Journal of Medical Internet Research

Volume 27 (2025) ISSN 1438-8871

Contents

Editorial

Crisis Text Line and Loris.ai Controversy Highlights the Complexity of Informed Consent on the Internet and Data-Sharing Ethics for Machine Learning and Research (e67878)
Gunther Eysenbach. . . . 37

Reviews

Apps and Digital Resources for Child Neurodevelopment, Mental Health, and Well-Being: Review, Evaluation, and Reflection on Current Resources (e58693)
Kelsie Boulton, Makana Hilton, Emilia Sutton, Adam Guastella. . . . 42

Machine Learning Approaches in High Myopia: Systematic Review and Meta-Analysis (e57644)
Huiyi Zuo, Baoyu Huang, Jian He, Liying Fang, Minli Huang. . . . 56

Social Media Potential and Impact on Changing Behaviors and Actions in Skin Health Promotion: Systematic Review (e54241)
Justyna Brzozowska, Joanna Gotlib. . . . 77

Digital Twins for Clinical and Operational Decision-Making: Scoping Review (e55015)
Vahid Riahi, Ibrahima Diouf, Sankalp Khanna, Justin Boyle, Hamed Hassanzadeh. . . . 94

Effectiveness of Integrated Digital Solutions to Empower Older Adults in Aspects Related to Their Health: Systematic Review and Meta-Analysis (e54466)
Ana Martins, Óscar Ribeiro, Gonçalo Santinha, Telmo Silva, Nelson Rocha, Anabela Silva. . . . 116

Clinical Decision Support Using Speech Signal Analysis: Systematic Scoping Review of Neurological Disorders (e63004)
Upeka De Silva, Samaneh Madanian, Sharon Olsen, John Templeton, Christian Poellabauer, Sandra Schneider, Ajit Narayanan, Rahmina Rubaiat. . . . 148

Enhancing HIV Cognitive Abilities and Self-Management Through Information Technology–Assisted Interventions: Scoping Review (e57363)
Hao Huang, MeiLian Xie, Zhen Yang, AiPing Wang. . . . 176

Participant Contributions to Person-Generated Health Data Research Using Mobile Devices: Scoping Review (e51955)
Shanshan Song, Micaela Ashton, Rebecca Yoo, Zoljargal Lkhagvajav, Robert Wright, Debra Mathews, Casey Taylor. . . . 190

Completeness of Telehealth Interventions Reporting in Randomized Controlled Trials for Caregivers of People With Dementia: Systematic Review (e53737)
Ling Zhu, Yurong Xing, Wenhui Xu, Hongfei Jia, Xiaoxiao Wang, Shiqing Liu, Yaping Ding. . . . 216

Parental Technoference and Child Problematic Media Use: Meta-Analysis (e57636)
Jinghui Zhang, Qing Zhang, Bowen Xiao, Yuxuan Cao, Yu Chen, Yan Li. . . . 229

Digital Health Solutions for Cardiovascular Disease Prevention: Systematic Review (e64981)
Yihan Qi, Emma Mohamad, Arina Azlan, Chenglin Zhang, Yilian Ma, Anqi Wu. . . . 245

Technologies for Interoperable Internet of Medical Things Platforms to Manage Medical Emergencies in Home and Prehospital Care: Scoping Review (e54470)
Mattias Seth, Hoor Jalo, Åsa Högstedt, Otto Medin, Bengt Sjöqvist, Stefan Candefjord. . . . 261

The Use of AI in Mental Health Services to Support Decision-Making: Scoping Review (e63548)
Hassan Auf, Petra Svedberg, Jens Nygren, Monika Nair, Lina Lundgren. . . . 304

Exploring the Use of Smartwatches and Activity Trackers for Health-Related Purposes for Children Aged 5 to 11 years: Systematic Review (e62944)
Lauren Thompson, Sydney Charitos, Jon Bird, Paul Marshall, Amberly Brigden. . . . 325

Rehabilomics Strategies Enabled by Cloud-Based Rehabilitation: Scoping Review (e54790)
Sejun Oh, SangHeon Lee. . . . 345

Implementing Internet-Delivered Cognitive Behavioral Therapy for Depression and Anxiety in Adults: Systematic Review (e47927)
Daniel Duffy, Derek Richards, Garrett Hisler, Ladislav Timulak. . . . 359

Digital Information Exchange Between the Public and Researchers in Health Studies: Scoping Review (e63373)
Nazli Soltani, Thilo Dietz, Doris Ochterbeck, Jens Dierkes, Katja Restel, Lara Christianson, Karina De Santis, Hajo Zeeb. . . . 378

Effectiveness of Different Intervention Modes in Lifestyle Intervention for the Prevention of Type 2 Diabetes and the Reversion to Normoglycemia in Adults With Prediabetes: Systematic Review and Meta-Analysis of Randomized Controlled Trials (e63975)
Yachen Wang, Xin Chai, Yueqing Wang, Xuejun Yin, Xinying Huang, Qiuhong Gong, Juan Zhang, Ruitai Shao, Guangwei Li. . . . 397

Impact of Online Interactive Decision Tools on Women's Decision-Making Regarding Breast Cancer Screening: Systematic Review and Meta-Analysis (e65974)
Patricia Villain, Laura Downham, Alice Le Bonniec, Charlotte Bauquier, Olena Mandrik, Tom Nadarzynski, Lorie Donelle, Raúl Murillo, Eleni Tolma, Sonali Johnson, Patricia Soler-Michel, Robert Smith. . . . 411

Families' Experiences With Family-Focused Web-Based Interventions for Improving Health: Qualitative Systematic Literature Review (e58774)
Diana Zhu, Aimee Dordevic, Zoe Davidson, Simone Gibson. . . . 436

Metrics for Evaluating Telemedicine in Randomized Controlled Trials: Scoping Review (e67929)
Yuka Sugawara, Yosuke Hirakawa, Masao Iwagami, Ryota Inokuchi, Rie Wakimizu, Masaomi Nangaku. . . . 457

Dynamic Augmented Reality Cues for Telementoring in Minimally Invasive Surgeries: Scoping Review (e63939)
Hawa Hamza, Omar Aboumarzouk, Abdulla Al-Ansari, Nikhil Navkar. . . . 474

Application of Patient-Generated Health Data Among Older Adults With Cancer: Scoping Review (e57379)
Yesol Kim, Geonah Kim, Hyeonmi Cho, Yeonju Kim, Mona Choi. 490

Effectiveness of Virtual Reality Technology Interventions in Improving the Social Skills of Children and Adolescents With Autism: Systematic Review (e60845)
Xipeng Yang, Jinlong Wu, Yudan Ma, Jingxuan Yu, Hong Cao, Aihua Zeng, Rui Fu, Yucheng Tang, Zhanbing Ren. 509

Digital Health Technology Interventions for Improving Medication Safety: Systematic Review of Economic Evaluations (e65546)
Widya Insani, Neily Zakiyah, Irma Puspitasari, Muhammad Permana, Kankan Parmikanti, Endang Rusyaman, Auliya Suwantika. 542

Mapping and Summarizing the Research on AI Systems for Automating Medical History Taking and Triage: Scoping Review (e53741)
Elin Siira, Hanna Johansson, Jens Nygren. 558

Patient-Accessible Electronic Health Records and Information Practices in Mental Health Care Contexts: Scoping Review (e54973)
Timothy Kariotis, Megan Prictor, Kathleen Gray, Shanton Chang. 575

Understanding “Alert Fatigue” in Primary Care: Qualitative Systematic Review of General Practitioners Attitudes and Experiences of Clinical Alerts, Prompts, and Reminders (e62763)
Illin Gani, Ian Litchfield, David Shukla, Gayathri Delanerolle, Neil Cockburn, Anna Pathmanathan. 601

Assessing the Uses, Benefits, and Limitations of Digital Technologies Used by Health Professionals in Supporting Obesity and Mental Health Communication: Scoping Review (e58434)
Amanda Kearns, Anne Moorhead, Maurice Mulvenna, Raymond Bond. 622

Machine Learning in the Management of Patients Undergoing Catheter Ablation for Atrial Fibrillation: Scoping Review (e60888)
Aijing Luo, Wei Chen, Hongtao Zhu, Wenzhao Xie, Xi Chen, Zhenjiang Liu, Zirui Xin. 642

Trends and Gaps in Digital Precision Hypertension Management: Scoping Review (e59841)
Namuun Clifford, Rachel Tunis, Adetimilehin Ariyo, Haoxiang Yu, Hyekyun Rhee, Kavita Radhakrishnan. 663

Interventions for Digital Addiction: Umbrella Review of Meta-Analyses (e59656)
Peng Lu, Jiamin Qiu, Shiqi Huang, Xinman Wang, Shasha Han, Sui Zhu, Youjing Ning, Fang-fang Zeng, Yuan Yuan. 686

Uses of Virtual Care in Primary Care: Scoping Review (e55007)
Payal Agarwal, Glenn Fletcher, Karishini Ramamoorthi, Xiaomei Yao, Onil Bhattacharyya. 701

Assessing the Effectiveness of Digital Health Behavior Strategies on Type 2 Diabetes Management: Systematic Review and Network Meta-Analysis (e63209)
Min Li, Shiyu Liu, Binyang Yu, Ning Li, Aili Lyu, Haiyan Yang, Haiyan He, Na Zhang, Jingru Ma, Meichen Sun, Hong Du, Rui Gao. 724

Simulation-Based Learning Supported by Technology to Enhance Critical Thinking in Nursing Students: Scoping Review (e58744)
Hege Stenseth, Simen Steindal, Marianne Solberg, Mia Ølnes, Anne Sørensen, Camilla Strandell-Laine, Camilla Olaussen, Caroline Farsjø Aure, Ingunn Pedersen, Jaroslav Zlamal, Jussara Gue Martini, Paula Bresolin, Silje Linnerud, Andréa Nes. 751

Virtual Reality Enhanced Exercise Training in Upper Limb Function of Patients With Stroke: Meta-Analytic Study (e66802)
Shiqi Xu, Yanwen Xu, Ruyi Wen, Jun Wang, Yuyu Qiu, Chetwyn Chan. 775

Advancing Health Care With Digital Twins: Meta-Review of Applications and Implementation Challenges (e69544)
Mickaël Ringeval, Faustin Etindele Sosso, Martin Cousineau, Guy Paré. 800

Impact of Patient Online Record Access on Documentation: Scoping Review (e64762)
Eva Meier-Diedrich, Camilla Lyckblad, Gail Davidge, Maria Hägglund, Anna Kharko, Brian McMillan, Charlotte Blease, Julian Schwarz. 812

Digital Interventions for Older People Experiencing Homelessness: Systematic Scoping Review (e63898)
Emily Adams, Eddie Donaghy, Caroline Sanders, Maria Wolters, Lauren Ng, Christa St-Jean, Ryan Galan, Stewart Mercer. 829

Digital Health Interventions to Improve Mental Health in Patients With Cancer: Umbrella Review (e69621)
Chuhan Zhong, Xian Luo, Miaoqin Tan, Jing Chi, Bingqian Guo, Jianyao Tang, Zihan Guo, Shisi Deng, Yujie Zhang, Yanni Wu. 846

Reporting Quality of AI Intervention in Randomized Controlled Trials in Primary Care: Systematic Review and Meta-Epidemiological Study (e56774)
Jinjia Zhong, Ting Zhu, Yafang Huang. 865

Effects of the Modern Digital Information Environment on Maternal Health Care Professionals, the Role of Midwives, and the People in Their Care: Scoping Review (e70108)
Elisabeth Wilhelm, Victoria Vivilaki, Jean Calleja-Agius, Elena Petelos, Maria Tzeli, Paraskevi Giaxi, Elena Triantiafyllou, Eleni Asimaki, Faye Alevizou, Tina Purnat. 880

Features of Structured, One-to-One Videoconference Interventions That Actively Engage People in the Management of Their Chronic Conditions: Scoping Review (e58543)
Yu-Ting Chen, Michelle Lehman, Toni Van Denend, Jacqueline Kish, Yue Wu, Katharine Preissner, Matthew Plow, Tanya Packer. 896

Using Virtual Reality to Improve Outcomes Related to Quality of Life Among Older Adults With Serious Illnesses: Systematic Review of Randomized Controlled Trials (e54452)
Bhagvat Maheta, Alexandra Kraft, Nickolas Interrante, Soraya Fereydooni, Jeremy Bailenson, Brian Beams, Christina Keny, Thomas Osborne, Karleen Giannitrapani, Karl Lorenz. 920

Effectiveness of Digital Diabetes Management Technology on Blood Glucose in Patients With Type 2 Diabetes at Home: Systematic Review and Meta-Analysis (e66441)
Yuping Xiao, Zhenzhen Wang, Lintao Zhang, Nina Xie, Fangyao Chen, Zihao Song, Sha Zhao. 954

Poststroke eHealth Technologies–Based Rehabilitation for Upper Limb Recovery: Systematic Review (e57957)
Margherita Rampioni, Sara Leonzi, Luca Antognoli, Anna Mura, Vera Stara. 967

Enabling Telemedicine From the System-Level Perspective: Scoping Review (e65932)
Xuezhu Li, Lifeng Huang, Hui Zhang, Zhanming Liang. 980

Natural Language Processing Technologies for Public Health in Africa: Scoping Review (e68720)
Songbo Hu, Abigail Oppong, Ebele Mogo, Charlotte Collins, Giulia Occhini, Anna Barford, Anna Korhonen. 997

Facilitators and Barriers to the Implementation of Digital Health Technologies in Hospital Settings in Lower- and Middle-Income Countries Since the Onset of the COVID-19 Pandemic: Scoping Review (e63482)
Sheng Yew, Daksha Trivedi, Nurul Adanan, Boon Chew. 1022

Diagnostic Performance of Artificial Intelligence–Based Methods for Tuberculosis Detection: Systematic Review (e69068)
Seng Hansun, Ahmadreza Argha, Ivan Bakhshayeshi, Arya Wicaksana, Hamid Alinejad-Rokny, Greg Fox, Siaw-Teng Liaw, Branko Celler, Guy Marks. 1044

Application of Machine Learning for Patients With Cardiac Arrest: Systematic Review and Meta-Analysis (e67871)
Shengfeng Wei, Xiangjian Guo, Shilin He, Chunhua Zhang, Zhizhuan Chen, Jianmei Chen, Yanmei Huang, Fan Zhang, Qiangqiang Liu. . . .

Factors Influencing eHealth Literacy Worldwide: Systematic Review and Meta-Analysis (e50313)
Zhong Hua, Song Yuqing, Liu Qianwen, Chen Hong. . . . 1096

The State of the Art of eHealth Self-Management Interventions for People With Chronic Obstructive Pulmonary Disease: Scoping Review (e57649)
Eline te Braake, Roswita Vaseur, Christiane Grünloh, Monique Tabak. . . . 1117

Intelligent Robot Interventions for People With Dementia: Systematic Review and Meta-Analysis of Randomized Controlled Trials (e59892)
Wenqi Fan, Rui Zhao, Xiaoxia Liu, Lina Ge. . . . 1140

Examining Challenges to Co-Design Digital Health Interventions With End Users: Systematic Review (e50178)
Anthony Duffy, Nazanin Boroumandzad, Alfredo Sherman, Gregory Christie, Indira Riadi, Sylvain Moreno. . . . 1154

Association of Digital Health Interventions With Maternal and Neonatal Outcomes: Systematic Review and Meta-Analysis (e66580)
Jianing Wang, Nu Tang, Congcong Jin, Jianxue Yang, Xiangpeng Zheng, Qiujing Jiang, Shengping Li, Nian Xiao, Xiaojun Zhou. . . . 1186

Digital Wellness Programs in the Workplace: Meta-Review (e70982)
Saeed Amirabdolahian, Guy Pare, Stefan Tams. . . . 1207

Digital Physical Activity and Sedentary Behavior Interventions for Community-Living Adults: Umbrella Review (e66294)
Eilidh Russell, Alison Kirk, Mark Dunlop, William Hodgson, Mhairi Patience, Kieren Egan. . . . 1236

Enhancing Patient Outcome Prediction Through Deep Learning With Sequential Diagnosis Codes From Structured Electronic Health Record Data: Systematic Review (e57358)
Tuankasfee Hama, Mohanad Alsaleh, Freya Allery, Jung Choi, Christopher Tomlinson, Honghan Wu, Alvina Lai, Nikolas Pontikos, Johan Thygesen. . . . 1253

Patients' Experiences of Digital Health Interventions for the Self-Management of Chronic Pain: Systematic Review and Thematic Synthesis (e69100)
Ashleigh Main, Haruno McCartney, Maryam Ibrar, Fiona Muirhead, Alexandra Mavroeidi, Harleen Rai, Roma Maguire. . . . 1274

Digital Health Education for Chronic Lung Disease: Scoping Review (e53142)
Chao Sun, Huohuo Dai, Rianne M.J.J. van der Kleij, Rong Li, Hengchang Wu, Cynthia Hallensleben, Sofie Willems, Niels Chavannes. . . . 1294

Behavioral Therapy–Based Digital Interventions for Treating Osteoarthritis: Systematic Review and Meta-Analysis (e56227)
Beiyao Zhu, Dian Zhu, Xiao'ao Xue, Hongyi Yang, Shurong Zhang. . . . 1308

Effectiveness of Digital Lifestyle Interventions on Depression, Anxiety, Stress, and Well-Being: Systematic Review and Meta-Analysis (e56975)
Jacinta Brinsley, Edward O'Connor, Ben Singh, Grace McKeon, Rachel Curtis, Ty Ferguson, Georgia Gosse, Iris Willems, Pieter-Jan Marent, Kimberley Szeto, Joseph Firth, Carol Maher. . . . 1330

AI-Derived Blood Biomarkers for Ovarian Cancer Diagnosis: Systematic Review and Meta-Analysis (e67922)
He-Li Xu, Xiao-Ying Li, Ming-Qian Jia, Qi-Peng Ma, Ying-Hua Zhang, Fang-Hua Liu, Ying Qin, Yu-Han Chen, Yu Li, Xi-Yang Chen, Yi-Lin Xu, Dong-Run Li, Dong-Dong Wang, Dong-Hui Huang, Qian Xiao, Yu-Hong Zhao, Song Gao, Xue Qin, Tao Tao, Ting-Ting Gong, Qi-Jun Wu. . . .

data ethics; data sharing; informed consent; disclosure; conflict of interest; transparency; trust

In January 2019, the *Journal of Medical Internet Research* published a viewpoint paper by Anthony Pisani and colleagues [1] related to a noncommercial data-sharing program for academic researchers offered by Crisis Text Line, a not-for-profit technology organization that provides a free 24-7 text line for people in crisis in the United States. Crisis Text Line has been described as a globally prominent online mental health support resource, where people in crisis (eg, with suicidal ideation) can exchange text messages with trained volunteer counselors. As is the case for many internet companies, these digital exchanges are a treasure trove for machine learning, quality improvement, education, and research.

Nancy Lublin, cofounder and former chief executive officer (CEO) of Crisis Text Line (as well as Loris.ai), gave an example in her 2015 TED talk on the internal use of these data [2]:

> *We know that if you text the words "numbs" and "sleeve," there's a 99 percent match for cutting. We know that if you text in the words "mg" and "rubber band," there's a 99 percent match for substance abuse. And we know that if you text in "sex," "oral" and "Mormon," you're questioning if you're gay. Now that's interesting information that a counselor could figure out but that algorithm in our hands means that an automatic pop-up says, "99 percent match for cutting -- try asking one of these questions" to prompt the counselor. Or "99 percent match for substance abuse, here are three drug clinics near the texter." It makes us more accurate.*

Former Crisis Text Line board member, Danah Boyd, recounts her motivation behind opening up data to researchers, which is the focus of the 2019 paper in the *Journal of Medical Internet Research* [3]:

> *From early on, researchers came to Crisis Text Line asking for access to data. This prompted even more reflection. We had significant data and we were seeing trends that had significant implications for far more than our service. (...) This then led to the more*

XSL•FO
RenderX

> *complicated issue of whether or not to allow external researchers to study our data with an eye towards scholarship. (...) Our texters come to us in their darkest hours. Our data was opening up internal questions right and left about how to best support them. We don't have the internal resources to analyze the data to answer all of our questions, to improve our knowledge base in ways that can help texters. I knew that having additional help from researchers could help us learn in ways that would improve training of counselors and help people down the line. I also knew that what we were learning internally might be useful to other service providers in the mental health space and I felt queasy that we were not sharing what we had learned to help others.*

The 2019 paper deals with the question of how these textual data could be ethically shared with academic researchers to answer a variety of research questions. As Pisani and colleagues observed, "few companies are willing to take on the potential work and risks involved in noncommercial data sharing, and the scientific and societal potential of their data goes unrealized" [1], so to Crisis Text Line's credit the nonprofit organization applied for a grant from the Robert Wood Johnson Foundation to create a pilot program for data sharing with academic researchers. The paper described "the process of defining core challenges underlying data sharing in technology-academia partnerships; discusses Crisis Text Line's trial solutions to these challenges; and offers lessons learned that might inform other technology companies' data-sharing partnerships" [1]. This is a viewpoint paper, not an original paper, and the paper in the *Journal of Medical Internet Research* does not use any of the data collected by Crisis Text Line nor does it share the results of the subprojects that Crisis Text Line enabled with their data-sharing program, rather it deals with the meta-question of how such data can be ethically shared with researchers. To that end, Crisis Text Line assembled a data ethics committee consisting of external academic researchers and technology experts (many of whom are coauthors of the paper), convened by then Crisis Text Line's chief data scientist and Crisis Text Line cofounder, Bob Filbin, who is also a coauthor on the paper. The ethics committee advised Crisis Text Line on processes and assessed the research proposals of other researchers who applied for access to Crisis Text Line's data. The paper proposes some general guidelines for other organizations that want to share data with third parties in a *noncommercial* context. The paper is seen by many as an important contribution to the complex question of how organizations can ethically share data with academics while preserving the privacy and integrity of the data, as evidenced by the selection of the article as "best paper of 2019" for the 2020 International Medical Informatics Association (IMIA) Yearbook, Special Section on Ethics in Health Informatics [4].

Data Ethics Called in Question

In November 2021, Tim Reierson, a former volunteer for the Crisis Text Line, and an advocate seeking reform of data ethics at Crisis Text Line and 988 Lifeline, published a 13-page open letter in response to the article published in the *Journal of Medical Internet Research*, where he raised several concerns related to informed consent and an alleged conflict of interest [5]; the full document was sent to us in February 2022.

Reierson's core concern related to *informed consent* was that the paper described the process where Crisis Text Line provided "texters with a link to an easy-to-understand Terms of Service" (Table 1 in [1]), thereby—according to Reierson—"establishing a Terms of Service consent standard." While we as *Journal of Medical Internet Research* editors agree that offering a terms of service (ToS) link does not necessarily equate to informed consent, we do not agree with the interpretation that this viewpoint paper establishes this as a generalizable "informed consent standard." Rather, the guidelines proposed in the viewpoint (Table 1 in [1]) include that researchers "inform users in an unobtrusive way that anonymized data are shared with select research partners", which was implemented by Crisis Text Line by referring users to their ToS. But the guidelines proposed in the viewpoint paper also had other critical requirements. Notably, they also require that academics who use (anonymized) Crisis Text Line data for research obtain institutional review board (IRB) approval for their data analysis projects (Table 1 in [1]: "Establish a review process that includes outside academics and ethics experts").

Informed consent is ideal but not always possible, especially on the internet [6]. There are some circumstances, for example, in urgent or emergency care settings, or in public health practice, where informed consent is considered legally effective when considering contextual variables [7]. Additionally, secondary use of data that has been de-identified or anonymized (as was the case with Crisis Text Line data) is usually allowable in the absence of explicit consent from the data subject [8]. Thus, the critique that the Crisis Text Line clientele can not be expected to read the terms of use is valid, but it is ultimately up to the IRBs to assess the risk—which is a key component mentioned in the Pisani paper [1].

Regarding commercial use, Reierson in his letter to JMIR Publications pointed to the fact that Crisis Text Line had also launched a for-profit subsidiary, Loris.ai, to which Crisis Text Line data was licensed in order to train artificial intelligence (AI) to handle text exchanges for customer service. These events took place after the study period.

Less than 2 months after Reierson made the letter to JMIR Publications public (but before we had seen it), on January 28, 2022, Politico ran a story bringing public scrutiny to the fact that Crisis Text Line had created Loris.ai as a profit-generating entity [9], which was met with widespread public "anger and disgust" [3], and prompted a letter from US Federal Communications Commission's commissioner, Brendan Carr, to Crisis Text Line and Loris.ai demanding they stop this practice immediately [10]. Three days later, Crisis Text Line backed down and "ended the data-sharing relationship with Loris" and requested "that Loris delete the data it has received from Crisis Text Line" [11,12].

Publication Ethics and Corrigendum of the Conflicts of Interest Section

Reierson's concern regarding the *conflict of interest* was that "Crisis Text Line itself had a vested monetary interest in commercial use of the data through its' subsidiary Loris.ai, and therefore vested interest in the 2019 paper's finding [*sic*] that the crisis conversation data is ethically sourced for research purposes." Here, it is important to note that from our point of view as *Journal of Medical Internet Research* editors, the term "finding" is slightly misleading because this is not an empirical study, rather it is a viewpoint paper, largely written by members of the independent Data Ethics Committee consisting of independent and respected ethicists and academics, describing how Crisis Text Line handled data sharing for research and outlining ethical challenges and how they were addressed by the Crisis Text Line's Data Ethics Committee.

From a publication ethics perspective, we are less concerned about the ethics of the arrangement between Crisis Text Line and Loris.ai, but primarily about whether any of the individual contributing authors benefitted (or had the potential to benefit) financially from Loris.ai or had any other ties to Loris.ai, as this would arguably be something that should have been disclosed to the editor and reviewers on submission of the paper [13]. Even though the 2019 paper published in the *Journal of Medical Internet Research* was about *noncommercial* data sharing for academic research, any hypothetical ties between authors and a company that benefits from Crisis Text Line data-sharing guidelines could have influenced the viewpoint.

We shared Tim Reiersons' letter with the corresponding author and received a reply on March 30, 2022, reassuring us that the academic members of the Data Ethics Committee were uncompensated and that there were no further conflicts of interest to disclose. We had no evidence of any wrongdoing that would require a retraction or even issuing an editorial expression of concern. Still, we wanted readers to be aware of the debate (in particular around informed consent) and invited Tim Reierson to submit a condensed commentary for publication alongside the article [14], and we also asked the original authors to respond [15]. We also decided to publish a corrigendum [16] to clarify author relationships with the noncommercial and commercial entities in greater detail [16].

Informed Consent in the Age of AI and Machine Learning

The invited commentary by Reierson highlights complex concerns regarding consent for research, data sharing, and machine learning [14], which are of course amplified given the initial intent of Crisis Text Line to share data with a *commercial* entity, Loris.ai.

Tim Reierson asks legitimate questions on whether it is sufficient to have users in crisis accept a ToS document (which in all likelihood nobody reads). Even former board chair of Crisis Text Line, Danah Boyd, readily admitted that a ToS is not consent [3]:

> *I knew how little data exists in the mental health space, how much we had tried to learn from others, how beneficial knowledge could be to others working in the mental health ecosystem. I also knew that people who came to us in crisis were not consenting to be studied. Yes, there was a terms of service that could contractually permit such use, but I knew darn straight that no one would read it, and advised everyone involved to proceed as such.*

Informed consent is a basic tenet for research; on the other hand, it can be waived when data are deidentified. IRBs routinely grant exemptions to the informed consent ideal when data are deidentified. While such assessments can be made in an academic context, many companies do not have IRBs that could assess the risk or ethical implications if data are analyzed, manually or with machine learning, and the reidentification risks are often not known.

The question of what the role of informed consent plays when academics or companies use data generated on the internet is one of the most vexing questions of our time and a topic of ongoing debate. It is also precisely why we published the 2019 viewpoint paper by Pisani et al [1], which illustrates in an exemplary way how organizations can and should deal with this risk. Ideally, organizations (profit or nonprofit) assemble independent ethics boards, like Crisis Text Line did. Independence is key—the ethics board should consist of independent academics who do not have a stake in the success of the business or organization.

As Danah Boyd further writes, "There have been heated debates in my field about whether or not it is ethical to use corporate trace data without the consent of users to advance scientific knowledge" [3]. Proponents of waiving informed consent requirements for analyzing anonymized big data argue that users implicitly consent to data mining and research by using "free" services—one could argue that people accept this bargain as a trade-off to receiving free services and free information. In the age of generative AI—where large parts of the internet, including discussion boards and other venues that once may have been deemed "private," are scoured by AI bots—users already may have adjusted their expectations regarding privacy and anonymity.

However, when it comes to digital health data, there is an important distinction to be made between noncommercial and commercial use of the data, and perhaps this was the cardinal mistake made by Crisis Text Line—to first communicate that data will never be shared with commercial entities, and then change course, assuming that people who may be fine with giving data (even anonymized) for research purposes to a noncommercial entity (including the volunteers at Crisis Text Line) are also OK with having these anonymized data shared with a commercial entity for machine learning purposes. Research in this journal [17] has shown that people generally distrust data use in a commercial context (technology companies, pharmaceutical companies) more than data sharing for pure research purposes.

XSL•FO
RenderX

The debate over informed consent in the use of "deidentified" internet-generated data for research and commercial use is complex, multifaceted, and constantly evolving.

In a recent 2024 paper [18], the authors argue that especially for digital mental health and other vulnerable populations, the standard to deidentify data to waive informed consent may not be sufficient, and other criteria should be used to address social justice issues. To mitigate the "social risk" of using deidentified data for research without explicit permission from participants, the authors urge researchers to consider the following additional guidelines [18]:

- create socially valuable knowledge,
- fairly share the benefits and burdens of research,
- be transparent about data use,
- create mechanisms for withdrawal of data,
- ensure that stakeholders can provide input into the design and implementation of the research, and
- responsibly report results.

Balancing these ethical considerations with the practical needs of research and innovation is a challenge that requires ongoing dialogue and thoughtful regulation. Ultimately, finding a middle ground that protects individuals' rights while fostering scientific and technological advancement is crucial for navigating this complex issue.

Conclusion

In summary, the commentary of Reierson [14] and the response of Pisani et al [15] highlight the difficult ethical questions nonprofit organizations and companies face when obtaining, analyzing, and sharing data with academics, and even more so for commercial use. The paper by Pisani et al [1] is commendable in that it lays open how data sharing for research has been handled by a nonprofit organization, and the approach of assembling an external data ethics committee to help vet research proposals from other researchers is exemplary. Unfortunately, this has been somewhat tainted by events that occurred after we published the paper, when it emerged that Crisis Text Line made the controversial decision to also share the data with its commercial subsidiary for machine learning purposes. The Data Ethics Committee members who authored the 2019 *Journal of Medical Internet Research* paper were apparently not involved or consulted on that. We see the controversy around Loris.ai as a separate debate that does not invalidate the guidelines and approach for noncommercial data sharing published in the 2019 paper. Many organizations (including nonprofits, hospitals, and research centers) have business development officers and commercialization units that think about how to harness the data they have to advance knowledge and how to commercialize their data in an ethical manner. As such, in the era of generative AI and machine learning, nonprofits creating spin-offs or holding equity in companies that commercialize deidentified data may become increasingly common, and the Crisis Text Line and Loris.ai case may serve as a cautionary lesson on the negative public perception of such arrangements.

Conflicts of Interest

GE is the founder, chief executive officer, and executive editor of JMIR Publications, editor-in-chief of the *Journal of Medical Internet Research*, receives a salary, and owns equity.

Abstract

Background: An increase in the prevalence of neurodevelopmental conditions worldwide, alongside resource constraints within clinical services, has led to increased interest in health information technologies, such as apps and digital resources. Digital tools are often viewed as a solution to bridge this divide and to increase supports for families. There is, however, a paucity of research that has evaluated digital health tools, their potential benefits for child neurodevelopment and associated concerns (eg, mental health, well-being), and their benefit for families.

Objective: This study conducted the first review of existing mobile apps and digital resources targeted at supporting the needs of children with developmental concerns or neurodevelopmental conditions.

Methods: We identified 3435 separate resources, of which 112 (43 apps and 69 digital resources) met the criteria. These resources were categorized according to their purpose or target and were then reviewed based on their engagement, information quality, and evidence base using the Adapted Mobile App Rating Scale.

Results: The most common condition of concern targeted by apps and digital resources was autism (19/112, 17% resources), with retrieved resources focusing on supporting challenging behaviors, promoting speech, language, and social development, and providing options for alternative and assistive communication. Other common areas of concern targeted by apps and digital resources included language and communication (16/112, 14.3%) and attention-deficit/hyperactivity disorder (11/112, 9.8%). Results showed that reviewed resources were engaging, with high levels of accessibility and functionality. Resources had various functions, including developmental or behavioral tasks targeted at children, assistive communication support, scheduling support, journaling, and advice, activities, and strategies for parents. The information quality of resources, such as credibility of source and evidence base was, however, mostly low. Apps and digital resources with good credibility and an existing evidence base were largely developed in partnership with research, health, or government institutions, and were rated significantly higher on overall quality compared with apps and digital resources not developed in partnership with such institutions (apps; t_{41}=–4.35, P<.001; digital resources; t_{67}=–4.95, P<.001).

Conclusions: The lack of evidence base across resources means that it is extremely difficult to provide recommendations to families with respect to apps or digital resources that may support their needs. Frameworks for the development of new tools are discussed, highlighting the novel approaches required to demonstrate the efficacy of tools for improving outcomes for children and families. Such a framework requires collaboration with multiple stakeholders (software developers, researchers, regulatory bodies, clinicians, children, and families) and engagement across multiple levels of expertise (app development, implementation,

XSL•FO
RenderX

and dissemination within services, policy, and clinical regulations), to harness the potential of digital health for improving outcomes and promoting support in child neurodevelopment, which at this juncture remains largely underdeveloped.

Introduction

In recent years, there has been a reported increase in the prevalence of neurodevelopmental conditions (NDCs) [1,2] and a rising awareness of the importance of early diagnosis and intervention in children with signs of developmental delay [3,4]. This has been matched with a growing number of recommendations and guidelines for multidisciplinary supports provided as early as possible [5-7]. Early identification and evidence-based supports are argued to be crucial for enhancing outcomes in the 1 in 10 children diagnosed with a neurodevelopmental condition [4].

Despite this, there is consistent evidence across nations of the considerable delays and barriers children and families face when seeking assessment [8,9] and support [10,11]. In addition, the wide range of multidisciplinary support needs often experienced by children and caregivers are frequently reported to result in fragmented care, where co-occurring conditions (eg, mental health) are often left unaddressed [12-14]. Caregivers can often report feeling overwhelmed and confused, and comment on the lack of coordination of care and difficulty in obtaining trustworthy, accessible information about supports [15-17].

It is unsurprising, given these resource constraints, that many families turn to health information technologies, such as apps and digital tools, to obtain information to supplement their health care [18,19]. The potential utility of such technologies has been reinforced internationally, with global commissioned reports recommending the integration of digital technologies to facilitate and optimize health care for children and adolescents [20,21]. Digital tools may bridge the divide between existing limited resources and growing demand [22], providing more instant access to supports that may be delivered in a flexible manner. Such tools may also bridge geographical barriers, facilitate access to care for diverse communities, and provide additional opportunities for assessment and feedback to support child and family needs across time [23-25].

Despite enthusiasm for the use of innovative digital solutions [26,27], there is an urgent need to understand the digital tools that currently exist for children with NDCs and their families, the platforms that these tools can be accessed on, and whether these tools are reliable, credible and have an existing evidence base to support their implementation. There is also a need for such evaluations to map existing resources so that supports can be strategically developed where gaps exist. For example, it has previously been shown that, despite the promise of digital tools for mental health, only a minority of apps purported to monitor and manage mental health symptoms have clinically validated evidence of effectiveness [28,29]. More recently, a meta-analysis of the efficacy of smartphone apps for symptoms of depression and anxiety reported overall small effects for symptom amelioration [30]. In addition, while there can be many valuable resources available, there are also many poor sources of information [31-33]. As a result, individuals may instead be influenced by factors such as the star rating of an app, which have been shown to have little relationship with clinical utility [34].

In addition to evaluating digital tools in terms of their evidence base and credibility, it is critical to also evaluate these tools in terms of their engagement, aesthetics, and user quality. Worldwide, there is consistent evidence that poor quality of an app or digital resource is associated with abandonment [35]. In contrast, the design and visual features of apps including an engaging interface, and being intuitive and easy to navigate, all increase engagement and use [36]. To illustrate, digital mental health tools have been shown to have continued uptake as low as 0.1% when rolled out at scale and this low rate is believed to be associated with low appeal and poor app maintenance to promote engagement [37]. This means that the ongoing use of a digital tool, no matter the evidence behind it, is likely to fail without high appearance and usability ratings [23,37]. This may be particularly important for families with NDCs as research shows that personal characteristics moderate the type of apps and digital tools that are used [38]. People with NDCs are more likely to learn from well-structured, easy-to-understand, and clear information, further highlighting the need to evaluate the quality and aesthetics of apps and digital resources [39].

The objective of this study was to review available mobile apps and digital resources that are targeted at supporting the needs of children with developmental concerns or NDCs. The study first sought to conduct a systematic review of all existing mobile apps and digital resources and to categorize them according to their purpose or target. Second, the review then sought to evaluate the information quality, utility, and evidence base for each resource by using the Adapted Mobile App Rating Scale (A-MARS) [40] to demonstrate the quality and evidence base of existing tools.

Methods

Design

This review used a stepwise approach in a similar manner to a systematic review. Our approach included a search strategy, assessment against prespecified eligibility criteria, app, and digital resource selection through an initial screening of all identified apps and digital resources, a full review of included apps and digital resources, data extraction and analysis, and

XSL•FO
RenderX

quality assessment of included apps and digital resources using a reliable quality assessment tool, the A-MARS [40,41].

Search Strategy

A search of the main online app stores, iTunes (Apple Inc, Australia) and Google Play (Google Inc, Australia), and a search of digital resources using the Google search engine was conducted from October 2023 to November 2023. To avoid a selection bias from personal Google algorithms, search histories were cleared before each search term as per previous recommendations [42]. Search terms were identified following consultations with researchers with expertise in NDCs, clinicians practicing in neurodevelopmental assessment services, and families with lived experience of NDCs. Search terms were selected based on keywords caregivers of children with developmental concerns or NDCs may use when attempting to access apps and digital resources. The final search terms also demonstrated the best performance in identifying apps and digital resources of interest for this review during preliminary searches. In total, 28 search terms were identified by an expert clinical team based on *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [Fifth Edition]) terms for neurodevelopment and transdiagnostic terms that families might typically use. Search terms included neurodevelopment kids, intellectual disability kids, global developmental delay, communication disorder, language disorder kids, stuttering kids, autism spectrum disorder, autism kids, attention-deficit/hyperactivity disorder (ADHD) kids, ADHD kids, learning disorder kids, motor disorder kids, Tourette's disorder kids, cerebral palsy kids, dyslexia kids, epilepsy kids, anxious kids, depressed kids, sleep problem kids, attention kids, social problems kids, restricted behaviors kids, repetitive behaviors kids, social skills kids, well-being kids, education kids, emotion kids, cognition kids.

Eligibility Criteria

To be considered for inclusion in this review, apps, and digital resources were required to meet the following inclusion criteria: (1) contain keywords of the search term in the title or description, (2) have a focus on the needs of children with developmental concerns or NDCs (eg, social skills, well-being, academic skills, or mental health), (3) be free of charge, and (4) be in the English language. To ensure the resources contained relevant and applicable information that was catered to families of children with developmental concerns or NDCs, a variety of exclusion criteria was applied. Apps and resources were excluded if they (1) had no actionable information for families to use (eg, purely game, social media site, news article, research paper, clinic website, or home assessment), (2) if they were selling products (eg, books, materials, or therapy sessions), (3) if the information was not relevant to our target population (eg, app or resource targeted only at adults or included information was overly general), or (4) if they were in unsuitable formats for review with the A-MARS (ie, PDF document, podcast, or video).

Selection Process

Three authors (MH, ES, and KB) carried out the app store and search engine searches. To balance feasibility and search comprehensiveness, the first 50 resources for each search term were selected from both the app stores and the search engine [43]. A predesigned Microsoft Excel spreadsheet developed for this review was used to enter information about the apps and digital resources. Information entered included the name of the app or digital resource, the name of the app developer or the URL for digital resources, the app store or stores in which the app was available, and the search terms or terms that identified each app or digital resource.

Following removal of duplicates between search terms, 1 rater (MH) conducted an initial screen for eligibility, by reviewing the title, description, and home page of the app or digital resource. Additional screening was conducted on the remaining apps and digital resources to confirm inclusion in the review. This screening was conducted by 2 raters (MH and ES) and involved the installation of the app and a more detailed review of the digital resource, including a review of written information, pictures, and videos. Any disagreements were discussed with a 3rd rater (KB) and resolved by consensus. Reasons for exclusion were recorded.

Data Extraction

Apps and digital resources identified as eligible in the screening phase were then assessed using the A-MARS [40]. The A-MARS consists of 28 items, developed to assess the quality of mobile apps and e-tools (eg, websites and digital resources). The A-MARS provides an evaluation of app and e-tool quality by grading each app or digital resource on several domains, as described below (Textbox 1). Each item was scored using a 5-point Likert scale (1: inadequate, 2: poor, 3: acceptable, 4: good, and 5: excellent). Supplementary questions within the A-MARS capture information pertaining to the health-related quality of the app or digital resource. Eight scores are calculated for the A-MARS, including the mean score for each domain (ie, engagement, functionality, aesthetics, information, subjective quality, and health-related quality), a mean quality score based on the engagement, functionality, aesthetics and information domains, and a mean total score.

XSL•FO
RenderX

Textbox 1. List of Adapted Mobile App Rating Scale subscales and subscale descriptions.

Subscale and description

Engagement (5 items)

- Is the app or digital resource engaging and interesting for the user? Does it have prompts (eg, send alerts, messages, or reminders)?

Functionality (4 items)

- How does the app or digital resource function, does it have a logical flow and design? Is it easy to navigate?

Aesthetics (3 items)

- How appealing is the app or digital resource in terms of its overall visual appeal, graphic design, and stylistic consistency?

Information (6 items)

- Does the app or digital resource contain high-quality information (eg, text, feedback, measures, or references) from a credible source?

Subjective quality (4 items)

- Subjective quality rating of the app or digital resource.

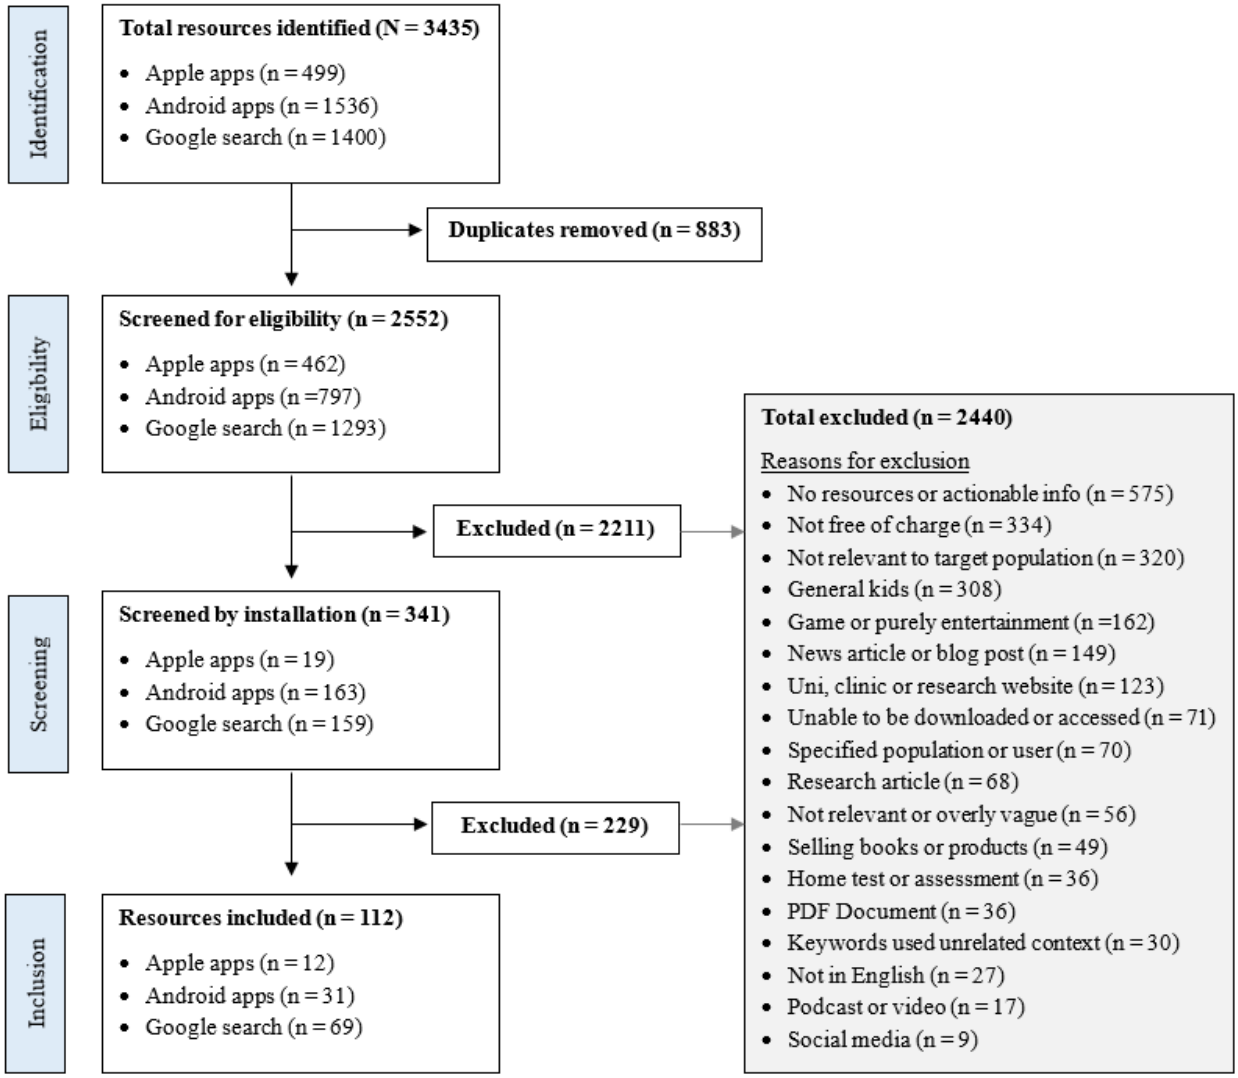
Health-related quality (6 items)

- Does the app or digital resource provide access to other resources, strategies linked to the target issue, or the option for real-time tracking?

All apps and digital resources were rated using the A-MARS instrument. Three expert raters conducted this review: (1) a senior research fellow with a PhD in Psychology and 10 years' experience working with pediatric NDCs and digital health; (2) a senior research assistant with a Master's degree in Brain and Mind Sciences and 3 years' experience in working with NDCs and digital tools to support children with NDCs and their families; and (3) a research affiliate with Bachelors' degrees in Psychology and Medical and Health Sciences and a Postgraduate Diploma in Psychology. Two of these raters were also people with a diagnosed NDC. All raters reviewed the A-MARS in depth before conducting initial pilot ratings. Two apps and 2 digital resources were initially reviewed independently for training purposes. After independently rating the apps and digital resources, the raters met to compare and review results and to resolve discrepancies in ratings. To reach a consensus, the raters reviewed the A-MARS in depth to improve the alignment of ratings. The remaining apps and digital resources were then rated independently by 2 raters. Based on the methodology described by others [40,41], each rater trialed the apps and digital resources for a minimum of 10 minutes and then independently rated their quality using the A-MARS.

Statistical Analyses

Statistical analyses were conducted using SPSS (version 28; IBM Corp). Descriptive statistics were used to summarize the A-MARS domain scores, the mean quality score, and the mean total score across apps and digital resources. Cronbach α and intraclass correlation coefficients were used to calculate the internal consistency and interrater reliability of the A-MARS domain scores, the quality score, and the total score. As this is the first study to our knowledge that has applied the A-MARS in apps and digital resources targeted at child development and NDCs, 2-tailed independent samples *t* tests were also used to compare mean domain scores, quality scores, and total scores between apps and digital resources. Bonferroni corrections were used for these comparisons and a *P* value of <.006 was considered statistically significant. To understand how the involvement of a reputable and credible organization impacted ratings for apps and digital resources, 2-tailed independent samples *t* tests were used to compare domain scores, quality scores, and total scores for apps and digital resources that had been developed in partnership with a university, health or government institution, relative to those that had not been developed in partnership with such institutions.



Results

Overview

The process of identification and inclusion of apps and digital resources is outlined in Figure 1. A total of 3435 apps and digital resources were initially identified. After the removal of duplicates, 2211 apps and digital resources were excluded following initial screening by title and description, and an additional 229 apps and digital resources were excluded following installation and more detailed screening. The most common reason for exclusion was an absence of actionable information that children and families could use (575/2440, 23.6%), followed by not being free of charge (334/2440, 13.6%), and not being relevant to the target population (320/2440, 13.1%). A total of 12 Apple apps, 31 Android apps, and 69 digital resources were included in the final review of this paper.

Figure 1. Flowchart of selection of included resources.

Features of Included Apps and Digital Resources

Table 1 displays the primary area of focus for retrieved apps and digital resources. The most common conditions that the resources targeted were autism, language, or communication difficulties, and ADHD. Both apps and digital resources were retrieved for most searched terms; however, resources retrieved for anxiety, attention, and developmental delay were mainly digital resources. Comparatively, the resources retrieved for epilepsy, cerebral palsy, and child well-being were mainly apps. Retrieved apps and digital resources had a range of functions, including developmental or behavioral tasks targeted at children, assistive communication support, scheduling support, journaling, and advice, activities, and strategies for parents.

Overall Assessment of Apps and Digital Resources

Across the 43 apps and 69 digital resources, excellent internal consistency and inter-rater reliability was found across the total and sub-domain A-MARS scales. Detailed item and domain statistics for the reviewed apps are displayed in Tables S1 and S2 in Multimedia Appendix 1. Table 2 displays the mean and median scores of the reviewed apps (n=43) and digital resources (n=69) across the 5 A-MARS domains, as well as for the quality and total scores. The apps, taken together, scored higher than the minimum acceptable score of 3.0 across most A-MARS domains, excluding the health-related quality domain (Table 2). Apps typically received low scores on this domain due to a lack of additional resources available (mean 1.81, SD=1.22), and limited access to further support or related information (mean 1.85, SD=1.24). Furthermore, the digital resources scored higher than 3.0 across all A-MARS domains except the subjective quality domain (Table 2).

Table 2. Adapted Mobile App Rating Scale ratings for apps and digital resources.

Apps				Digital resources			Values	
Domain	Mean (SD)	Median (range)	N (%) scoring ≥3.0	Mean (SD)	Median (range)	N (%) scoring ≥3.0	T-statistic (*df*)	*P* value
Engagement	3.67 (0.74)	3.60 (2.40-4.90)	36 (83.7%)	3.19 (0.54)	3.13 (2.00-4.50)	45 (65.2%)	3.97 (110)	<.001
Functionality	4.13 (0.68)	4.25 (2.25-5.00)	40 (93.0%)	4.09 (0.55)	4.13 (2.50-5.00)	66 (95.7%)	0.37 (110)	.72
Aesthetics	3.73 (0.72)	4.00 (1.84-5.00)	38 (88.4%)	3.66 (0.68)	3.67 (2.00-5.00)	62 (89.9%)	0.56 (110)	.57
Information	3.06 (0.95)	3.13 (1.00-4.75)	27 (62.8%)	3.57 (0.59)	3.67 (2.33-4.75)	61 (88.4%)	-3.16 (110)	.002
Subjective quality	3.21 (0.88)	3.50 (1.50-4.88)	26 (60.5%)	2.89 (0.68)	2.88 (1.38-4.25)	27 (39.1%)	2.04 (110)	.04
Health-related quality	2.58 (0.91)	2.33 (1.00-4.83)	13 (30.2%)	3.34 (0.78)	3.33 (2.00-5.00)	45 (65.2%)	-4.74 (110)	<.001
Quality score	3.40 (0.67)	3.40 (2.17-4.88)	32 (74.4%)	3.62 (0.53)	3.66 (2.38-4.69)	60 (87.0%)	–2.01 (110)	.04
Total score	3.40 (0.64)	3.29 (2.00-4.72)	31 (72.1%)	3.48 (0.55)	3.50 (2.32-4.67)	54 (78.3%)	–0.73 (110)	.47

Both apps and digital resources scored higher than 3.0 across quality and total scores. Apps and digital resources scored high on the functionality domain, with consistently high average scores across subcriteria. Of note, included apps scored relatively low in the information quality domain primarily due to questionable source credibility (mean 2.52, SD 0.79). Furthermore, a minority of apps (3/43, 7%) and no digital resources met the criteria for a verifiable evidence base as outlined by the A-MARS (has been trialed or tested and published in scientific literature). Independent sample *t* tests revealed statistically significant differences in mean scores between apps and digital resources on the engagement, information, and health-related quality domains ($P<.006$). While apps had higher ratings relative to digital resources for

XSL•FO
RenderX

engagement, digital resources had higher ratings relative to apps on information and health-related quality domains.

Overall, apps and digital resources that had been developed in partnership with a health, university, or government institution, or where such an institution was listed as a partner, were rated more highly across domains of engagement, functionality, information, subjective quality, and health-related quality, as well as on overall quality and total scores. As shown in Tables 3 and 4, these effects were moderate to large for most comparisons. In total, 19% (8/43) of apps were developed in partnership with a health, university, or government institution, and 48% (33/69) of digital resources were developed in partnership with these institutions.

Table 3. Adapted Mobile App Rating Scale ratings for apps split by partnerships with health, university, or government institutions.

Domain	Apps				
	Institution partnership (n=8), mean (SD)	No institution partnership (n=35), mean (SD)	Effect size	T-statistic (*df*)	*P* value
Engagement	4.23 (0.75)	3.54 (0.68)	0.69	–2.53 (41)	.02
Functionality	4.64 (0.30)	4.01 (0.69)	0.64	–2.53 (41)	.02
Aesthetics	4.15 (0.62)	3.64 (0.73)	0.70	–1.85 (41)	.07
Information	4.30 (0.42)	2.78 (0.80)	0.75	–7.52 (41)	<.001
Subjective quality	4.05 (0.58)	3.02 (0.83)	0.80	–3.29 (41)	.002
Health-related quality	3.53 (1.33)	2.36 (0.63)	0.79	–2.42 (41)	.04
Quality score	4.13 (0.58)	3.23 (0.57)	0.57	–4.04 (41)	<.001
Total score	4.14 (0.51)	3.23 (0.54)	0.54	–4.35 (41)	<.001

Table 4. Adapted Mobile App Rating Scale ratings for digital resources split by partnerships with health, university, or government institutions.

Domain	Digital resources				
	Institution partnership (n=33), mean (SD)	No institution partnership (n=36), mean (SD)	Effect size	T-statistic (*df*)	*P* value
Engagement	3.47 (0.51)	2.93 (0.44)	0.47	–4.76 (67)	<.001
Functionality	4.36 (0.46)	3.83 (0.51)	0.48	–4.58 (67)	<.001
Aesthetics	3.98 (0.62)	3.36 (0.59)	0.6	–4.24 (67)	<.001
Information	3.87 (0.53)	3.30 (0.50)	0.51	–4.60 (67)	<.001
Subjective quality	3.13 (0.70)	2.67 (0.58)	0.64	–2.95 (67)	.004
Health-related quality	3.69 (0.76)	3.02 (0.65)	0.7	–3.95 (67)	<.001
Quality score	3.92 (0.44)	3.35 (0.44)	0.45	–5.18 (67)	<.001
Total score	3.77 (0.50)	3.21 (0.45)	0.47	–4.95 (67)	<.001

Individual Assessment of Apps and Digital Resources

Figures 2 and 3 display scores of the top 5 and bottom 5 apps in terms of their A-MARS ratings. These radar charts show how individual apps and digital resources scored on each A-MARS domain, as well as on the overall quality and total scores. Showing the difference between the top 5 and bottom 5 highlights the disparity between apps and digital resources on A-MARS ratings. In general, the top 5 apps and digital resources were characterized by high levels of factually correct information, relevant resources, good visuals, and engaging and user-friendly interfaces. Highly rated apps and digital resources were developed in collaboration with research, health, or government institutions. In contrast, the bottom 5 apps and digital resources were characterized by less involvement with a reputable institution, defective or inactive links, difficult or cumbersome interfaces, and a lack of information relevant to the purported concern or condition.

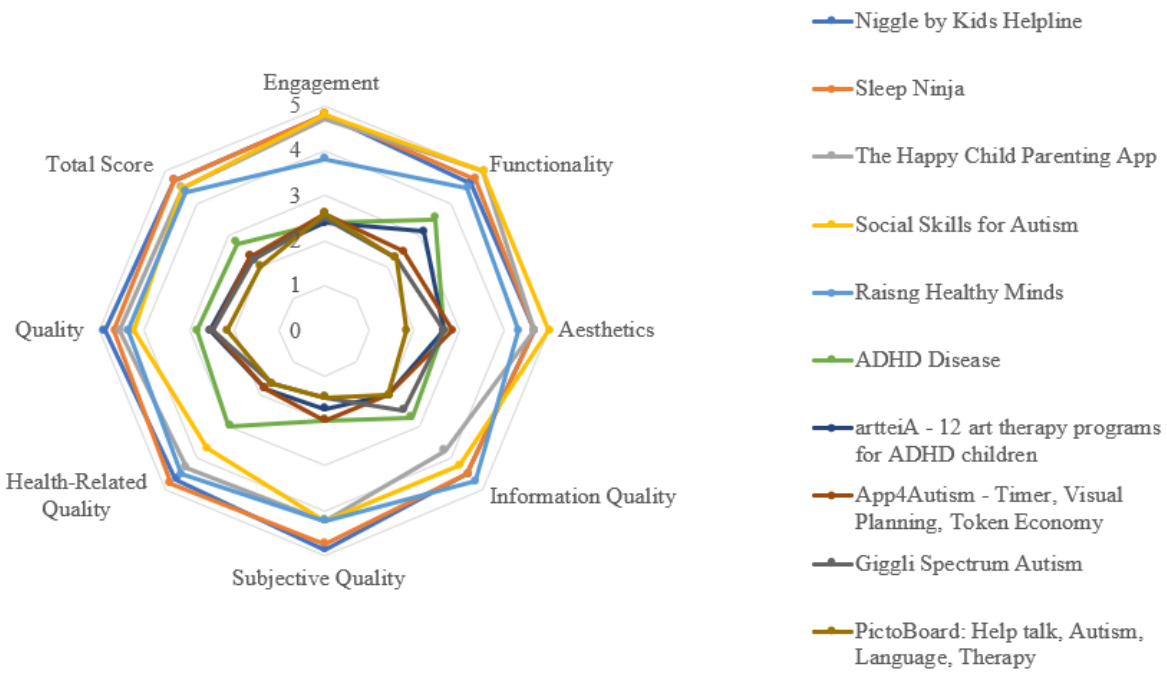

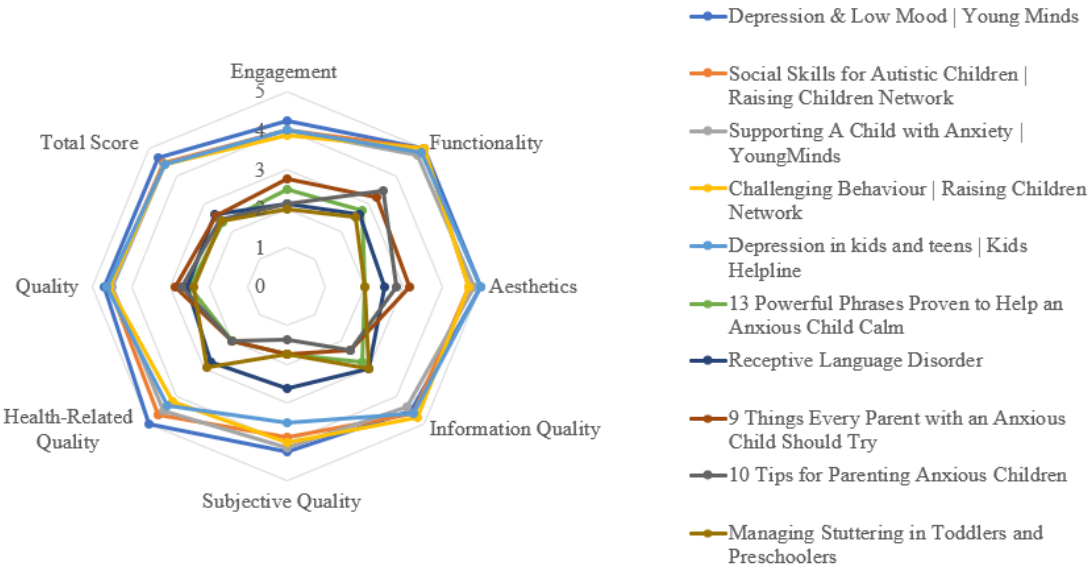

Figure 3. Radar chart of the top 5 and bottom 5 ranked digital resources.

Discussion

This study reviewed existing apps and digital resources that are targeted at the needs of children with developmental concerns or NDCs. To our knowledge, this is the first study that has evaluated apps and digital resources for child neurodevelopment and mental health broadly. From the initial 3435 resources identified, the study reviewed 112 resources in total (43 apps and 69 digital resources). Developed for children with NDCs and their families, the most common resources focus on supports for autism, language or communication difficulties, and ADHD. Most apps and digital resources exceeded the minimum acceptable score of 3.0, suggesting that retrieved resources were engaging, with high levels of accessibility and functionality. However, the results also showed items relating to information quality, such as credibility of source and evidence base, were generally low. Only 7% of apps or digital resources had an established evidence base. Interestingly, mobile apps and digital resources that were developed in partnership with a health, university, or government institution were rated significantly

XSL•FO
RenderX

higher across most domains in comparison to apps and resources that were not developed in partnership with such an organization. Unfortunately, the review showed there was almost no evidence for their efficacy or effectiveness in promoting supportive behaviors or improving outcomes. As a result, there is a significant existing divide between the availability of digital tools that can be integrated into family systems to support needs and evidence that warrants recommendations from clinical teams. While the findings of the review provide an evaluation and collation of existing tools, this conclusion highlights the urgent need to develop new frameworks to test efficacy for improving outcomes and promoting supportive behaviors.

These results show that most apps and digital resources alike met the minimum acceptable criteria in terms of quality (eg, highly engaging and functional). However, we did observe some differences as a function of resource type (ie, apps or digital resources). We found that apps displayed higher ratings on the domain of engagement, suggesting that the reviewed apps were more interesting, customizable, and entertaining, compared to digital resources. In contrast, reviewed digital resources had higher ratings on domains of information and health-related quality compared with apps. This indicates that the quality and credibility of information, as well as any additional resources and strategies provided, was higher in the reviewed digital resources.

Apps and digital resources were rated highly in terms of their engagement and functionality, but somewhat lower on information quality, particularly with respect to credibility of source and existing evidence base. We observed that apps and digital resources that had been developed by or in collaboration with a research, health, or government institutions were rated significantly more highly on information quality and credibility. This aligns with studies that have used evaluation tools like the Mobile App Rating Scale and A-MARS in other fields [40,44]. However, we note that very few apps or digital resources had a scientific evidence base to support their use, which points to the dearth of evidence evaluating the effectiveness of apps and digital resources [40,45]. This lack of evidence base may relate to the iterative, fast-paced nature of technological development and the linear, incremental approach to clinical science and research-based interventions. With established lags of up to 17 years for research to be translated into clinical practice, software developers may opt to move to large-scale dissemination of their product before developing a rigorous evidence base [24]. However, the consequence of this is an abundance of apps and digital resources that have little to no evidence base and may not be beneficial for consumers [27]. To resolve this issue, a novel framework with investment prioritized for development is critical, whereby the effectiveness of apps and digital resources can be rigorously evaluated in a streamlined and timely manner. Such a framework needs to incorporate the swift evaluation of real-world implementation alongside both the evaluation of resource development and the evaluation of efficacy. It is unlikely to be achieved by applying standard academic approaches or randomized controlled trial methods and may need to incorporate adaptive research designs within implementation science methodologies. Integrated research enabling platforms [46-48] that permit rapid implementation of clinical trials for multiple apps and resources within existing ethics and governance frameworks are also required for swift and sustained translation.

Our results show that the most common condition of concern targeted by apps and digital resources was autism (19/112, 17.0% of all apps and digital resources), with retrieved resources focusing on supporting challenging behaviors, promoting speech, language, and social development, and providing options for alternative and assistive communication. Given the growing prevalence of conditions like autism [1], an increase in the number of health information technologies focused on these conditions is relevant and has the potential to provide children and families with a variety of support tools. However, the proportion of resources targeted at comorbid conditions, such as mental health, was lower (10/112, 8.9% targeted at anxiety and 7/112, 6.3% targeted at mood or depression). Mental ill health is one of the fastest-growing health problems in children and adolescents, particularly in the wake of the COVID-19 pandemic [49]. Moreover, children with existing developmental delays and NDCs are more likely to experience mental health conditions relative to their neurotypical peers [12]. Together these findings point to a gap in existing digital resources for children with co-occurring developmental and mental health concerns.

It is unlikely that a single resource will meet the varied needs of children and families. The application and evaluation of digital resources to uplift support in the community may require integrated approaches targeting different needs at different stages of child development and different stages of support seeking. Recent arguments have also been made for the integration of digital navigators that can further facilitate the engagement and implementation of digital health tools within multidisciplinary care teams and standard clinical care [40,50]. With the increasing frequency of digital navigators in other disciplines, such as mental health [51,52], health systems providing child development and assessment services can benefit from adopting a similar approach, to support children and families in accessing reliable, credible, and efficacious digital tools across their health care journey.

While this study provided a first review of apps and digital resources targeted at child neurodevelopment, mental health, and well-being, we note certain limitations. The evaluation of apps and digital resources can be made difficult due to the growing number of app evaluation frameworks [50]. While the evaluation tool we selected, the A-MARS, has sound reliability [53], has been used across disciplines [54,55], and has been adapted for use specifically with digital resources [40], we note that there are challenges common across evaluation tools [50]. While it was deemed the most suitable evaluation tool for this review, we note specific limitations of the A-MARS, such as potential subjectivity in ratings, a relative lack of focus on the clinical effectiveness of health information, and a lack of validation across cultures and languages, which may warrant further evaluation of apps and digital resources with additional evaluation tools. However, there is currently no consensus for the evaluation and regulation of apps and digital resources, making it difficult to conduct standardized evaluations that can provide clear guidance and recommendations to patients and

XSL•FO
RenderX

clinicians. We also note that we restricted our search to apps and digital resources that were available free of charge. While this may have excluded potentially valuable paid resources, we argue that reviewing freely available resources increases the value of this study for use in the broader community and serves to increase equity in access to supports and resources. In a similar vein, we restricted our search to English language apps and digital resources, potentially limiting the applicability of our findings for non–English speaking populations. However, we have detailed a process that future researchers can use to identify and evaluate apps and digital resources in their region of interest, thereby facilitating evaluations in different countries and contexts. Further, we included a large number of search terms, which resulted in many retrieved resources. As a team we discussed restricting the search strategy; however, it was noted that children with developmental concerns or NDCs often experience multiple transdiagnostic concerns, with caregivers likely to search for support across many of these domains. As such, our more extensive search strategy was considered appropriate in order to capture the broad needs and concerns experienced by this patient population.

A crucial next step for this field is to understand how accessible, reliable, evidence-based health information technologies that meet the needs of children, families, and health care providers can be developed and disseminated across clinical settings. This requires collaboration with multiple stakeholders (app developers, researchers, regulatory bodies, clinicians, children, and families) as well as a reconceptualization of how to implement and recommend health information technologies across clinical services for maximum uptake and maintained engagement. At the development level, for example, partnerships between industry, research, and end-users are key to drive the timely co-production of evidence-based, accessible digital tools. Furthermore, given findings from digital mental health [56], a focus on developing tools that include gamification features may be key to optimizing uptake and engagement by children and families. At the implementation and dissemination level, existing models of care may need to be rethought to optimally engage recipients (ie, patients and clinicians) and encourage the integration of digital tools and solutions into clinical practice. Meanwhile, at the policy level, clinical regulation and recommendations require flexibility to enable innovative digital solutions to be adopted and embedded within health services and systems. While complex and multifaceted, such a framework would enable the development of evidence-based digital tools that are primed for accessibility and engagement with children and families and would facilitate the embedding of digital health into clinical service settings in a sustainable manner, uplifting the capacity of services to provide access to reliable, evidence-based digital tools that are likely to be used to support children and families.

In the current technology-driven world, apps and digital resources are being increasingly used and promoted as a source of information or an adjunct to support and therapy. In this review, we found that a large number of apps and digital resources targeted at child neurodevelopment, mental health, and well-being are engaging and functional, but lack an adequate evidence base. Those apps and digital resources that did show good credibility and an evidence base were largely developed in partnership with research, health, or government institutions. As a result, there is a pressing need to recognize, value, and promote this type of collaboration when developing new digital tools, and to also develop a framework where new digital tools can be rigorously evaluated in a timely manner, to promote swift translation from evidence-based research and development into practice. Clinicians and health care professionals can then be supported to recommend reliable, evidence-based apps and digital resources to children and families based on their individual needs, providing an ideal opportunity to evaluate the effectiveness of these tools for enhancing outcomes.

Acknowledgments

This work was supported by a Research Development Grant from the Brain and Mind Centre and an Emerging Researcher Grant from The Research Foundation of Cerebral Palsy Alliance (ERG01921).

Data Availability

The datasets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

KAB and AJG were involved in the study conceptualization and supervision. KAB, MH, and ES were involved in data extraction, data curation, and formal analysis. KAB and AJG wrote the original draft of the manuscript. All authors provided review and feedback on the manuscript and approved the final version.

Conflicts of Interest

None declared.

Abstract

Background: In recent years, with the rapid development of machine learning (ML), it has gained widespread attention from researchers in clinical practice. ML models appear to demonstrate promising accuracy in the diagnosis of complex diseases, as well as in predicting disease progression and prognosis. Some studies have applied it to ophthalmology, primarily for the diagnosis of pathologic myopia and high myopia-associated glaucoma, as well as for predicting the progression of high myopia. ML-based detection still requires evidence-based validation to prove its accuracy and feasibility.

Objective: This study aims to discern the performance of ML methods in detecting high myopia and pathologic myopia in clinical practice, thereby providing evidence-based support for the future development and refinement of intelligent diagnostic or predictive tools.

Methods: PubMed, Cochrane, Embase, and Web of Science were thoroughly retrieved up to September 3, 2023. The prediction model risk of bias assessment tool was leveraged to appraise the risk of bias in the eligible studies. The meta-analysis was implemented using a bivariate mixed-effects model. In the validation set, subgroup analyses were conducted based on the ML target events (diagnosis and prediction of high myopia and diagnosis of pathological myopia and high myopia-associated glaucoma) and modeling methods.

Results: This study ultimately included 45 studies, of which 32 were used for quantitative meta-analysis. The meta-analysis results unveiled that for the diagnosis of pathologic myopia, the summary receiver operating characteristic (SROC), sensitivity, and specificity of ML were 0.97 (95% CI 0.95-0.98), 0.91 (95% CI 0.89-0.92), and 0.95 (95% CI 0.94-0.97), respectively. Specifically, deep learning (DL) showed an SROC of 0.97 (95% CI 0.95-0.98), sensitivity of 0.92 (95% CI 0.90-0.93), and specificity of 0.96 (95% CI 0.95-0.97), while conventional ML (non-DL) showed an SROC of 0.86 (95% CI 0.75-0.92), sensitivity of 0.77 (95% CI 0.69-0.84), and specificity of 0.85 (95% CI 0.75-0.92). For the diagnosis and prediction of high myopia, the SROC, sensitivity, and specificity of ML were 0.98 (95% CI 0.96-0.99), 0.94 (95% CI 0.90-0.96), and 0.94 (95% CI 0.88-0.97), respectively. For the diagnosis of high myopia-associated glaucoma, the SROC, sensitivity, and specificity of ML were 0.96 (95% CI 0.94-0.97), 0.92 (95% CI 0.85-0.96), and 0.88 (95% CI 0.67-0.96), respectively.

Conclusions: ML demonstrated highly promising accuracy in diagnosing high myopia and pathologic myopia. Moreover, based on the limited evidence available, we also found that ML appeared to have favorable accuracy in predicting the risk of developing high myopia in the future. DL can be used as a potential method for intelligent image processing and intelligent recognition, and intelligent examination tools can be developed in subsequent research to provide help for areas where medical resources are scarce.

Introduction

Myopia is currently widely regarded as a significant public health issue, leading to substantial vision loss and serving as a risk factor for a range of other serious ocular diseases. It is estimated that by 2050, 4.758 billion people (49.8% of the world population) and 938 million people (9.8% of the world population) will suffer from myopia and high myopia, respectively [1]. A recent meta-analysis study proposed that the global economic burden due to productivity losses from uncorrected myopia and myopic macular degeneration is estimated to reach US $250 billion [2]. Therefore, the prevention of high myopia as well as the diagnosis and treatment of pathological myopia remain a formidable societal challenge.

High myopia is defined as the spherical equivalent ≤–6.0 diopter [3] when the accommodation of the eye is relaxed. However, increased severity of myopia and elongation of the eye's axial length could alter the posterior segment structures, causing posterior scleral staphyloma, myopic macular degeneration, and optic neuropathy related to high myopia, potentially leading to the loss of best-corrected visual acuity [3]. High myopia-related fundus lesions stand as an important contributing factor to blindness across the world as well as in China [4]. The detection of high myopia hinges primarily on artificial auxiliary techniques, like refraction detection, fundus examination, measurement of axial length, and fundus photography. Nevertheless, manual examination and analysis by ophthalmologists are still essential, necessitating a significant investment of time and effort [5]. Additionally, in regions with limited medical resources, the shortage of ophthalmologists and medical equipment impedes the early and accurate identification of high-risk patients with high myopia, resulting in missed opportunities for optimal treatment. Therefore, forecasting the risk of high myopia and precisely diagnosing pathological myopia are currently major research focus.

With the rapid advances in computing technology and the ongoing refinement of statistical theory, machine learning (ML) has gradually been promoted and applied in clinical practice. For instance, ML can not only improve image quality, reduce misregistration, and simulate attenuation correction imaging in core cardiology [6], but also be used for cancer screening (detection of lesions), characterization and grading of tumors, and prognosis prediction, thus facilitating clinical decision-making [7]. Since fundus images are noncontact, noninvasive, low-cost, easily accessible, and easy to process, ML has been extensively used to diagnose common retinal diseases, including diabetic retinopathy [8-10], macular degeneration [10], and glaucoma [11-13]. ML has been applied to various image-processing tasks. Novel techniques for analyzing fundus images of high myopia and pathological myopia are continuously emerging [14,15]. However, the accuracy of these ML detections has not been systematically studied. Consequently, the present study was executed to comprehensively describe the accuracy of ML in detecting different degrees of lesions in high myopia, furnishing an evidence-based reference for subsequent lesion management.

Methods

Study Registration

This study was implemented as per the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 guidelines and prospectively registered with PROSPERO (ID: CRD42023470820). The PRISMA checklist is available in Multimedia Appendix 1.

Inclusion and Exclusion Criteria

We established detailed inclusion and exclusion criteria for this systematic review. To enhance visualization, these criteria are presented in tabular form (Textbox 1).

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Study type: (1) case-control, cohort, nested case-control, and case-cohort studies and (2) studies reported in English.
- Machine learning (ML): studies that fully constructed ML models for the prediction or diagnosis of high myopia, the diagnosis of pathological myopia, or the diagnosis of high myopia-associated glaucoma.
- Outcome measures: at least one of the following outcome indicators were reported: receiver operating characteristic (ROC), *c*-index, sensitivity, specificity, accuracy, recovery rate, accuracy rate, confusion matrix, F_1-score, and calibration curve.
- Datasets: (1) some studies lacked independent validation sets, and only *k*-fold cross-validation was leveraged to verify the effect of the constructed mode; and (2) in some publicly available datasets, particularly those involving medical imaging, different studies have reported the efficiency of varying ML methods.

Exclusion criteria

- Study type: (1) meta, review, guide, expert opinion; and (2) studies with too few samples (less than 20 cases).
- ML: literature that only executed the risk factor analysis but did not develop a complete ML mode.
- Outcome measures: none of the following outcomes were reported: ROC, *c*-index, sensitivity, specificity, accuracy, recovery rate, accuracy rate, confusion matrix, F_1-score, and calibration curve.

Data Sources and Search Strategy

PubMed, Cochrane, Embase, and Web of Science were thoroughly retrieved up to September 3, 2023, using the form of MeSH (Medical Subjects Headings) + free term, without any restrictions on region or publication period. The specific search strategy is depicted in Multimedia Appendix 2.

Study Selection and Data Extraction

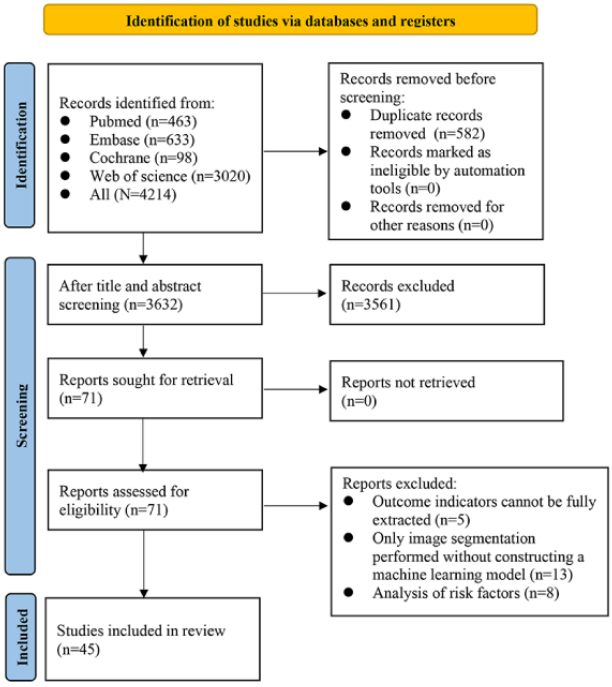
Duplicates were excluded from the retrieved literature, and titles and abstracts were reviewed to delete obviously irrelevant studies. The full texts of the remaining studies were then downloaded and thoroughly read to determine the final included studies in the systematic review. A standard electronic data extraction spreadsheet was prepared prior to extracting data. The extracted data encompassed the title, first author, type of study, year of publication, author's country, patient source, target event, number of cases of the target event, the total number of cases, number of training set cases, the total number of training set cases, method of validation set generation, number of events in the validation set, total number of cases in the validation set, type of models, and modeling variables.

Two researchers (HZ and LF) independently screened the literature and extracted data. Upon completion, their findings were cross-checked. A third reviewer (JH) was consulted for resolution in case of any dissents.

Risk of Bias in Studies

The risk of bias in the eligible studies was appraised by two independent reviewers (HZ and LF) using the prediction model risk of bias assessment tool [16]. This tool is comprised of a large number of questions in four domains (participants, predictors, outcomes, and analysis), which reflect overall bias risk and applicability. The 4 domains involve 2, 3, 6, and 9 specific questions, respectively, and each question may be answered by yes or probably yes, no or probably not, or no information. Following the quality evaluation, a cross-check was carried out. In the event of any disputes, a third researcher (JH) was consulted for resolution.

Synthesis Methods



In some of the original studies included in our research, there was not only 1 validation set. Therefore, the number of models included in the meta-analysis does not equal the number of studies. The meta-analysis of sensitivity and specificity was executed using a bivariate mixed-effects model [17]. Sensitivity and specificity were meta-analyzed as per the diagnostic 2×2 table. However, most included studies did not provide the diagnostic 2×2 table. In such cases, the following two approaches were used to calculate the diagnostic 2×2 table: (1) it was computed based on sensitivity, specificity, and precision, combined with the number of cases; and (2) sensitivity and specificity were extracted based on the optimal Youden index, and then combined with the number of cases for calculation. The meta-analysis was implemented using R (version 4.2.0; R Foundation for Statistical Computing).

Results

Study Selection

A total of 4214 records were retrieved from the databases, of which 582 were duplicates. After reading the titles and abstracts, 3561 studies unrelated to ML in high myopia were excluded, leaving 71 studies. Of these, 13 only conducted image segmentation without constructing ML models, 5 did not provide full extractable outcome indicators, and 8 analyzed risk factors. Ultimately, 45 studies were incorporated into this review. The literature screening process is depicted in Figure 1.

Figure 1. Flowchart of literature screening.

RenderX

Study Characteristics

The included studies were published from 2010 to 2023. Four of the studies [18-21] were about the prediction of high myopia, and the predicted variables were mainly derived from life characteristics, environmental and genetic factors, and routinely interpretable ocular clinical characteristics. Five of the studies [22-26] were about the diagnosis of high myopia, of which 1 study [22] also involved the diagnosis of pathological lesions of high myopia. Six studies focused on the diagnosis of high myopia-associated glaucoma [27-32]. Out of the included studies, 31 studies focused on the diagnosis of pathological myopia, primarily using optical coherence tomography and fundus imaging to construct artificial intelligence models. Of these, 26 studies [4,15,22,33-55] were based on DL (deep learning), while 5 studies [56-60] required manually coded ML for construction. Additionally, it was noted that in the 45 original studies, all 45 studies included binary classification tasks, with 9 studies [4,33,34,38,39,49,50,52,61] additionally incorporating multiclassification tasks. Regarding validation methods, 31 studies provided an external validation set, and 23 used a combination of internal and external validation sets. In terms of the generation method of validation set, 6 studies [23,24,34,40,47,59] used *k*-fold cross-validation, 29 [15,19-22,25-29,35-38,41,42,45,48-58,61] used random sampling, and 6 [4,18,32,33,44,60] applied a combination of *k*-fold cross-validation and random sampling. The detailed characteristics of the eligible studies are shown in Tables 1 and 2.

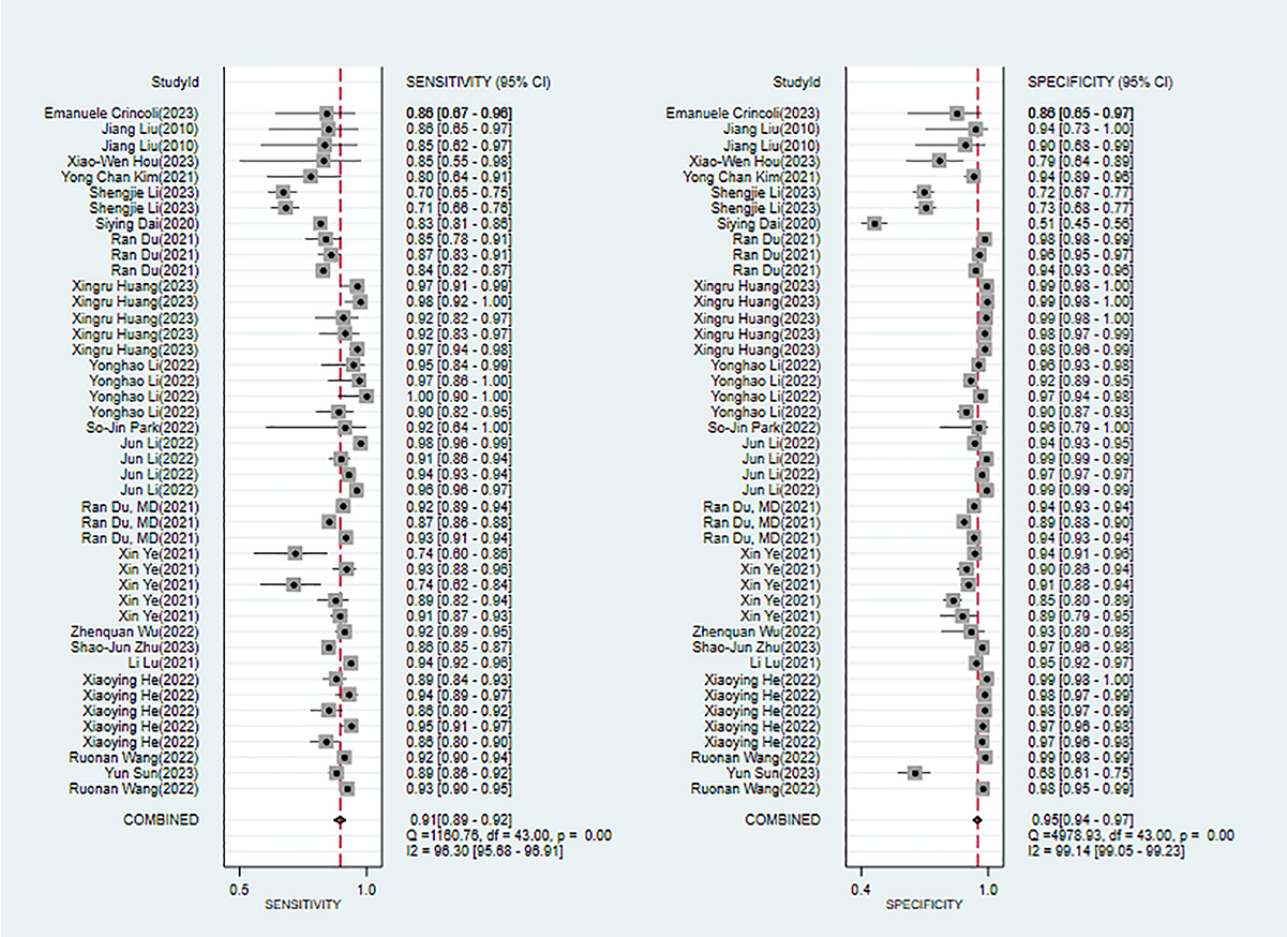
Risk of Bias in Studies

This review incorporated 67 models. There were 36 retrospective studies [4,15,22-26,28-30,32-42,44-50,52-55,57-59,61] that constructed 39 models, indicating a high bias in the choosing of study participants. Five case-control studies [21,27,31,51,56] constructed 13 models, also showing high bias in the selection of study participants. Since the predictors were evaluated in the context of a known outcome in the case-control studies, there was a high bias in the assessment of predictive factors. Twelve studies [19,20,23,24,27,30,31,56-60] constructed 22 models based on manually coded ML, with a high bias in predictive factors. In terms of statistical analysis, 2 studies [21,45] with 5 models did not meet the requirement of having an event per variable>20%, indicating a high risk of bias. In the statistical analysis, 32 models in 34 studies [4,15,18,21-23,25,26,28,29,32-42,44-55,61] could not estimate event per variable due to the use of the DL method. Additionally, 10 studies [19,20,24,27,30,31,56,58-60] with 29 models in ML did not report on the complexity of the data, rendering it difficult to determine their bias risk. Five studies [20,27,30,31,60] with 11 models were identified as having a high risk of bias in statistical analysis because they did not perform cross-validation to adjust the stability of models with different parameters. In summary, in terms of research participants, 14 models had a low risk of bias; 52 models had a high risk of bias, and 1 model had an unclear risk of bias. In terms of predictors, 37 models had a low risk of bias and 30 models had a high risk of bias. In terms of outcomes, all 67 models had a low risk of bias. In terms of statistical analysis, 3 models had a low risk of bias, 16 models had a high risk of bias, and 48 models had an unclear risk of bias.



Meta-Analysis of ML for Binary Classification Tasks

Pathological Myopia

Twenty studies [26,34-37,39,41,45,47-54,56,58,60,61] reported ML for diagnosing pathological myopia. Modeling algorithms included algorithms of conditional probability, support vector machines (SVMs), logistic regression (LR), extreme gradient boosting, convolutional neural networks (CNNs), and deep convolutional neural networks (DCNNs). The overall sensitivity, specificity, positive likelihood ratio (PLR), negative likelihood ratio (NLR), diagnostic odds ratio (DOR), and summary receiver operating characteristic (SROC) were 0.91 (95% CI 0.89-0.92), 0.95 (95% CI 0.94-0.97), 19.7 (95% CI 13.8-28.2), 0.10 (95% CI 0.08-0.12), 201 (95% CI 122-331), and 0.97 (95% CI 0.95-0.98), respectively. The Deek funnel plot indicated no substantial evidence of publication bias in the included ML models. Assuming that the prior probability of pathological myopia was 20% if the result of ML was pathological myopia, then the probability of true pathological myopia would be 83%. If the result of ML was nonpathological myopia, then the probability of true pathological myopia would be 2% (ie, the probability of true nonpathological myopia was 98%; Figure 2 and Figures S1-S3 in Multimedia Appendix 3).

XSL•FO
RenderX

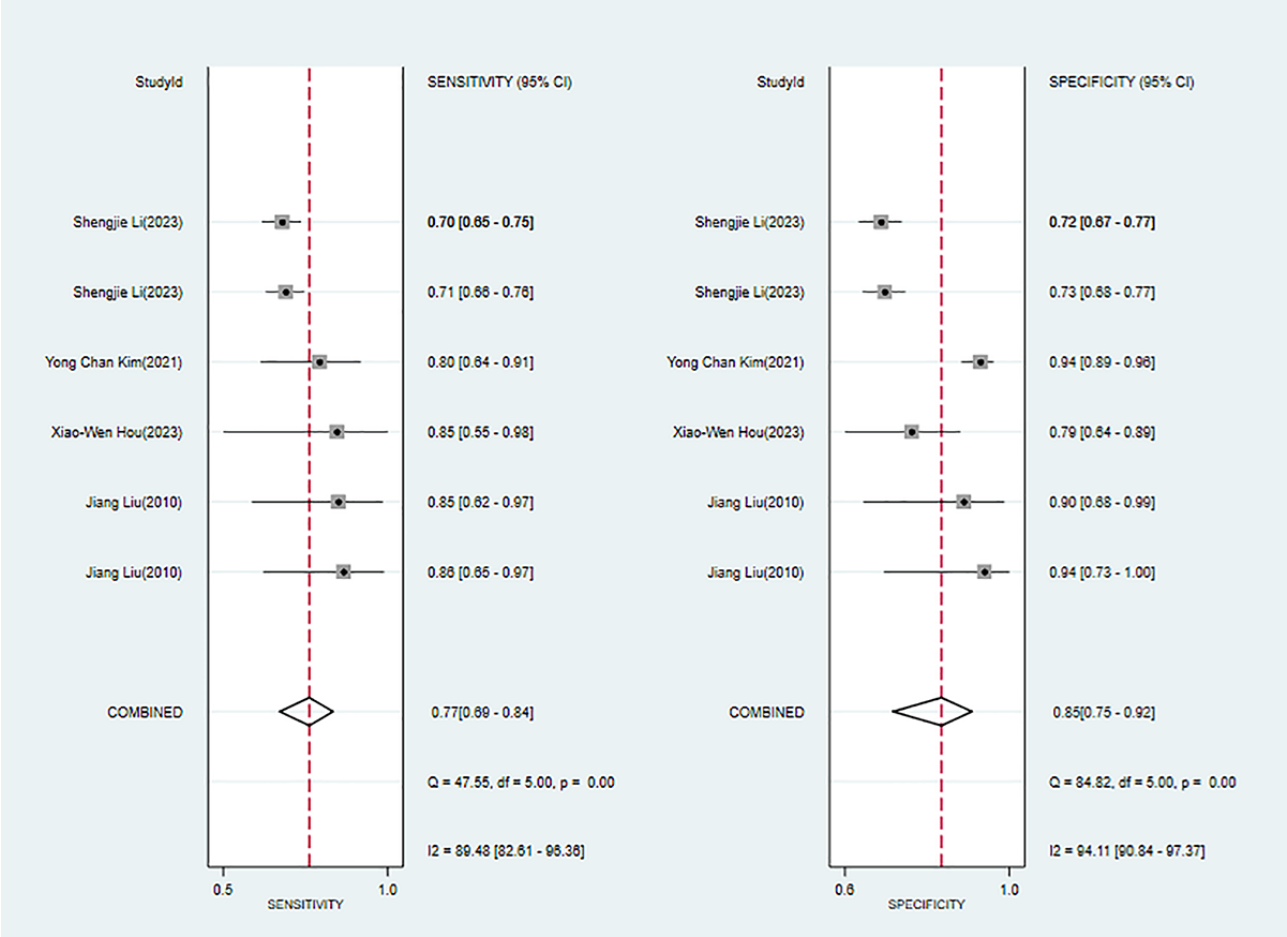


Figure 2. Forest plot for the meta-analysis of sensitivity and specificity of machine learning in detecting pathological myopia [26,34-37,39,41,45,47-54,56,58,60,61]. Note: the pooled sensitivity and specificity of 44 models from 20 machine learning studies on the diagnosis of pathological myopia were 0.91 (95% CI 0.89-0.92) and 0.95 (95% CI 0.94-0.97), respectively.

Five studies [53,54,56,58,60] reported conventional ML (non-DL) for diagnosing pathological myopia. Modeling algorithms included algorithms of conditional probability, SVM, extreme gradient boosting, and LR. The overall sensitivity, specificity, PLR, NLR, DOR, and SROC curve were 0.77 (95% CI 0.69-0.84), 0.85 (95% CI 0.75-0.92), 5.2 (95% CI 2.8-9.8), 0.27 (95% CI 0.18-0.39), 20 (95% CI 7-51), and 0.86 (95% CI 0.75-0.92), respectively. The Deek funnel plot indicated the presence of publication bias in the conventional ML (non-DL) models. Assuming that the prior probability of pathological myopia for conventional ML (non-DL) was 20% if the result of conventional ML (non-DL) was pathological myopia, then the probability of true pathological myopia would be 57%. If the result of conventional ML (non-DL) was nonpathological myopia, then the probability of true pathological myopia would be 6% (ie, the probability of true nonpathological myopia was 94%; Figure 3 and Figures S4-S6 in Multimedia Appendix 3).

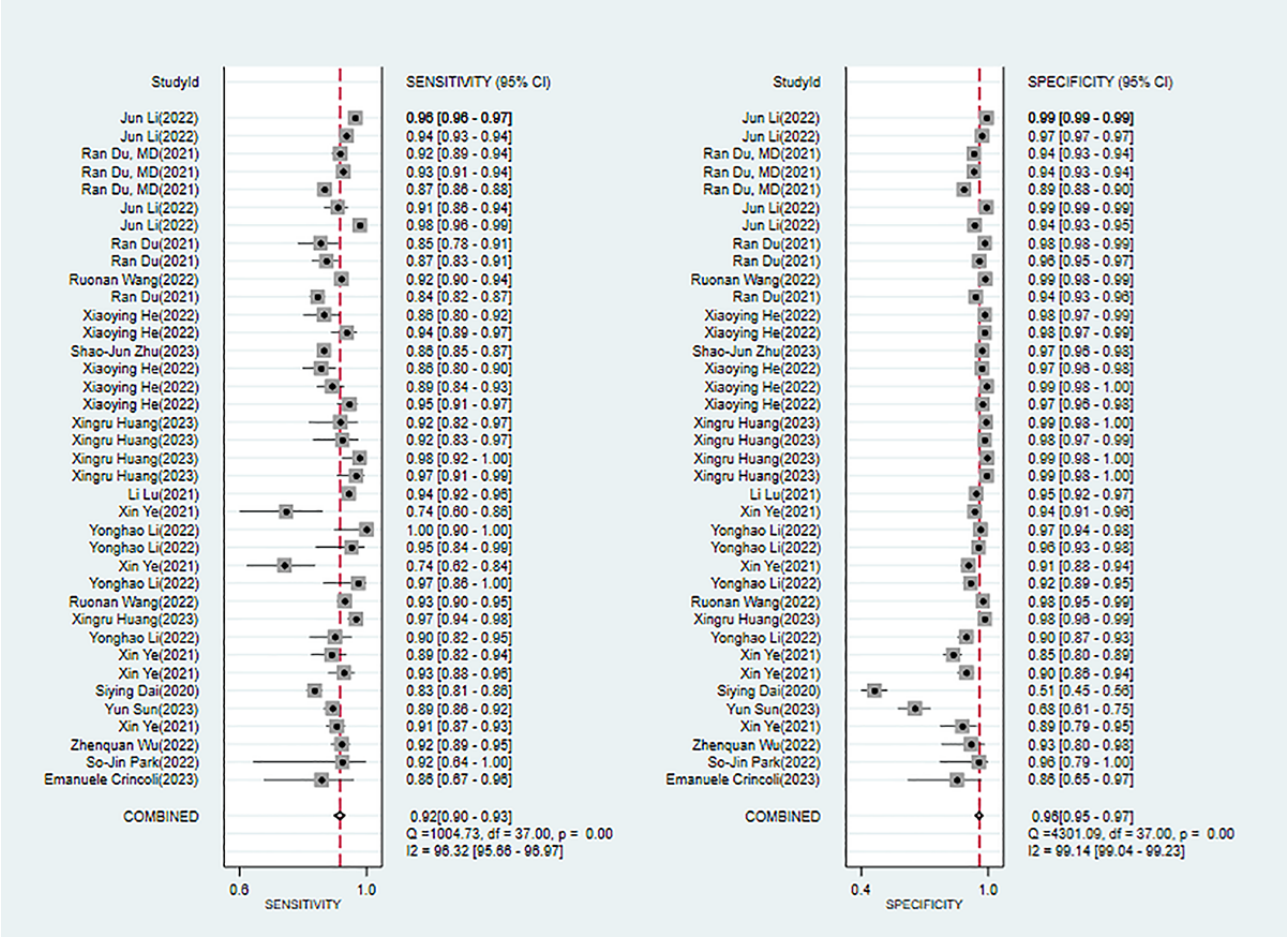

Figure 3. Forest plot for the meta-analysis of sensitivity and specificity of conventional machine learning (non-deep learning) in detecting pathological myopia [53,54,56,58,60]. Note: the pooled sensitivity and specificity of 6 models from 5 conventional machine learning (non-deep learning) studies on the diagnosis of pathological myopia were 0.77 (95% CI 0.69-0.84) and 0.85 (95% CI 0.75-0.92), respectively.

Fifteen studies [26,34-37,39,41,45,47-52,61] mentioned DL for diagnosing pathological myopia. Modeling algorithms included CNN and DCNN. The overall sensitivity, specificity, PLR, NLR, DOR, and SROC were 0.92 (95% CI 0.90-0.93), 0.96 (95% CI 0.95-0.97), 23.7 (95% CI 16.5-34.0), 0.09 (95% CI 0.07-0.11), 271 (95% CI 168-437), and 0.97 (95% CI 0.95-0.98), respectively. The Deek funnel plot revealed no remarkable publication bias in the DL models. Assuming that the prior probability of pathological myopia for DL was 20% if the result of DL was pathological myopia, then the probability of true pathological myopia would be 86%. If the result of DL was nonpathological myopia, then the probability of true pathological myopia would be 2% (ie, the probability of true nonpathological myopia was 98%; Figure 4 and Figures S7-S9 in Multimedia Appendix 3).

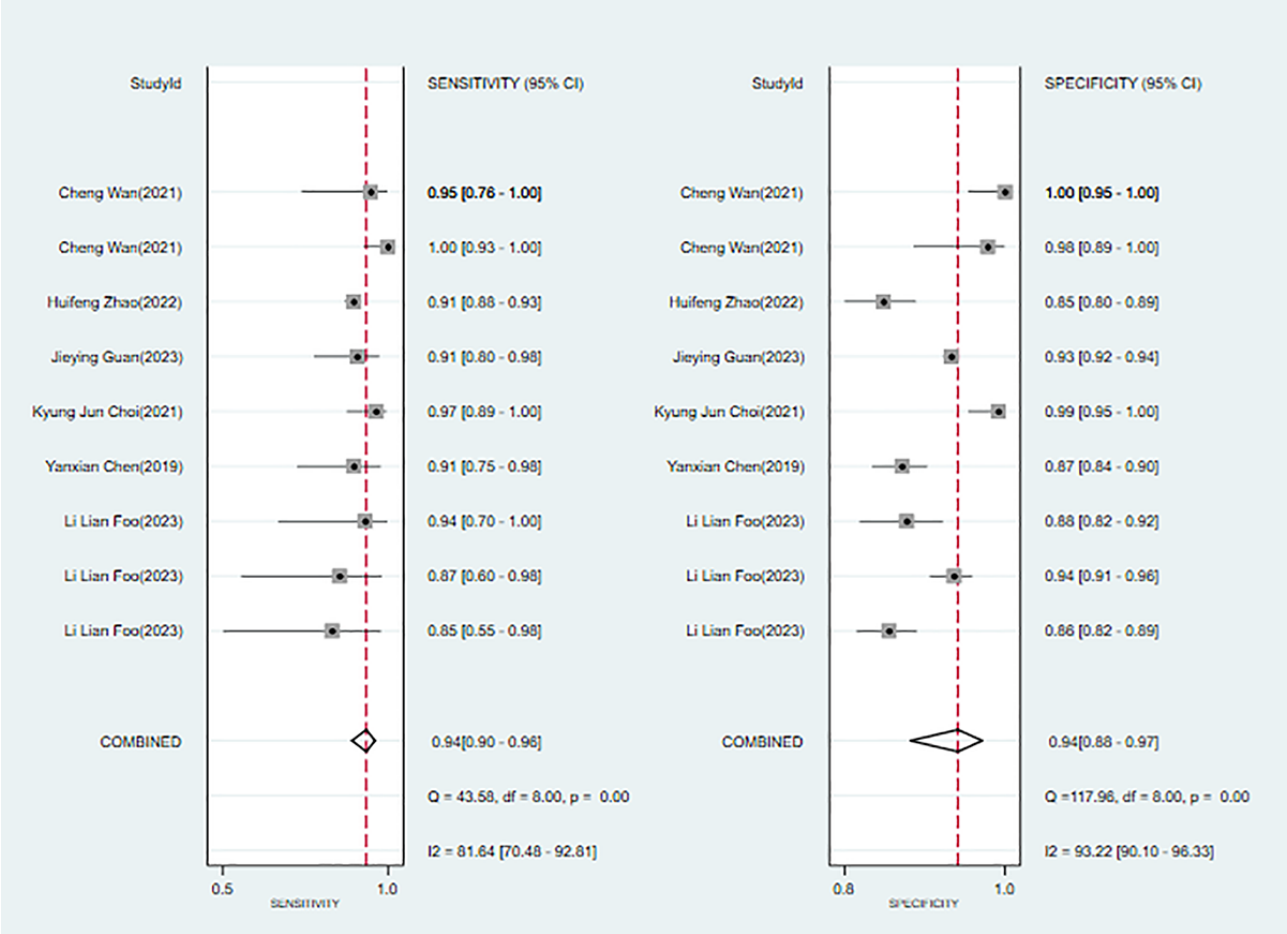
Figure 4. Forest plot for the meta-analysis of sensitivity and specificity of deep learning in detecting pathological myopia [26,34-37,39,41,45,47-52,61]. Note: the pooled sensitivity and specificity of 38 models from 15 deep learning studies on the diagnosis of pathological myopia were 0.92 (95% CI 0.90-0.93) and 0.96 (95% CI 0.95-0.97), respectively.



High Myopia

Six studies [4,18,20,23-25] discussed ML for diagnosing and forecasting high myopia. Modeling algorithms included DCNN, CNN, LR, SVM, random forest (RF), and linear mixed models. The sensitivity, specificity, PLR, NLR, DOR, and SROC were 0.94 (95% CI 0.90-0.96), 0.94 (95% CI 0.88-0.97), 16.2 (95% CI 7.7-33.8), 0.06 (95% CI 0.04-0.11), 255 (95% CI 79-822), and 0.98 (95% CI 0.96-0.99), respectively. The Deek funnel plot indicated no substantial evidence of publication bias in the included ML models. Assuming that the prior probability of high myopia for ML was 20% if the result of ML was high myopia, then the probability of true high myopia would be 80%. If the result of ML was non-high myopia, then the probability of true high myopia would be 2% (ie, the probability of true non-high myopia was 98%; Figure 5 and Figures S10-S12 in Multimedia Appendix 3).

Three studies [4,23,25] focused on diagnosing high myopia, while 3 studies [18,20,24] focused on predicting high myopia. Due to the limited number of studies included, we did not perform a meta-analysis for the diagnostic and prediction tasks. In the validation sets of the diagnostic tasks, sensitivity ranged from 0.91 to 1.00 and specificity ranged from 0.85 to 1.00, while in the validation sets of the prediction tasks, these values were 0.85-0.94 and 0.86-0.94, respectively. We found that both diagnostic and prediction tasks demonstrated highly favorable performance.

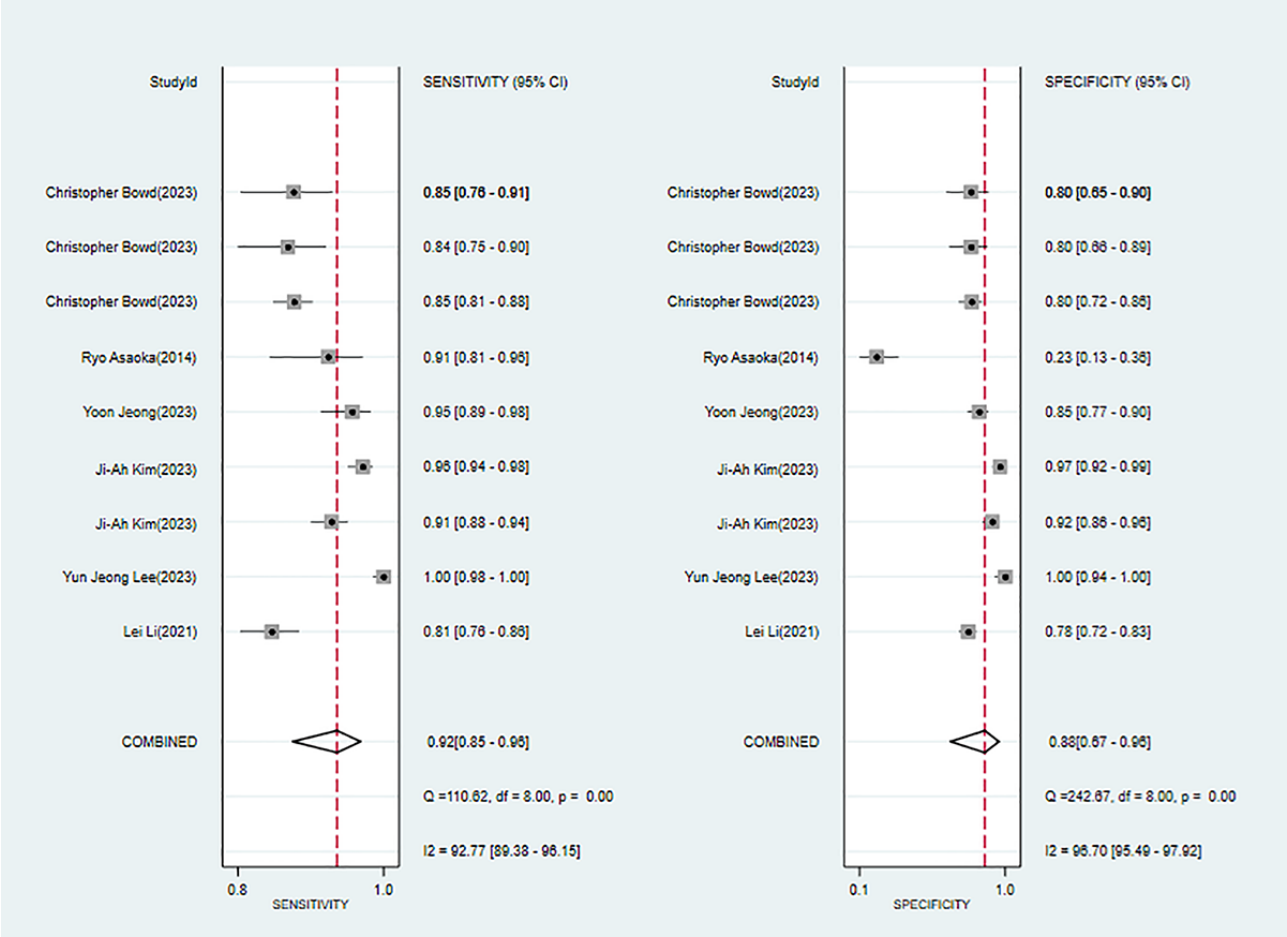
RenderX

Figure 5. Forest plot for the meta-analysis of sensitivity and specificity of machine learning in detecting high myopia [4,18,20,23-25]. Note: the pooled sensitivity and specificity of 9 models from 6 machine learning studies on the diagnosis and prediction of high myopia were 0.94 (95% CI 0.90-0.96) and 0.94 (95% CI 0.88-0.97), respectively.



High Myopia–Associated Glaucoma

Six studies [27-32] mentioned ML for diagnosing high myopia-associated glaucoma. Modeling algorithms included Lagrange multiplier, fully connected network, radial basis function network, decision tree, RF, and CNN. The sensitivity, specificity, PLR, NLR, DOR, and SROC curve were 0.92 (95% CI 0.85-0.96), 0.88 (95% CI 0.67-0.96), 7.6 (95% CI 2.4-23.8), 0.09 (95% CI 0.04-0.20), 84 (95% CI 13-555), and 0.96 (95% CI 0.94-0.97), respectively. The Deek funnel plot indicated no substantial evidence of publication bias in the included ML models. Assuming that the prior probability of high myopia–associated glaucoma was 20% if the result of ML was high myopia-associated glaucoma, then the probability of true high myopia–associated glaucoma would be 65%. If the result of ML was non-high myopia–associated glaucoma, then the probability of true high myopia–associated glaucoma would be 2% (ie, the probability of true non-high myopia–associated glaucoma was 98%; Figure 6 and Figures S13-S15 in Multimedia Appendix 3).

XSL•FO
RenderX

Figure 6. Forest plot for the meta-analysis of sensitivity and specificity of machine learning in detecting high myopia-associated glaucoma [27-32]. Note: the pooled sensitivity and specificity of 9 models from 6 machine learning studies on the diagnosis of high myopia-associated glaucoma were 0.92 (95% CI 0.85-0.96) and 0.88 (95% CI 0.67-0.96), respectively.

Review of ML for Multiclassification Tasks

Out of the included studies, 9 [4,33,34,38,39,49,50,52,61] used ML for multiclassification tasks. Due to significant variations in the diagnostic differences across these multiclassification tasks, a quantitative analysis was not feasible. Five studies [33,34,38,39,50] focused on fundus images–based DL to detect different types of myopic atrophy maculopathy in high myopia, with an accuracy ranging from 88% to 97%. Two studies [49,61] used optical coherence tomography (OCT) image–based DL to detect different types of myopic traction maculopathy in high myopia, with an accuracy ranging from 91% to 96%. One study [4] used fundus image–based DL to differentiate between normal, low-risk high myopia, and high-risk high myopia, with an accuracy of 99%. One study [52] applied fundus image–based DL to distinguish between normal, fundus tessellation, and pathologic myopia, with an accuracy of 94%, as illustrated in Table 3.

Discussion

Summary of the Main Findings

This study comprehensively described the accuracy of ML in detecting high myopia, high myopia-associated glaucoma, and pathologic myopia. ML demonstrated exceptionally favorable performance in detecting high myopia, while DL was highly accurate in diagnosing pathologic myopia.

Comparison With Previous Reviews

Previous studies have also explored the detection accuracy of ML in this field. A systematic review has reported that fundus image– or OCT image–based DL can effectively diagnose and classify myopic maculopathy. Additionally, ML examination of the optic disc area can detect myopic maculopathy that may not be easily identified during clinical examination [14]. A recent meta-analysis based on only 11 studies evaluated the performance of DL in identifying pathological myopia based on fundus images. The SROC, specificity, and sensitivity were found to be 0.9905, 0.959 (95% CI 0.955-0.962), and 0.965 (95% CI 0.963-0.966), respectively [62]. In the previous meta-analysis, the 11 original studies all constructed fundus images-based DL models, and studies on conventional ML (non-DL) were not incorporated. The number of studies included in our review was further expanded, with a total of 20 studies on the performance of ML in diagnosing pathological myopia. Moreover, subgroup analysis was executed between conventional ML (non-DL) and DL. Our finding also indicated that DL demonstrated exceptionally favorable efficiency in detecting pathological myopia.

As the understanding of the etiology of myopia deepens, growing evidence reveals risk factors for the onset or progression of myopia, including age, sex, parental myopia, susceptibility genes, and outdoor activities. For high myopia, early prediction appears to be more beneficial. Among the included studies, one incorporated 135 myopia-related single nucleotide polymorphisms to forecast the progression and onset of high myopia. ML for the prediction of high myopia was

XSL•FO
RenderX

mainly based on genetic factors, environmental factors, and ocular clinical characteristics. ML showed an SROC of 0.96, sensitivity of 0.91, and specificity of 0.87, respectively [20], suggesting that ML methods can effectively identify high-risk individuals with high myopia, thus effectively preventing this condition, especially in minors.

Glaucoma is a significant contributor to irreversible vision impairment and blindness all over the world. A 10-year study in Chinese individuals over the age of 40 years found that every 1 mm increase in axial length increased the risk of open-angle glaucoma by 1.72 times. In comparison to emmetropic and hyperopic eyes, highly myopic eyes had a 7.3 times higher risk of developing open-angle glaucoma [63]. Due to the changes in retinal structure caused by myopia, diagnosing glaucoma in myopic patients, especially those with high myopia, is challenging. Six studies were included to evaluate the diagnosis of high myopia glaucoma. Of them, 3 studies [28,29,32] used fundus OCT image-based DL techniques, while the remaining 3 [27,30,31] used non-DL ML (Lagrange multiplier, fully connected network, radial basis function network, decision tree, RF) approaches using OCT parameters, Heidelberg Retina Tomograph parameters, and ocular biometric parameters of patients. The findings indicated that ML yielded highly promising results in the detection of high myopia glaucoma.

It was also noted that different ML methods, conventional ML and DL, showed significant differences in their ability to identify positive or outcome events. Conventional ML is often used to construct models with interpretable clinical features. Lately, various image-based ML methods have emerged. However, a significant challenge in this context is the requirement for manual annotation to facilitate ML. From this standpoint, manual annotation poses a formidable barrier to effectively mitigating the risk of bias. DL, on the other hand, enables intelligent processing of medical images and has been widely applied in various fields, including detecting diabetic retinopathy [8-10], retinopathy of prematurity [64,65], age-related macular degeneration [10], and glaucoma [11-13]. With the rapid development of ML, imaging data are increasingly becoming a valuable source for medical analysis. Multiple studies have demonstrated that images from various sources, including fundus images [66], external eye appearance [67], and refractive images [68], can effectively estimate a patient's spherical refractive error, indicating the potential of imaging data in predicting the risk of myopia. This study also finds that image-based DL is more accurate than conventional ML, providing a theoretical basis for the creation of future intelligent tools.

Additionally, the dataset used in ML demands considerable attention. Many studies are hampered by a limited number of cases, raising concerns about the robustness of the findings. Additionally, validation methods often depend heavily on internal validation, which may not fully capture the model's generalizability. Hence, incorporating comprehensive patient data is essential for building a robust large-scale database, which will enable the development of ML models that are applicable to a broader population. Among the studies included, 7 [15,22,39,42,44,55,59] established ML models based on publicly available large databases.

Limitations

Although our review includes a larger number of studies than previous meta-analyses and provides an evidence-based basis for subsequent studies, this study has limitations. First, there were few studies on the prediction of high myopia, which limits the interpretation of our results, and clinically interpretable variables for predicting high myopia were not explained. Second, we did not conduct a subgroup analysis on the type of ML (conventional ML vs DL) owing to the insufficient number of included studies based on high myopia glaucoma and high myopia. Third, the majority of the models included in this study were assessed as having a high risk of bias, which may impact the interpretation of our results. Most included studies adopted a retrospective design, which might lead to selection bias.

Conclusions

In conclusion, this study comprehensively reviews and meta-analyzes the performance of ML in the diagnosis and prediction of high myopia, high myopia-associated glaucoma, and pathological myopia, providing valuable guidance and references for future research. Challenges exist within the emerging field of myopia prediction. With the development of new analytical methods and the accumulation of real medical datasets, future research holds the promise of improving the prediction of myopia onset and progression. This advancement brings us closer to the ultimate goal of identifying high-risk individuals promptly and implementing targeted interventions in clinical practice.

Abstract

Background: Social media is used as a tool for information exchange, entertainment, education, and intervention. Intervention efforts attempt to engage users in skin health.

Objective: This review aimed to collect and summarize research assessing the impact of social media on skin health promotion activities undertaken by social media users.

Methods: In accordance with the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) guidelines, the following scientific databases were searched: Scopus, Web of Science, PubMed, Academic Search Ultimate (via EBSCO), Academic Research Source eJournals (via EBSCO), ERIC (via EBSCO), Health Source: Consumer Edition (via EBSCO), and Health Source: Nursing/Academic Edition (via EBSCO). Using ProQuest Dissertations and Theses, OpenGrey, Grey Literature Report, and MedNar, the search was supplemented with gray literature. Articles on skin care, skin health, skin diseases, skin protection, and educational activities promoting healthy skin on social media were selected for review (search date: February 6, 2023). The following qualification criteria were used: original research; research conducted on social media; and research topics regarding educational activities in skin health promotion, skin care, skin health, skin diseases, and skin protection. To assess the risk of bias, the following tools were used: the Cochrane Collaboration tool for risk-of-bias assessment (randomized controlled trials and quasi-experimental studies) and the Centre for Evidence-Based Medicine checklist (cross-sectional studies).

Results: Altogether, 1558 works were considered, of which 23 (1.48%) qualified, with 3 (13%) studies on acne and 20 (87%) on skin cancer, sunscreen, and tanning. Social media interventions were dealt with in 65% (15/23) of the studies. The review made it possible to investigate cognitive and cognitive-behavioral interventions. In both observational and interventional studies, the most frequently discussed topics were skin exposure and protection against UV radiation and skin cancer. The analyzed research showed that social media is a source of information. Visualization has a strong impact on users. The involvement of social media users is measured through the amount of content shared and contributes to changing attitudes and behaviors regarding skin health.

Conclusions: This review outlined the impact of social media, despite its heterogeneity, on users' skin health behaviors, attitudes, and actions. It identified strategies for digital interventions to promote skin health. In health sciences, a standardized tool is needed to assess the quality of social media digital interventions. This review has several limitations: only articles written in English were considered; ongoing studies were omitted; and there was a small number of interventional studies on acne and a lack of research on daily skin care, education, and antiaging activities on social media. Another limitation, resulting from the topic being too broad, was a failure to perform quantitative data analysis, resulting in the studies that qualified for the review being heterogeneous.

skin; social media; prevention; behavioral intervention; skin cancer; sun protection; acne

Introduction

Background

For many people, social media platforms are now an integral part of daily life. Social media browsing is the most popular online activity. According to the statistics, >4.26 billion people used social media in 2021, and this number is likely to grow to almost 6 billion in 2027 [1]. In April 2023, a total of 4.8 billion people, or 59.9% of the world's population, were social media users [2].

Social media is a powerful means of communication, mainly used for an exchange of information and for entertainment. In addition, companies use it for marketing purposes to promote products and services. Currently, there is also a noticeable trend to develop educational platforms, especially on health education. According to Savas et al [3], because of an increase in the number of patients looking for medical information, physicians can use social media such as Facebook as a significant educational tool. Gantenbein et al [4] argue that medical information available on the internet and social media could be useful for most dermatological patients. The authors identified the most important needs of patients: online consultations, medical content on YouTube, and a possibility to chat with a specialist [4]. In turn, according to Banerjee et al [5], social media is a platform for increasing people's commitment and providing information about UV protection, skin cancer prevention, and its early detection.

The aforementioned research confirms the informational and educational role of social media. The aim of information activities is to increase knowledge about skin cancer and increase awareness of the risks of UV radiation. The effect of these activities should be a change in health behaviors (regular skin photoprotection, regular skin self-examination, and regular monitoring of skin lesions by a physician). Engagement in systematic activities by social media users is crucial.

In addition to its educational role, social media is a tool that supports life and work. Rew et al [6] created a prototype of an application based on content concerning social media users' daily activities. The application can assess the condition of the skin and provides advice on improving it, with suggestions for care products.

In addition, social media can be a motivational tool by motivating systematic care and protection activities aimed at healthy and well-groomed skin.

Focusing mainly on the analysis of social media content, previous reviews have discussed their impact on skin care [7] and skin cancer prevention [8]. They have also discussed the effects of social networking sites on health behavior change [9] and on available digital interventions, mainly stressing the importance of sun protection and skin self-examinations [10].

Unlike previous systematic reviews, we sought to understand the nature of motivation to act. We were interested in the following aspects: (1) What dermatological problem that is talked about on social media is the main area of interest for researchers? (2) What drives social media audiences to take goal-directed actions? (3) What is the level of involvement of social media users in achieving this goal? (4) What contributes to perseverance in pursuing a goal? The goal is healthy and well-groomed skin. To achieve this goal, health behavior changes must be made.

We wanted to draw attention to the role of social media as a tool for collecting data and a tool that encourages users to take actions to care for their skin (including preventing the development of skin cancer and alleviating the symptoms of dermatological diseases).

The main parts of skin health preventive measures are promoting skin care, skin protection, and control routines. The involvement and motivation of social media users is important. Therefore, research is needed to conduct a systematic review that evaluates the impact and effectiveness of social media in this field. In addition, such research should not only focus on the information provided by social media but also try to engage users in actions aimed at skin health.

This review helps understand and explores what is already known about social media potential and its impact on users' skin care behaviors and skin health preventive measures. This study suggests the need to optimize social media interventions and develop new studies that will assess long-term change in skin health behaviors. In addition, by increasing the importance of skin protection and its diseases, this review has practical significance. The results of this research can be helpful in practice and in research investigating the role of social media in preventive health care. This review may support the work of dermatologists, cosmetologists, and health educators because it provides information they need, sometimes on complex topics, in a simple and easily available way.

The novelty of this review is that, through the heterogeneity of the research, a broader view of the impact of social media on skin health behaviors is presented. This study provides new observations about the prespecified desired outcome to be achieved. It complements the theory of engagement with digital interventions.

This study differs from previous ones in that it presents social media as an important digital stimulus. It affirms the integration of motivation into specific physical, affective, and cognitive action. The empirical observations concerning, on the one hand, the demonization of the effects of the sun on the skin and, on the other, the image of an attractive tan, which occur in a cause-effect conflict, are surprising.

This review proves that the image, not just the content, is of great importance. There is a noticeable trend in which the image becomes more important than scientific reports. This review also presents the negative side of social media.

RenderX

Objectives

This paper presents a systematic review of the literature investigating the role of social media platforms as an educational and intervention tool in promoting preventive skin health measures. The aim of this review was to collect and summarize research assessing the impact of social media on skin health promotion activities undertaken by social media users. In the analyzed studies, we focused on the reception of information about the skin (eg, skin cancer, acne, and tanning) by social media users. The literature review comprised (1) studies assessing the impact of the content of social media on its users, (2) social media intervention studies, and (3) studies determining the impact of posts generated by users on their health decisions and their self-monitoring.

The following research questions were formulated:

1. What are the existing data on the use of social media as an educational intervention tool in skin health preventive measures?
2. What activities on social media can be effective in promoting skin health?
3. What intervention strategies are disseminated via social media and what is their role in promoting skin health?

Methods

Design

This systematic review was conducted in accordance with the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) guidelines [11,12] and with the Synthesis Without Meta-Analysis reporting guideline [13]. The PRISMA guidelines ensure the highest quality in scientific research. To more fully present the results of the review, a narrative form was additionally adopted.

Information Sources and Search Strategies

This review was conducted using the following databases: Scopus, Web of Science, PubMed, Academic Search Ultimate (via EBSCO), Academic Research Source eJournals (via EBSCO), ERIC (via EBSCO), Health Source: Consumer Edition (via EBSCO), and Health Source: Nursing/Academic Edition (via EBSCO). In addition, the search was supplemented with gray literature using ProQuest Dissertations and Theses, OpenGrey, Grey Literature Report, and MedNar. A reference list search for relevant articles was also conducted.

The search strategy was first constructed by the authors and then consulted with a librarian experienced in scientific information extraction. The developed phrase was as follows:

> *((“social media” OR “Facebook” OR “Instagram” OR “Twitter” OR “Pinterest” OR “YouTube” OR “TikTok” OR “SnapChat”) AND (“skincare” OR “skin care” OR “skin health” OR “skin diagnosis” OR “skin type” OR “beautician” OR “cosmetologist” OR “cosmetician” OR “cosmetic consultation*” OR “cosmetic dermatology” OR “cosmetic product*” OR “dermocosmetic*” OR “cosmetic procedure*” OR “skin cleans*” OR “skin moistur*” OR “skin massage” OR “facial cleans*” OR “facial moistur*” OR “facial massage” OR “photoprotection” OR “sunscreen*” OR “sun protection” OR “skin hydration” OR “skin rejuvenation” OR “skin cancer” OR “skin prevention” OR “acne” OR “rosacea” OR “anti-acne” OR “anti-aging” OR “anti-wrinkle” OR “skin aging” OR “oily skin” OR “dry skin” OR “combination skin” OR “sensitive skin” OR “pigmented skin” OR “pimple*” OR “pustule*” OR “papules” OR “blackheads”))*

The search was conducted on February 6, 2023, and on the same day, the records were imported from the databases into the Mendeley reference manager (Elsevier). The search was not limited to a period to obtain as many results as possible.

Study Selection

After applying the search strategy, the studies were imported and saved to the Mendeley reference manager, and then duplicates were removed. The selection of the studies consisted of 2 stages. The first stage was conducted by one of the authors (JMB), who considered the title and abstract to identify and exclude irrelevant studies. To reach a mutual agreement, the other author (JG) reviewed a randomly selected sample containing 10% of the titles and abstracts. When, based on the title and abstract, the decision whether to include a work was difficult, the full article was then downloaded. The second stage of the selection consisted of an analysis of the full texts of the articles by each author (JMB and JG) separately to determine whether they could be included, and the reasons for exclusion were listed. When the decision to include or exclude a study was unclear, the authors clarified ambiguities and different opinions through discussions. This stage of the article selection process required both authors to be present to resolve voting conflicts. All studies were assessed using the inclusion and exclusion criteria described in the next section.

Inclusion and Exclusion Criteria

All the inclusion and exclusion criteria were defined a priori (Textbox 1).

In particular, the following papers were excluded during the first stage of the selection process: papers written in a language other than English, papers not related to topics of skin care and skin health promotion on social media, conference papers, information from beauty and health blogs, posters of prevention campaigns, and interviews and articles from popular science magazines advertising a specific cosmetic brand. In addition, articles on social media safety rules, product protection, ethics, diet, COVID-19, and tele-dermatology and materials related to patient consent to post photos on social media were eliminated. During the second stage, articles were allocated to the following groups: articles fully meeting the inclusion criteria, comments, case studies, review papers, research protocols, papers in which skin care and skin health preventive measures were not the main topic, papers in which social media was not the main topic (eg, it was used to recruit study participants or to disseminate survey results), papers on plastic surgery and body image perception on social media, papers on social media marketing (eg, dealing with the impact of advertisements encouraging consumers to purchase cosmetic products or with methods of promoting the sale of cosmetic products or assessing the satisfaction with

XSL•FO
RenderX

cosmetic products and with brand image building of skin care products), papers on the psychological effects of social media (eg, self-acceptance of social media users; self-confidence; and the relationship among emotions, emotional states, and the use of social media), papers on social media search for medical information by dermatology patients, and papers focusing exclusively on the analysis of the content most frequently shared on social media (ie, posts and videos).

Articles with educational value and assessing the impact of social media skin-related information on its users were included. This review also included studies that investigated social media interventions (articles on behavioral interventions aimed at skin health promotion, which were included during the primary analysis) and studies that investigated the impact of social media data on users (articles on skin health promotion, which were included during the secondary analysis).

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Papers based on original research (ie, research articles)
- Papers on skin care, skin health, skin diseases, and skin protection and papers on educational activities directed at skin health preventive measures
- Papers on social media (eg, Facebook, Instagram, Twitter [subsequently rebranded X], Pinterest, YouTube, TikTok, and Snapchat)

Exclusion criteria

- Papers written in a language other than English
- Review papers
- Comment papers
- Case studies
- Conference papers
- Clinical trial reports
- Information from beauty and health blogs, popular science magazines, interviews, and posters from prevention campaigns
- Papers in which social media coverage of skin care, skin health, and preventive actions were not the main topic

Data Extraction

Research information from the included articles downloaded during the search process was rechecked by both authors (JMB and JG) to ensure that it met the inclusion criteria. The following details were extracted from each paper: authors, year of publication, geographic location of data collection (country where the research took place), type of social media platform, form of information, number and characteristics of study participants, type of study or data collection methods, and main topic and purpose of the research (Multimedia Appendix 1 [14-36]). In addition, one author (JMB) developed a form with questions (Textbox 2) in which both authors independently recorded their responses (summarized in Multimedia Appendix 2 [14-36]). The PRISMA checklist is provided in Multimedia Appendix 3.

Textbox 2. Questions related to qualified publications.

What are the authors and the year of publication?

- Is intervention a topic of the study?
- Does the study evaluate the impact of social media on users?
- Does the study deal with public health campaigns?
- Does the study mention skin self-examination?
- Does the study mention the use of cosmetic materials (eg, sunscreen)?
- Does the study contain a statistical analysis?
- What are the main results of the study?
- What are the conclusions or opinions of the authors on the effectiveness of information delivery strategies on social media?

Quality Assessment

The methodological quality of each study included in this review was assessed separately by both authors (JMB and JG), and their opinions were compared. In case of disagreement, the authors discussed their doubts and came to a consensus. The Cochrane Collaboration tool for risk-of-bias assessment was used to assess the risk of bias in randomized controlled trials and quasi-experimental studies [37]. A total of 6 domains were evaluated, with the plus sign (+) representing a low risk of bias, the en dash (–) representing a high risk of bias, and both (+ and –) representing an unclear risk of bias. Blinding of participants

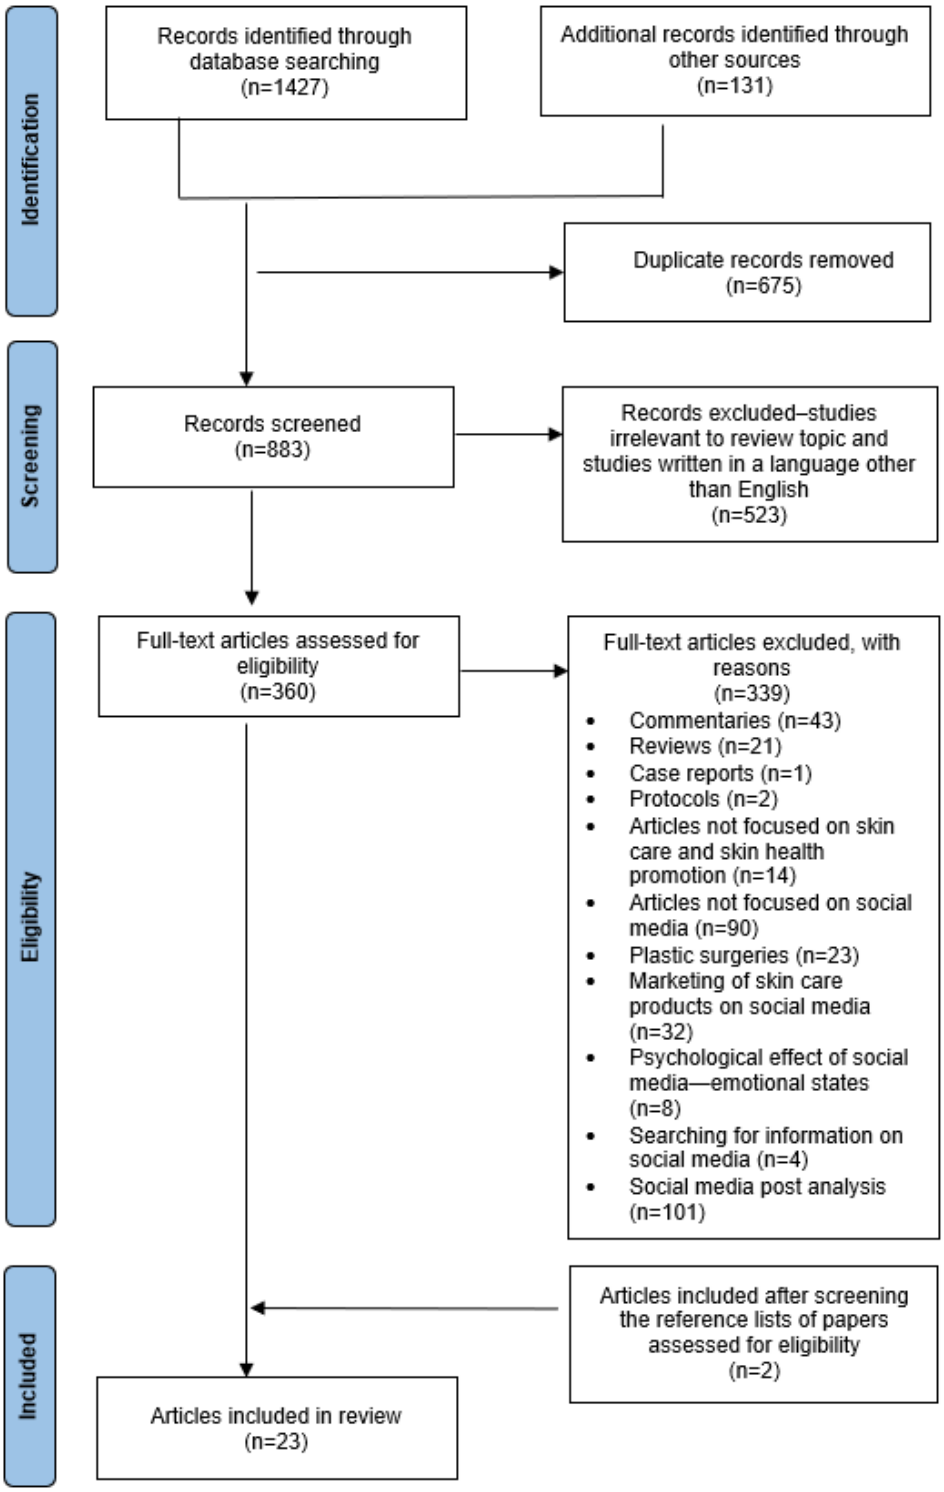
XSL•FO
RenderX

and staff was not assessed as this was considered impossible in some studies. A study that received a score of ≥4 plus signs was considered to be of high quality.

For cross-sectional studies, the Centre for Evidence-Based Medicine checklist for critical appraisal was used [38]. It consists of 12 questions with possible answers of "yes," "cannot tell," or "no." A cutoff value of 75% was used for the assessment. This means that, with ≥9 affirmative responses, the study was considered to be of high quality. Otherwise, the study was considered to be of low quality.

Data Synthesis Strategy

A narrative synthesis of the included studies was performed in accordance with the recommendations by Popay et al [39]. During data analysis, the authors considered the possibility of classifying the included publications according to the health problem. However, after reanalysis of the selected publications, the authors decided that a better conceptual model was to group them according to the type of intervention, if it was used.



Results

Search Results

A literature search revealed 1558 records (Scopus: n=485, 31.13%; Web of Science: n=305, 19.58%; PubMed: n=270, 17.33%; Academic Search Ultimate via EBSCO: n=234, 15.02%; Academic Research Source eJournals via EBSCO: n=26, 1.67%; ERIC via EBSCO: n=10, 0.64%; Health Source: Consumer Edition via EBSCO: n=35, 2.25%; Health Source: Nursing/Academic Edition via EBSCO: n=62, 3.98%; ProQuest Dissertations and Theses: n=22, 1.41%; OpenGrey: n=4, 0.26%; Grey Literature Report: n=0; MedNar: n=105, 6.74%). During the identification stage, 91.59% (1427/1558) of the records were obtained from scientific databases, and 8.41% (131/1558) of the records were obtained from gray literature. After removing 43.32% (675/1558) of duplicates, 883 records remained. After reviewing the titles and abstracts of these 883 records, 523 (59.2%) were excluded because they were irrelevant to the review topic or were written in a language other than English. A total of 40.8% (360/883) of the publications were selected for full-text download. After analyzing the full texts of the articles, 339 were excluded (n=43, 12.7% comments; n=21, 6.2% reviews; n=1, 0.3% case reports; n=2, 0.6% protocols; n=14, 4.1% articles not focused on skin care and skin health promotion; n=90, 26.5% articles not focused on social media; n=23, 6.8% articles about plastic surgeries; n=32, 9.4% articles about marketing of skin care products on social media; n=8, 2.4% articles about the psychological effect of social media—emotional states; n=4, 1.2% articles about searching for information on social media; and n=101, 29.8% articles about social media post analysis). These studies did not meet the inclusion criteria. A total of 21 articles met the inclusion criteria. In addition, after a detailed analysis of the eligible studies and their references, 2 publications were added. In total, 23 publications were included in this review (Figure 1).

RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) flow diagram.

Study Characteristics

The detailed characteristics and main results of the studies included in this systematic review are presented in Multimedia Appendix 1 [14-36] and Multimedia Appendix 2 [14-36]. Most of the research was conducted using Facebook. Of the 23 studies, most (n=14, 61%) were conducted in the United States [14-27], with a smaller number conducted in other countries: the United Kingdom (n=3, 13%) [28-30], Australia (n=3, 13%) [31-33], the Netherlands (n=1, 4%) [34], Denmark (n=1, 4%) [35], and Saudi Arabia (n=1, 4%) [36]. The highest number of studies was published in 2022 (5/23, 22%) [16,17,21,22,36], 17% (4/23) of the studies were published in 2020 [19,27,28,30], 13% (3/23) were published in 2019 [20,26,32], 13% (3/23) were published in 2018 [14,18,24], 13% (3/23) were published in 2017 [29,31,34], 9% (2/23) were published in 2021 [15,25], 9% (2/23) were published in 2011 [33,35], and 4% (1/23) were published in 2016 [23]. The oldest included publications dated back to 2011 (2/23, 9%) [33,35].

The vast majority of the studies were on skin cancer, sunscreen, and tanning (20/23, 87%), with only 13% (3/23) of the studies

XSL•FO
RenderX

on acne [19,27,36]. A total of 17% (4/23) of the studies dealt with skin self-examination [18,19,30,34]. On the other hand, 43% (10/23) of the studies mentioned the use of cosmetic products [14,18,21,22,25,27,28,31,33,36], whereas 35% (8/23) of the studies recommended sunscreen use [14,18,21,22,25,28,31,33]. In addition, 43% (10/23) of the studies discussed the impact of public health campaigns [15-17,20,22,28-30,33,35]. It is worth noting that several publications discussed the results of the same research (eg, 3/23, 13% of the studies by Buller et al [15-17])

Among the 23 studies included in this review, social media interventions were the topic of 15 (65%) [15-18,20-22,24,25,28,29,32-35], among which cognitive effects were assessed by Agha-Mir-Salim et al [28], Damude et al [34], Gough et al [29], and Mingoia et al [32]. On the other hand, both cognitive and behavioral effects were assessed in the studies by Buller et al [15-17], Coups et al [18], Køster et al [35], Morrison et al [20], Myrick et al [21], Pagoto et al [22], Potente et al [33], Stapleton et al [24], and Vraga et al [25]. Comparison groups were used by Agha-Mir-Salim et al [28], Buller et al [15-17], Gough et al [29], Køster et al [35], Mingoia et al [32], Morrison et al [20], Myrick et al [21], Pagoto et al [22], Potente et al [33], and Vraga et al [25].

