Introduction

COVID-19 Pandemic and Vaccination

The COVID-19 pandemic, declared by the World Health Organization in March 2020 [1], has had an unprecedented impact globally, affecting billions of lives and causing widespread health, social, and economic disruptions. Vaccination against COVID-19 emerged as a pivotal strategy in controlling the virus's spread, with over 10 billion vaccine doses administered worldwide by the end of 2022 [2]. The pandemic's toll has been significant, infecting more than 30 million people and resulting in over 70,000 deaths [3]. In addition, 104,736,436 people, or 80.7% of the population, had received their first vaccine dose by this study [4].

The Role of the Internet in Public Health and Theoretical Framework

During the COVID-19 pandemic, the way individuals sought health information underwent significant changes. The internet became an indispensable tool, playing a crucial role in public health by serving as the primary means by which people could register for vaccination [5,6]. This shift in information-seeking behavior is essential for understanding the public's response to health crises [7,8]. Meanwhile, the World Health Organization introduced a framework to address infodemics, characterized by the widespread dissemination of inaccurate information through digital and physical channels [9]. Similarly, the National Academy of Medicine offered recommendations to combat misinformation and disinformation on social media [10]. Indeed, the internet's influence on health behavior is profound, with misinformation notably undermining confidence in COVID-19 vaccinations [11].

This study is based on the Digital Divide Theory [12] and the Health Belief Model [13]. Digital Divide Theory indicates that disparities in Internet access and digital literacy are related to differences in access to health information and health behaviors. This theory encompasses not only the differences in physical access but also the concept of the second-level divide, which includes the necessary skills and literacy of users [14]. In addition, the Health Belief Model emphasizes factors that influence individuals to engage in health behaviors, such as perceived risk, perceived benefits, perceived barriers, and cues to action. Our research is based on the idea that individuals who can gather information through the internet are more likely to understand the risks and benefits of vaccination and, as a result, experience behavior change.

Information-Seeking Behavior Using the Internet and Vaccination

The association between vaccination uptake and information-seeking behaviors using the internet is a critical area of study, particularly in the context of the COVID-19 pandemic. Previous research has demonstrated the significant impact of online health information on vaccination behaviors across different vaccines [15-20]. For instance, individuals who actively seek formal health information from credible online sources and engage with health care providers are more likely to get vaccinated in the influenza vaccine [15]. Intervention studies have been conducted on Tetanus, diphtheria, acellular pertussis, and influenza vaccination during pregnancy, and it has also been reported that web-based vaccination information, including websites and interactive social networking services (SNS), can improve vaccination uptake [16]. Conversely, reliance on SNS for vaccination information has been associated with lower vaccination rates, such as the pertussis vaccine uptake during pregnancy, indicating that informal online sources may contribute to vaccine hesitancy [17]. Other studies have also yielded mixed results, with internet information gathering having a positive effect on pneumococcal vaccination of adults with heart diseases [18] and a negative effect on a mother's decision to vaccinate her daughter with human papillomavirus [19,20]. These findings underscore the complexity of online information's role in vaccination behavior and highlight the necessity of distinguishing between formal and informal sources to understand their differing impacts fully.

For COVID-19 vaccination, a study indicates that the behavior of seeking health information on the internet is positively linked to vaccination uptake in China [21]. Various studies have identified vaccination hesitancy as a concern, noting a reduction in hesitancy when the internet is the primary source of information about COVID-19 [22]. Conversely, some studies have highlighted the negative effects of social media on vaccine hesitancy [23,24]. In Japan, reliance on internet news and video sharing sites was found to exacerbate hesitancy toward COVID-19 vaccination among individuals younger than 65 years [25].

These findings indicate that the effects of internet-based information sources on COVID-19 vaccination uptake are mixed and inconclusive. There is a need for further analysis, as the impact appears to vary depending on the type of internet information sources, such as web news, social media, and video sharing sites. In addition, no studies have reported an association with the timing of vaccination, whether late or early, or with the presence or absence of vaccination.

RenderX

This study aims to investigate the association between COVID-19 vaccination uptake or timing and the use of internet-based information sources in more detail.

Methods

Study Design and Participants' Setting

This study used a cross-sectional study design using a subset of panel data, conducting nationwide web-based surveys 7 times from the first wave (October to November 2020) to the seventh wave (February to March 2022). The surveys were closed surveys facilitated through an internet research company, Rakuten Insight Inc, using their proprietary web platform and a self-administered, anonymized web form. The data across these panels were linked using user identification numbers known only to the research company. Rakuten Insight is among the largest internet research services, boasting 2.2 million registered active users as of September 2022. In this study, only complete cases with no unanswered items were collected, and multiple responses from the same person were eliminated using panel monitor registration information and IP addresses. Primarily, this study used data from the sixth panel (survey conducted between November 5 and 25, 2021), which coincided with the conclusion of the public's initial COVID-19 vaccination phase.

The survey initially sampled 10,000 participants, ensuring an equal distribution across gender, age, and prefectures through random selection during the first wave. If participants dropped out in subsequent surveys after the second wave, resampling targeted individuals who had responded in any of the previous waves. Should a shortfall persist, new samples were recruited, with replacements selected from the closest matching age group within the same prefecture and gender category. In the event of dropouts during the follow-up survey, new samples were added as necessary to maintain a total of 10,000 participants for each panel survey. The decision to establish a sample size of 10,000 was informed by the need for random sampling to ensure equitable allocation and representativeness, taking into account the distribution and prevalence of monitors. This sample size also facilitates effective stratification across age, gender, and prefectural demographics, enabling robust multivariate analysis.

Inclusion and Exclusion Criteria

The eligibility criteria for the survey, aimed at examining the psychological landscape of ethical values and anxiety, required participants to be adults aged 20 years or older. This age threshold was established to ensure the reliability of the feedback received. Furthermore, to reduce sampling bias inherent in internet-based surveys, professionals working in survey or advertising agencies were excluded from participation, which was in line with the regulations set by internet survey companies. The variable related to medical history was cross-referenced using user IDs from the fifth survey panel, conducted between September and October 2021. As a result, any cases where this variable was missing were systematically excluded from the analysis. Medical and caregiving professionals were also excluded from the analysis because they received vaccinations before the general public and possessed specialized expertise and unique access to information. In addition, participants who reported their vaccination dates as being before April 14, 2021 (the start date of mass vaccination) were excluded, as these entries were considered input errors.

Measures

Main Outcome

The primary outcome variable was the date of COVID-19 vaccination. This variable was converted into two binary variables: (1) one indicating whether individuals were vaccinated or not (vaccination uptake) and (2) the other differentiating between dates before and after the 75th percentile (vaccination timing).

In this study, the dependent variable of vaccination timing is defined based on Everett Rogers' Diffusion of Innovation theory [26]. According to this theory, the adoption of new innovations follows a specific pattern, and the population is categorized into 5 adopter categories that consist of innovators, early adopters, early majority, late majority, and laggards.

Given the unprecedented speed and scale of the COVID-19 vaccination rollout, we aimed to identify the segment of the population that adopted the vaccination last, corresponding to the "Laggards" category in Rogers' theory. This category is generally characterized by lower socioeconomic status, personality challenges, and limited social interaction, making its identification meaningful. Statistical methods such as mean and SD are proposed to determine the Laggards category. Considering the timing that most elderly individuals had completed their vaccinations and younger individuals were starting theirs, we determined that defining this group using the fourth quartile was more appropriate.

Exposure

The exposure variable was identified as the source of information related to COVID-19. Participants were asked to select their sources of information from a list provided in a multiple-choice format (Textbox 1). Based on their responses, the options were categorized into two groups, those that involved information seeking through the internet and those that did not. The "with Internet" category included participants who selected at least one of the following options, Twitter, Facebook (Meta), LINE News (LY Corporation), other social networking services, YouTube (Google), COCOA (COVID-19 Contact-Confirming Application, Ministry of Health, Labour and Welfare), web pages of local governments or the Ministry of Health, Labour and Welfare, web pages of professional associations, blogs by medical professionals, personal blogs (nonprofessional), and web news. Participants who selected only options outside of these were classified as engaging in information seeking without the internet.

XSL•FO
RenderX

Textbox 1. Ways of obtaining COVID-19–related information.

Television, Radio, Magazines/Books, Asahi Shimbun, Mainichi Shimbun, Yomiuri Shimbun, Sankei Shimbun, Nikkei Shimbun, Other newspapers, Twitter, Facebook, LINE news, Other social networking services, YouTube, COCOA (COCOA is an abbreviation for COVID-19 Contact-confirming Application, a smartphone application produced by the Japanese government for COVID-19 measures.), WEB pages of local governments or Ministry of Health, Labour and Welfare, WEB pages of professional organizations, Blogs of medical professional, Blogs of personal (nonprofessional), WEB news, Information from friends and acquaintances, Information from family members, Others

Control Variables

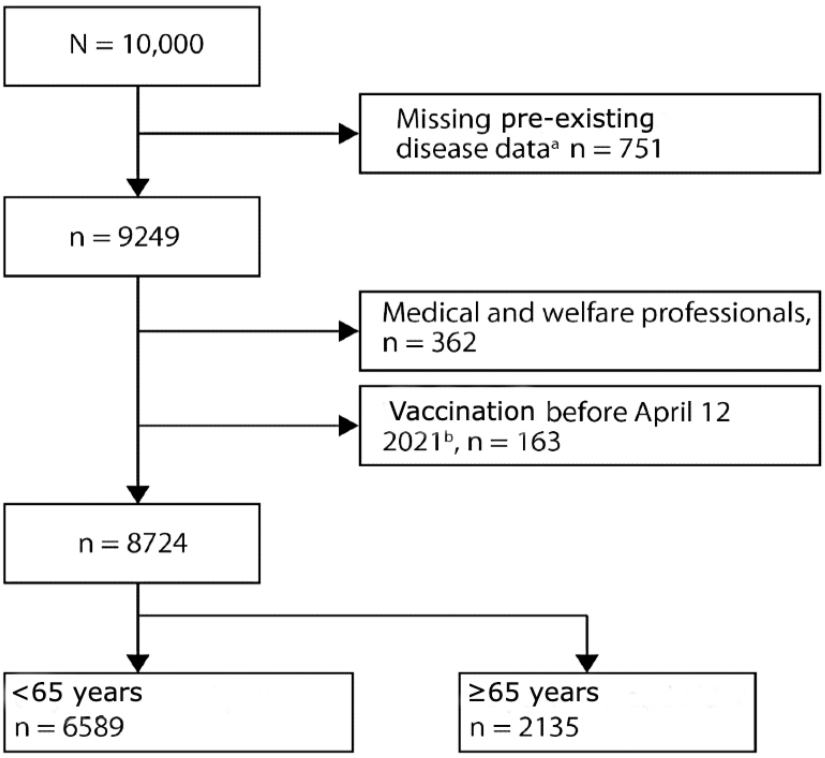
The control variables included gender, family structure, educational background, employment status, household income, pre-existing medical conditions eligible for priority COVID-19 vaccination (Multimedia Appendix 1), and the 14-item health literacy scale for Japanese adults (HLS-14) [27]. Family structure was categorized as either living alone or living with family members. Educational background was classified into three categories, less than a bachelor's degree, associate or bachelor's degree or higher, and unwilling to answer. Household income was defined as no income, less than 3 million yen (approximately US $19,355, at an exchange rate of 155 yen/US dollar), 3 million yen to 5 million yen (approximately US $19,355 to $32,258), 5 million yen to 8 million yen (approximately US $32,258 to $51,613), 8 million yen (approximately US $51,613) or more, or unwilling to answer. The HLS-14 measures health literacy across 3 domains: functional health literacy, communicative health literacy, and critical health literacy. Respondents rate each item on a 1 to 5 scale, with total scores ranging from 14 to 70 points; higher scores indicate greater health literacy.

Statistical Analysis

In Japan, priority for vaccination was given to individuals aged 65 years and older. Therefore, the analysis differentiated between those aged 65 years and older and those younger than 65 years. Descriptive statistics were used to profile the participants and their vaccination statuses. Two regression analyses generalized estimating equations accounted for prefecture-specific correlations, focusing on vaccination uptake and vaccination timing. In these analyses, the main exposure variable was whether information seeking was conducted with or without the internet. The models were adjusted for gender, family structure, educational background, employment status, household income, eligibility for priority COVID-19 vaccination due to pre-existing medical conditions, and HLS-14 scores. In addition, chi-square tests assessed the relationship between the use of each information source and vaccination uptake.

Ethical Considerations

This study was conducted with the approval of the Kyoto University Medical Ethics Review Committee (approval number: R2670). Informed consent was obtained through the initial screen of the online survey, where participants were informed that completion of the questionnaire implied consent. The data provided to the researchers by the commissioned internet research company was anonymized, ensuring no personally identifiable information was included. Participants received compensation in the form of points from the survey company, in accordance with their internal regulations. The exact number of points awarded was not disclosed to the researchers, as this information is confidential.



Results

Participants Included in the Analysis

The sixth survey, which involved 10,000 respondents, was linked with the data from the fifth survey, which led to the exclusion of 751 cases due to missing information on pre-existing medical conditions. In addition, further exclusions were made, 362 individuals working in medical or caregiving professions and 163 participants who reported vaccination dates before April 12, 2021, were deemed ineligible. As a result, the final sample size for analysis was 8724 participants, comprising 6589 individuals younger than 65 years of age and 2135 aged 65 years and older (Figure 1).

b. The date when the COVID-19 vaccine was approved in Japan and vaccination began.

Demographic Characteristics of the Participants

The analysis of demographic characteristics among the participants showed that of the 6589 individuals younger than 65 years, 3260 (49.5%) were women, with a median age of 44 (IQR 33-55). Among the 2135 respondents aged 65 years and older, 1009 (47.3%) were women, with a median age of 71 (IQR 68-73; Table 1). The use of internet-based information sources did not significantly vary between respondents younger than 65 years and those aged 65 years and older. A total of 42.0% (2765/6589) of participants younger than 65 years and 37.0% (791/2135) of those aged 65 and older used 2 or more sources of information. Television was the most popular information source, used by 86.3% (5684/6589) of respondents younger than 65 years and 94.0% (2006/2135) of the older group. Although there was no significant difference in the types of internet sources used, younger participants were more inclined to use social networking services such as Twitter and LINE news (Multimedia Appendix 2).

[a]HLS-14: 14-item health literacy scale.

Summary of Vaccination Uptake as Outcome Variables

Regarding vaccination uptake, 5325 individuals (80.8%, 5325/6589) younger than 65 years and 1921 (90.0%, 1921/2135) aged 65 years and older had been vaccinated. Internet-based information gathering was undertaken by 4632 individuals (70.3%, 4632/5689) younger than 65 years and 1435 (67.2%, 1435/2135) aged 65 or older (Table 1). Furthermore, the quartile values for vaccination dates for those younger than 65 years were: 25th percentile on July 7, 2021, 50th percentile on August 17, 2021, and 75th percentile on September 15, 2021; for those aged 65 years and older, the values were 25th percentile on June 2, 2021, 50th percentile on June 17, 2021, and 75th percentile on July 4, 2021. Consequently, regarding the vaccination timing variable, participants were classified as part of the delayed vaccination group if their vaccination occurred after September 15, 2021, for those younger than 65 and after July 4, 2021, for those aged 65 years and older (Figure 2).

XSL•FO
RenderX

Figure 2. Bar chart showing vaccination timing.

Regression Analysis Results

In the regression analysis with vaccination uptake as the outcome, seeking information through the internet was significantly associated with higher vaccination rates compared with not using the internet for information seeking (adjusted odds ratio [aOR] 1.42, 95% CI 1.27-1.60 for those younger than 65 years; aOR 1.66, 95% CI 1.16-2.37 for those aged 65 years and older). However, when examining vaccination timing as the outcome, there was no significant relationship between using the internet for information and delayed vaccination (aOR 1.12, 95% CI 0.96-1.31 for those younger than 65 years; aOR 1.25, 95% CI 0.98-1.59 for those aged 65 years and older; Table 2).

Chi-square tests assessing the relationship between the use of each information resource and vaccination uptake revealed that TV, government and professional web pages, and web news were more positively associated with COVID-19 vaccination. Conversely, blogs, YouTube, and some social networking sites had a negative association with vaccination uptake (Figure 3).

Discussion

Principal Results

This study offers a thorough analysis of the relationship between COVID-19 vaccination uptake and the use of various online information resources. Our results indicate that seeking information on the internet is positively associated with higher vaccination rates, highlighting the significant influence of online information on public health decisions. Interestingly, however, our data did not reveal a significant link between online information seeking and the timing of vaccination, suggesting that while online resources contribute to the decision to get vaccinated, they may not affect how promptly individuals act on this decision.

The further analysis presented in Figure 3 showcases the varied impact of different internet resources. Government web pages,

XSL•FO
RenderX

for instance, positively influenced vaccination decisions, emphasizing the critical role of credible, official sources in public health communication. On the contrary, information from blogs and SNS was found to have a negative effect. This highlights concerns about the spread of misinformation on less regulated platforms and underlines the necessity for more efficient measures to counteract misleading health information online. Considering the usage rates of each media type, TV emerged as a predominant information source, with 86.3% (5684/6589) of participants younger than 65 years and 94.0% (2006/2135) of those 65 years and older. This widespread use of TV suggests that even excluding TV's influence, internet usage would likely still be statistically significant in relation to vaccination uptake. Nevertheless, the potential interactive effects between television and specific online sources call for more detailed future investigations.

The insights gained from this study enhance our understanding of how the digital information landscape affects health behaviors and underscore the urgent need to ensure access to accurate and trustworthy health information during global health emergencies.

Comparison With Previous Work

The findings of this study align with those of previous research, indicating that obtaining COVID-19 information on the internet is positively correlated with vaccination uptake [21,28]. Similarly, concerning vaccination hesitancy, the results consistently showed that internet information-seeking behavior plays a positive role in reducing hesitancy [22,23]. While it is plausible that the type of information disseminated across various media, including the internet, may vary by country due to cultural and linguistic differences, these results suggest that the trends observed in Japan mirror those in other nations. However, a study by Hori et al [25] in Japan found that internet web news negatively affected vaccination hesitancy, diverging from some findings of this study. Despite using the same internet research firm for sampling, the exclusion criteria between the two studies significantly differed. Notably, focusing on specific target populations—excluding individuals aged 65 years and older, those who are obese, have pre-existing medical conditions, or have a clear intention regarding vaccination—might yield different impacts on COVID-19 vaccination outcomes. Many of these studies have been conducted in developed economies such as the United States, China, South Korea, Japan, and European Union countries [21-23,25,28], and different results could be obtained if studies were conducted in more diverse countries, including developing economies. Indeed, a paper tracking changes in search trends during the pandemic on Google Trends also reported that search trends were influenced by central government actions and news sources, with some search terms trending differently in different countries [29].

Moreover, reports on information-seeking behavior during the COVID-19 pandemic have indicated that traditional media such as television are more trusted than social media, and Information-seeking behavior through the internet is associated with higher levels of knowledge [30,31]. With regard to SNSs, there is a risk that the sharing of incorrect information may be accelerated because people who are more likely to share information are more confident in their own information and judgment due to a high degree of information sufficiency and trust in the source of information on SNSs [30]. In fact, the outcomes related to social media usage are consistent with previous findings, indicating a negative effect on vaccination rates [23,32]. The growing number of studies highlighting misinformation on social media [33] and the widespread misinformation on critical public health issues [34] advocate for cautious use of social media to prevent reliance on potentially misleading information [32]. However, it is also true that nearly half of people seek COVID-19 information from SNSs [35,36], and it has been shown that vaccination coverage is higher among those who follow reliable information sources on SNSs, so it is important to have a good relationship with SNSs [35]. Moreover, negative impacts have also been reported concerning video sharing sites [25], with some platforms, like YouTube, implementing measures to curb the spread of inaccurate health information by introducing eHealth services [37]. As recommended by the WHO framework [9], a multifaceted approach involving user literacy and ethics, the provision and translation of information by evidence-based professionals, and the analysis and improvement of services by platform operators is essential for fostering a well-informed society in terms of health information.

Therefore, using the internet can be effective in scenarios where vaccination is encouraged as part of a national strategy, such as the COVID-19 response. However, it is crucial to select reliable sources of information and enhance services to ensure the dissemination of accurate information.

Strength and Limitations

The strengths of this study include its close alignment with the demographic distribution of the Japanese population, featuring an aging rate of 24.5% (compared with the national average of 28.9%), a women representation of 49.5% (national average: 51.4%) [38], and a vaccination rate of 83.1% (national average: 75.2% as of November 30, 2021 [6]), ensuring representativeness. A unique aspect of this study is its focus on actual COVID-19 vaccination uptake rather than intentions or hesitancy, analyzing the association with various internet information sources in detail. However, the study is not without limitations. First, it did not thoroughly examine the effect of using multiple information sources on vaccination uptake. Second, the context of the COVID-19 vaccination campaign, being a specific situation with national strategies, including a large-scale vaccination effort, requires caution in generalizing these findings to vaccinations for other infectious diseases. Third, the simultaneous administration of vaccines over a brief period reduced the variance in vaccination timing, potentially making it challenging to identify a relationship between vaccination timing and information sources. While the impact of information sources may extend beyond the context of emerging infectious disease pandemics, as similar outcomes have been reported for other infectious diseases like influenza [39], more comprehensive studies are necessary in the future. Finally, since this survey was conducted through an internet web-form, people who do not use the internet at all were excluded from the survey. As a result, the participants may exhibit higher levels of information-gathering behavior through the internet compared with the general population. However,

XSL•FO
RenderX

this likely represents a conservative effect on the results of this study, suggesting that the true impact of the exposure may be even stronger. Future research using face-to-face or mail survey methods would be desirable to corroborate these findings. Finally, this study might have potential selection bias due to the nature of an internet survey. Individuals, particularly in 65 years old and older, without access to or interest in internet surveys may differ in vaccination behaviors, and unvaccinated individuals may have been less likely to participate. However, over 16.9% (1478/8724) of respondents reported being unvaccinated, suggesting that arrange of vaccination statuses was adequately represented. Despite this limitation, the impact on the study's conclusions is likely minimal.

Conclusions

Seeking information related to COVID-19 on the internet is significantly associated with COVID-19 vaccination uptake but not with the timing of vaccination. However, an analysis differentiated by types of internet media reveals a varied impact across these platforms. Specifically, platforms like blogs and social media networks have been identified as negatively affecting vaccination uptake. Public health policy makers should strategically use online information media during an emerging infectious disease pandemic such as COVID-19, taking into account the unique characteristics of each media type.

