQ3)

Methods

Corpus and Sample Period

This study focused on health misinformation correction, drawing on 2 representative platforms, the Taiwan Fact-Checking Center (TFC) and the Ministry of Health and Welfare (MOHW), with rich data, including fact-checking and clarifying health-related event or policy posts and user feedback. Data were collected from the Facebook pages of the TFC, which was established in 2018 and has >160,000 followers on Facebook, and the MOHW, which has a significant following of approximately 1.52 million Facebook users, accounting for 6.45% of the total population of Taiwan. We collected 3769 posts from the TFC and 5103 posts from the MOHW from January 2020 to December 2022. The TFC targets various misinformation issues such as health, politics, economics, and celebrities. By contrast, the post content of MOHW focuses on public health, such as health policy announcements, and the correction of health misinformation accounts for a small portion. To ensure our focus was on health misinformation correction, we manually reviewed each post to identify those that involved both health and misinformation correction. For TFC posts, the reference keywords included health, pandemic, disease, food safety, folk remedies, vaccine, and health care. For MOHW posts, the reference keywords included misinformation, false information, clarification, and fake news. Because relying solely on keywords may either miss or capture non-target content, we primarily relied on manual review. After the filtering process, we found 34.89% (1315/3769) posts from the TFC source and 2.14% (109/5103) posts from the MOHW source. Corresponding to the posts from TFC and MOHW, 26,458 (including 913 self-replies by the TFC manager) and 40,920 comments (including 97 self-replies by the MOHW manager) were downloaded, respectively. Finally, the dataset consisted of 1424 posts and 67,378 comments from both platforms.



Research Process

Overview

This study included three phases, as shown in Figure 1: (1) obtaining research data and organizing them into a dataset, (2) processing post and comment data, and (3) data integration and statistical analyses. First, after defining the research participants, we used web scraping techniques to acquire the necessary posts and relevant metrics and obtain the content of comments. Subsequently, to process unstructured data into structured data for further analysis, manual annotation was applied to posts to obtain 1 indicator (readability) using computational methods, whereas a large amount of comment data was automatically annotated using GPT-3.5 (OpenAI). Finally, a statistical analysis was conducted. Detailed information regarding data annotation processing is provided in the following sections.

XSL•FO
RenderX

Figure 1. Research procedure and data processing.

Annotation and Transformation Data for Posts

Regarding the posts, we categorized them into five main themes based on the emphasized content: (1) understanding and controlling diseases; (2) vaccine safety and policies; (3) health care, food safety, and home remedies; (4) livelihood, economy, and information security; and (5) misinformation awareness and identification. Livelihood, economy, and information security refers to daily life aspects impacted by the COVID-19 pandemic, such as subsidy applications. Two coders manually coded this component (Cohen κ coefficient=0.672). In addition, as control variables, this study considered the length of posts, their readability, whether they were from official platforms, whether they adopted a formal tone, and whether they used images.

Due to the lack of Chinese readability tools, this study created a difficult-word dictionary based on 2 resources: the “Chinese 8000-Word List” levels 3 to 5 [54] and the “National Academy for Educational Research Third Level Seven-Word List” level

XSL•FO
RenderX

7 [55]. In addition, the word frequency table of this dataset was examined, and 340 words, such as reagents and nucleic acid, were added to the dictionary. The difficult-word dictionary included 11,138 words. Then, we used the Dale-Chall readability formula to compute the scores. The formula of the Dale-Chall Readability Score is 0.1579 × [(number of difficult words / total number of words) × 100] + 0.0496 × (total number of words / total number of sentences) [56,57]. The original score ranges from 0 to 10, with higher scores indicating greater difficulty in reading. Furthermore, the additive inverse of this score was calculated for intuitive interpretation, with higher scores indicating easier readability.

Whether a post adopted a formal tone was determined by manual annotation (Fleiss κ=0.521). Because determining whether the tone is formal can be subjective, we gradually reached a consensus throughout the process. This included discussions on the use of common Chinese modal particles and slang. At least 2 annotators annotated each post, and after comparing the annotation results, we discussed and resolved any inconsistencies individually.

The last control variable was whether an image was used. The data we obtained through web scraping included information about attachments, such as images, links, or videos. Uploaded images were prioritized for display in Facebook posts. If no image was uploaded but the content included a link, a preview image was selected from the linked page for display. Similarly, a thumbnail image was shown when a video was uploaded in a post. When an image was used as an attachment, it was typically designed. We did not evaluate the content of the images. Of the 1424 posts, there were 1310 (91.99%) posts with uploaded images as attachments (ranging from 1 to 15 images), 109 (7.65%) posts that displayed an image from a link, 4 (0.28%) posts with an uploaded video, and only 1 (0.07%) post without any attachment. We assigned a dummy code of 1 to the 91.99% (1310/1424) posts with a designed image as an attachment, while the others were coded as 0.

This study focused on examining 6 representations: risk, awareness, value, numeric, authority, and facts, which serve as attributes of misinformation correction posts identified by the FTT and related literature. Please refer to Tables S2 and S3 in Multimedia Appendix 1 for the gist and verbatim coding schemes. This portion of the annotated data was converted into dummy variables. The first author and an annotator reviewed the data during the initial phase and conducted theoretical discussions to create the coding scheme. A 10.04% (143/1424) sample of the posts was manually annotated, and ambiguous concepts were clarified. Two annotators independently annotated another 9.97% (142/1424) of the sample. The interannotator agreement ranged from 87.32% to 94.37%, and Fleiss κ values ranged from 0.459 to 0.927. Each post was coded by at least 2 annotators, and any inconsistencies were discussed and confirmed to reach a consensus.

Annotation Data for Comments

Regarding the comments, we classified engagement in comments into 6 categories based on a literature review and empirical data observation. Three categories were related to cognition: knowledge-based, critical, and bias-based engagement. In addition, 3 categories were related to emotion: positive, negative, and neutral. Each comment was assigned 1 of these 6 constructs.

GPT-3.5 has been trained on sufficiently diverse multilingual data and can perform cross-lingual transfer learning by using knowledge from source languages to make inferences in target languages, even with limited target language data [58]. The comment content was mainly in Chinese, and the average length of a comment was 26.40 (SD 52.70) words. We assigned each comment to a category, although it is possible for a single comment to contain multiple categories in short texts. We prioritized using GPT-3.5 to determine cognitive engagement; if not, we assessed for emotional engagement. The comment was classified as None if it was indistinguishable and neither aspect could be determined from the content. Examples of the prompts and outputs are provided in Tables S4 and S5 in Multimedia Appendix 1.

GPT-3.5 has some issues with instability and hallucinations. Regarding annotation instability, we set the temperature parameter to 0.5. This parameter ranges from 0 to 1, with higher values increasing creativity. We found that setting the temperature too low could lead to conservative responses, resulting in frequent annotating as unidentifiable. In the study, approximately 100 comments were used for testing to improve the prompt and adjust the temperature parameter. We required GPT-3.5 to provide reasons during annotation to examine potential causes of annotating errors and incorporated more specific definitions into the prompt. Next, we performed automated annotation of all data. To ensure GPT-3.5 annotation reliability, we randomly selected 1000 comments for manual annotation. Cohen κ coefficient for manual annotations was 0.519 (moderate agreement). After discussion, a consensus on the annotation was reached. The consistency between manual and GPT-3.5 annotations was calculated, yielding a Cohen κ coefficient of 0.648 (substantial agreement). Then, to mitigate potential biases introduced by GPT-3.5, we systematically compared manual annotations with GPT-3.5 annotations and checked the comments for keywords that GPT-3.5 may not recognize. We revised 4233 comment annotations in this process. Finally, the data for the 6 categories of comments were summed and linked to their corresponding posts.

Data Analysis

We initially used descriptive statistics to provide an overall overview of the data to answer RQ1. The mean share count was 79.12 (SD 293.14; range 0-4259), with 57 posts without sharing. The mean reaction count was 914.35 (SD 2,582.93; range 13-34,403). The mean comment count, excluding self-replies by the platform manager was 46.61 (SD 212.82; range 0-5092), with 198 posts without commenting. The 1.5% (1010/67,378) comments made by the platform manager supplied full information links or expressed positive feedback to some comments. These comments were excluded because we aimed to understand engagement from regular users. After examining the data distribution with Q-Q plots, we found that share, reaction, and comment count were nonnormally distributed. In this situation, it may be appropriate to transform the dependent variable using a natural logarithm in a linear regression model

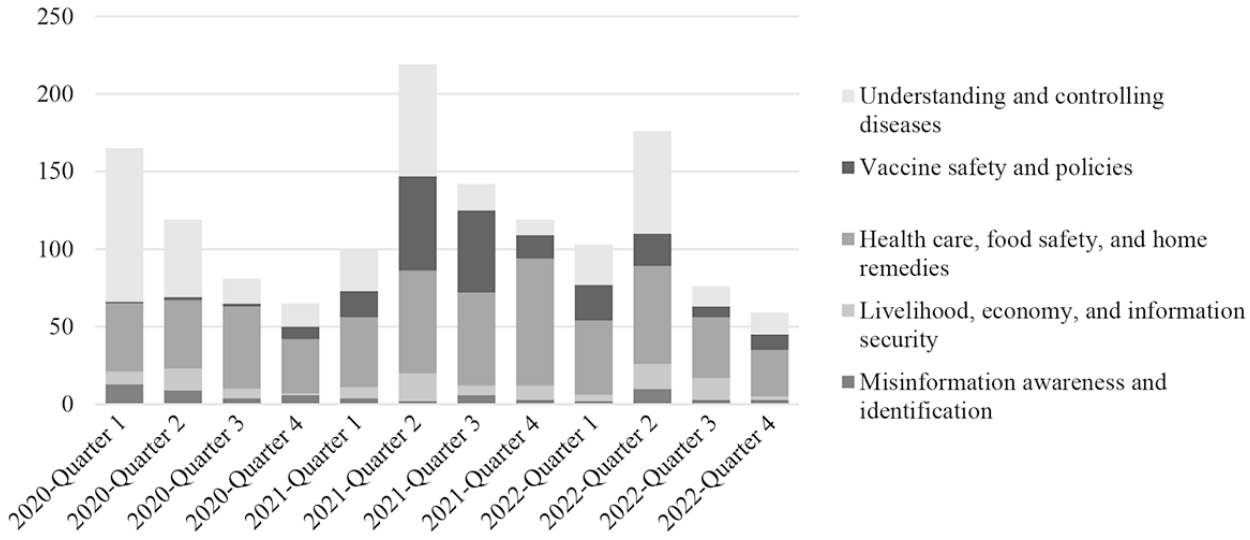
XSL•FO
RenderX

[9,59] or to use Poisson or negative binomial regression models [44,56]. We chose to use natural logarithms of the dependent variables as ln(shares+1), ln(reactions), and ln(comments+1). To improve the interpretability of the model, this study also transformed some independent variables using the natural logarithm, including ln(post length) and ln(engagement categories in comments+1). This study considered post length, readability, formal language use, and images as control variables based on prior literature [56,60]. For the regression models of 3 dependent variables, observations with studentized residuals that fall outside the mean of +3 or –3 were considered outliers and excluded. Then, regression analysis was performed to confirm the theory's applicability and answer the RQs.

Ethical Considerations

The study was approved by the National Tsing Hua University Research Ethics Committee (11308HT139). This study used publicly available data and processed and stored the data in compliance with the Personal Data Protection Act. As the data were publicly accessible, informed consent was not required.

Results



Overview

To answer RQ1 regarding user engagement trends with misinformation correction during the COVID-19 pandemic, we aggregated 3 years of data and analyzed various types of user engagement. For RQ2, we performed hierarchical multiple regression to examine the relationship between the identified attributes and user engagement in sharing and reactions. For RQ3, we considered the content in comments as additional information on the post, incorporating 6 categories of user engagement in commenting as independent variables in the models for RQ2.

Trends Related to Post Content and User Engagement During the COVID-19 Pandemic

First, this study organized the data to understand the data profile. We merged the MOHW and TFC datasets to obtain an overview of the situation. We categorized the data by themes based on a quarterly distribution, as shown in Figure 2, in which the distribution of misinformation correction themes aligned with the development trajectory of the COVID-19 pandemic. The peak of misinformation correction occurred in the second quarter of 2021, coinciding with Taiwan's level 3 alert and a vaccine shortage. The most common theme was health care, food safety, and home remedies, followed by understanding and controlling diseases and vaccine safety and policies.

Figure 2. Quarterly distribution of post counts by theme over 3 years.

To answer RQ1, we conducted a 1-way ANOVA to analyze user engagement over 3 years, and the results are shown in Table 1. Through homogeneity tests, these counts were found to be heterogeneous, and Welch ANOVA and Games-Howell post hoc comparisons were performed. We found that sharing (Welch $F_{2,\ 805.887}$=31.082; P<.001) and reactions (Welch $F_{2,\ 802.838}$=40.620; P<.001) declined significantly over time, while comments (Welch $F_{2,\ 909.388}$=11.253; P<.001) remained high in the first 2 years, before dropping in the third year. Under the general trends, we further examined the 3-year change patterns of comments based on user engagement categories. The patterns of the knowledge-based engagement (Welch $F_{2,\ 931.301}$=19.470; P<.001) and 3 emotional engagements (positive emotional: Welch $F_{2,\ 741.713}$=22.636; P<.001; negative emotional: Welch $F_{2,\ 845.244}$=11.857; P<.001; neutral emotional: Welch $F_{2,\ 849.284}$=21.055; P<.001) in commenting were similar, remaining consistent in the first and second years but significantly declining in the third year. Critical engagement declined significantly over time (Welch $F_{2,\ 785.780}$=32.996; P<.001), while bias-based engagement peaked in the second year and then significantly declined in the third year (Welch $F_{2,\ 922.113}$=3.120; P=.045).

Table 1. Variation in user engagement over 3 years.

User engagement	2020 (n=430), mean (SD)	2021 (n=580), mean (SD)	2022 (n=414), mean (SD)	Tests of homogeneity of variances		Robust tests of equality of means		Mean difference between groups (Games-Howell post hoc tests)
				Levene statistic	*P* value	Welch statistic	*P* value	
Share	192.65 (496.70)	38.78 (104.67)	17.72 (70.42)	85.546	<.001	31.082	<.001	• 2020>2021, • 2020>2022, • 2021>2022
Reaction	1871.12 (3799.06)	664.91 (2001.51)	270.06 (960.27)	60.753	<.001	40.620	<.001	• 2020>2021, • 2020>2022, • 2021>2022
Comment	54.28 (131.03)	59.26 (302.90)	20.91 (92.98)	10.115	<.001	11.253	<.001	• 2020>2022, • 2021>2022
Knowledge-based engagement in commenting	7.04 (13.23)	5.42 (22.07)	2.16 (9.98)	11.194	<.001	19.470	<.001	• 2020>2022, • 2021>2022
Critical engagement in commenting	6.80 (13.83)	3.80 (13.32)	1.51 (4.39)	29.049	<.001	32.996	<.001	• 2020>2021, • 2020>2022, • 2021>2022
Bias-based engagement in commenting	11.44 (40.04)	25.65 (152.21)	9.00 (44.68)	13.045	<.001	3.120	.045	• 2021>2022
Positive emotional engagement in commenting	6.87 (20.27)	4.18 (17.30)	1.16 (4.67)	22.438	<.001	22.636	<.001	• 2020>2022, • 2021>2022
Negative emotional engagement in commenting	11.44 (33.40)	11.71 (63.18)	3.67 (17.16)	10.159	<.001	11.857	<.001	• 2020>2022, • 2021>2022
Neutral emotional engagement in commenting	5.00 (11.62)	3.22 (12.38)	1.27 (5.20)	16.948	<.001	21.055	<.001	• 2020>2022, • 2021>2022

We further explored the relative proportions among different categories of user engagement in commenting, as shown in Figure 3. In the first year of the COVID-19 pandemic, the engagement across categories was fairly balanced, with cognitive and emotional engagement each accounting for approximately half. The sum of knowledge-based and critical engagement comments exceeded those of bias-based engagement in 2020 in overall data, suggesting that the 2 beliefs could counterbalance each other. However, bias-based engagement became predominant by the second and third years on both platforms. In overall data, in 2020, bias-based engagement accounted for 23.55% (4920/20,893) of the comments; in 2021, it accounted for 47.51% (14,876/31,309); and in 2022, it accounted for 47.95% (3726/7770). Specifically, based on the MOHW data, in 2020, bias-based engagement was 32.97% (2776/8419), which rose to 52.39% (11,976/22,858) in 2021 and remained at 52.57% (2662/5064) in 2022. On the TFC data, bias-based engagement was 17.19% (2144/12,474) in 2020, 34.32% (2900/8451) in 2021, and 39.32% (1064/2706) in 2022. The discussions were dominated by bias-based engagement in the later stages of the COVID-19 pandemic. When comparing platforms, there was relatively more knowledge-based and critical engagement on the TFC platform, while the MOHW platform had relatively more positive emotional engagement in the first year.

XSL•FO
RenderX

Figure 3. Variation in the proportion of different types of user engagement in comments over 3 years. MOHW: Ministry of Health and Welfare; TFC: Taiwan Fact-Checking Center.

Objective metrics such as shares, reactions, and comments for user engagement showed that interest in health-related misinformation significantly decreased in the third year. However, regarding the number of deaths due to COVID-19, the pandemic was most severe in Taiwan in its third year, with 7 deaths in 2020, 843 in 2021, and 14,636 in 2022 [61].

Post Attributes and User Engagement

In the annotated dataset, of the 1424 posts, 261 (18.33%) contained risk, 868 (60.96%) contained awareness, 527 (37.01%) contained value, 163 (11.45%) contained numeric information, and 768 (53.93%) contained authority. In addition, of the 1424 posts, 202 (14.19%) did not target specific misinformation, 505 (35.46%) provided a simple correction, and 717 (50.35%) offered a detailed correction. Subsequently, concerning RQ2, we focused on the relationship between post attributes and 3 user engagement metrics: shares, reactions, and comments, as shown in Table 2. Model 1 controlled for background variables including post length (transformed using the natural logarithm), official status (converted to a dummy variable, where 1 represents the official platform [MOHW] and 0 represents the nonofficial platform [TFC]), readability, formal tone (where 1 indicates formal and 0 indicates informal), and image (where 1 indicates the attachment of at least 1 image and 0 indicates none). The dependent variables were also transformed using the natural logarithm. These background variables contributed significantly to the regression models for shares (R^2=0.334; $F_{5,1412}$=141.380; P<.001), reactions (R^2=0.407; $F_{5,1404}$=192.994; P<.001), and comments (R^2=0.328; $F_{5,1414}$=137.794; P<.001). All background variables were predictive of these engagement metrics, except for post length, which did not significantly predict comment count.

Model 2 incorporated gist and verbatim representations. The R^2 changes for the 3 models were significant. In the model focused on predicting shares (R^2=0.353; $F_{11,1406}$=69.808; P<.001; Δ R^2=0.020), risk (β=.07; P=.001), awareness (β=.09; P<.001), and facts (β=.14; P<.001) were significant predictors. When predicting reactions (R^2=0.435; $F_{11,1398}$=97.292; P<.001;

XSL•FO
RenderX

Δ R^2=0.028), awareness (β=.07; *P*=.001) and facts (β=.24; *P*<.001) were found to be significant factors. Similarly, when predicting comments (R^2=0.351; $F_{11,1408}$=69.158; *P*<.001; Δ R^2=0.023), awareness (β=.06; *P*=.005), numeric (β=.06; *P*=.02), and facts (β=.19; *P*<.001) played significant roles. This finding suggests that 2 of the gist representations, risk and awareness, can enhance post endorsement and sharing, but only awareness was predictive of reactions and comments. Moreover, facts positively influenced the 3 metrics in the verbatim dimension, indicating that detailed clarifications enhanced shares, reactions, and comments.

Post Attributes and User Engagement: Considering Comment Content

For RQ3, we incorporated comments generated by 6 categories of user engagement into model 3, as presented in Table 3. To ensure the validity of our findings, we used the variance inflation factor to diagnose multicollinearity, which was within acceptable limits (<10). In the model predicting shares (R^2=0.668; $F_{17,1400}$=165.904; *P*<.001; Δ R^2=0.315), the 3 gist representations (risk: β=.08; *P*<.001, awareness: β=.08; *P*<.001, and value: β=.06; *P*<.001) were significant predictors, while facts (β=.02; *P*=.36) no longer predicted it. Then, when considering user engagement in commenting, in the cognitive aspect, only bias-based engagement (β=–.11; *P*=001) negatively predicted shares, and knowledge-based and critical engagement positively predicted shares (knowledge-based: β=.28; *P*<.001 and critical: β=.15; *P*<.001). In the emotional aspect, positive and negative emotional engagement both predicted shares, while neutral did not predict it (positive: β=.29; *P*<.001, negative: β=.09; *P*=.02, and neutral: β=.05; *P*=.15). Similarly, in the model predicting reactions (R^2=0.772; $F_{17,1392}$=277.743; *P*<.001; Δ R^2=0.337), the 3 gist representations (risk: β=.04; *P*=.007, awareness: β=.06; *P*<.001, and value: β=.05; *P*<.001) significantly predicted the reaction count, and facts (β=.12; *P*<.001) also predicted it. All comment categories, except for bias-based engagement (β=–.04; *P*=.15), significantly predicted reactions (knowledge-based: β=.19; *P*<.001, critical: β=.14; *P*<.001, positive: β=.26; *P*<.001, negative: β=.15; *P*=<.001, and neutral: β=.08; *P*=.002).

Discussion

Principal Findings

First, in response to RQ1, all metrics unsurprisingly decreased, and it is noteworthy that the proportion of bias-based engagement in comments increased on both platforms. At the outbreak of the COVID-19 pandemic, despite the potential chaos in information, the comment categories remained relatively balanced and were not dominated by any category. The increase in bias-based engagement in the second year was likely due to the first COVID-19 community transmission in Taiwan and the rise of COVID-19 vaccine–related issues. The result aligns with findings from previous studies, which show that comments often contain inaccuracies and are predominantly made by uninformed users [22,52].

Then, we compared our findings with similar studies that explored the relationship between post attributes and user engagement. Regarding background variables, according to model 1, readability aligned with previous research findings [56], which explained why readability influences social media engagement through fluency. Posts using a formal tone also showed higher user engagement, consistent with the literature [60], in which formality was a heuristic for credibility and importance. However, we did not control for the topics or timing

XSL•FO
RenderX

associated with using a formal tone; more severe events may be more likely to use a formal tone. Posts containing images also positively impacted user engagement, a finding supported and explained in the literature by the concept of media type richness [59] or an approach-motivated perspective [44].

Drawing on the FTT and literature on misinformation, we identified 3 key gist representations and tested their effectiveness. The theory suggests that a message with a clear core and causal explanation is more likely to resonate with people, leading to behaviors such as sharing [30]. Moreover, this study suggests that gist representations provide cues that enhance the probability of users finding the respective information relatable or practical. Risk may involve terms such as danger or harm. Awareness often describes tips and tricks and is relatively neutral. Value sometimes refers to reassurance and tends to have more positive terms. However, only awareness is a significant predictor in each model. When considering the content of comments, all gist representations significantly predict reactions, indicating that risk and value retain their value within social media posts that include comments. In addition, value was the only gist of predicting comments negatively, although not significantly. Whether value can further reduce bias-based engagement remains to be examined in future studies. Overall, providing gist information increased shares, reactions, and comments, consistent with previous research showing that gist information enhances article sharing [14]. Awareness of misinformation is the most crucial factor in this study, as a previous study has emphasized awareness of misinformation as the foundational concept of citizen resilience to misinformation [35].

Regarding the verbatim dimension, we found that numeric information cannot significantly predict shares and reactions but can predict comments. Statistics also failed to predict sharing in another study based on the FTT [14]. According to discussions related to the FTT, individuals' numerical abilities influence the numeric factor [38], and users might engage in discussions based on different perceptions of numeric information. However, statistics as a factor of source transparency was one of the predictors of shares and comments, suggesting that numerical information in news articles may increase the audience's perceived accuracy [9]. A previous study indicated that participants engaged more with corrections even without statistical information due to the simplicity of the material, which made it easier to assess credibility. Then, they put less cognitive effort when the information included statistical evidence [20]. We offered a different perspective through FTT, suggesting that numeric information did not significantly affect user engagement in sharing and reacting, as these forms of engagement relied more on top-down meaning. However, numeric information increased commenting, which might rely on detailed information and higher cognitive engagement. Furthermore, this study identified authority as verbatim because the names of experts or institutes as references were detailed. Nevertheless, the attribute still conveyed a sense of credibility. The concept was similar to source transparency but with slight differences, and a previous study showed that using official reports increased shares and comments, and references to laws and news articles also increased comments [9]. In this study, this variable did not significantly predict any metrics. This could also be due to both platforms being trustworthy sources. Finally, facts significantly predicted all 3 metrics in model 2, indicating that posts with detailed and complete content generated higher user engagement, which is consistent with past experimental results [12,13,18]. Detailed corrections might contain alternative interpretations and context information for understanding and discussion, generating user engagement.

Finally, we considered that readers might refer to comment content to decide whether to share or react in model 3. An increase in knowledge-based and critical engagement comments, which reflect scientific beliefs, led to higher shares and reactions. Conversely, comments reflecting bias-based engagement negatively predicted shares, suggesting that these comments, much like uncivil comments [47], may diminish the quality of discussion threads and reduce share counts. Comments with positive and negative emotional engagement both predicted shares and reactions. Although comment categories could predict shares and reactions, all 3 gist representations still play an important role, indicating that gist communication can still be effective.

In summary, this study defined post attributes based on the FTT and considered a more diversified array of user engagement types to explore their relationship with post attributes. The main theoretical contribution of our study is that it presents a framework applied to misinformation issues validated using real social media data. It examined user engagement in commenting to better reflect the content users are most likely to encounter. The main practical contribution is the introduction of gist representations—risk, awareness, and value—that serve as simple but important cues when publishing correction messages, helping users grasp and address misinformation issues and encouraging content sharing.

Implications, Limitations, and Future Directions

FTT emphasizes the mutually supportive relationship between our cognition and social values and recommends using reasoned approaches to guide decision-making and emotional responses, rather than emotional appeals, to counter misinformation [17]. Building on this foundation, we identified 3 rational gist representations that connect with social values. Among these, awareness of misinformation proved to be a highly effective gist when comment content was not considered. In our data, this concept included elements such as increasing awareness of misinformation and fraud, encouraging verification of sources, promoting cautious sharing, and identifying characteristics and sources of misinformation. Mentioning the risks associated with misinformation can increase share counts. The data for this study referenced health risks, social panic, legal risks, and information security risks. Mentioning the value of health promotion is effective when considering comment content. The data for this study referenced health promotion and health literacy, a positive attitude toward the COVID-19 pandemic prevention, media or eHealth literacy, public trust, psychological well-being, and social confidence. These attributes serve as guidelines for designing content in misinformation correction and science communication.

XSL•FO
RenderX

This study had some limitations. First, this study examined data from 3 years during the COVID-19 pandemic, during which attention to health misinformation was heightened. There were also some health crises before and after the COVID-19 pandemic. Whether inferences based on the results of this study remain valid requires further examination. Second, we used GPT-3.5 to code comments efficiently, followed by a manual review. Cultural characteristics may have caused GPT-3.5 to misinterpret specific comments. For example, the colors blue and green sometimes represent political parties, and GPT-3.5 may not always accurately interpret this from the context, leading to some classification inaccuracies. Nevertheless, GPT-3.5 offers several advantages over previous machine learning methods, such as cross-language capabilities and emoji interpretation. Third, authority, as one of the independent variables in this study, has implications for credibility in some types of research. In the heuristic-systematic model, it is viewed as having an intuitive role, and in the elaboration likelihood model, it is considered a peripheral cue, suggesting the credibility of a message. We cannot confirm whether the dual roles cause construct confusion or whether the platform symbolizes knowledge authority. Authority did not significantly predict the outcomes in models 2 and 3; however, this does not imply that it is unimportant. Finally, we considered whether there was an attached image but did not examine its content or whether the images contained gist messages. Images attract user attention more quickly and should be considered in future research.

In addition to addressing the abovementioned limitations, future research could consider simplifying the 6 comment categories we used. For instance, knowledge-based and critical engagement could be combined, as well as positive and neutral emotional engagement. In addition, some comments directly responded to the content design of certain corrections. We observed that some posts were criticized for lacking focus, while others were praised for being practical. If these comments can be accurately extracted and systematically analyzed, it would also help assess whether this type of gist communication is well received. We found that posts containing numerical information, such as vaccine adverse reaction rates, received more comments, as users may interpret and engage more with rates and numbers. This area requires more systematic analysis and effective framing of numeric information in correction design to prevent misinterpretation on social media, enhancing the application of FTT. Finally, this study used regression analysis to explore the impact of 6 attributes on metrics; however, a single post often contains multiple attributes, and it may be possible to identify an optimal combination. Future studies could further explore this area.

Conclusions

This study enriches the theoretical understanding of the relationship between user engagement and the effectiveness of web-based communication strategies in conveying corrections for health misinformation. It provides evidence-based web content for delivering health misinformation corrections, and FTT explains user engagement with specific post attributes. The theoretical contribution strengthens the link between FTT and multiple engagement metrics beyond sharing and discusses post attributes in terms of gist and verbatim dimensions. In addition, by incorporating comment content, gist communication increases shares and reactions effectively. Finally, these findings provide a foundation for designing more effective content strategies to combat health misinformation, ultimately contributing to more resilient public health communication.

Acknowledgments

The authors are grateful for the funding support from Academia Sinica in Taiwan (AS-HLGC-111-03). The authors acknowledge the contributions of the 3 human annotators. This study used generative an artificial intelligence tool, GPT-3.5, for large language model–based annotation of comment data.

Abstract

Background: Mumps is a viral respiratory disease characterized by facial swelling and transmitted through respiratory secretions. Despite the availability of an effective vaccine, mumps outbreaks have reemerged globally, including in China, where it remains a significant public health issue. In Yunnan province, China, the incidence of mumps has fluctuated markedly and is higher than that in mainland China, underscoring the need for improved outbreak prediction methods. Traditional surveillance methods, however, may not be sufficient for timely and accurate outbreak prediction.

Objective: Our study aims to leverage the Baidu search index, representing search volumes from China's most popular search engine, along with environmental data to develop a predictive model for mumps incidence in Yunnan province.

Methods: We analyzed mumps incidence in Yunnan Province from 2014 to 2023, and used time series data, including mumps incidence, Baidu search index, and environmental factors, from 2016 to 2023, to develop predictive models based on long short-term memory networks. Feature selection was conducted using Pearson correlation analysis, and lag correlations were explored through a distributed nonlinear lag model (DNLM). We constructed four models with different combinations of predictors: (1) model BE, combining the Baidu index and environmental factors data; (2) model IB, combining mumps incidence and Baidu index data; (3) model IE, combining mumps incidence and environmental factors; and (4) model IBE, integrating all 3 data sources.

Results: The incidence of mumps in Yunnan showed significant variability, peaking at 37.5 per 100,000 population in 2019. From 2014 to 2023, the proportion of female patients ranged from 41.3% in 2015 to 45.7% in 2020, consistently lower than that of male patients. After excluding variables with a Pearson correlation coefficient of <0.10 or *P* values of <.05, we included 3 Baidu index search term groups (disease name, symptoms, and treatment) and 6 environmental factors (maximum temperature, minimum temperature, sulfur dioxide, carbon monoxide, particulate matter with a diameter of 2.5 μm or less, and particulate matter with a diameter of 10 μm or less) for model development. DNLM analysis revealed that the relative risks consistently increased with rising Baidu index values, while nonlinear associations between temperature and mumps incidence were observed. Among the 4 models, model IBE exhibited the best performance, achieving the coefficient of determination of 0.72, with mean absolute error, mean absolute percentage error, and root-mean-square error values of 0.33, 15.9%, and 0.43, respectively, in the test set.

Conclusions: Our study developed model IBE to predict the incidence of mumps in Yunnan province, offering a potential tool for early detection of mumps outbreaks. The performance of model IBE underscores the potential of integrating search engine data and environmental factors to enhance mumps incidence forecasting. This approach offers a promising tool for improving public health surveillance and enabling rapid responses to mumps outbreaks.

mumps; deep learning; baidu index; forecasting; incidence prediction; time series analysis; Yunnan; China

Introduction

Mumps is an acute respiratory infectious disease caused by the mumps virus, characterized by unilateral or bilateral facial swelling [1]. It is transmitted through contact with the respiratory secretions of infected individuals, with an incubation period typically ranging from 16 to 18 days [2]. Nonspecific symptoms such as fever, headache, and malaise could occur before the inflammation of the parotid and other salivary glands [1,2]. While mild symptoms are more common, severe complications such as aseptic meningitis, encephalitis, sensorineural deafness, and orchitis can also develop [3,4]. Out of 2 doses of the mumps vaccine have shown nearly 90% effectiveness in protecting against mumps [5], reducing the global incidence of mumps by 97% [6] Until 2019, a total of 122 countries have introduced mumps vaccination [7], and the number reached to 124 Member States by the end of 2023 [8]. However, in recent years, mumps outbreaks have reemerged in many countries, even those with high vaccine coverage, such as the United States [9], the United Kingdom [10], and Ireland [11], which may have many potential reasons, but the waning immunity may contribute majorly [12].

In China, mumps is classified as a Class C notifiable infectious disease. Despite being vaccine-preventable, mumps remained the most prevalent disease among the 44 notifiable infectious diseases from 2008 to 2017 in persons aged 6 to 22 years, with incidences of 83.207 per 100,000 population in 2008 and 69.771 per 100,000 population in 2017 [13]. Similar to the global condition, even after mumps was included in the expanded immunization program in mainland China in 2008, an abnormal increase in incidence was observed after the program [13,14]. Although no exact reason, waning immunity, changing environment, high population mobility, along with misinformation about the vaccination may play roles [7,15,16]. After the onset of the COVID-19 pandemic, the incidence of mumps in mainland China was 7.37 and 6.48 per 100,000 population in 2022 and 2023, ranking fourth and fifth among Class C notifiable infectious diseases, respectively [17,18]. These trends highlight the continued public health challenge posed by mumps in China.

Yunnan, a province located in southwestern China, has experienced marked variability in mumps incidence. The average annual percentage change in incidence was 13.97% from 2004 to 2018, ranking third, just slightly lower than that of Hunan (15.15%) and Hainan (15.10%) provinces [19]. Furthermore, the mumps incidence in 2022 and 2023 was 14.2 and 12.8 per 100,000 population, respectively, both of which were notably higher than the national averages. These sharp fluctuations in the incidence of mumps, along with relatively higher incidence presented challenges in predicting mumps outbreaks, particularly given the lag of traditional surveillance system, which rely on case reports from medical and health institutions.

Several studies have developed prediction models for the incidence of mumps in China [20,21]. However, due to regional variations of mumps incidence, these models might not be suitable for Yunnan province. In addition, these studies only used mumps incidence, environmental factors data or both as predictors, which may not be able to explain the nonseasonal fluctuations. Incorporating alternative predictors, such as search engine query data, may improve the timeliness and accuracy of outbreak predictions. Previous studies have identified search engine data, such as that from Twitter [rename as X], Google, and Baidu, along with environmental factors, as effective predictors of certain infectious diseases such as influenza and chicken pox, due to their lower cost and higher timeliness [22-24]. Baidu, the most popular search engine in China, provides a rich source of real-time data that can be leveraged for predictive purposes. Long short-term memory (LSTM) networks, introduced by Hochreiter and Schmidhuber [25] in 1997, are a specialized type of recurrent neural network designed to capture long-term dependencies in sequential data by mitigating the vanishing and exploding gradient problems [25]. These networks have shown exceptional performance in capturing temporal dependencies in larger horizons [26]. Therefore, our study aims to use multisource data to develop a prediction model of mumps incidence in Yunnan province based on LSTM.

Methods

Data Sources

Our study used a total of 3 time series data about Yunnan province, including the incidence of mumps, the Baidu index [27], and environmental factors.

We obtained the daily number of mumps cases with their age, sex, and careers, and the annual population data from the Yunnan Center for Disease Control and Prevention, which collected accurate case characteristics from the Chinese information system for infectious diseases control and prevention, for the period between January 1, 2014, and December 31, 2023. From the system, we collected a total of 20 career types in our study, reporting the number of patients of the top 6 most common ones while grouping the remaining careers under the category “other careers.” In addition, since more than 80% of patients were younger than 20 years, we organized the age distribution into 5-year groups for those younger than 20 years, while others were presented as a separate category. The Baidu index [27] is the weighted sum of the search frequencies of various search terms by scientifically analyzing and calculating based on users’ search volumes on Baidu, which is the most popular search engine in China. By extensive search, we initially collected daily Baidu index for 30 search terms in Yunnan from January 1, 2016, and December 31, 2023. After group discussion, we excluded 3 search terms due to irrelevance and another 3 because they were introduced after 2016, resulting

XSL•FO
RenderX

in incomplete data (Table S1 in Multimedia Appendix 1). Ultimately, we included 24 search terms in our study.

We collected information about environmental factors during January 1, 2016, and December 31, 2023, from China Meteorological Administration [28], including maximum temperature (°C), minimum temperature (°C), air quality index, particulate matter (PM) with an aerodynamic diameter less than or equal to 2.5 μm ($PM_{2.5}$; measured as μg/m^3), PM with an aerodynamic diameter less than or equal to 10 μm (PM_{10}; measured as μg/m^3), sulfur dioxide (SO_2; measured as μg/m^3), nitrogen dioxide (NO_2; measured as μg/m^3), carbon monoxide (CO; measured as mg/m^3), and ozone (O_3; measured as μg/m^3).