Quality Appraisal

The risk-of-bias assessment for randomized controlled trials is summarized in Table 1. A total of 35% (8/23) of the studies turned out to be of high quality [15-17,20,22,25,28,32], and 4% (1/23) of the studies were of low quality [29]. A total of 57% (13/23) of cross-sectional studies were of high quality [14,18,19,21,23,24,26,27,30,31,33,35,36], and 4% (1/23) of cross-sectional studies were of low quality [34]. A summary is provided in Multimedia Appendix 2 [14-36].

Table 1. Cochrane risk-of-bias assessment.

Study	Random sequence generation	Allocation concealment	Blinding of participants and personnel or blinding of outcome assessment	Incomplete outcome data	Selecting reporting	Other bias
Agha-Mir-Salim et al [28], 2020	–[a]	+[b]	–	+	+	+

Vraga et al [25], 2022	+	+	+	+	+	+

[a]High risk of bias.

[b]Low risk of bias.

Data Synthesis

Overview

Among the assumptions we made for this review was that skin health promotion on social media is a broad concept that includes regular activities aimed at protecting the skin against the risk of developing skin cancer, as well as promoting skin care that can ensure good skin condition, prevent skin diseases, slow down the skin aging process, and keep the skin looking nice, which can contribute to one's well-being. However, most of the studies included in this review (20/23, 87%) focused on behaviors associated with skin cancer risk and prevention (exposure to and skin protection from UV radiation). Skin cancer was the main area of interest for researchers, undoubtedly because it is a high-profile problem. There were not enough studies on other skin conditions to draw firm conclusions about the effects of social media. Nevertheless, it is possible to analyze and compare the effect of information and motivational activities on social media on the engagement of users and their behavior changes and actions taken. This will enable social media moderators to develop overall motivational intervention strategies.

This review included observational studies in which social media was used as a tool to disseminate information about the skin, as well as intervention studies in which social media content was manipulated. Despite the fundamental differences in the methodology of these 2 types of research, the main goal was

XSL•FO
RenderX

the same—skin health promotion. Due to differences in research methodology, comparison and summary were difficult.

The results are presented in the following sections in narrative form. A division was made into studies that did not use an intervention and studies that did use an intervention. Then, to synthesize and integrate the results well and draw consistent conclusions, observational studies and then interventional studies were summarized and compared. Attention was drawn to the limitations of observational studies compared to interventional studies.

Assessing the Impact of Social Media on Skin Care and Skin Health Promotion Without an Intervention

The studies included in this review argued that social media is a useful source of knowledge about skin health. According to Bahaj et al [36], most individuals aged between 18 and 25 years choose social media as their first source of acne treatment advice. However, much of social media advice does not follow the current guidelines of the American Academy of Dermatology [40]. The aforementioned authors also found that 74.1% of those social media users had a college degree. There was a positive link between educational attainment and willingness to use social media for advice (P=.002). In addition, a significant link between the severity of acne and search for treatment advice on social media was found (P<.001) [36].

Similarly, in the study by Yousaf et al [27] with 130 participants with acne, 45% (n=58) of them used social media for advice on its treatment. Of these 58 participants, 72% were women (n=42), who were 75% more likely to use social media for advice on acne treatment (prevalence ratio=1.75, 95% CI 1.11-2.76; P=.01). In addition, only 31% of the respondents who consulted their problem on social media managed their condition in line with the American Academy of Dermatology clinical guidelines [27]. However, both Bahaj et al [36] and Yousaf et al [27] observed that the advice available on social media did not comply with the guidelines of the American Academy of Dermatology [40]. In the study by Basch et al [14] on skin cancer and tanning, it was found that people who did not fully adhere to proper sunscreen behavior were more likely than those who followed sun protection rules to believe that social media was an accurate source of health information (10.5% vs 3.3%; P=.046) or a helpful source of health information (62.5% vs 46.7%; P=.02).

According to Mingoia et al [31], the level of social media use was significantly and positively correlated with users' sun exposure (P<.001), sunburn (P<.001), and dissatisfaction with skin tone and negatively correlated with sun protection (P<.001). This meant that viewing photos, posting photos, sharing content, and the number of likes were significantly linked with greater sun exposure, lower sun protection, and greater dissatisfaction with skin tone. It is worth mentioning that the aforementioned study drew attention to the fact that women, to a greater extent than men, are image oriented and more attracted to visualization on social media. For them, the use of images in health messages may be effective in preventive skin health care campaigns [31].

In the study by Stapleton et al [23], 45.8% of participants had a college degree, and 14.8% had a bachelor's degree or higher (a sample of 463 participants). The authors found that higher rates of indoor tanning were associated with Twitter (subsequently rebranded X) and Instagram use among a sample of young adult women. As a result, the authors argued that the aforementioned social media platforms could be a valuable way to provide information about skin cancer prevention among compulsive indoor tanners [23].

In contrast, the sample in the study by Willoughby and Myrick [26] consisted of 502 female college students aged between 18 and 29 years, and it was found that participants who reported more frequent use of social media were more likely to sunbathe outside. Thus, the researchers found that greater use of visual social media platforms such as Instagram, Snapchat, and Pinterest was likely to increase tanning [26].

According to the studies by Bahaj et al [36], Yousaf et al [27], Basch et al [14], Mingoia et al [31], Stapleton et al [23], and Willoughby and Myrick [26], widely shared social media content could influence engagement in risky health behaviors, affecting users' knowledge, attitudes, and actions. Despite the negative impact of social media, the authors noted that it could be a powerful informational, educational, and intervention tool for preventive skin health care campaigns. In addition, the identification of the target group of health advice recipients made it possible to fight disinformation using specific prevention channels (ie, social media platforms). In contrast to the aforementioned studies, the studies by Guckian et al [30] and Martel et al [19] mainly pointed to the positive impact of social media.

Guckian et al [30] found that interventions via social media could have a positive impact on health-related behaviors. According to the authors, social media could motivate patients with distressing cutaneous lesions to visit melanoma screening clinics. However, the authors found that the most common motivating reason for visiting a melanoma screening clinic was skin self-examination. In this study, 65% (162/249) of the patients were regular users of social media, 33% (83/249) saw posts on the internet about cutaneous lesions, 10% (8/83) saw posts from physicians, 36% (30/83) saw posts from health authorities, and 37% (31/83) saw posts from other people (social media users). In addition, 33% (83/249) of patients searched for information about their cutaneous lesions on the internet, whereas one patient did so on social media. In addition, 24% (6/25) of patients said that more posts on cutaneous lesions should be shared [30].

Martel et al [19] found that social media use could be a motivating factor. According to the authors, editing one's own cutaneous lesions on social media, in particular acne and acne scars, contributed to an increase in users' awareness and encouraged them to seek dermatological care. Of 145 people who edited their skin lesions, as many as 128 (88.3%) edited acne and acne scars. This editing increased their awareness of the need for dermatological care (P=.02) [19].

Assessing the Impact of Social Media on Skin Care and Skin Health Promotion After an Intervention

Comparative Studies on the Role of Digital Social Media Interventions and Traditional Media in Health Promotion

The study by Agha-Mir-Salim et al [28] was one of those comparing the effects of digital interventions with those of printed materials. The research involved the SunSafe campaign that aimed to raise awareness of sun exposure risk, melanoma, and the need for sun protection among individuals aged 18 to 29 years. Using flyers and Facebook, the authors found that, after the intervention, the average knowledge score improved in both groups (Facebook=1.82; flyers=3.04; $P<.001$). However, printed flyers turned out to be more effective than Facebook posts (95% CI 0.35-2.09; $P=.006$) [28].

Social Media Interventions as an Educational Strategy

Damude et al [34] assessed the knowledge of patients with melanoma about their illness and their opinion on multiple ways of providing information. YouTube instructional videos presented in the research were designed to stress the need for self-examination of the skin and lymph nodes and demonstrate how to do this properly. It turned out that 63% of patients preferred to receive information in multiple ways, 92% of them preferred verbal instructions from their physician, 62% preferred educational YouTube videos, and 43% preferred to receive instructions via brochures. In addition, the authors concluded that there was an urgent need for educational activities focused on melanoma and for supplementing the methods of education with instructional YouTube videos [34].

In the study on skin cancer prevention by Gough et al [29], a trend toward increasing knowledge about preventive actions in response to social media educational interventions was observed. Those interventions increased awareness that fair-skinned people required the most protection and that skin cancer was the most common form of cancer, with melanoma being its most serious type. In addition, the authors noted a trend of increasing awareness of sun and UV ray exposure, skin cancer risk, and the need for sun protection.

Using an educational strategy and cognitive dissonance, Mingoia et al [32] investigated the effects of a social media intervention on the opinion that *tanned skin is desirable and beneficial for appearance*. The educational strategy was aimed at reducing positive attitudes toward sunbathing and improving the ability to critically analyze social media content [32].

The study by Pagoto et al [22] is another example of a dissonance-based social media intervention to promote sun safety. The intervention involved encouraging survey respondents to create social media posts on healthy skin or a healthy lifestyle. According to the authors, participants in the healthy skin intervention group reported a higher motivation to use protective clothing and sunscreen and a decreased motivation to tan. The authors suggested that this intervention, encouraging social media content creation and response, should enhance cognitive dissonance and affect social norms, which in turn might change attitudes and behaviors concerning tanning [22].

The study by Stapleton et al [24] is another example of a dissonance-based intervention focusing on healthy body image. As part of this intervention, a group of Facebook users was encouraged to publish posts and share their opinions on them. The aim of the dissonance-inducing intervention approach was to engage participants in group discussions related to body image [24].

The topic of skin cancer prevention and the use of tanning beds was also addressed by Morrison et al [20]. To educate the audience, the authors used 3 different short videos aimed at discouraging indoor tanning. The first was a humorous video created in collaboration with a physician, the second was a music video with an Instagram star, and the third one was based on facts about skin cancer. The humorous video received the highest engagement, measured via the number of comments, reactions, and shares, whereas the fact-based video received the lowest engagement [20].

Moreover, in the study by Potente et al [33], an ironic music video was also used, the aim of which was to engage young people in skin cancer prevention. Different forms of entertainment, education, and marketing were used on social media to change attitudes and behaviors regarding sun protection [33].

In contrast to the aforementioned studies, Vraga et al [25] used a video with incorrect information about sunscreen and skin cancer. The results indicated that the disinformation video, compared to an educational video, increased belief in sunscreen myths ($P<.001$) and decreased intent to use sunscreen ($P<.01$) [25].

In the study by Myrick et al [21], an intervention focusing on appearance and self-control–related emotions was used. The results indicated that the intervention focused on appearance contributed to a reduction in the time spent viewing Instagram images of tanned women. In contrast, after the intervention involving self-control emotions, an increase in anticipated pride and in a positive attitude toward solar safety was observed [21].

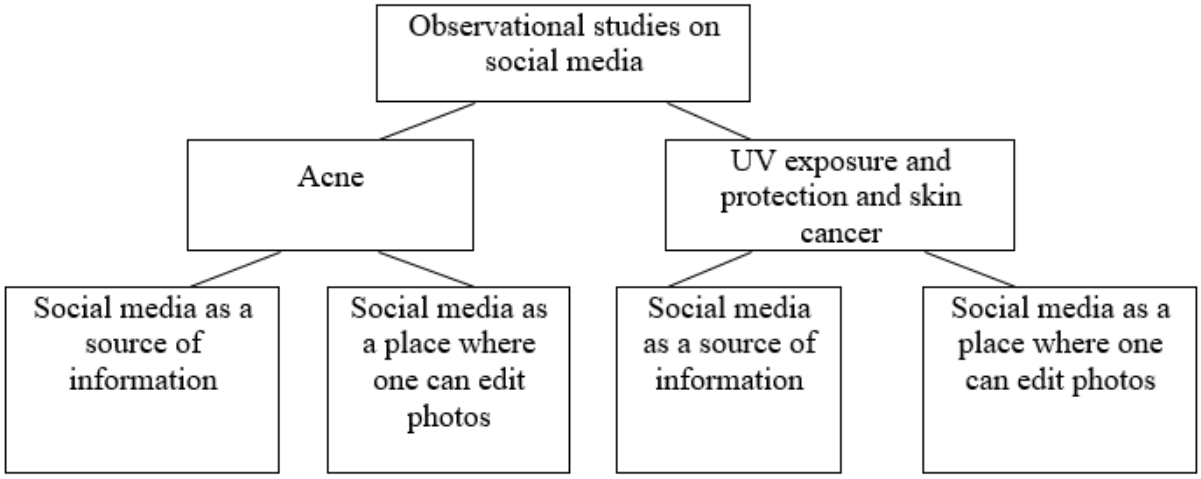
Digital Interventions on Social Media Based on Social Cognitive Theory, Transportation Theory, and Diffusion of Innovations Theory

Buller et al [15-17] conducted a year-long social media health campaign to reduce mothers' permissiveness of indoor tanning with their teenage daughters. Mothers became less lenient toward indoor tanning with their teenage daughters immediately after the campaign and 6 months after it ended [15,16]. According to the researchers, social media campaigns could motivate mothers to communicate with their daughters and share posts about the danger of indoor tanning [15]. In turn, Buller et al [17] measured engagement levels by measuring reactions (eg, sadness and number of likes) and mothers' comments on posts related to the campaign. They noted that users reacted with comments to 76.4% of posts. Immediately after the campaign ended and 32 months after, mothers who posted reactions or comments were less liberal about indoor tanning with their teenage daughters than mothers who did not engage with the posts [17].

XSL•FO
RenderX

Social Media Behavioral Interventions

In the study by Coups et al [18], a behavioral intervention was conducted via Facebook targeting young patients with melanoma and their families. The content of the intervention consisted of daily posts about skin cancer risk, total cutaneous exam, skin self-examination, and preventive measures (ie, sun protection). Preliminary analyses by the researchers showed an increase in intentions to use the total cutaneous exam, skin self-examination, and sun protection. In addition, Coups et al [18] found that posts that included personal stories, quizzes, skin care exercises, and an opportunity to ask a question to a specialist were perceived by survey respondents as particularly engaging.



An effective intervention was also demonstrated in the study by Køster et al [35], who reported that, in effect, the use of tanning beds decreased in parallel with antisun campaign activities, with an odds ratio of 0.61 (95% CI 0.54-0.69). The campaign was mainly conducted on social media but also in youth magazines and on the radio. It was supplemented with a music video available on the internet and television on skin damage and the negative effects of using cosmetic beds. In addition, respondents to the postcampaign survey were in favor of legislative changes to restrict the access of children and teenagers aged <18 years to tanning salons [35].

Result Summary

To sum up, social media is a place where observational studies and interventional studies can be carried out. Unlike interventional studies, observational studies do not assess cause and effect relationships, require a large sample, and carry a high risk of error. In both observational and interventional studies, the most frequently discussed topics were skin exposure to and protection against UV radiation and skin cancer. Only 13% (3/23) of observational studies focused on acne [19,27,36]. No skin care studies were found that met the inclusion criteria. Observational studies conducted on social media showed that social media is a source of information [14,23,26,27,30,36] and a place where one can edit one's own photos [19,31]. Observational studies on acne showed that dissatisfaction with the appearance of the skin (presence of skin lesions) stimulates individuals to use social media. In the case of observational studies on exposure and protection against UV radiation, it was shown that the use of social media increases dissatisfaction with appearance and, consequently, increases exposure to UV radiation.

Visualization in social media has a strong impact on users. Showing images contributes to taking actions that are both beneficial (in the presence of skin lesions)—seeking dermatological care—and unfavorable (the desire to have a nice tan)—increased exposure to UV radiation (Figure 2).

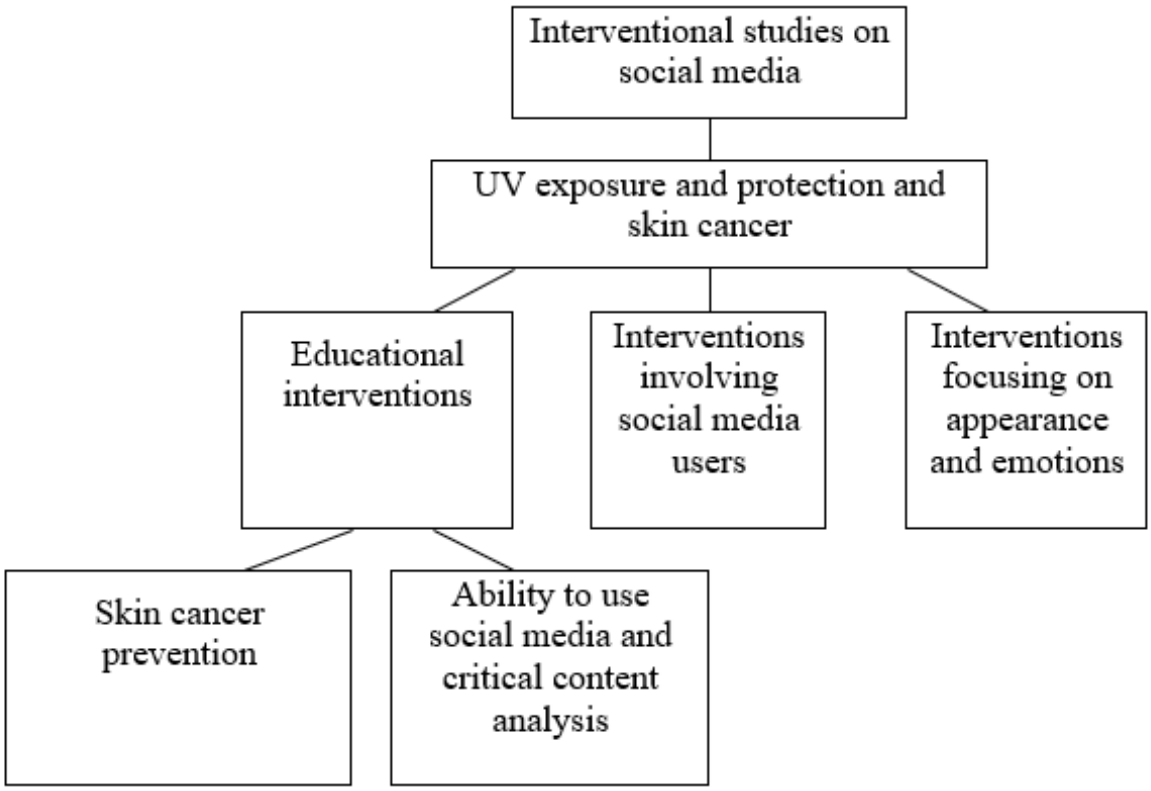


Figure 2. Summary of observational studies on social media.

The analyzed social media intervention studies mainly concerned skin exposure to and protection against UV radiation, tanning, skin self-examination, and skin cancer. Most studies (11/23, 48%) used educational interventions on skin cancer prevention [15-18,20,25,28,29,33-35]. One study used an educational intervention on social media literacy and critical content analysis [32]. A total of 13% (3/23) of the studies examined social media users' involvement in generating social media content [15-17,22,24]. These studies pointed out that social media is a motivating factor. Motivation is the readiness to take a specific action, triggered by a need. To take action, one needs the right attitude and the internal conviction that the action is advisable. The aim of educational interventions was to change attitudes toward skin health promotion. However, interventions encouraging participants to create content on social media were intended to engage participants to increase the effectiveness of the intervention and the belief in its purposefulness. A total of 9% (2/23) of the studies focused primarily on body image rather than skin health issues [21,24]. The study by Myrick et al [21] discussed a psychological approach to appearance and emotion self-control (Figure 3). Both in observational and interventional studies, attention was paid to visualization on social media (images, photos, and videos). In addition, attention was paid to the involvement of social media users, which was measured via the amount of content shared, comments, likes, and photos published. Intervention studies showed that educational strategies based on humorous films, interesting personal stories, and opportunities for discussion were more engaging for participants. In observational studies, it was not possible to measure the level of persistence in following recommendations (eg, regular photoprotection). Interventional studies provided this possibility, and their results can be checked after a period.

RenderX

Figure 3. Summary of interventional studies on social media.

Discussion

Principal Findings

The results of this review indicate that social media is a platform for disseminating health messages on an ongoing basis and for creating interventions targeted at specific groups. However, research on social media impact on education, attitudes, behaviors, and actions concerning skin health promotion was inconclusive and varied. Some studies (2/23, 9%) stressed the negative side of social media, noting that, for example, its acne advice was inconsistent with current guidelines [27,36]. Others (4/23, 17%) drew attention to the fact that social media can promote risky health behaviors concerning sunbathing without sunscreen, which may result in skin cancer [14,23,26,31]. On the other hand, without focusing on digital interventions, some of the studies included in this review (2/23, 9%) dealt with a positive impact of social media on skin care, skin protection, and skin health promotion. They noted that social media increases users' self-awareness and motivates them to take care of their skin [19,30]. According to Benetoli et al [41], social media has positively affected users' interaction with health care professionals. As a result, patients feel more confident and more assertive in their decision-making [41]. Most of the studies discussed in this review (14/23, 61%) argued that social media interventions resulted in positive effects on preventive skin health measures, changing users' behaviors, actions, attitudes, and knowledge levels [15-18,20-22,24,28,29,32-35]. Therefore, it is reasonable to ask how to make social media interventions effective and how to achieve a long-term change in user behaviors.

Agha-Mir-Salim et al [28] investigated the effects of social media digital interventions and found that Facebook was less effective than printed materials in improving awareness of skin cancer and the need for sun protection. However, without information about the level of audience engagement measured through the number of posts and reactions to them, it is difficult to explain the reasons why flyers were more effective than Facebook [28].

User engagement is critical to the success of social media interventions. The assessment of user engagement with social media interventions was presented in 35% (8/23) of the studies, determining the reactions to posts using the number of likes, comments under posts, and shares [17,18,20,22,24,29,32,33]. In addition, the concept of social media engagement plays a key role in health psychology [42]. Systematic reviews evaluating strategies that promote technology-based engagement have shown a potential positive impact of these strategies on health behaviors [43-47]. The success of social media engagement is based on its effect on society. Psychological factors and neural mechanisms are important [48]. Nahum-Shani et al [48] explain how positive engagement develops in response to a digital stimulus facilitating behavior change. By describing the neural basis of decision-making (by explaining its application to digital interventions), the researchers extend the concepts by Samanez-Larkin and Knutson [49] (affect-integration-motivation), creating the concepts of affect-integration-motivation and attention-context-translation of motivation to behavior. These additional elements can be used for targeted engagement of social media users with digital interventions [48].

Behavioral interventions through social media have many advantages, such as a large audience, low costs of disseminating information, and a possibility to create individual content and interact with other users with similar experiences or in a similar

XSL•FO
RenderX

situation. This allows for mutual support, the exchange of information, and an opportunity to interact with health professionals by consulting specialists and obtaining answers [18].

In the observational studies on acne by Bahaj et al [36] and Yousaf et al [27], the authors pointed out that much of the advice available on social media is not consistent with the guidelines of the American Academy of Dermatology. In addition, in the observational study on skin cancer by Basch et al [14], it was shown that people who believed that social media was an accurate source of health information were more likely to fail to follow proper sun protection practices. The aforementioned study showed that social media can increase belief in health myths. The study by Vraga et al [25] showed that videos with erroneous information had a stronger impact on users than educational videos. Social media actions should also be aimed at combating misinformation. The content posted should be in agreement with evidence-based medicine and with the guidelines of the American Academy of Dermatology. In addition, interventions should increase the knowledge of social media users about the dangers of improper skin care and change their positive attitude toward inappropriate activities such as too much tanning. Social media interventions should also contribute to an increase in assertiveness toward inappropriate, harmful content, building self-esteem in users and teaching critical analysis of the content shared. In the case of tanning, interventions should describe alternative options, such as the use of safe moisturizing bronzers.

It seems that effective interventions should not only aim at the health consequences of poor skin care and poor skin protection but also focus on monitoring skin texture. In addition, they should make an effort to shape social norms regarding attractiveness (ie, by questioning the ideal of tanned skin and promoting sun protection). The use of dissonance induction approaches in interventions also seems to be important. The goal of those approaches is to encourage participants to persuade others to engage in appropriate behaviors [22].

Behavioral health interventions concerning appearance and body image often use persuasive techniques based on cognitive dissonance theories. Those techniques encourage participants to engage in discussions and cognitive exercises. Participants endorse views that contradict their previous beliefs and, in the end, accept these views as their own [24]. According to the dissonance theory, when there is a conflict between a belief (eg, a perfect tan is good) and behaviors (eg, persuading others that a perfect tan must be avoided and sunscreen should be used), psychological discomfort (cognitive dissonance) is the result, which motivates an individual to change their original beliefs (ie, the person is motivated to use sunscreen because tanned skin is less important than healthy skin) [22,50]. The effectiveness of cognitive dissonance interventions has been confirmed in studies on eating disorders [51] and perfect tans [52].

Pagoto et al [53] proposed a methodology for adaptation of social media behavioral interventions. It requires that parameters be defined to determine whether the intervention is based on social media completely or partially. The objective of a social network should be defined, too. First, it should be decided whether the main objective of the intervention is to engage users, disseminate information, or both. The type of intervention should be related to the objective. One-way communication is adopted mainly for public health campaigns. In 2-way communication, the content is generated by both the intervention moderators and the audience. Two-way communication allows for discussions and for help with problem-solving and behavioral advice. When designing interventions, it is important to choose the social networking platform and the target population. Another important element when designing an intervention is content conversion, with short, catchy posts, videos, photos, graphics, and links to articles. When the main focus of the intervention is user engagement, a plan should be constructed. It should include the size of the group, the frequency of posting, and the number of engaged participants, and it should specify whether the posts are automated. In the design of interventions, it is also reasonable to create chat groups or use microcounseling, which involves the intervention moderator initiating the discussion. The engagement plan may also include recruiting friends or family members for the intervention. In addition, it is important to train users on how to clarify expectations and encourage them to express their opinions and publish posts [53].

Almost all the intervention studies analyzed in this review (13/15, 87%) were conducted after Pagoto et al [53] developed their methodology for adapting social media interventions. After analyzing the presented interventions, it can be assumed that the authors followed some of the advice by Pagoto et al [53] when designing their interventions. Intervention studies that focus on engaging participants have found greater intervention effectiveness.

In summary, the analysis of the studies included in this review indicates that, when designing social media interventions for skin health, it is necessary to pretest them in a pilot project with comparison groups, including control groups, and measure user engagement on a regular basis. In addition, designing interventions requires focusing on the content that is designed to engage the audience. Absorbing content should not only be educational but also entertaining and discourage abnormal health behaviors. The content should be focused on the benefits according to positive psychology (to increase its attractiveness); it should focus on thinking about the future using goal setting and motivation (to have nice and healthier skin). It is also reasonable to include personal stories, exercises to engage the audience, and various puzzles. When designing interventions, the theories of social psychology they are based on should be considered.

The results of this review may be useful in creating future skin health promotion programs on social media. It is aimed at all those who are ready to broaden their knowledge and effectively engage in activities related to skin care and skin protection.

This study aimed to fill the research gap in assessing the usefulness of social media for skin health promotion. Its main assumption was that it would contribute to the discussion on the importance of the information provided about the skin and

XSL•FO
RenderX

its impact on changing the attitudes and behaviors of recipients of this information.

Strengths and Limitations

As with any other study, this review had its limitations. The first one was that only articles written in English were analyzed, which meant that important publications written in other languages were not included. The second limitation was the omission of studies that were in progress (not completed). One of them was a Facebook intervention targeted at patients with melanoma and their families (randomized controlled trial) as the report on its results was expected to be completed by November 2023 [54]. Therefore, its analysis was not possible, and this review should be updated at a later time. The third limitation is the small number of interventional studies on acne and a lack of research on rosacea and atopic dermatitis, common conditions dealt with in dermatological and cosmetology clinics. In addition, there was a lack of research on daily skin care, education, and antiaging activities on social media. Some papers, such as those dealing with social media posts on esthetic medicine and more or less invasive plastic surgery, were not included in this review. This prevented a broader analysis and assessment of the impact of social media on users' skin care and health activities. The last limitation was the failure to undertake a quantitative data analysis because of too broad a topic, which resulted in the heterogeneity of the studies that qualified for analysis.

Despite its limitations, this paper presents an up-to-date review of social media impact on users' behavior change and the implementation of interventions mainly in the field of skin cancer prevention. In addition, this review identifies research gaps and topics worth focusing on and indicates what should be improved when conducting social media research.

Conclusions and Practical Implications

Social media remote consultations and digital interventions with the use of new technologies in education and research are a relatively new method of skin health promotion. Despite the limited number of studies and their heterogeneity, this review outlined the impact of social media on user behaviors, attitudes, and actions in terms of skin health. It provided insights into social media importance and identified strategies for digital interventions to promote health. In addition, this review underlines the need to conduct research on skin health promotion via social media and on new methods motivating users to take an active role. There is no doubt that more high-quality studies, consistent and with logical conclusions, on social media using standardized interventions are needed.

The observational studies analyzed in this review (8/23, 35%) showed that social media, according to social media users, is a reliable place to obtain information on skin health. Moreover, there was a noticeable tendency of social media influencing the behavior of social media users. On the basis of unpublished own research (by author JMB), of 150 surveyed social media users (people aged ≤25 years), in 2021, a total of 62% (93 people) believed that information from social media regarding skin cancer prevention, skin care and treatment of acne, and antiaging was very important to them. For 44% of respondents (66 people), information on social media influenced their behavior. In a repeated study in 2023, as many as 86% of respondents (129 people) stated that information on skin cancer prevention, skin care and treatment of acne, and antiaging was very important to them. However, 74% of respondents (111 people) stated that information on social media influenced their behavior.

The studies analyzed in this review showed that more frequent use of social media is significantly associated with more frequent exposure to UV radiation. Social media focuses on visualization. Photos and images are a powerful tool to influence users. In intervention studies, there was a noticeable tendency to encourage people to react to posts and create their own. It can be assumed that interventions involving social media users in generating content increase their motivation to take care of their skin. The aim of social media interventions should be education on promoting skin health based on visualization and motivating social media users to take care of their skin (using photoprotection, limiting sunbathing, using protective clothing, conducting skin self-examinations, and having regular skin checkups with a dermatologist).

The availability of social media worldwide provides unlimited possibilities for transmitting and managing information. Analyzing posts and evaluating user engagement by measuring the number of likes, comments, and followers can be a powerful tool for gathering knowledge and studying patients' opinions. After becoming familiar with the expectations of social media users and assessing information resources and their quality and credibility, appropriately targeted actions should be taken to educate, encourage, and motivate users to be active in skin care and skin health promotion in everyday life.

Social media has become a tool supporting the life and work of society. The model of Society 1.0 was based on hunting, Society 2.0 was based on agriculture, Society 3.0 was based on industry, and Society 4.0 is based on information. Social media implements the assumptions of the Society 4.0 model through information activities. The vision of Society 5.0 is a balance between technological progress and human needs. Model 5.0 enables the collection of data (eg, on health status) from patients on an ongoing basis. Social media can be a tool for digital interventions and for Society 5.0 implementation. The implementation of Digital Society 5.0 depends not only on the cooperation between countries but also on combined efforts of various branches of medicine, business, and science, which is the basis for creating innovations at both the national and global level. Innovations are not possible without cooperation; the use of global data (big data); and the coordination of many data systems and knowledge platforms, including social media.

Proper and specialized use of social media by dermatologists, pharmacists, cosmetologists, and health educators can increase awareness concerning skin condition and skin health preventive measures. It can encourage users to conduct a skin self-examination and visit a dermatologist. This review could also enable dermatologists, cosmetologists, pharmacists, and health educators to understand social media potential and its impact on users. This review presents social media use for intervention studies and indicates its educational and

XSL•FO
RenderX

motivational role in actions related to skin health. In addition, those actions have a clinical significance as social media increases user awareness of skin health promotion. As a result, users are not reluctant to seek medical help. Therefore, this review could be a basis for further research on the role of social media interventions in skin health promotion (including sun protection; mole control; and proper skin care for various dermatological diseases, such as acne, rosacea, or atopic dermatitis). It seems that social media, compared to traditional forms of mass communication, has the potential to make a change in skin care and health behaviors and activities among a larger population.

First, future studies should focus on effective social media strategies to promote skin health. Second, research assessing the effects of health and skin care recommendations would be useful. Third, studies assessing the short-term engagement of social media users would be of practical importance, as well as research assessing their commitment to long-term health and skin care habits. The results of this review, in addition to its theoretical value, could have potential applications in online dermatological and cosmetology consultations and in prohealth campaigns concerning increasingly common skin diseases such as acne and melanoma.

This research dealt with studies investigating individually developed social media strategies. It seems that it would still be appropriate to standardize tools assessing the quality of digital health interventions on social media. Such standardization would be helpful both in the design of new digital interventions and in the evaluation of existing ones.

Abstract

Background: The health care industry must align with new digital technologies to respond to existing and new challenges. Digital twins (DTs) are an emerging technology for digital transformation and applied intelligence that is rapidly attracting attention. DTs are virtual representations of products, systems, or processes that interact bidirectionally in real time with their actual counterparts. Although DTs have diverse applications from personalized care to treatment optimization, misconceptions persist regarding their definition and the extent of their implementation within health systems.

Objective: This study aimed to review DT applications in health care, particularly for clinical decision-making (CDM) and operational decision-making (ODM). It provides a definition and framework for DTs by exploring their unique elements and characteristics. Then, it assesses the current advances and extent of DT applications to support CDM and ODM using the defined DT characteristics.

Methods: We conducted a scoping review following the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) protocol. We searched multiple databases, including PubMed, MEDLINE, and Scopus, for original research articles describing DT technologies applied to CDM and ODM in health systems. Papers proposing only ideas or frameworks or describing DT capabilities without experimental data were excluded. We collated several available types of information, for example, DT characteristics, the environment that DTs were tested within, and the main underlying method, and used descriptive statistics to analyze the synthesized data.

Results: Out of 5537 relevant papers, 1.55% (86/5537) met the predefined inclusion criteria, all published after 2017. The majority focused on CDM (75/86, 87%). Mathematical modeling (24/86, 28%) and simulation techniques (17/86, 20%) were the most frequently used methods. Using *International Classification of Diseases, 10th Revision* coding, we identified 3 key areas of DT applications as follows: factors influencing diseases of the circulatory system (14/86, 16%); health status and contact with health services (12/86, 14%); and endocrine, nutritional, and metabolic diseases (10/86, 12%). Only 16 (19%) of 86 studies tested the developed system in a real environment, while the remainder were evaluated in simulated settings. Assessing the studies against defined DT characteristics reveals that the developed systems have yet to materialize the full capabilities of DTs.

Conclusions: This study provides a comprehensive review of DT applications in health care, focusing on CDM and ODM. A key contribution is the development of a framework that defines important elements and characteristics of DTs in the context of related literature. The DT applications studied in this paper reveal encouraging results that allow us to envision that, in the near future, they will play an important role not only in the diagnosis and prevention of diseases but also in other areas, such as efficient clinical trial design, as well as personalized and optimized treatments.

Introduction

Background

Digital twins (DTs) are an emerging concept that has recently attracted the attention of researchers and engineers. The development of new technologies, such as virtual reality, blockchain, and the Internet of Things (IoT), is considered a key factor for progress in the DT research field [1]. However, the role of the recent boost in digital transformation and exponential growth in investments by giant tech companies cannot be neglected [2]. DTs have their roots in the field of engineering [3-6] but are quickly expanding to a wide range of applications, such as city planning [7-9], energy [10,11], retail [12,13], and health care [14,15]. Although DTs are an emerging concept, they integrate well-established technologies as underlying components. The origin of the DT goes back to the 1970s when NASA (National Aeronautics and Space Administration) used the "twin" concept by creating simulated environments (ie, mirrored systems) to monitor the spacecraft in the Apollo 13 program [16,17]. Although this instance may not be considered as an advanced DT today due to the lack of data exchange to allow continuous or periodic "twinning" of the digital to the physical [16,18], it represents a very good example of the potential of DT and what DTs can empower in various industries.

A DT of the city of Zurich, Switzerland [7], is a good example of a DT application. In this project, spatial 3D data is transferred to a DT to support urban planning decision-making, for example, simulating climate change and noise issues within urban plans [7]. Another example of a DT was built by Unilever PLC to increase the flexibility and efficiency of their production process [19]. They use DT systems to predict optimal process parameters for new formulations, execute simulations to identify the best operational conditions, and investigate complex what-if scenarios. DT systems have also been applied in the field of water management in Porto, Portugal [20], by creating a virtual representation of the city water network. This DT was developed to predict water quality and flooding issues, simulate and analyze burst pipe scenarios, and ensure the resilience of water infrastructure. The initial results revealed that the developed DT reduced water-supply failures by about 30% and decreased the time needed to repair burst pipes by 8% [20].

There have been several efforts to develop DTs for various purposes in health care. Clinical decision-making (CDM) and operational decision-making (ODM) are 2 of the most important decision-making processes in health care settings. In this context, CDM refers to the decisions made by health professionals in regard to direct health care delivery (diagnosis, test, intervention, etc) based on a patient's health status and related clinical conditions, while ODM refers to the decisions made by managers and administrators after monitoring processes related to operations, such as patient waiting times and hospital revenue [21]. In subsequent sections of this paper, we present a scoping literature review to provide an up-to-date overview of the existing literature relevant to the application of DT systems in health care and to gauge the extent of the designed DT models for CDM and ODM purposes.

There have been several literature reviews on the applications of DTs in health care from different perspectives. Ahmadi-Assalemi et al [22] reviewed recent works in the field of precision health care and discussed the key enabling technologies (eg, IoT and cloud) of DTs. Hassani et al [2] provided a literature review that discussed the value of DTs in health care and proposed some key characteristics, including dynamic, real-time, and bidirectional data connections. Armeni et al [18] identified the opportunities as well as challenges regarding DT implementations in health care (eg, security and privacy, accessibility of the technology, and data collection and management). Elkefi and Asan [23] conducted a systematic review of studies that discussed the contribution of DTs to improving user experience in health care (eg, safety management or information management). They used *digital twin* and *health* as keywords and 17 papers were included in their review. Sun et al [1] provided a systematic review to explore the progress of prominent research on DT technology in medicine. They used the following terms: *digital twin*, *medicine*, *digital health*, and *virtual healthcare*. This resulted in the inclusion of 22 papers in their study after the screening process. They showed that the application of DTs to the cardiovascular system is an attractive area. Sheng et al [24] used structural topic modelling to analyze trends in *DT+healthcare* and their findings show that technology integration and practical applications, for example, IoT and artificial intelligence, are the main focus areas. Katsoulakis et al [25] conducted a scoping review on DTs for health. Using *digital twin* and *health* as search keywords, the authors selected 85 papers in their analysis. They first categorized the selected papers into 8 distinct categories based on their purpose and content, for example, DTs for biomarker and drug discovery as well as DTs in biomanufacturing. Then, they discussed the challenges hindering developments in this field, such as data privacy and security, computing infrastructure, and data quality and accuracy.

This Paper

In this paper, we present a distinctive approach that distinguishes our work from existing literature reviews. The key distinctions are discussed herein. First, the health care industry and academia use various definitions, necessitating research consolidation to establish a unified understanding and ensure future research builds on robust foundations. This study conducts a systematic literature review and thematic analysis of 86 publications on DTs and offers a comprehensive analysis of elements and characterization of the concept, which is absent in existing review papers. This explicit definition of DTs, along with the identification of their elements and characteristics, enables researchers to understand what distinguishes a DT as a unique system, separate from other known ones. Second, DTs represent a burgeoning research field, particularly in health care, prone to misconceptions and misinterpretations. A significant gap in the literature lies in distinguishing established models, such as machine learning and 2D or 3D modeling from true DTs. This paper pioneers an effort to clarify that not all papers claiming to develop DTs genuinely do so. Our analysis reveals that some are simply predictive models or simulations, branded under the DTs trend. This trend risks undermining the integrity of the research. Thus, this paper aims to educate readers on discerning

XSL•FO
RenderX

authentic DTs, emphasizing the essential components required for a system to qualify as such.

What Is a DT?

Overview

There are similarities between DTs and other related technologies, such as simulation, predictive modeling, and 3D modeling, which leads to apparent misconceptions about their definition [2,26]. A summary of DT definitions that are found in the literature is provided in Table 1. It shows the diverse views of DTs across studies and domains. Table 1 also shows the key points of DTs as defined by the respective authors to facilitate the categorization of such diverse definitions and to quickly identify their similarities or differences.

Table 1. Definitions of digital twins (DTs) and the key points in the literature.

Definition of DT	Key points	References
A DT of a human using sensors and other data sources to create an exact virtual copy of a human being	Virtual copy	[18,27-29]
A DT is a digital replica of an object, process, or system that can be used for various purposes	Digital replica	[30-34]
A DT is an instance of the model that mimics a real patient	Mimicking or mirroring	[35-38]
A DT of a patient is a simulation of the patient's trajectory that behaves identically to the patient in terms of outcomes	Simulation	[25,39-41]
A DT is deemed a virtual mapping of a physical entity where simulation clones the dynamic properties of physical entities in the DT	Virtual mapping	[42]
A DT is a digital representation of a physical asset reproducing its data model, behavior, and communication with other physical assets	Digital representation	[43-46]
In newer computer tomographic systems, avatars are fitted as DTs into the surface information of the positioned patients using machine learning	Avatars	[47,48]
DTs are a technology where a personalized computer model is developed that is capable of describing the physiological processes of a human body, tailored to the specific characteristics of a person	Computer model	[49]
The DT is a virtual and dynamic model in the virtual space that is completely uniform and consistent with its corresponding physical entity in the real space	Virtual model	[50,51]
The concept of DTs has emerged to enable modeling and the fusion of individual physical artifacts with digital models reflecting their status in real time	Digital model	[22,52]
DTs are virtual models that represent physical systems and their modifications in real time and there is a bidirectional flow of data, from the physical system to the virtual system and vice versa	Virtual model, bidirectional data flow	[53-56]

From Table 1, we can see that DTs are referred to as a virtual copy, digital replica, mirror, simulation, virtual map, digital representation, image, computer model, and digital and virtual models of a physical entity that are used in different ways, for example, simulating the patient trajectory, personalized treatments, monitoring real-time status, and mirroring the underlying biological systems. As can be observed, the definitions focus on different features of DTs, dependent on the application and purpose of the studies. As this domain could benefit from a universal definition and common understanding of DTs, we first discuss the known elements and underlying characteristics of DTs and then synthesize these into a definition and framework.

DT Architecture

In this section, we will first discuss the elements of DTs and then the characteristics of DTs that distinguish them from other similar technologies.

Real Entity

The aim of a DT is to create a virtual representation of physical entities which is a foundational definition of DTs [57]. In the context of manufacturing, various types of physical entities (eg, vehicles, products, components, etc) and their "real-world" existence have been studied and they are, needless to say, physical. This is a common element in the application of DTs in the field of manufacturing and health care [58]. In the health care context, the patient or hospital environment is typically considered the physical entity [2,15,18]. In ODM and CDM, operational and clinical systems, processes and workflows could also be a target of DTs, which may not be necessarily a physically existing entity. Therefore, real entity (ie, real-world entity) rather than physical entity could be a more generalized terminology.

Virtual Representation

A DT fully describes its real entity from the microatomic level to the macrogeometric level [59,60]. In general, a virtual representation may represent a real entity using 1 or more of the following 4 different dimensions: geometry (ie, the geometric shape, such as size), physics (ie, the physical characteristics and constraints), behavior (the dynamic behavior and responsive mechanism to internal and external changes), and rules (using historical data and domain experts to develop logical abilities, such as reasoning, evaluation, and decision-making) [61]. This representation of a real entity allows broader applications beyond static digital visualizations, for example, computer-aided design and 3D models.

Communication Channels

A bidirectional data connection which is one of the main components of DT systems acts as a communication channel

XSL•FO
RenderX

between the real entity and its virtual counterpart. The nature of this data connection between the real entity and its virtual representation may be interpreted differently. One perspective is that the data flow between the real and virtual product is fully integrated in a way that the real product is controlled by its virtual version and a change in one of them alters the status of the other [62]. An alternative view is that the connection from the real to the virtual product is continuous in a way that the status of the real product is continuously transferred to the virtual product, while the connection of the virtual product to the real one is rather a flow of information and processes that may be applied to the actual object [63]. Regardless of the differences, this live connection is considered one of the main differentiators between DTs and traditional modeling exercises [58].

Computational Models

DTs use computational models that leverage gathered data to analyze, understand, monitor, and predict a system's state and behavior. These models (eg, simulations, machine-learning implementations, and business logic) are the core of DTs [64]. Thus, a crucial step when building DTs is to create high-fidelity models that provide recommendations and capture the corresponding real entity's geometry, physical properties, behaviors, and rules. The multimodel aspects allow the consideration of scenarios that exceed the descriptive capabilities of any single model.

Feedback Mechanism

DTs perform through a closed loop between real and virtual entities. This feedback mechanism is a crucial element of a DT, which could be automated, semiautomated, or human-in-the-loop decision-making depending on several factors, for example, the application, the DT's performance, and the trust level between the DT and stakeholders. Although an automated DT is ideal, in a decision support system, especially in the context of health care where human lives are involved, the decision-making process is risk-oriented and requires a high level of frequent monitoring, consultation, and expertise. Thus, similar to other decision support algorithms, DTs may just provide suggestions and recommendations (eg, a better course of treatment) to decision makers rather than issuing orders. In this situation, the decision maker has the authority to accept or reject any offered suggestions and provide feedback to the virtual entity for further clarifications and improvements that enhance accuracy.

Knowledge Base

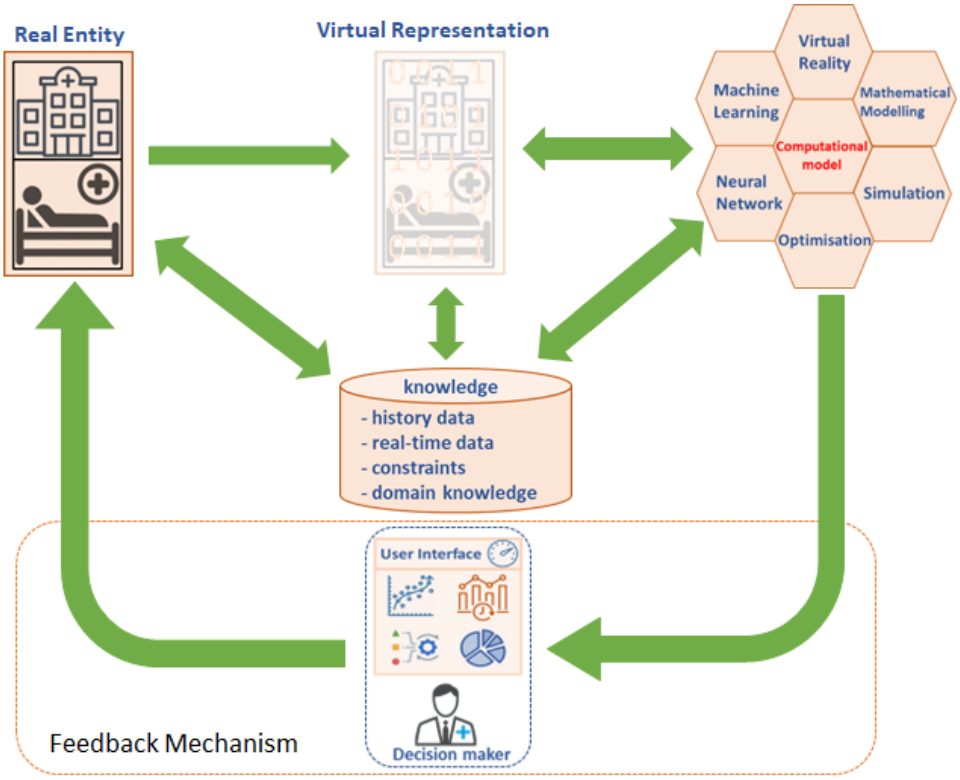
The DT is typically considered as a system that is data-driven and thrives on data. A lot of data is captured about the real entity in the development of the virtual representation. This collection of data grows as computational models are run, feedback is provided, resulting decisions are applied to the real entity, and the virtual representation is updated to represent the current state of the real entity. All of this data together constitute a knowledge base that can be used to inform future computational models and related feedback and decision-making processes.

User Interface

One of the advantages of DTs is their ability to handle and manage high information loads in a repetitive manner and provide feedback to decision makers. Considering the scale of their deployment, DTs may have various users (ie, stakeholders), and retrieving and displaying the necessary information for the right user may be challenging [65]. Therefore, a user interface (eg, dashboard, mobile app, etc) allows DTs to represent information in an insightful basis for decision-making and provide information to all users from varied perspectives. The dashboard may be viewed as a control room that provides users (ie, decision makers) a level of interaction to monitor the real-time state of the entities under investigation and view the results of desired experiments. In other words, users can interact with the DT through the user interface.

Considering the already explained elements, DTs have unique characteristics, as presented in Textbox 1.

Textbox 1. Unique characteristics of digital twins (DTs).



- Ongoing updates of virtual representations: a continuous data connection normally is the case when Internet of Things (eg, body sensors) are the source of data collection. However, health data is normally collected from multiple sources, such as electronic health records, laboratory results, and medical images and there is a delay related to capturing those data. As the nature of this connection is to enable a DT to reflect any changes in the state of the real entity in near real time, depending on the application, the frequency of data updates in a DT may vary from seconds to hours or days.
- Close to reality: synchronization is one of the key features of a DT, which is about making sure the virtual representation presented via a DT and the actual counterpart mirror each other as closely as possible. Therefore, building a virtual representation with a high degree of similarity, particularly functional similarity, ensures that when multimodel modeling is carried out on the virtual representation, it responds in the same way we would expect the real entity to respond.
- Ability for feedback to inform decision-making: one of the important aspects of DTs is their ability to analyze and notify findings to a decision maker through an always-active feedback loop. In other words, because DTs have a full knowledge of the real entity's historical performance and an accurate understanding of its future potential, it helps an end user to make an effective decision, for example, by considering multidimensional factors and nonlinear trade-offs that are challenging in reality.
- Multifunctionality: one of the unique aspects of the DTs is their ability to study (eg, simulate and predict) multiple physical properties and the interactions between them. This allows DTs to have many utilizations at the same time, for example, to optimize a process, continuously predict future states (eg, failures), simulate fixes and modifications to identify possible response actions, provide real-time monitoring, support the decision-making process, and provide realistic environments for virtual tests [17].

XSL•FO
RenderX

Our Definition and Framework

A universal and general definition of a DT is a knowledge-driven system that creates a close-to-reality virtual representation (twin) of a real entity (eg, clinical and operational processes). With the help of high-fidelity computational models (eg, simulation, prediction, and 3D modeling) and ongoing updates between virtual and real entities through a feedback mechanism, DTs inform decision makers (eg, administrators and clinicians) via user interfaces, to gain awareness of anticipated problems and gain an improved understanding of potential risks, challenges, and influences. The DT framework is shown in Figure 1.

Figure 1. The proposed universal digital twin (DT) framework.

In this framework, 2 environments (ie, real and virtual) are connected through data and a flow of information and processes (eg, dashboard). DTs integrate multiple approaches (eg, simulation, machine learning, and virtual reality) to create a virtual representation of the corresponding real entity. The multifunctionality of the DT provides user-care applications that are shared with the corresponding expert (eg, clinician, nurse, or administrative team) and may be transferred to the actual entity. The remainder of this paper provides a comprehensive review of the current advances and extent of DT applications to support clinical and ODM using this framework and the defined DT characteristics.

Methods

Guideline

We reported the review conducted in this study following the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines [66] (Multimedia Appendix 1).

Search Strategy

The search was performed through 8 scientific databases, including PubMed, MEDLINE, Scopus, Web of Science, Embase, CINAHL, Cochrane, and gray literature databases in June 2024. As DTs for clinical and ODM within the health care domain is a very new area of research, we included most of the academic databases and gray literature databases (eg, Google Scholar and OpenGrey) with no date restrictions.

To ensure relevant studies were captured in our search process, besides *digital twin**, we provided a list of search terms of which at least 1 needed to be mentioned within the title, abstract, or keywords, such as patient, hospital, Intensive Care Unit or ICU, surgery, clinic, and emergency. The following search terms were used with Boolean operators and wildcards: *digital twin** AND *hospital** OR **patient** OR *health** OR *ICU** OR *ward** OR *emergence** OR *surger** OR *ambulance** OR *clinic** OR *general practi** OR *doctor** OR *nurs**. The search strings used for all databases are shown in Multimedia Appendix 2.

Eligibility Criteria

To identify research papers aligned with our aims, publications had to meet the following criteria: (1) they had to describe the development of a DT model for health care, (2) they had to focus on CDM or ODM in health care (excluding papers focused on medical devices), (3) they had to propose a DT model with experiments, (4) any publication date was considered, (5) only peer-reviewed original research papers were included, and (6) only articles written in English were considered. Papers proposing ideas and frameworks or describing the capabilities of DTs without applications were excluded. Papers published as literature reviews, editorials, and conference posters were

XSL•FO
RenderX

excluded; duplicated papers and conference papers later published as extended journal papers were also excluded.

Data Extraction and Data Analysis

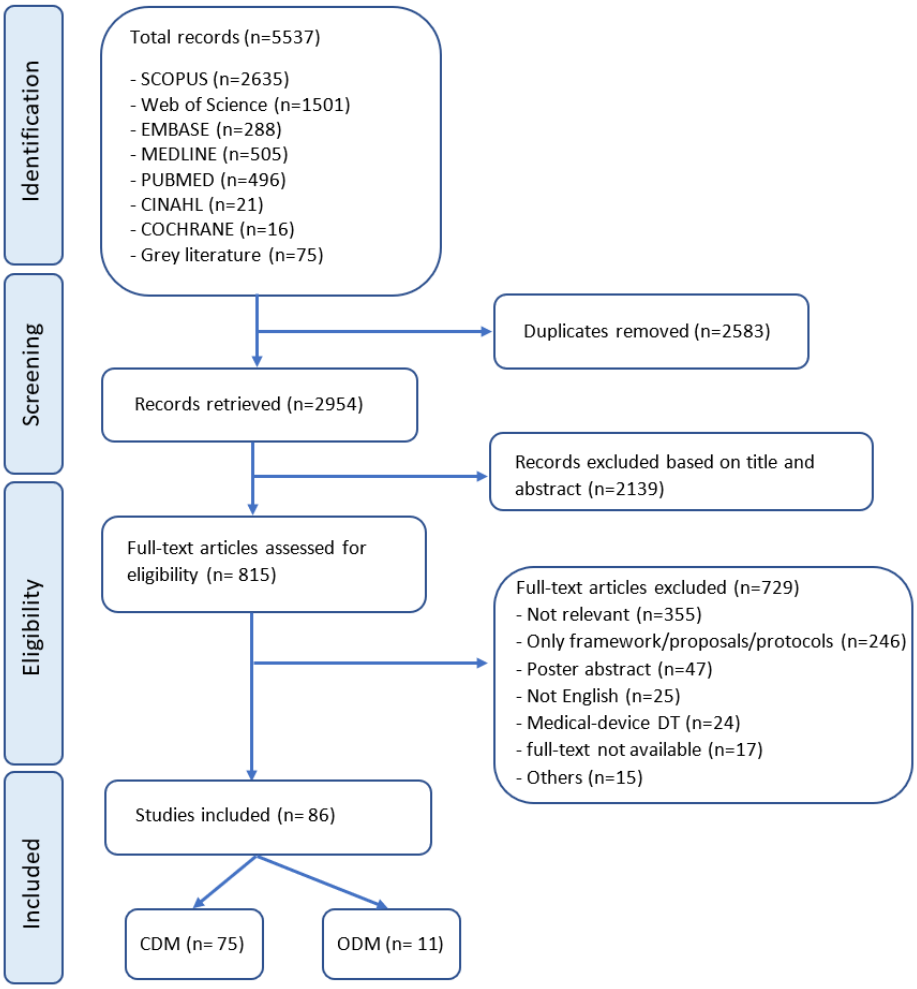
A web-based tool for systematic or scoping reviews, called Rayyan [67], was used to conduct all stages of the screening process. We developed a standardized data extraction form in Microsoft Excel to tabulate specific information. From the included studies (ie, after performing title, abstract, and full-text screening against exclusion and inclusion criteria), the following data were extracted: the country of the first author, publication type, DT characteristics, the environment that DTs were tested within, the sample size, the service, the target area, the main underlying method used in the DTs, the type of data collected to build DTs, the *International Classification of Diseases, 10th Revision* (*ICD-10*) codes, and a summary of included studies. Most included studies are presented in the following section, while the rest are provided in Multimedia Appendix 2.

The *ICD* coding consists of 22 chapters (1 to 22), each covering specific disease areas and courses of treatment. While the papers included in our review did not explicitly provide *ICD-10* codes, we classified them based on the specific disease areas and corresponding courses of treatment mentioned in the studies. For each paper, we first identified the main focus (ie, target area) and then mapped it to the relevant *ICD-10* code, starting from the most specific level and tracing it to the highest chapter level. For example, if a study focused on prostate cancer, it would be assigned the *ICD-10* code C61 (malignant neoplasm of the prostate), which is part of chapter 2, "Neoplasms."

In addition, in our qualitative synthesis, we systematically assessed the characteristics of DT implementations based on the developed framework, focusing on ongoing updates of virtual representations, closeness to reality, and the ability for feedback to inform decision-making. We examined the studies for discussions on the frequency and methods of data updates from real-world entities, considering various sources of data. We noted potential delays in data capture that could affect the real-time functionality of the DT. To evaluate how closely the virtual representation mirrored the actual entity, we examined the validation methods and metrics used to measure functional similarity, ensuring the DT could reliably represent real-world outcomes. We also considered the number and integration of models within each DT, as using multiple model types can enhance accuracy. We examined the mechanisms for ongoing feedback loops within the DTs, focusing on their ability to analyze historical performance and guide future decisions. This included identifying decision-support tools and user interfaces designed to help decision makers act on feedback. We also assessed whether a closed-loop system existed, where the DT actively influences decisions in the real twin. In addition, we explored how feedback is presented to various stakeholders, ensuring that insights from the DT effectively support informed decision-making in clinical and operational contexts. In assessing multifunctionality, we analyzed the range of problems the DTs were designed to address, exploring the distinct functions they served within health care. This involved evaluating the extent to which each DT tackled multiple facets of health care challenges, such as diagnosis, treatment planning, and monitoring. By adopting this structured approach, we ensured a consistent evaluation across studies, capturing the presence of these key characteristics.

Two reviewers collaborated in designing this form to capture the relevant variables effectively. Each reviewer independently extracted data from the included studies, followed by discussions to resolve any discrepancies. In instances where the reviewers could not reach an agreement, a third reviewer was consulted to extract the necessary data for those specific cases.

To synthesize the collated data, we used descriptive statistics to present frequencies and proportions for various characteristics of the included studies. Moreover, we provided a more in-depth qualitative synthesis of findings in the Results section. This qualitative synthesis highlights the nuances of the studies, such as the effectiveness of DT implementations, identified barriers and challenges, and insights into the broader implications for health care practice. The data analysis was performed using both Microsoft Excel and R software.



Results

Selection of Articles

A total of 5537 research papers were retrieved in the first step through all the given search databases. After screening titles and abstracts and removing duplicates, 815 (15%) papers were selected for full-text review. Considering the inclusion criteria, 86 (11%) out of 815 papers were selected for further analysis (ie, CDM: 75/86, 87% and ODM: 11/86, 13%). A total of 729 (89%) papers failed to meet the criteria. Around 34% (246/729) of these papers focused on providing ideas or frameworks and described the potential or capabilities of DTs which was the main reason for their exclusion. Moreover, 49% (355/729) of the papers were not relevant to the scope of this paper, for example, privacy and ethical aspects of DTs in health care, and big data and technology infrastructure required for DT implementations. The review process and results are shown as a PRISMA-ScR diagram in Figure 2.

XSL•FO
RenderX

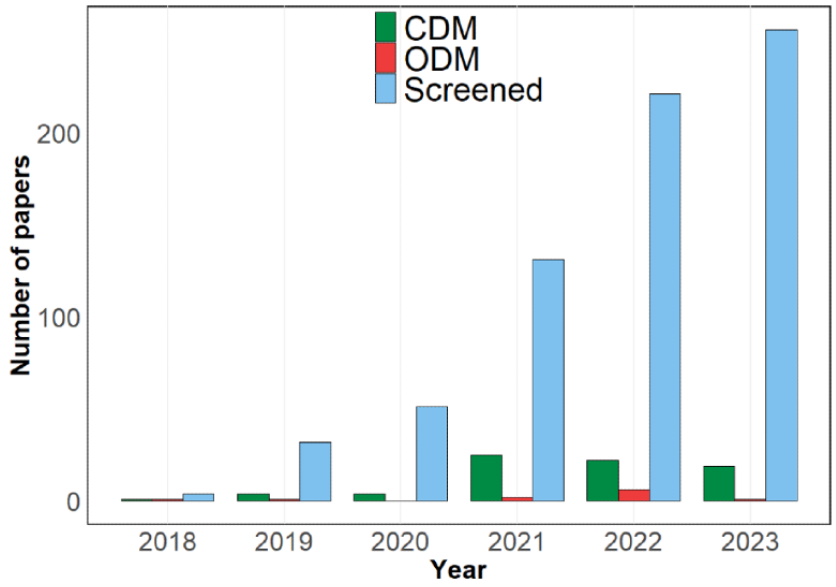


Figure 2. Flow diagram of the selection process of papers. CDM: clinical decision-making; DT: digital twin; ODM: operational decision-making.

Characteristics of Included Articles

Papers identified through our review reflect the current upward trend of publications in the DT research area as all screened and included studies were published after 2017 as shown in Figure 3. This figure also reveals the difference in research interest among researchers between CDM (more popular) and ODM.

Figure 3. Number of papers on digital twin technology that were screened and included for the review. CDM: clinical decision-making; ODM: operational decision-making.

XSL•FO
RenderX

Analysis of the distribution of the papers by the first author's country shows that the United States (17/86, 20%), China (11/86, 13%), and India (10/86, 12%) are the countries with the highest number of published studies. Other countries, including France, Germany, the United Kingdom, South Korea, Austria, Australia, Netherlands, Italy, and Canada contributed to DT research with at least 2 papers each. Out of the 86 papers included, 65 (76%) were published as journal papers and the rest were conference publications.

Data plays an important role within DTs as it allows the physical and virtual entities to communicate together. Besides a small number of studies (5/86, 9%) that used synthetic [40,54,68,69] or randomly generated data [50], most studies used data collected from real entities. Furthermore, analyzing the results shows that the data collected through medical images (eg, magnetic resonance imaging and computed tomography scans) are rich sources to build DT models for various purposes, for example, the His-Purkinje System [31], human vertebra [70], breast cancer [71], tibial plateau fracture [72], the tibiotalar joint [48], knee joint [52], patients with liver tumors [73,74], and the human brain [75].

For further analysis, a summary of the included papers along with their DT and health-related features is provided in Table 2. In this table, we have included characteristics that are featured in the DTs (refer to column "DT characteristics") based on the information reported in the article.

In Table 2, the CDM-based papers were categorized based on the targeted areas of the human body using the *ICD-10* codes. Textbox 2 provides the details of all the chapters in *ICD-10*.

Studies included in this review covered more than half (14) of all 22 chapters. Chapter 19 (“Diseases of the circulatory system”; 14/86, 16%) and chapter 21 (“Factors influencing health status and contact with health services”; 12/86, 14%) include the most studies, followed by chapter 4 (“Endocrine, nutritional, and metabolic diseases”; 10/86, 12%). These findings demonstrate the diversity of health care areas where DT models have been applied.

In terms of health care services in the included studies, for CDM, optimizing treatment (20/86, 23%), early prevention (16/86, 19%), and personalized treatment (15/86, 17%) are the 3 main service areas studied in the included papers, while for ODM, facility management (3/86, 3%) and efficiency improvement (3/86, 3%) are the most popular areas.

Regarding the main computational approach used in the proposed DTs, mathematical modeling (24/86, 28%), for example, moving least square and physiological models is the most common method followed by simulation techniques, for example, discrete event simulation (17/86, 20%) and neural network-based algorithms, for example, deep convolutional neural networks and graph neural networks, (17/86, 20%). Unsurprisingly, simulation-based models, such as discrete event simulation (9/11, 81%) are the most popular method used for ODM (as they can allow decision makers to investigate “what if” scenarios by quantifying the impact of potential changes in the operational settings [132]. The detailed distribution of disease areas, services, and computational methods in the included papers are provided in the Multimedia Appendix 3.

The following was also observed for these included studies: out of 86, only 32 (37%) studies demonstrated ongoing updates of virtual representations in their developed system, although it is the most fundamental characteristic of a DT. Among those 32 studies, 16 (50%) tested the developed system in a simulated environment, and the remainder were tested in real environments. Of the 4 defined characteristics of DTs, multifunctionality is a characteristic that was found to be lacking in most of the studies (81/86, 94%). Among the included papers, all studies missed at least one of the DT’s characteristics, and therefore, did not materialize all 4 characteristics of DT.

Although none of the studies had all the desired DT characteristics, the reported impact of the deployed DTs offers promising insight into their effectiveness. For example, a DT-based program for patients with type 2 diabetes helped all 12 insulin-dependent patients who attended the program to stop insulin injections and helped 38 out of 56 to stop taking metformin [79]. A DT technology used for assisting a surgeon with real-time performance of thermal ablation (a treatment to destroy tumor cells) provided significantly better results compared to other existing methods [73]. A DT for estimating the risk of posthepatectomy liver failure (a leading cause of postoperative death) was developed by modeling blood circulation and estimating 2 important determinants of the disease that could not be predicted before the development of the DT [84].

Textbox 2. Chapters in the International Classification of Diseases, 10th Revision.

- Chapter 1: Certain infectious and parasitic diseases
- Chapter 2: Neoplasms
- Chapter 3: Diseases of the blood and blood-forming organs and certain disorders involving the immune mechanism
- Chapter 4: Endocrine, nutritional and metabolic diseases
- Chapter 5: Mental and behavioural disorders
- Chapter 6: Diseases of the nervous system
- Chapter 7: Diseases of the eye and adnexa
- Chapter 8: Diseases of the ear and mastoid process
- Chapter 9: Diseases of the circulatory system
- Chapter 10: Diseases of the respiratory system
- Chapter 1: Diseases of the digestive system
- Chapter 12: Diseases of the skin and subcutaneous tissue
- Chapter 13: Diseases of the musculoskeletal system and connective tissue
- Chapter 14: Diseases of the genitourinary system
- Chapter 15: Pregnancy, childbirth and the puerperium
- Chapter 16: Certain conditions originating in the perinatal period
- Chapter 17: Congenital malformations, deformations and chromosomal abnormalities
- Chapter 18: Symptoms, signs and abnormal clinical and laboratory findings, not elsewhere classified
- Chapter 19: Injury, poisoning and certain other consequences of external causes
- Chapter 20: External causes of morbidity and mortality
- Chapter 21: Factors influencing health status and contact with health services
- Chapter 22: Codes for special purposes

Discussion

Principal Findings

The main finding of this study is that while DT systems in health care have shown promising results across multiple areas, they still do not fully incorporate all the desirable characteristics of a comprehensive DT. Nonetheless, DTs are making significant advances in clinical and ODM processes, particularly in areas such as cardiovascular disease, diabetes, cancer, orthopedics, and emergency department operations. The ability to integrate multiple techniques and technologies, such as big data, cloud computing, communication, virtual reality, blockchain, IoT, simulation, prediction, and optimization helps to create a digitally enabled environment for DTs to encapsulate and provide solutions for complex and multidisciplinary problems that were difficult to deal with using traditional methods. Key examples of such solutions include real-time monitoring, treatment optimization, risk factor early intervention, efficient clinical trial design, and improving operational efficiency.

The results of this study showed that the development and deployment of DTs within health care settings still lack maturity. Our review of the literature revealed a lack of a common definition and some inconsistency in the use of the term *digital twin*. Consequently, the focus of this study was shifted toward defining a DT and its underlying elements to support a common understanding and suggest a framework for designing and developing DTs. Building a DT is a complex process in terms of modeling, functionality, domain specificity, and data connectivity process. Therefore, research articles on DTs need to be transparent about their purpose (ie, functionality), the virtual representation that is being created, the data (eg, the frequency of data update, what data elements need to pass from the real entity to the virtual representation and vice versa), the feedback mechanism (eg, what are the outputs, who is receiving that feedback information, etc), and the computational models used (eg, the accuracy of the models and justification for the model's selection). This transparency helps any developed DTs be understandable and their potential for translation be gauged.

Assessing the identified studies against the defined characteristics of DTs revealed that while there are emerging applications of DTs for CDM and ODM, current efforts were not mature enough to include all desired features. As shown in Table 2, most of the reviewed studies did not include ongoing updates of virtual representations in their developed systems. Although they may not materialize a major characteristic of a DT, that is, fed by live data and synchronized with real-life events, they are proof-of-concept studies that provide evidence for the appetite for DTs in health care. One of the main aspects of DTs that is lacking in the included studies is the multifunctionality and scale of the proposed DTs. Studying the input and output data of the developed DTs revealed that they

XSL•FO
RenderX

are mostly designed with a single purpose although DTs are designed to create a complete virtual description of a real entity that is accurate at both the micro and macrolevels. The size of the samples used in the included studies shows that the developed DTs are still in experimental stages, and to fully embrace DT technologies, they need to move from custom expert-driven implementations to accessible robust implementations at scale [133].

As DTs are an emerging research area, especially in health care, it is not surprising to witness misconceptions, misunderstandings, and misrepresentations. It has been discussed that DTs are closely related to other research areas, such as 2D or 3D modeling, system simulation, and digital prototyping and this is a big factor in this confusion [2,26]. Reviewing some of the definitions of DTs over the years provides insight into their growth and development. Considering the fact that researchers are still trying to adopt DT concepts and technologies from manufacturing to health care and figure out how DTs can be implemented in such complex systems, it is understandable that there are still a few steps to go in designing, building, and executing a true DT system within a health care setting. Reviewing the selected papers in this study revealed that DT applications in health care are still in a transformative stage moving from offline systems, for example, digital models and simulations without any real-time connection with the real entity, toward DTs encompassing the aforementioned characteristics, and there is improved awareness of what separates DTs from similar technologies as interest in this field grows.

While none of the reviewed studies possesses all desired DT characteristics, the current state of the deployed models suggests that DTs have the potential for substantial impact once fully developed. They also showcase the versatility of DTs in CDM and ODM applications, from screening, diagnosing, detecting disease, and personal treatment to clinical trial design and optimizing hospital operations. While interest in the applications of DTs in health care is evident, the key focus area might be in understanding how health care operations could benefit from DT use. Developing DTs for designing clinical trials exemplifies how they provide personalized health care by allowing patient-specific responses to therapies to be simulated and treatment plans to be optimized [76]. Nevertheless, the impact of DTs can be extended to population health by providing insights into disease patterns and treatment efficacy across varied populations. Economically, they reduce costs related to traditional clinical trials, such as participant recruitment and logistics, and also position organizations at the forefront of innovation, attracting investment and fostering industry growth. Socially, virtual testing minimizes risks to human participants and enhances trial transparency, as well as addressing disparities by generating inclusive data that accurately represents diverse demographic groups. Thus, DTs promise significant advancements, offering broader societal and economic benefits.

Challenges and Barriers to Implementing DTs in Health Care

Overview

Alongside the promising opportunities, the application of DTs faces several challenges and concerns that could impede their full potential. As with other systems involving the exchange of health information, data security and integrity are essential for preserving patient privacy and ensuring high-fidelity models can be created. To implement DTs widely, significant investments are needed in both digital and physical infrastructure, including scalable cloud computing and high-performance computing for storing and processing the vast amounts of generated data and running complex simulations, and IoT devices with reliable networking for real-time data gathering and supporting rapid data transfer. Such a system upgrade will be particularly challenging due to the need to integrate DTs with existing legacy systems that often lack standardization and interoperability. To facilitate this transformation, it is essential to mitigate these challenges by establishing standardized data formats, communication protocols, and data exchange mechanisms that enhance efficient information flow across systems [134]. Besides, DTs' validation should be first established for an end user to trust the feedback, similar to how predictive performance and clinical validation of artificial intelligence and machine learning models are assessed before use.

There are some other unique aspects related to health care that make the implementation of a DT model challenging but compelling. One important property of DTs is having real time, live, and continuous data flow. However, health data normally is sourced from multiple collections, such as electronic health records, laboratory results, and medical images and there is a delay related to capturing those data. For example, the results of blood tests may take up to 24 hours to be ready or care providers may update coding within a patient record at the end of their stay in the hospital. Capturing accurate data is, in fact, another challenge. Today, the health care industry contributes approximately 30% of the data worldwide and by 2025, it is expected to reach close to 5000 digital device interactions per person per day [135]. This deluge provides an opportunity for developing data-driven models, such as DTs; however, assembling these data from various sources which are normally stored in different formats remains a significant challenge, along with the accuracy of underlying patient-level data stored within datasets. Moreover, the collection and storage of extensive data raises significant data privacy and security concerns, particularly given the sensitive nature of patient information. Solutions involve implementing robust security measures like encryption and access controls to ensure the protection of data during sharing and analysis [18,25,134,136].

Another big difference in DT applications in health care compared to other industries is human involvement, which raises a myriad of ethical issues. It has been discussed that a DT based on a virtual representation of a human may be created in such a way that the virtual version acts on behalf of the actual person and directly affects the person [137]. Therefore, not only does the digital model need informed consent, but also the person

XSL•FO
RenderX

needs to be granted adequate control over their digitally-twinned representation. Trust is another important consideration along the path of the development of DTs in health care. Because of the high level of sensitivity working with health data, DTs as an emerging technology not only need reliable results but also the trust of health care providers.

Future Directions and Policy Considerations for DTs in Health Care

With the rapid growth of DT models, driven by global investments in underlying technologies, such as IoT, and their potential to outperform traditional methods [138], the application of DTs in clinical and ODM is poised to accelerate in the foreseeable future. Effective policy improvement, such as enforcing interoperability standards, providing funding and incentives for technological upgrades, updating data privacy laws, and establishing clear artificial intelligence and machine learning regulatory frameworks will be crucial in facilitating this transmission.

Limitations and Strengths

This study has several limitations. First, the scoping review was limited only to papers published in English. Second, the search process was restricted only to original papers with the term *digital twin* included in either the title, abstract, or keywords which may have resulted in excluding other closely relevant studies that may not have used this term. Third, in the inclusion criteria, we focused on DT applications within ODM and CDM; however, this may have led to excluding a portion of DT applications in other health domains, such as medicine and drug discovery. Fourth, this study reviewed a wide range of DT applications in health care delivery without critically assessing their reporting quality. Therefore, more detailed quantitative analyses can be considered as future research activities that are beyond the scope of this work. Fifth, while our search strategy was comprehensive, some relevant studies indexed under different terminology or metadata, such as MeSH terms, may have been unintentionally missed. Finally, there are articles published between the completion of the search process (June 2024) and the publication of this study that we were not aware of and therefore were not included in this review.

Despite the challenges and limitations highlighted earlier, it is important to acknowledge the strengths of our work. This study offers a comprehensive framework for defining the key characteristics of DTs in health care, providing an essential resource for future research and practical applications. Our review not only outlines the current advancements in DT technology but also pinpoints critical gaps between present capabilities and their full potential, especially in clinical and ODM. The proposed framework serves as a guide for researchers and health care providers in developing DT systems, offering a reference for incorporating all the desirable characteristics of a comprehensive DT to effectively implement and use these technologies. Considering the rapid development of DTs, our review is both timely and highly relevant for researchers and health care practitioners. We adopted a deliberately broad scope, encompassing studies from diverse clinical settings and health care disciplines to ensure a comprehensive understanding of DT applications. By incorporating both academic and gray literature, our findings are further strengthened, offering a solid basis for those working to develop and implement DT systems.

Conclusions

The application of DTs in health care is exponentially growing and it is expected to play a major role in decision-making processes at both operational and clinical levels. This scoping review presents a broad overview of currently developed DT technologies, and the key findings can be summarized as follows: before this study, a common definition of DTs was missing, and researchers often confused other approaches with DTs. In this study, we provided a detailed description of DT elements and characteristics and synthesized these into a universal definition and architecture for DTs for clinical and operational decision support. Second, most prior work has not materialized a major characteristic of DTs: although bidirectional data connection between a real entity and the corresponding virtual one is a fundamental element of a DT, the ongoing update characteristic is lacking in most of the included papers. Third, the implementation of DTs is still in its infancy. Only 19% of the included studies tested the developed DT in a real environment and 95% of them were designed with a single-purpose functionality. Further study is warranted to explore the potential of DTs, for example, integrating ongoing updates into DT models, evaluating practical implementations in health care settings (ie, assessing effectiveness, feasibility, and scalability), and enhancing versatility for broader functionality and seamless integration.

Authors' Contributions

VR, ID, SK, JB, and HH were involved in the concept and design of the review. All authors made major contributions to literature search, data collection, data analysis, and data interpretation. VR created all the figures. VR, ID, SK, JB, and HH wrote and edited the manuscript. All authors read and approved the final manuscript.

Abstract

Background: Digital solutions, such as mobile apps or telemonitoring devices, are frequently considered facilitators in the process of empowering older adults, but they can also act as a source of digital exclusion or disempowerment if they are not adequate for older adults' needs and characteristics.

Objective: This study aimed to synthesize and critically evaluate existing evidence on the effectiveness of integrated digital solutions that enable interaction for empowering older adults in aspects related to their health and to explore potential factors (eg, type of technology, participants' characteristics) impacting effectiveness.

Methods: A systematic search was carried out in PubMed, ScienceDirect, SCOPUS, EBSCO, and SciELO using a combination of terms informed by previous reviews on empowerment. Screening of references was performed against predefined inclusion criteria. Data extraction and the methodological quality of included studies using the PEDro (Physiotherapy Evidence Database) scale were performed by 2 authors. The certainty of evidence was graded for the main comparisons and outcomes of the review using the GRADE (Grading of Recommendations Assessment, Development, and Evaluation) framework. When at least 3 studies were available within the same domain of empowerment (knowledge, support by others, capacities, and behaviors) and comparison group, a meta-analysis was performed.

Results: A total of 30 manuscripts were included in the review. Regarding knowledge, there was very low certainty of evidence of a medium effect size (ES) favoring the digital intervention group (k=5, ES=0.40, 95% CI 0.07-0.73, I^2=79%). Regarding capacities, there was low certainty of evidence of no between-group differences (k=5, d=0.13, 95% CI –0.02 to 0.29, I^2=0%) when comparing digital solutions against no intervention, low certainty of evidence of a medium ES favoring the digital intervention group (k=13, d=0.29, 95% CI 0.07-0.52, I^2=79%) when comparing digital solutions against usual care, and very low certainty of evidence of no between-group differences (k=4, d=0.97, 95% CI –0.62 to 2.56, I^2=97%) when comparing digital interventions to face-to-face interventions. Regarding social support and behaviors, no meta-analysis was possible, and existing evidence is conflicting.

XSL•FO
RenderX

Conclusions: There is very-low-to-low certainty of evidence that using integrated digital solutions results in increased knowledge and increased capacities (mainly self-efficacy) when compared to usual care and impacts capacities to an extent similar to face-to-face interventions at postintervention. Interestingly, results also suggest, with low certainty of evidence, that there are no differences between using digital solutions and no intervention for improving capacities. Included studies and technologies were diverse, and meta-analysis showed high heterogeneity, which limits the confidence in the results and suggests that further research might affect the conclusions of this review.

Introduction

Empowerment is a complex concept with multiple definitions [1,2] and is affected by multiple factors, including individual and contextual factors [3]. One definition refers to empowerment as a social process of recognizing, promoting, and enhancing people's ability to meet their own needs, solve their problems, and mobilize the necessary resources to feel in control of their own lives [4]. In other words, empowerment is a process by which people, organizations, and communities gain mastery over issues of concern to them [3]. When a person or group is empowered, they can make impactful decisions, allowing them to turn those decisions into the actions and results they desire [1,5].

Empowering older adults is of great importance as a means of promoting autonomy and independence by allowing them to make their own decisions, foster social connections that endorse social participation [1], and engage in activities that bring them joy and fulfillment [6]. In addition, empowering older adults contributes to ensuring that they are treated with dignity and respect; to acknowledging their life experiences, wisdom, and contributions to society [7]; and to fostering a sense of self-worth, value, and independence [8]. Empowered older adults feel encouraged to take control of their physical, mental, and emotional health and make informed decisions about their health care and well-being [8,9]. Overall, empowerment means having an opportunity to learn, discuss, decide, and act on decisions across all areas and dimensions of one's own life [10].

Digital solutions, such as mobile apps or telemonitoring systems, are frequently considered facilitators in the process of empowering older adults [11] as they often provide access to a vast amount of information, resources, and services [12] and improve social connection and communication, particularly with family members and friends who do not live nearby [13]. This enables older adults to stay informed, engage in lifelong learning, have access to services and products, make informed decisions about their health and well-being [14], and maintain social connections regardless of physical distance. However, digital solutions can also act as a source of segregation, digital exclusion, or disempowerment for older people as they are not adequate for older adults' needs and characteristics [15-17]. Interaction (ie, the ability to engage with a digital solution) is likely to be a key aspect of the potential of digital solutions for empowering as interactive solutions allow for a more personalized and immersive experience [18]. Nevertheless, several barriers hinder the effective use of digital solutions by older adults, and potentially its ability to empower them, such as the digital divide, the technological complexity, or the lack of flexibility and adequacy to their needs and characteristics, such as age-related or disease-related physical and cognitive constraints [19-21]. Therefore, the potential of digital solutions as a means of empowering older adults might not translate into an effective positive impact, or this impact might vary across different types of digital solutions or depend on the characteristics of older adults. However, and to the best of our knowledge, there is no available synthesis of evidence on the effectiveness of digital solutions for empowering older adults that clarifies the impact of digital solutions or that attempts to identify potential factors affecting their effectiveness. Thus, this study aimed to synthesize and critically evaluate existing evidence on the effectiveness of integrated digital solutions that enable interaction for empowering older adults in aspects related to their health and to explore potential factors (eg, type of technology, participants' characteristics) impacting effectiveness.

Methods

Study Design

This study was registered in PROSPERO (International Prospective Register of Systematic Reviews; CRD42022346823). The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines (Multimedia Appendix 1) were followed in this review [22].

Eligibility Criteria

Studies were included in this review if they met the following inclusion criteria:

- Participants had a mean age of 60 years or more.
- Studies reported randomized or quasi-randomized trials aiming primarily at assessing the effectiveness of technology for empowering older adults.
- One of the arms used an integrated digital solution that enables interaction with the users. Examples include complex technologies, such as remote health and social monitoring solutions, and ambient assisted living solutions or simpler solutions, such as mobile phone apps and

XSL•FO
RenderX

websites. A description and examples are presented in Multimedia Appendix 2.
- The comparison was no intervention, usual care, or any intervention (eg, education, written material) that did not use a digital solution.
- The outcome of interest was 1 of the following 4 dimensions of empowerment [23]: (1) patients' capacities (tolerance of uncertainty, skill and technique acquisition, constructive attitudes and approaches, self-monitoring and insight, emotional well-being, positive attitude, self-efficacy, ownership, and self-information search), (2) patients' knowledge (knowledge and confidence in decision-making, informed confidence), (3) patients' behaviors (positive and active engagement in life, health-directed behavior, health service navigation, enabling others, social advocacy, commitment, informed choice, navigation, partnership, and health maintenance), and (4) support by others (social integration and support, integration, client-provider relationship, client-client support, control, doctors' health locus of control, and other people's health locus of control).
- Studies were published in English, Spanish, or Portuguese. Other languages were excluded because of limitations in the language abilities of the research team.

Studies with measurement instruments including individual items on empowerment but not providing individual item scores were excluded.

Search Strategy

A systematic search was carried out in the following electronic databases: PubMed, ScienceDirect, SCOPUS, EBSCO, and SciELO. The search strategy consisted of a combination of terms based on previous reviews on empowerment [24] and technology [25] (for details, see Multimedia Appendix 3). In PubMed, the following search string was used: ((“Empowerment”[Mesh] OR “Patient Participation”[Mesh]) OR “self-efficacy” OR “locus of control” OR perceived autonomy OR perception of autonomy OR overconfidence) AND ((“Technology”[Mesh]) OR “Digital Technology”[Mesh] OR “Mobile apps” OR m-health OR ehealth OR e-health OR “digital solution” OR “Ambient Assisted Living” OR “digital services” OR website OR “digital platform” OR esocial). This string was adapted for the remaining databases. No filters were used. The search was conducted on May 4, 2022, and updated on September 6, 2022, and included papers from each database's inception until August 31, 2023.

Selection Process

After importing the papers into Mendeley (Elsevier), duplicates were removed. Next, the papers were imported to CADIMA (Julius Kühn-Institut), the software used to support screening, which was performed first by title and abstract and then by full text against the eligibility criteria. The entire selection process was performed independently by 2 authors (AIM and AGS). Disagreements or discrepancies during the selection process were resolved by consensus or consultation with a third author (NPR or OR).

Data Extraction and Management

A customized Microsoft Excel form was used for data extraction, which was piloted using 3 studies. The data extraction was manually completed by 1 author (AIM) and checked by a second author (AGS). The following data were extracted from each study: author and date, measurement instruments used to assess the outcomes of interest, intervention (type and duration), characteristics of the sample per group (health condition, sample size, age, sex), comparison, outcomes, and results (at postintervention and follow-up assessments). Data on the period of follow-up and the results of follow-up assessments were collected to allow for analysis of the effectiveness of digital solutions at different time points. When multiple outcomes within the same domain of empowerment were reported in the same paper, the choice of which to include in the meta-analysis was based on similarity with outcomes from other studies in the same meta-analysis. When data were not fully accessible (eg, presented in graphs), they were not extracted and authors were contacted.

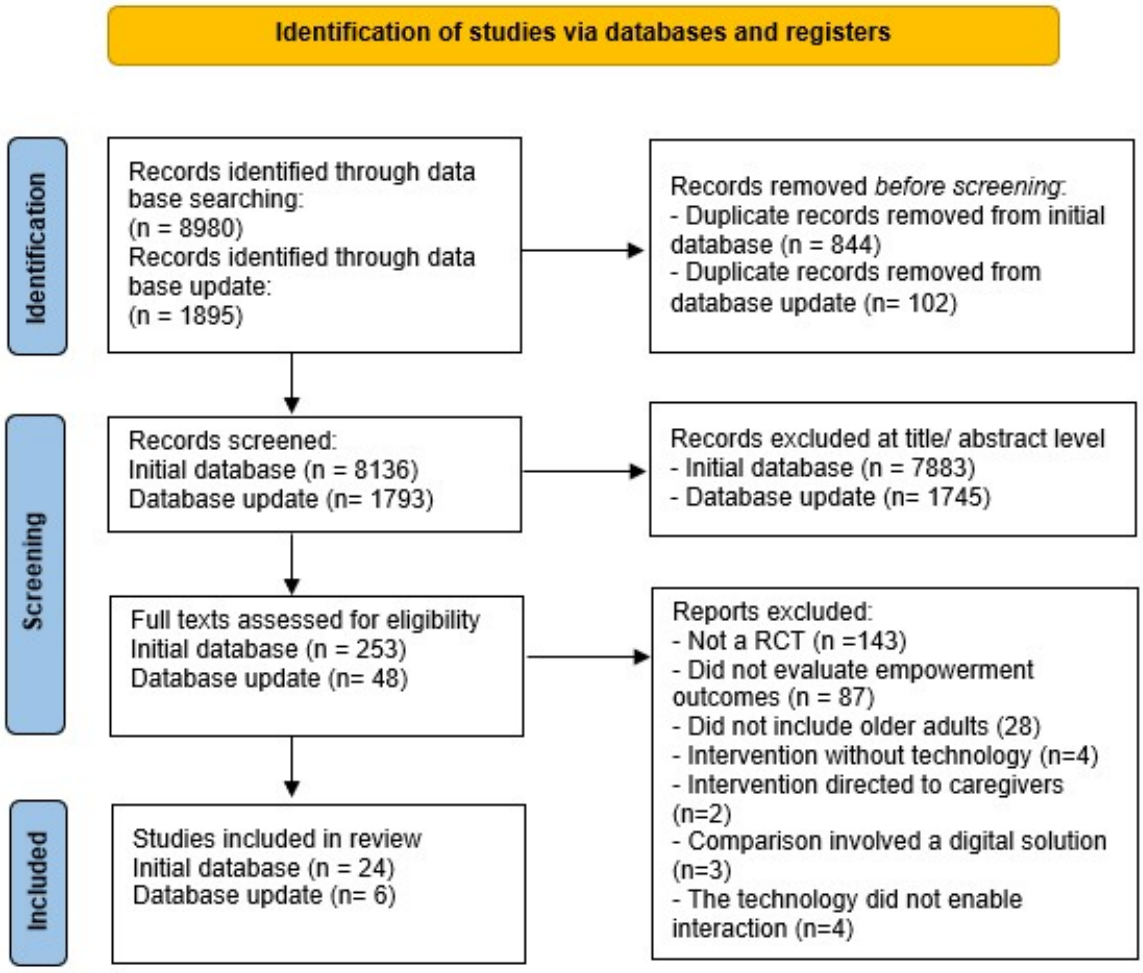
Extracted data were summarized under 1 of the 4 domains of empowerment previously defined (patients' capacities, patients' behaviors, patients' knowledge, and support by others). When necessary, the transformation of data, such as the conversion of SEs and CIs into SDs, was performed according to Cochrane recommendations [26].

Methodological Quality Assessment

The quality of studies was assessed using the PEDro (Physiotherapy Evidence Database) scale, which is a valid instrument [27]. Each study was assessed independently by pairs of reviewers (AIM and AGS, NPR and OR), and disagreements were resolved by a third author. The PEDro scale is composed of 11 items, and each item is scored as either present (1) or absent (0). The first item is not considered in the total score, leading to a maximum score of 10. The total score can be interpreted as follows: 0-3, poor; 4-5, fair; 6-8, good; and 9-10, excellent methodological quality [28].

Assessment of the Certainty of Evidence

The certainty of evidence was graded for the main comparisons and outcomes of this review. The overall quality and strength of the evidence per outcome was assessed according to the GRADE (Grading of Recommendations Assessment, Development, and Evaluation) framework. Evidence was assessed against (1) risk of bias, (2) inconsistency of results, (3) indirectness, (4) imprecision, and (5) publication bias, and the overall quality of evidence was classified as high, moderate, low, or very low [29,30]. We started with high evidence as studies included in the meta-analysis were randomized trials, and then, the evidence was downgraded, considering the researchers' assessment of each criterion.



Data Synthesis

When at least 3 studies were available within the same empowerment domain and comparison group (no intervention, usual care, or face-to-face intervention), a meta-analysis was performed. In addition, separate analyses were performed considering whether the digital intervention was the only intervention or was administered together with a face-to-face

XSL•FO
RenderX

intervention. A sensitivity analysis was performed excluding lower-quality studies. Effect sizes (ESs) and their 95% CIs were determined by the standardized mean difference (SMD) and classified according to Cohen's guidelines as small (0.20), medium (0.50), and large (0.80) effects [31]. Statistical heterogeneity was investigated using I^2 statistics interpreted as 25%, 50%, and 75%, reflecting low, moderate, and high statistical heterogeneity, respectively. When at least 10 studies were available, funnel plots were generated to inform publication bias. Follow-up periods were chosen to increase the similarity between studies in the same meta-analysis. The meta-analysis was performed using R version 4.2.2 (R Foundation for Statistical Computing). When no meta-analysis was possible, a qualitative synthesis was performed, indicating the comparisons investigated by the studies and the direction of the effect reported.

Figure 1. Flow diagram of the current review.

Results

Study Details

A total of 10,875 references were found, of which 946 (8.7%) were duplicates. The remaining 9929 (91.3%) references were screened by title and abstract, and 301 (3%) full-text manuscripts were retrieved and read. Of these, 30 (10%) manuscripts were included in the review (Figure 1). The included manuscripts assessed the impact of using a variety of digital solutions, including the following: websites (n=6, 20%), general mobile apps (n=4, 13.3%), condition-specific mobile apps (n=6, 20%), desktop software (n=1, 3.3%), remote monitoring (n=6, 20%), remote monitoring plus a website (n=1, 3.3%), remote monitoring plus mobile apps (n=5, 16.7%), and remote monitoring, a specific mobile app, plus a website (n=1, 3.3%).

Quality and Certainty of Evidence

The studies scored between 3 and 8 on the PEDro scale. Most studies scored 6-8 (n=20, 66.7%), suggesting good quality; 9 (30%) studies scored between 4 and 5, suggesting fair quality; and 1 (3.3%) study scored 3, suggesting poor quality (Multimedia Appendix 3). The certainty of evidence varied between very low to low and is presented next, along with the results of each meta-analysis (Multimedia Appendix 4).

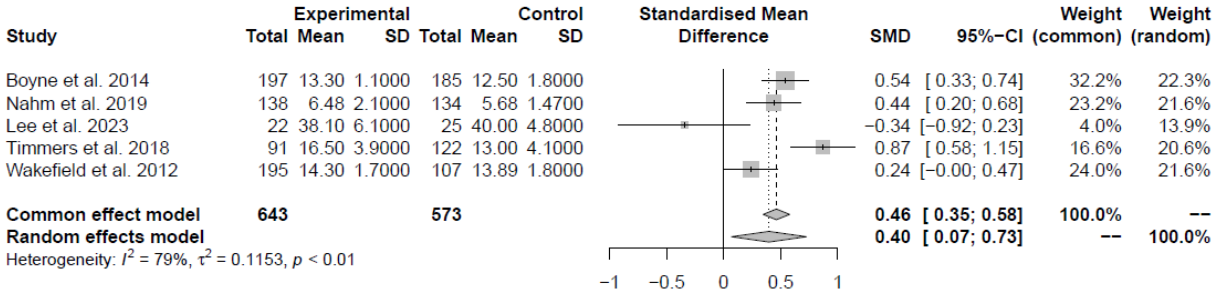
Impact of Digital Interventions on Empowerment at Postintervention

Data extracted from individual studies are presented in Multimedia Appendix 5.

XSL•FO
RenderX

Patients' Behaviors

Four studies [32-35] assessed the effect of digital solutions on behavior. One study [34] with fair quality compared a digital solution to usual care for patients with chronic obstructive pulmonary disease (COPD) and reported no between-group differences in self-management behavior. Two studies (one with good and the other with fair methodological quality) found the group receiving the digital intervention to report increased self-care behaviors when compared to usual care [32] and to a large written poster [35]. The other study [33], with fair quality, reported no differences between the group receiving the digital intervention and the no-intervention group for perceived participation in enjoyable activities. No meta-analysis was possible due to the unavailability of needed data.



Support by Others

Six studies [35-40] investigated the impact of digital interventions on support by others. Of these, 2 (33.3%) studies (with fair and good methodological quality) compared digital interventions against no intervention: one reported no between-group differences [39], while the other reported that the digital intervention significantly increased social support compared to no intervention [38]. Another study [37], with fair quality, reported no differences in social support between the group receiving the digital intervention and the group receiving usual care. Two studies (fair and good quality) [35,36] used a digital intervention plus a face-to-face component: one reported no significant differences compared to no intervention [36], while the other reported a significant improvement in social support compared to a written large poster [35]. Another study [40] of good quality reported a significant difference at 12 months between the digital intervention and a paper-based health education program, favoring the latter (medium ES).

Patients' Knowledge

Seven studies [32,37,41-45] investigated the impact of digital technologies on patients' knowledge. Of these, 3 (42.9%) studies [32,44,45], 2 (66.7%) of good quality and 1 (33.3%) of fair quality, compared digital solutions against usual care; another 2 (28.6%) studies [41,42], both of fair quality, compared digital solutions against education. There was very low certainty of evidence of a medium ES favoring the experimental group (ES=0.40, 95% CI 0.07-0.73, I^2=79%; Figure 2). The remaining 2 (28.6%) studies [37,43], not included in the meta-analysis, were of fair quality and reported digital solutions to have a greater impact on knowledge compared to usual care.

Figure 2. Plot of the meta-analysis of the standardized mean differences for patients' knowledge (comparison: digital solutions versus usual care or education).

Patients' Capacities

Twenty-five studies investigated the impact of technology on older adults' capacities. A meta-analysis of 5 (20%) studies (n=1, 20%, study with poor, n=1, 20%, study with fair, and 3, 60%, studies with good quality) [39,46-49] that compared digital solutions against no intervention found, with low certainty of evidence, no between-group differences (d=0.13, 95% CI –0.02 to 0.29, I^2=0%; Figure 3). A meta-analysis of 13 (52%) studies (n=10, 76.9%, studies with good and n=3, 23.1%, studies with fair quality) [32,34,40,44,45,50-57] comparing digital solutions against usual care indicated, with low certainty of evidence, a medium ES favoring the digital intervention group (d=0.29, 95% CI 0.07-0.52, I^2=79%; Figure 4). Sensitivity analysis including the 10 (76.9%) studies with good quality did not affect the results (d=0.27, 95% CI 0.02-0.53, I^2=81%).

A meta-analysis of 4 (16%) studies [51,58-60] with good quality that compared digital interventions to face-to-face interventions suggested, with very low certainty of evidence, no between-group differences (d=0.97, 95% CI –0.62 to 2.56, I^2=97%; Figure 5).

Of the 4 (16%) studies [35-37,61] not included in any of the meta-analyses, 3 (75%) of fair-to-good quality reported no between-group differences when the digital solution was compared against usual care/phone calls [37,61] or combined with a face-to-face component and compared against no intervention [36]. The fourth study [35] presented fair quality and reported a significant difference favoring the group that received a digital solution when compared to face-to-face education.

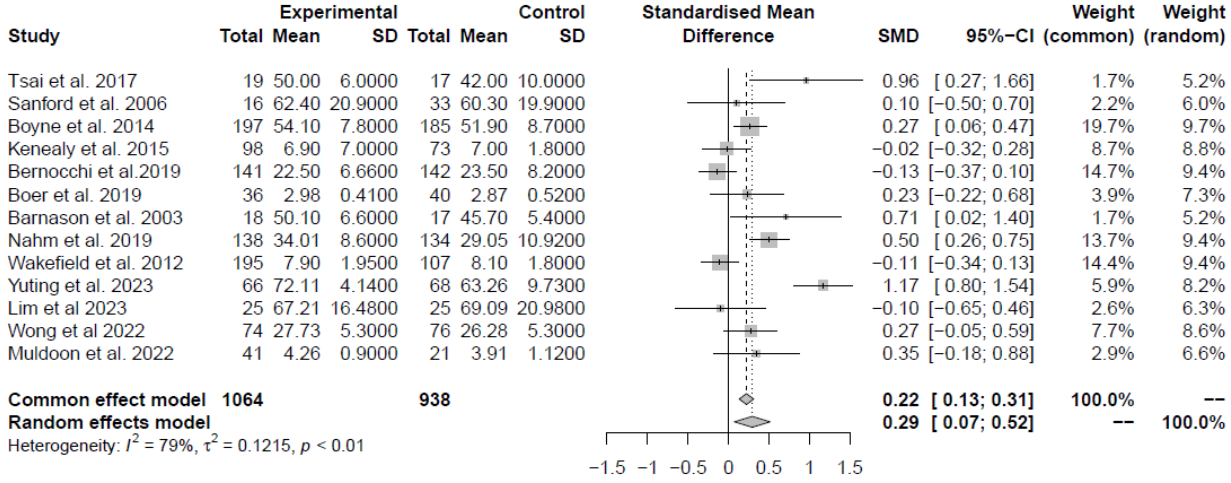

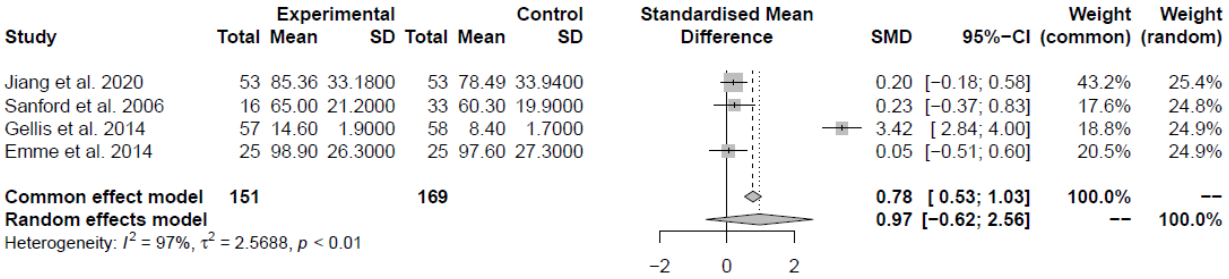

Figure 5. Plot of the meta-analysis of the standardized mean differences for patients' capacities (comparison: digital interventions to face-to-face interventions).

Impact of Digital Interventions on Empowerment at Follow-Up

Patients' Behaviors

Only 1 (3.3%) study [32] assessed the effect of technology on behavior at follow-up (6 and 12 months) and reported that the group receiving the digital intervention reported increased self-care behaviors when compared to usual care.

Support by Others

Two studies [38,39] investigated the impact of digital interventions against no intervention on support by others at up to 12 months' follow-up and reported no between-group differences.

Patients' Knowledge

Three studies investigated the impact of digital interventions against usual care on patients' knowledge at 3 [43], 4 [45], and up to 12 [32] months' follow-up. Two studies [32,43] reported a significant difference in favor of the experimental group, while the third study [45] reported no between-group differences.

XSL•FO
RenderX

Patients' Capacities

Two studies investigated the effect of digital solutions at 12 months' follow-up compared to no intervention: one reported no between-group differences [39], while the other reported significant improvements in self-efficacy in the intervention group [48]. Two studies investigated the effect of digital solutions against face-to-face intervention and reported no between-group differences at 3 [59] and 6 [58] months' follow-up. Three studies investigated the impact of digital solutions against usual care: 2 (66.7%) reported no between-group differences at 4 [45] and 12 [32] months' follow-up, but 1 (33.3%) [53] reported increased self-efficacy in the digital solution group at 3 months' follow-up.

Discussion

Principal Findings

This review synthesized existing evidence on the effectiveness of using integrated digital solutions for empowering older adults. Results suggest with very-low-to-low certainty of evidence that using digital solutions results in increased knowledge and increased capacities when compared to usual care and impacts capacities to an extent similar to face-to-face interventions. Interestingly, results also suggest, with low certainty of evidence, that there are no differences between using digital solutions and no intervention for improving capacities.

Comparison With Prior Work

Our results show an apparent contradiction as they suggest that digital solutions are better than usual care and equal to face-to-face interventions at improving patients' capacities but equal to no intervention. This might be explained by the characteristics of usual care, which, in the studies included, seems to equate to minimal care delivered over 1 or few sessions. As previously reported [62,63], usual care is generally not described in sufficient detail, hindering the interpretation of results. In addition, differences in the degree of interaction and support provided by the digital solutions, in the training given to individuals before the trial, in the amount of interaction with health professionals using the digital solutions, and in the personal and clinical characteristics of the participants might contribute to the differences found. Furthermore, the very-low-to-low certainty of the evidence, the wide CIs for the estimate of the effect, and the high heterogeneity in the usual-care meta-analyses suggest that further research is likely to impact the conclusions of the comparison of digital interventions against no intervention and usual care. Worth highlighting are the 2 studies that compared digital solutions against face-to-face interventions at follow-up and that confirmed the postintervention results by showing no between-group differences. Most studies within the capacity domain assessed self-efficacy (ie, people's beliefs in their own capabilities), which is reduced in older adults receiving care [64] and is an important determinant of health-related behavior change [65].

Digital interventions seem to improve older adults' knowledge to a higher extent than usual care, which, as previously reported, was not detailed in the included studies. The instruments used to assess acquired knowledge are diverse, but most relate to knowledge regarding a specific clinical condition. Other systematic reviews have reported that digital solutions can improve one's knowledge, for example, related to diabetes [66], and are better than usual care for eHealth literacy [67]. A previous study also reported that using digital solutions for seeking health-related information (eg, on specific diseases, medication, symptoms, and health promotion) is common among older adults [21], potentially facilitating adherence to digital interventions that promote knowledge acquisition.

This systematic review with meta-analysis results carefully suggests that the choice of using a digital solution or not might be left to individual preferences and that technology can be used to reach more individuals who would not have access to face-to-face empowerment strategies. Other studies have identified patients' needs and preferences as important aspects to consider when deciding between in-person health care delivery or remote health care delivery [68,69]. In addition, the decision on whether to use a digital solution might depend on the domain of empowerment being specifically targeted as relevant for a particular individual, potentially choosing digital solutions to target knowledge and capacities and face-to-face interventions for other domains. Choosing a mixed approach where some domains of empowerment are targeted with face-to-face interventions, while others are targeted with digital interventions might also be an option. In addition, issues of security and privacy should be considered when choosing digital solutions for older adults, as they often have lower levels of digital literacy and consequently are more exposed to privacy violations, frauds, scams, and phishing attacks [70,71]. Developing digital solutions that have user-friendly interfaces and implementing privacy by design (ie, incorporating privacy features into the design of digital solutions, such as data minimization principles) are essential. Additionally, education and awareness are a means to minimize the risk and to empower older adults with the knowledge and skills to identify online risks [70].

The similarity of results found in this review for the domains of patients' knowledge and capacities might suggest that increased knowledge might promote increased capacities by providing older adults with more knowledge about their health, resources, and management strategies. The study of causality was beyond the scope of this review. This result, rather, identifies a potential topic of study for future studies.

Regarding patients' behaviors and support by others, it was not possible to aggregate the evidence in a meta-analysis due to insufficient studies with a similar comparison. The qualitative analysis of the studies included in our systematic review identified conflicting results regarding the impact of digital interventions. The factors previously identified as potential sources of heterogeneity might also contribute to the conflicting results.

Future studies should detail the intervention administered to the control group, particularly if it is usual care, as well as detail the functionalities of the digital solution provided, including training, interaction with professionals, and adherence to the intervention, as these factors might have an impact on the

XSL•FO
RenderX

effectiveness of the digital intervention to facilitate empowerment. Future systematic reviews and meta-analyses should attempt to identify sources of heterogeneity that might impact the results, including the type of digital solution, the amount of support given to participants, participants' characteristics (age, education, digital literacy), the length of the intervention, and subdomains within each domain of empowerment.

Limitations

The studies included are highly diverse in terms of the type of digital solutions, health conditions, participants' characteristics, and instruments used to assess empowerment. All these aspects are reflected in the high heterogeneity found and undermine the confidence in the results of the meta-analysis. We aimed to run a subgroup meta-analysis considering the type of technology and users' characteristics, but the small number of studies precluded this. For some comparisons, a meta-analysis was not possible due to the reduced number of studies with a similar comparison. This might suggest that empowerment is more researched when related to health domains. Studies that were not based on empowerment theory were not included.

Conclusion

There is very-low-to-low certainty of evidence that using integrated digital solutions results in increased knowledge and increased capacities (mainly self-efficacy) when compared to usual care and that it impacts capacities to an extent similar to face-to-face interventions at postintervention. Interestingly, results also suggest, with low certainty of evidence, that there are no differences between using digital solutions and no intervention for improving capacities. Included studies and technologies are diverse, and the meta-analysis showed high heterogeneity, which limits the confidence in the results and suggests that further research might affect the conclusions of this review. The limited number of studies precluded a subgroup analysis considering the type of technology and user characteristics.

Abstract

Background: Alzheimer disease is incurable, but it is possible to intervene and slow down the progression of dementia during periods of mild cognitive impairment (MCI) through virtual reality (VR) technology.

Objective: This study aimed to analyze the effects of VR interventions on older adults with MCI. The examined outcomes include cognitive abilities, mood, quality of life, and physical fitness, including general cognitive function, memory performance, attention and information processing speed, executive function, language proficiency, visuospatial abilities, depression, daily mobility of individuals, muscle performance, and gait and balance.

Methods: A total of 4 web-based databases (Web of Science, PubMed, Embase, and Ovid) were searched up to December 30, 2023, for randomized controlled trials assessing the self-reported outcomes of VR-based technology on cognition, mood, quality of life, and physical fitness in older adults (aged ≥55 years) with MCI. Two reviewers independently screened the search results and reference lists of the identified papers and related reviews. Data on the intervention components and delivery and behavioral change techniques used were extracted. A meta-analysis, risk-of-bias sensitivity analysis, and subgroup analysis were performed where appropriate to explore potential moderators. The Grading of Recommendations, Assessment, Development, and Evaluations (GRADE) approach was used to assess the quality of evidence.

Results: This review analyzed 18 studies involving 722 older adults with MCI. VR was delivered through different immersion levels with VR cognitive training, VR physical training, or VR cognitive-motor dual-task training. VR interventions showed significant improvements in memory (standardized mean difference [SMD] 0.2, 95% CI 0.02-0.38), attention and information processing speed (SMD 0.25, 95% CI 0.06-0.45), and executive function (SMD 0.22, 95% CI 0.02-0.42). VR without therapist involvement improved memory as well as attention and information processing speed. VR cognitive training also resulted in significant improvements in attention and information processing speed in older adults with MCI (SMD 0.31, 95% CI 0.05-0.58). In addition, immersive VR had a significant impact on improving attention and information processing speed (SMD 0.25; 95% CI 0.01-0.50) and executive function (SMD 0.25; 95% CI 0.00-0.50). However, the effects of the intervention were very small in terms of general cognitive function, language proficiency, visuospatial abilities, depression, daily living ability, muscle performance, and gait and balance. Quality of evidence varied, with moderate ratings for certain cognitive functions and low ratings for others, based on the GRADE approach.

Conclusions: VR interventions can improve memory, attention and information processing speed, and executive function in older adults with MCI. The quality of evidence is moderate to low, and further research is needed to confirm these findings and explore additional health-related outcomes.

Introduction

Dementia is a medical condition characterized by a notable decrease in cognitive abilities, which disrupts individuals' ability to perform occupational, familial, or social responsibilities [1] and is currently the seventh leading cause of death worldwide [2]. As the worldwide occurrence of Alzheimer disease (AD) rises, the economic burden on society will also increase significantly, with greater disease severity being linked to higher expenses [3,4]. Mild cognitive impairment (MCI) is a transitional stage of cognitive performance that occurs between normal aging and dementia [5]. Treatments can be implemented to slow down the advancement of dementia during the preclinical phase [6]. Conventional nonpharmacologic lifestyle interventions, including moderate-intensity physical activity and autonomic training, encounter challenges such as inadequate adherence, exorbitant treatment expenses, and inequities in health care accessibility [7,8]. Since there are few medications or dietary therapy that can improve cognitive function or slow MCI progression, nonpharmacological treatments have received attention [9,10].

In nonpharmacological interventions, VR has received a lot of attention. It helps the user to create a real sense of presence and immersion in the virtual world by using multiple sensory stimuli (visual, auditory, tactile, and olfactory) [11,12]. This capability has the potential to augment participants' focus and boost the efficacy of training sessions. For patients with MCI, VR has shown potential in enhancing cognitive capacity and motor function [13-15]. VR technology has mostly been used for evaluating and diagnosing the extent of cognitive impairment, as well as for cognitive training and testing [16]. In the assessment of the degree of cognitive impairment, VR-based virtual supermarkets, virtual fire evacuation drills, and voice interaction based on VR and wearable devices have been used to detect and distinguish between older adults with MCI and healthy older adults [15,17,18]. These methods have also been used to differentiate between persons with MCI and those with dementia [19,20], which help clinicians to detect cognitive impairment at an earlier stage compared with current diagnostic models that address different cognitive deficits. Furthermore, in terms of cognitive testing and cognitive training, a growing number of studies, such as the Virtual Environmental Grocery Store [21] and the Virtual Supermarket [22], have discovered that patients' performance in VR tasks is closely related to their performance in traditional neuropsychological tests. This demonstrates the reliability of VR-based assessment tests compared with traditional neuropsychological tests [23-25]. Furthermore, it has the potential to enhance many cognitive capacities such as general cognitive ability, memory, attention, and executive function [26-28]. VR technology can enhance noncognitive aspects of capability or condition in individuals with MCI. For instance, older adults with MCI may experience a reduction in anxiety by engaging with virtual environments such as virtual nature or tourist attractions [29]. Other studies also indicated that VR-based cognitive training (cooking or wayfinding) could effectively enhance instrumental activities of daily living (IADL) in individuals with MCI and AD [30].

Several trials have investigated the impact of VR on older adults with MCI, but the findings have been inconclusive. For example, studies by Baldimtsi et al [31] and Park et al [32] revealed a significant effect of VR on general cognitive abilities. However, the findings from Park et al [33] showed that a 12-week, culture-based VR training program did not improve general cognitive abilities and did not show significant differences in scores on the Mini-Mental Status Examination (MMSE). Also, it is challenging to make definitive conclusions about the effectiveness of interventions because of variations in the content of the interventions and the way they interact with VR. In a study conducted by Yang et al [28], daily life-based VR training games (making juice, shooting crows, finding the number of fireworks, and memorizing objects in the house) were found to positively affect general cognitive performance. However, in a study by Delbroek et al [34], which involved a combination of VR cognitive and motor training for balance, weight-bearing, memory, attention, and dual-tasking, no significant differences in general cognitive performance were observed.

Now, only 1 comprehensive assessment has examined the effects of VR on the cognitive abilities of older adults with MCI [13]. Nevertheless, it solely concentrated on the efficacy of executive function and failed to provide a thorough examination of cognitive capabilities. A comprehensive assessment found that a VR-based neuropsychological intervention was helpful in enhancing cognitive performance in individuals diagnosed with MCI [35]. However, this review did not address the different VR interventions due to the inclusion of only 1 specific intervention based on VR technology and the lack of analysis of multiple VR technology–based interventions. Currently, there is no systematic review of the VR field, and limited knowledge exists regarding the most effective type or combination of VR solutions for improving cognitive capacities, emotional performance, daily functioning, and physical fitness in older individuals with MCI. A broad overview of the evidence through a more nuanced categorization of VR content, professionals, and system-level VR solutions is required. Therefore, this review aims to assess the effects of VR technology–based interventions on older adults, specifically those with MCI. The outcomes include cognition, mood, quality of life, and physical fitness. Also, it is important to identify the most effective combination of the most effective components (eg, VR intervention content, provider, and level of immersion) for use in clinical and managerial responses to the evidence, as well as policy decisions.

Systematic Literature Review

Guidance published in PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) [36] and the Cochrane Handbook of Systematic Reviews [37] was adhered to. The a priori protocol for the review is published in the International Prospective Register of Systematic Reviews (PROSPERO; CRD42024503488).

Search Strategy

Studies were identified by searching web-based databases with support and consultation provided by institutional librarians. Searches included Web of Science, PubMed, Embase, and Ovid using both Medical Subject Headings and free-text keywords relating to MCI, VR interventions, and outcomes. To include studies reflecting the latest advancements in VR technology and methodologies, the focus was on literature published from January 2013 to December 2023. The year 2013 was chosen to ensure consistency in the technological sophistication and usability standards of VR interventions, as VR technology and its applications in cognitive rehabilitation have rapidly evolved over the past decade. One of the two pre-2013 papers were excluded due to unspecified levels of cognitive impairment, which could have affected the identification of cognitive deficits [38]. The other paper was excluded because cognitive deficits were due to conditions such as stroke or cerebral infarction, to maintain sample specificity [39]. Therefore, the outcomes from January 2013 to December 2023 are listed below. Search strategies for the first 3 databases above and dates on which searches were conducted are listed in Multimedia Appendix 1. Searches of the reference list of the previous review papers and included studies were also conducted.

Eligibility Criteria

Type of Studies

Randomized controlled trials (RCTs) of any design, including parallel-group, crossover, and cluster RCTs published in the English language were included in this review.

Population, Intervention, Comparison, Outcome Framework

This study uses the PICO (Population, Intervention, Comparison, Outcome) framework to structure the research question and guide the systematic review and meta-analysis. The PICO approach is a well-established method for formulating research questions and conducting systematic reviews in health care research [40].

Participants

Studies concerning older adults (aged ≥55 years) with a confirmed diagnosis of MCI by neurologic examination or neuropsychological assessment were included. The age cutoff of 55 years and older was chosen because individuals in this age group are eligible for certain age-related benefits and programs in various contexts, such as early retirement plans, senior discounts, and health interventions targeting midlife transitions. This makes it a practical cutoff for researching populations that can access interventions aimed at promoting active aging. No restrictions were applied to the study design. Studies with healthy older adults; persons with schizophrenia, depression, or Parkinson disease; and participants who did not specify the level of cognitive deficits were excluded.

Intervention

The intervention criterion considered the use of virtual environments, virtual interactive means, and VR components, including VR-based physical training, VR-based cognitive training, VR-based cognitive-motor dual-task training, face-to-face cognitive VR rehabilitation system, and VR programs.

Control Condition

Studies with any type of control group were included (inactive controls include educational programs or no intervention; active controls include traditional rehabilitation or any other type of physical activity, physical-cognitive co-training, or video games without VR components).

Outcomes

We included any psychometric, physical functioning measure that was reasonably unidimensional or multidimensional and the relevant subscales associated with the outcomes in Textbox 1.

XSL•FO
RenderX

Textbox 1. Measurement scales related to the outcomes.

Primary Outcomes

- General cognitive function: the Mini-Mental State Examination, the Montreal Cognitive Assessment, Korean version of the Modified Mental State Examination-Dementia Screening Test, the Cognitive Abilities Screening Instrument, Subcategory VST of CNT 4.0, Montreal Cognitive Assessment and GP Cognitive Assessment (dementia screening tool), and Loewenstein Occupational Therapy Cognitive Assessment – Aging
- Memory performance [41]: the Digit Span Test; Rey Auditory Verbal Learning Test; Wechsler Memory Scale, Third Edition; Multifactorial Memory Questionnaire; Chinese Verbal Learning Test; 20-item version of the Everyday Memory Questionnaire (range: 20-180); and Seoul Verbal Learning Test
- Attention and information processing speed: Trajectory Making Test A and B, Symbol Digit Substitution Test, Attention Matrix Test, and Digit Span Test
- Executive function: Korean version of the Executive Function Performance Test, Symbol Digit Substitution Test, Trajectory Making Test B, Stroop Color and Word Test, Executive Interview 25, and Frontal Assessment Battery

Secondary Outcomes

- Language proficiency: Word Fluency Test (category and letter fluency), Verbal Fluency (phonological fluency; semantic fluency), Battery for Analysis of Aphasic Deficits, and Korean version of the Boston Naming Test
- Visuospatial abilities: Rey-Osterrieth Complex Figure Test, Clock Drawing Test, and Weschsler Adult Intelligence Scale Revised Block Design Test
- Depression: 30-item Geriatric Depression Scale, 15-item Geriatric Depression Scale, and Multidimensional Observation Scale for Elderly Subjects
- The daily mobility of individuals: the Lawton Instrumental Activities of Daily Living scale, the Quality of Life in Alzheimer's Disease scale, and the Multidimensional Observation Scale for Elderly Subjects
- Gait and balance: Gait Speed Test, Timed Up and Go Test, Instrumented Timed Up and Go Test, limit of stability (LOS) values (a subcategory of RM Ingénierie's BIORescue system), and Six Minute Walk Test
- Muscle performance: Hand Gauge Measurement, Arm Flexion Test, and Lower Body Strength using the 30-second Sit-Stand Test

Exclusion Criteria

The exclusion criteria were as follows:

1. Not RCTs: Studies that were not RCTs were excluded.
2. Participants' age ≤55 years: Studies where the participants' average age was 65 years or younger were excluded.
3. Not participants with MCI: Studies that did not include participants diagnosed with MCI were excluded.
4. Cognitive impairment caused by other conditions: Studies where cognitive impairment was attributed to other medical conditions, such as stroke, cerebral infarction, traumatic brain injury, or other neurological disorders, were excluded. This ensures that the cognitive impairment under study is specifically related to MCI and not secondary to other health issues.
5. No specific identification of cognitive impairment: Studies where VR was not used in the intervention group, or VR was used in the control group, were excluded.
6. Inappropriate use of VR: Studies where VR was not used in the intervention group, or VR was used in the control group, were excluded.

Minimum Studies for Analysis

Analyses were conducted only if there were at least 3 studies available for each specific outcome measure. This criterion ensures the reliability and validity of the meta-analytic results.

Study Selection and Data Extraction

Two reviewers (QY and ZL) independently screened the abstracts and full text of the search results. Any disagreements were resolved through discussion. Data were extracted by 2 researchers (HY and LZ) and cross-checked by a third researcher (FC). Data items included participant characteristics, intervention device, intervention means, expertise or guidance, duration of intervention, adherence, and fidelity.

Meta-Analysis

We used RevMan (version 5.3; Cochrane Collaboration) for all analyses. Outcome data were expressed as standardized mean difference (SMD) and were pooled in a pairwise fixed-effects model stratified based on the outcome and type of digital medium. We used the mean (SD) of within-group change from baseline to calculate the SMDs. Per Cohen [42], SMDs <0.2 were classified as small, those between 0.2 and 0.8 were classified as medium, and those >0.8 were classified as large. The SMD was converted to the percentage change in the outcome measure by multiplying the SMD with the SD of the control group of the sufficiently powered study (ie, the trial with the largest sample size).

A sensitivity analysis was conducted for the risk-of-bias assessment. Subgroup analyses were conducted to assess the effect of VR on the different immersion effects used, the different intervention components, and the presence or absence of therapist involvement in the intervention. Heterogeneity across pooled studies was examined using the chi-squared test and I^2 statistics. We did not conduct additional exploratory analyses to explore potential moderators because of an insufficient number of studies. The common study characteristics tables were supplemented by additional summary tables including the risk-of-bias assessment; effect estimates; Grading of Recommendations, Assessment, Development, and

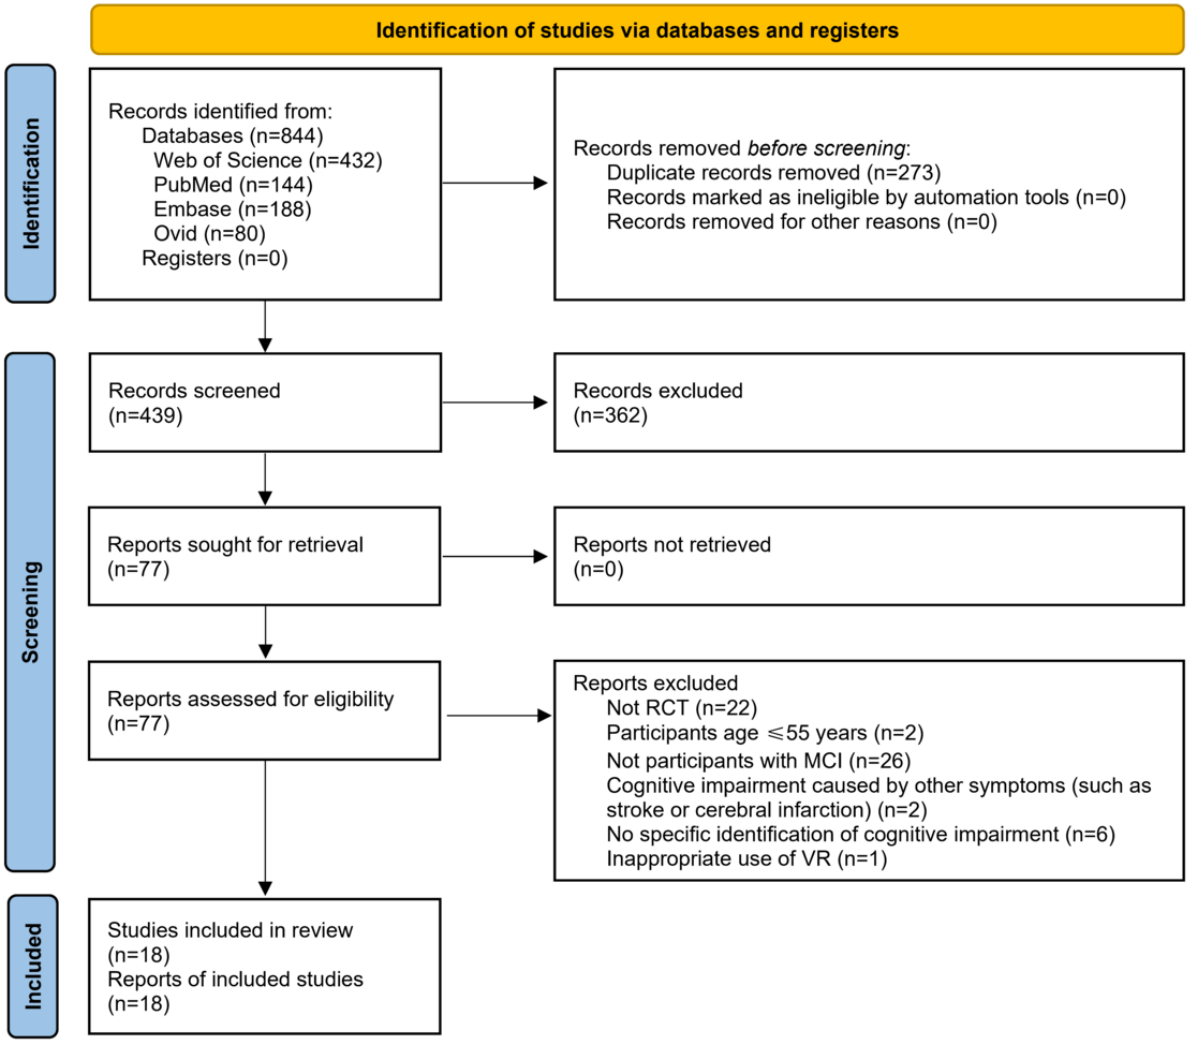
XSL•FO
RenderX

Evaluations (GRADE) analysis; and behavior change taxonomy groupings.

Dealing With Missing Data

RevMan calculator was used to estimate missing SDs based on test statistics reported in 2 studies. In addition, sensitivity analyses were conducted to assess the robustness of the results when missing data were imputed. Imputation methods were based on the assumption that data were missing at random.

Risk-of-Bias and GRADE Assessment



Risk of bias was assessed using the risk of bias tool of the Cochrane Handbook for Systematic Reviews [43]. Quality of evidence for outcomes was assessed according to the 5 GRADE domains, including study limitation (risk of bias), inconsistency, indirectness, imprecision, and publication bias [44,45].

Results

Study Selection and Characteristics

A total of 571 titles and abstracts were screened after excluding duplicates, of which 494 records did not meet the inclusion criteria (Figure 1). The full text of 78 potentially eligible records was read, including 18 studies published between 2017-2023. These studies included 722 (range 17-68) older adults with MCI. In total, 18 studies were RCTs [26-28,31-34,46-56]. Specific study characteristics and participant demographics are summarized in Multimedia Appendix 2.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram. MCI: mild cognitive impairment; RCT: randomized controlled trial; VR: virtual reality.

XSL•FO
RenderX

Participants

In total, 18 studies were included, with a total of 8 studies conducted in South Korea; 2 in Hong Kong, China; 2 in Taipei, China; and 6 in mainland China, Greece, Brazil, France, Turkey, and Japan.

The number of participants in the studies ranged from 17 to 68. The median age was 73.15 (IQR 66.07-87.5) years. Most participants in the studies were female (median 63.6%, IQR 16.7%-86.7%).

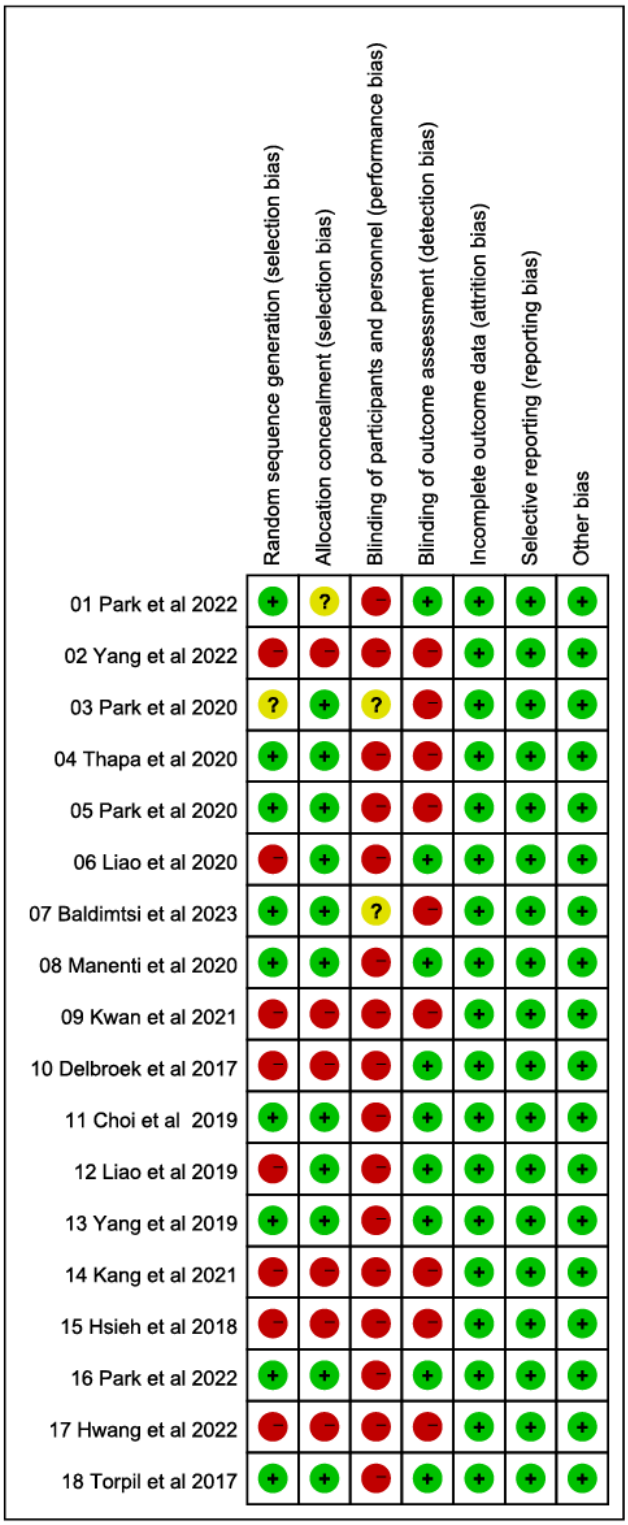
Nine studies reported participants' years of education, with a median age of 8.56 (IQR 7.20-9.90) years. Ten studies reported participants' baseline MMES scores, with a median score of 26.28 (IQR 25.30-27.4).

Detailed information on the characteristics of the included studies and the demographic data of the study participants are provided in the Multimedia Appendix 2.

Intervention Groups

Nine studies used VR headsets as the medium for VR intervention gear. Among these, 2 studies incorporated additional components, while 7 studies used stand-alone screens or projections. Furthermore, 6 studies were equipped with other components. One study used desktop computers, while 2 studies used tablets. Regarding control and perception, 10 studies used controllers while 4 studies used wearable devices for VR interventions. In terms of cognitive interventions, 15 studies were conducted, with 3 studies focusing on a single cognitive intervention modality and 12 studies using an integrated cognitive intervention system. In 9 of the studies conducted, 2 studies focused solely on motor interventions without involving cognitive interventions, whereas the remaining 7 studies included both motor and cognitive interventions. A total of 14 studies incorporated a gamification element, 9 studies included a feedback component, and 7 studies implemented a progressive difficulty level. Professional input and support were included in all of them. Specifically, 4 studies involved specialists who provided their expertise during the development of the intervention content, while 12 studies had a therapist involved in the intervention throughout its duration. Two studies did not provide relevant descriptions. Regarding the duration of the VR intervention, 3 studies had an intervention period of 4 weeks, 3 studies had an intervention period of 6 weeks, 5 studies had an intervention period of 8 weeks, 6 studies had an intervention period of 12 weeks, and 1 study had an intervention period of 24 weeks. For detailed information on the intervention implementation mechanisms, refer to Multimedia Appendix 2.

Comparison



VR-based interventions were compared with treatment as usual in 2 studies, combined physical and cognitive training group in 3 studies, conventional cognitive rehabilitation group in 3 studies, attention group (health education) in 2 studies, physical exercise group in 2 studies, computer and video games in 1 study, and no intervention in 5 studies.

Risk of Bias

The risk of bias was unclear in 1 study for random sequence generation, 1 study for allocation hiding, and 2 studies for performance bias. A high risk of bias was observed in 8 studies for random sequence generation, 6 studies for allocation concealment, 16 studies for performance bias, and 9 studies for detection bias (Figure 2 [26-28,31-34,46-56]). Due to the nature of the interventions and patient-reported outcome instruments, both detection bias and performance bias were rated high in most studies.

XSL•FO
RenderX

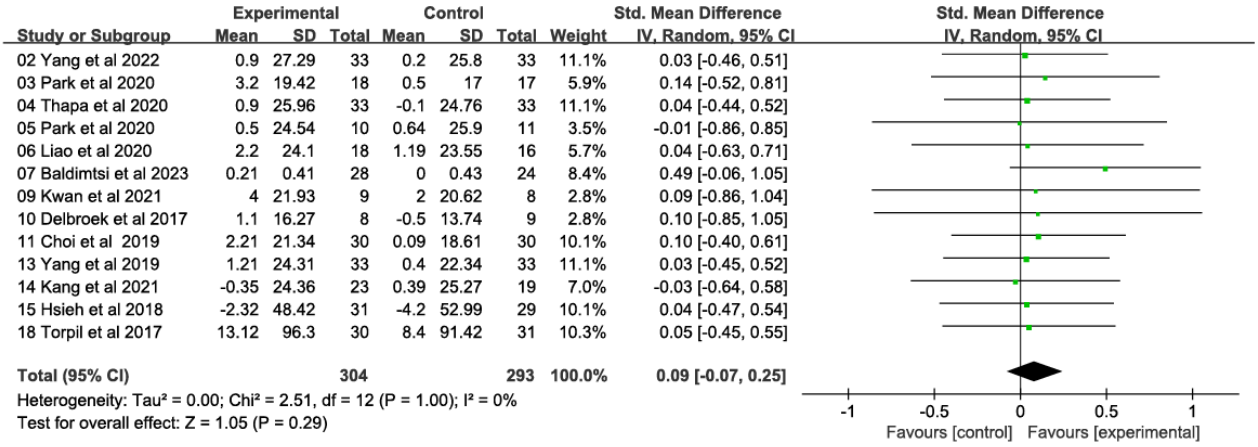
Figure 2. Summary of the risk-of-bias assessment.

Effects of Interventions

The main comparative results of the study with GRADE ratings are summarized in Multimedia Appendix 3.

Main Outcomes

Primary Outcomes



General Cognitive Ability

A total of 13 studies involving 597 participants reported on the effects of VR technology-based interventions on general cognitive function performance at postintervention time points (range 4-24 weeks) compared with conventional control conditions (Figure 3 [26-28,31-34,47,49,50,52-54]). In

XSL•FO
RenderX

summary, the intervention had a small impact on general cognitive function, but this effect was not statistically significant (SMD 0.09, 95% CI −0.07 to 0.25); there was also no significant heterogeneity (χ^2_{12}=2.51, *P*>.99; I^2=0%). Using the GRADE approach, the quality of evidence was rated moderate because of the high risk of bias in most studies (ie, study limitations).

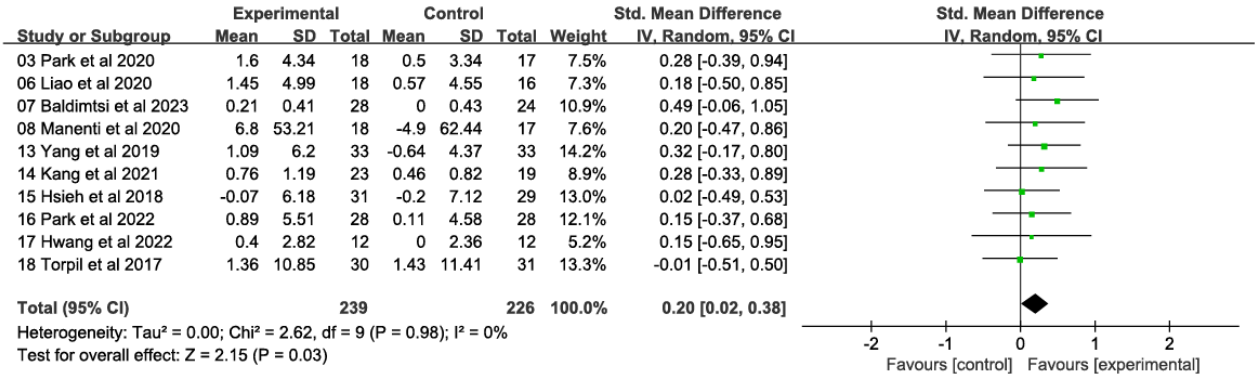


Figure 3. Forest plot of general cognitive ability: comparison of general cognitive ability improvement at postintervention time points based on virtual reality intervention versus conventional treatment or no intervention control group.

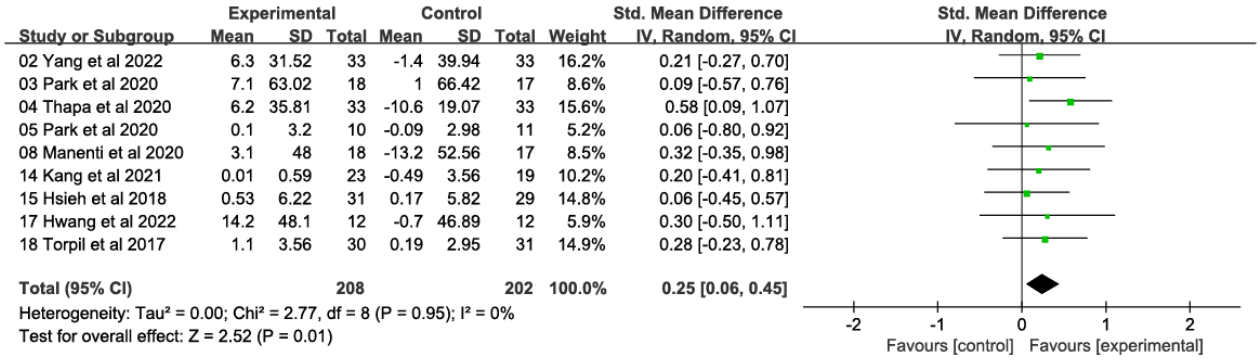
Performance and Memory

Ten studies, with a total of 465 participants, examined the impact of a VR technology–based intervention on performance and memory (Figure 4 [27,31,32,47,48,52-56]). The studies measured these effects at various time points after the intervention, ranging from 4 to 24 weeks. The VR technology–based intervention was compared with a traditional control condition. The overall effect sizes showed statistically significant and moderately sized impacts on performance and memory (SMD 0.20, 95% CI 0.02-0.38). There was some heterogeneity in the results (χ^2_9=2.62, *P*=.08; I^2=0%). The general cognitive function evidence was deemed moderate due to the high risk of bias in most studies (ie, study limitations).

Figure 4. Forest plot of performance and memory: comparison of performance and memory improvement at postintervention time points based on virtual reality intervention versus conventional treatment or no intervention control group.