Acknowledgments

This work was supported by the Kyoto University FY 2020 GAP Fund Program Type B (to YI), the Japan Society for the Promotion of Science (JSPS KAKENHI; grant number: 19H01075, 23H00448 to YI, 22K17549 to KT), and the Research Promotion Fund (FY2024) from the Japanese Medical Science Federation "Survey of the Impact of COVID-19 on Medicine, Medical Care, and Health (to YI). The funder is not involved in the study design, data collection, analysis, interpretation, writing of the manuscript, or decision to submit it for publication. Abstract

Background: The COVID-19 pandemic reshaped social dynamics, fostering reliance on social media for information, connection, and collective sense-making. Understanding how citizens navigate a global health crisis in varying cultural and economic contexts is crucial for effective crisis communication.

Objective: This study examines the evolution of citizen collective sense-making during the COVID-19 pandemic by analyzing social media discourse across Italy, the United Kingdom, and Egypt, representing diverse economic and cultural contexts.

Methods: A total of 755,215 social media posts from X (formerly Twitter) were collected across 3 time periods: the virus' emergence (February 15 to March 31, 2020), strict lockdown (April 1 to May 30, 2020), and the vaccine rollout (December 1, 2020 to January 15, 2021). In total, 284,512 posts from Italy, 261,978 posts from the United Kingdom, and 209,725 posts from Egypt were analyzed using the latent Dirichlet allocation algorithm to identify key thematic topics and track shifts in discourse across time and regions.

Results: The analysis revealed significant regional and temporal differences in collective sense-making during the pandemic. In Italy and the United Kingdom, public discourse prominently addressed pragmatic health care measures and government interventions, reflecting higher institutional trust. By contrast, discussions in Egypt were more focused on religious and political themes, highlighting skepticism toward governmental capacity and reliance on alternative frameworks for understanding the crisis. Over time, all 3 countries displayed a shift in discourse toward vaccine-related topics during the later phase of the pandemic, highlighting its global significance. Misinformation emerged as a recurrent theme across regions, demonstrating the need for proactive measures to ensure accurate information dissemination. These findings emphasize the role of cultural, economic, and institutional factors in shaping public responses during health crises.

Conclusions: Crisis communication is influenced by cultural, economic, and institutional contexts, as evidenced by regional variations in citizen engagement. Transparent and culturally adaptive communication strategies are essential to combat

XSL•FO
RenderX

misinformation and build public trust. This study highlights the importance of tailoring crisis responses to local contexts to improve compliance and collective resilience.

(J Med Internet Res 2025;27:e58656) doi:10.2196/58656

Introduction

Background

According to the World Health Organization, COVID-19 was one of the most significant global public health challenges. Italy, Egypt, and the United Kingdom were among the countries considered to be the worst affected [1,2]. Many studies have noted how the internet and social media are essential in communicating risks and emergencies before, during, and after a crisis [3,4]. Human behavior related to using and processing information has been enormously affected by the orientations of the digital world in the 21st century. This uniquely contrasts previous global deadly disease outbreaks such as the Black Death and the Spanish Influenza. Furthermore, a recent study by Christianson & Barton noted how COVID-19 had created a unique scenario that provides an opportunity to study "sense-making" [4].

Digital platforms allow users to converse with one another for collective sense-making, which involves seeking, generating, processing, and using information [5]. A prevalent platform for seeking and sharing health information alongside breaking news stories is X (formerly known as Twitter) [6].

Specifically, sense-making and social media usage during the COVID-19 pandemic have received much attention from scholars in various fields, including sociology, psychology, communication, and information systems [4,7,8]. Studies in this area have investigated how individuals use social media to make sense of the rapidly changing and complex situation posed by the COVID-19 pandemic. Research has shown that social media can be essential in providing access to information, shaping public opinion, and influencing behavior during a crisis.

One strand of research has investigated how individuals use social media to gather information and make sense of the pandemic. Studies have shown that social media, such as X, can serve as an essential source of information for individuals, especially during a crisis when traditional sources of information may be limited or unreliable. Social media also enables individuals to seek out information from various sources, which can help them form a more nuanced understanding of the situation [9].

Another strand of research has investigated the role of social media in shaping public opinion and behavior during the pandemic. Studies have shown that social media can be an essential factor in shaping public opinion and influencing individuals' decisions about things like their behavior and whether to seek medical treatment or follow recommended guidelines [10,11]. Despite this body of research, there are still some crucial gaps in our understanding of the relationship between sense-making and social media usage during the COVID-19 pandemic. More research is needed to investigate the role of social media in shaping public opinion and behavior, particularly in diverse populations and geographic regions. Additionally, there is a need for more cross-country digital research on how individuals use social media to make sense of the pandemic, including how they navigate and interpret the vast amounts of information available on social media platforms. While studies have explored the impact of social media on public opinion and behavior, more research is needed to understand how X influences public opinion and behavior during uncertainty and crises such as COVID-19 [12].

This study seeks to analyze data on X related to the 3 phases of COVID-19 and the response of citizens across different countries on X. Our study focused on examining data from Italy, the United Kingdom, and Egypt. Italy has a national health system and is a member of the European Union. The United Kingdom is a country that also has a national health system and has recently left the European Union. Egypt does not have a national health system nor is it a member of any allied institutions. For these reasons, these 3 countries provide an interesting comparison point. Our study would uncover the differences in public perceptions and cultural attitudes toward crisis information on social media. The discourse from certain countries may also vary depending on culture, freedom of speech restrictions, and events.

In order to contextualize the developmental differences between Egypt, Italy, and the United Kingdom, we made reference to the Human Capital Index [13]. This is a quantitative measure of development based on health and education outcomes. According to this index, Italy scores 0.73, the United Kingdom 0.78, and Egypt 0.49. The index highlights how there is a substantial developmental gap between Italy and Egypt (0.73 vs 0.49) compared to the gap between Italy and the United Kingdom (0.73 vs 0.78). The significant difference between Egypt's Human Capital Index and that of Italy and the United Kingdom substantiates our classification of Egypt as a developing country relative to these 2 more developed nations. This cross-country variation allows us to explore how diverse sociocultural contexts and government responses influence citizen engagement with COVID-19 information on social media. Italy, the United Kingdom, and Egypt had varied timelines and policies. Italy responded with strict early lockdowns, coupled with economic support programs intended to mitigate financial strain. The United Kingdom initially adopted a more gradual approach, balancing public health measures with economic interests before implementing more

XSL•FO
RenderX

extensive restrictions as the pandemic progressed. Egypt, on the other hand, maintained a comparatively limited governmental response, with religious institutions playing a crucial role in disseminating health guidance and encouraging precautionary behaviors.

Research Aims

This study examines the variation of public attention and interaction with COVID-19 by analyzing data from X. It tries to estimate how COVID-19 has captured the attention of citizens across Italy, Egypt, and the United Kingdom. The theoretical lens of the study is sense-making. More specifically, the research questions (RQs) of this study are as follows (Textbox 1).

Textbox 1. Research aims of this study.

- RQ1: To develop an understanding of public views shared on X toward COVID-19 across Egypt, Italy, and the United Kingdom.
- RQ2: To compare the response of citizens toward COVID-19 on X across Egypt, Italy, and the United Kingdom.
- RQ3: To examine the concept of sense-making concerning community responses to COVID-19 in Egypt, Italy, and the United Kingdom.

This study contributes to the existing body of knowledge by providing a cross-cultural analysis of public sense-making processes and reactions. This remains crucial for understanding how communities adapt to health crises. While the data were collected during the early stages of the pandemic, the lessons learned are still applicable to current and future public health challenges, particularly in designing culturally sensitive communication strategies and mitigating misinformation. Moreover, to the best of our knowledge, this is the first empirical investigation that systematically examines public discourse on X during the COVID-19 pandemic across Egypt, Italy, and the United Kingdom, offering a comparative perspective.

Literature Review: COVID-19 and Social Media Research

A wide range of research on the COVID-19 pandemic, which draws upon X datasets, has been conducted. A recent study proposed several algorithms to estimate work engagement. Other studies have ranged from the identification of misinformation [14], examining public views and opinions related to various issues around the pandemic [15], and research related to epidemiology [16]. In one of the earliest studies examining misinformation on X, the author examined how a conspiracy theory linking COVID-19 to 5G spread on X [16]. Social network analysis was used alongside a content analysis to identify key users, content, and websites related to the conspiracy. Other research has also examined the relationship between fact-checking and misinformation [17]. The study found that fact-checks tend to appear after the spread of misinformation but that their ability to reduce the spread of misinformation is limited. Furthermore, they found that topics such as conspiracies are more resistant to fact-checkers.

Scholars have also analyzed X data to better understand perceptions of face masks [18]. In one study, the authors analyzed the content of the posts that talked about the vaccine and categorized them into these categories (provaccine, antivaccine, and neutral). Consequently, they found that the antivaccine posts use the sarcasm method, and some of them come from bots, while the pro-vaccine posts depend on documented information [19]. It is worth noting that over time, trust in the information spread on the internet is affected by the recipient's political affiliation [20].

Several studies have conducted research looking at COVID-19 in relation to other platforms. Although not a study on social media data itself, Wang et al [21], through a web-based survey posted on Facebook, found that Taiwanese citizens were mostly using the internet for their health information. This is an important finding as it highlights that web-based sources are likely to be the most viewed sources of information for a subset of the population. In another study, Sesagiri Raamkumar et al [22] examined the outreach efforts of public health authorities on Facebook in Singapore, the United States, and England. They found that the most common theme among all posts was those related to prevention and safety measures. It is also important to mention that outside of COVID-19 research, X has also been used across a range of disciplines in innovative ways. For example, X has been used to identify the political affinity of web-based entities through X followers and for the automatic identification of eyewitness messages on X at the time of natural disasters.

Although previous research has examined content from social media related to COVID-19, there is a lack of empirical work that has compared user views across different geographical locations using time as a moderating variable. Our proposed study hopes to address this research gap and contribute to the wider public health literature by developing an understanding of social media user views across 3 countries.

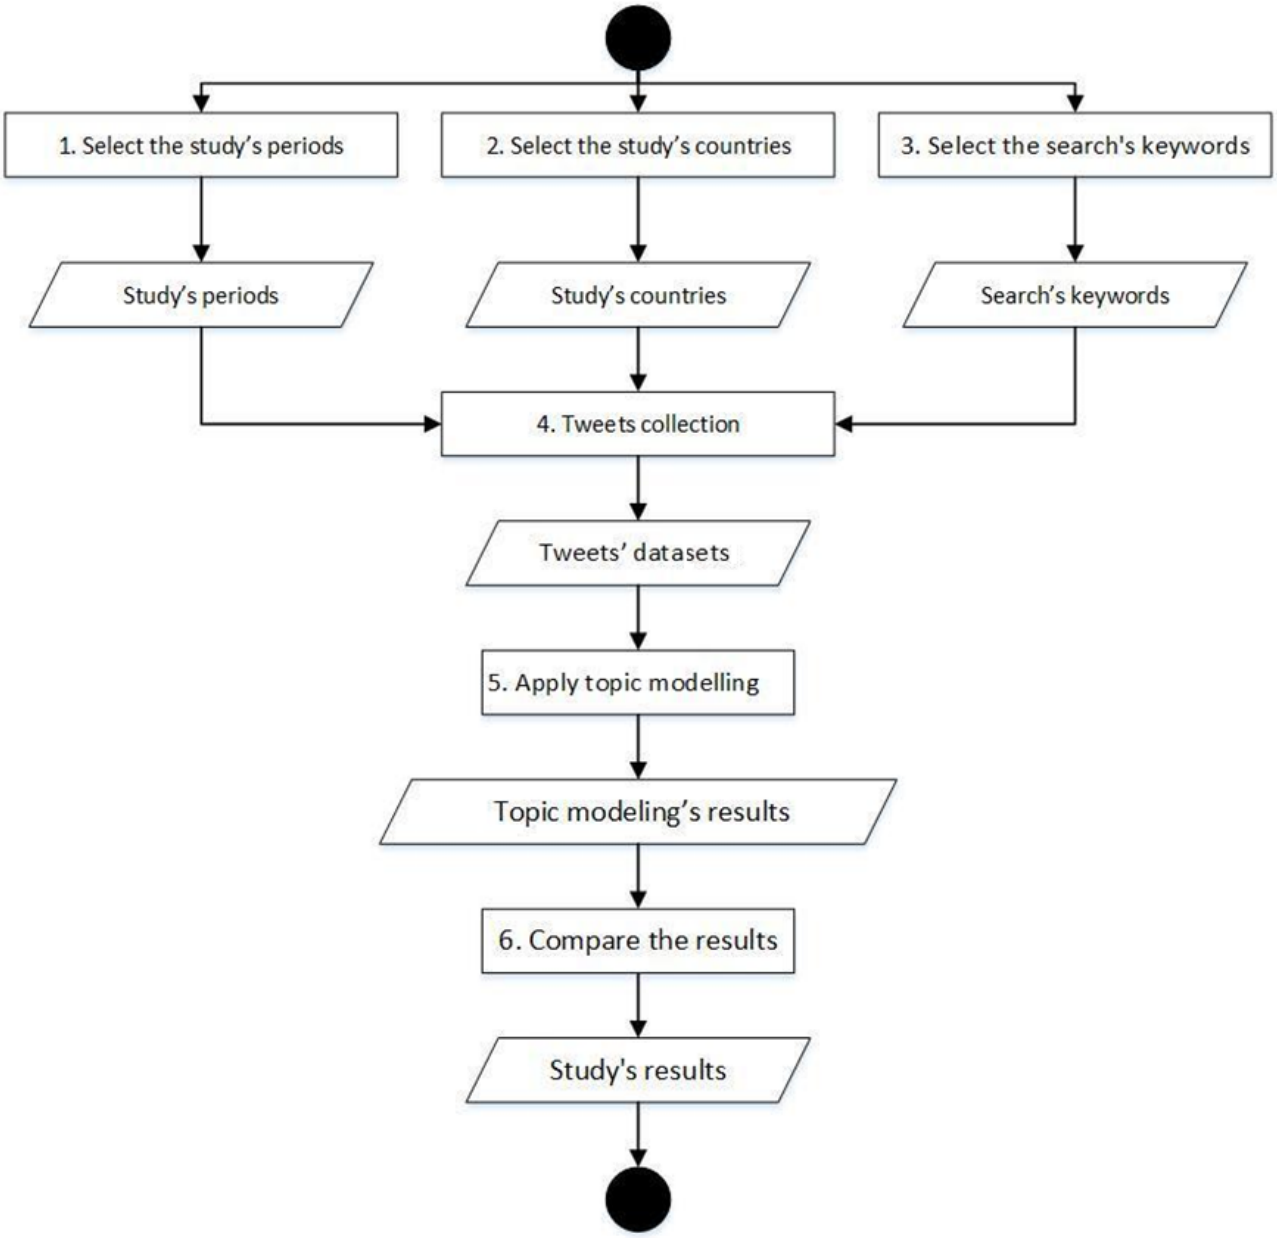
Theoretical Background

We define the term sense-making as a process through which individuals aim to develop an understanding of events that may be confusing, uncertain, and violent by interacting with others [20-25]. In recent years, scholars have studied the concept of sense-making about interactions on social media platforms. For instance, a study by Zolyomi et al [5] examined the #ActuallyAusistic hashtag on X and found that autistic individuals used X to engage with sense-making to understand themselves better. In this context, sense-making was applied to construct identities in relation to individual social groups, employment, education, and the use of technology. Another study [22] focused on X collective sense-making that was examined during the Berlin terrorist attack. The study found that X users made sense of the events that were occurring on X. The study highlighted how collective behavior occurred during the aftermath of a terrorist attack. There are many definitions and discussions of social media within academic

XSL•FO
RenderX

literature [26]. A popular definition notes that they are “a group of internet-based applications that build on the ideological and technological foundations of Web 2.0 and that allow the creation and exchange of user-generated content” [27].

Previous research has also examined sense-making on social media during other extreme events. For instance, Stieglitz et al [23] analyzed X data related to 3 events: the Sydney Lindt Café siege (2014), the Germanwings plane crash (2015), and the Brussels terror attacks (2016). They found that there were differences in how users communicated with one another across the 3 events. The authors note that citizens may use social media during extreme events to speak with one another and make sense of an event.



The researchers [24] noted that the information a person receives significantly impacts his behavior. Furthermore, they found a strong relationship between misinformation spread on social media and following preventive measures with the COVID-19 epidemic. Therefore, the researchers recommended publishing the correct news and confronting the misinformation to improve the citizens' behavior.

Methods

Study Design

The study was designed and executed in 6 phases, and a summary of these can be found in Figure 1, which provides a visual summary of our research design. Our study was pragmatic, inductive, and exploratory in nature, drawing upon the theoretical lenses of sense-making.

Figure 1. Overview of the 6 phases of our methodology.

XSL•FO
RenderX

Time Period Selection

COVID-19 appeared toward the beginning of 2020, and up to early 2021, there were 3 key periods for the pandemic, which can be characterized as follows: the emergence phase; during the initial lockdown; and when cases began to reappear during the second winter lockdown.

The difference between the 3 periods has been categorized based on the COVID-19 spreading and the political and governmental procedures and interventions that are undertaken. Therefore, the first period indicates the period of the virus' emergence and spreading, which took almost 2 months to be recognized as a pandemic by the World Health Organization. The second period includes the period of strict decisions that governments have made, which, in some countries, have reached total lockdown. The last period consists of the period of containing the virus and easing the severity of government restrictions. Since countries have responded to the pandemic situation differently, this study has tried to select countries that cover the spectrum of different situations.

All in all, we used the same time frames for Italy, the United Kingdom, and Egypt to analyze the influence of Italy's early pandemic responses on global strategies. This uniform approach allows for comparative insights into how different regions adapted measures pioneered by Italy, facilitating an understanding of both reactive and locally influenced responses. In addition, the gap between the studied periods allows us to examine the adjustments and preparations made after initial lockdowns and before the resurgence of the virus. This helps in understanding the balance countries maintained between economic reopening and health safety, which is crucial for evaluating the effectiveness of pandemic management over time.

The overview of the time intervals across these phases is shown in Table 1, which shows our 3 time periods and their associated time intervals for which data was collected.

Table 1. Overview of the 3 time periods examined.

Periods	Time intervals
The virus' emergence	From February 15 to March 31, 2020
Lockdown	From April 1 to May 30, 2020
Virus spreading	From December 1, 2020, to January 15, 2021

Keyword Strategy

A group of keywords most used by X users when conversing about COVID-19 was chosen using the website Getdaytrends. This website shows the most used hashtags during a specific time, including the number of posts attached to such hashtags for a particular country. This process allows for getting the most posts about COVID-19. Table 2 provides an overview of the keywords used to retrieve data for the respective countries examined.

Table 2. Overview of the keyword strategy to retrieve data.

Hashtag	Country
COVID_19	Italy, the United Kingdom, and Egypt
COVID-19	Italy, the United Kingdom, and Egypt
COVID19	Italy, the United Kingdom, and Egypt
COVID2019	Egypt
coronavirus	Italy, the United Kingdom, and Egypt
19 (en[a]: COVID19)	Egypt
_19 (en: COVID_19)	Egypt
(en: CORONA)	Egypt
(en: CORONA)	Egypt
_ (en: CORONA_VIRUS)	Egypt
_ (en: CORONA_EGYPT)	Egypt

[a]en refers to the English language.

Collecting X Data

Posts were collected in Python via the tweepy library. A requirement when collecting posts was to be written in the country's language and posted by its inhabitants. In order to fulfill these 2 conditions, some parameters were determined in the collection's algorithm. The algorithm uses the "lang" parameter to determine the post's language and the "geocode" parameter to determine the users' position when they have posted. Since the "geocode" parameter requires latitude and longitude, we have collected this information for all cities in our 3 countries via Google Maps. Consequently, the collection steps were executed as a loop for each keyword the algorithm

XSL•FO
RenderX

executes for each city. The posts collected contain at least 1 hashtag of the search's keywords list.

The posts from Italy were filtered based on the language, assuming that the Italian language is unlikely to be used significantly outside of Italy (ie, to represent another county or region). However, filtering the posts based on location and language was used to collect the posts from Egypt and the United Kingdom, as English and Arabic could represent other regions.

Posts that were retrieved contain at least 1 keyword from Table 2. Table 3 shows the number of posts collected for each country across the 3 time periods examined. It is important to note that the number presented in Table 3 represents the final collected posts after applying 3 separate types of filters on the collected posts, which were as follows (Textbox 2).

Table 3. Overview of data retrieved across phases and countries from X.

Country	Final collected posts, n		
	The virus' emergence (phase 1)	Lockdown (phase 2)	Virus spreading (phase 3)
Italy	98,475	100,746	85,291
United Kingdom	84,675	97,842	78,461
Egypt	75,712	91,846	42,167

Textbox 2. Filters applied to collected data.

- All repeated posts were deleted using the post ID.
- All posts that had the same text were deleted.
- All posts with less than 20 characters were deleted.

Application of Topic Modeling

Topic modeling algorithms are frequently used to analyze posts. This method was selected in this study due to the volume of posts being analyzed. One of the most important types of these algorithms is latent Dirichlet allocation (LDA) [25]. The LDA model is a generative model used in natural language study, which allows for extracting topics from a set of source documents. Each document is considered a group of words that form one or more latent topics when combined [26]. A particular distribution of terms characterizes each topic. LDA's generative process is based on analyzing the text's data (text mining). Word combinations are considered as random variables.

The LDA algorithm was used to identify frequently used conversation topics in the corpus of data collected within the COVID-19 context. The selected number of topics (T) were extracted from a collective dataset (C). Probability (Pi) of inclusion of individual posts (Ci) from the dataset can be represented as:

$$\text{Probability } (Ci \in ti) = Pi$$

$$\text{Collective posts } C = \{C1, C2, C3\ldots,Cn\}, \text{ where topic distribution } T = \{t1, t2, t3,\ldots,tn\}$$

Our topic models generated a topic matrix and the likelihood of individual topic strength. The bag of words constructed within the matrix can be designated as n-grams. In our case, a bigram model was selected due to its popularity in strengthening topic cohesion and topic relevance. We experimented with the optimum topic strength value up to the recommended 30. Several rounds of experimentation showed that the thematic importance of collective sense-making could be best captured between 2 and 7 sets of topics using bigram values.