Statistical Analysis

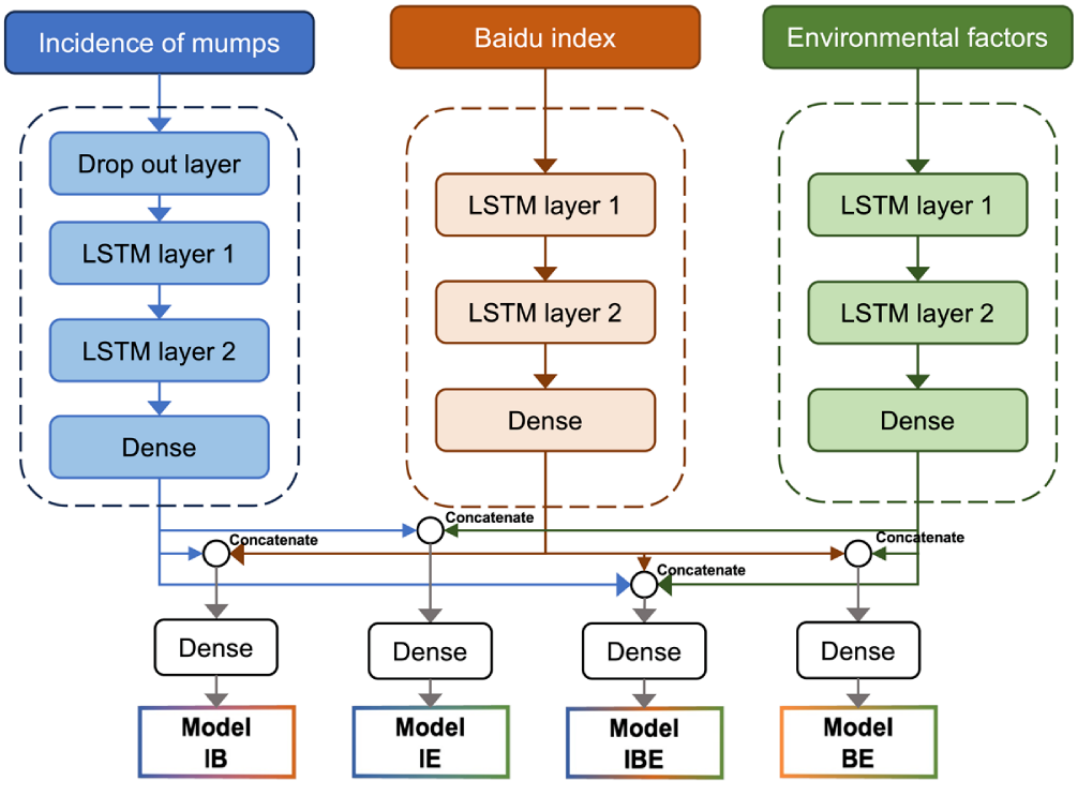
Feature Selection and Descriptive Analysis

To predict the weekly incidence of mumps, we calculated the weekly values for each variable. The weekly mumps incidence and Baidu index [27] were obtained by summing their daily values, while the weekly environmental factors were calculated as the mean values for each week. We performed Pearson correlation tests to determine the correlation between each variable and the incidence of mumps. After excluding variables with a Pearson correlation coefficient (PCC) of <0.10 or a *P* value of <.05, we consequently included 16 search terms and 6 environmental factors (Table S2 in Multimedia Appendix 1). These search terms were classified into 3 groups based on their content: disease name, symptoms, and treatment. We then calculated the weekly sum of the Baidu index for these 3 groups as the predictors.

Our study used the Kolmogorov-Smirnov test to inspect the normality of continuous variables. Normally distributed continuous variables were described as mean and SD, while nonnormally distributed continuous variables are described as median and IQR.

Log Correlation Analysis

Previous studies have demonstrated that environmental factors and the Baidu index [27] had a lag impact on the incidence of infectious disease, which means exposure affects health for a period of days [22,29]. To capture these complex relationships, we used the distributed lag nonlinear model (DLNM). DLNM is a modeling framework that simultaneously represents nonlinear exposure-response relationships and lagged effects using cross-basis functions [30]. We used natural spline functions for both the exposure-response and lag-response components, allowing for flexible modeling of nonlinear associations. We selected DLNM over other nonlinear methods, such as generalized additive models, because DLNM is specifically tailored to handle both nonlinear and lagged effects, which is crucial for understanding the temporal dynamics of environmental influences on mumps incidence. Our study used R package DLNM (version 2.4.7) to make DLNM between the Baidu index [27] and environmental factors and mumps incidence [31].



Yt represents the outcome value (mumps incidence) at week t while E[Yt] is its expected value. α refers to the interception term. p refers to the maximum lag time, which was 3 weeks in our study considering the incubation and previous study [32]. βi the regression coefficient for the i-th lag time, representing the effect size of the exposure variable at lag i on the outcome variable. cb(Xt - i, argvar, arglag) is a cross-basis function used to capture the nonlinear relationship between the exposure variable Xt-i and the lag time. This function depends on 3 parameters: Xt-i represents the value of the exposure variable at time t-i, argvar were parameters defining the effect of the exposure variable, and arglag were parameters defining the lag effect. Relative risks (RR) were used to assess the effect of a specific exposure level at one lag time compared with the reference exposure value.

Model Construction and Performance Evaluation

Our study developed 4 models based on LSTM to predict mumps incidence 1 week in advance (Figure 1). First, to better capture the characteristics of the 3 time series data, we constructed 3 primary LSTM models for each data set. The primary model for mumps incidence included a dropout layer to prevent overfitting, followed by 2 LSTM layers and a dense layer. The Baidu index [27] and environmental factors models each consisted of 2 LSTM layers followed by a dense layer. Among the 3 models, we used data from the previous 2 weeks to predict the incidence of mumps one week in advance. Subsequently, we concatenated the outputs of these primary models to construct composite models. Model IB combined the mumps incidence and Baidu index outputs, model IE combined the mumps incidence and environmental factors outputs, model BE combined the Baidu index [27] and environmental factors outputs, and model IBE combined the outputs from all 3 primary models. Each composite model then passed the concatenated outputs through an additional dense layer to produce the final prediction. This approach ensured that primary models effectively integrated information from different data sources for accurate predictions. To simulate real-world scenarios where future data are unknown and must be predicted based on past observations, we divided our data sets into train, validation and test set based on time. The train set interval was from January 1, 2016, to December 31, 2021. Data from January 1, 2022, to December 31, 2022, and those from January 1, 2023, to December 31, 2023, were used as the validation and test sets, respectively. These models were constructed by keras3 package [ONEIROS] (version 1.0.0), tensorflow package [Google Brain Team] (version 2.16.0) in R (version 4.4.1; R Core Team).

Figure 1. Model constructions. LSTM: Long short-term memory. Model BE: model including Baidu index and environmental factors; Model IB: model including mumps incidence and Baidu index; Model IE: model including mumps incidence and environmental factors; Model IBE: model including mumps incidence and Baidu index and environmental factors.

Out of 4 performance metrics were applied to evaluate these 4 models: coefficient of determination (R^2), mean absolute error (MAE), mean absolute percentage error (MAPE), and root-mean-square error (RMSE). R^2 refers to the proportion of the variance for a dependent variable that is explained by the model, with values less than 1, where larger values indicate better performance. MAE, MAPE, and RMSE measure the errors between predictions and actual values, with MAE and RMSE ranging greater than 0, and MAPE ranging from 0 to 100%, where lower values indicate better model accuracy. Compared with the MAE, MAPE represents the average of absolute percentage errors expressed as a percentage, making it more suitable for comparison across different data sets and models, while RMSE is more sensitive to outliers and larger errors.

In these equations, n was the number of observations, while y_i and y_i refer to the actual incidence of mumps in the i_{th} week and its prediction, respectively.

Ethical Considerations

Our research was approved by the Medical Ethics Committee, Xiangya School of Public Health, Central South University, Changsha, China (XYGW-2024-65). Informed consent was waived by our institutional review board because all data were fully anonymized before being accessed by the researchers, ensuring that no identifiable information about individuals was available. Therefore, compensation is not applicable in our study.

Results

The Temporal Distribution of Mumps Incidence and Predictors

In Yunnan Province, the incidence of mumps increased from 10.9 per 100,000 population in 2014, peaked at 37.5 per 100,000 population in 2019, and then steadily decreased to 12.8 per 100,000 population by 2023 (Figure 2). The outbreaks of mumps occurred from 2017 to 2020 in different cities in Yunnan. From 2014 to 2023, the proportion of female patients remained fairly stable, ranging from 41.3% in 2015 to 45.7% in 2020. (Table 1). The median age of patients showed some fluctuations over the years, starting at 7 years (IQR 4-12) in 2014, peaking at 11 years (IQR 7-14) in 2019, and then decreasing to 6 years (IQR 4-10) by 2023. The proportion of cases in children between 5 and 10 years old remained substantial, with the highest proportion recorded in 2023 (43.7%). Students consistently represented the largest affected group, comprising 44.3% to 67.5% of cases in 2014 and 2019, respectively.

The temporal distribution from 2016 to 2023 revealed distinct trends in both the Baidu search index and environmental factors (Figure 3). The distribution of the 3 Baidu index mirrored the pattern observed in mumps incidence, with a peak in 2019 and followed by a decline. Most environmental factors except SO_2 displayed obvious seasonal cycles. Maximum and minimum

XSL•FO
RenderX

temperatures reached peaks in summer, while air pollutants, including CO, $PM_{2.5,}$ and PM_{10}, had higher concentrations in winter. In addition, SO_2 and CO showed a long-term decreasing trend over the 10-year period.

Figure 3. The temporal distribution of weekly Baidu index and environmental factors in Yunnan Province from 2016 to 2023 CO: carbon monoxide; SO2: sulfur dioxide; PM: particulate matter; PM2.5: particulate matter with a diameter of 2.5 μm or less; PM10: particulate matter with a diameter of 10 μm or less.

Correlation Between Predictors and Incidence of Mumps

The Pearson correlation analysis reveals that 3 Baidu search terms, disease name (r=0.67), symptom (r=0.66), and treatment (r=0.53), show strong positive correlations with mumps incidence in Yunnan Province from 2016 to 2023 (Table 2). Among environmental factors, both minimum (r=0.17) and maximum temperature (r=0.16) have weak positive correlations, while pollutants including SO_2 (r=–0.16), CO (r=–0.12), $PM_{2.5}$ (r=–0.20) and PM_{10} (r=–0.10) show weak negative correlations with mumps incidence.

[c]CO: carbon monoxide.

[d]PM: particulate matter.

Considering the potential lag impact of these predictors on mumps incidence, we leveraged DLNM to explore their short-term impacts (Figure 4). The impact of various predictors on the incidence of mumps varies across different lag weeks. For 3 Baidu search terms, the RR consistently increases with the rising Baidu index. The analysis also revealed nonlinear associations between temperatures and incidence, with minimum temperature showing a U-shaped curve and maximum temperature exhibiting a complex pattern. In addition, elevated levels of SO_2, CO, $PM_{2.5}$, and PM_{10} generally corresponded with decreases in RR at a 1-week lag.

Model Performances and Comparisons

Table 3 shows the comparisons of the performance metrics of 4 models with different combinations of predictors. Model IBE, which includes all 3 predictors, consistently outperformed the other models in both the train and validation set, as well as the test set. Specifically, model IBE achieved the highest R^2 values (0.89 in the train and validation set, 0.72 in the test set) and the lowest error metrics, with an MAE of 0.51, MAPE of 15.2%, and RMSE of 0.74 in the train and validation set, and an MAE of 0.33, MAPE of 15.9%, and RMSE of 0.43 in the test set. In comparison, the IE model (R^2=0.54, MAE=0.45, MAPE=28.2%, and RMSE=0.55) and the IB model (R^2=0.49, MAE=0.45, MAPE=29.2%, and RMSE=0.58) showed similar levels of prediction accuracy in the test set, both outperforming model BE, which had the worst performance (R^2=0.33, MAE=0.54, MAPE=32.0%, and RMSE=0.66). The actual values and model predictions of the weekly incidence of mumps are presented in Figure 5.

Discussion

Principal Findings

Our study presented the incidence of mumps from 2014 to 2023 in Yunnan, a representative province of irregular mumps activity, and found continuous mumps outbreaks in different cities from 2017 to 2020. Using multisource data, we constructed models for predicting the incidence of mumps one week in advance based on LSTM. Model IBE (ie, the model including the incidence of mumps, Baidu index, and environmental factors) showed the best performance among 4 models.

Comparison to Previous Work

The mean incidence of mumps in Yunnan from 2014 to 2023 was 16.9 per 100,000 persons, which is lower than that of the period between 2004 to 2012 (26.2/100,000) in Yunnan and comparable to the incidence in mainland China from 2013 to 2018 (16.9/100,000) [19]. The 10-year incidence pattern of mumps in Yunnan shows an increase followed by a decrease starting in 2020. The decline may be related to the COVID-19 pandemic, which extensively reduced opportunities for interpersonal contact, thereby blocking the spread of infectious diseases. However, we do not have a definite explanation for the peak in 2019. Given the rapidly increasing number of cases among students in 2019, factors such as vaccine coverage, waning immunity, and the close gathering of adolescents on campuses may have contributed to the outbreak [3,33].

Previous studies have found nonlinear associations between meteorological factors and the incidence of several infectious diseases including mumps [34,35], influenza [23,24,36], and chickenpox [37]. These findings suggest meteorological factors are common predictors for the field of infectious disease

XSL•FO
RenderX

prediction. Our study found 6 environmental factors with a PCC of >0.10 and presented their lag correlations with the incidence of mumps. The most relevant factors were $PM_{2.5}$ and SO_2, both showing weak negative correlations (PCC=–0.2) with mumps incidence in Yunnan. Notably, the PCC is obviously lower than that of other infectious disease. For example, a study in Singapore found a stronger correlation (PCC=0.32) between minimum temperature and the COVID-19 pandemic incidence [38]. This variability suggests that while environmental factors can be valuable for predicting some infectious diseases, they may not be sufficient for accurate prediction across all diseases, highlighting the need for additional predictors.

In recent years, using search engine data, such as Google Trends [39], and the Baidu index [24,40], to predict the incidence of infectious disease has become popular and demonstrated excellent predictive performance. The advantages of search engine data included timeliness, low cost, and sometimes stronger correlation with disease incidence than other data sources. Given the different disease outcomes, fairly comparing our study with other research using search engine data is challenging, as this is, to our knowledge, the first study to construct a mumps prediction model using search engine data. However, we noted that Yang et al [24] and Choi and Ahn [39], who predicted influenza incidence in mainland China and South Korea respectively, achieved similar or even better performance using Baidu index and Google Trends alone, compared with our study's combination of the Baidu index and environmental factors. It suggests that the contribution of search engine data to incidence prediction may vary depending on types of disease, regions, and data sources. In our study, the PCCs of the Baidu index of 3 search term groups were higher than those of environmental factors. This may be because the Baidu index, derived from individuals' active search activities, better reflected the incidence peak between 2018 to 2020. In contrast, the relatively stable environmental factors might contribute more to the seasonal trends in incidence but failed to capture the sharp fluctuations observed during outbreaks.

Our study deployed multisource data to construct and compare 4 models, with the model IBE demonstrating superior performance. Notably, when Baidu index data was incorporated, model IBE exhibited even greater predictive accuracy compared with the IE model. This demonstrates the capability of the Baidu index to predict mumps incidence and the potential of integrating multiple data sources to complement the surveillance systems in predicting mumps more accurately, as these data sets can complement one another and provide a more comprehensive understanding of the influencing factors and early signs of disease spread. Further research could build on the proposed framework in our study or explore the integration of additional data sources, such as social media activity and movement behaviors, to further enhance the predictive models.

Strengths and Limitations

To our knowledge, our study is the first to develop a prediction model for the incidence of mumps that combines the Baidu index and environmental factors as predictors, and it is also the first to create such a model specifically for Yunnan province, China. In addition, by leveraging data such as the Baidu index, our model offers a novel and practical approach to monitor mumps incidence 1 week in advance.

However, there are several limitations to our study. First, at the city level rather than the provincial level, we observed different outbreak times among cities from 2017 to 2020, which may indicate the spread trajectory of mumps and be important for its control and prevention. Unfortunately, the time-series forecast model in our study cannot leverage this geographical information. Future studies could explore integrating temporal and spatial data, which may be crucial for preventing widespread transmission. Second, some Baidu search terms were introduced after 2016 (eg, the search term "Symptoms and treatment of mump" was introduced on April 2, 2018), thereby decreasing the number of available predictors of the Baidu index, which may compromise the performance of Baidu index. Nonetheless, after extensive research, our study identified and included a sufficient number of predictors. Third, we did not have access to some meteorological factors such as sunshine duration and wind speed, which have been identified as effective predictors in other studies, potentially hindering better performance of our models. Future research should incorporate a broader range of meteorological variables to improve prediction accuracy further. Fourth, applying the model to practical public health interventions still faced several challenges. Future work should focus on developing a user-friendly tool that can automatically collect predictors and output results, making the model more accessible and actionable for public health authorities. Finally, due to economic and geographic variations in China [19], various epidemic patterns of infectious diseases, and the different nature of data sets from other search platforms, this model may not generalize well across different regions, diseases, or data sources without careful adaptation and validation. While the model in this study was applied to mumps, similar approaches could potentially be applied to other infectious diseases with seasonal or outbreak-driven incidence patterns. Diseases such as influenza, chickenpox, and hand, foot, and mouth disease, where public awareness, mobility, and environmental factors play a role in transmission, might benefit from similar predictive frameworks. Future studies should focus on tailoring models to specific diseases and data sets to evaluate their broader applicability.

Conclusions

In conclusion, our study showed the incidence of mumps in Yunnan province, China, from 2014 to 2023, highlighting a sharp peak around 2019. We used data from 2016 to 2023, including mumps incidence, the Baidu index, and environmental factors, to construct 4 prediction models based on LSTM networks. Among these models, the model IBE demonstrates the best performance. This indicates the feasibility of using search engine data and environmental factors to forecast the incidence of mumps, offering a valuable tool for public health surveillance and rapid outbreak assessment.

Abstract

Background: The popularity of electronic cigarettes (e-cigarettes) has steadily increased, prompting a considerable number of individuals to search for relevant information on them. Previous e-cigarette infodemiology studies have focused on assessing the quality and reliability of website content and quantifying the impact of policies. In reality, most low-income countries and low- and middle-income countries have not yet conducted e-cigarette use surveillance. Data sourced from web-based search engines related to e-cigarettes have the potential to serve as cost-effective supplementary means to traditional monitoring approaches.

Objective: This study aimed to analyze the spatiotemporal distribution characteristics and associated sociodemographic factors of e-cigarette searches using trends from the Baidu search engine.

Methods: The query data related to e-cigarettes for 31 provinces in mainland China were retrieved from the Baidu index database from January 1, 2015, to December 31, 2022. Concentration ratio methods and spatial autocorrelation analysis were applied to analyze the temporal aggregation and spatial aggregation of the e-cigarette Baidu index, respectively. A variance inflation factor test was performed to avoid multicollinearity. A spatial panel econometric model was developed to assess the determinants of e-cigarette web-based attention.

Results: The daily average Baidu index for e-cigarettes increased from 53,234.873 in 2015 to 85,416.995 in 2021 and then declined to 52,174.906 in 2022. This index was concentrated in the southeastern coastal region, whereas the hot spot shifted to the northwestern region after adjusting for population size. Positive spatial autocorrelation existed in the per capita Baidu index of e-cigarettes from 2015 to 2022. The results of the local Moran's *I* showed that there were mainly low-low cluster areas of the per capita Baidu index, especially in the central region. Furthermore, the male-female ratio, the proportion of high school and above education, and the per capita gross regional domestic product were positively correlated with the per capita Baidu index for e-cigarettes. A higher urbanization rate was associated with a reduced per capita Baidu index.

Conclusions: With the increasing popularity of web-based searches for e-cigarettes, a targeted e-cigarette health education program for individuals in the northwest, males, rural populations, high school and above educated individuals, and high-income groups is warranted.

KEYWORDS

electronic cigarettes; Baidu index; web-based attention; spatiotemporal characteristics; China

Introduction

Electronic cigarettes (e-cigarettes), as emerging tobacco products, present a significantly appealing option to the public. In the European Union, 31.1% of current smokers, 10.8% of former smokers, and 2.3% of never smokers reported ever using e-cigarettes [1]. The world's first e-cigarette was invented in Guangzhou, China. To date, China remains the principal producer of e-cigarettes, responsible for 95% of global manufacturing [2]. In 2021, China's e-cigarette exports reached 101.5 billion RMB (US $15.91 billion; US $1=6.38 RMB), with a market size of 165.88 billion RMB (US $26 billion) [3]. Between 2015-2016 and 2018-2019, e-cigarette use among Chinese adults increased from 1.3% to 1.6% [4]. Similarly, the rate of e-cigarette use among middle school students rose from 1.2% in 2014 to 2.7% in 2019 [5].

The widespread marketing of e-cigarettes undoubtedly contributes significantly to this growth. In addition to conventional retail marketing tactics, e-cigarette manufacturers use web-based advertisement strategies to promote their merchandise [6]. On social media platforms, e-cigarettes are often portrayed as safer and healthier alternatives to traditional cigarettes [6-8]. Nonetheless, numerous studies have indicated that these products may elevate the risk of cardiovascular and respiratory diseases and adversely affect brain development and mental health [9,10]. Given the increasing prevalence of e-cigarette use and the persistent debate surrounding its health implications, an increasing number of individuals are turning to the web to access the latest information.

Web-based data offer a diverse array of perspectives and data points, with user query frequencies and concerns being well recorded. In contrast to data from traditional government communication channels, web-based data are typically anonymous, timely, and cost-effective [11,12]. Therefore, they were extensively used in disease incidence reporting, pandemic outbreak surveillance and forecasting, and public awareness analysis [13-15]. The seasonality and global nature of infectious diseases rendered them initial case studies for web-based surveillance. Tracking of influenza, HIV, and dengue outbreaks has been a continuous research hot spot [15,16]. Recently, the scope of web-based surveillance has expanded to encompass mental health, tobacco use, and noncommunicable diseases [12].

Scholarly inquiries into e-cigarette infodemiology have focused on trends in popularity, website content quality and reliability, policy impact assessments, and correlations with population use prevalence [8,17-22]. Ayers et al [17,18] used Google Trends to estimate the popularity of e-cigarettes in high-income countries such as the United States. Ghosh et al [20] suggested that web-based search data on e-cigarette–related topics in the United States and India correlate with their actual population-based prevalence. Another study conducted in the United Kingdom also confirmed this finding [19]. These studies demonstrated the great potential of using web-based search engine data to supplement and expand traditional channels for monitoring e-cigarette use. This is particularly important in low-income countries and low- and middle-income countries, where the majority have not started monitoring e-cigarette use and lack evidence to guide local policy and regulatory decisions [23,24].

To our knowledge, only 1 study has portrayed e-cigarette attention in China from 2011 to 2014 using search engine data [25]. It revealed regional differences in the Baidu search volume for e-cigarettes but did not delve into the long-term spatial and temporal evolution patterns, nor did it consider spatial effects when exploring the influencing factors. Spatiotemporal analysis can integrate multidimensional data, uncover spatiotemporal dynamic associations, and facilitate visual presentation. Previous research has used this method to explore web-based search characteristics for vaccines, migraine, and anxiety [26-28].

By December 2023, China's web user base had reached approximately 1.1 billion [29]. Baidu dominates the search engine market with a penetration rate of 90.9% [30]. Anchored in Baidu's vast search data, the Baidu index (BI) can quantify the search volume of specific terms in a certain geographical area within a given time range and convert it into a relative index value [31]. It largely reflects the search needs and awareness of Chinese web users and has been used for public health surveillance [26-28,31]. The purpose of this study was to use the BI to assess temporal and regional changes in web-based e-cigarette retrieval in mainland China and to identify factors associated with differences in public attention. The findings will contribute to enhancing and supplementing the traditional e-cigarette surveillance system in mainland China and provide a reference for the development and implementation of tobacco control policies and targeted health educational programs on e-cigarettes.

Methods

Data Sources

Web-Based Search Databases

The web-based search data related to e-cigarettes were derived from the official BI website. This platform allows researchers to capture search frequencies of different geographic regions using specific search terms over selected time frames. In this study, the corresponding Chinese characters for e-cigarettes and their synonyms were chosen as search terms. Considering the relatively low web-based search volume of e-cigarettes in China until 2015, the data sample period was set from January 1, 2015, to December 31, 2022. The geographical scope encompassed all 31 provinces in mainland China.

The daily average Baidu index (DBI) is the weighted sum of search frequency for search terms, calculated according to the daily search volume on Baidu. To further quantify the average number of searches per individual within each province, the per capita Baidu index (PBI) was defined as the ratio of the DBI to the year-end population.

XSL•FO
RenderX

Real-World Databases

To explore the influencing factors of web-based search volume, demographic and socioeconomic data were collected from the China Statistical Yearbook (2011-2022). The demographic variables included the male-female ratio, gross dependency ratio (the ratio of the nonworking-age individuals to the working-age population), and urbanization rate (the proportion of the urban population to the total population at the end of the year). The proportion of individuals with a high school education or above is the segment of the total population with at least a higher education, reflecting the educational level of the region. The per capita gross regional domestic product (GRDP), an indicator of economic development, was logarithmized in the analysis to eliminate the effects of heteroscedasticity and quantity stiffness. The descriptive statistical analysis of these variables is shown in Table S1 in Multimedia Appendix 1.

Statistical Analysis

Temporal Aggregation Analysis

The concentration ratio method was applied to analyze the temporal aggregation of the DBI for e-cigarettes [32]. The formula takes the following form:

(1)

where$R$ represents the degree of dispersion and $r_1$indicates the ratio of searches in month to the total searches for the year. M shows the degree of concentration, ranging from 0 to 1. A larger value of M indicates a stronger temporal aggregation and a value less than 0.3 suggests a relatively uniform time distribution.

Spatial Weight Matrix Definition

The spatial weight matrix is the main expression of spatial adjacency relationships. Its definition is a prerequisite for conducting spatial analysis. In our study, the widely used Rook adjacency method was adopted. This method assumes that if 2 provinces have a common boundary, they are considered adjacent with a weight of 1, otherwise, it is 0 [33]. Given that Hainan Province lacks a shared border with any neighboring provinces, we defined it as adjacent to the geographically closest Guangdong Province. The definition results of the spatial matrix Rook adjacency criterion are shown in Table S2 in Multimedia Appendix 1.

Spatial Autocorrelation Analysis

Spatial autocorrelation analysis was used to determine the spatial aggregation of the DBI for e-cigarettes [34]. It is generally categorized into global and local spatial analysis. We used the global Moran's I to analyze the spatial distribution pattern of the e-cigarette BI in each province of China, reflecting spatial dependence. The equation for the calculation is as follows:

(2)

Where w_{ij} represents the weight of the spatial relationship between observations i and j. The deviation of the attribute value of element i from its mean is denoted by . n is the total number of elements. The global Moran's I is between –1 and 1. I>0 suggests the presence of a positive spatial correlation, with values closer to 1 indicating a greater degree of spatial aggregation. Conversely, I<0 signifies a negative spatial correlation. When I equals 0, it is irrelevant.

Global spatial autocorrelation analysis fails to reveal the spatial relationships and evolutionary features within a region [35]. Therefore, the local Moran's I was applied to examine the correlation of provincial units and their neighboring provinces. It can identify the characteristics of aggregation and dissociation among districts. The local Moran's I is defined as follows:

(3)

The indicators within the formula carry similar meanings to those in the global Moran's I formula. The results of the local Moran's I analysis can be categorized into 4 significant types: high-high cluster, low-low cluster, high-low outlier, and low-high outlier. Specifically, a region with high values can be identified as a high-high cluster if its neighboring regions also have high values. If a regional unit with low values is surrounded by other regional units with low values, that unit may be classified as a low-value cluster. High-low outliers denote high-attention regions encircled by low-attention regions, whereas low-high outliers indicate low-attention regions surrounded by high-attention regions. The global and local Moran's I were computed using GeoDa 12.0 (Dr Luc Anselin's team). Regional distribution maps were drawn with ArcGIS 10.8 (Environmental Systems Research Institute).

Spatial Panel Econometric Model Description

Unlike traditional panel regression models, spatial panel econometric models consider the spatial correlation and heterogeneity among regions [36]. The classical spatial panel econometric analysis models include the spatial autoregressive regression model (SAR), spatial error model (SEM), and spatial Durbin model (SDM). These models differ in their assumptions regarding spatial interaction. SAR solely incorporates the spatial dependence of explanatory variables, SEM focuses exclusively on the spatial dependence of the random error term, and SDM integrates both effects. The basic formulas are defined as follows:

(4)

Where y_{it} is the dependent variable of province i at time t. x is the explanatory variable. α represents the intercept item. ρ is the spatial autocorrelation coefficient and w_{ij} is the spatial weight matrix. β is the vector of explanatory power, ε is the residual disturbance term, and λ is the spatial error coefficient. When λ=0 and β_2=0, the above model can directly degenerate into the SAR; when ρ=0 and β_2=0, the model can evolve into the SEM and when λ=0, the model transforms into the SDM.

XSL•FO
RenderX

Selection of a Suitable Spatial Panel Econometric Model

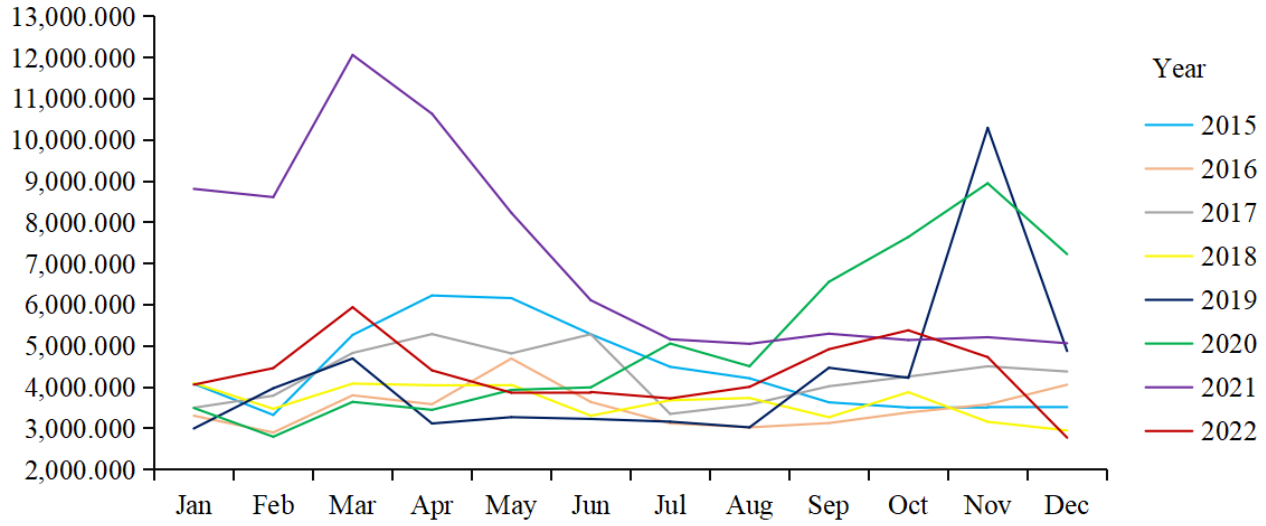
The Lagrange multiplier test was used to identify the presence of spatial effect [37]. The Wald test and likelihood ratio (LR) test were performed to evaluate whether SDM could be degraded into the SAR or SEM. The Hausman test was used to compare the suitability of fixed and random effects [38]. The LR time-space effect test was finally applied to determine the type of spatial effect. The selection process is shown in Figure S1 in Multimedia Appendix 1.

Table S3 in Multimedia Appendix 1 shows the results of the spatial panel model test. The Lagrange multiplier test suggested that the SDM was more appropriate than the SEM and the SAR. The Wald test and the LR test further confirmed that the SDM could not be degraded into the SAR and the SEM. The estimated values of the Hausman test rejected the null hypothesis, indicating that fixed effect was better than random effect in this study. In addition, the time-space double effect is more suitable for objective reality, as evidenced by the significant LR test results (LR-both/space=53.780; P<.001; LR-both/time=777.650; P<.001). Consequently, a time-space double fixed effects SDM was used to analyze the influencing factors of PBI for e-cigarettes. All tests were conducted using Stata/MP 16 (StataCorp). A 2-sided P value of <.1 was considered to indicate statistical significance.

Multicollinearity Test

Multicollinearity refers to the linear relationship between 2 or more independent variables. To address potential multicollinearity problems in this study, we conducted a variance inflation factor test. The results are shown in Table S4 in Multimedia Appendix 1. Notably, the variance inflation factor values for all variables did not exceed 10, indicating the absence of multicollinearity in our model.

Ethical Considerations



Data for this study were obtained from publicly available BI search data and statistical yearbooks. No human or animal subjects were involved. Data privacy and security were approved by the ethics committee of Wuhan University of Science and Technology (approval number 202 063).

Results

Temporal Characteristics

Table S5 in Multimedia Appendix 1 and Figure 1 show the temporal distribution characteristics of the DBI for e-cigarettes from January 2015 to December 2022. Over the 8-year period, the average DBI was 55,137.045. Generally, the DBI for e-cigarettes follows a fluctuating yet upward trajectory. The highest increase occurred in 2020-2021, with the DBI rising from 61,277.286 to 85,416.995. In 2022, the DBI decreased to 52,174.906. During the study period, the concentration ratios of DBI varied between 0.136 and 0.417. Specifically, the maximum values were recorded in 2019 (M=0.417) and 2020 (M=0.399). In both of these years, the peak DBI values appeared in October, November, and December.

Figure 1. Seasonal plot of the daily average Baidu index for electronic cigarettes (2015-2022).

Spatial Characteristics

Figures 2 and 3 depict the DBI and the PBI of e-cigarettes in each Chinese province from 2015 to 2022, respectively. Provinces with higher DBI for e-cigarettes include Shandong, Jiangsu, Zhejiang, and Guangdong, all located on the southeast coast of China. These regions consistently rank at the top, with annual DBI exceeding 450. Qinghai, Tibet, and Ningxia maintained the lowest DBI levels. The geographical pattern of the PBI contrasts significantly with that of the DBI, as the former is concentrated in Tibet, Qinghai, and Ningxia. Notably, the PBI for e-cigarettes in Beijing far surpassed that in neighboring provinces.

Table 1 indicates the global Moran's I of the PBI for e-cigarettes from 2015 to 2022. Throughout the period, all years had a global Moran's I value greater than 0, ranging between 0.151 and 0.265. The z scores revealed that spatial clustering of the PBI for e-cigarettes was statistically significant. Despite fluctuations in the global Moran's I and z values, the clustering pattern and positive spatial autocorrelation remained stable. The local Moran's I findings for the PBI of e-cigarettes are detailed in

XSL•FO
RenderX

Table 2. Low-low clusters exist in the central region of China. Guizhou and Hubei consistently demonstrated significant low-low clusters over the 8-year period. Tianjin displayed a high-high cluster only in 2015. Furthermore, Xinjiang, located in the northwestern region, was identified as a low-high outlier area in 2016, 2017, and 2022.

Figure 2. The daily average Baidu index of electronic cigarettes by province in China (2015-2022).

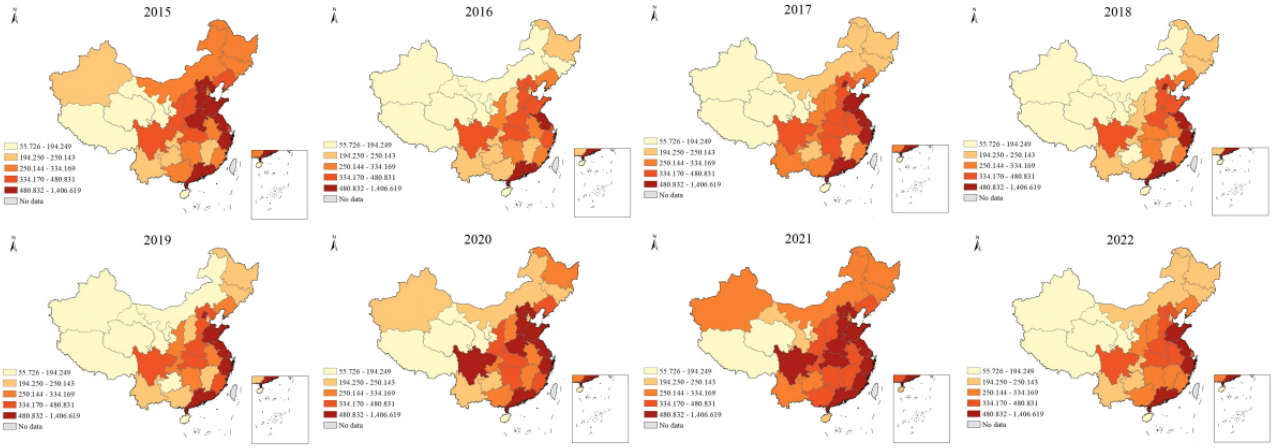


Figure 3. The per capita Baidu index of electronic cigarettes by province in China (2015-2022).

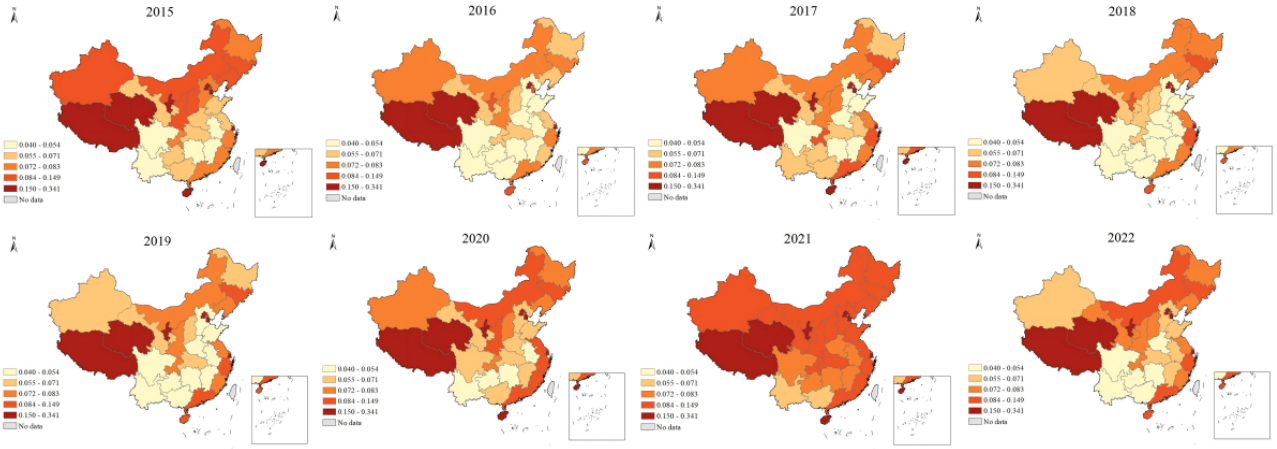

Table 1. The global Moran's I of the per capita Baidu index for electronic cigarettes (2015-2022)[a].

Year	Global Moran's *I*	*z* value	*P* value
2015	0.265	2.612	.009
2016	0.155	1.574	.07
2017	0.151	1.536	.08

Table 2. Local spatial aggregation of the per capita Baidu index for electronic cigarettes (2015-2022)[a].

Year	High-high cluster	High-low outlier	Low-high outlier	Low-low cluster
2015	Tianjin	—[b]	Hebei	Guizhou, Anhui, Chongqing, Jiangxi, Hubei, Hunan, and Guangxi
2016	—	—	Xinjiang	Guizhou, Anhui, Hubei, and Shandong
2017	—	—	Xinjiang	Guizhou, Chongqing, Hubei, Shandong, and Henan
2018	—	—	—	Guizhou, Chongqing, Hubei, Hunan, Henan, and Guangxi
2019	—	—	—	Guizhou, Chongqing, Hubei, Shandong, and Henan
2020	—	—	—	Guizhou, Chongqing, Hubei, Hunan, and Guangxi
2021	—	—	—	Guizhou, Chongqing, Hubei, Hunan, and Guangxi
2022	—	—	Xinjiang	Guizhou, Chongqing, Hubei, Hunan, Henan, and Guangxi

[a]Provinces with nonsignificant local Moran's *I* are not listed.