Attention and Information Processing Speed

A total of 9 studies involving 410 participants reported on the effects of a VR technology–based intervention on attention and information processing speed at postintervention time points (range 4-24 weeks) compared with a conventional control condition (Figure 5 [26-28,32,33,48,53,54,56]). Overall effect sizes indicated significant and moderate effects on attention and information processing speed (SMD 0.25, 95% CI 0.06-0.45); heterogeneity (χ^2_8=2.77, *P*=.95; I^2=0%). The quality of evidence for attention and information processing speed was rated as moderate due to the high risk of bias (ie, study limitations).

XSL•FO
RenderX

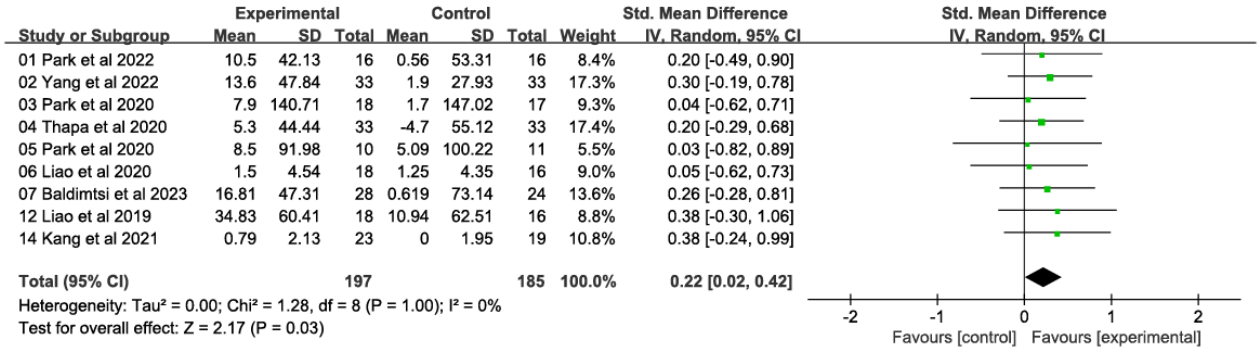


Figure 5. Forest plot of attention and information processing speed: comparison of attention and information processing speed improvement at postintervention time points based on virtual reality intervention versus conventional treatment or no intervention control group.

Executive Function

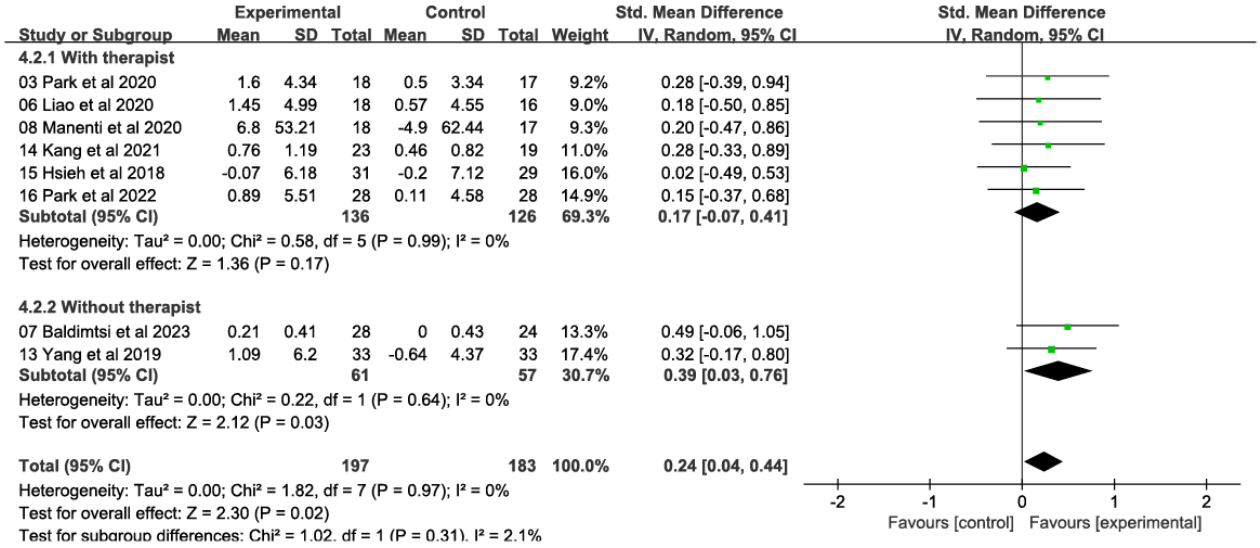
In total, 9 studies, with a total of 382 participants, examined the impact of VR technology–based intervention on executive function (Figure 6 [26,28,31-33,46,47,51,53]). These studies measured the effects at postintervention time points, which ranged from 4 to 12 weeks, and compared them with traditional control conditions. The intervention showed substantial and moderate effects on executive function (SMD 0.22, 95% CI 0.02-0.42). There was no heterogeneity among the studies (χ^2_8=1.28, P>.99; I^2=0%). The evidence on implementation capacity was assessed as intermediate in quality due to the high risk of bias (ie, study limitations).

Figure 6. Forest plot of executive function: comparison of executive function improvement at postintervention time points based on virtual reality intervention versus conventional treatment or no intervention control group.

Secondary Outcomes

No significant findings were seen for any of the secondary outcomes (Multimedia Appendix 4). The study found that there were no significant effects on language proficiency (SMD 0.21, 95% CI −0.20 to 0.61) and the quality of evidence was rated as very low. However, there were significant effects on visuospatial abilities, depression, and the daily mobility of Individuals, with effect sizes of 0.24 (95% CI −0.09 to 0.57), 0.06 (95% CI −0.29 to 0.42), and 0.10 (95% CI −0.23 to 0.43), respectively. The quality of evidence for these effects was rated as low. The study found that the impact sizes for gait and balance were statistically negligible, with an SMD of 0.05 and a 95% CI ranging from −0.17 to 0.27. The quality of evidence was considered moderate.

Subgroup Analysis



Therapist Involvement

Performance and Memory

In total, 2 studies involving 118 participants found that interventions to improve performance and memory had significant and moderate effects (SMD 0.39, 95% CI 0.03-0.76). These studies did not involve therapist involvement (Figure 7 [31,32,47,48,52-55]). There was no heterogeneity in the results (χ^2=0.22, P=.64; I^2=0%). On the other hand, 6 studies involving 262 participants did involve therapist involvement but did not find significant effects favoring performance and memory interventions (SMD 0.17, 95% CI −0.07 to 0.41). There was also no heterogeneity in these results (χ^2_5=0.58, P=.99; I^2=0%). Nevertheless, there was no substantial distinction observed between the 2 groups (χ^2_1=1.02, P=.31; I^2=2.1%).

XSL•FO
RenderX

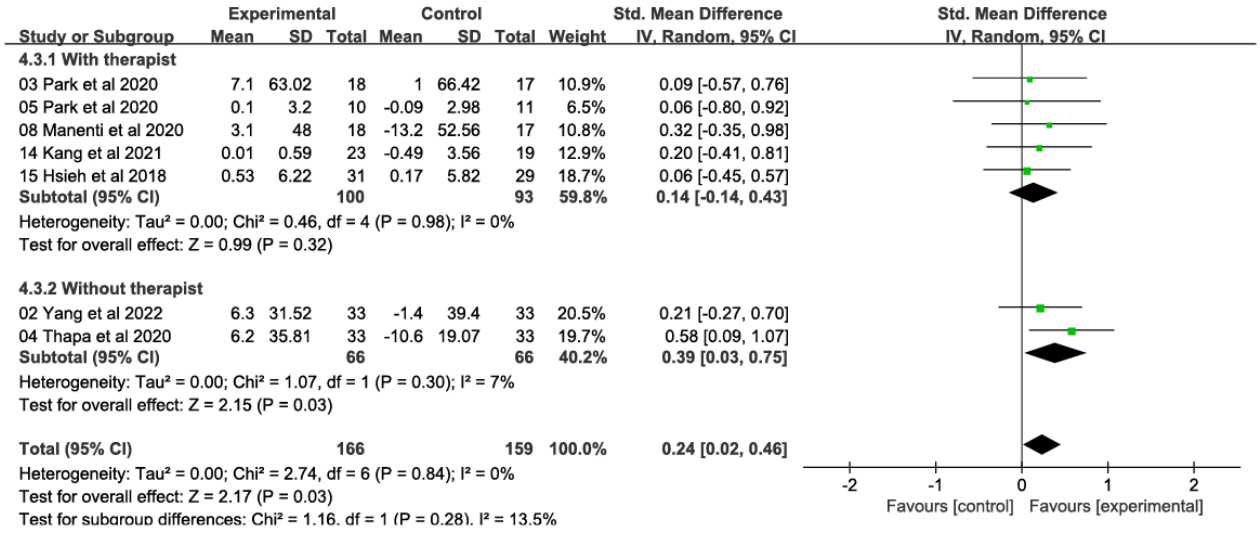


Figure 7. Forest plot of subgroups with and without therapist participation (performance and memory): comparison of performance and memory at postintervention time points based on therapist involvement or no therapist involvement.

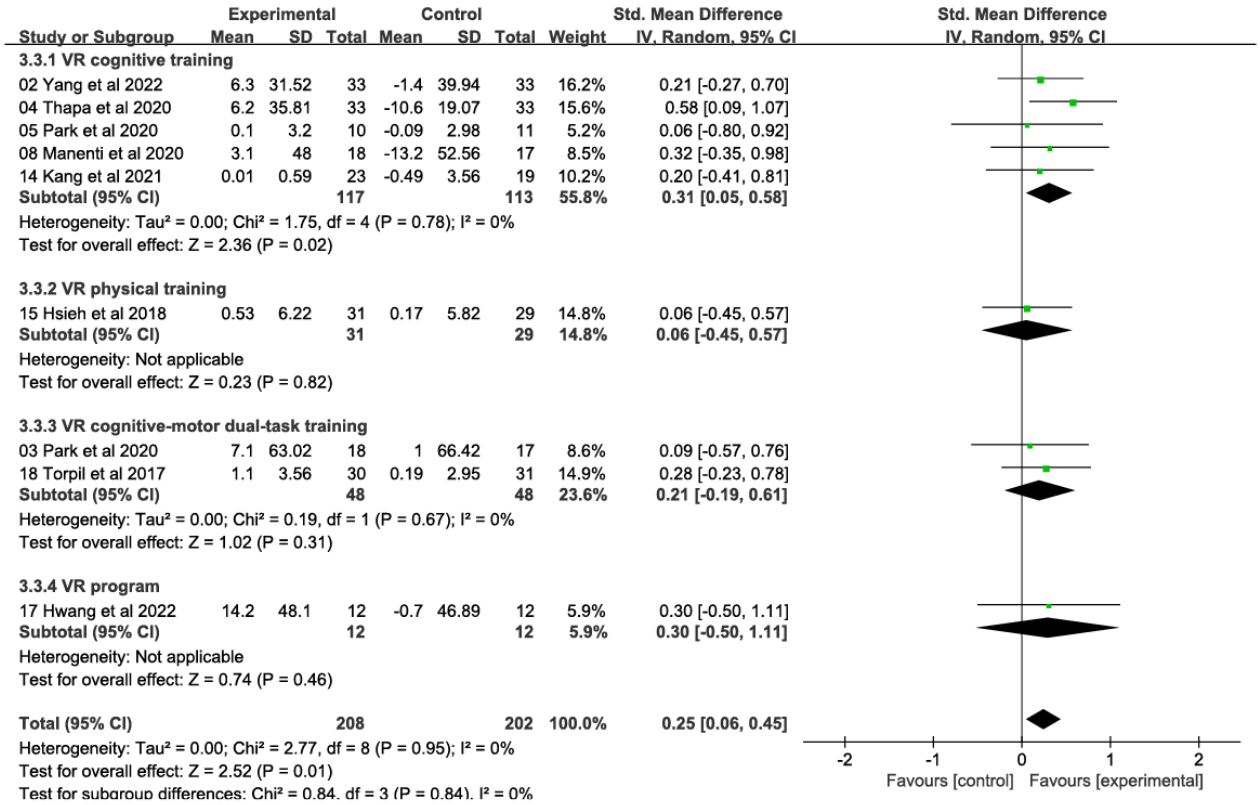
Attention and Information Processing Speed

Two studies involving 132 participants uncovered no therapist involvement results (Figure 8 [26,28,32,33,48,53,54]), with significant and moderate effects observed in favor of interventions to improve attention and information processing speed (SMD 0.39, 95% CI 0.03-0.75); there was no heterogeneity (χ^2_1=1.07, *P*=.30; I^2=7%). In contrast, 5 studies involving 193 participants uncovered results of therapist involvement but did not observe a significant effect in favor of the attention and information processing speed intervention (SMD 0.14, 95% CI –0.14 to 0.43); there was no heterogeneity (χ^2_4=0.46, *P*=.98; I^2=0%). However, the difference between the 2 groups was not significant (χ^2_1=1.16, *P*=.28; I^2=13.5%).

Figure 8. Forest plot of subgroups with and without therapist participation (attention and information processing speed): comparison of attention and information processing speed at postintervention time points based on therapist involvement or no therapist involvement.



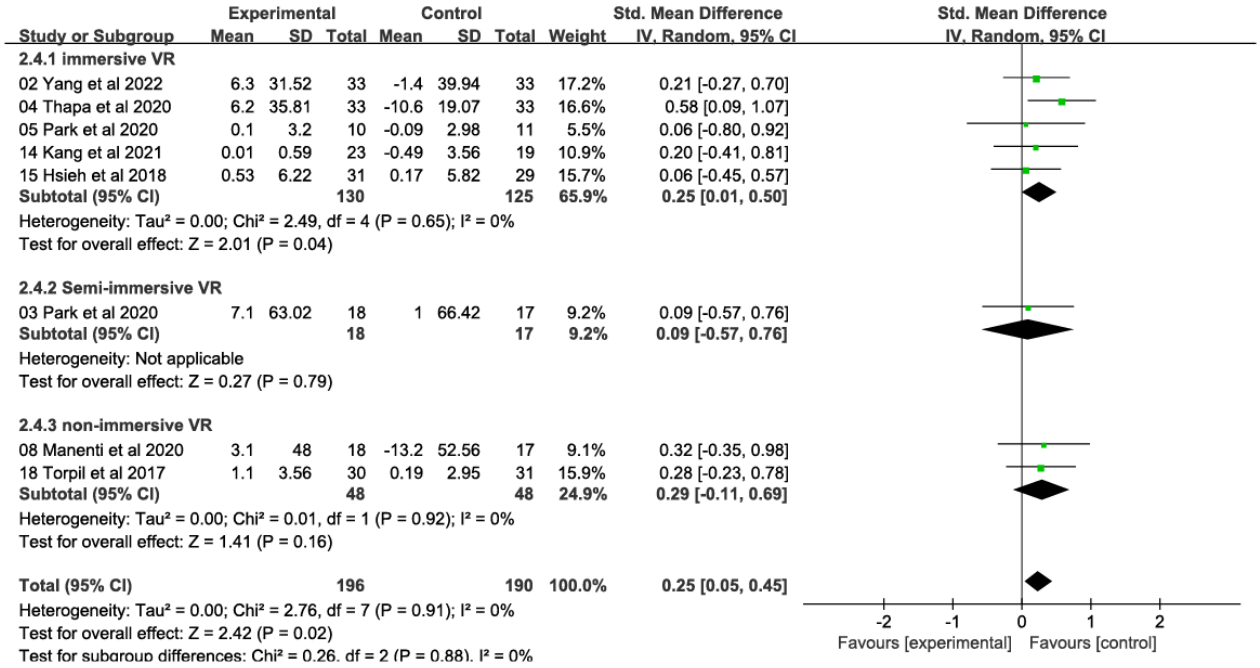
Content of the Intervention

Attention and Information Processing Speed

VR cognitive training (5 studies, 230 participants) produced significant and moderate effects in improving attention and information processing speed (SMD 0.31, 95% CI 0.05-0.58; χ^2_4=1.75, *P*=.78; I^2=0%; Figure 9 [26-28,32,33,48,53,54,56]). The other 3 intervention components—VR physical training (1 study, 60 participants; SMD 0.06, 95% CI −0.45 to 0.57), VR cognitive-motor dual-task training (2 studies, 96 participants; SMD 0.21, 95% CI −0.19 to 0.61; χ^2_1=0.19, *P*=.67; I^2=0%), and VR program (1 study, 24 participants; SMD 0.30, 95% CI −0.50 to 1.11)—did not have a significant effect on attention and information processing speed. The difference between the 4 groups was not significant (χ^2_3=0.84, *P*=.84; I^2=0%).

XSL•FO
RenderX

Figure 9. Forest plot of subgroups by intervention content (attention and information processing speed): comparison of virtual reality cognitive training, virtual reality physical training, virtual reality cognitive-motor dual-task training, and virtual reality program in improving attention and information processing speed at postintervention time points.



Level of Immersion

Attention and Information Processing Speed

Subgroup analyses based on level of immersion showed that immersive VR interventions (5 studies, 255 participants) produced significant and moderate effects on improving attention and information processing speed (SMD 0.25, 95% CI 0.01-0.50; χ^2_4=2.49, *P*=.65; I^2=0%; Figure 10 [26-28,32,33,48,53,54]). Semi-immersive VR interventions (1 study, 35 participants; SMD 0.09, 95% CI −0.57 to 0.76) and nonimmersive VR interventions (2 studies, 96 participants; SMD 0.29, 95% CI −0.11 to 0.69; χ^2_1=0.01, *P*=.92; I^2=0%) had no significant effects on attention and information processing speed. The difference between the 3 groups was not significant (χ^2_2=0.26, *P*=.88; I^2=0%).

XSL•FO
RenderX

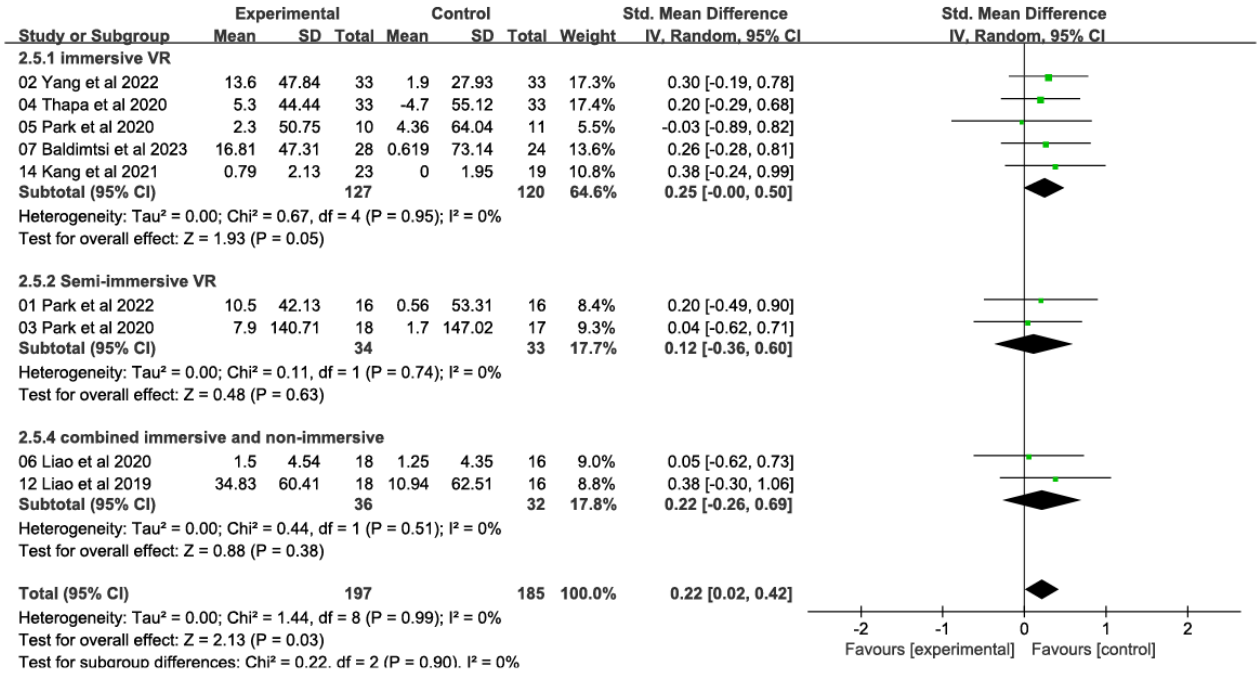


Figure 10. Forest plot of subgroups by immersion level (attention and information processing speed): Immersive, semi-immersive, nonimmersive, and combined immersive and semi-immersive immersion levels improved attention and information processing speed at postintervention.

Executive Function

Subgroup analyses based on level of immersion showed that immersive VR interventions (5 studies, 247 participants) produced significant and moderate effects in improving executive function (SMD 0.25, 95% CI 0.00-0.50; χ^2_4=0.67, *P*=.95; I^2=0%; Figure 11 [26,28,31-33,46,47,51,53]). Semi-immersive VR interventions (2 studies, 67 participants; SMD 0.09, 95% CI −0.57 to 0.76; χ^2_1=0.11, *P*=.74; I^2=0%) as well as combined immersive and nonimmersive VR interventions (2 studies, 68 participants; SMD 0.22; 95% CI −0.26 to 0.69; χ^2_1=0.44, *P*=.74; I^2=0%) had no significant effect in executive function. The difference between the 3 groups was not significant (χ^2_2=0.22, *P*=.90; I^2=0%).

Figure 11. Forest plot of subgroups by immersion level (executive ability): comparison of immersion, semi-immersive, nonimmersive, and combined immersive and semi-immersive immersion levels in improving executive ability at postintervention time points.

XSL•FO
RenderX

Risk-of-Bias Sensitivity Analysis

There was little evidence of funnel plot asymmetry in the intervention effects for general cognitive function, performance and memory, attention and speed of information processing, and executive function (Multimedia Appendix 5). In addition, excluding studies with no or unclear random allocation, inadequate concealment of treatment allocation, or incomplete outcome data, the effect sizes were as follows: improved general cognitive function (SMD 0.12, 95% CI −0.11 to 0.35); improved performance and memory (SMD 0.30, 95% CI 0.02-0.57); improved attention and information processing speed (SMD 0.41, 95% CI 0.05-0.77); and improved executive function (SMD 0.14, 95% CI −0.16 to 0.44). All the RCTs included in this analysis are parallel RCTs.

Discussion

Principal Findings

The findings of this review indicate that using VR as an intervention resulted in significant improvements in performance and memory (SMD 0.20, 95% CI 0.02-0.38), speed of attention and information processing (SMD 0.25, 95% CI 0.06-0.45), and executive function (SMD 0.22, 95% CI 0.02-0.42). Our study did not discover any notable disparities in general cognitive function and any secondary outcomes. However, the findings should be interpreted with caution as there is a risk of bias in the included studies, and therefore, the overall quality of the evidence is moderate and low.

This review examined how VR impacts performance and memory in older adults with MCI (SMD 0.20, 95% CI 0.02-0.38). Of the 10 included studies that assessed performance and memory, 9 showed positive changes. The results were similar to the study by Zhu et al [14]. This may be due to the fact that memory traces formed under the immersion of a virtual experience have richer content and a more complex associative network, and are part of an extensive autobiographical associative network [57,58]. A study showed that participants in the VR condition mostly relied on the mechanism of autobiographical memory, namely vivid recall, for retrieving memory task items. In contrast, participants in the 2D personal computer-game condition primarily relied on familiarity for retrieval [59]. VR offers advantages such as improved attitudes and heightened desire for training, in comparison with conventional motor or cognitive therapies [60]. Furthermore, VR has the ability to stimulate mirror neurons and improve individual empowerment and self-confidence by integrating perception, cognition, and action [61]. The findings of our study indicate that the use of VR intervention has a notable impact on both performance and memory. However, it is important to note that achieving this good effect may necessitate more comprehensive training during the VR intervention.

The effects of VR on the population with MCI in terms of attention and information processing speed were investigated in 9 included studies, all of which showed positive changes (SMD 0.25, 95% CI 0.06-0.45). The findings align with the research conducted by Yu et al [13], Gomez-Caceres et al [35], and Ren et al [62]. Previous studies demonstrated significant activation of the cuneate lobe, middle occipital gyrus, and regions involved in emotional processing (eg, the insula) during VR experiences [63]. In contrast, the right insula may be activated by a combination of attentional and response control demands that play a role in processing sensory stimuli related to the current target [64]. During VR attention training, engagement in visual attention tasks is associated with a number of significantly enhanced activation clusters, and stereoscopic presentation in VR may facilitate attentional engagement by reducing the metabolic costs of intermediate stages of visual processing [65].

The study examined the impact of VR on the executive function of individuals with MCI (SMD 0.22, 95% CI 0.02-0.42). All 9 of the included studies demonstrated beneficial changes. However, the results conflict with Yan et al [15]. This may be due to the fact that they focused only on VR in the form of combined cognitive and physical interventions, whereas combined interventions may lead to excessive stress and a reduction in the cognitive benefits of cognitive training or physical activity in combined interventions [66]. Most of the VR interventions in our study were goal-oriented tasks with IADL [14,35]. Executive function plays a dominant role in a person's ability to adapt to situations that arise in daily life [67,68]. Therefore, active experience-dependent plasticity triggered by task-oriented training leads to neurological changes in the brain and improves daily life performance [69]. Although this reference concerns poststroke patients, it is hypothesized that similar mechanisms of plasticity might be relevant for individuals with MCI engaged in VR-based cognitive training, based on the shared principles of neuroplasticity. Using IADL as a goal-directed task may improve the effectiveness of executive function interventions. Therefore, future research should consider this variable when developing intervention strategies.

Subgroup Analysis

The results of subgroup analyses show that the VR intervention without therapist involvement had better results in terms of improving performance and memory as well as in terms of attention and speed of information processing compared with the VR intervention with therapist involvement. The results conflict with the study of Manenti et al [48]. This may be due to the bias in this study [48], where the experimental and control groups were not equal in terms of intervention time, intervention measures, and the number of interventions was small. The lack of therapist guidance may have motivated participants to use cognitive strategies more actively, resulting in more effective processing of information and improved performance. Autonomous learning experiences can enhance individuals' cognitive processes, leading to deeper thinking and better integration of knowledge, ultimately resulting in more enduring memory effects. This aligns with the beneficial impact of self-directed learning on the strengthening of memory retention as observed in previous research [70-72]. Furthermore, a study conducted by Plancher et al [73] has noted that the advantages of active conditioning mostly rely on procedural abilities and the consequences of personal engagement in the encoding process. In terms of attention and information processing speed, users in contexts without therapist involvement were more likely to focus on the task itself, reducing the influence of external

XSL•FO
RenderX

incentives and cognitive distractions, resulting in more significant cognitive outcomes. In contexts with therapist involvement, users may be more susceptible to social comparisons and evaluations. The therapist's guidance and feedback may become part of the cognitive load and add additional psychological stress [74,75], which may have a negative impact on attention and information processing speed. In addition, the presence of a therapist introduces extrinsic motivation that may cause users to focus more on the therapist's expectations and feedback than on the task itself, which in turn affects the effectiveness of task performance [76]. It is important to note that this does not imply that the trainer is redundant in all contexts, but rather emphasizes that VR interventions without trainer intervention may be more conducive to achieving significant results in terms of performance and memory, as well as in terms of attention and speed of information processing, in specific contexts. Future research could further explore the interactive effects of different task types and individual differences on the presence or absence of trainer involvement to more fully understand the mechanisms behind this finding. Also, future research should be designed with more attention to user privacy issues to provide users with a stronger sense of security.

The results of the subgroup analysis regarding the content of the VR intervention indicate that VR cognitive training produces significant effects in improving attention and information processing speed compared with VR physical training, VR cognitive-motor dual-task training, and VR programs. This may be due to the fact that VR physical training and VR programs require lower intrinsic cognitive load, and VR cognitive training requires a higher cognitive load. The participants' cognitive systems are more actively engaged, thus stimulating more active cognitive processes [77]. In addition, exercise requires cognitive provision (engagement of attention, memory, and executive function) to fulfill its function [78]. Compared with single-tasking, dual-tasking is performed with higher brain activation in the prefrontal cortex and requires more cognitive resources [79]. Due to the limited capacity of the cognitive system, excessive cognitive load may affect learning and execution of the task [80]. VR cognitive training focuses on a specific cognitive task, whereas VR cognitive motor dual-task training may have introduced more distractions or loads that affected cognitive performance. Therefore, future VR intervention content should carefully consider the relationship between cognitive tasks and motor share, and should be designed to be more suitable for MCI patients.

Our study also find that immersive VR produced significant effects in terms of improving attention and information processing speed and in terms of executive function compared with semi-immersive VR, nonimmersive VR, and combined immersive and semi-immersive VR intervention situations. The results are similar to the study by Zhu et al [14] but conflicted with the study by Yu et al [13], which stated that semi-immersive VR was superior to fully immersive VR and nonimmersive VR in promoting cognitive flexibility. However, in recent years, VR technology has evolved and the use of immersive VR technology has been used to provide a more profound and holistic sensory experience through the creation of immersive virtual environments with more extensive sensory encounter [81]. The increased level of immersion in VR can promote interaction between the patient and the task, thus improving ecological validity [82]. Cognitive training in VR environments can enhance cognitive function in reality by facilitating the transfer of cognitive talents from games to real-life situations, thanks to cognitive function and brain plasticity [69,83]. However, the results should be interpreted with caution, as the included studies are at risk of bias, imprecise, and inconsistent, and therefore, the overall quality of the evidence is low or very low.

Limitations

This review has a number of limitations. First, only studies published in English were considered. Second, it is difficult to blind interventions and outcome assessments; as a result, all studies endure performance and detection bias. In addition, some of the most robust studies were at high risk of bias, reducing the overall quality of the evidence. Third, the sample sizes of most studies were small, limiting the statistical power and generalizability of the results, and secondary outcomes such as language proficiency, depression, and the daily mobility of Individuals were only reported in 4 studies. Fourth, defining thresholds of dysfunction remains a difficult task, and the included studies differed in inconsistency in their inclusion criteria for participants with MCI. Fifth, the age cutoff was set at 55 years and older, with the awareness that the definition of older adults varies across cultures, as some reviews include participants aged ≥40 years [84] and ≥65 years [13]. Given that many researchers have begun advocating against using age as the sole criterion for classifying older adults, future reviews could consider relaxing the inclusion criterion on age and include studies that investigate interventions for active aging. Finally, most studies did not take into account factors that can modulate participants' cognitive functioning, mood, the daily mobility of Individuals, and physical fitness (eg, cognitive reserve, diet, sleep, and physical and cognitive activities outside of the intervention). However, our findings can still provide compelling insights into the future of VR intervention design for older adults with MCI.

Conclusion

This review of 18 RCTs evaluates the effects of VR interventions on cognitive abilities, emotional functioning, daily mobility, and physical fitness in older adults with MCI. We found notable improvements in memory performance, attention, information processing speed, and executive function. VR training, particularly without therapist involvement, led to enhancements in memory, attention, and processing speed. These findings suggest that VR interventions can be an effective tool for cognitive rehabilitation in older adults with MCI, offering a practical approach to support their cognitive health and potentially delay the progression of dementia. Further research is needed to compare VR programs and validate these findings, considering patient diversity, intervention duration, and measurement accuracy.

Acknowledgments

This work was supported by the Natural Science Foundation of Shanghai as part of the Soft Science Project “Digital Rehabilitation Modeling for Patients with Schizophrenia” (Project 23692114900); by the Shanghai Jiao Tong University Medical-Engineering Crossover Fund for the Key Project “Research on Prediction and Intervention of Rehabilitation Status in Patients with Severe Mental Disorders Based on Multimodal Analysis and Artificial Intelligence Agents” (Project YG2024ZD24); and by the Shanghai Jiao Tong University Liberal Arts Youth Talent Cultivation Program (2023QN028). The funding agencies had no direct role in the publication of this article.

Authors' Contributions

QY, ZL, and LZ conceptualized and designed the study. QY, LZ, FC, and HY acquired, analyzed, and interpreted the data. QY drafted the manuscript. QY, ZL, BC, LZ, FC, and HY critically revised the manuscript for important intellectual content. LZ and QY conducted statistical analyses. BC and LZ supervised the study. All authors read and approved the final manuscript. QY and ZL had full access to all data in the study and take responsibility for the integrity of the data and accuracy of the data analysis.

Abstract

Background: Digital biomarkers are increasingly used in clinical decision support for various health conditions. Speech features as digital biomarkers can offer insights into underlying physiological processes due to the complexity of speech production. This process involves respiration, phonation, articulation, and resonance, all of which rely on specific motor systems for the preparation and execution of speech. Deficits in any of these systems can cause changes in speech signal patterns. Increasing efforts are being made to develop speech-based clinical decision support systems.

Objective: This systematic scoping review investigated the technological revolution and recent digital clinical speech signal analysis trends to understand the key concepts and research processes from clinical and technical perspectives.

Methods: A systematic scoping review was undertaken in 6 databases guided by a set of research questions. Articles that focused on speech signal analysis for clinical decision-making were identified, and the included studies were analyzed quantitatively. A narrower scope of studies investigating neurological diseases were analyzed using qualitative content analysis.

Results: A total of 389 articles met the initial eligibility criteria, of which 72 (18.5%) that focused on neurological diseases were included in the qualitative analysis. In the included studies, Parkinson disease, Alzheimer disease, and cognitive disorders were the most frequently investigated conditions. The literature explored the potential of speech feature analysis in diagnosis, differentiating between, assessing the severity and monitoring the treatment of neurological conditions. The common speech tasks used were sustained phonations, diadochokinetic tasks, reading tasks, activity-based tasks, picture descriptions, and prompted speech tasks. From these tasks, conventional speech features (such as fundamental frequency, jitter, and shimmer), advanced digital signal processing–based speech features (such as wavelet transformation–based features), and spectrograms in the form of audio images were analyzed. Traditional machine learning and deep learning approaches were used to build predictive models, whereas statistical analysis assessed variable relationships and reliability of speech features. Model evaluations primarily focused on analytical validations. A significant research gap was identified: the need for a structured research process to guide studies toward potential technological intervention in clinical settings. To address this, a research framework was proposed that adapts a design science research methodology to guide research studies systematically.

Conclusions: The findings highlight how data science techniques can enhance speech signal analysis to support clinical decision-making. By combining knowledge from clinical practice, speech science, and data science within a structured research framework, future research may achieve greater clinical relevance.

Introduction

Background

Clinical decision-making is key to effective patient care. It fundamentally relies on evidence derived from validated assessment tools. These assessments typically combine subjective observations (ie, observable signs and patient-reported symptoms) and objective measurements (ie, physiological measurements [1-4], such as blood pressure and heart rate) [5]. However, these traditional assessments face inherent challenges due to clinical feature complexity, potential clinician bias, varying levels of expertise, and substantial instrumentation costs.

Digital biomarkers emerge as a transformative paradigm in clinical decision support, providing precise, objective measurements that extend beyond traditional assessments. Through smartphone and wearable sensors, these biomarkers capture granular patient data previously inaccessible to clinicians. For example, motion sensors quantify fine motor control through typing patterns and touch screen interactions, whereas accelerometers and gyroscopes measure gait parameters, including stride length variability, postural sway, and turning speed. Cognitive functions can be continuously assessed through patterns of smart device use, including response times, error rates, and daily activity rhythms [6]. Speech signals captured through recording instruments can detect subtle speech variations such as changes in fundamental frequency, rhythmic disturbances, voice quality, articulatory precision, and prosodic features that may indicate psychiatric conditions [7,8]. Among these emerging digital biomarkers, speech feature measurements provide clinical insights through a noninvasive, nonintrusive approach using low-cost smart and wearable digital devices [9] at scale in real time and offline modes [10,11].

Speech production is a complex task that involves the orchestration and coordination of different body systems [12]. Deficiencies in any component of the speech production system could manifest in speech pattern changes [13]. Therefore, these alterations provide objective, quantifiable markers for differential diagnosis and disease progression monitoring. They can also provide insights into normal and pathological biological processes [6,14]. Traditional clinical speech assessment mostly relies on standardized tests administered by speech-language pathologists to assess motor speech production [13,15,16] for conditions such as traumatic brain injury, stroke [17], Parkinson disease (PD), and multiple sclerosis (MS) [18]. In current practices, acoustic measures and auditory perceptual judgments [19] are typically used based on guidelines such as the Darley, Aronson, and Brown system [20,21] in the characterization of motor speech control deficits. Despite these approaches and guidelines, limitations exist in these conventional procedures. Some assessments are time-consuming, require specialized clinical experts [22,23], and heavily rely on clinicians' subjective perceptual judgments. This subjectivity introduces interpretation variability [24] and challenges in maintaining consistent interrater reliability [25,26] although there is evidence showing consistent auditory-perceptual assessments [27]. The environmental, physical, and emotional states of patients during the assessments can also lead to further inconsistencies [22].

Therefore, digital speech signal analysis (hereafter referred to as "speech analysis") offers a promising solution through enhanced objectivity and retest capability [22] with reduced clinical burden and improved accuracy. Opportunities exist in identifying specific speech features or speech patterns related to different health conditions, including neurological diseases [18,28]. Recent advances in artificial intelligence and machine learning (ML) techniques further support detecting subtle changes and fine-grained speech features that can be related to associated health conditions [29].

There is a growing interest in investigating speech as a digital biomarker for clinical decision support. Several studies have explored speech analysis for clinical assessments of specific neurological health conditions. The prosodic aspect of speech production in PD was reviewed in the study by Moro-Velasquez and Dehak [30], whereas Moro-Velasquez et al [31] reviewed the articulatory and phonatory aspects. Early detection of PD using speech features and ML was discussed in the study by Gullapalli and Mittal [32]. Automatic speech assessment in Alzheimer disease (AD) was reviewed in the study by Pulido et al [33], whereas Martínez-Nicolás et al [34] included mild cognitive impairment (MCI) as well. Both the studies by de la Fuente Garcia et al [35] and Petti et al [36] also focused on AD but considered language assessments in addition to speech. Automated speech and language features were reviewed as an indication of deficits in content organization and thought processes considering related neurological impairments such as AD and MCI [15]. A meta-analysis of acoustic features on autism spectrum disorder (ASD) [37] and articulatory impairments in neurodegenerative motor diseases [38] also reviewed and compiled knowledge on speech signal analysis.

Objectives

Despite the growing body of research on speech analysis for different diseases, the field lacks a comprehensive synthesis of available studies, their approaches, and clinical applications for neurological diseases. Therefore, in this research, we aimed to investigate the technology revolution and trends in speech analysis to understand the key concepts and research processes across different neurological conditions. Our review focused on studies that investigated the physical features of speech, focusing on the underlying digital acoustic features instead of the content. We aimed to review the clinical and technical perspectives of the research process in relation to clinical application. Given the interdisciplinary nature of the research field and the premature stage of clinical integration, we emphasize the importance of establishing a suitable research

XSL•FO
RenderX

framework to guide future research. We also proposed a research framework for speech analysis in clinical decision support adapting a design science research process.

Methods

Overview

The review process adhered to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines [39] (Multimedia Appendix 1). We conducted a systematic scoping review following a predefined protocol to comprehensively identify, evaluate, and synthesize relevant literature. Our review was guided by the following research questions:

- In which health care disciplines or for which health conditions has speech analysis been investigated? (research question 1)
- What types of clinical outcomes or clinical services might be possible using speech analysis? (research question 2)
  - What data science methods have been used for these speech analyses? (research question 2.1)

No protocol was registered for this review.

Sources and Eligibility Criteria

As a part of a larger research program, we conducted a comprehensive data collection. The review was limited to the Scopus, IEEE Xplore, Google Scholar, MEDLINE via PubMed, SpringerLink, and ScienceDirect databases. Textbox 1 lists the inclusion and exclusion criteria followed during article selection.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Language: publications in English only
- Publication type: peer-reviewed journal articles and conference proceedings
- Publication period: published between January 2010 and December 2022
- Participants: human participants of any age
- Type of research: primary research
- Study characteristics:
  - Carried out analysis of features of speech signals
  - Used features for analysis that were language independent
  - Used data science approaches to derive clinical insights on health conditions that impact speech (statistical analyses and traditional machine learning and deep learning approaches were considered interesting data science approaches)

Exclusion criteria

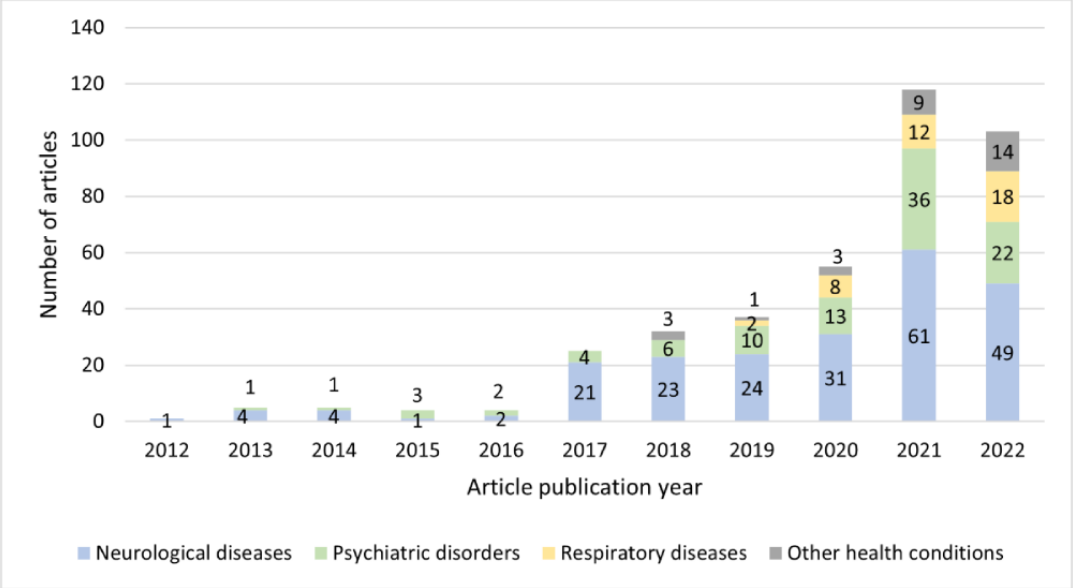
- Language: non–English-language publications
- Publication type: book chapters, theses, abstracts, editorials, and gray literature
- Publication period: published before January 2010
- Participants: nonhuman participants
- Study characteristics:
  - Analyzed only transcriptions or linguistics features, such as grammar and semantics
  - Investigated speech signal analysis on functional and structural voice disorders
  - Investigated only nonverbal audio sounds, such as breathing, coughing, crying, and snoring
  - Investigated only linguistic features of speech
  - Did not focus on a health care aspect (eg, the studies analyzed speech signals for emotion recognition without concerning a health condition)

Search Strategy and Study Selection

The following keywords and their synonyms were used in building searching queries and extracting articles: “Speech,” “Analysis,” “Health care,” “Data Science,” and “Artificial Intelligence.” The search strategy for the databases is presented in Multimedia Appendix 2.

The identified articles were exported to a reference management software where duplicates were removed. We then screened articles based on the titles and abstracts, followed by a full-text search. After a detailed examination of the retrieved full texts, those that met the eligibility criteria (N=389) were selected for the quantitative analysis of the research landscape. The full texts of articles that met the defined eligibility criteria and focused on a neurological disease with primary data collection (72/389, 18.5%) were included in this analysis and added to NVivo (Lumivero) [40], a qualitative data analysis software. We used qualitative content analysis followed by a mix of deductive and

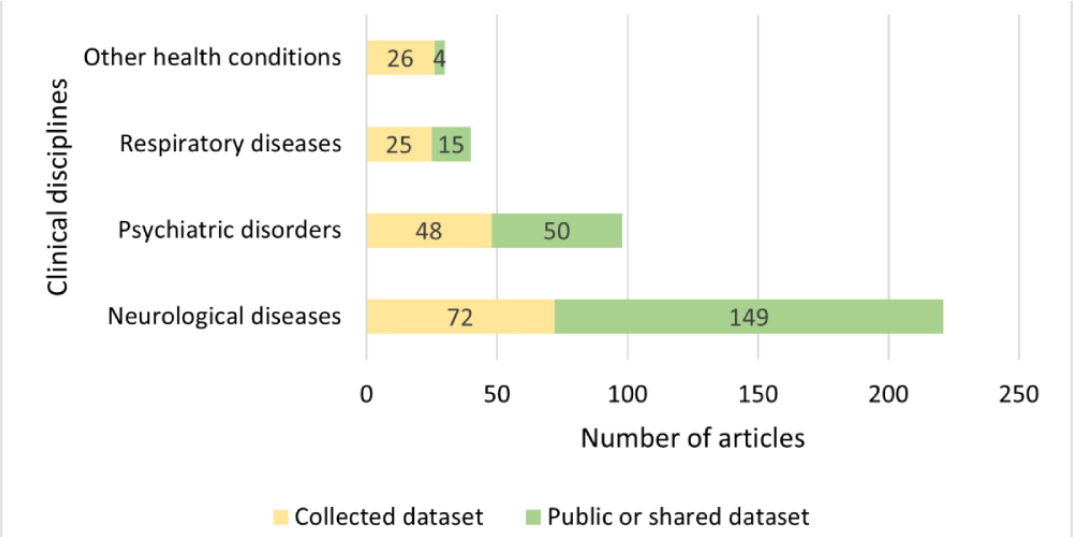
XSL•FO
RenderX



inductive reasoning [41] to identify key concepts in speech analysis for clinical decision support.

The details of the included research articles can be found in Multimedia Appendix 3 [42-113].

Study Characteristics

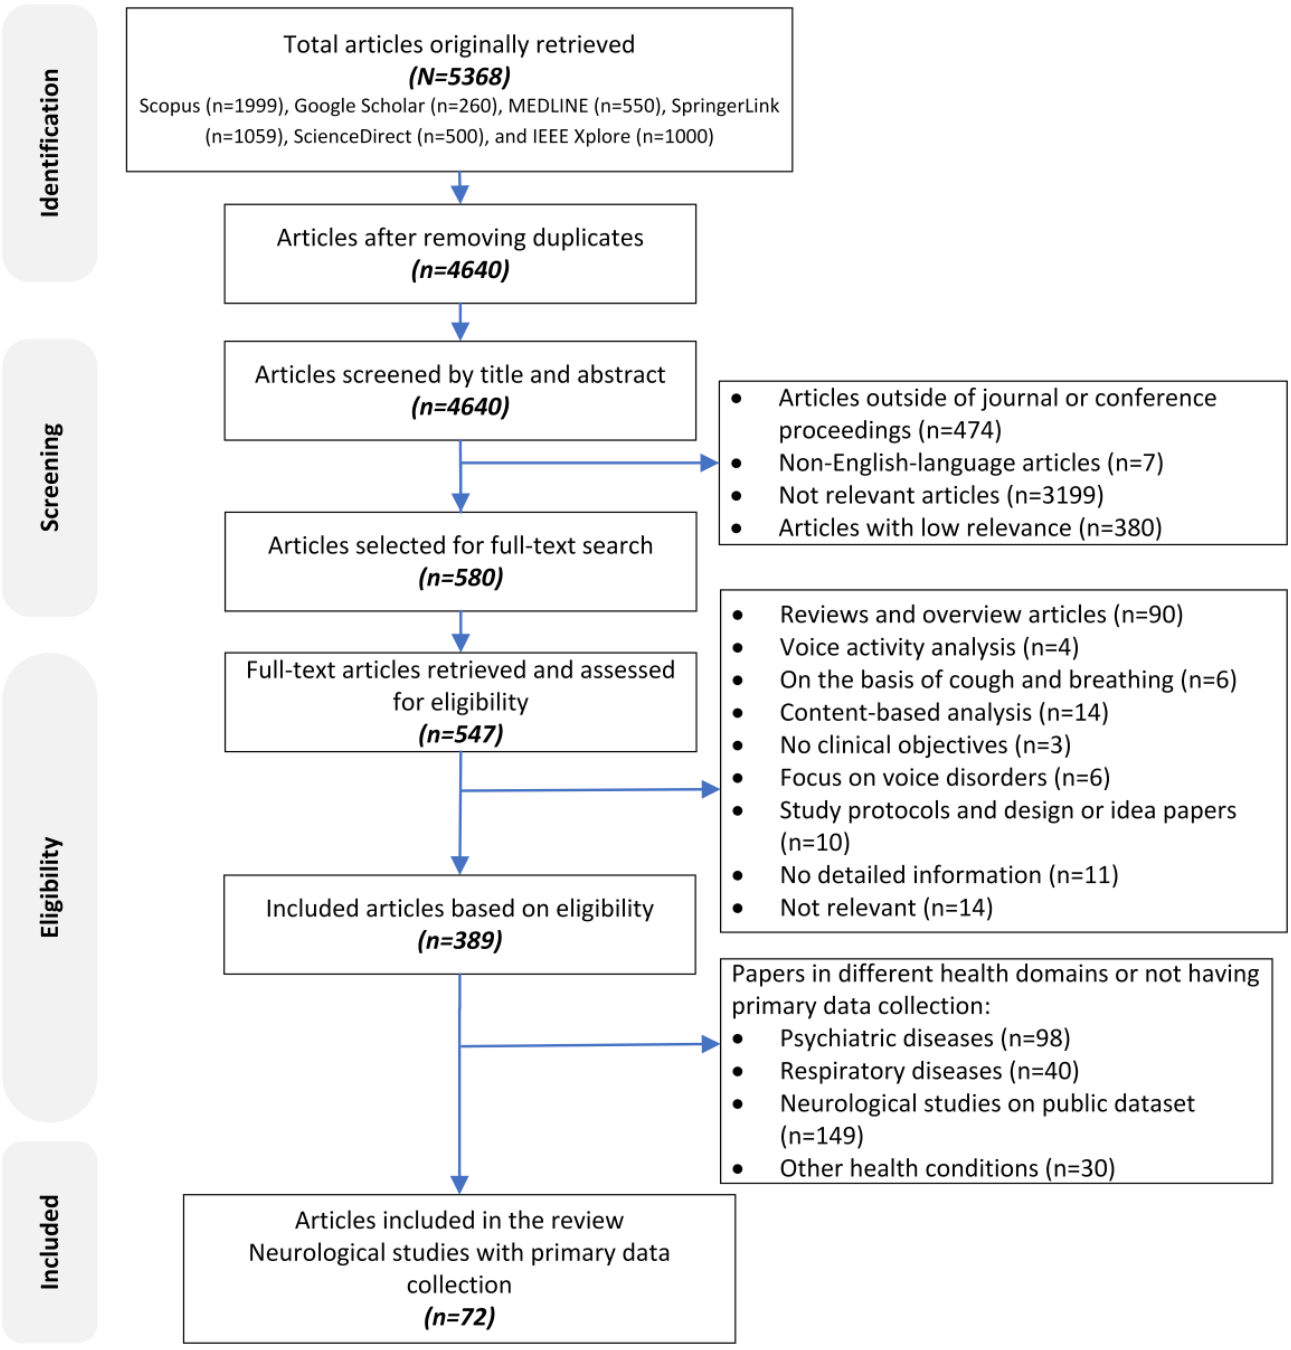


The clinical disciplines and the yearly distribution of the overall eligible articles (N=389) are plotted in Figure 1 to understand the potential health care disciplines for digital clinical speech analysis to answer our research question 1. The evaluation of the research field was clearly evident, with an increasing number of articles over the years. Neurological diseases attracted the highest research interest (221/389, 56.8%), including AD, PD, and amyotrophic lateral sclerosis (ALS). Psychiatric disorders such as depression, bipolar disorder, and schizophrenia were among the next most investigated disease categories (98/389, 25.2%), followed by respiratory diseases (40/389, 10.3%). The remaining articles (30/389, 7.7%) investigated other health conditions, such as heart disease and cancer.

Figure 1. Yearly distribution of the eligible articles (N=389) and their clinical disciplines.

Data sourcing in the studies varied across public datasets, institutionally shared datasets, and primary data collections (Figure 2). In this review, we focused on studies with primary data collection as they described the full research process from problem formulation, data collection, data analysis, and model building to model evaluation. Therefore, the analysis of this review considered 18.5% (72/389) of the studies, which investigated neurological diseases using primary data collection.

Figure 2. Distribution of the eligible articles (N=389) based on their data sourcing approach.



XSL•FO
RenderX

Results

Overview

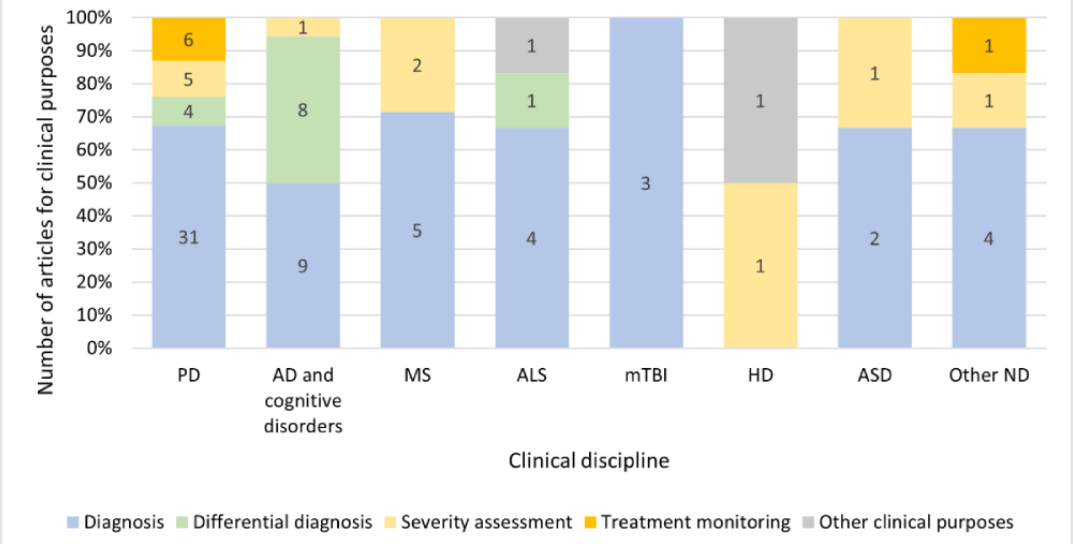
Figure 3 presents the detailed overview of the literature search and study selection process for this study. The qualitative content analysis of the 18.5% (72/389) of the studies on neurological diseases revealed the following key themes regarding digital speech signal analysis: (1) health condition and clinical purpose, (2) speech data (speech tasks and speech features), (3) data science approaches and evaluations, and (4) clinical applications. The following subsections provide details on these themes. The details of the included research articles can be found in Multimedia Appendix 3 [42-113].

Figure 3. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart for the study screening and selection process.

Neurological Conditions and Clinical Purposes

Overview

Many neurological conditions affect the sensorimotor control of speech movements (eg, PD) or cognitive processes, specifically memory and language and perceptual processing (eg, AD and MCI). While thought formulation and motor planning are distinct in speech production [114], alterations in motor planning can occur alongside cognitive impairments, as discussed in various stages of AD [115]. This can cause acoustic changes in the physical speech signal.



Among the neurological diseases, PD (40/72, 56%) was the most investigated disorder, followed by AD and cognitive impairment (12/72, 17%). Other investigated disorders were

XSL•FO
RenderX

MS (5/72, 7%), ALS (4/72, 6%), mild traumatic brain injury (mTBI; 3/72, 4%), Huntington disease (HD; 2/72, 3%), and ASD (2/72, 3%). A total of 4 articles focused on clinical purposes related to apathy (n=1, 25%); intellectual disability (ID; n=1, 25%); essential tremor (ET; n=1, 25%); and a group of central nervous system disorders (CNSDs), including HD and PD (n=1, 25%).

Disease diagnosis, differential diagnosis, severity assessment, and treatment monitoring were the most mentioned clinical purposes in the studies. Figure 4 depicts the distribution of articles with their clinical purposes according to disease categories. Some studies (18/72, 25%) addressed multiple clinical purposes, such as diagnosis and differential diagnosis or diagnosis and severity assessment. Disease diagnosis was widely researched. These studies focused on prevailing clinical challenges such as the lack of definitive objective biomarkers, the need for noninvasive biomarkers, challenges in discriminating diseases with similar symptoms (differential diagnosis), and challenges faced by vulnerable populations such as older adults or rural populations.

Figure 4. Distribution of the main clinical purposes based on disease categories. AD: Alzheimer disease; ALS: amyotrophic lateral sclerosis; ASD: autism spectrum disorder; HD: Huntington disease; MS: multiple sclerosis; mTBI: mild traumatic brain injury; ND: neurological disorder; PD: Parkinson disease.

PD Results

PD was the most investigated neurological condition in the studies (40/72, 56%). PD diagnosis, differential diagnosis, treatment monitoring, and severity assessment were explored. Many studies (28/40, 70%) investigated the diagnosis of PD by discriminating parkinsonian speech compared to healthy speech [42-69]. Several studies (3/40, 8%) carried out statistical comparisons of speech features in healthy and PD groups [70-72]. PD severity scores were predicted in the study by Viswanathan and Arjunan [73] for patients with PD and healthy controls. Early detection of PD was investigated in some studies (4/40, 10%) [42,47,57,65], in which participants with early PD were recruited to compare them with healthy participants. Early and mid-aged patients with PD were recruited in the studies by Montaña et al [65] and Wang et al [42], whereas the study by Lim et al [47] focused on patients with early- and advanced-stage PD according to the Hoehn and Yahr staging scale. Patients with PD were assessed in the study by Jeancolas et al [57] if they had been diagnosed with PD within 4 years before the study.

Some studies (4/40, 10%) investigated discrimination of similar-symptom diseases for differential diagnosis. For example, the study by Song et al [44] investigated distinguishing ataxic and hypokinetic dysarthria, which are commonly prevalent in neurodegenerative diseases. Patients with PD and cerebellar ataxia were considered representative cases of diagnosis. A statistical comparison of PD speech and MS speech was performed in the study by Vizza et al [72]. The challenge of differential diagnosis was addressed in the studies by Das et al [74] and Li et al [75] for atypical parkinsonian syndromes (APS) of progressive supranuclear palsy and multiple system atrophy.

In addition to diagnosis, the studies investigated PD severity predictions using the Unified Parkinson's Disease Rating Scale (UPDRS) and Hoehn and Yahr scale. The studies by Viswanathan and Arjunan [73] and Hemmerling and Wojcik-Pedziwiatr [76] predicted UPDRS scores from the speech of patients with PD considering their medication status. Furthermore, Zhang et al [61] and Sztaho et al [67] predicted PD severity level from speech features in relation to the UPDRS and Hoehn and Yahr scale, respectively. The severity of PD symptoms was assessed in the study by Tunc et al [77] through collected speech samples at different points after taking levodopa.

The studies analyzed the speech of patients with PD to assess the impact of antiparkinsonian treatments on speech and voice function. For example, Suppa et al [43] studied speech changes during highly effective and less effective periods from levodopa therapy for PD. PD severity using UPDRS scores was predicted in the study by Hemmerling and Wojcik-Pedziwiatr [76] at different time points after taking levodopa. The effects of dopaminergic medication on speech function were investigated in the studies by Vandana et al [78] and Jain et al [79]. The

XSL•FO
RenderX

impact of assistive speech devices in treating speech impairment was studied by Gaballah et al [80,81] considering these devices' treatment capability outside the clinical facility. In these studies, Gaballah et al [81] investigated discrimination of PD speech and healthy speech under different environments and amplification conditions, whereas Gaballah et al [80] predicted the perceived voice quality of patients with PD with and without assistive speech amplifier devices.

AD and Cognitive Impairment Results

Cognitive decline was assessed through speech analysis, including clinical conditions such as AD, dementia, and MCI. Dementia presents different symptoms at different severity levels of cognitive decline. MCI represents an early stage of cognitive decline without interference with everyday life but can act as a transition stage between healthy aging and dementia when it acts as preclinical AD [116]. AD can evolve over a continuum from normal cognition to MCI due to AD, followed by more severe AD dementia [117]. AD is identified as the most common form of dementia [117].

The studies in this review analyzed speech at different cognitive decline stages for diagnosis, differential diagnosis, and severity assessment (12/72, 17%). The focus was on discriminating impaired cognition from normal cognition. The discrimination of patients with AD [82] and MCI [83-85] from healthy controls was explored. Nagumo et al [85] studied differential diagnosis with global cognitive impairment as they considered patients with MCI, global cognitive impairment, and both forms of cognitive decline. On the other hand, some studies (3/12, 25%) [86-88] investigated both diagnosis and differential diagnosis of AD compared to patients with MCI and healthy participants. Automatic differentiation of patients with MCI and early dementia from healthy controls was studied by Bertini et al [89].

Differential diagnosis of AD and dementia with Lewy bodies was investigated in the study by Yamada et al [90], whereas Sumali et al [91] worked in discriminating between patients with depression and dementia as certain mental disorders (eg, depression) can cause pseudodementia, a temporary decline in mental cognition. While Al-Hameed et al [92] discriminated speech from neurodegenerative diseases, including patients with AD, MCI, and dementia, from speech from functional memory disorder, König et al [93] predicted neuropsychiatric inventory scores in a sample of patients with MCI through speech.

MS Results

MS is a chronic inflammatory disease of the central nervous system that affects cognitive and motor functions causing motor and sensory impairments, visual disabilities, cognitive disorders, and speech and language deficits [118]. Different studies (5/72, 7%) investigated MS diagnosis and severity assessment through speech analysis. Discriminating patients with MS from healthy controls was investigated in several studies (4/5, 80%) [94-97], whereas Fazeli et al [94] explored the relationship between selected speech quality indexes and MS severity. Speech analysis among patients with MS at 2 different disease stages, in addition to comparisons of patients with MS versus healthy patients, was conducted in the study by Vizza et al [98].

ALS Results

ALS is a progressive motor neuron disease that affects upper and lower motor neurons in the motor cortex, the brain stem, and the spinal cord. ALS leads to muscular weakness and spasticity that can result in difficulties with mobility, breathing, and motor speech production [119]. Research on speech in ALS concentrated on identifying differential diagnoses and detecting bulbar involvement (4/72, 6%). Differentiation of speech from 3 participant groups, including patients with ALS with and without bulbar involvement and healthy controls, was conducted in the study by Tena et al [99]. The studies by Illa et al [100] and Likhachov et al [101] investigated discrimination of speech from patients with ALS and healthy participants. The ALS populations in both studies had shown signs of bulbar involvement. Furthermore, Mallela et al [102] investigated the diagnosis of ALS and differential diagnosis of ALS from PD by including ALS patients with a range of speech dysfunction severities.

mTBI Results

Compared to other progressive neurological diseases that occur due to a physical or mental phenomenon originating within the body, mTBIs or concussions are initiated when a person experiences an external force to the head, causing some alteration in brain function [120]. Therefore, the studies in this review on concussion (3/72, 4%) were able to access baseline speech recordings from highly vulnerable populations such as athletes along with the postinjury speech and then aimed to discriminate concussed speech from that of healthy controls [103] and from the individuals' healthy baseline speech [104]. Concussion detection through baseline, postconcussion, and posthealthy speech comparison was also studied by Wall et al [105].

HD Results

HD is a rare severe neurodegenerative disease with a known natural history due to inheritance [106]. One study assessed the severity of HD, whereas the other study investigated the expression of emotions through vocal characteristics in participants with HD and pre-HD using emotion elicitation via speech. Riad et al [106] investigated the prediction of HD severity scores from speech features of a sample of participants with pre-HD and HD. Furthermore, they studied the relationship between speech variables and striatal volumes as well. In addition, the emotion expression capability of patients with HD was studied through speech-based emotion recognition [107].

ASD Results

ASD is a neurodevelopmental disorder that causes difficulties in social communication, particularly in verbal and nonverbal communication [121]. Most people living with ASD exhibit speech and expressive language abnormalities at different levels [121]. The 3% (2/72) of ASD articles in this review focused on discriminating ASD speech from healthy speech [108,109] and estimating autism severity by predicting Autism Diagnostic Observation Schedule scores from speech features [109]. It was noted that comorbid conditions were present in these populations, including attention-deficit/hyperactivity disorder [108] and children with suspicion of ASD, such as children with

XSL•FO
RenderX

other language or developmental delays [109], in addition to children with typical development.

Other Neurological Disease Results

The neurological conditions that were the focus of other studies included ET (1/72, 1%), apathy (1/72, 1%), ID (1/72, 1%), and a broader category of CNSDs (1/72, 1%).

ET is among the most common tremor syndromes, which can encompass voice tremor as well [122]. To complement conventional neurological examination–based assessments, voice tremor in patients with ET was studied by Suppa et al [110] by discriminating the speech of patients with ET who did and did not manifest clinically overt voice tremor. Moreover, they discriminated between patients at baseline and after having medical treatments [110]. Apathy is identified as a motivation disorder that can present in several psychiatric and neurological conditions. Discrimination between patients with and without apathy was done in the study by König et al [111] through speech from patients with mild to moderate neurocognitive disorders. ID is a neurodevelopmental disease similar to ASD that causes cognitive delays in early childhood, resulting in delays in adaptive function, language, and speech [123]. Speech samples from children with typical development and those with ID were compared in the study by Aggarwal et al [112]. Lauraitis et al [113] investigated discrimination of speech impairment in patients with early-stage CNSDs from healthy speech. They included patients with HD, PD, cerebral palsy, stroke, and early dementia in their CNSD population.

Speech Data

Overview

Across the 18.5% (72/389) of neurological studies, speech data were captured through a range of speech tasks, from simple production of sounds or words to spontaneous speech in conversations. The characteristics of the speech tasks impact the reliability of speech features [124]. For example, speech quality features from continuous speech may be less reliable compared to more structured sustained phonation tasks [124]. Therefore, speech tasks and speech features together define speech data in clinical speech analysis [14].

Speech Tasks

Speech tasks across the 18.5% (72/389) of neurological studies can be categorized along a continuum from highly constrained to naturalistic speech elicitation. At the most structured end are sustained phonations and diadochokinetic tasks. In the middle range are reading and picture description tasks, whereas prompted speech tasks elicit the most naturalistic speech production.

Highly constrained tasks frequently appeared in studies of neurological diseases. These included sustained phonation of vowels (/a/, /e/, /i/, /o/, and /u/) and sounds such as “ah,” “eh,” “iuh,” and “iamh.” Similarly structured were oral diadochokinetic tasks, including alternating motion rate and sequential motion rate tasks. Alternating motion rate tasks require rapid repetition of a single syllable (eg, /pa/, /ta/, or /ka/), whereas sequential motion rate tasks involve sequences of different syllables (eg, /pa-ta-ka/).

Semistructured tasks provided a balance between control and naturalistic speech production. Reading tasks typically included reading a set of words, sentences, and passages. Picture description tasks elicited spontaneous speech within a potentially limited vocabulary set associated with the provided visual aid. Activity-related speech included speech fluency tasks, recall and summary tasks, and number-related tasks such as counting and subtraction. On the other hand, prompted speech tasks encourage more free and spontaneous speech within a guided procedure. Monologues on own experiences, conversations including neurological examinations, and spontaneous speech induced by interactive questions were some examples. It was also common for the studies to use multiple speech tasks, combining structured and semistructured tasks. The studies used speech tasks from culturally adapted test batteries such as Thammasat-National Electronics and Computer Technology Center (NECTEC)-Chula’s Thai Language and Cognition Assessment [86].

Overall, structured speech tasks were more widely used for neurodegenerative diseases such as PD and ALS, whereas semistructured speech tasks were common for cognitive impairment–related disorders such as AD, MCI, and dementia. Textbox 2 shows the application of different types of speech tasks in the studies with examples.

XSL•FO
RenderX

Textbox 2. Types of speech tasks used in the included studies.

Structured tasks

- Sustained phonation tasks: the participant is asked to produce a vowel, usually with a steady pitch, for several seconds.
  - Sustained vowel: /a/ for multiple sclerosis (MS) [94,95], /a/ for amyotrophic lateral sclerosis (ALS) [101], /a/ for Parkinson disease (PD) [42,53,54,59,60,62,64,66,71,74,75,77,78], /e/ for PD [42,43,49], and /e/ for essential tremor (ET) [110]
  - Group of vowels (/a/, /e/, /i/, /o/, and /u/): MS [98], ALS [99], and PD [46,55,61,72,76,79]
  - Mix of phonemes and sounds: /s/, "sh," and /f/ (ALS) [102]; continuous phonation task (intellectual disability [ID]) [112]; /a/, /o/, and /m/ (PD) [45]; /a/, /u/, and /m/ (PD) [70,73]; different sounds ("ah," "eh," "iuh," and "iamh") (PD) [51]; and /a/ and /u/ (PD) [56]
- Diadochokinetic tasks: the participant is asked to rapidly repeat alternating syllables (eg, /Pa/, /Ta/, and /Ka/) for several seconds.
  - Monosyllables: /Pa/ and /Ka/ for mild traumatic brain injury (mTBI) [103]; /Pa/ and /Ta/ (PD) [55]; and /Pa/, /Ta/, and /Ka/ (PD) [52,63]
  - Multisyllable sequence: /Pa-Ta-Ka/ for mTBI [103]; /Pa-Pa-Pa/, Ta-Ta-Ta/, Ka-Ka-Ka/, and Pa-Ta-Ka/ and /Ba-Da-Ga/ (ALS) [102]; /Pa-Ta-Ka/, /Pa-Ka-Ta/, /Pe-Ta-Ka/, and /Pe-Ka-Ta/ (PD) [79]; /Pa-Ta-Ka/ (PD) [65,74,75]; and /Pa-Ta-Ka/, /Pe-Ta-Ka/, and /Pa-Ka-Ta/ (PD) [52,63]

Semistructured tasks

- Reading tasks: the participant is provided with a predefined text to read out.
  - Reading a set of words or sentences: set of words (MS) [94,97], set of words and sentences for mTBI [103], set of words and sentences for ALS [100], and reading sentences (PD) [42,43,46,49,50,52,54,55,57,60,63,66]
  - Reading paragraphs: reading a Czech text (MS) [96], Sport Concussion Assessment Tool, Fifth Edition reading paragraph (mTBI) [105], read a short text from predefined poems (central nervous system disorders) [113], read sentences from a French book (Alzheimer disease [AD]) [87], read a short passage (AD) [84], reading texts (PD) [44,52,55,57,58,63,74,79], and reading an article (PD) [47]
- Activity-based speech: The participant is asked to produce speech in response to a semistructured activity.
  - Number-related tasks: digit words (mTBI) [104], counting forward and backward (Huntington disease [HD]) [106], counting [88,90] and subtraction for AD [90], and counting for PD [44,79]
  - Recall and tell: summary of a story (MS) [97], immediate recall and delayed recall of a short film (AD) [83], and imitation of the instructor's voice (ID) [112]
  - Fluency tasks: verbal fluency task (AD) [88,90] and month-remembering task (PD) [79]
- Picture descriptions: the participant is asked to describe a visual aid presented to them.
  - Picture description: cookie theft picture description [90] and picture description [86] for AD, and cookie theft picture description for PD [52,79]
- Prompted speech tasks: the participant is asked to produce a speech with the support of speech prompts.
  - Monologue: talk about the previous day (MS) [97], a monologue (ALS) [100], monologue on a given topic (PD) [63,67,74,75], talk about positive and negative events in life (apathy) [111], talk about a positive event and negative event in life (AD) [93], and talk about the immediate day (AD) [83]
  - Clinical interviews and conversations: interviews by neuropsychologists to describe the last 24 hours and tasks to elicit emotions (HD) [107], conversations during Autism Diagnostic Observation Schedule sessions (autism spectrum disorder) [108,109], conversations (PD) [80,81], and neuropsychological examinations and conversations (AD) [91,92]
  - Spontaneous speech: speech induced through questions (eg, on a picture, about a working day, or about a dream; AD) [89] and 1-minute free talk with an artificial intelligence program (AD) [82]

Speech Features

The studies extracted speech features based on the characteristics of the speech tasks. From a signal processing perspective, the speech features included in the studies can be broadly categorized into 3 main types: fundamental and advanced signal processing–based speech features and audio images (Textbox 3). The primary difference between fundamental and advanced signal processing–based speech features lies in their capacity to correspond to phonetic aspects of speech production. This distinction is important for understanding how these speech features are explained from both a speech science and clinical perspective. Being single-dimensional, both these types of speech features are suitable candidates for statistical analyses, traditional ML approaches, and deep neural networks (DNNs). On the other hand, audio images, a form of multidimensional speech representation, act as candidates for image-specialized neural networks such as convolutional neural networks (CNNs).

XSL•FO
RenderX

Textbox 3. Speech feature types based on signal processing perspective.

Fundamental digital signal processing–based speech features

- Mostly linear signal processing techniques
- Can be described based on signal representation dimension (eg, time domain or frequency domain)
- Can be mapped to a physiological phonetic viewpoint (eg, phonation or articulation) more straightforwardly
- Can be used to create secondary voice indexes, such as voice quality measures (eg, Dysphonia Severity Index)

Advanced digital signal processing–based speech features

- Mostly nonlinear signal processing techniques
- May not be directly mapped to a physiological phonetic viewpoint

Audio images

- 2D representation of speech signals

Speech features can be analyzed through 2 complementary lenses: their representation dimension during speech feature extraction and their physiological phonetic characteristics, which are derived from the field of speech science. Speech signals can be represented and features can be extracted in the time, frequency, time-frequency, and cepstral domains. From the physiological phonetic viewpoint, speech features capture biological and anatomical aspects of speech production, including articulation, phonation, prosody, and speech quality. Within the studies, speech articulation was assessed through time-domain features (eg, AMR [75], diadochokinetic rate, and diadochokinetic period [103]), frequency-domain features (eg, formants [42,76], Bark band energy-based features [42,54], spectral moment, and power spectral moment [76]) as well as cepstral domain features (eg, MFCC [42,45,54]). Similarly, speech phonation was assessed in features from time domain (eg, jitter, shimmer [42,45,62,73,76], amplitude and speed-based glottic cycle features [62,73], Teager-Kaiser energy operator based features [45,77], energy [76]), frequency domain (eg, fundamental frequency [42,48,62,73,76], bark band energy-based features [48], harmonic-to-noise ratio [45,73], noise-to-harmonic ratio [45]) and cepstral domain (eg, MFCC [48,53], linear-frequency cepstral coefficients [53], gamma-tone cepstral coefficients [53], cepstral peak performance [73]). Pause-based features [109] and fundamental frequency [109] are some examples for time domain and frequency domain features for prosody and rhythm assessment.

Different structures have been proposed for categorizing these features. Speech features were categorized as voicing, articulation, and prosodic features in the study by Li et al [75], whereas Wang et al [42] grouped speech features as phonatory, articulatory, prosodic, and cognitive-linguistic features. Phonatory features modeled abnormal patterns in the vocal fold vibrations, whereas articulation features captured deficits in articulatory movements of the lips, tongue, and jaw. Prosodic features, such as speech rate and timing, investigated paralinguistic aspects such as emotions, whereas cognitive-linguistic features considered vocabulary, phrase construction, and word repetitions [42]. The domain of speech feature representation pertains to the complexity and resource demands for feature extraction, whereas phonetic elements relate to speech task characteristics and the biological process involved in speech production.

Speech features are also categorized as linear or base speech features (eg, fundamental frequency, jitter, and shimmer) and nonlinear features, which are mostly derived from advanced signal processing techniques. The studies by Zhang et al [61] and Tunc et al [77] investigated nonlinear speech features such as correlation dimension, recurrence period density entropy, detrended fluctuation analysis, and pitch period entropy. Tunable Q-factor wavelet transform and empirical mode decomposition–based speech features are some more advanced speech features [77]. Different spectrograms, including mel spectrograms [44,54], linear spectrograms [54], and constant-Q transform spectrograms [54] are examples of speech image representations assessed in the included studies.

Secondary voice indexes were another type of speech feature available in the studies. They were indexes defined from other primary speech features. Example measures included the Dysphonia Severity Index, formant centralization ratio, and vowel metrics. The Dysphonia Severity Index is calculated from phonation time, jitter, fundamental frequency, and intensity, whereas the latter 2 are calculated from the measures of formants of vowels [72,94]. Some studies used standard speech feature sets, for example, the extended Geneva Minimalistic Acoustic Parameter Set [107], INTERSPEECH2016 Computational Paralinguistics Challenge speech feature set [49,110], and the emobase feature set [86]. Speech feature embeddings derived from a deep learning (DL) approach were also a type of speech feature representation assessed in the included studies [50,57].

Data Science Approaches

Overview

Descriptive and predictive studies were included among the 18.5% (72/389) of neurological studies. Descriptive studies assessed the relationship between clinical variables and speech features (eg, whether speech features are associated with a disease or its severity), whereas predictive studies investigated the estimation of clinical variables from speech features (eg, predicting disease severity from speech features). Statistical analysis was largely applied in descriptive studies, whereas

XSL•FO
RenderX

predictions were made through traditional ML and DL approaches.

Statistical Analysis: Relationship Between Speech Features and Clinical Measurements

Univariate, bivariate, and multivariate analyses of speech features were observed across the 18.5% (72/389) of neurological studies. Univariate analyses investigated descriptive measures and the statistical significance of speech features in differentiating pathological and healthy groups. Descriptive statistics of speech features within first hour and after 12 hours of medication of PD [78] and at 2 stages of MS [98] are some examples.

Further statistical significance tests showed the differences between speech features, mainly between healthy and impaired speech due to neurological health conditions. Several statistical significance tests were applied depending on the relationship between discriminating groups and the normality of the variables. For example, Suppa et al [110] statistically compared speech with and without voice tremors using the Student *t* test, whereas the paired Student *t* test was used to compare speech features before and after medication. To differentiate AD, dementia with Lewy bodies, and healthy speech, Yamada et al [90] compared speech features between groups after controlling for medication using 1-way analyses of covariance. Both studies explored the relationship between speech features and disease characteristics before building predictive models. The studies used bivariate analyses to explore the association between speech features and clinical variables, such as the correlation between speech measures and UPDRS scores for PD severity [73,76,77]. The study by König et al [111] also assessed the correlation between speech properties and the Apathy Inventory subscales to assess the properties of apathetic speech in people with cognitive disorders. Multivariate analysis was applied to simultaneously explore the relationship among clinical variables, speech features, and other confounding factors such as age and sex. For example, Svoboda et al [96] applied multiple linear regression of speech features, age, and sex to differentiate MS from healthy speech.

Table 1 summarizes the statistical analysis approaches applied in the selected studies.

XSL•FO
RenderX

Table 1. Summary of statistical analysis approaches in the studies with examples.

Technique	Examples
Univariate analysis	
Statistical comparison of speech features between 2 independent groups	• Mann-Whitney U test to compare speech features between patients with MS[a] and healthy groups [94] • Kruskal-Wallis test to compare apathetic and nonapathetic speech [111] • Independent Student t test to compare speech features between patients with MS and healthy groups [95,98] and between patients with and without voice tremor [110] • Kolmogorov-Smirnov 2-sample test to compare speech features in MS and healthy groups [96]
Statistical comparison of speech features between 2 related groups	• Paired Student t test to compare the speech variables of the same patients with and without medication [110]
Statistical comparison of speech features among ≥3 independent groups	• 1-way ANOVA to explore how diseased status (AD[b], DLB[c], and healthy) impacted speech features to support differential diagnosis [90] • 2-way ANOVA to examine the effects of the dementia type (AD and DLB) and disease stage (MCI[d] and dementia) on speech features [90]
Bivariate analysis	
Statistical association between clinical variables and speech features	• Spearman correlation coefficient to assess the relationship between acoustic features and neurological status for MS [94] and assess the relationship between acoustic features and Apathy Inventory subscales [111] • Statistical association between ADOS[e] score and speech features via Pearson correlation coefficient [109]
Multivariate analysis	
Statistical comparison among multiple groups considering confounders on speech features	• Generalized linear regression to assess the statistical significance of speech features, age, and sex on differentiating MS against healthy populations [96]
Dimensionality reduction of speech features	• Application of principal-component analysis and observation of biplots to understand speech feature clusters in 3 discriminative groups related to ALS[f] [99]
Speech feature cluster analysis	• k-means clustering to unveil patterns within speech features obtained from patients with dementia and depression [91]

[a]MS: multiple sclerosis.

[b]AD: Alzheimer disease.

[c]DLB: dementia with Lewy bodies.

[d]MCI: mild cognitive impairment.

[e]ADOS: Autism Diagnostic Observation Schedule.

[f]ALS: amyotrophic lateral sclerosis.

ML Approaches

The studies used traditional ML, DL, and hybrid approaches to predict clinical variables from speech features. Disease diagnosis was formulated as a binary classification, whereas differential diagnosis was extended into multi-class classifications. The severity assessment was primarily treated as a regression problem, whereas treatment monitoring involved either regression or classification of patients based on medication status. Classification problems were the most commonly addressed.

Among traditional ML classifications, the following were the most common algorithms: support vector machine, k-nearest neighbor, random forest, decision tree, Extreme Gradient Boosting, multilayer perceptron, and logistic regression. Linear regression, support vector regression, random forest regression, and artificial neural network regression were among the traditional ML regression techniques, for example, in Autism Diagnostic Observation Schedule score prediction for autism severity assessment [109] and prediction of neuropsychiatric inventory scores [93].

DL approaches were applied as deep feature extractors and end-to-end predictors. In deep feature extractors, DL capability was explored in self-extracting efficient feature representations from speech features in a supervised or unsupervised manner. The studies retrained special DL models and built their own models as feature extractors. Example deep speech feature extractors included the implementation of a standard DNN in the study by Gosztolya et al [97] and an autoencoder network in the study by Bertini et al [89]. Regarding the development of end-to-end DL models, recurrent neural network models and CNNs were among the most promising ones. Different architectures such as CNN with a modified Hybrid Mask U-Net architecture with an adaptive custom loss function for PD assessment [46] and bidirectional long short-term memory neural networks [105] were implemented. Hybrid architectures such

XSL•FO
RenderX

as CNN–long short-term memory networks [102] and personalized convolutional recurrent neural networks [79] were also assessed in the studies. Transfer learning was applied to train computer vision–based approaches for clinical speech analysis. Examples included CNN14 [44] and AlexNet-based CNN for PD assessment [53].

There were fewer research attempts to explore DL approaches for clinical score prediction. Autism severity score prediction using DNN and CNN [109] and PD severity prediction using DNN [67] were among the few examples. Table 2 summarizes the ML and DL approaches applied in the selected studies.

XSL•FO
RenderX

Table 2. Summary of machine learning (ML) and deep learning (DL) approaches used in the studies with examples.

Technique	Examples
Traditional ML: classifiers	
Boosting technologies	• XGBoost[a] for MS[b] diagnosis [96], AD[c] assessment [82], and PD[d] assessment [50,77] • AdaBoost[e] for AD and cognitive impairment assessment [86,92] and AdaBoost for PD assessment [47] • LightGBM[f] for PD assessment [47,50]
KNN[g]	• MS diagnosis [96], ALS[h] assessment [101], AD assessment [87], and PD assessment [42,47,51,54,58,60,67,69]
Simple feed-forward neural networks	• MS diagnosis [96], PD assessment [54], and ID[i] assessment [112] • AD assessment [86], cognitive disorder assessment [92], and PD assessment [49,51,60,61,67]
RF[j]	• MS diagnosis [96], ALS assessment [99], and HD[k] assessment [107] • ID assessment [112], AD and cognitive disorder assessment [82,83,86,92], and PD assessment [47,50,66]
SVM[l]	• MS diagnosis [96], concussion diagnosis [104], ALS assessment [99,100,102], ASD[m] assessment [108], ID assessment [112], ET[n] detection [110], AD and cognitive impairment assessment [83,86-88,90-92], and PD assessment [43,45,47,49-51,53,54,58-61,63,67-69,74,75]
LR[o]	• Concussion diagnosis [103], diagnosis of apathy [111], ALS assessment [99], AD assessment [82,86], and PD assessment [42,47,59,61,75]
NB[p]	• ALS assessment [99], AD and cognitive disorder assessment [83], and PD assessment [42,47,49,54,60,61]
DT[q]	• AD assessment [87] and PD assessment [47,54]
Traditional ML: regressors	
Linear regression	• ASD severity prediction using multiple linear regression [109] • NPI[r] score prediction using linear regression with L1 regularization [93] • UPDRS[s] score prediction for PD assessment [61,76] • HY[t] score prediction for PD assessment [67]
SVR[u]	• ASD severity prediction [109] • NPI score prediction [93] • UPDRS score prediction for PD assessment [61,73,76] • HY score prediction for PD assessment [67]
RF regression	• UPDRS score prediction for PD assessment [73,76]
ANNs[v]	• Prediction of speech impairment in ET [110] • Prediction of the likelihood of speech impairment in PD [43] • HY score prediction for PD assessment [67]
DL and hybrid models: classifiers	
DNNs[w]	• DNN+SVM model for MS diagnosis [97] • ALS assessment [100,102] • AD and cognitive impairment assessment [84] • X-vector for PD assessment [57] • DNN for PD assessment [50,67]
RNNs[x]	• BiLSTM-A[y] for concussion diagnosis [105] • BiLSTM[z] for CNSD[aa] diagnosis [113] and PD assessment [54]
CNNs[ab]	• AlexNet-based CNN for PD assessment [53] • CNN14 for PD assessment [44] • CNN (modified Hybrid Mask U-Net architecture with an adaptive custom loss function) for PD assessment [46] • CNN (ResNet18 architecture) for PD assessment [52] • CNN for PD assessment [54,58,63]

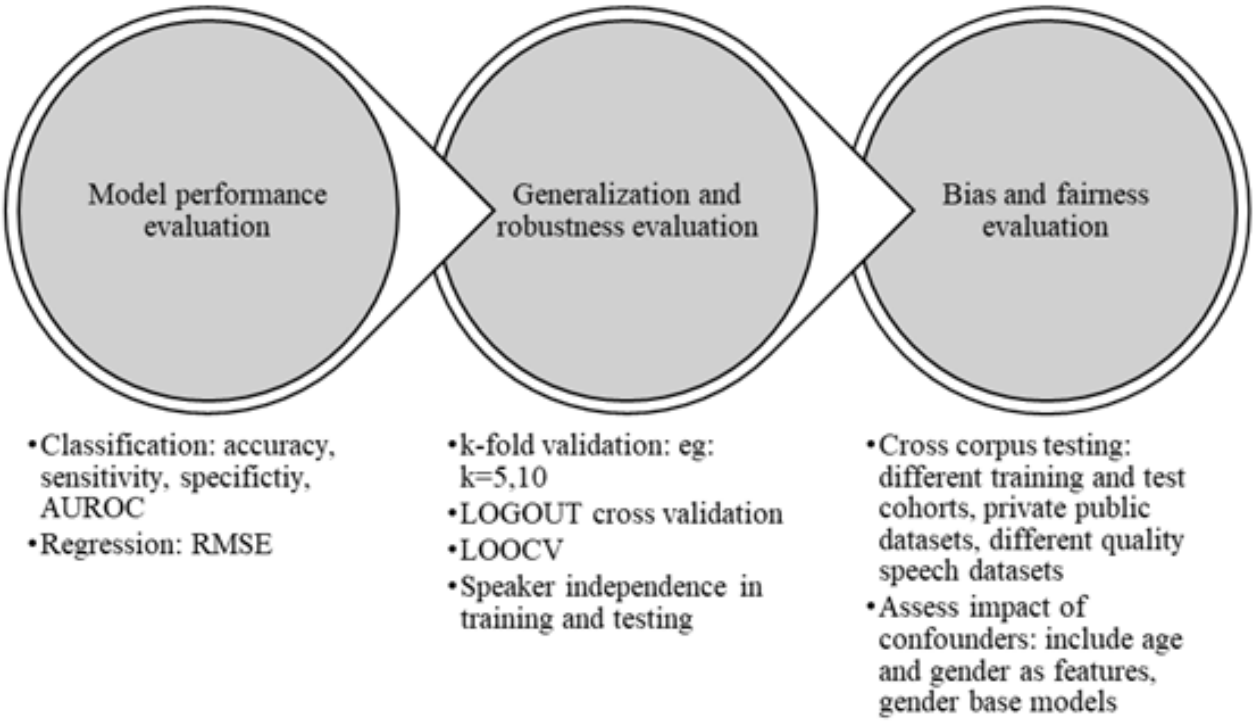
[ab]CNN: convolutional neural network.
[ac]LSTM: long short-term memory.
[ad]CRNN: convolutional recurrent neural network.
[ae]MLP: multilayer perceptron.

Some studies (24/72, 33%) integrated multiple data science approaches. They first applied statistical techniques to screen and filter speech features before feeding them into ML-based prediction models. Application of unsupervised learning techniques was the least common, with only one study exploring unsupervised clustering. The study applied statistical analysis, unsupervised learning, and supervised classification to address the classification of patients with depression and dementia based on speech, demonstrating comprehensive use of data science approaches in the speech analysis pipeline [91].

Model Evaluations

The analytical performance of algorithms was evaluated based on the model's prediction performance, generalizability, robustness, biases, and fairness. The classification model's prediction performance was assessed through a set of performance metrics, including accuracy, sensitivity, specificity, and the area under the receiver operating characteristic curve. In regression analysis, the root mean square error score was the most widely reported performance metric.

XSL•FO
RenderX



To ensure the model's generalization and robustness, cross-validation with speaker independence was applied to prevent overfitting. Variations of k-fold validations were applied, with *k*=5 and *k*=10 being the most common. In training and testing, speaker independence maintains all speech recordings of the same speaker only in either the training or testing set without splitting between the 2 to avoid overoptimistic performance from information sharing. The studies adapted speaker-independent cross-validation strategies with simple k-fold validation when utterance-level features were considered. Some studies (14/72, 19%) applied leave-one-out cross-validation to increase the training dataset, preserving speaker independence. In this case, data from one participant were kept for testing, whereas all remaining data were used for model training [45,67,83,93]. When low-level speech features such as frame-level speech features were analyzed, speech from the same utterance was treated as a separate input, making speaker independence challenging. To address that challenge, Al-Hameed et al [92] applied a leave-one-group-out cross-validation with segment-level speech features, whereas simple k-fold validation was used with utterance-level features.

The biases and fairness of model predictions were mainly evaluated through cross-corpus testing and confounder assessments. There were several cross-corpus test scenarios in the studies. Training with aged-matched groups and testing on different age groups [91] and recruiting different training and testing cohorts [47] were some examples of maintaining different corpora within data collection. Moreover, the studies combined public and private datasets from different ethnicities and different speech tasks to improve the heterogeneity of the sample populations [46,58,61,63,77]. Speech corpora with different speech recording qualities were also considered [48,52,55,57,59].

The impact of confounding factors such as age and gender were addressed differently in the studies. Mainly, the studies used age-matched disease and control groups in the experiments. Meanwhile, age mismatch between diseased and healthy groups was addressed through age correction of speech features [99]. Application of age and gender as features in their models [84,96] as well as evaluation of model performance for each gender was also conducted [111].

Figure 5 shows the model evaluation criteria commonly considered in the studies.

Figure 5. Model evaluation criteria used in the studies on neurological populations. AUROC: area under the receiver operating characteristic curve; LOGOUT: leave-one-group-out cross-validation; LOOCV: leave-one-out cross-validation; RMSE: root mean square error.

Only one study evaluated model predictions within a clinical setting. To discriminate between ataxia and hypokinetic dysarthria, Song et al [44] compared predictions of their artificial intelligence models and clinical decisions from a group of neurological resident physicians.

Clinical Applications

Several studies (6/72, 8%) extended their research into applications in the PD, ALS, and mTBI domains. For example, Rahman et al [50] proposed a web-based framework to record and analyze speech for PD screening. Meanwhile, Zhang et al [61] deployed their real-time speech analysis tool for PD diagnosis and severity assessment within a mobile app called No Pa for both Android and iOS. In addition, Likhachov et al [101] created a prototype of a mobile app named ALS Expert to assess the voice function of ALS. The studies used mobile apps for their speech data collection to demonstrate the feasibility of remote assessments and remote monitoring. For

XSL•FO
RenderX

example, Vasquez-Correa et al [52] collected smartphone-based speech data via an app called Apkinson, and Laganas et al [48] used a mobile app named iPrognosis to collect speech data from several countries and adopted an on-device feature extraction process. Both studies focused on PD assessment. A lightweight mobile app for speech data collection for mTBI assessment was also developed in the study by Daudet et al [103] to demonstrate the feasibility of on-device speech feature extraction, highlighting the importance of speech analysis at resource constraint devices to support on-field assessments.

Discussion

Principal Findings

On the basis of our review, speech analysis has emerged as a valuable tool across neurological, psychiatric, and respiratory diseases, with a particular focus on PD, AD, and cognitive impairment. Research in speech analysis has spanned the continuum of patient care, addressing diagnosis, differential diagnosis, severity assessment, and treatment monitoring. However, much research was conducted on diagnosing diseases by classifying healthy and diseased populations. Prediction of continuous clinical variables such as clinical scores was explored through regression. Statistical analysis was applied to assess the reliability of speech features and their relationship with clinical variables.

However, there are several limitations in the current research approaches to make their transition into health care settings. Conducting in controlled settings with homogeneous populations, typically single-ethnicity, single-center cohorts was observed as a common limitation across the studies. Early-stage patients—often the most challenging to diagnose—were underrepresented, and longitudinal studies across disease progression were scarce. However, the presence of studies from countries such as Italy, Thailand, China, Spain, and India with speech analysis in local languages is encouraging. This is appealing as speech features may or may not have similar meanings across different languages due to phonetic differences. Therefore, speech assessments within different populations and languages are recommended to assess the generalizability of speech analysis to a wider population [46]. Embedding heterogeneity into study populations and speech recordings through cross-corpus testing, using multiple speech tasks, and using different speech recording conditions were presented in the studies.

The diversity in the speech tasks used and extraction of speech features reflects both the field's complexity and its opportunities. The studies used multiple speech tasks as separate modalities, ranging from highly structured exercises to naturalistic speech. The speech tasks within the studies could largely be categorized into reading tasks, sustained phonations, diadochokinetic tasks, activity-related speech tasks, picture descriptions, and prompted speech tasks. The selection of speech tasks was guided by disease characteristics as structured speech tasks were common for neurodegenerative diseases such as PD and ALS, whereas semistructured speech tasks were common for cognitive impairment–related disorders such as AD, MCI, and dementia. Sustained vowel phonation and diadochokinetic tasks were widely identified in the literature for their ability to represent early signs of neurological diseases [125] and generally demand lower cognitive demands than semistructured speech tasks such as reading tasks. Sustained vowels can be applied across different languages as well due to less linguistic loading related to dialect, region, and language [126]. However, prompted speech tasks such as monologues might be impacted by personality traits, emotional status, sociocultural norms, and the ability to tell stories [124]. In speech feature extraction, the studies reported various associated parameters such as speech frame sizes, window overlapping, audio preprocessing stages, and signal processing algorithms, but no common format exists to present speech feature characteristics to act as biomarkers. When positioning speech features as a biomarker, it is recommended to report parameters associated with speech-processing techniques as they affect the accuracy and robustness of acoustic measures [124]. Adhering to the established guidelines for speech recording and analysis [127,128] along with transparent reporting of the relevant instrumental and computational specifications can lead to reliable data collection and analysis. This facilitates comparisons across studies, accelerates knowledge sharing across interdisciplinary fields, and supports research advancement and reproducibility.

Among data science approaches, statistical analysis approaches were applied to assess the clinical utility of speech features, but the exploration of unsupervised approaches was less present. Traditional ML approaches dominated predictive studies, but there are growing efforts in applying DL approaches with complex network architectures, transfer learning approaches, and audio image analysis. Although transfer learning from computer vision to audio images was explored, there is a void in transferring knowledge between speech analysis in different languages. Despite their limited presence, DL implementations encompassed end-to-end implementations, deep acoustic feature extraction, and transfer learning, which represent the main stems of DL approaches [129]. Among the end-to-end implementations, CNN, long short-term memory, and hybrid implementations were used, but it was noted that no transformer-based neural network models were included in the selected studies. However, recent literature provides evidence of the application of vision transformer–based models to analyze speech signals for neurological diseases. Differentiating PD severity levels using sustained vowels and Swin Transformer [130]; differentiating speech from neurological diseases, including PD and MS, from healthy speech by retraining Google's Vision Transformer Base model [131]; and differentiating PD speech from spinocerebellar degeneration speech by retraining the Patchout faSt Spectrogram Transformer [132] are some examples of vision-based transformers in speech analysis. It is noteworthy to mention that exploration of advanced DL approaches may improve the prediction performances. Additionally, incorporating a range of data science methods such as statistical analysis and unsupervised learning for hypothesis development and testing, conducting confounding factor analysis, and developing interpretable ML models can help researchers present their findings more interpretably and comprehensively to a wider audience.

XSL•FO
RenderX

Model evaluations in the included studies mainly considered analytical validations on prediction performance, generalization and robustness, and biases and fairness. Lack of clinical validations and narrow model assessment scopes can hinder translating research outcomes into clinical practices in the foreseeable future. Only a few studies (6/72, 8%) connected their investigations to clinical supportive applications. However, the development of applications can support further studies and usability assessments of prospective services within clinical and natural environments. In clinical settings, speech assessments can be conducted following standard speech recording protocols in optimal acoustic conditions to convey clinical insights for decision support. Routine health examinations might also be integrated with speech-based assessments to provide cost-effective longitudinal evidence in patient monitoring. Implementation of smartphone apps for speech collection, speech analysis, or transfer of speech data to remote clouds enables speech analysis in natural environments to empower telemedicine platforms. Opportunities exist in using telemedicine in neurological health care to ease the financial and accessibility burdens, such as in the rehabilitation of brain injuries and on-site concussion assessments [133]. Extending research into testable applications helps researchers explore challenges when converting research outcomes into clinical practice. Therefore, we believe that implementing a systematic research process leading to a clinical utility analysis could significantly accelerate advancements in this field. To support this, we organized the key concepts of speech analysis identified in this review into a research framework, aiming to provide more comprehensive guidance for future research.

Proposed Research Framework

Overview

We adapted the research process proposed in the study by Offermann et al [134] to operationalize research in design science. The proposed research process is structured in 3 main phases—problem identification, solution design, and evaluation—supporting both quantitative and qualitative research methods [134]. To build our research framework, we identified key activities and desired outcomes at each phase, focusing on research using primary speech data collection. Table 3 shows the research process, including proposed activities under each subprocess of the main stages of problem identification, solution design, and evaluation. Expected outcomes are proposed at each stage to guide the research progress.

XSL•FO
RenderX

Table 3. Proposed research framework for speech analysis for clinical assessments.

Subprocesses and activities	Outcome
Problem identification	

• Literature research and expert interviews
  • Identify clinical challenges of interesting health conditions
  • Characterize the speech impairment associated with the health condition through evidence from clinical science, speech science, and empirical research
• Identify the problem
  • Identify a research gap
• Pre-evaluate relevance
  • Define the research objective
  • Define research questions
  • Develop a research hypothesis
	• Selected health conditions and clinical purposes
	• Potential clinical applications
	• Characteristics of speech impairment
	• Research hypothesis

Solution design	

• Literature research
  • Identify standard clinical assessments
  • Identify speech assessments associated with specific health condition or similar health conditions
  • Identify study design approaches and research techniques
  • Identify suitable public or accessible datasets
• Design artifacts
  • Define ML[a] problem for the focused clinical purpose
  • Develop the study design of the research
  • Carry out data collection and analysis
	• Study population
	  • Participant recruitment and selection
	• Data collection protocol
	  • Ground truth
	  • Demographic data
	  • Speech tasks and speech features
	• Data analysis
	  • Primary analysis to build speech feature dataset
	  • Secondary analysis to assess the relationship between speech features and clinical variables
	  • Tertiary analysis to build predictive models

Evaluations	

• Refine hypothesis
  • Refine hypothesis based on data analysis
• Laboratory experiments
  • Internal validation (evaluate predictive performance; extend evaluations beyond predictive performance [eg, evaluate biases, fairness, and explainability])
  • External validation (with public dataset if available)
• Case study and expert survey
  • Case study in a clinical environment
  • Qualitative feedback from clinical and speech science experts
	• Internal validation of results
	• External validation of results
	• Case study and clinical feedback
	• Limitations and further improvements

[a]ML: machine learning.

Problem Identification

Problem identification defines the diseases of interest, clinical purpose, and potential clinical applications. Furthermore, it helps characterize the speech impairment associated with the disease to formulate research hypotheses.

As per this review's findings, digital clinical speech analysis addresses different clinical problems. For example, speech features are being researched as objective biomarkers for disorders such as AD, mTBI, and PD in cases in which a definite biomarker is not available. Moreover, speech analysis aims to empower the remote monitoring of patients with PD who are mostly older adults. Speech analysis tries to differentiate overlapping symptoms in different diseases, such as cognitive impairments and symptoms of natural aging. Therefore, researchers can focus on a particular health condition considering existing clinical challenges and evidence of associated speech impairments [114]. To explore clinical challenges and potential speech changes from diseases, existing literature and experiences from health care experts such as clinicians, speech-language pathologists, and frontline health professionals can be referred. Experiences from patients might also be beneficial when the target end applications are considered. Findings of this phase identify a research gap and define research objectives and research questions. Furthermore,

XSL•FO
RenderX

the researcher can qualitatively characterize speech impairments and define research hypotheses for empirical research.

Solution Design

In the solution design phase, specific literature research on current clinical practices and associated clinical speech assessments is beneficial to identify the ground truth [114] and potential speech characteristics to focus on. Study design approaches and state-of-the-art data analysis techniques can be used to ensure the scientific validity and novelty of the research. Clinical problems can be mapped into a predictive modeling problem, and an appropriate speech data collection plan can be developed. Data collection should include patients' demographics, assessment of health conditions through standard clinical measures, and speech recordings. Furthermore, it should define speech recording instances, conditions, recording equipment, and speech tasks. Recording instances define when to collect speech from the participants, such as before or after medication. Recording can be done in either controlled or uncontrolled environments based on the research objectives. For example, if the research objective is the remote monitoring of patients, recordings in an uncontrolled environment would be more appropriate. Speech tasks should be carefully selected to capture appropriate speech characteristics associated with the health condition.

We recommend a comprehensive analysis of speech features to conduct association analysis to clinical parameter predictions. The data analysis workflow can be divided into three main stages—primary analysis, secondary analysis, and tertiary analysis—to (1) explore participant characteristics and extract suitable speech features from speech signals, (2) examine the relationship between speech features and clinical variables, and (3) develop and optimize ML models to predict clinical variables from speech features.

The primary analysis quantifies speech features from the speech signals following appropriate audio preprocessing. Noise reduction, down sampling, and silent period removals are some examples of audio preprocessing steps. Different speech features represent different aspects of speech production. For example, energy-based speech features represent respiratory function, whereas pitch-based features represent phonatory function. On the basis of the anticipated speech impairment and speech task characteristics, a set of representative speech features could be extracted. The secondary analysis then encompasses the relationship between speech features and clinical variables through descriptive statistics, statistical comparisons, association mining, and unsupervised data explorations.

In tertiary analysis, research can exploit speech variability within diseases to build predictive models, typically through classification or regression. Insights derived from secondary analysis can be integrated into predictive model building through feature selection and patient clustering. In addition, the impact of confounding factors such as age and gender should be considered when developing predictive models. Algorithm-dependent advanced ML strategies such as feature selection, data augmentation, and transfer learning can be explored to improve model predictions.

Evaluation

Once the solution has reached a satisfactory state, the evaluation of the proposed solutions or approaches is recommended [134]. During evaluations, the hypothesis can be refined to a more precise level based on the data analysis. For example, data analysis might highlight speech impairments in a particular dimension of speech production, such as phonation or articulation, or a particular stage of disease. Therefore, specific hypotheses can lead to detailed insights. Moving forward, internal validations should extend to different dimensions of model performance, and evaluations can include surveys and case studies for clinical utility assessments.

Through a set of comprehensive experiments and evaluation metrics, internal validations should extend beyond prediction performance to include assessments of biases and fairness, reliability, and explainability of predictions to address challenges that persist in speech analysis [28]. With the aid of publicly available datasets or, if feasible, with external cohorts, external validation of predictions can be conducted. Few case studies can be carried out in a clinical environment to present model assessments to clinical experts and obtain their feedback on model usability.

Finally, study results can be presented including experimental results for internal validations, external validations, and feedback from expert observations. We believe that the research outputs will be more competent and thorough and contribute to long-term research directions, extending the short-term results of the specific research scope.

Limitations

We acknowledge that our research study has certain limitations. Among the eligible studies, we reviewed only 72 articles in the neurological domain. Although we considered only content-independent speech analysis, content analysis can also be relevant for certain clinical conditions. Furthermore, our main findings were synthesized from studies that conducted primary speech data collection. Nonetheless, studies on other clinical disciplines and studies that used publicly available datasets also contribute to the advances in the field. We confined the main concepts to diseases, clinical outcomes, speech tasks, speech features, data science approaches, evaluations, and clinical applications. The highly technical and algorithm-dependent speech feature extraction and feature selection methods were not covered in this review. However, such factors also remain crucial in speech analysis.

Conclusions

This review discussed the main concepts within the growing research field of speech analysis for clinical decision support. The principal findings were presented from both clinical and technical perspectives. The clinical context was addressed through diseases, clinical purposes, and clinical applications, whereas technical aspects were addressed through speech tasks, speech features, data science approaches, and model evaluations.

The main contribution of this research can be summarized as (1) carrying out a comprehensive and extensive systematic scoping literature review followed by qualitative content analysis

XSL•FO
RenderX

on digital clinical speech analysis and (2) presenting a research framework on speech analysis for clinical decision support.

The findings of this research reflect the potential of speech analysis for clinical decision-making and the contribution of data science approaches. Among clinical disciplines, neurological diseases have gained major interest, with PD being the most popular. Interestingly, research efforts are expanding beyond English-speaking populations, but more studies including less represented ethnicities and languages are much warranted. The lack of longitudinal studies also remains as a research gap. Designing experiments to address challenging clinical decision scenarios such as prognosis or early detection might be more appealing for clinical environments. Moreover, given the technical differences in speech features, an interpretable presentation of speech features as a digital biomarker would accelerate research progression and reproducibility. Integration of different data science techniques, including statistical analysis and unsupervised and supervised learning, can make data analysis more comprehensive and interpretable. Model evaluations should expand beyond analytical validations and include more comprehensive evaluations, including clinical utility assessments.

On the basis of the findings of this study, we proposed a research framework for primary research on speech analysis for clinical decision support. We encourage studies to adhere to design science research methodology by integrating both quantitative and qualitative research methods.

Acknowledgments

This research is part of an ongoing international collaboration supported by the Auckland University of Technology Faculty of Design and Creative Technologies and the Auckland University of Technology School of Engineering, Computer and Mathematical Sciences. This research is partially supported by Auckland University of Technology Faculty of Design and Creative Technologies Contestable Grant 2023 and 2024 (principal investigator: SM).

Abstract

Background: HIV/AIDS remains a significant global challenge, and with the rapid advancement of technology, there has been an increasing number of interventions aimed at improving HIV/AIDS cognition and self-management behaviors among patients. However, there is still a lack of detailed literature integrating relevant evidence.

Objective: This study aims to comprehensively review existing research on interventions using modern information methods to improve HIV/AIDS cognition and enhance self-management behaviors among patients. It systematically reports the theoretical frameworks and specific intervention strategies used in current research, providing a comprehensive overview of the development status of relevant studies. We aim to compile existing evidence through this scoping review to identify potential avenues for future research.

Methods: We followed the scoping review framework proposed by the Joanna Briggs Institute for the synthesis and reporting of evidence. Relevant literature was searched using electronic databases, including PubMed, Web of Science, Embase, CINAHL, and Cochrane Library. The time frame for inclusion was from 2018 to December 1, 2023. Inclusion criteria were (1) interventions using modern information technology or new digital media, (2) studies focusing on improving HIV awareness or self-management behaviors among people living with HIV, (3) intervention studies or evaluations of intervention effects, and (4) studies published within the last five years. Two reviewers (HH and MX) independently assessed each study at both the title and abstract screening stage and the full-text review stage, resolving any disagreements through discussion.

Results: A total of 55 studies that met the inclusion criteria were included. The Information-Motivation-Behavioral Skills model, Social Cognitive Theory, Health Belief Model, Theory of Planned Behavior, and Information Systems Research Framework are among the most commonly used theoretical frameworks. Modern information technology interventions are mainly constructed using smartphone apps, SMS text messaging, internet-based platforms, audiovisual materials, and digital health education platforms, with smartphone apps and SMS text messaging being the most widely used intervention media.

Conclusions: Modern information technology is becoming an important tool for health interventions among people living with HIV/AIDS. However, future research should focus on integrating theoretical framework guidance with intervention design, further exploring the diversity of intervention implementations, the applicability of different technological methods, their long-term effects, and how to more effectively combine traditional intervention strategies to maximize intervention outcomes.

Introduction

Currently, HIV/AIDS remains a severe and intricate global challenge. According to the 2023 report from the United Nations Program on HIV/AIDS [1], there are currently 39 million people living with HIV worldwide, with 29.8 million undergoing antiretroviral therapy (ART). In 2022, there were 1.3 million new HIV infections, and 630,000 individuals succumbed to AIDS-related illnesses. Thanks to collaborative efforts globally, the spread of HIV has slowed, and the annual death toll continues to decline [1,2]. Beyond the typical clinical symptoms of AIDS, patients often grapple with multidimensional challenges in their daily lives, including poor treatment adherence, exacerbated family conflicts, economic burdens due to high treatment costs, and mental health issues [3,4]. Research indicates that reinforcing self-management behaviors and enhancing disease awareness can lead to better treatment adherence, alleviate the burden of disease symptoms, and enable individuals to coexist more effectively with HIV [5,6]. Therefore, strengthening the self-management behaviors and disease awareness of people living with HIV becomes a crucial aspect of improving the quality of life for patients and reducing negative experiences associated with HIV.

Modern information technology rapidly and cost-effectively reduces the barriers to accessing disease-related information. It has been proven that leveraging modern technological means aids in expanding the dissemination of HIV prevention and treatment interventions [7]. Modern information technology, or new digital media, refers to user-controlled, shareable, and digital media [8]. Widely used new digital media, such as SMS text messages, websites, apps, and social media platforms, have significantly improved information sharing and communication. These technologies enable rapid, inexpensive, highly replicable, and widely covered interventions. Digital media achieve greater anonymity, repeatability, time flexibility, and customer sensitivity, meeting diverse learning needs [9]. They break down restrictions related to time and geography, maximizing the impact of information dissemination.

This study will comprehensively review evidence from the last 5 years regarding the use of modern information technology in enhancing HIV disease awareness and self-management. It underscores the enormous potential of contemporary technology in elevating self-management and disease awareness within the HIV community, guiding future research and practice.

Methods

Study Design

This scoping review uses the latest framework proposed by the Joanna Briggs Institute, encompassing the following stages: (1) formulation of research questions; (2) identification of relevant studies; (3) selection of studies; (4) charting the data; and (5) collating, summarizing, and reporting the results [10]. Reporting for this paper follows the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist, the preferred reporting item for scoping reviews [11]. All members of our research team have undergone systematic training in evidence-based research methodologies and are well-versed in conducting scoping reviews following established guidelines. Additionally, our team includes an expert in HIV research (MX), who has been available for consultation and reference throughout the study to ensure the quality and accuracy of our work. This scoping review has been registered on the Open Science Framework [12].

Formulating Research Questions

This study aims to summarize existing evidence regarding enhancing HIV disease awareness and self-management behaviors among people living with HIV through modern information technology.

Identifying Relevant Studies

We included studies that met the following criteria in this scoping review: (1) intervention involving modern information technology or new digital media, (2) research focusing on improving HIV disease awareness or self-management behaviors of people living with HIV, (3) intervention studies or studies evaluating intervention effects, and (4) studies published within the last five years. The exclusion criteria were (1) studies not reporting research outcomes, (2) gray literature, and (3) studies inaccessible for full-text retrieval.

We limited our literature search to studies published in 5 years to capture the most recent advancements in modern information technology interventions for improving disease awareness and self-management among people living with HIV/AIDS. This 5-year timeframe was chosen because the field is rapidly evolving, and recent studies are more likely to reflect current technologies and practices relevant to our research objectives [13].

Study Selection

English-language literature was retrieved from electronic databases, including PubMed, Web of Science, Cochrane Library, Embase, and CINAHL. The literature search in this study focused on HIV, telemedicine, cognitive training, and self-management. For specific search strings, please refer to Multimedia Appendix 1. EndNote (Clarivate Analytics) software was used to manage the studies and eliminate duplicate publications. After removing duplicates, the literature underwent a title and abstract screening, followed by a full-text review to determine inclusion or exclusion. Both stages were performed independently by two reviewers (HH and MX), and no disagreements were reported.

To ensure consistency among reviewers, we randomly selected 25 titles and abstracts for an initial screening exercise. All reviewers independently screened these based on predefined inclusion criteria. Formal literature screening commenced once a 75% interrater agreement was achieved [14]. Subsequently, HH and MX independently screened the remaining titles and abstracts using the criteria and conducted full-text reviews to determine inclusion or exclusion. In cases of disagreement between the two reviewers, a third reviewer was consulted to discuss and reach a consensus [14]. Excluded studies are documented and reported, and the results and search process

XSL•FO
RenderX

are presented in a flowchart following the PRISMA-ScR guidelines (Multimedia Appendix 2) [11].

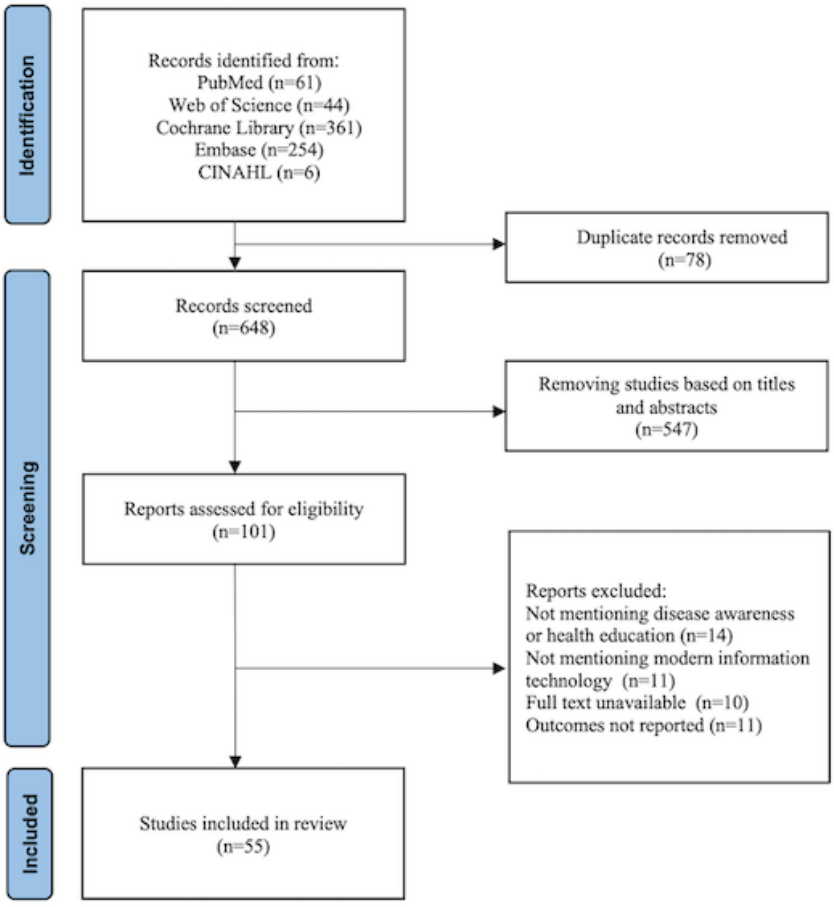
Data Extraction and Presentation

We conducted a comprehensive review of the full texts of studies meeting the inclusion criteria, focusing on how they enhanced disease awareness and self-management behaviors of patients with HIV through the application of theoretical frameworks and modern information technology interventions. Specifically, we extracted and reported on the theoretical frameworks and modern information technology used in each study.

Two researchers (HH and MX) independently extracted data and performed content analysis of the included studies. Any disagreements were resolved through discussion, with a third researcher (ZY) serving as an arbiter when necessary. Data were extracted and integrated using mind maps and Excel (Microsoft Corp) spreadsheets. The findings were then presented using a combination of text and tables.

We categorized and extracted the following information from each study: (1) basic study information, which includes authors, publication year, study design, sample size, and study location; (2) intervention methods, which includes details of the modern information technology interventions used in the studies; and (3) conceptual frameworks or models, which includes theoretical frameworks or models applied in the studies.

Collating, Summarizing, and Reporting Results



We reported the results of the included studies by focusing on the following points: (1) the theoretical frameworks or models used in the included literature, and (2) intervention methods based on modern information technology adapted in the included literature.

Results

Study Selection

According to our inclusion criteria, the results of English database searches are as follows: 61 studies were retrieved from PubMed, 44 studies from Web of Science, 361 studies from Cochrane Library, 254 studies from Embase, and 6 studies from CINAHL. After removing duplicates, a total of 648 studies remained. After evaluating titles and abstracts, 101 English-language studies were retained, and after a thorough examination of the complete texts, 55 studies were finally included. The search results are presented as a PRISMA-ScR flowchart (Figure 1).

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) flow diagram.

Characteristics of the Studies

Among the 55 studies finally included, the studies ranged from a minimum sample size of 21 participants to a maximum of 2125 participants. Of these, 33 studies were randomized controlled trials, 10 studies were feasibility studies, 5 studies were observational studies, 4 studies were evaluative qualitative studies, and 3 studies were mixed methods studies. Most of the

XSL•FO
RenderX

studies were conducted in the United States (n=28), followed by Kenya (n=4). Other countries include China (n=3), South Africa (n=3), Nigeria (n=3), Uganda (n=2), Thailand (n=2), and others. The general characteristics of the study are presented in Multimedia Appendix 3 [15-69].

Related Theoretical Frameworks

Information-Motivation-Behavioral Skills Theory

Information-Motivation-Behavioral Skills (IMB) theory is the most commonly used theoretical framework for designing interventions, with 7 studies basing their interventions on this theory. The IMB theory posits that information, motivation, and behavioral skills interact, with individuals acquiring information to understand the necessity of healthy behavior [70]. This, in turn, motivates them to desire and guide the adoption of such behavior. Ultimately, behavioral skills are used to transform motivation into concrete actions.

Five studies [15-19] used mobile phones as a platform, operationalizing the IMB model to enhance HIV self-management knowledge and beliefs. They developed apps or tailored SMS text messages aimed at improving HIV self-management behaviors and increasing HIV disease awareness among patients with HIV. Additionally, two studies [20,21] facilitated changes in HIV awareness and self-management behaviors by stimulating motivation, providing relevant information, and enhancing behavioral skills among intervention participants. These changes were implemented through websites and videoconferences.

Social Cognitive Theory

Five studies used the Social Cognitive Theory to develop their interventions. Social Cognitive Theory [71] emphasizes the importance of social learning, suggesting that individuals can acquire new knowledge and skills by observing others and adjusting and internalizing this learning through cognitive regulation and self-efficacy. In line with this theory, existing studies propose methods to enhance self-efficacy, including peer modeling and social persuasion, and build interventions based on these principles. Weitzman et al [22] and Côté et al [23] developed web-based interventions to improve self-management skills. Kalichman et al [24] and Tran et al [25] focused on individual differences among intervention recipients, providing personalized interventions based on the Social Cognitive Theory to enhance medication adherence and self-management skills. Kinuthia et al [26], using the Social Cognitive Theory, crafted intervention messages, integrated treatment adherence with other priorities, and delivered them as SMS text messages to intervention recipients.

Health Belief Model

Three studies developed their interventions based on the Health Belief Model. Despite sharing the same name, the Health Belief Model discussed in this review encompasses studies that different scholars have proposed. First, Tran et al [25] applied the Health Belief Model proposed by Becker [72] in his study. Throughout the research period and subsequent meetings, Tran et al [25] measured perceived severity and self-efficacy for comparison and sent personalized messages as cues for action. The theory-driven design helped in understanding the connections between patient behaviors and identifying clustered behaviors such as alcohol consumption and unemployment. Second, Kinuthia et al [26] applied the Health Belief Model modified by Janz and Becker [73]. Kinuthia used this model to compose messages providing care support to pregnant and postpartum women infected with HIV. Additionally, the Health Belief Model applied by Ditre et al [27] was proposed by Champion and Skinner [74]. Based on this model, the scholars provided computer-generated personalized feedback to modify smoking and opioid misuse behaviors in people living with HIV.

Theory of Planned Behavior

Two studies used the Theory of Planned Behavior to construct their interventions. The Theory of Planned Behavior [75] posits that one can effectively predict whether an individual will adopt a specific behavior by measuring and analyzing behavioral intentions, attitudes, subjective norms, perceived behavioral control, and actual behavior. Ditre et al [27] integrated the Theory of Planned Behavior along with other theories to construct a comprehensive intervention, predicting and improving smoking and opioid misuse behaviors in patients with HIV. Jiao et al [28] used this theory to design an intervention aimed at improving ART adherence among men who have sex with men (MSM).

Information Systems Research Framework

Two studies used the Information Systems Research Framework (ISR) as their theoretical foundation. The ISR [76] advocates for iterative cycles in the design and evaluation process to provide a systematic scientific design approach. Beauchemin et al [29] developed and evaluated the effectiveness of app intervention for improving self-management behaviors in people living with HIV based on the ISR. Similarly, Schnall et al [30] used ISR to create a mobile app to enhance ART adherence among people living with HIV.

Other Theories

In addition to the 5 theories mentioned above, a few have been used by researchers in intervention studies. Ezegbe et al [31], based on Rational Emotive Behavior Therapy Theory [77], used audiovisual interventions to enhance HIV disease awareness among high school students. Nestadt et al [32], based on Social Action Theory [78], developed a cartoon-based program for comprehensive psychosocial responses and treatment adherence intervention for adolescents who are HIV positive. Schnall et al [33], using Social Learning Theory [79], developed a mobile app to examine its effectiveness in reducing sexual risk behaviors among young men attracted to the same sex. Cordova et al [34] conducted a narrative intervention based on the Ecodevelopmental and Empowerment Framework [80,81], aiming to change risky drug use and behaviors among adolescents. Middleton et al [35] and Carroll et al [36], guided by the Capability, Opportunity, Motivation, and Behavior Model [82], developed SMS text messages to increase intervention recipients' knowledge of HIV prevention. Côté et al [23] implemented a web-based intervention guided by the McGill Nursing Model [83]. Sun et al [37], grounded in Cognitive

XSL•FO
RenderX

Behavioral Theory [84], developed an app and tested its effectiveness in promoting HIV prevention among transgender women. Weitzman et al [22] designed web-based interventions based on the Modified AIDS Risk Reduction Model [85], examining their effectiveness for the target population. Chenneville et al [38], using the Cognitive Theory of Multimedia Learning [86] and Dual Coding Theory [87], designed modules to enhance health literacy in young MSM regarding HIV retention care. Cordoba et al [39], guided by the Information System Success [88] framework, evaluated participants' experiences and satisfaction with a self-made app. In the psychological education segment of a comprehensive intervention, Ditre et al [27] primarily used the Transtheoretical Model [89] as guidance. Aladin et al [40], based on the Integrated, Design, Assess, and Share [90] theoretical framework, combined behavioral theories with design thinking and developed a mobile app as an intervention. Tran et al [25], based on the Integrated Theory of Behavior Change [91], developed a smartphone app to promote treatment adherence and self-efficacy among people living with HIV. To better illustrate the findings of this study, we have summarized the frequency of theoretical frameworks applied in the included studies. The results are visually represented in Table 1, providing a clear overview of the theoretical models and their respective utilization.

Table 1. Frequency of theoretical frameworks used in the included studies.

Theoretical framework	Frequency, n
Information-Motivation-Behavioral Skills Theory	7
Social Cognitive Theory	5
Health Belief Model	3
Theory of Planned Behavior	2
Information Systems Research Framework	2
Capability, Opportunity, Motivation, and Behavior Model	2
Rational Emotive Behavior Therapy Theory	1
Social Action Theory	1
Social Learning Theory	1
Ecodevelopmental and Empowerment Framework	1
McGill Nursing Model	1
Cognitive Behavioral Theory	1
The Modified AIDS Risk Reduction Model	1
Cognitive Theory of Multimedia Learning	1
Dual Coding Theory	1
Information System Success	1
Transtheoretical Model	1
Integrated, Design, Assess, and Share	1
Integrated Theory of Behavior Change	1

Intervention Methods Based on Modern Information Technology

Smartphone Apps

Smartphones have become widely popular globally with their high portability and rich features. In this review, it was found that interventions based on smartphone apps are the most favored among researchers. Among the included studies, 25 used smartphone apps as an intervention method.

This category's most popular intervention method involves providing self-management plans or tools to the intervention participants through smartphone apps, facilitating improvements in self-management behaviors. This is commonly observed in efforts to enhance compliance with medical advice, improve awareness of HIV, and ameliorate HIV-related symptoms [15,29,36,41-44,67,68]. Two studies integrated phone and SMS text message modules to build apps to enhance treatment adherence [45,46]. Communication-oriented mobile apps, such as WhatsApp (Meta), WeChat (Tencent), and Line (LY Corporation), were used to create group discussions for implementing interventions [17,47,48]. Finally, one study used the entertainment features of smartphones to develop an iPhone platform game to enhance the participant's compliance [49].

Additionally, some studies have developed apps for targeted populations to implement interventions. For HIV testing behavior, sexual education, and treatment adherence among gay men, four studies have collectively developed three apps for interventions [33,39,50,51]. Two studies have developed apps targeting vulnerable adolescent groups, aiming to improve self-management behaviors and prevent disengagement from care [34,40]. In addressing health, one study developed an app

XSL•FO
RenderX

to promote HIV prevention to meet the needs of transgender women [37].

SMS Text Message

Similar to interventions based on smartphone apps, using the SMS text message functionality of mobile phones for direct interventions has gained favor among many researchers. Sending SMS text messages to improve treatment adherence is the simplest and most direct method. Three studies have systematically sent timed or instant messages to intervention participants, covering medication reminders, peer education, and web-based group discussions, to enhance ART adherence among people living with HIV [16,28,52].

The included literature also takes into account specific populations. For instance, communication strategies in SMS text message content are tailored based on local cultural backgrounds for implementing prevention programs targeting 18- to 22-year-olds [53]. A combination of regular educational sessions and weekly health education SMS text messages are organized to enhance HIV prevention behaviors and reduce risky behaviors in African American youth [54]. Regularly sending SMS text messages for infant health education and promoting treatment adherence is implemented to provide care support for pregnant women and postpartum women living with HIV [26]. Planned SMS text messaging campaigns are carried out to raise HIV awareness among construction workers and encourage HIV testing [35].

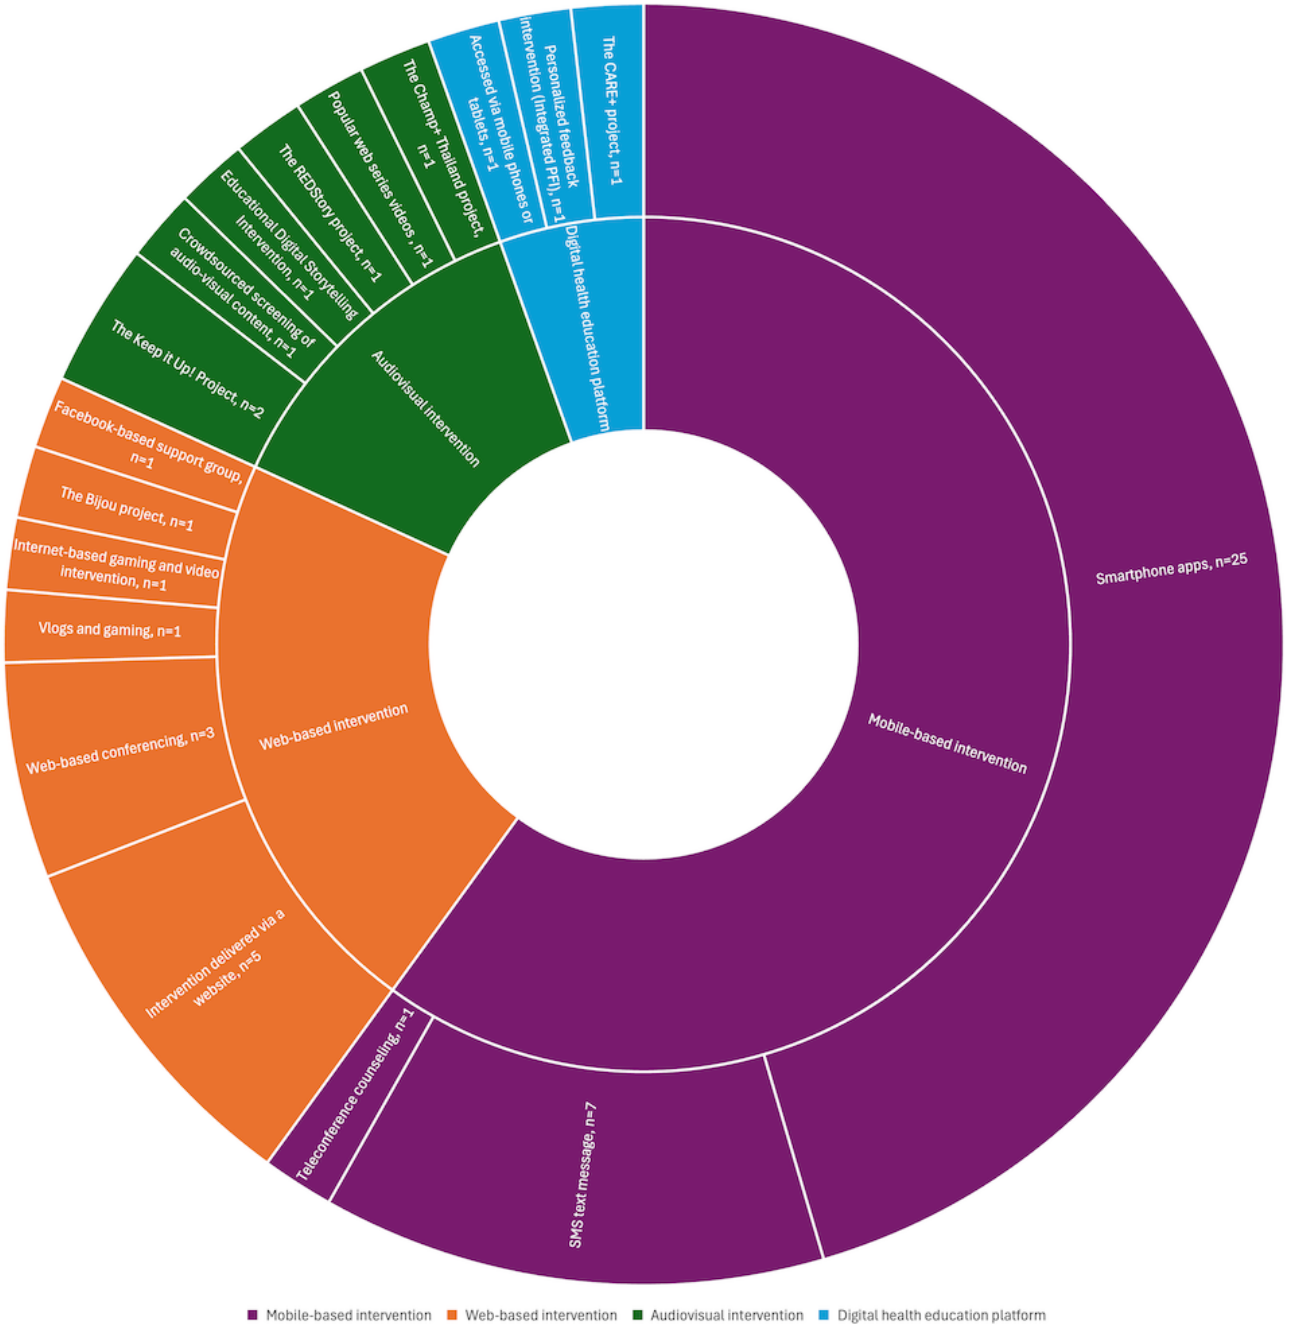
Web-Based and Digital Health Education Platforms

In internet-based interventions, most researchers choose to implement intervention programs by constructing websites. Building websites allows for the rapid dissemination of health education. Three studies used websites to create knowledge repositories for providing safety education. These websites comprehensively covered various topics, offering comprehensive and personalized health education to intervention participants through web-based interactions, sexual health information delivery, and modularized intervention methods. This approach aimed to promote HIV prevention and increase awareness of sexual health [55-57]. Using website platforms, two studies relied on teams with medical backgrounds to provide diverse learning methods. They combined social support and emphasized personalized web-based services to facilitate the effective transmission of health information [22,58]. Interventions providing counseling services through remote videoconferences typically use internet platforms to offer web-based video meetings to intervention participants. This involves hosting regular videoconferences and encouraging participant involvement through email, phone calls, and other means to enhance medical adherence and disease awareness among people living with HIV [21,23,59].

Furthermore, there are different forms of internet-based intervention programs. For example, one study created private discussion groups on social media platforms to enhance HIV-related knowledge and treatment literacy, thereby promoting the continuity of HIV care [60]. Other studies constructed internet-based electronic health education programs to strengthen health literacy among people living with HIV in HIV care through digital content [38], developed intervention programs using publicly available internet resources [20], and constructed HIV prevention interventions through video blogs that feature storytelling and digital gaming [61].

Finally, a minority of studies have implemented interventions by constructing digital health education platforms. These studies use computer-based personalized approaches, providing tailored health information and training videos through digital platforms to enhance treatment adherence and HIV-related knowledge and improve health care behaviors among intervention participants [27,62,63].

Performing and Multimedia Interventions



The commonality of audio and video interventions is the use of virtualized digital content to create various intervention plans tailored to different populations and needs. These interventions are delivered in audio and video, emphasizing the dissemination of disease-related knowledge and fostering connections between individuals and communities. Ultimately, they aim to enhance the understanding of intervention participants, boost self-efficacy among people living with HIV, and improve preventive behaviors.

For the adolescent population, considering their capacity for acceptance and understanding, researchers have developed a series of cartoon tutorials to strengthen parent-child communication, problem-solving, and negotiation skills. Participants pair with caregivers to attend the courses, enhancing internal family connections through learning and discussions [32]. For children, researchers have created captivating characters and carefully curated story content. With the assistance of qualified therapists, they deliver digital interventions to children using audio and video formats, achieving intervention goals while providing entertainment [64].

For specific populations, such as the gay and bisexual community, researchers have developed popular web series or short videos with a theme focused on gay, bisexual, and other MSM individuals. These videos capture the curiosity of the target audience while promoting HIV and other sexually transmitted infection testing behaviors [65,66,69]. Finally, some studies combine various communication channels, such as digital games, street interviews, and therapist-guided group psychological discussions, to enhance the effectiveness of performing multimedia interventions, providing participants with knowledge about preventing HIV/AIDS and sexually transmitted infections [18,19,31]. We have visualized the interventions included in the studies through Figure 2 to present the findings of this section more intuitively.

Discussion

Principal Findings

This scoping review reveals that most of the included studies have used one or more theoretical frameworks in the development of their interventions. Currently, the application of modern information technology primarily involves intervention construction, development of smartphone apps, feasibility studies, and analysis to intervene with the relevant population, yielding generally positive feedback. Thanks to the rapid advancement of modern technology, there has been an increasing emergence of modern information technologies, which better improve or innovate medical intervention measures and hold significant potential for the future development of medical technology. Modern information technology (or new media technology) plays a crucial role in HIV/AIDS research. This study explores the potential of information technology in enhancing HIV/AIDS awareness from multiple dimensions and systematically summarizes the theoretical frameworks and specific implementation methods of relevant studies. Through this research, we not only summarize the application cognition of modern information technology in health intervention but also provide new ideas and methods to improve HIV/AIDS awareness among older people, which is meaningful for enhancing HIV/AIDS awareness and inspiring future related research.

As early as 2000, scholars reported that theory-driven intervention measures have been proven to be more effective than non–theory-driven ones [92]. However, among the 55 studies included in this study, only 45% (n=25) of the intervention schemes were based on theory-driven approaches,

XSL•FO
RenderX

with the remaining studies either not reporting the research framework used or not using any theoretical framework. Among these 25 studies, the most commonly used theory was the IMB theory [70]. In health education interventions based on the IMB theory, accurate information about HIV/AIDS is first provided, emphasizing personalized interventions to increase individual awareness levels. Subsequently, by highlighting the serious threat of HIV/AIDS to individual health, individuals' positive motivations for prevention and treatment are stimulated, encouraging proactive behavior change. Finally, by providing practical behavioral skills training, individuals are helped to overcome barriers to implementing healthy behaviors, such as correctly using condoms and undergoing regular HIV testing, to achieve the intervention's objectives. The widespread application of the IMB theory in HIV/AIDS health education reflects its effectiveness in integrating information, motivation, and behavioral skills, providing theoretical support for designing targeted and effective health interventions. Additionally, some studies have integrated multiple theoretical frameworks as comprehensively as possible to construct intervention schemes [22,23,26,38,43]. Therefore, we encourage future research to use theory-driven approaches as much as possible to enhance the quality of interventions and improve intervention outcomes.

We found that the majority of studies used mobile phones as a platform for cognitive interventions, demonstrating diversity and innovation in HIV/AIDS cognitive interventions. From the results of this study, it is evident that the intelligent apps developed by various studies transcend the traditional role of communication tools in cognitive interventions. Leveraging the high portability and ubiquity of smartphones, these interventions offer convenient and personalized ways to reach the target population. By harnessing the mature functionalities of smartphones, such as integrating phone calls, SMS text messaging modules, and chat apps, these interventions provide communication pathways and methods rooted in traditional communication for intervention purposes [17,45-48]. The customization of apps tailored to specific populations, such as MSM [33,39,50,51], vulnerable adolescents [40], and transgender women [37], highlights the flexibility and adaptability of smartphone apps in meeting the diverse health needs of different groups.

Future Directions

Despite the promising future and wide-ranging applicability of smartphone app interventions, as evident from the studies included in this scoping review, only one study [45] mentions the relevance to the population of older people. Older people may face unique challenges and needs related to HIV/AIDS, such as unfamiliarity or discomfort with digital technology and preferences for accessing health information through specific channels. Therefore, developing specialized smartphone app interventions tailored to the population of older people is essential. These interventions should address the unique needs and preferences of older adults by incorporating user-friendly features that align with their specific contexts and lifestyles. For example, simplified navigation systems; larger font sizes; and real-time, one-on-one, web-based support are highly recommended. Additionally, for older people who may face challenges with typing or using smartphones, voice-guided navigation could be an especially effective solution. Such tailored interventions and innovations are crucial for enhancing accessibility and usability, ultimately improving the older people population's engagement with health information and interventions.

Through this review, it is evident that a significant portion of studies prefer using SMS text messaging for interventions, with only one study [16] emphasizing the importance of protecting user privacy. SMS text messaging interventions involve the collection, storage, and use of users' personal information. Therefore, safeguarding user privacy is crucial, especially when sensitive health information is involved. The lack of adequate protection for user privacy may lead to distrust and resistance among users, impacting their acceptance and engagement with the intervention.

Strengths and Limitations

To the best of our knowledge, this scoping review is the first to comprehensively summarize the theoretical frameworks used in interventions using modern information technologies to enhance HIV/AIDS-related cognition and self-management behaviors. Adhering to the Joanna Briggs Institute framework provides a structured and standardized approach to the scoping review process, enhancing the reliability and reproducibility of the findings. Additionally, it provides an updated integration of recent intervention studies leveraging contemporary digital tools, reflecting the rapid advancements in information technology. By systematically consolidating existing intervention strategies, this review offers diverse possibilities for future research and helps prevent the redundancy of developing similar intervention schemes.