The application of the topic modeling is divided into 3 steps. The first step is preparing the dataset to train the model, where each post is treated as a document. The second step is selecting the number of topics that are identified. The analysis will be conducted more than once, as each time, a different number will be determined for the number of topics that will range between 2 and 10. After each iteration, the coherence value will be extracted, indicating the model's efficiency [26]. Afterwards, the number of topics used in the model with the highest coherence value will be selected, and if all topics represent more than 5% of the dataset, we will decrease the topic numbers to achieve this condition. In the third step, the LDA model will be repeated, confirming the number of topics that are selected in the previous steps. Then, the LDA model will be used to extract a list of words representing each topic; consequently, the word lists will be used to describe each topic's connotation. Moreover, the LDA model classifies posts by their represented topic; consequently, the percentage each topic represents within the database will be calculated.

Identification of Topics

After completing the previous step, the study will have developed results for 9 datasets, 3 for each country. The results for each country are discussed separately and will be compared later. We have obtained 9 independent topic models by applying the LDA model to each country's datasets. Each topic model returns the number of topics representing the dataset and the top words of each one. In the next section, we give a label and a description for each topic.

Finally, the study used LDA and bigrams to analyze large-scale social media posts, aiming to extract meaningful topics. LDA was chosen for its effectiveness in handling vast textual data, while bigrams enhanced the contextual relationships between words. Despite challenges like broad topics and tweet brevity,

XSL•FO
RenderX

LDA proved suitable for capturing public discourse. The paper defines "sense-making" as how individuals interpret public health information, especially during crises. The topics derived through LDA reflect public interpretations of COVID-19, and manual labeling by experts ensured accurate insights into public responses.

Ethical Considerations

This research was covered by ethical approval gained from Newcastle University (ref: 1067/2020). Moreover, our study is conducted on aggregate data, and we do not draw attention to any individual users or publish any identifiable information.

Use of Tools to Support Proofreading

We drew upon large language models such as ChatGPT (version 4o) for basic proofreading as well as tools such as Grammarly to identify any errors in writing and sentence construction. However, no tools were used to generate text of their own.

Results

Table 4 provides an overview of the results of the study.

Content on X in Italy (Phase 1)

This information in Table 4 can be used to give the following descriptions for content in Italy during phase 1:

- Topic 1: General situation in Italy:
  The virus began to spread increasingly in northern Italy, especially the Lombardy region, which caused an increase in the number of patients in need of intensive care and increased the number of deaths.
- Topic 2: European role:
  With the start of the lockdown, citizens sensed the extent of the economic damage that the virus might cause. They also sensed the Italian government's inability to deal with these damages on its own. For this reason, discussions noted

XSL•FO
RenderX

how the European Union must intervene as soon as possible and help citizens and companies alike.
- Topic 3: Protection:
The virus is unknown by specialists, who cannot predict the mechanism of its spread. Therefore, all preventive measures must be taken, especially wearing masks when leaving the house. Consequently, the government has been asked to secure many masks to meet citizens' needs and distribute them free, as did a region of Tuscany.
- Topic 4: Media:
The media, in their various forms, played a significant role in reporting the stories and sacrifices of medical personnel in the face of this virus; besides, it focuses on the political disagreements between the government and the opposition.

Content on X in Italy (Phase 2)

This information in Table 4 can be used to give the following descriptions for content in Italy for phase 2:

- Topic 1: Region of Lombardy:
Despite quarantine, the number of injuries in the region is still on the rise. This rise has been accompanied by an increase in the number of deaths and increased pressure on the health sector, which has become weak and unable to bear more patients.
- Topic 2: Virus:
Some voices appeared on social media that deny the existence of the virus or claim to reduce its risk. For instance, some noted that the virus can be eliminated by taking certain vitamins and that the lockdown measures were created to destroy countries' economies. The presence of such voices prompted many to respond to them and prove that such claims were incorrect.
- Topic 3: Economic status:
With the increase in the quarantine period, fears of citizens' deteriorating economic situation and the fear of losing their jobs began to appear. A number of citizens noted that they did not have enough money to buy basic necessities.

Content on X in Italy (Phase 3)

This information in Table 4 can be used to give the following descriptions for content in Italy for phase 3:

- Topic 1: Virus mutated:
A new virus mutation in England was discussed, and users hypothesized that there would be an increased transmission. Meanwhile, the arrival of the new mutation to Europe increased fears, and the demand to close borders started.
- Topic 2: Quarantine process:
The government enacted a new law to regulate the quarantine process, giving color to each region according to the data on the epidemic. Each color symbolizes different restrictions on the inhabitants of the areas. This law was difficult for citizens to understand, especially the differences in color restrictions.
- Topic 3: The vaccine:
The government developed a nationwide plan to vaccinate citizens, which began with the arrival of the Pfizer vaccine. X users noted that the Lombardy region should be provided with more doses to cover faster. Concerns resurfaced after Pfizer announced a delay in reaching the agreed quantities.
- Topic 4: General situation:
The daily reports of the number of infections were being actively monitored by citizens. X users also requested that schools remain open regardless of the number of casualties.

Sense-making during the COVID-19 crisis started with wider discussions without a clear focus on selective topics. The trend eventually became more fixated on the cause and evolution of the crisis (SARS-CoV-2) and prevention measures (quarantine and vaccine).

Content on X in Egypt (Phase 1)

This information in Table 4 can be used to give the following descriptions for content in Egypt for phase 1:

- Topic 1: Places of worship:
The first measure to prevent the virus was to close the places of worship, which sparked a great debate among citizens, especially among the Muslim community members, due to the approaching month of Ramadan. Some of the users demanded for mosques not to close, and some insisted on closing the mosques due to the overcrowding during the month of Ramadan.
- Topic 2: Lack of confidence in the government:
The government was not transparent in handling the epidemic, which caused citizens to distrust the reality of the reports, especially the numbers of infections. Besides, many citizens accused the government of spreading false news about the virus.
- Topic 3: Evoking historical events:
Many invitations have appeared for the obligation to adopt the quarantine even if the government did not impose it. Indeed, these invitations were based on epidemics that occurred during the Prophet Muhammad's time and how he ordered people not to go to places where the epidemic was spreading and not leave the place of the epidemic for those in it now of its spread.

Content on X in Egypt (Phase 2)

The information in Table 4 can be used to give the following descriptions for content in Egypt for phase 2:

- Topic 1: Medical staff:
With the increase in the number of cases, hospitals' and medical staff's pressure increased, and they began to work as robots day and night. Meanwhile, the media highlighted the medical staff's sacrifices and the deaths that occurred among them.
- Topic 2: General situation:
Hospitals are no longer able to receive more injured patients. They experience difficulty from shortages in equipment, which has caused terror among citizens who demanded the government to impose a complete lockdown.
- Topic 3: Demanding the dismissal of the Minister of Health:
From many Egyptians' point of view on X, the minister was not up to the responsibility, and because they did not hire more doctors and nurses. And some Egyptians went to accuse the minister of killing patients.

XSL•FO
RenderX

Content on X in Egypt (Phase 3)

This information in Table 4 can be used to give the following descriptions for content in Egypt for phase 3:

- Topic 1: The vaccine:
  Jordan obtained the Chinese vaccine and started the vaccination campaign. Accordingly, there was a campaign beckoning for the government to follow Jordan's steps and to be able to limit the spread of the epidemic.
- Topic 2: General situation:
  The number of injuries increases daily, and the number of deaths increases. Also, problems increase in hospitals. One of the most serious of these problems was the lack of oxygen in Al Hasina Hospital, which caused the death of a group of patients in the intensive care unit.

As opposed to a developed nation like Italy, in Egypt, collective sense-making was narrowly focused during phase 1. In the absence of clear scientific logic, during the initial days of the crisis, people relied on religious and historical analogies. As time progressed, people started to understand the importance of preventative measures like vaccines, yet overall discussions were identified to become broad and dispersed as time progressed.

Content on X in the United Kingdom (Phase 1)

This information in Table 4 can be used to give the following descriptions for content in the United Kingdom during phase 1:

- Topic 1: Prepare for a pandemic:
  The people are sure of the epidemic's arrival; therefore, they declared the importance of preparing for it and strengthening the health sector.
- Topic 2: The situation in Europe:
  Citizens followed the news of the epidemic in Europe with great apprehension. The virus moved quickly between the Union countries; consequently, they were sure that it would reach them.
- Topic 3: Lockdown:
  The government suggested not to close, which caused great fear among the citizens, who immediately demanded the government to apply the lockdown.

Content on X in the United Kingdom (Phase 2)

The information in Table 4 can be used to give the following descriptions for content in the United Kingdom during phase 2:

- Topic 1: General situation:
  The number of injuries increased daily, and the number of deaths also increased. X users also note that problems have increased in hospitals.
- Topic 2: Economic impact:
  Citizens had a real state of terror of the economic effects of the epidemic. Accordingly, they turned to the government to ask it to adopt economic policies that help companies and individuals.

Content on X in the United Kingdom (Phase 3)

This information in Table 4 can be used to give the following descriptions for content in the United Kingdom during phase 3:

- Topic 1: General situation:
  Daily reports are still the focus of citizens' attention, especially the news of virus mutation. In addition, the government's demands for economic aid continued.
- Topic 2: The vaccine:
  The vaccine's arrival marked a significant turning point for citizens, giving them a dose of hope that the virus could spread, which increased significantly.

Collective sense-making in the United Kingdom shows unique characteristics with the transition of time. During the initial days, public opinion was varied and dispersed in terms of preparation for the pandemic. Due to early interventions from the government and health authorities, many people were questioning the preparedness and viability of the public health care system and whether it could withstand the unexpected crisis. With the passage of time, discussions and opinions became more dispersed and polarized in terms of the economy (during phase 2). Finally, during phase 3, collective sense-making topics were largely focused on the vaccine and its scientific viability, along with other general issues in terms of economic and employability support.

Comparing Responses

This section will compare the different phases and the resulting themes that emerged. There were differences and certain similarities in how X users made sense of the unfolding events. Table 4 provided an illustration of all the themes that emerged for the 3 cases within the periods of the study, and further insights can be extracted from it, as provided in Textbox 3.

XSL•FO
RenderX

Textbox 3. Insights from comparing themes.

- It shows how citizens were following posting or reposting the pandemic news, including the number of new cases, deaths, fatality issues, etc.
- It shows how posts in Italy and the United Kingdom covered mainly prevention measures imposed by the governments in their countries, the extent of their validity, and the need to adhere to them. However, posts from Egypt mainly focused on religious arguments to encourage people to take protection measures to cover the void left by the government. This trend has been adopted when the people feel that their government does not implement adequate preventive measures. On the other hand, many posts demanded that the houses of worship not be closed so that the prevention measures could be easily applied according to their description.
- It can be argued that the media has played a crucial role in following up on spreading the virus and discussing preventive procedures and government involvement, especially in the United Kingdom.
- The posts in Italy and the United Kingdom called on their governments to provide economic aid or increase this aid to match the extent of the damage they experienced, while the Egyptians did not demand that might be justified by people's belief in the government's inability to follow the same European economic policy.
- The virus mutation aligned with a great concern for Italian citizens, especially the fear of returning to complete closure again.
- Egyptian posts showed their lack of confidence in the government in its ability to manage the crisis. Many posts claimed that the Minister of Health was unable to protect the doctors working in the first line of defense and questioned how it would be able to protect the people.
- Overall, the posts in the 3 countries found that the only way out of the pandemic would be to use vaccines that had been developed.

Discussion

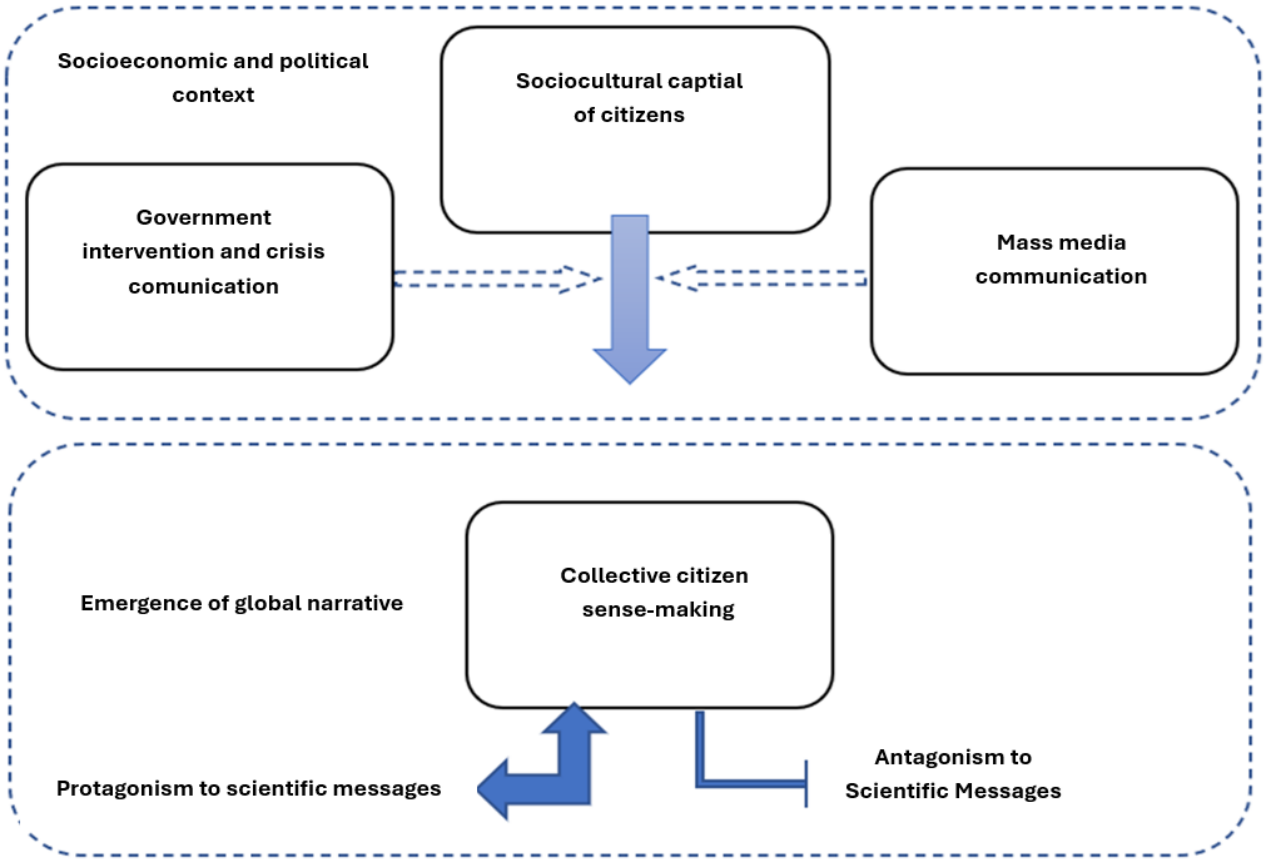
Principal Findings

In response to RQ1, the results of our analysis have developed an understanding of the key views shared on X toward COVID-19 across Egypt, Italy, and the United Kingdom. Table 4 provides insight into the differing views that X users shared during this time. In response to RQ2, we found that there were differences and some similarities in how X users responded to X across Egypt, Italy, and the United Kingdom. We provided a comparison of the key discussions that took place across different countries and phases. In response to RQ3, it was found that X users used X to seek, generate, and process information collectively. Henceforth, collective sense-making on X was taking place, and it was found that there were differences in how people gave meaning to their experiences. During phase 1, X users conversed about topics and events that were occurring around them, which also continued within phase 2. During phase 3, as global news of the vaccine began to emerge, the collective discussions across all 3 regions appeared to be focused on news of the vaccine. This was significant news, affected all citizens in all countries, and was a potential way to navigate out of the pandemic.

This analysis of social media posts from the United Kingdom, Italy, and Egypt highlights distinct variations in how citizens across different cultural contexts responded to the COVID-19 pandemic. Our study found that this was driven partly by differing levels of governmental trust and state intervention. Previous work highlights that public trust in government (shaped by historical, cultural, and political factors) can dictate the perceived credibility of government-issued health advice [28]. For example, the prevalence of religious discourse in Egypt's response aligns with studies that suggest that when formal institutional trust is low, people may turn to alternative social structures, such as religious communities, to interpret health risks and determine safe behaviors [29]. This has practical implications for policy makers who might need to engage non-governmental institutions. These could include religious leaders who could help to strengthen public adherence to health measures, and this could be particularly impactful in regions where government trust is low.

Furthermore, in Italy and the United Kingdom, the focus of social media posts on government-imposed prevention measures and economic aid highlights an expectation for government responsibility and support. Research has shown that public calls for government assistance in times of crisis often reflect a belief in the government's role as a welfare provider [30]. This observation reflects policy implications in that governments with higher trust levels are likely to see more public demands for direct economic relief, as opposed to countries where citizens may not expect or request such support due to institutional limitations. For instance, economic support policies in Italy and the United Kingdom were closely scrutinized by citizens on social media, suggesting that clear communication on relief measures can help manage public expectations and reinforce trust. Meanwhile, posts in Egypt often revealed skepticism toward government actions, particularly regarding the health sector's capacity to manage the pandemic. This finding highlights the need for targeted interventions to improve transparency and crisis management to build institutional trust, which is important for effective public health responses [31].

Regarding limitations, the study used the X Search API, which meant that certain posts might be missing from our analysis. Moreover, future research could seek to examine the influence of X and conduct an analysis of posts to identify users who were most influential by betweenness centrality across the 3 time periods. Further research could also seek to follow up with certain X users for in-depth qualitative interviews. Moreover, it is important to note that text-based social media data, such as posts from X, can reflect biases influenced by demographics, geographic location, and how users act on a daily basis. These factors may result in varying word choices and sentiment, even when discussing similar topics. For example, geographic differences can affect how happiness is expressed on the web [32], while daily routines and spatiotemporal context can shape sentiments related to specific locations or events [33,34]. It is important to acknowledge these biases because such factors could influence the patterns observed in our analysis.



XSL•FO
RenderX

Additionally, the population of users who geo-tag their posts may not be representative of the larger population, which may introduce further limitations when generalizing results [35,36].

Theoretical and Policy Contribution

Our study found that users on X were observing and being presented with unfolding events that they would assess in relation to their current location and their own situation. These factors would then lead to sense-making among users, and they would repeat the cycle as they were being presented with new information. Figure 2 provides an overview of the process that was taking place.

Figure 2. A visual overview of our proposed cycle of sense-making.

In this study, we interpret "sense-making" as the process by which individuals can interpret and assign meaning to complex events such as the COVID-19 pandemic by engaging with public discourse and personal reflection. Unlike opinion-sharing, sense-making involves actively integrating new information to form coherent narratives [37]. While prior work, such as Stieglitz et al [38], explores sense-making during crises using sentiment and social network analysis, our study is different because it focuses on topic modeling to capture thematic patterns in discourse. Topic modeling, unlike sentiment analysis, enables us to explore the substantive content of conversations, identifying recurring themes beyond emotional valence and offering insights into how users contextualize the pandemic. Zolyomi and Snyder [39] applied a process model and manual coding to study sense-making in the #ActuallyAutistic community and focused on identity formation through qualitative analysis. However, our topic modeling approach is designed for large-scale analysis. This allowed us to reveal dominant narratives across diverse sociocultural contexts rather than process-tracing individual experiences. Social media platforms like X support collective sense-making during crises by providing spaces for users to negotiate meaning and validate perspectives [40]. By analyzing trends and patterns in sampled hashtags, we capture how individuals construct understanding beyond expressing opinions. This allowed us to reveal high-level themes that illuminate public sentiment across distinct institutional settings.

Based on our proposition derived from the findings of this study, "sense-making of events during COVID-19 on X differs based on the location of a user and their relationship with the location," we have several practical insights, recommendations, and suggestions for public health authorities and governments (Textbox 4).

XSL•FO
RenderX

Textbox 4. Practical insights, recommendations, and suggestions for public health authorities and governments.

- Users of social media platforms such as X are likely to have varying information needs at different points of a pandemic.
- Researchers analyzing X data may wish to segregate data based on location.
- The information needs of users are likely to differ based on their location.
- Users' sense-making and reaction process will take place in relation to their past experiences.
- Considering the above, information provided through the likes of X should be highly specific and targeted.
- Topic modeling methods can be used for social listening purposes to identify common queries and concerns for different locations.
- This information can feed into local and international health messaging.

Our research identifies unique patterns in how citizens across different regions use social media during pandemics, which has direct implications for targeted health communication strategies.

For instance, a public health official in Egypt, where our study noted significant religious and cultural influences on information dissemination, could leverage our insights to tailor messaging that resonates with local cultural contexts. During a pandemic, when misinformation can spread rapidly alongside the virus itself, understanding these nuances allows for the development of culturally sensitive, effective public health campaigns. Officials could use localized social listening tools, guided by our findings, to monitor real-time public sentiment and misinformation trends. This enables them to quickly address misconceptions and provide clear, trustworthy information specifically designed to engage and educate distinct audiences effectively.

Moreover, our study's suggestion to segregate data based on geographic and cultural lines could help these officials to identify and respond to emerging local issues more rapidly, potentially curbing the spread of the disease by improving compliance with health directives tailored to the community's prevalent beliefs and behaviors.

This actionable approach not only demonstrates the direct applicability of our findings but also reinforces the value of our research in enhancing public health responses through strategic communication tailored to diverse populations during critical times.

Acknowledgments

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Abstract

Background: Both obesity and underweight are matters of global concern. Weight-related content frequently shared on social media can reflect public recognition and affect users' behaviors and perceptions. Although X (Twitter) is a popular social media platform, few studies have revealed the content of weight-related posts or details of dietary behaviors for weight loss shared on X.

Objective: This study aims to describe body weight–related content frequently reposted on X, with a particular focus on dietary behaviors for weight loss, in English and Japanese.

Methods: We collected English and Japanese X posts related to human body weight having over 100 reposts in July 2023 using an application programming interface tool. Two independent researchers categorized the contents of the posts into 7 main categories and then summarized recommended weight loss strategies.

Results: We analyzed 815 English and 1213 Japanese posts. The most popular main category of the content was "how to change weight" in both languages. The Japanese posts were more likely to mention "how to change weight" (n=571, 47.1%) and "recipes to change weight" (n=114, 9.4%) than the English posts (n=195, 23.9% and n=10, 1.2%, respectively), whereas the English posts were more likely to mention "will or experience to change weight" (n=167, 20.5%), "attitudes toward weight status" (n=78, 9.6%), and "public health situation" (n=44, 5.4%) than Japanese posts. Among 146 English and 541 Japanese posts about weight loss strategies, the predominant strategies were diet (n=76, 52.1% in English and n=170, 31.4% in Japanese) and physical activities (n=56, 38.4% and n=295, 54.5%, respectively). The proportion of posts mentioning both diet and physical activity was smaller in Japanese (n=62, 11.5%) than in English (n=31, 21.2%). Among 76 English and 170 Japanese posts about dietary behaviors for weight loss, more than 60% of posts recommended increasing intakes of specific nutrients or food groups in both languages. The most popular dietary component recommended to increase was vegetables in both English (n=31, 40.8%) and Japanese (n=48, 28.2%), followed by protein and fruits in English and grains or potatoes and legumes in Japanese. Japanese posts were less likely to mention reducing energy intake; meal timing or eating frequency; or reducing intakes of specific nutrients or food groups than the English posts. The most popular dietary component recommended to decrease was alcohol in English and confectioneries in Japanese.