[b]Not available.

Influencing Factors

Table 3 illustrates the SDM results of the PBI for e-cigarettes. The male-female ratio, the proportion of high school and above education, and the GRDP were positively correlated with the PBI for e-cigarettes. A higher urbanization rate was associated with a reduced PBI. The PBI for e-cigarettes had significant positive spatial spillover effects (spatial ρ=0.467; *P*<.001). The proportion of high school and above education significantly impacted the PBI for e-cigarettes in adjacent proximity. To further analyze these spillover effects, the SDM was decomposed into direct and indirect effects using partial differential decomposition. In terms of the direct effect, there was a significant association between the PBI and male-female ratio, urbanization rate, and GRDP in the local region. The indirect effects reveal a significant negative association between the proportion of high school education and above and the PBI for e-cigarettes in neighboring areas. Moreover, both the urbanization rate and the proportion of high school and above education negatively influence the PBI of e-cigarettes across all areas.

Table 3. Spatial Durbin model results of the per capita Baidu index for electronic cigarettes.

	Coefficient	95% CI	*P* value
Main[a]			
Male-female ratio	0.057	0.008 to 0.106	.02
Gross dependency ratio	–0.002	–0.071 to 0.067	.96
Urbanization rate	–0.145	–0.282 to –0.009	.04
Proportion of education at high school and above	0.069	0.002 to 0.137	.04
Ln (per capita gross regional domestic product)[b]	0.017	0.001 to 0.032	.03
Wx[c]			
Male-female ratio	0.022	–0.077 to 0.122	.66
Gross dependency ratio	–0.042	–0.181 to 0.098	.56
Urbanization rate	–0.094	–0.381 to 0.193	.52
Proportion of education at high school and above	–0.203	–0.342 to –0.064	.004
Ln (per capita gross regional domestic product)	–0.009	–0.033 to 0.016	.49
Spatial ρ[d]	0.467	0.333 to 0.602	<.001
Direct effect[e]			
Male-female ratio	0.065	0.008 to 0.122	.03
Gross dependency ratio	–0.008	–0.08 to 0.064	.82
Urbanization rate	–0.161	–0.287 to –0.035	.01
Proportion of education at high school and above	0.046	–0.021 to 0.114	.18
Ln (per capita gross regional domestic product)	0.016	0.001 to 0.032	.03
Indirect effect[f]			
Male-female ratio	0.090	–0.094 to 0.274	.34
Gross dependency ratio	–0.070	–0.321 to 0.181	.59
Urbanization rate	–0.295	–0.756 to 0.167	.21
Proportion of education at high school and above	–0.288	–0.523 to –0.053	.02
Ln (per capita gross regional domestic product)	–0.001	–0.04 to 0.037	.94
Total effect[g]			
Male-female ratio	0.155	–0.067 to 0.376	.17
Gross dependency ratio	–0.078	–0.365 to 0.209	.59
Urbanization rate	–0.456	–0.938 to 0.026	.06
Proportion of education at high school and above	–0.242	–0.503 to 0.02	.07
Ln (per capita gross regional domestic product)	0.015	–0.029 to 0.059	.50

[a]Main denotes the impact coefficient of the variable on the local region.

[b]Ln (per capita gross regional domestic product) indicates the logarithm of per capita gross regional domestic product.

[c]Wx refers to the spatial spillover coefficient of the variable to adjacent regions.

[d]Spatial ρ represents spatial autocorrelation coefficients.

[e]Direct effect is the influence of the change in the local independent variable on the local dependent variable.

[f]Indirect effect is the influence of the change in the local independent variable on the adjacent region.

[g]The coefficient of total effects is the sum of direct and indirect effects.

Discussion

Principal Results and Comparison With Prior Work

In this study, we used the BI to explore the spatial and temporal distribution of web-based searches for e-cigarettes in mainland China from 2015 to 2022 and identified the complex associations between the e-cigarette searches and demographic characteristics, economic development level, and education attainment.

The upward trend in e-cigarette–related BI observed in our study aligns with evidence from high-income countries [17,18]. This may be attributed to the increasing prevalence of e-cigarette usage, improved health literacy, and increased web penetration [4,29,39]. Notably, a pronounced spike in search queries was detected in November 2019. A possible explanation for this temporary surge is "policy shock" [22,40]. At the beginning of that month, the Chinese government successively issued the "Notice on Further Protection of Minors from E-cigarettes" and the "Notice on Further Strengthening Tobacco Control Work Among Young People." These 2 notices explicitly prohibited manufacturers from advertising and retailers from selling e-cigarettes on the web to minors [41,42]. This prompted the public and the media to focus on web-based information about e-cigarettes. In addition, the COVID-19 pandemic might be a crucial factor for the rise in e-cigarette web-based information-seeking behavior in 2019 and 2020. The implementation of stay-at-home orders and temporary retail closures fostered an environment conducive to heightened web-based engagement [43]. During this period, 18.2%-19.8% of e-cigarette users shifted their purchasing habits from retail to web-based stores [44].

In the spatial dimension, significant regional differences exist in e-cigarette web-based attention across provinces in mainland China. The DBI for e-cigarettes is high in eastern coastal regions. Although national epidemiological data on e-cigarettes are lacking, this geographic distribution may reflect the socioeconomic and population conditions. These eastern coastal regions are characterized by dense populations and well-developed economies [45]. Residents here boasted better web-based access and public health awareness [27,31]. Among the provinces, Guangdong holds the highest DBI rankings for e-cigarettes [46]. Besides demographic and economic considerations, Guangdong was the pioneer manufacturing and production base for e-cigarettes in China and the world [47]. Regarding provinces with higher PBI, Tibet and Qinghai stand out. These 2 western provinces are distinguished by their high altitudes and unique climatic conditions In such environments, traditional tobacco combustion may be impeded. E-cigarettes show greater adaptability due to their closed system and ignition-free operation [48]. It is noteworthy that Guizhou and Hubei Province in the central region were identified as a significant low-low cluster over the 8-year period. These are both large traditional tobacco-consuming provinces, where smokers may have deep-rooted consumption habits of traditional cigarettes and are been less receptive to emerging e-cigarette products [49].

The Influencing Factors of E-Cigarette Web-Based Attention Are Diverse

First, males reported a greater frequency of e-cigarette web-based inquiries than females did. A study indicated that the proportion of males who had used and heard of e-cigarettes surpassed that of females in China [50]. Meanwhile, males are more likely to obtain e-cigarette information from online platforms and forums [51].

Second, we found a positive correlation between the ratio of high school and above education and the e-cigarette PBI. The previous study has also revealed that a greater percentage of individuals with a higher level of education had both used and been informed about e-cigarettes than did those with lower educational attainment [50]. An individual's education level is a critical determinant of public health information literacy [52]. With the accumulation of knowledge, the understanding of e-cigarette potential harm has gradually increased. Furthermore, highly educated groups tend to be more socially active and susceptible to peer pressure.

As expected, GRDP was significantly positively correlated with web-based attention. This finding was in line with the results on regional differences. The growth of GRDP is often accompanied by improved infrastructure, comprehensive services, and increased digitalization [26,27].

However, our study found a negative correlation between the urbanization rate and the PBI of e-cigarettes. On the one hand, in highly urbanized cities, such as Beijing and Shanghai, the prohibition of smoking in public places was effectively enforceable [53]. On the other hand, in regions with higher urbanization rates, consumers' awareness of e-cigarettes may have matured and their preferences have been largely established. New users' curiosity-driven search behavior was substantially reduced. Moreover, there are more e-cigarette retail shops in these areas. Consumers are more likely to have on-site experiences instead of conducting web-based searches.

Limitations

Although this study provided valuable evidence on the status and trends of e-cigarette popularity in China, there are still several limitations. First, web-based search query activities are inherently biased toward groups with higher socioeconomic levels and educational attainment. It fails to capture some important populations for e-cigarette use, especially adolescents. Second, the data available on the BI platform are limited to search terms that meet established user access thresholds. As a result, less common or infrequently used expressions may be excluded from trend analysis. Third, even though Baidu is the primary search engine among Chinese users, a minority still use alternative searches such as Google and Bing. Our study did not cover these populations. Finally, the BI data we used were collected at the provincial level. Further research should consider smaller geographic units to obtain more accurate evidence.

Conclusions

Public interest in e-cigarettes is increasing in China. There are notable differences in the PBI for e-cigarettes among provinces,

XSL•FO
RenderX

with northwest and economically prosperous coastal areas becoming hot spots. In addition, the male-female ratio, urbanization ratio, education attainment, and level of regional economic development were important factors contributing to the web-based attention to e-cigarettes. These findings underscore the necessity of devising targeted e-cigarette health education programs for individuals in the northwest, males, rural populations, high school and above educated individuals, and those with higher incomes. For less concerned groups, the focus should be on educating them about the accuracy of the information they access, thereby preventing the spread of misinformation. Our study not only contributes to supplementing and enhancing the e-cigarette use monitoring systems in China but also provides a valuable reference method for other low-income countries and low- and middle-income countries with similar patterns of web use.

Abstract

Background: Depression, a highly prevalent global mental disorder, has prompted significant research concerning its association with social media use and its impact during Hong Kong's social unrest and COVID-19 pandemic. However, other mainstream media, specifically online news, has been largely overlooked. Despite extensive research conducted in countries, such as the United States, Australia, and Canada, to investigate the latent subthemes, sentiments, and coping strategies portrayed in depression-related news, the landscape in Hong Kong remains unexplored.

Objective: This study aims to uncover the latent subthemes presented in the online news coverage of depression in Hong Kong, examine the sentiment conveyed in the news, and assess whether coping strategies have been provided in the news for individuals experiencing depression.

Methods: This study used natural language processing (NLP) techniques, namely the latent Dirichlet allocation topic modeling and the Valence Aware Dictionary and Sentiment Reasoner (VADER) sentiment analysis, to fulfill the first and second objectives. Coping strategies were rigorously assessed and manually labeled with designated categories by content analysis. The online news was collected from February 2019 to May 2024 from Hong Kong mainstream news websites to examine the latest portrayal of depression, particularly during and after the social unrest and the COVID-19 pandemic.

Results: In total, 2435 news articles were retained for data analysis after the news screening process. A total of 7 subthemes were identified based on the topic modeling results. *Societal system*, *law enforcement*, *global recession*, *lifestyle, leisure*, *health issues*, and *US politics* were the latent subthemes. Moreover, the overall news exhibited a slightly positive sentiment. The correlations between the sentiment scores and the latent subthemes indicated that the societal system, law enforcement, health issues, and US politics revealed negative tendencies, while the remainder leaned toward a positive sentiment. The coping strategies for depression were substantially lacking; however, the categories emphasizing *information on skills and resources* and *individual adjustment* to cope with depression emerged as the priority focus.

Conclusions: This pioneering study used a mixed methods approach where NLP was used to investigate latent subthemes and underlying sentiment in online news. Content analysis was also performed to examine available coping strategies. The findings of this research enhance our understanding of how depression is portrayed through online news in Hong Kong and the preferable coping strategies being used to mitigate depression. The potential impact on readers was discussed. Future research is encouraged to address the mentioned implications and limitations, with recommendations to apply advanced NLP techniques to a new mental health issue case or language.

Introduction

Background

Depression is known as one of the world's most common mental disorders, with an estimated 5% of adults experiencing it around the globe [1]. The disorder involves a depressed mood, loss of interest in activities, feeling excessive guilt or tiredness, being disconnected from family and friends, and thoughts about dying or suicide that affect all aspects of life. According to the mental health review report [2] released by the Health Bureau in Hong Kong, approximately 1 in 7 Hong Kongers will experience a mental disorder at any given point in life.

Since the outbreak of civil unrest and the COVID-19 pandemic in Hong Kong, a surging number of studies have emerged to examine the intensity of local people's depression, particularly among adolescents, older adults, students, and health care workers [3-6]. In particular, these studies have been widely associated with social media use and its effect compared to other digital media use [7-11]. Although the online press is one of the most widely consumed digital media in Hong Kong, existing research on online news coverage of depression has primarily been conducted in the United States, Australia, Canada, and China [12-17]. Studies have rarely explored online news coverage of depression in Hong Kong, based on available research.

The consumption of news coverage on depression can have both beneficial and detrimental effects on its readers. According to the protection and motivation theory, which has been applied in investigating different health-related behaviors, the underpinned threat and coping appraisal shape individuals' belief of the potential dangers to their lives and the motivation to practice protective behaviors via communication [18,19]. Thereby, positively, news coverage can help to raise awareness, increase understanding of mental disorders, and may facilitate the intention of professional help-seeking behavior [18,20]. Negatively, news coverage can also facilitate misunderstanding of depression among the public, exacerbating the stigma regarding people with mental disorders and leading to undertreatment [12,16,21,22]. The impact of news consumption has been acknowledged, and in depression-related news, diverse subthemes have also been investigated.

According to research on US television news coverage, the primary latent subthemes associated with individual and family-related depression stories include entertainment and celebrity depression, personal experiences, crime, and public policy [23]. Most of the news reports were also found to be largely negative in tone and often occurred with the subthemes of violence and crime [16]. This was likely because negative news can disproportionally grab the readers' attention, while positive news is perceived as having minimal impact [24]. Such a trend of news coverage is thereby harmful to populations with depression as it may reinforce social stigma and decrease public support for individuals with mental health disorders [16].

Conversely, in other research, which analyzed the contents of Canadian print news, the primary theme was raising awareness with the subthemes of addressing policy issues or lack of resources, military mental health issues, workplace issues, stigma, and so on, followed by the theme of research advances encompassing subthemes of treatment discoveries, etiology or prevention, and personal stories of recovery [25]. These kinds of positive subthemes may bring a positive effect of news exposure, which leads to favorable outcomes on mental health, particularly in circumstances where access to social support is restricted [26]. It is a fact that depression is 1 of the 2 most frequent mental disorder diagnoses In Hong Kong and has continued to deteriorate in recent years [3,27]. Media coverage of depression may encourage positive outcomes such as enhancing social support for individuals with depression or otherwise lead to negative outcomes, such as strengthening the public stigma toward the population with depression and their self-stigma [15,16,22,26]. Investigating the underlying subthemes of online news could aid in comprehending the positive and negative impacts of news experienced by its readers and potential mental health outcomes on populations with depression. However, to the extent of available studies, limited research has investigated the subthemes associated with online news coverage of depression in Hong Kong.

Research Questions

This study aims to fill this gap by exploring the latent subthemes in the news, which constitutes our first research question (RQ): What are the latent subthemes in the online news coverage of depression in Hong Kong? (RQ1)

In contrast, the sentiment of the news, which can be categorized as positive, negative, or neutral, has a direct effect on the stigmatization or destigmatization of people with depression or mental disorders [28,29]. Compared to print media, online news coverage was found to have a more positive sentiment in Canada and Chile, which helps to raise awareness, increase rehabilitation and recovery, and reduce the stigmatization of populations with depression [29,30]. Conversely, another study in the United Kingdom found that half of the articles about mental health expressed a negative sentiment and were closely connected with subthemes of violence, danger, and criminality, which reinforced stigma toward individuals with depression [31]. Stigmatization of people with depression usually labels them as having bad character, being violent, and blaming their conditions as a personal weakness, consequently, adding more obstacles when they want to seek social support [13,21,25]. People who are experiencing depression may also internalize the stereotypes, leading to diminished self-esteem, reduced quality of life, reluctance to seek help, and an increased likelihood of engaging in suicidal behavior [22,25].

Therefore, the sentiment of online news can play a significant role in reproducing or challenging the stigma around depression [32]. Within the context of Hong Kong, the embedded cultural norms, particularly "face concern," make people with depression

XSL•FO
RenderX

avoid seeking help from mental health professionals to prevent shaming their own families [33]. A study that investigated the experiences of mental health service users comparatively in 2001 and 2017 found no positive attitudinal changes toward people with mental disorders in Hong Kong due to perceived stigmatization [34]. However, reporting of celebrity depression, particularly their stories of overcoming depression, has resulted in positive attitudinal changes in Hong Kong, motivating readers to learn about available treatments for depression [20]. News that expressed more negative sentiment is correlated with increased anxiety, depression, and psychological distress in its readers [35,36]. Given the potential impact of news, it is important to investigate its sentiment to enhance our comprehension of its influence on both populations with depression and the broader audience. As most journalists are unaware that their reporting may have varying impacts [37] and the sentiment of online news was also less studied in the Asian context, analyzing the sentiment could further provide practical suggestions for future news practices in Hong Kong based on solid research findings. Consequently, this study is also interested in exploring how different sentiments were reflected in different latent subthemes, which constitutes our second RQ: What sentiments are reflected in the online news coverage of depression in Hong Kong and are associated with the latent subthemes? (RQ2)

In addition, starting from early research, it is worth noticing that news coverage on mental disorders provided rare coping resources or information for populations with depression [12,15,25,37,38]. However, the provision of coping strategies (ie, information on skills and resources and emotional support) is important to reduce uncertainty about a certain disease and to facilitate the potential of help-seeking behavior [39]. Therefore, news coverage was suggested to leverage its impact and include more information and resources about depression treatments or prevention, as it may help to reduce the individual's uncertainty about depression, decrease public negative attitudes on depression, and increase public awareness and knowledge of this certain mental health disorder [13,18,40,41]. Therefore, this research also seeks to analyze whether online news coverage of depression provides coping strategies for supporting the population with depression in Hong Kong, which constitutes our third RQ: What kind of coping strategies were provided in the online news coverage of depression in Hong Kong? (RQ3)

Methods

Data Selection and Collection

This research aimed to collect depression-related news on Hong Kong mainstream news websites and analyze the collected news using the Natural Language Toolkit (NLTK) embedded in Python. The latent Dirichlet allocation (LDA) topic modeling was first conducted to address RQ1, followed by the Valence Aware Dictionary and Sentiment Reasoner (VADER) sentiment analysis to address RQ2. RQ3 involved manual coding of coping strategies by content analysis. The detailed methodology will be later elaborated in the Data Analysis subsection.

To conduct a comprehensive search and collection of depression-related news in Hong Kong, the *Hong Kong Free Press* (*HKFP*) and the *South China Morning Post* (*SCMP*) were carefully selected based on 3 criteria. First, news websites should be accessible to readers without membership needs to prevent potential news access privacy risks. Second, the news website could retrieve a certain amount of depression-related news (ie, >20) to guarantee adequate data for subsequent analysis. Third, the news websites are published in English. Given that Hong Kong is a multilingual society with diverse ethnicities, English is one of the most used languages and provides a broader reach among diverse reader groups in Hong Kong. Online news websites that do not meet these 3 criteria were excluded.

After selecting the websites, the news was searched by the keywords, "depression" and "depressed" separately in each news website to ensure all related news was included as per the search strategy used in previous research [21,41,42]. Only news articles published between February 2019 and May 2024 were collected during the search process. In February 2019, the introduction of the Fugitive Offenders and Mutual Legal Assistance in Criminal Matters Legislation (Amendment) Bill sparked protests and marches in Hong Kong due to divisive political viewpoints, leading to a significant rise in depression cases, which worsened in 2020 with the outbreak of COVID-19 [6,43,44]. Therefore, the data were aimed to be collected during and after this period to obtain a more updated picture of the media portrayal of depression in Hong Kong. News outside this time range was excluded, and data collection concluded on the author's final search day.

Eventually, 3648 news stories were collected. Specifically, when searching with the keyword "depression" in the *SCMP*, 2298 (62.99%) news articles were retrieved, and 1040 (28.51%) more news articles were collected by searching with the keyword "depressed." In the *HKFP*, each keyword retrieved 155 news articles, resulting in a total of 310 (8.5%) news articles being collected. Afterward, all collected news was manually exported to a Microsoft Excel file for screening and excluding duplicated news based on the titles. Meanwhile, nonnews articles, such as opinions and commentary, were excluded. Therefore, of 3338 *SCMP* news articles, 209 (6.26%) duplicated news articles and 846 (25.34%) nonnews articles were excluded, leaving 2283 (68.39%) news articles for subsequent analysis. Furthermore, 158 (51%) duplicated news articles were removed from 310 *HKFP* articles, resulting in 152 (49%) news articles. The dataset thus included 2435 news articles for data analysis.

Data Preprocessing

Before applying the natural language processing (NLP) techniques for each RQ, each news article was uploaded to Python and created as a news corpus. The corpus was first preprocessed and tokenized into words to ensure better clarity and results of analysis [45]. Tokenization in NLP means converting words or sentences in a text into understandable tokens that a program can work with. After tokenizing the corpus, lemmatization was performed to convert words to their root meaning, such as "works," "working," and "worked" to "work." Stop words were removed by using the NLTK library. Common stop words, such as, "the," "and," "in," and

XSL•FO
RenderX

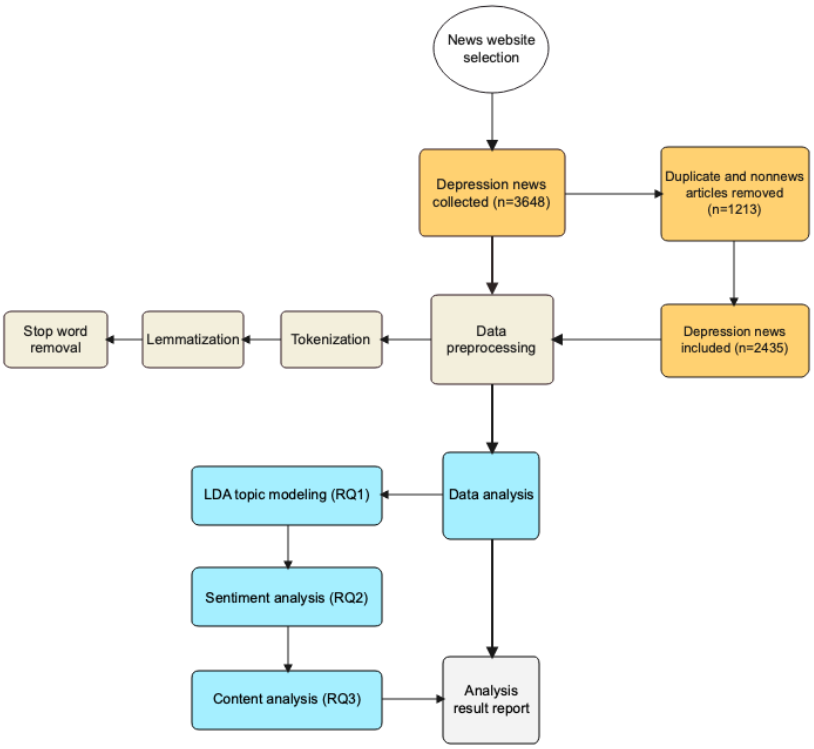
punctuations were removed as they do not provide meaningful information for subsequent data analysis. Afterward, we observed the top 200 words from the corpus and created a stop word list to remove other uninformative words, such as "say," "year," and "people."

Data Analysis

To uncover the subthemes underneath the online news for RQ1, LDA was first performed on the combined dataset to investigate the "hidden" thematic topics. The distribution of these topics will be then examined in each dataset separately to allow a more nuanced understanding. Specifically, LDA is one of the unsupervised topic modeling techniques and is becoming increasingly popular in communication research due to the ability to quickly identify the thematic structure of large amounts of text and allow more efficient explorative and descriptive analyses [45]. LDA assumed that each document or news was represented as a mixture of topics, and each topic was characterized by a distribution of words [46]. The algorithms started by assigning topics randomly to the document and then computed the distributions of words within a topic, as well as the distribution of topics within a document, then continued to update and iterate until the most suitable match was found [47]. The *genism* package was used in the NLTK to perform LDA analysis.

Meanwhile, after performing LDA analysis, coherence is an essential metric that decides the best number of topics (k) for the designated corpus. It measures the quality of the topics generated by the model and how semantically interpretable the topics are. A coherence range of 0.3 to 0.8 is acceptable [48-50]. To gain a more comprehensive understanding of the intertopic relationships, multidimensional scaling (MDS) is also used to assess and visualize the topic distance between each other based on their word distributions [51]. Specifically, topics exhibiting similarities will be positioned closer to each other on the MDS map, while topics with fewer similarities will be placed farther apart. MDS helps to facilitate the decisions regarding whether certain topics should be merged or excluded based on their similarities or distances. In contrast, the LDAvis tool (set λ=1) assists with inspecting the top keywords or most associated terms under each topic based on their relevance [52]. Relevance refers to the probability of occurrences of a term under a topic and is ranked from top to bottom to aid topic interpretation.

Moreover, sentiment analysis is another NLP technique that enables the analysis of sentiment being expressed in online news to address RQ2 [53,54]. VADER is a lexicon-based sentiment analysis tool that is included in the NLTK and shows high accuracy in news sentiment analysis [55]. In sentiment analysis, each news article was treated as a document, and the polarities of individual words within the document were calculated and summed to categorize each news into positive, negative, or neutral stances by providing a compound sentiment score [28]. The compound sentiment score ranged from –1 to 1, where –1 indicated the most negative sentiment and +1 indicated the most positive sentiment [56].



For RQ3, 2 authors who are doctoral students in language and communication studies coded each piece of news sentence by sentence to see whether the news provided coping strategies for the population with depression. Although NLP techniques can efficiently process large datasets, they may lack the nuance and contextual understanding that human coders could interpret. Manual coding can offer a deeper investigation into the news and provide more robust research findings [39,57]. The coding scheme was adapted from 2 social media studies investigating depression and coping strategies in health crises [12,39]. Specifically, each news was manually read and labeled by the first and fourth author in 2 rounds of coding.

The first round involved coding for the absence or presence of coping strategies in the news. The second round involved coding in the news that presented coping strategies and further labeled them based on the following categories: (1) information on skills and resources, (2) emotional support, (3) individual adjustment, and (4) others. The first and second categories correspond to the framework designed by Ngai et al [39] to assess if the news articles include information on coping with depression and provide supportive resources as well as emotional support. The third category aligns with the coding done by Pan et al [12], which examines whether the news provides self-adjustment strategies to cope with depression without seeking external help and is found to be the most used coping strategy to mitigate depression on social media. The fourth category refers to news that includes other coping strategies that are not covered by the previous 3 categories.

To ensure consistency in the application of the coding, Cohen κ, a statistical measure, was applied to measure the intercoder reliability on 2435 news articles [57]. The κ value ranges from –1 to 1, suggesting that a value of 0.8 in each round is the minimum acceptable intercoder agreement [58]. The flowchart in Figure 1 outlines the overall process of data collection, preprocessing, and analysis.

XSL•FO
RenderX

Figure 1. Flowchart of data collection, preprocessing, and analysis. LDA: latent Dirichlet allocation; RQ: research question.

Ethical Considerations

This study was conducted in accordance with ethical standards and guidelines. Institutional ethical approval was not sought as the research did not involve interaction with human subjects [59]. The data used in this study were obtained from publicly available resources and were analyzed in a manner that ensured the privacy and confidentiality of any individuals indirectly involved.

Results

LDA Topic Modeling

After data preprocessing, the LDA topic modeling was first used for RQ1. We examined the coherence scores in different k from 1 to 15 and found the coherence score reached its peak at k=8, where the coherence value equaled 0.5834 (Figure 2). Meanwhile, we visualized the intertopic relationships between the 8 topics by MDS, as illustrated in Figure 3 [51]. The topic keywords under each topic were also presented by LDAvis on the same figure [52]. However, it is worth noticing that LDA-generated topics might not be readily interpretable. Previous research has suggested labeling the topics into meaningful frames to better interpret the LDA-generated topics [60,61]. Having an expert in a related research field to label the frame or review the top documents and top words under each LDA topic are both feasible approaches that have been applied in previous research [45]. Therefore, the third author, who is a public health expert, particularly in the field of social psychology, reviewed each topic, the most relevant news under each topic, and top keywords from LDAvis to label the topic frames, as shown in Table 1.

In addition, drawing from observation, topic 3 and topic 8 were merged into one frame as topic 8 only occupied a small share of the news according to MDS, and its underlying top keywords and news were more aligned with the content of topic 3. Subsequently, we examined the LDA topic labels within the *HKFP* dataset and revealed that a significant proportion of the news articles, specifically 74 (48.7%) of the 152 news articles, were allocated to topic 1. This was followed by 59 (38.8%) of the 152 news articles assigned to topic 2. In addition, 10 (6.6%) news articles were labeled under topic 5, while 9 (5.9%) articles were equally assigned to topics 7, 4, and 3. On the basis of the identified topics, we also examined the reporting time of the news under each topic to visualize the overall temporal trend (Figure 4).

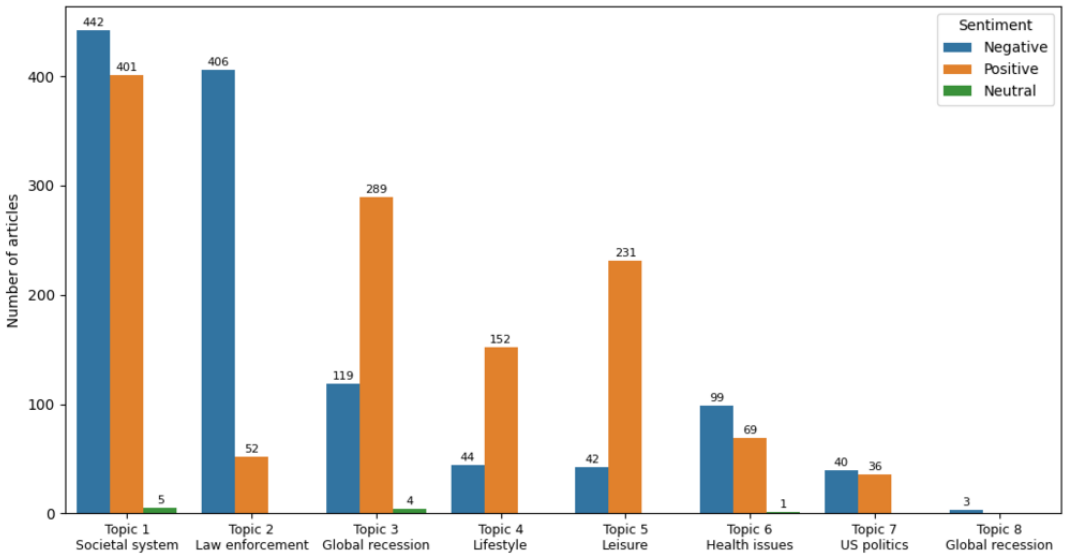
Table 1. Topic frames, top keywords, and illustrative quotes in Hong Kong depression news.

Topic frames or sub-themes	Topics	Top keywords	Illustrative quotes	News portion (N=2435), n (%)
Societal system	Topic 1	health, work, government, social, mental, help, family, support, student, and home	"The number of Hong Kong students with mental health problems shot past 1,400 in the last academic year...with experts and educators blaming the 2019 social unrest and the Covid-19 pandemic...Some feared that the actual number of young people with mental health issues could be much higher...included anxiety, depression, obsessive-compulsive disorder...and eating problems."	848 (34.83)
Law enforcement	Topic 2	police, law, protest, case, government, officer, china, protester, force, and security	"A real estate agent accused of slashing a man with a knife and assaulting another during an antigovernment protest on Friday has been remanded to a psychiatric facility, after a court heard he had been battling depression for a year."	458 (18.81)
Global recession	Topic 3	china, market, chinese, unitedstates, company, trade, business, Beijing, government, and bank	"After three years of the pandemic, the market should cope better than before, especially when valuation is so depressed,' he said. 'Nevertheless, investors should be prepared for market volatility ahead.'"	412 (16.92)
Global recession	Topic 8	economic, economic, growth, economist, lockdown, virus, recovery, spending, tax, and inflation	"New Zealand suffered its worst economic slump since the Great Depression in the second quarter as a strict nationwide lockdown to combat the coronavirus brought the country to a standstill."	3 (0.12)
Lifestyle	Topic 4	sleep, help, drink, eat, bed, body, work, stress, gas, and mind	"The genetic study...by the University of Colorado Boulder, the Broad Institute at MIT and the University of Harvard...found that waking just one hour earlier—but getting the same amount of sleep—reduces your risk of major depression by 23 percent."	196 (8.05)
Leisure	Topic 5	film, work, story, game, sport, woman, video, music, event, and book	"Osaka withdrew from last year's French Open after being fined and threatened with expulsion for refusing to do media duties, which she said had contributed to the depression she had struggled with for years."	273 (11.21)
Health issues	Topic 6	patient, health, treatment, study, symptom, doctor, diseases, cancer, drug, and hospital	"This discovery is expected to provide rapid and robust therapies, and most importantly, if the transcorneal electrical stimulation is effective in reducing the symptoms of depression and dementia, then this could be a major breakthrough for patients, families and caregivers."	169 (6.94)
US politics	Topic 7	election, trump, party, unitestates, candidate, democracy, president, political, vote, and gay	"Fetterman's dress style, or perhaps lack of style, became his signature on the campaign trail before entering the Senate this year. He also gained sympathy from many after he had to undergo treatment for clinical depression soon after taking office."	76 (3.12)

XSL•FO
RenderX

Figure 4. Trend of news articles by topic.



Sentiment Analysis

After uncovering the subthemes in the online news, our next objective was to ascertain the prevailing sentiment conveyed in the news. Sentiment scores were computed for each news using VADER. The findings indicated that the collective sentiment expressed in the news articles leaned toward the positive spectrum. Specifically, 50.51% (1230/2435) of the news articles reflected a positive stance, whereas 49.08% (1195/2435) of the news articles reflected a negative sentiment. Moreover, 10 (0.41%) pieces of news maintained reflected a neutral stance.

Consequently, we correlated the sentiment scores in different LDA topics to observe the sentiment variation in response to RQ2 (Figure 5). Notably, topics 1, 2, 6, 7, and 8 are more negatively inclined, while topics 3, 4, and 5 are positively oriented. Therefore, subthemes of the societal system, law enforcement, health issues, and US politics exhibited a predominantly negative sentiment. In contrast, subthemes of the global recession in a combination of topic 3 and topic 8 sentiment results as well as lifestyle and leisure exhibited a more positive sentiment.

Figure 5. Sentiment distribution by topic.

XSL•FO
RenderX

Coping Strategy Analysis

RQ3 focused on examining whether online news has provided depression-related coping strategies. It was found that >76% (1861/2435) of the news did not present coping strategies. After the two coders labeled all the news respectively, the interrater reliability in identifying and categorizing the coping strategies across 2 rounds was assessed using the Cohen κ statistic [58]. All disagreements between the coders were discussed. We used the SPSS (IBM Corp) crosstab function to calculate Cohen κ in both rounds of labeling. In the first round, the Cohen κ value obtained was 0.882, indicating a substantial level of agreement regarding the presence or absence of coping strategies in 2435 news articles. For the second round, we focused only on the news initially labeled as "2" in the first round, in which 501 (20.57%) news articles were consistently annotated by both coders, emphasizing particular coping strategies were presented. The κ value obtained for the second labeling round yielded a value of 0.849, suggesting a firm agreement between coders regarding the specific categories of coping strategies.

Among the news that presented coping strategies, most of the news articles (334/501, 66.7%) provided information on skills and resources to cope with depression. Under this category, local mental health organizations or charities launched diverse mental health programs and provided support hotlines to facilitate quick resource access. This was followed by individual adjustments, including making personal changes, such as adopting a healthier lifestyle through exercise, sleep, and diet. Emotional support was the third preferred coping strategy, including support from friends, family, partners, and pets to help individuals mitigate depression. The least mentioned category includes mental health advice suggested by experts, particularly focusing on parental guidance for the well-being of their children and coverage of past mental health initiatives.

Discussion

Principal Findings

This study investigated online news coverage of depression in Hong Kong, discovering prevalent subthemes (RQ1), overall sentiment (RQ2), and coping strategies (RQ3) in the news. In response to RQ1, the topic modeling results identified 8 LDA topics based on the coherence score, and 7 latent subthemes were eventually identified by using MDS, LDAvis, and expert insights. The primary subtheme is "societal system," accounting for a representation of 34.83% (848/2435) of overall news, followed by "law enforcement" (458/2435, 18.81%), "global recession" (415/2435, 17.04%), "lifestyle" (196/2435, 8.05%), "leisure" (273/2435, 11.21%), "health issues" (169/2435, 6.94%), and "US politics" (76/2435, 3.12%). The overall sentiment of the news was slightly more positive, which aligns with news reported in Canada and Chile [29,30,62]. Among the subthemes, "societal system," "law enforcement," "health issues," and "US politics" exhibited negative tendencies, while others tended to be more positive. The coping strategies were substantially inadequate, in line with previous research results [25,38,40]. However, this study has enhanced comprehension regarding preferred types of coping strategies provided in depression-related news, predominately featuring information on skills and resources and individual adjustment to cope with depression.

On the basis of the sentiment analysis, it becomes apparent that the primary subtheme, focusing on the societal system, exhibited a more negatively inclined sentiment. The subtheme was related to diverse systems in Hong Kong's society, including the health and social systems, such as family, education, and work. The amount of news by reporting time indicated a peak in reported news, notably during May 2020, April 2020, and July 2023. Therefore, we first examined the news content between April and May 2020 and found that COVID-19 lockdown measures greatly affected Hong Kong, contributing to a more depressed mood [6]. Specifically, the period signifies the second wave of the COVID-19 outbreak [63]. While the first wave in Hong Kong reported relatively few cases, the second wave saw a sharp increase in cases, leading to stricter measures to contain the virus, including school closures, work-from-home policies, and a ban on dine-in services [43]. School closures, as noted in the news, resulted in an increased rate of depression among children and heightened anxiety for parents who had to take care of both their children and the older adults at home. Work-family conflicts also elevated due to the disruption to normal work routine (ie, no office space and blurred working time), which was found to be depressing [8,64]. In July 2023, we continued to examine the news content and found that reported suicide cases surged. Notably, an influential star, Coco Lee, who experienced depression, died by suicide at home, raising more awareness for expanded mental health support services and enhanced accessibility, with support hotlines being frequently highlighted. This phenomenon is supported by previous research, which suggests that news of celebrity suicides is more likely to provide coping strategies, as readers, particularly fans, may become more proactive in seeking treatment for depression and increase their understanding of the condition [18,20].