This scoping review has several limitations. First, we excluded gray literature, such as conference abstracts and dissertations, from our inclusion and exclusion criteria, which may have restricted the literature retrieved during the search. Second, all the studies included in the review were in English, potentially overlooking high-quality studies written in other languages. Furthermore, some studies using modern information technologies may have used different keywords, which could have resulted in the omission of relevant research from our review. Finally, as a scoping review, this study does not assess the effectiveness of the interventions, which should be addressed in future systematic reviews or meta-analyses.

Conclusions

This study found that modern information technology has been widely used in designing intervention programs to improve cognitive function and self-management behaviors among people living with HIV/AIDS. These interventions primarily use mobile phones as carriers and the internet as the medium for dissemination. Such technological approaches enable personalized, convenient, and real-time interventions, expanding the methods and avenues of traditional interventions. However, we also observed that most of the included studies have not fully used existing theories or conceptual frameworks in constructing their interventions. The lack of support from theoretical frameworks may lead to research failing to achieve the established goals as originally designed, thereby slowing

XSL•FO
RenderX

the problem-solving process and potentially affecting the final effectiveness.

Acknowledgments

This study was funded by the Capital Health Development Research Program (First Issue 2024-2G-2174). All ideas, writing, and original content in this manuscript were conceived and developed exclusively by the authors. No generative artificial intelligence tools or models were used in the creation of any part of this work.

Data Availability

The datasets generated during or analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

HH and MX designed and produced this manuscript. ZY, MX, and HH contributed to the screening of literature and the creation of summary tables. AW contributed to the conception and design and critically revised the manuscript.

Abstract

Background: Mobile devices offer an emerging opportunity for research participants to contribute person-generated health data (PGHD). There is little guidance, however, on how to best report findings from studies leveraging those data. Thus, there is a need to characterize current reporting practices so as to better understand the potential implications for producing reproducible results.

Objective: The primary objective of this scoping review was to characterize publications' reporting practices for research that collects PGHD using mobile devices.

Methods: We comprehensively searched PubMed and screened the results. Qualifying publications were classified according to 6 dimensions—1 covering key bibliographic details (for all articles) and 5 covering reporting criteria considered necessary for reproducible and responsible research (ie, "participant," "data," "device," "study," and "ethics," for original research). For each of the 5 reporting dimensions, we also assessed reporting completeness.

Results: Out of 3602 publications screened, 100 were included in this review. We observed a rapid increase in all publications from 2016 to 2021, with the largest contribution from US authors, with 1 exception, review articles. Few original research publications used crowdsourcing platforms (7%, 3/45). Among the original research publications that reported device ownership, most (75%, 21/28) reported using participant-owned devices for data collection (ie, a Bring-Your-Own-Device [BYOD] strategy). A significant deficiency in reporting completeness was observed for the "data" and "ethics" dimensions (5 reporting factors were missing in over half of the research publications). Reporting completeness for data ownership and participants' access to data after contribution worsened over time.

Conclusions: Our work depicts the reporting practices in publications about research involving PGHD from mobile devices. We found that very few papers reported crowdsourcing platforms for data collection. BYOD strategies are increasingly popular; this creates an opportunity for improved mechanisms to transfer data from device owners to researchers on crowdsourcing platforms. Given substantial reporting deficiencies, we recommend reaching a consensus on best practices for research collecting PGHD from mobile devices. Drawing from the 5 reporting dimensions in this scoping review, we share our recommendations and justifications for 9 items. These items require improved reporting to enhance data representativeness and quality and empower participants.

Introduction

Collecting Person-Generated Health Data for Research Using Mobile Devices and Their Facilitators

The proliferation of mobile devices boosts the generation of person-generated health data (PGHD). In 2018, more than 80% of Americans owned a smartphone [1,2], with modest growth to 85% by 2021 [3]. Wearable health care devices were used by nearly 28% of the US population by 2020 [4,5]. Among smartphone users, over 50% are collecting "health-associated information" [6]. We use the phrase "person-generated health data (PGHD)" for health-related data created, recorded, or gathered by or from individuals, family members, or other caregivers to help address a health concern inside and outside clinical settings.

PGHD from mobile devices have significant research implications. Mobile devices could facilitate access to large pools of study participant data in a granular, longitudinal, and personal way, potentially accessing high-frequency data at low costs [7]. In this study, "mobile devices" refers to smartphones and wearables, which include fitness trackers and smartwatches; "research" covers biomedical and behavior studies [8].

Because of the above advantages, researchers have made numerous efforts to collect PGHD for mobile device research. Those efforts are enabled by participants willing to share their PGHD for research [9] and by using the informatics infrastructure needed for participants to share their data. Examples of informatics infrastructure to enable PGHD sharing for research dates from 2015 and 2016, with the releases of ResearchKit (Apple Inc) [10,11] and ResearchStack (Cornell Tech and Open mHealth) [12,13] and the launch of mPower [14], Sage Bionetwork's first major smartphone-based health research study. Research practices dealing with PGHD from mobile devices are, in part, guided by the European Union's General Data Protection Regulation (published in 2016; in effect since 2018) and the Food and Drug Administration's guidelines on clinical research, medical devices, and mobile health apps (released in 2013, 2015, and 2019). Between 2000 and 2020, more than 12,000 mobile device–related health research papers were published [15].

Potential Issues With Data Representativeness and Quality When Collecting Person-Generated Health Data From Mobile Devices

Despite the potential advantages of using PGHD for mobile device research, the wide variety of practices to collect PGHD may lead to issues with data quality. These issues may be due to emerging research strategies such as Bring-Your-Own-Device (BYOD; which uses participant-owned devices instead of provisioned devices) that can miss some patient demographics [16], thus leading to low generalizability. Similar issues are noticed in studies using crowdsourcing platforms to collect data [17]. Selection bias with wearables is a significant issue due to differences in access [18,19], which in turn can lead to differences in sharing data for research [20]. Both accessibility and self-selection could lead to lower study sample diversity for race and socioeconomic status. For example, National Institutes of Health's All of Us program allows participants to choose to contribute Fitbit (Google LLC) data through its BYOD subprogram. The All of Us BYOD subprogram has noticed a higher proportion of participants who are White, earn >US $25,000/year, and have college or advanced degrees in the BYOD subgroup compared with all participants [21]. When such data are used in machine learning, the low representation of some patient groups may lead to poor prediction accuracy when applied to those groups [22,23].

Motivation for This Work

To better understand methodological issues such as those related to data representativeness and quality, we aimed to review publications on research collecting PGHD from mobile devices and to characterize the reporting elements of that research thoroughly, particularly those elements relevant to BYOD and crowdsourcing. In doing so, we sought to capture aspects of this field not addressed by previously published reviews. Several reviews explore mobile health research. A review by Cao et al [15] covering the years 2000 to 2020 and a review by El-Sherif et al [24] covering 2020 to February 2021 identified 4 leading contributors (the United States, the United Kingdom, Canada, and Australia). The 2 reviews, however, focused only on bibliometrics. A scoping review by Fischer and Kleen [25] published in 2021 investigated data collection by smartphone apps in longitudinal epidemiological studies, and they found a limited number of studies that integrated apps in data collection. Studies with cross-sectional designs were excluded. A scoping review by Huhn et al [26] published in 2022 summarized wearables in health research and found that most studies were observational and that 93% of the participants were in global health studies. Smartphones were not included in their scope. Other reviews of interest include one that briefly mentioned data collection using mobile devices for health research [27] and another that discussed the application of sensors (eg, inertial measurement units) in health care [28]. Our review differs from these reviews by covering wearables and smartphones and their use to collect PGHD in research. We also attempt to be comprehensive in our characterization of reporting practices, our inclusion of a range of study types (eg, both longitudinal and cross-sectional studies), and our examination of bibliographic information. To the best of our knowledge, ours is the first review of publications on research collecting PGHD from mobile devices and the first to examine BYOD practices and the use of crowdsourcing platforms in this field.

This review characterizes the reporting elements of included publications and discusses the relevance of reporting practices

XSL•FO
RenderX

for supporting reproducible and responsible research. There are no current, ready-to-use guidelines for reporting research involving PGHD from mobile devices. For example, the Future of Privacy Forum's "Best Practices for Consumer Wearables & Wellness Apps & Devices" dates back to 2016 [29]. More recently, the Office of the National Coordinator for Health Information Technology released a white paper in 2018 to conceptualize a data infrastructure for the capture, use, and sharing of PGHD in care delivery and research through 2024 [30]. The final document, however, is still under development. Also relevant are the Structured Template and Reporting Tool for Real-World Evidence (STaRT-RWE) (2021) [31] and the Mobile Health Evidence Reporting and Assessment (mERA) checklist (2016) [32], although both are limited. STaRT-RWE does not specify requirements for mobile device studies, and mERA is limited to health interventions. There are also some focused guidelines for app development (2016) [33] and data integration (2021) [34], but none fully cover what is needed for high-quality reporting of mobile device research. In fact, reporting deficiencies are widely noted in studies involving mobile devices. A systematic review by Olaye et al [35] in 2022 found that 30% of publications failed to report quantitative adherence; such missingness can impede a complete understanding of study data. Our review characterizes the magnitude and types of reporting problems in publications on research collecting PGHD from mobile devices.

Methods

We performed a scoping review following the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist (Multimedia Appendix 1) [36]. The scoping review first involved implementing a comprehensive search and screening strategy. Next, the selected articles were characterized according to their bibliographic details and 5 reporting dimensions.

Search Strategy

A PubMed search was used to find instances of explicitly described participant data contributions (eg, through the use of language such as "data donation," "data sharing," etc) involving wearables, smartphones, or mobile apps (Textbox 1). A MeSH (Medical Subject Headings) term analysis of a preliminary sample of articles was conducted to support PubMed query development (Yale MeSH Analyzer [37]). We selected search terms to balance recall and precision in the search results. We ran the PubMed search on August 7, 2021.

Screening and Data Charting

Covidence [38] was used to screen publications for eligibility in 2 steps, first by eliminating publications based on a title and abstract review and then by reviewing the full text of the remaining journals. A pre-established set of eligibility criteria was used for screening (Table 1). As this an emerging field and our motivation to see the trends in full landscape, we did not set criteria for time range. Screening decisions were made only after 2 independent reviewers on the screening team (SS, MA, and RHY) agreed. All conflicts were resolved by group discussion. Library journal subscriptions and interlibrary loan were used to obtain full text, with the full text of 1 publication [39] not available from either source. All reviewers conducted pilots for each round of screening.

We charted publications for bibliographic details and along 5 reporting dimensions ("participant," "device," "data," "study," and "ethics"; double quoted here and in the text below). Because our focus is on health data contributions from participants through BYOD and crowdsourcing platforms, we modeled the reporting dimensions on existing work in the areas of citizen science data contribution [40], bioethical approaches to using personal health data [41], and mobile health apps [42]. Upon

XSL•FO
RenderX

reviewing the keywords of included publications (eg, “ethical code,” “consent,” and “informed consent”), we summarized frequent themes of keywords (eg, consent). Furthermore, we refined our charting template by selecting factors related to those frequent themes to improve data adequacy. The final factors included under the 5 reporting dimensions are listed in Table 2. A data charting pilot with a random sample of one-fifth of the final pool of publications was conducted before finalizing the data charting template [43]. A team of 4 reviewers (SS, MA, RHY, and ZL) charted the data using the template built in Covidence [38]. In addition, 2 reviewers independently charted each publication. Consensus was reached by group discussion.

Table 1. Inclusion and exclusion criteria overview.

Theme	Criteria
Phenomenon of interest	Data contribution (ie, data donation or data sharing).
Technology	Wearables, smartphones, or mobile applications: limit the scope of wearables to fitness trackers and smartwatches and include surveys through smartphone applications. Exclude surveys through websites.
Perspective	Individual: individual refers to either patient or nonpatient and exclude data transfer between researcher and researcher, researcher and organization, and organization and organization.
Goal	Collected data is used for research.
Data Type	Data concerning human health.
Study Type	—[a]
Language	English.
Time	—

[a]Not applicable.

XSL•FO
RenderX

Table 2. Definitions of 24 factors under bibliographic details and 5 reporting dimensions.

Factors	Definitions
Bibliographic details (3 factors)	
Publication year	• The year of publication, not the year of submission or acceptance.
Publication location	• The country or area of the affiliation of the first author or first authors.
Publication type	• Research: original research publication. • Protocol: protocol or proposal for original research. • Tech: publication describing a dataset, database, mobile app design, platform, or algorithm; or use case report. • Review: systematic review, scoping review, or any other type of review. • Other: including viewpoint, perspective, editorial, commentary, correspondence, letter, or needs assessment; mostly about ethics and regulations.
Reporting dimensions (21 factors)	
"**Participant"**	
Identity of data subject and data contributor	• This factor examines the question, "Are the data subject and data contributor the same individual?" • Participant in a study could be either data subject or data contributor. • Data subject refers to the person whose data is collected, held, or processed. • Data contributor refers to the individual who provides information for a research study. • Data contributor may contribute data on behalf of data subject. Data contributors may include, but are not limited to, guardians of children, health care providers of patients, and sheriffs or jail administrators of prisoners. • Identity refers to whether the data subject and data contributor are the same individual.
Living status of data subject	• Whether data subject is living or not at the moment of data contribution to research.
Purpose of data generation	• Whether the data contributed to research were generated particularly for this research or generated for other purposes and then used for research. If data were generated for participants themselves during routine use (eg, self-management), this is an example of "other purposes," and it is marked as "for self."
"**Device"**	
Device owner	• Owner of the device used to generate the data, not the owner of device used to transfer the data, although the 2 devices could be the same.
Device type	• Wearable devices include fitness trackers and smartwatches.
Data capture mode	• Passive or active.
"**Data"**	
Data type	• Location data is any type of data revealing location, which may include, but is not limited to, GPS data and self-reported location data. Genetics-biospecimen data may include, but is not limited to, genetics data extracted from biospecimens. • Genetics-non-biospecimen data may include, but is not limited to, genetics data not extracted from biospecimens; for example, data from commercial genetics tests. • Claims or administrative data may include, but is not limited to, insurance claims data and administrative data such as length of stay, date of service, etc. • Clinical data may include, but is not limited to, electronic health records (eg, laboratory results, vital signs, and treatments), health surveys, clinical trial data, and patient or disease registries. • Mental health or lifestyle data are those not included in the categories above. They may include data relevant to, but not limited to, mental health, diet, physical activity, or sleep.
Data owner	• Data ownership is charted based on explicit statements in the text of publications.
Participant access to data after contribution	• Whether participants can access contributed data after data contribution.
"**Study"**	
Research scenario	• Nonprofit, commercial, or public health.
Purpose of data collection	• For primary, secondary, or both primary and secondary data analysis.

XSL•FO
RenderX

Factors	Definitions
Used crowdsourcing platform to collect data	• In our review, we focused on crowdsourcing platforms for data collection. These platforms have 3 essential properties, that are researchers can access potential participants through the platform, researchers can distribute tasks to participants through the platform, and the number of potential participants and enrolled participants is large. Platform examples include Amazon Mechanical Turk and PatientsLikeMe (PatientsLikeMe website).
Research design	• Observational or experimental.
Design duration	• Cross-sectional or longitudinal, not restricted to observational studies.
Attrition reported	• Whether the publication reported attrition or not. In our review, we define attrition as "the loss of eligible participants from research at any time following consent to participate" (adapted from Siddiqi et al [44]).
"Ethics"	
Consent reported	• Whether the publication reported consent or not.
Informed consent reported	• Whether the publication reported informed consent or not.
Consent type	• Consent type is charted based on explicit statements in the publication's text or on the reviewer's best assumptions according to details mentioned in the publication. • Blanket consent: a process by which participants contribute their data without any restrictions [45]. • Broad consent: a process by which participants contribute their data, subject to specified restrictions, for multiple future studies in a broad range, the nature and specificities of which are unknown at the time of consenting [45,46]. • Tiered consent: a process by which participants have the option of giving broad consent for only certain types of research or research uses, including for only specific diseases or indications (eg, neurological diseases), for only publicly funded research, or for only specified institutions or researchers. With tiered consent, participants can also choose whether their data are identifiable or anonymized [47]. • Meta consent: a form of tiered informed consent in which participants can choose a different consent option within different research tiers. For example, a participant could give broad consent to all research conducted in certain institutions but only study-specific consent for genomic research or privately funded research [47]. Suppose a study reports both meta-consent and dynamic consent[a]. In that case, this study will be marked as "meta consent" because dynamic consent is considered to be a characteristic of meta consent by some, but not all, researchers. However, if a study only reports dynamic consent, this study will not be marked as "meta consent" or any other consent because dynamic consent itself is not a consent model [46]. • Explicit consent: a process in which the data subject must give an express statement of consent. An explicit consent statement should specifically refer to (1) the particular dataset that is to be processed, (2) the precise purpose of processing (including any automated decision-making), (3) any risks or implications that might arise for the data subject as a result of the data processing, and (4) any other relevant and specific information that might influence the decision of a data subject to give or not give their consent [48]. Here, explicit consent is used interchangeably with study-specific consent. With study-specific informed consent, research participants consent to their contributed data being used in a single specific research study. If researchers choose this form of consent, they will need to contact data contributors whenever they want to use a particular data point in a new study [47].
Consent subject	• Whether or not the publication reported consent subjects. Consent subjects are individuals who are consented to participate in research studies.
Right to opt-out reported	• Whether or not the publication mentioned the participants' right to opt out of research at any time.
Monetary benefits	• "Unconditional" refers to scenarios where participants can receive monetary benefits as long as they participate, no matter their responses or engagement. • "Conditional" refers to scenarios where participants can receive monetary benefits if they satisfy specific criteria after participation.

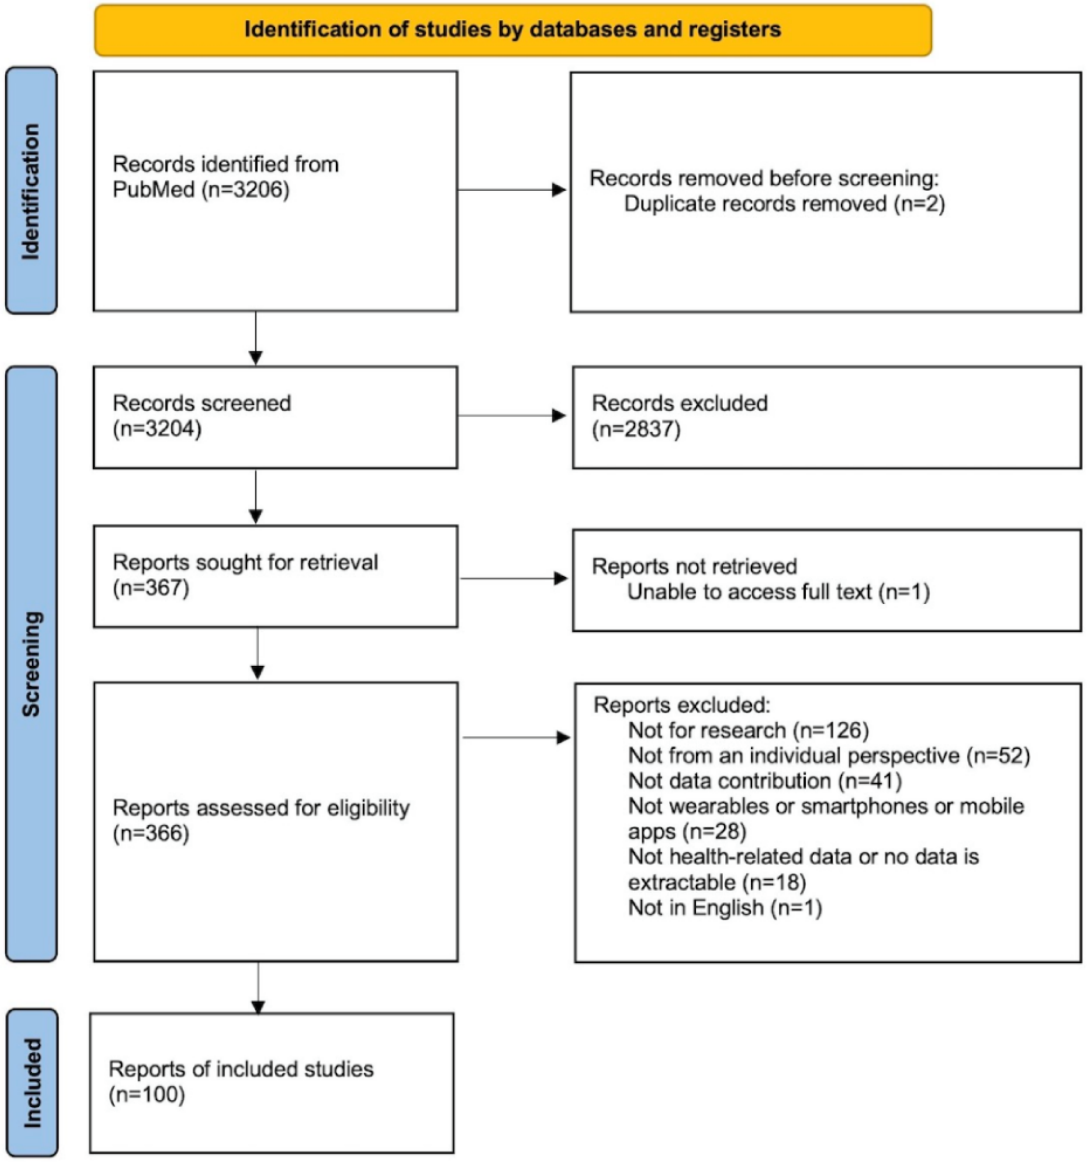
[a]Dynamic consent is a process facilitated by collaborative and online digital platforms that allows participants to regularly check research activities and modify their consent for any upcoming research projects [46,47]. Dynamic consent can also be described as an approach to consent that enables ongoing engagement and communication between individuals and the users and custodians of their data [49].

Data Analysis and Visualization

To determine the leading countries and their contributions to various publication types, we compared the counts and percentages of publications by type and location. In addition, we visualized the number of publications by year to evaluate publication trends. We also visualized publication counts by year and location for original research publications. Reporting dimensions, including factors concerning "participant," "device," "data," "study," and "ethics" (Table 2), were analyzed

XSL•FO
RenderX

for original research publications only. We charted the frequency and percentage of original research studies that included these 21 reporting dimension factors.



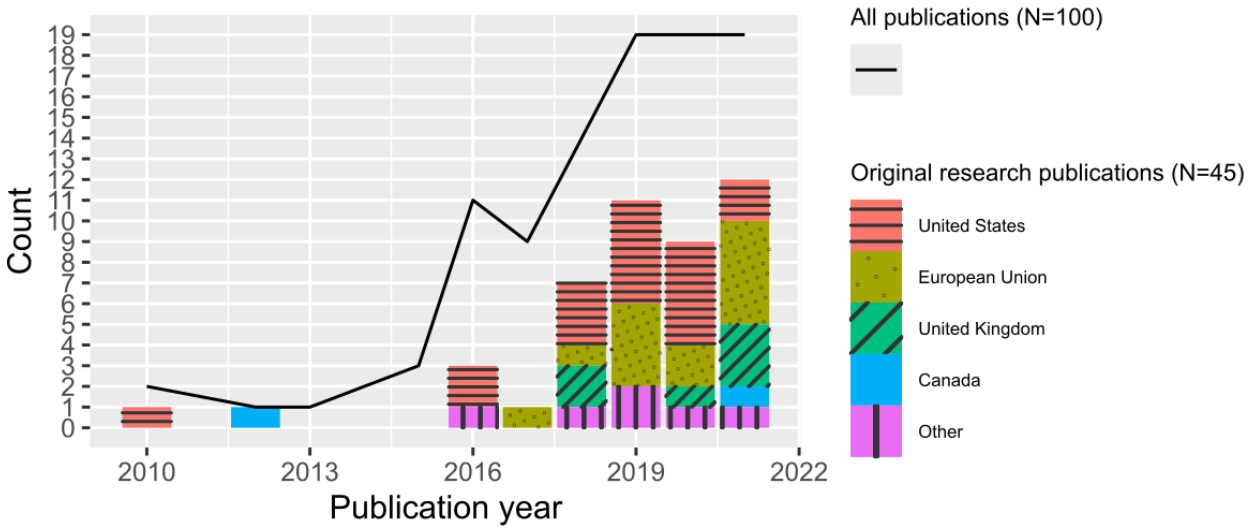
In addition, 4 factors with multiple-choice options were visualized using Venn (if options ≤3) or alluvial (if options >3) diagrams after excluding publications that did not report these factors. These 4 factors included 1 "device" dimension factor (device owner), 2 "data" dimension factors (data type and data owner), and 1 "study" dimension factor (research scenario). We also analyzed publications according to the frequency of data types collected. We assessed missing factors among original research publications to evaluate changes in reporting deficiencies for each reporting dimension. We compared the percentages of publications missing factors between 2 temporal groups (2010-2016 and 2017-2021). All analyses and visualizations were performed using R (version 4.2.1; R Core Team).

Results

Search and Data Charting

Our search strategy yielded 3206 results. A total of 100 publications remained following screening [50-149]. All 100 articles are included in our data analyses (Figure 1; bibliographic information in Multimedia Appendix 2).

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping reviews) flow diagram.



Trends by Publication Year, Location, and Publication Type

Publication year and location were extracted from the 100 included articles and organized by publication type (Figure 2, Multimedia Appendix 3). The majority of publications had a first author from the United States (46%, 46/100), European Union (20%, 20/100), United Kingdom (11%, 11/100), or Canada (6%, 6/100). Publications designated as "Research" (original research) made up the largest proportion of publications (45%, 45/100). These were followed by publications designated as "Tech" (20%, 20/100), "Other" (17%, 17/100), "Review" (13%, 13/100), and "Protocol" (5%, 5/100). Refer to Table 2 for definitions of these publication types.

XSL•FO
RenderX

There was a spike in total publications in 2016, with 11 publications in 2016 compared with 3 or fewer annually beforehand. Since 2016, a minimum of 9 publications have been published annually. There was another spike in output in 2019, with 19 publications. Other trends observed were US-dominant "Tech" publications and diversely geolocated "Review" publications.

Figure 2. Bibliographic details of all publications by year and original research publications by year and location (data from January 2010 to August 2021).

Reporting in Original Research Publications

Reporting of Participant Factors

Most publications (78%, 35/45) declared or implied that the data subject and contributor were the same individual. Almost all data subjects (96%, 43/45) were living at the time of data contribution. In most publications, analyses were conducted using data generated by data subjects for themselves during routine use (56%, 25/45) rather than explicitly for research (11%, 5/45; Table 3).

[a]Levels below reporting factors were cleaned to be binary if multiple choices were possible.

Reporting of Device Factors

Among publications reporting the device owner, more reported that devices were owned by participants (data subject or data contributor) than were owned by researchers (75%, 21/28 vs 32%, 9/28; Figure 3A). Furthermore, 2 publications reported a mix of device ownership (owned by data subject, data contributor, and researcher), indicating a transfer of ownership (ie, participants retained the provisioned device after the study). Wearables were more often used with smartphones than used alone (wearables and smartphones 44%, 20/45 vs wearables alone 16%, 7/45; Table 3). Most publications reported a combination of active and passive data capturing, and active-alone and passive-alone data capturing were equally popular (active and passive 49%, 22/45 vs active-alone 18%, 8/45 vs passive-alone 18%, 8/45; Table 3).

Figure 3. Publication counts for 4 reporting factors with multiple choices possible, excluding publications that did not report these factors, (A) device owner, (B) data type, (C) data owner, and (D) research scenario. The data type figure includes a table presenting publication counts by the number of reported data types.

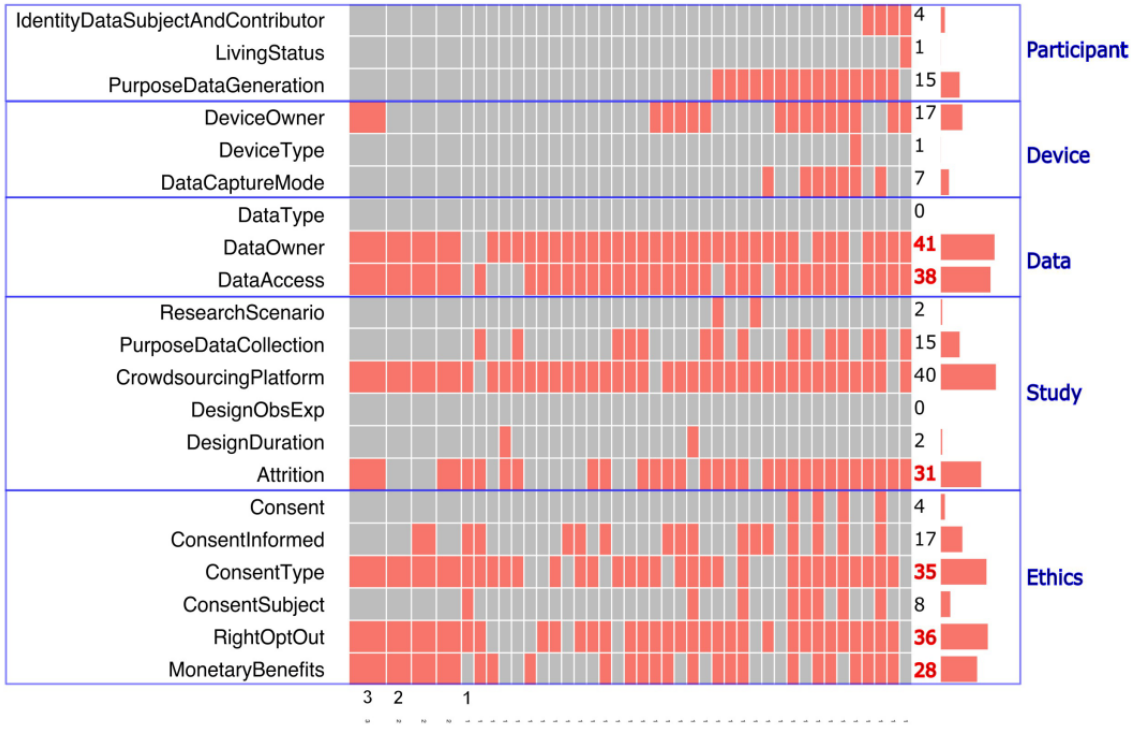
XSL•FO
RenderX

Reporting of Data Factors

With multiple choices possible, the mental health or lifestyle data type (84%, 38/45; Table 3) was the most collected, followed by clinical (56%, 25/45) and location (40%, 18/45) data types. In comparison, genetics data types (biospecimen 4%, 2/45 and nonbiospecimen 7%, 3/45 [Table 3]; in total 11%, 5/45 [Figure 3B]) and insurance claims or administrative data type (2%, 1/45; Table 3) were seldom collected. Most publications reported more than one data type (80%, 36/45; refer to table in Figure 3B). Overall, 40% (18/45) of publications' collected data included clinical data and mental health or lifestyle data (Figure 3B). No dominant data ownership arrangement was observed (data subject 7%, 3/45 vs data contributor 9%, 4/45 vs company 7%, 3/45; Table 3).

Reporting of Study Factors

Most studies that reported research scenarios were conducted within a strictly nonprofit milieu (47%, 20/43; Figure 3D). No study collected data solely for secondary analysis purposes (Table 3). A limited number of publications reported using crowdsourcing platforms to collect data (7%, 3/45; Table 3). Most studies were observational (91%, 41/45; Table 3). A prevalence of cross-sectional designs over longitudinal designs was observed (56%, 25/45 vs 40%, 18/45; Table 3).



Reporting of Ethics Factors

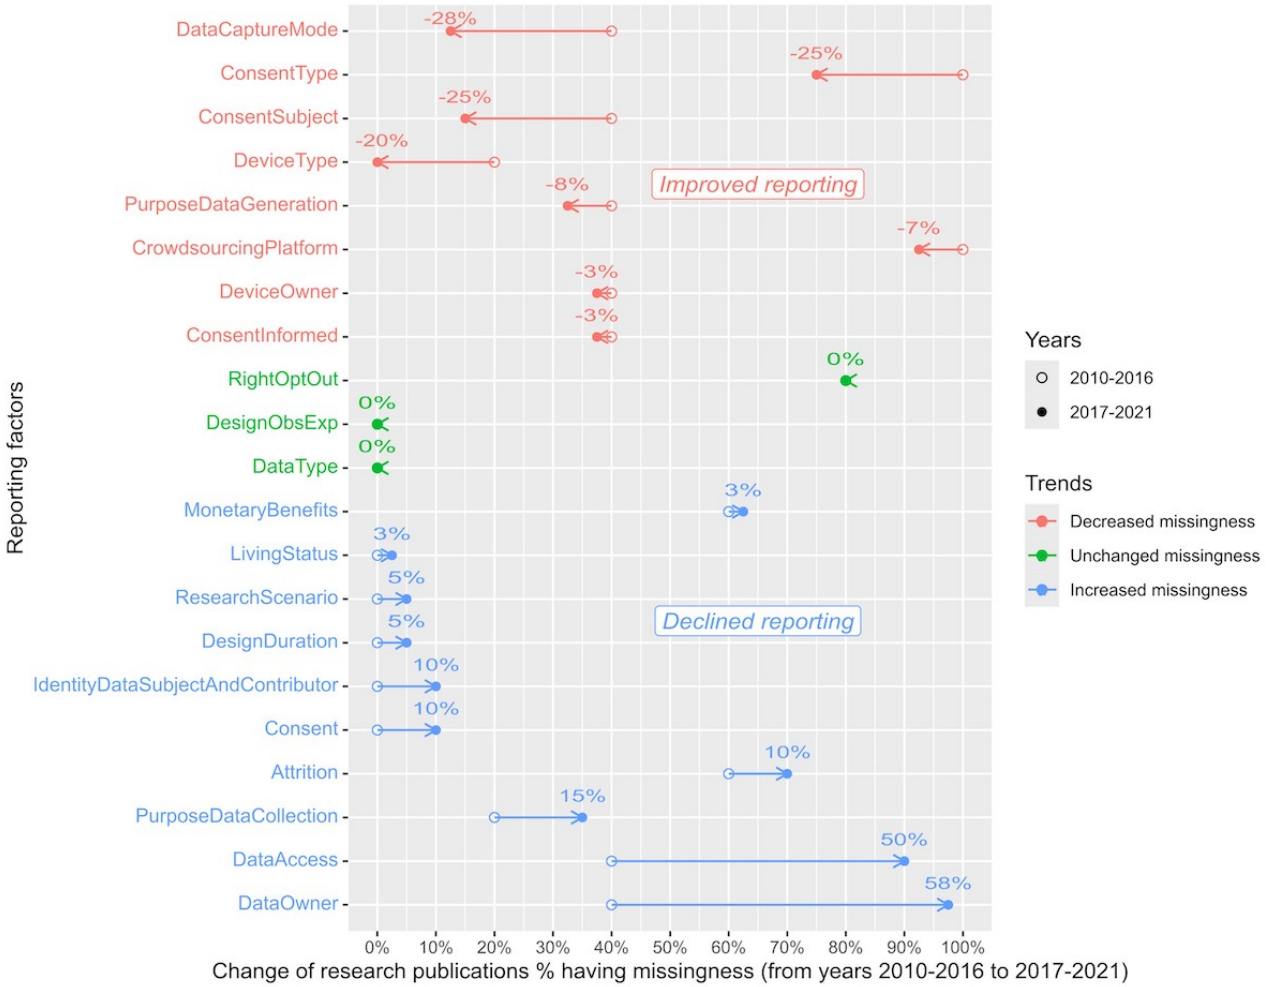
No publication reported blanket or meta-consent (Table 3). Among those publications reporting monetary benefits for participation, more than one-third reported giving no monetary benefits to participants (35%, 6/17; Table 3).

Reporting Deficiencies in Original Research Publications

The number of publications that missed reporting at least 1 factor under the 5 reporting dimensions broke down as follows: 36% (16/45) for the "participant" dimension, 42% (19/45) for the "device" dimension, 96% (43/45) for the "data" dimension, 78% (35/45) for the "study" dimension, and 96% (43/45) for the "ethics" dimension (Figure 4).

Figure 4. Missingness in 21 reporting factors in original research publications (N=45). The red color represents instances of missingness. Publication counts on the right vertical axis are highlighted in red if missingness existed in more than half of the publications for a particular reporting factor (excluding the factor "CrowdsourcingPlatform" for those that used crowdsourcing platforms to collect data). For a definition of each reporting factor, refer to Table 3.

Except for the data type factor ("DataType") and the observational or experimental study design factor ("DesignObsExp"), missingness existed in most factors under the 5 reporting dimensions. In total, 6 factors had missingness in more than half of the original research publications: data owner (91%, 41/45), participant access to data after data contribution (84%, 38/45), right to opt out (80%, 36/45), consent type (78%, 35/45), monetary benefits (62%, 28/45), and attrition (69%, 31/45). These 6 factors were often missing together (Figure 4).



The factor for marking studies that used crowdsourcing platforms to collect data ("CrowdsourcingPlatform") was excluded from the reporting deficiency analysis because using these platforms is optional for research.

Trends in reporting deficiencies were observed in original research publications over time. Reporting deficiencies were measured by the absence, or missingness, of specific reporting factors, with increased missingness reflecting declining reporting performance and decreased missingness reflecting improving reporting performance. The reporting performance of some

XSL•FO
RenderX

reporting factors showed declines and others improvements when compared across the years 2010-2016 and 2017-2021. Furthermore, 2 factors in the "data" dimension exhibited substantial declines in reporting performance: data owner (58% change in missingness; from 2/5, 40% in 2010-2016 to 39/40, 98% in 2017-2021) and participant access to data after contribution (50% change in missingness; from 2/5, 40% in 2010-2016 to 36/40, 90% in 2017-2021). In contrast, 4 factors in the "device" and "ethics" dimensions exhibited substantial improvements in reporting performance: data capture mode (–28% change in missingness; from 2/5, 40% in 2010-2016 to 5/40, 13% in 2017-2021), device type (–20% change in missingness; from 1/5, 20% in 2010-2016 to 0/40, 0% in 2017-2021), consent type (–25% change in missingness; from 5/5, 100% in 2010-2016 to 30/40, 75% in 2017-2021), and consent subject (–25% change in missingness; from 2/5, 40% in 2010-2016 to 6/40, 15% in 2017-2021). The magnitude of change in the percentage of publications with missingness was substantial if the absolute value of the difference was equal to or greater than 20% (Figure 5 and Multimedia Appendix 4).

Figure 5. Shift in the reporting deficiencies of original research publications, measured by the % of missingness across 21 factors between 2010-2016 and 2017-2021 (sorted by % change). For a definition of each reporting factor, refer to Table 3.

Discussion

Principal Results

We have characterized the reporting practices of published research studies that collected PGHD using mobile devices. Our findings show that the United States has gained momentum in publishing in this area over the past decade (Figure 2). In addition, a high proportion of the original research articles we identified used participant-owned devices or a BYOD strategy if they reported device ownership (75%, 21/28; Figure 3A), with few studies collecting data using crowdsourcing platforms (7%, 3/45; "Used crowdsourcing platform to collect data" in Table 3). We also found reporting deficiencies in the "data" and "ethics" dimensions among original research articles, where most original research articles were deficient in at least 1 factor concerning "data" (96%, 43/45) or "ethics" (96%, 43/45; Figure 4).

Trends by Publication Year, Location, and Publication Type

Our analysis of publications by year and location echoed trends seen in the field, with publication spikes in 2016 and 2019 and stable development afterward (Figure 2). Like others [15,24], we found that the United States is a leading contributor to these publications. Furthermore, the United States dominates contributions in several publication types, including original research (Multimedia Appendix 3).

XSL•FO
RenderX

Reporting in Original Research Publications

In the "participant" reporting dimension, we found that the mobile device data used for research were more often generated by participants for themselves through routine use rather than generated explicitly for research (56%, 25/45 vs 11%, 5/45; "Purpose of data generation" in Table 3). However, the quality of data acquired for routine use may not meet data quality requirements for research. For instance, individuals engaging in routine device use may not be trained in the best way to wear and use the device to ensure high-quality data collection, thereby leading to potential issues with low or missing wear time and user errors that impact the completeness and correctness of the collected data [150]. Systematic data quality assessment tools have been developed specifically for the secondary use of PGHD collected from mobile devices. These tools address the quality issues of routine use data by recommending research reporting clarity on the definition of nonwear time, the threshold for valid records, the definition of data completeness, and the identification of outliers [151].

In the "device" reporting dimension, among publications that reported device ownership, we found that three-quarters of original research publications (21/28; Figure 3A) reported using mobile devices owned by participants (data contributors or data subjects), which implies the popularity of the BYOD strategy. As mentioned in the introduction, BYOD may bring bias into demographics through disparate accessibility to device and self-selection, thus a comprehensive guideline on using BYOD to collect PGHD, which is not available so far, is a need. As an alternative to BYOD, some researchers provide devices to participants (9/28; Figure 3A). In our review, for studies that provided devices to participants, participants in 2 of them (Figure 3A) retained the device after the study (shown in Figure 3A as a mix of device ownership). This strategy may serve as an incentive and help improve device use simultaneously. In our own research [152], however, we found that providing a device when recruiting study participants for cardiovascular wearable studies did not improve sample representativeness in age, race, and education. Thus, more work is needed to understand effective incentives to participate in research that collects PGHD from mobile devices such that recruitment would lead to a more representative study sample.

We found that wearables were predominantly used as secondary devices connected to smartphones rather than as standalone devices (44%, 20/45 vs 16%, 7/45; "Device type" in Table 3), indicating that barriers may exist to the direct collection of data from wearables for research purposes. Evidence to support this supposition is provided by a study published in 2023 [153] that reported that among those who expressed a willingness to share data from a wearable, only 25% deposited their data in the study's research database. The primary reason for the refusal to deposit data was the inconvenience of the data transfer process. Previous research findings [154] have also raised concerns that wearables may be less sustainable than smartphones for remote monitoring over long periods [155]. However, the reliance on a smartphone for data transfer is not ideal if other data are not collected by the smartphone, such as information about heart rate or sleep. A review published in 2022 [156] found that a limited number of mobile health apps use Bluetooth, and an even smaller number use standard Bluetooth Low Energy. This indicates a potentially low capability of smartphone apps to interact with external devices, including different types of wearables.

Researchers adopt mobile devices for research due to their ability to capture data passively, thus reducing recall bias introduced by active approaches (eg, surveys). Our findings, however, suggest that active and passive data capturing were equally popular (18%, 8/45 for each; "Data capture mode" in Table 3) and frequently used in tandem (49%, 22/45; "Data capture mode" in Table 3). Researchers may have hesitated to depend solely on passive data collection because this approach can result in low participant engagement due to privacy concerns [157] and potential data quality issues [150]. An approach that uses both passive and active data collection can offer more comprehensive data and enable cross-validation of responses through data linkages.

In the "data" reporting dimension, a majority of the publications reported collecting multiple data types (80%, 36/45; refer to table in Figure 3B). Furthermore, 40% (18/45) of publications' collected data include clinical data and mental health or lifestyle data (Figure 3B). A subset of these publications indicated that clinical data were collected from participants' electronic health records, reflecting progress made to integrate mobile device data into electronic health records [158]. Studies seeking to connect multiple data types from study participants should exercise caution due to the increased risk of participant reidentification [6].

We found that certain data types were more infrequently collected than others. For example, insurance claim and administrative data were rarely collected (2%, 1/45; "Data type" in Table 3). This gap may be because of difficulties linking these data to other data [159]. Also, despite advancements in informatics infrastructure (eg, the HL7 FHIR [Fast Health Interoperability Resources] API) enabling patients to download these data (eg, Medicare claims and encounter data through Blue Button [160]), only a limited number of beneficiaries have done so. For example, while Blue Button, available since 2010, has been used by over one million Medicare beneficiaries [161], this is a small fraction of the 65 million people covered by Medicare as of 2022 [162]. Genetics data collection was also rare (11%, 5/45; Figure 3B), which is consistent with the prevailing observation that a limited number of genomics mobile apps serve to collect data, compared with other tasks (eg, education and communication) [163,164].

In the "study" reporting dimension, only 7% of original research publications used crowdsourcing platforms to collect data (3/45; "Used crowdsourcing platform to collect data" in Table 3), which may indicate a scarcity of streamlined mechanisms for using these platforms. Given the growing popularity of BYOD research, there is an opportunity for improved mechanisms to leverage such platforms to transfer data from device owners to researchers. We also found that the majority of the studies were observational (91%, 41/45; "Research design" in Table 3), aligning with previous research [26]. Although mobile devices enable facile longitudinal data collection, we discovered a slightly greater prevalence of cross-sectional studies over

XSL•FO
RenderX

longitudinal studies (56%, 25/45 vs 40%, 18/45; "Design duration" in Table 3). This could be due to researchers' apprehensions about device fatigue [165] and stakeholders' concerns regarding privacy [166].

In the "ethics" reporting dimension, we explored factors such as consent models and monetary benefits because they are relevant to the likelihood of participants to share data. For example, consent models, as noticed in a survey conducted by Ko¨ngeter et al [167], have different acceptance rates among patients with cancer. In our scoping review, we found no publication reported blanket or meta consent ("Consent type" in Table 3). Since no studies collected data purely for secondary analysis ("Purpose of data collection" in Table 3), the preference for nonblanket consent was justified. Despite debates about meta consent [168] and dynamic consent [49] as solutions for modern research, our finding that no studies used meta (dynamic) consent aligns with critics who posit that these innovative approaches require highly participatory technological platforms and may introduce bias due to participants' technical competence [169]. Over one-third of the original research publications that reported on monetary benefits provided no monetary benefits to participants (35%, 6/17; "Monetary benefits" in Table 3). Research generally indicates that even small monetary incentives increase consent and response rates [170], irrespective of risk level [171]. However, the impact of monetary benefits on wearable study participation remains undetermined and requires examination on a case-by-case basis (eg, for studies conducted on Amazon Mechanical Turk [9]) given the diversity of mobile device studies.

Prevalence of Reporting Deficiencies in Original Research Publications

Our results show a high level of reporting deficiencies in the "data" and "ethics" dimensions (Figure 4), with 5 reporting factors missing in over half of the original research publications—data ownership (91%, 41/45), participant access to data after data contribution (84%, 38/45), right to opt out (80%, 36/45), consent type (78%, 35/45), and monetary benefits (62%, 28/45). Among these 5 factors, we also noticed a trend over time of significantly declined performance in the reporting of data ownership (40% missingness, 2010-2016 vs 98% missingness, 2017-2021; Figure 5) and participant access to data after contribution (40% missingness, 2010-2016 vs 90% missingness, 2017-2021). However, over time, there was a significantly improved performance in reporting consent type (100% missingness, 2010-2016 vs 75% missingness, 2017-2021). In the "study" dimension, nearly 70% (31/45; Figure 4) of original research publications failed to report study participant attrition.

Recommendations for Reporting Based on Findings From This Review

Our findings highlight several areas to consider when reporting research with PGHD collected using mobile devices. Recommendations for reporting based on findings from this review are summarized in Table 4. Further work is needed, however, to gain consensus on a more comprehensive set of reporting items. Such a consensus on best practices would greatly facilitate responsible and reproducible research and improve research quality and impact [172]. For example, a 2012 systematic review indicated a positive association between journal endorsements of a reporting guideline and the quality of reporting in randomized clinical trials published in those journals [173]. Another study looking at the publications from one journal found that those publications whose papers received editorial interventions designed to ensure adherence to reporting guidelines were more highly cited, with citation counts 43% higher than those publications that had not received the editorial interventions [174].

Table 4. Recommendations for reporting research with PGHD[a] collected using mobile devices.

Reporting dimension	Reporting phenomena identified in this scoping review	Justification to include reporting dimension as a best practice
"Participant" (1 item)	• "Purpose of data generation" item: Many publications reported the use of real-world PGHD from study participants (ie, not collected in controlled or experimental settings).	• More detailed practices for correcting data quality issues that can arise with real-world PGHD should be documented so that others pursuing similar research can learn what works and does not work.
"Device" (2 items)	• "Device owner" item: Many papers reported using a device owned by participants. • "Device type" item: Many publications reported using wearables as secondary devices (ie, used with smartphones instead of as standalone devices).	• The practice of using participant-owned devices should be monitored closely as there is potential for disparities in study participation for some groups due to a lack of device access. • More details on the data transfer process should be given in study designs. It influences the ability to participate in research and the types of data that can be collected.
"Data" (2 items)	• "Data owner" and "participant access to data after contribution" items: Publications largely lack descriptions of data ownership and often fail to describe how study participants can access their shared data.	• If strategies for empowering study participants to maintain data ownership are not documented, studies cannot be performed to measure the effectiveness of these strategies or point to new approaches.
"Study" (1 item)	• "Attrition (reported)" item: Attrition is often not reported.	• Attrition can introduce selection bias and reduce statistical power due to data missingness [35]. Attrition should be documented so that others can evaluate the quality and fairness of data analyses.
"Ethics" (3 items)	• "Consent type," "right to opt out (reported)," and "monetary benefits" items: Descriptions of consent types, the rights of participants to opt out, and monetary benefits (if provided) are largely missing from publications.	• Options provided to participants at the time of recruitment may influence their willingness to participate in research [167,170] and thereby influence the composition of the study population. Such options also inform the ethical assessment of a study.

[a]PGHD: person-generated health data.

Limitations

Our review has limitations related to how we gathered evidence from the literature, our choice of reporting factors, and one of our data analysis methods.

Our PubMed search strategy (Textbox 1) has concepts with explicit data donation and data sharing terms to retrieve publications that describe participant data contributions. Because of this design, the search strategy only retrieved publications whose titles and abstracts had data donation and data sharing terms. Possibly, our search missed relevant publications that described participant data contributions only in the full text. The articles we analyzed were only collected from PubMed. Articles were not retrieved from other databases (eg, Embase or Web of Science), from the reference lists of included articles, or from the gray literature. Thus, it is possible that articles only available through these other sources were overlooked. Our preliminary searches, however, suggested that PubMed provided literature coverage sufficiently comprehensive for our research objectives.

While we selected reporting factors relevant to our goal of reviewing research that collects PGHD using mobile devices with the perspective of an individual's data contribution, we may have excluded relevant factors. For example, we did not include the demographic factors of study populations, which may be more broadly relevant to wearable PGHD research. Detecting the low representation of some groups when using wearables for PGHD collection can indicate where biases exist that could lead to downstream inequities. This need is apparent based on findings that aging populations were underrepresented in studies with wearables [175] and that studies of cardiovascular disease that involve wearables [175]. Such a need requires domain-specific examinations, and we regard it out of the scope of this review, which aims to explore the landscape as the first step. As an example of a second-step effort, we have investigated the studies of cardiovascular disease that involve wearables, and we noticed that they did not reflect the demographics of patient populations in terms of age, race, education, cigarette smoking status, and hypertension status [152].

We lowered the granularity of some factors to avoid issues of imbalance in categorical analysis. For example, when analyzing research scenarios, we consolidated academic institutions, for-profit commercial companies, corporations or foundations, independent research organizations, patient-led groups, citizen scientists, and so on, into 3 categories. Thus, our findings do not necessarily represent the full range of possible ways of describing this research.

Despite these limitations, we are confident that having used strict procedures to reduce bias (eg, 2-level screening, independent charting, and a predefined charting template), this review offers a solid foundation for future research. We also feel that the full PubMed query we provide (Textbox 1) is a valuable contribution to other researchers since it was developed and tested for wearables and smartphones and since publications

in the emerging field of mobile devices and PGHD are not well indexed.

Conclusions

We identified trends and patterns in the reporting of research that collects PGHD using mobile devices. Given the growing interest in using a BYOD model among researchers, there is an opportunity for a broader use of crowdsourcing platforms for data transfer from participant-owned devices. There is also the opportunity to develop best practices that address observed reporting deficiencies in this research and make it more reproducible and responsible. Based on our findings, we recommend 9 items for enhanced reporting.

Acknowledgments

SS, ZL, and COT were supported by National Institutes of Health grant NHGRI R35 HG010714.

Data Availability

The data underlying this article are readily available upon reasonable request to the corresponding author.

Authors' Contributions

All authors had full access to the data in the study, take responsibility for data integrity and analysis accuracy, and have approved the final manuscript. Study design was contributed by SS and COT. Review strategy was contributed by SS, RW, and COT. Data collection was managed by SS, MA, RHY, and ZL. Data analysis was done SS. Drafting was contributed by SS. Intellectual inputs were contributed by RW, DJHM, and COT. All authors contributed to manuscript revision. Supervision was handled by COT.

Abstract

Background: Telehealth interventions can effectively support caregivers of people with dementia by providing care and improving their health outcomes. However, to successfully translate research into clinical practice, the content and details of the interventions must be sufficiently reported in published papers.

Objective: This study aims to evaluate the completeness of a telehealth intervention reporting in randomized controlled trials (RCTs) conducted for caregivers of people with dementia.

Methods: A systematic search of relevant papers was conducted on July 26, 2023, in 9 electronic databases. RCTs of telehealth interventions for caregivers of people with dementia were included. Two independent researchers extracted the descriptive information and assessed the methodological quality (Cochrane risk of bias tool) and the completeness of reporting of the intervention by using the Template for Intervention Description and Replication (TIDieR)-Telehealth checklist, which consists of 12 items.

Results: Thirty-eight eligible RCTs were included finally, and the overall quality of the studies was assessed as moderate. None of the studies completely reported all the TIDieR-Telehealth items. The most frequently reported items were the brief trial name (35/38, 92%), rationale (38/38, 100%), materials and procedures (35/38, 92%), and the modes of delivery (34/38, 90%). The least reported items were the type of location (0/38, 0%), modifications (4/38, 11%), and assessment and improvement of fidelity (9/38, 24%).

Conclusions: Many details of the telehealth interventions in RCTs are reported incompletely. Greater adherence to the TIDieR-Telehealth checklist is essential for improving the reporting quality and for facilitating replicability, which has substantial implications for translation into clinical practice.

Introduction

According to the World Alzheimer Report 2023, over 55 million people live with dementia worldwide, and this number is expected to reach 139 million by 2050 [1]. Alzheimer disease is ranked as the seventh leading cause of mortality and poses the highest burden of disease globally [2], and dementia care has become the focus of global health services [3]. To perform activities of daily living, most people with dementia require care from informal caregivers such as family members and friends or from formal caregivers [4]. Studies have shown that caregivers for people with dementia may experience emotional stress that probably results in adverse effects on the patients [5,6]. Reports indicate that these caregivers frequently experience symptoms such as depression, anxiety, and stress [7]. Currently, there are many interventions for supporting caregivers for dementia care. With the development of the society and the progress of technology, telehealth as an alternative medium for delivering health care has boomed.

Telehealth is defined as the use of medical information exchanged via electronic communication from one location to another [8]. Various types of telehealth interventions have been widely used in medical care, which have been shown to improve the quality of care and provide better outcomes for patients [9,10]. Caregivers of people with dementia require favorable interventions because of the complexity of dementia care, and telehealth can increase the opportunities for caregivers to receive interventions. Studies have shown that telehealth interventions have benefits for caregivers, such as improving their perceived competency, reducing their burden, and relieving their depression and stress [11,12].

Randomized controlled trials (RCTs) are currently recognized as the gold standard for evaluating clinical treatments and for generating high-quality evidence for the effectiveness and efficacy of interventions [13]. One challenge identified in the reporting of clinical trials is the quality of the descriptions of interventions [14]. The reproducibility of RCT results is fundamental to improving evidence-based care and patient outcomes, but insufficiently published descriptions of interventions will affect the reproducibility of trials, raising concerns about the validity and reliability of the findings [15].

Although the CONSORT (Consolidated Standards of Reporting Trials) statement offers general recommendations for intervention reporting, it lacks detailed guidance on critical intervention components such as the particular techniques and modes of delivery [12]. To address this gap, the Template for Intervention Description and Replication (TIDieR) checklist was published in 2014 to emphasize the importance of adequate reporting of interventions in clinical trials, enabling detailed descriptions of the intervention content for the reproducibility of trials [15,16]. In 2022, the TIDieR-Telehealth checklist, as an extension of the original TIDieR checklist, provided additional guidance specific to reporting of telehealth interventions with the goal of improving reporting quality and maximizing reproducibility and implementation in clinical trials [17].

Previous studies using the TIDieR checklist for assessment have shown incomplete intervention reporting [15,16,18], raising concerns about the comprehensiveness of telehealth intervention reports for dementia caregivers. To our knowledge, no study has yet examined the quality of reporting of interventions within dementia care interventions or identified which components are the most underreported. Therefore, the purpose of this study was to assess the completeness of telehealth intervention reporting in RCTs for caregivers of people with dementia.

Methods

Study Design

This review assesses the completeness of telehealth intervention reporting in RCTs for caregivers of people with dementia by using the TIDieR-Telehealth checklist.

Search Strategy

Related papers were retrieved from PubMed, Embase, Cochrane Library, Web of Science, CINAHL, China National Knowledge Infrastructure, Chinese Biomedical Literature database, Wanfang database, and VIP Chinese Science and Technology Periodicals Full-Text database, without any restriction on the date of publication (from inception to July 26, 2023). Only RCTs published in English or Chinese were included. The search strategy can be found in Multimedia Appendix 1.

Inclusion Criteria

The criteria for the inclusion of the published papers were as follows: (1) participants were caregivers providing care for people with dementia at any stage (formal or informal caregivers); (2) telehealth interventions involved any treatments that were delivered remotely via text messaging, videoconferencing, audio-only communication, mobile apps, and other telecommunication tools [17]; (3) the control group received usual care, standard care, waiting list, face-to-face, or any other nontelehealth interventions; (4) all eligible studies were analyzed for completeness of reporting of the intervention, regardless of the outcomes; and (5) only RCTs.

Study Selection

Two independent researchers, systematically trained in evidence-based research, screened the titles and abstracts of the selected papers by using the inclusion criteria to identify potentially eligible studies. Full texts were obtained and again screened for final inclusion. Disagreements were resolved by a third researcher.

Data Extraction

Two independent researchers extracted information regarding the characteristics, methodological quality, and completeness of reporting of the intervention. A third researcher resolved disagreements arising at any stage. Regarding the study characteristics, we extracted the following data: first author, year of publication, sample size, age and gender of included participants, severity of dementia, intervention characteristics, outcomes and measurement tools, assessment times, risk of bias, and completeness of reporting.

XSL•FO
RenderX

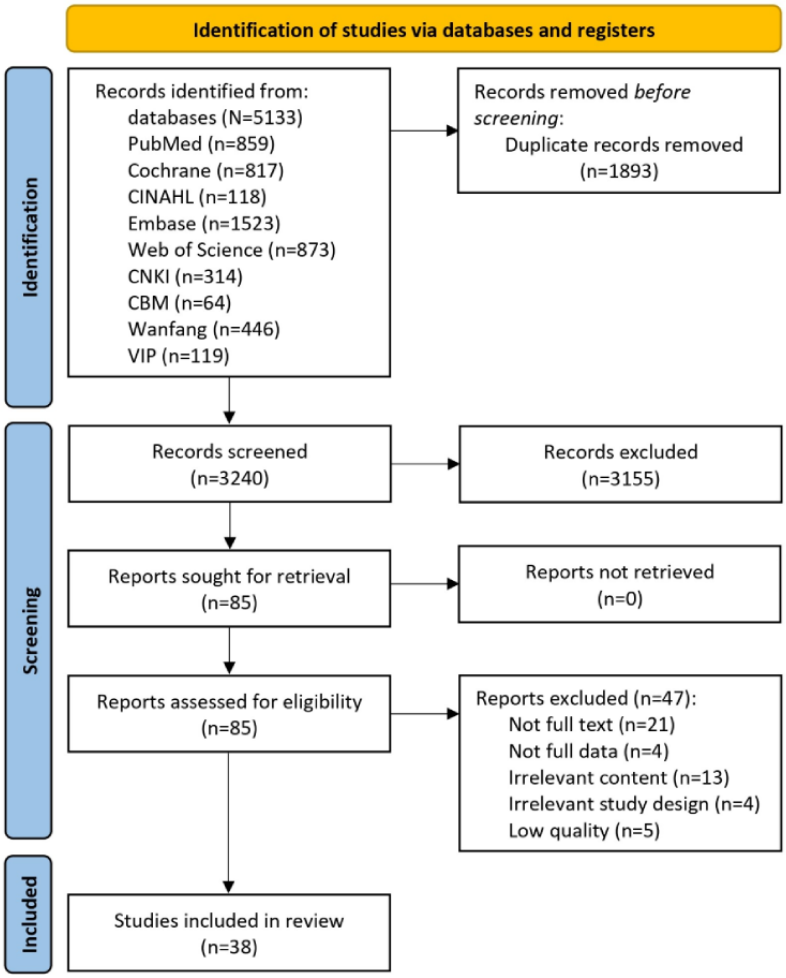
Risk of Bias Assessment

The Cochrane Risk of Bias tool [19] was used to assess the methodological quality of the eligible trials on random sequence generation, allocation concealment, blinding of participants and personnel, blinding outcome assessment, incomplete outcome data, selective reporting, and other biases. Each item was rated as low risk, high risk, or unclear risk. In addition, the overall risk of bias of the study was classified as A (low risk in all domains), B (low risk in some domains), or C (no low-risk domains) [20]. Due to the high risk of bias and low quality of grade C studies, those studies were not included [20-22].

Completeness of Reporting Assessment

The completeness of reporting was extracted using the TIDieR-Telehealth checklist, which has 12 items such as brief name, why, what (materials and procedures), who provided, how, where, when, and how much, tailoring, modifications, and how well (planned, actual). Considering that there are multiple aspects included in the items, each item was scored on a 3-point scale: 1 if all the criteria were met, 0.5 if some criteria were included, and 0 if no criteria were met or mentioned. The full score of each study was 12. It should be noted that item 10 was considered adequately reported if there was explicit mention of modifications during the study and was considered not adequately reported if no explicit mention of modifications was made during the study.

Data Analysis



We performed a descriptive analysis to describe the included trials, the methodological quality, and the reporting of the interventions. Overall scores were calculated on the completeness of reporting for each study, and numbers and percentages were used to summarize the adherence to each item of the checklist for all the included trials. Additionally, we used a histogram to represent the number of trials with different scores on each item. The methodological quality of the eligible trials was shown by a risk-of-bias summary graph created in Review Manager version 5.4.

Results

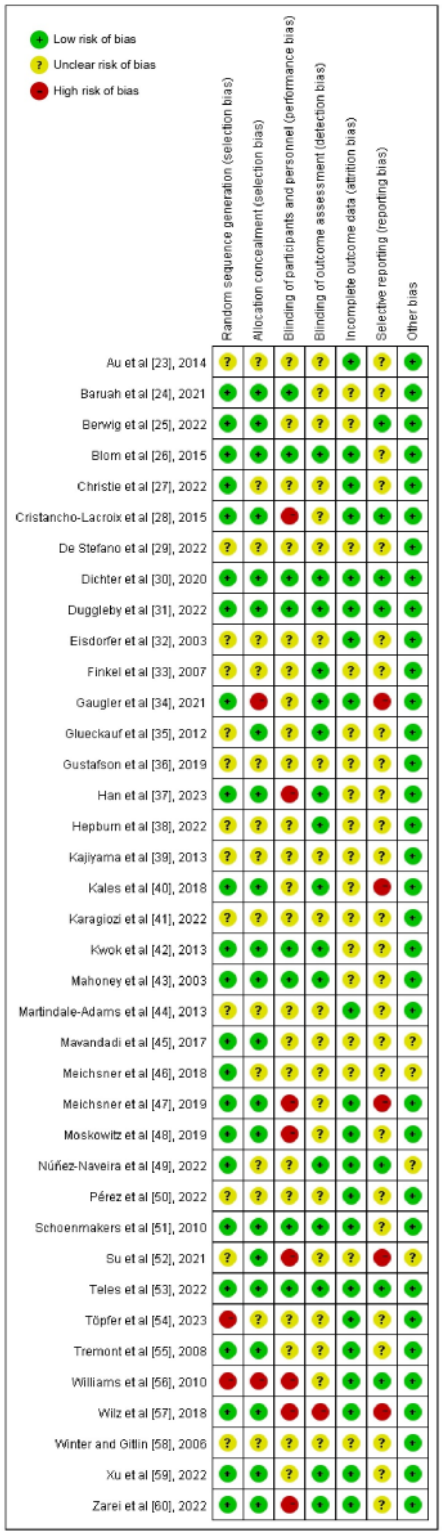
Study Selection

A total of 5133 results were obtained after the preliminary screening. After excluding 1893 duplicate studies and 3155 irrelevant studies that did not meet the criteria (as shown by their titles and abstracts), 38 studies were included after full-text review (Multimedia Appendix 2). The literature screening process and results are shown in Figure 1.

Figure 1. Flow diagram for the screening of studies. CBM: Chinese Biomedical literature; CNKI: China National Knowledge Infrastructure.

XSL•FO
RenderX

Description of the Included Studies



The characteristics of the eligible RCTs are described in Multimedia Appendix 3 [23-60]. Considering the recent publication of the telehealth checklist, our study mainly conducted a retrospective evaluation of the completeness of reporting in the relevant papers. All 38 papers included in this review were published from 2003 to 2023 in 12 countries, namely, the United States (n=16) [32-40,43-45,48,55,56,58], Germany (n=6) [25,30,46,47,54,57], China (n=4) [23,42,52,59], Canada (n=2) [31,60], Spain (n=2) [49,50], Netherlands (n=2) [26,27], Belgium (n=1) [51], France (n=1) [28], Greece (n=1) [41], Portugal (n=1) [53], India (n=1) [24], and Italy (n=1) [29]. The total sample size was 4001 (range 14-273), with an average age range of 37-72 years. Seven studies [25,29,32,33,35,41,55] did not specify the proportion of females, while the other studies [23,24,26-28,30,31,34,36-40,42-54,56-60] included 2676 (79.4%) females. All the trial interventions were delivered by the internet or telephone, with 15 studies [23,25,29,30,35,42,44,45,47,51,54,55,57-59] using the telephone to provide education or support to caregivers. Only 17 of the 23 studies that conducted interventions through the internet mentioned specific modalities of the intervention, of which 13 [24,27,28,31,36,37,40,41,49,50,52,53,60] provided caregivers with knowledge, skills, and support through a web page or app, and 3 [32,33,43] studies provided support via a computer-telephone integration system. One study [34] provided a monitoring system for caregivers.

Methodological Quality

The risks of bias for the included studies is shown in Figure 2 [23-60]. According to the risk of bias assessed by the Cochrane handbook, 38 papers were qualified, with 3 studies graded as A [30,31,53] and 35 as B. In general, the methodological quality of these RCTs was moderate. Specifically, 23 studies [24-28,30,31,34,37,40,42,43,45-49,51,53,55,57,59,60] described the generation of random sequences. Allocation concealment was not reported in 15 papers [23,27,29,32,33,36,38,39,41,44,46,49,50,54,58], and 22 papers [23,25,27,29,32-36,38-41,44-46,49,50,54,55,58,59] provided no information on the blinding of participants and personnel. As data were often collected online, the detection bias in 16 papers [26,30,31,33-35,37,38,40,42,43,49,51,53,59,60] was determined to be low risk. Researchers in 21 studies [23,26-28,30-32,34,44,47-51,53-57,59,60] reported completeness of data. In addition, reporting bias was uncertain in most papers (n=26) [23,24,26,27,29,32,33,35-39,41-46,48,50,51,54,55,58-60]. The overall quality of the included studies was moderate, and further high-quality studies are needed.

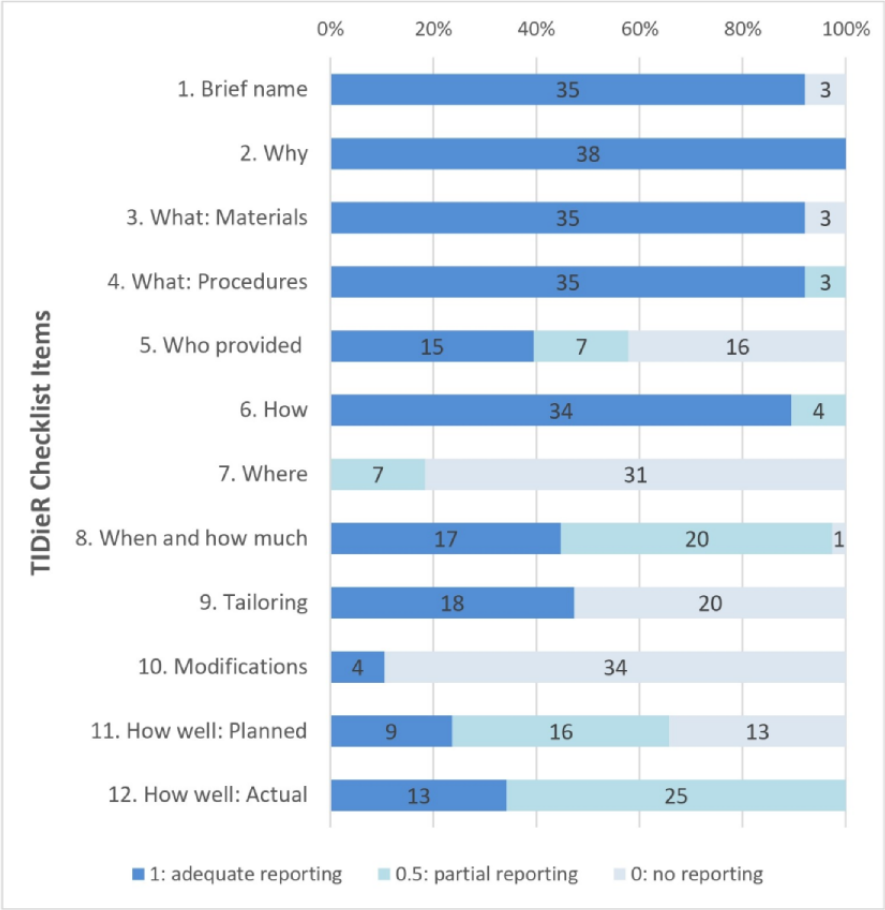
Figure 2. Risk of bias graph.



Completeness of Reporting

The item scores for each trial are shown in Table 1 [23-60]. None of the papers described all the items on the TIDieR-Telehealth checklist. The completeness of the reporting score varied between 5 and 11.5, with a mean of 7.7. Figure 3 shows the distribution of studies with different scores in each item of the TIDieR-Telehealth checklist. Nearly all trials (n=35) reported the name, the use of physical or informational materials, and the procedures of the interventions (item 1, item 3, item 4). All trials described a rationale (item 2). More than half (n=22) of the included studies [23,25,26,29,30,35,37,38,41,42,45-47,50-52,54,55,57-60] mentioned intervention providers (item 5), and 68% (15/22) of the studies [26,29,30,35,37,45-47,50,51,54,55,57-59] provided detailed information of the providers, including their expertise, background, and any specific training given. All trials described the mode of delivery (item 6), and 4 papers [26,39,53,54] did

XSL•FO
RenderX

not mention whether the interventions were provided individually or in a group. Only 7 studies [29,32,34,35,45,56,57] mentioned the types of locations where the intervention occurred (item 7). The majority of the studies (37/38, 98%) mentioned the number of times the intervention was delivered, while fewer than half (17/37) [23,25,28-30,32,35,37,38,41,42,44,50,55-57,60] reported the schedule and duration (item 8). Nearly half (n=18) of the studies [23,32,33,35,38,40-42,44-46,49-53,55,57] reported the tailoring of the interventions (item 9). The least reported item was item 10, with only 4 papers [25,28,35,48] mentioning modification of the intervention. Item 11, that is, strategies to improve fidelity/adherence, was reported in 25 (66%) of the 38 studies [23-27,31,32,34-38,40,45-48,51-55,57,59,60]. Only 13 (34%) studies [24,28,31,33,35-37,44-46,54,57,59] provided a complete description of the actual fidelity of the intervention delivery (item 12).

Figure 3. Distribution of studies with different scores in each item of the Template for Intervention Description and Replication-Telehealth checklist. Numbers in bars represent the number of interventions rated as 1 (adequate reporting), 0.5 (partial reporting), and 0 (no reporting). Discussion

Principal Findings

This review is a retrospective study evaluating the completeness of reporting on telehealth interventions for caregivers of people with dementia. The principal finding was that none of the telehealth interventions were reported in enough detail to satisfy every TIDieR-Telehealth checklist item, despite the checklist being published in 2022. This finding confirms the need for the introduction of the TIDieR-Telehealth checklist and suggests that there is a large shortfall in the reporting of information needed to accurately replicate telehealth interventions. In particular, the least frequently reported items were the ones referring to the type of location of the interventions (fully reported by no study), as well as the modifications (fully reported by 4 studies [25,28,35,48]), and fidelity assessment during the study (fully reported by 9 studies [26,27,31,35,46,53,55,57,59]). Importantly, these elements may be fundamental for enabling interventions to be adequately replicated, compared, and transferable in clinical practice [16].

Similar to our findings, a previous systematic review showed that the reporting of telehealth-delivered dietary interventions in chronic disease is inadequate, although this was assessed using the TIDieR checklist [61]. Given that the TIDieR-Telehealth checklist was published in 2022, there are currently no studies describing the completeness of telehealth interventions. However, some studies evaluated using the TIDieR checklist also indicated inadequate completeness of reporting across trials of weight management, cardiac rehabilitation, and manipulation and mobilization techniques [15,16,18]. Compared to those studies, the proportion of papers with complete descriptions of the intervention in our study was different. It might be that telehealth intervention had its unique evaluation standard: the TIDieR-Telehealth checklist. Another explanation might be that our interpretation of the

XSL•FO
RenderX

TIDieR-Telehealth checklist and guide produced a more stringent evaluation than previous studies of interventions reporting quality, and we adopted a more detailed way of keeping the score.

Unlike other studies [18,62], the names of the included trials were not fully reported as required, because the TIDieR-Telehealth checklist requires that the name of the trial should include the word "telehealth," which differs from the requirements in the TIDieR checklist. Most studies (>88%) reported intervention materials, procedures, and modes of delivery, which were similar to the findings of previous studies [15,18]. Information on intervention providers, such as category, experience, background, and any specific training given, was fully described in only 15 studies [26,29,30,35,37,45-47,50,51,54,55,57-59]. These descriptions are important for telehealth interventions because the delivery of telehealth interventions requires training to ensure the normativity of the study, and the expertise and disciplinary background of the provider might affect the outcome of a trial [18]. None of the trials fully described the location of the intervention, which may be related to the characteristic that telehealth is not limited by the location. However, the authors of the TIDieR checklist and guide emphasized that the location(s) of a trial might impact intervention feasibility and adherence. Nearly half of the studies fully reported the duration and number of interventions. Some interventions using remote monitoring systems or telehealth support programs were designed for participants to use when needed; therefore, the length and the number of interventions are not described. However, the arrangement of these interventions has a great influence on the effect of the intervention; therefore, the evaluation of the fidelity of intervention is particularly important. Tailoring, as an important part of the intervention, was mentioned in 18 trials [23,32,33,35,38,40-42,44-46,49-53,55,57]. The application parameters of technology are no longer predetermined but are constantly adjusted due to the feedback of the patients and the tailoring of the therapist to the responses of the individual patient [63]. Frequent shortcomings were items related to the reporting of modifications and the fidelity of interventions. In this study, only 4 trials (11%) [25,28,35,48] mentioned modifications in the interventions, which are essential for refining the intervention content and enhancing the replicability and the validity of the trial. Moreover, only 9 studies [26,27,31,35,46,53,55,57,59] fully described the methods for assessing and improving the fidelity of intervention. The assessment of fidelity remains a challenge in intervention trials, particularly in telehealth, where maintaining consistency can be difficult. Given that fidelity substantially affects treatment outcomes, this is an important factor to consider when interpreting study results [14,17].

Limitation and Strengths

Different from other studies [15,61], our research employs a 3-point method, accounting for both fully and partially reported items. From these statistics, we can identify the missing parts in a report and urge that study to improve the completeness of that report. Moreover, one limitation of our study is that we did not compare the completeness of a report before and after the publication of the TIDieR-Telehealth checklist, as this checklist has been published only recently and related studies were limited. More trials are needed to confirm the usefulness of this checklist.

Conclusion

We found the reporting of interventions according to the TIDieR-Telehealth checklist to be inadequate in our sample of related trials. Fundamental details were often not described, affecting research validity and reproducibility. Future RCTs on telehealth interventions for dementia should adhere to standardized reporting. It is necessary to consider other mechanisms to improve TIDieR adherence or to find other solutions to improve intervention reporting. Meanwhile, telehealth interventions, as an intervention method in the new era, have brought many benefits to patients and caregivers but also posed challenges to intervention providers. Therefore, the next step in the implementation of telehealth interventions is how to properly utilize the benefits of telehealth to maximize its value.

Acknowledgments

We thank all the members of our study team for their cooperation and the original authors of the included studies for their work. Abstract

Background: Parental technoference, the interruption of parent-child interactions by technology, has been associated with negative outcomes in children's media use. However, the magnitude of this relationship and its moderating factors remain unclear.

Objective: This study aims to systematically examine the relationship between parental technoference and child problematic media use, as well as to identify moderating factors such as age, parental technoference group, study design, and type of problematic media use.

Methods: Following PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines, a comprehensive literature search was conducted up to August 2024 across multiple databases, including Web of Science, EBSCO, ProQuest, PubMed, PsycINFO, and China National Knowledge Infrastructure, using predefined search strings. A total of 53 studies with a total of 60,555 participants (mean age of 13.84, SD 1.18 years) were included. Inclusion criteria comprised studies involving children under the age of 22 years, assessing the association between parental technoference and child problematic media use with valid measures, and reporting necessary statistical data. Exclusion criteria included studies focusing on other child outcomes, having sample sizes <30, or being case reports or review papers. The risk of bias was assessed using the Quality Assessment Tool for Observational Cohort and Cross-Sectional Studies. A random-effects meta-analysis was performed using R (version 4.2.1; R Foundation for Statistical Computing) with the *meta* and *metafor* packages to evaluate the association and conduct moderator analyses.

Results: The meta-analysis identified a significant positive association between parental technoference and child problematic media use (r=0.296, 95% CI 0.259-0.331). Moderator analyses revealed that both parental technoference group (P<.001) and study design (P=.008) significantly influenced this relationship. Specifically, the association was stronger when both parents engaged in technoference compared to when only 1 parent did, and in cross-sectional studies compared to longitudinal studies. Age, gender, publication status, and type of problematic media use did not significantly moderate the relationship (all P>.05).

Conclusions: This meta-analysis provides robust evidence of the association between parental technoference and child problematic media use. The findings highlight the need for family-based interventions and underscore the importance of longitudinal research to understand the temporal dynamics of this relationship better.

Introduction

Background

Problematic media use in children refers to excessive screen engagement that disrupts functioning and development, transcending mere time metrics [1,2]. Globally, problematic media use is on the rise [3,4], with significant implications for the developmental health of children and adolescents [5-10]. A key factor implicated in the rise of problematic media use among youth is parental technoference. Technoference, a term coined by combining "technology" and "interference," refers to the disruption or disturbance of daily interpersonal communication and shared time caused by digital and mobile technology devices [11,12]. Parental technoference, which refers to the interruptions in parent-child interactions due to digital and electronic media devices, is a concern that has been increasingly recognized within the domain of family dynamics [13-15]. Numerous empirical studies have explored the relationship between parental technoference and child problematic media use, yet the findings have been inconsistent, possibly due to variations in research methodologies and sample characteristics [2,16-18]. Despite the growing body of literature, there is a conspicuous absence of systematic reviews or meta-analysis studies aimed at synthesizing these findings to address the discrepancies and draw reliable conclusions. To fill this gap, this study used a meta-analysis method to quantitatively integrate the extant research on this topic. Our objectives are twofold: to establish a more robust and reliable estimate of the effect size of parental technoference on child problematic media use, and to identify potential moderators that may influence the strength of this relationship. Through this work, we aim to contribute valuable insights into the dynamics of family media use and to promote healthier media habits that support the well-being of children and adolescents.

Association Between Parental Technoference and Child Problematic Media Use

Parental technoference may affect child problematic media use, and this association can be explained through various theories and psychological processes. First, the interactional theory of childhood problematic media use [19] posits that problematic media use in children is influenced by both individual and contextual factors. It suggests that children's media use patterns are shaped by their interactions with their environment, including parental behaviors. Specifically, parental technoference may lead to unclear media use rules in the family environment and reduce interaction and communication between parents and children [11,20-22]. In such cases, children may be more inclined to engage in excessive media use to compensate for the reduced parent-child interaction caused by parental technoference. Indeed, research has found that poor parent-child relationships are a significant risk factor for children's problematic media use [23,24]. Second, based on the accept-rejection theory [25], children's behavior is influenced by their perception of acceptance or rejection from significant others, especially their parents. When parents are preoccupied with technology and fail to provide emotional availability and responsiveness, children may perceive this as rejection or neglect. In response, children may seek alternative sources of comfort and stimulation, such as excessive media use, to compensate for the lack of emotional connection with their parents. Thus, parental technoference can contribute to problematic media use as a coping mechanism for perceived parental rejection. Finally, social learning theory [26] emphasizes the role of observational learning and modeling in shaping behavior. According to this theory, children learn by observing and imitating the behaviors of others, particularly their parents. When parents engage in excessive media use or prioritize technology over other activities, children are more likely to adopt similar behaviors. Parental technoference, by modeling problematic media use, may contribute to the development of problematic media use in children through observational learning processes. In conclusion, parental technoference can influence child problematic media use through multiple theoretical perspectives. It disrupts parent-child interactions, may contribute to children's perception of rejection, and models problematic media use.

Extensive empirical research has investigated the relationship between parental technoference and child problematic media use, including smartphone addiction [18,27-32], internet gaming disorder [33-37], social networking site addiction [2,38], and short-form video addiction [39]. The findings consistently indicate a significant positive correlation between parental technoference and child problematic media use, raising concerns for children across different age groups, from children with an average age of 10.33 (SD 0.98) years [37] to adolescents with an average age below 20 years [39-41]. However, there are fair-sized discrepancies in the magnitude of association between the same parental technoference and child problematic media use in the literature. For example, the correlation between parental technoference and child problematic media use ranged from 0.11 [17] to 0.54 [16]. These conflicts may be due to differences in study design, study characteristics, and result characteristics.

Impact of Moderator Variables

Gender differences in children's susceptibility to parental technoference and its association with problematic media use have been extensively documented in the literature. For instance, Xie et al [31] found that gender moderates the relationship between parental technoference and smartphone addiction in children, with a greater impact on smartphone addiction observed in boys compared to girls. However, Wang et al [42] did not find gender differences in the relationship between parental technoference and child problematic smartphone use. This discrepancy may be due to the uncertain nature of gender differences in problematic media use. Some studies have reported a significant correlation between gender and children's problematic media use. Among these studies, some have indicated a more severe tendency toward problematic media use in boys compared to girls [36], while others have found the opposite [35]. Additionally, some studies have not established a significant relationship between parental technoference and child problematic media use [2,29,43]. Overall, the impact of parental technoference on child problematic media use may differ between boys and girls, although a definitive conclusion

XSL•FO
RenderX

is currently lacking. Therefore, in this study, we examined the moderating effect of gender.

In addition, the age of children may also play a moderating role in the relationship between parental technoference and child problematic media use. On one hand, parental technoference may be related to the age of the child. Previous studies have found a significant positive correlation [2], a significant negative correlation [37], and a nonsignificant correlation [29,35,36] between parental technoference and child age. This variation may stem from the fact that each empirical study has only investigated a limited age range, failing to examine the relationship between parental technoference and child age from a broader perspective. On the other hand, the age of children may also influence their problematic media use. For example, researchers have found a significant positive correlation between child age and problematic media use [28,31,44], indicating that as children get older, their problematic media use becomes more severe. In summary, both parental technoference and child problematic media use vary with the child's age. Therefore, in this study, we also examined whether child age moderates the association between parental technoference and child problematic media use.

Moreover, this study aims to explore the separate effects of parental technoference on problematic media use in children. It is well documented that fathers and mothers often have different parenting roles and practices, which can influence children's development in unique ways [45,46]. For example, McDaniel and Radesky [15] observed a positive association between mother technoference in parenting and children's externalizing and internalizing behaviors, while father technoference in parenting did not show a significant correlation with the child's problem behavior. Thus, it is imperative to separately examine the influences of father and mother technoferences on children's development. Notably, existing research has predominantly focused on the relationship between technoference from both parents and child problematic media use [2,18,28,29,31,42,44], without distinguishing the specific impacts of fathers and mothers. Therefore, this study aims to fill this gap by exploring the moderating effects of parental technoference groups on child problematic media use.

Finally, we examine the impact of different types of child problematic media use, publication status, and study design on the relationship between parental technoference and child problematic media use. Specifically, we investigated whether various types of problematic media use influence this relationship. Furthermore, we compared the findings of published studies with those of unpublished master's thesis to determine the consistency of conclusions. Additionally, we examined potential differences in conclusions between cross-sectional and longitudinal research in the context of parental technoference studies.

Objectives

As discussed earlier, the empirical research investigating the relationship between parental technoference and child problematic media use has yielded inconsistent results. To our knowledge, there are no meta-analysis studies in this area to explain these differences. Therefore, this study performed a meta-analysis to synthesize the findings of previous studies examining the association between parental technoference and child problematic media use to better understand the associations between these constructs. The meta-analysis aims to address two core research questions.

- What is the overall relationship between parental technoference and child problematic media use?
- Are there any moderating variables that influence the relationship between parental technoference and child problematic media use?

We also explored potential moderating variables, such as the child's age, gender, type of problematic media use, parental technoference group, publication status, and research design.

Methods

Study Design

The meta-analysis followed the Preferred Reporting Items for Systematic Review and Meta-Analysis (PRISMA) guidelines [47]. The PRISMA–Individual Participant Data checklist for this review is presented in Multimedia Appendix 1. To ensure transparency and avoid unintentional duplication of effort, the protocol for this meta-analysis was registered in the International Prospective Register for Systematic Reviews (PROSPERO CRD42023471997).

Search Strategy

A systematic literature search was conducted based on the PRISMA statement [47]. Multiple electronic databases, including Web of Science, EBSCO, ProQuest, PubMed, PsycINFO, and China National Knowledge Infrastructure, were searched using a predefined search string. The search terms consisted of three elements: (1) parent (eg, parent* OR parental* OR caregiver* OR guardian* OR dad* OR father* OR mom* OR mother* OR family); (2) child (eg, child* OR infant* OR baby OR babies OR toddler* OR preschool* OR kid* OR youth* OR teen* OR adolescent* OR young*); and (3) technoference (eg, technoference* OR phubbing* OR "technology interference*" OR "distraction with phone*" OR "digital distraction*" OR "smartphone distraction*" OR "device distraction*" OR "technology interruption*" OR "digital interruption*" OR "smartphone interruption*" OR "device interruption*" OR "parental media use*" OR "parental smartphone use*" OR "parental device use*"). The search strategy for all databases is presented in Multimedia Appendix 2. To avoid potential bias, outcome terms related to child problematic media use were not included in the search strategy, as suggested by Frandsen et al [48]. The last search was conducted in August 2024. Additionally, to ensure comprehensive coverage, the reference lists of eligible study reports and relevant reviews in the field of parental technoference were manually searched. This iterative process continued until no further studies could be identified.

Inclusion and Exclusion Criteria

The inclusion criteria for the literature in this meta-analysis were as follows: (1) studies involving children under the age of 22 years; (2) investigations examining the association

XSL•FO
RenderX

between parental technoference and child problematic media use; (3) use of a valid and reliable measure to assess parental technoference and child problematic media use; (4) clear reporting of correlation coefficients (*r*) between parental technoference and child problematic media use, or provision of 2-tailed *t* test values, *F* test values, or chi-square test values that could be converted into *r*; (5) reporting of the sample size; (6) inclusion of cross-sectional or longitudinal study designs; and (7) availability of studies written in either Chinese or English. Conversely, studies were excluded if they (1) assessed child outcome indicators other than problematic media use; (2) had a sample size of <30; or (3) were case reports or review papers.

Selection Procedure

The study selection process was conducted in multiple stages following standard systematic review procedures. First, duplicate studies were removed. Subsequently, four authors (JZ, QZ, Y Cao, and Y Chen) working in pairs independently screened the remaining articles. Each record was assessed independently by 2 authors in a 2-stage process: initial screening of titles and abstracts, followed by full-text evaluation of potentially eligible studies. The screening process was conducted under blinded conditions to minimize selection bias. Any discrepancies between the raters were resolved through discussion with the corresponding author until a consensus was reached.

Data Extraction

The following data were extracted: (1) first author names and publication year, (2) correlation coefficient, (3) the number of study samples, (4) gender distribution of children (measured by "boy ratio"), (5) average age of children, (6) measurement instrument, (7) parental technoference group (father technoference vs mother technoference vs parental technoference), (8) participant's country, and (9) publication type (journal paper vs thesis).

In the process of data extraction, we followed specific guidelines. First, effect sizes were generated based on independent samples, with each independent sample contributing 1 effect size for a specific parental technoference and child problematic media use. Second, when 2 effect sizes from the same sample could be classified into 2 different subgroups for moderator analysis, they were considered separate. For example, if a sample reported correlation coefficients for both father and mother technoferences with children's problematic media use separately, these were treated as independent when assessing the moderating effect of the parental technoference category. In other scenarios, to maintain the independence of effect sizes, when multiple effect sizes for the same variable within a group were reported, we used the average correlation to address dependency issues. Third, for longitudinal studies, only 1 longitudinal correlation between the initial measurement of parental technoference and the final measurement of child problematic media use was retained. Lastly, if participant characteristics, such as gender, were reported separately, they were coded as such.

To ensure coding reliability, 2 authors independently conducted the coding, and agreement levels were assessed. Interrater reliability was calculated using the intraclass correlation coefficient (ICC) for continuous variables and Cohen κ for categorical variables. For continuous variables, intercoder reliability was calculated for correlation coefficients (ICC=0.982), sample (ICC=0.997), gender (ICC=0.996), and age (ICC=1.000). For categorical variables, intercoder reliability was calculated for publication year (κ=1.000), publication status (κ=1.000), measurement of parental technoference (κ=1.000), parental technoference group (κ=1.000), and research design (κ=1.000). These results indicated excellent interrater reliability, reflecting a high level of agreement between the coders on the characteristics of the studies. Any discrepancies were resolved through discussion.

Risk of Bias Assessment

The risk of bias for all included studies was assessed using the Quality Assessment Tool for Observational Cohort and Cross-Sectional Studies [49]. This tool comprises 14 items, each offering 5 response choices: yes, no, cannot be determined, not reported, and not applicable. A score of 1 was assigned for "yes," while the other response choices did not receive any points. The total score was used to categorize the quality of the literature as good (total score>7), fair (total score between 5 and 7), or poor (total score<5). A high-quality study is generally characterized by minimal risk of bias. Two authors independently conducted the coding process, and their agreement on the total score demonstrated a high level of consistency (ICC=0.987). Any discrepancies in the coding process were resolved through consensus discussions. The specific details of the quality assessment for each study can be found in Multimedia Appendix 3 [2,16-18,27-44,50-80].

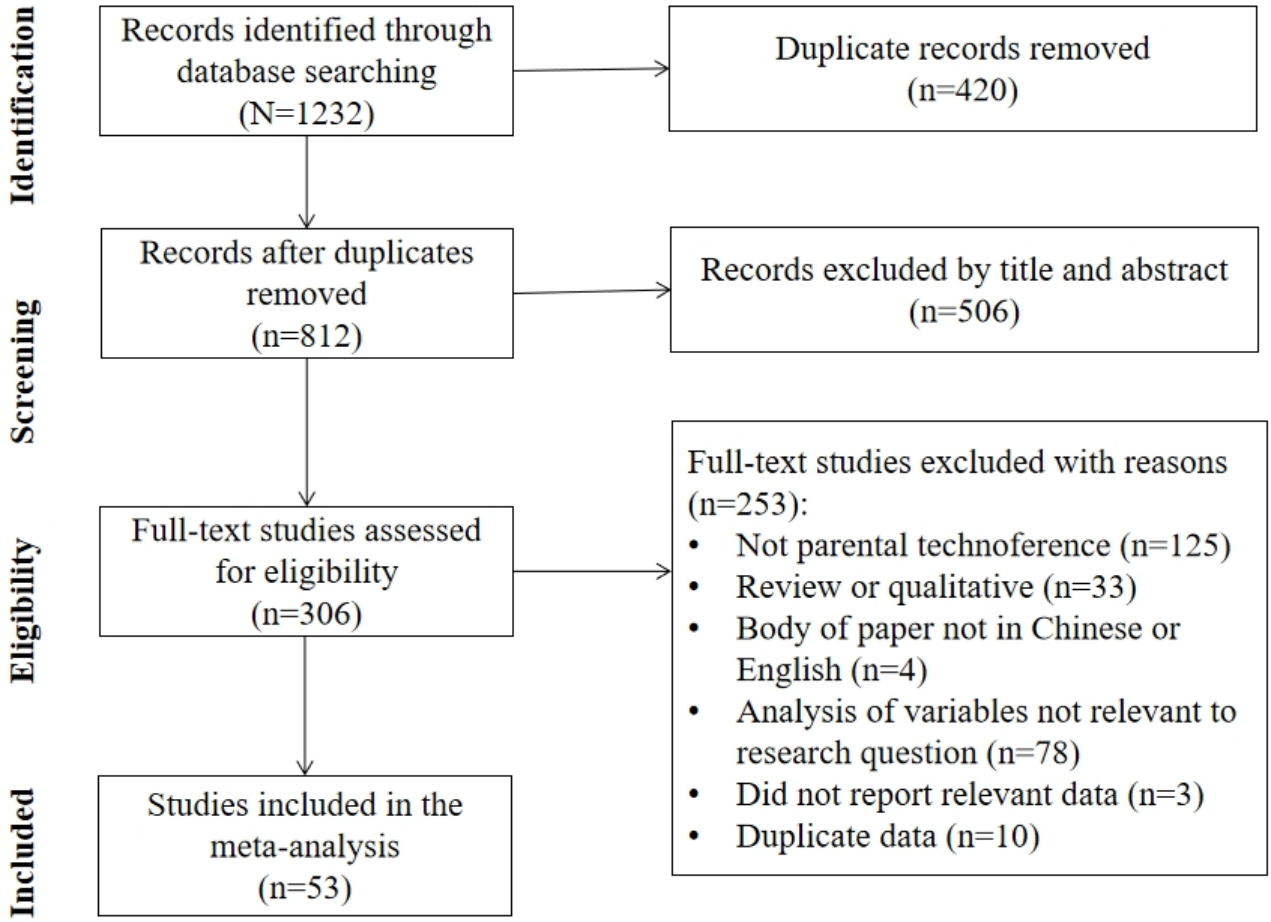
Statistical Analyses

The meta-analysis was conducted using R (version 4.2.1-win; R Foundation for Statistical Computing) with the *meta* and *metafor* packages. Effect sizes were measured using correlation coefficients (*r*). Before the meta-analysis, all correlation coefficients were transformed into Fisher *z* scores. After the analysis, Fisher *z* values were converted back to Pearson correlation coefficients for easier interpretation. Given the anticipated heterogeneity in measurement methods for parental technoference and child problematic media use, as well as variations in participant characteristics (eg, gender, age, cultural background) across the included studies, we used a random effects model for our meta-analysis. Heterogeneity was assessed using the Q and I^2 test statistics. A significant Q test or an I^2 value above 75% indicated substantial heterogeneity, supporting the use of a random effects model [81].

For the moderator analysis, continuous moderators were analyzed using meta-regression, while categorical moderators were analyzed using subgroup analysis. The significance of moderators was assessed using the Q statistic. As recommended by Huang [82], each subgroup should include a minimum of 3 studies for the analysis of categorized moderating variables.

Publication bias refers to the tendency for significant results to be more likely to be published, while nonsignificant results may remain unpublished. To address publication bias, this study included both published journal papers and unpublished theses when selecting literature, which helped to control the influence

XSL•FO
RenderX



of publication bias on the research findings. Additionally, to ensure the reliability of the meta-analysis results, funnel plot and Egger regression intercept were used to assess the presence of publication bias. If the funnel plot exhibited a symmetrical inverted funnel shape and the Egger regression intercept was nonsignificant, publication bias was considered negligible.

Results

Study Characteristics

Out of 1232 initially identified studies (Figure 1), 420 duplicates were excluded. After screening the titles and abstracts, 506 studies were excluded, leaving 306 studies for full-text screening. Following predefined inclusion and exclusion criteria, 253 studies were excluded. Consequently, 53 studies met all eligibility criteria and were included in the meta-analysis.

Figure 1. Flow diagram of study search.

The specific information of the literature included in the meta-analysis is shown in Table 1. The meta-analysis included a total of 60 effect sizes from 53 studies, encompassing 60,555 participants. The sample sizes of the studies ranged from 227 to 4172, with an average participant age of 13.84 (SD 1.18) years. The publication years of the included studies varied from 2018 to 2024. Of the total studies, 46 were cross-sectional, while 7 were longitudinal. The literature consisted of 44 published journal papers and 9 unpublished master's theses. The primary measurement method used in parental technoference research was questionnaire surveys. Commonly used questionnaires included the Partner Phubbing Scale, Phubbing Scale, and the Generic Scale of Being Phubbed. The analysis directly assessed parental technoference in 44 studies, while 7 studies evaluated father technoference and mother technoference separately, 1 study exclusively evaluated mother technoference, and 1 study solely evaluated father technoference. Regarding child problematic media use, the analysis covered problematic smartphone problem use, problematic internet use, problematic social media use, internet gaming disorder, and short-form video addiction, with 34 studies, 8 studies, 5 studies, 5 studies, and 1 study, respectively. Furthermore, 50 of the studies were conducted in China, while the remaining studies were from the United States, Italy, and the Netherlands. In terms of literature quality, 6 studies were rated as "fair," while the remaining 47 were rated as "good."

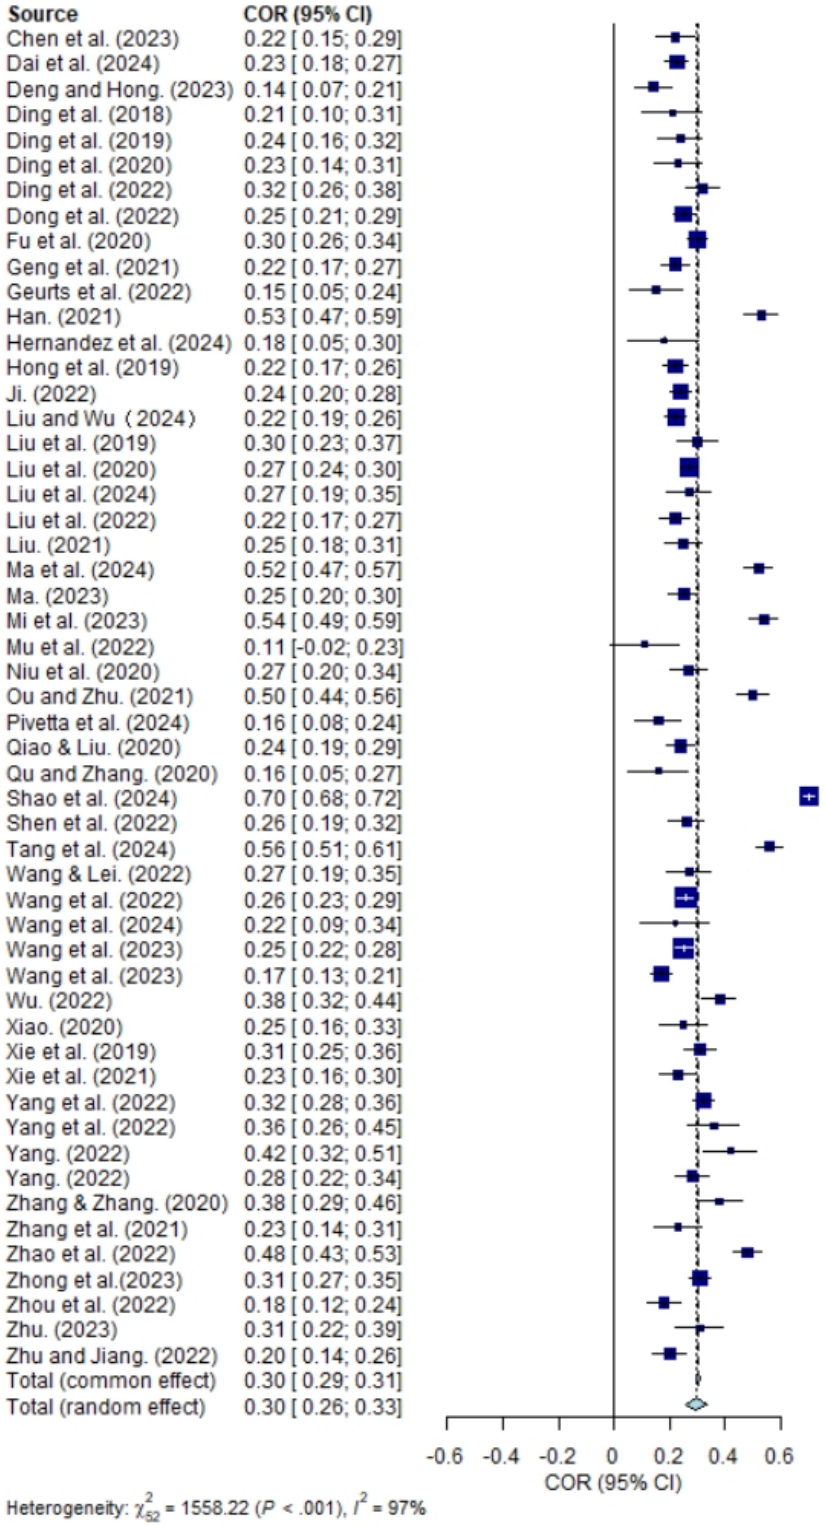
Analysis of Publication Bias

Funnel plots show that effect sizes were roughly evenly distributed on either side of the total effect (Figure 2). The Egger test showed no intercept values in the outcome categories were statistically significant. Specifically, the intercept was –0.78 (P=.71). Collectively, these analyses suggest that the findings of this meta-analysis are robust and unlikely to be substantially influenced by publication bias.

Figure 2. Funnel plot of the association between parental technoference and child problematic media use.



XSL•FO
RenderX

Overall Relation Between Parental Technoference and Child Problematic Media Use

The homogeneity test revealed significant heterogeneity among the effect sizes (Q_{52}=1558.22; P<.001; I^2=96.7%). These findings indicate that there was substantial variability in the effect sizes, suggesting the presence of real differences. Consequently, a random effects model was used to examine both the overall effect and the moderating effect.

The analysis showed a significant positive correlation between parental technoference and child problematic media use (r=0.296; 95% CI 0.259-0.331), as shown in Figure 3 [2,16-18,27-44,50-80]. According to Lipsey and Wilson [83], correlation coefficients can be categorized as low (|r|≤0.1), medium (0.1<|r|<0.4), or high (|r|≥0.4). In this study, the mean effect sizes of the correlation between parental technoference and child problematic media use were considered medium.

Figure 3. Forest plot for correlation between parental technoference and child problematic media use.

XSL•FO
RenderX

Analysis of Moderator Variables

The results of the meta-regression analysis indicated that the moderating effects of gender (B=0.123; SE 0.341; 95% CI 0.546 to 0.792; z=0.360; P=.72) and age (B=0.004; SE 0.010; 95% CI 0.015 to 0.022; z=0.368; P=.71) was found not significant.

Table 2 presents the detailed analysis results for the categorized moderating variables. The analysis revealed no significant moderating effects for publication status (P=.39) or the type of problematic media use (P=.24). However, the parental technoference group emerged as a significant moderator (P<.001), indicating that the effect size of technoference on children's problematic media use was larger when both parents engaged in technoference compared to when only one parent exhibited such behavior. Furthermore, the study design demonstrated a significant moderating effect (P=.008). Specifically, cross-sectional studies yielded larger effect sizes for the relationship between parental technoference and child problematic media use compared to longitudinal studies.

Table 2. Categorical moderator analysis of parental phubbing and internalizing problems.

Moderator variables	Studies, n	*r*	95% CI	*Q* test (*df*)	*P* value
Parental technoference group				18.08 (2)	<.001
Both parents	44	0.313	0.272-0.354		
Father	8	0.211	0.182-0.239		
Mother	8	0.208	0.171-0.246		
Publication status				0.73 (1)	.39
Journal paper	44	0.290	0.248-0.330		
Thesis	9	0.325	0.254-0.392		
Study design				6.84 (1)	.008
Cross-sectional	46	0.306	0.265-0.345		
Longitudinal	7	0.223	0.174-0.270		
Type of PMU[a]				1.38 (1)	.24
General problematic media use	42	0.305	0.261-0.348		
Specific problematic media use	12	0.211	0.202-0.316		

[a]PMU: problematic mobile use.

Sensitivity Analysis

Furthermore, sensitivity analysis was performed to assess the impact of each study using the leave-one-out method. The sensitivity analysis results indicated that the effect size r remained significant, ranging from 0.275 to 0.307, even after excluding any single sample. This suggests that the findings of this study remained relatively stable and reliable.

Discussion

Principal Findings

Despite the growing body of empirical research exploring the relationship between parental technoference and child problematic media use, inconsistencies in research conclusions persist. No meta-analysis had been conducted to systematically synthesize these findings—until now. This study used a meta-analytical approach to quantitatively aggregate existing research, examining the relationship between parental technoference and child problematic media use, as well as identifying moderating factors within this relationship. The results indicated a positive association between parental technoference and child problematic media use. Furthermore, moderator analyses showed that the parental technoference group and study design significantly influenced this relationship.

Parental Technoference and Child Problematic Media Use

The present meta-analysis provides compelling evidence for a significant positive correlation between parental technoference and child problematic media use. This finding aligns with the interactional theory of childhood problematic media use [19], which posits that children's media use patterns are influenced by their interactions with their environment, including parental behaviors. Parental technoference, characterized by reduced parent-child interaction and unclear media usage rules [11,20-22], may lead children to engage in excessive media use as a means of compensating for the lack of parental attention and communication.

Moreover, the accept-rejection theory [25] offers another perspective on the relationship between parental technoference and child problematic media use. When parents are preoccupied with technology, children may perceive this as a form of rejection or neglect. Consequently, children may turn to excessive media use as an alternative source of comfort and stimulation to cope with the perceived lack of emotional connection with their parents.

Furthermore, social learning theory [26] suggests that children learn by observing and imitating the behaviors of their parents. When parents engage in excessive media use or prioritize technology over other activities, they inadvertently model

XSL•FO
RenderX

problematic media use behaviors. As a result, children may adopt similar problematic media use patterns through observational learning processes.

This meta-analysis, in conjunction with the theoretical perspectives discussed, provides a more comprehensive understanding of the potential mechanisms underlying the relationship between parental technoference and child problematic media use. However, it is important to acknowledge that the strength of this association may vary across studies due to methodological differences, such as sample characteristics, measurement tools, and cultural contexts [16,17]. Future research should aim to further elucidate these factors and their role in modulating the relationship between parental technoference and child problematic media use.

In conclusion, the meta-analysis substantiates the theoretical assertions that parental technoference is a significant contributor to child problematic media use. This relationship can be understood through the lenses of the interactional theory of childhood problematic media use, accept-rejection theory, and social learning theory, which collectively suggest that parental technoference may disrupt parent-child interactions, contribute to children's perception of rejection, and model problematic media use behaviors.

Moderator Analysis

The significant moderating effect of the parental technoference group on the relationship between parental technoference and child problematic media use suggests a compounded risk when both parents are involved in technoference. This finding aligns with Zhang et al [84], who reported a stronger association between parental technoference and children’s internalizing problems when both parents, rather than one, engaged in technoference. Our finding extends this understanding to problematic media use, indicating that the combined technoference of both parents may create a more pervasive environment of digital distraction, which could amplify negative outcomes in children’s media behaviors. This could be due to a cumulative lack of parental attention and modeling of poor media habits, indicating the necessity for interventions that address family media use as a whole. Future research should explore the mechanisms through which the combined technoference of both parents exerts a greater influence on child outcomes, potentially informing targeted family-based strategies to mitigate problematic media use in children.

The significant moderating effect of study design, with cross-sectional studies yielding larger effect sizes compared to longitudinal studies, suggests that the impact of parental technoference on child problematic media use may diminish over time. This finding highlights the potential for adaptation or the development of coping mechanisms in children exposed to parental technoference. It also emphasizes the importance of longitudinal research to capture the dynamic nature of this relationship and to inform long-term intervention strategies.

The study did not find significant moderating effects for child gender, age, publication status, or type of problematic media use. This indicates that parental technoference exerts a consistent impact on child problematic media use across different genders, ages, and types of media use issues. Such consistency underscores the pervasive influence of parental technoference, suggesting its stable impact on children’s media behaviors irrespective of individual or contextual differences.

Limitations and Future Directions

This meta-analysis provides valuable insights into the relationship between parental technoference and child problematic media use. However, several limitations warrant consideration. The predominance of Chinese participants in the sample limits the generalizability of findings to other cultural contexts, particularly those with differing parenting dynamics and societal values. Future research should encompass a broader cultural spectrum to assess the global applicability of these results. Moreover, the reliance on cross-sectional studies in the analyzed literature presents challenges in establishing causality and may introduce recall biases. To address these limitations, future studies should use experimental methods to isolate the direct impact of parental technoference on child outcomes. Additionally, longitudinal designs spanning extended periods would enable the examination of developmental trajectories and the dynamic interplay between parental technoference and child problematic media use over time. Implementing these methodological approaches in future research will enhance our understanding of the causal mechanisms and long-term implications of parental technoference, ultimately informing more effective interventions to promote healthy family media use practices.

Conclusions

This meta-analysis provides robust evidence for a significant positive association between parental technoference and child problematic media use. The findings reveal that this relationship is particularly pronounced when both parents engage in technoference and are stronger in cross-sectional studies compared to longitudinal ones. These results underscore the pervasive influence of parental digital distraction on children’s media habits across various demographics and types of media use. The study highlights the critical need for family-based interventions targeting parental technology use and emphasizes the importance of longitudinal research to understand the temporal dynamics of this relationship better. By addressing parental technoference, we may significantly impact children’s problematic media use, potentially improving developmental outcomes and overall well-being in the digital age. Future research should focus on developing targeted interventions and exploring the underlying mechanisms of this relationship across diverse cultural contexts.

Abstract

Background: Cardiovascular disease (CVD) is a major global health issue, with approximately 70% of cases linked to modifiable risk factors. Digital health solutions offer potential for CVD prevention; yet, their effectiveness in covering the full range of prevention strategies is uncertain.

Objective: This study aimed to synthesize current literature on digital solutions for CVD prevention, identify the key components of effective digital interventions, and highlight critical research gaps to inform the development of sustainable strategies for CVD prevention.

Methods: Following PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines, we conducted a comprehensive search in Web of Science, Scopus, and PubMed to identify original English-language studies published between January 2000 and May 2024 that examined primary or secondary CVD prevention through digital solutions. The exclusion criteria included: telephone-only interventions, abstract-only publications, methodology-focused studies without primary data, studies without participants or specific groups, and studies with no follow-up period. The literature search used the string with terms like “digital health,” “mHealth,” “mobile health,” “text message,” “short message service,” “SMS,” “prevention,” “prevent,” “cardiovascular disease,” “CVD,” etc. Study bias was assessed using the RoB 2 (Cochrane Collaboration) and the ROBINS-I tool (Cochrane Collaboration). Data on prevention components, prevention types, study design, population, intervention, follow-up duration, personnel, and delivery settings were extracted.

Results: A total of 2871 studies were identified through the search. After excluding ineligible studies, 30 studies remained, including 24 randomized controlled trials. The reviewed digital solutions for CVD prevention focused on baseline assessment (29/30, 97%), physical activity counseling (18/30, 60%), tobacco cessation (14/30, 47%), blood pressure management (13/30, 43%), and medication adherence (10/30, 33%). The technologies used were categorized into 3 types, smartphones and wearables (16/30, 53%), email and SMS communications (12/30, 40%), and websites or web portals (3/30, 10%). The majority of the study outcomes addressed blood pressure (14/30, 47%), exercise capacity (12/30, 40%), weight (12/30, 40%), and lipid profile (11/30, 37%), while fewer focused on nicotine dependence (9/30, 30%), medication use (8/30, 27%), quality of life (7/30, 23%), dietary habits (5/30, 17%), intervention adherence (4/30, 13%), waist circumference (4/30, 13%), and blood glucose levels (2/30, 7%).

Conclusions: Digital solutions can address challenges in traditional CVD prevention by improving preventive behaviors and monitoring health indicators. However, most evaluated interventions have focused on medication use, quality of life, dietary habits, adherence, and waist circumference. Further studies are needed to assess the long-term impact of more comprehensive interventions on key cardiovascular outcomes.

KEYWORDS

cardiovascular disease prevention; cardiovascular outcomes; digital technologies; remote care; mobile phone

Introduction

Cardiovascular disease (CVD) remains a significant worldwide health issue, making a contribution to global mortality. Approximately 70% of CVD cases are due to modifiable risk factors [1], these include lifestyle-related elements such as physical inactivity, poor dietary habits, high levels of blood pressure, and tobacco use. CVD prevention encompasses three stages: primary, secondary, and tertiary prevention. Primary prevention targets high-risk individuals without CVD [2], secondary prevention focuses on those with established CVD, and tertiary prevention is for individuals seriously affected by CVD and aims to enhance their life expectancy [3]. Despite the evidence supporting the effectiveness of CVD prevention initiatives, there is a significant difference between the potential benefits and the actual participation of individuals. Participation rates in preventive strategies still remain low, and adherence to lifestyle changes and medical recommendations is still unstable [4,5]. This arises from challenges such as socioeconomic inequalities, differences in the timing of participation, limited awareness or understanding of preventive strategies, restricted access to health care resources, and barriers related to transportation and distance [6]. Furthermore, barriers in health care systems, such as insufficient funding, fragmented care delivery, and inadequate integration, further hinder the adoption of CVD prevention measures [3].

Recent technological advances in CVD prevention offer solutions to the limitations of traditional facility-based measures. Mobile apps, wearable devices, telemedicine, and remote monitoring systems can improve individual engagement and adherence. These approaches can provide personalized instructions, real-time monitoring, and remote consultations, making it easier to manage their cardiovascular health. Moreover, they can reach broader populations, including those with limited access to health care facilities. This review employs digital health solutions to incorporate a range of technologies to facilitate care delivery. This way acknowledges the variety of digital tools available, including eHealth, mobile health (mHealth), SMS, wearable devices, mobile apps, and telemedicine.

Current studies have shown that digital solutions, such as mobile apps, hold promise for CVD prevention, but their effectiveness has mainly been demonstrated in limited settings, and broad implementation in clinical practice remains rare [7,8]. In addition, there is limited understanding of how comprehensively these digital solutions address the key components of CVD prevention and achieve targeted health outcomes. While these innovations hold the potential to enhance CVD prevention by improving accessibility, efficiency, and individual engagement, significant barriers remain. Challenges such as regulatory constraints, interoperability issues, and systemic limitations must be addressed to facilitate their effective integration into routine healthcare practices.

This study aims to evaluate the current landscape of digital technologies for CVD prevention, focusing on the comprehensiveness and effectiveness of digital solutions. Specifically, we serve multiple purposes, first, it integrates existing literature on digital solutions for CVD prevention; second, it identifies key components of CVD prevention that are effectively addressed through digital solutions; and third, it charts the gaps that need attention to facilitate the sustainable integration of digital solutions for CVD prevention into clinical practice.

Methods

Study Design

A systematic review was conducted following PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [9] (Multimedia Appendix 1) to ensure transparency and consistency in reporting. This review aimed to answer two key research questions, that are (1) “What types of digital technologies are utilized in CVD prevention studies, including their sample sizes, intervention durations, follow-up periods, and primary findings?” and (2) “How comprehensive and effective are these CVD prevention solutions?”

Eligibility Criteria

All studies published in English from January 2000 to May 2024 that examined digital solutions aimed at CVD prevention were considered for inclusion. Since Frank introduced the term “digital health” in the 2000s [10], it has transformed health care practices, bringing innovative approaches to CVD prevention worldwide. This review focused on the period from January 2000 to May 2024 (present) to capture the comprehensive applications of digital health technologies in CVD prevention, with an emphasis on primary and secondary prevention. In contrast, tertiary interventions, including coronary angioplasty, stenting, and bypass surgery, were excluded because their primary focus was on halting disease progression rather than prevention, which was beyond the objectives and scope of this study. In this review, the term “digital” refers to advanced technologies that facilitate remote, interactive, and personalized interventions. These technologies went beyond basic telephonic communication and included internet-based platforms, wearable devices that monitored and provided real-time physiological feedback, as well as mobile apps designed to track health behaviors, deliver educational content, and offer virtual guidance. As noted in the American College of Cardiology Scientific Statement on CVD Prevention [11], studies that only relied on telephone interventions were excluded. Specifically, studies were included if they (1) were original research using telemedicine or digital methods specifically targeting primary or secondary CVD prevention, (2) reported findings on feasibility and usability, and (3) were published in English. In contrast, studies were excluded if they (1) relied exclusively on telephone interventions, (2) were only available as abstracts without full-text access, (3) only focused on methodology

XSL•FO
RenderX

without primary data, (4) did not involve participants or specific groups, or (5) lacked a follow-up period, such as cross-sectional studies without outcome tracking over time.

Information Source

A comprehensive search was conducted for studies published between January 2000 and May 2024, using the Web of Science, Scopus, and PubMed databases for the selection process.

Search Strategy

The search strategy used the PICO (Population, Intervention, Comparison, Outcome)-based search string, combining keywords and abbreviations related to digital health care technologies, prevention strategies, and CVD. Terms included "digital health," "mHealth," "mobile health," "text message," "short message service," "SMS," "prevention," "prevent," "cardiovascular disease," "CVD," etc. A comprehensive list of search terms was provided in Multimedia Appendix 2. 2 researchers (YQ and CZ) independently screened and identified relevant studies. Any discrepancies were resolved through discussion, with additional input from other researchers (EM and AAA) as needed to reach a consensus.

Selection Process

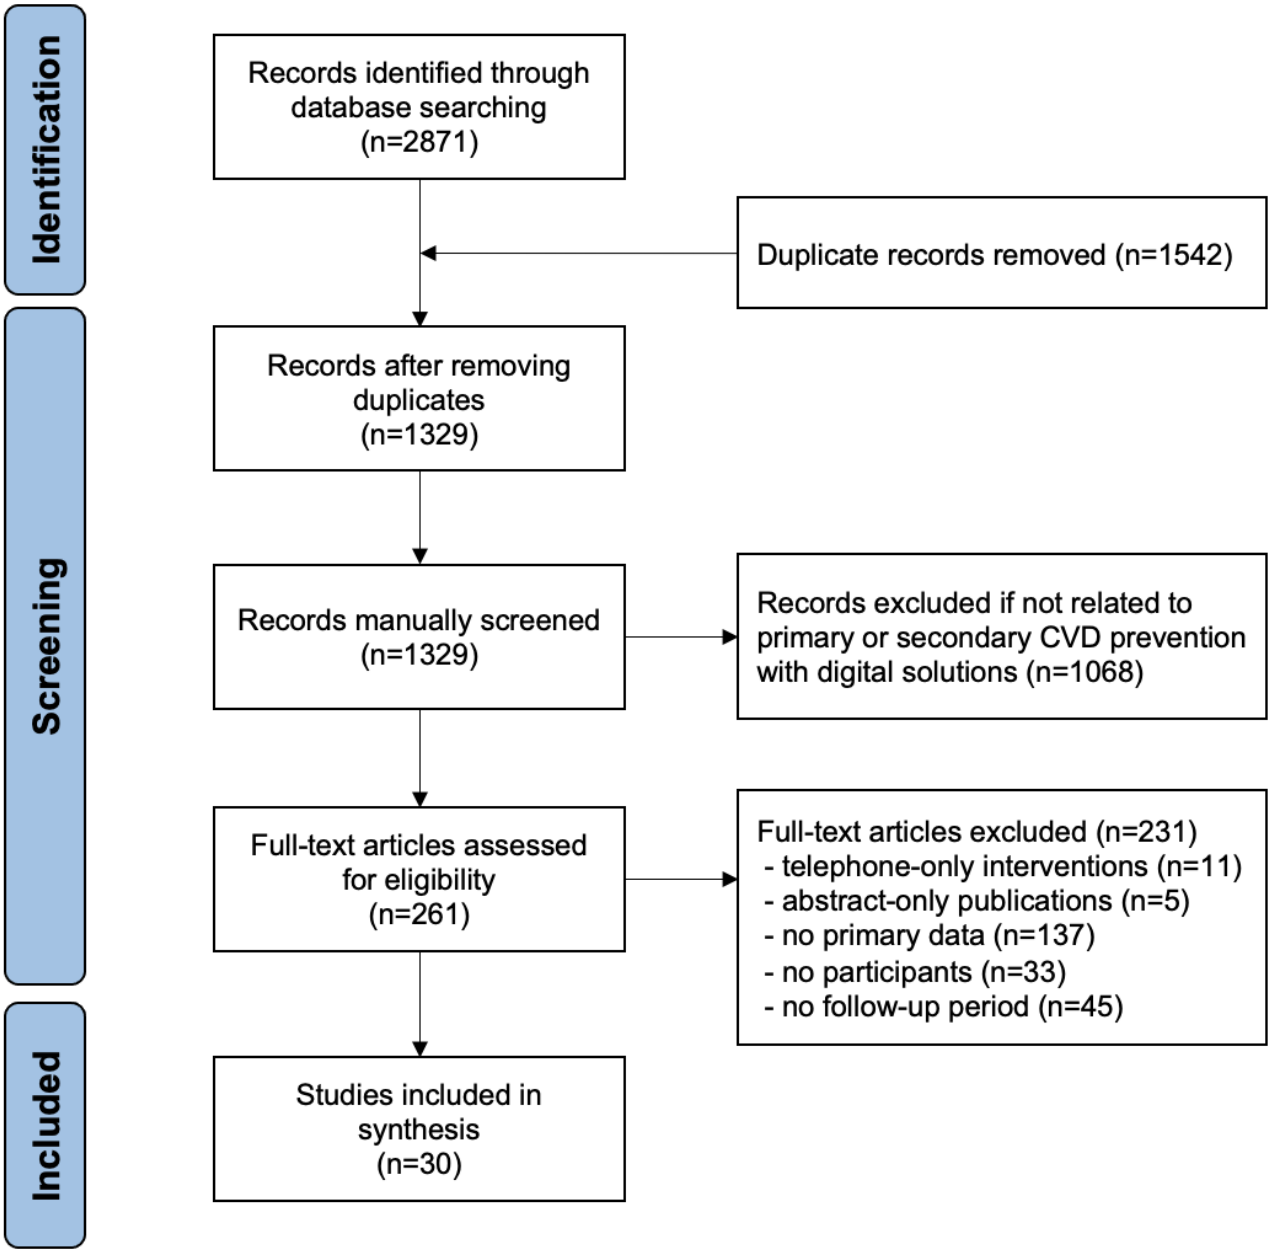
To ensure reliability and remove duplicates, 2 researchers (YQ and CZ) independently imported the articles into EndNote 21 (Clarivate) and conducted the initial screening. Discrepancies in screening decisions were resolved by a third researcher (EM). Following title and abstract screening, 2 researchers (YQ and CZ) independently conducted a full-text review, with any discrepancies resolved through consultation with the third researcher (EM).

Data Collection, Data Items, and Data Synthesis

Data collection was conducted by 2 researchers (YQ and CZ), and any disagreements were resolved through consultation with a third researcher (EM). Our approach follows the American Heart Association consensus statement [12] and Guide to Primary Prevention of Cardiovascular Diseases [13] about the components of primary and secondary CVD prevention. In addition, we divided the digital solutions outlined in each study into two groups: (1) those that operated independently and (2) those that enhanced traditional approaches to CVD prevention. According to Wongvibulsin et al [14], studies were classified as standalone solutions if the intervention primarily involved remote teaching, with the initial face-to-face meeting used for onboarding, baseline assessment, or outcome evaluation, provided that the primary intervention was delivered remotely. Moreover, we observed other characteristics including CVD prevention types, study countries, study designs applied, participation and population, duration of intervention or follow-up, personnel used, and delivery settings. Due to the significant heterogeneity among the publications, a quantitative synthesis and meta-analysis were not feasible. As a result, this study emphasized a qualitative synthesis, and data collection was conducted using Microsoft Excel 2023.

Risk of Bias Assessment and Reporting Bias Assessment

The risk of bias for all included studies was independently assessed by 2 researchers (YQ and CZ), who also verified each other's findings. Any disagreements were resolved through consultation with a third researcher (EM). Methodological rigor was ensured for each study type by the Cochrane Collaboration's Risk of Bias (RoB) 2 tool [15] for randomized studies and the ROBINS-I tool [16] for nonrandomized studies. For randomized studies, we evaluated risks associated with the randomization process, deviations from intended interventions, missing outcome data, outcome measurement, and result selection. Each risk was classified as "low risk," "some concerns," or "high risk," based on standardized criteria and expert judgment. For nonrandomized studies, we examined risks related to confounding bias, selection bias, intervention classification bias, deviations from intended interventions, missing data bias, outcome measurement bias, and reporting bias. Each risk was rated as "low," "moderate," "serious," or "critical," based on standardized criteria and expert judgment.



Results

Study Screening

Following PRISMA guidelines, we conducted a comprehensive search on the Web of Science, Scopus, and PubMed, identifying a total of 2871 articles published in English. During the initial title and abstract screening, 1542 duplicate records were identified and removed, resulting in 1329 articles proceeding to the next stage. After further title and abstract review, 1068 articles were excluded due to their lack of relevance to telemedicine or digital solutions for primary or secondary CVD prevention, leaving 261 articles for full-text screening. Among these, 231 articles were subsequently excluded for reasons such as telephone-only interventions, abstract-only publications, no primary data, no participants, and no follow-up period. When articles met multiple exclusion criteria, they were classified under the first applicable category based on priority. Finally, 30 studies were included. A PRISMA flowchart of the screening process is provided in Figure 1.

Characteristics of the Eligible Studies

This review included 30 studies meeting the inclusion criteria detailed in Multimedia Appendix 3, with their characteristics detailed in Table 1. Of the 30 studies, 24 (80%) were randomized controlled trials, 6 (20%) were nonrandomized, and 23 (77%) focused on secondary prevention. The majority were conducted in the Americas (9/30, 30%). Of the 30 studies, 16 (53%) studies used smartphones and wearables, 12 (40%) studies used email or SMS communications, and 3 (10%, 3/30) studies used websites or web portals. Interventions are most often directed by research team staff (26/30, 87%), followed by health coaches (3/30, 10%), physicians (3/30, 10%), general health professionals (3/30, 10%), nurses (2/30, 7%), dietitians (1/30, 3%), pharmacists (1/30, 3%), and community health workers (1/30, 3%). The median sample size was 465.5 (IQR 162.75-751.5), with a median follow-up period of 6 (IQR 3.5-12) months and a median intervention duration of 6 (IQR 3-12) months. In total, 28 out of 30 (93%) studies were standalone digital CVD prevention interventions. A bar chart was used to compare the number of studies that included each component of CVD prevention (Figure 2). The most common components of CVD prevention were baseline assessment (29/30, 97%), physical activity counseling (18/30, 60%), tobacco cessation (14/30, 47%), blood pressure management (13/30, 43%), and medication adherence (10/30, 33%). Approximately one-third of the studies covered additional components of CVD prevention, such as disease knowledge (9/30, 30%) and exercise training (9/30, 30%). Less than one-third of the studies focused on nutrition counseling (8/30, 27%), lipid (8/30, 27%), psychological management (7/30, 23%), diabetes (6/30, 20%), weight (6/30, 20%), heart rate (5/30, 17%), blood glucose (1/30, 3%), and alcohol use (1/30, 3%).

Bias Reporting of the Eligible Studies

In the assessment of bias among the 24 randomized controlled trials using the RoB 2 tool, 2 [17,18] studies were found to have a high risk of bias, 14 [19-32] had some concerns for risk of bias, and 8 [33-40] were rated as having a low risk of bias. Although all studies applied randomization, 9 [19,20,22,23,25,27,28,30,32] did not clearly specify the implementation details of the randomization process, and 2 [17,18] reported that participants were not blinded to their allocation due to unavoidable research limitations. For the 6 nonrandomized studies, evaluated with the ROBINS-I tool, 1 [41] study was judged to have a serious risk of bias, 4 [42-45] were assessed as having moderate risk, and 1 [46] was rated as low risk. 4 [41-44] of these studies presented concerns due to insufficient control of confounding factors in before-and-after designs, and 1 [41] study exhibited issues with missing data. Figures 3 [17-40] and 4 [41-46] summarized the results of the risk of bias assessments for the eligible studies using the RoB 2 and ROBINS-I tools.

Technology Use in Digital Solutions

The analysis of 30 selected studies categorized the use of technology in digital health solutions for CVD prevention into 3 main categories: smartphones and wearables (53%, 16/30), email-SMS communications (40%, 12/30), and websites or web portals 10% (3/30). In addition, 3% (1/30) study incorporated both email-SMS communications and websites or web portals.

More than half of the selected studies integrated smartphones or mobile devices with wearable technology for monitoring and managing patients' health conditions. Notable researchers including Johnston et al [19], Morawski et al [35], Beratarrechea et al [36], Brasier et al [43], Dorje et al [24], Perez et al [46], Grau-Pellicer et al [28], Sengupta et al, [44], Redfern et al [37], Broers et al [27], Kang et al [29], Muralidharan et al [30], and Li et al [41] focused on the efficacy of smartphone applications in preventing CVD. For instance, Johnston et al [19] evaluated an interactive patient support tool through a smartphone application designed to enhance treatment adherence and cardiovascular health among patients with myocardial infarction. According to Grau-Pellicer et al [28], they evaluated the effectiveness of a mHealth application on physical activity adherence and suggested that this technology provides a way to promote adherence to home exercise programs poststroke. Sengupta et al [44], Feldman et al [45], and Beckie et al [40] examined interventions that use smartphones and smartwatches to enhance CVD prevention. Xu et al [39] explored the smartphone-based gamification intervention for CVD prevention. The use of email-SMS communications was also considerable, indicating the popularity of interventions such as the TEXT ME program [20,21,23,26,33]. In addition, the use of email or SMS programs [18,25,34], and SMS intervention [22,32,42], illustrated the various approaches employed in the field. There was relatively limited research on the use of websites or portals. Coorey et al [38] introduced a purpose-built, versatile web-based application intervention. Sakakibara et al [31] developed an attention control memory training program delivered through the web. Maddison et al [17] took a multifaceted approach, integrating email-SMS communications and websites or portals into their interventions.

Key Outcomes

Across the 30 studies, the most common key findings are summarized in Table 2. The most frequently evaluated outcome was blood pressure (14/30, 47%). Other commonly assessed outcomes included exercise capacity (12/30, 40%), weight (12/30, 40%), lipid profile (11/30, 37%), nicotine dependence (9/30, 30%), medication use (8/30, 27%), quality of life (7/30, 23%), dietary habits (5/30, 17%), intervention adherence (4/30, 13%), waist (4/30, 13%), and blood glucose (2/30, 7%). We have distinguished between findings related to enhancing

XSL•FO
RenderX

preventive behaviors and those related to monitoring health indicators for a more nuanced understanding of the results. For instance, blood pressure was categorized as a health indicator, whereas exercise capacity was categorized as a preventive behavior for CVD prevention. After the analysis of the key findings, it was found that individuals using digital solutions generally performed better when receiving interventions compared with individuals using traditional CVD prevention measures. For instance, due to reminders and personalized feedback, digital interventions promoted more consistent medication use [19,22,32,35,36,41]. Furthermore, as a result of the enhanced engagement and support provided by these technologies, the quality of life indicators of participants using digital solutions improved significantly [17,18,27,28,31]. Dietary habits had also improved substantially, with digital platforms often providing tailored nutrition advice and monitoring that was more effective than traditional measures [18,22-24,40]. Intervention adherence was notably higher, which could be attributed to the real-time feedback provided by digital tools [19,26,41,44]. Waist circumference also showed a slight reduction among those using digital interventions [30,40,42].

Table 2. Summary of key findings by thematic outcomes.

Key findings	Studies, n	Summary
Blood pressure (health indicator)	14	8 of the 14 studies reported that the digital solutions improved blood pressure management and were no worse than the control group [18,20,24,33,35,37,40,42]. In contrast, 6 studies concluded that it did not have a statistically significant influence on blood pressure management [25,26,29,30,32,34].
Exercise capacity (preventive behavior)	12	7 studies examined exercise capacity as outcomes showing that the performance of the intervention group was comparable to that of the control group [20,21,24,28,33,37,39]. Notably, in 5 of these studies, no significant difference in exercise capacity was observed [17-19,25,26].
Weight (preventive behavior)	12	7 of the 12 studies, digital solutions were effective in addressing weight management [18,20,23,33,39,42,44]. However, 5 studies found no significant change or a slight decrease in body weight or BMI after the digital intervention [19,24-26,37].
Lipid profile (health indicator)	11	4 of the 11 studies reported elevated high-density lipoprotein levels in the intervention group [18,23,24,37]. 3 other studies showed reductions in low-density lipoprotein and total cholesterol levels [20,33,42]. No significant changes were observed in the remaining 4 studies [25,26,29,32].
Nicotine dependence (health indicator)	9	Of the 9 studies included, 4 showed a positive trend towards improvement in smoking habits, as evidenced by a reduction in nicotine dependence scores [20,29,33,36], while the remaining 5 did not change significantly [19,22,24,26,37].
Medication use (preventive behavior)	8	6 studies found that medication use was beneficial and had a positive effect [19,22,32,35,36,41]. However, 2 studies reported slight or insignificant changes due to medication [37,45].
Quality of life (preventive behavior)	7	5 studies documented an improvement in quality of life for participants in the intervention group [17,18,27,28,31]. Conversely, 2 studies failed to observe significant differences in quality of life [19,24].
Dietary habits (preventive behavior)	5	Of the 5 studies reviewed, all reported improvements in dietary habits [18,22-24,40].
Intervention adherence (preventive behavior)	4	4 studies provided evidence to support the idea that digital solutions can improve individuals' adherence to interventions [19,26,41,44].
Waist (health indicator)	4	3 studies showed a slight reduction in waist circumference after the digital intervention [30,40,42]. However, there was also 1 study in which no significant effects were observed [34].
Blood glucose (health indicator)	2	1 study showed the effectiveness of interventions in managing blood glucose levels [25]. In contrast, 1 study found no significant benefit in this regard [18].

Notably, the digital solution showed efficacy comparable to the traditional control group across outcomes, including nicotine dependence, blood pressure, blood glucose levels, exercise capacity, and weight management. For example, digital interventions had the same impact on nicotine dependence as traditional interventions, with nearly half of the studies showing a positive trend toward improving smoking habits [20,29,33,36], and the remaining half showing no significant change [19,22,24,26,37]. Similarly, blood pressure, blood glucose levels, exercise capacity, and weight management results were comparable to those of the traditional control group. However, the effectiveness of digital solutions varies when it comes to lipid profiles. Of the 11 studies reviewed, 4 reported elevated high-density lipoprotein levels in the intervention group [18,23,24,37]. 3 other studies showed reductions in low-density lipoprotein and cholesterol levels [20,33,42]. No significant changes were observed in the remaining 4 studies [25,26,29,32].

Study outcomes varied across follow-up times. Dietary habits and intervention adherence yielded positive results at various intervals, including 3, 6, and 12 months [18,22-24,40], as well

XSL•FO
RenderX

as 3, 5, 6, and 8 months [19,26,41,44]. Waist circumference decreased at 3 months in studies by Beckie et al [40], Jones et al [42], and Muralidharan et al [30], but Anand et al [34] found no significant effects at 12 months. Quality of life was assessed at 6-month intervals [17,18,27,31] and at 2 months [28], with Johnston et al [19] and Dorje et al [24] finding no significant differences in the digital intervention versus usual care groups at 6 and 12 months. Medication uses improved health outcomes over 3, 5, 6, and 12 months [19,22,32,35,36,41], although Feldman et al [45] and Redfern et al [37] observed minimal changes over longer periods (12 and 43 months). Studies on nicotine dependence showed varied results, with some studies indicating positive trends over longer follow-ups [20,29,33,36], while others reported different outcomes [19,22,24,26,37]. Positive blood pressure outcomes were reported within 3 months by Beckie et al [40], Jones et al [42], and Morawski et al [35], with improvements observed at 6 months by Chow et al [33] and Yousuf et al [18]. Dorje et al [24] and Redfern et al [20,37] noted significant benefits at 12 months, whereas Anand et al [34], Kang et al [29], and Cheung et al [32] respectively found no significant impact at 12 and 6 months. Muralidharan et al [30], Huo et al [25], and Zheng et al [26] did not observe notable improvements over 3, 6, and 8 months. Few studies exist on blood glucose levels, with Huo et al [25] showing effectiveness at 6 months, but Yousuf et al [18] found no significant benefits during the same period. For exercise capacity, positive findings were reported at 6 and 12 months by Chow et al [33], Thakkar et al [21], Dorje et al [24], and Redfern et al [20,37], with shorter follow-ups also supporting these findings. However, no significant differences were found between digital intervention and usual care groups at 6 or 8 months [17-19,25,26]. For weight management, significant reductions were noted at 6 and 12 months by Chow et al [33] and Redfern et al [20], while Jones et al [42] and Sengupta et al [44] reported favorable outcomes at 3 months. However, minimal to no improvements were found by Dorje et al [24] and Huo et al [25] at 6 months. Johnston et al [19] and Redfern et al [37] also showed no significant changes at 6 and 12 months, respectively. Studies with 3 to 6-month follow-ups predominantly showed no significant changes in lipid profiles, with minimal impacts observed within 6 months [23,32,42]. Conversely, longer follow-ups tended to show more pronounced effects, such as significant increases in high-density lipoprotein reported by Dorje et al [24] and Redfern et al [37] and reductions in low-density lipoprotein and total cholesterol observed by Redfern et al [20] and Chow et al [33]. However, Huo et al [25] and Kang et al [29] found no significant lipid changes in long-term studies.

The review examined the comprehensive standalone interventions and found that the interventions in 7 studies identified as standalone included 5 components or more for CVD prevention, excluding baseline assessments [18,23,24,26,29,30,37]. Outcomes associated with most of the key outcomes associated with the prevention of CVD components were heterogeneous throughout the intervention. Among these 7 studies, Redfern et al [37] documented outcomes regarding medication use, showing no significant effects. Regarding blood glucose, Yousuf et al [18] did not find a significant benefit. With regard to waist circumference, Muralidharan et al [30] demonstrated a reduction in waist circumference after the digital intervention. Santo et al [23], Dorje et al [24], and Yousuf et al [18] observed improvements in mood within the intervention group, while Redfern et al [37] found similar results. Nevertheless, Kang et al [29] and Zheng et al [26] discovered that the digital solutions did not significantly impact lipid profiles. Regarding weight management, Santo et al [23], Yousuf et al [18], and Redfern et al [37] observed that digital solutions were effective. In contrast, Dorje et al [24] and Zheng et al [26] reported that there was no significant change, or even a slight decrease, in body weight or BMI after the digital intervention. Santo et al [23], Dorje et al [24], and Yousuf et al [18] all recorded improvements in dietary habits. Dorje et al [24], Yousuf et al [18], Redfern et al [37], and Muralidharan et al [30] reported that the digital solution significantly enhanced blood pressure management and was no worse than the control group. However, Kang et al [29] found that digital solutions did not significantly affect blood pressure management. In terms of exercise capacity, Dorje et al [24] and Redfern et al [37] showed that the intervention group was similar to the control group. Yousuf et al [18] and Zheng et al [26] discovered that there was no difference in exercise capacity between the digital intervention group and the control group. For nicotine dependence, Kang et al [29] showed a positive trend toward improving smoking habits, while Dorje et al [24], Zheng et al [26], and Redfern et al [37] showed no significant change. In terms of quality of life, Yousuf et al [18] reported enhanced quality of life, while Dorje et al [24] reported no significant difference in the quality of life of intervention groups. Overall, interventions taken and reported outcomes varied.