Conclusions: This study characterized user interest in weight management and suggested the potential of X as an information source for weight management. Although weight loss strategies related to diet and physical activity were popular in both English

XSL•FO
RenderX

and Japanese, some differences in the details of the strategies were present, indicating that X users are exposed to different information in English and Japanese.

(J Med Internet Res 2025;27:e64739) doi:10.2196/64739

Introduction

Obesity and underweight pose critical challenges to public health globally. Obesity or overweight is prevalent in approximately 39% of the world's population [1] and increases the risk of diseases such as type 2 diabetes and cardiovascular diseases [2], with substantial economic cost [3,4]. Simultaneously, being underweight and eating disorders are of particular concern among young women [5-8], which may lead to higher mortality [9,10]. Notably in Japan, more than 20% of women aged 20-29 years are underweight, with a BMI of less than 18.5 kg/m^2 [11]. There is a clear need to establish strategies to maintain a healthy weight, free from obesity and underweight, for promoting health and well-being. In addition, beyond actual weight status, body image (perception of body weight and appearance) is important for mental and physical health. For example, negative body image (body dissatisfaction) can cause eating disorders and depression [12,13]. The estimated prevalence of body dissatisfaction was 11%-72% for women and 8%-61% for men in the United States [14,15], although estimates varied considerably by assessment method and population (including age and sex). Similarly, despite the low obesity rate among young Japanese women [11], 34%-84% of Japanese female adolescents perceived themselves as "fat" [16], with variations by population. Thus, body dissatisfaction is a serious concern in both Western and non-Western countries [16]. Body dissatisfaction is caused by various factors; in particular, sociocultural factors, such as exposure to mass media, play an important role [13,17]. In sociocultural theory, mass media in modern Westernized society presents unrealistic, thin beauty ideals, and individuals (especially women but also men) are encouraged to desire thinness and compare their appearance with these unrealistic ideals, resulting in body dissatisfaction [18].

In addition to traditional media such as television and magazines, the internet and social media have emerged and expanded in recent years. Similar to traditional media, the content of social media has the potential to influence users' behaviors and perceptions. A previous review showed that thin-ideal media images are associated with body dissatisfaction and eating disorders [19]. Additionally, exposure to health-risk behavior content on social media has been associated with unhealthy food intake [20] and a higher desire for junk foods [21]. Meanwhile, the content of social media can often reflect public perceptions or interests, especially when shared among many users. For example, negative attitudes toward obesity, including weight stigmatization, were found to be pervasive on social media [22-25]. Additionally, contents related to obesity prevention and individual-level causes of obesity tended to be shared [26-28], indicating public attention toward the struggle against obesity.

X (formerly Twitter), one of the most popular social media platforms, typically allows users to post messages within a character limit of 140, which are referred to as posts. Since its launch in 2006, X has grown and currently has over 200 million active users accessing it on any given day in 2022 [29]. As of 2023, the United States had the largest number of active users, at 65 million, followed closely by Japan with 52 million, while other countries had fewer than 17 million active users [29]. On X, users can publish posts to their profile pages, subscribe to other users' posts using the "following" function, and share posts of other users with their followers using the "repost" function. The repost function makes sharing content easy and efficient, allowing X to amplify information. Considering these features and the large number of users, X may be an important social media platform for health information, including weight management and body image.

Previous studies have examined obesity-related posts on X and reported a prevalence of negative attitudes toward obesity [22-25], obesity prevention strategies, and obesity causes [26-28]. Most of these studies, however, were limited to search terms such as obesity, overweight, and fat [22-26,28,30]. This resulted in a lack of comprehensiveness, such as a paucity of descriptions that included aspects of underweight and weight loss. Indeed, few studies have examined underweight and weight loss [31-34], and most of these collected posts with hashtags such as #weightloss or #diet [31] or used specific search terms such as "thinspiration" (a word combining "thin" and "inspiration") [33,34]. Additionally, although weight management strategies are major topics of posts about obesity on X [26,28,30] and diets are the predominant strategies mentioned [26,28], the details of recommended dietary behaviors have not been revealed. Given the importance of dietary behaviors in weight management [35], a detailed examination of the dietary behaviors spread on X will help in understanding what information users are exposed to and may accordingly influence their dietary behavior.

Moreover, most previous studies have examined posts that were written in English [22,24,26,28,30-34], as have studies of X in other health-related fields [36,37], despite potential variation in public health and cultural situations and perceptions across different languages. A comparison of the content of posts in multiple languages with different public health concerns may be useful in understanding the differences in public attitudes toward body weight and the information to which users are frequently exposed. In Western countries, body positivity, which encourages individuals to appreciate and accept their bodies regardless of size or appearance, has been popularized on social

XSL•FO
RenderX

media in recent years [38]. Meanwhile, body positivity remains relatively uncommon in Japan [39]. Alongside Western ideals of beauty, in Japan, social and cultural factors, such as traditional gender roles and the "kawaii" (cute) culture, may influence attitudes toward thinness [39,40]. Additionally, differences in dietary habits may also influence recommended dietary behaviors for weight loss. For example, dietary intake in Japan differs from that in Western countries, and includes a higher intake of seafood, white rice, plant food, and sodium, and a lower intake of whole grains, saturated fat, and added sugars [41,42]. The prevalence of excessive intake of saturated fat and added sugars, which can contribute to excessive energy intake and consequent obesity, is lower in Japan than in Western countries [41,43]. Also, Japanese people generally adhere to a stable meal schedule, with relatively rare meal skipping and low frequency of snacking compared to Western countries [44]. These cultural differences in dietary intake may contribute to distinct obesity rates, public attitudes toward body image, and dietary practices for weight loss.

Therefore, this study aimed to examine frequently shared content about body weight on X, with a particular focus on dietary recommendations for weight loss. Specifically, we compared content between English and Japanese, the languages used by the countries with the two largest numbers of X users (United States and Japan), and which have different weight-related concerns and sociocultural contexts.

Methods

Data Collection

The search strings in English and Japanese were determined based on previous studies [22,26,30] and the authors' knowledge, including gain or loss of body weight, obesity, or underweight (Table S1 in Multimedia Appendix 1). We collected posts using Social Insight (User Local Inc), a tool for analyzing social media. It collects posts according to the search strings using an application programming interface and has been used in research for collecting posts [45]. Social Insight does not necessarily collect all posts identified by search strings, and data on the exact collection rate were unavailable. Further, this tool did not collect protected posts (not available to the public).

This study restricted posts to those with more than 100 reposts to analyze frequently shared content. This repost cutoff point was determined considering that the top 0.1%-0.2% of posts in both languages acquired more than 100 reposts in a pilot study in May 2023. We arbitrarily aimed to estimate categories that constitute 10% of the total content with a 95% CI of ±2.5%, which required 554 posts in the final sample in both languages. Assuming half of the posts were excluded, we aimed to collect more than 1108 posts which had been reposted more than 100 times in each language. To collect more than 1108 posts, we assumed that collecting posts made over a 1-month period would be sufficient, based on a sufficient number of posts created in the pilot study (during May 2023).

We collected 1,621,010 English and 1,459,517 Japanese posts created during July 2023 using Social Insight with the search strings. Then, quotes (reposts with some additional comments) were removed, resulting in 720,451 English and 838,028 Japanese original posts (Table S1 in Multimedia Appendix 1). Among these, we extracted 1194 English and 1501 Japanese posts having over 100 reposts. We then excluded posts that: (1) were not related to body weight (eg, "The X algorithm will add weight to posts that *get…*"); (2) were related to animals (eg, "Please find this thin dog"); (3) were related to characters in anime, comic books, or drawings; (4) included sexual content; and (5) were not in one of the targeted languages (English or Japanese; Figure S1 in Multimedia Appendix 1).

Using Social Insight on August 31, 2023, we derived the following characteristics of the posts: username, user ID, user profile, the presence of pictures or videos attached to posts, and the number of following users, followers, reposts, and likes. We assumed that those posts created during July 2023 had a stable number of reposts and likes on August 31, 2023, because Social Insight collected these numbers from up to a few days (for posts with few reposts) to 1 month (for posts with many reposts) after a post was created.

Coding of Content

We manually coded each post according to the type of content [46]. The unit of analysis in this study was the post. The codebook was primarily developed using an inductive approach to content analysis [47,48]. One author (FO) developed a draft of the codebook based on approximately 200 English and 200 Japanese posts with 100 or more reposts in the pilot study. These posts were searched using the same search strings in May 2023. The findings of previous studies [26,28,30] were also used to refine the codebook. Insights from both the pilot data and previous research were used to accurately characterize the content of the posts while maintaining consistency with previous research. The author (FO) then coded sample posts in accordance with the draft codebook to organize and revise it. The other authors (MM, RO, and MS) then categorized the same posts and further revised the codebook by consensus.

We developed seven categories of content: (1) how to change weight (causes, habits, or strategies), (2) will or experience to change weight (including reports of action to change weight), (3) recipes to change weight, (4) attitude about weight status or appearance, (5) results or effects of weight change (including health outcomes, appearance, and social treatment), (6) public health situation (eg, prevalence of obesity), and (7) miscellaneous (including jokes). We then developed subcategories within each category using the same process, resulting in 34 subcategories (Table S2 in Multimedia Appendix 1).

According to the codebook, each post was categorized by 2 of 4 coders independently. One English-native coder holding a PhD in psychology categorized all English posts; another Japanese-native coder (researcher; MS) categorized all Japanese posts. Additionally, both of the other 2 coders (Japanese native researchers with English as a second language; FO and RO) categorized half of the English and Japanese posts. Upon the completion of categorization, disagreements between the 2 independent coders were resolved through discussions among the coder and researchers. Before categorizing the posts, the

XSL•FO
RenderX

English-native coder received 2 hours of instruction in the codebook and coded sample posts.

We further examined the details of the strategies and recipes for weight loss using an inductive approach [47,48]. After overviewing all posts, the researchers (FO, MM, RO, and MS) further modified the codebook by creating categories of strategies and recipes that reflected the frequency of their mention. Dietary habits and physical activity were further categorized into detailed methods. Three independent researchers (FO for posts in both languages, RO for posts in English, and MS for posts in Japanese) categorized the posts in accordance with the codebook, and any disagreements were resolved through discussion with a fourth researcher (MM). Additionally, we examined whether the posts had a thread (a series of connected posts from 1 person to provide additional content by connecting multiple posts together) or not. Information in threads was also used in categorizing the content (main and subcategories) and weight loss strategies.

Users were categorized into the following five types: (1) government and academic institutions (eg, World Health Organization), (2) hospitals or clinics, (3) media outlets, (4) businesses (eg, food or health-related companies, sports teams), and (5) individuals and others (eg, fitness coaches, anonymous accounts). These categories were created in consideration of previous studies [49,50]. The users were categorized independently by 2 researchers (FO and MS), and any disagreements were resolved through discussion with a third researcher (MM).

Ethical Considerations

This study was exempt from ethical approval because of its use of publicly available data without human participants. To maintain X users' anonymity in accordance with recommendations, the study does not provide any identifying information or direct quotes [51].

Statistical Analysis

Data were described using the number and percentages of posts. The 95% CIs for the proportions of each category were calculated using the Clopper-Pearson method. Spearman correlation coefficients were used to examine the correlation between the number of reposts and likes. We compared the content between English and Japanese posts using the chi-square test. When the expected frequency was less than 5 in more than 20% of category values, the Fisher exact test was used instead of the chi-square test. Cohen κ and its 95% CI were calculated to assess interrater agreement in categorization by the 2 independent coders. We considered a κ coefficient between 0.40 and 0.60 as moderate agreement, 0.61 and 0.80 as substantial agreement, and 0.81 and 1.00 as almost complete agreement [52]. All analyses were performed using SAS statistical software (version 9.4; SAS Institute Inc), with 2-tailed *P* values <.05 considered statistically significant.

Results

This study included 815 English and 1213 Japanese posts having over 100 reposts related to human body weight and weight management. Among them, 52% of the English and 22% of the Japanese posts included words related to obesity or weight gain, whereas 56% of the English and 83% of the Japanese posts included words related to underweight or weight loss (Table S1 in Multimedia Appendix 1). Approximately 45% of English and 32% of Japanese posts had less than 200 reposts, whereas 10% of English and 16% of Japanese posts had 1000 or more (Table 1). The number of reposts was correlated with the number of likes (Spearman correlation coefficients of 0.65 in English and 0.73 in Japanese). The collected posts were created by 652 English and 642 Japanese accounts. More than 95% of these accounts were individuals and others in both languages (Table 1).

[a]n=652 in English and n=642 in Japanese.

[b]Including anonymous accounts.

As shown in Table 2, although the most popular content was "how to change weight" in both languages, the English and Japanese posts differed in the proportion of the main categories of their contents. The Japanese posts were more likely to mention "how to change weight" and "recipes," whereas the English posts were more likely to mention "will or experience," "attitudes toward weight status," and "public health situations." The detailed subcategories of contents also differed between the English and Japanese posts (Table S2 in Multimedia Appendix 1). For example, 5.4% (n=44) of English posts showed negative attitudes toward obesity or gaining weight, versus only 0.9% (n=11) of Japanese posts. Excluding the "miscellaneous" category, subcategories with more than 5% of the posts were: "how to lose weight" and "negative attitudes toward obesity or weight gain" in English; and "how to lose weight," "will to lose weight," and "recipes for weight loss" in Japanese.

Table 2. Main contents of 815 English and 1213 Japanese body weight–related posts with more than 100 reposts during July 2023[a].

	English		Japanese	
	Value, n	Percentage (95% CI)	Value, n	Percentage (95% CI)
How to change weight	195	23.9 (21.0-27.0)	571	47.1 (44.2-50.0)
Will or experience to change weight	167	20.5 (17.7-23.4)	149	12.3 (10.5-14.3)
Recipes to change weight	10	1.2 (0.6-2.0)	114	9.4 (7.8-11.2)
Express negative or positive attitudes toward weight status or appearance	78	9.6 (7.6-11.8)	31	2.6 (2.0-3.6)
Results or effects of weight change	27	3.3 (2.2–4.8)	56	4.6 (3.5-6.0)
Public health situations	44	5.4 (4.0-7.2)	11	0.9 (0.5-1.6)

[a]$P<.0001$ for differences in content between English and Japanese posts (chi-square test).

Among 146 English and 541 Japanese posts mentioning weight loss strategies, diets and physical activities were frequently mentioned (Table 3). Diets were more likely to be mentioned in English (n=76, 52.1%) than in Japanese posts (n=170, 31.4%), whereas physical activities were more likely to be mentioned in Japanese (n=295, 54.5%) than in English posts (n=56, 38.4%). The proportion of posts mentioning both diet and physical activity was smaller in Japanese (n=62, 11.5%) than in English (n=31, 21.2%). In English posts, other strategies frequently mentioned for weight loss were supplements, medicines, or vaccines (n=25, 17.1%); sleeping (n=24, 16.4%); and drinking water (n=21, 14.4%). In Japanese posts, 11.3% (n=61) included

XSL•FO
RenderX

campaigning for products or apps for weight loss, such as "someone who reposts this post will get our products for weight loss." Although the number of posts was small, bathing and sauna and improving posture were unique to Japanese posts, while motivation, reducing stress, sunlight, and bariatric surgery were unique to English posts. The proportion of posts with a thread was higher in English (n=53, 36.3%) than in Japanese (n=15, 2.8%).

[b]N/A: not applicable.

[c]A series of connected posts from 1 person to provide additional content by connecting multiple posts together.

The details of dietary behaviors for weight loss also differed between English and Japanese posts (Table 4). The proportion of posts that recommended reducing energy intake was lower in Japanese (n=21, 12.4%) than in English (n=23, 30.3%). Also, Japanese posts were less likely to mention meal timing or eating frequency (n=37, 21.8%) than English posts (n=26, 34.2%). In both languages, more than 60% of posts recommended increasing the intake of specific nutrients or food groups. The most popular component recommended to be increased was vegetables in both English (n=31, 40.8%) and Japanese (n=48, 28.2%), followed by protein and fruits in English and grains or potatoes and legumes in Japanese. Natto (fermented soy) and miso soup were unique to Japanese posts, whereas "nutrient-dense foods" (including a "nutrient-dense diet" and "high-quality foods") were unique to English posts. English posts were more likely to recommend decreasing the intake of specific nutrients or food groups (n=31, 40.8%) than Japanese posts (n=45, 26.5%). The most popular component recommended to decrease was alcohol in English (n=22, 28.9%) and sweets/confectioneries in Japanese (n=16, 9.4%).

Recipes for weight loss were described in 10 English and 114 Japanese posts (Table S3 in Multimedia Appendix 1). In the English posts, all posts included recipes for drinks (most were water with fruits). In the Japanese posts, recipes for sweets, vegetable dishes, and protein and vegetable dishes accounted for approximately 20% of the posts each.

Among 56 English and 295 Japanese posts that mentioned physical activity for weight loss, the type of recommended physical activities differed between the English and Japanese posts (Table S4 in Multimedia Appendix 1). The English posts were more likely to recommend aerobic exercise and muscle training than the Japanese posts. On the other hand, the Japanese posts were more likely to recommend stretching and massage than the English posts. A total of 200 Japanese posts (67.8%) had attached pictures or videos on how to exercise, versus only 17 English posts (30.4%).

Cohen κ coefficients of the main contents between the 2 independent coders were 0.39 (95% CI 0.35-0.43) for 815 English posts and 0.66 (95% CI 0.63-0.69) for 1213 Japanese posts. Cohen κ coefficients regarding mention of dietary strategies for weight loss were 0.89 (95% CI 0.82-0.96) for 146 English posts and 0.88 (95% CI 0.83-0.92) for 541 Japanese posts.

Discussion

In this study, we described body weight–related content in posts having more than 100 reposts on X in English and Japanese, with a particular focus on dietary behaviors for weight loss. The proportion of main contents differed between posts in English and Japanese. English posts were more likely to mention will or experience to change weight, attitudes toward weight status, and public health situations, whereas Japanese posts were more likely to mention strategies and recipes to change weight. Nevertheless, the most popular content was how to change weight in both languages. The predominant strategies for weight loss involved diet and physical activities in both languages, but the details of the strategies differed between languages. The descriptions identified in our study may be useful in understanding which information X users share and are frequently exposed to.

This study showed that individual-level strategies for weight loss are prevalent in English and Japanese on X. Among them, the most frequently mentioned in both languages were physical activity and diet. These results are consistent with previous studies which reported that obesity-related X posts frequently mentioned physical activity and diet as causes of obesity [26] and strategies to manage obesity [28]. These results and ours suggest that X users, in both English and Japanese, are interested in physical activity and diet in managing their weight status. This in turn indicates that the X has the potential to influence users' behaviors to change weight, especially physical activity and diet. In contrast, less mention was made of public health situations and population-level causes of obesity, especially in Japanese posts. X's users may be more interested in individual-level factors than population-level factors. Considering the importance of socioecological factors in the development of obesity, it may be useful to raise public awareness that individual-level factors play only a limited role and that combating obesity requires a multilevel approach [53]. Additionally, we found that approximately 5% of English posts expressed negative attitudes toward obesity, in accordance with previous studies showing the dissemination of negative attitudes toward obesity in English posts [22,23,25]. There is also a need to address not only obesity prevention and management but also the stigma of obesity.

Although diet and physical activity were the predominant strategies for weight loss shared on X in both English and Japanese, the specific method differed between the languages. English posts were more likely to mention reducing energy intake, and both diet and physical activities than Japanese posts. Energy balance is essential for weight management, and both diet and physical activity are important [54]. Further, a higher proportion of English posts than Japanese posts had threads. English posts may tend to show a comprehensive strategy for weight loss compared to Japanese posts, partly due to the higher seriousness of obesity prevalence [4]. Nevertheless, despite the importance of reducing energy intake for weight loss [54,55], this was not often mentioned even in English posts. Also, posts tended to mention increasing intakes of specific nutrients or food groups rather than decreasing intakes of fatty or sugary foods. Therefore, weight loss strategies frequently shared on X may not include sufficient information to help users make informed decisions about weight management. In Japan, the obesity rate is much lower than in Western countries, and underweight among young women is a concern [11]. Japanese posts were more likely to be limited to showing only videos on how to exercise than English posts and less likely to mention dietary behaviors. Additionally, improving posture was unique to Japanese posts. Japanese posts may focus on body appearance rather than merely reducing body weight, which may affect body image and the desire for thinness. In any case, few posts originated from government or academic institutions. It may be beneficial for government and academic institutions to create posts that provide evidence-based, comprehensive information on weight management, including balanced diets with adequate energy intake, regular exercise, and healthy body image, and aim to get them frequently reposted.

Among posts mentioning dietary habits for weight loss, more than 60% of posts in both languages recommended increasing specific nutrients or foods. Although vegetables were frequently recommended in both languages, other recommended foods and nutrients somewhat differed between English and Japanese posts. English posts were at least 15% more likely to recommend increasing intakes of fruits and protein than Japanese posts. Additionally, nutrient-dense foods were often recommended in English posts (14.5%) but only in 1 Japanese post (0.6%). On the other hand, 11.2% of Japanese posts recommended increasing natto (fermented soy product) intake but no English post did so. These differences in recommended dietary components may reflect differences in dietary culture and user intake and interest. Current evidence supports the advantages of frequently mentioned foods and nutrients in weight management, including vegetables, fruits, and protein [35,56-58]. On the other hand, little evidence exists regarding the effect of natto intake on weight management, despite the

XSL•FO
RenderX

interest in this topic among Japanese X users. Decreasing intake of dietary components such as alcohol, sugar-sweetened beverages, sugars, and fast and processed foods was more likely to be mentioned in English than in Japanese. This may be partly explained by the higher intakes of some of these items in Western countries than in Japan [41,59-61]. Although English X users may be exposed to the importance of reducing these intakes, their intake nevertheless remains high, as is seen in the United States [41,59].