The second leading subtheme focuses on law enforcement, mainly negative sentiment, and coincides with the subtheme in other news studies [23,42,65]. The amount of reported news peaked during November 2020 and August 2019. In the former month, individual crimes and court cases were reported, particularly centering on an event of a Hong Kong professor murdering his wife, which may have brought great social shock and attention. Notably, depression was often cited as an explanation for the perpetrator's illegal actions in the news, which may reinforce stigmatizing attitudes and portray people with depression as violent, dangerous, and more likely to commit crimes [13,16,23,31]. The stigmas associated with depression could have been strengthened by the news report, making the public more unlikely to associate with, employ, and work with people affected by depression [25]. In Hong Kong, a study on media reporting of homicides committed by patients with schizophrenia found an increase in negative attitudes and the belief that people with psychosis are dangerous [66]. In the latter month, the online news focused on antigovernment demonstrations regarding the extradition bill. A sequence of protests and marches transpired in opposition to the Hong Kong government's ratification of the bill, which would allow the transfer of criminal suspects to China, China Taiwan, and China Macau, raising local people's distress about the potential erosion

XSL•FO
RenderX

of autonomy [67]. This event marked the largest protest activities in Hong Kong's history, as evidenced by a survey conducted from June to August 2019, where >90% of protesters acknowledged that if the government persisted in advancing the bill, protest activities would likely escalate [5,67]. Meanwhile, the rate of depression among locals continued to rise, along with suicidal ideations, surpassing the levels recorded during the larger-scale protests of 2014 [68].

The third leading subtheme centers on the global recession resulting from the economic hardship induced by widespread COVID-19 across industries but with more contradicting positive sentiment. Distinctly, the news story's structure would initially depict economic challenges and then emphasize the initiative underway to facilitate recovery in response to the crisis. A significant change in overall sentiment occurred, where up to January 2021, the continued decrease in the quantity of positive news ceased. Subsequently, the aggregate number of positive news exceeded negative news almost every month, signalizing an overall shift from negative to positive sentiment surrounding the discussed economic circumstances. This may be attributed to the fact that people were forced to adapt to a "new normal" and start to restore health, economy, and societies after the pandemic had emerged for one year [69]. Strict social distancing measures were gradually relaxed worldwide, such as school reopening, shortened quarantine days, and global trade resumes [70]. Meanwhile, the Hong Kong government has also launched various initiatives and campaigns to stimulate the economic market through issuing digital consumption vouchers to eligible residents; supporting enterprises and the general public with tax cuts; and subsidizing older adults, working families, and child-raising families with more allowances [71].

The fourth and sixth subthemes share greater similarities, as observed on the MDS graph. The fourth subtheme, lifestyle, presented a more positive sentiment by offering different healthy lifestyle suggestions and ways to help its readers improve their well-being. This can be credited to the insights gained from the analysis of coping strategies. Individual adjustment emerged as the second most prominent coping strategy category, emphasizing ways to mitigate depression by considering altering their lifestyle to promote better health through adjustments, such as maintaining adequate sleep, doing regular exercise, and having a nutritious diet while quitting unhealthy behaviors, such as drinking, smoking, and staying up all night. In recent years, lifestyle-based mental health interventions were suggested to be implemented in clinical practices for adults with depression, with growing recommendations on practicing physical activity and exercise, relaxation techniques, work-directed interventions, sleep, and mindfulness-based therapies [72]. Likewise, the sixth subtheme, health issues, was more inclined toward negative sentiment and shared information about the symptoms and negative effects of mental illness as well as available treatments or therapies that are effective in tackling mental health conditions.

The final 2 subthemes were inclined toward positive and negative sentiment, respectively, focusing on leisure and US politics. The leisure subtheme shared depression-related dramas or narratives about celebrities who were and are experiencing depression. However, it is worth noticing that while reading the news, successful stories of how individuals combat depression are rare. Earlier research found that only 7% of depression-related news covered successful treatment or stories of individuals recovering from mental illness, and only 18% emphasized recovery and rehabilitation of those affected as part of their content [16,29]. The concluding subtheme centers on US politics, specifically emphasizing the rivalry and electoral process for the presidency as well as politicians from different parties who experienced depression.

Finally, based on the coping strategy analysis, we found that information on skills and resources was the leading coping strategy category to offer mental health support for populations with depression. Under this category, the suicide intention and prevention helplines were the most frequently cited information, as depression is a strong indicator of suicide [73]. In contrast, various mental health programs were introduced by local mental health organizations such as Mind HK, Kely Support Group, and the Mental Health Association of Hong Kong to offer counseling services and therapies for people with depression. Under the individual adjustment category, exercise is the most cited one, with leading recommendations on different types of running, yoga, and mindfulness activities to enhance self-efficacy in dealing with depression. Regular exercise can bring positive mood change and serve as an antidepressant for individuals with depression [74,75]. Regarding the emotional support category, friends, family, and loved ones are protective factors [76]. However, having a bad relationship may further exacerbate depressive symptoms [77]. In addition, companion pets played a critical role in reducing feelings of depression, particularly during the COVID-19 pandemic period with poor social contact [78]. Although there exists a variety of coping strategies, the overall quantity of strategies offered in the news is deemed rare. In addition, we have observed the inadequacy of policy interventions or support as well as financial assistance for individuals with depression, which implies the deficiency in the societal level of coping strategies in the news coverage. The news media should raise awareness by incorporating more varieties of coping strategies in depression-related news to leverage its positive impact, which might potentially foster positive mental outcomes among individuals with depression and facilitate early mental intervention [79,80].

Implications for Future Practices

The media portrayal of depression has a dual effect on its readers. In a positive way, the news can help to reduce the uncertainty experienced by an individual with depression, spread information and knowledge about depression, and increase the recognition and understanding of the public [39,81]. In contrast, news can also exacerbate the social stigma and self-stigma of individuals with depression, resulting in decreasing support resources or information from the public, which may deteriorate the well-being of individuals with depression, and may lead to less intentions of help-seeking [22,32,35]. The subthemes highlighted in the news were predominantly negative, suggesting that Hong Kong news agencies and journalists should expand the range of topics they cover when portraying depression. Preferably, incorporating successful treatment of depression and achievements of individuals with depression as potential subthemes can help to reduce the stigmatization of people with

XSL•FO
RenderX

depression and foster a better understanding, positive attitude, and accurate beliefs toward populations with depression among the public [14,24,30]. Meanwhile, the overall sentiment of the news was slightly more positive, with 50.51% (1230/2435) positive versus 49.07% (1195/2435) negative news, suggesting that more efforts are needed to report positive content, which could help reduce the stigmatization toward depression [29]. Containing more coping strategies in the news is also suggestive. Specifically, enhancing the inclusion of individual adjustment category in depression-related news was relatively more achievable and preferable as studies found that improving self-efficiency, a key component of the coping appraisal in the protection motivation theory, is more effective in forecasting health-related intention and behavior than eliciting fear or threat [12,18].

Implications for Future Research

On the basis of the methods and findings of this research, we would like to suggest several points for interested scholars to expand on the current research. First, we would highlight a potential future research direction focusing on coping strategies. In this study, we have analyzed the coping strategies in the online depression news; however, we do not know whether the public or individuals with depression will literally increase their knowledge and awareness of depression and facilitate health-seeking behaviors among populations with depression. Future research is recommended to explore the social media platforms of these news websites and examine the interactions between the news posts and users' engagement (ie, comments and likes) to see whether their interactions can promote attitudinal changes and potential links with behavioral change.

Second, from a methodological standpoint, sentiment analysis is a powerful tool, notably through techniques such as EmoBank, which analyzes emotions from both the reader's and writer's perspective and examines emotion dimensions, such as valence, arousal, and dominance [82,83]. This technique is constructive to explore the topic proposed earlier. Other more advanced techniques such as the multidimensional relation model (examining the relationships between valence, arousal, and dominance) and tree-based regional convolutional neural network–long short term memory (examining text sequential tendency, text regional information, and even nontext elements such as images in the news) are also encouraged for more in-depth research analysis [84,85]. In contrast, for acknowledgment, different score ranges of sentiment analysis are also available beyond –1 to 1. For example, the Semantic Orientation Calculator and AFINN lexicon-based resources provided a score range from –5 (most negative) to +5 (most positive) [86,87]. The Extended Affective Norms for English Words and Chinese EmoBank range from 1 to 9 (negative-neutral-positive), which may also provide a delicate interpretation and quantification of sentiment analysis results [83,88]. Meanwhile, it is also suggested to perform error analysis in sentiment analysis, as demonstrated in these 2 case studies, whether through different computational support or human inspection [89,90].

Third, we would also encourage the replication of this study design and its application to different mental health problems or language cases. However, it is important to note that the resources required for performing LDA and sentiment analysis may differ. For example, except for alphabetical languages such as English, nonalphabetic languages such as Chinese require other packages and resources such as Jieba and Chinese EmoBank due to differences in the language system [61,83].

Limitations

The study has several limitations that should be acknowledged and recommended for future research to address and advance. Due to the international nature of Hong Kong society, we primarily selected English-reported news as our focus. English news tends to reach more diverse audiences, including disadvantaged groups such as ethnic minorities and foreign domestic helpers who may not be proficient in Chinese, face more stigmas, and are more susceptible to mental health issues [91-93]. However, for future research, this study has presented the steps for investigating the news reports of a mental health issue. Future research can also consider incorporating Chinese as another mainstream language to provide a more comprehensive understanding of portraying depression in Hong Kong, particularly focusing on the local population.

Second, after news coverage collection, we recognized the practical flaw of the imbalance of the number of news items being collected from *SCMP* and *HKFP*. This imbalance may be primarily due to *SCMP* standing out as the most widely read paid newspaper in Hong Kong in terms of news and current affairs, according to the Hong Kong Media Survey report [94]. In contrast, the *SCMP* website places special emphasis on mental health and has dedicated a section called the "Wellbeing" page to report on mental health issues, including depression, which may contribute to the imbalance in coverage between these two news websites.

Third, while screening the news coverage, a further step can be implemented in the screening process, which is to exclude news stories that mention depression as only an incidental topic rather than as the main topic of the news coverage [42]. Future research could explore the possibility of excluding news articles that mention "depressed" or "depression" only once, whether through NLP techniques or human inspection, to ensure a more focused analysis targeting mental health–centered discussion.

Conclusions

In conclusion, this study is the first to explore latent subthemes, sentiment, and coping strategies in online depression-related news in Hong Kong based on available research. The findings offer a deeper understanding of the underlying subthemes, revealing a predominance of slightly more positive sentiments, inadequate coping strategies, and associated categories that warrant increased attention. For future news reporting, it is recommended that news organizations and journalists take into account the recommendations discussed in the Implications for Future Practices section. Future research is also recommended to explore the topics and methodologies discussed in the Implications for Future Research section and tackle the acknowledged limitations. We encourage the application of NLP techniques to other prevalent mental health disorders such as anxiety, schizophrenia, and bipolar disorder and in different

XSL•FO
RenderX

language contexts. In general, this study enhances our comprehension of how depression is portrayed in online news coverage in Hong Kong, particularly during and after periods of social unrest and the COVID-19 pandemic, by providing the latest findings and perspectives.

Acknowledgments

This research was funded by the Hong Kong Polytechnic University (P0046380).

Data Availability

The datasets generated and analyzed during this study are available from the first author on reasonable request.

Authors' Contributions

SC conceptualized the study and curated, collected, and analyzed the data. SC wrote the original draft of the manuscript and reviewed and edited it. CSBN supervised the quality of the manuscript, reviewed and edited it, and acquired funding. CC investigated the data and provided comments. YH analyzed the data.

Abstract

Background: Adolescent substance use disorder is a pressing public health issue, with increasing prevalence as individuals age. Social media platforms like Reddit (Reddit Inc) serve as significant venues for teenagers to discuss and navigate substance use. Social media platforms, such as Reddit, serve as increasingly important spaces where teenagers discuss, share, and navigate their experiences with substance use, presenting unique opportunities and challenges for understanding and addressing this issue.

Objective: This study aims to explore how teenagers frame substance-use discussions on the r/teenagers subreddit, focusing on their personal interpretations, causal attributions, and the social and psychological contexts that shape these online support groups. By identifying these interpretive frames, we aimed to better understand the complex drivers of adolescent substance use behavior and their potential interventions.

Methods: Using natural language processing techniques, we analyzed 32,674 substance use–related posts from 2018 to 2022. A framing approach was used to identify and categorize prevalent themes, supplemented by emotional profiling using the EmoLLaMA-chat-13B model developed by Liu and colleagues.

Results: In total, 7 primary frames emerged: normalization, risk awareness, social integration, autonomy and rebellion, coping mechanisms, media influence, and stigmatization. These frames varied in prevalence and were associated with distinct emotional profiles, highlighting the complex interplay between substance use and adolescent experiences. We observed that, for example, the normalization frame was often associated with a mix of sadness and anxiety, while the coping frame exhibited elevated levels of anger, sadness, and anxiety. These distinctive emotional landscapes associated with each frame reveal unique insights into the mental state of adolescents navigating substance use.

Conclusions: The findings underscore the multifaceted nature of adolescent substance-use discussions on social media. Interventions must address underlying emotional and social factors as well as identity to effectively mitigate substance use disorder among adolescents. By understanding the frames teenagers use to interpret substance use, we can pave the way for more effective and personalized public health campaigns, and support services designed to resonate with adolescents' unique lived experiences.

Introduction

Overview

Adolescent substance use disorder (SUD), characterized by a problematic pattern of substance use causing clinically significant impairment or distress, remains a significant public health concern [1]. Data from the monitoring of the future survey in the United States underscore a clear age-related increase in substance use during adolescence. Cannabis use and nicotine vaping remain particularly prevalent, with 29% of 12th graders, 17.8% of 10th graders, and 8.3% of 8th graders reporting cannabis use in the past year [2]. This trend reflects the progressive escalation of substance use as adolescents age, with nicotine vaping and cannabis being the most commonly used substances [2]. These findings align with the 2019 National Survey on Drug Use and Health, which reported a 4.5% prevalence of SUD among adolescents aged 12-17 years, rising to 14.1% among young adults aged 18-25 years. This further illustrates the role of age in substance use patterns [3]. A global meta-analysis found that older teenagers (aged 15-18 years) exhibit higher rates of substance use, with cannabis and methamphetamine becoming more prevalent as age increases [4]. This progression mirrors US patterns, where substance use typically escalates during mid-to-late adolescence.

The high prevalence of SUD among adolescents is particularly concerning owing to the potential risks and negative impacts associated with substance use [5-8]. SUD poses immediate health risks and can precipitate mental health challenges, infectious diseases like HIV or AIDS, and other negative societal impacts [9]. Families of those struggling with SUD often face profound disruptions, including strained relationships, communication breakdowns, and financial difficulties, all of which could further elevate the risk of SUD transmission across generations [5]. Despite these detrimental impacts, the stigma surrounding drug addiction frequently deters individuals from seeking help through traditional channels such as individual or group counseling [10]. In contrast, the anonymous nature of social media platforms like Reddit enables users to engage in discussions about sensitive topics such as substance-use experiences and seek support for recovery without fear of judgment. These platforms offer insights into a wide array of experiences, underscoring their importance in addressing the challenges of SUD [6].

An increasing number of studies have explored discussions of substance use and mental health on social media platforms such as Reddit. For example, research highlights Reddit's role as a vital support network for opioid recovery, offering emotional and informational support [11,12]. Recent work using Reddit data reveals pandemic-related shifts in discussions about mental health, substance use, and lifestyle changes, highlighting correlations between the pandemic and shifts in health-related behaviors [13,14]. Other research focuses on specific emotional experiences related to substance use [15,16]. Collectively, this body of research illustrates the potential role of social media platforms in monitoring the evolving landscape of mental health and substance-use issues over time.

This research on discussions around substance use on Reddit has generally overlooked 2 critical areas. First, demographic factors, especially age differences, have largely been ignored. For instance, inhalant use is more prevalent among adolescents, whereas substances like nicotine, cannabis, alcohol, opioids, and benzodiazepines are more commonly used by individuals aged 21 to 30 years [17]. Existing studies of substance use discussions on Reddit have mainly focused on specific substances such as alcohol [12], marijuana [18], and opioids [19], disregarding the variations in substance use patterns and substance use among different age groups. Notably, there is a lack of focus on teenagers' discussions about substance use, despite its significance as a growing concern.

Second, there is a substantial gap in understanding the interpretations of substance use by teenagers on these platforms. While existing studies have shed light on aspects such as language use [14], emotional expression [15], prevalent topics [14,20], and topical correlation [13], they fall short in investigating the deeper discourse within these conversations. In addition, research has highlighted how media portrays substance use primarily as an issue of criminal justice [21], but this perspective overlooks the importance of individual framing [22,23]. Particularly in matters with adverse personal and social outcomes, understanding teenagers' personal interpretations and causal attributions is crucial for addressing the challenges associated with substance use.

To address these concerns, this study uses a framing approach to investigate teenagers' discussions about substance use on Reddit, focusing on personal interpretations, causal attributions, and the broader social and psychological contexts influencing these conversations. Reddit is a social media platform consisting of numerous communities called subreddits, each dedicated to specific topics. The subreddit r/teenagers is a community where individuals aged 13 to 19 years share experiences and discuss issues relevant to their age group [24]. Goffman's [25] concept of frames provides the theoretical foundation for our analysis. Frames are "schemata of interpretation" that enable individuals to "locate, perceive, identify, and label" occurrences within their life experiences and the world at large. By analyzing the frames used in r/teenagers discussions, we aim to reveal the interpretive lenses through which teenage users construct meaning around substance use. This approach allows us to uncover the narratives and attributions they use to make sense of the issue and how these framing processes relate to broader social and cultural contexts. Previous research has demonstrated the utility of framing theory in understanding health-related communications and behaviors. For example, studies have shown that framing influences individuals' perceptions and responses to health messages [26]. Applying framing analysis to social media discussions provides a unique opportunity to explore how teenagers frame substance uses in their own words, offering insights that may not be accessible through traditional survey methods.

To systematically analyze the large volume of textual data available on Reddit, we use natural language processing (NLP) techniques. Automated NLP methods enable the processing of extensive datasets, capturing a more comprehensive picture of the discourse as compared with manual qualitative analyses.

XSL•FO
RenderX

This approach enhances the reliability and generalizability of the findings by reducing potential biases introduced through selective sampling and human subjectivity [27]. The NLP techniques have been successfully used in previous studies to identify patterns and themes in social media data related to mental health and substance use [28], demonstrating their effectiveness in uncovering subtle linguistic and thematic patterns that might be overlooked in manual analysis. By leveraging these techniques, we aim to provide deeper insights into teenagers' perspectives on substance use, which can inform targeted interventions and support strategies. Ultimately, we hope that our findings will contribute to the literature on adolescent mental health and substance-use prevention, supporting efforts to address these critical public health concerns.

Literature Review

Teenagers' Substance Use

Adolescent substance use is influenced by a complex interplay of peer dynamics, family environment, romantic relationships, and external factors. Peer influence, crucial in this context, manifests through peer selection and socialization, where adolescents align with peers having similar substance use behaviors and attitudes [8]. Concurrently, family dynamics significantly impact substance use, with factors like parenting styles, parental substance use, and family conflicts playing key roles [29,30]. Adolescents from authoritarian or conflicted family backgrounds, or those with parents who abuse substances, demonstrate a higher propensity for substance use [29].

In the context of romantic relationships, substance use can serve as a response to relationship-induced stress and may also contribute to adolescent dating violence [31]. For example, substance use often initiates at the onset of relationships and may persist or escalate as a coping mechanism for relationship stress and breakups. Research by Rothman et al [31] indicates that adolescents view alcohol consumption as intensifying aggression in dating violence by increasing irritability and anger. Moreover, external factors such as the COVID-19 pandemic have influenced substance use trends. While lockdown-induced reductions in social interactions have generally led to decreased substance use among teenagers [32], Alambo et al [13] observed an uptick in online support group discussions related to substance use disorders during the pandemic, indicating heightened awareness or concern.

Despite the critical insights these factors provide into adolescent substance use, research focusing on teenagers' personal narratives within these contexts remains limited. A notable study in Australia identified four primary narratives among teenagers aged 13 to 15 years who were involved in alcohol and other drug programs: (1) viewing substance use as purposeful, (2) controlled, (3) a component of future competent use, and (4) not necessitating treatment [33]. However, a deeper understanding of how teenagers frame and make sense of substance use within their lived experiences and social contexts is still needed. This study aims to address this gap by using a framing approach [25] to analyze teenagers' narratives on substance use. Frames represent interpretive lenses through which individuals make sense of and assign meaning to issues. By examining the frames used in teenagers' discussions, we can gain insights into how they interpret and ascribe significance to substance use within their lived experiences and social environments.

Frame Approach

Frame research investigates the conceptual and interpretive mechanisms through which individuals comprehend the world. Rooted in interactionism and the School of Chicago, frame theory emphasizes the schemas that help individuals identify, perceive, and categorize experiences within their personal and broader environments [25]. These frames guide the interpretation of experiences and are shared by fellow actors, often taken for granted in daily interactions [25]. This study adopts an interpretive approach to frames, focusing on how individuals construct meaning and make sense of their lived experiences through cognitive schemas or "interpretive lenses."

Understanding the collective framing processes used by teenagers is crucial for several reasons. First, in online support communities such as Reddit's r/teenagers subreddit, users are not merely passive consumers but active creators of content. This user-generated content possesses the potential to influence and modify the interpretive frames of others, fostering a dynamic interplay between personal and collective framing processes [34]. As teenagers engage in discussions, share personal experiences, and collectively interpret substance use issues, collective action frames can organically emerge within the online support community.

Second, frames within social media discourse can significantly influence emotions, thereby shaping public understanding and engagement [35]. For instance, a study analyzing mental health frames on Twitter (X Corp) revealed 7 distinctive frames, including "Awareness," "Feelings and Problematization," "Classification," "Accessibility and Funding," "Stigma," "Service," and "Youth" [23]. These frames not only shape the conversation but also carry emotional weight that can vary in intensity, affecting the audience's likelihood to engage civically [36]. The relationship between emotion and action extends to other areas of public discourse, such as substance use. For instance, a teenager's Reddit post about recreational drug use can evoke a spectrum of emotions, ranging from concern to recognition of stress relief. Understanding these emotional responses is crucial for identifying discussions that may either hinder or promote positive societal change.

Several studies have individually examined the influence of specific frames surrounding substance use. One study explored how framing addiction as a brain disease within genetic and neuroscience research on nicotine addiction could undermine public health efforts, create unrealistic expectations regarding drug therapies, and divert attention from significant social factors [37]. Another study critiqued the framing of recreational substance use as potentially misleading and potentially detrimental [38]. While these studies highlighted issue-specific frames, they may not generalize across different contexts.

To date, there is a paucity of research investigating the frames and emotions associated with substance use discussions among teenagers. This gap is particularly concerning given the

XSL•FO
RenderX

heightened vulnerability of this demographic to substance use disorder and its potential long-term repercussions. Exploring the prevalent frames and emotions in teenagers' discourse surrounding substance use could yield valuable insights for developing tailored and effective prevention and intervention strategies. Consequently, the following research questions (RQs) are proposed: (1) RQ1: What frames do users in r/teenagers use to assign to substance use? (2) RQ2: Which of these frames on substance use are most prominent in these discussions? and (3) RQ3: Which emotions are commonly associated with individual frames in substance use discussions in r/teenagers?

Methods

Data Collection and Preparation

We analyzed originating posts from the r/teenagers subreddit, the largest online support forum for adolescents on Reddit, targeting users aged 13 to 19 years and boasting over 3 million subscribers. This subreddit offers a broad perspective on teenage life, making it a valuable resource for studying adolescent experiences, including substance use. Our analysis was confined to originating English-language posts, defined as the primary submissions made by users to the subreddit, rather than comments or replies to these submissions. This focus allowed us to prioritize the initial framing and self-expression by teenagers when discussing substance use.

To construct our dataset, we obtained 2,145,997 originating posts spanning from 2018 to 2022 through Reddit's submission archives [39]. Posts related to substance use were identified through a systematically curated keyword-based methodology involving 3 distinct stages to ensure comprehensiveness and linguistic inclusivity. First, an initial list of keywords was compiled from authoritative sources, including the 2022 National Survey on Drug Use and Health by Substance Abuse and Mental Health Services Administration, which documents substances commonly used by adolescents; peer-reviewed studies such as Rutherford et al [40]; and the Drug-Use Insights web application [41], a resource providing substance-related terminology observed in social media contexts. Second, this list was expanded to include synonyms, abbreviations, and slang terms frequently used by adolescents, derived from an analysis of online support forums, social media platforms, and adolescent behavioral studies. This step was critical to capturing the diverse linguistic expressions used by teenagers when discussing substance use. Third, the expanded list underwent systematic refinement to eliminate terms deemed ambiguous, redundant, or irrelevant; for example, broad and nonspecific terms such as "party" were excluded, while slang terms directly related to substance use, such as "zaza" (referring to high-grade cannabis), were retained for their contextual relevance. This iterative process resulted in a final list of 150 terms, categorized into substance-use areas (refer to Table 1), enabling the identification of 32,674 substance-use-related posts within our dataset. Table 1 represents the finalized coding schema used to identify substance use-related posts from Reddit's r/teenagers subreddit.

To prepare the extracted posts for analysis, we performed comprehensive text preprocessing to normalize the content and reduce noise. The steps included converting all text to lowercase; expanding contractions and replacing abbreviations using a custom dictionary tailored to adolescent slang (eg, "idk" to "I do not know"); removing HTML tags, numbers, punctuation, and special characters; normalizing elongated words and repeated characters (eg, "loooove" to "love"); removing stop words using natural language toolkit's English stop word list supplemented with context-specific terms; and applying lemmatization to reduce words to their base forms. Duplicate posts were removed based on the cleaned text, and posts that were excessively short (fewer than 30 characters) after cleaning were excluded to ensure data quality.

XSL•FO
RenderX

Table 1. Substance-use keyword schema.

Categories	Keywords
Alcohol use	alcohol, beer, wine, liquor, whiskey, vodka, gin, rum, tequila, drunk, intoxicated, booze, hammered, tipsy, binge drinking, wasted, brandy, cocktail
Tobacco and nicotine use	nicotine, vape, vaping, tobacco, cigarettes, cigs, cigars, e-cigarettes, e-cigs, JUUL, dip, smoking, snuff, chewing tobacco, JUULing, hookah, nicotine patches, nicotine gum
Cannabis use	marijuana, weed, pot, THC[a], cannabis, hash, hashish, ganja, skunk, dabbing, joints, blunts, reefer, Mary Jane, stoned, zaza (slang for high-grade cannabis), kush, 420, CBD[b], hemp
Opioids (Prescription)	oxycodone, OxyContin, hydrocodone, Vicodin, Percocet, codeine, morphine, fentanyl, Dilaudid, Tramadol, painkillers, percs (slang for Percocet), Lorcet, Norco
Benzodiazepines	Xanax, Valium, Ativan, diazepam, clonazepam, Klonopin, alprazolam, lorazepam, temazepam, Restoril, midazolam, Dormicum, oxazepam, Serax, chlordiazepoxide, Librium, estazolam, Prosom, nitrazepam, Mogadon, benzos (slang for benzodiazepines), xans (slang for Xanax), flurazepam, Dalmane, triazolam, Halcion
Stimulants (Prescription)	Adderall, Ritalin, Vyvanse, Dexedrine, amphetamines, study drugs, addy (slang for Adderall)
Opioids (Illicit)	heroin, smack (slang for heroin), black tar, china white, fentanyl, chasing the dragon (slang for inhaling vaporized heroin or fentanyl)
Cocaine	cocaine, yayo (slang for cocaine)
Amphetamine-type stimulants	methamphetamine, meth, crystal meth
MDMA[c]	MDMA, ecstasy, Molly, candy flipping (slang for combining MDMA and LSD[d])
Hallucinogens	LSD, shrooms, psilocybin, magic mushrooms, mescaline, DMT[e], peyote, ayahuasca, 2C-B[f], 2C-E[g], 2C-I[h], DOM[i], STP[j], DOB[k], NBOMe[l], 25I-NBOMe[m], 25C-NBOMe[n], 25B-NBOMe[o], Iboga, Salvia, Psilocin, Bufotenin, 5-MeO-DMT[p], Ergot, Ergine, Morning Glory, LSA[q], Fly Agaric, Mescalito
Dissociative drugs	ketamine, Special K, PCP[r], angel dust, DXM[s], dextromethorphan, robo (slang for DXM abuse), nitrous oxide, whippets, methoxetamine, MXE[t], Mexxy, eticyclidine, PCE[u], DXO[v], 2-oxo-PCE, O-PCE[w], ibogaine, muscimol, tiletamine
Synthetic cannabinoids	K2[x], fake weed, synthetic cannabinoids
Novel psychoactive substances	Flakka, research chemicals, RCs[y], designer drugs

[a]THC: tetrahydrocannabinol.
[b]CBD: cannabidiol.
[c]MDMA: methylenedioxymethamphetamine.
[d]LSD: lysergic acid diethylamide.
[e]DMT: dimethyltryptamine.
[f]2C-B: 2,5-dimethoxy-4-bromophenethylamine.
[g]2C-E: 2,5-dimethoxy-4-ethylphenethylamine.
[h]2C-I: 2,5-dimethoxy-4-iodophenethylamine.
[i]DOM: 2,5-dimethoxy-4-methylamphetamine.
[j]STP: serenity, tranquility, and peace.
[k]DOB: 2,5-dimethoxy-4-bromoamphetamine.
[l]NBOMe: N-methoxybenzyl derivatives of the 2C family.
[m]25I-NBOMe: 2C-I-NBOMe (2-(4-Iodo-2,5-dimethoxyphenyl)-N-(2-methoxybenzyl)ethanamine).
[n]25C-NBOMe: 2C-C-NBOMe (2-(4-Chloro-2,5-dimethoxyphenyl)-N-(2-methoxybenzyl)ethanamine).
[o]25B-NBOMe: 2C-B-NBOMe (2-(4-Bromo-2,5-dimethoxyphenyl)-N-(2-methoxybenzyl)ethanamine).
[p]5-MeO-DMT: 5-methoxy-N,N-dimethyltryptamine.
[q]LSA: lysergic acid amide (D-lysergamide)
[r]PCP: phencyclidine
[s]DXM: dextromethorphan
[t]MXE: methoxetamine
[u]PCE: eticyclidine (N-ethyl-1-phenylcyclohexan-1-amine)
[v]DXO: dextrorphan
[w]O-PCE: N-ethyl-1-(2-fluorophenyl)-2-(methylamino)propan-1-one.

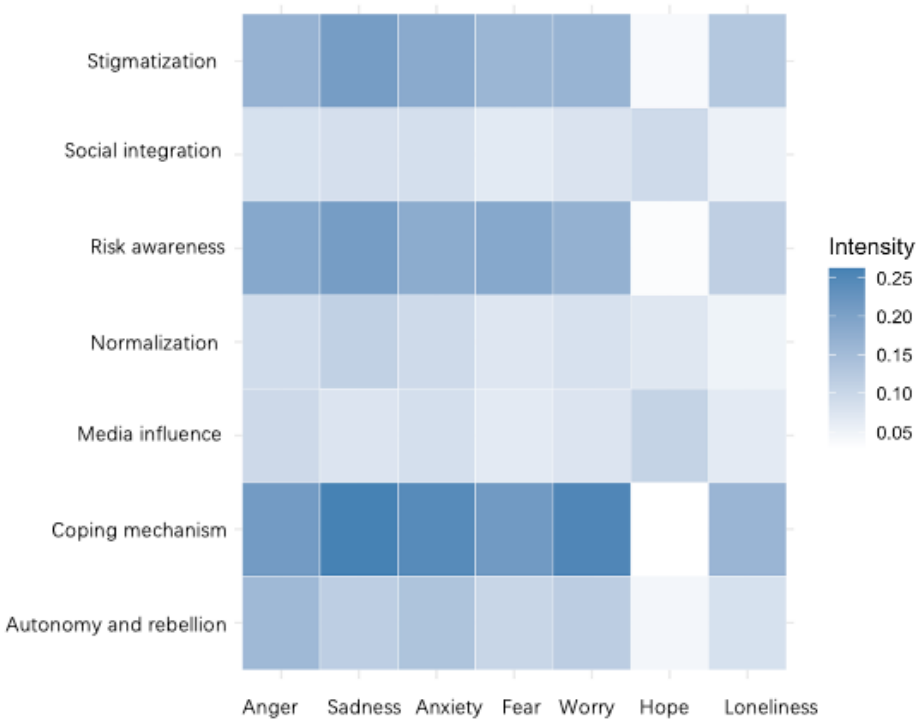
RenderX

[x]K2: synthetic cannabinoids.

[y]RCs: research chemicals.

Data Analysis



The labeling of Reddit posts was conducted through a systematic approach combining machine learning techniques with qualitative analysis. Initially, the BERT (Bidirectional Encoder Representations from Transformers)–based topic modeling algorithm identified topic clusters by capturing semantic relationships and patterns within the text. These clusters were provisionally labeled based on the most representative terms and phrases extracted by the algorithm.

To refine these labels, the author independently reviewed a representative sample of 30 posts from each cluster, conducting inductive coding to identify emergent themes, linguistic nuances, and contextual elements not fully captured by the algorithm. Following this independent analysis, collaborative discussions were held to reconcile differing interpretations, refine thematic categories, and develop operational definitions for each label. This iterative process ensured that the labels accurately represented the content and context of the posts, facilitating robust, contextually grounded labels tailored to the unique characteristics of the Reddit dataset.

Subsequently, the 34 identified topics were organized into 6 distinct frames, and the distribution of posts across these frames was calculated to assess their prevalence within the dataset. In the *Results* section, detailed descriptions and examples of these topics and frames are provided, illustrating their thematic relevance and enhancing the interpretability of the findings.

To analyze the sentiment characteristics of posts, we used the EmoLLaMA-chat-13B model, a state-of-the-art tool within the EmoLLMs series built on Meta's LLaMA2-chat-13B and fine-tuned using the affective analysis instruction dataset. This model notably outperforms previous state-of-the-art models on benchmarks like SemEval-2018, particularly in ordinal emotion intensity classification and emotion intensity regression [42]. In addition, it consistently outperforms advanced alternatives, including GPT-4 and ChatGPT, across various sentiment analysis tasks. It calculates emotion intensity scores for 7 core emotions: anger, sadness, anxiety, fear, worry, hope, and loneliness. These scores quantified the degree to which each emotion was expressed in the posts, allowing nuanced detection of emotional tones. For example, a post with scores of 0.33 for anger and 0.5 for sadness indicated moderate anger and substantial sadness, while other emotions remained minimal. This integrated approach facilitated a robust understanding of the emotional and thematic context of substance use discussions among adolescents. The average emotion scores for each frame were visualized using a heat map, as shown in Figure 1, further illustrating the emotional dynamics underlying these conversations. This heat map visualizes average intensity scores for 7 emotions across 7 substance-use frames identified in Reddit's r/teenagers posts (2018-2022). Color intensity indicates the degree of emotion expression, ranging from 0.05 (lighter blue) to 0.25 (darker blue) based on EmoLLaMA-chat-13B model profiling.

Figure 1. Frame-specific emotion intensity heat map.

RenderX

Ethical Considerations

The procedures conducted in this study adhered to ethical standards and were exempted from institutional review board review, as the research involved publicly available, anonymized data containing no identifiable information [28]. To further safeguard privacy, all posts included in the results were paraphrased to preserve their original meaning while ensuring that they could not be traced back to individual users.

Results

Overview

Table 2 displays the 3 topics identified by BERTopic. The "KeyBERT" column shows the top keywords associated with each topic, while the "Custom label" column was generated by our team through qualitative assessment. This process involved reviewing the top keywords and representative documents for each identified topic. Table 2 lists the 34 topics identified via BERTopic modeling from 32,674 Reddit posts on r/teenagers (2018-2022) related to substance use, along with their corresponding keywords ("KeyBERT") and custom labels derived through qualitative analysis.

In accordance with various frames from other studies and the framing attribute of substance use, our team collaboratively analyzed and interpreted the themes to identify 7 overarching frames related to substance use within the r/teenagers subreddit discussions. These frames were normalization (17014/32674, 38.14%), risk awareness (1379/32,674, 4.22%), social integration (9573/32,674, 29.3%), autonomy and rebellion (1146/32,674, 3.51%), coping mechanism (5762/32,674, 17.64%), digital media influence (1310/32,674, 4.01%), stigmatization (1042/32,674, 3.19%). The identification of these frames highlights the interconnectedness of various factors influencing adolescent substance use, including social, familial, psychological, and cultural influences (refer to Figure 1).

XSL•FO
RenderX

Table 2. BERTopic-generated topics on adolescent substance use.

ID	KeyBERT[a]	Custom label	Percentage (N=32,674), n (%)
0	dad, mom, family	Family dynamics reinforcing substance use	6495 (19.88)
1	friend, girl, like	Peer relationships encouraging substance use	5093 (15.59)
2	personal, event, back	Stress coping through substance use	4099 (12.55)
3	school, teacher, class	Stress from school normalizing substance use	2552 (7.81)
4	juul, vape, vaping	Vaping as part of everyday life	1892 (5.79)
5	social, accept, drug	Substances as tools for peer acceptance	1689 (5.17)
6	birthday, party, friend	Party culture and group bonding	1359 (4.16)
7	feel, crisis, suicide	Mental health struggles and self-medication	1157 (3.54)
8	alcohol, taste, drinking	Teenage drinking as a social routine	1111 (3.40)
9	media, alcohol, rubbing	Social media promoting substance glamor	833 (2.55)
10	age, alcohol, drinking	Challenging legal drinking and vaping ages	753 (2.25)
11	anti-vaping, ads, campaign	Anti-vaping campaigns and social stigma	647 (1.98)
12	chat, drunk, social media	Drunken interactions on social media	618 (1.89)
13	concern, survey, test	Drug testing and its social implications	484 (1.48)
14	christmas, party, nicotine	Celebratory use of nicotine	412 (1.26)
15	iphone, phone, apple	Platforms encouraging substance trends	376 (1.15)
16	drunk, love, tomorrow	Romanticizing drinking in social settings	363 (1.11)
17	friend, social, group	Social situations facilitating substance use	350 (1.07)
18	died, death, driver	Death and accidents from substance use	284 (0.87)
19	covid, pandemic, virus	COVID-19 and awareness of substance risks	268 (0.82)
20	environment, health, pollution	Environmental impacts of substance use	261 (0.80)
21	juul, buy, access	Accessing restricted substances	209 (0.64)
22	sleep, drunk, alcohol	Using alcohol to manage sleep deprivation	196 (0.60)
23	religion, Muslim, god	Religion’s moral judgment of substance use	176 (0.54)
24	soda, nicotine, celebration	Alcohol as a comfort	176 (0.54)
25	poem, music, writing	Personal expression reflecting emotional struggles	134 (0.41)
26	drunk, friend, trend	Online portrayals of substance use	101 (0.31)
27	consent, rape, alcohol	Alcohol, consent, and youthful rebellion	101 (0.31)
28	russia, america, geopolitics	Sociopolitical resistance and substance use	101 (0.31)
29	game, play, video	Social connections through gaming	101 (0.31)
30	injury, surgery, shoulder	Health consequences of substance use	82 (0.25)
31	adderall, medication, price	The role of medication in adolescence	82 (0.25)
32	irish, culture, nationality	Cultural identity and substance perception	75 (0.23)
33	gay, trap, chromosome	LGBTQ+[b] substance use and social stigma	62 (0.19)

[a]BERT: Bidirectional Encoder Representations from Transformers.