Discussion

The Role of Digital Solutions for CVD Prevention

The study highlights the potential of digital technologies to enhance health care delivery and expand CVD prevention by enhancing preventive behaviors and monitoring health indicators. These digital solutions can significantly improve individual outcomes and facilitate the wider implementation of preventive approaches. Unlike previous systematic reviews, which often focused narrowly on specific aspects of digital health, our study provides a comprehensive assessment of digital solutions, including primary and secondary CVD prevention. Our review demonstrates the varied effectiveness of these digital solutions. However, variations in potential risks of bias, as assessed, should be considered when interpreting the findings. Based on existing studies, our review supports remote CVD prevention through internet-based platforms and digital devices, which offer innovative ways to monitor, educate, and engage individuals. Our findings show that using digital solutions to prevent CVD is both feasible and effective, and the results are comparable to traditional approaches. Whether as a complement or substitute for traditional approaches, digital solutions show great potential in improving individual health outcomes [19,21-28,30,33,35,36,39-43]. Notably, the integration of digital technologies into CVD prevention can make more efficient use of health care resources, reduce the burden on health care systems, and provide cost-effective solutions for individuals [17,18].

XSL•FO
RenderX

The results of our review are consistent with previous studies, including Gray et al [47], which demonstrated the effectiveness of remote consultation, smartphone applications, wearables, remote monitoring, and predictive analytics in influencing individual behavior. These digital solutions can greatly contribute to the primary and secondary prevention of CVD and play a role in preventing and managing disease. In addition, Moshawrab et al [48] showed that wearable devices were highly accurate in detecting, predicting, and even treating CVD. Their study highlighted the potential of digital health solutions to improve individual outcomes and optimize the use of health care resources, further supporting their integration into standard CVD prevention strategies. Our review and the included studies highlight the role of effective communication strategies in the success of digital health solutions for CVD prevention. Effective communication influences user engagement, adherence, and the overall impact of these interventions. Specific strategies, such as using interactive features to boost engagement, providing reminders to support adherence, offering support through virtual coaching, tailoring experiences to individual needs, and implementing feedback mechanisms, can significantly motivate individuals to participate and commit to preventive behaviors. By fostering a supportive environment, effective communication strengthens relationships between health care providers and patients, empowering individuals to take an active role in managing their health and promoting health outcomes. However, the effectiveness of communication strategies in digital health solutions is hindered by barriers related to digital literacy and access. Many individuals, particularly those at higher risk of CVD, may lack the skills required to use digital tools effectively. Without sufficient digital literacy, the potential benefits of remote consultations, smartphone applications, wearables, and remote monitoring systems may remain inaccessible for some individuals. The digital divide, marked by disparities in digital skills and access, poses a significant obstacle to the equitable and effective implementation of digital health solutions [49]. To address these barriers, targeted strategies to improve digital literacy are essential. Initiatives may include specialized training programs designed to help users develop the skills necessary to engage effectively with digital health tools, with a focus on older adults and underserved populations who may face greater challenges. Furthermore, designing user-friendly interfaces and simplifying onboarding processes can facilitate initial engagement and reduce usability obstacles. Health care providers also play a role in offering technical support, instructions, and tutorials that guide users in understanding and integrating digital tools into their daily routines. Enhancing digital literacy and access is important to enabling effective communication, thereby amplifying the impact of digital health solutions for CVD prevention. By improving digital skills and accessibility, individuals can more effectively set baselines, customize treatment plans, monitor progress, and receive tailored support, which strengthens their capacity to engage with preventive behaviors and optimize health outcomes.

Limitations and Future Research Recommendations

Some limitations appeared in our review. First, although this review aimed to address the effects and factors surrounding specific phenomena, we did not use meta-analysis methods to summarize empirical evidence due to the heterogeneity of the studies. The reviewed articles exhibited significant variation in study designs, main outcomes, technologies, and control groups. For instance, some studies focused on a single digital health intervention, such as a mobile health application, while others looked at a combination or multiple uses of various digital technologies. In addition, when considering control groups, some studies used standard care in people with traditional CVD prevention, while others did not include control groups. Second, this review used RoB 2 and ROBINS-I tools to assess the risk of bias in the included studies. While both tools were widely recognized for evaluating bias, they might be influenced by subjective judgment, particularly in complex cases where interpretations of criteria can vary among evaluators. Third, our review was limited in scope and time frame. While we included studies published between 2000 and 2024, the earliest studies meeting our inclusion criteria were from 2015, likely because digital solutions for disease prevention represent a relatively new field that has emerged with recent technological advances. Furthermore, our search was limited to 3 databases and did not include reference list searches and gray literature. As this is a rapidly evolving field, studies published after the search date may have been missed. Fourth, our review only highlighted primary and secondary prevention of CVD. However, tertiary prevention, which involved advanced medical procedures and interventions aimed at managing and mitigating the long-term effects of diagnosed CVD, also played a role in the integrated management of CVD. Therefore, we suggested several strategies for future research. First, it is crucial that future studies standardize the objectives of interventions to ensure consistency in study design, outcome measures, and control groups. Specifically, researchers should clearly define whether their digital solutions are intended as comprehensive standalone programs or as complementary tools to traditional prevention approaches. Second, future research should also aim to standardize and provide detailed descriptions of the specific CVD prevention components targeted by the intervention. This includes specifying whether the intervention's goal is to enhance preventive behaviors, monitor key health indicators (eg, blood pressure and cholesterol), or address both aspects simultaneously. Third, it is essential to incorporate robust measures of user engagement and behavior modification in evaluating digital solutions. Researchers should use validated metrics such as compliance rates, user satisfaction surveys, and long-term health outcomes to assess the impact of digital interventions on user behavior and sustained engagement. Finally, exploring the cost-effectiveness of digital solutions for CVD prevention, including tertiary prevention, compared to traditional approaches is crucial. Future studies should assess not only direct costs but also factors such as scalability, maintenance, and initial setup costs.

We have identified several key aspects for future research in the field of digital interventions for CVD prevention. First, while digital solutions effectively address factors such as eating habits, interventions targeting other risk factors, including blood glucose control, are still lacking. Moreover, further evaluation is needed to assess the ongoing efficacy of these digital solutions, so studies using a larger population and implementing suitable control groups are needed [8,50]. Second, future

XSL•FO
RenderX

research should focus on integrating multifaceted interventions to address a wide range of CVD risk factors, including stress management. It is crucial to study the synergies of combining digital tools such as mobile apps, wearables, and telemedicine. Understanding the psychological and behavioral mechanisms behind user engagement, such as motivation, digital literacy, and personalization, is also critical to improving adherence and sustained behavior change [51]. Third, it is crucial to evaluate the incidence of adverse events among individuals undergoing these interventions compared to traditional methods [14]. Rigorous monitoring and reporting of adverse events will provide insight into the potential risks associated with these technologies, helping to refine protocols and ensure individual safety. Finally, exploring the potential of artificial intelligence (AI) to improve communication effectiveness by personalizing and tailoring interventions in real time could significantly improve user experience [52,53]. As an emerging field, AI has shown great potential in fields such as health care and education. In the field of CVD prevention, its ability to analyze large datasets, predict individual outcomes, and tailor interventions to individual health conditions holds great potential for strengthening prevention measures and optimizing patient care pathways [52-54]. As research in this field continues to advance, the integration of AI into clinical practice could lead to more effective, personalized, and accessible solutions to combat CVD worldwide.

Conclusions

Our study highlights the potential of digital technologies to alleviate challenges associated with traditional CVD prevention approaches by enhancing preventive behaviors and monitoring health indicators. The widespread implementation of digital solutions in CVD prevention is expected to have a significant impact, increasing accessibility, affordability, and cost-effectiveness, and improving individual outcomes beyond what can be achieved with traditional approaches. However, interventions evaluated focused primarily on medication use, quality of life, dietary habits, intervention adherence, and waist circumference, with limited attention to other components of CVD prevention. In addition, our study primarily assessed the technical aspects and comprehensiveness of digital procedures in the prevention of CVD. However, the complexities associated with the certification of CVD prevention programs are beyond the scope of this review. Future studies should aim to explore more comprehensive CVD prevention interventions to assess their long-term and sustained impact.

Abstract

Background: The aging global population and the rising prevalence of chronic disease and multimorbidity have strained health care systems, driving the need for expanded health care resources. Transitioning to home-based care (HBC) may offer a sustainable solution, supported by technological innovations such as Internet of Medical Things (IoMT) platforms. However, the full potential of IoMT platforms to streamline health care delivery is often limited by interoperability challenges that hinder communication and pose risks to patient safety. Gaining more knowledge about addressing higher levels of interoperability issues is essential to unlock the full potential of IoMT platforms.

Objective: This scoping review aims to summarize best practices and technologies to overcome interoperability issues in IoMT platform development for prehospital care and HBC.

Methods: This review adheres to a protocol published in 2022. Our literature search followed a dual search strategy and was conducted up to August 2023 across 6 electronic databases: IEEE Xplore, PubMed, Scopus, ACM Digital Library, Sage Journals, and ScienceDirect. After the title, abstract, and full-text screening performed by 2 reviewers, 158 articles were selected for inclusion. To answer our 2 research questions, we used 2 models defined in the protocol: a 6-level interoperability model and a 5-level IoMT reference model. Data extraction and synthesis were conducted through thematic analysis using Dedoose. The findings, including commonly used technologies and standards, are presented through narrative descriptions and graphical representations.

Results: The primary technologies and standards reported for interoperable IoMT platforms in prehospital care and HBC included cloud computing (19/30, 63%), representational state transfer application programming interfaces (REST APIs; 17/30, 57%), Wi-Fi (17/30, 57%), gateways (15/30, 50%), and JSON (14/30, 47%). Message queuing telemetry transport (MQTT; 7/30, 23%) and WebSocket (7/30, 23%) were commonly used for real-time emergency alerts, while fog and edge computing were often combined with cloud computing for enhanced processing power and reduced latencies. By contrast, technologies associated with higher interoperability levels, such as blockchain (2/30, 7%), Kubernetes (3/30, 10%), and openEHR (2/30, 7%), were less frequently reported, indicating a focus on lower level of interoperability in most of the included studies (17/30, 57%).

Conclusions: IoMT platforms that support higher levels of interoperability have the potential to deliver personalized patient care, enhance overall patient experience, enable early disease detection, and minimize time delays. However, our findings highlight a prevailing emphasis on lower levels of interoperability within the IoMT research community. While blockchain, microservices, Docker, and openEHR are described as suitable solutions in the literature, these technologies seem to be seldom used in IoMT platforms for prehospital care and HBC. Recognizing the evident benefit of cross-domain interoperability, we advocate a stronger focus on collaborative initiatives and technologies to achieve higher levels of interoperability.

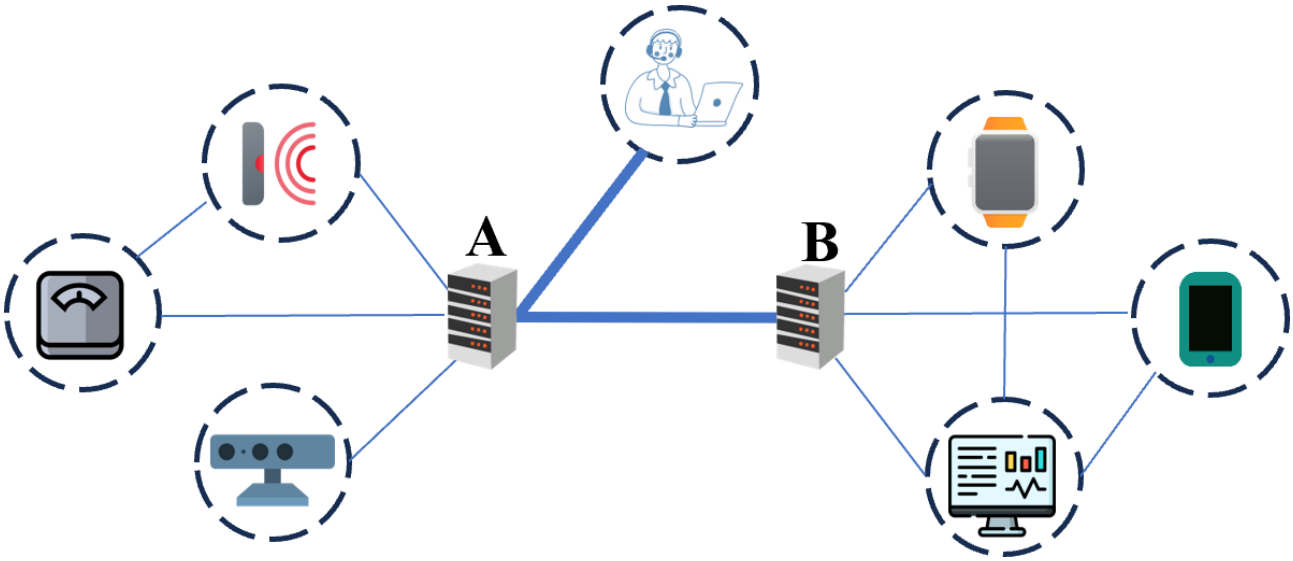
KEYWORDS

Internet of Medical Things; enabling technologies; standards; cross-domain interoperability; scoping review; technology; medical emergency; internet; prehospital care; gerontology; global population; chronic disease; multimorbidity; health care system; home-based care; innovation; digital health; health informatics; telehealth; artificial intelligence

Introduction



Background

The aging world population and an increased prevalence of chronic conditions and multimorbidity have placed greater pressure on health care systems and professionals [1]. In Europe, over 50 million people have at least 1 chronic disease [2]; and in the United States, it is estimated that the number of people aged 50 years and older with at least 1 chronic disease will increase by 100%, from 71 million in 2020 to 142 million by 2050 [3]. The incidence of life-threatening falls among older adults (aged ≥70 y) continues to rise globally [4]; together with other age-related medical emergencies, such as stroke [5], these events claim millions of lives each year [5,6]. The notable changes in global demographics, combined with the prevalence of frailty among older adults, underscore the importance of expanding the human resources available in the public health sector. Nevertheless, due to economic and occupational constraints, this may not be a feasible solution [7]. To alleviate the pressure on health care systems, more sustainable initiatives need to be implemented. One potential solution often discussed in the literature is the transition to home-based care (HBC) [8,9]. HBC covers a wide continuum of care and involves delivering increasingly complex health care services to individuals in their own residences, allowing them to maintain their independence as an alternative to relying on residential, long-term, or institutional nursing care [10,11]. This transition is often supported by older adults because the majority choose to remain in their own homes for as long as possible [12,13].

To support the transitioning to HBC, there is a growing demand for new technological innovations and collaborative initiatives [14]. This often involves modifications of peoples' homes and the use of medical equipment that not only facilitates long-term health monitoring but also enables the management of medical emergencies that demand rapid medical attention [15-17]. This is particularly important in the case of older adults (aged ≥65 y) because their inability to manually initiate an emergency alarm after a sudden deterioration in physical condition (eg, acute stroke or hip dislocation after a fall) may lead to long-term consequences and increased mortality [15]. Studies have shown that Internet of Medical Things (IoMT; Figure 1) platforms have the potential to support the transitioning to HBC by streamlining workflows, reducing costs and time delays, and improving patient well-being [18-20]. While previous research has demonstrated the usefulness of stand-alone platforms for the monitoring of chronic conditions and detection of abnormalities, there has been limited focus on achieving higher levels of interoperability within IoMT [21-24]. Although stand-alone platforms may be feasible in certain situations, the lack of interoperability with external systems such as electronic health records (EHRs), emergency medical services, and public safety answering points (PSAPs) may lead to data becoming trapped within silos, potentially resulting in delayed information transfer, suboptimal decision-making, and patient harm [7,21,25,26]; for example, a study conducted by Magrabi et al [27] showed that approximately 20% of reported patient safety hazards were linked to deficient information transfer. Furthermore, Hyvämäki et al [26] showed that inadequate documentation and use of information in HBC plays a significant role in interorganizational health information exchange–related incidents, resulting in, for example, delayed care and patient harm.

XSL•FO
RenderX

Figure 1. In this study, the Internet of Medical Things (IoMT) was defined as a network of interconnected medical devices and health care systems that use the internet to collect, transmit, and exchange health care data. The figure illustrates device-to-device (thin lines), device-to-system (thin lines), and system-to-system (thick lines) communication, with 2 IoMT platforms (A and B) interacting with each other.

At Chalmers University of Technology in Gothenburg, Sweden, the Care@Distance research group is active in the field of remote and prehospital digital health. The group is dedicated to improving health care delivery through interoperable cutting-edge solutions, encompassing clinical decision support systems, artificial intelligence (AI), modern IT, and innovative user interactions. While interoperability offers numerous advantages, we acknowledge that current medical data still contain nonstandard elements [28,29], and vendors continue to use their own proprietary solutions [29]; for example, most inpatient EHRs include over 5000 variables [28,29], making it difficult to ensure a shared understanding of medical concepts across domains and organizations [29]. One system may code "A fall on and from stairs and steps" as W10 in the *International Classification of Diseases, Tenth Revision, Clinical Modification* (*ICD-10-CM*), while another system uses Systematized Nomenclature of Medicine–Clinical Terms (SNOMED CT) code 900000000000448009 for "Fall on stairs." Establishing a shared understanding of these 2 terms requires a translation [21]. As the number of unique systems and standards increases, the need for separate translations also increases, especially considering that SNOMED CT includes over 340,000 medical concepts (clinical findings, procedures, substances, etc) [29]. Due to these complex translation processes within health care, involving various file formats (eg, text, video, images, and audio), communication protocols, and semantics, over 80% of all medical data tend to be overlooked or discarded [19]. This not only hampers communication between systems but also limits the use of AI, international cooperation, and research [29]. As the technological landscape expands, navigating among the available technologies and standards is becoming increasingly challenging. Hence, in this study, we summarize existing knowledge and best practices to overcome interoperability issues in IoMT platform development to manage medical emergencies within HBC and prehospital care settings.

Objectives

This scoping review aims to summarize and map the enabling technologies that can be used to develop interoperable platforms to manage medical emergencies in HBC and prehospital care. We have proceeded from a 6-level interoperability model comprising device, network, syntactical, semantic, cross-platform, and cross-domain interoperability and a 5-level IoMT reference model comprising perception, transport, processing, application, and business layers [11]. These models provide adequate granularity and context to be applied within the context of IoMT [10]. Relevant actors and domains within the IoMT domain include homes, sensor providers, emergency medical services, PSAPs, social security services, and hospitals. The aim is to describe technologies and their use in an accessible way, enabling cross-disciplinary discussion between clinicians and engineers. This scoping review can potentially serve as a guide for software developers, clinicians, and other practitioners aiming to develop interoperable IoMT platforms.

Methods

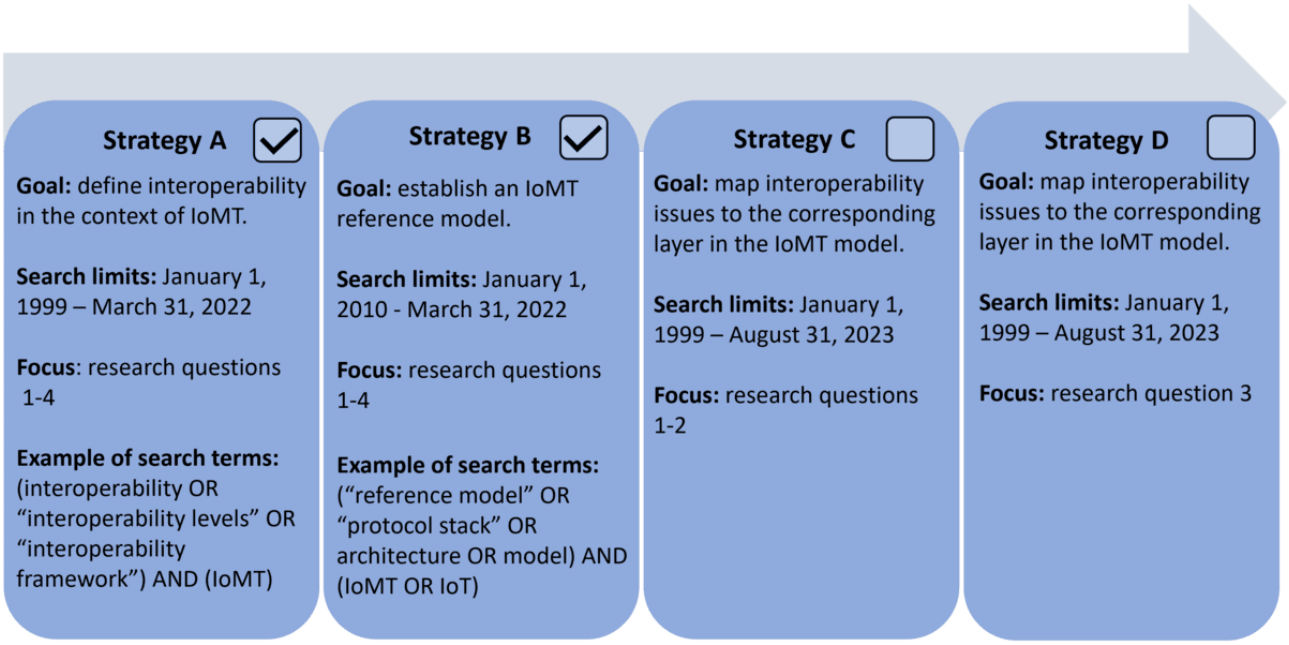
Overview

This scoping review follows the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines for scoping reviews (refer to Multimedia Appendix 1 for the PRISMA-ScR checklist) [30] and adheres to the methodology outlined in the research protocol [11]. Given the broad spectrum of research questions addressed in this scoping review, the methodology includes 4 distinct search strategies, referred to as strategies A to D in the research protocol [11]. The relationships between these search strategies are illustrated in Figure 2.

This approach allows each research question to be addressed more systematically by separating the search terms, search periods, and goals within each search strategy. Search strategies A and B were completed with the research protocol [11] (Figure 2) and addressed the following research questions:

1. What are the current challenges of developing a real-time IoMT platform for managing medical emergencies such as falls?

XSL•FO
RenderX



2. What is interoperability? How can it be defined in the context of IoMT?
3. What types of models are used to visualize the different layers of interoperability? When talking about medical devices in an IoMT setting, which model is preferable and why?
4. Which reference model with corresponding protocols can best describe and define the structure of key aspects of the information being managed in a real-time IoMT system? How is the model being used today?

These 4 research questions were addressed in the research protocol [11], resulting in the definition of a 6-level interoperability model and an IoMT reference model to be used as reference materials in this scoping review. On the basis of these definitions, this scoping review will proceed with search strategies C and D (Figure 2), focusing on answering the following research questions:

1. Have any studies examined which current technologies are associated with the layers in the IoMT reference model, comprising device, network, syntactical, semantic, cross-platform, and cross-domain interoperability, and how these are being used to fulfill the set of rules defined by each layer? If so, what are the results?
2. How can interoperability solutions be mapped to the layers in the interoperability model?
3. What recommendations regarding enabling technologies can be given to clinicians and practitioners who want to develop IoMT platforms that can aggregate, store, and process data from relevant actors in prehospital care and HBC settings?

Research questions 1 and 2 are addressed in search strategy C, and research question 3 is addressed in search strategy D in this review.

Figure 2. This scoping review used a 4-strategy approach to streamline the search process. Strategies A and B were conducted as part of the research protocol [11], while strategies C and D are addressed in this scoping review. HBC: home-based care; IoMT: Internet of Medical Things.

Search and Screening Process

Six electronic databases were used in this study: IEEE Xplore, PubMed, Scopus, ACM Digital Library, Sage Journals, and ScienceDirect [11]. In the published protocol, we had proposed using the Google Scholar database, but we replaced it with the ACM Digital Library in this review to ensure higher precision in search results [31,32] (refer to Multimedia Appendix 2 for the search terms used for search strategies C and D). The retrieved articles were assessed for inclusion based on predefined eligibility criteria and underwent a 2-step screening process using the web application Rayyan (Rayyan Systems Inc) [33]. The screening was performed by HJ and MS, and any disagreements were resolved through discussion between them [11].

Eligibility Criteria

The eligibility criteria were originally defined in the research protocol [11]. However, a minor adjustment was necessary to streamline the screening process and enhance clarity (Textbox 1). The last inclusion criterion was updated to emphasize a stronger focus on technologies that address interoperability issues.

XSL•FO
RenderX

Textbox 1. Eligibility criteria.

Inclusion criteria

- Published peer-reviewed journals and conference papers
- Written in English
- Published between January 1,1999, and August 31, 2023
- Studies describing or reporting the development or design of Internet of Medical Things (IoMT) systems with a focus on technology
- Studies reporting challenges and barriers to integrating IoMT platforms into prehospital care or home-based care settings with a focus on technology
- Studies describing the enabling technologies that can be used to solve interoperability issues in IoMT platform development

Exclusion criteria

- Full-text articles that were unavailable or not written in English
- Conference abstracts, book reviews, commentaries, and editorial articles
- Studies focusing on hardware, project management processes, or regulatory compliance
- Studies reporting on the design or development of IoT applications with no focus on health data (eg, Industry 4.0, including the automotive, food, and manufacturing industries)
- Studies describing the design or development of machine learning methods to achieve interoperability

Data Extraction

In search strategy C, data were extracted to map interoperability solutions to their respective interoperability models, categorizing them based on the specific level of interoperability addressed. The mapping was based on the 6-level interoperability model and the 5-level IoMT reference model established in the research protocol [11]. Similar mappings that could be found in the literature acted as a reference and, combined with the expertise of our research group, were used to validate the mappings.

In search strategy D, previous efforts in IoMT platform development for prehospital care and HBC were examined. A thematic analysis approach was used to identify and summarize the technologies and standards used in these development processes (Textbox 2). This analysis was performed by 1 reviewer (MS) using Microsoft Excel (version 2403) and the web application Dedoose (version 9.0.107; SocioCultural Research Consultants LLC). The thematic analysis was based on the framework outlined by Braun and Clarke [34]. The framework was adapted to this study and included five steps:

1. Reading through the literature and recording valuable aspects of the data, including the technologies and standards used
2. Organizing data into meaningful groups and creating codes relevant to the research questions (each technology was assigned a code, represented by a short descriptive summary of its intended use; Textbox 2)
3. Collating codes and assigning different keywords to them (each code could be assigned multiple keywords; the keywords were used to facilitate thematic analysis, aiming to conceptualize the functionality of each level in the interoperability model)
4. Assigning a nonoverlapping theme to each technology based on the codes and keywords (technologies with similar codes and keywords were assigned the same theme; a theme was defined as one of the following interoperability levels: device, network, syntactical, semantic, cross-platform, or cross-domain interoperability)
5. Compiling the thematic insights into a coherent review

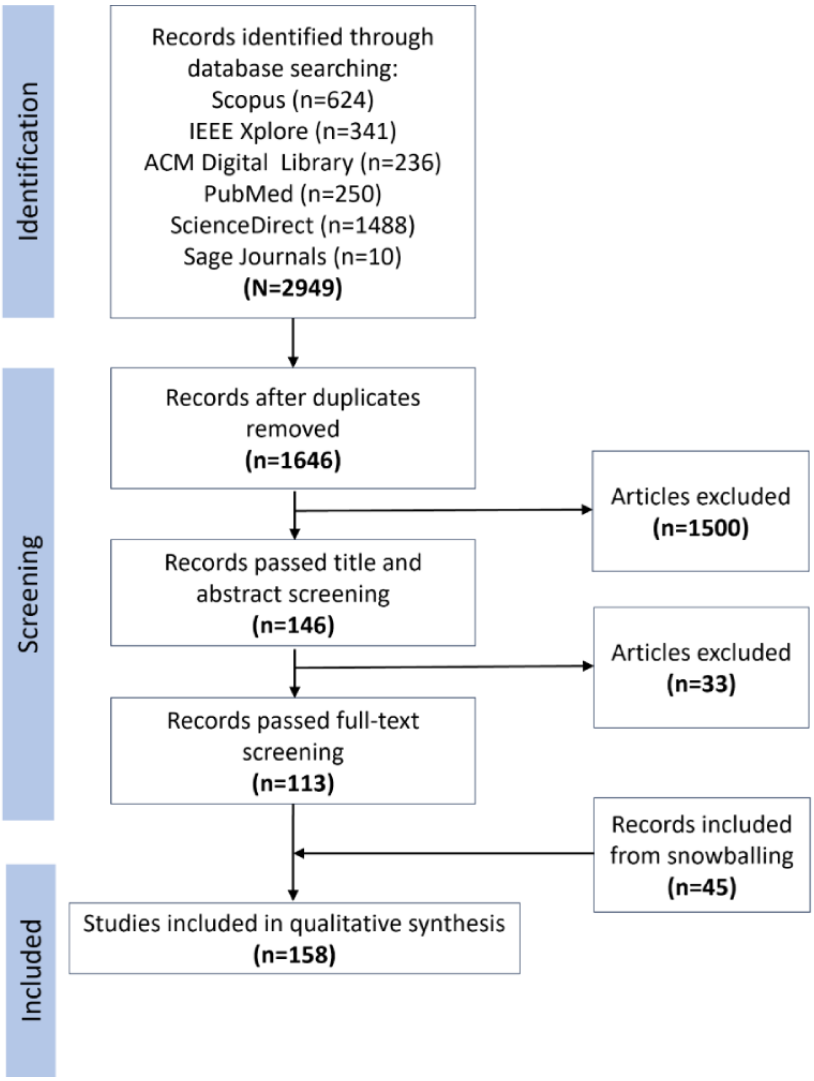
Textbox 2. An example of the thematic analysis process. The applicability of the mapping was confirmed by our research group through tests with multiple articles [35].

Blockchain technology mapped to cross-domain interoperability

- Technology: blockchain
- Description in literature: “integration of blockchain into healthcare applications, including all aspects of privacy, validity of safety, and access to patient and electronic health records”
- Code assigned: blockchain can be used to preserve privacy and integrity of health data
- Keywords: security, data privacy, and integrity
- Assigned theme: cross-domain interoperability

From the thematic analysis, a list of commonly used technologies was compiled. Each technology was accompanied by a descriptive overview of its application area and function, along with a mapping to one of the levels in the interoperability model defined in the research protocol [11]. For each study, the main areas of interest were identified, such as citation details (eg, author, year of publication, and country of origin) and key study characteristics (eg, type of IoMT platform, platform

XSL•FO
RenderX



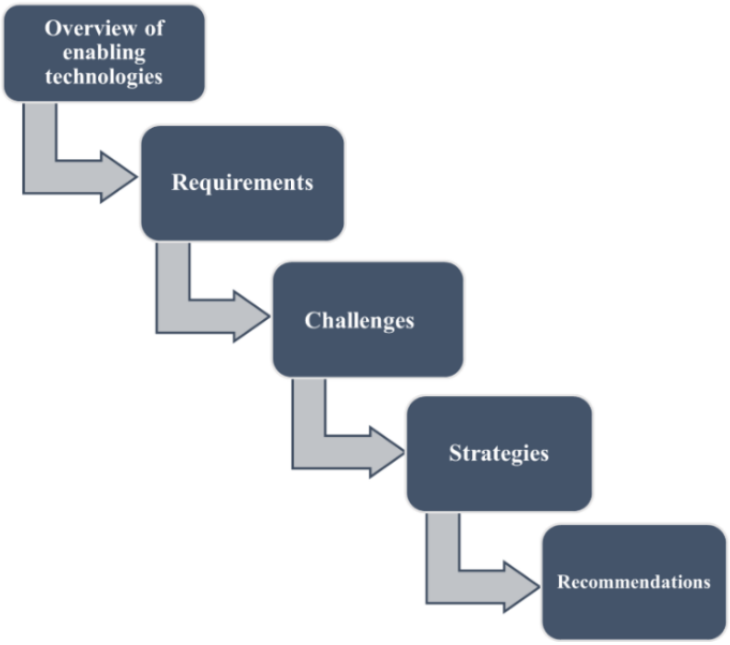
requirements, interoperability challenges, and the technologies and standards used to achieve different levels of interoperability). The results were summarized using narrative descriptions as well as figures and tables. The data extraction process ensured that sufficient data were gathered to answer each research question.

Results

Study Selection

The study selection flowchart is presented in Figure 3. A total of 2949 articles were identified (n=2306, 78.2% retrieved through search strategy C and n=643, 21.8% retrieved through search strategy D). After screening and snowballing, 158 articles were included in this study (n=84, 53.2% from strategy C, n=29, 18.4% from strategy D, and n=45, 28.5% from snowballing). Of the 33 articles excluded after title and abstract screening, 7 (21%) were left out because they were in non-English languages.

Figure 3. Study selection flowchart.



Subsections

This section is divided into 5 subsections (Figure 4). In the first, we provide an overview of the technologies and standards applicable to IoMT, emphasizing their relevance in addressing various levels of interoperability, as introduced in the research protocol [11]. In the second subsection, we present common interoperability requirements identified in the included studies, focusing on their application in prehospital care and HBC scenarios. Next, in the third subsection, we explore the interoperability challenges associated with IoMT platform development. In the fourth subsection, we summarize previous efforts in IoMT platform development and the technologies and standards used in these initiatives. Finally, in the fifth subsection, we draw upon our research findings to present actionable insights and recommendations for addressing interoperability challenges.

XSL•FO
RenderX

Figure 4. The main Results section is divided into 5 parts: overview (a summary of the enabling technologies that address various levels of interoperability), requirements (mapping Internet of Medical Things [IoMT] platform needs to the enabling technologies), challenges (presenting common interoperability challenges), strategies (outlining strategies to overcome these challenges), and recommendations (offering our research group's suggestions for addressing interoperability issues in IoMT platform development).

An Overview of the Enabling Technologies That Address Interoperability Issues Within IoMT

In the following subsections, we have categorized and summarized the enabling technologies based on the specific interoperability level they address (refer to Multimedia Appendix 2 for a description of the enabling technologies).

Device Interoperability

Device interoperability is the foundational level of interoperability [36] and involves ensuring that heterogeneous devices can physically connect and communicate in a restricted network, typically a personal area network (PAN) [36]. Solving issues at this level is often the first step in IoMT platform development processes because interoperable sensors are a prerequisite for subsequent analysis and decision-making processes. However, the widespread use of vendors' proprietary solutions often hinders the achievement of this level of interoperability [37]. Consequently, patients receiving hypertension management services from a particular company, for example, are often required to use a blood pressure device provided by the same company [38].

A variety of standards and protocols, including the Institute of Electrical and Electronics Engineers (IEEE) 11073 personal health device (PHD) [38-40], Zigbee [41], and Bluetooth Low Energy (BLE) [42], play a crucial role in addressing interoperability among medical devices, such as weighing scales, blood pressure monitors, and blood glucose monitors [39,43]. These technologies and devices can often be mapped to the perception layer in the IoMT reference model [44], a layer that is responsible for gathering raw data [45].

Network Interoperability

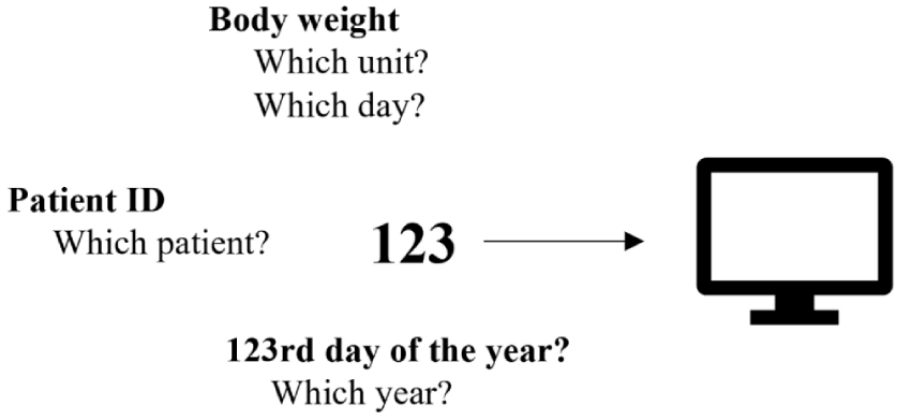
Network interoperability focuses on information exchange over the internet, including the ability of different networks or devices on separate networks to communicate [46]. Typically, network interoperability involves extended communication compared to device interoperability, which includes communication within local area networks (LANs) or wide area networks (WANs).

Technologies that focus on solving issues at the network interoperability level can primarily be mapped to the transport or processing layer in the IoMT reference model and include IP [47], user datagram protocol [48], transmission control protocol, IPv6 over low-power wireless PAN (6LoWPAN) [48,49], software-defined networking [36,50], gateways [51-53], message queuing telemetry transport (MQTT) [54], and WebSocket [55].

Syntactic interoperability

Syntactic interoperability, the third level of interoperability, involves data formats and data structures [36]. In the health care sector, both unstructured (eg, images, audio, and video streams) and structured data are used, which means that technologies used to address syntactic interoperability must be able to process diverse data types. Without syntactic interoperability, data might be sent to a system that is unable to process and use the information [56].

Technologies that focus on syntactic interoperability issues can be mapped to the processing layer in the IoMT reference model and include JSON [57], Health Level 7 version 2 (HL7v2) [58], and XML [59].



Semantic Interoperability

Semantic interoperability refers to the ability of different computer systems to have a common understanding of message contents, enabling them to share data with unambiguous, shared meaning [25]. This level of interoperability is essential for enabling automatic data processing and decision-making in IoMT settings [60]. Shared semantics within health care can

XSL•FO
RenderX

help to avoid knowledge mismanagement, clinical misinterpretation, misdiagnosis of a patient's illness, and even patient deaths [61]; for example, a system that receives "123" as input from another system (Figure 5) cannot interpret the data without additional information. For the receiving system to process and use the received data, the value "123" must be complemented by relevant metadata tags, such as "systolic blood pressure" or "patient ID." To achieve this contextual enrichment, well-established standards such as RxNorm [62], openEHR [63], *ICD* [37], Logical Observation Identifiers Names and Codes (LOINC) [62,64], and SNOMED CT [62] can be used. These standards offer a structured framework for associating informative labels and classifications with data [62].

Figure 5. An example of the lack of semantic interoperability. If a system receives insufficient data, it cannot interpret the information correctly. In the absence of semantic interoperability between the sending and receiving systems and without additional context or information, the receiving system cannot interpret the value "123".

Cross-Platform Interoperability

Cross-platform interoperability denotes the ability of different platforms within a single domain to work together seamlessly. It could be various systems (eg, PSAPs, EHRs, mobile apps, and laboratory information systems) running on different platforms (web, mobile, desktop, etc) located in different hospital wards or hospitals. Cross-platform interoperability challenges emerge at this level primarily due to the presence of a wide range of operating systems (Windows, Android, Linux, iOS, etc), programming languages, data structures, architectures, and access methods for both entities and data (eg, application programming interfaces [APIs]) [36]. Technologies that focus on addressing these levels of interoperability issues can be mapped to the application layer in the IoMT reference model and include Fast Healthcare Interoperability Resources (FHIR) [65-68], representational state transfer APIs (REST APIs) [66], microservices [7,69], Docker [70], Kubernetes [70], and cloud services [67,69-72].

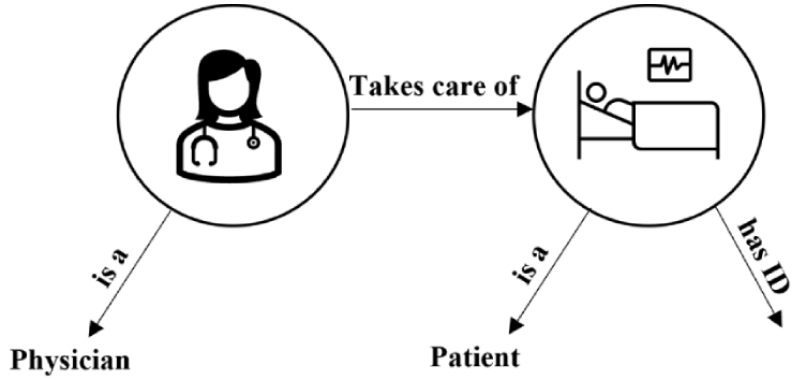
Cross-Domain Interoperability

Patients are likely to receive medical attention from several institutions and across various domains over their lifetime. Hence, communicating vital information across organizational and national boundaries is essential to ensure proper patient care and treatment [29]. This level of communication is enabled by cross-domain interoperability, which represents the highest level of interoperability [36].

In this context, a domain refers to a sociotechnical system defined by shared objectives and interests. These domains, or systems, are often separable from other systems by social, technical, and legal boundaries (Figures 6 and 7). Examples of domains include a medical device manufacturing company or a hospital. Each domain might have distinct goals, processes, security policies, and terminologies. Technologies and standards such as BioPortal [73], blockchain [74], ontology mediation [13,75], Web Ontology Language (OWL) [13], ontologies [25,74,76], General Data Protection Regulation (GDPR) [77,78], and Health Insurance Portability and Accountability Act (HIPAA) [78,79] can help achieve cross-domain interoperability.

XSL•FO
RenderX

Figure 6. Ontologies define domain knowledge, and semantics provide data meaning. Semantics can tag data (eg, "systolic"), while ontologies provide context, such as relating "123" to "blood pressure" and defining "elevated systolic level" within the domain.



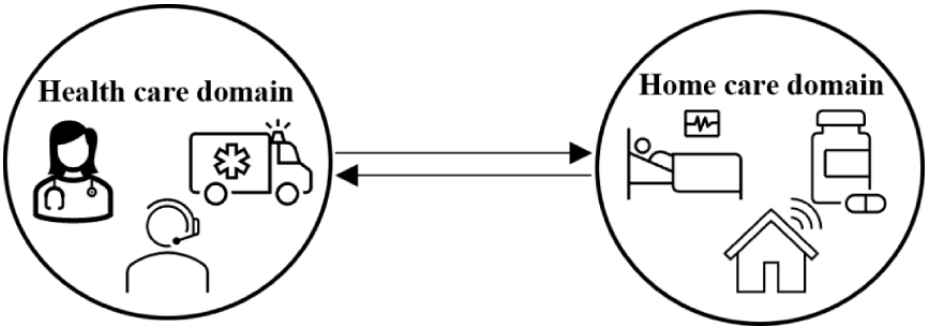


Figure 7. Technologies and standards such as blockchain, the General Data Protection Regulation (GDPR), and ontologies can enable data sharing between 2 separate domains.

Common IoMT Interoperability Requirements for Prehospital Care and HBC

IoMT platforms for prehospital care and HBC have specific requirements. These platforms are required to operate in time-critical environments, where large amounts of sensitive data need to be exchanged in real time across various domains. In this subsection, we have summarized common interoperability requirements identified in the included studies and grouped them based on their potential application in IoMT settings (Table 1).

XSL•FO
RenderX

Table 1. The enabling technologies for interoperability and their application in Internet of Medical Things (IoMT) for prehospital care and home-based care. Suitable technologies are mapped to various IoMT platform requirements and potential use, with supporting references provided in the last column.

IoMT platform requirement	Potential use	Suitable technologies	References
Real-time text communication	Alerts, notifications, chats, and data visualization	MQTT[a], WebSocket, and webhooks	[19,54,80-88]
Real-time videoconferences or audioconferences	Video and voice calls between patients and caregiver	WebRTC[b] and VOIP[c]	[83,89]
Common data formats	Data interoperability and sharing	JSON, XML, CSV, and SenML[d]	[7,23,24,60,77,80,83,84,87,90,91]
Common semantics	Automatic data exchange, processing, and interpretation; persistent data storage and enabling use of AI[e]	FHIR[f], LOINC[g], SNOMED CT[h], RxNorm, openEHR, ontologies, BioPortal, DMTO[i], and HL7 CDA[j]	[19,23,24,60,77,82,88,92-94]
Data privacy and security	Encrypted data communication, access controls, and consent management services	Blockchain, HTTPS, TLS[k], SSL[l], GDPR[m], and HIPAA[n]	[7,24,54,77,79,82-85,87,89,92,95,96]
Extended sensor communication	Allowing devices in LAN[o] or PAN[p] to send their data over internet (WAN[q]; eg, allowing monitoring applications outdoors)	Gateways, LPWAN[r] (LoRa[s] or LoRaWAN), and 3G, 4G, or 5G	[19,24,60,80,83,91,95,97-99]
System-to-system communication	Allowing systems located on different networks to connect over WANs	HTTP, REST API[t], API, AMQP[u], and SOAP[v]	[7,19,23,24,60,77,79,80,82-89,92,94,96,100-102]
Allowing sensors from different vendors to communicate	Allowing sensors from different vendors to adhere to common data format and semantics	OneM2M and IEEE[w] 11073	[19,24,94]
Translation or transcoding between ontologies in different domains or creation of common ontologies	Interpreting and processing information coming from a separate domain (eg, using AI)	OWL[x], RDF[y], OM[z], Semantic Web, and HeTOP[aa]	[23,24,60,82,83,99,100,102]
Timely data processing and immediate responses in emergency situations	Minimizing delays and information loss in latency-sensitive and real-time applications (eg, heart monitoring systems)	Fog and edge computing	[7,19,79,80,83,85,91,97,98]
Device-to-device communication in PANs or LANs	Creating a smaller network of integrated medical devices that can collect patients' vital signs	Zigbee, BLE[ab], Bluetooth, Z-Wave, 6LoWPAN[ac], ANT+[ad], NFC[ae], CoAP[af], Wi-Fi, RFID[ag], and IEEE 11073 PHD[ah]	[7,19,23,24,80,83,84,89-91,94,95,97,99,100,103]
Modular system	Enhancing scalability and flexibility in IoMT; ensures consistent deployment and efficient application management	Microservices, Docker, and Kubernetes	[7,77,79,80,83,85]
Data availability and processing power	Improving administration and availability of data; enabling large-scale storage, computationally intensive data processing and advanced analysis tasks	Cloud services (computing and storage, etc)	[7,19,23,24,77,79,80,83,87,88,91,93,95,97,100]
Common infrastructures or middleware	Platforms, frameworks, and infrastructure for creating interoperable, standardized, and scalable solutions	FIWARE, IHE[ai], Continua, and OpenICE[aj]	[54,80,94]

[a]MQTT: message queuing telemetry transport.

[b]WebRTC: Web Real-Time Communication.

[aj]OpenICE: Open Integrated Clinical Environment.

Common Interoperability Challenges in IoMT

Achieving interoperability is not a trivial task. The higher the interoperability level, the more complex the endeavor due to the involvement of additional technologies and standards. Previous research has reported recurring interoperability challenges frequently encountered in IoMT platform development for prehospital care and HBC. Some of these challenges are reported in Table 2.

Table 2. Common interoperability challenges in Internet of Medical Things (IoMT) platform development for prehospital care and home-based care. Each challenge is mapped to studies (references) that discuss it in the context of previous IoMT platform developments efforts.

Challenges	References
Latency	[11,13,22,75,79,81-85,91,101]
Privacy or security	[11,13,24,60,79,82,83,85,91,101-103]
Volume and complexity of data	[11,22,75,82-84,91,94,97,98,100,101,104]
Multiple or proprietary protocols	[11,56,60,79,83,85,91,98]
Different terminologies or semantics	[19,23,24,60,82,88,100,102]
Poor connectivity	[84,95,97,103]

Among the examined studies (n=25), we could identify 7 frequently reported challenges associated with interoperability. Among the 7 reported challenges, 12 (21%) were related to latency problems, 8 (14%) to proprietary protocols, 13 (23%) to the volume and complexity of data, 12 (21%) to privacy and security concerns, 8 (14%) to semantic coding issues and 4 (7%) to poor connectivity.

Common Strategies to Overcome Interoperability Issues in IoMT Platform Development

In this section, we provide an overview of the technologies and standards used frequently to address interoperability challenges in IoMT platform development for prehospital care and HBC (Table 3).

XSL•FO
RenderX

Table 3. Summary of Internet of Medical Things (IoMT) platform development for home-based care and prehospital care as presented in 30 (19%) of the 158 studies reviewed, highlighting each IoMT platform's primary purpose and objective, publication year, and the technologies and standards used to address interoperability issues.

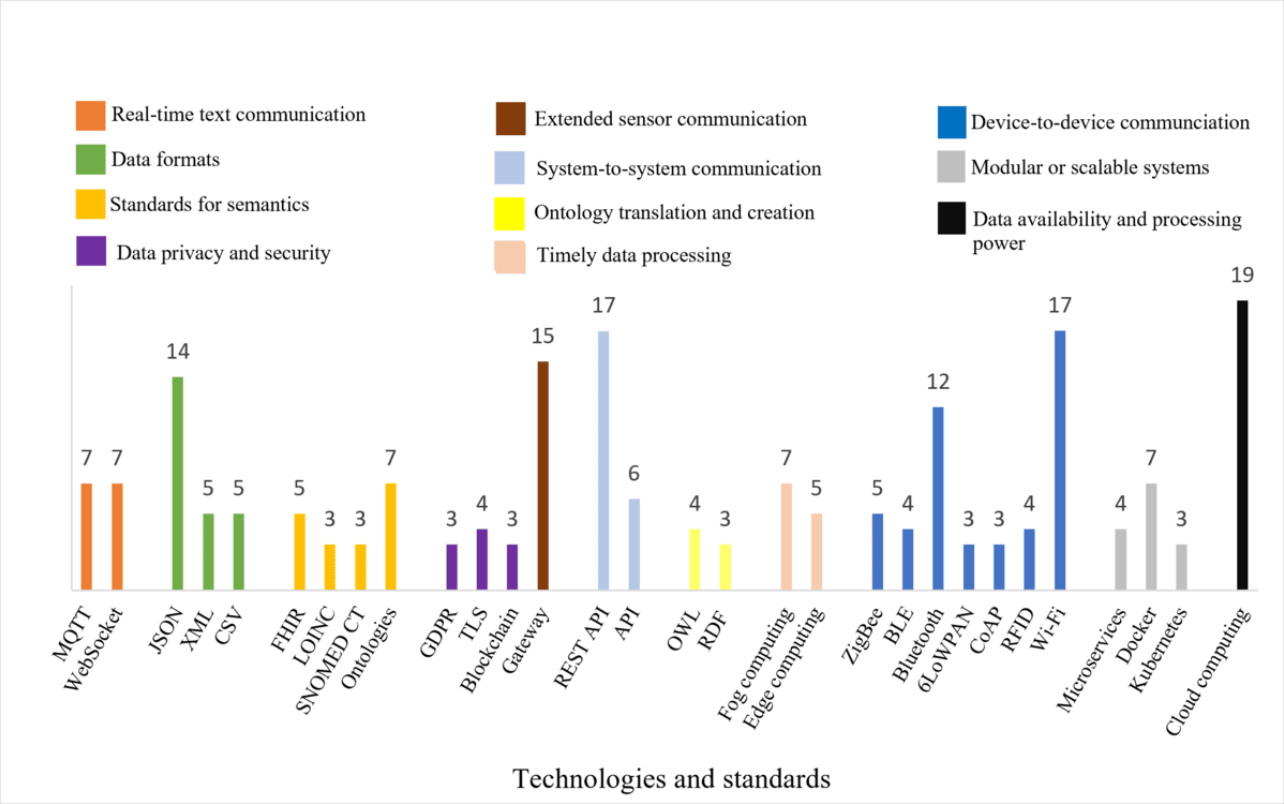
IoMT platform	Objective	Publication year	Technologies and standards
System for sleep monitoring [80]	Real-time, remote monitoring of patients with sleep apnea to support diagnosis and treatment	2018	Fog and cloud computing, MQTT[a], Zigbee, BLE[b], CoAP[c], 6LoWPAN[d], FIWARE, JSON, CSV, HDFS[e], REST API[f], gateways, microservices, and Docker
IoT[g]-based message broker system [18]	Individual patient vital signs monitoring in potential emergency or prehospital applications	2022	RFID[h], MQTT, REST API, Wi-Fi, CSV, XML, PDF, and JPEG
Platform for management of chronic diseases [23]	Care plan management tool integrated with clinical decision support services, EHRs[i], and sensors	2019	FHIR STU3[j], HL7 CDA[k], CSV, XML, SOAP[l], JSON, SNOMED CT[m], LOINC[n] and WHO ATC[o], local versions of *ICD-10*[p], REST API, cloud computing, HeTOP[q], and SMART[r] on FHIR
RePulmo[s] [54]	Open-source platform for secure and accurate remote pulmonary data monitoring	2019	MQTT, OpenICE[t], TLS[u], and API
SPIDEP[v] [7]	Support the early diagnosis of infectious diseases in older people	2020	Microservices, Docker, Kubernetes, cloud and edge computing, REST API, JSON, gateways, HTTPS, TLS, Wi-Fi, and SMART on FHIR
Semantic IoMT platform for eHealth [60]	An interoperable IoMT platform	2020	openEHR, OWL[w], ontologies, protocol converter, Bluetooth, Zigbee, Wi-Fi, SenML[x], gateways, JSON, REST API, cloud computing, and Semantic Web
IoMT platform for aggregation, processing, and sharing [19]	A platform to cover the domain of health care, following widely adopted standards, enabling semantic interoperability, and considering a big data approach	2019	REST API; MQTT; CoAP; openEHR; FHIR; SenML; Wi-Fi; cloud, fog, and edge computing; OneM2M; gateways, and Wi-Fi
Platform for health care promotion and cardiovascular disease prevention [96]	Smart health care platform oriented to multiple point-of-care scenarios for health care promotion and cardiovascular disease prevention	2021	REST API, TCP[y], JSON, XML, SOAP, Bluetooth, Wi-Fi, ANT+[z], HTTPS, TLS, cloud computing, and Wi-Fi
SemPryv [84]	SemPryv supports REST APIs to consume and produce interoperable streams of health care data, following the HL7 FHIR standard and using the Pryv.io platform	2023	FHIR, ontologies, SNOMED CT, LOINC, BioPortal, REST API, WebSocket, webhooks, RxNorm, UCUM[aa], Docker, GDPR[ab], Kubernetes, and RDF[ac]
LoRaWAN[ad]-based NXTGeUH[ae] [103]	System for vital signs monitoring and fall detection	2018	Zigbee, LoRaWAN, TCP/IP, Bluetooth, and gateways
Monitoring platform for patients with diabetes [90]	Support treatment, monitoring, and data collection	2021	API, Bluetooth, JSON, and NFC[af]
VITASENIOR-MT [83]	Remote monitoring of health parameters of older people	2019	Cloud and fog computing, microservices, CoAP, JSON, BLE, WebSocket, REST API, MQTT, gateways, 6LoWPAN, AMQP[ag], Bluetooth, WebRTC[ah], GDPR, and HTTPS
Apnea MedAssist 2 [104]	Monitoring for Alzheimer disease diagnosis and rehabilitation	2013	Bluetooth, Wi-Fi, cloud computing, and 4G
IC-SMART[ai] [100]	Monitoring for Alzheimer disease diagnosis and rehabilitation	2019	OWL, ontologies, gateways, REST API, RFID, Wi-Fi, Bluetooth, cloud computing, Docker, and HTTP
HealthFog [101]	Automatic diagnosis of heart diseases	2020	REST API; cloud, edge, and fog computing; gateways; CSV; blockchain; and HTTP
HABITAT[aj] [102]	Platform for independent older people	2019	RFID, HTTPS, WebSocket, RDF, JSON, Semantic Web, ontologies, and SPARQL[ak]

XSL•FO
RenderX

IoMT platform	Objective	Publication year	Technologies and standards
SensorHub [84]	A central platform that acts as a bridge between sensors and a user's smartphone	2022	BLE, Bluetooth, REST API, HTTPS, WebSocket, CSV, JSON, and Docker
Energy-aware IoT-based architecture [85]	On-wrist fall detection system	2023	MQTT, HTTPS, Wi-Fi, Docker, and API
Real-time remote monitoring system [91]	Low-cost health system for continuous monitoring of ECG[al]	2017	Bluetooth, Wi-Fi, gateways, cloud and fog computing, JSON, XML, API, and TCP
Fall detection system [97]	A system that can be used to monitor, for example, cardiovascular diseases or diabetes	2019	LoRa; edge, fog, and cloud computing; BLE; and gateways
ChainSDI [79]	Securing health care applications at home	2020	Edge and cloud computing, blockchain, Wi-Fi, Kubernetes, Docker, HIPAA[am], HTTP, and API
SmartHabits [77]	A home care assistant system to support informal caregivers caring for persons living alone	2019	REST API, JSON, AMQP, gateways, cloud computing, ontologies, Z-Wave, HTTP, microservices, GDPR, and Wi-Fi
DALÍ [87]	A personal assistant platform for older people and those who are visually impaired	2020	JSON, MQTT, HTTPS, REST API, cloud computing, WebSocket, and SSL[an]
Integrated health monitoring system [94]	Integrated monitoring system	2015	FHIR, REST API, IEEE[ao] 11073, Zigbee, Bluetooth, IHE[ap], Continua, SOAP, JSON, and XML
A mobile health monitoring-and-treatment system [24]	Platform for diabetes monitoring and to provide customized, long-term, and real-time treatment plans	2019	FHIR, ontologies, OWL, JSON, HTTPS, REST API, Bluetooth, cloud computing, SNOMED CT, LOINC, RxNorm, BioPortal, DMTO[aq], IEEE 11073, Wi-Fi, 3G, 4G, or 5G, and BFO[ar]
Patient monitoring system in smart homes [98]	Remote monitoring platform for monitoring patients in smart homes	2018	Cloud and fog computing, RFID, gateways, and Wi-Fi
VitalCore [88]	Allowing patients access to their health data in real time	2021	REST API, WebSocket, and HL7 data
Health care system for older people [99]	An ontology-based IoMT platform to alleviate problems related to chronic diseases	2021	Ontologies, gateways, Wi-Fi, Zigbee, LoRaWAN, RDF, and OWL
We-Care [95]	Platform to assist older people in their homes and trigger alarms in case of emergency situations; works offline	2017	Bluetooth, 6LoWPAN, gateways, UDP, Wi-Fi, cloud computing, and API

XSL•FO
RenderX

IoMT platform	Objective	Publication year	Technologies and standards
Remote pain monitoring system [81]	A scalable IoT system for real-time automatic pain assessment using facial expressions	2018	Gateways, UDP, TCP, Wi-Fi, WebSocket, TLS, and cloud computing



[a]MQTT: message queuing telemetry transport.

[ar]BFO: Basic Formal Ontology.
[as]UDP: user datagram protocol.

As can be seen in Table 3, IoMT platform development often requires a combination of technologies and standards. Simply specifying “Bluetooth,” “Wi-Fi,” or “SNOMED CT” is not sufficient because no single standard, protocol, or technology can address higher levels of interoperability [100]; for example, SNOMED CT can be complemented by more domain-specific standards such as LOINC [29], while Bluetooth can be used in conjunction with a gateway, MQTT, and FHIR to enhance interoperability within IoMT [19]. Table 2 reveals variations in the frequency of the technology and standards used. Consequently, we have summarized the most used technologies and standards in Figure 8. Technologies and standards that

XSL•FO
RenderX

appeared in 2 or fewer articles were excluded from Figure 8. These include Web Real-Time Communication (WebRTC), openEHR, voice over IP, webhooks, and Substitutable Medical Applications, Reusable Technologies (SMART) on FHIR, as well as the interoperability guidelines and frameworks such as FIWARE, Integrating the Healthcare Enterprise (IHE), Continua, and Open Integrated Clinical Environment (OpenICE). The top 5 reported technologies were cloud computing (19/37, 51%), REST APIs (17/37, 46%), Wi-Fi (17/37, 46%), gateways (15/37, 41%), and JSON (14/37, 38%).

Figure 8. Occurrences of common technologies addressing interoperability in Internet of Medical Things (IoMT) platforms for prehospital care and home-based care, grouped by application area (each color). Only technologies and standards reported in 2 or more separate articles are included. 6LoWPAN: IPv6 over low-power wireless personal area network; API: application programming interface; BLE: Bluetooth Low Energy; CoAP: constrained application protocol; FHIR: Fast Healthcare Interoperability Resources; GDPR: General Data Protection Regulation; LOINC: Logical Observation Identifiers Names and Codes; MQTT: message queuing telemetry transport; OWL: Web Ontology Language; RDF: resource description framework; REST API: representational state transfer application programming interface; RFID: radio frequency identification; SNOMED CT: Systematized Nomenclature of Medicine–Clinical Terms; TLS: transport layer security.

Recommendations

Our recommendations (Textbox 3) are based on the findings presented in Table 3 together with discussions within our research group. These recommendations focus on technologies and standards that support cross-domain interoperability across all layers of the IoMT reference model, spanning from data collection by sensors to cloud-based data processing and secure cross-domain data exchange. In broad terms, an IoMT platform for HBC and prehospital care should include, in our opinion, the capabilities presented in Textbox 3.

XSL•FO
RenderX

Textbox 3. Capabilities required by an Internet of Medical Things (IoMT) platform for home-based care and prehospital care.

Compatibility for medical device integration and secure and reliable real-time data transfer to the cloud

- The IoMT platform should ensure seamless integration of medical devices and enable secure, real-time transmission of data to the cloud.
- Recommended technologies and standards: Bluetooth Low Energy (BLE), Zigbee, Institute of Electrical and Electronics Engineers (IEEE) 11073 personal health device (PHD), Open Integrated Clinical Environment (OpenICE), and FIWARE

Real-time and low latency data processing and communication

- The IoMT platform should be capable of processing and visualizing data in real time with minimal latency to support timely decision-making and data processing.
- Recommended technologies and standards: message queuing telemetry transport (MQTT), WebSocket, and Web Real-Time Communication (WebRTC)

Data persistence for reliable data storage

- The IoMT platform should ensure that data are stored in a consistent and secure way.
- Recommended technologies and standards: openEHR and blockchain

Open data standards and data exchange mechanisms for secure and efficient system-to-system communication.

- The IoMT platform should adhere to open data standards and secure exchange mechanisms, facilitating efficient communication between different systems.
- Recommended technologies and standards: JSON and representational state transfer application programming interface (REST API)
- Common semantics and domain knowledge descriptions for automatic knowledge extraction

Common semantics and domain descriptions enable automatic extraction of knowledge from data, enhancing system understanding.

- Recommended technologies and standards: Fast Healthcare Interoperability Resources (FHIR), Systematized Nomenclature of Medicine–Clinical Terms (SNOMED CT), Web Ontology Language (OWL), resource description framework (RDF), Logical Observation Identifiers Names and Codes (LOINC), and BioPortal

Security measures to protect patient data and ensure data confidentiality

- The IoMT platform should ensure the privacy and integrity of patient data throughout its life cycle.
- Recommended technologies and standards: transport layer security (TLS), General Data Protection Regulation (GDPR), Health Insurance Portability and Accountability Act (HIPAA), blockchain, and Open Authorization 2.0 (OAuth2)

Scalability to accommodate a growing number of connected devices and generated data volumes

- The platform should scale effectively to handle an increasing number of devices and growing data volumes.
- Recommended technologies and standards: Docker, Kubernetes, cloud services, and fog and edge computing

Discussion

Principal Findings and Study Contribution

This scoping review provides insights into the enabling technologies that can address interoperability issues in IoMT settings. Although the primary focus has been on solutions for prehospital care and HBC, the results are also applicable to other settings with similar characteristics and requirements. The results show that higher levels of interoperability in IoMT can be achieved by combining various technologies and standards from multiple interoperability levels.

On the basis of the studies (n=30) presented in Table 3, it seems that contemporary IoMT studies on prehospital care and HBC tend to focus on lower levels of interoperability. This conclusion is in line with previous research conducted by Rubí and Gondim [19]. One possible explanation for the predominant focus on device integration and lower levels of interoperability among the reviewed studies is our use of “IoMT” as a search term. Although IoMT is broad and includes integration with medical devices as well as medical applications, the term is somewhat ambiguous and might introduce some biases toward device-centric approaches. We believe that future research could benefit from using a more refined definition to emphasize a shifted focus toward higher levels of interoperability. Therefore, we propose the introduction of the term Internet of Medical Systems (IoMS) to address this gap. This new terminology could help distinguish studies focusing on device-to-device integration from those focusing on integration with EHRs and other health applications.

We acknowledge that some may argue that technologies and standards such as blockchain, fog computing, GDPR, and the like may primarily focus on aspects other than interoperability (eg, security, communication, networking, data transfer, or architectural design). However, proceeding from the 6-level interoperability model [11], our interpretation of interoperability extends beyond mere data exchange and interpretation. Even if two systems possess the capabilities to exchange and interpret

XSL•FO
RenderX

information, we believe that it is not enough to achieve higher levels of interoperability within health care without considering privacy and security aspects. However, our findings indicate varying levels of focus on technologies such as blockchain and SMART on FHIR within the research community, with some of the studies (4/30, 13%) analyzing these technologies in depth, while others (26/30, 87%) tend to overlook them. As an example, of the 30 included studies, 8 (27%) reported the use of authentication and authorization mechanisms [79,80,90,91,95,96,101,105], but only 7% (2/30) reported the use of Open Authorization (OAuth) or SMART on FHIR as mechanisms for authentication and authorization [7,23].

On the basis of our findings, it seems that more comprehensive platforms tend to incorporate a wider range of technologies compared to simpler platforms (Table 3); for example, platforms that reported interoperability capabilities with external systems or the use of AI seem to more frequently use technologies and standards to semantically code the data, including ontologies, FHIR, LOINC, *ICD*, openEHR, RxNorm, and SNOMED CT. However, this relationship was not confirmed statistically, and we acknowledge that other factors may influence platform complexity, such as regulatory requirements, available technologies, and expertise among developers.

Table 3 reveals that 30% (9/30) of the IoMT platform development studies for prehospital care and HBC reported the use of semantic frameworks or ontologies. As the creation of ontologies is a necessary but time-consuming and labor-intensive task, research has examined the potential to achieve ontology alignment by using AI; for example, Dam et al [106] used augmented intelligence to map data across various domains to facilitate the integration of diverse data sources. According to Tangi et al [107], AI has the potential to not only establish a common language and foster a shared understanding of data but also clean and structure the data. While we acknowledge that using AI for interoperability is an emerging trend, such studies have not been incorporated in this review.

In the reviewed literature, semantic standards and ontologies were described as essential for establishing connections with external systems and enabling the use of AI. Interestingly, standards for image and video formats, such as Digital Imaging and Communications in Medicine (DICOM), have not been mentioned in the examined studies. Interoperability enhancing organizations and initiatives such as FIWARE, IHE, Continua, and OpenICE were reported to guide researchers and developers [88], but these organizations and initiatives were only mentioned in 3 (10%) of the 30 studies.

Fog and edge computing were reported to be used to overcome problems related to limited bandwidth, often associated with high data rate applications, such as fall detection systems or electrocardiography monitoring [97]. Our findings suggest that fog and edge computing are often combined with cloud computing, especially in AI-intensive applications that require more processing power. To improve the performance of AI algorithms and enable machines to correlate data, studies reported the use of ontologies, resource description framework (RDF), and OWL [24,99]. Furthermore, platforms requiring real-time functionalities (alerts or notifications) reported the use of MQTT (7/30, 23%) and WebSocket (7/30, 23%) [82,85].

While we have documented the use of commonly used technologies and standards in this study, it is important to acknowledge that the accuracy of these findings depends on the transparency and thoroughness of the explanations within the included studies; for instance, some of the studies (30/63, 48%) offered detailed insights into their IoMT platform development processes and the technologies and standards used, while others (33/63, 52%) focused on broad aspects of the topic, as in the studies by Rakhman et al [108] and Shim et al [109]. As a result, some of the studies (33/63, 52%) were excluded from Table 2. Furthermore, because technologies and standards can have versatile applications, specifying their exact application area can often be challenging. Therefore, the findings presented in Table 3 should be considered as a guidance rather than absolute truths.

Mapping the Enabling Technologies to the Interoperability Model

In this study, the mapping was performed based on a 6-level interoperability model defined in the study protocol [11]. To facilitate the mapping process, any inconsistencies between our model and the levels described in the included studies were addressed using a flowchart model [11]. This was done to manage different naming conventions across different models; for instance, one study may label a specific interoperability level as “technical interoperability,” [105] while others may refer to it as “foundational interoperability” [110]. Similarly, the specific functions and components of each level may not be consistent across different models or frameworks, which can create ambiguity and uncertainty about how to define and interpret interoperability. Hence, proceeding from a different interoperability model [71] would most likely result in a somewhat different mapping outcome.

It is important to note that although we mapped the enabling technologies to specific interoperability levels, it is uncommon for a technology to address a single interoperability level; for example, the FHIR standard not only specifies data exchange formats and semantics but also supports REST APIs, enabling it to address syntactic, semantic, and cross-platform interoperability concurrently. Hence, in this study, we mapped FHIR to cross-platform interoperability, which represents the highest level of interoperability addressed by FHIR. However, saying that the FHIR standard *solves* cross-platform interoperability is not completely true because it needs to be combined with technologies on lower interoperability levels. We argue that the correct phrasing should be that FHIR *can* solve cross-platform interoperability issues if it is appropriately combined with other relevant technologies and standards.

Another aspect worth mentioning regarding the mapping is the importance of examining the primary focus of the technologies and standards; for example, the IEEE 11073 PHD standard involves data models that specify how a measurement and observations of vital signs should be represented, including descriptions of the different units, data types, and semantic meanings [38,40]. On the basis of this description, it is likely that the IEEE 11073 PHD standard should be categorized at the

XSL•FO
RenderX

semantic interoperability level. However, due to its primary focus on device-to-device communication within LANs or PANs, the IEEE 11073 PHD standard does not fully meet the requirements for network interoperability, let alone semantic interoperability. Hence, the IEEE 11073 PHD standard was mapped to the device interoperability level in this study.

Summarizing the Enabling Technologies That Address Interoperability Issues

In our study, we found that technologies such as BLE and Zigbee, which primarily target device interoperability, are not sufficient for IoMT applications in prehospital or HBC settings due to their restricted physical communication range (ie, 20-100 meters) [41,111]. For physicians to remotely monitor patients and for devices to automatically send alarms during medical emergencies, the first step is to extend the communication range by enabling network interoperability [49]. Otherwise, the physician's system would need to be in the same room as the patient, which obviates the concept of remote monitoring; for example, by combining BLE with long-range wide area network (LoRaWAN) or 4G or 5G—or 6LoWPAN with CoAP—long-range data transmission can be achieved [112]. This allows physicians to remotely monitor patients residing several kilometers away from the hospital [25]. However, choosing a particular combination of technologies from different interoperability levels does not ensure the achievement of the desired level of interoperability. This is because interoperability initiatives require collaboration among all involved stakeholders; for instance, a standard such as IEEE 11073 can be adopted in several ways, which means that simply specifying the use of IEEE 11073 may not be sufficient to achieve device interoperability. Instead, a standard should be tailored to meet the specific requirements of a particular use case or application. This can be achieved using profiles to ensure that the standard is implemented in a way that suits the needs.

Although close collaboration among stakeholders is essential to achieve higher levels of interoperability, studies have shown this endeavor to be challenging; for example, a study conducted in 2021 by Everson et al [113] revealed that more than half (55%) of health information exchange organizations in the United States reported varying degrees of intentional information blocking. The authors showed that the most prevalent form of information blocking involved the refusal to share information, which 14% of the health information exchange organizations routinely observed among EHR vendors. The reason for blocking information according to Everson et al [113] had to do with regional competition among vendors. By limiting the sharing of information with other actors, vendors can ensure that health care providers stick to their platform [113,114]. While this approach benefits vendors, it creates disadvantages for patients and the health care industry. The findings of Everson et al [113] suggest that while technologies and standards can streamline data exchange in health care, the reluctance of organizations to engage in such efforts impedes progress toward higher levels of interoperability.

Comments on Our Recommendations

The recommendations provided in this study draw on insights from previous IoMT platform development projects and our research group's expertise. They focus on technologies and standards that together can support cross-platform or cross-domain interoperability. We acknowledge that multiple technologies and standards can be used to develop IoMT platforms. We are also aware that there is no "one right way" of adopting a specific technology or standard. Rather, we argue that interoperability initiatives and development projects should be facilitated by close collaboration among the stakeholders involved.

With this study and our recommendations, we hope to bring together the research, developer, and health care communities by highlighting relevant technologies and standards to foster collaboration and improve interoperability initiatives within the health care domain. While we recognize the importance of independence in driving innovation, we hope to see more IoMT platforms using common standards and best practices already available in the market. We further hope to see an increased engagement in interoperability initiatives such as FIWARE, IHE, and OpenICE.

We acknowledge the advantages of IoMT platforms capable of delivering personalized patient care and enhancing patient safety. However, we do not believe that technologies and standards are the only solutions. To achieve the highest level of interoperability, we argue that it is necessary to have a profound understanding of organizations' working processes, routines, and policies. Hence, we look forward to delving into these challenges in close collaboration with relevant stakeholders and developing an IoMS platform that supports cross-domain interoperability.

Limitations and Biases

This scoping review adheres to the published protocol [11] and focuses on technologies addressing interoperability issues within the context of IoMT platform development in HBC and prehospital care settings. Hence, studies focusing on hospital systems [115], platforms for intensive care units [81], integration platforms [93], or platforms for research or clinical trials [92,116] were omitted. Furthermore, most of the studies (33/63, 52%) displayed a deficiency in information or a lack of transparency regarding the development process and the technologies used; therefore, they were excluded from Table 1 and Table 3. As the focus of this study was to identify and summarize best practices and frequently used technologies, we did not assess the effectiveness of technology implementations in detail.

To manage the scope of this review process effectively, the reviewers made a deliberate decision to limit the included studies to those specifically addressing interoperability in an IoMT context. This was necessary to avoid overwhelming screening efforts with an unmanageable number of studies. We are aware that we might have missed relevant articles with this strategy. Furthermore, we are aware that technologies used in other sectors, for example, Industry 4.0, manufacturing, and transportation, could also be applicable to IoMT, especially considering that these domains share some common characteristics (eg, requirements for real-time, cross-domain information exchange). Another limitation of this study might be the use of the term "IoMT" in our literature search. Although

XSL•FO
RenderX

IoMT is often defined as the interconnection of medical devices and applications, there seems to be a predominant focus on devices and lower levels of interoperability among these studies. This limitation could potentially be eliminated by the introduction and use of the new term IoMS.

Although recent advancements in AI have demonstrated its potential to enhance interoperability, studies reporting the use of AI for this purpose were excluded from this review. Another limitation of this study is that, to expedite the process, the coding scheme was tested by only 1 reviewer (MS).

Conclusions

In this study, we have demonstrated that the highest level of interoperability can be theoretically achieved through a strategic combination of various technologies and standards. Furthermore, we have provided a summary of the relevant technologies and standards that can be used in IoMT platforms to overcome interoperability issues in HBC and prehospital care settings.

Despite the availability of innovative and suitable technologies, the IoMT research community has reported limited interest in adopting technologies and standards such as Docker, blockchain, SMART on FHIR, HIPAA, and GDPR to achieve cross-domain interoperability. Most of the studies (17/30, 57%) have primarily focused on lower levels of interoperability (up to the semantic interoperability level). This observation highlights a significant research gap, particularly in achieving cross-domain interoperability within IoMT for HBC and prehospital care. To emphasize the need for higher levels of interoperability and to support future research, we advocate for the introduction of the term IoMS. In addition, the reluctance of organizations and vendors to share information and participate in interoperability initiatives highlights the importance of considering these aspects when addressing interoperability challenges, especially in procurement processes [117].

Acknowledgments

This study was supported by the following funding bodies: the Kamprad Family Foundation for Entrepreneurship, Research & Charity; the European Interreg project “Kontiki – AI som Beslutsstöd for patienter och helsetjenesten” (“Kontiki – AI as decision support for patients and health care”); and the strategic innovation program IoT Sweden, a joint venture by Vinnova, Formas, and the Swedish Energy Agency, through the IoT project “ASAP PoC – bättre militära och civila prehospitala Point-of-Care beslut med hjälp av datafusion och AI” (“ASAP-PoC – better civil and military prehospital point-of-care decisions using data fusion and AI”; 2022-03748). The funding bodies did not have a role in the design of the study or in the writing of the manuscript.

Data Availability

All datasets generated or analyzed during this study are included in this published paper and its supplementary information files.

Abstract

Background: Digital technologies for type 2 diabetes mellitus (T2DM) care hold great potential to improve patients' health in the long term. Only a subset of telemedicine offerings are digital interventions that meet the criteria for prescribable digitale Gesundheitsanwendung (digital health apps; DiGAs) in Germany. Digital treatments further provide vast amounts of patient data that are important to generate evidence.

Objective: This systematic review aims to analyze the efficacy of multimodal digital therapies that mainly meet the DiGA criteria for patients with T2DM and to elicit the potential of such therapies. This includes evidence from randomized controlled trials (RCTs) as well as from real-world data. The outcome of interest was a reduction in glycated hemoglobin (hemoglobin A_{1c} [HbA_{1c}]; long-term blood glucose measurements).

Methods: A systematic literature search was conducted in the literature bases PubMed, LIVIVO, and Cochrane, based on the predefined PICO (Population; Intervention; Control; Outcome) scheme. Identified studies were assessed for risk of bias, pragmatism, and overall quality of evidence. Meta-analyses were conducted for between group differences using RCTs only, and for within-group differences using RCTs and non-RCTs, to examine the effect of the interventions on HbA_{1c}.

Results: In total, 795 records were identified, of which 24 were eligible for this systematic review and 23 studies were eligible for the meta-analysis. The results of the meta-analyses showed significant and clinically relevant reductions in HbA_{1c} in patients with T2DM. Regarding the between-group difference for HbA_{1c} reduction, the pooled effect of the RCTs showed a reduction of –0.36% (95% CI –0.59% to –0.14%; P<.001), favoring app-based interventions. The average mean within-group reduction in HbA_{1c} was –0.79 (95% CI –1.02 to –0.55), with no significant difference between RCTs (–0.69, 95% CI –1.13 to –0.24) and non-RCTs (–0.87, 95% CI –1.16 to –0.57; P<.01, differences between RCTs and RCTs P=.44). A pragmatism rating showed that both study types were on average (very) pragmatic, that is, close to usual care. However, the overall quality of evidence was low to very low.

Conclusions: This systematic review shows that digital therapies that mainly meet the DiGA criteria can effectively improve HbA_{1c} in patients with T2DM. The integration of digital health care into usual care holds great potential and should be considered as a complementary option to usual care in the future.

Introduction

Background

Type 2 diabetes mellitus (T2DM) is one of the leading causes of death as well as disability-adjusted life years [1]. The rapidly rising global prevalence of T2DM in adults, especially in rural and high-income areas, was estimated to be 10.5% in 2021 [2]. Those levels were previously estimated to occur in 2030 [3]. The metabolic disease is characterized by elevated blood glucose levels, which are associated with an increased risk for vascular and cardiovascular complications, such as heart disease, chronic kidney disease, diabetic retinopathy, and diabetic foot ulcers [4,5]. In addition, T2DM is related to the occurrence of mental health disorders, such as depression [6]. This causes T2DM to be associated with an increased mortality rate in patients enduring the disease [4,7]. Consequently, the chronic condition poses a major health burden on the physical and mental health of those affected as well as on their families [3].

There are several known risk factors for developing T2DM. In particular, conditions such as obesity, high blood pressure, and hyperlipidemia, are associated with relevant lifestyle factors such as high-caloric diets, sedentary behavior, smoking, and alcohol consumption [8,9]. To counteract the multiple risk factors of the disease, guidelines describe lifestyle modification measures as the foundation of all therapeutic interventions in patients with T2DM [10]. Behavioral interventions toward a healthy lifestyle play an important role in preventing the onset of T2DM in individuals at high risk and decreasing the development and progression of diabetic complications for patients with manifested T2DM [11].

Multimodal Therapy

A multimodal therapeutic approach for people with obesity and T2DM combines nutritional medical intervention, exercise, and behavioral therapy support and addresses treatment adherence to enhance the long-term success of such interventions [12]. These components of interdisciplinary treatment can be communicated to patients digitally. For example, eating behavior can be tracked and then a reduction in calorie intake and optimization of food composition can be implemented using app features. In addition, training sessions or tasks to increase physical activity can also be integrated. To increase therapy engagement, interventions should not only be multidisciplinary but also patient-centered and address as many risk factors as possible [5,11].

In line with that, behavioral interventions can also reduce the pharmacotherapy escalation. In a trial applying a multimodal approach, including nutritional and behavioral counseling, educational content, digital coaching, and medication management, most participants, 42.7%, decreased their medication, while another 8% eliminated their medications. Hemoglobin A_{1c} (HbA_{1c}; long-term blood glucose) levels were also significantly reduced with 56.1% of participants achieving a HbA_{1c} value of <6.5% [13].

Blood glucose control is a key target for such interventions, to lower cardiovascular risk as well as mortality from T2DM [5]. In adults with T2DM, the HbA_{1c} target value is set individually, depending on various factors, such as diabetes duration, comorbidities, and patient preference, but it lies within the corridor of 6.5%-8.5% [10]. Accordingly, guidelines for the treatment of T2DM formulate lifestyle interventions to manage indicators such as weight, blood pressure, and blood lipids as the foundation of the prevention and treatment of T2DM and also promote self-management and patient autonomy as a therapeutic goal [10,14]. Due to the chronic nature of T2DM, patients must manage their disease in their daily lives independently of medical care [15].

Digital Therapy

In this context, digital technologies, for example, tracking and providing a feedback loop with health care professionals (HCPs) are already included in guidelines as having great potential to improve diabetes care [5,16].

With the Digital Healthcare Act (January 2020) Germany was the first country to use a legal health claim for insured individuals to receive evidence-based treatment in the form of digitale Gesundheitsanwendung (digital health apps [DiGA]), that is, apps prescribed by health care providers [17]. Generally, DiGAs are not primary prevention tools but support the monitoring, discovery, and treatment of diseases, injuries, and disabilities. Other countries, in particular France and Belgium, are following the example and pursuing easier market access for digital solutions in the health care sector [18].

The potential of digital interventions to reduce HbA_{1c} levels has been shown in previous systematic reviews [19-21]. For instance, one umbrella review reports mean reductions in patients with T2DM using telehealth interventions of between −0.01% and −1.13% [21]. The medical purpose of a DiGA is achieved through the interaction of the patient with digital technology [22]. This means that DiGAs are not purely digital communication channels between patients and HCPs, but treatment is largely carried out independently by the patient through an app [20,22]. This means that therapy with DiGAs is independent of the prescription site in which it is used, as the driver of the therapeutic effect is the patient's interaction with the application. By focusing on apps that meet the definition of DiGA, we aim to analyze the evidence for these technologies in diabetes care. This also allows us to expand the current evidence base for the digitalization of usual care, for example, delivering care through phone calls or chats.

Evidence Based on Different Study Designs

For a medical device to be approved as a DiGA in Germany, its effectiveness has to be shown with clinical evidence

XSL•FO
RenderX

generated by randomized controlled trials (RCTs) [23]. Especially before approval or after a device is already approved and on the market, digital applications, including DiGAs, offer new opportunities to generate evidence based on vast amounts of actual user and patient data. In this context, real-world data (RWD) and real-world evidence are increasingly recognized as complementary to RCTs. For example, user data allows us to continuously investigate the efficacy after approval as part of postmarket research, offering additional insights into how medical devices perform [24]. The European Medicines Agency, defines RWD as "routinely collected data relating to a patient's health status or the delivery of health care from a variety of sources other than traditional clinical trials" [25]. One type of such data is health records directly tracked in-app. Evidence generated with RWD is often considered pragmatic and externally valid, making it cost- and time-efficient, particularly for regulatory purposes, such as postmarket surveillance under the European Medical Device Regulation [23,24,26,27].

RCTs provide high internal validity by controlling for confounding variables and minimizing bias through more controlled circumstances and more rigid protocols. Non-RCTs contribute by offering evidence generated outside a study setting and, while less controlled, still provide valuable information on how interventions perform in the real world. Both approaches offer opportunities for implementation in pragmatic settings [28]. To better distinguish between the internal and external validity of trials and the potential balance between them, we use both the GRADE (Grading of Recommendations, Assessment, Development and Evaluation) and Pragmatic Explanatory Continuum Indicator Summary (PRECIS-2) tools, respectively.

Research Question

Current evidence on digital therapies exists for a broad range of intervention types but not specifically for apps that meet the definition of a DiGA addressing T2DM. The objective of this systematic review was to analyze the efficacy of such and to elicit their potential, including explanatory as well as pragmatic studies.

Methods

Search Strategy and Eligibility Criteria

A systematic literature search was conducted in January 2023 to identify evidence on the efficacy of multimodal, app-based lifestyle interventions that meet the definition of DiGAs in reducing HbA_{1c} in patients with T2DM. The search was performed in the electronic databases PubMed, LIVIVO, and Cochrane and the search strategy was individually tailored for each database. A combination of search terms, MeSH (Medical Subject Headings) terms, and appropriate Boolean operators was developed (Multimedia Appendix 1) based on the PICO (Population; Intervention; Control; Outcome) scheme (Table 1) to identify relevant studies. To generate a broader evidence base, not only RCTs but also other study designs were considered eligible (eg, observational studies or analyzing user data). Study selection was carried out per the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [29] and the title-abstract screening and full-text screening of the search results were performed using CADIMA [30]. The screening was independently conducted by EB and LR, and disagreements were resolved through discussion and consensus, involving a third party if necessary.

Table 1. Inclusion and exclusion criteria according to the PICO[a]-scheme.

	Inclusion	Exclusion
Population	Adult patients with diagnosed diabetes mellitus type 2 and HbA_{1c}[b] ≥6.5%	Age <18 years, type 1 diabetes, gestational diabetes, or focus on special subgroups of populations (eg, low income)
Intervention	App-based lifestyle interventions meeting the digitale Gesundheitsanwendung (digital health app) definition, that is, primarily stand-alone (additional human support was possible, if not as the main driver) or multimodal, that is, covering at least two areas of diabetes care (diet, exercise, self-management, etc)	Interventions not primarily app-based (ie, the need for human resources to deliver intervention) or not multimodal (ie, covering only one area of diabetes care, eg, diet intervention), pharmacological interventions, or interventions for prevention
Control	All kinds of control groups or no control group	N/A[c]
Outcome	Glycemic control (HbA_{1c})	HbA_{1c} not reported
Study design	Systematic reviews[d], meta-analyses[d], randomized controlled trials, observational studies, or pilot studies	Study protocols, case reports, surveys, qualitative studies, narrative literature reviews, cross-sectional studies, scoping reviews, economic analyses, or books

[a]PICO: Population, Intervention, Control, Outcome.

[b]HbA_{1c}: hemoglobin A_{1c} (long-term blood glucose).

[c]Not applicable as control was not defined as an exclusion criteria.

[d]Identified systematic reviews were screened for studies that met the inclusion criteria of the present review.

Grading of Pragmatism (PRECIS-2)

Both RCTs and non-RCTs were graded by EB, KW, and LR using the PRECIS-2 tool [31] to represent how explanatory or pragmatic the trials were. The PRECIS-2 tool covers nine domains: "eligibility," "recruitment," "organization," "setting," "flexibility (adherence)," "flexibility (delivery)," "follow-up," "primary endpoint," and "primary analysis." All domains are rated on a 5-point Likert scale from 0 (very explanatory) to 5 (very pragmatic). Generally, a trial is more pragmatic the less strict its protocol is or the fewer additional resources are used, and is therefore closer to usual care. On the other hand, a very explanatory trial would differ vastly from the usual care setting, using strict protocols, a lot of extra resources, specific patients as well as study settings or collecting a vast amount of extra data.

To grade the pragmatism of the studies included in this systematic review, a mean over all domains for each study and across all studies within the respective study type (RCT vs non-RCT) was calculated and was used to compare pragmatism between domains, studies, and study types.

Grading of Evidence (GRADE) and Risk of Bias Assessment

Risk of bias (RoB) assessments for the included studies were independently performed by 2 reviewers, and disagreements were resolved through discussion and consensus. The RCTs were assessed by CB and EB using the RoB 2 tool [32] and nonrandomized and observational studies were assessed by EB and LR, using the Risk Of Bias in Non-Randomized Studies of Interventions (ROBINS-I) tool [33]. The quality of evidence was evaluated by EB, KW, and LR using the GRADE tool [34]. This established tool was used to assess the overall certainty of evidence according to RoB, imprecision, inconsistency, indirectness, and publication bias (see Multimedia Appendix 2) [34]. This was carried out using the GRADEpro Guideline Development Tool (GRADEpro GDT) for the three outcomes: changes in HbA_{1c} between groups in RCTs, within groups in RCTs, and within groups in non-RCTs. In addition, publication bias was evaluated with the help of funnel plots using the R (R Foundation) function *meta::forest.meta* [35].

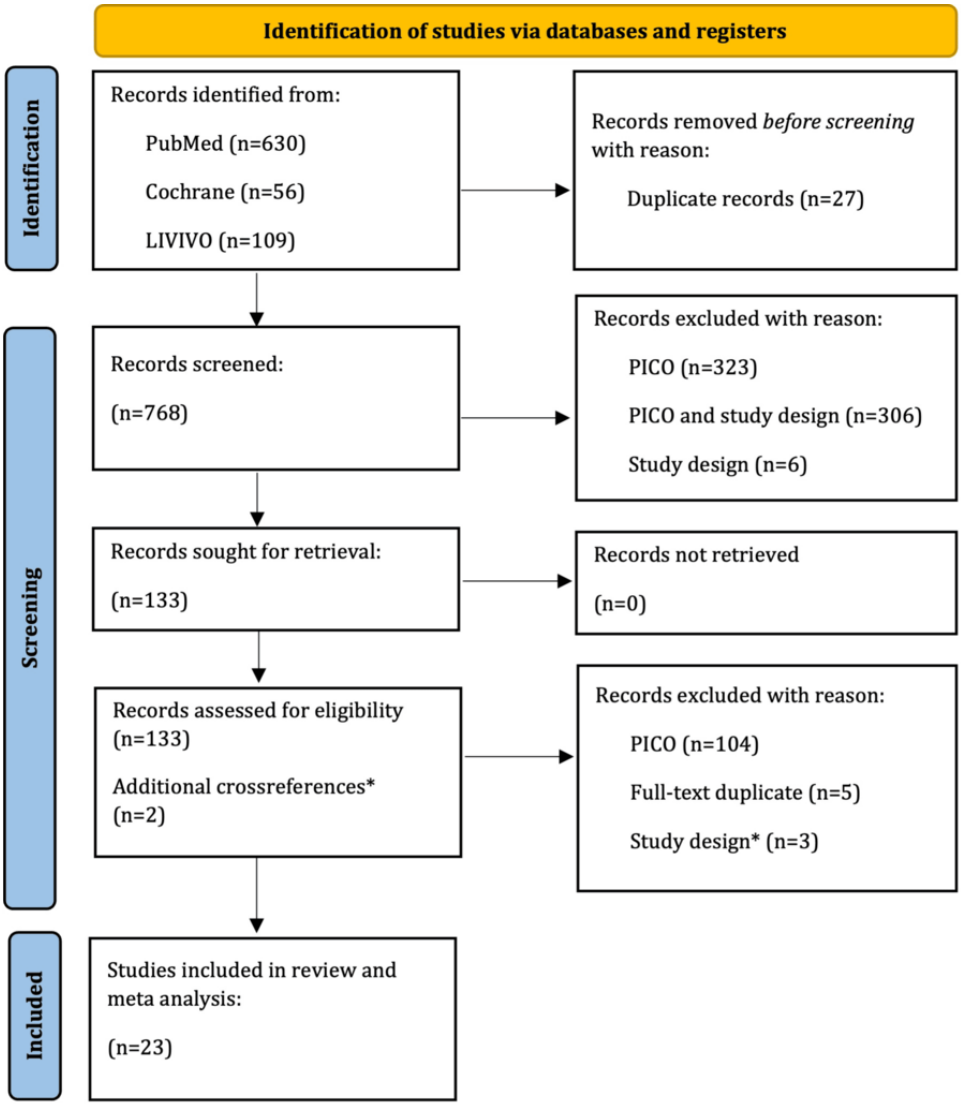
Statistical Analysis

The data analysis, that is, pooling the results, was performed with R (version 4.3.0) in the RStudio environment.

Two approaches were used to pool the results of the studies. First, the unstandardized between group differences were used to assess the effect of the intervention group (IG) or unit compared with the control group (CG) or unit. Second, with the within-group mean differences (MDs) the absolute change in HbA_{1c} postintervention was quantified. Both effect sizes were not standardized because the included studies measured the relevant outcome on the same scale, that is, HbA_{1c} (in percentage) [36]. The results (mean [SD]) with the highest statistical quality were extracted: (1) for RCTs intention-to-treat (ITTs) analyses that analyze all participants as randomized independent of protocol adherence (with imputation or complete cases analysis) were preferred over per-protocol analyses including only patients adhering to the protocol and hence hold the potential of biased "best case" results and (2) generally adjusted values were preferred over the potentially confounded.

While *meta::metacont* can calculate the mean between group difference and the respective 95% CIs based on each within-group MD and corresponding SD, the within-group MD and corresponding SE needed to be precalculated before effects could be pooled with *meta::metagen* [37,38]. The function further allowed us to calculate prediction intervals for the expected intervention effect in a single new study [39]. Random-effects models were used to pool results because study heterogeneity cannot be excluded (ie, due to different observation periods and different digital apps). Missing within-group MDs and SDs for the IG (and CG) were calculated from the available information reported in the studies per the following suggested procedures. MDs between IG and CG were calculated based on the formula for within-group differences, that is, the mean of the follow-up value subtracted by the mean of the baseline value [36]. In case 95% CIs, *t* statistic values, or *P* values were available, the SD was calculated based on the formulas provided by Higgins et al [40]. If only baseline or follow-up SDs were available, one was substituted with the other; under the assumption that the intervention did not alter the variance [40]. Assuming that the correlation coefficient between the pre- and postvalue of the IGs was similar, missing SDs for the within-group differences were calculated by the mean of the baseline and follow-up SDs [40].

For heterogeneity assessment, the I^2 statistic was used. It quantifies the amount of variation in the results that is not random. Generally, an I^2 below 40% can be considered low, an I^2 between 30%-60% moderate, and an I^2 between 50%-70% or even 70%-90% high [41]. In case of high heterogeneity outlier analysis based on the study by Harrer et al [42] was conducted and reported.



Results

Study Selection

Overall, 21 trials and 3 systematic reviews met the inclusion criteria and were found to be eligible. Systematic reviews were not included in this review and meta-analysis but were used to identify further eligible trials. Their content was screened and thereby, two further trials were identified and included as cross-references. In total, 23 studies were included in this systematic review and were eligible for meta-analysis (see PRISMA flow diagram in Figure 1 and checklist in Multimedia Appendix 3).

XSL•FO
RenderX

Figure 1. PRISMA flow chart of included and excluded studies within this systematic review and meta-analysis. *The content of identified systematic reviews (n=3) was screened to identify further eligible trials that were included as crossreferences. Systematic Reviews were not included in this study. PICO: Population; Intervention; Control; Outcome; PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

Characteristics of Included Studies

A total of 23 studies were eligible for the review, 12 RCTs and 11 non-RCTs. Of those final studies, 3 were performed as secondary analyses looking at specific subgroups from another study (Lee et al 2021 [43] and Lim et al 2022 [44]) or presented preliminary results of a trial (Torbjørnsen et al 2014 [45]). They were hence not included in the meta-analysis because the main results are covered by other included studies. Another study (Dixon et al 2020 [46]) only looked at HbA_{1c} changes based on different HbA_{1c} baseline categories and was also not included in the meta-analysis because a result for the whole sample could not be obtained and including several subgroups would overrepresent the single study.

Overall, nine of the studies included in the meta-analysis were RCTs and 10 were non-RCTs. Most of the non-RCTs were single-arm observational (pilot) studies and two had an intraindividual CG (Table 2). The average calculated pragmatism of each study is reported in Table 2, while detailed information on each domain is provided in Multimedia Appendix 4. Detailed information on the content and the features of the apps is provided in Multimedia Appendix 5. Most RCTs were performed in Asia, most non-RCTs were performed in the United States. The patient characteristics of study participants and app users are provided in Table 3.

[h]HCP: health care professionals.

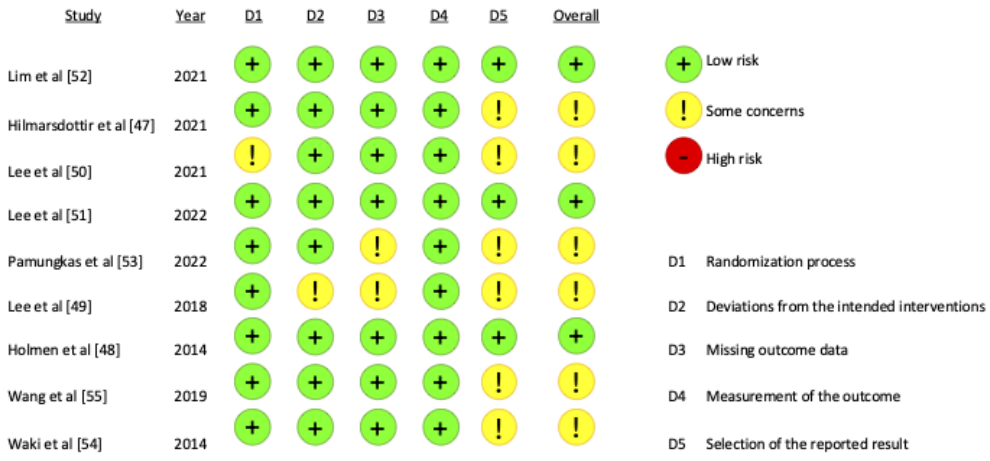
[i]N/A: not applicable.

[j]O: oral medication only.

[k]Mean (SD).

[l]Drop out for analysis of real-world users was defined as the users initially included in this study but excluded for the analysis due to missing (follow-up) HbA_{1c} values.

Grading of Pragmatism



To rate the level of pragmatism of the included studies, the PRECIS-2 tool was used (Multimedia Appendix 4). The mean score of pragmatism for RCTs was 4.2 and for non-RCTs 4.5, that is, both study types were on average (very) pragmatic, that is, close to usual care. As a routinely collected parameter in usual care, the HbA_{1c}, is a very pragmatic parameter, resulting in high ratings in the domain of "primary outcome" in all studies. The "eligibility," that is, inclusion and exclusion criteria were also rated as rather pragmatic, as they were close to real-world conditions in almost all studies for the use of a health app; including mostly patients who would be eligible under real-world conditions as well. The organization was mostly rated (very) pragmatic as well, carrying out the study in the usual care environment.

Due to more extensive data collection, RCTs had a slightly lower average score in the domain of "follow-up," mostly due to patient-reported outcomes. Non-RCTs, on the other hand, were rated as less pragmatic than RCTs in the domains of "primary analysis" and "recruitment" due to insufficient inclusion of all available data and sometimes extensive recruitment strategies. The highest rating of pragmatism was achieved when studies analyzed actual user data.

RoB Assessment

Only 3 RCTs were rated as having a low RoB (Figure 2 [47-55]). All of the remaining RCTs were rated as having some concerns, with domain 5 raising concerns in all of them, due to missing study protocols. Missing blinding of participants was present in all studies and some studies also lacked blinding of the outcome assessor (domain 4). We nevertheless decided to rate the RoB as low in this respect, as the outcome of interest, the HbA_{1c}, is a physiological parameter that is less likely to be affected by knowledge of the received intervention, when compared to patient-reported outcomes [26].

Figure 2. Cochrane risk of bias assessment of randomized controlled trials included in the meta-analysis [47-55]. D: domain.

All of the non-RCTs had at least a serious (n=4), if not a critical (n=5) RoB according to ROBINS-I; the detailed ratings can be found in Multimedia Appendix 6. Due to missing information on clear time frames for assessment as well as patient flow, one study could not be ranked [57]. All of the ranked studies had a serious RoB due to confounding because no adjustment for possible confounders was performed or, as in the case of Berman et al [58], adjustment for postintervention variables was performed. The categories leading to critical risks were due to bias in the selection of participants. This particularly relates to observational studies that analyzed app users but excluded all participants who did not have a follow-up HbA_{1c}, leading to exclusion rates of up to almost 80% [60] (Table 3). As it has to be assumed that reporting and continuation of the intervention is influenced by the intervention itself, the RoB of selection was judged to be critical. Another problem of RWD that led to a critical selection bias, was that start and follow-up times did not coincide for all users. Again, the lack of statistical adjustments to correct for missing data resulted in a selection bias and also did not offer evidence that the results were robust to missing data. Two of the studies also had a serious RoB in

XSL•FO
RenderX

the category of measurement outcome due to self-reported HbA_{1c} values.

Grading of Evidence

The grading of evidence was based on the meta-analyses results for the between group differences using 9 RCTs and the within-group differences using 12 RCTs as well as 11 observational studies. Using the GRADE Framework, the levels of certainty for the HbA_{1c} outcomes were rated as low quality of evidence for the RCTs and very low quality of evidence for the observational studies (Table 4).

Table 4. Summary of findings table.

Certainty assessment							Patients, n		Effect		Certainty
Studies, n	Study design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other factors	App-based intervention	Standard care	Relative (95% CI)	Absolute (95% CI)	
9	RCTs[a] (between groups)	Serious[b]	Not serious	Serious[c]	Not serious	None	523	522	—[d]	MD[e] –0.36% (–0.59 to –0.14)	2/4 low
10	Non-RCTs	Very serious[f]	Very serious[g]	Very serious[h]	Not serious	None	2358	271	—	MD –0.87% (–1.16 to –0.57)	1/4 very low
9	RCTs (within-group)	Serious[b]	Not serious	Serious[c]	Not serious	None	523	522	—	MD –0.69% (–1.13 to –0.24)	2/4 low

[a]RCT: randomized controlled trial.

[b]Mainly moderate risk of bias (RoB2-Tool).

[c]Mainly Asia, widely varying intervention duration.

[d]Not applicable.

[e]MD: mean difference.

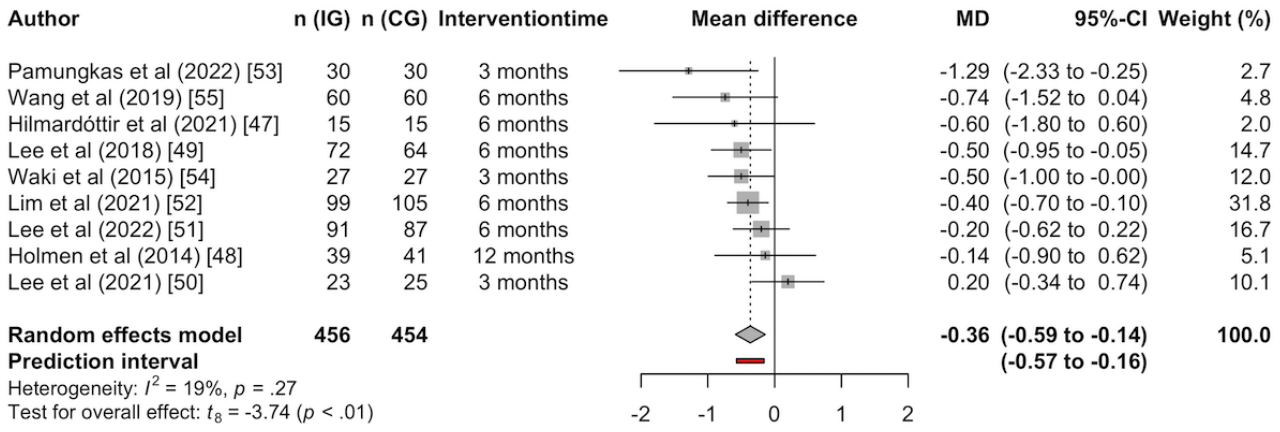
[f]Serious to critical Risk Of Bias in Non-Randomized Studies of Interventions (ROBINS-I-Tool).

[g]High heterogeneity I^2 82%-94%.

[h]Mainly in the United States, widely varying intervention duration and intervention duration are often unclear.

For the between group differences in RCTs, this rating is due to a serious RoB, illustrated by the low to moderate RoB 2 rating. It also reflects a serious indirectness of the results, which arises from the RCTs being conducted primarily in Asia with widely varying intervention durations of 3 to 12 months. However, imprecision was not detected and neither was inconsistency, based on a low heterogeneity score of I^2=19%. The same applies to publication bias, which was also not detected. For the RCTs used for the within-group differences, the same grading applies.

For the non-RCTs, the very low quality of evidence arose from a very serious RoB rating, pictured by the results of the ROBINS-I-Tool, which showed a serious to critical RoB in the non-RCTs (Multimedia Appendix 6). A high heterogeneity score of I^2=82%-94% showed a high, very serious inconsistency. Due to studies being primarily conducted in the United States with intervention durations widely varying or remaining unclear, as is the nature of RWD, the quality was further downgraded for very serious indirectness. It was further downgraded for publication bias because funnel plots showed some asymmetry in favor of positive results. Imprecision however was not detected.



Results of Meta-Analysis

Between Group Differences

To assess the effect of app-based interventions compared to usual care, the results of the RCTs were pooled. The meta-analysis was performed independent of the intervention period because the number of studies that fell in the same category was too small. Most studies reported results after 6 months, two after 3 months, and one after 12 months. The average MD between IG and CG in the reduction of HbA_{1c} was –0.36% (95% CI –0.59% to –0.14%), favoring app-based interventions (Figure 3). The random effects model yielded significance implying that the group differences were significant (P<.001). The between-study heterogeneity can be assumed to be low with an I^2 of 19% and the test for heterogeneity does not yield significance (P=.27). The prediction interval ranged from –0.57% to –0.16% and hence is very similar to the effect size, indicating robust results.

RenderX

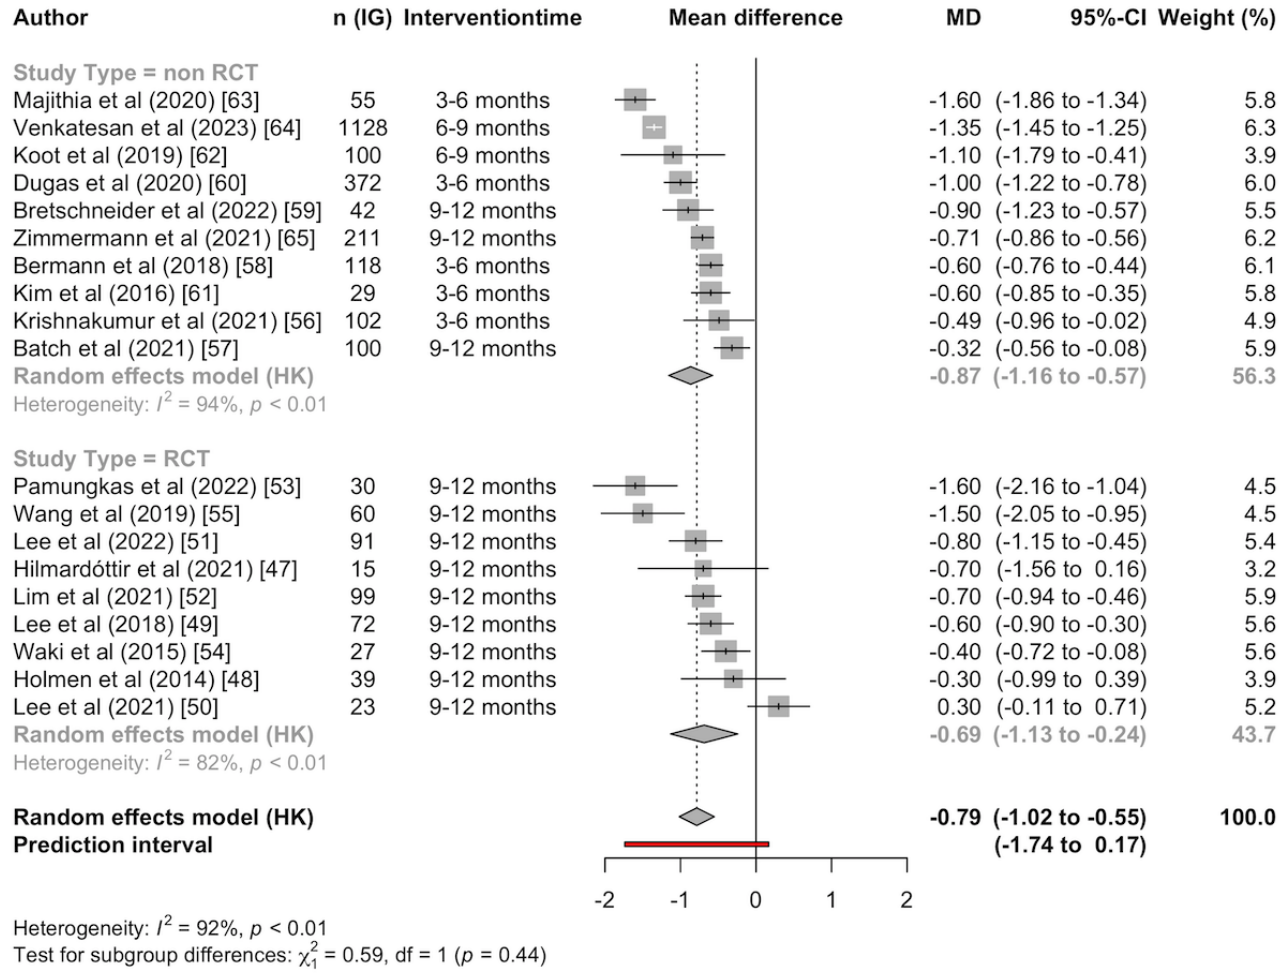

Figure 3. Meta-analysis of change in HbA1c after app-based lifestyle intervention meeting DiGA definition. DiGA: digitale Gesundheitsanwendung (digital health app); HbA1c: hemoglobin A1c (long-term blood glucose); MD: mean difference.

Within-Group Differences

To compare the effects of RCTs and non-RCTs, pre-post effects within the IG of the apps were considered due to a lack of a CG in most non-RCTs. Again, the analysis was performed independent of the duration of the intervention. Non-RCTs had varying observation periods that, on average, were shorter compared to RCTs. The average mean pre-post reduction in HbA_{1c} levels is –0.79 (95% CI –1.02 to –0.55), not differing significantly (P=.44) between RCTs (–0.69, 95% CI –1.13 to –0.24) and non RCTs (–0.87, 95% CI –1.16 to –0.57; Figure 4). The high heterogeneity (I^2=82%-94%) and the prediction interval that also included positive values indicate a potential lack of robustness of the results. The heterogeneity remains moderate to high (RCTs: 55%; non-RCTs: 59%) in the outlier analysis (Multimedia Appendix 7).

Figure 4. Meta-analysis of the pre-post effects within the IG of RCTs and non-RCTs. IG: intervention group; MD: mean difference; RCT: randomized controlled trial.

Discussion

Principal Findings

Overall, this systematic review and meta-analysis aimed at giving an overview of the current evidence regarding the efficacy and effectiveness of app-based interventions for the treatment of T2DM. For this, RCTs as well as non-RCTs were included. To our knowledge, this review is the first to include RCTs and non-RCTs for a pooled pre-post effect of digital lifestyle therapy on the HbA_{1c} in patients living with diabetes. Evidence from 9 RCTs shows that app-based interventions for the treatment of T2DM support patients in significantly reducing their HbA_{1c} levels by, on average, –0.36% and had favorable results compared to CGs receiving usual diabetes care. Looking at the within-group differences, patients were able to reduce their HbA_{1c} values on average by –0.79% after 3-12 months. While non-RCTs showed slightly higher reductions compared to the RCTs, the differences between study types were not significant. However, the heterogeneity (I^2 statistic) for the within-group differences across study types, as well as within-study types was high, likely due to differences in the study duration and setting, methodology, and patients' characteristics [66]. In contrast, the RCTs' between-subject analysis resulted in a low heterogeneity. This shows the importance of controlling for baseline characteristics in statistical models to analyze outcomes. The pre-post effects only adjusted for confounding factors within their study population. In contrast, between group differences cancel out several effects unrelated to the intervention. First, the effect of the patient population characteristics itself. Second, the effect of the "usual care" that potentially differs between study sites (nationality, resources, study information provided to the participants, etc). Third, both groups are followed up over the same period, which allows controls for unexpected or spontaneous outcome-related events influencing the disease process of the whole population. As a result, only the between group differences show the isolated efficacy of the intervention, while within-group differences show the effectiveness of the intervention including external factors that might influence study outcomes, that is, the clinical effect under real-world conditions. This review shows that non-RCTs are likely to produce similar outcomes to RCTs per the effectiveness of interventions and as such can complement the evidence from RCTs. To address the limiting factor of a missing comparator in non-RCTs, appropriate artificial CGs could be used, such as matching methods or intraindividual cohorts. In fact, some of the included non-RCTs used the latter method.

Comparison to Prior Work

The average additional mean HbA_{1c} reduction of –0.36% achieved with app-based interventions in comparison to usual care only, is comparable to previous systematic reviews on tele-medical treatment of diabetes that found mean group-differences of –0.44% [19] and –0.52% [21]. To reduce long-term diabetes-related complications, an HbA_{1c} reduction of 0.3% is considered clinically meaningful [67-69]. Stronger reductions in previous reviews could be due to broader inclusion criteria because the current review only included studies on apps that meet the DiGA definition and thus largely function through their technology independently of HCPs. Systematic reviews that analyze the efficacy of app-based interventions for type 1 diabetes mellitus and T2DM show that additional remote access to HCPs [19] as well as a higher frequency and intensity of feedback and interaction are associated with greater HbA_{1c} reductions [20]. Whether or not the feedback is automated or manual, on the other hand, might not be relevant [70].

Pragmatism (PRECIS-2) Versus Quality of the Study (GRADE)

RCTs are designed such that the result is highly controlled, providing strong internal validity. However, this does not mean an RCT cannot be implemented in a real-world setting. The reasons for choosing a non-RCT design can be very diverse, with pragmatic implementation being a major aspect. In our study, the concept of pragmatism was used to judge the external validity of studies with the help of the PRECIS-2 tool. The most pragmatic studies were those that analyzed actual users of the app-based interventions [46,60]. Both RCTs and non-RCTs had, on average, high grades for pragmatism indicating (very) pragmatic trials and good external validity. Due to a lack of transparency and suitable statistical methods to account for missing data, non-RCTs had slightly lower grades than RCTs in the domains "primary analysis" and "recruitment."

The GRADE ratings in both RCTs and non-RCTs further showed potential for improvement in future trials aiming for analyzing in-app user data or studies without a CG. First of all, improved statistical methods should be used to control for baseline covariates. Especially in studies analyzing user data or data collected from health records, clear information on data selection and suitable statistical methods are lacking. Particularly, in the absence of a CG, the handling of missing data needs to be clearly justified (eg, patients who do not use the app or do not provide any data). One way to improve the quality might be the use of preregistered analysis that predefines statistical methods and inclusion or exclusion criteria of patients [23]. Additional sensitivity analyses under different assumptions or conditions may increase the interpretability of results, as might blinding that so far is a major limitation of most digital interventions.

While non-RCTs in the context of explanatory trials show several limitations, they do have strengths in depicting results in a real-world context as pragmatic trials. However, the results of the PRECIS-2 rating showed that non-RCTs and RCTs included in our study can be classified as similarly pragmatic, and as such hold the potential to analyze interventions under real-world conditions to complement RCTs conducted in a controlled setting. Especially, in the context of fast-changing digital interventions, non-RCTs offer a cost- and time-efficient addition to RCTs. It is important to note that, for both RCTs and non-RCTs, the results of the study depend on the specific recruitment strategy and patient characteristics. The findings offer insights into the shortcomings of both RCTs and non-RCTs concerning pragmatism, however, they should be read with care, and translation of the evidence to other care settings should be made with great caution.

XSL•FO
RenderX

Limitations

This study has several limitations. First, it cannot be ruled out that relevant publications were overseen in the course of the conducted search. However, this was counteracted by building extensive search terms, based on the PICO scheme, and by using text words as well as MeSH terms. In addition, the search was also conducted in three different databases, which might have further contributed to limiting the risk of selection bias. Second, the present results are limited to studies without long-term, follow-up periods, generating short-term rather than long-term evidence of the interventions. Other reviews suggest that the initialization of a treatment and as such the immediate short-term outcomes of treatment duration might be associated with better treatment success [21] making long-term and follow-up effects of particular interest. Third, even though the comparator of the included RCTs was theoretically the same, that is, usual care, in practice diabetes care differs between countries and could not be considered thoroughly which might have influenced the results. Due to the limited number of studies that fit the inclusion criteria, the heterogeneity between studies could not be accounted for in further subgroup analyses, for example, based on the time of the interventions. In fact, the results of the GRADE rating further resulted in (very) low evidence for the results of meta-analysis. Therefore, the results should be evaluated with caution. Finally, it is important to note that non-RCTs including real-world evidence exist on a broad continuum of possible settings. Unlike RCTs, which are more clearly defined per their study conditions, they vary greatly in their design and context. The PRECIS-2 tool was used to obtain an estimate of how pragmatic the delivery of digital care was in the different studies, including RCTs and non-RCTs. The PRECIS-2 tool was originally developed for designing pragmatic RCTs. As the authors leave freedom and flexibility in the usage of the tool, we applied it for the retrospective grading for RCTs as well as for non-RCTs. Downgrading of specific dimensions within the PRECIS tool depends on the deviation from the usual care condition, which can also vary across different settings. This makes it difficult to apply coherent criteria to a set of different studies.

Conclusions

Overall, it can be concluded that app-based lifestyle interventions that meet the definition of DiGA can effectively reduce HbA_{1c} in patients with T2DM. This has been shown not only in RCTs but also in non-RCTs. While the latter still have several limitations per their design and statistical analyses, non-RCTs that implement suitable designs and methodologies have the potential to become an important source of complementary evidence, for example, in the context of postmarket analyses or piloting studies.

A DiGA approval requires high-quality evidence with minimal sources for biases, such as RCTs, before manufacturers can claim their medical product as a DiGA. Non-RCTs and in particular the analysis of in-app data can complement evidence from RCTs as a cost and time-efficient source of evidence to continuously monitor clinical outcomes of the medical device after being placed on the market.

Beyond the monitoring of the clinically relevant endpoints of DiGAs, in-app data can be a relevant addition to understanding patients' needs and support postmarket analysis. As such the combination of evidence generated by both RCTs and non-RCTs is gaining relevance to develop the potential of DiGAs, for example, implemented in usual care as hybrid models. Moreover, introducing digital care solutions in the health care system may pave the way for artificial intelligence to further enhance the treatment of T2DM worldwide. Yet, future studies should aim for more methodological transparency and appropriate statistical evaluation procedures and methodologies to account for current limitations of non-RCTs, such as the missing comparator.

Acknowledgments

Data Availability

Data sharing does not apply to this article as no data sets were generated or analyzed during this study.

Authors' Contributions

EB and LR designed this study and conducted the systematic literature search; including the critical evaluation, data extraction, and presentation of the results. Different gradings were performed by EB, LR, CB, and KW as mentioned in the text. LR was responsible for the meta-analysis and its visual representation. KW advised on improvements. EB and LR drafted this paper. All authors critically evaluated and reviewed the article.

Conflicts of Interest

EB, CB, and KW are employees of Sidekick Health Germany GmbH (formerly aidhere GmbH).

Abstract

Background: Recent advancements in artificial intelligence (AI) have changed the care processes in mental health, particularly in decision-making support for health care professionals and individuals with mental health problems. AI systems provide support in several domains of mental health, including early detection, diagnostics, treatment, and self-care. The use of AI systems in care flows faces several challenges in relation to decision-making support, stemming from technology, end-user, and organizational perspectives with the AI disruption of care processes.

Objective: This study aims to explore the use of AI systems in mental health to support decision-making, focusing on 3 key areas: the characteristics of research on AI systems in mental health; the current applications, decisions, end users, and user flow of AI systems to support decision-making; and the evaluation of AI systems for the implementation of decision-making support, including elements influencing the long-term use.

Methods: A scoping review of empirical evidence was conducted across 5 databases: PubMed, Scopus, PsycINFO, Web of Science, and CINAHL. The searches were restricted to peer-reviewed articles published in English after 2011. The initial screening at the title and abstract level was conducted by 2 reviewers, followed by full-text screening based on the inclusion criteria. Data were then charted and prepared for data analysis.

Results: Of a total of 1217 articles, 12 (0.99%) met the inclusion criteria. These studies predominantly originated from high-income countries. The AI systems were used in health care, self-care, and hybrid care contexts, addressing a variety of mental health problems. Three types of AI systems were identified in terms of decision-making support: diagnostic and predictive AI, treatment selection AI, and self-help AI. The dynamics of the type of end-user interaction and system design were diverse in complexity for the integration and use of the AI systems to support decision-making in care processes. The evaluation of the use of AI systems highlighted several challenges impacting the implementation and functionality of the AI systems in care processes, including factors affecting accuracy, increase of demand, trustworthiness, patient-physician communication, and engagement with the AI systems.

Conclusions: The design, development, and implementation of AI systems to support decision-making present substantial challenges for the sustainable use of this technology in care processes. The empirical evidence shows that the evaluation of the use of AI systems in mental health is still in its early stages, with need for more empirically focused research on real-world use. The key aspects requiring further investigation include the evaluation of the use of AI-supported decision-making from human-AI interaction and human-computer interaction perspectives, longitudinal implementation studies of AI systems in mental health to assess the use, and the integration of shared decision-making in AI systems.

Introduction

Background

There has been an increasing interest in the use of artificial intelligence (AI) systems in health care in recent years as part of supporting health care professionals and individuals with health problems to facilitate care processes. This technology is taking advantage of the abundance of health care data to assess and support decision-making across multiple dimensions. Numerous studies have investigated the prospective utility of AI systems in augmenting decision-making across various health care domains. These encompass early detection, diagnostics, treatment modalities, and self-care initiatives [1-3]. While extensive research has examined the ethics, performance, and potential applications of AI models [4-6], there remains a notable gap in the literature regarding the integrative and empirical use of implemented AI systems in health processes.

AI systems for decision-making are equipped to enhance health care and self-care processes. These systems not only have the potential to improve the efficiency of health care processes but also act as a bridge, integrating health care with self-care by enabling seamless information exchange between the 2 domains [7]. From a health care viewpoint, AI systems hold transformative potential for the future, particularly in the identification and diagnosis of health problems, as it can introduce more objectivity and precision [8]. Self-care, in contrast, refers to the personal management of health and daily life activities outside the formal health care system, while self-help encompasses the use of external resources for the management of health and well-being, both within and beyond the formal health care system [9].

From the standpoint of clinical workflows and end users, AI systems present several advantages, including personalized decision-making, enhanced patient-physician communication, and support for shared decision-making (SDM) [10-12]. However, concerns have been raised by both clinicians and patients regarding the widespread adoption of AI systems, underscoring the need for cultural adjustments within health care to facilitate acceptance [10]. Clinicians have expressed reservations about integrating AI systems into decision-making processes, given the challenges around accepting a second opinion without validation from another clinician [12]. Beyond issues of acceptability, the implementation of AI in SDM poses various challenges, including potential delays in decision-making, communication barriers between health care professionals and patients, and uncertainty surrounding the role of AI in decision-making [13]. Research into the use of AI systems in the context of SDM is still in its nascent stages, emphasizing the need for further exploration into how AI systems can effectively support SDM processes in the future [14].

The potential use of AI for SDM holds particular significance in the context of mental health care given the challenges in the identification and management of mental health problems faced by the contemporary mental health care institutions. However, the complex and heterogeneous nature of mental health problems presents considerable obstacles for AI systems in delivering accurate diagnostics, effective treatment guidance, and tailored interventions. Instead, AI systems currently demonstrate greater efficacy in aiding the identification of symptoms of mental health problems rather than diagnosing specific disorders [10,15]. Given this context, it becomes imperative to understand the interplay between the complexities of mental health problems and AI decision-making support mechanisms, emphasizing the incorporation of the perspectives of end users. Such an inclusive approach is essential for guiding the effective implementation of AI systems in mental health settings [16]. Numerous studies underscore the necessity for a nuanced understanding of AI system use within real-world mental health care to inform future implementation strategies [1,17-19].

Objectives

Despite the potential promises and inherent challenges associated with AI systems in supporting decision-making processes within mental health care, there remains a notable research gap concerning their practical utility. Fundamental questions persist regarding the types of decisions AI systems can support in real-world environments, the extent to which these systems engage patients in the decision-making process, and the methodologies used for their evaluation. Given this backdrop, this study aims to explore the empirical evidence for the use of AI systems to support different types of decision-making in mental health. This includes how it has been researched, applied, and evaluated for use and implementation, contributing to the understanding and improvement of future design, development, and implementation of AI systems in mental health.

Methods

Study Design

A scoping review approach was considered the preferable method to address the explorative nature of the study and to systematically map the available empirical studies within the study domain. The design of this scoping review was guided by the 5-phase framework put forward by Arksey and O'Malley [20] to ensure quality and a systematic approach to the study. The framework phases included defining the research questions (RQs); identifying relevant studies; selecting the study; charting the data; and collating, summarizing, and reporting results. The reporting process was conducted following the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist [21], as shown in Multimedia Appendix 1.

Identifying the RQs

A multidisciplinary research team comprising experts from health care, nursing, AI systems, and implementation research engaged in discussions in the initial phase of the study to identify the scope of the research and RQs. Four main concepts were defined to guide the study: mental health, AI, decision-making, and implementation (Table 1).

XSL•FO
RenderX

Table 1. Operational definitions of the main concepts used in the article.

Concept	Operational definition	Specification
Mental health	• It is conceptualized as including mental health problems, mental illnesses, and disorders for patients and individuals seeking care [22].	• This enabled the exploration of broader types of users with mental health problems, not only patients in clinical settings but also individuals seeking care in a nonclinical environment. The term patient is used to refer to a person receiving or registered with a health care provider. The term individuals refers to people seeking care regardless of being registered in health care.
AI[a] systems	• The AI concept refers to systems described to use AI types relevant to health care, including ML[b], neural networks, deep learning, computational intelligence, supervised ML, or robotics in connection to supporting decision-making utility [23].	• Exploring the AI models as part of a system facilitates understanding the processes within which the AI is integrated into the care settings.
Decision-making	• Decision-making is defined as a cyclical process from situation awareness to acting on a decision [24,25]. • Decision-making support provided by the AI systems are systems that "provide clinicians, staff, and patients with knowledge, patient-specific information, and recommendations" and are "designed to assist decision-makers and interactively support all phases of a human decision-making process." [26,27]. • Decision-making in mental health may include a collaboration between the patients and health care professionals to reach a decision. Shared decision-making in this study is defined as "an approach where clinicians and patients make decisions together using the best available evidence" [28].	• This concept allowed the investigation of AI systems from a decision-making support utility perspective in health care and self-care settings.
Implementation	• The criteria for the level of implementation of AI systems in practice were based on a TRL[c] of ≥6 [28]. A TRL of 6 indicates that the technology has advanced beyond the basic development phase and is now being demonstrated in a relevant real-world or simulated environment, meaning it is now ready for operational testing within its intended context.	This study focuses on researching AI systems specifically in terms of their use and implementation within care settings, with an emphasis on how these technologies are used and adopted in practice. Thus, AI systems with a TRL of ≤5 were excluded, as they are not sufficiently developed to allow end-user interaction or for meaningful evaluation in real-world care environments.

[a]AI: artificial intelligence.

[b]ML: machine learning.

[c]TRL: technology readiness level.

The following three RQs were formulated to address the aim of the study:

1. What are the characteristics of research on AI systems used in relation to support decision-making in mental health?
2. Which types of technologies, decisions, actors, and user flows of AI systems to support decision-making are described?
3. How were the AI-based decision support systems evaluated in research in the mental health context, and what discernible consideration might enable or hinder the adoption or implementation of these systems?

Identifying Relevant Studies

A search strategy was developed within the research team with the assistance of a librarian. Literature searches were carried out using the 5 main health research databases: PubMed, Scopus, PsycINFO, Web of Science, and CINAHL. Keywords used in the searches were guided by the following concepts and Medical Subject Headings terms: *mental health*, *artificial intelligence*, *decision-making*, and *implementation*. Synonyms were joined by the Boolean operator OR; next, we combined the search strings for each keyword with the Boolean operator AND (Multimedia Appendix 2). Eligibility criteria were followed for the search and study selection, as shown in Textbox 1.

XSL•FO
RenderX

Textbox 1. Eligibility criteria.

Inclusion criteria

- Written in English
- Peer-reviewed
- Publication date between January 2011 and September 2022
- All artificial intelligence (AI)–based decision support systems intended for use in relation to mental health interventions
- AI tools with user interaction with patients or health professionals aiming to support decision-making
- All mental health care settings and providers
- Empirical study design

Exclusion criteria

- Interventions that use AI for other purposes than to support decision-making
- Interventions that deliver support for other than mental health professionals and care receivers
- Proof-of-concept, viewpoints, or validation studies not related to the implementation and use of AI

Study Selection (Screening)

All articles identified from the searches were uploaded to EndNote (version 20.1; Clarivate) to remove duplicates. The remaining articles were then uploaded to Rayyan (Rayyan Systems Inc), a web-based tool used to screen articles on the abstract level and identify eligible studies for full-text screening. Rayyan was selected as it provides a systematic approach and facilitates organized teamwork [29]. In the first phase of screening, researchers (HA and MN) reviewed the abstracts and held regular follow-up meetings to ensure criteria consistency. In the second phase, full-text articles were reviewed by 2 reviewers in the research team and screened to meet the eligibility criteria and address the RQs. Throughout both phases, articles where there were uncertainties about meeting the inclusion criteria were discussed among the full research team until a consensus was reached. The screening process followed a decision tree process for excluding the studies that did not meet the inclusion criteria, then illustrated in a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram.

Charting the Data (Data Extraction)

A template sheet was developed to extract data from each of the included articles regarding the characteristics of research to respond to the first RQs, including the author's name, publication date, title, aim, country, study design, care settings, mental health problems, and types of AI. A descriptive summary was performed to answer RQ1 concerning the characteristics.

Collating, Summarizing, and Reporting Results

The reporting of the results for RQ2 was performed in 3 parts. First, we categorized the AI systems described in the included articles according to their utility in supporting decision-making in mental health. Second, we mapped the AI system's utility of supporting decision-making in relation to the end user's interaction and use. This mapping was carried out in terms of types of interaction and decision-making stages as per a conceptual model [24,25], which describe decision-making as a cyclical process spanning from situational awareness to the execution of decisions. Third, we conducted an explorative analysis, mapping data flow and user interaction in relation to the AI system's basic structure as elucidated by Sremac et al [30], comprising 3 primary phases: training data, AI model, and AI output (decision). In the identified articles, the study by Sadeh-Sharvit et al [31] did not provide sufficient data in the reporting for RQs 2 and 3.

An abductive analysis was conducted for RQ3 [32] combining inductive and deductive reasoning when looking at the data by firstly conducting inductive thematic analysis and connecting the emerged themes deductively to the human, organization, and technology-fit (HOT-fit) framework [33]. This framework provides 3 essential components when an AI system is being used; the human factor focuses on the individual user experience of the AI system; the organization factor focuses on the structure and environment evaluation of use; and the technology factor focuses on the quality of use of the system and the information provided by the AI system. These factors consist of subcategories or dimensions, and each dimension includes several elements. First, the content in each article was collated by the first author (HA) and inductively abstracted into themes. The framework was then used to deductively map the themes into the factors and their included elements. Two new elements, *trustworthiness* and *explainability*, were found in the abductive analysis and were included because they were relevant to the study objectives. Explainability refers to the ability of the AI system to provide clear and understandable reasoning of its output or decision support provided to the intended end users [34]. Trustworthiness refers to the extent to which the AI system is trusted by the end users to use, including being reliable, ethical, and dependable for use and in supporting decision-making [35]. The analysis was iteratively and repeatedly discussed between all the authors until consensus was achieved.

Results

Overview and Study Characteristics

The literature search resulted in 1773 articles between the years 2011 and 2022. Following the removal of duplicates, 1217 articles remained for abstract-level screening. Of these, 1159 (95.23%) articles were excluded based on the inclusion and exclusion criteria, leaving 58 (4.77%) articles for full-text screening. A total of 12 (0.99%) articles were found to meet our study eligibility criteria after the completion of the screening process as seen in the PRISMA flowchart (Figure 1).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart—study search and selection process. TRL: technology readiness level.

The articles included were published between 2020 and 2022, and a variety of designs were used (Table 2). Most of the articles were from the United States (7/12, 58%); 25% (3/12) were from Canada, 8% (1/12) were from the United Kingdom, and 8% (1/12) were from China. The included studies encompass 3 settings of investigation: health care, self-care (remotely), and simulation environment. The health care studies took place in primary care, emergency department, and specialized mental health care. The self-care studies focused on AI systems using mobile apps or wearables with sensors. Simulation studies were conducted in the psychiatry department within a university-based setting. The spectrum of severity and types of mental health problems found to be supported by the AI systems varied. Depression was the most common mental health problem targeted by the AI system support (5/12, 42%), followed by substance misuse (2/12, 17%), autism spectrum disorder (2/12, 17%), suicide and mental health crisis (2/12, 17%), and psychotherapy for different mental health problems (1/12, 8%).

Table 2. General characteristics of the included articles (N=12).

Study, year, and country	Study aim	Study design	Care setting	Mental health problems	Type of AI[a] (ML[b], DL[c], etc)
Dosovitsky et al [36], 2020; United States	To understand how users engage and are redirected through a chatbot for depression (Tess) to provide design recommendations.	Descriptive study	Self-care and online access	Depression	Not specified (using AI or AI model)
Benrimoh et al [37], 2021; Canada	To explore the use of a simulation center environment in evaluating the usability of (Aifred), particularly its impact on the physician–patient interaction.	Simulation-based study design	Simulation in a specialized care context (research and development)	Depression (major depressive disorder)	DL
Dimeff et al [38], 2021; United States	To evaluate the feasibility, acceptability, and effectiveness of (Jaspr Health) among suicide adults in emergency departments.	Pilot RCT[d]	Emergency department	Suicide	Not specified (using AI or AI model)
Jacobs et al[e] [39], 2021; United States	To investigate the influence of ML and AI on clinician decisions in major depressive disorder treatment.	Experimental study design	Primary and specialized health care	Depression (major depressive disorder)	ML
Popescu et al[e] [40], 2021; Canada	To examine the feasibility of an AI-powered CDSS[f], which combines the operationalized 2016 Canadian Network for Mood and Anxiety Treatments guidelines with a neural network–based individualized treatment remission prediction.	Longitudinal feasibility study	Primary and specialized health care	Depression (major depressive disorder)	DL
Prochaska et al [41], 2021; United States	To evaluate the efficacy and use of Woebot-SUDs[g] in managing SUD relative to a waitlist group in an RCT.	RCT	Self-care and online access	SUD	Not specified (using AI or AI model)
Prochaska et al [42], 2021; United States	To examine the feasibility, acceptability, and preliminary efficacy of Woebot-SUDs in managing SUD.	Development and usability study	Self-care and online access	SUD	Not specified (using AI or AI model)
Deng et al [43], 2022; China	To evaluate the effectiveness of sensory management recommendation system device for children with autism.	Experimental study	Self-care (wearables and app)	Autism	ML
Garriga et al [44], 2022; United Kingdom	To explore the added value of an implemented ML model in a clinical context.	Prospective cohort study	Specialized and primary care	A range of mental health problems	ML
Megerian et al [45], 2022; United States	To test the accuracy of an AI-based software as a medical device designed to aid primary care health care providers in diagnosing autism spectrum disorder.	A double-blinded, multisite, prospective, active comparator cohort study	Primary care	Autism	ML
Sadeh-Sharvit et al [31], 2022; United States	To explore therapists' use of a standard component that is pertinent across most behavioral treatments—prompting clients to summarize their treatment session as a means for consolidating and augmenting their understanding of the session and the treatment plan.	Retrospective study	Specialized care—behavioral health treatments	A range of mental health problems	ML and NLP
Tanguay-Sela et al [46], 2022; Canada	To evaluate the utility of a CDSS as perceived by physicians participating in simulated clinical interactions.	Simulation-based study design	Simulation in a primary and specialized care context (research and development)	Depression (major depressive disorder)	DL

[a]AI: artificial intelligence.

[b]ML: machine learning.

[c]DL: deep learning.

[d]RCT: randomized controlled trial.

[e]Jacobs et al [39] and Popescu et al [40] did not explicitly state the study aim in the articles.

[f]CDSS: clinical decision support system.

[g]SUD: substance use disorder.