The strength of our study was its collection of X posts using broader search terms, not limited to obesity and related hashtags, across 2 languages with large numbers of users. We found that 48% of the English posts and 78% of the Japanese posts did not contain obesity-related words but were rather words related to weight loss or underweight only. This study accordingly included posts that may have been overlooked in most previous studies using obesity-related search terms only. This wide range of search terms enabled us to collect posts related to body weight on X in a broad and comprehensive manner. However, several limitations should also be mentioned. First, as in many previous studies, we are unable to estimate the collection rate of related posts. Although we collected a large number of posts, we acknowledge the possibility that our sampling strategy was not random [37].

Second, the coding process had a subjective nature despite the use of a predefined codebook. Although 2 independent coders (including at least 1 native speaker in each language) categorized contents, some subjectivity and errors cannot be ruled out. In particular, the interrater agreement did not reach moderate for the main content of English posts. Therefore, the possibility of misclassification and the difficulty of coding a post into 1 specific category should be noted.

Third, the posts were collected during a certain time window (July 2023). A previous study showed that weight loss content was more commonly posted during holidays and after holidays than before holidays [31]. Additionally, social media trends are influenced by global events and prominent figures, which can lead to a temporal increase in posts related to specific topics. Because it is unknown whether the contents of posts differ by time frame, this study should be interpreted as a snapshot of the time it was conducted. Although analyzing past data is an inevitable limitation of any research, future studies could consider examining trends over time to understand dynamic variations in social media content.

Fourth, the study did not examine whether the content of posts affects user's perceptions and behaviors. A randomized controlled trial showed that exposure to junk food-related content on Instagram increased the desire for junk food and reduced the desire for healthy foods [21]. Thus, the highly reposted content was likely to be viewed by many users and may impact at least some users' perceptions and behaviors.

Finally, it should be noted that the posts in English could have been created in any of the various countries that use English. Nevertheless, the United States has the largest number of active users, at more than 3 times the number of active users of any country other than Japan [29], and a previous study showed that the majority of posts about "healthy diet" came from the United States [62]. We therefore speculate that most of the posts in our study also came from the United States.

This study examined the content of human body weight–related posts having more than 100 reposts in English and Japanese. While we found some differences in the content of weight-related X posts between English and Japanese—such as a higher prevalence of posts with negative attitudes toward obesity in English (5%) than in Japanese—the most popular contents were weight loss strategies in both languages. While diet and exercise were predominant weight loss strategies, the proportion of posts mentioning both diet and physical activity was small in both languages. Among posts about dietary strategies for weight loss, 60%-70% recommended increasing intakes of dietary components, such as vegetables, in both languages, whereas only 30% of English and 12% of Japanese posts recommended reducing energy intake. The results of this study suggest users' major interest in weight management in both English and Japanese and the potential of X as an information source on weight management. Additionally, our results identified similarities and differences in information about body weight between the languages, which in turn indicates that challenges in the use of X for weight management differ by language.

Acknowledgments

The authors would like to thank James Anderson of Dmed for coding the content of English posts and Guy Harris DO and Hiromi Inoue of Dmed for their support with the coding. The authors declare that generative artificial intelligence was not used in any part of the manuscript writing. This work was supported by a grant (number 22FA1022) from the Ministry of Health, Labour and Welfare, Japan; by the 2022 Tochigi Prefectural Health and Nutrition Survey Analysis project; and by JSPS KAKENHI grants (JP22K02121 and JP24KJ0098). The funding organizations had no role in the design, analysis, or writing of this paper.

Abstract

Background: Data sharing plays a crucial role in health informatics, contributing to improving health information systems, enhancing operational efficiency, informing policy and decision-making, and advancing public health surveillance including disease tracking. Sharing individual participant data in public, environmental, and occupational health trials can help improve public trust and support by enhancing transparent reporting and reproducibility of research findings. The International Committee of Medical Journal Editors (ICMJE) requires all papers to include a data-sharing statement. However, it is unclear whether journals in the field of public, environmental, and occupational health adhere to this requirement.

Objective: This study aims to investigate whether public, environmental, and occupational health journals requested data-sharing statements from clinical trials submitted for publication.

Methods: In this bibliometric survey of "Public, Environmental, and Occupational Health" journals, defined by the Journal Citation Reports (as of June 2023), we included 202 journals with clinical trial reports published between 2019 and 2022. The primary outcome was a journal request for a data-sharing statement, as identified in the paper submission instructions. Multivariable logistic regression analysis was conducted to evaluate the relationship between journal characteristics and journal requests for data-sharing statements, with results presented as odds ratios (ORs) and corresponding 95% CIs. We also investigated whether the journals included a data-sharing statement in their published trial reports.

Results: Among the 202 public, environmental, and occupational health journals included, there were 68 (33.7%) journals that did not request data-sharing statements. Factors significantly associated with journal requests for data-sharing statements included open access status (OR 0.43, 95% CI 0.19-0.97), high journal impact factor (OR 2.31, 95% CI 1.15-4.78), endorsement of

XSL•FO
RenderX

Consolidated Standards of Reporting Trials (OR 2.43, 95% CI 1.25-4.79), and publication in the United Kingdom (OR 7.18, 95% CI 2.61-23.4). Among the 134 journals requesting data-sharing statements, 26.9% (36/134) did not have statements in their published trial reports.

Conclusions: Over one-third of the public, environmental, and occupational health journals did not request data-sharing statements in clinical trial reports. Among those journals that requested data-sharing statements in their submission guidance pages, more than one quarter published trial reports with no data-sharing statements. These results revealed an inadequate practice of requesting data-sharing statements by public, environmental, and occupational health journals, requiring more effort at the journal level to implement ICJME recommendations on data-sharing statements.

Introduction

Data sharing plays a crucial role in health informatics, contributing to improving health information systems, enhancing operational efficiency, informing policy and decision-making, and advancing public health surveillance including disease tracking [1]. Specifically, sharing individual patient data (IPD) from clinical trials promotes scientific advancement, enhances transparent reporting, and meets ethical obligations to trial participants [1,2]. In 2017, the International Committee of Medical Journal Editors (ICMJE) required that all papers submitted after July 1, 2018, must include a data-sharing statement [3].

Data sharing is of special importance for trials in the field of public, environmental, and occupational health, where findings can translate to policies with population-level impact. Given the fact that many trials incorporate public engagement and are commonly designed as community-based cluster trials, IPD sharing may improve public trust and support by enhancing transparent reporting and reproducibility and helping patients access their health data information and make informed health care decisions [4]. While public perception and willingness to share IPD are generally affected by concerns about privacy, transparency is a critical step toward getting buy-in from the public, particularly since environmental and public health policies may have implications on individual rights [4-6]. Specifically, addressing the ethical and regulatory issues surrounding the confidentiality of shared data is crucial for actual data sharing [7]. Nonetheless, enhancing transparency and providing detailed information about how data will be collected, used, and shared can effectively improve trust among individuals and facilitate actual data sharing. In the setting of public health emergencies such as epidemics, timely data sharing fosters societal-level preparedness, helps advance discovery in disease prevention and therapy, and allays fear of the unknown [8]. Of note, challenges and barriers to data sharing remained for public health emergencies, including poor accessibility, language difficulties, mistrust toward the health system, or concerns about insurance eligibility [4]. Global policymakers and researchers have advocated data sharing for the COVID-19 pandemic and developed publicly available platforms to enhance the sharing of IPD [9-11]. Nevertheless, a study based on trial registration information showed that the proportion of intent to share IPD for COVID-19 clinical trials did not differ from the contemporary non–COVID-19 trials [12].

Some previous studies explored journal requests for data-sharing statements in high-profile journals or specific clinical fields, with no focus on the field of public, environmental, and occupational health [13-16]. It is unclear whether public, environmental, and occupational health journals adhere to ICMJE's requirement for data-sharing statements. Clinical trials are the gold standard for causal inference, and their data sharing is particularly relevant as trials change policy and practice. Therefore, we conducted a survey to investigate whether public, environmental, and occupational health journals request data-sharing statements in clinical trial submissions. We also explored associations between journal characteristics and journal requests for data-sharing statements.

Methods

Study Design

We followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) guideline to report this study [17]. According to previous publications exploring the field of public, environmental, and occupational health, we included all 400 journals that were in the category of "Public, Environmental, and Occupational Health" defined by the Journal Citation Reports (as of June 2023) [18-20]. Subsequently, we searched the journal webpages using the keywords "trial" or "clinical trial" to assess whether the journal had published clinical trial reports between January 1, 2019, and December 31, 2022. Journals that did not publish clinical trial reports with IPD between 2019 and 2022 were excluded because the ICMJE required data-sharing statements in clinical trials after July 2018. A total of 202 journals were included for analysis (Figure S1 in Multimedia Appendix 1).

Study Outcome

The study outcome was a journal request for data-sharing statements. We searched journals' webpages about their data-sharing statement request by using the keywords "data sharing," "data availability," "research data," "data accessibility," "data deposition," and "data deposit." Google Translate was used for journals that were in non-English and non-Chinese languages. A journal was deemed to request

XSL•FO
RenderX

data-sharing statements if the journal clearly asked trial authors to provide a data-sharing statement on the paper submission instructions. Table S1 in Multimedia Appendix 1 shows the list of descriptions of data-sharing statement requests from journals' paper submission instructions.

Although some journals did not request statements on the paper submission instructions, it was possible that the journals would request trial authors to upload a statement or ask the authors about their willingness to share data in the journal submission system. These journals were also considered to have requests for data-sharing statements. A random sample of 10 journals that had no request on their submission guidance pages was used for the mockup submission process. Specifically, we evaluated whether these journals without requests from their submission guidance would ask for information on data-sharing statements from trial authors in their submission systems. None of these journals were found to request a data-sharing or availability statement in their submission systems.

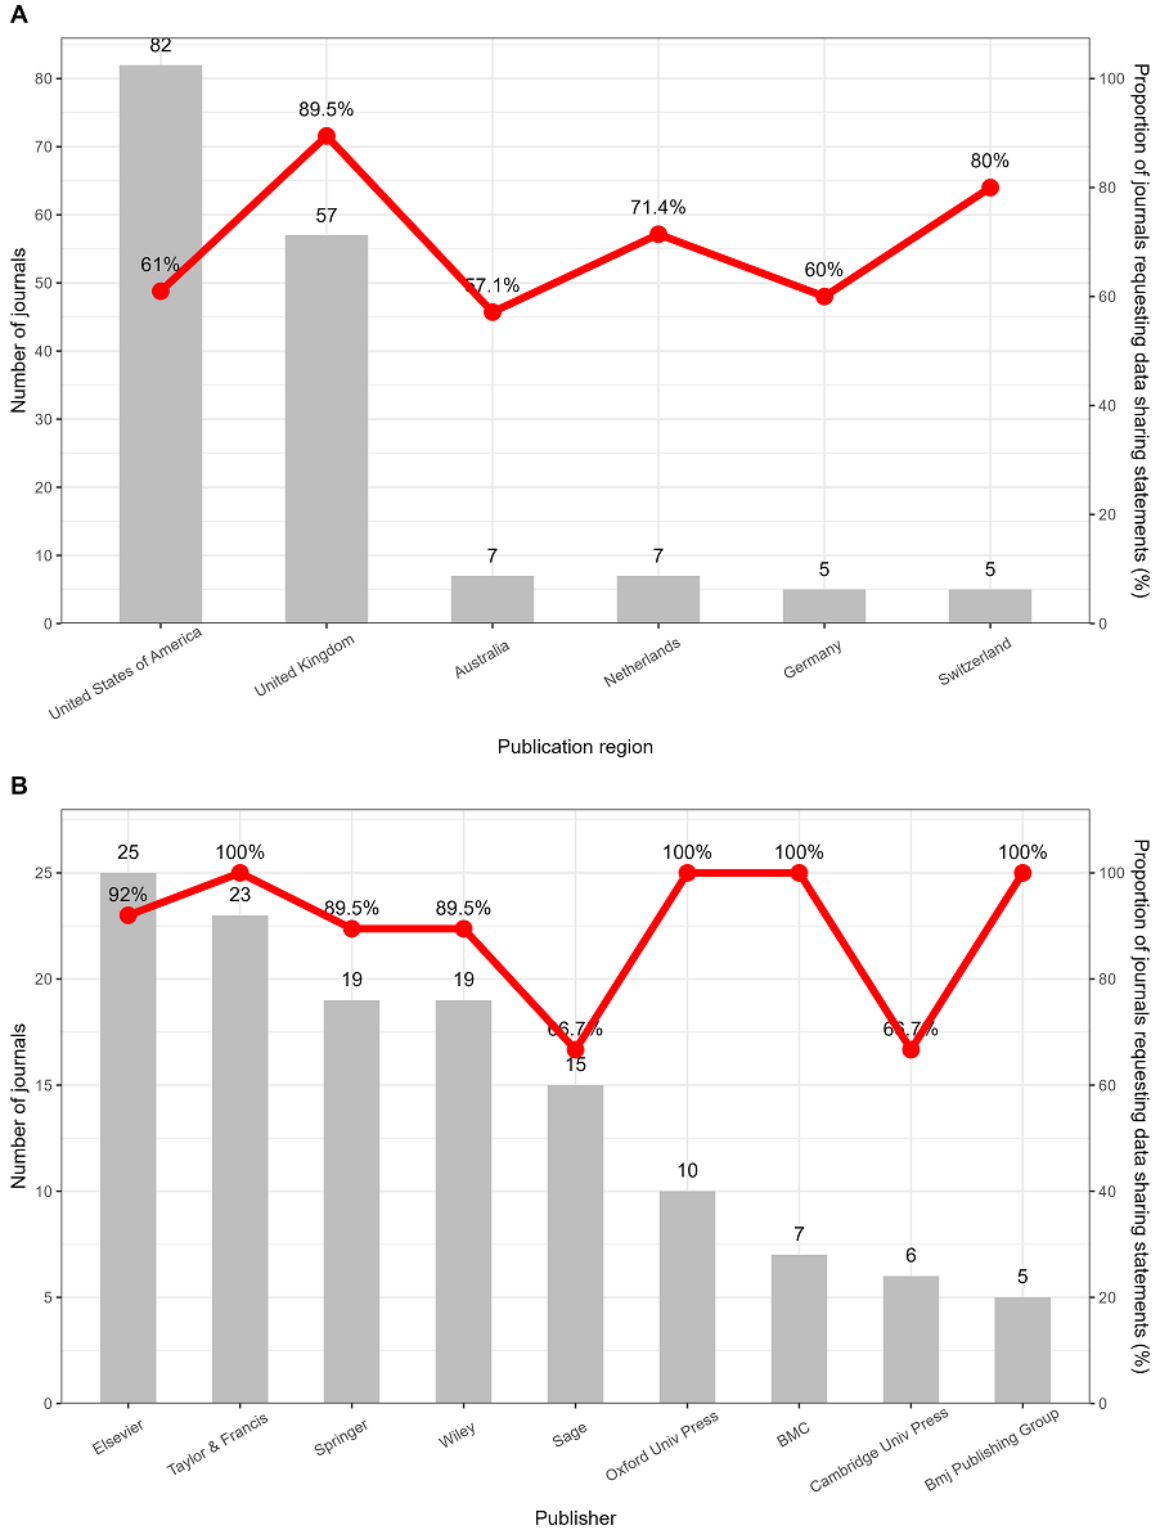
The journals with data-sharing statement requests differed in how strongly they worded the request in the description. Specifically, if a journal used the terms "encourage" or "recommend" (eg, we encourage the use of data-sharing statements), we categorized the type of journal request for data-sharing statements as Weak. If a journal worded the terms "require," "request," "should," "mandate," or "must" (eg, all research articles must contain a data-sharing statement), we categorized the journal request as Strong (Table S1 in Multimedia Appendix 1). These terms used to classify the type of journal requests for data-sharing statements were mainly adopted from previous literature [16]. To minimize the potential for misclassification, we performed data extraction and categorized the type of journal request in duplicate (YL and JZ). Any disagreement was resolved by discussion or in consultation with a senior investigator (GL).

Data Extraction

Data extraction was performed by study investigators in duplicate and pairs (YL and JZ, XB, and LK) from September 1, 2023, to March 31, 2024. If there was a disagreement between these study investigators, we tried to reach a consensus by double-checking the extracted information and discussing it with the group. If a consensus could not be reached, we consulted with a senior investigator for a decision (GL). Data on journal characteristics were extracted, including the percentage of open access, its publication region, publisher, publication language, journal impact factor in 2022 (released in June 2023), Journal Citation Reports quartile, whether the journal was on the ICMJE list, whether the journal explicitly endorsed the Consolidated Standards of Reporting Trials (CONSORT) in its submission guidance page, and the total number of trials published between 2019 and 2022 for each journal.

The percentage of open access, as extracted from the open access section in the Journal Citation Reports, denoted the percentage of open access items among all the citable items published in the journal in the previous 3 years.

Both data on publishers and publication regions were collected from the Journal Citation Reports. Journals from the same publisher could belong to different publication regions, thereby potentially providing more information on social and cultural differences. For example, 3 journals (*Disability and Health Journal*, *Cancer Epidemiology*, and *International Journal of Hygiene and Environmental Health*) belonged to Elsevier, which has its headquarters in Amsterdam (Netherlands), while these journals were published in the United States, United Kingdom, and Germany, respectively. Therefore, we collected both the data on the publisher and the publication region of each journal for potential inclusion in analyses.



Statistical Analysis

Continuous characteristics were described using medians with lower and upper quartiles (Q1-Q3), and categorical variables using counts and percentages. Comparisons between journals with and without data-sharing statement requests were conducted by *t* test and chi-square test for continuous and categorical variables, respectively.

Multivariable logistic regression analysis was conducted to evaluate the relationship between journal characteristics and a journal's request for data-sharing statements. Some journal characteristics were considered as covariates in the model including publication region (United Kingdom and United States vs others), publisher, and Journal Citation Reports quartile (Q1-Q2 vs Q3-Q4), in which these characteristics had been reported to associate with journal request in previous studies [15,16]. In this survey, the United States and the United Kingdom had the top 2 numbers of public, environmental, and occupational health journals, far more than the remaining publication regions (Figure 1A). Therefore, we treated the variable of publication region as 3 levels (United States, United Kingdom, and others) and took the other regions as the reference group. Other characteristics were also adjusted for in the model based on our expertise and group discussion, including open access (yes vs no, taking 50% of open access as threshold), journal impact factor (≥ vs <2.9, taking the median of 2.9 as a threshold), whether the journal was on the ICMJE list (yes vs no), whether the journal endorsed the CONSORT (yes vs no), and the number of trials published between 2019 and 2022 (≥ vs <11, taking the median of 11 as a threshold). We assessed the potential multicollinearity in the model by calculating variance inflation factor (VIF) values for each journal characteristic, with a VIF >4 indicating severe multicollinearity [21]. Two variables, the Journal Citation Reports quartile and publisher, were removed because they had a VIF >4 (6.8 for Journal Citation Reports quartile and 4.3 for publisher), leaving all the other journal characteristics remaining in the final model. Results were presented as odds ratios (ORs) with corresponding 95% CIs. An OR >1 indicated that the variable was associated with increased odds of having requests for data-sharing statements.

XSL•FO

Figure 1. Characteristics of journals according to data sharing statement request by publication region and publisher. Only publication regions and publishers with ≥5 journals were listed. Proportions were presented as lines. (A) The count and proportion of journals according to data sharing statement request by publication region. (B) The count and proportion of journals according to data sharing statement request by publisher.

Two sensitivity analyses were conducted to evaluate the robustness of the main findings. First, journals from the same publisher may share a similar or same journal request for data-sharing statements. Given the removal of the publisher from our main analysis due to its VIF, to account for this cluster effect, we performed a sensitivity analysis by using the generalized estimating equations (GEE) approach with an exchangeable correlation structure to model the intraclass correlation of the journals within the same publisher [22]. GEE is specifically designed to handle correlated data from clustered or repeated measures. By using an exchangeable correlation structure, GEE allows for the assumption that the correlation between any 2 observations within the same cluster (eg, publisher) is constant. This could accurately reflect the

XSL•FO
RenderX

underlying data structure and improve the validity of the statistical inferences made [22]. Furthermore, we performed another sensitivity analysis by using the continuous forms for three journal characteristics (percentage of open access, journal impact factor, and number of trials published between 2019 and 2022) for the multivariable regression analysis. Using continuous forms in the model could make full use of the information provided by the continuous variables, which may therefore generate estimates with larger uncertainty when compared with the model using categorical forms [23]. Thus this approach could test the robustness of our main findings from multivariable regression analysis.

We further performed 3 exploratory analyses for this survey. First, we evaluated the relationship between journal characteristics and the type of journal request for data-sharing statements (weak or strong). Multinomial logistic regression analysis was used for this analysis, taking no request as the reference.

Second, to assess whether the journal request for data-sharing statements from the paper submission instructions was in line with their published clinical trial reports, we extracted information on data-sharing statements from 3 recent clinical trial reports published after September 1, 2023. We identified the recent trial reports by searching PubMed in descending order by publication date for each journal. We determined whether there was any data-sharing statement in these clinical trial reports by thoroughly searching the reports, the web pages where the journals published these reports, and their supplemental materials. Journals were therefore categorized into having any or no data-sharing statements in their published trial reports. We used the McNemar test to explore whether there was a significant discordance between journal requests (identified on the paper submission instructions) and the publication of a data-sharing statement (in their published trial reports). Furthermore, multivariable logistic regression was used to evaluate journal characteristics in relation to journals having data-sharing statements in trial reports, taking journals having none of the statements as a reference.

We conducted a third exploratory analysis trying to explore the temporal trend of journal requests for data-sharing statements. The study by Siebert et al [15] included the largest number of journals from the “Clinical Medicine” group defined by Journal Citation Reports in 2018 (n=489), among previous studies assessing journal requests for data-sharing statements. We matched our included journals with this previous publication to evaluate any potential difference in journal requests for data-sharing statements from 2018 to 2023 by using the McNemar mid-*P* test [24]. A significant difference would indicate there was a significant increase or decrease in journal requests for data-sharing statements over the past 5 years.

All statistical tests were 2-sided with a significance level of .05. Analyses were conducted in R software (version 4.1.0; R Core Development Team) and SAS software (version 9.4; SAS Institute).

Ethical Considerations

The present analysis was a secondary analysis based on published materials and website. In accordance with current regulations and the hospital's policy, studies that do not involve human participants or animals are exempt from the requirement for formal ethical approval.