[b]LGBTQ+: lesbian, gay, bisexual, trans, and queer.

Frame 1: Normalization

The normalization frame, accounting for 38.14% (12462/32674) of the discussions, reveals a substantial perception among adolescents that substance use is an accepted and routine part of daily life. This frame intertwines several topics: family dynamics reinforcing substance use (6495/32,674, 19.88%), stress from school normalizing substance use (2552/32,674, 7.81%), vaping as part of everyday life (1892/32,674, 5.79%), teenage drinking as a social routine (1111/32,674, 3.40%), and celebratory use of nicotine (412/32,674, 1.26%). Collectively, these topics illustrate how various facets of adolescents’ environments contribute to the normalization of substance use.

XSL•FO
RenderX

Family behaviors and attitudes play a significant role, with substance use often perceived as a familial norm. Academic pressures lead to shared coping mechanisms like vaping and drinking, embedding these behaviors into daily routines. Social interactions further reinforce this normalization, as substance use becomes an expected component of communal activities and celebrations.

These shared understandings coalesce into collective action frames by fostering a collective identity where substance use is not only normalized but also encouraged. Adolescents internalize these behaviors as standard, leading to widespread participation and reinforcement within their social groups. One adolescent reflected, “In my family, everyone unwinds with a drink; so when I started drinking with friends, it just felt natural.” Another shared, “Vaping between classes is how we deal with stress—it’s just what we all do to get through the day.” Such narratives demonstrate how substance use is reinforced through family acceptance, peer practices, and shared coping strategies, solidifying its place in adolescent culture.

Emotional analysis within the normalization frame reveals moderate levels of sadness (0.092) and anxiety (0.112), indicating underlying emotional distress despite the outward acceptance of substance use. The topic “Stress from School Normalizing Substance Use” exhibits higher levels of sadness (0.14) and anxiety (0.18), suggesting that academic pressures significantly contribute to emotional turmoil and the adoption of substance use as a coping mechanism. Lower levels of positive emotions such as joy (0.072) imply that normalization does not necessarily enhance overall well-being. This suggests that while substance use is normalized, it may also be a response to deeper emotional challenges, further perpetuating its role in adolescents’ lives.

Frame 2: Risk Awareness

The risk awareness frame accounts for 4.22% (1379/32,674) of the discussions, indicating a growing consciousness among adolescents about the negative consequences of substance use. This frame interconnects topics such as “Drug Testing and Its Social Implications” (484/32,674, 1.48%), “Death and Accidents from Substance Use” (284/32,674, 0.87%), “Environmental Impacts of Substance Use” (261/32,674, 0.80%), “COVID-19 and Awareness of Substance Risks” (268/32,674, 0.82%), and “Health Consequences of Substance Use” (82/32,674, 0.25%). Collectively, these discussions reflect an increased awareness of health risks, legal implications, and broader societal impacts associated with substance use.

The association among these topics illustrates how adolescents are developing a comprehensive understanding of the multifaceted risks involved. They express concerns not only about personal health but also about legal repercussions and the broader impact on their communities and the environment. This shared awareness leads to a collective reassessment of substance use, as adolescents weigh the perceived benefits against potential negative outcomes. One teenager remarked, “After my school started random drug testing, I realized how serious the consequences could be—not just for me but for my family too.” Another shared, “When I heard about someone from our town dying in a drunk driving accident, it hit me hard. It made me think about how my actions could affect others.”

These shared understandings coalesce into a collective action frame centered on caution and responsibility. Adolescents are not only reevaluating their own behaviors but are also contributing to a broader dialogue about the risks associated with substance use. The heightened emotional responses—elevated levels of sadness (0.188), anxiety (0.208), fear (0.188), and worry (0.181)—underscore the depth of their concern. As one individual noted, “With COVID-19 affecting people’s lungs, continuing to vape just doesn't seem worth it anymore.” Another stated, “I’m starting to see how smoking and littering impact the environment—we have to think about the bigger picture.” These narratives demonstrate a collective shift towards greater risk awareness and a desire to make more informed, responsible choices.

Frame 3: Social Integration

Representing 29.30% (9573/32,674) of the discussions, the social integration frame underscores how adolescents use substance use to navigate social dynamics and achieve peer acceptance. This frame interweaves topics such as “Peer Relationships Encouraging Substance Use” (5093/32,674, 15.59%), “Substances as Tools for Peer Acceptance” (1689/32,674, 5.17%), “Party Culture and Group Bonding” (1359/32,674, 4.16%), “Social Situations Facilitating Substance Use” (618/32,674, 1.07%), “Drunken Interactions on Social Media” (363/32,674, 1.89%), “Romanticizing Drinking in Social Settings” (350/32,674, 1.11%), and “Social Connections Through Gaming” (101/32,674, 0.31%). Collectively, these topics illustrate the role of substance use as a means for group bonding and social interaction, revealing the complexities of adolescent social behavior.

The interconnections among these topics highlight a collective understanding among teenagers that substance use is integral to social belonging and acceptance. Adolescents often feel pressured to engage in substance use to align with peer norms and avoid isolation. One teenager shared, “If you’re not drinking at the party, it’s like you’re not really there. Joining in just makes you part of the group.” This sentiment reflects the drive to conform and the importance of participating in shared behaviors to maintain social bonds. Another adolescent noted, “Vaping with my friends between classes is just what we do; it’s our way of hanging out and decompressing together.” These narratives demonstrate how substance use becomes embedded in social rituals, reinforcing group cohesion and collective identity.

Moreover, the romanticization of drinking in social settings and the portrayal of “drunken interactions on social media” amplify this phenomenon, solidifying substance use’s role in adolescent culture. An individual observed, “Some of our best memories are made when we’re all a bit tipsy, laughing and just enjoying each other’s company.” Social media platforms often showcase these moments, further reinforcing the behavior. Despite this perceived enhancement of social connections, the emotional analysis reveals elevated levels of sadness (0.083), anxiety (0.085), and loneliness (0.054), suggesting that reliance on substances for social integration may not fully alleviate

XSL•FO
RenderX

underlying emotional distress. This collective action frame reflects a complex interplay between the desire for social connection and the potential emotional costs associated with substance use, highlighting the need for a deeper understanding of adolescent social dynamics.

Frame 4: Autonomy and Rebellion

Comprising 3.51% (1146/32,674) of the discussions, the autonomy and rebellion frame highlights how adolescents use substance consumption as a means of asserting independence and resisting authority. This frame intertwines topics such as "Challenging Legal Drinking and Vaping Ages" (735/32,674, 2.25%), "Accessing Restricted Substances" (209/32,674, 0.64%), "Sociopolitical Resistance and Substance Use" (101/32,674, 0.31%), and "Alcohol, Consent, and Youthful Rebellion" (101/32,674, 0.31%). Collectively, these topics reveal a shared desire among teenagers to assert control over their own decisions and to challenge societal restrictions, illustrating how substance use becomes a symbolic act of personal freedom and defiance.

The interconnections among these topics demonstrate a collective action frame where adolescents perceive substance use as a way to test boundaries and resist external control. One teenager asserted, "Why should the law tell me when I'm old enough to make my own choices? If I'm responsible enough to work and pay taxes, I should be able to decide if I want to drink." This sentiment reflects a common challenge to age-based regulations, emphasizing a desire for self-determination. Another shared, "They keep making it harder to get vapes, but that just makes us more creative. It's about proving that we won't be controlled." Such narratives underscore how obtaining and using restricted substances becomes a form of rebellion against perceived overreach by authorities.

Moreover, some adolescents connect their personal defiance to broader sociopolitical contexts. An individual remarked, "Using substances is our way of pushing back against a system that doesn't listen to us. It's not just about drinking or vaping; it's about showing that we have a voice." This perspective highlights how substance use can be intertwined with a larger critique of societal structures, reinforcing group identity through shared acts of resistance. Emotionally, this frame exhibits elevated levels of anger (0.156), sadness (0.114), and anxiety (0.136), reflecting the frustration and tension associated with challenging authority. Despite relatively low levels of hope (0.045) and loneliness (0.083), adolescents in this frame find solidarity in their collective pursuit of autonomy, united in their challenge to societal norms and expectations.

Frame 5: Coping Mechanism

Accounting for 17.64% (5762/32,674) of the discussions, the coping mechanism frame illustrates how adolescents use substances to manage emotional stress and personal challenges. This frame integrates topics such as "Stress Coping Through Substance Use" (4099/32,674, 12.55%), "Mental Health Struggles and Self-Medication" (1157/32,674, 3.54%), "Using Alcohol to Manage Sleep Deprivation" (196/32,674, 0.60%), "Alcohol as a Comfort" (176/32,674, 0.54%), and "Personal Expression Reflecting Emotional Struggles" (134/32,674, 0.41%). Collectively, these topics reflect the significant role that emotional distress plays in adolescents' decisions to engage in substance use, highlighting how substances become a means of coping with various stressors in their lives.

The interconnection among these topics underscores a shared understanding that substance use serves as a mechanism for self-medication and emotional regulation. Adolescents facing stress, mental health challenges, sleep deprivation, or emotional struggles turn to substances as temporary relief, seeking to alleviate negative emotions and escape from their problems. This collective behavior demonstrates how substance use becomes an ingrained coping strategy within this demographic, forming a collective action frame centered on managing personal hardships through substance use.

Teenagers' narratives vividly capture this phenomenon, illustrating how their shared experiences coalesce into this collective frame. One adolescent admitted, "When school gets overwhelming, vaping is the only thing that helps me relax." Another shared, "I can't sleep at night, so sometimes I drink a little to help me drift off." These statements reveal how substance use is perceived not merely as recreational but as a necessary tool for managing emotional and physical distress. Further emphasizing this point, an adolescent explained, "Dealing with anxiety is tough, and smoking weed is the only way I can feel normal." Another added, "Writing songs while I'm high helps me express feelings I can't put into words otherwise." These authentic accounts highlight the reliance on substances to navigate their emotional landscapes and the collective interpretation of substance use as essential for coping.

Emotionally, this frame exhibits elevated levels of sadness (0.212), anxiety (0.262), and anger (0.244), indicating significant emotional distress among adolescents using substances to cope. Notably, the topic "Mental Health Struggles and Self-Medication" shows particularly high levels of sadness (0.23), anxiety (0.28), and loneliness (0.18), reflecting severe emotional turmoil. One post expressed, "My depression gets so bad that drinking is the only thing that numbs the pain, even if just for a little while." Another shared, "I know relying on substances isn't healthy, but it's the only way I can get through the day." The elevated levels of fear (0.215) and worry (0.253) further underscore the depth of their struggles. The relatively low level of hope (0.029) suggests a lack of optimism about their situations, reinforcing the reliance on substances for temporary relief. These shared sentiments illustrate how adolescents, through collective experiences and interpretations, normalize substance use as a coping mechanism for emotional distress. This collective action frame emphasizes the urgent need for supportive interventions, as teenagers mobilize around shared understandings to navigate their challenges.

Frame 6: Media Influence

Accounting for 4.01% (1310/32,674) of the discussions, the media influence frame examines how social media and digital platforms shape adolescents' perceptions of substance use through media socialization. This frame integrates topics such as "Social Media Promoting Substance Glamor" (833/32,674, 2.55%), "Platforms Encouraging Substance Trends" (376/32,674, 1.15%), and "Online Portrayals of Substance Use"

(101/32,674, 0.31%). Collectively, these topics highlight the significant role of media in normalizing and glamorizing substance use among adolescents, thereby influencing their attitudes and behaviors.

The interconnections among these topics demonstrate the mechanisms by which media-driven norms operate. Adolescents are frequently exposed to portrayals of substance use as desirable and socially advantageous, fostering a perception of these behaviors as normative. This collective exposure leads to shared cognitive schemas and social comparisons that reinforce these impressions. The prevalence of substance-related content on social media platforms encourages adolescents to perceive substance use as an integral part of social identity and acceptance.

Teenagers' narratives vividly capture this phenomenon, illustrating how their shared experiences coalesce into this collective frame. One adolescent remarked, "Scrolling through Instagram, it seems like everyone's partying and having a great time with drinks in hand. It makes you feel like you're missing out if you're not doing the same." Another shared, "All the popular kids are posting videos with vapes and flashy setups. It's like you have to join in to be part of the trend." These authentic accounts highlight the influence of media representations in shaping adolescents' behaviors, as they adopt substance use to conform to perceived social expectations promoted by online support groups.

Emotionally, this frame is associated with elevated levels of sadness (0.096) and anxiety (0.086), suggesting that media portrayals contribute to negative effects among adolescents. The relatively high level of hope (0.108) indicates a complex emotional response, where optimism is intertwined with negative emotions. One user confessed, "I thought posting pics of me at parties would make me feel more connected, but I still feel alone when the likes stop coming in." Another reflected, "Seeing everyone else having fun online support group makes me wonder if they're really happy or just putting on a show like I am." These shared sentiments underscore how media influence fosters a collective understanding that substance use is necessary for social inclusion, while also highlighting the emotional complexities involved. Through these shared experiences, adolescents collectively reinforce the media influence frame, which shapes their perceptions and actions regarding substance use.

Frame 7: Stigmatization

The stigmatization frame, accounting for 3.19% (1042/32,674) of the discussions, centers on the moral and social judgments surrounding adolescent substance use, particularly within familial, religious, and cultural contexts. This frame includes topics such as "Anti-vaping Campaigns and Social Stigma" (647/32,674, 1.98%), "Religion's Moral Judgment of Substance Use" (176/32,674, 0.54%), "LGBTQ+ Substance Use and Social Stigma" (62/32,674, 0.19%), "Cultural Identity and Substance Perception" (75/32,674, 0.23%), and "The Role of Medication in Adolescence" (82/32,674, 0.25%). These discussions collectively highlight how adolescents face criticism and moral condemnation from societal norms and authority figures, shaping their behavior and self-perception.

The interconnectedness of these topics underscores the pervasive experience of moral judgment, leading to the stigmatization that fosters guilt, shame, or defiance among adolescents. Antivaping campaigns often reinforce social ostracization, as reflected in the sentiment of one adolescent: "I feel like everyone looks down on me just because I vape—like I'm some kind of delinquent." Such societal disapproval adversely impacts adolescents' self-image, reinforcing isolation. Religious and cultural expectations further intensify this stigmatization, as illustrated by another adolescent's experience: "In my community, drinking is considered a sin, but it's hard when all my friends do it. I constantly feel torn between my beliefs and wanting to fit in." These statements underscore the internal conflicts adolescents endure while negotiating personal desires and cultural values.

The stigmatization faced by lesbian, gay, bisexual, trans, and queer (LGBTQ+) adolescents is particularly acute, as they often experience dual layers of judgment concerning both their identity and substance use. One individual conveyed, "It's hard enough being judged for who I am, but when they find out I smoke to cope, the judgment just doubles." This compounded stigma exacerbates their sense of alienation. Similarly, the topic "The Role of Medication in Adolescence" reflects the stigmatization of prescribed medication use, even when these substances are essential for managing mental health. As one adolescent stated, "People think I'm weak because I take meds for my anxiety, but they don't understand how much it helps." These narratives demonstrate that stigmatization extends beyond illicit substances, affecting adolescents' willingness to seek help and manage their health needs effectively.

The emotional dynamics of the stigmatization frame are marked by high levels of sadness (0.168), anxiety (0.183), and anger (0.161), indicating significant emotional distress due to societal and familial judgment. The topic "Religion's Moral Judgment of Substance Use" exhibits particularly high levels of anger (0.256) and loneliness (0.145), suggesting that moral condemnation tied to religious beliefs exacerbates feelings of isolation and resentment. Moreover, the low levels of hope (0.039) within this frame indicate adolescents' difficulty in finding optimism amid pervasive stigmatizations. One adolescent reflected, "Sometimes it feels like no matter what I do, I'll never meet their expectations." These narratives illustrate a collective experience of stigmatization that impedes well-being, reinforcing a shared perception of being marginalized and judged.

Discussion

Principal Findings

The findings of this study provide insights into interpretive frames adolescents use to construct and negotiate their perspectives on substance use, revealing intricate connections to broader sociocultural, emotional, and developmental contexts. At a conceptual level, the research underscores how adolescents engage with substances used as a mechanism to address sociocultural and identity-related challenges, situating these behaviors within collective-action frames that reflect both individual agencies and shared cultural dynamics. This framing

XSL•FO
RenderX

highlights substance use not as an isolated behavior but as a socially embedded phenomenon with deep implications for adolescent development.

One key contribution is the identification of the normalization frame, which captures how substance use becomes embedded in adolescents' everyday lives through familial, social, and institutional influences. Unlike previous studies that narrowly focused on peer influence or environmental factors, this research situates normalization within a wider cultural framework. It demonstrates how academic stress, parental modeling, and peer interactions collectively foster a shared perception that substances are used as routine. Such findings broaden the scope of existing literature by emphasizing the systemic reinforcement of these behaviors across multiple social domains.

The emergence of the risk awareness frame provides a compelling counter-narrative to normalization, illuminating adolescents' critical reflections on substance-related risks despite their concurrent acceptance of such behaviors. This duality complicates simplistic dichotomies that frame adolescents as either deviant or compliant. Consistent with previous studies [43], this study shows heightened risk awareness, particularly in the wake of the pandemic, which intensified adolescents' health consciousness and self-reflective capacities. The findings also resonate with Marinelli et al [44], who documented how the pandemic prompted adolescents to re-evaluate habitual behaviors, fostering a unique environment for behavioral reassessment.

The social integration frame further underscores the role of substance use in mediating adolescent social dynamics, positioning substances as tools for navigating group identity and peer acceptance. However, this narrative is complicated by findings that reveal underlying emotional vulnerabilities, such as sadness and anxiety; these findings suggest that while substance use may facilitate social connection, it also masks significant emotional distress. This creates a paradoxical feedback loop in which substance use both addresses and exacerbates emotional challenges, underscoring the need for interventions that address these deeper vulnerabilities.

Adding another layer to this analysis, the autonomy and rebellion frame portrays substance use as a symbolic act of resistance against societal and institutional constraints. This dimension situates adolescent substance use within a broader context of sociopolitical critique, where behaviors function as both a developmental milestone of individuation and a performative challenge to authority. These findings align with theoretical perspectives on youth subcultures, which emphasize resistance as a core characteristic while raising critical questions about the efficacy of punitive or prohibitive approaches to regulating adolescent behaviors.

The coping mechanism frame provides perhaps the most poignant insights, revealing that emotional distress (manifested in elevated levels of sadness, anxiety, and anger) is a pervasive driver of substance use among adolescents. This frame underscores the urgent need for mental health interventions that address the root causes of emotional distress rather than merely its behavioral manifestations. By situating these coping behaviors within a collective framework, the study highlights how adolescents share and normalize their struggles, entrenching substance use as a widely accepted strategy for emotional regulation. The lack of hope observed in this frame reflects systemic failures to provide adolescents with viable alternatives for managing psychological challenges, further reinforcing the importance of holistic and proactive support systems.

The media influence frame introduces a contemporary perspective, illustrating how social media amplifies cultural narratives around substance use by portraying it as glamorous or socially advantageous. While such portrayals exert considerable influence, the study also reveals adolescents' growing skepticism and critique of these representations, reflecting an awareness of their constructed nature. This dual engagement suggests potential avenues for media literacy programs aimed at deconstructing harmful narratives and promoting more critical consumption of digital content.

Lastly, the stigmatization frame explores how moral and cultural judgments surrounding substance use profoundly affect adolescents' experiences, contributing to heightened feelings of sadness, anxiety, and anger. This frame is particularly salient for marginalized groups, such as LGBTQ+ adolescents, who face compounded stigmatization based on both identity and behavior. The findings align with critiques of stigma-based deterrents, advocating instead for inclusive approaches that address systemic inequalities and provide supportive alternatives to punitive or judgmental responses. Therefore, the focus needs to be shifted away from blame and judgment and towards inclusive approaches that address inequality and offer alternative supportive environments, as has also been discussed in light of the pandemic by Marinelli et al [44].

Moreover, the findings of this study are particularly pertinent in light of the ever-evolving landscape of new psychoactive substances (NPSs), which pose a significant and novel challenge to public health and adolescent mental health in particular. While our research focuses on how teenagers frame and interpret substance use in online support discussions, it is critical to acknowledge the broader context in which this occurs. As Rinaldi et al [45] emphasize, the complexities of these NPSs (their diverse chemical structures and their ability to evade traditional drug enforcement) create novel risks. These substances are not just a theoretical concern; they can be found on illicit markets and, increasingly, online support groups, shaping the very discourse we analyzed on Reddit. Moreover, consistent with Meherali et al [46], the isolation and social disruption brought about by the COVID-19 pandemic, which potentially exacerbated online support interactions, have created new opportunities for illicit drug markets, as noted by Marinelli et al [44] and Negro et al [47]. This highlights the importance of online support group spaces, where adolescents are engaging in substance use discussions, as potential avenues for both risk and intervention. This understanding calls for a need to not only analyze the frames used to discuss substance use but also to address the underlying context of rapidly evolving substance markets and information streams that influence these narratives.

Theoretically, this study integrates these diverse frames into a cohesive framework, challenging reductionist models that view substance use as purely pathological or recreational. It highlights

XSL•FO
RenderX

the interplay between individual agency and collective dynamics, offering a more comprehensive perspective on the social, emotional, and cultural dimensions of substance use. Practically, the findings advocate for targeted interventions tailored to the specific interpretive frames adolescents employ. For instance, strategies addressing normalization might focus on disrupting familial and peer modeling behaviors, while those targeting coping mechanisms should prioritize mental health resources and resilience-building initiatives.

By contextualizing substance use within broader sociocultural and emotional frameworks, this research deepens our theoretical understanding of adolescent behavior while offering actionable insights for fostering healthier environments. It calls for a shift in both policy and practice, emphasizing the importance of addressing systemic factors and respecting adolescents' lived experiences to promote meaningful and sustainable change.

Limitations and Futural Studies

While our study provides valuable insights into adolescent discourse on substance use, it is limited by the exclusive use of data from Reddit's r/teenagers subreddit, an English-speaking online support forum. This introduces inherent biases, restricting the generalizability of our findings to the global adolescent population, as the perspectives captured predominantly reflect Reddit's specific user demographic rather than a comprehensive view of teenage behaviors and attitudes worldwide. Moreover, our analysis does not fully contextualize substance use within the dynamics of the COVID-19 pandemic and the emergence of NPSs. Although we included keywords related to NPSs to capture emerging substances, we did not address the complex trafficking dynamics, pandemic-related changes, or broader mental health implications, which limits the depth of our findings concerning current societal influences on adolescent substance use.

Future research should address these limitations by incorporating more diverse data sources to enhance generalizability and by situating substance use within the context of the COVID-19 pandemic and NPS proliferation. Investigating discrepancies between online support discussions and offline attitudes can illuminate the influence of digital environments on real-world behaviors. In addition, examining the impact of significant societal events, such as public health crises and changes in drug legislation, on online support discourse could provide insights into the adaptability of adolescent attitudes and behaviors. By expanding the scope to include diverse data sources and contextual factors, future studies can deepen our understanding of adolescent substance use and inform more effective interventions. Such research would enhance the relevance and applicability of findings, ultimately contributing to solutions for the complex issues surrounding adolescent substance use.

Conclusion

This study reveals that adolescents' discussions about substance use on social media are predominantly framed around normalization, social integration, coping mechanisms, risk awareness, autonomy and rebellion, media influence, and stigmatization. The normalization and social integration frames indicate that substance use is perceived as a routine part of adolescent life, reinforced by family dynamics, peer relationships, and social media portrayals. Coping mechanisms highlight the use of substances to manage emotional distress, reflecting significant mental health challenges among youth. Although there is growing risk awareness, this consciousness does not consistently lead to behavioral change. The autonomy and rebellion frame illustrates substance use as a means for adolescents to assert independence and resist authority, while the stigmatization frame emphasizes the moral and social judgments contributing to feelings of isolation.

These findings underscore the multifaceted nature of adolescent substance use discussions and the necessity of addressing underlying emotional, social, and identity-related factors. Interventions should consider these frames to develop strategies that resonate with adolescents' experiences and perceptions. By fostering supportive environments and promoting open dialogues about mental health and identity, health communication efforts can more effectively mitigate substance use among adolescents.

Abstract

Background: During the COVID-19 pandemic, US Latino individuals were more likely to report accessing coronavirus information on social media than other groups, despite copious amounts of health misinformation documented on these platforms. Among the existing literature on factors associated with engagement and use of health information, racial minority status has been associated with greater susceptibility to health misinformation. However, literature to date has not reported national trends on how Latino individuals engage with or use health information on social media compared to non-Latino White (NLW) individuals, nor whether perceptions of the amount of health misinformation on social media influence health information engagement and usage.

Objective: This study aimed to examine differences in engagement with and use of health information on social media among Latino and NLW individuals in the United States.

Methods: We examined a nationally representative cross-sectional sample of Latino (n=827) and NLW (n=2563) respondents of the 2022 Health Information National Trends Survey who used social media in 2022 to assess differences in engagement with and use of health information. Items related to the perceived quantity of health misinformation on social media, social media use frequency, health information engagement (sharing content; watching videos), and health information usage (health decision-making; discussions with health care providers) were selected to conduct weighted bivariate analyses and logistic regressions.

Results: Latino individuals perceive lower amounts of health misinformation on social media (28.9% perceived little to no misinformation vs 13.6% NLW individuals, $P<.001$). Latino audiences also reported higher health information engagement compared to NLW individuals (20% vs 10.2% shared information several times a month or more, $P<.001$; 42.4% vs 27.2% watched videos several times a month or more, $P<.001$), as well as higher information usage for health decision-making (22.8% vs 13.7%, $P=.003$). When controlling for ethnicity and other sociodemographic variables, perceiving lower amounts of health misinformation on social media was associated with higher odds of watching videos more frequently, making health decisions, and discussing health-related content with a health care provider ($P<.001$). Furthermore, Latino audiences were 1.85 times more likely to watch videos ($P<.001$), when controlling for the perceived amount of health misinformation and other sociodemographic variables. Finally, when compared to NLW individuals perceiving little to no health misinformation, Latino audiences perceiving little to no health misinformation were 2.91 times more likely to watch videos ($P<.001$).

Conclusions: The findings suggest that Latino individuals engage with visual health (mis)information at higher rates. Digital health literacy interventions should consider video formats and preferred social media platforms among Latino individuals. Further research is warranted to understand sociocultural factors important to Latino social media users when consuming health information, as these may impact the success of digital media literacy interventions that teach users how to navigate misinformation online.

Introduction

Background

Social media's ubiquitous presence in daily life has allowed for the democratization of health information and for individuals and communities to view, engage with, and share a variety of content with people in their networks. However, it has also contributed to the rise of health misinformation [1-4], which tends to evoke an emotional response and a reaction from its readers [5-7]. This drive to act can propel social media users to share viewed content with others without necessarily validating its credibility and integrate it into their own behaviors, including health-seeking behaviors. This can have a significant impact on their overall health outcomes [8], particularly in light of misinformation shared unintentionally to voice people's concerns, find answers to their questions, and understand those answers in the context of their own life experiences [9]. Understanding the ramifications of misinformation in health outcomes, thus, requires an interdisciplinary approach that intersects the fields of health communication, communication and technology, and public health education.

Social Media Usage and Health Information Consumption Among US Latino Individuals

Individuals identifying as Hispanic, Latino, Latina, or Latinx (henceforth Latino) are the largest and fastest growing minority group in the United States [10] and are also avid social media users [11]. In 2021, the Pew Research Center reported general social media usage rates among Latino adults in the United States, where 85% used YouTube, 72% used Facebook, 52% used Instagram, and 46% used WhatsApp [11]. YouTube (Google) has also been reported to be a top source for news content among Latino adults, particularly among those seeking content in Spanish: 48% of Latino households that predominantly speak Spanish rely on YouTube for news content compared to 36% among those that speak English [12]. Latino individuals also report a greater reliance on social media and messaging platforms than other groups, viewing platforms like WhatsApp, Instagram, and Facebook (Meta) as trustworthy tools to connect with families and friends in the United States and internationally [13]. This reliance on social media contributes to Latino individuals being at a higher risk for health misinformation exposure, as has been seen with topics like COVID-19, guns, and reproductive health matters including abortion [14]. For example, the National Association of Latino Elected and Appointed Officials' 2022 National Latino Voter tracking poll reported that 76% of Latino survey respondents were exposed to news that abortion is now illegal in the United States and that individuals can be imprisoned for seeking abortion services [15]. Furthermore, Latino individuals may engage with content in English, Spanish, or a combination of both [13], adding another challenging layer in efforts to understand how these audiences engage with and use health information found on these platforms. Previous literature has highlighted inequities in Spanish-speaking Latino individuals' ability to access and understand cancer information compared to English-speaking counterparts [16], yet studies exploring Spanish health content on social media are limited. This is particularly concerning given reports that platforms like Facebook have failed to flag misinformation in Spanish more so than misinformation in English, with one 2020 study reporting that an estimated 70% of Spanish-language misinformation on Facebook lacked warning labels [17].

Early during the COVID-19 pandemic, Latino individuals were reported to use social media to access COVID-19 information at higher rates than other groups in the United States [18]. However, given that social media platforms also contain user-generated content that is oftentimes not evidence-based, there is an increased likelihood for users to engage with and use health misinformation. For example, qualitative research exploring the Latino individuals' engagement with cancer information on Facebook pre-COVID found that participants mainly engaged with content from potentially unreliable sources predominantly shared by Facebook friends [19]. Some participants also reported using encountered cancer information to discuss with friends and family and to implement new or reinforce current health behaviors, despite this content not always being evidence-based or reliable [19]. Despite these findings, the literature to date has not reported national trends in how Latino individuals engage with health information on social media compared to non-Latino White (NLW) individuals, nor whether the information they have engaged with has triggered offline actions that can influence health outcomes. As such, our first research question (RQ) asks "Does engagement with and usage of health information encountered on social media differ between Latino and NLW social media users?"

Factors Associated With Health (Mis)Information Susceptibility and Their Role in Engagement and Usage

In an effort to better understand why some individuals may be more susceptible to health misinformation on social media, Nan and colleagues [20] conducted a systematic review of 61 studies to explore the psychological, demographic, and behavioral predictors of susceptibility. After presenting an integrative psychological model of susceptibility to health misinformation, authors found that psychological predictors included directionally motivated reasoning or actions driven by one's emotions; placing greater trust in information shared by family, friends, politicians, or journalists; conservative or political ideology; and religiosity. Greater social media use was generally observed to increase one's susceptibility to health misinformation, while demographic factors like age, education, sex at birth, and income showed mixed correlations to increased susceptibility to misinformation. The review also noted studies that suggest Latino individuals tend to be more susceptible

XSL•FO
RenderX

[21-23], although none of these explicitly focused on this ethnic group.

One area that has received less attention relates to whether an individual's perceptions of the amount of health misinformation that exists on social media has an impact on subsequent engagement and usage of that information. Chou et al [4] briefly bring attention to this issue in their 2020 commentary, "Where We Go From Here: Health Misinformation on Social Media," which calls for research identifying the characteristics that make certain populations more vulnerable to the impacts of health misinformation. More recently, Goldsmith et al [24] conducted a systematic review exploring the use of social media as a source of COVID-19 information among migrant and ethnic minority populations, which found that some populations may rely on health misinformation to shape their understanding and inform their actions. The authors specifically referenced a study by Cervantes et al [25] that had a sample of 60 US Latino adults who were hospitalized for COVID-19. Many individuals in the study discussed using social media for COVID-19 recommendations, despite some acknowledging that COVID-19 misinformation was circulating at the time [25]. Similarly, Rivera et al [26] reported cases of Latino interviewees not verifying cancer-related information from Facebook because "someone must have" previously done so. Combined, these qualitative findings raise the question of whether differences in the Latino individuals' perceptions about the amount of health misinformation on social media may impact engagement with and use of that content. It also begs the question of whether any such differences in perception impact engagement and usage outcomes differently than for NLW individuals. Therefore, we also ask the following:

RQ2. Do perceptions of the amount of health misinformation on social media differ between Latino and NLW social media users?

RQ3. Are perceptions of the amount of health misinformation on social media associated with engagement with and use of health information on social media upon controlling for social media usage and other sociodemographic variables?

RQ4. Does engagement with and use of encountered health information differ between Latino and NLW social media users who perceive the same amount of health misinformation on social media, upon controlling for social media usage and other sociodemographic variables?

Methods

Overview

This paper analyzes data from the 2022 Health Information National Trends Survey (referred to as HINTS 6). HINTS is a national cross-sectional survey conducted annually by the National Cancer Institute to assess access and use of health information by the general adult public in the United States. HINTS 6 covers topics related to looking for health information; finding information online; health care access and infrastructures; general health prevention; cancer screening and awareness; cancer beliefs; and cancer history [27]. HINTS 6 was conducted via a self-administered web or paper survey from March to November 2022. An equal-probability sample of addresses provided by Marketing Systems Group was selected from within four sampling strata (urban and rural areas with high vs low concentrations of minority adults) [28]. A total of 6252 individuals participated in the survey (response rate=28.1%). Full sample selection details are available in the HINTS 6 Methodology Report [28]. In order to explore engagement with and use of health information encountered on social media among individuals identified as Latino or Hispanic compared to NLW individuals, the analyses in this paper focus on participants who identified their race/ethnicity in the survey and reported using social media (n=3390). Acknowledging the heterogeneity that exists in Latino communities in the United States, it is important to delineate that HINTS 6 defines Latino or Hispanic participants as anyone who answers "yes" to the question, "Are you of Hispanic, Latino/a, or Spanish origin?" This includes anyone living in the United States who identifies as being part of any Latino subethnicity, regardless of racial background.

Measures

Dependent Variables

Engagement With Health-Related Information

Two items were selected to measure engagement with health-related information on social media: frequency of sharing general health–related information on social media and frequency of watching health-related videos on a social media site. These outcomes were assessed by survey items asking participants: "In the past 12 months, how often did you share general health-related information on social media (eg, a news article)?" and "In the past 12 months, how often did you watch a health-related video on a social media site (eg, YouTube)?" Response options for both items included 1=almost every day, 2=at least once a week, 3=a few times a month, 4=less than once a month, and 5=never. Exploratory data analyses reported skewed findings (mean scores for sharing information 4.48, SD 0.82, and mean scores for watching videos 3.93, SD 1.05). Therefore, final binary outcome variables were created by recoding each response option as 0=never to less than once a month and 1=a few times a month or more.

Use of Health-Related Information

Two items were selected to measure the use of encountered health-related information on social media: using information encountered on social media to make health decisions and discussing information encountered on social media with a health care provider. These outcomes were assessed by survey items asking participants how much they agreed or disagreed with the following statements: "I use information from social media to make decisions about my health" and "I use information from social media in discussions with my health care provider." Response options for both items included 1=strongly agree, 2=somewhat agree, 3=somewhat disagree, and 4=strongly disagree. Exploratory data analyses reported skewed findings (mean scores for making decisions 3.49, SD 0.76, and mean scores for discussing with health providers 3.38, SD 0.84). Therefore, final binary outcome variables were created by recoding each response option as 0=disagree and 1=agree.

XSL•FO
RenderX

Independent Variable: Perception of the Quantity of Misinformation on Social Media

The main factor associated with engagement with and usage of social media health information was the perception of the amount of health misinformation on social media. To explore differences in perception between Latino and NLW individuals, we first identified all participants who responded to the question "How much of the health information that you see on social do you think is false or misleading?". Response options included 1=a lot, 2=some, 3=a little, 4=none, and 5=I don't use social media; any participant who stated they did not use social media was dropped from the analysis. The remaining responses were recoded as 0=a little or none, 1=some, and 2=a lot.

To further assess whether differences in perceptions of the amount of health misinformation on social media between Latino participants and NLW participants were associated with engagement with and usage of social media health information, responses were divided by ethnicity (Latino vs NLW individuals). To do so, a final variable was created with the following six groups: 0=NLW individuals perceiving little to no health misinformation on social media, 1=NLW individuals perceiving some health misinformation on social media, 2=NLW individuals perceiving a lot of misinformation on social media, 3=Latino individuals perceiving little to no health misinformation on social media, 4=Latino individuals perceiving some health misinformation on social media, and 5=Latino individuals perceiving a lot of misinformation on social media.

Other covariates included categorical variables for age, education, sex at birth, and social media usage frequency (refer to Table 1 for category options). Social media use frequency was assessed by an item asking, "In the past 12 months, how often did you visit a social media site?" Responses were recorded as 0=never, 1=less than once a month, 2=a few times a month, 3=at least once a week, and 4=almost every day.

[a]NLW: non-Latino White.

[b]Based on Pearson chi-square statistic.

Data Analysis

Data were analyzed using SPSS (version 28; IBM Corp). Any missing variable responses were dropped from the corresponding analyses. Sampling weights provided in the dataset were applied using Taylor Series for variance estimation [29]. Frequencies were calculated by comparing all independent variables by ethnic group (Latino: n=827; NLW: n=2563) using chi-square tests. Bivariate analyses were conducted comparing the effects of perceived amount of health misinformation on social media, ethnic group, age, sex at birth, and social media use frequency in the past 12 months on all four outcomes. This was followed by multivariate logistic regressions to assess whether the perceived amount of health misinformation on social media and ethnic groups was associated with each outcome. Only statistically significant covariates were included in logistic regressions. Adjusted odds ratios, confidence intervals, and their *P* values for the independent variables were reported, and the significance level of all analyses was set at α=.05.

Results

Participants in this sample were predominantly NLW individuals (75.6%, n=2563), female (61.5%, n=2078), 35-64 years old

XSL•FO
RenderX

(52.4%, n=1768), had a college degree or higher (51.2%, n=1730), and had incomes of US $50,000 or more (62.6%, n=2027). Weighted demographics are listed in Table 1. Compared to NLW participants, Latino participants were more likely to be younger (*P*<.001), less educated (*P*<.001), and have lower incomes (*P*<.001).

Perceptions of the Amount of Health Misinformation on Social Media Among Latino Audiences Compared to NLW Audiences

Table 1 also reports how participants use and perceive the social media environment. There were statistically significant differences in social media use, with the Latino individuals reporting more almost daily social media use than NLW individuals (75.5% vs 67.8%; *P*=.04). Latino individuals were also more likely to perceive there was little to no false or misleading health information on social media compared to NLW individuals (28.9% vs 13.6%; *P*<.001).