Decision Support Utility, Data Flow, and User's Interaction With the AI System

Decision Support Utility

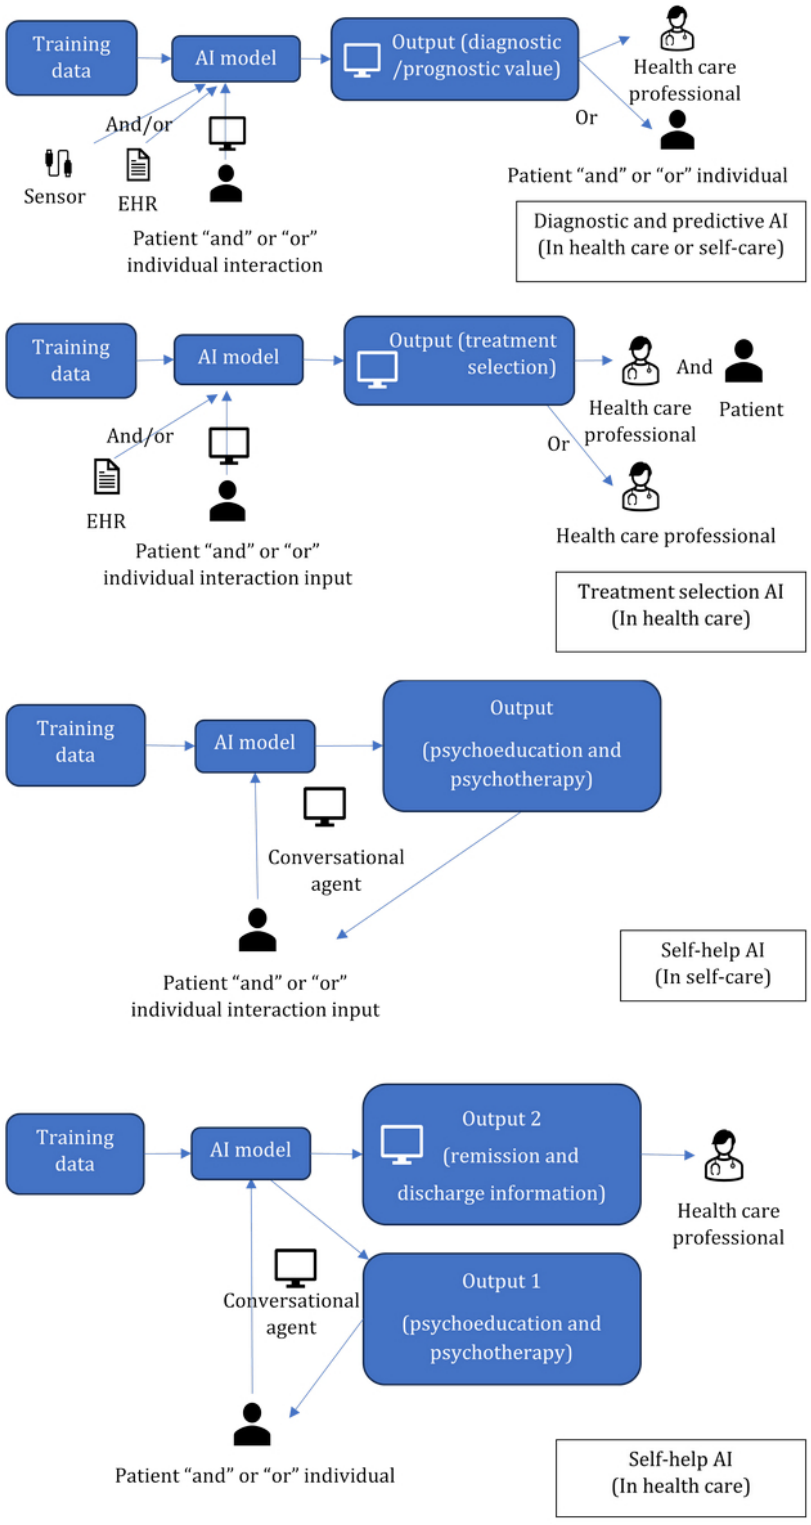
In our findings, 3 types of AI systems emerged based on their decision support utility and the form of output they provide to support decision-making in mental health, as shown in Multimedia Appendix 3. These three types are as follows: (1) *diagnostic and predictive AI*, including AI systems providing support in the identification of mental health states with diagnostic or prognostic output in binary or categorical forms; (2) *treatment selection AI*, including AI systems providing options for treatment with information explaining each option, designed to assess health care practitioners and patients in the therapy selection process; and (3) *self-help AI*, including AI systems designed to support patient and individuals in managing their own mental health, either in health care setting or through self-care practices. The self-help AI in the reviewed studies were all based on conversational agents, which address various mental health problems through psychoeducation and behavioral therapy methods.

These 3 types of AI systems differ in relation to the intended end user's engagement with the AI output to make a decision and with the extent of actionability of decisions the AI output is assisting (Figure 2 [31,36-46]). In Figure 2, *awareness* represents the extent to which the AI supports the end user's understanding of the situation related to decision-making, while *acting on a decision* refers to more direct and explicit AI support on which decision to be made. It could be seen that the 3 systems have different interaction dynamics. The figure shows that different AI systems require varied engagement of end users, including patients and health care professionals, to finalize a decision. Moreover, the urgency and requirement to act on a health-related decision in a care process provided by the AI systems differ as well (Figure 2).

Figure 2. Mapping the decision-support utility of the artificial intelligence (AI) systems on two dimensions: (1) the extent of actionable output the AI system provides and (2) the types and variety of potential end users using the AI system output. * Indicates the studies included: (1) Dosovitsky et al [36]; (2) Benrimoh et al [37]; (3) Dimeff et al [38]; (4) Jacobs et al [39]; (5) Popescu et al [40]; (6) Prochaska et al [41]; (7) Prochaska et al [42]; (8) Deng et al [43]; (9) Garriga et al [44]; (10) Megerian et al [45]; and (12) Tanguay-Sela et al [46].

The dot's locations represent the positions of the *intended primary end users* who are expected to interact directly with the AI system interface, and the intended primary decision-making utility (as represented in the 2 dimensions). The dot size reflects the number of AI systems that share the same location. The transparent background highlights the potential variety of involvement of secondary end users who may use the AI output alongside the primary intended user to make a decision.

In reference to Figure 2, the findings show diagnostic and predictive AI systems had the broadest potential number of primary end users from the health care and patients that needed to follow-up with the same AI output until reaching a decision without the need to interact with the AI interface. Treatment



XSL•FO
RenderX

selection AI systems had a broader need for interaction through the same interface by both the health care professionals and the patients. The systems in self-help AI varied between supporting psychoeducation (closer to awareness) and psychotherapy (closer to acting on a therapeutic decision). Compared to the other types of AI systems, this was the most multifunctional type in relation to supporting various decisions.

Data Flow and User's Interaction With the AI System

It can be seen in a closer analysis of the use of AI systems for mental health issues that the 3 systems are different in the flow of data, both as input and output to the AI model; user interaction with the AI system; and the dynamics of the decision makers using the AI output. Four data flow and interaction modalities were found as seen in Figure 3.

Figure 3. Illustration of the 4 data flow and interaction modalities of the 3 types of artificial intelligence (AI) systems. EHR: electronic health record.

XSL•FO
RenderX

Mapping the structure of the AI system's use journeys shows 3 key differences: the variations in AI input data sources, the use of AI output interface, and the different user interaction interfaces along the AI use journey. First, the sources of AI input data varied in the 3 systems, and a broader range of sources of data were used in the diagnostic and predictive AI. This indicates a more diverse array of new input being incorporated into the AI data analysis. In contrast, self-help AI systems, which were based on conversational interactions, incorporated the end user's textual interaction with a loop of self-help outputs. Second, the use of the AI output interface differed in the 3 AI systems, with more complicated dynamics of use in the treatment selection AI, where both patients and health care professionals potentially needed to interact with the same AI output interface. This is in contrast to the other 2 AI system types, where the interface was only used by 1 type of user at a time, either the health care professional or patient. Third, the interfaces used in the user journey from data input to output revealed variations in the dynamics of interaction. The interfaces for data input and output in the diagnostic and predictive AI and the treatment selection AI were separated, indicating a clear distinction between how information is entered into the system and how it is presented. In the self-help AI systems in health care settings, the input and output were integrated into a single interface for the patient's or individual's use, which in addition showed the potential for providing an extended interface for output for the health care professional to follow-up with the patient interaction.

Evaluation of the Implementation and Use of the AI Systems to Support Decision-Making

Overview

The findings revealed a varied distribution in how the studies evaluated AI-based decision support systems. The human factor in the self-help AI had a predominant focus compared with the other 2 AI types. AI factors were more balanced in representation in diagnostic and predictive AI and treatment selection. The organization factor emerged as the least evaluated aspect in terms of frequency in all AI system types (Table 3). The assessment of the AI systems using the HOT-fit elements, as detailed in Table 3 and Multimedia Appendix 4 [33], reveals the different focus of evaluation across the 3 types of AI systems, illustrating potential challenges and enablers for use and implementation.

XSL•FO
RenderX

Table 3. Summary of the human, organization, and technology-fit (HOT-fit) elements found in the 3 types of artificial intelligence (AI) systems and key findings of potential challenges and enablers of use and implementation.

HOT-fit elements	AI system type	Key findings, challenges (–), and enablers (+)
Human		
Amount and duration	Diagnostic and predictive, treatment selection, and self-help	• (–) Prominent inconsistent duration of use found in self-help AI in self-care settings
Motivation to use	Self-help	• (–) Potential lack of motivation for long-term of use without external support
Acceptance	Self-help	• Different acceptance according to user's socioeconomic status
Recurring use	Self-help	• (–) Unstable recurring use can disturb the evaluation of self-care conversational agent's effectiveness
Expectations and belief	Self-help	• Most users expressed that the conversational agent met some of their goals or needs, only few users expressed that it met most or all their needs
Resistance and reluctance	Self-help	• (–) Potential onboarding resistance and discontinuation after the first or second step in self-care settings
Percentage used	Treatment selection and self-help	• (–) Low completion rates in self-help AI in self-care settings
Voluntaries of use	Self-help	• Users are more likely to engage when initiated by the conversational agent
Knowledge and expertise	Treatment selection	• (+) Knowledge about the AI model can potentially improve the ability to explain the AI output • (–) Previous knowledge about the AI in general may reduce the trust
Overall satisfaction	Diagnostic and predictive and self-help	• (+) Overall satisfaction was relatively high in relation to the amount of help the end users got from the system, the consistency of the system, and if they would use it again or recommend it for others
Perceived usefulness	Diagnostic and predictive, treatment selection, and self-help	• (+) When evaluated most of participants perceived that the AI systems can successfully assist them
Satisfaction with specific functions	Treatment selection and self-help	• Self-help AI satisfaction varied according to the self-help topic • Treatment selection AI satisfaction was related to information the AI provided and can help with the communication with the patient
Decision making satisfaction	Treatment selection	• (–) When evaluated only 60% expressed that the model is somehow satisfactory to support treatment decisions
Organization		
Communication	Treatment selection	• (+) Potential participation in improving the communication of options or decisions
Clinical process	Diagnostic and predictive and treatment selection	• (+) Positive responses on the ability to transform current clinical practice • (–) Can lead to increase of workload by introducing additional steps into their practice
Localization	Diagnostic and predictive	• Potential change of AI performance when used in different environments in relation to stability
Technology		
Ease of use	Diagnostic and predictive and self-help	• (–) Potential difficulty requiring the need for technical support during the use of AI system
Technical support	Diagnostic and predictive	• (–) Expressed need for assistance to get introduced to the system to be able to start using it

XSL•FO
RenderX

HOT-fit elements	AI system type	Key findings, challenges (–), and enablers (+)
Usefulness of system features and functions	Diagnostic and predictive, treatment selection, and self-help	• (+) Providing options, identification of cases and prioritization support features were found useful by participants of the different systems • (–) The need for time to onboard to use the different features were expressed
Data accuracy	Diagnostic and predictive	• (–) Outdated data and misrepresentation of data can lead to lower AI model accuracy
Trustworthiness	Treatment selection	• (–) Affected by the end user's knowledge, the AI processing methods, and onboarding use
Explainability	Diagnostic and predictive and treatment selection	• (–) Lack of explainability can affect trust negatively
Usefulness	Diagnostic and predictive, treatment selection, and self-help	• (–) Potential misalignment between what the end users found useful compared with AI intended purpose of use
Relevance	Diagnostic and predictive	• (+) Most end users found the self-help service relevant to their wants.
Reliability	Treatment selection	• (–) Potential misalignment of AI processing method compared with the health care method
Accuracy	Treatment selection	• Potentially affected by the environment used in, and health care professional's confidence in their decision.
Empathy	Treatment selection and self-help	• (–) Potential skepticism by health care professionals "AI interprets data, but people are not data"

In relation to the 3 types of AI systems, the study identified the following findings.

Diagnostic and Predictive AI

In relation to the evaluation of the use and implementation of diagnostic and predictive AI systems, the articles had a greater focus on evaluating technology elements compared with a less detailed evaluation of human and organization factors.

The human factor was considered only in terms of the amount and duration of use of the AI system, overall satisfaction, and perceived usefulness in the studies by Garriga et al [44] and Megerian et al [45] indicating positive outcomes in this regard.

In relation to the investigation of the technology factor, the main elements were accuracy and ease of use. The accuracy of the AI system was associated with several issues and considerations in relation to the relevance of the data used, illustrating the importance of including different stakeholders in the development of AI models to ensure that relevant data are included. However, in the study by Garriga et al [44] with a predictive AI system based on electronic health record data, the health care professionals highlighted that there was outdated information fed to the AI model and important qualitative data from the patients were not included. While in the study by Deng et al [43], the data used in the diagnostic AI model for children with autism were only based on the child's input, excluding the input from their caregivers. The study illustrated that caregivers were concerned about not having their input for better outcomes.

The environment in which the AI system is used is found to contribute to affecting the accuracy. Deng et al [43] found that the prediction of the autism symptoms was less accurate when using the AI system in a less comfortable environment for the patients, and it gave more accurate output when implementing strategies that adjust the environment for the use of the AI system. Another consideration found affecting accuracy was health care professionals' confidence in their own decisions. Megerian et al [45] showed that greater confidence in one's decision in ruling out the disease over AI output was associated with less accuracy of negative diagnostics (compared with false positive accuracy, which was notably higher).

The ease-of-use element was evaluated in 2 studies reporting that the AI system was relatively easy to use, with the possible need for technical support due to use difficulties [43,44]. The design and ease of use of the AI system was found to influence the health care professional's adoption of decisions provided by the AI system. The low level of understanding of the AI output by a few health care professionals in the study by Garriga et al [44] was a reason for them to not follow-up with the decisions of the AI system.

The evaluation of the organization factor was mainly focused on the clinical process element. Garriga et al [44] reported that the predictive AI tool was used as an additional resource to identify cases, and it led to additional workload due to the need for contacting more patients, arranging visits, and reviewing patient cases in a multidisciplinary team for medical SDM. While in terms of the clinical process change in this paper, the health care professionals reported that the tool did not change the method they followed to assess risk; it rather notified them of the unseen cases that might been missed in the standard practice processes. The identified facilitators for the adoption of the AI system in the study by Garriga et al [44] for the clinical processes were good training and technical support. In contrast, the barriers reported were related to concerns about the

XSL•FO
RenderX

responsibility of acting on the AI output and the potential increase in workload and time when using the AI system.

Treatment Selection AI

Several elements affecting the use and implementation of AI systems were evaluated in this AI type within the 3 factors of the HOT-fit model.

Duration of use, users' knowledge, and perceived usefulness were the main elements in the human factor found affecting the use of AI. The willingness of health care professionals to use the *treatment selection AI* systems was ≤5 minutes per session in the study by Benrimoh et al [37]. Moreover, 40% of the physicians in the study by Benrimoh et al [37] stated that they would only use the AI system in complicated or treatment-resistant patients, while 50% stated they would use it for all cases. The frequency and amount of use of the AI systems in the study by Jacobs et al [39] regarding *treatment selection AI* were associated with the amount of clinician's knowledge in machine learning (ML). The increased familiarity of the health care professionals about ML was associated with the reduction of use of the ML recommendation, despite the higher level of perceived utility of ML. The health care professionals, in the 4 studies looking at the contexts in which treatment selection AI was used, expressed two main ways in which they found the AI system useful: (1) improving patient-clinician communication, which included improving patient understanding for treatment options, making communication less personal, and improving trust in treatment and (2) improving clinical practice such as potentially saving time, providing more objectivity to the practice, confirming or suggesting options, using it as a guideline, or as a source of extra information.

The main technology-related elements in this type of AI system were related to accuracy and trustworthiness. Consistent with the findings in the diagnostic and preventive AI system, the increased familiarity of ML was associated with a decrease in accuracy, despite the increase in clinician confidence in their decisions [39]. Three studies [37,40,46] investigated trustworthiness of the AI system and most of the participants had a high level of trust in using the AI system. Trust in the AI model was reported in the study by Tanguay-Sela et al [46] to be improved with sessions only for participants who reported their trust as unsure in the first session of use, while ratings of either low or high levels of trust did not change for participants who reported low or high levels of trust in the first session (ie, a low level of trust did not improve with increased sessions of use). A lack of trust in particular AI features were found to be an aspect affecting the overall trust of the AI system. The participants in the study by Tanguay-Sela et al [46] reported that their trust in the AI system was reduced due to them finding one of the features of the AI analysis irrelevant. A lack of explainability and evidence of the used models were mentioned in the study by Tanguay-Sela et al [46] as potentially affecting trust in the AI system.

AI system use in terms of the organization factor has been found to affect clinical processes, particularly in patient-physician communication. Some health care professionals in the study by Tanguay-Sela et al [46] had negative opinions about the use of the AI tool stating that it was negatively interfering with the interaction flow with the patient, while others saw it as a valuable tool in the communication process. Benrimoh et al [37] showed that physicians turned their screen to include the patients in the medication selection process even though it was not required in the study design. The AI system was reported in the study by Tanguay-Sela et al [46] to be potentially used in clinical processes other than direct treatment selection for the health care professionals. It was mentioned that the AI system can support clinical processes such as in assisting communication and SDM by visualizing the different options and being able to motivate options for the patients. For this to be valid, the study illustrated that the AI tool needs to be well understood by the physicians, and with transparent explanation of the options, for them to be able to communicate it to the patients.

Self-Help AI

The human factor was the center of focus of evaluation in this type of AI system. Duration of use, percentage used, frequency of use, acceptability, and user satisfaction were the main elements evaluated.

More consistent duration of use and better completion rates of self-help content were found in the conversational agents with health care–supervised type [38], compared with the unguided self-care AI agents [36,41,42]. The duration of use in the study by Dosovitsky et al [36] was inconsistent ranging from 31 minutes to 48 hours to finish 1 module of content. The frequency of use in the studies by Dosovitsky et al [36] and Prochaska et al [42] was inconsistent as well, with a connection found in relation to the intrinsic motivation and passive engagement of the users with the conversational agents [36], where it was found that the users would be more likely to engage in a session when it is initiated by the conversational agent. Satisfaction scored relatively high in all studies looking at satisfaction and perceived usefulness, but in relation to acceptability of use for self-care conversational agents it was found to vary according to the severity of the mental health condition, the socioeconomic status, such as cultural or racial background, marital status, and education [41].

Technology elements such as ease of use, usefulness, and empathy were investigated only in score-based evaluation showing positive outcomes, while organization elements in this AI system type were not found to be investigated.

Discussion

Principal Findings

This study explored the empirical evidence surrounding the use and implementation of AI systems for decision-making support in mental health. The identified studies primarily focused on AI systems developed for health care and self-care settings, with articles predominantly sourced from high-income countries. The state of research on AI systems in mental health is in the preimplementation stage in clinical processes. Although studies have evaluated the use of AI systems and their potential impact on clinical processes, none of the studies have explored the full adoption or long-term implementation of AI systems in care

XSL•FO
RenderX

settings. Of the 12 studies, 8 (67%) evaluated the use of AI systems in real-time care use, while 4 (33%) studies focused on simulations or clinical case studies.

A total of 3 main types of AI systems were categorized according to their utility in mental health: diagnostics and predictive AI, treatment selection AI, and self-help AI. These systems exhibited differences in their use process and interaction with end users. The findings about the types of AI systems and the variety of end users engaged in using these systems were found to be consistent with previous research [47-49], which underscored the potential use of AI in mental health, and emphasized the importance of understanding the sustainable design, which enables the collaboration in decision-making and the integration of these technologies into clinical processes. The AI systems provided support to a diverse range of actors both in health care, including primary care physicians, community psychiatric nurses, psychiatrists, and occupational therapists, as well as outside the health care services, including patients, individuals with mental health problems, and caregivers.

Evaluating the AI systems through the lens of HOT-fit highlighted several challenges in the integration and use of AI systems in care flow. These challenges included potential issues affecting accuracy and use biases, increased demand, physician-patient communication, and engagement with the AI system in self-care. However, despite the existing insights, there remains a pronounced lack of evidence that can help assess the integrative use and implementation of AI systems in different care contexts.

AI System Design for Decision Support and Interaction

The studies demonstrated the diverse interaction dynamics between end users of AI decision-making support systems. Interactions were influenced by the types of users and the data flow within the AI systems. There were variations in how data flows through the 3 types of AI systems. From the methods used to input data, to the types of interfaces presented to users, to the inner functionality of the AI models, and finally, to the nature of the output data—each system painted a unique picture. These variations align with the 4 central human-computer interaction (HCI) aspects identified by Rundo et al [50] for investigating decision-support systems, emphasizing the necessity of integrating HCI principles into AI technology development and implementation to ensure they effectively serve user needs, enhance decision-making outcomes, and ensure the sustainable use of AI in decision-making in mental health care.

Diagnostic and predictive AI systems in the articles showed the greatest diversity in data sources, which can complicate user understanding and create a *black-box* effect due to lack of explainability, which can reduce user acceptance and decision-making quality [51,52]. Furthermore, how the AI model functions to support decision-making based on data input is crucial for acceptance and sustainable use [12,53]. Nevertheless, none of the studies showed how the AI model is being sustainably trained or how the end user's use of the AI systems contributed to the continual learning process of the AI model. This process is a fundamental part of AI or ML apps that provide continual adaptation of the AI model for improvement of its performance with further use [54]. End user–inclusive strategies, such as the human-in-the-loop approach, where health care professionals and patients actively participate in providing feedback to enhance the AI model's functionality, can be useful in addressing this knowledge gap. This ensures that both humans and technology are aligned toward common long-term goals, promoting their joint improvements and effectiveness [54,55].

Three main types of interfaces for end users were discernible when examining the use and data flow within the AI systems: data collection interfaces, AI output visualization interfaces, and combined input and output interfaces in which interaction loops take place as in self-help AI type. These interfaces were designed to be used by a single user (patient or health care professional) or multiple end users. The differences in interface types and end-user interaction can pose challenges in examining these systems and ensuring fluency in care flows. For example, while self-help AI interaction loop interfaces can simplify the flow of use and enhance automation, compared with separated input and output interfaces, it can also complicate measuring interaction effectiveness in the health care [56-58]. Moreover, when multiple end users with different backgrounds use a single AI interface for decision-making, there is a growing need for interfaces to provide on-demand customized explanations to fit the understanding and reasoning of multiple stakeholders [59]. This also points to the need for co-design approaches to involve stakeholders from the early stages of development [60-62].

Using AI system interfaces to support decision-making presents varied dynamics of interaction, not only between the end users and the AI system but also among the end users themselves. Interestingly, none of the reviewed studies included an AI system explicitly designed to facilitate SDM between health care professionals and patients nor did they assess the role of SDM when using AI systems. This absence raises questions about the extent to which collaboration between health care professionals and patients, often highlighted as crucial for improving decision quality in mental health care, is being integrated into AI-assisted processes [51,52,63]. Drake et al [64] emphasized the need to incorporate SDM into the clinical workflows for effective implementation of patients' involvement [64]. As AI systems become more integrated into clinical decision-making workflows, they could alter traditional clinician-patient interactions, introducing new modalities such as clinician-AI, clinician-patient, and patient-AI interactions [65]. Each of these modalities may bring normative challenges that affect the roles of agency, transparency, trustworthiness, and responsibility among end users. Future research should explore how to thoughtfully integrate SDM in the design, implementation, and practical use of AI systems in care processes, while also addressing the broader normative shifts that may arise in clinical workflows because of AI integration.

Types of AI Systems for Supporting Decision-Making

The evaluation of the 3 types of AI systems described in the articles using the HOT-fit framework highlighted several challenges impacting the use and potential implementation of these systems in mental health care processes. General challenges were observed affecting the accuracy of the AI systems due to the use of nonrepresentative or skewed data

XSL•FO
RenderX

input, in addition to the selective use of the AI system participating in potential future biases. Other challenges found more in one AI system than another included the increase in usual care process steps when using the predictive AI systems, the need for adjustment for patient-physician communication when using the treatment selection AI type, and user engagement issues when using the conversational agents in self-help AI.

It was noted in some studies that health care professionals had a selective use of the AI systems for cases with specific severity, or the systems were preferred to be used by specific health care professionals more than others. This selective use with the continuous learning of the AI model may lead to feedback loop biases. This type of bias refers to the distortion of the AI output affected by the skewed use for specific cases over an extended span of time. Consequently, the AI output becomes more accurate to the selected cases and less toward the general use, which can affect the overall accuracy [66]. Furthermore, users in some of the studies described that the AI systems are useful for purposes that deviate from the AI model's primary objective. If the potential deviated use was not considered during the implementation efforts, this issue can lead to *concept drift* bias. This refers to the bias that may happen when the AI processing method differs from the actual use of the AI system leading to degradation of the AI output performance over time [67]. This underscores the need for including health care professionals and patients in the development and implementation phases to ensure that the AI system is designed and implemented in alignment with the sustainable use dynamics [68,69]. Co-design methods for analyzing sociotechnical scenarios can facilitate this by engaging stakeholders in early phases using prototype drafts to validate key AI-related concepts such as its goal and potential risks [62]. Early stakeholder involvement is also essential for building trust and ensuring implementation and adoption. Research shows that collaboration among a diverse, interdisciplinary team, including clinicians, potential AI users, hospital leaders, quality improvement teams, human resources, and IT departments is key to achieving effective implementation. This collective expertise ensures that the AI system meets clinical needs, aligns with organizational goals, integrates smoothly into workflows, and addresses technical, operational, and user concerns [70].

In diagnostic and predictive AI, the utility of the AI systems in detecting mental health state and identifying potentially hidden cases can disrupt common clinical processes by increasing demand and requiring additional steps or time to validate the decision support presented by the AI system. Nevertheless, none of the studies evaluated how this disruption of the care process can be adjusted to and integrated into the usual care routines. If not addressed in the future, this can lead to a dilemma of consequences between undertrusting or overtrusting the AI output in decision-making. Undertrusting of the AI output may require additional steps to validate the decisions provided by the AI system leading to additional workload and time consumption or abandoning the AI system use [12,71]. In contrast, the overreliance on AI systems, particularly when they have a high success rate, can lead to *automation bias*, where decision makers favor AI recommendations over other sources information including their own [72]. This may result in increased dependency on AI, discarding both health care professionals' and patients' judgments and preferences. Such a shift could move clinical care away from person-centered care toward the paternalized style of decision-making raising ethical and safety challenges [73,74]. A prominent example is a commercial AI model implemented in the health care system in the United States, which led to a racial bias discriminating access to health care for millions of patients [75]. These concerns highlight the need for caution in scaling and adopting AI for critical decision-making tasks without robust evidence. Initiatives such as the AI Act aim to address these ethical issues by setting requirements for AI development and implementation. Current recommendations emphasize that final decisions in diagnosis and care should remain with human judgment, with AI serving as an assistive tool, a view supported by numerous studies in mental health care [8,76-78].

Treatment selection AI systems were the only type evaluating the patient-physician relationship when using the AI system. Health care professionals used the AI system in their communication with the patients in some of the studies to discuss options and guidelines. However, this integration of AI decision support can disrupt the communication process, introducing sociorelational challenges into the clinical processes that need to be addressed in the design and implementation of the AI to avoid such challenges [13]. The average time willingness to use the AI system was limited to 5 minutes in one of the studies. This time constraint may present a challenge of integrating the AI support into the patient-physician communication. It highlights the need for efficient and explainable AI that can facilitate communication within a short span of time and tailored to the individualized care processes considering both technical and end-user preferences [79].

A main challenge identified in the studies with self-help AI systems based on conversational agents is inconsistency in user engagement, including frequency of use, duration, and completion rates. The self-help AI systems, primarily used for psychotherapy and psychoeducation, face distinct challenges in both self-care and health care settings. Low engagement can reduce the effectiveness of self-help AI systems, particularly because behavioral change and cognitive behavioral therapy (CBT) techniques require long-term engagement to attain effectiveness [80,81]. While conversational agents show great potential in facilitating mental health services [82,83], several studies indicate a lack of clarity about effectiveness and evidence-based design for therapy and mental health assessment [84-88]. This challenge highlights the need for additional research on long-term effectiveness and reliability of conversational agents across various mental health applications. Jabir et al [89] examined how conversational agents are typically evaluated and found that effectiveness assessment usually includes at least 1 clinical outcome and 1 user experience outcome. Given the need for sustained engagement with CBT-based conversational agents and the findings of our study, we recommend that future studies incorporate a third type of outcome measurement to better validate effectiveness. This additional measurement should focus on behavioral change, which is a fundamental aspect of CBT and chronic health conditions [90,91]. Cole-Lewis et al [92] demonstrated that

XSL•FO
RenderX

engagement with technology can lead to real-world behavior changes and consequently supporting health outcomes. Including behavioral change as an outcome is important to ensure that the mediated behaviors are successfully targeted not just the clinical outcomes or the user engagement. This is crucial because long-term life changes may mislead the association between self-help AI effectiveness and other positive life-related factors. Using behavior change techniques can serve as validated instruments for assessing health or decision-making behavior change, thus guiding the evaluation of conversational agents [93-97].

Overall, from the findings it is evident that successful integration and implementation of AI systems in existing mental health care workflows requires substantial efforts to create evidence regarding its sustainable use. There is a lack of empirical studies evaluating the long-term implementation of AI in mental health care. Nair et al [70] identified strategies and barriers for successful implementation that lead to sustainable use in 3 essential areas (planning, implementing, and sustaining the use). When integrating AI systems for decision-making support, the evaluation of changes in clinical workflows needs to be considered proactively during the planning phase to avoid unseen organizational or increased demand issues when put in place [68]. This step requires the inclusion of multidisciplinary individuals who will engage with the workflow using simulations or prototypes to enable the detection of any barriers or potential risks before putting the integrated AI systems in place [98,99]. Regarding implementation strategies and ensuring sustainable use, it is important to investigate approaches relevant to the context of mental health care processes addressing resistance of change, staff training, and monitoring of AI performance. This can help create evidence participating in planning for sustainable AI systems. Future studies, including case studies and longitudinal implementation research, are necessary to generate evidence for how to successfully plan, implement, and integrate AI for sustainable use in mental health. These studies can support proposing strategies for integrating AI decision-making utility in mental health practices, with the consideration to, including all relevant stakeholders in the research process.

Strengths and Limitations

Some methodological considerations are worth noting. The literature search was conducted using 5 relevant databases, which were selected based on the study's focus and the research field. However, it is important to acknowledge that using different databases may yield varying results, potentially affecting the comprehensiveness of the review. The keywords used in the search strategy were thoroughly discussed within the research group and with librarian assistance to align with the study's aims. Nonetheless, the evolving nature of interdisciplinary field, such as health care, implementation science, and AI technology means that the literature may use a broad range of terminology. This variability could impact the identification and inclusion of relevant studies, as different keywords might yield different sets of literature.

Furthermore, the decision to include only AI systems with technology readiness level ≥6 intended to focus the exploration on AI systems that are close to the implementation phase and investigating the AI use in care settings. While this criterion ensured relevance to real-world applications, it also narrowed the scope of the review, excluding studies that focus on the earlier developmental stages of AI models. This limitation means that the review does not address the potential capabilities of emerging AI systems that are still in the research or proof of concept phase but might have profound implications for mental health applications in the future. In addition, the limited number of studies available in implementation phase restricts the ability to draw generalized conclusions about the long-term effectiveness or scalability of these AI systems in mental health.

Moreover, 2 researchers independently conducted the selection and review, enhancing the reliability and reducing potential bias in study inclusion. However, assessing SDM in relation to these AI systems posed a challenge, as most studies did not report on the interaction dynamics between health care professionals, patients, and the AI system in a mutual decision-making context. This lack of detailed reporting on SDM limits the understanding of how AI influences or facilitates collaborative care in mental health.

Implications and Future Research

This study sheds light on the knowledge gaps regarding the empirical evidence of the use and integration of AI systems in mental health decision-making processes, offering insights that can guide the development and design of human-centered AI systems. It underscores the need to consider the utility of AI systems and end-user perspectives in the planning for the development and implementation of AI systems to support decision-making in mental health, in addition to the need for more empirical evidence to validate the factors affecting behavioral sustainable use. Furthermore, this study presents the current state of complexity in which the HCI perspective is fundamental in combination with co-design methodologies to ensure person-centered care when implementing AI systems in care processes.

Future research is advised to explore the integration of support for SDM in the AI system's design and development, addressing the gap identified in the current literature. In addition, there is a need for conceptual refinement of the current SDM process due to the disruptive effect of AI use. As the care process is evolving from the traditional physician-patient SDM, potentially adding the AI component as a third decision maker in the SDM dynamics. This adjustment is leading to changes in the essential elements of the process, and the 3-talk model, in particular when it comes to the technology-human SDM dynamics [28,100]. Conducting implementation studies are needed for creating robust empirical evidence, and to address potential long-term challenges by identifying barriers and facilitators of AI implementation and sustainable use in mental health care.

Conclusions

The scoping review demonstrated the diverse range of uses of AI in the mental health field, including health care settings, self-care contexts, and hybrid approaches. However, there was a lack of empirical evidence from an implementation perspective on how the AI systems should be integrated into clinical

XSL•FO
RenderX

processes. None of the studies discussed how to adjust clinical processes to accommodate aspects such as patient-physician communication and SDM.

The results showed that the utility of AI systems in supporting decision-making in mental health varies and illustrates the complexity of evaluating the utility of decision-making, influenced by the type of actors involved in decisions, the level of decision actionability, and the dynamics of data flow through the AI system. The evaluation of the use of AI systems in care settings through human, organization, and technology lenses revealed several challenges for the implementation of AI systems for sustainable use in care settings. As a consequence, these use- and implementation-related challenges may impact the accuracy of the decisions supported by the AI system, disrupt physician-patient communication, pose trust issues, and present engagement problems impacting the effectiveness and adoption of AI decision support. Future studies are needed to address stakeholder's needs in AI systems design, evaluate the implementation of AI systems in clinical processes for sustainable use, and assess the integration of SDM in AI systems.

Acknowledgments

This research study was part of Center for Applied Intelligent Systems Research (CAISR) Health profile and was funded by the Knowledge Foundation (grant 20200208 01H) and Halmstad University. The Knowledge Foundation was not involved in any aspect of study design, data collection, analysis, interpretation of data, or in the writing and publication of this study.

Abstract

Background: Digital health interventions targeting behavior change are promising in adults and adolescents; however, less attention has been given to younger children. The proliferation of wearables, such as smartwatches and activity trackers, that support the collection of and reflection on personal health data highlights an opportunity to consider novel approaches to supporting health in young children (aged 5-11 y).

Objective: This review aims to investigate how smartwatches and activity trackers have been used across child health interventions (for children aged 5-11 y) for different health areas, specifically to identify the population characteristics of those being targeted, describe the characteristics of the devices being used, and report the feasibility and acceptability of these devices for health-related applications with children.

Methods: We searched 10 databases (CINAHL, Embase, ACM Digital Library, IEEE Xplore, Cochrane Library, PsycINFO, Web of Science, PubMed, Scopus, and MEDLINE) to identify relevant literature in March 2023. The inclusion criteria for studies were as follows: (1) peer-reviewed, empirical studies; (2) published in English; (3) involved a child aged 5 to 11 years using a smartwatch for health-related purposes. Two researchers independently screened articles to assess eligibility. One researcher extracted data relating to the 3 aims and synthesized the results using narrative and thematic synthesis.

Results: The database searches identified 3312 articles, of which 15 (0.45%) were included in this review. Three (20%) articles referred to the same intervention. In 77% (10/13) of the studies, the devices were used to target improvements in physical activity. Other applications included using smartwatches to deliver interventions for emotional regulation and asthma management. In total, 9 commercial devices were identified, many of which delivered minimal data feedback on the smartwatch or activity tracker, instead relying on a partner app running on a linked parental smartphone with greater functionality. Of the 13 studies, 8 (62%) used devices designed for adults rather than children. User feedback was positive overall, demonstrating the acceptability and feasibility of using these devices with children. However, the studies often lacked a child-focused approach, with 3 (23%) studies gathering user feedback only from parents.

Conclusions: Interventions involving smartwatches and activity trackers for children aged 5 to 11 years remain limited, primarily focusing on enhancing physical activity, with few studies investigating other health applications. These devices often provide limited data feedback and functionality to support children's independent engagement with the data, relying on paired smartphone apps managed by caregivers, who control access and facilitate children's interaction with the data. Future research should adopt child-centered methods in the design and evaluation of these technologies, integrating children's perspectives alongside their caregivers, to ensure that they are not only feasible and acceptable but also meaningful and effective for young children.

children; systematic review; wearable activity trackers; smartwatches; feasibility; mobile phone

Introduction

Background

Health during childhood is a key predictor of health outcomes in adolescence and adulthood [1-5]. Poor physical health during childhood that continues into adulthood can result in higher health care costs and poorer quality of life [6]. As the prevalence of childhood ill health increases [7], it is important to consider novel approaches to help improve health outcomes in children. Behavioral interventions can be used to promote positive lifestyle behaviors (eg, engaging in physical activity [PA]) as well as support the management of chronic conditions (eg, promoting treatment adherence) [8].

For adults and adolescents, there is evidence that digital health interventions are effective in promoting health behavior change while also being cost-effective, appealing, and accessible [9-11]. However, in a systematic review of digital health interventions for children, of the 17 digital interventions identified, only 5 were found to be promising in producing a positive impact on clinical outcomes [12]. The lack of effective interventions indicates a need for progress in the field of digital health interventions for children, investigating technological innovations that meet the specific needs and contexts of children.

The development of wearables and sensors presents innovative solutions for delivering behavioral interventions. There are now a large number of commercial products that enable the real-time tracking and monitoring of personal health information and behaviors such as step count, heart rate, and sleep [13]. Devices such as smartwatches are well-suited for use as health intervention tools, as they are widely available and allow users to reflect on the health information collected via sensors in real time to gain a better understanding of their health and engage in self-management behaviors [14]. In this review, we define a smartwatch as a wrist-worn device that uses sensors to collect at least 2 types of personal health data (eg, steps and heart rate) and has an interactive display. With the popularity of adult trackers, there is also an established market for wearables and smartwatches for children [15]. These devices may be more appropriate for younger users, as they can be used independently from mobile devices, as device ownership is uncommon in young children [16].

There is a growing body of evidence for activity tracker and smartwatch health interventions for adults and adolescents, but despite the promise, there has been inadequate attention to their use with children [17,18]. Designing and deploying wearable health interventions for children needs specific attention due to the distinct developmental characteristics of this age group (social, emotional, and cognitive) and their greater reliance on parents and carers for support [8,19,20]. This includes considering how wearable hardware and software should be designed to meet the distinct needs of children. It also includes considering wider systems, such as family systems, for example, considering how multiple devices should be integrated into one intervention to meet the needs of different users (eg, adult and child) and how issues such as wearable data sharing and data privacy should be navigated. To understand these technical and sociotechnical issues, understanding the end users' experience, such as the technology's feasibility and acceptability, is essential [21].

Few reviews have focused on the design and user experience of wearables for children. Systematic reviews of the acceptability and feasibility of wearable devices to promote PA in children have identified that wearables can increase children's motivation for PA using behavior change techniques but noted novelty effects and uncertainties over long-term use and impact [17,18]. However, these reviews had a narrow focus on wearables for PA and a broad age range; they were not designed to explore developmentally sensitive design implications for children across health contexts. Previous work has identified common design adaptations for children's devices such as being more colorful, having fewer health metrics (eg, calories burned not included), and including features, such as games, to boost children's engagement [15,22]. However, these did not use a systematic review methodology and are limited to presenting a description of design adaptations without analysis of the end users' experiences or engagement with these design adaptations.

Aims

This systematic review aimed to investigate how smartwatches and activity trackers have been used across the full range of child health interventions (for children aged 5-11 y), spanning public health and prevention interventions to interventions for clinical populations, focusing on their acceptability and feasibility for children. This review aimed to build on the established literature on digital interventions for children by investigating design considerations to support young children's engagement with the smartwatch and the data collected for their health. Therefore, we focused on devices with an interactive display that supports data feedback. In this review, we investigated the following research questions (RQs): (1) What are the population characteristics of those being targeted in the health-related smartwatch and activity tracker interventions for children aged 5 to 11 years? (2) What are the characteristics of the smartwatches and activity trackers being used for health-related applications with children aged 5 to 11 years (eg, device type and features included)? (3) What is the feasibility and acceptability of using smartwatches and activity trackers for health-related applications with children aged 5 to 11 years?

Methods

This review was registered in the PROSPERO database and follows the guidance of the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [23]. See Multimedia Appendix 1 for the full checklist.

Search Strategy

The literature search was conducted in March 2023 in the following databases: CINAHL, ACM Digital Library, PsycINFO, Embase, MEDLINE, Cochrane Library, IEEE

XSL•FO
RenderX

Xplore, PubMed, Scopus, and Web of Science. The search included key terms for (1) children aged 5 to 11 years, such as "school child" or "minor" and (2) smartwatches, such as "smartwatch" or "wearable electronic device" (Multimedia Appendix 2 provides an example of the full list of search terms used in Embase).

Inclusion and Exclusion Criteria

Studies were included if they fulfilled the following criteria: (1) peer-reviewed or empirical studies with any study design; (2) published in English; and (3) the research involved a child (aged 5-11 y) using a smartwatch for health-related purpose, including behavior change intervention (physical, mental, or social). We use the term intervention to apply to any activity undertaken to improve health [24]. For the purpose of this review, a smartwatch is defined as a wrist-worn device that uses sensors to collect at least 2 types of personal health data (eg, steps and heart rate) and has an interactive display. We also extended this to include activity trackers with a visual display (excluding those that do not reflect on the data via the device), as they are largely similar to smartwatches but are typically cheaper with fewer sensors and can be used without a smartphone [25]. We selected devices that collect at least 2 types of personal health information and incorporate a visual, interactive display, thereby excluding simpler devices such as pedometers, which lack these functionalities and therefore do not meet our criteria of being a smartwatch or activity tracker. The devices could be used in conjunction with a partnering app if the child engages with the wearable device independently as part of its use.

Studies were excluded if they fulfilled the following criteria: (1) the study did not use a smartwatch or activity tracker with an interactive display; (2) the children in the study only wore the smartwatch or activity tracker as a passive data collection tool, and they did not otherwise interact with the device, by which we mean actively collect or view the data it collected as part of an intervention or feasibility assessment (eg, accuracy or validation studies); (3) the study included children aged <5 years or >11 years or do not report on the eligible age range specifically; or (4) the article was considered a review on previously reported studies, protocol, nonempirical or nonscientific paper (eg, book chapters), or when the full text was not available.

Screening Procedures

The search results were imported into Zotero (Corporation for Digital Scholarship) and duplicates were removed. Each title and abstract were independently screened by 2 authors (LT and SC) for relevance. If an inclusion decision could not be made based on the title and abstract, the articles were included for full-text review. Articles deemed relevant at the title and abstract screening stage were independently double-screened against the inclusion and exclusion criteria using the data management platform Rayaan (Rayyan Systems Inc), with reasons for exclusion recorded. Disagreements at both stages were discussed and resolved in meetings by the reviewers (LT and SC), with persistent disagreements being resolved through discussion with the wider research team (AB and JB). If the full text did not contain the information needed, 2 attempts were made to contact authors by email; if the information was not provided, the study was excluded.

Data Extraction and Synthesis

Data related to our RQs were extracted by the primary author (LT), as described in Textbox 1. Due to the heterogeneity in the study designs and the data reported, we synthesized data using narrative and thematic synthesis [26,27]. The extracted data are summarized in Textbox 1. For qualitative data, open coding was conducted by the primary author on the available qualitative data referring to participants' experiences of using the device, which included quotations from participants or authors' interpretations of participants' experiences. Themes were developed top-down using the technology acceptance model (TAM) [28], in which codes generated were grouped under each relevant theme of the TAM (perceived ease of use and perceived usefulness). The remaining analysis was data driven (bottom-up) to develop themes for any codes that fell outside the scope of the TAM. Wherever possible, quotes from the participants of the included studies (primary data) have been presented. In addition, to understand the characteristics of the device relevant to behavior change, we used the taxonomy of app features [29] and coded whether the features were present on the smartwatch device or partner app in each research study as shown in Multimedia Appendix 3.

XSL•FO
RenderX

Textbox 1. Data extraction categories and details extracted.

General study information

- Publication details: authors, year of publication, country of study, and publication location
- Study aim
- Sample size

Research question 1: What are the population characteristics of those being targeted in the health-related smartwatch or activity tracker interventions?

- Health behavior or condition targeted
- Stakeholders involved (eg, target child, parent, or other)
- Child sample characteristics: age and gender
- Child's device experience

Research question 2: What are the characteristics of the smartwatch or activity trackers?

- Intervention summary: a description of the wearable element of the intervention
- Device details: name, type (smartwatch or activity tracker), technology readiness level [30] (consumer device or experimental prototype), and if there is a partner app or device
- Device rationale and justification: information that the authors provide describing why the device was selected
- Smartwatch software details: description of features, functionality, and interaction modality and whether the software used was modified or bespoke, including any justification or rationale for design choices
- Software on partner app: using the taxonomy of app features [29] to identify app features used to promote behavior change
- Data sharing features: who the data is shared with and if data sharing is part of the interventions

Research question 3: What is the feasibility and acceptability of using a smartwatch and activity tracker for health-related applications with children aged 5 to 11 years?

- Qualitative data relating to acceptability and feasibility and who reported these data (eg, child or parent)
- Quantitative data relating to acceptability and feasibility (eg, measures of use and who reported these data)
- Any information captured about acceptability and feasibility but not captured through formal qualitative or quantitative data collection, that is, authors' interpretations in the results and discussion

Quality Assessment

Two authors conducted quality assessments independently, discussing disagreements to reach a consensus. As the studies varied in study design, we used different quality assessment tools. We used the Critical Appraisal Skills Programme systematic review checklist [31] for qualitative studies. This is a 10-item checklist with 3 responses: "yes," "no," and "cannot tell." The Quality of Survey Studies in Psychology checklist [32] was used to assess articles that collected user feedback via surveys and questionnaires. This checklist comprises 20 items under 4 categories: introduction, participants, data, and ethics. Finally, the National Heart, Lung, and Blood Institute pre-post and controlled studies assessment tools were used. These are 12- and 14-item checklists with 5 responses: "yes," "no," "cannot determine," "not applicable," and "not reported" [33,34]. Full details of the quality assessment can be found in Multimedia Appendix 4 [35-49].

Results

In this section, we summarize the data extracted to address our RQs as outlined in Textbox 1.

Search Results

After deduplication, 3312 (69%) of the 4772 articles were identified from the database searches. After abstract and title screening, 150 (4.5%) articles were considered for a full-text review, and of these, 15 (10%) were identified as eligible for inclusion. In total, 3 articles reported on the same intervention; therefore, we identified 13 studies detailing children's (aged 5-11 y) use of smartwatches for health-related purposes. A summary of the study details can be found in Table 1. Table 2 provides a summary of the population characteristics. We will refer to these 13 distinct studies unless otherwise indicated. Most (11/13, 85%) studies focused on using a single device, but 2 (15%) studies [35,36] used multiple devices during the study period. Additional devices not meeting the study criteria (n=5) are not reported here. The most common reasons for exclusion were participants being outside the target age range, wrong publication type, and wrong device type. The PRISMA flow diagram can be found in Figure 1.

XSL•FO

Table 1. Summary of included studies.

Study	Location	Sample size	Summary
O'Brien et al [37], 2020	NR[a]	1 child	Investigated the acceptability of a smartwatch intervention that sends visual directives to children with autism spectrum disorder
Buchele Harris and Chen [38], 2018	NR	116 children	Investigated the impact of a technology-enhanced physical activity classroom intervention
Saksono et al [39], 2018	United States	9 children and 11 parents	Explored the experiences of low SES[b] families using physical activity tracking technologies
Schoeppe et al [40], 2020	Australia	40 families; 58 children	Examined the short-term effects of an activity tracker and app intervention to increase physical activity in families (Step it Up Family program)
Schoeppe et al [41], 2023	Australia	19 families	Explored families' experience and satisfaction with a physical activity intervention using wearable activity trackers and apps (Step it Up Family program)
Schoeppe et al [42], 2022	Australia	40 families; 58 children	Explored the feasibility of a family-based activity tracker intervention to increase physical activity (Step it Up Family program)
Torrado et al [43], 2017	Spain	2 children	Assessed the usability of a personalized emotional self-regulation tool
Creaser et al [44], 2022	United Kingdom	36 adults and 29 target children	A mixed methods observational study that explored the acceptability of using wearables in a family setting
Masteller et al [36], 2017	NR	16 children	Explored children's perceptions of activity trackers and their associated websites
Wing et al [45], 2022	United States	137 children	Explored the usability and acceptability of Fitbit Charge with families via pre- and poststudy questionnaires
Hosseini et al [46], 2017	United States	1 adult and 1 child	Pilot study to assess the feasibility of the mobile health asthma system in a real-world setting
Jackson et al [47], 2022[c]	United States	64 children; 35 children; 39 children; 56 children; 38 children; 25 children	Evaluated the impact of Fitbit Charge HR on children's activity levels during school
Schaefer et al [35], 2014	United States	25 children	A qualitative study to assess the acceptability and compliance of wearable activity trackers
Duck et al [48], 2021	United States	35 children	A quasi-experiment to assess the effectiveness of an activity tracker with altruistic motivation at increasing physical activity behavior
Saksono et al [49], 2019	United States	16 parents and 15 children	A qualitative study investigating how parents and children interact with their activity trackers in a naturalistic low SES context

[a]NR: not reported.

[b]SES: socioeconomic status.

[c]This study reported several conditions with unique participant demographics and study procedures.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.

RQ1: What Are the Population Characteristics of Those Being Targeted in Health-Related Smartwatch and Activity Tracker Interventions?

Health Behaviors Targeted

Most studies (10/13, 77%) targeted PA behavior. The remaining 23% (3/13) of the studies targeted specific health conditions or recruited participants from specific demographic groups, including autism spectrum disorder (ASD; n=2, 15%) and asthma (n=1, 8%).

Demographics of Child Participants

Of the 13 studies with >1 participant, where information was provided, the mean child age ranged from 6 to 10 years, and all but one reported that at least 50% of the sample was female. Only 2 (15%) of the studies reported their motivation for the selected age range of participants. Reasons included (1) targeting elementary school-aged children as they were the target demographic of the wearable being used [36] and (2) focusing on children aged 6 to 10 years due to the developmental importance of forming PA behaviors, parental social support, and role modeling. The authors also reported that children aged <5 years were excluded due to concerns about their ability to comprehend and engage with the smartwatch and partner app [40,42].

Stakeholders Involved in the Intervention

In total, 3 of the interventions were family-based PA interventions [39-42,44], one of which extended beyond immediate family (parents and siblings) to include stepparents, cousins, and grandparents [44].

Of the 13 studies, 5 (38%) took place within a school setting in which teachers played a role in data collection or had a facilitating role in the intervention [37,38,43,47,48].

Device Experience

In total, 2 (15%) of the 13 studies reported on children's previous experience using smartwatches or activity trackers. In one study, 86.2% of the target group had never owned one. Only 4 children currently owned one, and the duration of use ranged from <1 month to >2 years [44]. In one study [43], both children had previous experience wearing a smartwatch so neither they nor their classroom peers found them distracting. In contrast, child participants in the Step It Up Family intervention [40-42] had to have no previous experience using an activity tracker to be eligible to take part in the study.

RQ2: What Are the Characteristics of Smartwatch and Activity Trackers Used for Health-Related Applications With Children Aged 5 to 11 Years?

Device Details

A total of 9 different devices were used. All of the studies used commercial devices, with Fitbit, Garmin, and UNICEF Kid Power Band being the most common. Three of the selected devices (UNICEF Kid Power Band, Garmin Vivofit Jr, and Movband) are specifically designed for children. Seven devices were described as having a partner app. A summary of the devices and the features reported can be found in Tables 3 and 4.

XSL•FO
RenderX

Table 3. Summary of device characteristics (research question 2)[a].

Study	Device	Bespoke software design?	Partner app; partner app owner	Motivation for device choice or design considerations reported?	Duration of use	Wearable part of a wider intervention?
O'Brien et al [37], 2020	Apple Watch	No	No	Yes; SMS text messages were used to deliver intervention via smartwatch rather than images due to the speed of transfer compared to images	16 days	No
Buchele Harris and Chen [38], 2018	Fitbit Charge HR	No	No	No	5 school days, for 4 weeks	Yes
Saksono et al [39], 2018	UNICEF Kid Power Band	No	Yes; not reported	Yes; accuracy, ease of use, comfort, on-band display and battery life, tailored for children	2 months	No
Schoeppe et al [40], 2020; Schoeppe et al [41], 2023; Schoeppe et al [42], 2022	Garmin Vivofit Jr	No	Yes; parent's phone	Yes; decision based on feasibility demonstrated previously	6 weeks	Yes
Torrado et al [43], 2017	LG Watch Urbane	Yes	Yes; parent's phone	Yes; they used recognized pictograms that children had familiarity with	4 hours a day, for 9 days (total of 36 h wear)	No
Creaser et al [44], 2022	Fitbit Alta HR	No	Yes; not reported	No	4 weeks	No
Masteller et al [36], 2017	Movband	No	Yes; website	No	4 days	No
Wing et al [45], 2022	Fitbit Charge HR	No	Yes; parent's phone or child's if they had their own	No	22 days	No
Hosseini et al [46], 2017	Samsung Gear Live	Yes	Yes; parent's phone	Yes; an animated dragon was considered to be more engaging for children	Several weeks	Yes
Jackson et al [47], 2022	Fitbit Charge HR	No	No	Yes; previous research had determined it appropriate to use with children	8 days to 8 weeks	No
Schaefer et al [35], 2014	Polar Active	No	No	No	5 days	No
Duck et al [48], 2021	UNICEF Kid Power Band	No	Yes; child's tablet	Yes; the device reward system used the theory of altruistic motivation	10 weeks	Yes
Saksono et al [49], 2019	UNICEF Kid Power Band	No	Yes; not reported	Yes; accuracy, ease of use, comfort, on-band display and battery life, tailored for children	2 months	No

[a]In this paper "bespoke software" design refers to any feature that is not present in existing commercial devices.

XSL•FO
RenderX

Table 4. Summary of the wearable devices used (research question 2).

Study	Device	Device type	Target user	Interaction modality	Measures on display	Features in the partner app
Saksono et al [39], 2018; Duck et al [48], 2021; Saksono et al [49], 2019	UNICEF Kid Power Band	Activity tracker	Children	Not reported	Not reported	Reward points
Creaser et al [44], 2022	Fitbit Alta HR	Activity tracker	Adults	Touch (tap display and vibration)	Daily steps, distance traveled, calories burned, active minutes, and heart rate	Goal setting, reminders, challenges, rewards, information sharing, and tracking of further health behaviors (eg, sleep)
Torrado et al [43], 2017	LG Watch Urbane	Smartwatch	Adults	Touch (tap display and vibration), auditory	Personalized self-regulation strategy (eg, pictogram of listening to music)	—[a]
O'Brien et al [37], 2020	Apple Watch	Smartwatch	Adults	Touch (vibration), auditory	Not reported	Not reported
Schoeppe et al [40], 2020; Schoeppe et al [41], 2023; Schoeppe et al [42], 2022	Garmin Vivofit Jr	Activity tracker	Children	Touch (vibration)	Daily steps, goal progress (60 min of activity)	Family leaderboard, challenges, goal setting, personal name, animal images on display, rewards (virtual coins), and virtual interactive game
Hosseini et al [46], 2017	Samsung Gear Live	Smartwatch	Adults	Touch (tap display)	Asthma attack risk (happy, neutral, or sad dragon)	Trend lines for each sensor and risk level, enabling users to focus on points of interest and review data over the last several hours. The app also had a study coordinator and physician interface
Masteller et al [36], 2017	Movband	Activity tracker	Children	Not reported	Daily steps (moves)	Displays collected points, steps, miles, and activity averages
Schaefer et al [35], 2014	Polar Active	Smartwatch	Adults	Not reported	Daily activity bar (amount of time in moderate-to-vigorous intensity zones) and animated figure that indicated activity intensity	—
Buchele Harris and Chen [38], 2018; Wing et al [45],2022; Jackson et al [47], 2022	Fitbit Charge HR	Activity tracker	Adults	Not reported	Daily steps, distance traveled, calories burned, and heart rate	Not reported

[a]Not applicable.

Device Rationale and Justification

Of the 13 studies, 5 (38%) reported their motivation for the wearable chosen for the study. The Garmin Vivofit Jr was selected due to the author's review of previous research, which demonstrated high feasibility for monitoring PA in children [40]. Similarly, the Fitbit Charge HR was selected as it had previously been considered appropriate for children [47]. The UNICEF Kid Power wristbands were selected in 2 (15%) studies due to their accuracy, battery life, comfort, on-band display, and age-appropriate design [39,49]. This device was also used in an additional study that investigated the impact of altruistic motivation due to the charity component of the device [48].

Intervention Summary

Of the 15 articles, 11 (73%) reported on behavior change, with 3 (23%) relating to the same intervention [37-44,47-49]. Of these, most (n=9, 69%) used the wearables to motivate an increase in PA. The devices were primarily used to provide immediate activity feedback to users, with step count being the

XSL•FO
RenderX

most common data point displayed on all devices. Moreover, 2 of the 13 (15%) studies used smartwatches to deliver personalized self-regulation strategies to children with ASD [37,43]. One (8%) study used the wearable to measure and visualize asthma attack risk via a dragon animation [46]. In 2 (15%) of the studies, the wearables were used primarily for research purposes. Wing et al [45] aimed to identify the parameters for determining valid wear time (a measure of how much the device is worn to determine typical patterns of activity) of the smartwatch, and Schaefer et al [35] investigated the feasibility of different wearables to inform future research on measuring PA in children.

The study periods ranged from 4 days to 2 months. Most (9/13, 69%) studies were stand-alone wearable interventions while 4 (31%) studies used the wearables as part of a wider intervention [38,40,46,47]. These included additional behavior change techniques such as motivational and educational messages (n=3, 23%) or required additional equipment as part of the wearable intervention such as a spirometer (n=1, 8%).

Smartwatch Software

Using the taxonomy of app features [29], the most common behavior change strategy incorporated into the device was activity feedback (eg, displaying step count), which was reported in 77% (10/13) of the studies. Other features included having preset activity goals and reminders. One study used the built-in SMS text messaging functionality of the Apple Watch to deliver the intervention.

In total, 2 (15%) of the 13 studies used a bespoke or modified software design using an existing commercial smartwatch [43,46]. In one study, a smartwatch system was used to assist with behavior challenges due to emotional dysregulation. The system displays self-regulation activities selected by the children's caregivers (eg, parents and teachers) via a partner device on the watch face [43]. Hosseini et al [46] described the development of a smartwatch system, which calculates and communicates asthma attack risk. Animated dragon graphics were designed based on previous research, which has shown that animations are a more engaging, age-appropriate design for children [46].

Software on Partner App

Overall, 73% (11/15) of the studies (3 refer to the same intervention) described the use of a partner app or web-based dashboard linked to the wearable. Of these, 55% (6/11) reported that the wearable was paired with a parent's smartphone [40-43,45,46] and 27% (3/11) did not report this information [39,44,49]. For the remaining 18% (2/11) of the studies, children had primary control via a website [36] or were given a compatible tablet [48]. In one study, children were not allowed to use the Fitbit mobile app or web-based dashboard alone (including on their own devices) in line with Fitbit's privacy policy [45].

The partner apps commonly had more features than the wearable device, such as access to greater data granularity, games, and access rewards. Some of the apps also allowed users to compare their performance against others and set activity goals.

Data Sharing Features

Of the 15 studies, 7 (47%; 3 reporting on the same intervention) explicitly reported that the primary data collected via the wearable were shared with other stakeholders [38,40-42,45-47]. These included parents or carers, clinicians, teachers, and peers. Data sharing was a component of the intervention to target behavior change. This included step count being shared in the classroom with peers and teachers [38,47] or among the wider family unit via step-count leaderboards within the partner app to try and encourage increased PA [40]. As part of the wearable system for asthma [46], the authors described an additional interface for physicians to access deidentified data collected via the wearable system, though this was not evaluated. In 3 interventions, parents had control over the wearable's partner app and thus had access to the data collected via the wearable [40-42,46]. Only 2 (13%) of the 15 articles in this review reported any user feedback relating to data sharing [41,44].

RQ3: What Is the Feasibility and Acceptability of Using Smartwatch and Activity Trackers for Health-Related Applications with Children Aged 5 to 11 Years?

Overview

In total, 3 (20%) of the 15 included studies did not report on the wearable's acceptability and feasibility or collect any user feedback on this [38,47,48]. 6 of the 15 articles (40%) reported gathering user feedback directly from children [35,36,44-46,49]. Feedback was also provided by parents (n=7, 47%), and in one study, treatment acceptability was completed by staff at the children's school [37].

It was not possible to statistically synthesize quantitative measures of acceptability and feasibility (response rate and wear time) as there was heterogeneity across the studies in how these statistics were reported. Instead, we provide a descriptive overview.

Quantitative Data on Usability, Acceptability, and Feasibility

Total Device Wear Time

Of the 13 studies, 5 (38%) [35,36,38,39,45] explicitly reported instructing participants on wear time. This included encouraging participants to wear the wearables as much as possible and specifying a minimum time for wearing or engaging with the partnering app or website. Only 1 (8%) study reported contacting participants if there were no new data for 3 days [45].

In total, 2 (13%) of the 15 studies reported quantitative data on device wear time. In one article, the authors reported the average number of valid recording days (≥1000 steps/d) per week as an indicator of wearable use across the 4-week intervention. This showed that wearable use was generally high, ranging from 71% (wk 3) to 91% (wk 2) [44]. Similarly, in the other article, the authors reported that during the 42-day intervention, the mean number of recording days from the children's wearables was 36.5 (SD 8.3) days [40].

In total, 2 (13%) of the 15 studies used self-reported data to indicate device use. First, parental logging was used to capture

XSL•FO
RenderX

when the device was removed, which authors reported as the children's level of compliance with the study protocol. The device was reported as being used 98% of the time during the 5 days of data collection [35]. Second, the children's self-reports indicated that 74% of them checked the device several times per day for updates on their activity. In addition, 62% of children reported removing the device daily and 29% reported forgetting to put it back on [45].

Software Use

In total, 2 (13%) of the 15 articles quantitatively reported on partner app use. One study detailed children's use as indicated by parents in a web-based survey. While the article primarily focused on parents' use, the authors reported that 42% of children used the Garmin app 2 to 6 times per week during the study [42]. When using the Fitbit Charge HR [45], 80% of children reported using the associated app to see activity information during the study period.

Experience Using the Devices

Of the 15 studies, 5 (33%) provided quantitative user feedback on the acceptability and feasibility of using the devices and associated software [35,37,42,44,45], most of which were collected via user surveys or questionnaires. Moreover, 1 (7%) article reported the frequency of common interview responses [35].

After using the Fitbit Charge HR, 98% of children reported feeling comfortable wearing the device among their peers, 87% enjoyed wearing the device over the deployment period, and the majority (98%) would be interested in wearing the device for longer in the future [45]. Most children (23/24, 96%) rated the Movband as the preferred device compared to the wrist-worn tracker without a display, and the hip-worn tracker (not discussed in this review) due to its comfort (10/23, 43%) and its feedback features (8/23, 35%) [35]. Parents reported the perceived usefulness of the Garmin Vivofit JR device and partner app, with 85.9% and 76.6% of parents rating it as very or quite useful, respectively [42]. In the visual directive intervention for ASD by O'Brien et al [37], the overall intervention was evaluated by school staff via a treatment acceptability survey with an average score of 42.75 out of 50. All participants agreed that it was an acceptable method for school staff to deliver directives; however, 2 participants did not think that the treatment was likely to result in permanent improvement.

In total, 2 (13%) of the 15 studies described experiencing data loss due to difficulties with the wearables, such as syncing errors leading to data corruption, user error, or insufficient wear [9,15]. In a study, the authors reported that 1 family withdrew their participation due to issues with setting up the devices [44].

Qualitative Data on Usability, Acceptability, and Feasibility

Overview

Of the 15 studies, 7 (47%) included qualitative data on users' experience of using the devices and therefore were included in the thematic synthesis [35,36,39,41-44,49]. Of the 7 studies which collected qualitative data, 5 (71%) provided quotations from participants, which can be found in Table 5. We identified 3 themes: the perceived ease of use (TAM), perceived usefulness (TAM), and the perceptions of engagement.

XSL•FO
RenderX

Table 5. Participant quotes extracted from studies (primary data).

Theme, study, and supporting quotes	Participant
Perceived ease of use	
Schoeppe et al [41], 2023	
"Sometimes it wouldn't sync properly or I thought it was syncing and I am not sure if it actually did"	Parent
"My son was getting a bit of a rash from wearing it all the time.. it would come undone really easily"	Parent
"I didn't find it particularly easy but then I am not really technology proficient"	Parent
Creaser et al [44], 2022	
"It hurt and it—it made a mark on my arm"	Child aged 5 years
Perceived usefulness	
Creaser et al [44], 2022	
"I don't really understand the calories that I've burnt. But when I am older I'll probably understand more"	Child aged 10 years
"It really did depend if I was in class or not [if they responded to 'reminders to move'] because I couldn't just run out of class to get the steps...sometimes if fit into my break so that would be good"	Child aged 9 years
"He's only 5 if he was a little bit older, I would consider getting him one"	Parent
"Maybe when I am older, but I don't think so right now"	Child aged 10 years
"It had like 2 more steps to do so I did those two more steps and then noticed that it wasn't picking it up"	Child aged 10 years
"Well I didn't really want to compare them because I thought they might be a bit more than me...I was going to do a thing where at the end of the day there's a winner for how many—for the biggest amount of steps, but I quitted that because I saw mum did a lot of steps at work...it made me jealous"	Child aged 7 years
Masteller et al [36], 2017	
"The MovBand I didn't really like it because you couldn't realty do anything active, you just look at it which wasn't really fun to me. It did have one advantage which was seeing if you're average or not average"	Child aged 9 years
"This one I thought was the least interesting because you could barely do anything"	Child aged 10 years
Schoeppe et al [41], 2023	
"My son often got told by the teacher to put it away as it was a bit distracting for him in the classroom"	Parent
"It actually made us a little more aware of our child's sleep patterns. Something we've investigated a little further"	Parent
"Kids were disappointed when swimming and cycling did not record as steps but they could have still entered them"	Parent
"Difficulty came when the kids wanted to win...[child] is cheating because he is moving his arm around...but he is going to be top of the leaderboard"	Parent
Saksono et al [39], 2018	
"I don't think hers is accurate. Because sometimes if tells you, 'she's at 10,000 steps,' I'm like 'you didn't do 10,000 steps. Like I moved more than you did'"	Parent
Saksono et al [49] , 2019	
"We just look at them [...] I mean, it's pretty much like just look at the, see what the numbers say. Um and it's I leave it"	Parent
"I've told them, but they be so into their the world. [...] They just be like brushing me off. [...] They're used to walking around, and moving and activities. [...] They don't know that they're completing the things on the challenges [in the Kid Power app]"	Parent
Experience using the devices	
Creaser et al [44], 2022	
"I already saw by the end of the week the novelty was wearing off"	Parent
"I liked uh I liked going on walks because you could check how much steps you've done"	Child aged 10 years
"I like the firework when you get to 10,000"	Child aged 6 years
"I didn't really like the sleep bit in it because of that...because they [parents] could check when I was sleeping"	Child aged 12 years

Theme, study, and supporting quotes	Participant
Saksono et al [49], 2019	
"I give [Kid Power app a] 10 [out of 10] because like I love walking. And like I love, love to walk and it gives you missions. And points, which I really love points"	Child aged 9 years
Schoeppe et al [41], 2023	
"The kids absolutely loved the kids app with the little activities and getting coins for things"	Parent

Theme 1: Perceived Ease of Use

In total 2 of the 15 (13%) studies reported that children reported finding wearing the devices uncomfortable and, in some cases, wearing them caused skin irritation [41,44]. In addition, parents described finding the devices and partner apps difficult to use and revealed practical and technical challenges with the devices, such as syncing them and the partner app [41,44]

Theme 2: Perceived Usefulness

Most parents and children expressed a positive experience of using wearables overall, with many considering using a device again in the future. However, in a study, there was some discussion regarding the appropriateness of using these devices with younger children. For example, it was highlighted that children cannot respond to the hourly "reminder to move" prompts when they conflict with their school schedule. Children in the study also described challenges with interpreting the data output and visual display of the Fitbit device [44]. Some parents also highlighted some negative consequences of using the devices, such as the devices becoming distracting during school and causing negative emotions or sibling conflict due to competition elements [41,44].

Articles reported that users liked receiving feedback on their activity, with many families describing how this helped increase motivation for engaging in PA [39,41,42,44]. However, children and parents highlighted their concerns regarding the accuracy of the devices to be able to detect and record PA [39,44]. In addition, children were disappointed that not all activities (eg, swimming) could be tracked using some of the devices and thus did not contribute to their overall activity summary [41,44].

In a study, parents described facing challenges when trying to get their child to engage with how the wearable works and to explore the additional features of the companion app. In addition, families reported having limited discussions about the PA data collected via the wearables, including the meaning of the data within the context of their overall health and well-being [49].

Theme 3: Perceptions of Engagement

Overall, children enjoyed using the wearables and their partner apps. Step count was frequently reported as a popular feature along with gamified features, such as rewards [35,36,41,44,49]. Devices with these additional features were preferred over those that supported little or no interaction [36]. However, some parents reported that children's engagement with the devices declined over time due to a novelty effect resulting in a loss of interest [41,44].

Only 1 (7%) of the 15 studies described participant comments in relation to sharing data among participants. Parents liked that the trackers captured additional data (eg, sleep patterns) and described using the partner app to monitor their child often without their involvement [41]. However, there was no exploration of children's comfort with sharing their data with other stakeholders.

Discussion

Principal Findings

This systematic review aimed to answer three RQs by identifying (1) the population characteristics of children targeted in health-related wearable interventions, (2) the characteristics of the devices used, and (3) the feasibility and acceptability of using these devices in wearable interventions for children aged 5 to 11 years. We found that most (10/13, 77%) of the studies focused on PA, with only 23% (3/13) focusing on clinical conditions. The devices were typically used to provide activity feedback to support behavior change, with additional features often available on an accompanying app. Many (10/13, 77%) studies included wider stakeholders (parents, teachers, and peers) and data sharing, either as part of the intervention or implicitly due to the device being linked to a partner app. The quantitative and qualitative user feedback shows that using smartwatches for health interventions is acceptable and feasible with children aged 5 to 11 years, though there were common usability issues (eg, discomfort, technical issues, and short battery life). Overall, several studies included in this review lacked sufficient detail for data extraction, were considered not to have a rigorous data analysis procedure, and thus are considered to be of poor quality (Multimedia Appendix 3 provides full quality assessment). Sample sizes varied from n=1 to n=137 and small sizes limit our ability to generalize their findings, which should be rectified in future research. There was a limited focus on child-centered design, with many studies using commercial adult devices that require parent involvement rather than developing bespoke child-friendly designs. Furthermore, when gathering user feedback, children's views were often not the focus, with 3 of the 12 (25%) studies not gathering feedback from children but instead focusing on their parents.

Comparison With Prior Work

All of the studies in this review used existing commercial smartwatches and activity-tracking devices. These provide limited data feedback, often only reporting step count on the device. More detailed information was generally only available through a partner app, which was usually under the control of a parent. This is consistent with previous research, which found that children were frustrated by the limited data feedback available in real time due to it being on the app rather than the device [50]. The devices and their partner apps included a

XSL•FO
RenderX

number of behavior change techniques, such as feedback or monitoring and goal setting, both of which are consistent with previous child and adult research [51,52]. The studies also identified usability issues, including discomfort, technical challenges such as syncing issues, and logistical challenges such as poor battery life, which is consistent with previous research [50,53,54].

Despite this, the studies in this review reported high levels of engagement and enjoyment using these devices and their partner apps. In total, 2 (13%) of the 15 studies also reported a novelty effect, indicated by declining use across the study period. This effect has also been observed with adults' use of wearable devices, where it is common to see initial high engagement levels, followed by abandonment after a few months [55]. One potential way to combat abandonment and support motivation is through the use of gamification, as research has shown that gamified apps have longer use than nongamified apps for PA [56]. Furthermore, while the children were mostly content with wearing the devices, in one of the studies participants described that children were not actively engaging with the data collected via the device. This highlights an important distinction between engagement with the data collection process and the use of or reflection on the data collected. According to the staged-based model of personal informatics by Li et al [57], reflection is an important distinct stage that takes place before action, in which individuals can enact behavior change with their new information. Previous research has shown that the way people reflect on their data can be impacted by both the phase of self-tracking and the feedback they receive such as data visualizations, which help individuals gain insights from their data [58]. This is particularly relevant as children can struggle to understand the data collected and visualized on smartwatches [59], which, in turn, may impact their engagement. For example, research with children aged 10 to 15 years has shown that children can misinterpret biofeedback metrics, including heart rate and calories [60,61]. Therefore, further work is needed to understand how to support children's sensemaking of personal health data collected via wearables.

To ensure that children understand and can reflect on the data being collected via smartwatches, it is important to consider their needs and preferences by including them and other stakeholders in a user-centered design process [62]. Considering the end users' experience and including these individuals in the design process has been shown to produce technology, which is more engaging and acceptable to users [63,64]. This is particularly relevant when using children's wearables in health interventions, as research has shown that children conceptualize health differently from adults. It was found that children extended their understanding of health beyond traditional health measures to include other metrics, such as time spent playing outside [59], highlighting the importance of exploring children's health-tracking interests. However, many studies in this review did not seem to take a user-centered approach to the design and choice of devices in their studies. For example, a few (3/13, 23%) studies in this review outlined the rationale for their choice of wearable and failed to detail the specific design features of the device or software that supported children to use it in relation to their health. In addition, most of the devices used across the studies were adult devices and not designed specifically for use by children. Moreover, the device partner apps included additional features and behavior change techniques, such as leaderboards, games, and rewards; however, these were often only accessible via a parent's smartphone as young children did not have their own smartphone. This can lead to the issue identified in previous research of parents acting as "gatekeepers" to their child's interaction with an intervention. This dynamic can result in children no longer being the focus of the design and generates additional "invisible" work for parents [50,51].

However, including parents in pediatric behavioral interventions has previously been shown to be a key component for achieving sustained behavioral change [8,12]. In this review, 77% (10/13) of the studies included additional stakeholders such as parents and teachers, but it was rare that they considered the child's perspective on their inclusion. Ethical and privacy issues around collecting and sharing self-tracked data via wearables are rarely discussed [65]. Potapov and Marshall [66] found that teenagers had concerns about the consequences of sharing their data with others; however, this has not been thoroughly investigated in younger children. In this review, privacy concerns were not directly explored or raised by younger children. However, previous research that has investigated the impact of sharing children's PA and sleep data with their parents or carer found that children reported being uncomfortable with the surveillance. Furthermore, shared access to the data appeared to influence trust between children and their parents or carers negatively, as parents used the data to assert further parental control and impose additional restrictions [67]. Similarly, when using co-design methods with families with children aged 7 to 15 years, it was found that parents and children raised concerns about the impact of data sharing on children's privacy and autonomy, to which the authors suggested the need for child-controlled data sharing options to help set boundaries and minimize conflict [68]. As these privacy concerns were raised in studies with children older than the focus of this review, this may be indicative of a change that occurs during the transition to adolescence, whereby children are working toward increased independence and autonomy [69]. A robust investigation of end users' views (children, parents, carers, and other stakeholders) on wearable data sharing and data privacy is an important research gap, with significant implications for design consideration for wearable interventions for children. This should be considered in future research, where it would be valuable to investigate both children's current preferences for data sharing and privacy as well as their shifting views as they mature and the sociotechnical design considerations that could meet these changing needs.

In this review, most (9/13, 69%) studies focused on using smartwatches and activity trackers to promote PA. Future work should consider the potential of using these devices for more novel health applications. One growing use case for smartwatches within health care and health care research is just-in-time adaptive interventions (JITAIs) [70,71]. JITAIs use mobile and sensing technology to offer personalized and timely support [72] and have been used in a variety of adult and adolescent health domains including PA [70] and substance use behavior [71,73]. In this review, 23% (3/13) of the studies used

XSL•FO
RenderX

the devices to deliver interventions in real time. This included using the watch display and SMS text messages to deliver emotional regulation strategies to children with ASD. However, most of the devices in this review only provided basic data summaries on the watch face. Only one study reported the use of a novel visualization using data analytics, in which an animated dragon was used to convey a risk score as part of a JITAI. This highlights the immense potential for novel uses of smartwatches in pediatric health and further work is needed to explore how smartwatch interventions can be adapted to be developmentally appropriate to convey health information to children in a way that is meaningful to support behavior change.

Strengths and Limitations

Digital health is an interdisciplinary field, and a key strength of this review is the interdisciplinary approach taken by searching both health science databases as well as human-computer interaction venues. The review aimed to investigate how wearables are designed and used for children (5-11 y) to understand developmentally sensitive design implications. To investigate this, we looked across the broad spectrum of child health behaviors and conditions, which means our review is not limited to PA interventions, making the findings relevant to a broader scope of researchers working within pediatric wearable interventions. However, we excluded studies that included our target age group (5-11 y) but also included older and younger children (eg, 5-18 y) that did not report the results separately, as it was not feasible to stratify the results by age. We also conducted a narrative synthesis, which has previously been criticized for lacking transparency [74]. To mitigate this, we have included primary data where possible in our qualitative summary. The limited qualitative data available in the articles also resulted in our synthesized themes having limited richness.

Conclusions

This systematic review addresses the gap in understanding children's wearables by expanding the scope of the review to a broad range of health applications, with a focus on identifying developmentally sensitive design features and understanding the experience of younger children. We identified a total of 15 articles (13 distinct studies) that involved children aged 5 to 11 years using a smartwatch for health-related purposes. Most of these were using commercial smartwatches and activity trackers as tools to help increase PA, but other novel applications included uses to support children with ASD and asthma. Of those that gathered user feedback, experiences using the devices were positive, although there was an indication that the children may not have been engaging with the visualization of their data. Overall, the studies lacked a child-centered focus with (1) many (9/15, 60%) studies not including children's opinions reflecting on the designs, (2) most of the functionality and data visualization was placed on partner apps usually under the control of parents, and (3) most smartwatches and activity trackers being used were adult devices. Further work is needed to better understand children's perspectives on the design and evaluation of these devices while also investigating other potential areas of research beyond PA tracking for children, such as managing chronic health conditions. In addition, future research should provide richer details about the devices used, including the rationale for the choice of device, and who has access to the data to consider how this aligns with their research aim and user experience.

Abstract

Background: Rehabilomics, or the integration of rehabilitation with genomics, proteomics, metabolomics, and other "-omics" fields, aims to promote personalized approaches to rehabilitation care. Cloud-based rehabilitation offers streamlined patient data management and sharing and could potentially play a significant role in advancing rehabilomics research. This study explored the current status and potential benefits of implementing rehabilomics strategies through cloud-based rehabilitation.

Objective: This scoping review aimed to investigate the implementation of rehabilomics strategies through cloud-based rehabilitation and summarize the current state of knowledge within the research domain. This analysis aims to understand the impact of cloud platforms on the field of rehabilomics and provide insights into future research directions.

Methods: In this scoping review, we systematically searched major academic databases, including CINAHL, Embase, Google Scholar, PubMed, MEDLINE, ScienceDirect, Scopus, and Web of Science to identify relevant studies and apply predefined inclusion criteria to select appropriate studies. Subsequently, we analyzed 28 selected papers to identify trends and insights regarding cloud-based rehabilitation and rehabilomics within this study's landscape.

Results: This study reports the various applications and outcomes of implementing rehabilomics strategies through cloud-based rehabilitation. In particular, a comprehensive analysis was conducted on 28 studies, including 16 (57%) focused on personalized rehabilitation and 12 (43%) on data security and privacy. The distribution of articles among the 28 studies based on specific keywords included 3 (11%) on the cloud, 4 (14%) on platforms, 4 (14%) on hospitals and rehabilitation centers, 5 (18%) on telehealth, 5 (18%) on home and community, and 7 (25%) on disease and disability. Cloud platforms offer new possibilities for data sharing and collaboration in rehabilomics research, underpinning a patient-centered approach and enhancing the development of personalized therapeutic strategies.

Conclusions: This scoping review highlights the potential significance of cloud-based rehabilomics strategies in the field of rehabilitation. The use of cloud platforms is expected to strengthen patient-centered data management and collaboration, contributing to the advancement of innovative strategies and therapeutic developments in rehabilomics.

Introduction

Background

Rehabilitation is a crucial component of health care aimed at improving the functional capacity and quality of life for individuals facing various health challenges [1,2]. Traditionally, standardized approaches have been used in rehabilitation, sometimes failing to fully consider the unique needs and characteristics of each patient. However, the need for more personalized rehabilitation has become important after COVID-19 [3]. Advancements in genomics [4], epigenomics [5], proteomics [6], metabolomics [7], and related fields have made personalized rehabilitation approaches more feasible [8,9]. The convergence of rehabilitation and *omics* sciences has given rise to the concept of *rehabilomics* [10]. This concept uses an individual's biological characteristics or biomarkers to tailor rehabilitation approaches, providing a pathway for personalized rehabilitation programs, and enabling the integration of "omics" for studying rehabilitation processes and outcomes [10,11].

Rehabilomics seeks to leverage cutting-edge molecular and genomic information to tailor rehabilitation interventions for optimal patient outcomes [10,12]. By understanding the genetic, proteomic, and metabolic profiles of patients, health care providers can design rehabilitation programs that are not only more effective, but also better aligned with an individual's genetic and physiological makeup [11-13]. This paradigm shift holds immense promise for improving rehabilitation outcomes and enhancing patient experiences [14].

Rehabilomics can build systematic patient information based on large data using cloud-based solutions, use data from medical experts through patient consent, and establish customized treatment and rehabilitation strategies for patients [10,15]. In addition, evaluation- and monitoring-based rehabilitation interventions can be performed at home by collecting quantitative and objective information [16,17]. Owing to the nature of the cloud, there are advantages, such as simultaneous data sharing through the network; however, if the security measures are insufficient, there may be problems, such as data loss or patient information leakage; therefore, it is necessary to prepare for establishing data management system functions and security [18].

Simultaneously, the proliferation of cloud computing technologies has revolutionized data storage, sharing, and analysis in the health care domain based on the Fourth Industrial Revolution [19,20]. Cloud-based solutions offer scalable, secure, and cost-effective platforms for managing vast amounts of patient data, including genomic and clinical information [21]. Particularly, blockchain-based cloud solutions ensure a user-centric electronic health record system, offering enhanced security controls and a platform that securely safeguards health care data, emphasizing privacy and stability [22,23]. This technological convergence of rehabilomics and cloud computing opens up new horizons for data-driven rehabilitation practices, facilitating data sharing among health care professionals (rehabilitation medicine specialists, physical therapists, occupational therapists, speech-language pathologists, and other advocates of rehabilitation-related professionals), researchers, and patients [24].

Despite these exciting possibilities, there remains a need to comprehensively explore the current landscape of cloud-based rehabilitation in the context of rehabilomics [25].

This Review

This scoping review aims to fill this gap by providing an overview of the existing literature and shedding light on key trends, challenges, and opportunities in this emerging field. By examining the integration of cloud-based technologies with rehabilomics strategies, we aim to contribute to understanding how these approaches can be harnessed to optimize rehabilitation interventions and ultimately improve patient outcomes. Therefore, this study examined the latest trends through a scoping review of cloud-based rehabilitation. Accordingly, we sought to derive strategies for rehabilomics. The rehabilomics approach, which uses an individual's genomic, proteomic, and metabolomic information to deliver personalized rehabilitation, has tremendous potential to enhance the effectiveness and patient experience of rehabilitation services. Moreover, the integration of cloud computing technology can facilitate data sharing and collaboration among health care providers, researchers, and patients, thereby opening opportunities to develop innovative, data-driven rehabilitation solutions.

Methods

Literature Search Strategy

The primary objective of this scoping review was to investigate and synthesize current literature trends in cloud-based rehabilitation for rehabilomics strategies. To initiate the research, we conducted searches across major academic databases, including CINAHL, Embase, Google Scholar, PubMed, MEDLINE, ScienceDirect, Scopus, and Web of Science. The search terms and syntax were designed to encompass terms such as "cloud-based rehabilitation," "rehabilomics," "cloud computing in rehabilitation," "personalized rehabilitation," and "omics technologies in rehabilitation." The search included articles that were published between January 2000 and July 2024. The literature review was conducted using a 2-step process. First, we examined the abstracts as a preliminary step toward gaining an initial understanding. This was followed by a more detailed review of the full-text of the selected articles, based on insights gathered from screening the abstract. The study protocol was registered in the Open Science Framework [26,27]. The research questions were as follows:

- Have cloud-based rehabilitation systems been developed and evaluated recently?
- What rehabilomics strategies are based on primary outcomes and user perceptions of cloud-based rehabilitation systems?

Inclusion and Exclusion Criteria

The study adhered to established reporting guidelines (Multimedia Appendix 1), including the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) Extension for Scoping Reviews (PRISMA-ScR). Scoping

XSL•FO
RenderX

reviews aim to summarize the breadth of evidence on a topic and identify gaps in future studies. Consistent with best practices for scoping reviews, the authors designed and registered a priori protocol in the Open Science Framework, ensuring rigor and transparency throughout the review process.

Inclusion and exclusion criteria were established to select articles from the search results. The inclusion criteria included papers discussing the integration of cloud computing and rehabilomics strategies, applications in the fields of rehabilitation and health care, data sharing and collaboration, and personalized therapy. Papers unrelated to relevant topics or those lacking sufficient information were excluded. Two independent reviewers conducted a thorough examination of the papers, and the final selections were made through discussion.

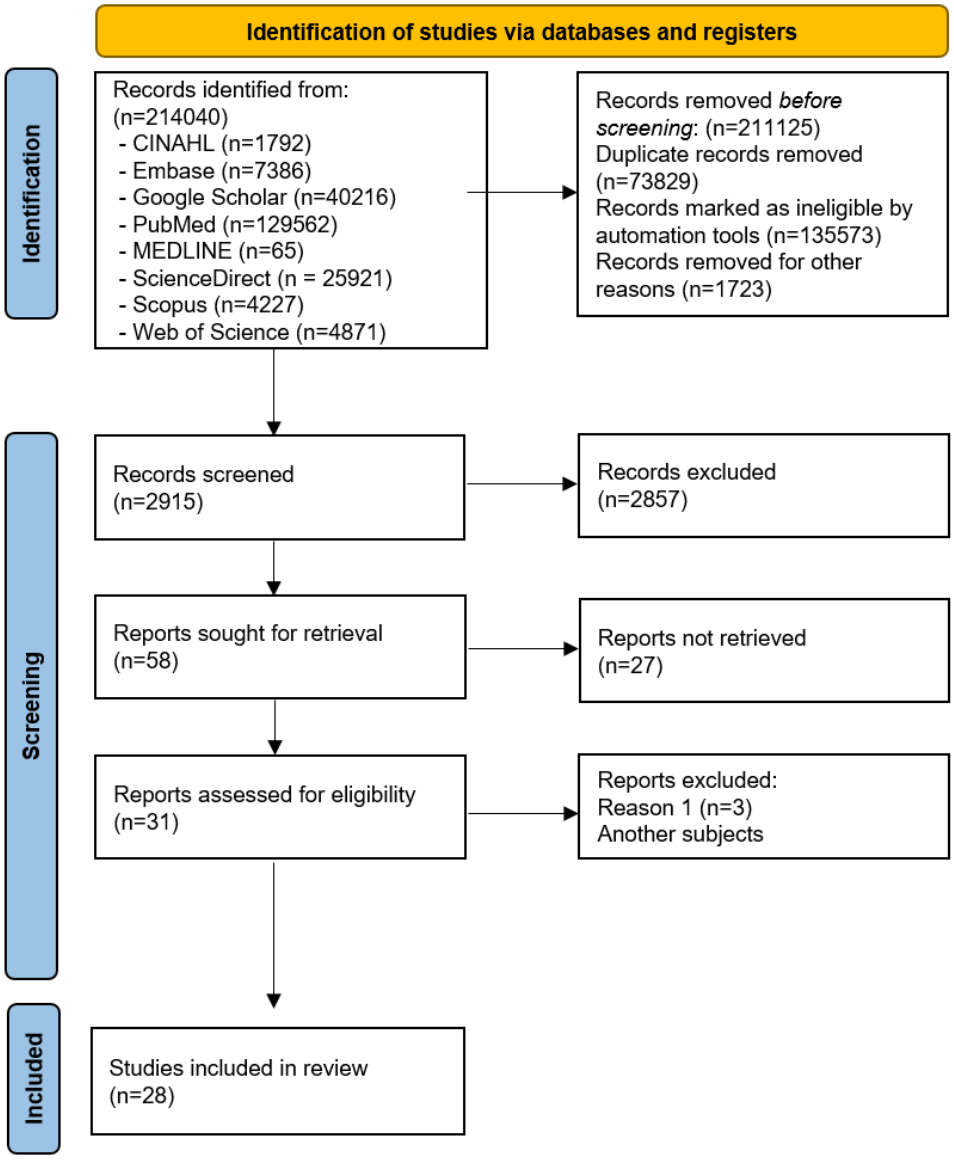
Studies were only included when (1) full texts were available and (2) cloud-based rehabilitation was used. Owing to the broad nature of this scoping review, we were not limited by participants, study design, intervention, or outcomes. Exclusion criteria were as follows: (1) full text was not available, (2) papers which were not in English, (3) cloud-based rehabilitation was not used in the study, (4) unclear rehabilomics, and (5) studies focusing only on rehabilitation.

Data Extraction and Analysis

Relevant information was extracted and analyzed from the selected papers. This includes details such as paper titles, authors, publication years, research topics, methodologies, key findings, and conclusions. Extracted data were synthesized in relation to key themes and subjected to statistical and content analyses to ascertain current research trends in cloud-based rehabilitation and rehabilomics strategies. The data were analyzed by 2 researchers, of whom one had >15 years of experience as a physical therapist and 20 years of experience as a rehabilitation medicine specialist. The data were analyzed through a basic literature search and review, a detailed review and screening, and a final review and decision.

Reporting of Findings

The results from this scoping review are presented as a comprehensive overview of key themes, research trends, and related topics. This review summarizes the current research trends in cloud-based rehabilitation and rehabilomics strategies and offers suggestions for future research. Overall, 214,040 databases were searched, 2915 records were screened, 58 were retrieved, and 31 were assessed for eligibility.



Results

Characteristics of Included Studies

These studies cover a wide range of topics related to cloud-based rehabilitation and rehabilomics strategies (Multimedia Appendix 2). Figure 1 provides an overview of the selection process based on the PRISMA diagram to identify studies using databases and registers.

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) diagram to identify studies using databases and registers.

Key Themes

The Analysis of the Included Studies Revealed Several Key Themes

Integration of Cloud Computing

A total of 28 of the included studies [16,17,28-53] explored the integration of cloud computing technologies in the context of rehabilitation and rehabilomics. Cloud platforms are used for data storage, analysis, and sharing to facilitate collaborative research efforts.

Personalized Rehabilitation

Out of 28 studies, 16 (57%) studies [16,17,28,29,33-35,38,39,42,46,48,49,52,53] focused on the concept of personalized rehabilitation by leveraging omics data to tailor rehabilitation programs for individual patients. This approach aims to improve treatment efficacy and patient outcomes.

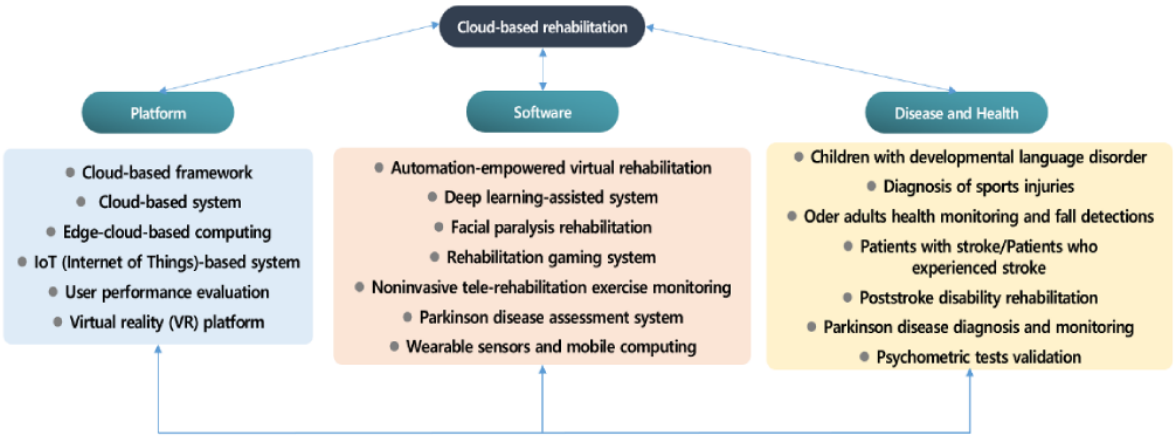
Data Security and Privacy

Out of 28 studies, 12 (43%) studies [16,17,28,34-36,41,44,47,49,52,53] addressed the critical issues of data security and patient privacy in cloud-based rehabilitation. Ensuring the confidentiality and integrity of patient data has become a key concern.

Interdisciplinary Collaboration

Collaboration between researchers from diverse backgrounds, including rehabilitation specialists, geneticists, and data scientists, was a recurring theme [16,17,28-53]. Such interdisciplinary collaboration is essential for advancing this field.

Cloud-Based Rehabilitation



Overview

We identified and included a total of 28 studies focused on cloud-based rehabilitation. These studies can be categorized into platform, software, and disease and health topics (Figure 2).

XSL•FO
RenderX

Because of the synthesis of the contents of the categories of these studies, the platform included cloud-based frameworks [28], cloud-based systems [2,3,14,23,29], Internet of Things (IoT)–based systems [12,30], user performance evaluation, virtual reality (VR) platforms [19,31], and edge-cloud–based computing. Software included rehabilitation gaming systems [20,22], noninvasive telerehabilitation exercise monitoring [31], Parkinson disease (PD) assessment systems [6], wearable sensors [10], mobile computing [5], deep learning-assisted systems [16], facial paralysis rehabilitation [25], and automation-empowered virtual rehabilitation [33]. Diseases and health conditions included stroke, poststroke disability rehabilitation [8,21,24], neurorehabilitation [13], PD diagnosis and monitoring [17], psychometric test validation [47], developmental language disorders in children [51], and diagnosis of sports injuries [52]. It also included health monitoring and fall detection in older people [35].

Figure 2. Trends of cloud-based rehabilitation.

Cloud

CRehab

This refers to a cloud-based framework for rehabilitation management [28].

The authors introduced "CRehab," a cloud-based framework featuring web-based and augmented reality support aimed at managing the rehabilitation processes. This framework targets the administrative, communication, and patient-motivation aspects by leveraging cloud capabilities. The primary objective was to devise an architecture adaptable to diverse rehabilitation types, irrespective of the diagnosis, environment, or patient demographics.

Rehab-aaService

This refers to a cloud-based motor rehabilitation digital assistant [29]. The integration of body sensor networks with cloud computing for motor rehabilitation enables remote monitoring, reduces costs, and provides comfort and safety to patients. Rehab-aaService, the newly introduced motor rehabilitation digital assistant, is based on wearable motion sensor nodes, a personal mobile device, and a cloud-based backend, offering enhanced support and a more comprehensive rehabilitation experience.

Open-Source Cloud-Based Platform for Health Monitoring and Fall Detection in Older People

The authors designed an open-source eHealth monitoring and fall detection system that integrated medical sensors, a microcontroller, and cloud communication [35]. This system stores data in the cloud to aid diagnosis, real-time monitoring, and rehabilitation facilitation. In addition, it features a fall detection system that promptly alerts medical personnel in the event of unexpected falls.

Platforms

Cloud-Based Rehabilitation Exergames System

A low-cost rehabilitation gaming system using Microsoft Kinect was developed for individuals with chronic arm pain [30]. This system encompasses goal-oriented exercises, enabling accurate performance measures for quantitative evaluation of the treatment plan. It notably boosts user motivation, hastens muscle recovery, and provides therapists with a means to assess patient progress.

Development of a VR Platform for Cloud-Based Neurorehabilitation

The authors designed a cloud-based VR platform for neurorehabilitation to analyze its impact on the sense of agency and ownership in healthy individuals [40]. The experimental platform featured a virtual avatar that replicated the individual's movements using motion capture technology and a head-mounted display. The findings revealed that perceived arm length changed according to the displayed arm length of the avatar, demonstrating the considerable potential of the VR system.

SIGVERSE: a Cloud-Based VR Platform for Human-Robot Interaction Research

The authors introduced a cloud-based VR platform to explore human-robot interaction and obtain social intelligence for robots [50]. This successfully showcased the system's practicality in real human-robot interaction scenarios, indicating its potential for fostering social intelligence development.

Edge-Cloud–Based Wearable Computing for Automation-Empowered Virtual Rehabilitation

This study referred to technology-enhanced rehabilitative care for patients with stroke through the use of edge cloud and IoT

XSL•FO
RenderX

technology [53]. This involved the development of an edge-cloud model to track the vital signs and rehabilitation progress of patients in real time. The system exhibited remarkable operational efficiency and significantly improved rehabilitation treatment outcomes, paving the way for more advanced and intelligent medical service systems.

Hospitals and Rehabilitation Centers

Cloud-Based Rehabilitation System for Patients With Stroke

A cloud-based rehabilitation system focused on improving motor function in patients with stroke was developed. This study used data from healthy participants to accurately assess hand function [33]. Using the autoregressive integrated moving average model with the dynamic time-warping algorithm, this study made predictions regarding the rehabilitation and recovery of patients with stroke. Over a 10-week period involving 3 patients, the system showed significant improvements in upper limb control.

Monitoring of Upper Limb Rehabilitation and Recovery after Stroke: An Architecture for a Cloud-Based Therapy Platform

The Limbs Alive project was introduced at the Newcastle University and is dedicated to using video games for therapeutic movements to assist patients with stroke [34]. The authors developed a cloud-based therapy platform that gathers data from therapeutic games played by patients with stroke, estimates performance metrics, and delivers results to patients and clinicians via web applications.

System-Level Design of a Cloud-Based Training Device for Upper Limb Spasticity Rehabilitation

A robotic part-task trainer was developed to evaluate upper limb spasticity using cloud-stored clinical data [39]. It enables the remote coaching of trainees and continuous updates by rehabilitation physicians, thereby fostering a dynamic learning environment.

Cloud-Based Training and Evaluation System for Facial Paralysis Rehabilitation

This study referred to focusing on aiding facial paralysis rehabilitation via cloud-based information and communication technologies [46]. The proposed system aims to support patients and physicians by delivering rehabilitation training, automating progress reviews, and evaluating the results. It involves training a client for patient rehabilitation and data collection, leveraging machine learning on a cloud platform to analyze outcomes.

Telehealth

Cloud-Based Noninvasive Telerehabilitation Exercise Monitoring

The authors developed a conceptualized cloud-based telerehabilitation framework using cost-effective, noninvasive Microsoft Kinect for rehabilitation exercises [31]. This framework enables patients to engage in rehabilitation exercises at home while maintaining high-quality care standards. The initial experiments validated the potential of the system for training healthy participants to mimic physical rehabilitation exercise motions.

Mobile Cloud–Based PD Assessment System

The authors designed "PD Dr," a mobile health app aimed at gathering PD-related motion data and evaluating symptoms [16]. The system was examined using information from 40 patients with PD to validate its efficiency in capturing significant symptoms and estimate their severity. It demonstrated robust connections between the collected motion features and the severity of PD, hand-resting tremors, and gait difficulty.

Cloud-Based PD Diagnosis and Monitoring Framework

The authors suggested a cloud-based framework designed to detect and monitor patients with PD, particularly in low-resource settings [17]. The goal was to provide remote diagnosis for patients in areas with limited health care access, achieving high accuracy in the process.

Remote Cloud-Based Automated Stroke Rehabilitation Assessment Using Wearables

These studies showcase a broad spectrum of cloud-based rehabilitation applications, ranging from pediatric developmental language disorder rehabilitation to stroke rehabilitation assessments using wearable technology [45]. These efforts aim to enhance rehabilitation outcomes through innovative technological approaches and data-driven analyses by incorporating cloud computation and sensor-based data for accurate assessment.

IoT Cloud-Based Telerehabilitation Service for Smart Cities

This study was centered on telerehabilitation as a service by leveraging cloud computing, IoT, and big data analytics [49]. It emphasizes the management of significant health care data generated from remote rehabilitation devices within the hospital cloud using NoSQL databases.

Home and Community

Integration of Wireless Wearable Sensors and Mobile Computing with Cloud-Based Service for Patient Rehabilitation Monitoring

The authors proposed a system that used wearable wireless sensors and handheld devices to track body motion, focusing on patients with stroke [36]. This setup allowed patients to conduct rehabilitation exercises at home while health care providers remotely monitored their progress. This system integrates cloud services for remote monitoring, eliminating the need for expensive hardware and software licenses for data storage. Initial user tests demonstrate the feasibility of the system.

IoT-based System for Physical Rehabilitation Monitoring

The authors described an IoT-based wearable system designed for monitoring physical rehabilitation using accelerometer and gyroscope sensors [37]. This system can record movement data to characterize patient movement and estimate their condition, thereby enabling remote monitoring through a cloud-based service with accurate capabilities for monitoring elbow rehabilitation characteristics.

XSL•FO
RenderX

Cloud-Based Platform for Autonomous Home Rehabilitation With Exergames

The authors developed a cloud-based platform that facilitates independent at-home rehabilitation through customizable exercise games [43]. This system uses a flexible database and structured rehabilitation data to allow clinicians to review and fine-tune exercise parameters efficiently. The platform incorporates parameterized exercise games designed to offer personalized goal-oriented rehabilitation.

Cloud-Based Smart Home Environment for Home Health Care

The authors developed "CoSHE," a cloud-based smart home environment for monitoring the health of older populations within their homes [44]. The system incorporates wearable sensors and environmental data to provide real-time information to remote caregivers. The integration of contextual information successfully enhances understanding of an individual's health status.

User Performance Evaluation and Real-Time Guidance in Cloud-Based Physical Therapy Monitoring and Guidance System

A cloud-based physical therapy monitoring and guidance system was developed to address the limitations of traditional therapy owing to the restricted interaction time [48]. The system leverages the actions of a physical therapist recorded as an avatar to guide patients in real time for self-training. By aligning the physical therapy and user motion sequences with a gesture-based dynamic time-warping algorithm, it evaluates user performance based on the physical therapy criteria and provides real-time guidance, optimizing patient learning.

Disease and Disability

Speech-Controlled Cloud-Based Wheelchair Platform for Disabled Persons

A prototype speech-controlled cloud-based wheelchair platform using WebKit Speech Application Programming Interface in the cloud was developed, which introduced a graphical user interface compatible with the web and mobile devices that enabled live video streaming [32]. It achieved speech recognition accuracy between 60% and 97% and recorded latencies spanning from 0.4 to 1.3 seconds. Through clinical testing, it exhibited promising outcomes, signaling potential for future implementation.

Cloud-Based Architecture Proposal for Aphasia Rehabilitation

The authors designed a cloud-based architecture specifically tailored for aphasia rehabilitation in Romanian-speaking patients [38]. The system comprises an application database, logic, and interfaces for patients and therapists. Using a virtual assistant, the system guided patients through exercises crafted by therapists. Treatment adjustments were made based on the obtained scores and the data were stored in a statistical module for further assessment.

Comparison of Python and Java Capabilities for Somatosensory Games in Cloud-Based Rehabilitation

The authors investigated the performance and stability of cloud-based somatosensory games in rehabilitation systems, while handling various user loads [41]. In this study, Python and Java programming languages were compared, and the findings indicated that Python consumed fewer resources in both the simulation and monitoring systems.

Cloud-Supported Framework for Poststroke Disability Rehabilitation

The authors suggested a cloud-based rehabilitation framework that combined augmented reality and sensor gloves for patients after an episode of stroke [42]. Notably, considerable enhancements in finger strength were observed after 6 weeks of therapeutic exercise. Sensor gloves were used to recognize the real-time conditions of the patients engaging in rehabilitative exercises.

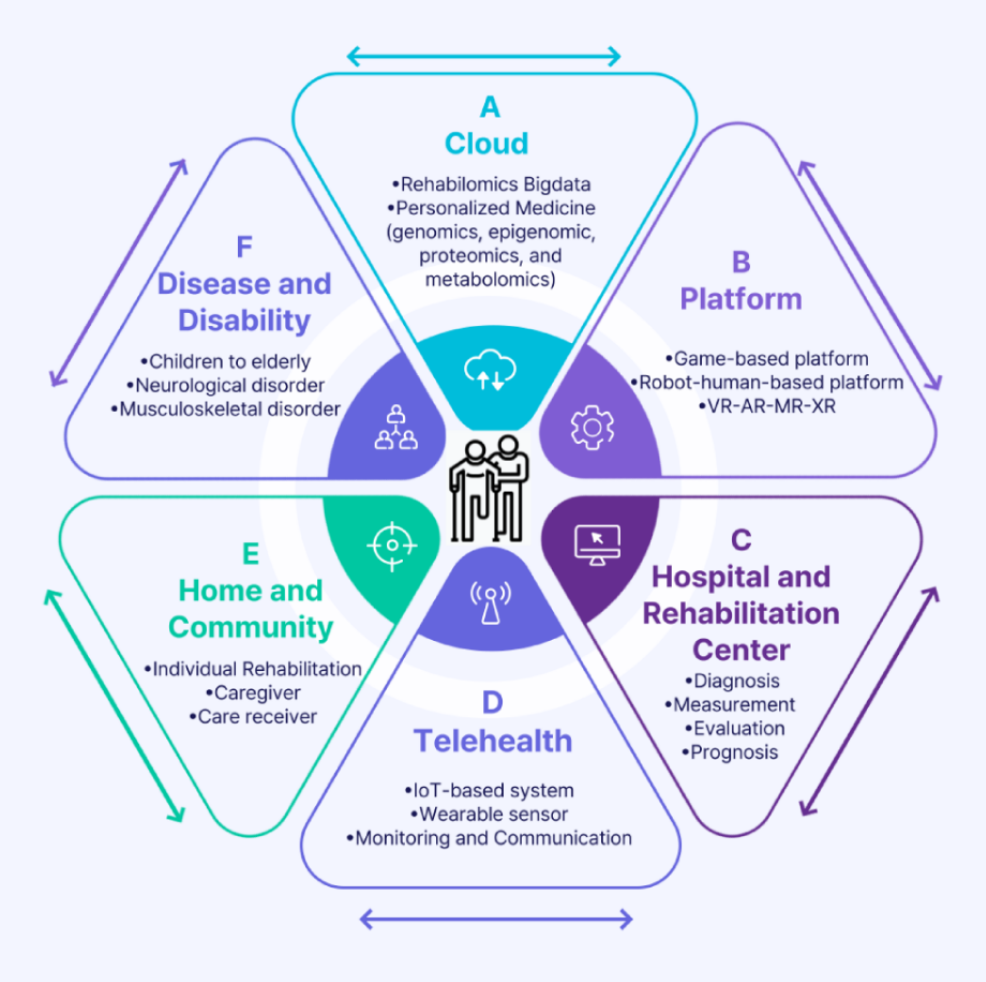
Cloud-Based Flexible Solution for Psychometric Test Validation, Administration, and Evaluation

A unified cloud-based resource was developed to manage psychometric tests used for attitude evaluation, personal selection, educational purposes, rehabilitation, and diagnosis of cognitive disorders [47]. This resource aims to simplify the process of validation, standardization, and reorganization of tests traditionally conducted using complex statistical methods.

Effectiveness of Cloud-Based Rehabilitation in Children With Developmental Language Disorders During the COVID-19 Pandemic

This study referred to the application of cloud-based rehabilitation for children with developmental language disorders during the COVID-19 pandemic [51]. The authors investigated the effectiveness of the JingYun Rehab Cloud Platform on language and cognitive outcomes in 162 children with developmental language disorders through a prospective cohort study. Patients who underwent remote cloud-based rehabilitation were compared with a control group that received home-based rehabilitation. The results indicated significantly better language abilities among the children in the cloud-based rehabilitation group.

Cloud-Based Deep Learning–Assisted System for Diagnosis of Sports Injuries



The authors proposed a deep learning-assisted system incorporating IoT sensors in a body area network to diagnose sports injuries using cloud computing resources. IoT sensors gather data for diagnosis of injury and cloud computing to provide flexible computing resources [52]. They developed a brain injury monitoring framework and optimized neural networks to forecast sports injuries and evaluated the model performance using accuracy, precision, recall, and F_1-score metrics.

Our study established a strategy for personalized rehabilomics tailored toward individual needs by integrating clinical information from hospitals and extending it further to genomics, epigenomics, proteomics, and metabolomics for intervention, measurement, assessment, and prognosis (Figure 3). We

XSL•FO
RenderX

emphasized the active use of clouds and platforms. In addition, we derived a strategic direction emphasizing the integration of hospitals and homes, promoting active community-based rehabilitation and linking it with individualized care providers. The first aspect involves a cloud that encompasses rehabilomics big data along with genomics, epigenomics, proteomics, metabolomics, and personalized medicine. The second aspect includes game-based platforms; robot–human-based platforms; and the use of VR, augmented reality, mixed reality, and extended reality. The third aspect involves hospitals and rehabilitation centers conducting diagnosis, measurement, evaluation, and prognosis, and using and linking such rehabilitation data. The fourth aspect is telehealth, which actively uses IoT-based systems, wearable sensors, and monitoring and communication. The fifth aspect involves home and community, using individual rehabilitation, and actively using information and rehabilitation between caregivers and care receivers. The sixth aspect focuses on disease and disability, actively using rehabilitation and data from children to the older adults, and targeting neurological and musculoskeletal disorders. All these processes, interconnected and used, ultimately lead to the development of a strategy for individualized rehabilitation.

Figure 3. Rehabilomics strategies enabled by cloud-based rehabilitation. AR: augmented reality; MR: mixed reality; VR: virtual reality; XR: extended reality.

Discussion

Principal Findings

Future Prospects of Cloud-Based Rehabilitation

The findings of this scoping review provide valuable insights into the prospects of cloud-based rehabilitation. Cloud computing technology offers innovative opportunities in the health care domain [44,54] and is increasingly being leveraged as part of rehabilomics strategies. This integrative approach has the potential to open new horizons in rehabilitation therapy and enhance patient-centered personalized treatment. Particularly, telehealth [55] and telemedicine rehabilitation [56,57] offer the advantage of providing medical support and monitoring through connectivity, especially for patients with chronic conditions, such as PD [16,17], stroke [42], and traumatic brain injury [11,12,58]. Daily routines and rehabilitation data are aggregated in the cloud, enabling individuals to review their personal data [49]. With their consent, patients can share these data with local community hospitals when seeking medical consultation or treatment, allowing health care professionals to assess their rehabilitation patterns at home [48].

Cloud-based rehabilitation related to the large data of rehabilomics and personalized medicine is needed [10,59]. This can be achieved through construction by a software company with cloud-related technology or using an existing cloud. Identifying aspects of cloud-based rehabilitation platforms to

XSL•FO
RenderX

integratively manage patients' exercise data, symptom reporting, and progress tracking will be helpful [60].

For example, cloud-based rehabilitation based on rehabilomics provides acute and subacute hospital treatment for patients with neurological damage, such as stroke and rehabilitation at home in the chronic phase [33,34,42,45,61,62].

Cloud-based rehabilitation based on rehabilomics continuously records cloud-based medical devices, rehabilitation exercises, and medications and visits the hospital during midterm evaluations to check records with rehabilitation experts [15,28,59]. This may help establish future intervention directions. In addition, combining web-based systems, such as telehealth, [63,64] with cloud-based rehabilitation, hospitals, and clinics allows intervention or evaluation to be performed in real time by linking with the medical system and is beneficial to both patients and caregivers [65,66]. Carrying out steady and sustainable rehabilitation is motivating, and it is cloud-based. A significant advantage exists in sharing and viewing various data in real time.

Hospitals can use these individualized data to collaborate, diagnose, and treat patients. Through the analysis of aggregated data among patient groups, they can offer research insights and develop tailored rehabilitation prescriptions. This facilitates the provision of personalized rehabilitation programs [48]. Particularly, it seems necessary to upgrade to an extensive and secure personal data system [18].

Security and Privacy Concerns

One of the prominent challenges associated with cloud-based rehabilitation is data security [67] and privacy. Ensuring confidentiality and integrity of patient data is of paramount importance and requires further research and policy development. Establishing stringent data security and privacy protocols between cloud service providers and health care institutions is essential, and patients must be confident that their data will be handled securely. Specifically, the protection of big data based on health care delivery and chronic disease management is necessary, particularly concerning systems integrating personal medical and rehabilitation information, such as application [68].

A cloud-based rehabilitation system needs to be integrated with electronic medical records and personal health records, based on individual consent for personal medical information and information protection policies founded on international standards, such as International Organization for Standardization and International Electrotechnical Commission 27018 for secure cloud services [69-71].

Enhancing Interdisciplinary Collaboration

The successful implementation of rehabilomics strategies underscores the importance of enhanced interdisciplinary collaboration [10,15]. Close cooperation between rehabilitation specialists, geneticists, data scientists, and health care information technology experts is expected to contribute significantly to the advancement of cloud-based rehabilitation and personalized therapy. Opportunities to foster dialogue and collaboration among researchers, clinical practitioners, and health care administrators should also be explored.

Future Research Directions

The consideration of future research directions in the field of cloud-based rehabilitation and rehabilomics strategies is crucial. Further research should prioritize the safety and efficiency of cloud services [67,72] based on blockchain technology [23,73-75], with a focus on data sharing and the development of standardized protocols [76,77]. More extensive clinical studies and evaluations are needed to validate the effectiveness of individualized rehabilitation programs and identify best practices for improving patient outcomes.

Strengths of the Study

This study holds significant value for charting the development trajectory of cloud-based rehabilitation in the context of rehabilomics strategies. This study provides important insights by systematically analyzing the key factors for realizing personalized rehabilitation and emphasizing the importance of data security and interdisciplinary collaboration. Future studies should focus on developing standardized data-sharing protocols and rigorously evaluate the clinical efficacy of these approaches. Enhanced patient experience and treatment outcomes will serve as a driving force for advancing cloud-based rehabilitation. The findings of this study offer valuable information and directions for relevant researchers and clinical practitioners.

Limitations

First, although the detailed variables and algorithms of each rehabilomics model were not known in the review process, various interventions and rehabilitation strategies according to each disease, body type, constitution, and gene are needed based on the models and strategies presented in this study. Second, this study did not involve a scoping review conducted by a librarian. However, the author received training on review search strategies from the affiliated library and proceeded with the research.

Conclusions

This scoping review sheds light on the evolving landscape of cloud-based rehabilitation in the context of rehabilomics strategies. The integration of cloud computing technologies holds immense promise in revolutionizing rehabilitation practices and advancing personalized therapy. However, critical challenges must be addressed, particularly in the domains of data security and interdisciplinary collaboration.

Secure handling of patient data in cloud-based rehabilitation remains a paramount concern. As the field continues to expand, the development and implementation of robust data security and privacy measures are becoming increasingly nonnegotiable. This involves establishing stringent protocols, fostering transparency, and building trust among patients regarding data protection.

The success of rehabilomics strategies relies heavily on effective interdisciplinary collaboration. Collaboration between rehabilitation specialists, geneticists, data scientists, and health care IT experts should be encouraged. Bridging the knowledge

XSL•FO
RenderX

gaps between these diverse fields is crucial for achieving comprehensive patient-centered care.

Future studies should prioritize the refinement of cloud services, emphasize data integrity, and develop standardized protocols for data sharing. Moreover, it is essential to conduct robust clinical studies to evaluate the efficacy of personalized rehabilitation interventions. These efforts will not only provide evidence of improved patient outcomes but also guide the implementation of best practices in clinical settings.

When harnessed effectively and responsibly, cloud-based rehabilitation has the potential to transform the field and usher in a new era of patient-centric data-driven therapy. As researchers and health care practitioners, it is our collective responsibility to navigate the challenges, collaborate across disciplines, and advance this promising frontier for better patient care.

Acknowledgments

The authors would like to thank Editage for the technical editing of the manuscript. This research was supported by a grant (grant RS-2022-KH129263) from the Korea Health Technology R&D Project through the Korea Health Industry Development Institute, funded by the Ministry of Health and Welfare, Republic of Korea.

Data Availability

Data sharing is not applicable to this paper as no datasets were generated or analyzed during this study.

Authors' Contributions

SO participated in conceptualization, data curation, formal analysis, investigation, methodology, resources, visualization, writing the original draft, reviewing, and editing. SL participated in conceptualization, formal analysis, methodology, project administration, supervision, validation, writing, reviewing, and editing.

Abstract

Background: Scientific implementation findings relevant to the implementation of internet-delivered cognitive behavioral therapy (iCBT) for depression and anxiety in adults remain sparse and scattered across different sources of published information. Identifying evidence-based factors that influence the implementation of iCBT is key to successfully using iCBT in real-world clinical settings.

Objective: This systematic review evaluated the following: (1) aspects that research articles postulate as important for the implementation of iCBT and (2) aspects relevant to the day-to-day running of iCBT services. A mixed methods systematic review using a convergent synthesis design was conducted to bring together evidence across this sparse literature consisting of divergent scientific article types to investigate the implementation of iCBT for depression and anxiety in adults.

Methods: We searched the PsycINFO, PsycArticles, MEDLINE, CINAHL Complete, and Embase databases for any published peer-reviewed scientific articles that report on the implementation of iCBT for depression or anxiety disorders in adults. A total of 40 articles spanning the case study, commentary, meta-analysis, mixed methods study, pilot randomized controlled trial, randomized controlled trial, qualitative study, quantitative study, review, and systematic review article types were identified as eligible for this mixed methods review. Data were analyzed qualitatively using the descriptive-interpretive approach.

Results: The first domain highlighted the impact of therapist and patient attitudes when implementing iCBT, the superiority of guided iCBT over unguided iCBT, its noninferiority to equivalent face-to-face treatments, and its utility outside of the original target of mild-to-moderate depression and anxiety. In total, 3 subdomains were identified under the second domain: (1) the management of iCBT in the workplace, detailing the importance of managing the iCBT service, related staff, and their motivations for using it; (2) the practice of iCBT in the workplace, describing the therapeutic aspects of iCBT provision, such as the provision of support, the background of supporters, and screening procedures; and (3) contextual considerations, detailing the impact of governmental legislation on therapy conducted over the internet, the lack of an iCBT workforce as a limiting factor, and the cost estimates associated with iCBT provision.

Conclusions: Broadly, the findings describe several aspects that should be taken into account when researchers or practitioners implement iCBT as part of their work. However, the findings should be interpreted with caution, as the articles reviewed spanned many article types, and few of the included studies were directly focused on evaluating the implementation of iCBT. While findings provide insight into important factors to consider during iCBT implementation, these findings and their limitations highlight the need for more implementation-specific research in this area.

Introduction

Background

Internet-delivered cognitive behavioral therapy (iCBT) for depression and anxiety has been developed to help increase access to evidence-based therapies. There is empirical support for its use in treating depression and anxiety [1-4]. End users experience it positively [5] and find it to be satisfactory and acceptable [1,6,7]. However, disseminating iCBT at scale remains a challenge [8,9], and COVID-19 has brought its relevance to light now more so than ever [10-12]. A 2019 commentary [13] discussed the evidence-to-practice gap in digital mental health treatments. The authors postulated that the reason for this gap is a lack of knowledge in the field of iCBT around implementing interventions within routine care. They suggested the adoption of implementation science methodologies to bridge this evidence-to-practice gap.

Implementation science has been defined as the scientific study of methods to promote the systematic uptake of research findings and other evidence-based practices into routine practice to improve the quality and effectiveness of health services and care [14]. Central to this definition is the problem statement behind it: it takes almost 17 years for health care research to achieve its intended benefit, which is termed as the "evidence-to-practice gap" [15,16]. As a newly emerging academic field, implementation science is largely integrative; it borrows and adapts theories from multiple fields and uses these to understand the determinant mechanisms as to why (or why not) a specific implementation succeeds [17]. Implementation science theories provide a framework that allows for implementation plans to be developed and relevant outcomes to be measured [18], and it has been posited that using these methodologies in future studies of iCBT could generate learnings relevant to its real-world application [13,19,20].

In a recent review focusing on determinants of implementation for eHealth interventions [8], 37 determinants associated with successful implementation were identified. However, it should be noted that "eHealth interventions" in this case contained a wide variety of digitally enabled interventions, including iCBT and psychotherapy delivered via videoconferencing. When comparing iCBT and other eHealth interventions, "complexity" is a factor for consideration, that is, the degree to which an intervention contains multiple components that require interaction from many individuals, from various levels within an organization, to enact the intervention effectively [21]. iCBT's level of complexity is highlighted in service illustration articles by Titov et al [22,23]; for example, therapists' skill set to operate iCBT efficiently (technical knowledge and constructing written messages), revised services delivery pathways, adherence to regulatory frameworks, and newly aligned clinical governance procedures are some elements of how delivering iCBT may differ from more traditional or less complex services. Conversely, although administering psychological therapy through videoconferencing software may require some altering of specific therapeutic skills and technical upskilling [24], relative complexity across other areas may be lower (eg, referral pathways and wider system integration). Similarly, some authors have illustrated the need for both iCBT [25,26] and telehealth-specific competency frameworks [27], further illustrating the need for specialized skills to extend the traditional therapist skill set.

Attempts to mobilize implementation science information on eHealth interventions, generally to the point of having pragmatic, clinical relevance for iCBT, have been sparse [28]. As a consequence, the availability of implementation findings relevant to iCBT remains low. This study is a mixed methods systematic review that aimed to account for literature that specifically references or can inform factors relevant to the implementation of iCBT, specifically for depression and anxiety treatment in adults. The benefit of a mixed methods systematic review over traditional systematic literature reviewing is that it seeks to extract relevant information across qualitative, quantitative, review, and illustration-based articles. Mixed methods synthesis affords a way to effectively capture this information and synthesize it qualitatively to produce relevant insights into the implementation of iCBT. Therefore, a convergent integrated approach to the mixed methods review was chosen due to its appropriateness over other review methods for the subject; a traditional systematic review on the implementation of iCBT for depression and anxiety would not be appropriate due to insufficient qualitative or quantitative findings to generate insights [29]. Furthermore, there are no restrictions imposed on the type of evidence included within the synthesis, which aligns with the anticipated variety of articles that would be identified [30]. The disorder domains of depression and anxiety were chosen due to them being the most substantive areas of research for iCBT.

A mixed methods systematic review departs from and complements previous work in the ways mentioned subsequently [8]. First, it will specifically focus on iCBT-based interventions, which can be considered relatively "complex" in their administration [21]. Second, it will provide a rich description of the current "practice behind the science" by focusing on reportage within the methods, results, and discussion sections of the articles. Third, it will contribute to the existing literature regarding specific implementation strategies that are associated with the use of iCBT [31]. Finally, it will allow the interpretation of research findings in a way that is hoped to be productive for future implementations specific to iCBT for the treatment of depression and anxiety.

Review Objectives

The overarching objective of the review was centered on the pragmatic question of "What can we learn from published peer-reviewed literature about the implementation of iCBT for depression and anxiety?" This objective was further broken down into 2 domains of focus, on which data extraction and subsequent data analysis were based (refer to the Methods section).

The first domain was centered on *implementation insights derived from iCBT research*. This objective and domain center on understanding the novel information that is often presented in published research and how this information can have relevance and be mobilized for the benefit of iCBT implementation.

XSL•FO
RenderX

The second domain was *implementation process considerations for the successful implementation of iCBT*, which consisted of establishing the strategies that are used within the literature to facilitate the implementation of iCBT. According to implementation science literature, implementation strategies are methods used to facilitate the implementation of an intervention, where strategies can consist of training packages, management approaches, developing protocols for intervention use, etc [31,32].

Methods

Design

Because implementation science information on eHealth interventions that has pragmatic, clinical relevance for iCBT has been sparse and scattered across different article types, a mixed methods systematic review was conducted. This mixed methods systematic review used a convergent integrated approach and was conducted to identify literature that was central to the review objective mentioned earlier [30,33,34]. The convergent integrated approach to conducting a mixed methods systematic review consists of "qualitizing" numerical or statistical findings; that is, quantitative findings are extracted and allocated textual descriptions to allow for integration and simultaneous synthesis with other qualitative data. The resulting qualitative data were then analyzed using the descriptive-interpretive approach [35]. This review was not registered, and a review protocol was not prepared.

Search Strategy

The general search strategy used was as follows: ("ICBT" OR "CCBT" OR "internet-delivered CBT" OR "internet-delivered cognitive behavioural therapy" OR "internet-delivered cognitive behaviour therapy" OR "internet-based cognitive behaviour therapy" OR "internet-based cognitive behavioural therapy" OR "internet-administered cognitive behaviour therapy" OR "internet-administered cognitive behavioural therapy" OR "internet-supported cognitive behaviour therapy" OR "internet-supported cognitive behavioural therapy") AND ("Anx*" OR "depress*" OR "low mood" OR "GAD" OR "phobia" OR "SAD") AND "Implement*." Databases searched included PsycINFO, PsycArticles, MEDLINE, CINAHL Complete, and Embase. A full description of terms and derivatives for the different databases is included in Multimedia Appendix 1. Search engine limitations required that the search date had to start from 2007. The search was initially conducted in June 2020 (January 1, 2007-June 1, 2020) and further repeated in September 2021 (June 1, 2020-August 31, 2021) to identify any new or relevant publications. The inclusion and exclusion criteria are given in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Study provides reports on outcomes related broadly to the 2 domains of interest:
  - Implementation insights derived from internet-delivered cognitive behavioral therapy (iCBT) research
  - Implementation process considerations for the successful implementation of iCBT
- The study types included in the review:
  - Empirical research, encompassing pre-post experimental (eg, feasibility or randomized controlled trial), case study, observational, or qualitative designs in naturalistic, nonefficacy settings
  - Review-type studies, including systematic, meta, umbrella, narrative, and scoping reviews
  - Service-illustration articles that report on the effectiveness of iCBT clinics over time or describe their operating model
- Studies targeting adult patient populations, mental health care workers (eg, clinicians, therapists, and service managers), or prospective users of iCBT
- The study must be conducted in reference to iCBT (eg, patients undertaking iCBT, clinicians or therapists, or patients reporting on their views of iCBT).
- The study must be primarily conducted in reference to depression and anxiety disorders (eg, patients undertaking iCBT for depression and anxiety, clinicians and therapists, or patients reporting on their views of iCBT for depression and anxiety)

Exclusion criteria

- Nonpeer reviewed research
- Research not in the English language
- Protocols
- Dissertations (due to the difficulty in identifying and accessing these at a wide scale)
- Book chapters
- Conference presentations and abstracts
- Research with participants aged <18 years
- Studies reporting only on clinical effectiveness data with no information on the implementation of iCBT reported on in the study.

XSL•FO
RenderX

Screening

The screening consisted of two steps: (1) review the title and abstract and (2) review the full-paper. We chose to first review the titles and abstracts of all identified records due to the nature of this review and the wide range of study types that were anticipated to result from the search. For example, it was noted throughout the reviewing process that articles frequently cited the terms "implementation" or "feasibility" in the title but failed to provide any relevant information under these constructs when abstracts were reviewed. Where articles provided inadequate information in their abstracts (eg, "the results inform the feasibility of implementing iCBT within XYZ context") to apply the inclusion criteria, DR acted as a second reviewer for these abstracts and consulted with DD (primary reviewer) to make a decision on inclusion or exclusion. Once step 1 was completed, full texts of all articles were reviewed by DD at full text to discern their relevance to the domains of interest. During this review, articles were rejected during full text screening for the following two reasons: (1) incorrect record specification from the databases (eg, conference presentations being mislabeled) and (2) provided little (eg, minor comments relating to the implementation of iCBT within "future research" sections) or no information on implementation. Once all articles were screened and the final dataset established, data extraction commenced.

Data Analysis

Meaning Unit Extraction

Meaning unit extraction began by identifying qualitative meaning units within the methodology, results, and discussion sections of articles relevant to the study objective, that is, learning about the implementation of iCBT for depression and anxiety. Meaning units are discrete data chunks (either paragraphs or sentences) that contribute stand-alone meaning toward a particular research question or objective [36]. Throughout the mixed methods systematic review process, relevant quantitative findings were translated (or "qualitized") to qualitative meaning units. The resulting qualitative meaning units were identified and subsequently extracted to an Excel (Microsoft Corporation) file for analysis and assigned relevant identifiers. In addition to assigning identifiers, each meaning unit was also assigned brief, textual summary labels that provided a way to quickly identify the information being conveyed by longer meaning units.

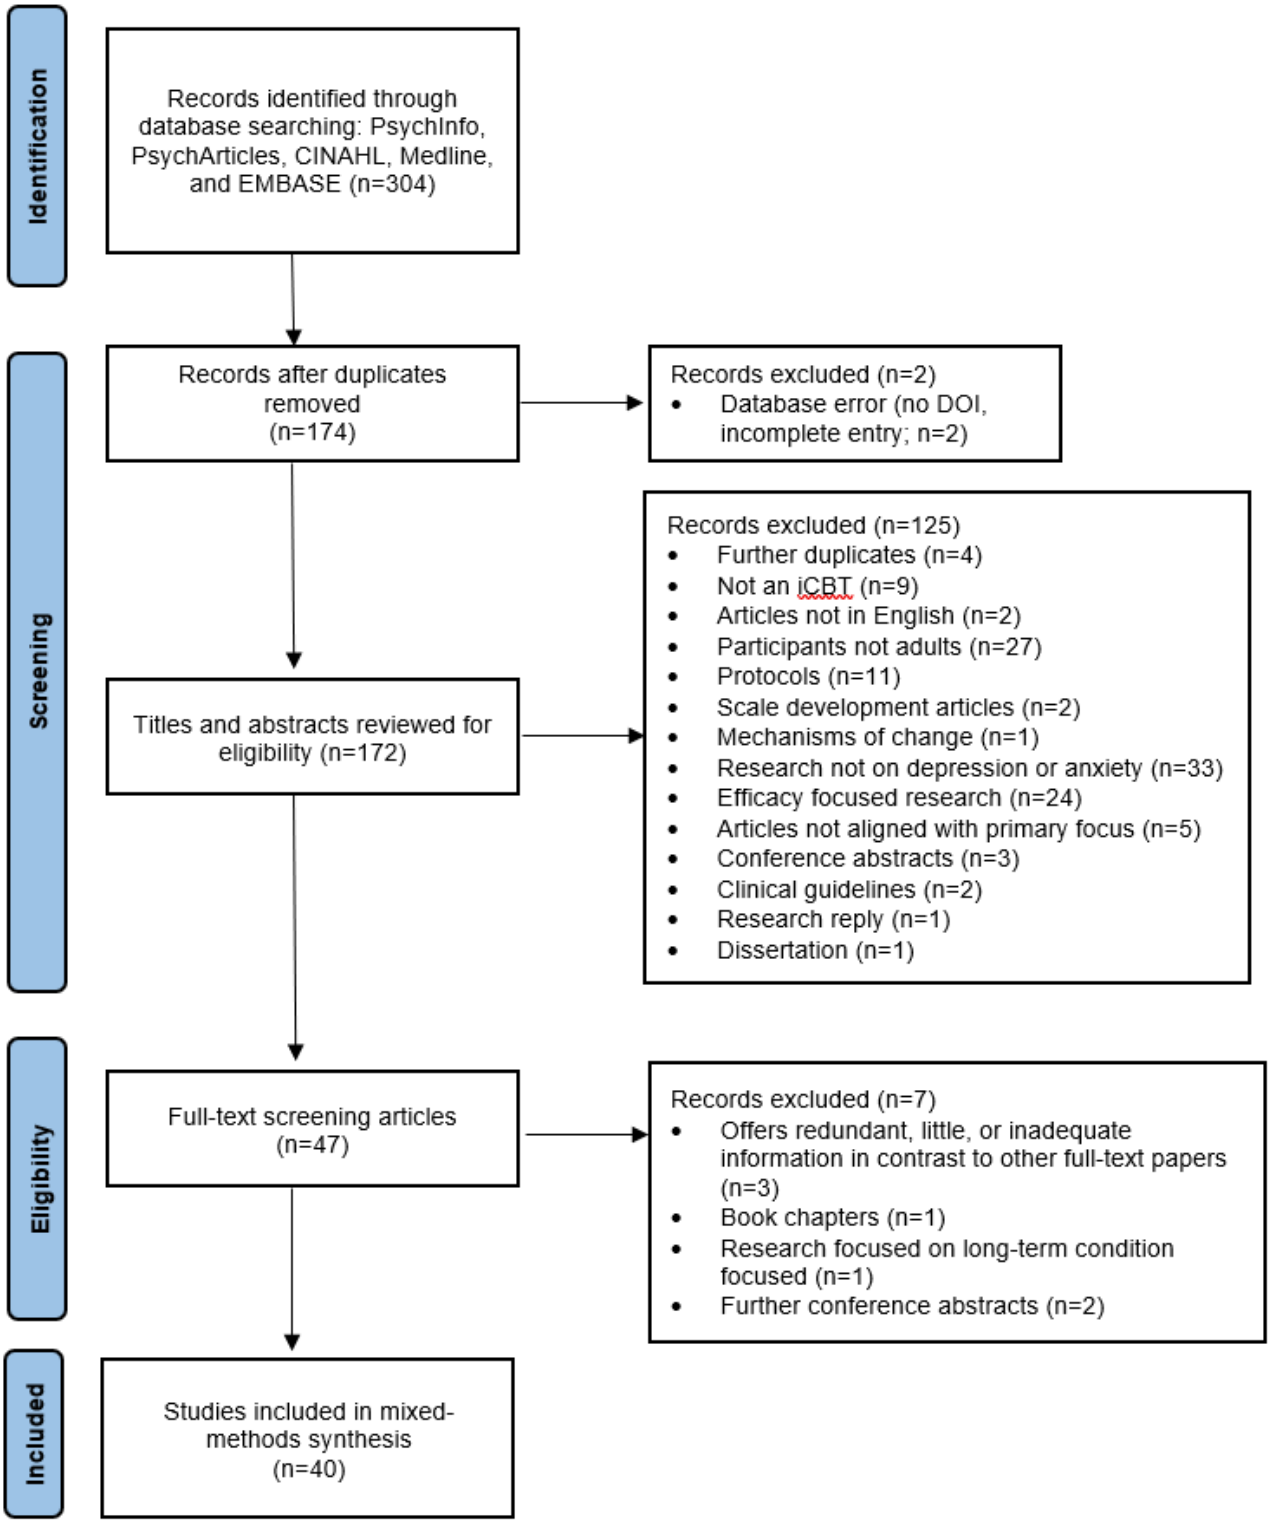
To address the review objective of learning about the implementation of iCBT for depression and anxiety, 2 main focus areas were identified that allowed for the structuring of the relevant data to guide meaning unit extraction.

The first focus area was the implementation process considerations for the successful implementation of iCBT. It consisted of the following questions: (1) What strategies do articles report on that are related to the process of implementing iCBT (eg, training clinicians or therapists, screening procedures, referral pathways, and service operations)? (2) Do articles report on the impact of these strategies on specific stakeholder groups (eg, patients and clinicians or therapists)? and (3) Do articles acknowledge or cite factors within the context of the implementation (eg, governmental policy, service infrastructure, and funding)?

The second focus area was the implementation insights derived from iCBT research. It involved the following questions: (1) What implications do authors of the included studies cite as important for the future of the implementation of iCBT? and (2) How do authors interpret their findings in discussion sections of articles, and can these interpretations have implications for how iCBT is implemented?

Category Generation

Meaning units within these 2 focus areas were then further analyzed for similarities and clustered together into categories and subcategories grouping meaning units of similar meaning. The categories and subcategories were named to capture the meaning of the meaning units they contained. The process of organizing and naming categories and subcategories was an ongoing activity led by DD and involving feedback from DR and another colleague. The consensus was agreed upon through group discussion, where the core component of each subcategory was established (eg, this subcategory describes x), and the revised category names were generated based on this shared understanding. As per the descriptive-interpretive approach, it was important that progress was continuously audited through group meetings with DD, DR, JP, and LT.



Results

Overview

A total of 40 eligible articles published between 2010 and 2021 were included in the mixed methods synthesis. Multimedia Appendix 2 provides the types of articles included in this mixed methods systematic review and brief summaries of these included articles. Article types included in this review were case study (1/40, 2%), commentary (4/40, 10%), meta-analysis (5/40, 12%), mixed methods study (3/40, 8%), pilot randomized controlled trial (1/40, 2%), randomized controlled trial (2/40, 5%), qualitative study (5/40, 12%), quantitative study (13/40, 32%), review (3/40, 8%), and systematic review (3/40, 8%). Multimedia Appendix 3 [4,9,22,23,28,37-71] includes a numbered list of all articles analyzed as part of this mixed methods systematic review. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram constructed to illustrate the search findings is illustrated in Figure 1 and the PRISMA checklist is provided in Multimedia Appendix 4.

Domain and Category Structure

Two domains (and lower subdomains, categories, and subcategories) were identified: (1) implementation insights derived from iCBT research and (2) implementation processes related to the successful implementation of iCBT in care settings (Tables 1 and 2). Subcategories are discussed as talking points within each category as opposed to adding further organizational levels within this study.

XSL•FO
RenderX

Table 1. Categories and subcategories identified under the domain implementation insights derived from internet-delivered cognitive behavioral therapy (iCBT) research and illustration of the number of contributing articles (N=40).

Category and subcategory	Articles, n (%)	Study reference number
Clinician attitudes toward iCBT		
Negative attitudes toward iCBT can impact referral rates and patient outcome	10 (25)	[4,5,13,23,25-27,29,34,36]
Positive attitudes toward iCBT can increase acceptability and help to grow iCBT in service	3 (8)	[29,31,34]
Patient attitudes toward iCBT		
Positive attitudes toward iCBT content, support, privacy, and convenience of iCBT can foster engagement	10 (25)	[3,8,27,29,32,33,36,72-74]
Attitudes as moderators of clinical outcome, perceived helpfulness, and adherence	3 (8)	[18,36,73]
Negative attitudes relate to preference for face-to-face therapy and issues with the utility of iCBT to patient needs	5 (12)	[25,26,36,72,73]
The delivery of internet-delivered therapies can be helped by technological and clinical augmentation	7 (18)	[11,16,23-25,27,34]
Specific patient characteristics need to be considered when implementing iCBT		
Age is negatively associated with adherence and clinical outcomes in guided iCBT and not associated with symptom deterioration in unguided iCBT	4 (10)	[1,20,36,74]
The relationship between gender or sex and adherence is unclear in iCBT overall, but gender or sex is not associated with symptom deterioration in unguided iCBT	2 (5)	[1,36]
Patient technological literacy is tentatively positively associated with adherence and clinical outcomes in iCBT	2 (5)	[36,75]
Medication and alcohol use are not associated with iCBT adherence	1 (2)	[36]
Racial or ethnic minority group membership is negatively associated with adherence to iCBT	1 (2)	[35]
The relationship between adherence and marital status, employment status, and education level is mixed overall, but they are not associated with symptom deterioration in unguided iCBT	3 (8)	[1,36,74]
Having a lower income is positively associated with dropout	1 (2)	[74]
Comorbidity of disorders can moderate treatment outcome	1 (2)	[74]
Making sudden clinical gains is associated with greater improvements after the treatment	1 (2)	[24]
The severity of depression can positively impact clinical outcomes and adherence	2 (5)	[10,36]
Symptoms of depression can negatively impact iCBT adherence	2 (5)	[12,18]
Chronic mental health problems are negatively associated with iCBT adherence	1 (2)	[74]
Guided iCBT is superior to unguided iCBT in regard to symptom outcomes and adherence	11 (28)	[1,7,17,23-25,27,34,36,73,74]
iCBT is as effective as face-to-face delivery of the same protocol, yet preference is often for face-to-face treatment	13 (32)	[6,11,13,14,16,23-25,27,29,36,72]
iCBT appears to be effective beyond the original target of mild-to-moderate depression and anxiety	10 (25)	[8,10,13,14,23,26,27,29,32,33]
Conducting future research that has relevance for iCBT implementation is important		
More implementation research is needed to understand the uptake of iCBT within routine care	9 (22)	[7,18,23-25,27,28,33,34]
More research is needed on adverse events to understand the negative effects of iCBT	2 (5)	[19,23]
More research is needed to understand the relationship between adherence and iCBT	4 (10)	[8,23,28,36]

Table 2. Subdomains, categories, and the contributing articles identified under the domain implementation processes related to the successful implementation of internet-delivered cognitive behavioral therapy (N=40).