Results

We included a total of 202 public, environmental, and occupational health journals for analysis (Figure S1 in Multimedia Appendix 1). As shown in Table 1, the included journals were mainly non–open access (71.8%) and published in the English language (96.0%). Overall, 18.8% of the journals were on the ICMJE list and 60.4% endorsed CONSORT. The United States (40.6%) and the United Kingdom (27.7%) had the top 2 numbers of journals among all publication regions, while Elsevier, Taylor & Francis, Springer, Wiley, and Sage were the top 5 publishers with the largest number of journals (Figure 1 and Figures S2 and S3 in Multimedia Appendix 1). The median journal impact factor was 2.9 (Q1-Q3: 1.9-4.5), and the median number of trials published between 2019 and 2022 was 11.0 (5.0-26.8).

XSL•FO
RenderX

There were 134 (66.3%) journals requesting data-sharing statements in clinical trials (Table 1). Journals requesting data-sharing statements had a higher journal impact factor and a larger proportion of being in the Journal Citation Report Q1-Q2. They were more likely to endorse CONSORT and publish more clinical trials compared with journals that did not request data-sharing statements. Significant differences were also found in publication regions and publishers between journals with and without request. As displayed in Figure 1A, the United Kingdom (89.5%) had the largest proportion of journals requesting data-sharing statements among all the publication regions.

Figure 2 demonstrates results for the relationship between journal characteristics and journal requests for data-sharing statements. Being open access was significantly associated with lower odds of journal requests for data-sharing statements (OR 0.43, 95% CI 0.19-0.97), while journal impact factor ≥2.9 and endorsement of CONSORT were significantly associated with increased odds (OR 2.31, 95% CI 1.15-4.78 and OR 2.43, 95% CI 1.25-4.79, respectively). Compared with other publication regions, UK journals had significantly higher odds of journal request (OR 7.18, 95% CI 2.61-23.40), while no significant relationship was observed in US journals (OR 0.95, 95% CI 0.43-2.08). Results from sensitivity analyses by using the continuous forms of 3 variables (percentage of open access, journal impact factor, and number of trials published between 2019 and 2022) and the GEE approach were largely in line with our main findings (Figures S4 and S5 in Multimedia Appendix 1).

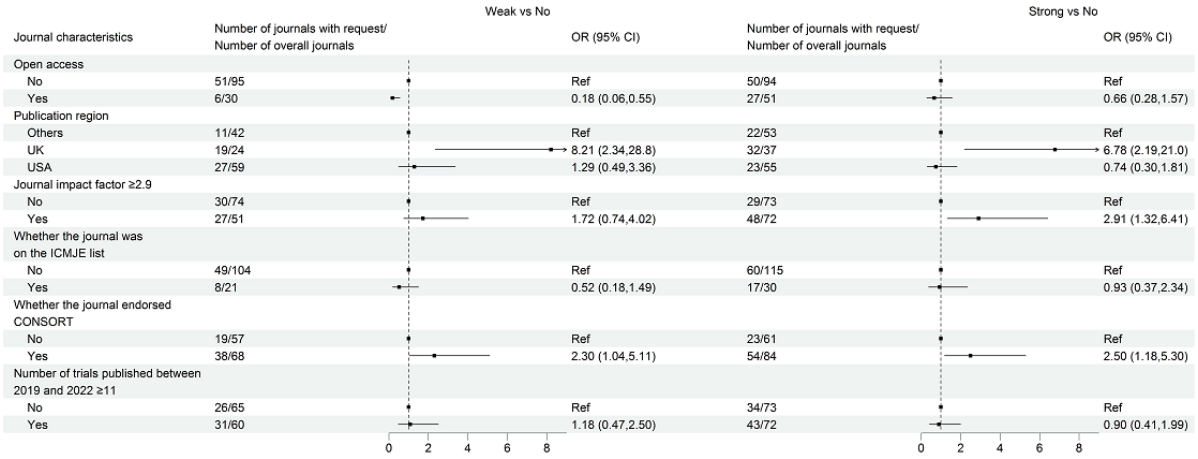

Figure 2. Multivariable logistic regression assessing the association between journal characteristics and request for data-sharing statements. CONSORT: Consolidated Standards of Reporting Trials; ICMJE: International Committee of Medical Journal Editors.

Among the 134 journals requesting data-sharing statements, there were 57 (42.5%) and 77 (57.5%) journals categorized as weak and strong, respectively. Figure 3 shows the results for journal characteristics in relation to the 2 types of journal requests. Both the comparisons between journals with weak requests and those with no requests, and between journals with strong requests and those with no requests, yielded similar results to our main findings.

XSL•FO
RenderX

Figure 3. Multinomial logistic regression assessing the association between journal characteristics and two types of journal requests for data-sharing statements. CONSORT: Consolidated Standards of Reporting Trials; ICMJE: International Committee of Medical Journal Editors.

A significant discordance was observed between journal requests identified on the paper submission instructions and the publication of data-sharing statements identified from published clinical trial reports (P<.001, Table 2). Among the 134 journals requesting data-sharing statements, 36 (26.9%) journals did not have statements in the clinical trial reports, while there were 92.6% of the journals without request (63/68) that did not present statements in trial reports. The findings of the association between journal characteristics and journals with any data-sharing statement in their published clinical trial reports were largely consistent with the main results (Figure S6 in Multimedia Appendix 1).

Table 2. Data-sharing statements in published clinical trial reports versus journal requests for data-sharing statements identified on the paper submission instructions. Results are shown as count (%) unless otherwise specified.

	Whether the journal requested data-sharing statements on the paper submission instructions		Total
	No	Yes	
Whether there was any data-sharing statement in clinical trial reports published in the journal, n (%)			
None	63 (31.2)	36 (17.8)	99 (49)
Any	5 (2.5)	98 (48.5)	103 (51)
Total	68 (33.7)	134 (66.3)	202 (100)

There was a total of 7 journals included in both Siebert's study and our own (Table S2 in Multimedia Appendix 1). One journal (out of 7 journals, 14.3%), the *International Journal of Epidemiology*, that did not request data-sharing statements during Siebert's study, was found to have changed to requesting data-sharing statements at the time of our survey. However, the difference in journal requests was not statistically significant (P=.50).

Discussion

Principal Findings

In this survey, we explored the data-sharing statement request of public, environmental, and occupational health journals. The principal findings were as follows: (1) over one-third of journals did not request data-sharing statements in clinical trial reports; (2) being open access was significantly associated with decreased odds of journal request, while publication in the United Kingdom, higher journal impact factor, and endorsement of CONSORT were significantly associated with increased odds of journal requests; and (3) among the journals requesting data-sharing statements, approximately 27% had published trial reports that indeed had no data-sharing statements.

Despite the ICMJE recommendation, our study showed over one-third of the included journals did not request data-sharing statements on their web pages. This data-sharing statement request remained inadequate for public, environmental, and occupational health journals, even though the importance of sharing IPD in public health and health informatics had been prominently highlighted during the COVID-19 pandemic [25]. Ramdjee et al conducted a study to include 148 COVID-19 interventional phase 3 trials registered between September 1, 2020, and March 1, 2021, reporting that the intent to share IPD at registration did not differ between these COVID-19 trials and 296 contemporary non–COVID-19 trials [12]. Furthermore, their subgroup analysis showed that among vaccine trials, COVID-19 trials were significantly related to decreased odds of intent to share IPD when compared with non–COVID-19 trials (OR 0.08, 95% CI 0.01-0.46). Likewise, another study that included 36 COVID-19 vaccine trial reports found that 86% of trials reported data-sharing statements [26]. Even though all

XSL•FO
RenderX

36 trials were from 3 high-impact journals (*New England Journal of Medicine*, *The Lancet*, and *The Lancet Infectious Diseases*), representing the best-case scenario, this again indicated a suboptimal practice in journal requests for data-sharing statements. Vaccines are known as the most effective strategy to safeguard public health especially during a pandemic, while COVID-19 vaccine trials have received major concerns over their data integrity [27-30]. Therefore, more efforts are urgently needed to enhance journal requests for data-sharing statements and thus the actual IPD sharing in trials in the field of public, environmental, and occupational health.

In our exploratory analysis, we observed that 1 journal that did not request data-sharing statements in 2018 changed to requesting data-sharing statements in 2023 [15]. This may reflect a potential improvement toward journal requests in public, environmental, and occupational health journals temporally. Nonetheless, the small sample size may tend to yield spurious findings by chance that should thus be interpreted with caution.

Our study revealed that among the journals on the ICMJE list, more than one-third did not request data-sharing statements. Furthermore, being on the ICMJE list was associated with decreased odds of journal requests for data-sharing statements, although the relationship was not statistically significant (Figure 2). Despite the ICMJE acknowledging that "there may be some listed journals that do not follow all of the many recommendations and policies in the document," more actions would be needed to enhance the request and eventually promote the actual IPD sharing among the ICMJE-listing journals [31]. Open access journals were less likely to request data-sharing statements than subscription journals, in line with a previous study [32]. Some open access journals may be reluctant to have data-sharing requests, because this may further increase trial authors' burden besides costly publication fees [33]. Furthermore, studies suggested that open access journals might lack the resources to enforce data sharing [32,33], which may partly explain the decreased odds of requesting data-sharing statements in open access journals.

Although the United States and the United Kingdom had the greatest numbers of public, environmental, and occupational health journals, our study showed that UK-based journals were more likely to request data-sharing statements. Nevertheless, guidelines on data sharing have been established by the national agencies in both the United Kingdom and the United States [34,35]. The elevated odds of requesting data-sharing statements in UK journals may be due to a combination of regulatory frameworks (ie, UK Research and Innovation Guidelines and General Data Protection Regulation), encouraging attitudes toward open science, and more support from academic institutions. Another possible explanation was that a higher distrust of sharing data had been reported in the United States than in the United Kingdom [4]. Besides, journal endorsement of CONSORT and a higher journal impact factor were associated with increased odds of journal requests for data-sharing statements. Journals with a higher impact factor were found to generally have more stringent peer-review processes and higher-quality publications [36]. Similarly, trial reports published in journals with the requirement of adhering to the CONSORT checklist were typically of higher quality than those trial reports published in journals without the CONSORT requirement [37]. However, these results should be treated with caution, especially given the existence of potential residual confounding effects and unmeasured biases from a nonrandomized survey.

Notably, we found a significant discordance between journal requests on the paper submission instructions and journal practice of including a data-sharing statement in their published trial reports (Table 2). Again, this information emphasized a large room for improving the current practice of journal requests, even in those journals that declared to request trial authors to provide data-sharing statements on the paper submission instructions.

Some previous studies have explored journal requests for data-sharing statements; however, none of these studies focused on public, environmental, and occupational health journals [13-16]. For example, a recent study included top journals in each quartile from 178 categories to examine requests for data-sharing statements in journals of life, health, and physical sciences [16]. While we ran a post hoc analysis by matching their included journals with ours, there were only 5 public, environmental, and occupational health journals included in their study. Similarly, to the best of our knowledge, the survey by Siebert et al involved the largest number of biomedical journals among previous studies, yet it only included 7 public, environmental, and occupational health journals for analysis [15].

Therefore, our survey may provide comprehensive evidence of whether public, environmental, and occupational health journals requested data-sharing statements in clinical trial submissions, thereby potentially generating some new insights into enhancing reporting transparency and eventually improving the actual sharing of IPD in clinical trials. The risk factors identified in this study might be targeted to improve the deficiency of current data-sharing statement request practice. Effective communication between publishers, journals, authors, academic institutions, and funders is encouraged to reach a potential consensus on data-sharing statement requests. Some perspectives on improving data-sharing statement requests may be considered. Publishers and journals may consider applying strict enforcement of their data-sharing statement request and actively monitoring compliance with it. Assigning specific human resources for evaluating data-sharing statements and actual data-sharing could be another possible option. Funders may provide user-friendly data-sharing platforms or tools and specific strategies to encourage data sharing. Editors and peer reviewers need to be tasked with evaluating the adequacy of data-sharing statements provided in submitted trial papers. The societies and associations in the field of public, environmental, and occupational health may consider establishing resource-sharing alliances for scholars and prioritizing publishing incentive policies, aiming to promote a culture of collaboration and openness in human research. Researchers are encouraged to adopt a data management plan at the beginning of a trial and closely adhere to their plans. Overall, joint endeavors from multiple stakeholders would be required to improve the journal request for data-sharing statements and to address the important gap between declared data-sharing statement requests in

XSL•FO
RenderX

journals' webpages and the actual statements provided in their published trial reports, ultimately promoting advancement, information transparency, and reproducibility in public, environmental, and occupational health research.

Strengths and Limitations

This survey was the first to systematically explore whether public, environmental, and occupational health journals requested data-sharing statements in their clinical trial report submissions. Rigorous methodology and detailed analyses strengthened our findings.

Several limitations need to be noted. First, no causal effects of journal characteristics on journal requests for data-sharing statements could be obtained in this observational study. Similarly, potential biases and confounding could not be fully precluded. As Google Translate was used in our study, potential errors due to misinterpretation of non-English or Chinese-language journals (n=8) could not be addressed. In addition, some journals involving multiple fields of health research (eg, *The New England Journal of Medicine* and *The Lancet*) that were not in the category of "Public, Environmental, and Occupational Health" indeed frequently published trials in the field of public, environmental, and occupational health. Even though we aimed to target public, environmental, and occupational health journals by using the definition of Journal Citation Reports for inclusion, this may fail to include a comprehensive list of public, environmental, and occupational health-related journals for analysis. Moreover, we did not contact journal editors or publishers who may determine or at least get involved in making the request for data-sharing statements to further verify our study outcome, mainly due to the low feasibility. Nevertheless, the results of our mockup submission in a random sample of journals without request identified from their submission guidance pages could partly support the accuracy of our outcome measures. Notably, these findings could only reflect the practice of journal requests for data-sharing statements during the time of our study. Given the dynamic change in policy endorsement, future explorations are needed to investigate the latest practice of journal requests for data-sharing statements.

Conclusions

Over one-third of the public, environmental, and occupational health journals did not request data-sharing statements in clinical trial reports. Among those journals that requested data-sharing statements in their submission guidance pages, more than one quarter published trial reports with no data-sharing statements. These results revealed an inadequate practice of requesting data-sharing statements by public, environmental, and occupational health journals, requiring more efforts at the journal level to implement ICJME recommendations on data-sharing statements.

Acknowledgments

We acknowledge Mr Jianfeng Li, Miss Yaoyao Wang, Mr Xibin Sun, and Mr Runquan Zhang for their help with data collection. Abstract

Background: Men who have sex with men (MSM) are at high risk for HIV infection and sexually transmitted diseases (STDs). However, there is a lack of accurate and convenient tools to assess this risk.

Objective: This study aimed to develop machine learning models and tools to predict and assess the risk of HIV infection and STDs among MSM.

Methods: We conducted a cross-sectional study that collected individual characteristics of 1999 MSM with negative or unknown HIV serostatus in Western China from 2013 to 2023. MSM self-reported their STD history and were tested for HIV. We compared the accuracy of 6 machine learning methods in predicting the risk of HIV infection and STDs using 7 parameters for a comprehensive assessment, ranking the methods according to their performance in each parameter. We selected data from the Sichuan MSM for external validation.

Results: Of the 1999 MSM, 72 (3.6%) tested positive for HIV and 146 (7.3%) self-reported a history of previous STD infection. After taking the results of the intersection of the 3 feature screening methods, a total of 7 and 5 predictors were screened for predicting HIV infection and STDs, respectively, and multiple machine learning prediction models were constructed. Extreme gradient boost models performed optimally in predicting the risk of HIV infection and STDs, with area under the curve values of 0.777 (95% CI 0.639-0.915) and 0.637 (95% CI 0.541-0.732), respectively, demonstrating stable performance in both internal and external validation. The highest combined predictive performance scores of HIV and STD models were 33 and 39, respectively. Interpretability analysis showed that nonadherence to condom use, low HIV knowledge, multiple male partners, and internet dating were risk factors for HIV infection. Low degree of education, internet dating, and multiple male and female partners were risk factors for STDs. The risk stratification analysis showed that the optimal model effectively distinguished between high- and low-risk MSM. MSM were classified into HIV (predicted risk score <0.506 and ≥0.506) and STD (predicted risk score <0.479 and ≥0.479) risk groups. In total, 22.8% (114/500) were in the HIV high-risk group, and 43% (215/500) were in the STD high-risk group. HIV infection and STDs were significantly higher in the high-risk groups (P<.001 and P=.05, respectively), with higher predicted probabilities (P<.001 for both). The prediction results of the optimal model were displayed in web applications for probability estimation and interactive computation.

Conclusions: Machine learning methods have demonstrated strengths in predicting the risk of HIV infection and STDs among MSM. Risk stratification models and web applications can facilitate clinicians in accurately assessing the risk of infection in individuals with high risk, especially MSM with concealed behaviors, and help them to self-monitor their risk for targeted, timely diagnosis and interventions to reduce new infections.

Introduction

HIV Infection and Sexually Transmitted Disease Situation of Chinese Men Who Have Sex With Men

Men who have sex with men (MSM) are at high risk of contracting HIV infection and other sexually transmitted diseases (STDs), and the number of infections is growing fast. The latest report released by the Joint United Nations Program for HIV and AIDS 2023 stated that HIV prevalence was 11 times higher among MSM compared to adults in the general population [1]. According to the results of the current large-scale systematic analysis study in China, the national HIV prevalence rate in the MSM population from 2001 to 2018 was 5.7%, compared to 0.037% in the general population in 2014 [2,3]. At the same time, the burden of other STDs (eg, syphilis, gonorrhea, and condyloma acuminata) among MSM was also high and increasing [4]. The prevalence of syphilis in the MSM population was as high as 35%, comprising both known and newly diagnosed cases [5]. The prevalence of gonorrhea and chlamydia among MSM in Southern China has been reported to be as high as 12.5% and 18.2%, respectively [6,7]. In addition, these STDs have the potential to facilitate HIV transmission and infection [8]. Therefore, given the severe HIV infection and STD situation of Chinese MSM, improving risk perception strategies and developing accurate risk prediction tools can help to prevent and control these infections, thereby improving their quality of life.

Using Machine Learning for Accurate Risk Assessment

Establishing accurate risk assessment and prediction tools for the MSM population is beneficial for clinical services to identify high-risk individuals and prioritize resources. Currently, existing models, such as multivariate logistic regression, Poisson regression, and Cox proportional hazards regression, have been widely used in the context of HIV infection or other STDs [9-11]. However, data structures that were often nonlinear, anomalous, and heterogeneous could lead to poor prediction performance. Despite the existence of traditional statistical methods, research exploring more sophisticated analytical approaches to enhance disease classification and predictive capabilities among the MSM population has been limited. Machine learning provides an innovative perspective on evaluating the risk of infections in population with high risk, allowing more flexibility in handling complex, nonlinear relationships between the variables, thus minimizing error [12]. Furthermore, machine learning is composed of a set of powerful algorithms that have the ability to acquire knowledge, predict outcomes, and review data. The use of these algorithms has attracted great attention in the development of patient-centered predictive models, which can provide valuable clinical insights [13]. However, currently, there are few studies using machine learning methods to predict the risk of HIV infection and STDs in China, and our study extended the literature in this context.

Risk Prediction for Serving Clinical Applications

The ultimate goal of risk prediction is intended to serve clinical applications prioritizing the screening of high-risk individuals in need of intervention. However, if too many predictors were included in the prediction model, it would not be conducive to collecting and applying them in clinical situations. In addition, there were various feature selection methods, each offering unique advantages but also having inevitable drawbacks. If multiple methods were used, the likelihood of screening for excellent predictors could be increased. Therefore, when faced with a large number of variables or when trying to construct a predictive model with a small number of predictors, a *combined* feature screening method was necessary. This method could help to decrease the data dimensions, reduce the amount of computation, and increase the applicability while eliminating some irrelevant or redundant variables and improving the prediction effect [14]. In addition, due to the “black box” of machine learning algorithms, understanding why a specific prediction was made for an individual or how a particular characteristic of an individual influenced a prediction was challenging [15]. The lack of interpretability limited the widespread use of more robust machine learning methods to support medical decision-making [16]. The limited intuitive understanding of machine learning models was still a significant barrier to their implementation in health care due to their inability to reflect the true correlation between individual characteristics and predicted outcomes [17]. As a result, the ability to correctly interpret predictive model outputs is important for generating appropriate user trust, providing insights to improve the model, and supporting an understanding of the modeling process to leverage the potential and productivity benefits of machine learning approaches. Moreover, some studies have failed to effectively address the data imbalance issues in their datasets, and further efforts to address this imbalance may improve model performance [18].

Developing Risk Screening Tools

To address the limitations of previous research, our study comprehensively considered feature selection, model interpretability, and strategies for handling class imbalance in the data. First, we applied a “combined” feature selection process using 3 methods, including univariate analysis, least absolute shrinkage and selection operator (LASSO), and Boruta, to select features and incorporate variables common to each method. At the same time, a series of data processing techniques and machine learning methods were used to identify individuals at risk for HIV infection and STDs in the MSM population. The risk factors for infection were analyzed, and interpretations were supported by the use of partial dependence plots (PDPs), which were designed to provide theoretical support for targeted screening strategies and risk management. Our study had a more comprehensive modeling strategy than previous studies. Moreover, our study did not incorporate difficult-to-obtain clinical information, such as blood-related, immunologic, or

XSL•FO
RenderX

cytologic data. All predictors were relatively easy to assess, making them more suitable for widespread use in screening studies among the MSM population. Finally, regarding clinical applications, the deployment of machine learning predictions into web applications showed good potential and application value. The user-friendly web applications served as pioneering digital tools that have been widely used in managing diabetic blood glucose, analyzing gliomas, and predicting early mortality in patients with bone metastases; however, in MSM populations, the risk of HIV infection and STDs has had limited application [19-21]. At the same time, the MSM population may conceal their sexual behavior due to external pressures from family members, traditional social attitudes, and fear of discrimination and stigmatization [22]. Web applications can help MSM conduct real-time, interactive self-monitoring anytime, anywhere, serving the sexual minority individuals and helping to protect their privacy. These web applications are a simple, practical, and effective risk management tool that can be widely used by clinicians and MSM individuals, and web applications offer advantages such as time efficiency, user-friendliness, and privacy protection. In summary, our study aimed to use machine learning methods to develop accessible, user-friendly web applications and tools to provide valuable insights into the risk factors influencing HIV infection and STDs, as well as to tailor screening models for the MSM population to accurately predict the risk of HIV infection and STDs in this population.

Methods

Study Design and Participants

Our study was a multistage, multicenter cross-sectional survey conducted from 2013 to 2023, based on the key projects of infectious disease research funded by the Chinese Ministry of Science and Technology during the 12th Five-Year Plan and 13th Five-Year Plan periods. Because of the particularity of the MSM population as sexual minority individuals, we used a nonprobability sampling method to recruit MSM in Western China (ie, Chongqing, Xinjiang, Guangxi, and Sichuan) through collaboration with nongovernmental organizations.