Differences in Engagement With and Use of Health Information Encountered on Social Media Between Latino and NLW Individuals

Overall, Latino individuals reported higher levels of engagement with health information on social media in the last 12 months compared to NLW individuals (Table 2). Compared to 10.2% of NLW individuals, 20% of Latino individuals shared general health information on social media several times a month or more (*P*<.001). They also watched health videos on social media several times a month or more at higher amounts than NLW individuals (42.4% vs 27.2%, *P*<.001). Upon controlling for the perceived amount of health misinformation, frequency of social media usage, age, sex at birth, and education (Table 3), Latino individuals were 1.85 times more likely to watch health videos several times a month or more than NLW individuals (CI 1.38-2.47). They were also 1.65 times more likely than NLW individuals to share general health information on social media several times a month or more; these findings were marginally significant (CI 0.97-2.80).

Table 2. Reported engagement with and usage of health information on social media by perceptions of the amount of health misinformation on social media, Latino/a versus non-Latino/a White (NLW) individuals, weighted percentages. All values presented, except for n, are weighted.

Outcome variables	Latino/a, Unweighted n (Weighted %)	NLW, Unweighted n (Weighted %)	*P* value[a]
Engagement			
Shared general health information on social media several times a month or more	137 (20)	248 (10.2)	<.001
Watched health-related videos on social media several times a month or more	330 (42.4)	658 (27.2)	<.001
Usage			
Used information to make a health decision	160 (22.8)	335 (13.7)	.003
Discussed information with health care provider	189 (22)	479 (18.4)	.12

[a]Based on Pearson chi-square statistic.

Latino individuals also reported higher levels of use of health information encountered on social media when compared to NLW individuals; specifically, 22.8% of Latino individuals reported using encountered health information for health decision-making, compared to 13.7% of NLW individuals (*P*=.003; Table 2). However, differences between Latino and NLW individuals were not statistically significant upon controlling for perceptions of the amount of health misinformation on social media, frequency of social media usage, age, sex at birth, and education (Table 4). No statistically significant differences in discussing health information encountered on social media with a health care provider were found.

XSL•FO
RenderX

Table 3. Perceptions of Quantity of Health Misinformation on Social Media as a Factor Associated With Information Engagement and Use by Ethnicity

As seen in Tables 3 and 4, perceptions of the amount of health misinformation on social media were associated with engagement with and usage of encountered health information on social media in 3 of the 4 models, when controlling for ethnicity and other covariates. Specifically, individuals who perceived little to no health misinformation on social media were 2.15 times more likely to watch videos several times a month or more compared to individuals who believed there is a lot of health misinformation on social media (CI 1.53-3.02; Table 3). They were also 6.26 times more likely to use encountered information to make health decisions (CI 3.95-9.92) and 2.86 times more likely to discuss encountered health information with a health care provider (CI 1.97-4.16) than individuals who believed there is a lot of health misinformation on social media (Table 4).

Table 5 reports differences in engagement and usage between the Latino and NLW individuals by perceived amount of health misinformation to assess differences in these outcomes between ethnic groups who perceive the same amount of health misinformation on social media. Compared to NLW individuals perceiving little to no health misinformation on social media, Latino individuals perceiving little to no health misinformation were 2.91 times more likely to watch videos (CI 1.69-5.03), controlling for social media use frequency, age, sex at birth, and education. They also reported marginally significant higher odds of using encountered information to make health decisions when compared to NLW individuals perceiving little to no health misinformation (adjusted odds ratio 1.87, CI 0.96-3.63).

XSL•FO
RenderX

Table 5. Weighted adjusted odds ratios of perceived amount of health misinformation and ethnicity (Latino/a vs non-Latino/a White individuals) on engagement and usage of health information. Weighted adjusted models include frequency of social media usage, age, sex at birth, and education.

Perceived amount of health misinformation on social media	Engagement		Usage	
	Shared, Adjusted OR[a] (95% CI)	Watched, Adjusted OR (95% CI)	Decided, Adjusted OR (95% CI)	Discussed, Adjusted OR (95% CI)
Models 1-4[b]				
Latino audiences perceiving little to no health misinformation	1.67 (0.82-3.40)	2.91 (1.69- 5.03)[c]	1.87 (0.96- 3.63)	0.88 (0.46- 1.66)
Models 5-8[b]				
Latino audiences perceiving some health misinformation	1.51 (0.66- 3.46)	1.87 (1.22- 2.88)[c]	1.31 (0.66- 2.60)	1.12 (0.69- 1.82)
Models 9-12[b]				
Latino audiences perceiving a lot of health misinformation	1.84 (0.81- 4.17)	1.24 (0.72- 2.12)	0.92 (0.44- 1.91)	1.44 (0.78- 2.66)

[a]OR: odds ratio.

[b]Reference group for each is non-Latino White individuals with the same perceived amount of health misinformation on social media.

[c]$P<.05$.

When comparing Latino audiences to NLW audiences perceiving some health misinformation on social media, there were only statistically significant differences in the amount of health videos watched, with Latino audiences being 1.87 times more likely to watch videos on social media than NLW audiences (CI 1.87-2.88). No differences in engagement and usage were found when comparing Latino audiences to NLW audiences who perceived there is a lot of health misinformation on social media.

Discussion

Principal Findings

Multiple calls to action in the disciplines of public health and health communication have detailed the importance of honing in on subsets of communities that are most vulnerable to the impacts of health misinformation, so as to better target resources for intervention [4,30]. This work provides insights to the engagement and usage patterns of social media users who perceive little to no health misinformation exists on social media, despite evidence to the contrary [1-3]. Our findings suggest that perceptions of the amount of health misinformation may be an important factor of engagement and usage. More importantly, Latino populations appear to have lower perceptions of the amount of health information on social media compared to NLW populations. In addition, Latino individuals who actively seek health advice on social media have been reported to be more likely to hear or believe at least one false health claim [14]. Coupled with higher social media usage patterns [11,13], these trends may place members of the Latino population at a higher disadvantage when navigating the media landscape. It is important that future work focus on digital health literacy tailored to these subgroups.

Comparisons With Previous Work

A growing body of literature has specifically highlighted concerns about the amount of health misinformation the Latino population may be exposed to on social media through visual formats. Rivera and colleagues [19,26] found evidence of Latino individuals both engaging with cancer misinformation encountered on Facebook in predominantly visual formats (ie, videos and images) and using it to make health decisions, despite most of the content not being evidence-based. Similarly, COVID-19 vaccine narratives in video format were highlighted as being easily accessible and shareable among Latino audiences, particularly those available in Spanish and shared through closed network platforms like WhatsApp [31]. These studies are consistent with findings that the Latino population has higher odds of watching health-related videos multiple times a month. In fact, Latino audiences spend more time streaming video content than other groups in the United states, with YouTube being the most used streaming platform [32]. Given recent evidence of YouTube's poor quality of health-related content [33,34], future endeavors should target multilingual visual forms of health misinformation.

According to the Kaiser Family Foundation, almost half of Latino adults in the United States report using social media to seek health advice and information at least once a week [14]. In light of this, two additional findings merit further discussion despite their marginal significance. First, we found that Latino audiences were more likely to share general health information with others on social media than NLW audiences. Latino individuals have been reported higher trust in media shared and recommended by their friends and family than from other sources [31], signaling a potential point of intervention in efforts to minimize the dissemination of health misinformation and its downstream impacts. We also found that Latino audiences who perceived that little to no health misinformation exists on social media were more likely to make decisions with health-related content found on these platforms. This merits further exploration, as Rivera et al [19] also identified extreme cases where individuals reported potentially harmful behaviors (such as canceling a mammogram) in response to breast cancer misinformation videos shared via Facebook. Their qualitative work illuminated the role of interpersonal relationships in

XSL•FO
RenderX

enhancing (and sometimes superseding) engagement with culturally relevant cancer content that came from potentially unreliable online sources, highlighting the interrelated ways in which cultural values and message and source factors contribute to engagement with social media health information [19]. As a budding area of inquiry, future research should identify important sociocultural factors and critical thinking skills that may predict engagement with content on social media among individuals with low digital health literacy, so as to better design interventions that curtail its negative impacts.

Limitations

Several limitations to this work must be acknowledged. First, there is no way to ascertain how often surveyed individuals actually encountered health misinformation on social media. HINTS 6 items only ask about overall social media health information engagement and usage, which may include different rates of exposure among different populations [35]. Similarly, perceptions of misinformation were only assessed by one item and relied on personal interpretations of what misinformation is—a term that may be unfamiliar to some or misrecognized by others. This study also failed to control for regional differences, which may impact trends. Finally, given the cross-sectional nature of the dataset, we cannot make causal inferences related to the predictive nature of the amount of health misinformation individuals perceive exists on social media and how they engage with and use this information. It may be that engagement and usage impact perceptions of the amount of health misinformation on social media, as has been suggested by Stimpson and Ortega [36]. Future studies should design surveys to better assess causality.

Despite initial attempts to explore differences in engagement and usage by Latino subethnic groups, sample size limitations did not allow for these comparisons. HINTS 6 reports Latino population subethnicities as Mexican, Puerto Rican, Cuban, and Other. While a preliminary look at these subgroups suggests that Puerto Ricans living in the continental United States have engagement and usage rates similar to NLW individuals, a larger sample is needed to explore these factors. Similarly, the HINTS 6 dataset no longer includes items asking language preferences, making it difficult to explore the role of language as an antecedent to health information engagement and use of social media. While it does include an item for the selected survey language, bilingual individuals who prefer Spanish are missed. Finally, while HINTS 6 collects information about social media use generally, there are no items that identify the specific social media platforms used by respondents. Given Latino audiences' reliance on platforms that are less popular to other US populations (ie, WhatsApp) [37], future iterations of HINTS may consider including this measure in their survey.

Finally, it is important to note that, as has been delineated by scholars elsewhere [16,38], the HINTS dataset was not designed to examine differences within Latino subgroups, nor does it include questions that may provide important sociocultural factors at play within this heterogeneous community. These may include cultural values like "familismo," "personalismo," "respeto," and "simpatía"–values oftentimes associated with Latin American collectivist identities [39]. As researchers centering their work on the Latino community, we have discussed some of these complexities elsewhere [19,40] and believe future work should explore the impact these may have on social media engagement. Furthermore, there may be other mechanisms impacting engagement with online information such as trust [38], patient engagement [41], and media literacy [42] that should be explored in future studies. Nonetheless, the findings reported in this paper lay a foundation for this important line of inquiry.

Conclusions

Our findings present new considerations for social media interventions to adequately deliver evidence-based health information to Latino populations. It is evident that video formats may better reach Latino audiences, despite the poor validity of many health-related videos on platforms like YouTube [33]. This raises the importance of building the digital health literacy of individuals and populations to improve their perception of whether a specific video or other modality of health information is actually valid and coming from a trustworthy source that can be used for health decision-making. Interventions should also consider multilingual digital media literacy training tailored to the specific social media platforms used by Latino populations, teaching them how to navigate each platform's unique features and how to use these to better assess content that may be false. This is particularly important in light of recent changes in social media platforms that call for the cancelation of fact-checking services and replacing these with user-generated fact-checking labels [43,44].

Abstract

Background: Google Trends (GT) data have shown promising results as a complementary tool to classical surveillance approaches. However, GT data are not necessarily provided by a representative sample of patients and may be skewed toward demographic and clinical groups that are more likely to use the internet to search for their health.

Objective: In this study, we aimed to assess whether GT-based models perform differently in distinct population subgroups. To assess that, we analyzed a case study on asthma hospitalizations.

Methods: We analyzed all hospitalizations with a main diagnosis of asthma occurring in 3 different countries (Portugal, Spain, and Brazil) for a period of approximately 5 years (January 1, 2012-December 17, 2016). Data on web-based searches on common cold for the same countries and time period were retrieved from GT. We estimated the correlation between GT data and the weekly occurrence of asthma hospitalizations (considering separate asthma admissions data according to patients' age, sex, ethnicity, and presence of comorbidities). In addition, we built autoregressive models to forecast the weekly number of asthma hospitalizations (for the different aforementioned subgroups) for a period of 1 year (June 2015-June 2016) based on admissions and GT data from the 3 previous years.

Results: Overall, correlation coefficients between GT on the pseudo-influenza syndrome topic and asthma hospitalizations ranged between 0.33 (in Portugal for admissions with at least one Charlson comorbidity group) and 0.86 (for admissions in women and in White people in Brazil). In the 3 assessed countries, forecasted hospitalizations for 2015-2016 correlated more strongly with observed admissions of older versus younger individuals (Portugal: Spearman ρ=0.70 vs ρ=0.56; Spain: ρ=0.88 vs ρ=0.76; Brazil: ρ=0.83 vs ρ=0.82). In Portugal and Spain, forecasted hospitalizations had a stronger correlation with admissions occurring for women than men (Portugal: ρ=0.75 vs ρ=0.52; Spain: ρ=0.83 vs ρ=0.51). In Brazil, stronger correlations were observed for admissions of White than of Black or Brown individuals (ρ=0.92 vs ρ=0.87). In Portugal, stronger correlations were observed for admissions of individuals without any comorbidity compared with admissions of individuals with comorbidities (ρ=0.68 vs ρ=0.66).

Conclusions: We observed that the models based on GT data may perform differently in demographic and clinical subgroups of participants, possibly reflecting differences in the composition of internet users' health-seeking behaviors.

Introduction

The assessment of internet users' behavior can be a valuable source of information regarding their specific interests, preferences, and perceptions pertaining to diverse health topics. Such an assessment not only enables the identification and exploration of emerging trends in health-related interests but also facilitates an understanding of the factors influencing health information seeking, dissemination, and consumption in the digital age [1,2]. In this context, there are different methodological approaches that can be used, including the assessment of the relative volume of searches on specific health topics and keywords (i.e, assessing what internet users seek) [3-7] or the assessment of content available online, including social media posts by internet users [8-10]. These approaches are part of a recent field of studies termed "infodemiology," which is defined as "the science of distribution and determinants of information in an electronic medium, specifically the Internet, or in a population, with the ultimate aim to inform public health and public policy" [1,11].

Infodemiology studies have been conducted to accomplish different goals [7,12,13]. For instance, Google Trends (GT) data, which measure the relative volume of searches on a specific topic or term, have shown promising results as a complementary tool to classical surveillance methods [6], in forecasting influenza spread and hospitalizations [14-16], for modelling COVID-19 spread [17,18], and for forecasting asthma admissions [19]. However, GT data are not necessarily provided by a representative sample of individuals within a certain country or region [20] but can rather preferentially reflect demographic or clinical groups that are more likely to use the internet for health-related inquiries. For instance, the online behavior of younger, more educated, or technologically literate individuals may be overrepresented in GT data. Moreover, health-related search behaviors can be influenced by a host of factors, including the severity and type of health conditions, the availability and quality of health information online, and individual health literacy levels. Therefore, it is possible to hypothesize that GT data should not be seen as a "one-size-fits-all" tool for health research since we do not know the clinical and demographic composition of the individuals searching for a specific health term or topic. As such, it is probable that there may be relevant differences from what is observed in the general population, with relevant implications for the performance and interpretability of GT-based models.

Therefore, in this study, we aimed to assess whether GT-based models can have a different performance when considering different population subgroups (according to their clinical and demographic characteristics). To achieve that goal, we assessed a case study of asthma hospitalizations. Specifically, we (1) assessed the correlation between GT data for the *common cold* and the number of hospitalizations for asthma considering admissions of subgroups of patients (according to their age, sex, ethnicity, and presence of comorbidities) and (2) compared the performance of models predicting asthma hospitalizations based on GT for these specific participant segments (according to their age, sex, ethnicity, and presence of comorbidities).

Methods

Study Design

This study adhered to the methodological framework proposed by Mavragani and Ochoa [21]. In a previous study by our team, we had (1) established a correlation between GT data related to common cold–related search terms and asthma hospitalizations and (2) evaluated whether GT data on the *common cold*, combined with data on admissions, could help forecast asthma hospitalizations. In this study, we applied the same methodology (correlations and forecast models) and used the same GT data but specifically considered those hospital admissions occurring in patients of each sex, age group (18-64 years old versus ≥65 years old), ethnicity (White versus Black or Brown ["pardo"]), and the presence or absence of at least one Charlson comorbidity [22]. We assessed a period of approximately 5 years (2012-2016), assessing data from Portugal, Spain, and Brazil.

Data Sources and Variables

GT Data

GT is a tool that offers insight into the popularity of search terms by providing their relative search volume data on a scale of 0 to 100 (where 100 represents the peak interest at a specific time and location). It allows users to compare the popularity of different keywords, topics, or queries across regions and time periods. The data are indexed to show the proportion of searches for a specific term relative to all searches on Google at that specific time and location [6,12,23].

We obtained GT data on January 13, 2020, as already described by Sousa-Pinto et al [19]. In brief, we retrieved country-level GT on rhinovirus-related search terms for 5 years (between 2012 and 2016) in Portugal, Spain, and Brazil: 5 years is the maximum amount of time for which GT displays data on a weekly level. These countries and timeframe were chosen (1) to allow comparability with a previous study [19] and (2) due to the accessibility of nationwide data regarding the frequency of weekly hospitalizations presented by age and sex. No specific categories or subcategories of GT data were selected. We accessed GT data exclusively through its web interface, with a

XSL•FO
RenderX

single data extraction performed for each country included in the study.

For each country, we applied 2 different GT queries. The first query focused on the *pseudo-influenza syndrome topic*, which was subsequently renamed as the *common cold* topic (of note, "topics" encompass groups of search terms associated with a specific concept regardless of language [12,19,21,24]). The second query consisted of a combination of search terms related to the *common cold*, carefully selected through discussions with native speakers of each language:

- Portugal: constipação + resfriado
- Spain: resfriado + resfrío + catarro + constipado + refredat + constipate + arrefriado + hotzeri
- Brazil: resfriado

We did not include quotation marks for the search terms as each term represented a single word. Misspellings or nonaccentuated forms were also excluded from the search term combinations, as we identified identical relative search volumes observed whenever misspelt words were or were not included in search term combinations.

Asthma Hospitalization Data Sources

We analyzed hospitalization data from January 1, 2012, to December 17, 2016 (we excluded the last 2 weeks of 2016 due to unavailable information on discharges in Portugal and Brazil—as many patients admitted toward the end of 2016 were discharged in 2017). In the 3 countries under investigation, we examined all hospitalizations in which asthma was identified as the primary diagnosis. Specifically, we used the International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM), code 493.x or International Classification of Diseases, Tenth Revision (ICD-10-CM) [25], code J45.x to identify these cases. The hospitalization data were obtained from the following sources: (1) the Hospital Morbidity database, provided by the Portuguese Central Administration of the Healthcare System, for Portugal [26]; (2) the Hospital Morbidity Survey databases (*Encuesta de morbilidad hospitalaria, Instituto Nacional de Estadistica*) for Spain [27]; and (3) Departamento de Informática do Sistema Único de Saúde (DATASUS) data from the Single Health System (*Sistema Único de Saúde*) for Brazil [28].

For each country, separate analyses were performed by participants' sex and age group (we considered only the age groups 18-64 years and ≥65 years to ensure a sufficient weekly number of hospital admissions for each analysis). Based on data availability for Portugal [20], analyses were also separately performed for episodes with at least one comorbidity from the Charlson comorbidity group and without any comorbidity from the Charlson comorbidity group. Likewise, based on data availability for Brazil, analyses were also separately performed by participants' ethnicity (White versus Black or Brown). Information on ethnicity was not available for Portugal and Spain, and information on the presence of comorbidities was not available for Spain and Brazil.

Statistical Analysis

Data analysis encompassed 2 different steps: (1) assessing the correlations between GT data and asthma hospitalizations in each country after applying time series analysis methods and (2) building models forecasting asthma hospitalizations for a period of 1 year based on GT and hospitalization data from the previous 4 years. To evaluate the predictive capability of the models, we compared the forecasted asthma admissions with the observed hospitalization data. For both GT and the frequency of hospitalizations, we worked with data displayed on a weekly basis (as it allowed detection of short-term variations while mitigating the impact of large random fluctuations that can occur when data are examined on a daily basis).

First, we performed a cross-correlation analysis to examine the correlation between GT data and asthma hospitalizations (cross-correlation can be understood as a statistical method used to analyze the relationship [correlate] between 2 continuous variables that can be measured or sampled at different points in time) [29]. Given that (1) for GT data, a relevant secular trend was expected (reflecting an increase in Google searches over time) and (2) GT and hospitalization data are expressed on different scales (GT results are expressed as relative search values [ie, percentages in relation to the maximum observed value of the whole period], whereas hospitalizations are expressed as absolute values), we removed the secular trend component for both GT and hospitalization data then assessed the correlation between search volumes and asthma hospitalizations. We analyzed Spearman correlations between GT and hospitalization data registered in the same week, as well as cross-correlation coefficients for a lag of 1 and 2 weeks to determine if search volumes demonstrated a stronger correlation with asthma hospitalizations occurring afterward rather than those happening concurrently. Correlation coefficients were presented alongside 95% CIs, which were computed using bootstrap methods for Spearman correlation coefficients.

Second, we built seasonal autoregressive integrated moving average (ARIMA) models to forecast variations in asthma hospitalizations over a period of 1 year [19,30]. Seasonal ARIMA models are used to forecast time series data that exhibit repeating patterns over fixed intervals (in this case, yearly cycles). These models take into account both the nonseasonal patterns and the seasonal variations in the data to make accurate predictions for future time points [31]. For each analysis, seasonal ARIMA models parameters $(p, d, q)(P', D, Q)s$ were defined, where p denotes the order of autoregression, d denotes the degree of difference, q denotes the order of the moving average part, P' denotes the seasonal order of autoregression, D denotes the degree of difference following seasonal integration, Q denotes the seasonal moving average, and s denotes the length of the seasonal period. We chose d and D so that the 2012-2016 time series appeared stationary (ie, with constant variance and no extreme fluctuations or overall increasing or decreasing behavior), including by testing a measure of seasonal strength [32]; we chose s=52 weeks (since there are roughly 52 weeks in a year); we chose p and P' based on spikes in partial autocorrelation function plots; and we chose q and Q based on spikes in autocorrelation function plots. Identification of these parameters using autocorrelation and

XSL•FO
RenderX

partial autocorrelation plots allowed us to define candidate models. Final seasonal ARIMA models were then selected based on the results of the Ljung-Box test (which was applied to assess whether residuals look like white noise) and on the minimization of the Akaike information criteria and Bayesian information criteria (see Table S1 in Multimedia Appendix 1 for the parameters defined for each model). In this study, we used asthma hospitalization data alongside GT data to forecast future asthma hospitalizations. The data set was split into a training set and a testing set. Specifically, the training set comprised asthma hospitalizations and GT data collected from July 1, 2012, to June 20, 2015. We then used this trained model to forecast asthma hospitalizations for the testing set, which included hospitalizations between the weeks of June 21, 2015, and June 19, 2016. This split allowed for the evaluation of model performance on previously unseen data.

To evaluate the predictive performance of the models, several measures were used: (1) the Spearman correlation coefficients between the predicted variation in hospitalizations and the actual number of asthma hospitalizations (ie, without time series decomposition), (2) the average weekly difference between the numbers of predicted and observed hospitalizations, and (3) the number of weeks whose number of observed asthma hospitalizations fell outside the 95% CI for predicted admissions.

All analyses were performed using R software, version 4.3.0 (R Foundation for Statistical Computing) [33], using the *forecast* and *urca* packages.

Ethical Considerations

Ethics Approval

The data used in this study were provided by the Central Administration of the Health System (Administração Central do Sistema de Saúde [ACSS]) in accordance with their institutional data-sharing policies. These data consist of the Morbidity Hospital Database (Bases de Dados de Morbilidade Hospitalar), which includes anonymized and de-identified data. Per the ACSS's internal guidelines, data anonymization and de-identification are conducted before any access is granted to external researchers. As a result, specific ethical approval was not required, as the use of anonymized data aligns with both Portuguese data protection regulations and the institutional policy governing secondary data analysis. [34-36],

Privacy and Confidentiality

The ACSS guarantees that the provided data sets are fully anonymized, making it impossible to identify individual patients. In addition, strict data use agreements are in place, which ensure that external entities, such as the authors of this study, commit to (1) using the data exclusively for research within the scope of their project, ensuring secure and fair data processing; (2) requesting explicit authorization from ACSS for any other use beyond the agreed scope; (3) not sharing the data with third parties; (4) citing ACSS as the source of the data in any resulting publications; (5) providing ACSS with copies of all publications that use the data; and (6) taking full responsibility for any analysis or conclusions drawn from the provided data sets.

Compensation

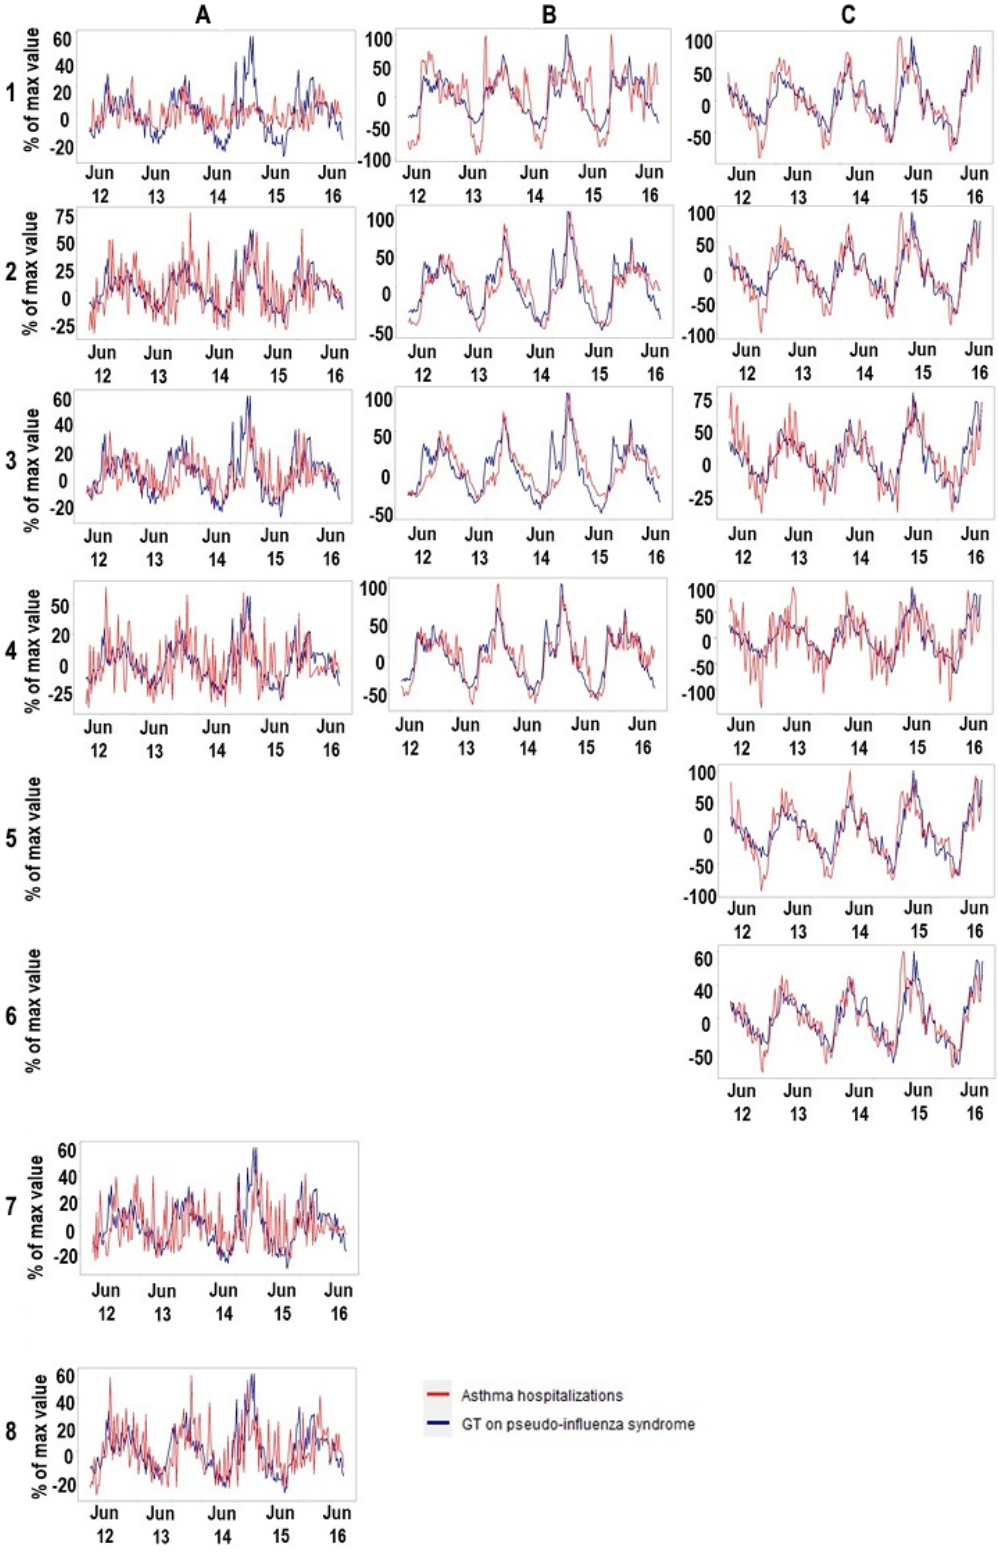
No compensation was provided, as the study did not involve direct patient recruitment or interaction.

Additionally, any identification of specific hospitals or the disclosure of medical device pricing data requires explicit approval from the respective institutions. This confidentiality further strengthens the protection of sensitive information while allowing for the comprehensive analysis of anonymized data.

Results

Between 2012 and 2016, GT data for *pseudo-influenza syndrome* presented similar patterns across the 3 countries for which GT data were plotted, with peaks in the winter and valleys in the summer of the respective hemispheres (Figure 1). This pattern was also observed for asthma hospitalizations in each subgroup of patients in each country.

In the assessed countries and for each subgroup of admissions, correlations between GT on the *pseudo-influenza syndrome* topic (after removing the trend component) and asthma hospitalizations ranged between 0.33 (in Portugal for admissions with at least one Charlson comorbidity group) and 0.86 (for admissions of women and White individuals in Brazil; Table 1). Similar values were observed when analyzing the correlations between GT and terms for the *common cold*. In the 3 countries, stronger correlation coefficients were observed for admissions occurring for women. In Portugal and Spain, stronger correlations were found for admissions of younger individuals, while in Brazil, the inverse phenomenon occurred. In Brazil, no differences were observed between correlations for admissions of patients of White or Black/Brown ethnicity. In Portugal, stronger correlations were observed for admissions of patients without comorbidities than for those with at least one comorbidity.



In most cases, GT on the *pseudo-influenza syndrome* topic correlated more strongly with asthma hospitalizations occurring in the subsequent week than with those occurring in the same week (Table 1).

In the 3 assessed countries (Table 2; Figure 2), forecasted hospitalizations for 2015-2016 obtained through seasonal ARIMA models correlated more strongly with observed admissions of older adults versus younger individuals (Portugal: correlation coefficient [ρ]= 0.70 vs ρ= 0.56; Spain: ρ=0.88 vs ρ=0.76; Brazil: ρ=0.83 vs ρ=0.82). In Portugal and Spain, forecasted hospitalizations displayed a much stronger correlation with admissions occurring for women than for men (Portugal: ρ=0.75 vs ρ=0.52; Spain: ρ=0.83 vs ρ=0.51). Consistent results were observed when performing a sensitivity analysis by age group (Table S2 in Multimedia Appendix 1). In Brazil, stronger correlations were observed for admissions of White individuals than of Black or Brown individuals (ρ=0.92 vs ρ=0.87). In Portugal, stronger correlations were observed for admissions of individuals without any comorbidity compared with admissions of individuals with comorbidities (ρ=0.68 vs ρ=0.66). The numbers of weeks with observed hospitalizations outside the confidence interval for predicted values ranged between 1 and 7 for Portugal, 2 and 12 for Spain, and 0 and 1

XSL•FO
RenderX

for Brazil (according to subgroups of admissions in each country).

Figure 1. Google Trends (GT) data on pseudo-influenza syndrome and asthma hospitalizations (2012-2016) for (A.1) men in Portugal, (B.1) men in Spain, (C.1) men in Brazil, (A.2) women in Portugal, (B.2) women in Spain, (C.2) women in Brazil, (A.3) older adults in Portugal, (B.3) older adults in Spain, (C.3) older adults in Brazil, (A.4) younger adults in Portugal, (B.4) younger adults in Spain, (C.4) younger adults in Brazil, (C.5) White people in Brazil, (C.6) Black or Brown people in Brazil, (A.7) people with comorbidities in Portugal, and (A.8) people without comorbidities in Portugal. The trend component of the time series has been plotted after removing the seasonal effects and random error components.

Discussion

Principal Findings

In this study, we assessed the correlations of GT data and the performance of GT-based models in different subgroups of patients (as defined by clinical and demographic characteristics: age, sex, ethnicity, and presence of comorbidities) using the case study of asthma. Overall, our results point out that GT-based models may not necessarily have the same performance in all subgroups of patients, highlighting that GT data may vary across different segments of users. In fact, we

XSL•FO
RenderX

observed stronger correlations between GT data and asthma hospitalization data or between forecasted and observed hospitalizations when assessing admissions of women or patients without comorbidities. Less consistent results were observed, in particular in Brazil, according to age group.

Overall, studies using GT data for surveillance purposes have obtained mixed results. On the one hand, GT has been shown to have an effective potential to monitor the spread of infectious diseases, track public interest in health-related topics, and identify emerging trends in public health [37,38]. However, there have also been instances where GT has shown inconsistencies or failed to provide accurate predictions, emphasizing the need to carefully interpret the data [23]. In part, these failures may be related to differences in the composition of internet users compared with that of patients with a particular disease. Although we cannot necessarily generalize the results observed in the use case of asthma hospitalizations to other conditions or countries, this paper is relevant from a methodological point of view, as it demonstrates, through a case study, how the association between GT and disease data is not always the same for all groups of individuals, pointing to the need to study these associations according to the characteristics of the patients.

This study is also relevant for asthma care, as this was the condition we particularly assessed. Regarding our findings of the performance of GT-based models in the distinct subgroups of asthma hospitalizations, we observed relevant gender-related differences. In fact, women have higher asthma prevalence, severity, and health care utilization than men [39,40]. The better correlations and model performance observed in female admissions may be related to the higher prevalence of asthma in this population. On the other hand, women often exhibit more proactive health information–seeking behaviors, with a particular emphasis on their own health and well-being as well as that of their families—which may partly explain the higher internet use by women than men [41]. In addition, in some cultures, women may have primary caregiving responsibilities for family members' health, including managing asthma [42]. This can also contribute to increasing interest and information-seeking behavior and enhance engagement with online platforms, possibly explaining the higher correlations and better performance of models in admissions of women.

Younger adults, especially those who are generally healthy, may exhibit different health-seeking behaviors than older adults or individuals with chronic illnesses [43]. Younger adults may tend to be more proactive in seeking health care information online and to be more likely to use search engines [44], in part given their historically higher access and rates of internet use [44] (which can be attributed to factors such as greater digital literacy, increased reliance on technology for information and communication, and higher rates of smartphone ownership [44,45]). However, that access has also been proliferating very quickly among older adults, who may possibly be more concerned about their health [46]. These changing patterns may partly explain the heterogeneity of our results obtained on age groups, with higher correlations found for younger adults in contrast with better performance of forecasting models in admissions of older adults. Such a pattern was also observed when performing separate analyses for age groups of 15 to 44-year-olds and 45 to 64-year-olds in Spain and Brazil. All things considered, our findings may offer insights into digital divides, hinting at disparities in internet access, digital literacy, and health information–seeking behaviors across demographic groups. The use of GT-based tools for complementing surveillance systems may have important implications in terms of health equity, considering the discrepancies in internet access across clinical and demographic subgroups.

Information on the presence of comorbidities or ethnicity of patients was only available for one country each (Portugal and Brazil, respectively). The presence of comorbidities has been associated with worse health outcomes for asthma admissions [47]. In addition, we observed a less pronounced seasonal pattern in Portuguese hospitalizations of individuals with comorbidities than in those without, potentially explaining the worse performance of GT-based models in forecasting those admissions. Small differences were observed regarding ethnicity, with a slightly better performance of models for Whites in Brazil, possibly reflecting different regional demographics, internet use patterns, or health care–seeking patterns.

Strengths and Limitations

Several limitations should be discussed. First, the differences observed in the performance of GT across different subgroups are not necessarily generalizable to other countries and conditions (eg, we cannot state that GT-based models always display better performance when considering data from female participants). Second, data availability on hospitalizations was limited to 3 countries and, regarding the presence of comorbidities or ethnicity, we only had that information for Portugal and for Brazil, respectively. In addition, the small frequency of weekly admissions precluded the comparison of the performance of the models' unspecific sets of Charlson comorbidity groups. Third, GT provides data on search term popularity and relative interest (ie, GT presents searches as a relative volume instead of as an absolute number of searches), which makes comparisons between queries difficult and reveals less information about the absolute search interest in each aspect being assessed. In addition, it does not provide detailed information about the context or intent behind the searches, thus making it prone to bias due to possible media coverage [48]. In the particular context of this study, we were not able to quantify the number of searches on the "common cold" resulting from individuals experiencing cold symptoms versus reflecting other intentions (eg, search for news on the common cold). This lack of specificity can make it challenging to establish a causal link between search behaviors and the studied outcomes. However, this is an inherent limitation of GT, and our goal was not so much to establish an association between searches on "common cold" and asthma hospitalizations but rather to assess how that association varies considering different subgroups. Finally, during the assessed period, there was an increase in the use of the internet. However, we applied time series analysis methods, removing the estimated trend components for both GT and hospitalization data.

This study also had several strengths. In particular, this study has an important novelty component—to the best of our

XSL•FO
RenderX

knowledge, this is the first time that the performance of GT-based models has been investigated across diverse demographic and clinical subgroups, with relevant potential implications for considering digital divides and health equity–related aspects in interpreting results of GT-based tools. In addition, we assessed 3 different countries (1 in Europe and 1 in South America) using nationwide data for a period of 5 years. We applied 2 different strategies to retrieve common cold–related GT data—GT data on the *pseudo-influenza syndrome* topic and search terms regarding the *common cold*—which obtained comparable results. We examined asthma as a case study since (1) asthma, in comparison with other diseases (such as COVID-19), is less subject to a high or variable media coverage, thus not particularly biased for GT data [30,48]; (2) the relationship between asthma admissions and GT data on the common cold has been already established [19]; and (3) the influence of patients' characteristics on asthma outcomes has been assessed [20]. Although this study relied on a case study on asthma admissions, there is potential application of this methodology to other diseases and segments of the population to better understand the context in which GT-based models can be better applied.