Subdomain and category and subcategory	Articles, n (%)	Studies
Management of iCBT in the workplace		
Successful training of supporters is important for the provision of iCBT	8 (20)	[4,14,16,22,26,29,31,34]
Training stakeholders within the health system is important in creating awareness of iCBT	2 (5)	[14,29]
Effective management of risk and adverse event management in iCBT is important for its delivery	10 (25)	[5,8,12,14,22,23,27,30,33,75]
iCBT should be delivered through secure and interoperable systems that facilitate clinician and client access	11 (28)	[4,11,12,15,24,27,29,30,34-36]
Operational considerations for managing iCBT and related staff are important		
Effective management and leadership support facilitate the implementation	7 (18)	[12,14,22,24,29,31,34]
Management of workplace resources is necessary to facilitate staff time to use iCBT	4 (10)	[4,26,29,31]
Staff motivation to use iCBT needs to be fostered	4 (10)	[26,27,29,34]
Use of routine monitoring of iCBT to convey intervention effectiveness and enhance its delivery	5 (12)	[27,29,33,34,74]
Effective marketing and service promotion enhance the uptake of iCBT	6 (15)	[4,18,21,29,33,35]
Staff recruitment and retention in iCBT is a challenge that needs to be mitigated against	2 (5)	[4,14]
Scaling of iCBT within services is challenging and requires multiple considerations (eg, infrastructure, funding, proper testing, and governance)	7 (18)	[4,12,14,15,22,33,74]
The practice of iCBT in the workplace		
Appropriate referral pathways and management of waiting times are important for the delivery of iCBT	19 (48)	[2,4,9,12,14,18,20-23,27,30-33,35,73-75]
Screening and inclusion criteria for accessing iCBT need to be thoroughly defined	21 (52)	[8,9,11-14,16,18,20,22,24,26,29,30,32,33,35,72-75]
Considerations of the level of support for patients are crucial in the provision of iCBT		
Positive impact of support on patients	11 (28)	[2,3,5,10,13,23-25,33,36,73]
The quality of support impacts the success of iCBT provision	13 (32)	[8,12,16,22-24,27,29,30,34,36,73,74]
Appropriate considerations should be given to the mediums and modalities of support to fit service and user needs	20 (50)	[2,8,11-13,16,21-27,30,32-35,73,74]
The time demand associated with the provision of support needs to fit service and user needs	18 (45)	[2,7,11,12,18,21-24,26,27,30,32-35,73,74]
The optimal personal and professional background of the supporter needs to be considered in the provision of iCBT	17 (43)	[4,11,12,14-16,21,23-27,30-33,35]
Contextual considerations		
Governmental and health care regulations affect the implementation of iCBT	10 (25)	[4,12-15,24,29,31,33,34]
Lack of workforce availability for iCBT as a limiting factor in the provision of iCBT	4 (10)	[5,27,31,34]
Considering the cost estimates associated with iCBT for patients and health care providers before implementing	11 (28)	[4,8,12-14,22,26,27,29,31,75]

Domain 1: Implementation Insights Derived From iCBT Research

This domain includes categories that contribute to the success of iCBT in either research or routine practice settings or further learning to inform it.

Category 1: Clinician Attitudes Toward iCBT Affect Patient Outcomes and Implementation of iCBT

Clinician attitudes toward iCBT are mixed [48]. Negative attitudes hinder the successful dissemination of iCBT to clients [58]. These attitudes consist of skepticism about the effectiveness and quality of iCBT [9,38], technological limitations of iCBT [56], the inability to generate a therapeutic alliance through this medium [9], preference for face-to-face

XSL•FO
RenderX

therapy [42,65,67], the perceived lower priority of the intervention in the workplace [28], and its highly standardized nature being incompatible with other psychological interventions [28,58]. Such negative attitudes can arise from a lack of iCBT exposure or training [59] and can be transferred to patients and undermine patient outcomes [28]. Accordingly, there is a need to engage with these negative attitudes to successfully implement iCBT [28,65].

In contrast, positive attitudes toward iCBT can increase acceptability and help grow iCBT in service. Positive attitudes include acknowledging the benefits of iCBT in terms of time efficiency, cost-effectiveness, evidence base, program design quality, accessibility, and ability to bridge treatment gaps for those on waiting lists [28]. Professionals with more experience implementing iCBT regard iCBT more positively in terms of its applicability to service provision [62]. Even health care professionals with little exposure to iCBT are generally positive and accepting toward iCBT but have biases around suitability and large knowledge gaps [65].

Category 2: Patient Attitudes Toward iCBT Affect Engagement, Adherence, and Outcomes

The first subcategory under this larger category relates to patients reporting positive attitudes toward the iCBT treatment, its content, and the associated therapist support they receive [28,41,63,67,69,71]. They also report strong motivations to seek out iCBT [45] and acknowledge advantages in terms of convenience, cost, privacy, and self-directed nature [38,67-69]. A second subcategory relates to attitudes, where greater positive initial attitudes predict greater symptom reduction and adherence, and improvement or decline in attitudes during treatment predicts better or worse adherence and outcomes [52,67,69]. The third subcategory relates to negative attitudes, which can be a barrier to treatment success [59]. Such negative patient attitudes include skepticism toward the effectiveness and credibility of iCBT [68,69] as well as toward motivation and accountability to progress through iCBT [68]. There is also a reported preference for face-to-face therapies over iCBT [58,67-69]. Interestingly, offering iCBT as a waiting list treatment can create “unfavorable comparisons” between iCBT and face-to-face therapy, resulting in negative perceptions of iCBT [69].

Category 3: The Delivery of iCBT can be Augmented by Technological and Clinical Design Factors

iCBT has been augmented with novel design elements or treatment strategies to understand their utility and benefit. Such elements and strategies include integrating sensors [57], gamification [57], transdiagnostic elements [38,57,58], iCBT as an add-on or adjunct to existing care pathways [47,56,65], incorporating “persuasive technology” components [57], iCBT use in a blended care model [50,56,57], and its use as a first-line intervention to promote interest in further mental health care [65].

Category 4: Patient Characteristics Related to iCBT Outcomes

A variety of demographic, medical, and technological factors have been implicated to affect iCBT and are reported in the subsequent subcategories. There is mixed evidence for age influencing iCBT outcomes wherein null or negative associations have been observed between age and adherence [67,71] and symptom reduction [39,54]. Mixed results are also reported for gender and sex. Females can have greater or similar iCBT adherence to males [67], and sex was found to be associated with symptom deterioration in unguided iCBT [39]. Perceived technological literacy has been posited to promote adherence [67,70] and clinical outcomes [70], though the evidence is unclear regarding the impact of tech literacy on iCBT outcomes [67]. A review reported that patient-reported medication and alcohol use were not associated with iCBT adherence [67]. Racial and ethnic minority group membership has been negatively associated with adherence to iCBT [66]. Both positive and negative associations have been observed for marital status, employment status [39,67,71], and education level [67] with adherence. Individuals with both lower income levels and marital status of single were more likely to drop out from iCBT [71]. Comorbidity of mental health disorders can reduce the effect of iCBT treatment [45]. Chronic mental health problems are negatively associated with iCBT adherence [71].

Making sudden, large clinical gains on symptom measures at the start of treatment is associated with greater improvements after the treatment [57]. The severity of depression can positively impact clinical outcomes of depression; for example, higher pretreatment severity results in greater effect sizes [4,67]. Symptoms of depression have also been found to negatively impact iCBT adherence, where symptoms like low motivation have been found to be negatively associated with iCBT adherence [23,52]. Chronic mental health problems are further associated with iCBT adherence, where years of living with chronic mental health conditions was found to be negatively associated with adherence to iCBT [71].

Category 5: Guided iCBT as Superior to Unguided iCBT in Regards to Symptom Outcomes and Adherence

Guided iCBT shows superiority over unguided iCBT in terms of adherence and clinical outcomes [44,51,56-58,65,67,71]. However, an individual participant data meta-analysis [39] postulates that the small effects achieved by unguided iCBT are superior to control groups (or no intervention) and can be best used when implemented at scale, such as at the public health level. The therapist element of guided iCBT, in particular, is posited to improve adherence to iCBT [65,67]. Guided iCBT support also fulfills an expressed need to navigate through and explain therapeutic content when patients encounter difficulties [69].

Category 6: iCBT Is as Effective as Face-to-Face Delivery of the Same Protocol, Yet Preference is Often for Face-to-Face Treatment

iCBT produces similar adherence [38,57] and clinical outcomes [48,50,56,57] to equivalent face-to-face therapy. iCBT has advantages over face-to-face therapy in terms of time efficiency, access rates [28,57], and its ability to deliver standardized treatment [22,47]. However, patients demonstrate a preference for face-to-face treatment over iCBT, which can be a reason for the dropout of iCBT [28,43,58,67,68]. In such instances, these

XSL•FO
RenderX

preferences for iCBT over face-to-face treatment can be reduced by introducing a time delay when accessing treatment [43].

Category 7: iCBT Appears to be Effective Beyond the Original Target of Mild-to-Moderate Depression and Anxiety

iCBT is not typically offered for severe presentations of depression and anxiety [59], but real-world data illustrate that a large proportion of patients seen by iCBT clinics have symptoms in this range [22]. Patients with severe symptoms at baseline can make large clinical gains [4,38,45,56], show comparable adherence rates to patients with less severe symptoms [38], and, in some cases, produce larger gains than patients with more severe symptoms [38]. Studies requiring greater treatment-seeking behaviors tend to recruit individuals with more severe symptoms of depression, illustrating the willingness and motivation of this cohort to initiate treatment [38,56]. After treatment initiation, the effect of higher pretreatment severity on adherence and completion is unclear, with a study positing that higher pretreatment severity may be associated with lower iCBT completion rates [64]. Similarly, patients whose symptoms are in the subclinical range also benefit from iCBT [56,63]. Those with suicidal ideation are also found to benefit from iCBT [38,48,56]. iCBT may also be applicable to conditions where depression is secondary to the presenting problem (eg, addiction, trauma, schizophrenia, and bipolar disorder [28,38]).

Category 8: Future Research on Implementation Critical to Advancing iCBT

Several key areas critical to advancing the implementation of iCBT were apparent. First, a plethora of articles stated a lack of research that details the process of implementing iCBT in naturalistic settings; therefore, more research is needed to understand and improve iCBT uptake [38,44,52,56-58,60,64,65]. Second, more research is needed regarding adverse events within iCBT and that current reporting of the adverse events in studies is poor [53,56]. Third, more research is needed to understand the relationship between adherence and iCBT outcomes [45,56,67]. It was also suggested that the definition of "dropout" should not be conceptualized in a binary way because varying dosages of iCBT have been found to produce positive clinical change when less than the intended program is completed. A further study stated that high rates of dropout observed in iCBT research should similarly be expected for practical implementations [60].

Domain 2: Implementation Processes Related to the Successful Implementation of iCBT

This domain includes categories of factors that are important for the successful implementation of iCBT.

Subdomain 1: Management of iCBT Day-to-Day Workplace Operations

This subdomain consists of factors important for managing the day-to-day operations of iCBT, with categories pertaining to the training of staff, risk management, marketing and service promotion, IT infrastructure, working with other services, and managing the staff who work in the provision of iCBT.

Category 1: Successful Training of Supporters Is Important for the Provision of iCBT

Effective training of supporters in iCBT requires technical training in the use of the program [22,50], developing competencies around computer skills and web-based written communication [9,22,62], and practice providing support to fictional patients [50]. Training on writing skills (as many iCBTs rely on supporters messaging the patients on the iCBT platform) should occur before patient interactions rather than through trial and error during their interactions with patients [9]. Training supports, including a manual [59,65], giving clinicians access to training resources [28,65], and providing them with feedback on their written reviews [50], were considered helpful. A study stated that there are limited opportunities for support training in iCBT [37].

Category 2: Educating Stakeholders Within the Health System Is Important to Create Awareness of iCBT

Training and educating other relevant stakeholders (eg, nonclinical staff, referral providers, and patients) about the benefits of iCBT is important to create awareness of the intervention and its clinical effectiveness [28] increasing the perceived viability of the intervention as a treatment option [22].

Category 3: Effective Management of Risk and Adverse Events in iCBT Is Important for Its Delivery

Successfully implemented iCBT has to be supported by a risk monitoring system (eg, suicidal risk measures) that alerts clinicians to risk (eg, triggered automated messages within the iCBT software) and allows clinicians to act on indicated risk (eg, clinician contacts identified risk cases; [22,23,37,42,45,56,64,70]).

Category 4: iCBT Requires Secure, Interoperable Systems That Facilitate Clinician and Client Access

Reviewed articles suggested that iCBT interventions should be hosted on secure servers [28,38,66], should be optimized to run on a variety of mediums (tablets, desktops, and phones) [38], should be integrated with larger patient databases [9,47,61], and should have security standards that adhere to relevant governing bodies [23,57]. Internet connection difficulty [49,65], enabling service computers to access iCBT and its related websites, a lack of integration of iCBT apps with health care records [65], and providing patients access to technology to use iCBT have been cited as limiting factors and may contribute to patient dropout [49,67].

Category 5: Operational Considerations for Managing iCBT and Related Staff Are Important for the Successful Implementation

This category details operational factors that impact the successful implementation of iCBT within clinics or workplaces. First, reviewed articles suggest that management and leadership are important to implement iCBT [28] and include activities such as developing guidelines and service procedures [23,28,37,57], change management [22], and planning implementation and engaging stakeholders [28,65]. In addition, management of workplace resources is necessary to facilitate staff time to use iCBT. For instance, clinicians with already

XSL•FO
RenderX

high workloads may experience time shortages for administering or reviewing the program [28,59]. iCBT clinic managers worry about clinicians balancing iCBT and face-to-face work workloads [9], and it may be necessary to have a dedicated workforce to support iCBT delivery [62].

Second, staff motivation to use iCBT needs to be fostered, as motivation to use iCBT is "essential" [59] because iCBT proponents facilitate the implementation of iCBT [28]. However, fostering this motivation and changing the way clinicians practice is difficult [28,38,65]. One way to foster this motivation may be through routine monitoring of iCBT outcomes, which can provide persuasive evidence of intervention effectiveness to stakeholders as well as enhance its delivery. Services in Australia and Canada reported that they regularly conducted audits of service effectiveness [38,64,71], and such routine monitoring data were used so that staff could evaluate and understand the effectiveness of iCBT in their service [28,65] and to ensure compliance with treatment manual [64].

Third, effective marketing and service promotion are essential to spreading iCBT initiatives [9,28]. Advertisement campaigns (eg, web-based and print media) are frequently successful in recruiting participants for trials and routine care [52,55,64,66], though such marketing campaigns can require a large quantity of resources [28]. Recruitment and retention of therapists in iCBT-related positions is also critical. Clinician recruitment can be an issue as some therapists believe that iCBT limits professional freedom due to its highly structured working requirements and that the working conditions are not attractive [9,22].

Fourth, scaling of iCBT within services is challenging and requires consideration of multiple factors. The physical infrastructure (eg, internet) must be in place [49], funding needs to be procured [9], service decision makers must be convinced of the intervention's feasibility [9], there needs to be evaluation frameworks for existing and new iCBT programs [22,37], and governance frameworks (eg, clinical, IT, and organizational) must be implemented that adhere to the wider legislative context [23]. Exploring new service pathways that are developed when considering iCBT services may allow for existing iCBT services to scale their offering [64]. A study stated that iCBT services should start with a small offering (eg, minimally monitored iCBT) and then acquire human and financial resources over time to build out the service [71].

Subdomain 2: The Practice of iCBT in the Workplace

Category 1: Appropriate Referral Pathways Are Necessary for the Delivery of iCBT

Reviewed articles suggested that successful implementation of iCBT requires the development of appropriate referral pathways, though there are many different referral strategies. Such pathways include self-referral [9,22,23,37,54,64], health care provider referral [22,23,38,40,46,52,54,56,61,62,64,66,70], access to pathways through marketing materials [52,55], contacting patients by email [63], contacting patients on waiting lists for face-to-face services [69], or clients applying through a secure website [71].

Category 2: Screening and Inclusion and Exclusion Criteria for iCBT Are Wide Ranging

Successfully implemented programs required patients to complete a web-based [22,23,28,37,54,63,64,66,68], in-person [23,48,61], or phone screening assessment [57,64,66]. As part of the screening, patients were asked about demographic information, mental health symptoms, commitment to iCBT, treatment history, level of risk, internet access, and language proficiency [28,37,45,48,61,63,64,66,68-71].

A variety of inclusion and exclusion criteria for accessing iCBT are reported as follows: no severe depression [37,59,63,71], no severe anxiety [63], no chronic or recurrent depression [47], no dementia [47], no past history of psychotic symptoms [28,64], aged >18 years [23,45,63,64,66,70,71], aged between 18 and 65 years [52], diagnosis of disorder via psychiatric interview or exceeding cutoff on established measure [23,37,45-47,50,52,64], no comorbid substance abuse [23,45,46,52,64,66] or use of benzodiazepines [46], no suicide risk [23,37,45,46,64,66,69-71], no bipolar disorder, psychosis, or obsessive compulsive disorder [23,45,46,52,66,69,71], adequate understanding of program language [45,46,50,52,66,71], no developmental disorders or other cognitive disabilities [69], no comorbidities or nonpsychiatric diseases that could cause depressive symptoms [70], no concurrent treatment [47,64,66,70,71], no change in medication before 1 month of commencing treatment [71], no email address or technological means to access treatment [46,82,70,71], patients with low motivation [37,64], and patients to far outside of the geographic location of the clinic [37,64,66,70].

Category 3: Use of, and Processes for, Providing Support That Are Crucial to the Provision of iCBT

Supported iCBT achieves positive clinical outcomes for patients [4,40,56-58], provides superior clinical and adherence outcomes over unguided interventions [4,40,56,64,67], and is regarded positively by the patients [41,69]. Therapeutic alliance is implicated as a mechanism behind the positive effects of supported interventions [48]; however, its effects are still unclear in iCBT, as it has been associated with positive outcomes [42] or no effect [48].

The purpose of support in iCBT is to "recognize and reinforce the participants' work with the self-help material" [56] and promote engagement with the intervention [65,71]. The supporter in iCBT is posited to assume the role of a motivator, where the iCBT platform delivers the core treatment elements [38,56], and involves therapists monitoring patient progress [23,28,37,69], responding to their iCBT-related needs [28,67,69], and guiding the user through the initial setup [45,61]. Through written support, clinicians can encourage and affirm patients by expressing interest in the thoughts, feelings, and behaviors that patients share [50,57]. The quality of support affects client outcomes. For instance, leniency toward patient accountability (eg, homework completion) is associated with poorer patient outcomes [57]. Moreover, within written messages, the studies found that misspellings were frequent, emojis and emoticons were seldom used, and less detailed, shorter messages were associated with fewer web-based sessions completed [50].

XSL•FO
RenderX

iCBT support has been delivered in many ways [56]: in person [55,59], over email [38,64,71], by telephone [23,40,55,64,69,71], through the iCBT platform [23,45,50,55,63,66], through videoconferencing software [63], or by SMS text message [23]. Support can occur in real-time [58], on an "on-demand" basis [37], or asynchronously [48,58,64,66]. Support can be delivered weekly [23,47,55-57,61,64-66] or constantly through ongoing therapist monitoring [63]. Some programs incorporate homework assignments to inform clinicians when conducting support sessions [23,37]. In total, 3 programs implemented "step-wise" access to modules, where new content could not be accessed without completing a supported session [37], was unlocked 7 days after the completion of the previous module [69], or released gradually over an 8-week period [64].

Such decisions around how support is delivered and its frequency likely influence clinician time demand. Time spent delivering support varies widely [56], ranging from 10 to 100 minutes per session [23,38,40,44,55-57,59,61,64,69,71] and up to 8 hours per individual per course of treatment [38]. Support can be delivered weekly [23,47,55-57,64-66] or constantly through ongoing therapist monitoring [63]. Some programs involve 6 to 12 supporter telephone calls [40], emails from the supporter [52], or that the supporter contacts the patient ≥1 time a week for 8 weeks [47]. The end of treatment for some programs was based on a specific time or the number of support sessions received; for example, iCBT was cited across articles to be delivered over a varying course of 7 to 20 weeks [23,37,44,49,55,61,63,64].

Category 4: iCBT Can Be Successfully Implemented Across Supporters With a Variety of Personal and Professional Backgrounds

Successful implementation of iCBT included supporters who were volunteer peer-supporters with lived experience of the mental health condition [61], trained volunteers [49], psychologically trained experts (unspecified qualifications; [38]), clinical psychologists [9,23,47,50,61-64,66], psychiatrists [9], registered or provisionally registered mental health professionals [22,61], graduate students of psychology [22,66], trained health care professionals [49], psychologists in training [50,62], psychotherapists [62], social workers [62,64], mental health nurses [50], nurses [64], therapists with training on addictions [64], trained technicians [55,56,58], and general practitioners [59]. There is evidence that untrained technicians [56,58] or novice clinicians [57] achieve equal outcomes compared to trained clinicians, and that support from a technician is more effective than a waitlist control group [55].

Subdomain 3: Contextual Considerations for iCBT Implementation

Category 1: Governmental and Health Care Regulations Affect Implementation of iCBT

Governmental and health care regulations influence how iCBT can be implemented. An example of this is in Canada, where iCBT has been recognized by the Canadian government, which provides specific funding streams for iCBT services and research [28,64,65]. Other countries have implemented policies that incentivize the use of iCBT to improve access to psychological therapy [9,49]. Other regulations impacting iCBT include limitations placed on therapeutic contact taking place over the internet [48,49], requiring iCBT clinics to adhere to existing frameworks for the delivery of therapy [22,23,57] and policies around the delivery of therapy over the internet [57,62].

Category 2: Lack of Workforce Availability for iCBT as a Limiting Factor in the Provision of iCBT

The lack of workforce availability can limit the implementation of iCBT, particularly because as access to mental health care increases, so does the demand for services [38,42]. One study in Sweden observed only 1 to 2 therapists participating in iCBT initiatives among implementing services and further commented that due to face-to-face resources being expensive and scarce, a dedicated iCBT workforce could resolve this issue in terms of resource and cost [62]. Another study stated that the presence of trained iCBT professionals in certain health sectors (eg, veteran care in the United States) is rare [65].

Category 3: Cost Models and Cost-Effectiveness of iCBT Maybe an Asset for Successful Implementation

iCBT was provided to patients through the following 5 cost models: free of charge [59], through publicly funded health care systems [9,22,23,28,37,45,48], subsidized by health care providers [23,38], at a cost to patients when they are not within certain catchment areas or countries [38], or as part of insurance plans [48]. The establishment of reimbursement systems for iCBT was cited as an important factor for cost estimates in the future [9,48]. Moreover, it was hypothesized that as iCBT cost-effectiveness becomes more salient, health care providers (public or private) will advocate for it as a first-line intervention to efficiently gatekeep therapeutic resources [38]. iCBT did not incur extra costs to public health care systems [28] and was cost-effective (depending on the "willingness to pay" standards of the health care body) [70]. One study posited that a dedicated iCBT workforce should be developed to create a less expensive alternative [62].

Discussion

Principal Findings

Our mixed methods systematic review highlights the knowledge we have gained from the available literature on the implementation of iCBT. Some of our key findings regarding the process for implementing iCBT include the practice of iCBT, with special reference to determining client eligibility and effectively supporting patients in iCBT. The management of iCBT in the workplace, especially staff and operational considerations, also surfaced as an important process to consider when implementing. Other related findings include the importance of staff training, the management of treatment pathways, security, and factors for consideration within the wider context that impact the implementation of iCBT. In terms of implementation insights, this review has highlighted that clinician and patient attitudes toward iCBT can influence its ability to achieve intended outcomes and the need to continually tailor iCBT for patient benefit and that further research can help to develop our understanding of implementing iCBT successfully.

XSL•FO
RenderX

As would be expected, the practice of iCBT was highlighted as important to the implementation process for iCBT within a mental health service. For instance, what constitutes eligibility for an iCBT intervention manifested in two categories: (1) screening and inclusion criteria for accessing iCBT need to be thoroughly defined and (2) consideration of the usefulness of iCBT beyond the original target of mild-to-moderate depression and anxiety. Historically, eligibility for iCBT has been characterized by low symptom presence (mild to moderate) and no significant risk issues. This approach was sensible while establishing iCBT's safety and effectiveness as an intervention, subsequently resulting in a well-validated evidence base supporting iCBT for treating depression and anxiety. Consequently, the preponderance of historical eligibility seems to be an artifact in need of revision. This is particularly important in light of the growing body of literature to support iCBT's applicability to more severe presentations of mental health difficulties [72-75]. In addition, real-world data from iCBT clinics highlight that a substantial proportion of patients accessing these services have presentations within the moderate to severe range [22].

There is a clear need for services to consider the populations they serve (eg, general severity levels and client demographics) and tailor their model of iCBT provision. Still, despite the available evidence, clinical guidelines lag in their support for iCBT in extended service delivery pathways [76]. This situation poses some difficulty for certain services or health systems to innovate their use of digital interventions (eg, the improving access to psychological therapies program in England, which offers treatment based on National Institute for Health and Care Excellence guidelines). Specifically in the English context, the original guideline for the use of iCBT was rolled out in 2004 [77,78] and was updated in 2022. Since then, technologies and research have developed and would suggest the utility of iCBT for the broader population.

Our results highlight the importance of the operational aspects of iCBT services. First, the importance of effective management and leadership to support the implementation of iCBT was identified through the review. Transformational leadership approaches, that is, leadership styles associated with motivating and compelling employees to participate in a shared vision [79], have been found to be associated with increased levels of innovation climate, further defined as an organizational climate that is conducive to the adoption of novel, evidence-based practices [80]. Implementing iCBT requires leaders to navigate interactions across multiple levels of a service and motivate staff to ensure the vision of iCBT is fulfilled. However, the current studies identified do not illustrate in depth the effects of leadership nor was it their primary or secondary focus. Despite this, it is still important that this finding was communicated through this small pool of studies, and more research is needed to inform this gap in knowledge.

Training staff in iCBT and increasing their motivation to use it were both cited as important. As an in-service activity, training clinicians and therapists in the use of evidence-based practice has a substantial literature base [81,82]. However, our findings highlight variance in the training delivered to therapists charged with delivering iCBT, ranging from hours to up to a year of continued education, and the components of the training were also not described at length across articles. The wider literature on training stands in contrast to what we identified; training programs for evidence-based practice tend to produce better outcomes (eg, competency, evidence-based practice use, and positive attitudes) when multicomponent approaches are used (eg, workshop, follow-up, and audit of skills acquired) [81]. To date, no systematic evaluation of iCBT training programs has been conducted, and it has also been cited by one of the included studies that training programs for these interventions are rare [37]. Similarly, we identified that staff motivation to use iCBT needs to be fostered. This motivation can also be developed through training initiatives, where implementers can illustrate the benefits that iCBT brings to routine clinical practice (eg, improves patient symptoms and access to care, is usable, and is not time consuming), and this activity may potentially influence motivation around intervention use [83,84].

Furthermore, routine monitoring of the intervention and its outcomes was also cited as important for the continued development of iCBT within the service. This activity can allow supporters in iCBT to reflect on their own practice to improve service provision, with an article stating that clinicians who administer iCBT desire comprehensive updates regarding iCBT to understand its impact on wider service outcomes [28]. This activity is reminiscent of the construct "reflexive monitoring" from normalization process theory [84], where individual and group reflections on processes around a specific evidence-based practice can lead to revisions in practice that are adapted to best suit the needs and structures of the service context. The results regarding the operational aspects of iCBT, despite not being widely reported across the literature, indicate that factors associated with evidence-based practice success in the implementation literature are being considered when iCBT is implemented, which is a promising finding. More widespread reporting of this information could be beneficial to practicing professionals when making choices about using iCBT with their patients.

Patients tend to be positive about iCBT and the support they receive, but clinician attitudes generally lean toward the negative. From service illustrations, we can infer that clinicians receive significant exposure to iCBT when it is implemented [22,23,38], and its effectiveness is grounded in the literature. Negative attitudes can result in the abandonment of the implementation effort due to a lack of acceptance or misunderstandings around the perceived value of the treatment [85,86]. A better understanding of negative clinician attitudes can be attained if iCBT were to be interpreted as a novel, evidence-based practice. A literature search around clinicians' attitudes toward evidence-based practice provides some insights, including that clinicians rate "other" sources of information (eg, colleague opinion and previous experience) as more impactful than published evidence on their decisions for treatment [87-89]. Fostering attitudes conducive to the uptake of evidence-based practice has been associated with transformational leadership styles [80] and systematic training initiatives that highlight how the evidence-based practice is integrated with the wider service system [82], both of which were evident within the current review. However, where there is a disconnect between clinicians

XSL•FO
RenderX

and service management or staff does not understand the relative advantage (from the diffusion of innovations) [90], iCBT over existing practice can subsequently create barriers to evidence-based practice uptake [90,91]. This disconnect is well documented in implementation science theories, such as readiness for change [92] and implementation climate [93,94], both of which also emphasize the role of attitudes in evidence-based practice use and implementation.

iCBTs vary widely in their delivery (guided and self-guided), support time frames, and those who provide the support, but the take-home insight is that patients receive the interventions well in terms of satisfaction and clinical outcomes achieved. This malleability of iCBT, where it can assume many forms yet achieve the intended results, underlines the scalability of the intervention. A narrative review of factors associated with scaling public health interventions described that, once an intervention has proven its effectiveness in both small- and large-scale trials, management and practice factors, such as having systems for monitoring intervention performance, funding, and interacting with stakeholders within the wider health care system, become important for the scaling process [95]. Despite this, an "implementation gap" remains, where effectiveness reductions and high levels of attrition occur when we transition from efficacy settings to real-world service provision [96]. This further creates a treatment gap within users assigned iCBT as a treatment option, where implementation factors (eg, abandonment due to encountering bugs and not having a care provider to explore these with) may cause attrition, lowering the promise of scalability purported by these treatments [97].

Limitations

In total, 4 main limitations were identified as part of this mixed methods systematic review. First, we used a targeted search strategy to produce a dataset that the authors acknowledge is incomplete due to a lack of proper use of terminology within the field to reference implementation. Therefore, we acknowledge that this review is not definitive on the implementation of iCBT and only reports on relevant factors within the articles identified. There is already a movement to standardize the reporting of digitally delivered psychological treatments in research studies (eg, use of CONSORT [Consolidated Standards of Reporting Trials] for eHealth) [98], and perhaps this should be succeeded by an attempt to standardize how we report implementation learnings too.

The second limitation consisted of the "blind spots" associated with the development of the analytic framework that may have resulted from the background of the researchers. The authors mainly come from a background in psychology, and none would consider themselves to be implementation specialists. Other review types (eg, realist, scoping, or narrative reviews) conducted by different research groups may uncover nuances that were otherwise unidentified by this review.

The third limitation of the study relates to the limitations present in the original papers included in this review. The heterogeneous nature of the articles included prevented a formal quality appraisal from being conducted. For instance, we had considered using a tool, such as the Critical Appraisal Skills Programme checklist, but this tool did not provide for a quality review of the narrative-type articles (eg, Schröder et al [56], Andersson et al [57], Andersson et al [58], and others) that were included. Furthermore, there are issues around assessing the quality of qualitative evidence within review-type studies and whether studies should be excluded based on perceived quality, which further compounds the issue [99-101]. Thus, we did not assess the quality of the included articles, and no articles were excluded based on methodological flaws. Relatedly, a few articles had a primary objective of exploring a facet of the implementation of iCBT for depression and anxiety, which is important to note when interpreting the results.

The fourth and final limitation of the study is whether an expansion of search terms could have been used. For instance, the term "computerized CBT" was not used in the search terms. However, while the search string did not include this term, we did include an abbreviated term for this, "ccbt," and it is notable that by using this abbreviated term we identified specific studies that referenced computerized cognitive behavioral therapy (eg, Wells et al [44], Wright et al [4], Kenicer et al [49], Wright et al [51], and Grist and Cavanagh [54]). Regardless, it is possible that the search string may not have completely captured all possible studies.

Conclusions

This mixed methods systematic review has identified several strategies for consideration when attempting to implement iCBT. Broadly, these strategies emphasize the importance of effective leadership, managing staff and operations associated with the practice of iCBT, implementing and developing professionals to provide the supported component of iCBT, accounting for context, and deriving implementation insights from novel research contributions in iCBT for patient benefit. Future research into iCBT in real-world settings should endeavor to supply appropriate supplemental information that details the efforts associated with implementing the intervention within care pathways. In tandem, efforts could be made to standardize practices that can support the transferability of learning and scalability through the use of a standardized lexicon of terms that are appropriately used.

Acknowledgments

The authors would like to acknowledge Angel Enrique, senior manager and digital health scientist at SilverCloud Health, for his feedback on early iterations of this review. This research was supported with joint funding from the Irish Research Council and SilverCloud Health under the employment-based postgraduate program (grant EBPPG/2018/198).

Data Availability

Data sharing is not applicable to this paper as no datasets were generated or analyzed during this study.

Authors' Contributions

DD was responsible for conceptualization, data curation, formal analysis, funding acquisition, investigation, methodology, writing the original draft, and reviewing and editing the manuscript. DR was responsible for supervision, formal analysis, funding acquisition, and reviewing and editing the manuscript. GH was responsible for conceptualization, visualization, writing the original draft, and reviewing and editing the manuscript. LT was responsible for funding, supervision, and reviewing and editing the manuscript.

Conflicts of Interest

DD, DR, and GH are employees of SilverCloud Health (now a subsidiary of American Well Corporation). DR and GH are shareholders of American Well Corporation, a company specializing in the development of telehealth solutions for physical and mental health conditions. This study formed part of the doctoral research conducted by DD, which was funded by the Irish Research Council and SilverCloud Health as part of the employment-based postgraduate research program and was hosted by Trinity College Dublin, Ireland. LT is a professor in counseling psychology at Trinity College Dublin and an external research consultant to SilverCloud Health.

Abstract

Background: Information exchange regarding the scope and content of health studies is becoming increasingly important. Digital methods, including study websites, can facilitate such an exchange.

Objective: This scoping review aimed to describe how digital information exchange occurs between the public and researchers in health studies.

Methods: This scoping review was prospectively registered and adheres to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines. Eligibility was defined using the population (public and researchers), concept (digital information exchange), and context (health studies) framework. Bibliographic databases (MEDLINE, PsycINFO, CINAHL, and Web of Science), bibliographies of the included studies, and Google Scholar were searched up to February 2024. Studies published in peer-reviewed journals were screened for inclusion based on the title, abstract, and full text. Data items charted from studies included bibliographic and PCC (Population, Concept, and Context) characteristics. Data were processed into categories that inductively emerged from the data and were synthesized into main themes using descriptive statistics.

Results: Overall, 4072 records were screened, and 18 studies published between 2010 and 2021 were included. All studies evaluated or assessed the preferences for digital information exchange. The target populations included the public (mainly adults with any or specific diseases), researchers, or both. The digital information exchange methods included websites, emails, forums, platforms, social media, and portals. Interactivity (ie, if digital information exchange is or should be active or passive) was addressed in half of the studies. Exchange content included health information or data with the aim to inform, recruit, link, or gather innovative research ideas from participants in health studies. We identified 7 facilitators and 9 barriers to digital information exchange. The main facilitators were the consideration of any stakeholder perspectives and needs to clarify expectations and responsibilities, the use of modern or low-cost communication technologies and public-oriented language, and continuous communication of the health study process. The main barriers were that information exchange was not planned or not feasible due to inadequate resources, highly complex technical language was used, and ethical concerns (eg, breach of anonymity if study participants are brought together) were raised. Evidence gaps indicate that new studies should assess the methods and the receiver (ie, public) preferences and needs that are required to deliver and facilitate interactive digital information exchange.

Conclusions: Few studies addressing digital information exchange in health studies could be identified in this review. There was little focus on interactivity in such an exchange. Digital information exchange was associated with more barriers than facilitators, suggesting that more effort is required to improve such an exchange between the public and researchers. Future studies should investigate interactive digital methods and the receiver preferences and needs required for such an exchange.

Introduction

Public Engagement With Health Research

Public engagement with research can improve the visibility, quality, and impact of such research. The term "public engagement" is used to describe the various ways in which the public (ie, the general population) can be involved in the design, conduct, and dissemination of research. It may be employed to inform and inspire, to advise and listen, or to collaborate with the public. Engagement is by definition a 2-way process involving interaction and listening and intending to generate mutual benefit [1]. A conceptual review of 142 peer-reviewed articles published between 1996 and 2019 showed that the term "public engagement" converges with the term "public involvement." This is supported by the increasing use of the combination term "patient and public involvement and engagement" [2].

In the context of health research with human participants, the public (ie, the general population) should have a say on how to safely participate in studies and how the data collected in such studies is used [3]. Integrating public engagement in the whole research process includes sharing research with nonacademic audiences by contributing to dissemination plans and materials for the public and supporting the use of research in practice [4]. It has been suggested that enhanced involvement of the public (eg, study participants or other interested laypeople) can improve executive procedures such as recruitment and data collection [5,6]. For clinical trials, information exchange, including bidirectional sharing of information, such as data and feedback, between researchers and the public creates a more satisfying trial experience for all involved (ie, study participants and researchers) [7]. The dissemination of study results is defined as one of the key aspects of patient and public involvement and engagement in health research, where patients should provide input on the communication strategy of the study and be co-authors of study publications [8]. A systematic review on youth involvement in health research identified several benefits of such involvement, including that it provides unique perspectives that help to improve research questions and priorities and that it leads to improved translation, dissemination, and uptake of research findings [9].

Furthermore, incorporating the perspectives of the public in research right from the beginning can help researchers to identify and focus on issues relevant to the target group. This might not only improve the proximity of research to practice and thus enhance its translation, but also increase the acceptance and willingness to participate in health studies [1,8]. A mixed-methods study using quantitative surveys and qualitative interviews with researchers and patients assessed patient experiences and perceptions of engagement in health studies [10]. Survey results identified key factors influencing engagement, such as communication quality and participant expectations, highlighting areas for improved collaboration. Interviews provided deeper insights into patient experiences, emphasizing the importance of mutual respect, transparency, and addressing barriers, including unclear roles or logistical challenges of communication. These findings suggest that well-structured frameworks are needed to plan meaningful patient involvement that is required to enhance the effectiveness of patient-researcher partnerships [10].

Digital Information Exchange

Owing to the great advancements in technology during the past decades and the increased accessibility of technological tools and devices, health information exchange is now possible with less effort and expense than before. It can thus help transform the role of study participants from passive observers and subjects in research studies to active members of study teams, who can have an impact on the conduct and outcome of a research study. For example, citizen scientists (participants in a study on arthritis) recorded their daily pain intensity in a smartphone app [11]. The GPS location of their phones was then linked to local weather data to look for possible associations between weather conditions and pain intensity. It was thus possible to collect large datasets and develop a tool to assist patients in better managing their respective health condition [11]. However, there are various barriers associated with the use of digital methods for health information exchange, including poor digital health literacy, ethical and legal issues, low trust in online information sources, and poor technological affinity. For example, in the context of COVID-19, it was difficult for the public to obtain appropriate and accurate online information due to uncertainty about the disease and a plethora of inconsistent content [12]. When it comes to the dissemination of research results, the complexity of the research process and the use of appropriate plain rather than technical language are problematic. Well-designed websites built in association with medical professionals, which have a clear interface and contain quality health information, can draw the attention of patients and lead them to access trustworthy information [13]. Having broad access to additional health information over the internet, which patients can use for discussions with health care professionals, can lead to more patient involvement and engagement in medical decision-making [14].

To develop and establish participation and information exchange opportunities using digital methods, it is vital to explore what is available and, in particular, if these methods are accepted by the target group, that is, the public, including study participants and any laypeople. The goal of such participatory research is to assess the wants and needs of all stakeholders involved in health research.

Digital Portals for Health Information Exchange

The lexical definition of a portal describes a door, passageway, or entrance area that allows entry into a large or grand building,

XSL•FO
RenderX

thus providing access to a new separate area [15]. This meaning can also be applied to digital infrastructure. In this context, an internet-based digital portal aggregates information from numerous sources and makes it accessible to a diverse group of users [16]. Thus, digital portals offer an opportunity for digital information exchange in health research.

The early literature distinguishes between different types of health portals [17] that provide access to a range of functions [18]. The first developments of patient portals for access to personal health information can be traced back to the 1990s [19-21]; however, their more widespread use started later in about 2006 [22]. The definitions of the term "patient portal" and its functions vary. A patient portal refers to an application provided by a health care institution (eg, a hospital) that allows patients to access general health information [23]. However, a patient portal could also provide secure access to the patient's electronic health record (EHR) [20,24-26]. Studies indicate the benefits of patient portals, as they can enhance doctor-patient communication [27] and link patient information with other information on the internet in the case of digital portals [23]. Further studies indicate other benefits in terms of active patient participation and increased satisfaction and treatment adherence [28-31]. The use of a patient portal depends on the expected benefit to the user and the cognitive resources that need to be invested to use it. On average, users are younger, chronically ill, and able to understand digital health information compared to patients who do not use such portals but are aware of their existence [32].

The onset of the COVID-19 pandemic was associated with the increased availability of "open health data." This type of data can originate from public authorities (eg, health authorities), clinical records (eg, EHR), or public health–related surveys [33]. The increasing availability of these data has been accompanied by the development and organization of digital networks and portals for data exchange. These digital portals allow, in part, unrestricted, free, and unlimited access to open health data in machine-readable format for all interested parties [33]. While patients may be interested in the development and progression of a disease, authorities, governments, and medical institutions may need information on the spread of diseases [34]. To meet these demands, there is an increasing need for sophisticated and user-oriented digital portals with health data [33].

According to nonsystematic searches of the internet via Google, we identified 5 examples of digital portals with health data (Table 1). These digital portals are available in German, English, or multiple languages. The target population of the portals included either the public or researchers. Overall, 4 portals focused on data exchange, while 1 portal allowed patients to search for health information using a filter option.

Table 1. Examples of digital health portals.

Portal name	Targeted population	Portal aim	Portal focus	Search terms used to locate the portal in Google
Gesund.bund.de: Verlässliche Informationen für Ihre Gesundheit [35]	Patients, family members, care takers, and the public (interested parties)	Detailed search for information on diseases and the provision of assistance in the event of a disease	Information exchange	"Patientenportal" OR "patient information portal"
European Health Information Portal [36]	Researchers	Search for existing study records; data exchange	Data exchange	"Patientenportal" OR "patient information portal"
Health Data Lab [37]	Researchers and legislators	Access and exchange of health and care data	Data exchange	"health study data" OR "health data portal"
HealthData.gov [38]	Researchers, entrepreneurs, and legislators	Identification of trial and health data	Data exchange	"health study data" OR "health data portal"
Add Health – The National Longitudinal Study of Adolescent to Adult Health/Add Health Navigator [38,39]	Public (participants and interested parties) and researchers	Access study data by searching for records using the "Add Health Navigator"; study-specific portal for data sharing and exchange	Data exchange	"health study data" OR "health data portal"

NFDI4Health (The National Research Data Infrastructure for Personal Health Data) Initiative in Germany

The National Research Data Infrastructure for Personal Health Data (NFDI4Health) is one example of a nationwide digital health portal established in Germany that has the overarching goal of providing new opportunities for the scientific use of personal health data while respecting privacy requirements. The central element of NFDI4Health is the operationalization of the FAIR (findable, accessible, interoperable, reusable) principles [40] around health data, especially those from epidemiological and clinical trials, to promote their reuse and strengthen the reputation of collaborating researchers. One important objective of NFDI4Health is the transfer of research results and study knowledge to the public, which should strengthen the interaction among the public, researchers, and health research institutions [41]. As part of this objective, a digital portal called Research Dialogue [42] has been developed to provide the public with online access to study information, results, and aggregated data from research projects listed in NFDI4Health. In the long term, this digital portal should enable an interactive (ie, bidirectional) exchange between the public and researchers to improve the understanding of health data and health research, ensure a low-threshold exchange of information, and promote participation in clinical studies in Germany. This study was designed to identify digital evidence-based methods from other studies that could be used in the development of the Research Dialogue portal for digital information exchange between the public and researchers.

XSL•FO
RenderX

Study Aims and Objectives

This study aimed to describe how digital information exchange occurs between the public and researchers in health studies, using a scoping review methodology. A scoping review is particularly applicable when a body of scientific evidence needs to be described and mapped into categories without a focus on health outcomes. This review has the following 6 objectives:

1. Studies: What are the characteristics of assessments on digital information exchange between the public and researchers in health studies?
2. Population: What populations were addressed in these studies?
3. Concept: What methods of digital information exchange were described in these studies?
4. Context: What content and aim of digital information exchange were addressed in these studies?
5. Factors associated with digital information exchange: What facilitators and barriers associated with digital information exchange were identified in these studies?
6. Evidence gaps: What evidence gaps and ideas for future research were identified in these studies?

Methods

Study Design

This scoping review adheres to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines [43]. The PRISMA-ScR checklist is presented in Multimedia Appendix 1.

Protocol and Registration

A protocol for this review was prospectively registered [44]. There were no changes between the protocol and the content of this review. At the time of protocol registration, preliminary searches were conducted to design the search strategy.

Eligibility Criteria

The eligibility for this scoping review was based on the PCC (Population, Concept, and Context) framework (Textbox 1). The 3 components of this framework were defined as follows. “Population” includes the public that can include patients, study participants, or any laypeople (ie, the general population). This group is considered as the primary receivers of health information. “Population” can also include researchers (ie, any experts, such as academics, health care professionals, or other relevant stakeholders) who are primary generators and providers of health information (ie, they exchange or plan to exchange health information with the public). “Concept” includes the actual or planned health information exchange using any digital methods (eg, a website with health study content that can be accessed by the population). “Context” includes the health information from specific or any health studies.

XSL•FO
RenderX

Textbox 1. Eligibility criteria.

Inclusion criteria

- Population: Public (ie, laypeople, general population, study participants, and patients) of any age and with any health status (ie, healthy, at risk for any disease, or with any disease) or researchers (eg, any experts, such as academics, health care professionals, or any relevant stakeholders) who exchange or plan to exchange information with the public
- Concept: Digital health information exchange or need for health information using any digital methods (eg, websites accessed using any devices, such as computers or smartphones)
- Context: Health study; (1) Focus on information exchange in a specific health study; (2) Focus on public or researcher perspectives on information exchange or need for health information in any health study
- Study design: Primary study with any design (eg, observational study or survey) or data type (quantitative or qualitative); reports on digital portals with health content
- Study type: Published in a peer-reviewed journal
- Language: English or German
- Access: Full text available

Exclusion criteria

- Population: (1) No focus on the public (eg, focus on information exchange among researchers, health care professionals, politicians, stakeholders, students, or other population groups); (2) Nonhuman populations (eg, veterinary health; meta-research studies on published articles or research methods)
- Concept: (1) Digital health information exchange in health care settings (eg, for clinical data collection or recording); (2) Nondigital health information exchange (eg, information exchange on paper or in face-to-face settings)
- Context: (1) No focus on health studies; (2) Focus on specific topics in the health context, including clinical treatment, online support groups, individual clinical data, electronic health records, and genome data; development of health systems, health frameworks, digital health technologies, clinical guidelines, procedures, or tools; marketing and sales of health products; ethical and legal issues in consent and data sharing; teaching, training, and health education for health care professionals; participant recruitment; health literacy; and quality of health information
- Study design: Nonprimary study (eg, literature review, comment, editorial, correction, or study protocol)
- Study type: Other study types (eg, conference papers, dissertations, or books)
- Language: Language other than English or German
- Access: Full text not available

Information Sources

The information sources for this scoping review include 4 international bibliographic databases (MEDLINE, PsycINFO, CINAHL, and Web of Science), bibliographies of any included studies, and the internet (eg, Google Scholar).

Search Strategy

The search syntax was developed by the team (NS and KKDS) with support from an experienced information specialist (LC). The search terms addressed the PCC criteria (Textbox 1) and included relevant synonyms and subject terms (Textbox 2). The search, using Boolean connectors, adjacency operators, and truncation, was designed in MEDLINE and adapted to other databases (Multimedia Appendix 2). The keyword search was limited to the title and abstract fields, and there were no language or other limits applied.

XSL•FO
RenderX

Textbox 2. Example search terms used in database searches. Population, concept, and context terms were combined with the Boolean operator "AND" in the search.

Population: public

- Search terms: patient, subject, public, citizen, participant, lay, user, general population
- Subject terms: patients, "research subjects"

Concept: digital information exchange

- Search terms: digital or online health education, digital or online health information, digital or online health knowledge, health education or health information or health knowledge portal, health education or health information or health knowledge platform, health education or health information or health knowledge website, digital information exchange or communication or dissemination, online information exchange or communication or dissemination, information portal or information website or information platform access
- Subject terms: "health information exchange," "consumer health information," "information seeking behavior," "information dissemination"

Context: health study

- Search terms: health research, health study, health trial, medical research, medical study, medical trial, epidemiological research, epidemiological study, epidemiological trial

The search was performed (by LC) from database inception to February 1, 2024. The search documentation is shown in Multimedia Appendix 2. All search results were exported to the Systematic Review Accelerator Deduplicator (Bond University Institute for Evidence-Based Healthcare) for deduplication and EndNote 20 (Clarivate) for management. Manual searches of bibliographies of the included studies and the internet via Google Scholar were performed (by NS, JD, and KR) up to February 2024. All search results were exported and managed in EndNote 20.

Study Selection

Screening was performed in EndNote by 3 researchers (NS, KKDS, and a team assistant). Overall, 50% of all studies were screened by at least 2 researchers. As recommended by the PRISMA-ScR guidelines [43], the screening procedure was discussed in the team to increase the consistency among the screeners. The eligibility criteria (Textbox 1) were pilot tested on randomly selected studies (at least one study per criterion) until consensus was reached. Title and abstract screening was supported by the *smartgroups* function in EndNote that was used to identify studies for exclusion (eg, reviews, books, or conference papers). Two researchers (KKDS and a team assistant) checked and confirmed the exclusion of such studies identified by EndNote. Screening of all titles and abstracts was performed by 1 researcher (KKDS) and checked by another researcher (NS or a team assistant). Screening of full-text articles was performed by 2 researchers (NS and KKDS) independently, and final consensus was reached by discussion within the team (NS, KKDS, and a team assistant). Studies were included if they addressed any of the objectives of the review and if they provided details of any digital exchange methods or the intention to exchange the research findings with the public.

Data Charting

A data charting form was developed and calibrated within the team. Data were charted by 2 researchers (NS and TD) who extracted author statements from the included studies and agreed on the final statement selection by discussion. The extracted data were processed into meaningful categories by 2 researchers (NS and TD), and a final consensus was reached by discussion with a third researcher (KKDS). Data processing was subsequently discussed within the team (NS, TD, and KKDS), and a consensus was reached by discussion.

Extracted data included quantitative information (eg, publication year) and qualitative information (eg, description of digital information exchange methods) per study. In scoping reviews, qualitative information is organized by categorizing data into main themes to provide structured insights [43]. In this scoping review, 2 researchers (NS and TD) read all extracted data and then classified them into meaningful categories that were inductively identified in the data. For example, we classified the methods of digital information exchange as "active" or "passive" based on the description of digital exchange extracted from each individual study. The categories were discussed within the team (NS, TD, and KKDS) and calibrated by discussion until a consensus was reached. The final categories were entered into the data charting form for each study for further analysis. The main themes were identified in the process of data synthesis.

Data Items

A list of data items (Table 2) was developed by 1 researcher (NS) and discussed within the team (NS, TD, and KKDS).

XSL•FO
RenderX

Table 2. Data items based on the objectives of this scoping review.

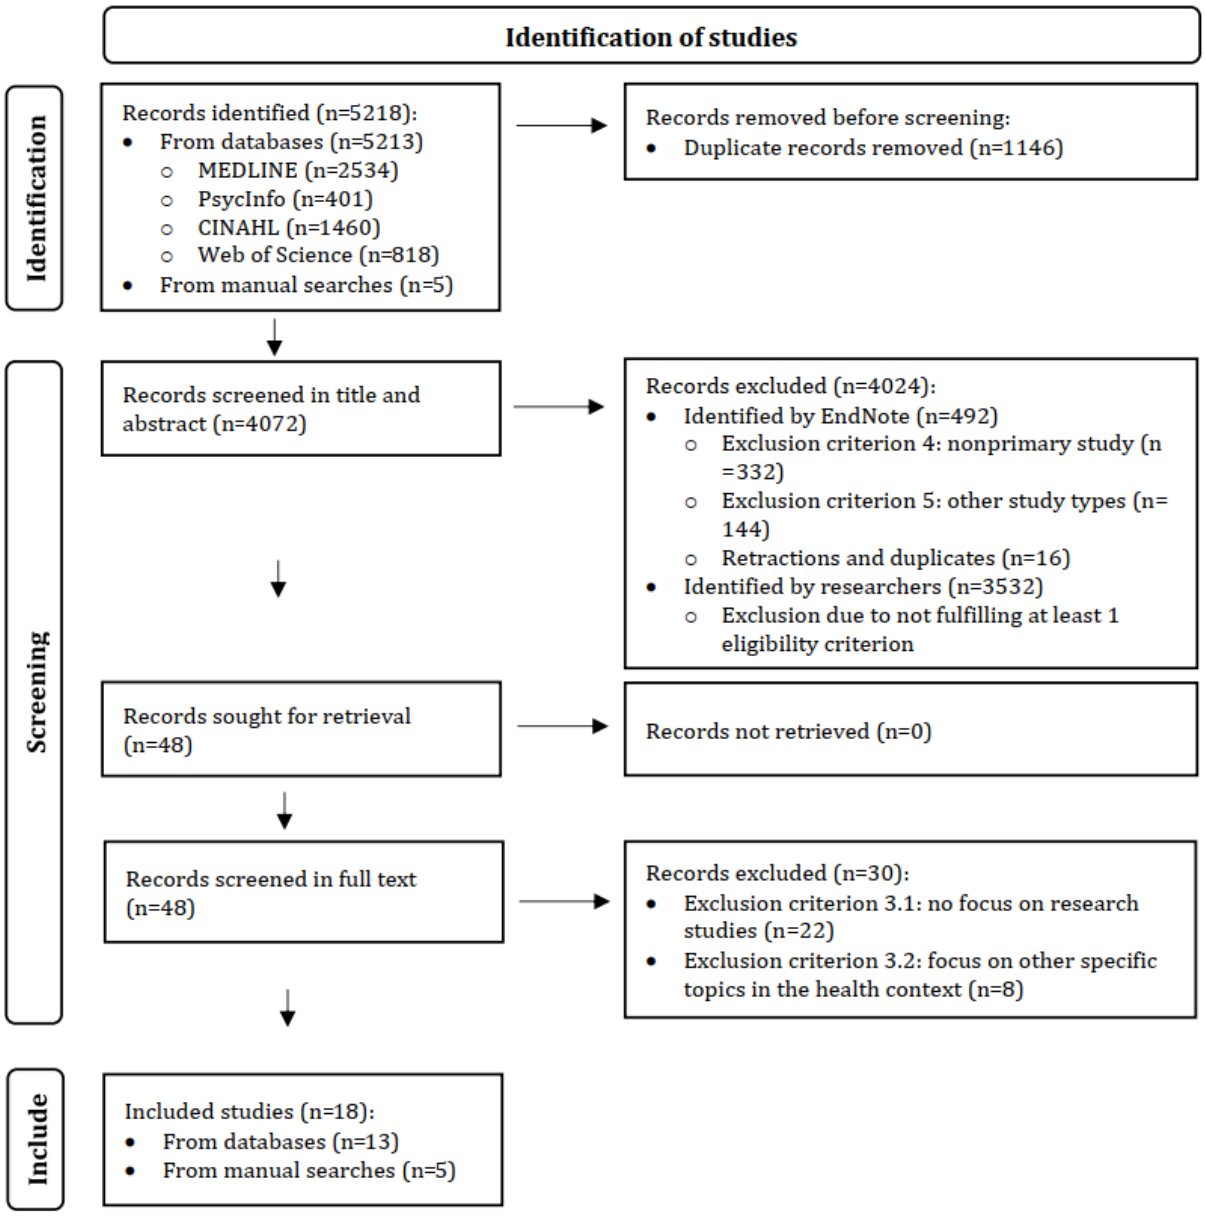
Objective and data item	Data item content or definition
Objective 1 (Studies: design and aim)	
1. Bibliographic characteristics	First author, title, publication year, corresponding author continent, funding source
2. Study characteristics	Design (ie, primary study or report), aim (eg, evaluation or preferences for digital information)
Objective 2 (population)	
3. Population characteristics	Type: Public (ie, laypeople, general population, study participants, and patients) who are primary receivers of digital health information or researchers (eg, any experts, such as academics, health care professionals, or any relevant stakeholders) who are primary providers of digital health information, age, location (continent), health focus (eg, specific disease or any disease)
Objective 3 (concept: digital information exchange)	
4. Modality	Modality according to study authors (eg, website or other)
5. Interactivity	Interactivity implicitly or explicitly described by study authors (ie, passive exchange or interactive exchange)
Objective 4 (context: health study)	
6. Digital exchange content	Content (eg, data exchange, information exchange, or both); if data exchange, type of exchanged data (eg, aggregated study data or individual patient data, or both)
7. Digital exchange aim	Aim (eg, to inform the public about the health study), format (eg, video or other)
Objective 5 (factors associated with digital information exchange)	
8. Facilitators	Factors that could facilitate digital information exchange
9. Barriers	Factors that could hinder digital information exchange
Objective 6 (evidence gaps)	
10. Evidence gaps	Evidence gaps and ideas for future research with a focus on information exchange addressed in studies (eg, conclusion)

Critical Appraisal

Critical appraisal was not performed because this scoping review aimed to describe central topics and questions related to digital information exchange rather than to evaluate the effectiveness of such exchange.

Data Synthesis

The data processed into categories in each study were synthesized for all 18 studies using absolute and relative frequencies or means and SDs in Excel (version 10; Microsoft Corp) to address the 6 objectives of this scoping review. For example, 2 researchers (NS and TD) listed all categories relevant for objective 3 (methods of digital information exchange), counted all studies out of 18 that were assigned into each category, and noted their citations. The main themes in the data were identified by 3 researchers (NS, TD, and KKDS) by discussion. We read all individual categories assigned to each objective and clustered them based on their content. For example, we clustered the categories “active” or “passive” digital information exchange into a main theme “interactivity” as part of the methods of digital information exchange. For objectives 5 (factors associated with digital information exchange) and 6 (evidence gaps), we clustered the categories from individual studies into 3 main themes (ie, facilitators, barriers, and evidence gaps) and reported example author statements to further explain the meaning of each theme. These 3 themes were either explicitly mentioned by the study authors or were derived based on our interpretation of categories assigned to individual studies.



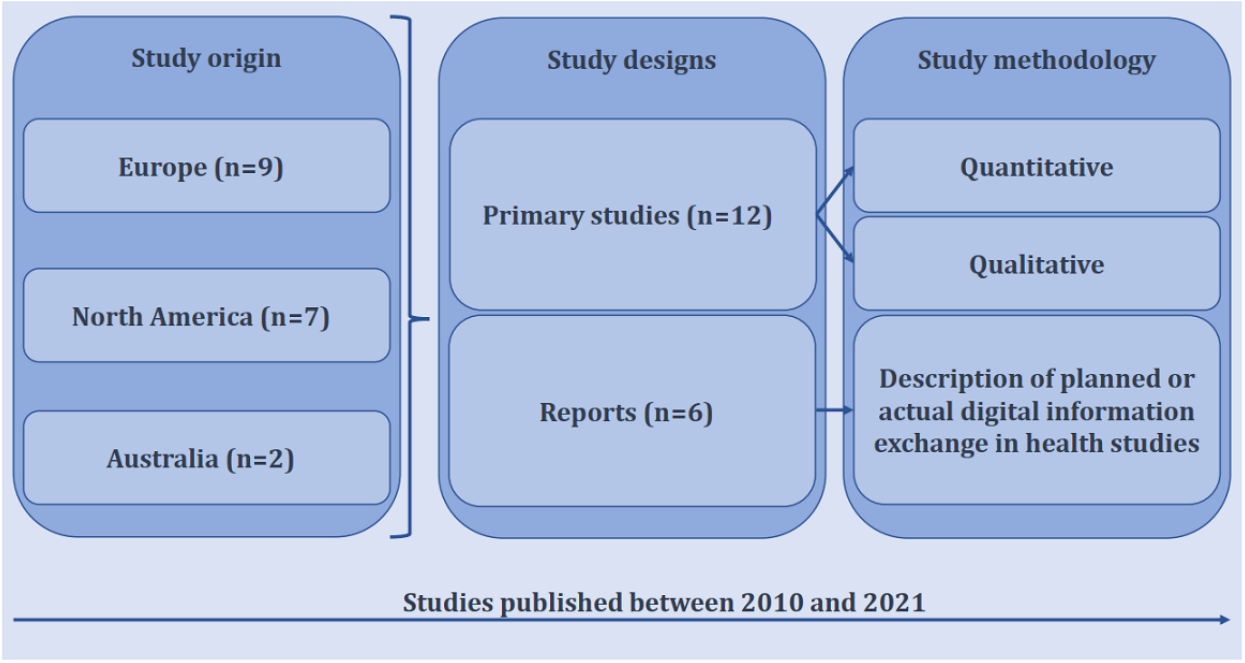
Results

Study Selection

The electronic and manual searches identified 5218 records (Figure 1). Following the removal of duplicates, 4072 records were screened based on the title and abstract and 48 records were screened based on the full text. Overall, 492 of the 4072 records were selected for exclusion using EndNote (ie, nonprimary studies, including reviews and study protocols; other study types, including conference papers, dissertations, and books; and retracted articles or duplicates that were not detected by Deduplicator). Further, 3532 of the 4072 records were excluded as they did not fulfill at least 1 eligibility criterion (Textbox 1). The specific reasons for exclusion of these records were not documented, as suggested by the PRISMA-ScR guidelines [43]. Full-text screening identified 18 of 48 studies [7,45-61] that met the inclusion criteria and were included in this scoping review. The list of the 30 excluded studies with individual reasons for exclusion is presented in Multimedia Appendix 3.

XSL•FO
RenderX

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) flow diagram.

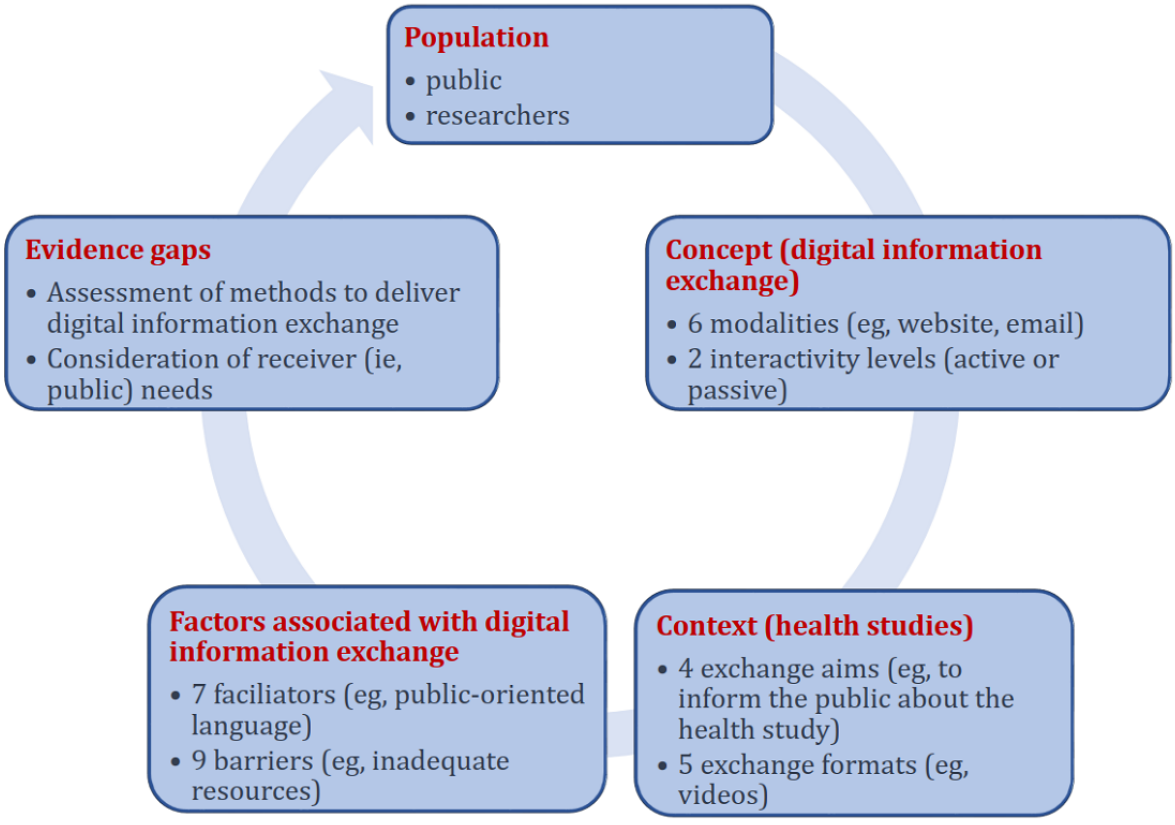


Bibliographic Characteristics of the Included Studies

All charted and processed data from the 18 studies are reported in Multimedia Appendix 4. The 18 studies were published between 2010 and 2021 (Figure 2). The studies originated from Europe (9/18, 50%), North America (7/18, 39%), and Australia (2/18, 11%). Funding source or a lack of funding was reported in 17 (94%) studies.

XSL•FO
RenderX

Figure 2. Characteristics of the 18 included studies.



Objective 1: Study Designs and Aims

The 18 studies included 12 (67%) primary studies [7,45,46,48,50,51,53,54,57,59-61] with quantitative or qualitative data and 6 (33%) reports [47,49,52,55,56,58], which described the actual or planned digital information exchange in health studies (Figure 2). Overall, 12 (67%) studies [45-47,49,54-61] aimed to evaluate the existing strategies for digital information exchange. The remaining 6 (33%) studies [7,48,50-53] assessed preferences for such information exchange.

Objective 2: Population Characteristics

The PCC characteristics of the included studies are summarized in Figure 3.

Figure 3. Characteristics of the 18 included studies based on objectives 2-6 in the scoping review.

XSL•FO
RenderX

All 18 studies addressed digital information exchange for 1 to 2 (mean 1.3, SD 0.5) population types. The addressed populations included the public in 10 (56%) studies [45-47,50,51,54-57,59], the researchers in 2 (11%) [52,53], and both the public and researchers in 6 (33%) [7,48,49,58,60,61].

Among the 18 studies, 9 (50%) [7,46,47,49,54,56,58,59,61] focused on populations in Europe, 4 (22%) [7,51,53,55] focused on populations in North America, and 1 (6%) each focused on populations in Asia [50], Australia [48], or Africa [7]. Overall, 4 (22%) studies [45,52,57,60] did not state the region of the assessed population.

Moreover, among the 18 studies, 7 (39%) [48,50,51,59,60] addressed only adults or adolescents (ie, people aged 18 years or 16 years or older) and 3 (17%) [47,54,55] addressed people of any age (ie, children and adults). In 8 (44%) studies [45,46,49,52,56-58,61], the age of the addressed population was not mentioned.

Most of the 18 studies focused on clinical populations. Overall, 8 (44%) studies [7,47,49,51,53-56] addressed any diseases, 5 (28%) [46,48,57,58,60] addressed specific diseases (eg, rare diseases or chronic kidney disease), and 3 (17%) [45,59,61] addressed any cancer diagnoses. In 2 (11%) studies [50,52], the health focus was not mentioned.

Objective 3: Concept (Digital Information Exchange Methods)

Among the 18 studies, 13 (72%) [45-47,49,51,54-61] described 1 to 6 (mean 1.6, SD 0.7) exchange modalities. All 13 studies described methods of digital information exchange using diverse terminology. According to this terminology, digital information exchange occurred through websites, emails, forums, platforms, social media, or portals (Table 3). Some of those studies (6/13, 46%) [47,54-56,58,61] described multiple modalities of digital information exchange.

Table 3. Digital information exchange methods.

Variable	Studies (N=18), n (%)	Study citation
Modality		
Website	10 (56)	[45,47,49,54-59,61]
Email	3 (17)	[47,51,54]
Forum	3 (17)	[47,55,58]
Platform	2 (11)	[46,60]
Social media	2 (11)	[54,56]
Portal	1 (6)	[61]
Not mentioned	5 (28)	[7,48,50,52,53]
Interactivity		
Active (eg, bidirectional communication via a website with a discussion forum)	4 (22)	[46,56,58,61]
Passive (eg, 1-directional dissemination of information though a website)	3 (17)	[47,55,60]
Any (active or passive)	2 (11)	[45,54]
Not mentioned	9 (50)	[7,48-53,57,59]

Interactivity in the method of digital information exchange was implicitly or explicitly addressed in 9 (50%) studies and not addressed in the remaining 9 (50%) studies. We classified the interactivity of digital information exchange as active, passive, or any (Table 3).

Objective 4: Context (Content and Aim of Digital Information Exchange)

Among the 18 studies, 11 (61%) [45-47,49,55-57,59-61] mentioned exchange content (ie, data or information exchange regarding the health studies) and 7 (39%) [7,48,50-54] did not mention exchange content. Studies that addressed data exchange (3/11, 27%) [47,55,59] mentioned a digital exchange of individual and aggregated study data (1/3, 33%) [47] or only aggregated study data (2/3, 67%) [55,59].

Among the 11 studies [45-47,49,55-61] that addressed exchange content, there were 1 to 3 (mean 1.7, SD 0.7) exchange aims. The exchange aims focused on four themes: (1) to inform the public about the health study, (2) to recruit participants for the health study, (3) to link study participants with each other, and (4) to gather innovative research ideas from study participants (Table 4).

XSL•FO
RenderX

Table 4. Aim and format of digital information exchange.

Variable	Studies (N=18), n (%)	Study citation
Exchange aim		
To inform the public about the health study	10 (56)	[45,47,49,55-61]
To recruit participants for the health study	4 (22)	[49,58,60,61]
To link study participants with each other	3 (17)	[46,47,61]
To gather innovative research ideas from study participants	2 (11)	[46,58]
Not mentioned	7 (39)	[7,48,50-54]
Format		
Video	6 (33)	[46,47,55,56,58,61]
Audio	3 (17)	[46,58,61]
Picture	3 (17)	[46,47,58]
Infographic	1 (6)	[55]
Plain language summary	1 (6)	[58]
Not mentioned	12 (67)	[7,45,48-50,52-54,57,59,60]

Within these 11 studies that addressed exchange content, 6 (33%) [46,47,55,56,58,61] mentioned the format of exchange. Those 6 studies mentioned 1 to 4 (mean 2.3, SD 0.9) exchange formats that included videos, audio data, pictures, infographics, or plain language summaries (PLSs) (Table 4).

Objective 5: Factors Associated With Digital Information Exchange

Among the 18 studies, we identified 7 facilitators of digital information exchange in 17 (94%) [7,46-61] and 9 barriers of digital information exchange in 16 (89%) [7,45,47,48,50-61]. There were 1 to 3 (mean 1.9, SD 0.8) facilitators and 1 to 5 (mean 2.3, SD 1.2) barriers of digital information exchange per study.

Among all 7 facilitators (Table 5; Multimedia Appendix 5), the most commonly identified facilitators in 6 of the 17 studies (35%) were: (1) consideration of any stakeholder perspectives and needs (by clarifying expectations and responsibilities), (2) use of modern or low-cost communication technologies, (3) use of public-oriented language, and (4) continuous communication of the health study process. Further facilitators identified in less than 6 of the 17 studies were: (1) appropriate dissemination of study results to participants, (2) appropriate amount of information content, and (3) interactive co-design of communication.

XSL•FO
RenderX

Table 5. Factors associated with digital information exchange.

Factors	Studies (N=18), n (%)	Study citation
Facilitators of digital information exchange		
Consideration of any stakeholder perspectives and needs to clarify the expectations and responsibilities	6 (33)	[46,48,55,56,58,59]
Use of modern or low-cost communication technologies	6 (33)	[7,47,51,52,55,60]
Use of public-oriented language	6 (33)	[47,50,54,55,57,61]
Continuous communication of the health study process	6 (33)	[7,48,49,53,57,58]
Appropriate dissemination of study results to participants	4 (22)	[7,50,51,53]
Appropriate amount of information content	3 (17)	[47,54,61]
Interactive co-design of communication	2 (11)	[54,58]
Barriers of digital information exchange		
Information exchange not planned in study design or inadequate resources for planned information exchange	9 (50)	[7,48,50-55,61]
Too complex technical language for the public	6 (33)	[45,47,54,56,60,61]
Ethical concerns (eg, breach of anonymity if study participants are brought together)	5 (28)	[51-54,59]
Information exchange not wished from the public (eg, due to anticipated burden of potentially worrying research results, such as the detection of serious clinical symptoms)	4 (22)	[51,52,54,59]
Lack of interactive communication features	4 (22)	[45,54,58,61]
Low trust in digital health information	3 (17)	[58-60]
Poor health literacy among the public	2 (11)	[53,56]
Difficulties with finding or accessing digital health information	2 (11)	[57,60]
No possibility to contact the researchers	1 (6)	[45]

Among all 9 barriers (Table 5; Multimedia Appendix 5), the most commonly identified barriers in 5 to 9 of the 16 studies were (1) information exchange not planned in study design or inadequate resources for planned information exchange, (2) too complex technical language for the public, and (3) ethical concerns. Other barriers identified in less than 5 of the 16 studies were (1) information exchange not wished from the public, (2) lack of interactive communication features, (3) low trust in digital health information, (4) poor health literacy among the public, (5) difficulties with finding or accessing digital health information, and (6) no possibility to contact the researchers.

Objective 6: Evidence Gaps

Among the 18 studies, 9 (50%) [7,45-47,51-53,57,60] identified evidence gaps and provided suggestions for future research. Within these 9 studies, there were 1 to 2 (mean 1.2, SD 0.4) evidence gaps. These evidence gaps indicate that new studies are needed to address two themes: (1) assessment of methods to deliver and facilitate interactive digital information exchange and (2) consideration of receiver (ie, public) needs in the context of digital information exchange (Table 6).

Table 6. Evidence gaps and ideas for future research.

Evidence gaps	Studies (N=18), n (%)	Example statements from the included studies	Study citation
Assessment of methods to deliver and facilitate interactive digital information exchange	7 (39)	"[…], the quality of that information is highly variable, […], few sites offer interactive features. More research is needed to determine the best way of harnessing the power of the Internet—and its progeny, social media—to communicate high-yield cancer-related clinical trial information." ([1], page 1631)	[45-47,51,53,57,60]
Consideration of receiver (ie, public) needs in the context of digital information exchange	3 (17)	"Studies […] identify participants' specific goals with respect to using the information that they receive. Those studies could help researchers and funders gauge the extent to which they should focus on […] referring participants to specific resources, etc." ([53], page 3)	[7,46,52]
No gaps identified	9 (50)	—[a]	[48-50,54-56,58,59,61]

Discussion

Principal Findings

The aim of this scoping review was to identify strategies for digital information exchange between the public and researchers in health studies. Our search identified only 18 peer-reviewed studies or reports that addressed various aspects of this topic. In general, very few details regarding such digital information exchange were reported. All studies described the actual or planned digital information exchange and focused mainly on receivers of health information, who were predominantly adult and clinical populations. The modality of digital information exchange was referred to using heterogeneous terminology, including websites, platforms, or portals. Exchange content included mostly health information and seldom study or individual patient data. Despite suggesting that digital information exchange should aim to inform, recruit, link, or gather innovative research ideas from participants in health studies, only half of the included studies addressed the issue of interactivity (ie, if digital information exchange is or should be active or passive). In addition, there were more barriers than facilitators associated with digital information exchange identified in the included studies. Thus, a key finding of this scoping review is the notable gap in evidence around standardized methods for digital information exchange in health studies. It is unclear how such digital information exchange should be designed and implemented across various platforms and audiences. Since digital platforms are increasingly used to share health research, evidence-based guidance on the best practices is needed to ensure that digital information exchange is effective, engaging, and accessible to a wide range of audiences, and contributes to long-term health benefits. This review identified several facilitators and barriers impacting digital information exchange that could be considered by researchers who plan such an exchange in their health studies. Overall, new studies are needed to assess the methods and public needs required to design, implement, and facilitate interactive digital information exchange.

General Benefits of Digital Information Exchange in Health Studies

The past literature suggests that public participation and interest in clinical or medical trials has a positive impact on the visibility and influence of the trials [1,62] and that the aspect of participation has gained importance in recent decades, both scientifically and politically [8,63,64]. For example, digital information exchange between the public and researchers can enhance the inclusivity, accessibility, and acceptance of research among the public and ensure that research delivery aligns with their needs [62]. In addition, the COVID-19 pandemic has led to an increase in the development and use of digital portals with health data [33]. Digital information exchange methods like apps can facilitate communication between the public and health care providers by providing users access to health information, with consideration of challenges, such as privacy and security concerns, reliability, and accuracy of health information, through implementation to maximize their effectiveness [65].

Content and Format of Digital Information Exchange in Health Studies

The studies included in this review suggest that digital information exchange should aim to inform, recruit, link, or gather innovative research ideas from participants in health studies. While most studies described the digital exchange of health information (eg, information on study content), only 3 studies addressed digital exchange of data [47,55,59]. Such data could include individual patient data [47] or aggregated study data [55,59]. In general, sharing of study data may be problematic due to ethical and legal reasons [66]. The investigation of study participant preferences for receiving research results [51] showed a spectrum of positive and negative responses, including anxiety, anger, guilt, relief, and pleasure, associated with receiving research results. Despite some negative responses, a median of 90% of participants reported the need to receive study results [51]. However, generalizing the results of studies on participant reactions and preferences regarding receiving research results is challenging due to relatively small sample sizes in such studies and a focus on specific and sensitive issues relevant for the targeted populations. Thus, different target populations may have potentially different needs for obtaining any study results or individual data.

Several formats of digital information exchange are available due to technological advancements, including not only text-based information but also other formats identified in this review, such as videos, blogs, and graphics. Given the effectiveness of PLSs based on comprehension, understanding, and enjoyment over graphical abstracts or published abstracts [67] and the availability of various PLS templates for several decades [68], it is surprising that this form of digital information exchange was mentioned in only 1 study in this review [58]. We have shown that studies with health content, such as Cochrane reviews that have mandatory PLSs according to Cochrane guidelines, are frequently mentioned online via channels accessible by the public (eg, social media, blogs, news, Wikipedia, and others) [69]. Although it is unclear how the public uses such information, exposure to information on health studies written in a nontechnical language could positively affect digital information exchange in terms of informing the public about health research. Health studies planning the digital information exchange of health data should consider the needs of different groups of relevant stakeholders. For example, target group–specific language should be used, and a lack of such language was frequently identified as a barrier to digital information exchange in this scoping review. This addresses both the lack of consideration mentioned above and the added value of this form of communication, which has been confirmed in previous studies [57,67].

According to the findings of this review, videos were the most used digital information exchange method. As suggested by others [67], if the research findings are of public relevance, researchers might consider investing time and money into creating a video of their results, as videos make viewers feel confident and positive about the presented research. However, other formats and methods, such as communication via interactive apps with gamification [70], could also be used in digital information exchange, enabling direct feedback options.

Facilitators and Barriers of Digital Information Exchange in Health Studies

The results of this scoping review showed that websites, forums, and portals are the main methods of digital information exchange for connecting with the desired audience online. Despite the benefits of interaction as a form of participation (by or for the public) [71], only half of the identified studies provided information on the possibility of active or passive interaction (Table 3). Thus, despite the social relevance and the potential benefits, digital interaction between information providers (ie, researchers) and receivers (ie, the public) was neglected in the identified studies. Another review [72], which included 28 studies on patient participation, indicated that an average of 90% of participants were interested in their own or general study results. Another study also showed that individuals who requested study results did not receive feedback on these requests [51]. There could be several explanations for this finding as evident in the list of facilitators and barriers associated with digital information exchange identified in this review (Table 5). The main barrier to dissemination was that communication was not planned in the initial study design. Research suggests that even when community-based participatory research is conducted with public involvement as a central element, no more information is disseminated than is actually published in the form of a scientific publication [73]. One reason for this could be that study participants explicitly express no interest in receiving their own study results. This could be due to anticipated burden of potentially worrying research results, such as the detection of serious clinical symptoms [74].

Other key aspects that should be considered to improve the communication of study results and the communication of health information are adequate interaction with the information provided and an appropriate volume of such information. The latter is also a barrier to the dissemination of information and can be related to the poor health literacy among the public. Information can be burdensome when it seems too complex and not tangible [75]. The filtering function could be used to counteract potential information overload [76]. This approach suggests that interactivity rather than a passive provision of health information is necessary. Incorporating interactivity when sharing research studies with the public can increase engagement, improve understanding, and make complex information more accessible [77]. Examples of interactive communication methods are interactive graphs and maps that show data over time (eg, COVID-19 spread) to help users explore trends [78], interactive quizzes [79], and serious games related to study content that can improve health literacy or online forums where people can discuss the research findings, give feedback, and see responses [80].

This scoping review also identified several facilitators that can strengthen communication between researchers and the public as well as increase trust in the information presented online (on websites or portals). In particular, the trustworthiness of information is a relevant aspect to be addressed in future studies [81]. To improve trust in health information online, such information could be discussed with health professionals who continue to be important reference persons [82].

Evidence Gaps

Evidence gaps in the included studies suggest that appropriate methods required to deliver and facilitate interactive digital information exchange need to be identified in future research. Furthermore, the preferences and needs of the receiver (ie, public) to facilitate such digital information exchange should be investigated. Interestingly, the consideration of the preferences and needs of the target populations (ie, the public being the health information receivers) was mentioned as a requirement for future studies already several years ago [7,46,52] and was the most commonly reported facilitator of digital information exchange in this review (Table 4).

Strengths and Limitations

The main strength of this review is that it addresses a highly relevant topic on how information generated in health studies can be exchanged between the public and researchers using digital methods. In particular, we identified a detailed list of facilitators and barriers associated with digital information exchange that could be considered in health studies. The literature search was supervised and performed by an experienced information specialist, and a standardized methodological approach was used to select studies and extract, process, and synthesize the data.

The main limitation of this review is the difficulty in finding relevant studies in bibliographic databases. Identifying the most suitable terminology for our objectives was challenging because some of the less specific search terms, such as public and health studies, frequently appear in diverse contexts within the health literature. Despite numerous iterations, our search syntax identified only 18 studies published up to 2021 that met the inclusion criteria. It cannot be ruled out that we missed other published studies that did not include our search terms in their titles, abstracts, or other searched fields. However, the peer-reviewed literature on this topic might be truly limited, as it is possible that researchers do not report how they share research results with the public in their studies even if they do so. Thus, we would like to encourage researchers working on health studies to comment on and share their experiences regarding digital information exchange from such studies in academic articles. Other research designs, such as comprehensive assessments of existing online data sharing databases and portals and qualitative interviews with health information providers and receivers, could be used to further investigate digital information exchange in health studies as the field evolves.

Furthermore, there was relatively little information available on the details of digital information exchange in the included studies. Despite this, we identified various factors that may help other researchers to facilitate digital information exchange and reduce the barriers in such an exchange. Although our list of such facilitators and barriers is extensive, further factors may exist that need to be identified in future research. Finally, probably due to the fact that the included studies were somewhat dated (ie, published up to 2021), we could not identify any studies discussing more recent methods of digital information exchange, such as study-related communication via apps or the use of artificial intelligence in supporting such communication.

XSL•FO
RenderX

One example of a relevant app is PIA (Prospective Monitoring and Management App) developed for monitoring, managing observational epidemiological studies, and systematically collecting user feedback [70].

Conclusions

This scoping review describes how digital information exchange occurs between the public and researchers in health studies. Our search strategy identified only 18 studies on this topic that were published mostly in Western countries (Europe and North America) between 2010 and 2021. In these studies, there was little focus on interactivity in digital information exchange, and more barriers than facilitators of such an exchange were identified. The facilitators and barriers associated with digital information exchange offer crucial insights for gaining a deeper understanding of how effective digital information exchange can be designed and implemented. Given the evidence gaps identified in the included studies, further research is needed to explore how to improve digital information exchange between the public and researchers. Future studies should investigate interactive digital methods and receiver preferences and needs required for such an exchange.

Acknowledgments

We thank Lisa Stiens (Leibniz Institute for Prevention Research and Epidemiology) for her assistance with screening. The study was performed as part of the NFDI4Health (National Research Data Infrastructure for Personal Health Data) Consortium [41]. The consortium is publicly funded by the German Research Foundation (Deutsche Forschungsgemeinschaft) under project number 442326535.

Data Availability

The datasets generated and analyzed during this study are reported in the article and multimedia appendices.

Authors' Contributions

NS conceptualized the study; developed the methodology; selected the studies; extracted, processed, and analyzed the data; visualized the results; wrote the first draft of the manuscript; and reviewed and edited the manuscript. TD extracted, processed, and analyzed the data; visualized the results; wrote the first draft of the manuscript; and reviewed and edited the manuscript. DO performed pilot data extraction and reviewed and edited the manuscript. JD and KR conceptualized the study, developed the methodology, selected the studies, and reviewed and edited the manuscript. LC developed the methodology, performed bibliographic searches, and reviewed and edited the manuscript. KKDS developed the methodology, selected the studies, wrote the first draft of the manuscript, and reviewed and edited the manuscript. HZ conceptualized the study, developed the methodology, and reviewed and edited the manuscript.

Abstract

Background: Lifestyle interventions have been acknowledged as effective strategies for preventing type 2 diabetes mellitus (T2DM). However, the accessibility of conventional face-to-face interventions is often limited. Digital health intervention has been suggested as a potential solution to overcome the limitation. Despite this, there remains a significant gap in understanding the effectiveness of digital health for individuals with prediabetes, particularly in reducing T2DM incidence and reverting to normoglycemia.

Objective: This study aimed to assess the effectiveness of different intervention modes of digital health, face-to-face, and blended interventions, particularly the benefits of digital health intervention, in reducing T2DM incidence and facilitating the reversion to normoglycemia in adults with prediabetes compared to the usual care.

Methods: We conducted a comprehensive search in 9 electronic databases, namely MEDLINE, Embase, ACP Journal Club, Cochrane Central Register of Controlled Trials, Cochrane Database of Systematic Reviews, Cochrane Clinical Answers, Cochrane Methodology Register, Health Technology Assessment, and NHS Economic Evaluation Database through Ovid, from the inception to October 2024. This review included randomized controlled trials (RCTs) that studied the effectiveness of lifestyle interventions in adults with prediabetes. The overall intervention effect was synthesized using a random-effects model. The I^2 statistic was used to assess heterogeneity across the RCTs. We performed a subgroup analysis to explore the effectiveness of digital health, face-to-face, and blended interventions compared with the control group, which received usual care.

Results: From an initial 7868 records retrieved from 9 databases, we identified 54 articles from 31 RCTs. Our analysis showed that face-to-face interventions demonstrated a significant 46% risk reduction in T2DM incidence (risk ratio [RR] 0.54, 95% CI 0.47-0.63; I^2=43%; P<.001), and a 46% increase in the reversion to normoglycemia (RR 1.46, 95% CI 1.11-1.91; I^2=82%; P=.006), when compared with the control group. On the other hand, digital health interventions, compared with the control group, were associated with a 12% risk reduction in T2DM incidence (RR 0.88, 95% CI 0.77-1.01; I^2=0.6%; P=.06). Moreover, the blended interventions combining digital and face-to-face interventions suggested a 37% risk reduction in T2DM incidence (RR 0.63, 95% CI 0.49-0.81;I^2<0.01%; P<.001) and an 87% increase in the reversion to normoglycemia (RR 1.87, 95% CI 1.30-2.69; I^2=23%;

XSL•FO
RenderX

P=.001). However, no significant effect on the reversal of prediabetes to normoglycemia was observed from the digital health interventions.

Conclusions: Face-to-face interventions have consistently demonstrated promising effectiveness in both reductions in T2DM incidence and reversion to normoglycemia in adults with prediabetes. However, the effectiveness of digital health interventions in these areas has not been sufficiently proven. Given these results, further research is required to provide more definitive evidence of digital health and blended interventions in T2DM prevention in the future.

KEYWORDS

mobile phone; prediabetic state; digital health intervention; intervention mode; lifestyle intervention; type 2 diabetes mellitus; meta-analysis; systematic review; review

Introduction

Type 2 diabetes mellitus (T2DM) is a significant global public health issue. Up to 2021, there were 529 million individuals with T2DM [1], and 6.7 million deaths attributable to T2DM [2] with a cost of over a trillion dollars in health care worldwide [3].

Prediabetes is a high-risk condition for developing T2DM [4]. Without appropriate interventions, 5% to 18% of prediabetes will progress to T2DM annually [5]. In 2018, the estimated prevalence of prediabetes among Chinese adults was 38%, highlighting the urgent need for early interventions to prevent the progression to T2DM.

According to the World Health Organization (WHO) definition provided in 1998, a lifestyle intervention aims to modify an individual's way of living and improve their physical and psychological health by changing patterns of behavior that are harmful to health [6]. There is substantial evidence indicating that lifestyle interventions can prevent T2DM progression [7-9], and even reverse prediabetes to normoglycemia [10,11]. However, most of this evidence stems from face-to-face interventions, which are time-consuming and reach a limited audience. Digital health intervention, defined as a discrete functionality of digital technology, is applied to achieve health objectives and is implemented within digital health applications, including SMS, smartphones, and wearable devices, to achieve health objectives. Meanwhile, it offers immense opportunities for self-management and the prevention of chronic diseases [12-14].

While previous meta-analyses have demonstrated the effectiveness of digital health interventions in promoting physical activity and dietary changes, leading to weight loss and improved glucose control in individuals with prediabetes [15-17], evidence regarding their effectiveness in reducing T2DM incidence and reverting prediabetes to normoglycemia remains limited. Therefore, T2DM incidence and reversion to normoglycemia are essential endpoints for providing evidence on the application of digital health interventions in T2DM prevention.

This systematic review and meta-analysis aims to evaluate the effectiveness of face-to-face, digital health, and blended interventions in reducing T2DM incidence and reversing prediabetes to normoglycemia based on randomized controlled trials (RCTs).

Methods

Overview

The systematic review followed the PRISMA (Preferred Reporting Items for Systematic Review and Meta-Analysis) 2020 checklist [18]. The review protocol was registered at PROSPERO (International Prospective Register of Systematic Reviews; CRD42023414313).

Search Strategy and Eligible Criteria

Electronic searches of 9 databases (MEDLINE, Embase, ACP Journal Club, Cochrane Central Register of Controlled Trials, Cochrane Database of Systematic Reviews, Cochrane Clinical Answers, Cochrane Methodology Register, Health Technology Assessment, and NHS Economic Evaluation Database) were done through Ovid. We performed the initial search on May 31, 2022, and updated the search on October 2, 2024, with no language restrictions. The search terms were developed in consultation with librarians incorporating MeSH (Medical Subject Headings) terms and text words and piloted before being used in the current review. The search strategy was: "prediabetes or high-risk of diabetes" and "lifestyle intervention or digital health intervention" and "RCTs." The detailed search strategy can be found in Multimedia Appendix 1 [15,19]. The reference lists of the included studies and previous reviews were thoroughly hand-searched to identify any additional relevant research. The eligibility criteria were guided by the Population, Intervention, Comparison, Outcome, and Study Design (PICOS) framework, as illustrated in Textbox 1.

XSL•FO
RenderX

Textbox 1. Population, Intervention, Comparison, Outcome, and Study Design (PICOS) to determine the eligibility

Inclusion criteria

- Population
- Prediabetes, including impaired fasting glucose, impaired glucose tolerance, impaired fasting glucose and impaired glucose tolerance, elevated hemoglobin A_{1c}, and intermediate hyperglycemia by different guidelines (Multimedia Appendix 2 [20-25])
- Intervention
- Lifestyle intervention (see "Definition and Examples of Lifestyle Intervention") lasted for at least 1 year.
- Comparison
- Usual care.
- Outcome
- Type 2 diabetes mellitus incidence or reversion to normoglycemia.
- Study design
- Randomized controlled trial.

Exclusion criteria

- Population
- High risk of diabetes identified by risk scores.
- Intervention
- Pharmacological intervention or a combination of pharmacological and lifestyle intervention.
- Comparison
- Pharmacological intervention.
- Outcome
- Intermediate outcomes such as weight loss.
- Study design
- Nonrandomized controlled trial.

A total of 2 authors (YCW and XC) independently screened the titles and abstracts of studies and assessed the full text for eligibility. Disagreements, if any, were resolved through discussion with a third author (XJY). For efficient management of the selection process, all retrieved studies were imported into Covidence.

Definition and Examples of Lifestyle Intervention

According to the 1998 World Health Organization definition, a lifestyle intervention aims to modify an individual's way of living and improve their physical and psychological health by changing patterns of behavior that are harmful to health [6].

For example, in our meta-analysis, the behavior pattern changes mainly include nutrition, physical activity, and weight management.

Data Extraction and Quality Assessment

Data extraction was carried out independently using standard data extraction forms. Extracted data included (1) study information (author, year of publication, and study location); (2) study participants (prediabetes phenotype, diagnostic criteria, ethics, age, the proportion of male participants, baseline, BMI, fasting plasma glucose [FPG], and sample size); (3) intervention and control details (the intervention treatment, the control group, intervention settings, delivery format, intervention mode, intervention duration, and the follow-up duration was defined from the intervention year to the first year in which reported T2DM incidence occurred, as well as the time to reversion to normoglycemia); (4) for the studies applying digital health interventions, the theoretical framework, intervention adherence, digital health intervention categories, and its intervention components categorized by the WHO [26]; (5) outcome measurements; and (6) key study results including T2DM events, proportion or numbers of individuals reverting to normoglycemia and effect size between intervention group and control group.

The risk of bias was assessed using the revised Cochrane Risk-of-Bias tool (RoB 2.0) for randomized trials [27]. The assessment considered the following elements: (1) randomization process, (2) deviations from intended interventions, (3) missing outcome data, (4) measurement of the outcome, (5) selection of the reported result, and (6) overall bias.

Data extraction and quality assessment were independently carried out by 2 authors (YCW and XC). Any disagreements between the 2 authors were resolved through discussion or with a third author (XJY).

Synthesis of Results

Results were sought for both baseline and end-of-intervention or postintervention outcome data, specifically focusing on the data that first observed the primary outcome. If the original article provided 95% CI or SE without SD, we converted them into SD, following the guidelines in the Cochrane Handbook for Systematic Reviews of Interventions [27]. To facilitate the interpretation of the findings, we used standardization techniques to unify measurement units across studies. Both blood glucose and blood lipids indicators were measured in mmol/L, except hemoglobin A_{1c} (HbA_{1c}) in percentage.

The primary outcomes of this systematic review and meta-analysis were the incidence of T2DM and the reversion from prediabetes to normoglycemia, both compared with the usual care, expressed in terms of risk ratios (RRs), hazard ratios, or odds ratios. Secondary outcomes encompassed the changes in blood glucose, specifically FPG, 2-hour postprandial glucose, and HbA_{1c}. This study also examined variations in key indicators including body weight, BMI, waist circumference, blood pressure, and blood lipid profiles. The lipid profiles encompass triglycerides, high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, and total cholesterol.

Statistical Analysis

Intervention effects were defined as the differences in outcomes between the intervention and control groups. For dichotomized outcomes, synthesized measures were presented as RRs; and for continuous outcomes, we presented mean differences. The pooled estimates were synthesized by random-effect models and presented in the forest plots. The I^2 statistic was used to assess statistical heterogeneity between trials. For studies with 2 or more intervention groups, each group was treated independently and annotated in the forest plots [28].

A prespecified subgroup analysis was conducted to assess the effectiveness of digital health interventions, face-to-face lifestyle interventions, and the combined application compared with the usual care. The subgroups were categorized into 3 intervention modes [29], face-to-face, digital health, and blended. Based on the provision of behavioral support, digital health interventions can be divided into stand-alone interventions and digital support interventions (Textbox 2). Sensitivity analysis was conducted to verify the robustness of the pooled RRs. Funnel plot and Egger test were used to investigate the publication bias [30]. All analyses were carried out using Stata (version 16.0; StataCorp). We considered *P* less than .05 as significant.

Textbox 2. Categories of examples of intervention modes based on the provision of behavioral supports.

(i) Face-to-face interventions

- In-person support from a counselor face-to-face: for example, group sessions on lifestyle modification.

(ii) Digital health interventions

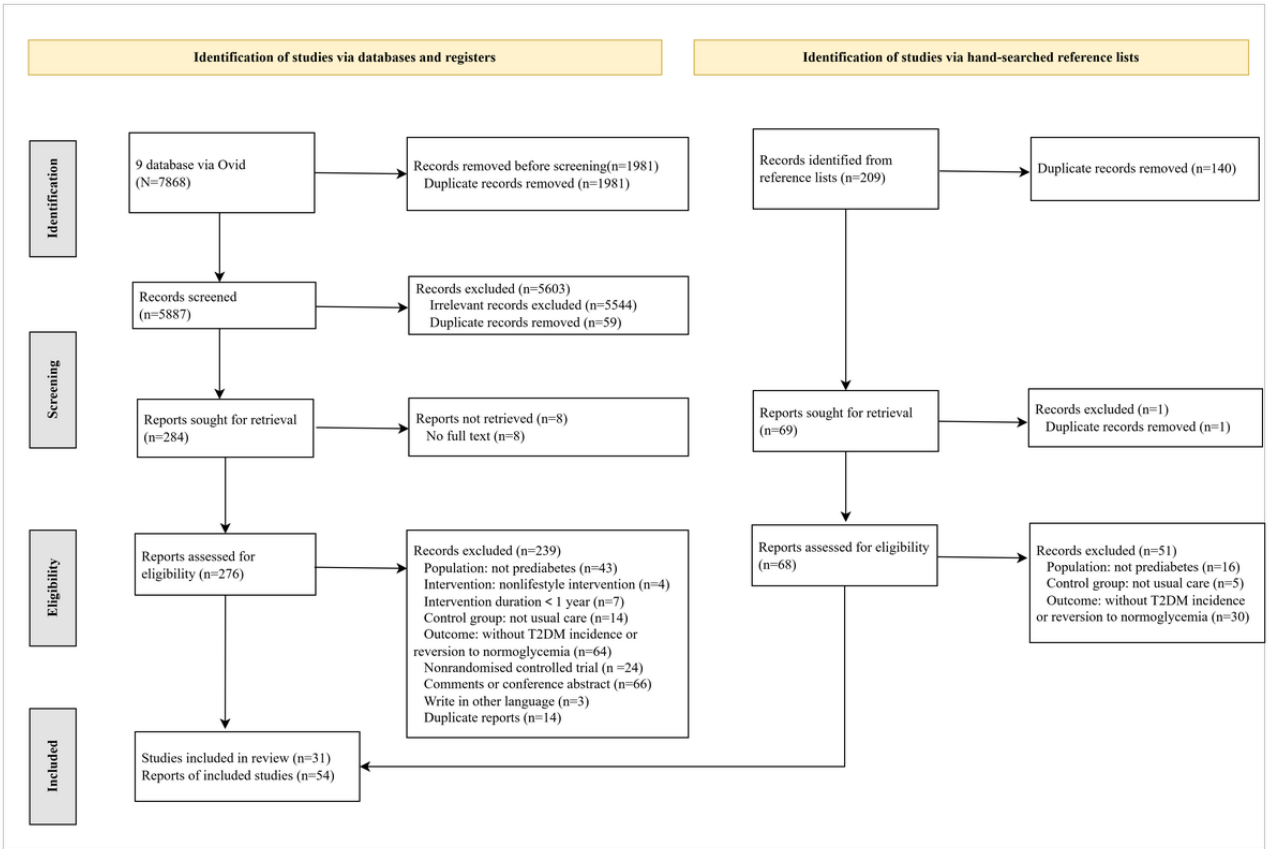
- Stand-alone interventions: participants were not offered ongoing support from a counselor. For example, self-management or self-monitor smartphone apps.
- Digital support intervention: remote support with behavioral support through mobile health technologies. For example, emails, text messaging prompts, or phone calls with a counselor.

(iv) Blended interventions

- Combination of face-to-face intervention and digital health intervention.

Ethical Considerations

This review does not involve human subject information, primary data collection, or any form of experimentation on individuals.



Results

Study Selection

The database search yielded 7868 articles from the 9 databases and identified 37 articles as eligible. We manually identified an additional 209 articles from the reference list of relevant reviews, of which 17 articles were deemed eligible. Finally, a total of 54 articles from 31 studies met the eligibility criteria and were included in the review (Figure 1).

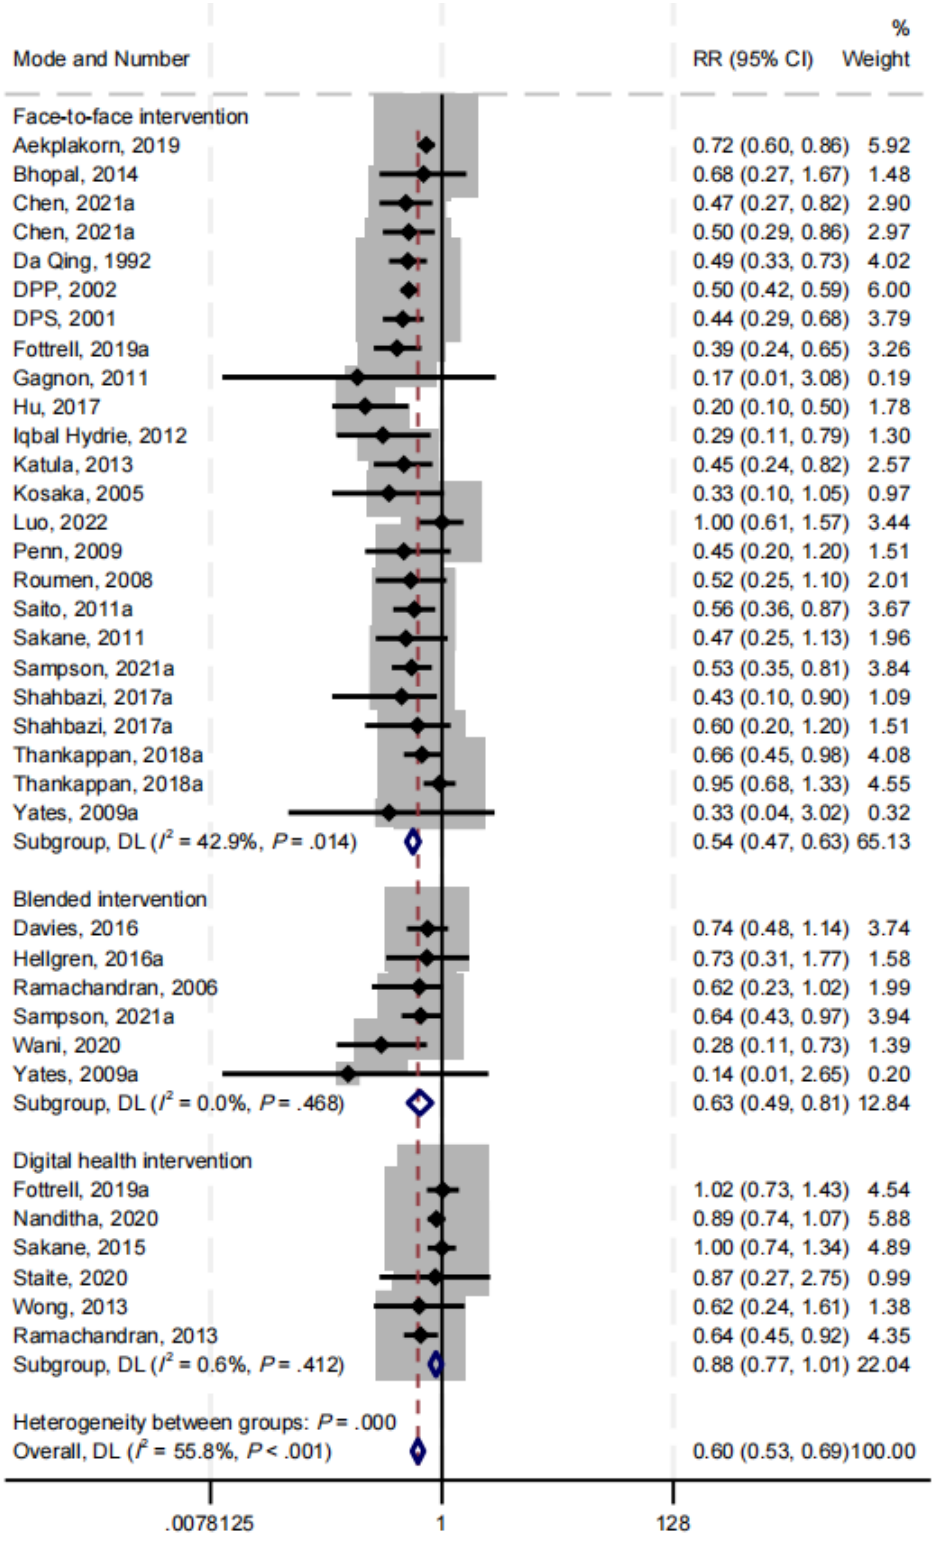
Study Characteristics

Baseline characteristics of the included studies are shown in Multimedia Appendix 3 [7-11,31-56]. The systematic review and meta-analysis included 23,684 individuals with prediabetes in total, with studies ranging from 48 to 2865 participants. Prediabetes identifications were primarily based on the WHO criteria since 1999 (15/31, 48%), which defined prediabetes by FPG of 6.1 to 6.9 mmol/L or 2-hour postprandial glucose of 7.8 to 11.0 mmol/L (Multimedia Appendix 2 [20-25]). Among the included studies, the majority (18/31, 58%) reported an average participant age exceeding 50 years. Among 31 studies, 30 studies reported the T2DM incidence as the outcome [7-11,31-54,57], and 10 studies reported the reversion to normoglycemia as the outcome [8-11,36,38,39,44,53,55].

Description of Interventions

Intervention characteristics are outlined in Multimedia Appendix 3 [7-11,31-56], including intervention content, comparative interventions, settings, delivery method, intervention duration, and follow-up duration. Intervention durations and follow-up durations across the studies varied, ranging from 1 to 6 years. A majority of the studies (22/31, 70% [7-10,35-38,40-44,46-52,55,57]) used face-to-face intervention, 6 studies used digital health intervention [10,11,32,34,45,54], and 6 studies used blended intervention [31,33,39,50,53,57]. No study with digital health intervention used stand-alone intervention. In the face-to-face interventions, group sessions (22/28, 79%) were the most common delivery format applied (Multimedia Appendix 3 [7-11,31-56]).

Of all the studies that included digital health components, SMS text messaging (5/12, 42%) and telephone contacts (6/12, 50%) were the most used. One of these studies used a web-based approach [11], and 3 studies used wearable technology [11,31,58]. According to the WHO classification of digital health interventions, targeted client communication was the most used digital health category (11/12, 92%), followed by personal health tracking (4/12, 33%). Transmitting targeted health information to clients was the intervention mostly used in targeted client communication including behavior change communication, health promotion communication, and client-centered SMS text messaging. Among the 12 studies that included digital health interventions, only 5 were published within the last 5 years [10,11,45,50,53]. The transtheoretical model of behavioral change and social cognitive theory was the most common theoretical method used in digital health interventions.



Main Outcomes

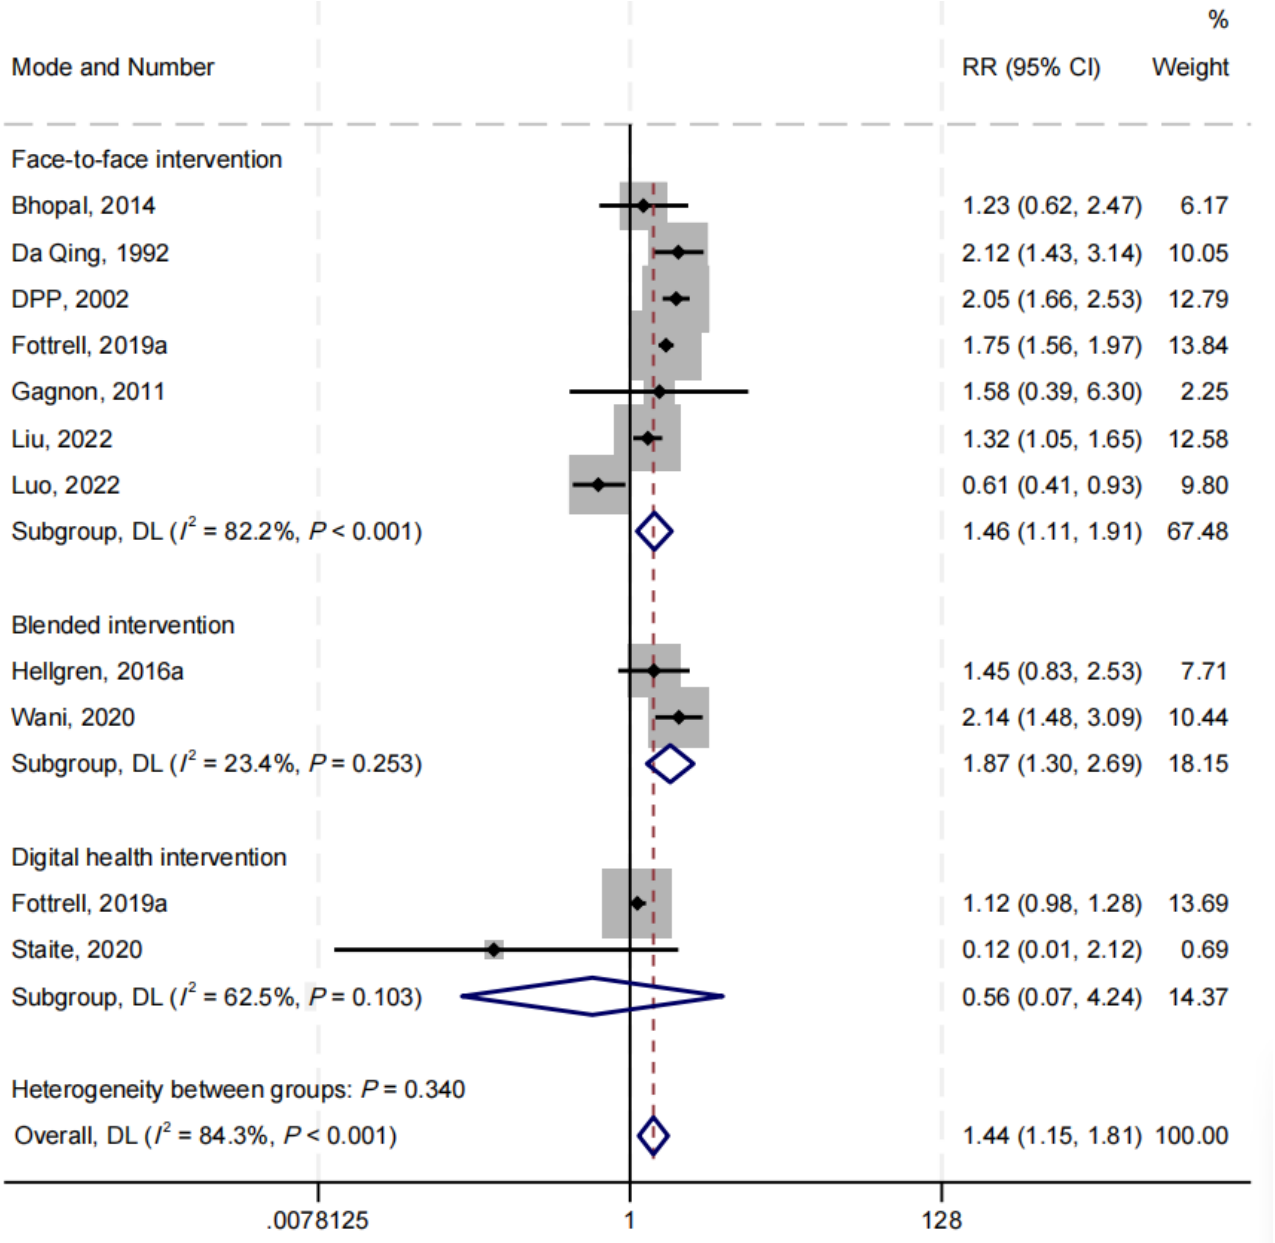
Type 2 Diabetes Mellitus Incidence

The pooled estimate of 30 studies revealed the significant effectiveness of lifestyle interventions in reducing the incidence of T2DM (RR 0.60, 95% CI 0.53-0.69; I^2=55%; P<.001; Figure 2).

XSL•FO
RenderX

Figure 2. The forest plot on the reduction of type 2 diabetes mellitus incidence by intervention mode subgroups (face-to-face, blended, and digital health interventions) compared with the usual care group [7-11,26-30,51-70]. Multiple intervention arms within a single study were treated as distinct intervention groups. DL: DerSimonian-Laird, a method to estimate the heterogeneity variance.

In subgroup analysis, face-to-face interventions were found to reduce the incidence of T2DM among adults with prediabetes by 46% (RR 0.54, 95% CI 0.47-0.63; I^2=43%; P<.001) compared with the control group (Figure 2). The digital health interventions (RR 0.88, 95% CI 0.77-1.01; I^2=0.6%; P=.06) observed a 12% risk reduction in T2DM incidence compared with the control group, although no statistical difference was observed. Notably, one study reported a 36% risk reduction in T2DM incidence through SMS test messaging [32]. However, no statistically significant difference was observed in the other two similar studies, despite observing a reduction in T2DM incidence [33,57]. Studies using telephone contacts and voice messages did not report any significant reduction in T2DM incidence [10,34]. The blended interventions (RR 0.63, 95%



XSL•FO
RenderX

CI 0.49-0.81; I^2<0.01%; P<.001) observed a 37% risk reduction in T2DM incidence compared with the control group.

Reversion From Prediabetes to Normoglycemia

A total of 10 studies were included in the meta-analysis of reversion from prediabetes to normoglycemia [8-11,36,38,39,44,53,55]. Compared with the control group, the lifestyle intervention group demonstrated a 44% increase in the rate of reversion from prediabetes to normoglycemia (RR 1.44, 95% CI 1.15-1.81; I^2=84%; P<.001; Figure 3).

Figure 3. The forest plot on reversion to normoglycemia by intervention mode subgroups (face-to-face, blended, and digital health interventions) compared with the usual care group [8-11,52,54,55,60,69,71]. Multiple intervention arms within a single study were treated as distinct intervention groups. DL: DerSimonian-Laird, a method to estimate the heterogeneity variance.

In subgroup analysis (Figure 3), the face-to-face intervention and blended intervention group exhibited significant effectiveness by 46% (RR 1.46, 95% CI 1.11-1.91; I^2=82%; P=.006) and 87% (RR 1.87, 95% CI 1.30-2.69; I^2=23%; P=.001) increase in reversion to normoglycemia compared with the control group, respectively. A total of 2 studies used digital health interventions: one used voice messages [10], while the other incorporated wearable technology, web-based education, and motivational SMS text messages [11]. In the digital health intervention group, neither of the 2 studies observed significant effectiveness of digital health interventions on the reversion of prediabetes to normoglycemia. One study [10] observed the potential effectiveness on reversion but produced no statistical difference (RR 1.12, 95% CI 0.98-1.28) [10]. In another study [11], the CI was too wide to determine the effect (RR 0.12, 95% CI 0.01-2.12).

Secondary Outcomes

Face-to-face interventions' standard mean difference (SMD=–0.25, 95% CI –0.35 to –0.15; I^2=48%; P<.001)

XSL•FO
RenderX

demonstrated a significant decrease in weight loss than digital health interventions (SMD=–0.07, 95% CI –0.17 to 0.03; I^2=48%; P=.15). Similarly, reductions in waist circumference, BMI, FPG, 2-hour postprandial glucose, HbA_{1c}, systolic blood pressure, diastolic blood pressure, and TG were more effectively pronounced in the face-to-face intervention. Contrarily, low-density lipoprotein cholesterol showed a significant decrease through digital health interventions (SMD=–0.10, 95% CI –0.19 to –0.02; I^2=0%; P=0.01) while no effectiveness was observed in face-to-face interventions (SMD=–0.13, 95% CI –0.41 to 0.14; I^2=81%; P=.34; Multimedia Appendix 4).

Risk-of-Bias Assessment and Publication Bias

Among 30 studies that reported T2DM incidence as the outcome, 10 studies were classified as “low risk” [9,10,32,36,42,44,45,48,52,56], 7 studies as having “some concerns” [7,8,31,33,39,40,54], and the remaining 13 studies as “high risk” [11,34,35,37,38,41,43,46,47,49-51,53], assessed by RoB 2.0 judgment. Among the 10 studies that reported reversion to normoglycemia as the outcome, 4 studies were classified as “low risk” [9,10,36,44], 2 studies as having “some concerns” [8,39], and the remaining 4 studies as “high risk” [11,38,53,55] (Multimedia Appendix 4). The high risk of bias primarily stemmed from the biased selection of reported results, followed by missing outcome data. In other domains, most studies were considered low risk. Publication bias was detected for T2DM incidence (Egger test P=.02), but not for prediabetes reversion (Egger test P=.66). Funnel plots suggested that studies with small sample sizes were less likely to be published (Multimedia Appendix 4).

Sensitivity Analysis

The sensitivity analysis found no significant change after excluding studies one by one in both T2DM prevention and reversion to normoglycemia. After excluding studies with certain concerns and those deemed to be at high risk of bias, sensitivity analysis indicates that our meta-analysis results for T2DM incidence are stable. However, the number of studies on reversion to normoglycemia was too small to conduct a meta-analysis (Multimedia Appendix 4).

Discussion

Principal Findings

Our systematic review and meta-analysis demonstrated that face-to-face and blended interventions can effectively prevent T2DM incidence and promote reversion to normoglycemia. Digital health interventions would be a possible solution in T2DM prevention based on our review; however, more evidence is required to substantiate the effectiveness. There is limited evidence to support digital health intervention in reversion to normoglycemia among adults with prediabetes.

The findings in face-to-face interventions showed consistent effectiveness in T2DM prevention and reversion to normoglycemia, which is similar to the previous meta-analysis reported [59,60]. In addition, the study found that the face-to-face intervention group showed greater improvements in blood glucose, blood lipid levels, and other indicators compared with the digital health group, which is similar to previous studies [15].

The results of the blended interventions, which combine face-to-face and digital health interventions, showed significant effectiveness in reducing T2DM incidence and promoting the reversion to normoglycemia. This is in accordance with our earlier observations, which showed that blended intervention can effectively help people lose weight [61].

Although no statistical significance is observed in digital health intervention, the risk reduction in T2DM incidence indicates its potential effectiveness. These results are similar to those reported by previous systematic reviews among older adults with prediabetes including 3 RCTs [62], which contrast with earlier studies that reported the effectiveness of glucose indicators or lifestyle modification [63] in digital health intervention.

The inconsistency between studies using T2DM incidence and those focusing on weight loss and lifestyle changes as outcomes in digital health interventions may stem from several factors. First, it necessitates a multiyear observation period to ascertain the effectiveness of these interventions on the T2DM incidence and the reversal of hyperglycemia [7-9]. However, the studies of digital health intervention included in this meta-analysis had relatively short intervention periods ranging from 1 to 3.8 years, which may not be sufficient for observing the effectiveness. Second, it is recognized that adherence is an important indicator of expected good results [15,32]; however, 10 of 12 studies with digital health intervention included in this meta-analysis have not provided adherence information, which may explain why the digital health intervention has not reported the significant changes [10,11,31,32,39,45,50,53,54,56]. Finally, a possible explanation for the results may be the lack of adequate studies, resulting in CIs that are too wide to detect significance. Therefore, we should interpret the results with caution in digital health interventions.

Implications

Face-to-face lifestyle intervention, even when effective, adherence is not ideal in the real world [64]. Recently, studies have used digital health intervention in the Diabetes Prevention Program (DPP) in the real world, called the digital DPP [65,66]. The results showed that, in comparison to traditional face-to-face small-group education, the dDPP exhibits good reach and adherence [67]. Also, promising effectiveness in weight loss was found in dDPP; however, it is unclear in the T2DM incidence in the real world [65,68]. It is recognized that behavioral changes necessitated by such interventions require a more extended time period to assess their impact on T2DM incidence [69,70], although the American Diabetes Association recommends using digital health interventions in diabetes prevention programs for its effectiveness in glycemic control [71]. Therefore, more studies are needed to explore the effectiveness of digital health and blended interventions, observing outcomes related to T2DM incidence and reversion to normoglycemia, in order to provide more evidence for T2DM prevention.

XSL•FO
RenderX

Moreover, a prevailing challenge associated with digital health interventions is the observed decline in adherence over extended periods of use, which may account for the generally short intervention durations characteristic of digital health interventions [65]. Thus, digital health interventions should use certain behavioral change techniques or adhere to a theoretical model, as demonstrated in previous studies [72-74], as most studies used the transtheoretical model of behavioral change and social cognitive theory in lifestyle modification. Future research should not only focus on lifestyle modification but also collect information on adherence using digital health interventions.

In addition, for high-risk patients, the dDPP group had, on average, lower costs [75]. For social care use, cost-effectiveness analyses also support the preferential selection of DPPs over face-to-face small-group education per quality-adjusted life years [68]. Further research is required to develop accessible, effective, and cost-efficient diabetes prevention interventions incorporating digital health.

Furthermore, although the studies included in our meta-analysis did not use machine learning or generative artificial intelligence, these technologies have now been extensively applied in chronic disease prevention and control. In the future, machine learning with data from wearable devices will be capable of making informed judgments and providing individualized recommendations for the precision prevention and treatment of diabetes through the application of generative artificial intelligence [76]. However, it is crucial to pay attention to its fidelity to maximize its value and promote health care equity, given the challenges of compatibility between different artificial intelligence devices, standardization of data, and risks to data security [77,78].

Finally, even though there are several digital health interventions, digital support interventions have been used in diabetes prevention research limited to T2DM incidence and normoglycemia for the primary aim. For instance, a recent meta-analysis of diabetes management found that smartphone app and SMS test message interventions, but not website-based interventions, were associated with better glycemic control [15], which was defined as the primary aim of the research. Once the results with T2DM incidence and reversion of normoglycemia are available sufficiently, analyses can be performed to further explore the effective components within digital health interventions.

Strengths and Limitations

To the best of our knowledge, this is the first meta-analysis to assess the effectiveness of digital health and blended interventions on T2DM prevention using T2DM incidence and reversion to normoglycemia instead of weight loss and changes in blood glucose levels. We conducted a quantitative synthesis to explore the effectiveness of digital health interventions in T2DM prevention, which is different from other systematic reviews constrained by a limited number of studies to conduct a meta-analysis.

The study also has some limitations. First, digital health has been widely used in health research; however, 5 of 12 studies encompassed digital health interventions were published within the last 5 years, which does not meet the expectation in novel studies. To ensure robust findings, we conducted sensitivity analyses to exclude studies with potential biases from small samples or weak designs. Second, publication bias was found in the study for the T2DM incidence, and these results need to be interpreted with caution. Third, the limited studies on digital health interventions restrict our ability to conduct subgroup analyses on the effectiveness of their components. We have summarized the components and their theoretical bases in our results to aid further research. Finally, our research does not directly compare the effectiveness of different intervention modes; instead, it focuses on comparisons within control groups due to the lack of direct comparative studies in the literature.

Conclusion

While digital health interventions for lifestyle changes suggest potential effectiveness in preventing T2DM, further evidence is needed to confirm their effectiveness. There is limited evidence supporting the effectiveness of digital health interventions in reversing prediabetes. Face-to-face lifestyle interventions are effective but limited by accessibility and low adherence. With the rapid annual increase of diabetes globally, there is an urgent need to prevent T2DM, particularly among those with prediabetes. Future research is needed to consolidate the effectiveness of interventions incorporating digital health in T2DM prevention and to increase the accessibility of lifestyle interventions.

Authors' Contributions

YCW, XC, RS, XY, JZ, QG, YQW, and XH developed the search strategy, selected which trials to include, and extracted data from the randomized controlled trials. YCW and XC conducted the quality assessment of trials. YCW carried out the analysis, interpreted the analysis, drafted the final review, and kept the review up to date. YCW and YQW wrote the main manuscript text. All authors reviewed the manuscript.

Abstract

Background: The online nature of decision aids (DAs) and related e-tools supporting women's decision-making regarding breast cancer screening (BCS) through mammography may facilitate broader access, making them a valuable addition to BCS programs.

Objective: This systematic review and meta-analysis aims to evaluate the scientific evidence on the impacts of these e-tools and to provide a comprehensive assessment of the factors associated with their increased utility and efficacy.

Methods: We followed the 2020 PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines and conducted a search of MEDLINE, PsycINFO, Embase, CINAHL, and Web of Science databases from August 2010 to April 2023. We included studies reporting on populations at average risk of breast cancer, which utilized DAs or related e-tools, and assessed women's participation in BCS by mammography or other key cognitive determinants of decision-making as primary or secondary outcomes. We conducted meta-analyses on the identified randomized controlled trials, which were assessed using the revised Cochrane Risk of Bias 2 (RoB 2) tool. We further explored intermediate and high heterogeneity between studies to enhance the validity of our results.

Results: In total, 22 different e-tools were identified across 31 papers. The degree of tailoring in the e-tools, specifically whether the tool was fully tailored or featured with tailoring, was the most influential factor in women's decision-making regarding BCS. Compared with control groups, tailored e-tools significantly increased women's long-term participation in BCS (risk ratio 1.14, 95% CI 1.07-1.23, P<.001, I^2=0%). Tailored-to-breast-cancer-risk e-tools increased women's level of worry (mean difference 0.31, 95% CI 0.13-0.48, P<.001, I^2=0%). E-tools also improved women's adequate knowledge of BCS, with features-with-tailoring e-tools designed and tested with the general population being more effective than tailored e-tools designed for or tested with

XSL•FO
RenderX

non-BCS participants (χ^2_1=5.1, *P*=.02). Features-with-tailoring e-tools increased both the rate of women who intended not to undergo BCS (risk ratio 1.88, 95% CI 1.43-2.48, *P*<.001, I^2=0%) and the rate of women who had made an informed choice regarding their intention to undergo BCS (risk ratio 1.60, 95% CI 1.09-2.33, *P*=.02, I^2=91%). Additionally, these tools decreased the proportion of women with decision conflict (risk ratio 0.77, 95% CI 0.65-0.91, *P*=.002, I^2=0%). Shared decision-making was not formally evaluated. This review is limited by small sample sizes, including only a few studies in the meta-analysis, some with a high risk of bias, and high heterogeneity between the studies and e-tools.

Conclusions: Features-with-tailoring e-tools could potentially negatively impact BCS programs by fostering negative intentions and attitudes toward BCS participation. Conversely, tailored e-tools may increase women's participation in BCS but, when tailored to risk, they may elevate their levels of worry. To maximize the effectiveness of e-tools while minimizing potential negative impacts, we advocate for an "on-demand" layered approach to their design.

Introduction

Breast cancer constitutes 11.6% (2.309 million new cases) of global cancer incidence and 6.9% (665,684 deaths) of global cancer mortality [1].

Mammography is the most widely used screening method in breast cancer screening (BCS) programs for detecting breast cancer. These programs primarily target women at average risk of the disease. A woman is considered at average risk if she lacks risk factors associated with a significantly increased likelihood of breast cancer, such as a personal history of the disease, a strong family history, a genetic mutation known to elevate risk (eg, a *BRCA* mutation), or prior high-dose radiation therapy to the chest at a young age [2-4]. Conversely, a woman is considered at high or very high risk of breast cancer if she has 1 or more of these risk factors. Such high-risk women do not participate in standard BCS programs; instead, they undergo more personalized screening options [2,5].

Despite the proven efficacy of mammography-based BCS and national health policies promoting regular screening for women at average risk, participation in BCS remains suboptimal in many countries, falling well below the recommended rates set by the European Union and other organizations [6-8].

Numerous barriers to women undergoing BCS have been identified in the literature, such as fears of a breast cancer diagnosis or the mammography procedure itself [9-11]. For some women, participation in a BCS program may also be perceived as a dilemma due to ongoing debates surrounding BCS. Indeed, scientific and medical discussions continue about specific aspects of BCS, including the optimal screening interval [12,13]. Furthermore, public discourse often highlights controversies and potential risks associated with BCS, such as overdiagnosis and overtreatment [14,15].

The use of decision aids (DAs), either independently or as part of a shared decision-making (SDM) process, appears particularly suitable and important for both women and BCS programs. These tools help women make an "informed choice" about their participation in BCS, enabling them to make a reasoned and justifiable decision after receiving reliable and sufficient information about the procedure or examination and its associated risks [16]. DAs are evidence-based cognitive tools designed to elucidate the decision-making process and help patients clarify their values and preferences [17-19]. Similarly, SDM is described as an interactive, balanced, step-by-step discussion between health professionals (HPs) and patients, often incorporating DAs to support the dialogue [20,21].

Patients faced with decisions about cancer screening (including BCS) who are exposed to DAs tend to be better informed and more aligned with their values [19,22-26]. Although promising, evidence regarding the effectiveness of SDM remains limited, particularly in real-world settings where its implementation is often hindered by the busy and demanding schedules of HPs [27-30]. Additionally, there is insufficient evidence on when it is more beneficial for patients to engage in an SDM discussion with an HP rather than relying solely on a DA [20,31-34].

Global interest in digital health and eHealth tools, including telehealth, has surged in recent years, largely driven by the COVID-19 pandemic [35-37]. Online delivery offers the potential to enhance access to DAs for patients and HPs, particularly for those in underserved communities, while also enabling more integrated implementation of SDM. As a result, incorporating online DAs and related tools into BCS programs could support women in making informed decisions. A review of web-based DAs found these tools to be effective in increasing women's knowledge and ability to make informed choices while reducing decisional conflict or dilemmas about BCS [38].

However, to better inform future BCS programs about the utility and implementation of online tools for women's decision-making, it is necessary to go beyond Yu et al's review [38] and provide additional evidence. First, it is important to evaluate not just web-based DAs but also all types of online interactive tools (e-tools) to fully explore their potential for supporting women's decision-making about BCS [38-40]. An overall assessment of the effect of these e-tools, including web-based DAs, on women's participation in BCS and important cognitive determinants in decision-making (eg, women's attitudes or perceptions of risk) was lacking [19,22,25,26,38]. Additionally, there was a need for a comprehensive evaluation

XSL•FO
RenderX

of factors associated with the greater utility and effectiveness of these e-tools to support more informed BCS programs. This includes exploring aspects related to information delivery (eg, mobile vs computer-based e-tools, degree of message tailoring), user characteristics (eg, nonadherent to BCS vs the general population), and the methods used to evaluate these e-tools (ie, the outcomes assessed to measure their impact on decision-making). Finally, evidence of the effect of these e-tools on the SDM process was also missing.

Through a combined systematic review and meta-analysis, our research aimed to address these evidence gaps and synthesize the scientific literature on e-tools designed to support decision-making in the context of BCS by mammography. The primary objective of this review was to inform future BCS programs about the utility and implementation of such e-tools.

Methods

Review Design

This review was registered with the International Prospective Register of Systematic Reviews (PROSPERO; CRD42020164479) [41]. The main deviation from the original protocol was the inclusion of studies without comparator arms. This change was made for 2 reasons: (1) a preliminary review of the databases indicated that the total number of studies might be limited if only those with comparators were included, and (2) to provide the most comprehensive assessment of the effects of e-tools, including web-based DAs, on women's participation in BCS and important cognitive determinants in decision-making. The type of design for each study included in this review was considered when assessing the overall certainty of the evidence using the GRADE (Grading of Recommendations Assessment, Development, and Evaluation) methodology (outlined below). A workshop held in December 2019, organized by PV, on developing and implementing e-tools as DAs to support women's decision-making about BCS, played a significant role in shaping the development of this review. We conducted our systematic review in accordance with the 2020 PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [42] (see Table S1 in Multimedia Appendix 1).

Study Search, Selection, and Data Extraction

We systematically searched the MEDLINE (via PubMed), PsycINFO, Embase, CINAHL, and Web of Science databases from August 2010 to August 2020, with an update in April 2023 (see Appendix S1 in Multimedia Appendix 1). We limited the search to articles published from 2010 onward to minimize the risk of including e-tools that may have become technologically obsolete—those using outdated technology and no longer considered useful, efficient, or functioning well compared with newer alternatives [43]. Additional websites (eg, the International Patient Decision Aid Standards [IPDAS] website) were also searched nonsystematically. The following inclusion criteria were applied: (1) women considered to be at average risk of breast cancer, that is, those without risk factors associated with a significantly increased risk of the disease [2-4]; (2) the tool, whether identified as a DA or not, was used for women's decision-making about BCS, aimed to inform users at least about BCS by mammography, and was an e-tool defined as one that runs on the internet, computer, phone/tablet, or other electronic device and is interactive (ie, allowing users to "participate in modifying the form and content of a mediated environment in real time") [39,40]; and (3) the study, of any design, reported as primary or secondary outcomes any of the following: women's participation in BCS by mammography (behavior), intention to participate, knowledge, attitudes, self-efficacy, worry, perceptions of risk, regrets, decisional conflict, and informed choice—measures shown to reflect decision-making and behavior and to be important in decision-making [19,22,25,26]. Exclusion criteria were as follows: (1) participants at high risk of breast cancer, that is, those with 1 or more risk factors associated with a significantly increased risk of the disease [2-4]; (2) screening limited to breast examination by an HP or self-examination; (3) non–peer-reviewed publications; and (4) studies focused on BCS cessation.

The search yielded 16,061 records, which were managed using Covidence software [44]. Three independent reviewers (PV, ALB, and CB) assessed titles and abstracts, followed by full-text evaluation against the study inclusion criteria. A total of 227 papers were selected for full-text eligibility assessment, and 196 were subsequently excluded. A data extraction form was used (see Appendix S2 in Multimedia Appendix 1); it was completed by a main reviewer (PV or ALB) and independently assessed by 2 additional reviewers (PV, LD, ALB, or CB).

Qualitative and Quantitative Syntheses

Extracted data were synthesized both qualitatively and quantitatively, as detailed later.

The qualitative synthesis aimed to provide an overview of the characteristics of the e-tools and a description of the reported outcomes and the instruments used to measure them. These are reported in the Results section. Additionally, the characteristics of the studies included in this review and the study populations are reported in Tables S2 and S3, respectively, in Multimedia Appendix 1.

Quantitative synthesis was conducted to report the effect of the e-tools on women's decision-making about BCS. Main results are reported in the Results section, with additional results reported in Appendix S4 and Figures S1-S8 in Multimedia Appendix 1.

Description of the e-Tools

The main descriptive variables were identified through discussions and consensus among the authors. These variables were considered important as they could potentially influence the effects of e-tools on women's decision-making about BCS. The e-tools identified in this review were classified as either "tailored"—when the e-tools provided individualized or personalized notifications, messages, or information based on an individual's assessment [40,45,46]—or "features with tailoring"—when the e-tools presented some degree of tailored information but not based on an individual assessment [40].

Effect of the e-Tools on Women's Decision-Making About BCS

Overview

The effect of the e-tools was assessed through the following outcomes: women's participation in BCS by mammography (behavior), intention to participate, knowledge, attitudes, self-efficacy, worry, perceptions of risk, regrets, decisional conflict, and informed choice. These outcomes have been shown to reflect decision-making and behavior and are particularly important in the context of BCS [19,22-26,38]. The effects of the e-tools on SDM or communication with HPs were also evaluated.

For each outcome, quantitative synthesis was conducted and reported through a 2-step process. First, where possible, we performed meta-analyses with the randomized controlled trials (RCTs) identified in this review, following Cochrane guidance [47]. Additionally, the synthesis without meta-analysis (SWiM) guideline was used to synthesize evidence from RCTs not included in the meta-analyses or other study designs (see Table S2 in Multimedia Appendix 1) [48]. Second and finally, for each outcome, the overall certainty of the evidence collected through the meta-analyses and SWiM exercise was independently evaluated by PV and LD using the GRADE methodology [49-51]. Results from the risk-of-bias assessment (discussed later) were used to downgrade the overall certainty of the evidence, if necessary. Because of the low total number of studies included in this review, we did not downgrade the overall certainty of the evidence, assessed with GRADE, based on the imprecision (number of studies, SD) criteria, except when only 2 studies (meta-analyses) or 1 study were available. This applied to the "intention not to participate," "worry," "perception of risk," and "decisional conflict" outcomes assessed through meta-analyses, as well as the "self-efficacy," "regret," and "discussion/SDM" outcomes. Any discrepancies between the 2 independent reviewers were resolved through the intervention of a third reviewer (RS).

Meta-Analyses and Risk of Bias

Meta-analyses were conducted with RCTs following Cochrane guidance [47] (see also Part A in Appendix S3 in Multimedia Appendix 1).

Data were extracted from the original publications, and additional information was obtained by directly contacting the authors when necessary. Only data related to BCS by mammography, as reported by the authors for "women," were extracted.

PV and LD, along with ALB or CB, independently performed the risk-of-bias assessment for all RCTs included in this review using the revised Cochrane Risk-of-Bias 2 (RoB 2) tool for RCTs [52]. Any discrepancies between the 2 independent reviewers were resolved through the intervention of a third reviewer. As a result of the low number of studies, none were excluded based on RoB 2 results. The level of risk for each RoB 2 domain (A: randomization process; B: deviations from the intended protocol; C: missing data; D: outcome measurement; E: reporting results) and overall risk (F) were evaluated for each RCT and reported on the forest plots (discussed below) as low (green), moderate (yellow), or high (red).

To minimize sources of heterogeneity between studies, we chose to include only RCTs that reported the most similar outcomes based on their definitions and the instruments used to measure them in the meta-analyses described in this review. Therefore, contrary to Yu et al's review [38], we reported the decisional conflict outcome only for RCTs using the "SURE" scale and did not report the pooled effect for the "regret" outcome.

We used Review Manager software (RevMan, version 5.4.1; Cochrane) [53] to conduct meta-analyses, perform subgroup analyses, and display forest plots, including risk-of-bias assessments.