Specifically, we advertised on websites, QQ (Shenzen Tencent Computer System), and WeChat (Tencent Holdings Ltd) groups, and we collaborated with local nongovernment organizations to provide information on HIV prevention, counseling, and testing for lesbians, gay men, bisexual, and transgender individuals on each platform. We used this approach to present the details of the study (ie, objectives, procedures, potential benefits, and risks) to the leaders to gain their support and, with their help, recruit participants from the organizations. MSM were included in our study to complete the questionnaire if they were aged ≥18 years, had sexual contact with a man in the past 12 months, and had negative or unknown HIV serostatus. Participants who met the requirements went to local hospitals or community centers with which we had collaborated, where our researchers conducted face-to-face questionnaires and performed the appropriate tests. If participants encountered any unclear terms, trained investigators explained their meaning to them. All questionnaires were subsequently checked for completeness and consistency.

Outcomes

We tested MSM for HIV to determine whether they had experienced HIV infection. Those who were previously infected with STD among MSM were measured by the question, “In the last six months, have you been diagnosed by a doctor with the STD (for example, syphilis, gonorrhea, condyloma acuminatum, genital herpes, non-specific urethritis, and so on)?” On the basis of HIV test results, patients who obtained positive results were labeled as positive outcome indicators, and those who obtained nonpositive results were labeled as negative outcome indicators. Those who were previously infected with an STD were labeled as positive outcome indicators. and those who were never infected with an STD were labeled as negative outcome indicators. Predictive models were developed based on each of the 2 outcome indicators, HIV and STD.

Predictors

A total of 24 variables were selected for the personal characteristics of MSM, including four main aspects: (1) demographic characteristics; (2) HIV-related knowledge, behavior, and risk perception; (3) sexual behavior–related characteristics; and (4) substance use. Among them, demographic characteristics included age, household registration location, ethnicity, degree of education, employment situation, marital status, and monthly disposable income. HIV-related knowledge, behaviors, and risk perception included HIV knowledge scores (≥11 was defined as “high level” [22]), HIV testing and counseling, and HIV risk perceptions. Sexual behavior–related characteristics included sexual role (ie, the insertive partner and the receptive partner), number of sexual partners, high-risk sex, and condom use. Substance use included internet dating (ie, finding sexual partners through the internet), alcohol use, commercial sexual services (eg, offering and receiving sexual services), and recreational drug use. We excluded samples with too much missing data or where the presence of HIV infection or STD could not be determined. After a preliminary analysis, all variables had a missing rate of <10%, so we used the multiple imputation method to fill in the missing values.

Feature Selection

Redundant information in survey data from the MSM population may lead to suboptimal categorization of HIV infection or STD, as excessive dimensions in the data can reduce the accuracy and validity of the models [15]. Therefore, it is promising to use the “combined” feature selection method to select variables for the raw data. Univariate analysis, LASSO, and Boruta were used in our study. In this study, variables with $P<.10$ were included in the univariate analysis; variables with regression coefficients not equal to 0 were included in LASSO; and variables that were classified as confirmed or tentative were included, while rejected variables were excluded in Boruta. Using 3 different methods for feature selection, we ultimately included factors common to all these methods as predictors in the predictive models.

Prediction Models

Our dataset showed a significant imbalance in the number of individuals with and without HIV and STDs. Data-level

XSL•FO
RenderX

resampling techniques have been increasingly used to address unbalanced datasets due to its simplicity and ease of implementation. Therefore, our study used the synthetic minority oversampling technique to deal with the unbalanced dataset. This method oversampled the minority class samples in the boundary region, and it expanded the decision space of the minority class samples with little effect on the decision space of the majority class samples.

Logistic regression, decision tree, random forest, K-nearest neighbor, light gradient boosting machine, and extreme gradient boosting (XGBoost) were used to predict the risk of HIV infection or STDs in the MSM population. To train, construct, and evaluate the 6 predictive models, we divided 75% (1499/1999) of the data into a training set, 25% (500/1999) into a testing set, and used the data from the Sichuan MSM as an external validation set. Using the training data, a cross-validation grid search was conducted to determine the optimal hyperparameters for the predictive model. In this study, we used 7 standard performance metrics, including accuracy, balanced accuracy, sensitivity, specificity, positive predictive value, negative predictive value, and area under the receiver operating characteristic curve, to evaluate the classification performance of the prediction model. Meanwhile, 10-fold cross-validation was used to assess the stability of several machine learning prediction models. These evaluation metrics were calculated from a binary confusion matrix, and based on the results of previous studies, these metrics were ranked according to their predictive performance [21,23]. On the basis of each evaluation metric, the highest score was assigned to the best-performing model, followed by the next best-performing model. The total score of the model was the sum of the scores for each metric. The data were heat mapped using the *pheatmap* package in R (R Foundation for Statistical Computing).

Model Interpretation

Interpretable analyses of the model included both variable importance ranking and PDP to identify key predictors of HIV infection or STDs in the MSM population. Feature importance refers to quantifying the contribution of each variable in the predictive model to the prediction outcome and ranking them accordingly, which reflects the magnitude of each predictor's influence on the model. Our study used PDP to conduct an explanatory analysis of the predictive model, assessing the degree and direction of influence of each variable on the prediction outcome.

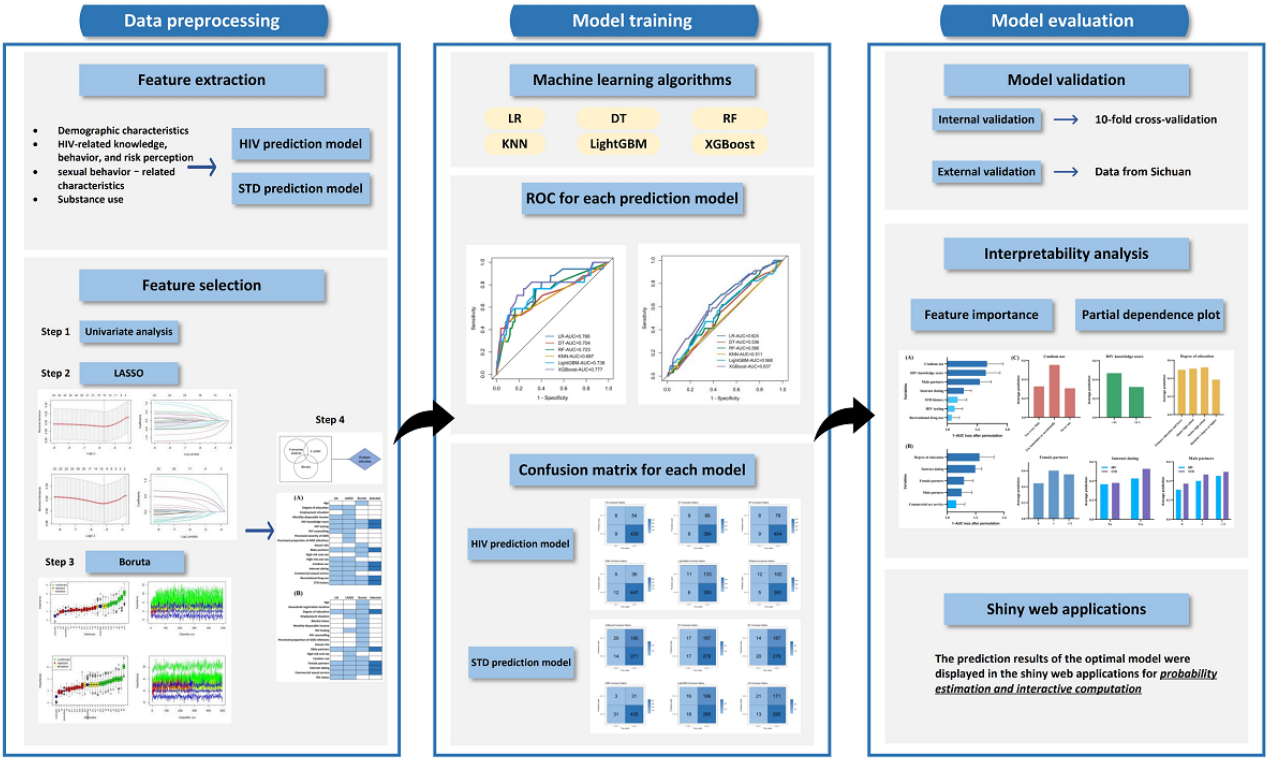
Risk Stratification

The probability of the optimal model output was defined as the predicted risk score (PRS) [24]. The cutoff point could be used as a basis for risk definition, and based on this threshold, MSM were categorized into low-risk and high-risk individuals. MSM with a predicted probability less than the threshold were assigned to the low-risk group, while MSM with a predicted probability greater than or equal to the threshold were assigned to the high-risk group. This approach allowed differentiation of MSM based on predicted risk, facilitating targeted interventions and individualized management strategies.

Web Applications

Using the algorithm of the optimal model in this study, we developed web-based calculators to predict the risk of HIV infection or STDs in the MSM population. The applications were composed of 3 main parts, which were the input box, the prediction result, and the result box. The input box included the predictors of the prediction model, and the user could input the values of the predictors independently according to the individual situation. This interactive panel allowed the user to customize the prediction based on specific individual characteristics. Clicking on the Predict button below the input box displayed the predicted outcome under different conditions, which was the probability of an individual MSM being infected with HIV or STD. This information could provide valuable insights for clinical decision-making, and web applications can predict outcomes under different conditions and save these multiple predictions in the results box.

Sensitivity Analysis



According to the sexual behavior–related characteristics, MSM could be categorized into MSM and women (MSMW), MSM only (MSMO) [25], men who have sex with multiple men (MSMM), and non-MSMM [26]. Previous studies have found differences between MSMW and MSMO in HIV-related high-risk sexual behavior and HIV infection or STD prevalence [27]. At the same time, MSMM had a higher risk of infection than other men [28]. For these subgroups with different risks of infection, we included MSMW and MSMO as well as MSMM and non-MSMM into the optimal model to predict the risk of HIV infection or STDs in these subgroups. This was done to perform sensitivity analyses and validate the stability of the prediction model.

Statistical Analysis

For all statistical analyses, we used SAS (SAS Institute) and R software. Multiple imputation and univariate analysis were accomplished using SAS. For continuous variables that did not follow a normal distribution, we used nonparametric tests for comparison; for comparisons involving categorical variables, we used the chi-square test. If the expected count in 25% of the cells was <5, the chi-square test was deemed ineffective, and the Fisher exact probability test was used. LASSO, Boruta, machine learning algorithms, and plotting were performed using the *glmnet*, *Boruta*, *tidymodels*, and *ggplot* packages in R, respectively. The model interpretability analysis was performed using the *dalex* package for variable importance ranking and PDPs, and the web applications used the *shiny* package in R. The flowchart of the data analysis and machine learning modeling process is presented in Figure 1.

Ethical Considerations

The study was approved by the Chongqing Medical University Ethics Committee (reference numbers 2012010 for 12th Five-Year Plan and 2019001 for 13th Five-Year Plan). Before participating in this research, the participants were fully informed about the purpose, significance, voluntary participation, and confidentiality of the research. Each participant signed an informed consent form and was also compensated with RMB 80 (US $10.90) for transportation and breakfast. The study data were anonymized and deidentified to ensure participant privacy and confidentiality. All images in the manuscript and Multimedia Appendix 1 were reviewed to ensure that individual participants and users cannot be identified.

Results

Overview

In total, we collected individual characteristics from 2345 MSM and excluded those who did not meet the requirements, resulting in 1999 (85.24%) MSM being included in the analyses (refer to Figure S1 in Multimedia Appendix 1 for a flowchart of the participant screening process). The percentage of HIV-positive MSM was 3.6% (72/1999), and the percentage of those who self-reported as previously infected with STD was 7.3% (146/1999). The basic demographic information of the 1999 MSM is shown in Table 1.

Feature Selection

LASSO and Boruta were used for feature selection and incorporating factors common to these methods, respectively (refer to Tables S1 and S2 and Figures S2 and S3 in Multimedia Appendix 1 for results of variable screening for each method). On the basis of the results of the statistical analysis, 7 predictors were finally included in the HIV prediction model: HIV knowledge score, HIV testing, number of male partners, condom use, internet dating, recreational drug use, and STD history. A total of 5 predictors were included in the STD prediction model: degree of education, number of male partners, number of female partners, internet dating, and commercial sexual service. The process of variable screening is presented in Figure 2. The results of the selected predictors in the univariate analysis are provided in Table 2.

Model Construction

We randomly divided the data according to a 75% (1499/1999) training set and a 25% (500/1999) testing set, and comparisons of each predictor between the training and testing sets of the HIV and STD prediction models are provided in Tables S3 and S4 in Multimedia Appendix 1. The synthetic minority oversampling technique was used to balance against the dependent variable of the training set. The balanced data were used to predict the risk of HIV infection and STDs using 6 machine learning algorithms, and the predictions were applied to the testing set. The evaluation indicators of the prediction results of each model obtained through the confusion matrix are provided in Table 3 (refer to Figures S4 and S5 in Multimedia Appendix 1 for the confusion matrix of each prediction model).

Table 3. The prediction results of each model obtained through the confusion matrix.

Interpretability Analysis

The XGBoost algorithm was chosen as the optimal model to rank the importance of all predictors, and the top 4 variables were analyzed for interpretability using the PDPs (Figure 4). According to the results of the study, condom use, HIV knowledge score, number of male partners, and internet dating were the more important variables in the HIV risk prediction model. Degree of education, internet dating, number of female partners, and number of male sexual partners were the more important variables in the STD prediction model. According to the PDPs, MSM who sometimes or occasionally use condoms, have an HIV knowledge score of <11, have ≥2 male partners, and use internet dating reported a higher risk of HIV infection than other MSM. MSM with a low degree of education, those using internet dating, having a female partner, and having ≥2 male partners had a higher risk of STDs than other MSM.

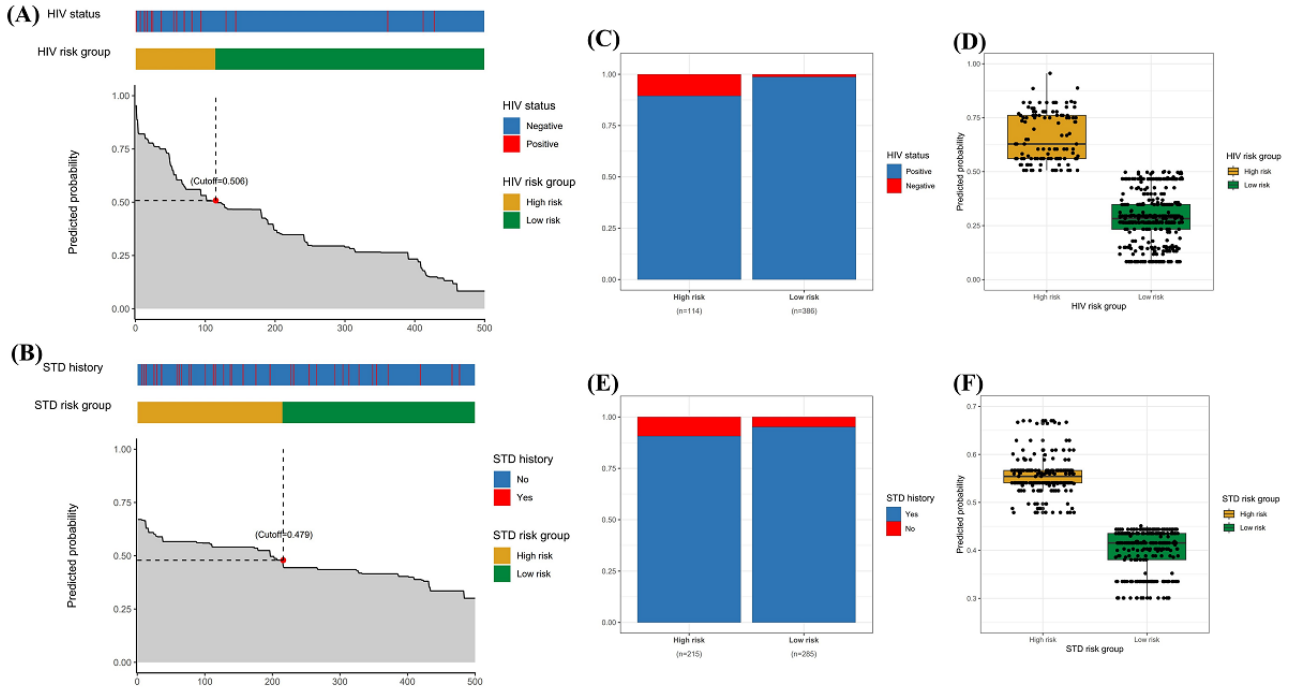
Interpretability analysis of optimal model: (A) importance ranking of variables for HIV prediction model, (B) importance ranking of variables for sexually transmitted disease (STD) prediction model, and (C) partial dependence plots for each variable in the top 4 rankings. AUC: area under the curve; STD: sexually transmitted disease.



Risk Stratification

On the basis of the cutoff points of the receiver operating characteristic curves of the testing set prediction models, in the HIV prediction model, we defined PRS<0.506 as the low-risk group and PRS ≥0.506 as the high-risk group; in the STD prediction model, we defined PRS<0.479 as the low-risk group and PRS ≥0.479 as the high-risk group. The PRS and risk group distribution of HIV infection and STDs among MSM in the testing set are presented in Figures 5A and 5B. Of the 500 MSM, 386 (77.2%) were in the HIV low-risk group and 114 (22.8%) were in the HIV high-risk group, and 285 (57%) were in the STD low-risk group and 215 (43%) were in the STD high-risk group. The actual number of HIV infections was statistically different in the high- and low-risk groups (P<.001; Figure 5C), and the predicted probability of HIV was significantly higher in the high-risk group than in the low-risk group (P<.001; Figure 5D). In the high-risk group, the actual number of STDs was higher than in the low-risk group (P=.05; Figure 5E), and the predicted probability of STD was significantly higher in the high-risk group than in the low-risk group (P<.001; Figure 5F).

XSL•FO
RenderX

Figure 5. Evaluation of the predicted risk scores of the optimal model in the testing set: (A) distribution of predicted risk scores and risk groups among men who have sex with men (MSM) in HIV prediction model, (B) distribution of predicted risk scores and risk groups among MSM in sexually transmitted disease (STD) prediction model, (C) HIV predicted model's actual number of infections compared among the risk groups, (D) HIV model's predicted probability compared among the risk groups, (E) STD predicted model's actual number of infections compared among the risk groups, and (F) STD model's predicted probability compared among the risk groups.

Sensitivity Analysis and Web Applications

Applying the optimal model to an external validation set showed that the model had a fair ability to predict the risk of HIV infection and STDs, with AUC values of 0.627 (95% CI 0.518-0.836) and 0.687 (95% CI 0.528-0.846), respectively. A comparison of differences in demographic characteristics between the external and internal validation sets is provided in Tables S5-S7 in Multimedia Appendix 1. Meanwhile, based on the results of the sensitivity analysis, the optimal model was applied to the MSMM, non-MSMM, MSMO, and MSMW datasets, respectively, and the AUC values ranged from 0.634 to 0.839, indicating that the model was also capable of predicting the risk of HIV infection and STDs in the subgroups (Figure S6 in Multimedia Appendix 1). Finally, the prediction results of the optimal model were displayed in the shiny web applications for probability estimation and interactive computation [29].

Discussion

Principal Findings

Our study demonstrated the accuracy of machine learning methods in the prediction of the risk of HIV infection or STDs among MSM. Among the 6 machine learning methods, the XGBoost model outperformed the others, achieving higher AUC values as well as greater accuracy and sensitivity. Furthermore, the most useful predictors were conventional and easy to collect. Optimization-based models were able to stratify the risk of HIV infection and STDs in MSM well. Sensitivity analyses showed that the prediction models for HIV or STD also demonstrated good performance in predicting MSM subgroups with different risks of infection. In addition, the web-based calculators developed in this study provided a valuable tool for clinicians and MSM to make more informed behavioral decisions. These data could guide prevention and intervention programs, allowing users to tailor interventions to the risk profile of the individual. The routine collection of data, the accuracy of the prediction models, and the convenience of the web applications suggested that machine learning methods may be of value in HIV infection or STD risk assessment services.

Machine learning methods offer flexibility and scalability, making them suitable for a variety of tasks, such as risk stratification, especially when analyzing big data [30]. Risk prediction models are widely used in clinical scenarios, and clinicians may be able to use clinical prediction models to quantify predictions and more intuitively present their risk of infection and intervention options to the MSM population, potentially moderating the information asymmetry between physicians and patients to some extent. In addition, risk prediction models can play a role in the tertiary prevention system of diseases. For example, according to the individual characteristics of high-risk groups, the risk of potential future infections can be quantified, providing a more intuitive and scientific reference for health education and behavioral interventions, and noninvasive, cost-effective, and convenient indicators can be used for risk screening, thus realizing secondary prevention of "early detection, early diagnosis, and early treatment." Clinicians can more accurately screen appropriate study participants, and government departments and health management decision makers can better manage the quality of health care and rationally allocate health care resources. Meanwhile, for MSM, web applications enable self-assessment of infection risk anytime and anywhere based

XSL•FO
RenderX

on their individual situations, which is conducive to protecting their privacy and strengthening awareness of self-management and self-monitoring among high-risk groups.

In our study, for the MSM population in Western China, our prediction results were consistent with previous prediction studies and better predicted the risk of infection. A study conducted to predict future occurrence of syphilis in a high-risk cohort of MSM and transgender women in Peru reported an AUC value of 0.690 [10]. In HIV diagnosis studies of MSM in Australia, the AUC value of their prediction models ranged from 0.698 to 0.763, and for the diagnosis of other STDs, the AUC value ranged from 0.632 to 0.858 [31]. However, the STD prediction model in this study had a slightly lower AUC value (0.777 vs 0.637) compared to the HIV prediction model, which may be related to the way the dependent variables were collected. We objectively measured the HIV infection status of MSM through HIV antigen-antibody testing, whereas the STD history of MSM was obtained through subjective self-reports. MSM may have chosen to conceal their infection history due to social desirability bias, leading to an underestimation of outcomes [32]. Although subjective measurements may lead to a reduction in the efficacy of prediction models, their predictions were generally reliable. At the same time, according to the results of the HIV prediction model, STD history was also an important factor in HIV infection, which was consistent with the results of previous studies [10,33]. In our study, we developed separate prediction models for HIV infection and STDs, designed to function as a *2-step* risk assessment tool. The first step evaluates the risk of STDs in MSM, followed by the second step, which assesses the risk of HIV, offering more comprehensive information for HIV risk prediction.