Conclusions

In this study, we observed better performance of models forecasting asthma hospitalizations in women, White individuals (Brazil), and patients without comorbidities (Portugal), suggesting that the models based on GT may perform differently in subgroups of participants, which may indicate variations in the patterns of health-related information seeking among different segments of internet users. Although GT data have increasingly been assessed as a potential complementary tool to more classical surveillance approaches, determining the best practices for using GT data and understanding its limitations requires exploring in which segments of users it performs better. Although this study assessed the use case of asthma in 3 countries and shows differences in different segments of the population, future studies should explore how GT-related models may differentially perform in accordance with other variables, such as sociodemographic variables (like age, gender, education, income, urban/rural context, underserved populations), as well as to test differences observed in other diseases, countries, and clinical data sources. This study contributes to advancing our understanding of the complexities inherent in the infodemiology field and hints at the need to consider population subgroups and health contexts for the applicability of GT-based surveillance systems.

Acknowledgments

The authors wish to thank the Portuguese Ministry of Health for providing access to the hospitalization data managed by the Portuguese Central Health System Administration (Administração Central do Sistema de Saúde).

Abstract

Background: Understanding how social media platforms facilitate information exchange and influence behavior during health crises can enhance public health responses during times of uncertainty. While some risk factors for COVID-19 susceptibility and severity (eg, old age) were clear, whether e-cigarette use increased risk was not clear. People who used e-cigarettes had to navigate both the COVID-19 infodemic and a conflicting, politicized, and changing information environment about the interaction between COVID-19 and e-cigarette use.

Objective: This study aims to characterize and contextualize e-cigarette–related behavior changes during the early COVID-19 pandemic and illuminate the role that social media played in decision-making.

Methods: We conducted a qualitative analysis of COVID-19–related e-cigarette discussions on 3 Reddit forums about e-cigarettes. We collected 189 relevant discussion threads made in the first 6 months of the pandemic (collected from June 27, 2020, to July 3, 2020). Threads included 3155 total comments (mean 17 comments) from approximately 1200 unique Redditors. We developed and applied emergent codes related to e-cigarette perceptions and behaviors (eg, the role of nicotine in COVID-19 and do-it-yourself narratives) and web-based community interactions (eg, advice), identified thematic patterns across codes, and developed a model to synthesize the socioecological context of e-cigarette behaviors.

Results: e-Cigarette subreddits provided a platform for Redditors to discuss perceptions and experiences with e-cigarettes, make sense of information, and provide emotional support. Discussions reflected an array of e-cigarette–related behavioral responses, including increases and decreases in use intensity, changes in purchasing practices (eg, stockpiling), and changes in vaping practices (eg, reusing disposable pods). This study presented a theoretically and empirically informed model of how circumstances created by the pandemic (eg, changes in activity space and product shortages) compelled behavior changes. Redditors drew from their existing perceptions, intentions, and experiences with nicotine and tobacco products; their personal pandemic experiences; and their participation on Reddit to decide whether and how to change their e-cigarette behaviors during the early pandemic. Forums reflected uncertainty, stress, and debate about the rapidly evolving and complicated public health information. Consumption and discussion of media (eg, news articles and peer-reviewed publications) on Reddit informed e-cigarette perceptions and behaviors. Decisions were complicated by distrust of the media.

Conclusions: Variations in individual traits and environmental circumstances during the early COVID-19 pandemic provide context for why there was no unified direction of e-cigarette behavior change during this period. Information and discussion on Reddit also informed risk perceptions and decisions during the pandemic. Social media is an effective and important place to communicate public health information, particularly during crisis or disaster situations. Moving forward, transparent, accurate,

XSL•FO
RenderX

and specific message development should consider the stress, struggles, and stigma of people who use e-cigarettes and address the roles mistrust and misinformation play in decisions.

vaping; nicotine; tobacco; health communication; social media; new media

Introduction

Background

During the first year of the COVID-19 pandemic, risk perceptions, related behaviors, and public health guidance changed rapidly, as both the virus and our understanding of it evolved. The COVID-19 pandemic was accompanied by an "infodemic," a glut of accurate and inaccurate information about a disease outbreak, which can cause confusion and undermine public trust [1-3]. Conflicts and changes in public health messaging confused some members of the public and seemed untrustworthy to others [4,5].

In this era of high stress, evolving public health information, and politicization of science, the public used social media as a tool to inform their health-related decisions [6]. During crises and disasters, social media facilitates information dissemination and communication but can also facilitate the intentional and unintentional spread of information that is "inaccurate, incomplete, vague, or ambiguous," [7] that is, *misinformation* [8-10]. During the intense isolation of the early pandemic, social media also provided essential human connection. In 2020, nearly one-third of Americans reported viewing COVID-19–related content on social media daily, and almost two-thirds of social media users reported they were unlikely to fact-check information about COVID-19 they read on social media with a health professional [6]. Understanding how social media platforms facilitate information exchange and impact behavior during health crises is critical to improving infodemic management and future public health response [1]. Moreover, social media conversations provide a unique record of the human experience during the pandemic.

Globally, the pandemic influenced multiple addictive behaviors, including alcohol consumption [11,12], gambling [13], cannabis use [14,15], and tobacco and nicotine use [12,16-20]. Evidence suggests that nicotine e-cigarette use, purchasing, and risk perception were all impacted [21] and that changes were mixed (ie, toward e-cigarette use and away from it) for both adolescents and adults [22-25]. e-Cigarette use is influenced by personal beliefs and experiences and interpersonal, informational, organizational, community, and policy contexts (ie, socioecological context) [26]. Influences include risk perceptions, social norms [27], e-cigarette advertising [28], social media [29], and access to e-cigarettes [30]. By transforming multiple domains of an individual's life (eg, activity space and social connections), the pandemic likely influenced e-cigarette use through multiple pathways [31].

People who used e-cigarettes exchanged e-cigarette–related information on the web during the pandemic [4,32], leveraging already-established social media forums on which individuals discussed products, flavors, current regulations, and personal experiences [33]. While some risk factors for COVID-19 susceptibility and severity, such as old age, were clear, whether e-cigarette and tobacco use increased risk was not clear [34-36]. People who used e-cigarettes or tobacco products not only had to navigate the COVID-19 infodemic but also make sense of conflicting, politicized, and changing information about the interaction between COVID-19 and e-cigarette and other nicotine and tobacco product use [37]. The mixed effect of the pandemic on e-cigarette use, the compounding and interacting uncertainties about COVID-19 and e-cigarette use, and the existing e-cigarette communities on the web suggest e-cigarette use is an excellent context to investigate how social media captured lived experience during the pandemic and how it facilitates health-related information exchange during public health crises. The COVID-19 pandemic will influence health and well-being long after the threat of severe illness subsides. Documenting *how* the profound personal and social changes of the pandemic influenced health risk behaviors in the early months of the crisis can reveal facilitators and barriers to health promotion, help us contextualize and interpret behavioral trends as they unfold in the years following, and suggest future communication interventions during crises.

Objectives

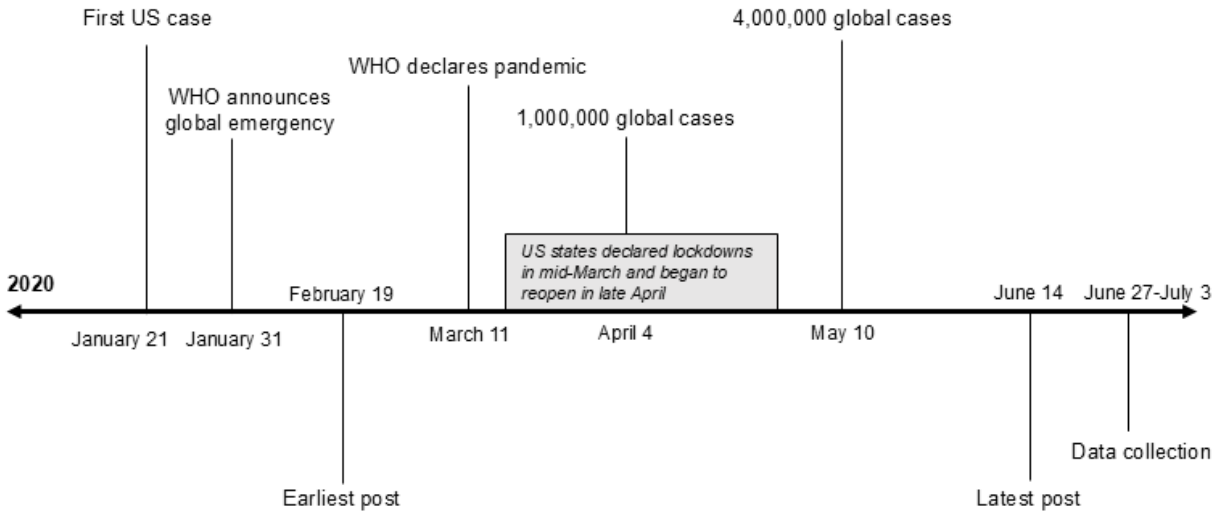
We aimed to explicate the mechanisms of e-cigarette behavior change, including engagement in web-based forums, during the early months of the COVID-19 pandemic. We leveraged social media as a source of qualitative data and conceptualized social media use as a phenomenon of study, conducting a qualitative analysis of e-cigarette forums on the social media platform Reddit (Reddit, Inc). Understanding the discourse in web-based e-cigarette communities during the COVID-19 pandemic can illuminate the range of individual experiences of vaping during that time; show how health information, including misinformation, is consumed, analyzed, and implemented on the web; and illuminate how individuals make health decisions during crisis.

Methods

We thematically analyzed randomly selected Reddit posts (posted from January 31, 2020, to July 3, 2020) related to the COVID-19 pandemic from 3 e-cigarette subreddits.

Study Site

Reddit is a social media site that allows anonymous users (Redditors) to post content on discussion boards (subreddits) dedicated to specific topics. Redditors interact by creating an original post (OP) related to the subreddit, commenting on an OP, and "upvoting" (liking) or "downvoting" (disliking) OPs and comments. The term OP refers to both *original posts* and



XSL•FO
RenderX

the Redditor who created that OP. Because each subreddit is dedicated to a specific topic, it provides space for relevant discussions, questions, and advice. Each month, approximately 500 million visitors participate on Reddit, and the site hosts 73 million unique users daily [38]. Because of these attributes, Reddit has been effectively used to investigate e-cigarette perceptions and behaviors [39-42] and is uniquely situated to study web-based social interactions during the pandemic through unobtrusive observation. A large study of psychosocial language markers in health discussions on Reddit reported substantial differences in topic and sentiment before and during the pandemic [43]. This qualitative study included 3 e-cigarette subreddits over 6 months to capture a range of reactions to the pandemic.

Data Collection

In each subreddit, we searched for OPs using 8 terms: "COVID," "corona," "coronavirus," "pandemic," "quarantine," "virus," "lockdown," and "isolation." For inclusion, OPs had to be written in English and posted no earlier than January 31, 2020, when the United States declared the novel coronavirus a public health emergency. KS conducted searches from June 27, 2020, to July 3, 2020. We captured a range of reactions to COVID-19, as our data collection window included many other important dates, including the virus being named COVID-19 on February 11, Italy's lockdown beginning on February 23, the first community spread case in the United States on February 26, the first report of a US death on February 29, and the declaration of a pandemic on March 11. Figure 1 presents a timeline of COVID-19 pandemic events, data collection, and date range of OPs. Posts had to relate to both e-cigarette use and the COVID-19 pandemic. Because posts were made in e-cigarette subreddits, mentions of "vaping" were assumed to be related to nicotine vaping unless there was an explicit mention of cannabis vaping and no mention of nicotine vaping. To capture interactions between Redditors, eligible posts had to have at least 1 comment from another Redditor. We excluded OPs that mentioned cannabis vaping and made no reference to nicotine vaping or e-cigarettes.

Figure 1. A timeline of events related to the COVID-19 pandemic in early 2020. We collected Reddit data from June 27, 2020, to July 3, 2020. The final dataset included original posts made between February 19, 2020, and June 14, 2020. WHO: World Health Organization.

For each search, we screened OPs randomly (to decrease algorithmic bias where newer or more popular posts appeared first) until we collected 10 relevant posts and all comments (ie, threads) or reviewed all search results. KS saved 189 conversation threads (PDF) and recorded search metadata, including search terms, number of hits, number of ineligible posts removed before hitting 10 relevant posts, search date, and qualitative observations about the search (eg, June 27 entry for search term *coronavirus*, "I'm noticing individuals like to leave articles with little to no commentary and then ask for others' interpretations. In the comments, a robust discussion often occurs. It is interesting to see individuals using others' interpretations/community discussion."). When saved, OPs had an average of 17 comments (range 1-167; total: n=3155), an average of 25 "points" (assigned by Reddit), and were 81% upvoted on average. Approximately 1200 unique usernames engaged in conversation. If a Redditor deletes their account, their comment remains but their username does not. This occurred infrequently in our dataset. Still, we could not determine how many additional Redditors participated.

Data Analysis

We conducted a qualitative thematic analysis to (1) contextualize e-cigarette–related behavior changes during the early COVID-19 pandemic and (2) characterize web-based discussions about e-cigarettes during that time. After the first complete reading of the data, KS and ES led codebook development using an iterative process of reading, note-taking, and discussion to identify recurrent ideas and come to an agreement on codes and definitions. They developed an initial codebook of inductive codes, definitions, and examples; tested the codebook; and refined it to ensure comprehensiveness and clarity between codes. SLW provided suggestions and mentorship throughout the process. The final codebook included 7 codes related to e-cigarette perceptions and behaviors and 3 codes related to web-based community interactions. Finally, we used a 3-tiered quality code of "priority," "average," and "low priority" to

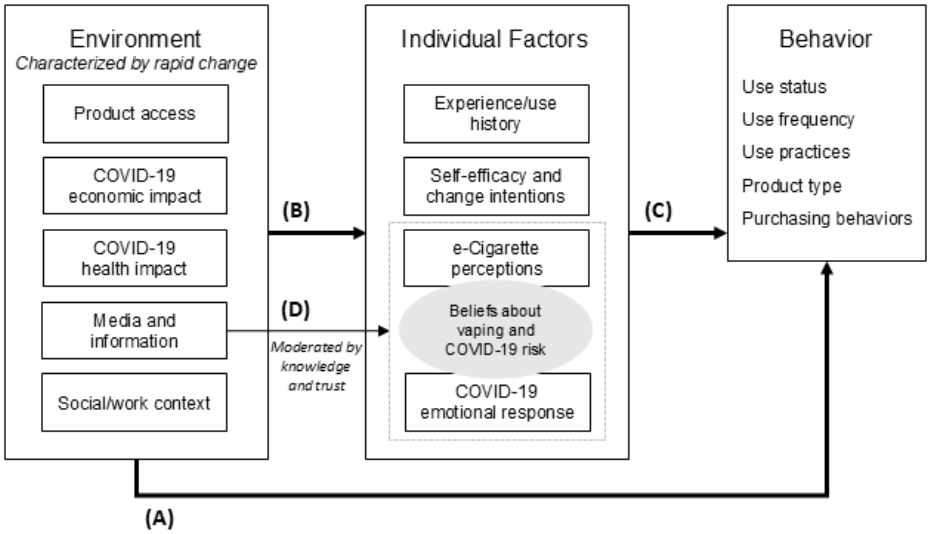
XSL•FO
RenderX

indicate richness (a qualitative determination based on the number, length, and detail of posts) of the thread's content.

KS completed coding and led the analysis. We applied codes to threads in their entirety to preserve the interrelated, unique interactions between Redditors within each threaded conversation, and codes were assigned based on relevant content in the OP, comments, or both. We assigned multiple codes to a single thread when relevant and used Microsoft Excel to track coding.

For each code, KS combined all relevant threads into a single document (PDF, then converted to a Microsoft Word document) and performed data reduction, a process that involved reading each post in its entirety, summarizing relevant content, saving illustrative quotes, and keeping analytic notes to document emerging ideas and interpretations. For each code, we used summaries, illustrative quotes, and analytic notes to identify patterns. *Priority* threads were analyzed first, and *average* threads were read if posts continued to add unique information to our analysis (ie, saturation was not yet met). KS and SLW used the collaborative web-based whiteboarding application Miro to organize cases and analytic ideas, returning to original texts to test emerging themes. During this analytic process, we used the socioecological model—which posits that individual behavior is influenced by their social, physical, and cultural environment—as an organizing framework to tease apart the external and internal factors Redditors mentioned. This iterative process produced the final model and thematic findings presented subsequently.

Ethical Considerations



This study was determined not to be human participants research by the University of Iowa Institutional Review Board (project title "202006140 e-cigarette conversations in online social media platforms"). All posts in our dataset were accessible on the web and might be considered publicly available data. Furthermore, Redditors select usernames, which can conceal their identity. However, they did not formally consent to the inclusion of their comments in research and might not have conceptualized their posts as truly "public." To avoid the reidentification of contributors, we used only short quotes in our examples, did not name the subreddits we collected data from, and did not identify Redditors by their usernames. We did not engage with Redditors for this study. Documents were stored on shared cloud storage through the University of Iowa and accessible only to team members.

Results

Overview

Reddit served as an information hub, debate platform, public journal, and a place of emotional support for people who used e-cigarettes early in the COVID-19 pandemic. Our analysis reflected the multifaceted experiences of people who use e-cigarettes, represented in a model of the environmental and individual influences on behavior change discussed by Redditors (Figure 2). Our findings indicate that circumstances created by the pandemic compelled behavior changes as they affected the context, pace, and environment in which individuals experienced life. Redditors drew from their existing perceptions, intentions, and experiences with e-cigarettes and cigarettes; their pandemic experience; and their participation on Reddit to decide whether and how to change their e-cigarette behaviors. Consumption of media and information (eg, peer-reviewed publications) and associated commentary shared on Reddit played a role in shaping behavior. Posts revealed how decisions were complicated by media distrust and by tobacco regulatory context.

Figure 2. A model of environmental and individual influences on 5 categories of behavior, developed through qualitative document analysis, visualizes the complexity of the pandemic's downstream impact. Changes in circumstances during the early COVID-19 pandemic compelled behavior changes (A) and changed perceptions and intentions (B), which in some instances also led to behavior change (C). Information and misinformation in the media and social media environment (D), especially information about the risks of COVID-19 for people who use e-cigarettes and tobacco, indirectly influenced behavior change through changes in perceptions of risk. Participation on Reddit itself exposed Redditors to information and advice of varying quality, which in turn might have impacted product perceptions and use practices. Findings are based on a qualitative analysis of 189 discussion threads from Reddit, posted between February 19, 2020, and June 14, 2020, and collected from June 27, 2020, to July 3, 2020.

RenderX

Reddit as a Source of Support, Information, Debate, and Influence

Rapidly evolving public health information about COVID-19 created uncertainty, stress, and confusion. The subreddits acted as community spaces for individuals seeking to express these emotions and receive advice and support. Subreddit posts during the pandemic included solicitation and sharing of e-cigarette knowledge. For example, one Redditor who could not afford to replace their broken device sought expertise from other Redditors, stating "All advice is appreciated." Suggestions included power cycling (ie, turning off and turning on again), ensuring the coil of the device was not damaged, and checking the charging pins. Other OPs asked subjective questions, such as advice on whether they should quit vaping because of the pandemic. One Redditor who reported having asthma and being a "pretty heavy vaper" explained they feared a more severe illness but a lack of "solid evidence" about vaping made them unsure about what they should do, so they asked others for their opinions.

Reddit also served as a space for discussion of information from other media, such as news articles, research publications, and blog posts related to the COVID-19 pandemic. The discourse about media seemed to change opinions for some Redditors, while for others it confirmed their existing beliefs. For example, when a commenter questioned a study's validity because it was published in the 1940s, the OP acknowledged the observation was a "good call." Another Redditor described propylene glycol (PG) and vegetable glycerin in detail, inaccurately claiming that vegetable glycerin had antimicrobial and antiviral properties, to which another Redditor expressed gratitude for the information.

Redditors shared anecdotes and stories, and other Redditors used these stories to form ideas about COVID-19. In response to an OP wondering whether they should quit vaping during the pandemic, one Redditor opined that there is "no evidence" of a relationship between COVID-19 and vaping because their whole family contracted COVID-19 except for them, and they were the only one in their family who vaped. The anecdote was used to support the OP's decision to continue vaping.

Comments providing emotional support or sharing experiences in solidarity reflected a sense of community. For example, one OP experiencing nicotine withdrawal asked whether their symptoms were normal, and a commenter affirmed their experience and assured them they would "wake up more and more happy" over time. Another Redditor received 6 recommendations after requesting e-cigarette device options for their mother who had lost her husband to COVID-19 and "desperately want[ed] to quit [cigarettes]." Posts reflected solidarity with people who were using e-cigarettes as a harm reduction strategy, encouraging people to avoid relapse (eg, "stay strong and don't do it") or advocating for vape shops to remain open to support the people who "rely on vape shops to make sure they don't return to cigarettes" and the many people who are "one cigarette away from giving up on vaping." Many Redditors disagreed, arguing their closure was important for COVID-19 prevention.

Behavior Changes and Their Contexts

Overview

Thematic analysis revealed how the early COVID-19 pandemic directly and indirectly motivated changes in e-cigarette use and e-cigarette practices. We found no consistent pattern of change; some Redditors reported increasing use, and others reported decreasing or pausing use (ie, at least temporary cessation). Synthesizing our thematic analysis, Figure 2 visualizes pandemic-related behavior changes as influenced by environmental factors (ie, physical, economic, and legal environment that constrained individual behavior) and personal characteristics (ie, individual perceptions and experiences with e-cigarettes), which could be modified during the pandemic by personal experiences and exposure to information and misinformation, including Reddit participation. Posts indicated that the impact of environmental context, consumed media, and personal experience depended on prepandemic risk perceptions and behaviors.

Direct Impacts of the COVID-19 Pandemic on e-Cigarette Behaviors

Redditors explicitly and implicitly referred to life changes during the COVID-19 pandemic, including working from home, job loss and financial insecurity, exposure to COVID-19, and reduced access to e-cigarettes. These changes in circumstances led to changes in behavior. For example, one Redditor reported having fewer hours of work and therefore more time to play video games. Their already-established practice of vaping while playing video games meant they increased their e-cigarette use when their gameplay increased. A Redditor who previously smoked cigarettes and lived in a state with a flavored product ban lost access to their usual flavored e-cigarette products when they stopped commuting to work across state lines. Because of this loss of access, they were considering reinitiating cigarette smoking. One Redditor who used e-cigarettes socially and could not spend time with friends because of the COVID-19 pandemic social distancing restrictions reported they "stop[ped] vaping for a while," although they implied that they might start again. In contrast, a few Redditors who worked in essential services or already worked from home cited their lack of job change as the reason they had not changed their vaping intensity.

COVID-19 itself prompted behavior change, largely temporary reduction or cessation, for a few Redditors who reported COVID-19 symptoms, such as shortness of breath, a cough, or fatigue that made vaping difficult or impossible. One Redditor with a "terrible cough" switched to nicotine patches, and another decreased use when COVID-19–like symptoms made vapor inhalation difficult. Some posts revealed potentially harmful practices, like one Redditor who diluted e-liquid with water and consumed it orally while they had a cough and suggested that other people who were sick try the same.

Several posts reflected e-cigarette changes in response to other effects of COVID-19, such as the loss of a loved one or high test positivity rates, including one account of increased vaping while coping with the loss of their grandfather to COVID-19.

The economic impact of the early pandemic left some Redditors with less discretionary income to spend on e-cigarettes. For

XSL•FO
RenderX

example, one Redditor shared that they had not worked in a week, ran out of e-liquid, and had < US $1 left in their bank account. Because they could no longer afford e-cigarette products, they "resorted" to their fiancé's cigarettes, sharing their disgust with the emojis " ."

Purchasing patterns adapted to changing circumstances; vape shop closures, curbside pickups, web-based purchases, limited supplies, and shipping delays altered purchasing behaviors. Some individuals began "stockpiling" e-cigarette devices and accessories because of real or anticipated shortages (Figure 3). In response to observed or anticipated reduction in access, some Redditors altered their use and personal practices, including reducing volume (eg, abstinence when unable to buy their favorite e-liquid) and changing products (eg, turning to pipe tobacco after running out of pods and e-liquid because they were "still addicted"). Redditors reported "DIY" activities in the face of shortages, for example mixing their own e-liquid from a bulk purchase.

Figure 3. e-Cigarette stockpile shared on Reddit.

Redditors referenced potentially risky adaptations, such as using other wires in place of standard product coils, attempting their own device repairs, or trying to clean disposable pods to reuse. Replies to these posts included encouragement, suggestions, and discouragement. One Redditor who realized they bought expired e-liquid still considered vaping it because it was their only option. Another shared that their local shop was selling 3-year expired juice with fake stickers to look fresh; some responses suggested it might be usable, but most responses strongly discouraged this behavior and some suggested reporting the retailer.

A Redditor shared an image of their stockpile after going to their local vape shop. The owner of the store was in the process of closing for the pandemic, but the Redditor shared they felt prepared (because of their stockpile), asserting "Bring on the lockdown."

Reddit discussions reflected an array of e-cigarette–related behavioral responses to the COVID-19 pandemic and infodemic, including increases and decreases in use intensity, changes in purchasing practices (eg, stockpiling), and changes in vaping practices (eg, reusing disposable pods). These findings are based on a qualitative analysis of 189 discussion threads from Reddit, posted between February 19, 2020, and June 14, 2020, and collected from June 27, 2020, to July 3, 2020.

People who used e-cigarettes were impacted by both the pandemic response and the existing e-cigarette regulatory scheme in their locale. A few Redditors made references to changing e-cigarette policy or stay-at-home orders, illustrating this impact. For example, some individuals had already stockpiled devices, e-liquid, or accessories in response to regulatory changes, and thus were not as severely impacted by the pandemic.

Impacts of Individual Perceptions and e-Cigarette or Cigarette History on e-Cigarette Behaviors

Two key beliefs anchored risk perception during the pandemic: (1) COVID-19 was a serious illness and (2) e-cigarette use increased COVID-19–related risk. The belief that e-cigarette use made COVID-19 more dangerous (either in disease susceptibility or severity) sufficiently increased the perceived risk of vaping to prompt behavior change for some Redditors. For example, one Redditor stopped vaping entirely because of an underlying belief that vaping was not "exactly 100% safe and healthy" and a desire for their body not to "suffer unnecessarily" if they contracted COVID-19. Others reduced their e-cigarette use "just in case" using e-cigarettes increased COVID-19 risk or severity. One Redditor who had COVID-19 shared that they felt their vaping did not make their symptoms worse but still took a 2-week hiatus when their symptoms were severe. Alternatively, Redditors who did not perceive both COVID-19 and e-cigarettes as risky were unlikely to alter their behavior. Some Redditors perceived COVID-19 as a nonserious or nonexistent condition. Others believed they had negligible exposure and were therefore unconcerned about contracting COVID-19. This lack of concern meant no change in behavior for one Redditor who asserted they would continue to vape

XSL•FO
RenderX

alone at home. While washing their hands. And not touching their face (punctuation in the original comment).

Perceived addiction, previous cigarette smoking, existing intentions to quit, and self-efficacy to change behavior help explain the extent to which people who used e-cigarettes changed their behavior in response to the pandemic. One Redditor's post reflected a tension between underlying intentions to quit and low self-efficacy, describing the pandemic as "the perfect reason" to fulfill their quit intentions but admitting that it has been hard due to the stress they had experienced. Another Redditor who read a report that vaping increased the severity of COVID-19 decided that it would be "way too difficult…[to quit] during a stressful time," even after the study made them believe quitting might be beneficial. Product shortages left one Redditor who had previously smoked with what he saw as 2 unappealing options: "go cold turkey" or "return to cigarettes."

e-Cigarette– and COVID-19–Related Beliefs and Their Development

The complex environment of COVID-19 and e-cigarette information during this time resulted in an array of interpretations of the health risks that COVID-19 posed to people who used e-cigarettes. Redditors offered multiple explanations for why e-cigarette use disproportionately increased the health risks for people who used e-cigarettes, including COVID-19 and vaping impacting the same bodily systems, the vape device itself acting as a transmission vector, or nicotine harmfully impacting the angiotensin converting enzyme 2 (ACE2; a protein) receptor system. For example, one Redditor expressed concern with vaping during the pandemic, stating nicotine may increase the number of ACE2 receptors, which are the "[receptors] this specific virus hijacks to get into cells." However, some Redditors suggested vaping may be beneficial for fighting or preventing COVID-19. One Redditor described how studies show inhaling PG can "prevent you from getting the flu" and argued PG has "incredible antimicrobial effects," reporting they would continue vaping. Another said "nicotine [and PG] kill bacteria," concluding that vaping was beneficial. Others made claims without proposing a mechanism, such as "vaping...help[s] against pneumonia."

Some posts reflected the salience of former smoking on e-cigarette– and COVID-19–related beliefs. For example, in response to an OP who asked whether concern about the risks of vaping and COVID-19 was causing people to stop vaping, several Redditors commented on how vaping "makes a huge difference" (compared to smoking cigarettes) on the severity or frequency of respiratory infections, implying that the relative wellbeing is evidence that vaping does not increase COVID-19 risks.

Reddit threads served as a forum to discuss information about the COVID-19 pandemic, and Redditors cited information from a variety of sources, including public health authorities and scientific organizations, traditional media sources, such as newspapers and televised broadcasts, and informal news sources, such as blog and social media posts. The thread mentioned earlier, which included the OP asking about the risk of vaping (submitted on March 18, 2020) and 120 comments, offers an interesting case of how Redditors pieced together the range of questions about vaping-related risks. The tone and quality of the debate varied across comments, which included personal anecdotes, scientific claims, and commentary on the quality of the discussion. Many posts included unsubstantiated claims. Other comments supported claims with a range of sources, including articles from PubMed, a publicly accessible database of scientific and medical research funded by the US federal government. Some comments asked for evidence to support others' claims, offered corrections, and identified logical fallacies (eg, noting the claim that vaping was better for respiratory health than smoking did not address the question of whether, in the absence of smoking, vaping was better than not). One post asked the subreddit to avoid circulating opinions and stay very close to high-quality sources of information to protect public safety, and a comment on another thread noted to the OP that the subreddit was the not the best place to ask about perceptions about vaping and covid risk, "seeing as everyone is going to have a biased opinion."

As we have documented, Redditors credited beliefs about whether and how COVID-19 and e-cigarette risk interacted for driving their behavior change. In some instances, it was apparent that the conversations in subreddits influenced the development of these beliefs. Some conversations suggested that the media individuals consumed had a profound impact on their perceptions, thoughts, and behaviors during this time. Perhaps most colorfully, one Redditor commented, "HOLY FUCK. There is so much contradictory evidence. I'm like a sheep. I read one comment and put my [vape] away. I read another and pick it up! I just need to stop using this shit."

We found evidence that individual factors moderated one's interpretation and understanding of Reddit and media content (Figure 2). Perceived contradictions between sources, a Redditor's level of trust in each source, assumptions, and understanding of the scientific process altered how Redditors weighed new information. For some Redditors unfamiliar with the research process, distrust emerged when recommendations for pandemic safety changed as additional research was published.

The underlying trust of an information source influenced a Redditor's assessment of risk regarding COVID-19, vaping, and their intersection. When an OP asked whether they should vape less during the pandemic, a commenter said no, stating "all the bs" in the media is grounded in "zero actual science." Another Redditor complained that officials "refer to all nicotine intake as 'smoking'" and emerging studies regarding ACE2 receptors and smoking show "how incompetent and ignorant" officials are in the United States. These generalizations across nicotine delivery methods and seemingly conflicting scientific evidence likely deepened the distrust of the media for this individual.

Discussion

Principal Findings

Our qualitative thematic analysis of e-cigarette–related conversations on Reddit during the early months of the COVID-19 pandemic revealed changes in amount, frequency,

XSL•FO
RenderX

product type, purchasing behaviors, and use practices from the widespread effects of the COVID-19 pandemic. By examining the "nuanced deliberations" [40] in social media communities of people who use e-cigarettes, our study illuminates how the variety in behavioral responses during the pandemic evolved in response to socioecological changes, individual nicotine and tobacco product use history, perceptions and beliefs, the information environment, and the interactions between these factors.

Our finding of mixed behavioral changes from the pandemic's impact on everyday life is consistent with other reports about e-cigarettes [24,44], and we hope our model can help piece together the growing work on the contextual and individual factors [45] to explain *why* behavior change was so varied. On the one hand, Reddit conversations suggested that reduced access to e-cigarette products, salient health messages and concerns [46,47] (although Klemperer et al [48] report mixed findings), and changes in circumstance encouraged cutting back and quitting. On the other hand, stress, boredom, unstable routines, and changes in activity space (eg, working from home [49]) encouraged more nicotine use [50] or deterred cessation. Other findings suggest that for individuals trying to quit, pandemic-related stress might have undermined coping skills and therefore suppressed cessation [51]. Studies on alcohol consumption [52] and cigarette smoking [12] suggest variations in the types and sources of stress may explain some of the divergence in e-cigarette use behavior. Our observation that some Redditors were concerned about product access and stockpiled vaping materials early in the pandemic is consistent with previous reports about e-cigarettes [53] and resembled stockpiling of essential goods (eg, meat and toilet paper). The similarity suggests that these individuals considered e-cigarettes an essential good.

Our research builds upon previous work that identifies social media as a key space for individuals to seek health-related advice, information, and community, demonstrating in the context of vaping during the pandemic how the community-building and knowledge-sharing functions of social media can affect people's health behavior. In another Reddit study, Sharma et al [40] found that people with mental illness perceived that web-based discussion about the shared interest in vaping facilitated social connectedness for them. We speculate that during the early months of the COVID-19 pandemic, when other socializing may have been scarce and access to substances was limited, Reddit and other social media platforms were particularly important for connectedness and support among individuals who use substances [54-56]. Still, using social media has also been associated with cigarette and e-cigarette use [29,57,58], and an intervention during the first year of the pandemic reported that a 30-minute reduction in daily social media use decreased smoking behavior [59].

Misinformation can easily circulate on the web because the credibility of information on social media cannot be certified, and social media algorithms create "echo chambers." The Online Misinformation Engagement Framework identifies four stages in which people engage with web-based misinformation as follows: (1) selecting information sources, (2) choosing to consume or ignore the information they are exposed to, (3) evaluating that information (ie, evaluation), and (4) engaging with the information (ie, reaction). In times of scientific and social uncertainty, when public health messaging is limited and competing with misinformation, people might turn to social media communities seeking advice, information, and strategies from people they perceive as trustworthy (ie, the pandemic might have impacted stage 1: source selection) [1]. Our findings suggest Reddit served as a trusted source of information about e-cigarettes for community members during the early pandemic. Previous work has documented social media conversations about the intersection of vaping and COVID-19, including health concerns and unsubstantiated claims (Twitter [60] and YouTube [32]). In the discussion we observed, some Redditors critically evaluated the claims (stage 3: evaluation) and engaged in peer-to-peer debunking (stage 4: reaction); however, we do not know the extent to which all viewers engaged in these behaviors and whether these actions impacted perceptions of those reading.

There remains no definitive information about the intersection of COVID-19 and vaping risk [36]. Some claims in our dataset do appear to be supported by scientific evidence [36]. In addition, it is likely that Redditors were sincere in their discussion, as evidence suggests that people rarely share misinformation intentionally. Still, most posts engaged with just one or a few dimensions of this complicated question, and it appears individuals made decisions based on incomplete information. Cognitive bias might also be at play. A UK study reported that adults who used e-cigarettes were more likely to assert that using e-cigarettes decreased or did not affect the risk of severe COVID-19 symptoms [34], although empirical evidence of the effects was uncertain. The conversations we analyzed likely reflected and potentially perpetuated this optimism bias. In addition, misinformation (including incomplete information) might spread more easily in vaping subreddits, which engage a relatively homogenous network than a more general subreddit with more diverse participants [61].

We posit that Reddit conversations impacted behavior both directly (eg, providing advice for vape repair) and indirectly by informing beliefs (including both accurate and inaccurate perceptions). Consistent with our finding that information on Reddit influenced decision-making for some Redditors, a study of college students found that exposure to and seeking COVID-19–related news was related to lower odds of pausing smoking or vaping [62]. We speculate that the sometimes heated discussion of information, including misinformation, in these subreddits might have increased some Redditors' already heightened pandemic-related stress and perhaps contributed to vaping escalation or avoided reduction in vaping intensity. Moreover, exposure to inaccurate information might have a lasting impact; for example, Redditors who vaped more believing that it would decrease their odds of contracting COVID-19 would inadvertently increase their e-cigarette–related health risks. An observational study of people who had tried to quit using e-cigarettes reported higher relapse among people who recalled at least one misinformation claim about COVID-19 and nicotine [63]. Other information might have also increased the risk. Redditors who followed suggestions on how to extend the life of their e-cigarette devices (eg, making their own coil) might have been exposed to more toxic chemicals. Studies on

XSL•FO
RenderX

the health effects of improper use of e-cigarette devices can inform our understanding of the extent to which the pandemic not only influenced use frequency but changed the risk profile of e-cigarette use.

Our study demonstrates the value of qualitative work in behavioral research, as it illuminates the nuance of how often, how much, or in what way people use vaping products. Our qualitative analysis elucidates the array of socioecological and personal considerations Redditors had at the time. This array of experiences might help explain conflicting findings between quantitative studies with different samples [17,64]. It also suggests that, because summary statistics obscure bidirectional impacts, cross-sectional analyses will likely underestimate the extent to which e-cigarette practices were impacted during the crisis. Longitudinal, quantitative surveillance will determine how widespread and long-lasting the pandemic's impacts were on vaping at a population level. Qualitative work can contextualize those impacts. In addition, while quantitizing social media data can reflect overall discussion topics [43], qualitative analysis can reveal the community dynamics, such as the role of personal anecdotes on risk perceptions, that play out in those discussions.

The lack of unified messaging about e-cigarettes reflected on Reddit is not a new problem and follows a decade of conflicting messages. The e-cigarette industry has advertised e-cigarettes as a cigarette cessation device. Scientific evidence is mixed on their effectiveness for cessation and relative health benefits. The outbreak of e-cigarette, or vaping, product use–associated lung injury resulted in a growing but unsubstantiated perception that e-cigarettes may be more dangerous than combustible cigarettes [65]. There is a need for consistent, easy-to-understand messaging to fight misinformation on the web about COVID-19 and the risks and practices associated with e-cigarettes. Applying the tools of infodemic management might improve vaping-related communication [3]. Although an experimental study reported that US adults perceived messages that linked smoking to COVID-19 as effective for decreasing vaping [66], our findings suggest that messages and evidence specific to e-cigarette use rather than tobacco products overall would be viewed as more trustworthy and acceptable. Leveraging many communication channels can be an effective way to reach target audiences with antivaping campaigns [67], and Reddit itself might be a potential avenue for health communication interventions [68].