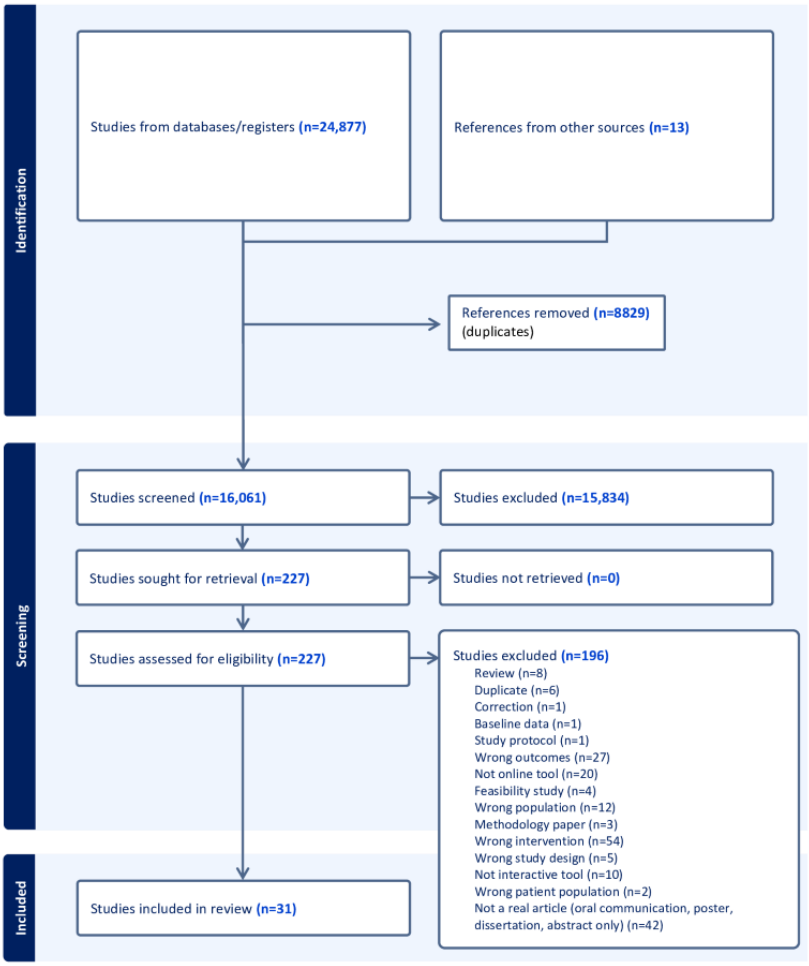
We reported pooled estimates as mean difference (MD) for continuous variables (adequate knowledge, worry, and accurate perception of risk) and relative risk/risk ratio (RR) for dichotomous variables (other outcomes). Heterogeneity or inconsistency between studies was assessed using the I^2 statistic. A fixed-effect (FE) model was applied when low heterogeneity was found ($I^2 \leq 30$), while a random-effects (RE) model was used in other cases. Results from meta-analyses with intermediate or high heterogeneity between studies ($I^2 \geq 35$) were further explored to strengthen the validity of our findings.

Exploration of Heterogeneity and Subgrouping Analysis

Where meta-analyses showed intermediate or high heterogeneity between studies ($I^2 \geq 35$), further analyses were conducted. The main results are reported in the text (see also Figures S1-S8 and Appendix S4 in Multimedia Appendix 1). Two approaches were used to explore the causes of intermediate/high heterogeneity [47]: (1) exclusion of 1 study when it differed from the others in the meta-analysis based on either the type of e-tool used (eg, web application or mobile app) or the control used (eg, a website or a video). We also explored the exclusion of studies with a high risk of bias(es). Exclusion of Lee et al's [54] study, which used a mobile app downloaded on a mobile phone, or Roberto et al's study [55], which used a website as a control, in the meta-analysis assessing short-term participation or adequate knowledge, respectively, was effective in reducing heterogeneity (reported); (2) additionally, subgroup analyses were conducted based on various variables that could have explained the source of heterogeneity, for example, characteristics of the e-tools such as the type or degree of tailoring, the type of outcomes or instruments, or characteristics of the study populations such as age, ethnicity/rurality, and nonparticipation in previous BCS by mammography (see also Table S3 in Multimedia Appendix 1).

Besides exploring heterogeneity, subgroup analysis was also conducted to examine the effect of different variables (described above) on the reported outcomes.

Results



Overview of Included Studies and e-Tools

We identified 31 published papers/studies (Figure 1; also see Table S2 in Multimedia Appendix 1) [54-84], representing 22

XSL•FO
RenderX

different e-tools [54-75]. The majority of these were designed and evaluated in the United States (n=16) and tested through RCTs (n=14). Study populations are detailed in Table S3 in Multimedia Appendix 1.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flow diagram. The diagram was generated using the Covidence software [44].

Description of the e-Tools

Among the 22 e-tools, the majority (n=16) were web applications, either standalone or integrated into patient portals [55,56,58,59,61,63,65,67-75] (Table 1; see also Table S4 in Multimedia Appendix 1).

Two e-tools used artificial intelligence (AI)–based virtual doctors [58,64].

Most of the e-tools (16/22; Table 1) were tailored to the individual's (1) breast cancer risk (n=7) [63,65,71-75]; (2) barriers, beliefs, or screening status identified at baseline (n=8) [56,57,59,61,64,66-68]; or (3) preferences regarding the content, number, and timing of daily messages [54]. Of these 16 tailored e-tools, 8 targeted nonparticipants in BCS (see Table S3 in Multimedia Appendix 1) [54,56,57,59,63,66-68]; 11 out of the 16 tailored e-tools included specific features designed to facilitate or enhance opportunities and the quality of discussions about BCS between women and HPs (Table 1) [54,59,61,63-65,67,72-75].

The remaining 6 e-tools (out of 22) were not tailored to individual users and were classified as "features-with-tailoring" e-tools (Table 1) [55,58,60,62,69,70]. None of these tools were evaluated specifically with BCS nonattenders (see Table S3 in Multimedia Appendix 1). The tailoring features in these tools were designed to either (1) address BCS screening barriers for specific subpopulations (n=2) [60,62] or adapt the communication style of an AI-based virtual HP to meet the needs of specific user groups [58], or (2) prompt users to identify their personal beliefs and values regarding BCS (Table 1) [55,69,70].

XSL•FO
RenderX

Table 1. Description of the e-tools[a] used to help women's decision-making about breast cancer screening by mammography.

Descriptive variables	Characteristics of e-tool
Theoretical model[b]	• Not reported [55,58,59,61,62,67,69,70,74,75] • The Transtheoretical Model of Behavior Change [56,57,64,66,68], the Health Belief Model [54,56,57,66], the Decisional Conflict Theory [72,73], the Exemplification Theory [63,71], the Elaboration Likelihood Model of Persuasion [71], the Self-Regulation Model [65], the Theory of Planned Behavior [56], the Conceptual Framework to Measure Engagement [60], and the Fogg Behavioral Model [54]

Decision aids[c]	• Identified as decision aids [55,61,63,67,69-75]
	  • All except 2 e-tools [61,71] were reported to be developed based on international standards: either the International Patient Decision Aid Standards Framework [55,63,69,70,72-74] or the Ottawa Decision Support Framework [67,75]
	  • Quality assessment against International Patient Decision Aid Standards criteria was performed by the authors themselves [63,75] or by others and through a systematic review [85] in which 4 e-tools were evaluated and assessed to be of either high overall quality [69,70,75] or below the overall mean quality [72]
	• Not identified as decision aids [54,56-60,62,64-66,68]

Type[d]	• Standalone web-based applications [55,56,58,63,65,68-71,74,75], which were optimized for smartphones [72]; Fissler et al's e-tool [58] used an artificial intelligence–based virtual doctor • Patient portal: either a new one [61] or "embedded" or "linked" to an existing one [59,67,73] • A mobile app either on a smartphone with a global positioning system [54] or on an iPad [64]; Walsh et al's e-tool [64] used an artificial intelligence–based virtual doctor • Interactive DVD [57,66] • Social media–based: either Facebook [60] or WhatsApp [62]
Information provided	• Breast cancer screening and breast cancer [54,55,57,58,60,62,63,68-75] • Breast cancer screening and breast cancer with additional information[e], such as other cancer screening [56,59,61,64,66,67], or other prevention messages (eg, diet) [59,61,64,65]

Degree of tailoring[f]	• Tailored
	  • To address woman' breast cancer risk[g] [63,65,71-75]; some e-tools also allowing to clarify value[h] [63,65,72-75]
	  • To address individuals' barriers, beliefs, or screening status at baseline [56,57,59,61,64,66-68], including the stage of change based on the Transtheoretical Model [68]
	  • To adapt the content, number, and timing of daily messages to each individual [54]
	• Features-with-tailoring
	  • To address the screening barriers specific to a group of the targeted population [60,62]
	  • To target the communication style of the factious health professional to the needs of a specific group of patients [58]
	  • To allow individuals to clarify their values[h] [55,69,70]

XSL•FO
RenderX

Descriptive variables	Characteristics of e-tool

Access to health professionals[i]	• The e-tools were part of clinical pathways or referred to actual health care services [55,59,61,63,65,67,70,72,73,75]
	  • Being a patient portal or embedded in an existing one [59,61,67,73]
	  • patients with medical preappointments were automatically invited to use the tool [67]
	  • patient being directly informed of a care gap (eg, delay in getting breast cancer screening), and could directly book an appointment through the portal [59]
	  • both patients and health professionals were informed automatically when the former were at a higher risk of breast cancer [73]
	  • individual recommendations targeting 18 preventive health services were provided [61]
	  • Being available before/after a booked medical appointment: before [72,73], or most probably only or at the first instance at clinics [63,75], or in advance of a prescreening appointment made by breast cancer screening programs [55,70]
	  • Offering counseling sessions online or discussions with health professionals [65]
	• Used artificial intelligence–based virtual doctor to simulate an appointment between a health professional and their patient [58,64], designed to encourage the user to continue [64] or to improve [58] discussion with a health professional
	• Providing a personalized report
	  • All being downloadable [55,63,64,67,70,72-75] or probably being downloadable [61]
	  • Either a summary with a list of questions [61,63,64,67,72-75] or the results of the value clarification exerciseh [55,70]
	  • When the tools were part of clinical pathways, reports were put directly in the patient folder [63,64], a specific appointment to discuss was offered [72], or the report was sent to the health professional through the patient portal [61,67,73]
	  • Women were encouraged to either share or discuss this report with their health professional [61,63,67,72-75], or with people they trust [55], or to talk with a health professional about any concerns [64,70] or in case of indecision about screening [70]
	• Being tailored e-tools based on risk: women at higher risk receive automatic messages to follow-up including talking with health professionals [65,72-75], and health professionals are informed automatically [73]
	• Includes an option to contact a health navigator for assistance in navigating through cancer screening information, addressing technical problems, and providing transportation and interpretation services [54]
	• With a global positioning system facilitating cancer screening clinics localization and other information [54]

[a]The e-tools were categorized into groups and subgroups based on the descriptive variables as indicated (see also Table S4 in Multimedia Appendix 1).

[b]Any psycho-theoretical model reported to be used to develop the e-tool.

[c]We classified the e-tools as "identified as decision aids" when the authors explicitly used "DA" or "decision-making" to describe the e-tool, or when the e-tool contained a decision aid/decision-making module or a link to decision aids. The remaining tools were classified as "not identified as decision aids." A rapid assessment of these tools against the 5 previously described decision aids criteria [86], that is, (1) information about options, decisions, and outcomes, including benefits and harms; (2) evidence-based information on options; (3) probabilities; (4) value clarification; and (5) decision guidance, did not provide sufficient information to determine whether or not these tools could be classified as decision aids.

[d]The tools were classified as previously described [40,87].

[e]In this group of e-tools, the study population was either only women [56,65,66] or both men and women [59,61,64,67].

[f]Tools were classified as either "tailored" or "features-with-tailoring" e-tools, as previously defined [40,45,46]. Tailored tools provided individualized or personalized notifications based on an individual's assessment. This assessment could be conducted through participants' responses to questionnaires, which were either external to the e-tool and completed before its use or integrated into the e-tool itself, addressing factors such as the individual's breast cancer risk or other characteristics. By contrast, "features-with-tailoring" e-tools offered some degree of personalization or tailoring, but it is not based on individual assessments.

[g]Risk was estimated using 2 validated instruments: the Breast Cancer Risk Assessment Tool for personal risk estimates and the Breast Cancer Genetics Referral Screening Tool for assessing familial breast cancer risk. In 1 study, a different instrument was used, and it was unclear whether the risk estimation was communicated to the women involved [74]. Among the 7 tailored-to-risk tools, 4 utilized risk assessment to exclude women with above-average breast cancer risk from accessing the decision aid, instead directing them to receive messages for appropriate follow-up based on best practices [72-75]. For the remaining 3 tools, risk assessment was conducted online to personalize the features of the tools according to each woman's individual risk [63,65,71]. One tool provided 6 levels of tailored-to-risk messages, and its effects were evaluated [71].

[h]The tools aimed to encourage users to identify their personal beliefs and values regarding breast cancer screening. The methods used were all explicit, meaning they required active user participation—such as moving sliders, assigning weights to scales, or inputting numbers—to express their values, preferences, and concerns [88].

[i]Specific features aimed to facilitate access to or communication with health professionals.

Effect of the e-Tools on Women's Decision-Making About BCS

Overview of the Outcomes

The effect of the e-tools on women's decision-making about BCS was assessed through various outcomes in the studies included in this review. A comprehensive overview of these outcomes and the instruments used to measure them are provided in Table 2.

The synthesized results regarding the effects of the e-tools are presented in the following paragraphs, with the outcomes listed in the same order as in Table 2. We encourage readers to refer to this table for the definitions of each outcome.

XSL•FO
RenderX

Table 2. Outcomes and instruments to assess the effect of e-tools on women's decision-making about breast cancer screening by mammography.

Outcomes[a]	Definitions[b] and instruments[c]

Participation (behavior) [54-57,59,61,63-67,70]	• Authors reported the rates of women who have participated in breast cancer screening by mammography.
	• Participation in breast cancer screening was reported by the authors as "participation rate" [55], "adherence" [57], "uptake" [54,63,70], "receipt" [54,56], "screening behavior" [65], "getting screened" [67], "being up to date" [64,66,67], or "screening gap closure" [59].
	• Instruments used to measure women's participation were self-report questionnaires/surveys [54,55,65,70], health records [59,63,67], or both, with self-reports used to supplement missing medical records [56,57,61,64,66].
	• In 1 study [70], the authors differentiated participation in the breast cancer screening program, which was reported, and opportunistic screening.
	• Depending on the study, participation was assessed as follows:
	  • At short-term (up to 6 months): measured at 0.5-2 months [55], at 3 months [59,67,70], at 4 months [61], or at 6 months [54,56,57]. In Krist et al [67], a non–randomized controlled trial, measures were done after each invitation phase.
	  • At long-term (12-16 months): measured at 12 months [63,65,66], at 14 months [64], or at 16 months [61]. It must be highlighted that in Champion et al's [66] study, participation after the 12-month window was classified as "no screening."

Intention to undergo breast cancer screening [54,55,60,68-74,76]	• Intention, as defined in the Theory of Planned Behavior [89], is assumed to capture the motivational factors that influence a behavior; it indicates how hard people are willing to try or how much effort they are planning to exert to perform the behavior. Intention assessment was reported as the rates of women with intention/willingness to undergo breast cancer screening. Reder and Kolip [70] differentiated the breast cancer screening program and opportunistic screening and reported intention to participate in the breast cancer screening program. • In the randomized controlled trials, intention was assessed just after using the e-tool [54,68-74] or 7-10 days after [55]. • Generally, intention was assessed through 1 or 2 items in a questionnaire/survey with anchors defined by the authors themselves to be either cross-checked [54,55,68,70-74,76] or evaluated with a Likert scale [60,69]. • Intention was formulated either as a general statement [55,73] or as a more specific one and anchored to a specific time or age. Specific time(s) was/were linked to the near future either now [69], in the next 3 months [70], in the coming/next year [60,68], or at different possible times (within 1 month, 3 months, or up to 1 year) [54]. In 1 study it was evaluated for a more distant future (in the next 1-2 years) [74]. When anchored to age, women's intention was evaluated to start or continue in their forties [71,72], or to start at 50 years [71]. We used the cumulative value of intention to assess Lee et al's [54] and Seitz et al's [71] tools in the meta-analysis (see Part A in Appendix S3 in Multimedia Appendix 1): intention "to get screened within 3 months to 1 year" and intention "to start or continue in the forties, or to start at 50 years old" were reported.
Intention *not* to undergo breast cancer screening (negative intention) [69,70]	• It was assessed in 2 randomized controlled trials and reported as the rates of women with intention/willingness not to undergo breast cancer screening [69,70].
Knowledge [54,55,62-65,67,69,70,72,77]	• Knowledge was assessed about breast cancer screening (most studies) and, in some studies, about breast cancer. • With Walsh et al's [64] and Krist et al's [67] e-tools, participants were asked to evaluate whether the tool improved their own knowledge; the authors reported rates of participants presenting different degrees of agreement [64,67,77]. With Eden et al's [72] e-tool, women rated how much new information they learned from the e-tool on a scale from 1 (lowest) to 10 (highest), with the authors reporting median and IQR. • In the remaining 7 e-tools (ie, 6 randomized controlled trials [54,55,63,65,69,70] and 1 mixed method study [62]), the instrument used to measure knowledge was more complex and heterogeneous; the instrument was a series of 5-18 items created or adapted by the authors to assess participants' knowledge accompanied by anchors. The format of the anchors was either multichoice responses [62,63], both multichoice and numerical responses [55,69,70], true/false responses [54], or response scales of 1-4 [65]. Lee et al [54] used a validated knowledge instrument, which was revised to reflect the current American Cancer Society's breast cancer screening guidelines. Adequate knowledge was reported as a quantitative value to reflect the number of items the participants answered correctly [54,55,62,63,65,69,70]. In some studies, the percentage of women with adequate knowledge was also reported; those were defined as women providing correct answers to at least half plus 1 of the total number of questions [55,69,70].

XSL•FO
RenderX

Outcomes[a]	Definitions[b] and instruments[c]
Attitudes about breast cancer screening [55,58,69,70]	• Refers to the degree to which a woman has a favorable or unfavorable evaluation or appraisal of an undergoing breast cancer screening program [16,89]. • In 4 randomized controlled trials [55,58,69,70], the instrument to measure attitudes toward undergoing breast cancer screening was adapted from Marteau et al's [16] definition and measure. It was either 4 items [55,58,70] or 6 items from Dormandy et al's scale [69,90]; all these items were linked to a Likert scale. In 1 of those randomized controlled trials [58], the authors reported attitudes score, with higher scores reflecting higher positive attitudes toward undergoing breast cancer screening. In the other 3 randomized controlled trials [55,69,70], Marteau et al's [16] method was used. A predefined threshold was set to differentiate women with positive attitudes [55,70] or values [69], that is, women scoring higher than the threshold, from women with negative attitudes [55,70] or values [69], and the percentage of women with positive attitude was reported.
Self-efficacy [54,72]	• Confidence in one's ability to take action as described in the Health Belief Model [91]. Also includes the concept of perceived behavioral control in the Theory of Planned Behavior models, referring to the perceived ease or difficulty of performing the behavior and assuming to reflect past experience as well as anticipated impediments and obstacles [89]. • Instruments used to measure self-efficacy were validated instruments. They were either the 8 related items from the Champion's Health Belief Model Scale [54] or the Decision Self-Efficacy Scale [72]. The level of self-efficacy was reported. One component of the Decision Self-Efficacy scale measures self-confidence or belief in one's ability to make decisions and participate in shared decision-making.
Worry [63,67,69,71,75,78]	• Assessment of emotional reactions related to breast cancer was exclusively based on assessing changes in anxiety, worry, or fear either in general, "feeling fear and worry" [69,71,78], or specifically breast cancer [63,67,75]. • In Krist et al's [67] study, the level of fear and worry was assessed through a series of questions related to breast cancer prompted by the e-tool. The authors then evaluated whether discussion with health professionals was helpful to reduce women's fears and worries if fears/worries were identified. • For other e-tools, instruments used to measure worry were heterogeneous. It was a validated instrument: either the Lerman Breast Cancer Worry Scale [63] or adapted from the McCaul Breast Cancer Worry Scale [75]; a Likert scale was used to rate the answers, and the means of scoring was reported. In other cases, it was created by the authors themselves and was generally 1-2 questions linked to a Likert scale [69,71,78]. Seitz et al [71,78] adapted a previous instrument.
Risk perceptions [54,63,71,75]	• Personal risk estimation to develop a breast cancer. It could also include "perceived susceptibility" from the Health Belief Model (ie, beliefs about the chances of experiencing a risk or getting a condition or disease) [91]. • In the randomized controlled trial by Lee et al [54], risk perception was reported through "perceived susceptibility" from the HBM model. In 3 additional e-tools, all tailored-to-risk (Table 1), the authors evaluated women's risk perceptions differently [63,71,75]. In Elkin et al's [75], the participants were all at low-to-average risk based on their personalized risk estimates; the authors assessed the rates of women with this adequate "accurate" perception of their own risk. To evaluate the 2 other e-tools, instruments were adapted from previous studies/scales. Participants were asked to evaluate their chance of getting breast cancer as a percentage (0% being no chance and 100% being sure of getting cancer) [71], or as frequency (ie, a number out of 1000) [63,71]. The difference between the risk perception evaluated by the women itself and objective risk estimates was measured and reported by the authors, with a decrease of difference reflecting an increase in women's accurate perception of risk.
Quality of decision	
Regret [63,70]	• The effect of the e-tool was evaluated on decision regret [70] or on anticipated regret [63]. • Decision regret describes regret associated with self-recrimination around having made a bad decision or regret associated with the knowledge that another choice would have resulted in a better outcome. • Anticipated regret measure is future oriented; anticipated inaction regret was associated with engaging in protective health behaviors, while anticipated action regret was associated with nonengaging. Findings suggest that anticipated inaction regret is more strongly felt and has more reliable associations with behavioral intentions and health behaviors.

XSL•FO
RenderX

Outcomes[a]	Definitions[b] and instruments[c]
Decisional conflict [55,63,70,72,74,75]	• Personal uncertainty about which option to choose. • Decisional conflict is a multidimensional outcome measuring either 4 dimensions (ie, being "SURE[d]") or 5 (previous dimensions plus "effective decision-making"), and measured with the SURE scale and the Decisional Conflict Scale, respectively. These 2 instruments are validated and negatively correlated scales [92]. • With the SURE scale, a score of ≤3 indicates decisional conflict and a score equal to 4 an absence of conflict; the authors reported the number of women with a decisional conflict. This instrument was used in 2 randomized controlled trials [55,70]; whereas in the study by Reder and Kolip [70], the instrument was specifically about the intention to undergo breast cancer screening, this was not the case in the study by Roberto et al's [55] in which the instrument was more general and about "decision." • The Decisional Conflict Scale used was either the low literacy version (ie, including 10 questions with 3 response categories) [72,74] or the traditional one (ie, including 16 statements with 5 response categories) [63,75]; Decisional Conflict Scale scoring ranged from 0 (no decisional conflict) to 100 (ie, extremely high decisional conflict or poor decision process); means of scoring was reported to reflect the decisional conflict.
Informed choice [55,69,70]	• Based on Marteau et al's [16] definition: "an informed choice to undergo a screening test occurs when an individual has a positive attitude towards undergoing a test, has relevant knowledge about the test and undergoes it. An informed choice to decline a test occurs when an individual holds a negative attitude towards undergoing a test, has relevant knowledge about the test and does not undergo it. The choices that occur when individuals do not have relevant knowledge or when their attitudes are not reflected in their behavior, are uninformed." • Following Marteau et al's [16] definition, only 1 study [70] reported informed choice regarding participation in breast cancer screening. Informed choice was usually reported toward intention to undergo breast cancer screening [55,69,70]. "Informed choice about intention" was then reported in our meta-analysis as the measure of informed choice. Except for Roberto et al [55], results regarding informed choice were reported in the original scientific publications only for participants who had made a decision about their intention to participate, excluding those who remained undecided [69,70]. This was made to strictly follow Marteau et al's [16] definition (ie, measure of informed choice only among those who made either a positive or a negative decision). In our meta-analysis, we reported informed choice over the total number of women for whom data related to informed choice measurement (ie, knowledge, attitude, and intention) were available.
Shared decisions and communications with health professionals [64,67,72,75]	• Eden et al [72] assessed the readiness of women to make a shared decision using the Graham Preparation for Decision Making scale. A higher level of scoring indicated that the women felt the decision aid prepared them to make a shared decision with clinical providers. • Among the 22 e-tools, including the 6 identified as preparing for or facilitating shared decision-making [63,64,72-75], none was evaluated against whether a shared decision-making discussion occurred. Instead, the tools were assessed by measuring women's readiness to discuss mammography [64], whether this discussion occurred [64,75], or the characteristics of the discussion including its quality [67]. The perspective of the health professionals was also evaluated regarding the 2 latest variables [67,75].
Other outcomes	• Few studies assessed outcomes related to the stage of adoption or stage of decision other than behavior or intention, such as "having made a decision" [70] or "readiness to be tested" [64]; data were not reported here. Perceived quality of life was reported in 1 study [65]. Satisfaction with the decision was not reported. Among implementation outcomes, "Reach" (ie, how the tool reached target populations) was the most reported after efficacy/effectiveness (detailed above) and through a variety of instruments.

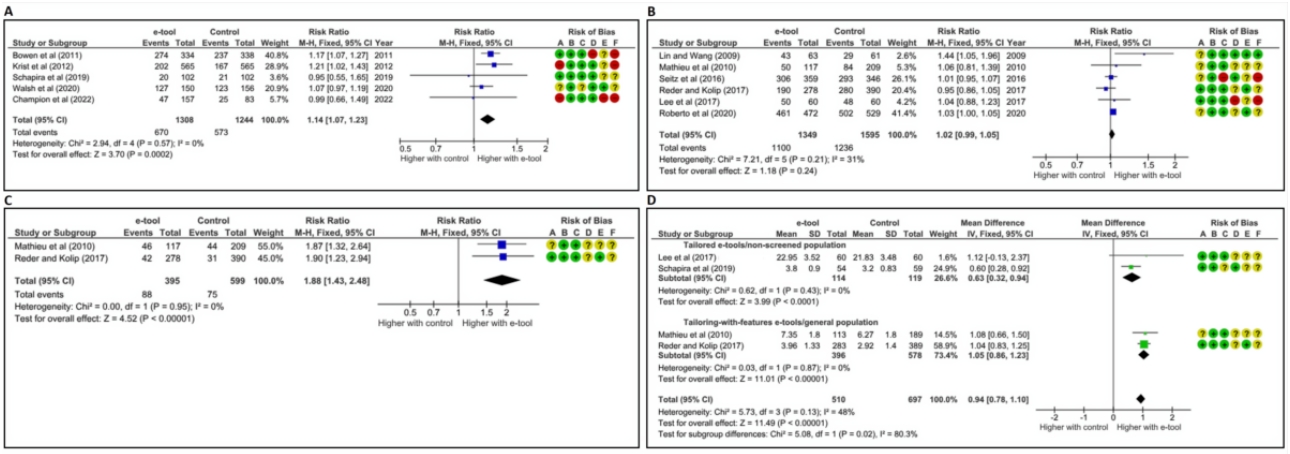
[a]The outcomes are reported in the following order: first, we present participation in breast cancer screening (behavior), followed by related determinants/factors based on the main theories, models, and concepts used to explain or understand cancer screening behavior [89,91]. Among those, intention, identified as the most proximal determinant of behavior in the Theory of Planned Behavior [89], is reported first. Next, we include outcomes related to the "quality of decision," such as "regret" and the composite outcomes "decisional conflict" and "informed choice." The outcomes reported last are those that were less frequently assessed in the included studies.

[b]Although reported by the authors, we did not include some studies; the reasons are detailed in Part B in Appendix S3 in Multimedia Appendix 1.

[c]"Instruments" were any item (eg, scale, questionnaire, or medical records) used to measure the outcomes.

[d]SURE: Sure of myself (Uncertainty), Understand information, Risk-benefit ratio (value clarity), and Encouragement.

Participation in BCS (Behavior)



Our meta-analysis found that e-tools, including a mix of tailored-not-to-risk e-tools (ie, tailored e-tools but not to the individual's breast cancer risk; n=4) and features-with-tailoring tools (n=2), did not significantly increase women's participation in BCS up to 6 months after using the e-tools (RR 1.09, 95% CI 0.97-1.23, P=.16, I^2=78%, RE model) compared with the control group, which included either usual care [54,56,57,61,70]

XSL•FO
RenderX

or a control website [55] (see Figure S1A in Multimedia Appendix 1). Excluding Lee et al's study [54] significantly reduced heterogeneity (see the "Methods" section) without altering the overall pooled result (RR 1.03, 95% CI 0.98-1.08, P=.28, I^2=14%, FE model; see Figure S1B and S1C in Multimedia Appendix 1). No subgroup differences were observed between tailored and features-with-tailoring e-tools (χ^2_1=1.2, P=.28; see Figure S1D in Multimedia Appendix 1). Two interventional studies without concurrent controls that assessed tailored-not-to-risk e-tools reported an increase in BCS participation among users compared with nonusers [59,67].

Our meta-analysis further demonstrated that e-tools (n=5), all tailored to either risk (n=2) or other variables (n=3), increased women's participation in BCS assessed at long-term follow-up (12-16 months after tool use; RR 1.14, 95% CI 1.07-1.23, P<.001, I^2=0%, FE model) compared with the control group, which included usual care [61,63,65,66] or a control video [64] (Figure 2A). Subgroup analysis indicated a significant difference in effect between tailored-to-risk e-tools and other tailored e-tools, while highlighting a high heterogeneity within one subgroup (χ^2_1=23.54, P<.001, risk-based group: I^2=0%, non-risk–based group: I^2=98%; see Figure S2 in Multimedia Appendix 1).

Figure 2. Forest plots of studies comparing the effect of e-tools with that of control on women's (A) participation in breast cancer screening (BCS) by mammography at long term [61,63-66], (B) intention to undergo BCS [54,55,68-71], (C) intention *not* to undergo BCS [69,70], and (D) adequate knowledge about BCS [54,63,69,70]. We reported in (B) the data corresponding to Lin et al.'s "tailored message intervention" (TMI) [68] and Seitz et al.'s "extended information with untailored exemplars" e–tools [71]. Data for the other Lin et al.'s [68] and Seitz et al's [71] e-tools are presented in in Appendix S4 in Multimedia Appendix 1. In (D) subgrouping was based on tailoring complexity of the e–tools (ie, tailored e-tools compared with features–with–tailoring e–tools), which end up being identical to subgrouping based on previous breast cancer screening status (ie, nonparticipants in BCS [tailored e–tools] compared with general population [features–with–tailoring e–tools]). Control was usual care, except in the studies by Lin and Wang [68], Roberto et al [55], and Seitz et al [71] (website), and Walsh et al [64] (video). The risk of bias was assessed using the Risk-of-Bias 2 (RoB 2) tool [52]. The risk level for each domain of RoB 2 (A: randomization process, B: deviations from the intended protocol, C: missing data, D: outcome measurement, and E: reporting results) and the (F) overall risk were evaluated as low (green), moderate (yellow), or high (red). M-H: Mantel-Haenszel.

Intention

Our meta-analysis, which incorporated 6 RCTs, showed that a mix of tailored (n=3, with 2 not based on risk) and features-with-tailoring (n=3) e-tools did not affect the rate of women intending to undergo BCS (RR 1.02, 95% CI 0.99-1.05, P=.24, I^2=31%, FE model) compared with the control group, which included either usual care [54,69,70] or a control website [55,68,71] (Figure 2B; also see Appendix S4 in Multimedia Appendix 1). No subgroup differences were observed between tailored and features-with-tailoring e-tools (χ^2_1=0.6, P=.43; see Figure S3 in Multimedia Appendix 1). Similarly, no significant difference in intention was reported in 2 pre-post studies evaluating tailored-to-risk e-tools [38,72,74]. In 2 other studies with no control and small sample sizes (N=8 or 49), participants either expressed an intent to undergo BCS [60] or showed no change in intention [73].

Moreover, in 2 RCTs [69,70], the effect of 2 features-with-tailoring e-tools on the rate of women with negative intention (willingness not to undergo BCS) was assessed. Our meta-analysis showed that these tools increased the rate compared with usual care (RR 1.88, 95% CI 1.43-2.48, P<.001, I^2=0%, FE model; Figure 2C).

Knowledge

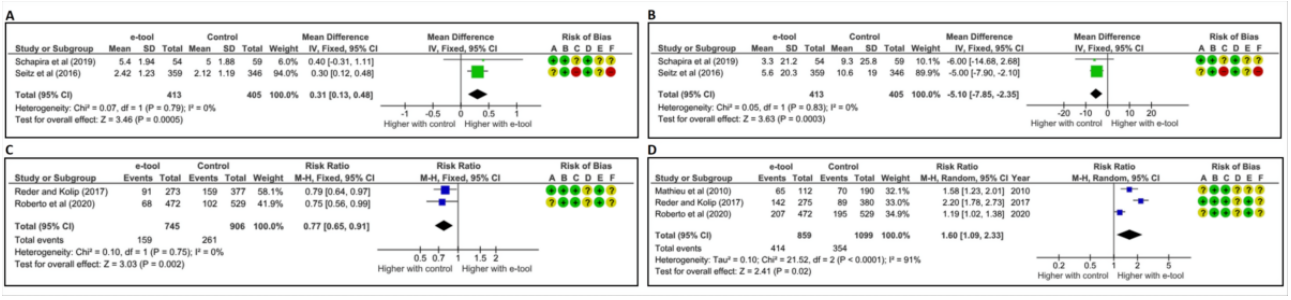
One RCT evaluating a tailored e-tool reported a positive correlation between increased knowledge and participation in BCS [65]. Our meta-analysis, conducted with 5 RCTs assessing a mix of tailored (n=3) and features-with-tailoring (n=2) e-tools, demonstrated that the e-tools increased women's adequate knowledge about BCS (MD 0.75, 95% CI 0.31-1.19, P<.001, I^2=89%, RE model; see Figure S4A in Multimedia Appendix 1) compared with the control group, which consisted of either usual care [54,63,69,70] or a control website [55]. We conducted subanalyses to explore the sources of heterogeneity, with all analyses not altering the overall result (see Figure S4B and S4C in Multimedia Appendix 1). Excluding Roberto et al's [55] study (see the "Methods" section) and subgroup analysis based on the degree of tailoring of the e-tools successfully reduced heterogeneity. Our findings indicated that adequate knowledge was higher with the features-with-tailoring e-tools, which were designed and tested with the general population, compared with the tailored e-tools, which were designed for and tested with

XSL•FO
RenderX

women who were nonparticipants in BCS (χ^2_1=5.1, *P*=.02; Figure 2D) [54,63,69,70]. In a pre-post study [62], a significant increase in adequate knowledge was reported with 1 features-with-tailoring e-tool (*P*=.001). For 2 tailored e-tools, with no reported control group, 48%-64% of users indicated increased knowledge or reported receiving new information, while approximately 15% either disagreed or had some level of disagreement with that statement [64,67,77].

Attitudes

Our meta-analysis showed that features-with-tailoring e-tools, compared with the control group (either usual care [69,70] or a control website [55]), had no significant effect on the rate of women with positive attitudes toward undergoing BCS (ie, being favorable to undergo BCS; RR 0.98, 95% CI 0.95-1.01, *P*=.19, I^2=0%, FE model; see Figure S5 in Multimedia Appendix 1). In another RCT with a 2×2 design that tested a features-with-tailoring e-tool featuring a virtual AI physician, the communication style of the physician and whether the women's needs were made salient were found to influence women's attitudes toward undergoing BCS [58].



Self-Efficacy

The impact of e-tools on women's level of self-efficacy regarding BCS was reported for 2 tailored e-tools. One study, an RCT, found no significant difference in self-efficacy compared with a brochure [54]. By contrast, a pre-post study [72] demonstrated a significant increase in self-efficacy.

Worry

Emotional changes, including anxiety, worry, or fear, were assessed either in general [69,71,78] or specifically related to breast cancer [63,67,75] (Table 2). Our meta-analysis, conducted with 2 RCTs evaluating tailored-to-risk tools, showed that compared with the control group (usual care [63] or a control website [71]), the e-tools increased women's level of worry (MD 0.31, 95% CI 0.13-0.48, *P*<.001, I^2=0%, FE model; Figure 3A), irrespective of the complexity of the tailored messages (see Figure S6 in Multimedia Appendix 1). In a prospective single-arm study, a tailored-to-risk tool that predicted breast cancer risk for women also increased their frequency of worry, which correlated with their level of risk (*P*<.01 by analysis of variance) [75]. In 2 other studies not comparing with controls [67,69], women reported not being particularly worried about breast cancer after using a features-with-tailoring tool [69]. Additionally, 80.9% of users of a tailored-not-to-risk tool indicated that the clinician helped reduce their fears and worries [67].

Figure 3. Forest plots of studies comparing the effect of e-tools with that of control on women's (A) level of worry [63,71], (B) accuracy of perception of individual breast cancer risk [63,71], (C) decisional conflict [55,70], and (D) informed choice [55,69,70]. We reported in (A) and (B) the data corresponding to Seitz et al's [71] "extended information with untailored exemplars" e-tool, which was the most comparable to Schapira et al's [63] e-tool. Data for the other Seitz et al's [71] e-tools are presented in Figures S6 and S7 in Multimedia Appendix 1. The control group was usual care, except for Seitz et al's [71] and Roberto et al's [55] e-tools, which used a website as the control. The risk of bias was assessed using the Risk-of-Bias 2 (RoB 2) tool [52]. The risk level for each domain of RoB 2 (A: randomization process, B: deviations from the intended protocol, C: missing data, D: outcome measurement, and E: reporting results) and the (F) overall risk were evaluated as low (green), moderate (yellow), or high (red). M-H: Mantel-Haenszel.

Perceptions of Risk of Breast Cancer

Two tailored-to-risk e-tools were evaluated for their effect on women's accuracy in perceiving their breast cancer risk. Accuracy was determined by measuring the difference between the risk perception assessed by the woman herself and her objective risk estimates provided by the e-tool. Our meta-analysis showed a significant decrease in this difference, indicating that women's accurate estimation of breast cancer risk improved with the use of the e-tools compared with the control group, which consisted of usual care [63] or a control website [71]. A significant improvement in the accuracy of breast cancer risk perception was observed when extended information with untailored examples was used in the e-tool (MD –5.10, 95% CI –7.85 to 2.35, *P*<.001, I^2=0%, FE model; Figure 3B), but not with other types of tailored messages (see Figure S7 in Multimedia Appendix 1). In another study using a tailored-to-risk tool without a control group, 70% of users reported having an "accurate perception" of their breast cancer risk, correctly identifying themselves as at low or average risk [75]. Additionally, the perceived susceptibility of breast cancer was assessed using a tailored-not-to-risk e-tool, which showed no significant difference compared with a control brochure ($F_{1,118}$=0.73, *P*=.01, effect size = 0.01) [54].

Regret

One RCT [70] assessed women's regret about their decision to undergo BCS. The study found no significant difference in regret between the group using the features-with-tailoring e-tool and the usual care group. Additionally, anticipated regret for decisions to delay or initiate mammography was evaluated using

XSL•FO
RenderX

a tailored-to-risk e-tool in another RCT [63], which also showed no significant difference compared with usual care.

Decisional Conflict

Our meta-analysis, which included 2 RCTs comparing 2 features-with-tailoring e-tools with either usual care [70] or a control website [55], found that the e-tools significantly reduced the rate of women experiencing decisional conflict (ie, uncertainty regarding the choice to be made or the decision to undergo BCS). The results showed an RR of 0.77 (95% CI 0.65-0.91, P=.002, I^2=0%, FE model; Figure 3C).

Other results obtained with tailored-to-risk tools were more mixed [63,72,74,75]. One RCT reported no change in the average decisional conflict (RR –0.34, 95% CI –0.71 to 0.03, P=.07) [63]. For 2 other e-tools tested through pre-post study designs [72,74], Yu et al [38] reported a significant decrease in decisional conflict. In a prospective single-arm study, women were found not to have difficulties in implementing decisions, as indicated by their average decisional conflict score [75].

Informed Choice

Our meta-analysis showed that, compared with the control group (either usual care [69,70] or a control website [55]), 3 features-with-tailoring tools increased the rate of women who made an informed choice regarding their intention to undergo BCS by mammography (RR 1.60, 95% CI 1.09-2.33, P=.02, I^2=91%; RE model; Figure 3D). Subanalyses to reduce heterogeneity were conducted but did not yield a significant decrease (data not shown).

Shared Decision-Making and Communications With Health Professionals

The effect of the tools on discussions about BCS during appointments between HPs and women was evaluated with 4 tailored tools [64,67,72,75]. One study reported that an additional 17.2% of women discussed mammography with their HPs compared with a control video group (P<.01) [64]. Another study found that women felt well-prepared to make shared decisions with clinical providers [72]. In 2 other studies comparing e-tool users with nonusers, HPs reported no significant difference in the rates of mammography discussions (90% vs 92%) [75], and the rates of medical “wellness” appointments did not increase (16.3% vs 21.5%) [67].

Grading of the Available Evidence

We summarized and graded the evidence detailed above in Table 3.

With a moderate to high level of certainty, the evidence supports the findings that e-tools (1) increased women’s long-term participation in BCS, intention not to participate, adequate knowledge, worry, and informed choice, while decreasing decisional conflict, and (2) had no effect on short-term participation in BCS, intention, and positive attitudes toward undergoing BCS (Table 3). Additionally, evidence indicates that the tailoring nature of the e-tools is the most influential factor in driving their effectiveness (Table 3).

XSL•FO
RenderX

Table 3. Grade summary of certainty of evidence related to the outcomes used to assess the effects of e-tools.

Outcome and e-tool effect (compared with control)	Main source of evidence (number of e-tools and type of control)	Certainty of evidence (GRADE[a])[b] (reasons for downgrading)	E-tool or population main characteristics
Participation at short term in BCS[c]			
No effect	• Meta-analysis with RCTs[d] (5 tools, control was either usual care [4 tools] or website [1 tool])	⊗⊗⊗◯ Moderate[e] (downgrading due to the presence of 2 high-risk of bias studies in the meta-analysis)	Mix of tailored-not-to-risk and features-with-tailoring e-tools, no differences between the 2 types of e-tools
Participation at long term in BCS[c]			
Increased	• Meta-analysis with RCTs (5 tools, control was either usual care [4 tools] or video [1 tool])	⊗⊗⊗◯ Moderate[e] (downgrading due to 3 high-risk of bias RCTs)	All tailored tools, but not only based on risk. Results suggest a difference between tailored-to-risk and other tailored e-tools
Intention to undergo BCS[c]			
No effect	• Meta-analysis with RCTs (6 tools, control was either usual care [3 tools] or website [3 tools]) • Yu et al's [38] meta-analysis with pre-post study design (2 tools)	⊗⊗⊗⊗ High[f]	Mix of tailored and features-with-tailoring e-tools, no differences between the 2 types of tools, further suggested by Yu et al's results with 2 tailored-to-risk e-tools
Intention not to participate (negative intention) in BCS[c]			
Increased	• Meta-analysis with RCTs (2 tools, control was usual care [2 tools])	⊗⊗⊗◯ Moderate[e] (downgrading due to very low number of RCTs [2 studies])	Features-with-tailoring e-tools
Adequate knowledge			
Increased	• Meta-analysis with RCTs (4 tools, control was usual care [4 tools])	⊗⊗⊗⊗ High[f]	The increase is independent of whether the e-tool is tailored or featured-with-tailoring; however, adequate knowledge is higher with features-with-tailoring e-tools assessed with the general population compared with tailored tools assessed with the nonscreened population
Positive attitude			
No effect	• Meta-analysis with RCTs (3 tools, control was usual care [2 tools] or website [1 tool])	⊗⊗⊗⊗ High[f]	Features-with-tailoring e-tools
Self-efficacy			
No effect	• 1 RCT and 1 pre-post study	⊗◯◯◯ Very low[g] (downgrading due to very low number of studies, contradictory results obtained with 1 RCT and 1 pre-post study)	Tailored e-tools

XSL•FO

[a]GRADE: Grading of Recommendations, Assessment, Development, and Evaluation.

[b]We adopted the GRADE Working Group methodology of grading evidence [49-51]. Our baseline statement was high for meta-analyses with RCTs (our results), moderate for RCTs without meta-analysis, and low for non-RCTs. Where indicated, we decreased the certainty in the evidence to at least one level based on the assessment of the following domains: risk of bias, imprecision (number of studies, SD), inconsistency (inconsistent effect between several studies, I^2), indirectness, and publication bias; additionally, downgrading and reasons why it was performed are indicated. As a result of the low total number of studies selected in this review, we did not downgrade based on imprecision (number of studies, SD) criteria except where only 2 studies were available and as detailed in the table. We graded evidence as in footnotes e, f, g, and h.

[c]BCS: breast cancer screening

[d]RCT: randomized controlled trial.

[e]Moderate certainty: we are moderately confident in the effect estimate: the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

[f]High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.

[g]Very low certainty: we have very little confidence in the effect estimate; the true effect is likely to be substantially different from the estimate of effect.

[h]Low certainty: our confidence in the effect estimate is limited; the true effect may be substantially different from the estimate of the effect.

[i]SDM: shared decision-making.

Discussion

Principal Findings

This is the first systematic review to provide a comprehensive overview of the effects of e-tools on women's decision-making about BCS. The findings indicate that e-tools increase women's long-term participation in BCS, intention not to participate, adequate knowledge, worry, and informed choice. They also reduce women's decisional conflict. However, e-tools have no effect on women's short-term participation in BCS, intention, or positive attitudes toward undergoing BCS. Additionally, the review identifies variables that could influence these effects. Among all the variables explored, the degree of tailoring in e-tools (ie, whether the tools were fully "tailored" or "featured with tailoring") appeared to be the most influential (Table 3).

While all e-tools were shown to increase knowledge about BCS, the extent of the increase depended on the degree of tailoring or the study population. The increase was greater with "featured-with-tailoring" e-tools assessed in the general population than with tailored e-tools assessed in non-BCS participants. However, the observation that 1 tailored e-tool was more effective in less-educated women [57,79] supports the notion that the degree of tailoring plays a key role in driving a greater or lesser effect on knowledge. Our results suggest that complex e-tools (ie, tailored tools) are not necessarily more effective in ensuring that women are adequately informed about BCS than less complex e-tools (ie, features-with-tailoring). This finding aligns with recent studies, particularly those involving women from low socioeconomic backgrounds, which indicate that complex information about cancer screening may not be essential for women to be adequately informed [93,94].

Our results indicate that features-with-tailoring e-tools influence women's decisions about undergoing BCS. These tools reduce decisional conflict regarding BCS as well as increase both the intention not to undergo BCS and informed choice about this intention (Table 3). However, they have no effect on positive attitudes toward BCS. The reduction in decisional conflict concerning BCS aligns with findings from a previous meta-analysis of web-based tools [38]. By contrast, a meta-analysis that included both e-tools and printed DAs did not report this effect [23], which may be attributable to the quality of one of the assessed printed DAs [95,96]. An increase in women's informed choice regarding BCS has been consistently reported in all meta-analyses conducted to date on DAs used for BCS, regardless of whether the tools were web-based or printed [23,24,38]. Similar to our findings, these reported effects were associated with features-with-tailoring tools, as defined in our study [23,24,38]. However, a more detailed analysis of our results suggests that this increase in informed choice may stem from a rise in both negative intentions and negative attitudes toward BCS. As defined by Marteau et al [16], individuals are considered to have made an informed choice about BCS if they possess adequate knowledge and hold either positive attitudes and intentions or negative attitudes and intentions. Our results showed that while the e-tools by Reder and Kolip [70], Mathieu et al [69], and Roberto et al [55] increased informed choice (Figure 3D) and knowledge (see Figure S8A in Multimedia Appendix 1), they did not increase either positive attitudes toward BCS (see Figure S5 in Multimedia Appendix 1) or the intention to undergo BCS (see

XSL•FO
RenderX

Figure S8B in Multimedia Appendix 1). It is likely that the observed increase in informed choice among women using these e-tools was driven by an increase in negative intentions, as evidenced by 2 of the 3 tools (Figure 2C), and possibly by negative attitudes toward participation in BCS, as reported in other studies [24]. Interestingly, these 3 e-tools are among the highest-rated BCS DAs based on the IPDAS criteria. This was formally evaluated for the e-tools by Reder and Kolip [70] and Mathieu et al [69] in a recent systematic review [85]. Although Roberto et al's [55] e-tool was not formally assessed in the same review, it is expected to be of similarly high quality due to its strong resemblance to Reder and Kolip's [70] tool [85]. Our results suggest that even high-quality e-tools, as assessed by IPDAS criteria, and their ability to achieve higher levels of adequate knowledge, increase informed choice, and reduce decisional conflict, do not guarantee the promotion of positive intentions and attitudes toward undergoing BCS. On the contrary, these tools may increase negative intentions and attitudes. BCS programs should take this finding into consideration.

Our results on participation in BCS (Table 3) strongly suggest that only tailored e-tools have a significant effect on participation. Two factors may explain this finding regarding tailored-to-risk e-tools. First, these e-tools, when appropriately designed, increase women's accurate perception of their own breast cancer risk (as shown by our results). Second, they may also heighten women's levels of worry (Table 3), which is likely a key driver of increased participation in BCS. Indeed, while fear of breast cancer has been reported as a barrier, it has also been identified as a facilitator of BCS participation [9,10,97]. BCS programs should address women's feelings of worry if they aim to implement tailored-to-risk e-tools. However, further studies are needed to assess women's acceptability of feeling worried in comparison to their perceived benefits of using these e-tools. In addition, it is important to note that the tailored e-tools evaluated in this review incorporate multiple features that allow for their effective integration into clinical pathways or health care services (Table 1). These features can be seen as opportunities to reduce barriers and increase access to BCS participation, such as by facilitating helpful discussions with health care providers (HPs) or simplifying the appointment process [9,10,97]. Additionally, these features could help mitigate the impact of the tools on increasing worry [67].

Among the 22 e-tools investigated in this research, including the 6 identified as preparing for or facilitating SDM [63,64,72-75], none were evaluated using any validated SDM instruments [98-106]. There was no evidence to indicate whether the e-tools had an effect on SDM. Although this review suggests that e-tools, particularly tailored e-tools, may improve SDM by enhancing the quality of appointments with health care providers (HPs), this is likely due to their multiple features, which enable effective integration into clinical pathways or health care services (Table 1).

Recommendations for Future Developments

While all types of e-tools appeared effective in increasing users' knowledge about BCS, our results highlight important dilemmas for BCS programs that are using or planning to use e-tools to support women at average risk of breast cancer [2-4] in making decisions about BCS. Although features-with-tailoring e-tools can potentially increase informed choice and reduce decisional conflict, they may also be perceived as negatively impacting BCS programs by fostering negative intentions and attitudes toward undergoing BCS. Conversely, tailored e-tools, despite lacking evidence to support their effects on informed choice and decisional conflict, would increase women's participation in BCS but, when tailored to risk, these tools may also heighten their levels of worry. One potential approach to minimize risks to both women's well-being (worry) and BCS programs would be an "on-demand" model. In this model, women would "tailor" their own information needs, deciding on the nature and amount of information they feel is necessary. In this approach, we recommend that (1) all women be provided with a minimum of important, carefully assessed information about BCS in both text and audio formats, with multiple language options; and (2) women who do not wish to participate in BCS be given the option, through the e-tool, to obtain estimates of their breast cancer risk or, at the very least, to have a discussion with health care providers (HPs) about breast cancer risk in general. Some women may be unaware of the average breast cancer risk for women or of their own increased risk [2-4]. We also suggest that e-tools be well integrated into clinical pathways or health care services in various ways to reduce access-related barriers, especially those specific to low socioeconomic groups, such as health literacy. Notably, embedding e-tools in a health portal (Table 1) would facilitate appointments and communication with health care providers (HPs). AI tools, which have not been fully explored in the context of BCS according to this review, could support the "on-demand" approach. However, both the efficacy of such AI-based tools and potential ethical issues or biases need to be carefully assessed [107-110].

Limitations

This study has several limitations that should be considered in future research. Caution is needed when generalizing our results due to (1) the limited number of studies included, particularly in the meta-analyses, with some outcomes assessed by only 2 RCTs (eg, "intention not to undergo BCS," "level of worry," "accuracy of perception of individual breast cancer risk," and "decisional conflict"), some of which were at high risk of bias; (2) the high heterogeneity between the studies and e-tools; (3) the fact that almost all studies were conducted in high-income countries, mostly in the United States, which may limit the applicability of the results to other settings or low- and middle-income countries; and (4) the lack of assessment of implementation factors (eg, comparing users vs nonusers or completers vs noncompleters) and their impact on decision-making outcomes. Additionally, (1) we did not thoroughly review the content of the BCS information provided in the e-tools evaluated in this review, so we cannot draw conclusions about the tangible value of the increase in knowledge [95]; and (2) we did not have enough information to determine whether some of the e-tools could be classified as DAs. However, we applied a robust methodology to minimize some of these limitations, notably by comprehensively exploring the variables that could explain the heterogeneity of the results,

XSL•FO
RenderX

using RoB 2 and GRADE assessments. A review is currently underway to explore implementation outcomes.

Conclusions

Although no evidence was available to assess the efficacy of the tools in supporting SDM, this review demonstrates that the e-tools designed to assist women's decision-making regarding BCS do impact this process. The degree of tailoring of the e-tools (ie, whether they are tailored, particularly to risk, or include features with tailoring) appears to be the most significant factor influencing decision-making. This review provides valuable insights for BCS programs when implementing such e-tools and offers directions for future development.

Acknowledgments

The authors would thank Dr. Marie-Anne Durand (Unisanté, Lausanne) for her valuable comments and participation. We are also grateful to all the study authors with whom we communicated to gather additional data for our meta-analyses. We thank our IARC colleague Mrs. Karima Bendeddouche for her support with the submission process. Our thanks also go to Teresa Lee (IARC Knowledge Manager) and Latifa Bouanzi (IARC Information Assistant) for their help in developing the research question and building it across all databases. This review is dedicated to the memory of our kind and highly professional colleague from WHO/Geneva, Tomas John Allen (Librarian, WHO), who helped identify the search strategy for Embase.

Data Availability

Multimedia Appendix 1, which cites additional references [111-115], contains extra information about the methods used and reports additional meta-analyses and subanalyses. The complete qualitative data sets generated or analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

PV conceived the review, conducted the analyses, including meta-analyses, and wrote the publication. RS supervised the study and the writing. PV and ALB performed the initial data search and PV updated the search. PV and LD, ALB, or CB extracted the data. Risk-of-bias of the RCTs was assessed by PV and LD, ALB, or CB. Grade assessment was performed by PV and LD. All authors contributed to establishing the data extraction form. All authors critically reviewed the preliminary results and the final report. The main contributors at the 2019 workshop on e-DAs and in further discussions are all listed as co-authors or in the Acknowledgments (Marie-Anne Durand). PV/IARC obtained funding from the Institut National du Cancer, France (INCa, grant DEP18-066). The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: eHealth interventions can favorably impact health outcomes and encourage health-promoting behaviors in children. More insight is needed from the perspective of children and their families regarding eHealth interventions, including features influencing program effectiveness.

Objective: This review aimed to explore families' experiences with family-focused web-based interventions for improving health.

Methods: Five databases were searched on October 26, 2022—updated on October 24, 2023—for studies reporting qualitative data on participating children or their caregivers' experiences with web-based programs. Study identification was performed in duplicate and studies were independently appraised for quality. Thematic synthesis was undertaken on qualitative data extracted from the results section of each included article.

Results: Of 5524 articles identified, 28 articles were included. The studies examined the experiences of school-aged children (aged 5-18 years) and their caregivers (mostly mothers) with 26 web-based interventions that were developed to manage 17 different health conditions or influence health-supporting behaviors. Six themes were identified on families' experiences: connecting with others, agency of learning, program reputability or credibility, program flexibility, meeting participants' needs regarding program content or delivery, and impact on lifestyle.

Conclusions: Families positively perceived family-focused web-based interventions, finding value in quality connections and experiencing social support; intervention features aligned with behavioral and self-management principles. Key considerations were highlighted for program developers and health care professionals on ways to adapt eHealth elements to meet families' health-related needs. Continued research examining families' experiences with eHealth interventions is needed, including the experiences of families from diverse populations and distinguishing the perspectives of children, their caregivers, and other family members, to inform the expansion of family-focused eHealth interventions in health care systems.

Introduction

Pediatric Health

A growing number of children are engaging in health risk behaviors or living with a health condition [1-6]. Children's management of health conditions greatly influences their physical, emotional, and psychosocial growth; development; and well-being as well as their health into adulthood [1,3,7-9].

The family unit, namely children and their immediate family members (ie, caregivers and siblings), plays an important role in shaping children's health-related behaviors [6-8,10,11]. Children also assume varied degrees of responsibility for their health with age and into adulthood [3,6]. Long-term multicomponent, multidisciplinary interventions incorporating behavioral change and self-management techniques (eg, disease education, goal setting, and self-monitoring) and involving the family unit are recommended for treating or managing childhood health conditions or encouraging health-promoting behaviors in children [3,12]. Such services are traditionally administered in person; offer limited enrollment with strict eligibility criteria; require extensive time from trained health care professionals (eg, physicians, allied health practitioners, and nurses); and have limited accessibility, particularly in areas of lower socioeconomic advantage or regional or remote areas [3,5,13].

Pediatric eHealth Interventions

Using digital technologies to adapt conventional services to a web-based setting—offering eHealth interventions—has the potential to overcome the limited accessibility and reach of traditional services for treating childhood health conditions or to influence health-supporting behaviors. Studies have suggested that the use of digital technologies (eg, mobile or video communication platforms or websites) allow the continuation of health care when conventional or specialized care, beyond primary care, is unavailable [5,14].

Existing literature has considered the breadth of eHealth interventions delivered through various eHealth modalities. A 2021 systematic review reported that in the last decade and up until the beginning of the COVID-19 pandemic, there has been a surge in eHealth interventions, largely developed to treat mental illnesses and noncommunicable diseases and delivered through telehealth platforms or mobile phones [15]. Another systematic review in 2021 [4] found that eHealth technologies were mostly used for monitoring, tracking, and reporting purposes. Existing research on eHealth interventions for treating or managing specific health conditions or encouraging health-promoting behaviors in children has focused on evaluating program effectiveness [3,9,12,16-18]. Studies have found that such interventions have improved condition-specific outcomes (eg, disease markers, symptom management, and adherence to disease management plans) and health behavior changes in children [3,12,17-20]. Web-based programs were proposed as a potentially favorable type of eHealth intervention for children and their caregivers [4,21].

With an increased number of families with children living with health conditions needing treatment, urgent action is needed to optimize the development and delivery of eHealth interventions for children and families. Although the evidence base on the effectiveness of such interventions is expanding, there is limited research exploring the experiences of eHealth interventions for children and their families. The needs, values, and perceptions of program end users (ie, children and their caregivers) are essential for program development; participants are key informants of their health, including engagement in health-supporting behaviors or medical treatment [22,23]. Understanding their experiences with eHealth interventions can provide valuable insight on the program's potential to impact the participating child's health, including on health outcomes overtime, sustainability of changes, design features to maximize program effectiveness, uptake and engagement, and mechanisms underlying children's and their families' health. There is a developing body of literature exploring participants' lived experiences with family-focused eHealth interventions to prevent or treat health conditions in children.

This qualitative systematic review aims to synthesize the viewpoints of children and their families on their experiences with family-focused web-based programs for improving health. Findings from this review will inform the development of eHealth interventions and enhance our understanding of the ability of eHealth interventions to meet the health-related needs of children and their families.

Methods

The qualitative systematic literature review was conducted and reported in line with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) and the Enhancing Transparency in Reporting the Synthesis of Qualitative Research statements [24,25]. The review protocol was prospectively registered via PROSPERO (CRD42022363874). The PRISMA checklist for the review is included in Multimedia Appendix 1.

Eligibility Criteria

Eligibility criteria were determined using the Population, Intervention, Comparator, Outcome and Study design framework.

Population

Studies involving the family unit (at least a child aged ≤18 years and a caregiver) were included in this review. There were no limits on study participants regarding gender, ethnic or medical background, and locality.

Intervention

Included study interventions were web-based programs targeted at the family unit. A web-based program was defined as an eHealth intervention where the primary component of the program was completed on the web, including web-based modules and activities. The web-based intervention included the active participation of both the participating child and at least one caregiver (ie, the program included activities for both the participating child and caregiver to complete). The eHealth intervention could have been accessed via multiple technological modalities, such as computers, phones, and tablets. Interventions may have included other adjunct eHealth components (eg, a mobile app for monitoring, tracking, or reporting purposes;

XSL•FO
RenderX

email; and phone messaging or calls) or health care services (eg, feedback or support from medical and allied health practitioners). eHealth interventions delivered solely through smartphone apps were not included.

Studies on eHealth interventions where the web-based program was used to support conventional face-to-face health care interventions (including telehealth) or where the web-based component was not the primary part of the intervention were excluded. Studies on web-based interventions used as decision-making, screening, or assessment tools, where the program content was delivered primarily through live sessions (eg, videoconferencing sessions), or on programs targeting the caregiver or child exclusively were also excluded.

Comparator

A comparator was not specified for this review.

Outcomes

Included studies described the child or caregiver's perceptions of participating in a web-based program (eg, perceptions of the intervention as a whole or specific intervention features; reflections on occurrences or attitudes before, during, or after the intervention) using qualitative methods, such as interviews, focus groups, and open-ended responses retrieved through surveys.

Study Design

All study designs were considered for inclusion if they included a qualitative component exploring participants' experiences and were published in English. Review articles, doctoral theses, and conference abstracts were excluded.

Search Strategy

Ovid MEDLINE, Ovid Embase, Cochrane Library, Scopus, and CINAHL were searched for articles that met the eligibility criteria in October 2022 and updated in October 2023. Search results were limited to human studies published in English and within the last decade to capture evidence on the most up-to-date eHealth developments and updated versions of web-based interventions.

The search used both keyword and subheading search terms related to families, web-based programs, experiences or perspectives, and qualitative research methods. The search strategy for each database is included in Multimedia Appendix 2.

To test the validity of the search strategy, 3 key articles that met the inclusion criteria were identified [26-28]. The search strategy was developed with senior researchers with experience in pediatric research or interventions and qualitative research and confirmed with a university librarian. The reference lists of included articles were hand searched for additional relevant articles.

Study Selection and Data Extraction

Retrieved citations were exported into EndNote 20 software (Clarivate). Duplicates were removed and the remaining results were imported into and managed using Covidence (Veritas Health Innovation). Titles and abstracts were screened independently by at least 2 authors (DZ, SG, and ZED), after which full-text articles were screened independently against the eligibility criteria by 2 authors (DZ, SG, and ZED). Disagreements on the inclusion of articles were resolved by consensus.

Data were extracted using a bespoke data extraction template that was piloted by 2 authors (DZ and SG) before data extraction. Information extracted from articles included publication details (authors and year and country of publication); study aim; participant characteristics (participating children's age health status and the participating caregivers); study design (qualitative methodology and sample size); intervention characteristics (purpose and key features of the intervention and level of guidance or support provided throughout the intervention); and outcomes (themes and representative quotes relating to participants' experiences). Data were extracted independently by one author (DZ) and confirmed with a second author (SG); 3 papers were selected randomly where SG independently extracted data to compare and confirm the data extraction process.

Quality Appraisal

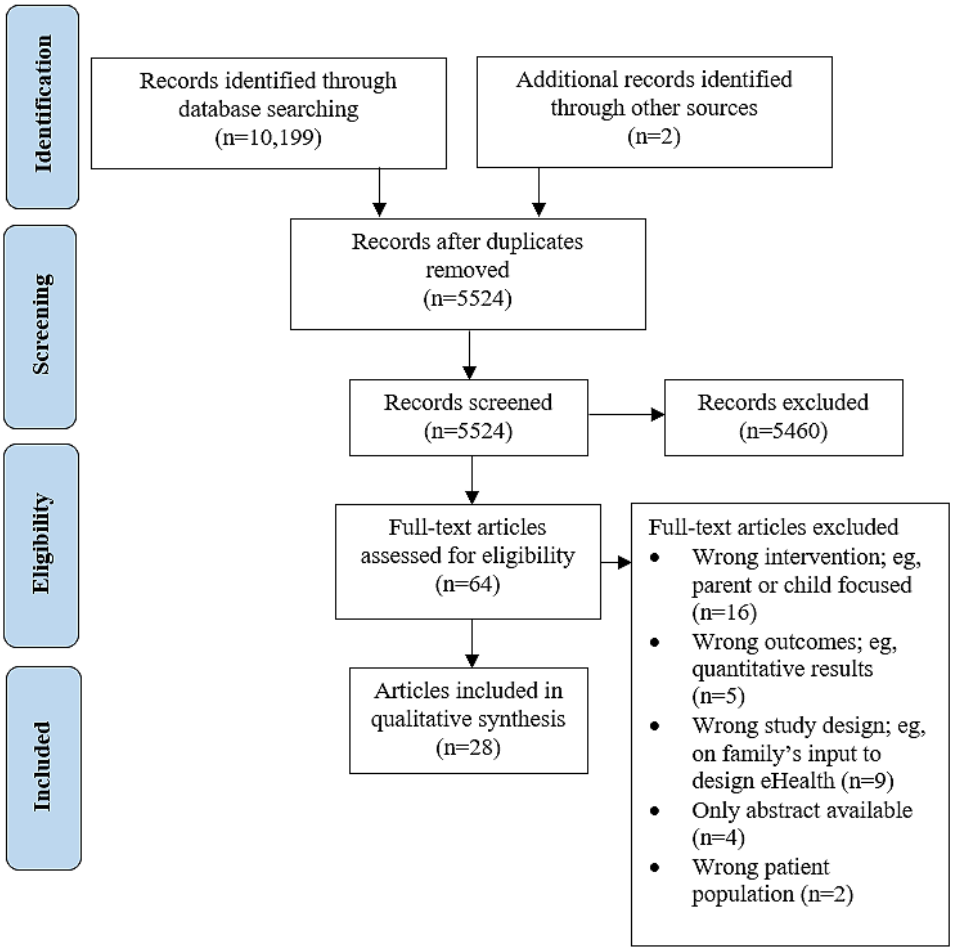
Studies were appraised using the Critical Appraisal Skills Programme qualitative checklist [29]. Included studies were independently assessed by one author (DZ) and confirmed with a second author (SG). Three papers were selected at random and independently appraised by both authors, after which assessment results were discussed, discrepancies were addressed, and the first author appraised the remaining papers.

Data Synthesis

Thematic synthesis [30] was undertaken on the extracted data about participating children and caregivers' experiences with the intervention using inductive line-by-line coding of the results and representative quotes extracted from the included studies. Four papers were selected at random and independently and manually coded by 2 authors (DZ and SG). Codes were discussed by both authors (DZ and SG) and refined, whereby the coding process was confirmed. The remaining papers were then coded by DZ, where new codes identified throughout the process were discussed and further verified by SG. One author (DZ) then independently developed descriptive categories from these codes that were discussed and critically reviewed regularly between 2 authors (DZ and SG) until a consensus was reached. These descriptive categories were then synthesized into overarching themes.

Individual and collaborative reflexivity were undertaken during the planning and implementation of the review methodology [31]. Authors were dietitians or nutritionists and researchers, with clinical or research experience in pediatric nutrition, weight management or lifestyle programs, or education. Most authors have been developing their knowledge of or capacity in qualitative methodology, and one author has extensive experience with qualitative research. All authors reflected on and acknowledged their personal and professional experiences by engaging in reflexive writing (eg, researcher notes and journaling) or team discussions throughout the review process. Authors collaborated as a team to resolve disagreements during

XSL•FO
RenderX



the screening process and when analyzing and reporting the data. During team discussions, authors also communicated their expertise in the review methodology, assumptions made during decision-making, and expectations of results.

Results

Search Results and Study Characteristics

The search identified 5524 articles after the removal of duplicates, of which 28 articles were included in the qualitative synthesis (refer to Figure 1 for the PRISMA diagram). Two articles included in this review reported findings from the same study [32,33]. The studies included in this review examined 26 distinct interventions, where 1 study explored 3 versions of an intervention (ie, adapted to 3 cultures) [34], 1 study examined 2 versions of an intervention (ie, partly guided versus entirely self-guided versions) [35], 5 studies evaluated 2 separate interventions (ie, including the conductance of process evaluations on the web-based program) [26,27,36-38], and the remaining studies investigated one web-based program each [28,39-56].

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram outlining the study selection process.

The characteristics of the included articles are summarized in Table 1. Studies examined web-based programs delivered in the United States [39-46], Canada [28,47-49], United Kingdom [34,50,51], England [32,33], Sweden [35,52-54], Australia [37,38,55], New Zealand [34,56], Italy [34], and Spain [26,27,36]. Participants included children in their school-aged years (aged 5-18 years): primary school–aged children [26,27,32,33,36,42,50,56], secondary school–aged children [28,34,35,37-41,43-46,51,52,54], or both primary and secondary school–aged children [47-49,53,55]. Children in 24 studies were formally diagnosed or screened to be at higher than normal risk for a health-related condition or risk factor by a health care professional (eg, physicians, allied health practitioners, and nurses) [26-28,32-45,47-49,51-54,56]. One study included families with children who may have self-identified with having a health disorder [55]. Of the included studies, 15 reported the gender of the participating caregivers; mostly mothers participated in the intervention program [32,35,37,39-44,48,50,51,53-55]. A total of 8 studies included information on the parent or caregiver's academic background, where all caregivers noted completing higher education [32,40,42-44,46,48,49]. Only 2 studies reported the socioeconomic statuses of the families [44,46], where families from both studies mostly reported having an average annual income.

Table 1. Study design of included studies and program characteristics.

Study	Study aim	Program characteristics (partly guided or self-guided; frequency or duration of intervention)	Family characteristics	Qualitative data collection method
Guagliano et al [50], 2019; United Kingdom	To assess the feasibility and acceptability of a web-based physical activity intervention (FRESH[a])	Self-guided; weekly challenges; 6 wk	• n=12 families • Children[b]: 8-10 y (average 8.3 y) • Caregivers[b]: 39.8 y (average) • Mostly mothers	Feedback questionnaire and semistructured focus with families at 6 wk
Hatfield et al [37], 2018; Australia	To determine the effectiveness, usability, and barriers and facilitators related to an online transition program for adolescents with autism spectrum disorder program (BOOST-A[c])	Partly guided; 2 mo	• n=39 families • Children[b]: secondary school–aged (8-11 y; average 14.8 y); mostly boys • Caregivers[b]: mostly mothers; mostly with moderate-high SES[d]	Feedback questionnaire and semistructured interviews with families within 2 mo post program completion
Jogova et al [47], 2013; Canada	To conduct a process evaluation of an online healthy lifestyle program for children with obesity (LiGHT[e])	Partly guided; 4 wk	• n=20 families participated in the intervention • Children[f]: 10-17 y (average 13-15.5 y); mostly girls	2-h focus groups with families and feedback questionnaires collected from families post program
Bevan Jones et al [51], 2020; United Kingdom	To evaluate the feasibility, acceptability, and potential impact of an online psychosocial program for children with a history of depression (MoodHwb[g])	Self-guided; 2 mo	• n=44 children; n=31 caregivers • Children[b]: ≥13 y (average 16.3 y); mostly girls • Caregivers[b]: mostly mothers	Feedback questionnaire and semistructured interviews with families post program completion (2 mo)
Khan et al [32][h], 2021; England	To explore the fidelity and experiences of families with a behavioral intervention for children with tics disorder (ORBIT[i])	Partly guided; 10-12 wk	• n=112 families received intervention • Children[f]: 9-16 y (average 12y); mostly boys with moderately severe symptoms • Caregivers[f]: mostly mothers; completed higher education[j]	Feedback questionnaire and semistructured interviews with families at post program completion (3 mo)
Lalloo et al [39], 2022; United States	To characterize families' engagement with a pain management intervention for children with SCD[k] (iCanCope with SCD)	Self-guided	• n=56 families; n=1 child received intervention • Children[b]: 12-18 y (average 14.8 y); mostly girls • Caregivers[b]: mostly mothers	Semistructured interviews with families within 6 mo post program completion
Lenhard et al [52], 2016; Sweden	To describe participants' experiences with a cognitive behavioral therapy program for children with obsessive compulsive disorder (BiP OCD[l])	Partly guided	• n=21 families received intervention • Children[f]: 12-17 y	Interviews with families at 3-6 mo post program completion
Muller et al [55], 2024; Australia	To gain parents' insights on their engagement with a program for the management of childhood anxiety (BRAVE[m] Self-Help)	Self-guided	• n=14 families received family version • Children[b]: 3-17 y • Caregivers[f]: average 44y; mostly mothers	Semistructured interviews with caregivers at 6 mo
Murray et al [40], 2022; United States	To evaluate the feasibility and acceptability of a pain management program for children undergoing spinal fusion surgery	Partly guided; weekly or fortnightly modules; presurgery period: 4-6 wk, postsurgery period: 6-8 wk	• n=13 families received the intervention • Children[b]: 12-17 y (average 14.3 y); mostly girls • Caregivers[b]: mostly mothers; mostly completed higher education and with high SES	Semistructured interviews with families 3 mo postsurgery

Study	Study aim	Program characteristics (partly guided or self-guided; frequency or duration of intervention)	Family characteristics	Qualitative data collection method
Nieto et al [36], 2015; Spain	To assess the feasibility of a pain management program for children with functional abdominal pain (DARWeb[n])	Self-guided; weekly modules	• n=15 families received intervention • Children[b]: 9-14 y; mostly girls	Feedback questionnaire and semistructured interviews with families at 2 wk post program completion
Nieto et al [26], 2019; Spain	To explore the impact and families' perspectives of a pain management program for children with functional abdominal pain (DARWeb)	Self-guided; weekly modules	• n=22 families • Children:f 9-14 y (average 11.23 y); mostly girls and with low pain severity	Semistructured interviews with families at post program completion
Nieto et al [27], 2019; Spain	To evaluate the efficacy of a pain management program for children with functional abdominal pain (DARWeb)	Self-guided; weekly modules	• n=25 families received intervention • Children[b]: 9-15 y (average 11.28 y); mostly girls	Feedback questionnaire and semistructured interviews with families post program completion (11 wk)
O'Sullivan et al [48], 2018; Canada	To evaluate the acceptability of a self-management program for Irish children with JIA[o] and their families (TTC[p])	Self-guided; weekly modules;12 wk	• n=20 families received intervention • Children[f]: 12-18 y (average 14.19 y); mostly girls • Caregivers[f]: mostly 40-49 y; mostly mothers who completed higher education	Focus groups or interviews with families at 2 wk program commencement
Palermo et al [41], 2018; United States	To evaluate the acceptability and feasibility of a cognitive behavioral intervention for children with sickle cell disease and their families (Web-MAP[q])	Partly guided	• n=15 families received CBT[r] version • Children[b]: 11-18 y (average 14.8 y); mostly girls • Caregivers[b]: mostly mothers with low to moderate SES	Semistructured with families at post program completion
Sonney et al [42], 2020; United States	To evaluate the feasibility, acceptability and efficacy of a sleep intervention for children with asthma and their families (SKIP[s])	Self-guided; weekly modules	• n=29 families received the intervention • Children[b]: 6-11 y (average 8.3 y) • Caregivers[b]: mostly mothers who completed higher education	Feedback questionnaire and semistructured interviews with families at 12 wk
Stasiak et al [56], 2018; New Zealand	To evaluate the feasibility and acceptability of a cognitive behavioral intervention for children with mild to moderate anxiety related to the experience of a natural disaster and their families in primary care (BRAVE-ONLINE[t])	Partly guided; weekly modules	• n=42 families received the intervention • Children[b]: 7-15 y (average 11.1 y); mostly with generalized anxiety disorder • Caregivers[b]: mostly with moderate-high SES	Feedback questionnaires with families at post program completion (12 wk)
Stinson et al [28], 2015; Canada	To explore the usability of a self-management program for children with cancer and their families (Teens Taking Charge: Managing Cancer Online)	Self-guided	• n=22 children, n=15 caregivers received intervention • Children[b]: 12-18 y (average 15.2 y); mostly boys	Semistructured interviews with families following receipt of intervention
Thompson et al [43], 2019; United States	To evaluate the feasibility and acceptability of a self-management program for children with type 1 diabetes and their families (FTO[u])	Self-guided; fortnightly modules; 3 mo	• n=27 families received intervention • Children[f]: 10-15 y; mostly girls • Caregivers[f]: mostly mothers who completed higher education and with moderate-high SES	Phone interviews with families post program completion
Thorén et al [53], 2021; Sweden	To explore parents' experiences with a lifestyle program for children with obesity (Web-COP[v])	Partly guided; weekly sessions; in-person group sessions–4 wk, web-based modules–12 wk	• n=51 families received intervention • Children[b]: 5-13 y; mostly girls • Caregivers[f]: mostly mothers with history of obesity	Semistructured interviews with caregivers at 2-4 mo post program completion

XSL•FO
RenderX

Study	Study aim	Program characteristics (partly guided or self-guided; frequency or duration of intervention)	Family characteristics	Qualitative data collection method
Wade et al [44], 2017; United States	To assess the feasibility and acceptability of a problem-solving and communication skills training program for children with traumatic brain injury and their families (TOPS[w])	Partly guided	• n=49 families received the family version • Children[b]: 11-18 y (average 14.7 y); mostly boys with moderate-severe brain injury • Caregivers[b]: mostly mothers who completed higher education and with moderate-high SES	Satisfaction surveys and interviews with families at 6 mo
Wade et al [34], 2021; New Zealand, United Kingdom, and Italy	To adapt a problem-solving and communication skills training program for children with traumatic brain injury and their families (TOPS) in New Zealand, United Kingdom, and Italy	Partly guided; New Zealand: 5 wk	• Childrenb: New Zealand: 12-17 y • Italy and United Kingdom: adolescent years	Focus groups with caregivers or families following receipt of the intervention in Italy and New Zealand; feedback questionnaire with families in the United Kingdom at post program completion (1 mo)
Yuen et al [45], 2016; United States	To develop and evaluate the usability of a psychoeducation intervention for children affected by a natural disaster and their families (BBN[x])	Self-guided	• n=24 children accessed intervention module • Children[f]: 12-17 y (average 14.12 y); mostly girls with some degree of PTSD[y]	Children were observed and provided feedback (verbal and written) while completing selected program module; feedback questionnaire and interviews with children after completing selected program module
Simonsson et al [54], 2021; Sweden	To explore the experiences of families with a treatment program for children with nonsuicidal self-injury disorder and their families (online ERITA[z])	Self-guided; 12 wk	• n=25 families received the intervention • Children[f]: 14-17 y; mostly girls • Caregivers[f]: 43-55 y; mostly mothers	Semistructured interviews with families post program completion
Lee et al [46], 2023; United States	To evaluate the effectiveness and usability of an intervention on human papillomavirus vaccination for Hmong-American families (Hmong Promoting Vaccines—HmongHPV website)	Partly guided; daily modules; 1 wk	• n=30 families received intervention • Children[f]: 12-16 y (mostly <15 y) • Caregivers[f]: mostly completed higher education and with average SES	Surveys with families post intervention completion (1 and 5 wk); interviews with families at 6 wk post intervention completion
Andersson et al [35], 2024; Sweden	To explore families' experiences completing an intervention for children with depression (online BA[aa])	Self-guided; 10 wk	• n=11 families received intervention programs • Children[f]: 13-17 y (average 15.2 y); mostly boys • Caregivers[f]: all mothers	Semistructured interviews with families at post program completion
Connan et al [49], 2019; Canada	To assess the usability of an intervention on the gluten free diet for children with celiac disease and type 1 diabetes and their families	Self-guided	• n=20 families recruited • Children[f]: mostly secondary school–aged years (average 13.4-13.5 y); mostly girls • Caregivers[f]: mostly completed higher education	Families were observed and engaged in usability interviews during and post module completion
Khan et al [33][h], 2022; England	To explore the factors influencing the efficacy and engagement of families with a behavioral intervention for children with tics disorder (ORBIT)	Partly guided; 10-12 wk	• n=112 families received intervention • Childrenb: 9-17 y (average 12.2 y); mostly boys with moderately severe symptoms	Semistructured interviews with families post program completion

Most of the web-based programs were developed for the management of a medical condition (24 distinct interventions for the treatment or management of 17 unique health-related conditions: autism [37,38], overweight or obesity [47,53], depression [35,51], tic disorder [32,33], sickle cell disease [39,41], obsessive compulsive disorder [52], anxiety [55,56], spinal fusion [40], functional abdominal pain [26,27,36], juvenile idiopathic arthritis [48], sleep disturbance related to having asthma [42], cancer [28], type 1 diabetes [43,49], celiac disease [49], traumatic brain injury [34,44], nonsuicidal self-injury [54], and posttraumatic stress disorder [45]). Two interventions were developed to influence health-related behaviors in school-aged children (unrestricted to a medical diagnosis or condition) [46,50]. All but 2 interventions were entirely technology based (no in-person elements) [37,53]. A total of 19 studies reported on the intervention program's frequency [26,27,34,36,40,42,43,46,48,50,53,56] or length [32,33,35,37,39,40,43,46-48,50,51,53,54], where interventions mostly included weekly modules and lasted 4 to 12 weeks.

A total of 13 interventions were self-guided [26-28,35,36,39,42,43,45,48-51,54,55], of which 7 interventions included other eHealth components [26,27,36,39,42,43,50,54,55]. The eHealth components had personalized functions in 3 programs (ie, pedometer [50] and a mobile app used for monitoring or tracking purposes [39,54]) and automated functions in 4 programs (ie, email reminders [26,27,36,42,43,55]). Studies also examined partly guided programs [32-35,37,40,41,44,46,47,52,53,56]. A total of 12 interventions included adjunctive support from professionals (eg, doctoral or postdoctoral research fellows, psychologists, and exercise specialists) who used eHealth technologies such as a videoconferencing platform [34,44], a phone [32,33,35,40,47,56], an email [47], and a built-in messaging platform [32,33,35,52,56]. Adjunct features of included programs are summarized in Table 2.

[a]Reminder (automatic) or responsive communication.

[b]Reminder (responsive communication) or session call.

[c]Videoconf: videoconferencing.

[d]For example, pedometer, stopwatch, or GPS locator.

[e]Cannot tell.

[f]var: variable.

[g]resp: responsive.

[h]rem: reminder.

[i]psych: psychology.

[j]MS: master's.

Qualitative data were mostly collected using semistructured interviews conducted at post program completion (3 months post program completion or shorter) [26-28,32,33,35-37,39-46,48,50-55]. A total of 23 studies examined the experiences of the family unit [26-28,32-37,39-44,46-52,54-56], with only 1 study focusing solely on the point of views of the participating caregivers [53], and 1 study reporting on feedbacks of the participating children [45]. All except 1 study involved the delivery of the web-based program in its entirety to families; 1 study explored families' experiences with the intervention

XSL•FO
RenderX

following their completion of one representative program module [45].

Quality Appraisal

The Critical Appraisal Skills Programme checklist [29] completed for each study is summarized in Table 3. All studies were clear about their research aims, included qualitative methodology appropriately, and discussed the value of the research. All except 1 study [34] clearly described the recruitment strategy or the collection of all data. Similarly, all except 2 studies [38,44] clearly described the research design. All studies considered ethical issues; however, 1 study was unclear whether ethics approval was obtained [45]. Most studies adequately described the analysis process [26,27,35-37,40,42,45-48,51-55]. Most studies also provided a clear statement of findings [26-28,33,35-37,40-43,45,47-49,51-55]. It was unclear whether most studies adequately considered the relationship between researcher and participants; most studies lacked reports of authors' reflexivity or information on whether the researcher critically examined their own role, potential bias and influence during study design, data collection, analysis, and presentation [26-28,32-34,36,38-51,53,54,56].

Results of Data Syntheses

The key themes identified on families' experiences with family-focused web-based health programs were (1) connecting with others, (2) agency of learning, (3) program reputability or credibility, (4) program flexibility, (5) meeting participants' needs regarding program content or delivery, and (6) impact on lifestyle. Themes reported by authors of included studies are summarized in Multimedia Appendix 3 [26-28,32-56].

Theme 1: Connecting With Others

Connecting with others related to forming quality relationships and established by the constructs of the web-based program and the influence of interpersonal relationships on families' experiences with the intervention. Building new or strengthening existing relationships encouraged the uptake of and engagement with treatment [32,36,39,42,43,50,52-55]. Subthemes included connecting with own family members (internal), other families (external), experts or health care professionals, and artificial intelligence (AI; eg, relational or conversational agent and chatbot).

Connecting With Own Family Members (Internal)

Families reflected on connecting with own family members during the intervention. The interventions created an opportunity for family members to involve themselves or realize their roles in making changes to support health collectively [28,35,37,39,42,43,47,50,52-54] or complete the intervention [27,32,33,36,39,43,47,50,52,53]. Families described the active participation of the entire (ie, immediate) family or at least one other family member (eg, sibling, other parent, or grandparents) in the program, including having "within-family competitions" [50] and nonparticipating siblings using program resources [53]. Parents and children expressed the importance of involving the family unit or parents to achieve goals or engage in the web-based program [27,32,35,36,39,42,43,50,52-54]. For instance, parents were key supporters of participating children and motivated program engagement [27,32,35,36,39,42,50,52,53]. Some parents reported that their motivation to engage with the program was dependent on their child's engagement [55]. Children also positively perceived their parent's involvement throughout the program; children felt less alone and found it beneficial to have their parent partake with them [35,52].

Families described improved relationships with each other post program completion [35,44,50,54]. Parents suggested that the program helped them better understand their child and their experiences [35,54], "opened lines of communication" [47] or allowed them to "have common language" [54] that was not possible before the program. Similarly, parents wanted the intervention to provide more structured opportunities for them to converse or complete an activity with their child [46,54].

Connecting With Other Families (External)

Families expressed the benefits of having the opportunity to connect with other families during the intervention [36,39,47,48,50,53,55]. Parents recognized that establishing a sense of community or network was an important feature of conventional treatment programs and recommended these elements to be preserved in eHealth interventions [47,55]. Families suggested that building relationships and interacting with other families, whether through group sessions or eHealth technologies or program features, supports their engagement [53,55] with and enjoyment [39] of the program. Parents indicated that having the opportunity to connect with other families throughout the program was reassuring for them and helped them know that they are "not alone with [their] struggles" [55]. Families suggested that eHealth intervention features, including shared forums, web-based chats, and support groups, enable the exchange of ideas [36,39,47,53] and shared experiences [47,48,53,55].

Connecting With Experts, Health Care Professionals, or Responsive AI

Families conveyed the importance of receiving support from professionals [32,35,37,44,47,52-56] or AI [43]. Families appreciated the responsive support received from health care professionals or AI to navigate the treatment [37,55], address queries [33,35,43,47,52-54], or maintain their confidence or motivation throughout the program [32,35,52,55]. Families described connecting with or feeling supported by a health care professional—actual human [32,52]—or AI [43], like they "had never been before." For instance, families who participated in partly guided web-based programs, reflected on the increased accessibility and strengthened connections established with experts, including increased "self-disclosure" [52] and the likelihood of families to "ask direct questions at any time" [53] or any questions freely [54]. Some children noted that program materials may be used to enhance sessions with experts in conventional services (ie, during hybrid care) or serve as an alternate intervention in between sessions [51].

Families also expressed that having interactions and support from human experts preserved the merit of conventional services [54], including the notion that professionals "wanted to help them" [54] and were on their side [52]. Participants noted favorable features of these relationships (both human-to-human or human-to-AI): the responders being prompt [35,43,47,52,54], optimistic [47], and personable [35,43,52,54]. Conversely, some families suggested the need for in-person contact with experts to establish or re-establish engagement with treatment [52,55].

XSL•FO
RenderX

Having contact with an actual person was preferred by some families over interacting with AI [43,52,54]. Families from the study on a self-guided web-based program with inbuilt support from a relational agent noted the limited ability of AI to meet unique needs [43]. Similarly, families who completed partly guided intervention programs noted their ambivalence with having all things digital or receiving responses from "robots" (automated response) [52,54].

Theme 2: Agency of Learning

Agency of learning related to an individual's sense of self-responsibility for their learning and includes their intention, self-efficacy, autonomy, and motivation. The increase in learning agency noticed by participating children or caregivers in themselves or others influenced program uptake, engagement, or sustainability [32,35,37,39,42,47,50-54]. Families often reported that the participating children had low agency, namely low self-confidence or motivation for or ownership of plans to improve their health in the beginning of the intervention [37,39,47,50,53,55]. Parents also conveyed similar reluctance and low motivation in their family to engage with program activities, related to having negative preconceived thoughts (eg, having apprehension about completing an activity well) [37,50]. Conversely, some families perceived that the structure or contents of the intervention aligned with their intent and respected their autonomy, which supported their engagement and positive experiences [52,54,55]. Some children enjoyed "feeling that [they] had the treatment to [themselves] and [helped themselves] rather than just [receiving] help" [54]. Families described that the program provided resources, such as new knowledge and ideas, that empowered them to take active roles to improve their health; they gained an understanding [26,27,46,53,54] of and ways to address [37,39,42,46,51-54] their symptoms, condition, or situation. Families also reflected that goal setting was facilitated by the intervention and strengthened learner agency [39,40,42,47,51]; goal setting helped families recognize that change was "manageable and possible" [47]. They suggested achieving goals or making progress further empowered them [42,47,51].

However, some children recounted that increased self-responsibility influenced negative experiences throughout the intervention [54,55]. Whereas children appreciated the independence to manage and have ownership of their treatment or changes, their perceived failure to achieve goals and complete activities increased feelings of "shame and guilt and decreased self-confidence" [54]. Families also expressed that the self-guided nature of the intervention (ie, intervention encouraging independence) was counterproductive when they had "doubts about their own capabilities" [54] or "whether they were completing the program correctly [or] on the right track" [55]; some families experienced moments of decreased self-confidence during the program [54,55]. Some children expressed that these negative experiences reminded them of their disorder and decreased agency [54]. When participants had low learning agency, they were poorly engaged with the intervention [26,50,53,55].

Theme 3: Program Reputability or Credibility

Knowledge of the program developers or affiliates impacted families' engagement with the intervention. For instance, families perceived programs developed by well-known institutions or health care professionals as trustworthy and were therefore motivated to uptake or engage with the web-based program [47,55]. Similarly, families noted being more likely to participate in and trust programs recommended to them by "friends, allied health professionals, hospitals and educational facilities" [55]. Families expressed the desire to learn from these sources; participating in the program was their opportunity to access the evidence-based knowledge [55]. Families also regarded the intervention as credible when the information presented matched their prior knowledge or lived experiences [28].

Theme 4: Program Flexibility

Program flexibility relates to the adaptability of program components into families' ways of living and family's reflections on the ease of program use. Families expressed that they were able to adapt the intervention to their lifestyles [27,35,36,39,43-45,47,50,52-54]. For instance, families noted that they were able to choose when to engage with the program or at their own pace, including using program resources and scheduling services when deemed most necessary, while adhering to the overall timeline of the web-based program [27,35,36,47,52-54,56]. Engaging in the program also required an acceptable amount of their time [39,43,47] or was a valuable use of their time [42,47]. Families reported that they preferred the web-based delivery of the intervention [27,35,36,52,56]; the program supported their ability to "prioritize other activities in life, as well as [fit] the treatment into [their] weekly schedule" [52]. Families suggested that program features, such as the compatibility of the intervention across multiple devices [40,55] and being able to freely navigate content (eg, return to completed sections or skipping content) [46,49,55] were favorable and supported program engagement.

On the other hand, some families reflected on difficulty participating in the intervention due to a lack of time [26,35,39,50,53,55], competing priorities [26,32,34,35,39,50,55], or a lack of energy from a demanding schedule [39]. Families also described the incompatibility of the intervention program to their preferred platform as an inconvenience, which further "wasted" time (eg, families mentioned website features that did not work on their preferred digital device) [32,36-38,51,56].

Theme 5: Meeting Participants' Needs Regarding Program Content or Delivery

Families reflected on whether the intervention met their needs regarding the intervention program's content or delivery, including the appropriateness of program content for children or a subset of children with respect to their age or disease and symptom severity. Families expressed that positive experiences with the program were related to learning new, tangible information (eg, ideas and knowledge) [26,27,33,35-37,39-44,46-49,52-56]. Before participating in the intervention program, families shared that most of their condition-specific knowledge

XSL•FO
RenderX

were retrieved from searching the internet [49]. Families conveyed that including condition-specific elements [28,36,37,39-41,43,44,48,51,52] and age-appropriate language or content [39,47,51] supported program engagement. Families suggested that program design features often perceived to support children's participation or understanding of the content included, having greater use of friendly and complementary visuals [27,28,41,42,45,47,49,51,56], videos or animations [33,37-39,42,47], interactive content particularly for younger primary school–aged children [28,33,39,40,42,46,47,49,53], simple wording [28,35,39,47,51], affirmative or respectful language [51,53], and customizable features [28,34,39,45-48, 51], having rewards particularly physical rewards [33,50, 51], and being easy to navigate [28,39,41,42,45,49,51,53,55,56]. Families described that relatable and personable features of the program, such as the use of storylines featuring children as the main characters or case studies portraying relatable scenarios further motivated or encouraged their participation [27,28,34,36, 40,43-45,47,51,52,54,55].

Parents suggested that program elements that were unappealing to children included having an excessive amount of text [27,36,47] or using advanced language or jargon [47]. Families described the intervention as unsupportive of their needs when they found the program's content redundant [27,32,39,42,47], too simple [47], lengthy [38,39,49], or irrelevant [35,39,55]. Families also wanted the intervention to include further or more specific information on their condition, health-related behaviors, or skills [35,37,43,49,51]. Families found the program irrelevant when they had prior education or lived experiences with the disorder or situation for a longer duration [35,55]. Such families often perceived the intervention as an "immediate lifeline" [55] or early intervention for participants who were first diagnosed with or having an early onset of a condition or experiencing mild symptoms [28,39,48,51,55]. Conversely, some families perceived the intervention being more suitable for children experiencing more severe symptoms [26,35]. Families recommended the development of different versions of the program to meet the needs of children in different age groups; children in older age groups found the program too simple and unengaging [32,33,47].

Theme 6: Impact on Lifestyle

Families reflected on the sustained health-related behavioral changes they noticed or actively made during or following program completion, which impacted their lifestyle. Families described that the intervention was a first step that helped them improve engagement in health-supporting behaviors or establish health-supporting routines, including healthy eating, physical activity, and sleep [40,42,50,53]. For instance, parents noted that because their participation in the intervention program, they set new boundaries at home to support healthy behaviors or habits [53]. Some families reported that they continued practicing techniques or skills learned from the program, which in turn enhanced their quality of life [27,35,36,40,54] or allowed them to "return to regular activities" [35,40], even "normal life at 100%" [27].

Discussion

Principal Findings

This review identified 28 articles on 26 studies, resulting in 6 themes describing children or caregivers' perception of family- and web-based eHealth interventions. Descriptions of each theme encompassed families' reflections on program features regarded as valuable to them and that influenced their uptake of or engagement with the intervention.

Comparison With Existing Literature

On the basis of the studies included in this review, families mostly had positive experiences using web-based programs supporting health. This review found that families positively perceived elements of the web-based program that imitated features of their conventional counterparts delivered in person. Existing literature on eHealth interventions for children and their families suggests that as with essential features of conventional interventions, eHealth interventions should incorporate behavioral or self-management principles involving the family unit, such as symptom management, lifestyle behaviors, relationship management, and psychosocial management [3,12]. Similarly, this review found that families favored self-guided features aligned with behavioral and self-management principles of the web-based programs, including goal setting; self-monitoring and self-reflection tasks; having interactive, tangible, relatable, and credible content; and personable activities that are easily adaptable to daily living (ie, themes: agency of learning, program reputability or credibility, program flexibility, and meeting participants' needs regarding program content or delivery). The web-based nature of web-based eHealth programs further empowers families during treatment by enabling flexibility to access resources when needed and unconstrained by locality and in whether or how resources (eg, information) are used [57]. Families also shared that such features enabling this flexibility encouraged their engagement with the intervention or health-supporting behaviors.

The included studies highlighted the importance of quality relationships to bolster the health and well-being of children and their families. Evidence suggests that children with chronic health conditions feel lonelier compared to children lacking health conditions [58]. Loneliness detrimentally impacts health, including the trajectory of health conditions, and hinders children from seeking help or communicating with others [58]. The proliferated use of technology affects social interactions, and passive use (ie, using technology in a way that decreases opportunities for social connectedness) also risks exacerbated feelings of loneliness [59]. This review found that web-based eHealth interventions can promote connections for families—including families with children with health conditions—within and outside the family unit (ie, theme: connecting with others). As suggested by other literature examining children's perspectives of digital technologies, opportunities to engage with web-based communications preserved or enhanced children's relationships with others (eg, family members and friends) [57]. Findings from this review suggest that web-based eHealth programs can cultivate quality

XSL•FO
RenderX

connections with others, regardless of the absence of in-person interactions, and may therefore influence health-related outcomes in children. Our findings extend existing evidence on the health-supporting effects of social connections by providing insight into the benefits of designing web-based programs involving the family unit (ie, subtheme: connecting with own family members). A web-based program that involves children and their families, or at least a caregiver, can satisfy the sense of relatedness required for children to engage in the desired health-promoting activities or behaviors. Existing literature recognizes the importance of the social environment and personable support to facilitate learning and influence children's self-management of or responsibility for their health [3,60-62]. Web-based program features that enable social interactions encourage active learning; individuals are more likely to apply learned behaviors when informational and emotional support are received from others [60-62]. Children, in particular, learn through modeling or observing others [61,62]. School-aged children, particularly primary school–aged children (ie, children <12 years of age), significantly depend on their caregivers to manage their health; caregiver involvement is commonly characteristic of conventional behavioral interventions for children [8]. Depending on the level of guidance provided by the web-based program, direct digital translations of conventional health care services may lack humanized elements, including psychosocial support or human connections, which may deter achieving intended health outcomes [63]. We also found that families valued human connections and were more likely to engage with the intervention when the program supported or enhanced their relationships with others, including children with their caregivers and vice versa, families with other families with children undergoing similar health conditions or situations, and health care professionals (ie, theme: connecting with others).

Novel insights were gained on families' relationships with health care professionals or the role of health care professionals in family-focused web-based programs (ie, subtheme: connecting with experts, health care professionals, or responsive AI). It was found that families improved their communication with a health care professional throughout the web-based program. Participating children may have found comfort with the web-based nature of the intervention—related to them being able to participate in the intervention at a physical environment of their choice—which supported them to feel safe and actively communicate or build a rapport with others [57,61]. Web-based programs can cultivate collaborative relationships or social engagements between participating families and involved health care professionals, supported by features including web-based discussion forums, inbuilt messaging platforms, and phone or videoconferencing platforms. This collaborative relationship further increases the likelihood that children engage with the intervention (ie, the learning process) and assume increased responsibility for their health [60,61].

This review found that families may prefer support received from human-to-human over human-to-AI interactions throughout the intervention (ie, subtheme: connecting with experts, health care professionals, or responsive AI). This is consistent with previous literature on the limitations of AI in eHealth interventions to support the specialized or therapeutic needs of patients [63,64]. However, this review also noted families' appreciation for responsive AI when included in web-based programs due to its rapid responses and accessibility. Generative and responsive AI is rapidly developing, with increased efforts to humanize AI features and evidence that AI technology has the potential to provide compassionate health care [65,66]. It is important to note that the limitations of AI found in this review may not be applicable in the future [65]. Involving families in the development of AI features in eHealth interventions is essential for ensuring acceptable family-centered education [67].

This review also identified unmet needs experienced by families with the web-based program (ie, theme: meeting participants' needs regarding program content or delivery). Families noted unsatisfied informational needs, where the content was described as being too simple or irrelevant to them, given their age, education background, or experience with the pediatric health condition. Children have individual and dynamic needs with age and stage or degree of health conditions [8,60,64]. This finding suggests that web-based programs may satisfy the foundational needs of children and their families when managing health conditions. However, more complex and specialized needs, including diminishing motivation or troubleshooting decreased self-confidence or self-management experienced during eHealth interventions, may require support from a health care professional or more sophisticated integration of contemporary AI [12,64]. On the other hand, this finding may also suggest that web-based eHealth interventions can create opportunities for families to realize their unmet health-related needs or intentions to seek further support from health care professionals [57].

Strengths and Limitations

This is the first qualitative systematic review, to the researchers' knowledge, that synthesizes research reported in the last decade on the experiences of both the participating children and caregivers with family-focused web-based intervention programs. Whereas this review applied a search strategy that involved Boolean searching versus, for example, subject searching and was translated across databases to identify articles that met the eligibility criteria, the evidence base on family-focused web-based programs to improve children's health is still developing. The search method of this review was therefore chosen to maximize flexibility. The search strategy was also confirmed with a university librarian to ensure focus. A limitation of the identified studies is the lack of clarity on whether researchers engaged in reflexivity, which is a core component to ensure transparency of the research process and quality of qualitative research. Limitations of this review also include that findings are representative of research from economically advanced countries, where resources, including access to the internet, may be more available. It is unclear whether this review equitably captures the perspectives of families from diverse populations, as not all studies have reported on characteristics that were found to influence participants' experiences with eHealth interventions, including caregivers' education background or socioeconomic information [64,65]. Similarly, families in the identified studies may have

XSL•FO
RenderX

also disproportionally conveyed positive feedback with the web-based programs. This review also explored the experiences of the family unit. Most studies in this review reported on the combined perspectives of participating children and their caregivers. Children, caregivers, and other family members may have different understandings of or priorities and motivators with children's health that may influence their experiences with treatment or health management, including eHealth interventions. More research is needed to distinguish these perspectives of children, caregivers, caregiver-child dyads, and other family members on family-focused eHealth interventions and across disease trajectories and children's developmental stages. This review focused on web-based programs directed at the family unit, which may exclude families' experiences with other types of family-focused eHealth interventions such as smartphone app–based programs. This review also presents a snapshot of findings on families' experiences with web-based eHealth programs in the last decade. With progressive advancements in digital technologies and AI and families' adaptations to the digital culture, continued exploration of this phenomenon is needed to inform the development of family-focused eHealth interventions.

Implications for Practice

On the basis of the findings of this review, key considerations when developing eHealth interventions for improving children's health and incorporating eHealth in health care systems include those outlined in Textbox 1.

Textbox 1. Key considerations for developing eHealth interventions to improve children's health.

- Children and their families highly regard eHealth interventions directed at the family unit and that create opportunities for cultivating quality social connections within or external to participating families. Web-based education may be supported by interventions that leverage features recognized by families to influence children's agency or self-management skills relative to improving their health: goal setting, self-monitoring and self-reflection tasks, interactive, tangible, relatable and evidence-based content, and personable activities that are easily adaptable to daily living.
- Family members, namely caregivers, were identified as social factors to support children's engagement in health-supporting activities and behaviors. Self-guided eHealth interventions require features that are positively perceived by families and related to foundational or informational needs of families lacking prior experiences with the health condition and treatment.
- Families highlighted that web-based programs need to be adaptable to meet children's changing needs throughout the program, including features that respond to fluctuations in motivation and their often-dynamic experience of their health conditions.
- eHealth (ie, web-based) interventions may present opportunities for families to recognize unmet health-related needs.
- Responsive features have the potential to humanize self-guided eHealth interventions. Advancements in responsive AI may serve similar functions as health care professionals in web-based programs, including meeting families' health-related needs.

Conclusions

This review synthesized the evidence on families' experiences with family-focused eHealth (ie, web-based) interventions. Insights were gained on the potential of eHealth interventions to satisfy health-related needs of children and their families. Key considerations presented in this review highlight the need for program developers and health care systems to adapt the elements of eHealth interventions to child developmental stages and the complex dynamism of childhood health conditions. In doing so, the benefits of eHealth interventions may be maximized to meet the growing number of families needing treatment for childhood health conditions. More research is needed to equitably tailor family-focused eHealth (ie, web-based) interventions to diverse populations and explore this phenomenon in the context of novel advancements in digital technologies and AI. Future research could also distinguish the perspectives of children, their caregivers, and other family members on eHealth interventions. These considerations can be used to enhance the design of family-focused eHealth interventions and better inform their inclusion in treatment plans to improve children's health.

Acknowledgments

The authors would like to thank the university librarian Mario Sos for supporting the refinement of the search strategy of this review.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

ZED, SG, and DZ conceptualized and designed the review, and screened for articles that met the predefined eligibility criteria. DZ extracted, analyzed, and interpreted the data, and wrote the original draft. SG verified the analysis process and interpretation of the data. All authors contributed to the drafting of the manuscript and have approved the final version of the manuscript.

Conflicts of Interest

The PhD stipend of DZ is provided by the Better Health Company for the evaluation of a family-focused web-based healthy lifestyle program. ZED is the senior investigator on the research funded by the Better Health Company. Better Health Company had no role in any aspect of this review. The authors conceptualized, completed, and submitted the review independently. All other authors declare no other conflict of interest.

Abstract

Background: Telemedicine involves medical, diagnostic, and treatment-related services using telecommunication technology. Not only does telemedicine contribute to improved patient quality of life and satisfaction by reducing travel time and allowing patients to be seen in their usual environment, but it also has the potential to improve disease management by making it easier for patients to see a doctor. Recently, owing to IT developments, research on telemedicine has been increasing; however, its usefulness and limitations in randomized controlled trials remain unclear because of the multifaceted effects of telemedicine. Furthermore, the specific metrics that can be used as cross-disciplinary indicators when comparing telemedicine and face-to-face care also remain undefined.

Objective: This review aimed to provide an overview of the general and cross-disciplinarity metrics used to compare telemedicine with in-person care in randomized controlled trials. In addition, we identified previously unevaluated indicators and suggested those that should be prioritized in future clinical trials.

Methods: MEDLINE and Embase databases were searched for publications that met the inclusion criteria according to PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analysis Extension for Scoping Reviews). Original, English-language articles on randomized controlled trials comparing some forms of telemedicine with face-to-face care from January 2019 to March 2024 were included, and the basic information and general metrics used in these studies were summarized.

Results: Of the 2275 articles initially identified, 79 were included in the final analysis. The commonly used metrics that can be used across medical specialties were divided into the following 3 categories: (1) patient-centeredness (67/79, 85%), including patient satisfaction, workload, and quality of life; (2) patient outcomes (57/79, 72%), including general clinical parameters such as death, admission, and adverse events; and (3) cost-effectiveness (40/79, 51%), including cost assessment and quality-adjusted life year. Notably, only 25 (32%) of 79 studies evaluated all the 3 categories. Other metrics, such as staff convenience, system usability, and environmental impact, were extracted as indicators in different directions from the three categories above, although few previous reports have evaluated them (staff convenience: 8/79, 10%; system usability: 3/79, 4%; and environmental impact: 2/79, 3%).

Conclusions: A significant variation was observed in the metrics used across previous studies. Notably, general indicators should be used to enhance the understandability of the results for people in other areas, even if disease-specific indicators are used. In addition, indicators should be established to include all three commonly used categories of measures to ensure a comprehensive evaluation: patient-centeredness, patient outcomes, and cost-effectiveness. Staff convenience, system usability, and environmental impact are important indicators that should be used in future trials. Moreover, standardization of the evaluation metrics is desired for future clinical trials and studies.

Introduction

Background

Telemedicine involves any type of medical, diagnostic, or treatment-related service using telecommunication technology [1]. In Japan, the term "online medical care," defined more specifically by the government, is used instead of telemedicine, which refers to the act of examining and diagnosing a patient, communicating the results of the diagnosis, and prescribing medical treatment in real time involving a doctor and a patient through telecommunication technology [2]. Recent developments in telecommunications technology have been remarkable. The telemedicine environment is changing with the spread of smartphones, improvements in data transmission speeds, and the development of wearable devices. Furthermore, although the use of telemedicine had been attempted earlier, it was adopted widely during the COVID-19 pandemic because of social distancing [3]. These findings indicate that the telemedicine content and environment have changed over the past few years.

The reports on the implementation of telemedicine in various medical fields are limited. Compared with standard face-to-face medical care, telemedicine reduces the risk of infection by minimizing physical contact and offers advantages to patients, such as shorter visit times, including waiting and travel times, which can improve patient satisfaction rates [4]. Ease of access to medical care provided by telemedicine may also improve disease management and clinical outcomes [5]. Telemedicine can be effective in many aspects of health care [6,7]. Therefore, the metrics that should be used to evaluate telemedicine should be carefully considered.

For evaluating disease management, using disease-specific indicators, such as hemoglobin A_{1c} (HbA_{1c}) for diabetes, is necessary to determine the usefulness of telemedicine. Additionally, general indicators, including non–disease-specific indicators, are required to compare results among studies on different diseases. Telemedicine can also influence patient satisfaction and quality of life (QoL). Furthermore, the use of patient-reported outcomes (PROs) was recently proposed for the evaluation of "patient-centeredness," the concept in which medical care is provided "for the benefit of the patient" [8].

Telemedicine affects various aspects of medical care; thus, it requires multiple measures rather than a single measure for efficacy evaluations. It is possible that indicators that have not been widely used in the past should be used in the future. A variety of metrics have been used across previous studies, and reports summarizing the general metrics used for evaluating telemedicine remain lacking.

Telemedicine does not oppose face-to-face care but rather complements it, similar to the relationship between outpatient, inpatient, and home care. However, when examining the usefulness of telemedicine, it is commonly compared with face-to-face care, which is the well-established, long-standing method of medical care. Further research into telemedicine, particularly randomized controlled trials (RCTs), is essential to generate solid evidence. To identify the metrics that should be used in future RCTs, it is essential to first understand the actual use of general metrics in past RCTs.

Objectives

In this study, we conducted a scoping review of articles comparing telemedicine with in-person care in RCTs and summarized the metrics used to understand their usefulness. This study also aimed to identify indicators that were not thoroughly evaluated in previous clinical trials but will be useful in the future and suggest which indicators should be prioritized in future clinical trials.

Methods

Literature Search

This systematic literature review was conducted and reported in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analysis Extension for Scoping Review) guidelines [9]. The completed PRISMA checklist is presented in Multimedia Appendix 1. MEDLINE and Embase databases were systematically searched on March 15, 2024, for peer-reviewed full papers published between January 1, 2019, and March 14, 2024. We searched only the MEDLINE and Embase databases because we assumed that most of the articles of interest (metrics used in RCTs) would be included in them. Owing to the significant advancements in telemedicine in recent years, older publications were deemed outdated, and the search was limited to the most recent publications from the past 5 years since 2019. The search string used for the search in MEDLINE contained the following terms related to telemedicine: (telemedicine OR "online medical care" OR teleconsultation OR "online consultation" OR "telemedical consultation") AND ("randomized controlled trial") AND (outcome OR effectiveness) AND (control OR conventional OR face-to-face). Multimedia Appendix 2 lists the search terms used in the MEDLINE and Embase databases.

The review was registered with Open Science Forum Registries (YH5S7).

Inclusion and Exclusion Criteria

The inclusion criteria were as follows: (1) studies published between January 1, 2019, and March 14, 2024; (2) RCTs

XSL•FO
RenderX

comparing some form of telemedicine with a standard of care (face-to-face care); (3) studies involving telemedicine, including online monitoring (ie, information measured using the device is automatically sent to the medical facility) or synchronous communication through telephone or video; and (4) studies involving both disease-specific metrics (eg, HbA_{1c} for diabetes) and general (ie, non–disease-specific) cross-disciplinary metrics.

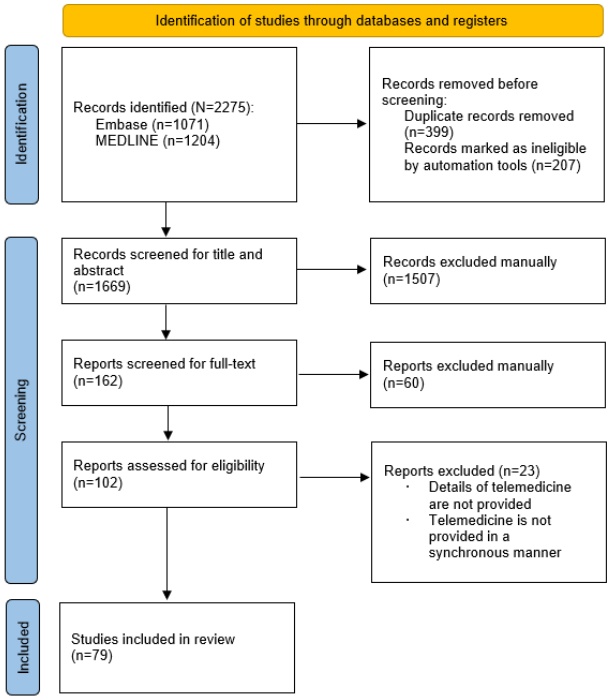
The following studies were excluded: (1) protocols and proposals; (2) systematic reviews, commentaries, and scoping reviews; and (3) gray literature.

Study Selection

Two investigators (YS and YH) independently screened the titles and abstracts of the identified studies using the Covidence systematic review software (Veritas Health Innovation). Subsequently, the investigators (YS and YH) independently reviewed the full text of the selected studies based on the inclusion and exclusion criteria. Disagreements regarding the classification of a reference were resolved by a third reviewer (MI) by conducting an additional review and confirming the final classification.

Data Collection and Summary

Data regarding study details were extracted using the Covidence software (Veritas Health Innovation) and Microsoft Excel. One reviewer (YS) extracted the additional data from eligible studies, including the content of telemedicine and the disease-specific and general (ie, non–disease-specific) indicators for evaluating telemedicine. All extracted data were cross-checked for accuracy by a second reviewer (YH), and any discrepancies were resolved through discussion. The extracted data elements included the study title, year of publication, country, target disease or population, total sample size, type of telemedicine used, and disease-specific and general metrics used for evaluating telemedicine. A meta-analysis was deemed inappropriate because of heterogeneity in the study design, populations, and outcome measures for quantitative studies, and a narrative synthesis of quantitative study results was conducted. The evaluation metrics were categorized through the following process. Initially, all unique metrics identified by a single author (YS) were reviewed and confirmed by two additional authors (YH and MI). Following this, the 3 authors engaged in collaborative discussions to group the metrics into primary and subcategories based on shared directional perspectives.



This study examined the actual use of metrics for evaluating telemedicine and did not focus on the results or conclusions (superiority or noninferiority of telemedicine compared with face-to-face care) of the included studies.

Results

Literature Search

Initially, 2275 studies were considered relevant according to the inclusion criteria. However, 606 duplicate studies or those marked as ineligible by automation tools were removed before screening. Furthermore, 1507 studies were excluded after screening the titles and abstracts, and 83 studies were excluded after reading the articles in greater depth during the assessment of extracted data. Finally, 79 studies were included in the analysis. The PRISMA flow diagram summarizing the article selection process is presented in Figure 1. A list of all 79 studies and their information is provided in Multimedia Appendix 3 [7,10-87].

Study Description

Table 1 presents the characteristics of the 79 included studies. After 2020, a total of 10 - 20 papers comparing telemedicine and face-to-face care in RCTs were consistently published annually. These studies were conducted and published commonly in the United States (11/79, 14%), Australia (10/79, 13%), and European countries (France: 6/79, 8%; Norway: 6/79, 8%; and: Spain 6/79, 8%), with China (5/79, 6%) and Japan (5/79, 6%) being the most common in Asia.

The most common departments in which the studies were conducted were internal medicine (39/79, 49%), psychiatry (11/79, 14%), and rehabilitation (9/79, 11%). Most dealt with outpatient care (76/79, 96%); however, a few reports dealt with telemedicine from home as an alternative to inpatient care (3/79, 4%). The specific contents were as follows: early discharge from the hospital with telemedicine versus discharge on a regular schedule (study number 57 [65]), home care under telemonitoring versus long-term hospitalization (study number 71 [79]), and initiation of treatment at home versus in the hospital (study number 74 [82]).

Regarding the targeted diseases and populations, the most common was postoperative follow-up (11/79, 14%), followed by chronic diseases, such as coronary artery disease (7/79, 9%), diabetes (6/79, 8%), and chronic obstructive pulmonary disease (4/79, 5%). The median total sample size was 106 (IQR 59 - 240), with 10 and 2185 being the minimum and maximum numbers, respectively.

When examining the details of telemedicine, online medical care was the most common (69/79, 87%; Table 1), including telepsychiatry involving cognitive behavior therapy. Furthermore, online monitoring and telerehabilitation were also common practices. In several studies, telemedicine included apps for patient education and the ability to make emergency calls. Online monitoring (information measured by the device automatically sent to the medical facility) or synchronous communication through telephone or video was considered telemedicine in this review.

[a]Two or more reports.

[b]According to the following definition by the Japanese government: the act of examining and diagnosing a patient, communicating the results of the diagnosis, and prescribing medical treatment in real time involving a doctor and a patient through telecommunication technology

General Metrics for Evaluating Telemedicine

We identified 25 unique metrics that can be generally used (patient satisfaction, patient workload, patient time spent in medical visits, absence from work, travel distance, waiting time, QoL, patient choice of subsequent type of care, death, admission, hospital days, emergency department visits, frequency of visits or contacts, duration of visits or contacts, treatment adherence, change in diagnosis or treatment, adverse effects or safety, cost, quality-adjusted life years [QALY], staff satisfaction, staff work, staff time spent per patient, system usability, environmental impact, and feasibility for future clinical trials). A median of 4 (IQR 3-5, with a minimum of 1 and a maximum of 10) metrics were used per study. We classified commonly used metrics into three categories: (1) patient-centeredness (67/79, 85%), (2) patient outcomes (57/79, 72%), and (3) cost-effectiveness (40/79, 51%) (Table 2). Notably, 32% (25/79) evaluated all these categories.

We further subdivided the metrics into nine subcategories and examined the numbers and combinations of uses per article. Patient centeredness was divided into three categories: (1) patient satisfaction, (2) patient work, and (3) QoL. Patient outcomes were classified as (4) general clinical parameters. Cost-effectiveness was divided into two categories: (5) costs, and (6) QALY. Other metrics were categorized into three categories: (7) staff satisfaction, (8) staff work, and (9) feasibility for future clinical trial. Most studies (69/79, 87%) used two or more general metrics (ie, non–disease-specific metrics), and the median number of the nine subcategories used in each study was 3 (IQR 2-4, with a minimum of 1 and a maximum of 6) metrics. The most frequently used combinations in the nine subcategories were as follows: general clinical parameters and patient satisfaction (7/79, 9%); general clinical parameters (5/79, 6%); QoL and patient satisfaction (5/79, 6%); QoL and general clinical parameters (5/79, 6%); costs, QoL, and general clinical parameters (5/79, 6%); and costs, QALY, and QoL (5/79, 6%)

Table 2. General metrics for evaluating telemedicine (n=79).

Metric	Value, n (%)
Patient-centeredness	67 (85)
Patient outcomes	57 (72)
Cost-effectiveness	40 (51)
Other	40 (51)

The evaluation metrics by department are summarized in Table 3. With regard to internal medicine, psychiatry, and rehabilitation, for which a relatively large number of articles were included in this review, the utilization rate of patient outcomes was high in internal medicine (33/39, 85%) but was rather low in psychiatry (5/11, 45%) and rehabilitation (5/9, 56%). In contrast, the utilization rate of patient-centeredness was very high in psychiatry (10/11, 91%) and rehabilitation (8/9, 89%) compared with that in internal medicine (31/39, 79%).

XSL•FO
RenderX

Table 3. Utilization rate of general metrics by department.

Department.	Patient-centeredness, n (%)	Patient outcomes, n (%)	Cost-effectiveness, n (%)
Internal medicine (n=39)	31 (79)	33 (85)	21 (54)
Psychiatry (n=11)	10 (91)	5 (45)	7 (64)
Rehabilitation (n=9)	8 (89)	5 (56)	3 (33)
Surgery (n=5)	5 (100)	5 (100)	2 (40)
Orthopedics (n=4)	4 (100)	2 (50)	3 (75)
Pediatrics (n=3)	2 (67)	1 (33)	2 (67)
Anesthesiology (n=2)	2 (100)	1 (50)	1 (50)
Gynecology (n=2)	1 (50)	1 (50)	0 (0)
Urology (n=2)	2 (100)	2 (100)	1 (50)

Patient-Centeredness

Patient satisfaction, work associated with medical visits, and QoL were considered metrics relevant to patient-centeredness, and these metrics were evaluated in most studies (67/79, 85%). The metrics used for evaluating patient-centeredness are summarized in Table 4.

Table 4. General metrics for evaluating patient-centeredness (n=67).

Metric	Value, n (%)
Patient satisfaction	41 (61)
Patient workload	17 (25)
Time spent in visit or contact	9 (13)
Absence from work	7 (10)
Travel distance	7 (10)
Waiting time	3 (4)
Quality of life	45 (67)

More than half (41/67, 61%) of the studies evaluated patient satisfaction. Table 5 presents the questionnaires used to evaluate patient satisfaction. Approximately half of the studies that addressed patient satisfaction used their own set of questions, whereas the other half used previously developed questionnaires, such as the Client Satisfaction Questionnaire [88], Telemedicine Satisfaction Questionnaire [89], and Outpatient Experiences Questionnaire [90]. In addition, 2 other studies evaluated patient experience (study numbers 48 [56] and 68 [76] in Multimedia Appendix 3), which refers to the patient's specific "experience" of health care services. This concept is an evolution of patient satisfaction and is internationally recognized as an important quality indicator in health care [91]. Only one study evaluated "PROs."

XSL•FO
RenderX

Table 5. Questionnaires used to assess patient satisfaction and quality of life (QoL). Regarding questionnaires for QoL, two reports used both the EQ-5D and SF-36[a] QoL measures, and other two used both the EQ-5D and SF-12[b]. Others included general and disease-specific QoL measures other than EQ-5D, SF-36, and SF-12.

Questionnaires	Value, n (%)
Patient satisfaction (n=41)	
Questions developed for the study	19 (46)
Client Satisfaction Questionnaire [88]	3 (7)
Telemedicine Satisfaction Questionnaire [89]	3 (7)
Outpatient Experiences Questionnaire [90]	2 (5)
Satisfad10 Questionnaire [92]	2 (5)
Other questionnaires from previous studies	12 (29)
Quality-of-life (n=45)	
EQ-5D-3L/5L [93,94]	26 (58)
SF-36[a] [95]	9 (20)
SF-12[b] [96]	4 (9)
Others	10 (22)

[a]SF-36: Medical Outcomes Study (MOS) Short Form 36-Item Health Survey.

[b]SF-12: MOS Short Form 12-Item Health Survey.

Some studies (17/67, 25%) focused on work or burden associated with medical visits, including factors such as the time spent or travel distance for medical visits or contacts. Other related indicators, such as absence from work and waiting time, were also investigated in a few studies.

More than half of the studies evaluated QoL (45/67, 67%). Table 5 summarizes the metrics used to measure QoL. The most frequently used measure was the EQ-5D-3L/5L [93,94], which was used by more than half of the studies that evaluated QoL. The Medical Outcomes Study Short Form 36-Item Health Survey (SF-36) [95] and Medical Outcomes Study Short Form 12-Item Health Survey (SF-12) [96] were also frequently used. In addition to these general QoL measures, some studies also used disease-specific QoL measures.

Patient Outcomes

When comparing telemedicine and face-to-face care in RCTs, various clinical metrics for patient outcomes, including disease-specific ones, are used to assess their superiority or noninferiority. Table 6 summarizes general metrics that appear to be applicable for evaluating various disease populations. The most commonly used general clinical parameters were admission (26/57, 46%), adherence (23/57, 40%), adverse events or safety (21/57, 37%), and frequency of visits or contacts (17/57, 30%).

Table 6. General metrics for evaluating patient outcomes (n=57).

Metrics	Value, n (%)
Death	10 (18)
Admission	26 (46)
Hospital days	8 (14)
Emergency department visits	10 (18)
Frequency of visits or contacts	17 (30)
Duration of visit or contact	8 (14)
Treatment adherence	23 (40)
Change in diagnosis or treatment	4 (7)
Adverse events or safety	21 (37)

Cost-Effectiveness

The following ranges of costs were considered when evaluating cost-effectiveness: medical costs (fees for consultation, examination, medication, injection, surgery, and hospitalization), nonmedical costs (costs indirectly incurred by medical interventions, such as transportation, welfare equipment, or home improvements), and indirect costs (loss due to injury, illness, or death). The method of calculating medical costs and the range of costs included in the calculations differed across studies, partly because of differences in the reimbursement systems of the countries in which the studies were conducted

XSL•FO
RenderX

and differences in perspectives (patient, insurer, or society). QALY was evaluated in 28% (11/40) of the studies that evaluated cost-effectiveness.

Staff Convenience

Staff convenience including staff satisfaction, staff workload, and time spent per patient was evaluated in a few studies (8/79, 10%). Staff satisfaction was not frequently evaluated (4/79, 5%) compared with patient satisfaction (41/79, 52%). Similarly, fewer studies examined staff workload (5/79, 6%) than patient workload (17/79, 22%). Notably, the time spent per patient was evaluated to assess the staff work in the studies.

System Usability

A small number of studies (study numbers 8 [18], 14 [24], and 49 [57] in Multimedia Appendix 3) have evaluated the user-friendliness of telemedicine systems using items such as usability questionnaires or the number of technical challenges encountered.

Others

Other metrics that were not included in either of the aforementioned categories were greenhouse gas impacts (study numbers 6 [16] and 18 [27] in Multimedia Appendix 3), mental health of caregivers (study number 12 [22]), health literacy (study number 79 [87]), and self-efficacy (study number 17 [26]). Details of each are provided in Multimedia Appendix 3.

Discussion

Principal Findings

In this study, we conducted a scoping review of RCTs comparing telemedicine with face-to-face care published in the last 5 years and summarized the cross-disciplinary measures used in these studies. Notably, several studies used multiple measures, and metrics related to patient-centeredness, patient outcomes, and cost-effectiveness were commonly used. However, the measures used and their combinations varied across studies, and only a few studies evaluated staff satisfaction, system usability, and environmental impacts. These results highlight the requirement to standardize evaluation indicators for comparing telemedicine with face-to-face care. Although establishing evaluation measures for telemedicine is challenging owing to its multifaceted impact, the evaluation indicators can be classified into three main categories: (1) patient-centeredness, (2) patient outcomes, and (3) cost-effectiveness.

We believe that in addition to using disease-specific indicators, these three categories of general metrics should be used in telemedicine evaluations. From the papers analyzed in this study (Multimedia Appendix 3), some pertinent examples from the identified studies are as follows: Gayot et al [10] evaluated QoL for patient-centeredness, unplanned hospitalization and death for patient outcomes, and direct costs and incremental cost-effectiveness ratios for cost-effectiveness in addition to disease-specific metrics, and Mínguez Clemente et al [11] evaluated patient satisfaction for patient-centeredness; admission, hospital days, frequency of visits, and adherence for patient outcomes; and cost per patient for cost-effectiveness while using other parameters (study numbers 16 [10] and 73 [11] in Multimedia Appendix 3, respectively). Our results suggest that within a single study, at least three indicators, each belonging to a different category, should be simultaneously evaluated to ensure a comprehensive assessment of the impact of telemedicine. However, given that different diseases have different management approaches, our results indicate that the choice of metrics differs by clinical specialty (Table 3). Therefore, they need to be considered more deeply and individually in special circumstances. In particular, studies of replacing inpatient care with telemedicine were not well represented in this review and may require separate consideration.

In this study, we summarized the evaluation metrics commonly used in previous reports, identified 3 categories that should be covered, and described other 3 indicators that should be evaluated in the future. However, it did not provide a more rigorous standardization of which indicators should be used for each of the three categories. We believe that this should be discussed among the expert panel and finally decided using approaches such as the Delphi method [97].

Patient-Centeredness

Patient-centeredness is a concept closely related to PROs [8]. Although measures of patient prognosis are relatively objective, PROs are subjective to the patient, with no intervention from a physician or measurement using instruments. However, considering such subjective evaluations as evidence is debatable [98]. Patient-centeredness is a crucial concept based on the premise that medical care is performed “for the patient,” while also emphasizing the need for standardization and clear validation. In this review, we adopted a broad perspective of patient-centeredness, considering not only studies using the term “PROs” but also the following terms as relevant: patient satisfaction, patient work associated with medical visits, and QoL.

Patient satisfaction, experience, and PROs were the main indicators used to assess patient-centeredness. Patient satisfaction is an abstract concept of “satisfaction” that also depends on individual expectations, making the standardization of measurement scales challenging and complicating the identification of specific issues from the results [99,100]. Although several questionnaires have been developed to assess patient satisfaction [88-90], their use varies across studies, and in approximately half of the studies, questions used to evaluate satisfaction were originally designed in those studies. In contrast, patient experience deals with specific “experiences” and is easier to standardize than patient satisfaction, with more convenience in identifying specific issues from the results [99,101]. PROs are even broader measures that reflect various aspects of patient health, as they are reported directly by the patient without additional interpretation by a health care professional or anyone else [8]. They may be divided into disease-specific and comprehensive PROs. Patient satisfaction, patient experience, and PROs are interrelated and cannot be studied separately. Assessing patient experience or PROs may be preferable over patient satisfaction to help identify issues.

Among the various QoL scales, EQ-5D-3L/L [93,94], SF-36 [95], and SF-12 [96] are used most commonly. Notably, even

XSL•FO
RenderX

while using the disease-specific QoL assessment scales, the aforementioned general scales may be used in combination.

Patient Outcomes

The indicators of patient outcomes can be divided into disease-specific and cross-disciplinary outcomes. In this study, disease-specific indicators are listed only in Multimedia Appendix 3 and are not tabulated as they vary across fields. Moreover, even if disease-specific indicators (eg, HbA_{1c} for diabetes) are evaluated, they may be difficult to understand for readers in other fields. Therefore, cross-disciplinary general indicators should be used in addition to disease-specific indicators. The specific parameters that should be used as general indicators depend on the severity and progression pattern of the disease but can include death, hospitalization, emergency visits, and frequency of general outpatient visits.

Cost-Effectiveness

The most common cost-effectiveness evaluation was the calculation and comparison of the costs of telemedicine and usual face-to-face care. From the health care payer's perspective, only medical costs are important, whereas from the patient's perspective, only the copayment of medical costs is important. Furthermore, from a societal perspective, all medical, nonmedical, and indirect costs should be included in the analysis [102-104]. When comparing telemedicine to traditional face-to-face care, a broader spectrum of parameters must be evaluated. These encompass the costs associated with software development and hardware implementation, as well as the potential economic advantages such as reduced transportation expenses and fewer missed workdays, which are not typically considered in comparisons of in-person treatment modalities. Therefore, evaluating not only medical costs but also nonmedical and indirect costs is crucial. However, standardizing the calculation method is difficult because costs may differ depending on the reimbursement system, prices, and social environment in each country.

The QALY is a cost-effectiveness index based on QoL and survival time and is considered a common effectiveness index, even if the target diseases are different [105]. However, although various factors are associated with evaluating the cost-effectiveness of telemedicine, QALY evaluates only QoL and survival time. Therefore, this should be considered when using QALY.

Other Metrics

In addition to the metrics mentioned earlier, future studies should also consider other metrics for evaluation. The first candidate is the metric for staff convenience. We all know that health care is "for the patient"; as noted earlier, patient-centeredness has been well investigated in many studies. On the other side of the coin, its convenience for health care professionals has not been considered important or thoroughly evaluated. However, it is an undeniable fact that the health care providers (medical professionals) are the counterparts of the health care recipients (patients), and it is easy to imagine that a system that health care providers find inconvenient is unlikely to be widely adopted. Particularly in telemedicine, health care professionals are accustomed to a well-established and easy-to-use form of care, which is face-to-face care. Therefore, evaluating whether telemedicine is easy to use for health care professionals is vital. Such information would aid in assessing how favorable telemedicine is likely to be received by health care providers when implemented in general clinical practice. Careful examination of the reasons why staff members felt telemedicine was inconvenient would also provide insight into how to improve it.

Another important factor is whether the system is easy to use, as the most important component of telemedicine is the digital equipment and internet connection. The degree of digital literacy varies among individuals, and if the system is difficult to use, telemedicine may even worsen access to health care for some people, as symbolized by the term "digital divide." Although it has not been well evaluated so far, the evaluation metrics of system usability are also considered important for ensuring equitable access to health care.

In addition, a small number of studies evaluated the impact of greenhouse gases and environmental costs. Given the seriousness of global warming, considering a health care delivery system that is sustainable for the entire planet is also important. The Greenhouse Gas Protocol divides carbon emissions into 3 categories: scope 1, direct emissions secondary to energy use; scope 2, indirect emissions secondary to purchased electricity; and scope 3, indirect emissions [106]. Most emissions related to the health care system reportedly correspond to scope 3, which includes indirect emissions occurring as a consequence of health care activities such as disposables, equipment (medical and nonmedical), and pharmaceuticals, as it includes a wider range of emission sources than other scopes [107]. Therefore, it may be necessary to consider a wide range of targets to assess the environmental impacts of telemedicine. There is a scoping review on the inclusion of environmental impacts in evaluations of health care economics [108]. Greenhouse gas emissions, energy use, water use, and physical waste impacts were frequently used in the past, and 10 methods for assessing environmental impacts have been described. However, it remains unknown which metrics should be evaluated and in which units, creating an issue for discussion in the future.

Limitations

Although our scoping review was thorough, it has some limitations. First, we searched only the MEDLINE and Embase databases for peer-reviewed, full-text articles, although we assumed that most of the articles in our scope would be included within them because we focused on the metrics used in RCTs. Second, only papers published in 2019-2024 were included because the content of telemedicine has changed rapidly with technological advancements and the emergence of COVID-19, and it is unclear whether it is appropriate to apply the content of the distant past to current analyses. This limited the scope of the search and emphasized the most recent data. Third, a narrative synthesis is a secondary analysis of data that focuses on the interpretations presented by the authors of original papers and is not based on primary data. Furthermore, our findings represent an interpretation of the data and should be viewed as a heuristic theory.

RenderX

Conclusions

In studies comparing telemedicine with face-to-face care from 2019 to 2024, the most commonly used metrics were patient-centeredness, patient outcomes, and cost-effectiveness. These are important indicators of telemedicine and should be evaluated simultaneously in future clinical studies. In addition, our study also indicates that staff satisfaction could be an important evaluation metric for future clinical trials.

Abstract

Background: Remote surgeons use telementoring technologies to provide real-time guidance during minimally invasive surgeries (MIS). Such technologies are continuously improving with the integration of dynamic augmented reality (AR) cues. This includes virtual overlays of hand gestures, pointers, and surgical tools onto the operating surgeon's view. The operating surgeon comprehends this augmented information to operate on the patient. Thus, understanding these dynamic AR cues (either during surgical training or live surgery) is crucial.

Objective: In this paper, we aimed to review the existing telementoring technologies that use dynamic AR cues during MIS. This review describes the MIS (including surgery type, specialty, procedure, and clinical trial), the telementoring system, the dynamic AR cues generated by these systems, and evaluation of the technology in terms of technical aspects, user perceptions, skills gained, and patient outcomes.

Methods: A scoping review was conducted using PubMed, Web of Science, Scopus, IEEE Xplore, and ACM Digital Library databases. The search terms included "telementoring," "minimally invasive surgery," and "augmented reality" without restrictions imposed on the publication year. Articles covering telementoring using dynamic AR cues during MIS, including laparoscopic and robot-assisted, were identified.

Results: A total of 21 articles were included and categorized based on type of surgery, the telementoring technology used, and evaluation of the technology. Most of the articles reported on laparoscopic suturing performed using synthetic phantoms. Hand gestures and surgical tools were the most frequently used dynamic AR cues (10 articles on each cue), while the mentors and mentees primarily consisted of experienced surgeons and medical students. The studies assessing the telementoring technologies were either descriptive (7 articles) or analytical (14 articles) where it was compared against no cue, prerecorded visual cue, in-person guidance, audio cue, or static AR cue. Outcomes were measured mostly using skills gained (13 articles) and user perception about the telementoring system.

Conclusions: In general, telementoring using dynamic AR cues resulted in positive outcomes during MIS. In some cases, they were considered on par with conventional methods such as audio cues and in-person guidance. Further randomized controlled trials are required to objectively assess its clinical benefits.

Introduction

One of the telemedicine technologies that is gaining considerable interest is telementoring, during which an expert medical professional (mentor) can provide real-time instructions to a novice (mentee) even if they are remotely located [1]. A growing application of telementoring technologies is seen in the field of surgery as a result of rising demands for specialized surgical expertise coupled with limited training opportunities [2]. Minimally invasive surgery (MIS) is one such specialized surgical field, which has emerged as the standard practice [3]. During MIS, which includes laparoscopic and robot-assisted procedures, surgeons use long, thin surgical instruments inserted through small incisions on the body. The operative view is captured through a camera scope and displayed on a screen. MIS is increasingly adopted due to the benefits it provides to patients, in terms of significant reduction in pain, surgical site infection, scarring, and recovery time as compared with the highly invasive open approach [4]. Despite these pronounced advantages, its widespread implementation is hindered due to the challenges in adequate skills acquisition. Surgeons performing MIS have an indirect view of the operative view through the screen projecting the live camera scope feed and experience a longer learning curve as compared with open surgery [5]. Hence, specialized training is needed to develop sufficient expertise. While basic MIS skills are learned outside the operating room, intraoperative training is vital for attaining proficiency [5]. Unlike open surgeries where the expert surgeon can easily point at critical structures with their hands over the operative view, mentors must rely on verbal instructions during MIS, which are prone to communication errors [6]. In some cases, the mentor must take complete control of the instruments from the mentee to show the required surgical technique. While the dual surgeon console in robot-assisted surgeries facilitates such takeovers by the mentor, the cost can be prohibitively high. Furthermore, many countries experience challenges in implementing MIS due to inadequate training programs and high costs associated with bringing in expert surgeons [7]. Telementoring technologies that allow an expert surgeon to efficiently guide the operating surgeon play a major role in addressing this gap [8].

Implementing telementoring technologies during MIS is relatively easier, as compared with open surgeries, since a live view of the operating field is already captured through the camera scopes [9,10]. During conventional telementoring, video captured from the operating room is transmitted in real time to an expert mentor at the remote location. Verbal instructions (audio cues) from the mentor are transferred to the mentee [11]. The mentor can also play surgical videos (prerecorded visual cues) to guide the mentee on a particular step [12]. However, such cues may not be sufficient for intraoperative instructions [6]. To overcome the communication challenges posed by verbal instructions, expert surgeons need a way to point at anatomical structures on the screen displaying the operative view to the mentee [13]. For this purpose, the mentor may use augmented reality (AR), which involves the use of computer-generated virtual objects that are superimposed on the mentee's view of the operative field [14]. The AR cues may be rendered to the mentee on a visualization screen, or the surgeon's console with stereoscopic vision during robot-assisted surgery. In some cases, external AR devices such as Microsoft HoloLens head-mounted display (HMD) or iPad tablets may also be used [15]. The cues could be in the form of 2-dimensional (2D) annotations (static AR cues) demonstrating an incision line or highlighting a specific anatomy [16,17]. Such forms of telementoring have been applied extensively for MIS demonstrating improved communication and performance [18]. Nonetheless, static AR cues are limited while compared with in-person guidance as complex tool-tissue interactions may not be accurately depicted [19,20].

Telementoring can be enhanced with the use of dynamic AR cues to effectively communicate surgical steps. As opposed to static AR cues, which remain stationary on the mentee's field of view, dynamic AR cues move in real time under the mentor's control [21]. These virtual cues can be in the form of hand gestures, pointers, or surgical tools. They are often 3-dimensional (3D) in nature, providing depth perception as the mentor guides the mentee through surgical sub steps. In cases where the mentor and mentee have similar macro skills, such as proficiency in critical anatomy and movement of surgical tools, these dynamic cues can aid the mentee's development of micro skills related to a particular unfamiliar surgical technique [22]. Dynamic AR cues are not only useful for telementoring when the mentor is situated in a remote location, but can also be used to enhance in-person guidance during MIS where the mentor and mentee are in the same operating room [23].