Moreover, e-cigarette interventions might address underlying causes of substance use, misinformation, and distrust. Much of our data revealed the impact of stress, coping, mental health struggles, and feelings of stigmatization, including from public health officials. We expect cessation messaging that acknowledges the experiences and struggles of individuals who use e-cigarettes and the meaning that e-cigarettes have in their lives (eg, stress relief) might better resonate with this population. This and other work highlight the role of community dynamics of social media in information exchange; health communication might leverage these relationships to disseminate accurate health information. Structural- and individual-level misinformation interventions across stages of engagement (eg, content labels, introducing friction that encourages the viewer to pause before sharing information) will also likely improve the quality of decision-making [69] about vaping.

Limitations

Our analysis aimed to document e-cigarette behavior change and reveal mechanisms through which the early pandemic and related infodemic impacted behavior; our findings may be an incomplete list or overemphasize the experiences of more active Redditors. Moreover, many individuals may not have changed their e-cigarette use behavior at all and the behavior changes that we report may have been only temporary.

The unobtrusive methods that allowed us to observe Reddit conversations were limited in several ways. Because we did not communicate with Redditors, our ability to contextualize narratives in the specific national and local policy and social norms was restricted to the information Redditors disclosed, we are unable to determine how long changes lasted, and we cannot describe our sample's demographic characteristics or baseline use behaviors. Redditors are predominantly White and male; therefore, it is likely that our study overemphasized their experiences [70,71]. Pandemic-related stressors might have intersected with and compounded experiences of minority groups' stress [72,73] and resulted in increased vaping [74-76]; by contrast, resilience, optimism, and sense of community might have buffered some individuals with minoritized identities from that stress [77,78]. Work that investigates the digital experiences of minoritized groups during the pandemic is essential [79]. Our team is composed of female researchers in the United States; therefore, we might have missed cultural cues outside of our experience or expertise. We have not documented how perceptions and behaviors have evolved since June 2020 as new information emerged, policies changed, and more recent waves of the pandemic occurred. Although the specific perceptions about the relationship between vaping and COVID-19 might not be transferable today, we believe our findings speak to broader questions about the role of social media in information exchange during a crisis and the relationship between people who use e-cigarettes and public health.

Conclusions

This study elucidated how people make decisions about their health during a time of informational and social uncertainty. Information is gathered from a variety of sources, increasingly from social media platforms like Reddit, making public health research on these platforms critical. We were able to gain insight into the way people processed and discussed information and identify individual and environmental changes (eg, local laws and supply chain) that provide an explanation for why there was no unified direction of e-cigarette behavior change during the early pandemic. Social media is an effective and important place to communicate public health information, particularly during crisis or disaster situations, and it is crucial that e-cigarette information is accurate, transparent, accessible, nonstigmatizing, and specific to the target population.

Acknowledgments

The authors express gratitude to Minji Kim, Alyssa Bercasio, and Kamara Shaw for their help, support, and feedback on this work and to the Redditors for sharing their insights and experiences during this unprecedented time. This work was supported by the American Cancer Society (IRG 18-165-43), administered through the Holden Comprehensive Cancer Center at the University of Iowa, the University of Iowa Office of Undergraduate Research, and the University of Iowa College of Public Health. KS conducted this work as an undergraduate student at the University of Iowa. ES and LF completed this work as Master's of Public Health students at the University of Iowa.

Data Availability

The dataset generated and analyzed during this study is not publicly available; although Reddit posts are publicly available and anonymized by username, Redditors did not consent for their content to be shared publicly in a curated dataset. The dataset is available from the corresponding author on reasonable request for research purposes.

Authors' Contributions

SLW (principal investigator) contributed to conceptualization; methodology; investigation; validation; writing the original draft; writing, reviewing, and editing the manuscript; supervision; and funding acquisition. KS contributed to conceptualization; methodology; investigation; data curation; writing the original draft; writing, reviewing, and editing the manuscript; visualization; and funding acquisition. ES contributed to the methodology and writing, reviewing, and editing the manuscript. LF contributed to investigation; writing the original draft; and writing, reviewing, and editing the manuscript.

Abstract

Background: Virtual follow-up (VFU) has the potential to enhance cancer survivorship care. However, a greater understanding is needed of how VFU can be optimized.

Objective: This study aims to examine how, for whom, and in what contexts VFU works for cancer survivorship care.

Methods: We conducted a realist evaluation of VFU among patients with breast cancer and prostate cancer at an urban cancer center during the COVID-19 pandemic. Realist evaluations examine how underlying causal processes of an intervention (mechanisms) in specific circumstances (contexts) interact to produce results (outcomes). Semistructured interviews were conducted with a purposive sample of patients ≤5 years after diagnosis. Interviews were audio-recorded and analyzed using a realist logic of analysis.

Results: Participants (N=24; n=12, 50% with breast cancer and n=12, 50% with prostate cancer) had an average age of 59.6 (SD 10.7) years. Most participants (20/24, 83%) were satisfied with VFU and wanted VFU options to continue after the COVID-19 pandemic. However, VFU impacted patient perceptions of the quality of their care, particularly in terms of its effectiveness and patient centeredness. Whether VFU worked well for patients depended on patient factors (eg, needs, psychosocial well-being, and technological competence), care provider factors (eg, socioemotional behaviors and technological competence), and virtual care system factors (eg, modality, functionality, usability, virtual process of care, and communication workflows). Key mechanisms that interacted with contexts to produce positive outcomes (eg, satisfaction) were visual cues, effective and empathetic communication, and a trusting relationship with their provider.

XSL•FO
RenderX

Conclusions: Patients value VFU; however, VFU is not working as well as it could for patients. To optimize VFU, it is critical to consider contexts and mechanisms that impact patient perceptions of the patient centeredness and effectiveness of their care. Offering patients the choice of in-person, telephone, or video visits when possible, coupled with streamlined access to in-person care when required, is important. Prioritizing and addressing patient needs; enhancing physician virtual socioemotional behaviors and technology competency; and enhancing VFU functionality, usability, and processes of care and communication workflows will improve patient perceptions of the patient centeredness and effectiveness of virtual care.

cancer; follow-up; virtual; outcomes; realist evaluation; survivorship

Introduction

According to report "Canadian Cancer Statistics 2023," 1 in 2 Canadians will be diagnosed with cancer in their lifetime, and two-thirds of Canadians diagnosed with cancer today will live for ≥5 years after their diagnosis [1]. Among the most common cancers in men and women, the 5-year net survival rate is 87% for breast cancer (BC) and 95% for prostate cancer (PC) [1]. While these outcomes reflect advances in early detection and treatment, they have substantially increased the demand for follow-up care services. Optimal follow-up care consists of surveillance for cancer spread, recurrences, or secondary cancers; prevention and management of acute and persistent treatment side effects; and promotion of healthy behaviors to mitigate new and ongoing health concerns [2]. To be effective, this involves ongoing assessment and comprehensive care, including referral to specialized supportive care services to improve quality of life, reduce disability, and restore function [3,4].

In Canada, and internationally, follow-up cancer care is typically provided by oncologists in outpatient secondary or tertiary care settings. Evidence suggests that this model of in-person follow-up care with a specialist is not sustainable and is not working well for patients [5]. Oncology offices are often overcrowded with long wait times, short appointments, and high costs per visit [6]. Furthermore, the high burden of unmet posttreatment supportive care needs suggests that the existing model of follow-up care is not meeting patients' needs [7,8]. Alternatives such as follow-up with primary care providers are comparable to oncologist-led follow-up in terms of detection of recurrence, survival, and quality of life [9,10]. However, prior work [6,11,12] shows that many survivors of cancer prefer to be seen by an oncologist for follow-up due to concerns about the quality and continuity of care.

One method proposed to improve the experience and effectiveness of cancer follow-up care is virtual care, defined as remote interactions between patients and care providers using technology (ie, video calls, telephone, email, etc) [13]. Virtual follow-up (VFU) could alleviate pressure on clinicians and health care services and better meet patient needs by providing patients with access to timely, convenient, and tailored follow-up care [14]. Before the COVID-19 pandemic, virtual care was infrequently used in Canada, mainly to provide care to rural and remote populations [13], and the evidence of its effectiveness was limited [15]. During the COVID-19 pandemic, there was rapid and widespread adoption of virtual care in Canada and globally [16]. In a prior study, we demonstrated that most patients with cancer were satisfied with VFU during the COVID-19 pandemic, but some did not want VFU to continue after the COVID-19 pandemic [17]. In addition, while virtual visits made care more accessible for some, other studies have shown that virtual care has exacerbated access disparities by widening the digital divide for those who lack the knowledge or technological means to access care virtually [18,19].

To sustain VFU as an option for patients with cancer, we need a better understanding from patients on how, for whom, and in what contexts this model of care works. Patient perspectives on how to optimize VFU care can inform updates to telehealth clinical practice guidelines, such as those offered by the American Association of Clinical Oncology (ASCO) early in the COVID-19 pandemic [20], to ensure patient-centered virtual care. Realist evaluations are ideally suited to answer these questions. Realist evaluations are a proven, theory-driven method that enable a rigorous understanding of context and its influence on causal processes (ie, mechanisms) to explain how and for whom an innovation works best [21,22]. This method is increasingly used to assess complex innovations in health care, particularly those that involve multiple interconnected components and are dependent on individual responses and the wider context for their success [23,24]. Therefore, we conducted a realist evaluation [21] to examine how, for whom, and in what contexts VFU works for patients with BC and PC and conclude with recommendations for optimizing VFU for patients with cancer.

Methods

Ethical Considerations

The study was approved by the University Health Network Institutional Research Ethics Board (ID 21-5397). Informed consent was obtained from all study participants before data collection, and all data were deidentified before analysis. All study participants received a CAD $25 honorarium to compensate for their time. At the time of the study, US $1 was equal to CAD $1.30.

Study Design

We conducted a realist evaluation following the steps by Pawson and Tilley [21] and RAMESES [23] quality and reporting guidelines.

Step 1 involved developing an initial program theory, which is a kind of conceptual framework, to explain how VFU could be

XSL•FO
RenderX

delivered to work most effectively. This involved explaining how the underlying processes of VFU care (mechanisms) interact with specific circumstances (contexts) to produce results (outcomes). For this step, we used prior evidence to understand patient views [25] and the effectiveness of virtual versus in-person cancer care [15], theories from technology adoption [26-28] to understand factors that influence the adoption of VFU and theories from patient-provider communication [29] to determine the essential elements of effective clinical encounters, and the 6 domains of health care quality identified by the Agency for Healthcare Research and Quality [30] to understand the attributes of quality VFU. Using these information sources, we created a figure to illustrate how VFU can bring about the desired outcomes. We then held a 2-hour virtual workshop with project team members and stakeholders, consisting of clinicians, researchers, and patient partners (N=10) to obtain their views on the initial theory.

Step 2 involved collecting evidence on the contexts, mechanisms, and outcomes of VFU. For this, we (1) administered a web-based survey to patients at a cancer centre to obtain information on their sociodemographic characteristics, experience, and satisfaction with VFU [17]; (2) purposively recruited a subsample of survey respondents to participate in semistructured interviews to explore their views and experiences with VFU in greater depth; and (3) administered a short follow-up survey to collect information on interview participants' psychosocial well-being.

Steps 3 and 4 involved data integration and synthesis using a realist logic of analysis. The goal of this analysis was to determine whether data were functioning as context, mechanism, or outcome, and if so, within which context-mechanism-outcome configuration (CMOC) [23]. We then held a 2-hour virtual stakeholder workshop with a wider group of stakeholders (N=12) to obtain feedback on the relevance of our findings more broadly.

Setting and Participants

This study was conducted at the Princess Margaret (PM) Cancer Centre, a tertiary, university-affiliated, teaching hospital, which is a part of the University Health Network in Toronto, Canada. Before COVID-19, <1% of visits at PM were conducted virtually [31]. After the declaration of the COVID-19 pandemic, 68% of visits at PM were virtual [31]. The participants in this study comprised a subsample of patients with BC and PC who had completed the PM Virtual Care Evaluation Survey between May and July 2021 [17] and who agreed to participate in a follow-up interview. Interviews occurred between September and November 2021. Survey participants had to meet the following criteria: they must have received a cancer diagnosis, be aged >18 years, have participated in at least 1 virtual appointment (eg, by phone or video) in the last 12 months, and have a valid email address on file. We used the survey data to intentionally select interview participants who varied in age, ethnicity, geographic location, and satisfaction with VFU. In addition, to be eligible to participate in an interview, survey respondents must have agreed to be contacted about a follow-up interview, received a diagnosis of BC or PC within the last 5 years, and completed treatment for cancer or were receiving adjuvant hormone therapy. On the basis of previous research, a sample size of 15 per patient group (30 in total) was estimated to be sufficient [32,33]. However, data collection continued until theoretical saturation [34].

Data Collection

First, data on participants' sociodemographic characteristics and virtual care use and perceptions were extracted from the PM Virtual Care Evaluation Survey to describe the sample and inform each interview. Demographic data included age, whether they were born in Canada (yes or no), English as a first language (yes or no), race or ethnicity (10 response options), highest level of education (high school or less, college or technical school, university undergraduate, or postgraduate), and household income (CAD <$60,000, CAD $60,000-$99,000, or CAD ≥$100,000). Virtual care use and preferences were assessed by asking participants to indicate the type of virtual appointments they had received and would have liked to receive in the past 12 months (phone, video, or both). Patient satisfaction with virtual care was captured using a 5-point Likert response (very satisfied, satisfied, neutral, dissatisfied, or very dissatisfied). Patient desire for virtual care options after the COVID-19 pandemic was captured by asking participants to indicate their level of agreement with the statement "I would like to continue to have virtual options for some of my visits after the COVID-19 pandemic ends," using a 5-point Likert response option (strongly agree, agree, neutral, disagree, or strongly disagree).

Each participant then took part in one 45- to 60-minute semistructured interview based on the realist approach [21,22]. They were asked about their initial expectations and desired outcomes of VFU, how it worked or did not work for them, and how VFU could be made to work optimally. The interviews were conducted by a research coordinator with experience in qualitative interview methods (SB) who was trained in realist methodology by a realist expert on the team (GW). Interviews were audio-recorded and transcribed verbatim.

After the interview, participants completed a brief survey on their level of patient activation, anxiety, and depression. Patient activation was measured using the Patient Activation Measure [35], which scores a patient's knowledge, skills, and confidence for proactively managing their health and health care using a 13-item tool with 4-point Likert scales. The Patient Activation Measure scores (between 0 and 100) were converted into four levels of activation: (1) not believing (patient) activation is important (score of ≤47.0), (2) a lack of knowledge and confidence (score of 47.1-55.1), (3) beginning to take action (score of 55.2-67.0), and (4) taking action (score of ≥67.1). Anxiety was measured using the Generalized Anxiety Disorder 7-item [36], and depression was measured using the Patient Health Questionnaire-9 [37]. Anxiety and depression scores were converted into the following categories: minimal (score of 0-4), mild (score of 5-9), moderate (score of 10-14), moderately severe (depression score only [15-19]), and severe (score of 20-27 on Patient Health Questionnaire-9 or 15-21 on Generalized Anxiety Disorder 7-item). Fear of recurrence was measured using the Fear of Cancer Recurrence Inventory-Short Form [38], a 9-item severity scale that evaluates intrusive thoughts associated with fear of cancer recurrence using 4-point

XSL•FO
RenderX

Likert scales. A score of ≥13 on the Fear of Cancer Recurrence Inventory-Short Form denotes a clinically relevant fear of cancer recurrence.

Data Analysis

A realist logic of analysis was used to analyze interview transcripts [21], with the support of NVivo (version 14; Lumivero). The coding was both deductive (some codes were created in advance informed by the initial program theory) and inductive (some codes emerged from the data). The data were initially sorted into broad conceptual categories or "buckets" by 2 team members independently (SB and SS) through consultation with the lead author (JLB). The buckets were developed following data collection both deductively and inductively based on the initial program theory and what was found in the data. They were further analyzed by 1 team member (SS) to develop preliminary themes and CMOCs. As there were no meaningful differences across the 2 groups of BC and PC participants, the data were analyzed and reported jointly. The themes and CMOCs underwent an intensive refinement process with 3 research team members (JLB, GW, and SS) to ensure they were clear, concise, and representative of the interview data. Repetitive or redundant CMOCs were removed. The data were then used to refine the program theory. Descriptive statistics were used to summarize patient demographic characteristics, virtual care use, patient activation, and psychosocial well-being using R (version 4.1.2; R Foundation for Statistical Computing).

Results

Participant Characteristics

In total, 24 patients were interviewed; of these, 12 (50%) had been diagnosed and treated for BC and 12 (50%) had been diagnosed and treated for PC (Table 1). On average, the participants were aged 65.9 (SD 8.65) years, 100% (24/24) attended postsecondary school, and 71% (17/24) reported a household income of CAD ≥$100,000. Approximately half (11/24, 46%) of the sample identified as racialized, 50% (12/24) were born outside of Canada, and 20% (5/24) had a non-English first language. The most common treatment type was surgery (18/24, 75%), followed by radiation therapy (17/24, 71%) and chemotherapy (9/24, 37%). This was a highly activated sample, with most (18/24, 75%) at level 3 or 4 on the patient activation scale and most with relatively mild or minimal depression (18/24, 75%) or anxiety (20/24, 83%), and most participants (15/24, 63%) reported nonclinical levels of fear of recurrence.

VFU Use and Preferences

All participants received a phone call appointment (Table 2). Most patients with BC also received a video appointment (20/24, 83%); none of the patients with PC received a video appointment. Overall, most participants (20/24, 83%) were satisfied or highly satisfied with their virtual care visits, and most participants (20/24, 83%) would want VFU options to continue after the COVID-19 pandemic. When asked which type of VFU appointment they would prefer in the future, most patients (15/24, 63%) indicated video appointments.

Views and Experiences With VFU

Overview

We identified 8 overarching concepts that captured patients' views on how VFU could be made to work effectively. These 8 concepts consisted of 24 themes and 46 CMOCs (Multimedia Appendix 1). Due to the number of CMOCs that were developed, each CMOC is labeled with a code (eg, A1, A2) found in Multimedia Appendix 1 (for ease of reference). The findings related to each CMOC are labelled with a matching code throughout the Results section. The concepts, themes, and CMOCs were used to refine the program theory (Figure 1).

XSL•FO
RenderX

Figure 1. Refined program theory.

Effectiveness

Effectiveness of VFU appears to be influenced by patient-, physician-, and disease-related contextual factors. For example, VFU was considered ineffective if it replaced physical appointments all together, as physical examinations and speaking to a physician in person reduced patient anxiety about recurrence and management of ongoing side effects (A1). In-person appointments provided visual cues (ie, body language, facial expression, etc) that helped patients understand the meaning of information received from their provider and feel more confident in their care (A2). However, participants felt that this may be partly overcome through video appointments, as video allows patients and care providers to read each other's body language and facial expressions. This may be particularly important for patients experiencing high levels of anxiety about their cancer, as the lack of visual cues with phone calls causes VFU to be insufficiently reassuring (A3). Participants also felt that it was important for physicians to see the visual cues of the patient, as this would enable the physician to pick up on distress or concern that may not be verbally expressed by patients and act accordingly (A4). The final contextual factor described to impact effectiveness of VFU was the perceived loss of the appreciation of the seriousness of cancer. In-person appointments act as a reminder of the seriousness of the condition. Without in-person appointments, patients were concerned that they may become less vigilant in their self-care and self-management (eg, nonadherence to medication or forgetting self-examinations; A5).

Efficiency and Timeliness

If participants felt that the VFU they received was both efficient and timely, they were more likely to be satisfied with their care. These participants felt that VFU would likely improve the overall efficiency of follow-up care, as they believed hospitals could save time and money by scheduling more appointments per day (B1). Participants also believed that greater use of virtual appointments could improve the experience of in-person appointments (when required), as hospital waiting rooms would be less crowded and stressful (B2).

However, some participants expressed concerns that VFU could lead to delays in receiving care. Many described being given very long windows of time for their VFU appointments, which

XSL•FO
RenderX

were difficult and frustrating to plan around (B3). In some cases, physicians called outside of these time windows, which led to missed appointments or patients having to speak to someone other than their principal care provider (B4). These types of situations were anxiety inducing for patients, particularly if they had concerns to share with their provider as they feared that their condition would worsen while waiting for a rescheduled appointment (B5). Issues with timeliness may also occur if patients have difficulty booking timely appointments due to long wait times for callbacks or uncertainty about whom to contact (B3).

Patient Centeredness

The largest conceptual bucket by far was related to patient centeredness. Participants described ways in which VFU can be more or less patient-centered compared to in-person care, and how this impacted how well VFU worked for them. This included references to personal values, preferences, and expectations of VFU and how these measured up to their experiences. A patient's preferences and expectations were influenced not only by their unique life circumstances but also by health system characteristics, such as continuity of care. Participants were concerned that the number of care providers involved in their care may increase with VFU due to physicians being busier with more appointments. Participants explained that receiving care from multiple care providers made them feel less cared for because they had less time to form trusting relationships with each provider (C1). This was particularly anxiety inducing for those who were newly diagnosed, as they were particularly vulnerable and in need of a strong physician-patient relationship (C2). In addition, they explained that receiving care by multiple care providers led to poor continuity and quality of care due to a lack of communication between care providers. This was frustrating for participants, as they felt they had to continually repeat their history to their care providers, and they were concerned that their care would be negatively impacted by their physician not having a comprehensive understanding of their case (C3 and C4).

Difficulty forming relationships with care providers was also heightened when participants had never been given the opportunity to meet their provider face-to-face, as they felt this hindered their ability to open up emotionally (C5). Some participants felt that the care they received was more holistic and empathetic when provided face-to-face, and they valued the ability to visually see that they had the full attention of their care provider (C6). Therefore, participants appreciated when their care providers would make use of video calls for their VFU appointments. However, most participants also expressed that their VFU appointments felt rushed compared to in-person appointments, which made them feel less cared for as they were unable to take the time needed to process information and ask questions (C7). Many participants felt their VFU appointments only addressed their clinical or medical issues, as opposed to the personal issues that accompany a cancer diagnosis, which caused them to have unmet needs (C8). This may be because the nature of VFU tends to favor information provision rather than emotional support (C9).

When patients leave active treatment, some described feeling "lost in the system." This may be increased with VFU, as not entering hospitals means that it may be more difficult for patients to access support when needed (C10). Participants felt that VFU may be improved if it included straightforward processes to obtain information, support, and care when needed, which would prevent them from feeling abandoned. This could include the ability to communicate with their care provider via technology (ie, email) in between appointments (C11 and C12). In addition, participants expected their care providers to continue to provide referrals to supportive care programs, but this was not always the case with VFU (C13).

Finally, participants appreciated that VFU improved the convenience of care. Patients did not have to travel to the hospital for their appointment, which saved them time and money (C14). They also appreciated that they could attend their appointments from anywhere, including from the comfort of their own home, which avoided stressful and slow waiting rooms (C15). This also meant they could multitask while waiting for appointments, meaning VFU was less disruptive to their schedule (C15). VFU also allowed family members to be included in VFU appointments, which was particularly valuable when COVID-19 prevented family members from attending in-person appointments (C16). Many participants felt that these advantages of VFU outweighed the benefits of in-person care.

Equity

Follow-up care works best when it is equitable for every patient. Participants noted that VFU may limit access to care for those with certain sociodemographic characteristics such as a disability, older age, or low socioeconomic status. For example, participants expressed concern that someone with hearing loss may face difficulties speaking over the phone, and someone with vision loss may struggle with video appointments (D1). Some participants also considered that some individuals may not have access to fast internet or that those with a lower level of education may be unable to search for medical information on the internet if they are not given time to ask questions during VFU appointments (D2 and D3).

Safety

Participants noted that VFU could improve safety by decreasing their risk of being exposed to infectious diseases such as COVID-19 (E2). However, some participants felt that VFU may be less safe because it removed the ability to be physically examined by an oncologist, potentially resulting in poorer care. Turning elsewhere for care (such as the emergency room) caused participants to feel they were being inadequately cared for (E1).

Patient Characteristics

Whether VFU worked well depended on patient characteristics that impacted their suitability and preferences for virtual care. This included comfort with technology, as some participants described challenges that they and others may have with navigating and using VFU technology (F1). Participants who had experience working within a virtual environment had an easier time using VFU and therefore were more likely to be satisfied with it (F2).

XSL•FO
RenderX

Other patient factors that influenced whether VFU was suitable included clinical characteristics such as mental health, disease characteristics, or comorbidities. Those with complex issues (ie, fear of recurrence, severe side effects, anxiety, and recently completed treatment) reported a greater need for reassurance, acknowledgment, and help coping with their adversities, along with a higher reliance on physical examinations, making them a poorer candidate for VFU (F3). The opposite was true for those who experienced fewer side effects and whose appointments mainly addressed simple routine check-ups, making them ideal candidates for VFU (F4).

At the same time, VFU seemed to overcome access barriers experienced by those who are less likely to seek health care. Participants who described themselves as being reluctant to access the health care system (eg, due to a lack of time, downplaying their condition, not the type to seek care, etc) appreciated the convenience and efficiency of VFU, which they explained motivated them to access health care (F5). Finally, a patient's preference for VFU seemed to depend on their coping style. Those who described themselves as requiring considerable emotional support (ie, emotional coping) felt that VFU did not work as well for them because VFU tends to focus on information provision over emotional support (F6). In contrast, those who did not require as much emotional support (ie, problem-focused coping), appreciated the simple, quick information-provision appointments (F7).

Physician Characteristics

Many participants described the importance of physician competence and bedside manner regardless of whether the appointment was virtual or in person. If a physician did not appear to be comfortable with the VFU technology, participants judged the physician as less competent in providing care and were concerned that this could impact the quality of their care (G1). In addition, if a physician was less empathetic, patient, or comforting during VFU compared to in-person appointments, participants stated that they would not prefer this type of care as they would feel less cared for (G2). Most participants described feeling more rushed and less listened to during phone appointments, as if the appointments were only for the purpose of sharing information such as test results and not for the purpose of addressing emotional concerns (G3). Some participants felt that "webside manner" is something that could be improved with proper training (G4).

Virtual Care System Characteristics

The final factor found to impact whether VFU works well for patients was the characteristics of the virtual care system itself. The most discussed topic was VFU modality, as most patients were not offered the choice between having their VFU appointments via phone or video. Some participants were okay with this, as they felt the VFU modality that they were offered was effective for their needs. However, others were disappointed that they were not given a choice in the modality. They felt that being provided the option for video appointments would have increased the quality of their care as they could have benefitted from face-to-face communication (H1). That said, this was only true if the VFU technology worked well (functionality) and was easy to use (usability). Some participants were frustrated with the VFU technology because it was difficult for them to use and did not work well for them (H2). However, when VFU technology does work well, participants described being appreciative of the fact that they could easily access appointments and test results and communicate with their care providers. Participants felt that physicians should be responsible for offering fallback plans if the VFU technology did not work well, such as what to do when a call drops, so that they need not be fearful of the technology malfunctioning (H3). Some participants noted the lack of virtual care processes and communication channels (virtual communication workflows). This caused issues when they did not know how to contact support staff and schedule appointments, when they did not know if their appointment would occur outside of the scheduled time window, and when they did not know what to do if their VFU call or internet connection was dropped or the technology malfunctioned (H4).

Recommendations

The study findings point to several strategies that health care providers and health care systems can use to enhance the patient centeredness and perceived effectiveness of VFU appointments for patients. We have outlined these patient-derived recommendations in Textbox 1, which align with ASCO's guidelines for telehealth in oncology [38] and provide additional considerations to optimize VFU for patients.

Textbox 1. Patient-derived recommendations for improving virtual follow-up (VFU) care.

1. Offer patients the choice of an in-person or virtual visit
2. Offer patients the choice of virtual visit modality (eg, telephone or video)
3. Ensure there is an easy-to-use and efficient process for patients to schedule an in-person visit if needed
4. Clearly communicate how the appointment can be continued if the technology fails and provide technical support
5. Ensure that virtual visit booking and scheduling processes are flexible enough to cater to patient's changing needs and expectations and reduce wait times where possible
6. Make time to listen to patient concerns and provide emotional support during virtual visits
7. Demonstrate empathy and provide your full attention using active listening skills during virtual visits
8. Demonstrate competency with virtual care technology
9. Ensure patients are provided resources and referrals to survivorship care programs during or after a virtual visit
10. Improve the quality of VFU technology and work flows to create a seamless and reliable care experience for patients

Discussion

Principal Findings

To our knowledge, this is the first realist evaluation of VFU for cancer care. This study has helped to answer for whom and in which contexts VFU is most suitable and has identified ways in which VFU could be optimized to better meet the needs of patients with cancer receiving follow-up care. Overall, the patients with BC and PC in this study described themselves as being satisfied with VFU during the COVID-19 pandemic and wanted VFU options to continue after the COVID-19 pandemic. However, VFU impacted patient perceptions of the quality of their care, particularly in terms of its effectiveness and patient centeredness. Whether VFU worked well for patients depended on patient factors (eg, needs, psychosocial well-being, and technological competence), provider factors (eg, socioemotional behaviors and technological competence), and virtual care system factors (eg, modality, functionality, usability, and virtual processes of care and communication workflows). Key mechanisms that interacted with contexts to produce positive outcomes (eg, satisfaction and reassurance) were visual cues, clear empathetic communication, and a trusting relationship with their provider.

Is Virtual Care Suitable for All Cancer Follow-Up Appointments?

While follow-up appointments have been identified by patients with cancer and health care providers and recommended by clinical practice guidelines as suitable for virtual care delivery because of their relative brevity and simplicity [20,39,40], they can be anxiety provoking and complex depending on the circumstances. For example, moderate to severe “scanxiety” (the fear, stress, and anxiety in anticipation of surveillance tests in follow-up cancer care) is present in as many as 28% of survivors of cancer [41]. In a prior study, we reported that survivors of cancer who experienced distress (anxiety or depression) were less likely to be satisfied with VFU and less likely to want VFU in the future compared to those who did not report distress [17]. This study has revealed that patients experiencing distress may not be satisfied with VFU because the quality of emotional support provided virtually is less effective. Participants felt more comforted during in-person visits because they had more time to discuss their concerns and the type of emotional support received was more effective because the visual cues of the provider conveyed empathy and understanding. Interestingly, a systematic review comparing virtual to in-person cancer care on the psychosocial outcomes of patients with cancer found that virtual care from physicians or nurses was more beneficial for patients during active treatment than follow-up [42]. However, a systematic review comparing virtual versus in-person cancer care found virtual psychosocial counseling to be equally effective for follow-up care [15]. The ASCO telehealth guidelines recommend providing individualized orientation and instruction to patients and care providers on the specific technology that will be used for the virtual care interaction [20]. Our findings highlight a need for care provider training in empathetic virtual communication as well, which has been expressed by care providers themselves [43], accompanied with seamless referrals to psychosocial professionals for follow-up psychosocial issues.

For Whom and in Which Contexts VFU Is Most Suited

Importantly, this study has identified for whom and in which contexts VFU is most suited—a knowledge gap that has been identified by many [39,44,45]. In doing so, the study findings align with and considerably expand upon the recommendations of the European Society of Medical Oncology on which patients should be offered telehealth [46]. In its current form, this study has found that VFU is more suited for patients with cancer who are doing well—physically and emotionally—often termed “the well follow-up patient” [11]. From a clinical perspective, this includes patients with no evidence of disease; with limited or well managed treatment side effects including no-to-mild depression, anxiety, and fear of recurrence; who have problem-focused coping styles; and who require limited emotional support from professionals to deal with the effects of cancer and its treatment. From a sociodemographic perspective, this also includes patients who are comfortable speaking in English (for appointments that are in English); who do not have auditory, visual, cognitive, or physical impairments that limit their effective use of VFU technology; who have access to and experience with VFU technology; and who have the education and skills needed to proactively manage their health and health care. VFU is also well suited for patients with cancer with busy schedules and many competing demands, as they appreciate the convenience of virtual visits. It may even increase health care access for those who are typically reluctant to seek care due to the inconvenience of in-person visits.

Hence, it its current form, if VFU was the only option, it would likely increase disparities in access to care for some patients with cancer. Other studies have demonstrated this to be the case. Notably, a study of health care use during the COVID-19 pandemic in the United States found that Black patients had 0.6 times of the adjusted odds of accessing care through telemedicine compared to White patients [19]. However, subgroup analysis revealed that younger Black women were more likely to access care through telemedicine, particularly for urgent care issues. In contrast, a study of access disparities conducted at the same institution as this study identified no differences in virtual care use based on patient demographics [47]. This may be due to the higher socioeconomic status of their study sample, as only 7% identified as low income. Importantly, they found that regardless of visit type, patients who were structurally marginalized by ethnocultural, situational, and residential status, as well as gender, were less satisfied with their care whether it was virtual or in person. These findings highlight the need for proactive and continuous efforts to identify and intervene to address health disparities in access, experience, and outcomes.

How Health Care Providers Can Optimize Virtual Care for Patients

This study also identified strategies that care providers can use to enhance the patient centeredness and perceived effectiveness of VFU for patients. In fact, health care provider behavior was the key contextual factor that triggered the mechanisms (eg, assessment of visual cues, providing full attention, etc) that led

XSL•FO
RenderX

to positive outcomes (eg, patient responses such as trust, reassurance, feeling cared for, and satisfaction). VFU was considered ineffective for patients if care providers did not give patients the option of choosing in-person versus virtual appointments; were not competent using virtual care technology; did not give patients their full attention and time; were less empathetic, patient, and comforting during the virtual visit; or focused on collecting or providing information at the expense of emotional support. Collectively, except for technological competence, these behaviors reflect socioemotional behaviors critical for the effectiveness of the patient-physician encounter. Drawing on social interaction theory, Roberts and Aruguete [48] have shown that patients mostly recognize and react to physician socioemotional behaviors (eg, concern, affection, and attention displayed verbally and nonverbally) due to a lack of understanding of physician task behaviors (eg, explanation of etiology, symptoms, and treatment). In a series of experiments using videotapes of varied levels of physician task versus socioemotional behavior, they demonstrated that high levels of socioemotional behaviors increased patient self-disclosure, trust, satisfaction, and likelihood of recommending the physician. Participants in this study recognized that physician "webside manner" could be improved through training. Likewise, a study of key informants representing Canadian provincial and national health care organizations with expertise in virtual care delivery [43] identified a need to train care providers in how to use technology and integrate virtual care into practice, adapt their clinical skills (including examination skills) to virtual care, build rapport through good communication with patients, and understand when an in-person visit is necessary based on the nature of the appointment and patient contextual factors.

How Health Care Systems Can Optimize Virtual Care for Patients

System transformation is needed to deliver virtual care optimally and equitably to patients. First, health care systems need to enhance virtual care infrastructure and workflows for virtual care to realize its potential for greater efficiency. From a patient perspective, this includes ensuring that VFU technology is accessible, easy to use, and reliable. To increase accessibility, high technology (eg, video) and low technology (telephone and text) VFU solutions are required. Most Canadian studies of virtual care during the COVID-19 pandemic [17,30,49], including this study, reported greater use of telephone than video for virtual care. This was likely due to limited virtual care infrastructure, problems encountered using video, and limited video technology proficiency of patients and care providers. As virtual care technology innovates, low technology options should remain and be offered to patients to ensure equitable access, as broadband connectivity remains inconsistent across Canada [50]. However, the virtual care reimbursement structure needs to change to adequately reimburse care providers for telehealth services. Currently, Ontario's virtual care funding model limits telephone-based care by compensating physicians less for telephone visits compared to in-person visits or video visits [51]. Consequently, physicians might opt to limit their use of telephone visits, potentially leading to reduced access to care for those without high-speed internet access. Establishment of virtual care processes and workflows, along with patient education materials, are needed to seamlessly navigate patients through their virtual care appointment. From a patient perspective, this includes ensuring patients are given the option to choose their virtual visit modality, informed how to use VFU technology optimally, and what to do and who to contact if the technology fails or they require help. Support for technological issues needs to be provided by the system itself, to avoid the responsibility falling on health care providers. These strategies will enhance patient reactions and responses to virtual care, which will result in better outcomes by increasing patient confidence in their ability to use virtual care and patient confidence in the health system's ability to support them if the technology malfunctions or does not work as intended.

Limitations

This study has certain limitations. First, while theory-driven research can provide transferable context-specific understandings of phenomena (in the case of this study, VFU for cancer), inferences about transferability must be tested. In other words, while we may assume that a CMOC operates in a different setting due to the presence of similar mechanisms, this claim should be tested using locally collected primary data. Any testing is aided by the fact that CMOCs are a form of middle-range theory and are expressed in a way that permits empirical testing using primary data. Though our sample was diverse in terms of race, ethnicity, first language, etc, the participants were predominantly high-income, highly educated, and highly activated individuals. As such, our findings may not fully represent the perspective of less activated or less educated patients who may have lower health literacy, be less involved in their care, and face more challenges with virtual care. It is possible that these individuals would differ in their satisfaction with VFU and its suitability as a method of follow-up care. This highlights a need for future research to better understand how VFU could be optimized for populations who face systemic and structural barriers to the use of virtual care. Finally, it may be a limitation that a small subset of participants (6/24, 25%) did not experience an in-person appointment within 12 months of participation. Though it is likely they received an in-person appointment before this date, it is possible that they lacked experience with in-person cancer care with which to compare virtual cancer care. However, we found no obvious differences in the findings between participants who did and did not report in-person appointments during the 12-month period.

Conclusions

Patients value VFU as a part of their care; however, VFU is not working as well as it could for them. To optimize VFU, it is critical to consider the contextual factors and underlying mechanisms that influence patient perceptions of the patient centeredness and effectiveness of their care. Offering patients the choice of in-person, telephone, or video visits when possible, coupled with streamlined access to in-person care when required, is important. Prioritizing and addressing patient needs; enhancing physician online socioemotional behaviors and technology competency; and enhancing VFU functionality, usability, and processes of care and communication workflows will improve the patient centeredness of virtual care. By improving these contextual factors, VFU can be aligned with

XSL•FO
RenderX

patient needs and preferences, resulting in effective, efficient, safe, and equitable follow-up care.

Acknowledgments

The authors would like to gratefully acknowledge all participants who took the time to participate in this study as well as the patient partners who supported this study. This study was funded by the Canadian Institutes of Health Research (grant TT7 128272).

Abstract

Background: Patients undergoing surgery often experience stress and anxiety, which can increase complications and hinder recovery. Effective management of these psychological factors is key to improving outcomes. Preoperative anxiety is inversely correlated with the amount of information patients receive, but accessible, personalized support remains limited, especially in preoperative settings. Face-to-face education is often impractical due to resource constraints. Digital health (DH) interventions offer a promising alternative, enhancing patient engagement and empowerment. However, most current tools focus on providing information, overlooking the importance of personalization and psychological support.

Objective: This study aimed to assess the viability of a DH intervention known as the Adhera CARINAE DH Program. This program is specifically designed to offer evidence-based and personalized stress- and anxiety-management techniques. It achieves this by using a comprehensive digital ecosystem that incorporates wearable devices, mobile apps, and virtual reality technologies. The intervention program also makes use of advanced data-driven techniques to deliver tailored patient education and lifestyle support.