Our results showed that the XGBoost algorithm performed optimally in predicting the risk of HIV infection and STDs in the MSM population in Western China. XGBoost is an enhanced version of the gradient boosting machine. The optimal performance of XGBoost has been reported in studies predicting HIV infection in Zimbabwe from 2005 to 2015 and in studies predicting timely clinic attendance and acceptance of HIV infection or STD testing [34,35]. The XGBoost algorithm incorporates regular terms to control the complexity of the model, which can effectively prevent overfitting. In addition, XGBoost modeling has been shown to gain signal from missingness without resorting to imputation techniques [36]. In summary, in predicting the risk of HIV infection and STDs in the MSM population in Western China, XGBoost has reported the best prediction performance in terms of discriminative ability and clinical application. XGBoost can be used as a prioritized algorithm in future risk prediction tools.

According to the interpretability analysis of the prediction model, condom use was one of the important factors in predicting the risk of HIV infection in the MSM population, which was also consistent with the results of previous studies [31]. High-risk sexual behaviors, such as unprotected sex and inconsistent condom use, may accelerate HIV transmission between MSM [37,38]. According to our findings, MSM who sometimes or occasionally used condoms were predicted to have a higher mean probability of infection than MSM who used condoms every time. However, the probability of infection among MSM who never used condoms was not high, and we believe that it may be related to the social desirability bias of MSM, which made them reluctant or afraid to admit that they did not use condoms, leading to an underestimation of this outcome.

In addition, our findings showed that MSM who found sexual partners through the internet (ie, internet dating) had a higher risk of both HIV infection and STD than MSM who did not. Considering that individuals have free access to explicit sexual content on the internet, coupled with the increased risk of MSM infection, the role of the internet in sexual partner encounters and its correlation with risky sexual behavior has become an important topic [39]. The internet was known to be a popular place for MSM to find sexual partners; for example, previous studies found that 40% of MSM used the internet to find sexual partners [40,41]. Previous studies have shown that MSM who use internet dating are more likely to engage in psychotropic drug use and unprotected intercourse compared to other MSM [42]. This result was consistent with our findings. It is evident that targeted measures should be taken to improve their attitudes and perceptions and reduce their risk of infection.

A study in the United States showed that MSM with multiple partners are at higher risk of HIV infection [43]. This finding was confirmed by 2 national cross-sectional surveys conducted in Brazil in 2009 and 2016 [44]. In addition, previous studies in China have found that MSM with multiple sexual partners and those having unprotected sex were at increased risk of HIV infection [26]. These were consistent with our findings. It is clear that MSM with multiple sex partners should be given timely attention and education to reduce their risk of infection. Moreover, our prediction model screened for variables such as HIV knowledge score, degree of education, and HIV testing. All of these variables were significant predictors of infection risk, and interventions targeting these variables were also important for HIV infection and STD prevention in the MSM population.

Limitations

In summary, we have developed risk prediction tools that can be widely used in real-life settings. All predictors are self-reported risks, and a user-friendly, web-based self-assessment tool has the potential to help MSM identify their risk of HIV infection or STDs in a nonclinical setting, which enables them to determine their risk of infection and seek timely medical help. Meanwhile, in clinical scenarios, these tools will help clinicians stratify high-risk individuals and be more attentive to individuals who are potentially at high risk of infection. However, there were some limitations in our study. First, we recruited participants using nonprobability sampling, which may have led to bias and limited the generalizability of this study (refer to Multimedia Appendix 1 for the evaluation of the bias in the data relative to the population). In addition, our study relied on voluntary participation by MSM, and the characteristics of participants may have differed from those of nonparticipants, leading to self-selection bias. The validity of risk prediction models depended on the accuracy of self-reported information, which was influenced by MSM recall bias and social desirability bias. In future research on MSM, some

XSL•FO
RenderX

accurate and reliable information gathering tools are necessary, for example, computer-assisted self-interview [31]. Our study revealed significant spatial heterogeneity in the demographic characteristics and the risk of HIV infection or STDs among the MSM population in Western China. This heterogeneity reflects regional differences in population structure, socioeconomic conditions, behavioral patterns, and access to health care services. Considering the epidemiological context, these findings suggest the need to develop tailored prevention and control strategies based on regional characteristics to effectively reduce the risk of HIV and STD transmission in various areas (Figure S7 and Table S8 in Multimedia Appendix 1). Second, the sample size of our study may be smaller than that of other large-scale national survey studies. As the study focused the MSM population, conducting a large-scale national survey was difficult. However, the results of risk prediction models and sensitivity analyses showed that, with the current sample size, the predictions were considerable and could be used in real-world applications. Third, we only used 6 machine learning methods for risk prediction, and others may be explored as part of future research. Fourth, although the optimal prediction model performed moderately well in the MSM in Sichuan (ie, the external validation set), our analysis, presented in Tables S5-S7 in Multimedia Appendix 1, revealed significant differences in demographic variables between the external and internal validation sets. These discrepancies may have contributed to inaccurate predictions, but they also highlighted the authenticity of the external data used to test the risk prediction model, as such differences in the external validation dataset were unavoidable. Future attempts should be made to apply external validation to data from multiple regions to demonstrate the robustness of the prediction model. Finally, our study represented risk projections of outcomes and characteristics from cross-sectional surveys rather than prospective cohort projects, and longitudinal projections will be part of future surveys. As the models were constructed only from Western China, further exploration and validation were needed to generalize the optimal model to the whole country to make it universally applicable.

Conclusions

Our results showed that the machine learning approach demonstrated good performance in predicting the risk of HIV infection or STDs in the MSM population in Western China. The method could be used for the risk stratification of MSM, which would help clinicians and MSM to conduct risk assessment and intervene and prevent the risk in a timely manner. At the same time, user-friendly and easily operated web applications have important public health implications in risk monitoring among the MSM population and can be widely used in reality.

Acknowledgments

The authors would like to thank all the men who have sex with men participants, the members of the nongovernmental organizations, and the physicians working at the First Hospital of Chongqing Medical University. Abstract

Background: While the COVID-19 pandemic has induced massive discussion of available medications on social media, traditional studies focused only on limited aspects, such as public opinions, and endured reporting biases, inefficiency, and long collection times.

Objective: Harnessing drug-related data posted on social media in real-time can offer insights into how the pandemic impacts drug use and monitor misinformation. This study aimed to develop a natural language processing (NLP) pipeline tailored for the analysis of social media discourse on COVID-19–related drugs.

Methods: This study constructed a full pipeline for COVID-19–related drug tweet analysis, using pretrained language model–based NLP techniques as the backbone. This pipeline is architecturally composed of 4 core modules: named entity recognition and normalization to identify medical entities from relevant tweets and standardize them to uniform medication names for time trend analysis, target sentiment analysis to reveal sentiment polarities associated with the entities, topic modeling to understand underlying themes discussed by the population, and drug network analysis to dig potential adverse drug reactions (ADR) and drug-drug interactions (DDI). The pipeline was deployed to analyze tweets related to the COVID-19 pandemic and drug therapies between February 1, 2020, and April 30, 2022.

Results: From a dataset comprising 169,659,956 COVID-19–related tweets from 103,682,686 users, our named entity recognition model identified 2,124,757 relevant tweets sourced from 1,800,372 unique users, and the top 5 most-discussed drugs: ivermectin, hydroxychloroquine, remdesivir, zinc, and vitamin D. Time trend analysis revealed that the public focused mostly on repurposed drugs (ie, hydroxychloroquine and ivermectin), and least on remdesivir, the only officially approved drug among the 5. Sentiment analysis of the top 5 most-discussed drugs revealed that public perception was predominantly shaped by celebrity endorsements, media hot spots, and governmental directives rather than empirical evidence of drug efficacy. Topic analysis obtained 15 general topics of overall drug-related tweets, with "clinical treatment effects of drugs" and "physical symptoms" emerging as the most frequently discussed topics. Co-occurrence matrices and complex network analysis further identified emerging patterns of DDI and ADR that could be critical for public health surveillance like better safeguarding public safety in medicines use.

Conclusions: This study shows that an NLP-based pipeline can be a robust tool for large-scale public health monitoring and can offer valuable supplementary data for traditional epidemiological studies concerning DDI and ADR. The framework presented here aspires to serve as a cornerstone for future social media–based public health analytics.

COVID-19; natural language processing; drugs; social media; pharmacovigilance; public health

Introduction

The emergence of the COVID-19 pandemic has induced an immediate need for effective pharmacotherapies. While the development and application of such therapies are critically important, they are also influenced by an array of political, economic, and social factors. Meanwhile, an overabundance of drug-related information during the COVID-19 pandemic has rapidly proliferated across social media platforms, drawing significant attention from governments and health organizations. This phenomenon, referred to as an "infodemic," has exacerbated the pandemic's impact, caused additional harm to individuals, and undermined the effectiveness and sustainability of the global health system [1,2]. For example, public pronouncements by high-profile figures, such as former US President Donald Trump's endorsement of hydroxychloroquine, have led to its irrational use and consequential public health crises [3]. Traditional pharmacovigilance mechanisms, reliant on clinical trials and formal reporting systems like MedWatch and DrugBank [4-6], offer valuable but lagged information. These traditional approaches are plagued by inefficiencies, reporting biases, and a lack of timeliness, thereby lacking comprehensive coverage of the population's sentiments and experiences [7-10].

In this context, real-time public comments on pharmacotherapies such as medications on social media provide a valuable resource for complementing research on drug use or repositioning for the COVID-19 pandemic. In addition to the fast accessibility, timeliness, and comprehensive population coverage, social media can also supply real-world evidence on how people respond to different drugs, thus helping researchers mine novel drug potency or side effects [11-13]. Social media also offer data on drugs not typically included in pharmacovigilance datasets, such as over-the-counter drugs [14], herbal remedies [15], and other nontraditional treatments [16]. However, the sheer volume and noise in social media data require robust computational methodologies for effective analysis [17].

Natural language processing (NLP) technologies offer a solution to these challenges. Earlier studies, such as the study conducted by Aramaki et al [18] in 2011, demonstrated that Twitter (subsequently rebranded X) data could be mined to monitor influenza outbreaks using machine learning and rudimentary NLP techniques. Contemporary research in this domain has benefitted immensely from technological advancements, such as deep-learning–based NLP tools specifically for analyzing social media data [19-22]. These have made it increasingly feasible to understand large volumes of colloquial, noisy text for the extraction of meaningful insights on public health.

Substantial efforts such as topic modeling and sentiment analysis have been made to analyze pharmacotherapy-related topics during the COVID-19 pandemic. Notably, existing research lacked of data-driven pipeline with state-of-the-art NLP tools and other big data analysis techniques [23-27] or just involved longitudinal data with a small time span [28]. There is still a gap in how to automatically and accurately extract drug information through social media data for longitudinal monitoring of the drug infodemic.

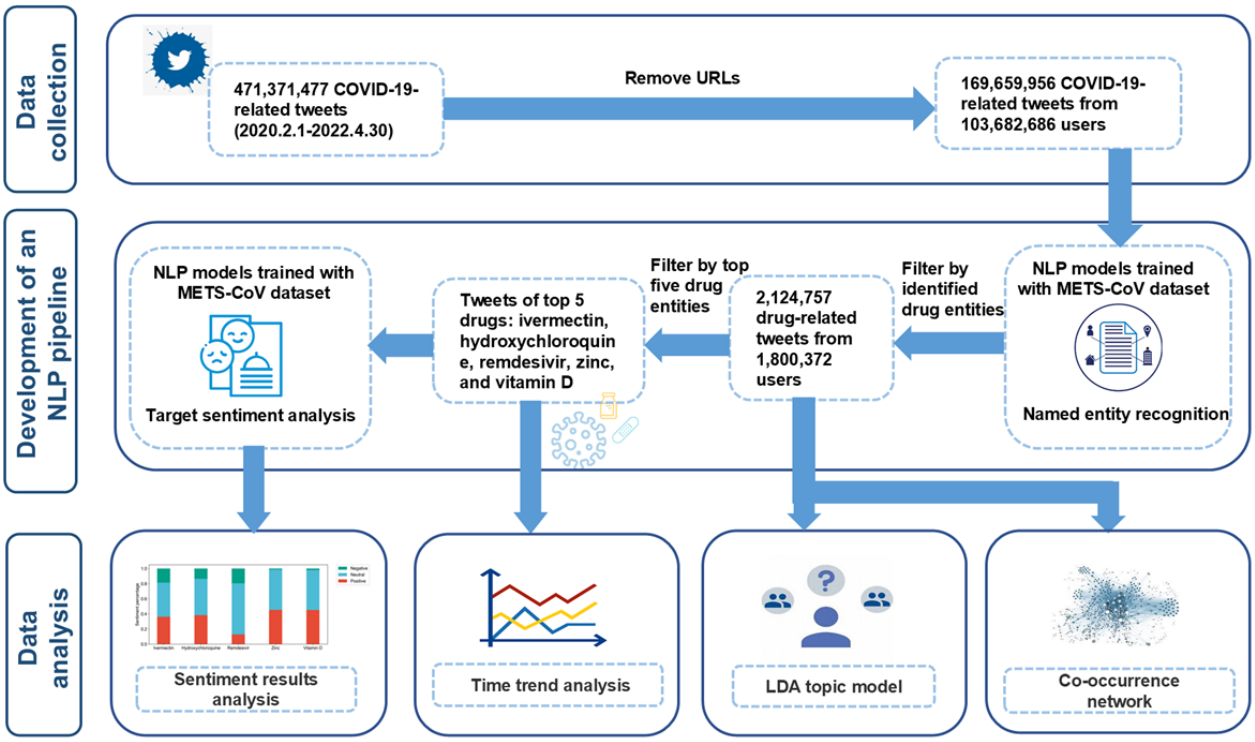
To address these gaps, this study uses NLP methodologies and network analysis for an extensive assessment of COVID-19 drug-related discourse on social media. We contribute to the existing literature in several ways:

(1) Using deep learning methodologies for named entity recognition (NER), thereby reducing the false positives associated with traditional keyword matching.

(2) Re-examining public sentiments and concerns regarding COVID-19 medications, using target sentiment analysis (TSA) and topic modeling.

(3) Conducting a comprehensive assessment of adverse drug reactions (ADR) and drug-drug interactions (DDI) through network analysis techniques.

We demonstrate that our integrated NLP pipeline can serve as a robust framework for extracting and analyzing drug-related information, thereby enhancing the scope and effectiveness of social media–based pharmacotherapy analysis.



Methods

Overview

As shown in Figure 1, the study workflow is organized into three primary stages: data collection, development of an NLP pipeline, and subsequent data analysis using the constructed pipeline. Initially, we curated a dataset of English tweets related to the COVID-19 pandemic. After a preprocessing phase that excluded tweets with URLs, an NLP pipeline was developed to extract and normalize the drugs and symptoms mentioned in these tweets. Finally, we examined the time trends of drug mentions, public sentiment, and discussion topics toward drugs, as well as the co-occurrence network of drug-drug and drug-symptom pairs [22].

Figure 1. Workflow of drug analysis with natural language processing on Twitter. LDA: latent Dirichlet allocation; METS-CoV: Medical Entity and Targeted Sentiment on COVID-19 Related Tweets; NLP: natural language processing; NER dataset containing medical entities and targeted sentiments from COVID-19–related tweets.

Data Collection and Preprocessing

COVID-19–related tweets from February 1, 2020, to April 30, 2022 were downloaded using Twitter's application programming interface (API) through unique tweet IDs, which were obtained from a public dataset provided by Chen et al [29]. Due to the privacy restrictions of Twitter data, the raw tweets were not publicly available and could only be shared by tweet ID. Therefore, we downloaded tweets by Twitter API based on the provided tweet IDs. The downloaded data included full tweet texts and corresponding metadata such as timestamps and user information. Tweets containing URLs were excluded from the analysis, as they often only contained summaries or quotations of the original tweet. The data collection process adhered to Twitter's privacy and data use management policies.

NLP Pipeline Development

The NLP pipeline consists of 4 principal modules: NER, TSA, topic modeling, and drug network analysis. For the NER and TSA modules, we leveraged state-of-the-art models developed in our previous work "Medical Entity and Targeted Sentiment on COVID-19 Related Tweets (METS-CoV)" [22]. Details on model construction can be found in Figure S1 in the Multimedia Appendix 1.

Named Entity Recognition and Normalization

The NER model aims to extract drug entities from tweets. The model we developed, CT-BERT-NER (COVID Twitter with Bidirectional Encoder Representations from Transformers for Named Entity Recognition) [22], was constructed using the COVID-Twitter-BERT (CT-BERT), a widely adopted language model pretrained on 160 million COVID-19–related tweets. CT-BERT-NER was trained on the entire training set of the NER subset of METS-CoV [22]. Upon evaluation, it showed F_1-scores of 86.35% for drug entity recognition and 81.85% for symptom entity recognition on the corresponding test set, respectively [22]. We used the model trained on all entity types (ie, disease, drug, symptom, vaccine, person, location, and organization) instead of on drug entities only to enable the nuanced differentiation of drug entities from other types of entities.

To standardize colloquial expressions of drugs among the extracted entities, we manually searched Wikipedia for NER-identified drug entities with a frequency of more than 1000 to map colloquial drug expressions and their standardized concepts (ie, drug trade names, chemical names, and generic names). We conducted an accuracy assessment using a random sample of 100 tweets for each of the top 5 most frequently mentioned drugs and symptoms, as identified through 2 methods: NER combined with lexicon-based extraction (NER+lexicon) and lexicon-based extraction alone, with a total of 1000 tweets being manual review. Our results demonstrated that the NER+lexicon method achieved an accuracy rate of 97.8%, significantly surpassing the 89% accuracy achieved by the lexicon-only approach (χ^2_1=61.4, P<.001). Further details on this comparison are available in Table S1 in Multimedia Appendix 1.

Targeted Sentiment Analysis

The TSA module is designed to analyze users' sentiments toward specific drug entities within tweets. Inspired by BERT-SPC [30], we first concatenate the original tweet and the identified drug entity, separated by 1 special token "[SEP]," to

XSL•FO
RenderX

form a combined tweet-entity sentence. The tweet-entity sentence is then fed into a pretrained language model to capture semantic features, which are subsequently passed to a linear layer for 3-class sentiment prediction (positive, neutral, or negative). Notably, instead of using the original BERT model, we used CT-BERT, which has been further trained on 97 million COVID-19–related tweets. This adaptation enhances its understanding of COVID-19–related tweet data [22]. Therefore, although there existed several sentiment-specific embeddings and pretrained models [31-34], we chose the pretrained CT-BERT model as it was trained to understand COVID-19–related tweets. On the TSA test set of METS-COV, the model achieved an F_1-score of 62.67% and an accuracy rate of 75.07% across 4 entity types: person, drug, disease, and vaccine. For our own TSA study, we randomly selected 100 drug-related tweets and assessed their emotional orientation toward drug entities using both model predictions and manual review by a researcher with medical expertise. The results indicated that the model's accuracy, when compared to manual review, was 77% (77/100), aligning closely with the TSA model's original accuracy of 75.07%. Furthermore, both our hand-labeled fine-tuned dataset (METS-CoV) and the final applied dataset (169,659,956 drug-related tweets) were derived from the same source, ensuring the reliability and credibility of the predictions.

Topic Model Analysis

To discern prevailing public interests in the most discussed drugs, we implemented latent Dirichlet allocation (LDA) for topic modeling, using the LdaModel function from the Gensim package [35]. Topic numbers were determined based on conventional evaluation metrics, including low perplexity [36] and high coherence scores [37]. Detailed methodologies are delineated in Figure S2 in Multimedia Appendix 1.

Drug Network Analysis

To illustrate potential relationships among drugs, we constructed a drug network analysis module to generate incidence matrices according to a previous study [38] and visualize co-occurrence networks using Gephi [39] and ForceAtlas2 algorithm [40]. For enhanced comprehensiveness, we incorporated a variant supported by the Anatomical Therapeutic Chemical classification system (ATC) [41], in addition to the Gephi-based visualization. In addition, we used the NER model to extract symptom entities and normalize them through a presummarized lexicon list [42] to extend our analysis to drug-symptom networks. The constructed networks feature nodes represented drugs (Table S3 in Multimedia Appendix 1) or symptoms (Table S4 in Multimedia Appendix 1). Node sizes displayed node degrees (ie, the number of linked entities). Edge weights denoted the cosine similarity score of 2 linked nodes. As our focus is not on causal relationships but rather on the interplay between entities, we used undirected graphs and semantic cosine similarity [43] as the distance metric just as we did in the previous work [38]. Cosine similarity is a widely implemented metric in information retrieval and related studies [44]. In our study, each drug or symptom entity can be represented as a vector, with each dimension of the vector corresponding to 1 tweet text. Details for calculation can be found in Methods in Multimedia Appendix 1.

Pipeline Deployment

Upon completion of the NLP pipeline, we proceeded to its deployment on the preprocessed dataset of COVID-19–related tweets. We first applied the NER and normalization module on the preprocessed dataset (ie, removing URLs) to extract and standardize drug entities to drug concepts. Then we filtered the preprocessed COVID-19–related tweets dataset to get the drug-related tweets dataset according to these drug concepts. Following this standardization, we conducted a distributional analysis of drug mentions to discern time trends, thereby capturing the evolving popularity of these drugs. We also gather related news and the trend of weekly new COVID-19 cases to show a more holistic view of the shift in drug popularity over time. For clarity and simplicity, we only illustrate the top 5 most discussed drugs.

Subsequently, we used the TSA model for drug-related tweets of the top 5 drugs mentioned above to assign each drug entity a sentiment type. To gain a deeper understanding, we also conducted a time-trend analysis on the positive and negative tweets for the 5 drugs and visualized the results. Building upon our understanding of public sentiment, we turned to topic modeling via LDA in all drug-related tweets to explore the thematic concentrations in the discourse surrounding drugs. The model yielded the 20 most probable keywords and bigrams for each identified topic, enabling us to summarize the primary themes. We further analyzed the topic distribution associated with each of the top 5 drugs.

Finally, we constructed co-occurrence networks for drug-drug and drug-symptom interactions to provide a relational overview that complements our earlier analyses. All 67 drugs with more than 1000 mentions and 69 symptoms with more than 250 mentions over time were included in the analysis. Meanwhile, we also zoomed in to analyze the 5 most-discussed drugs.

Statistical Analysis

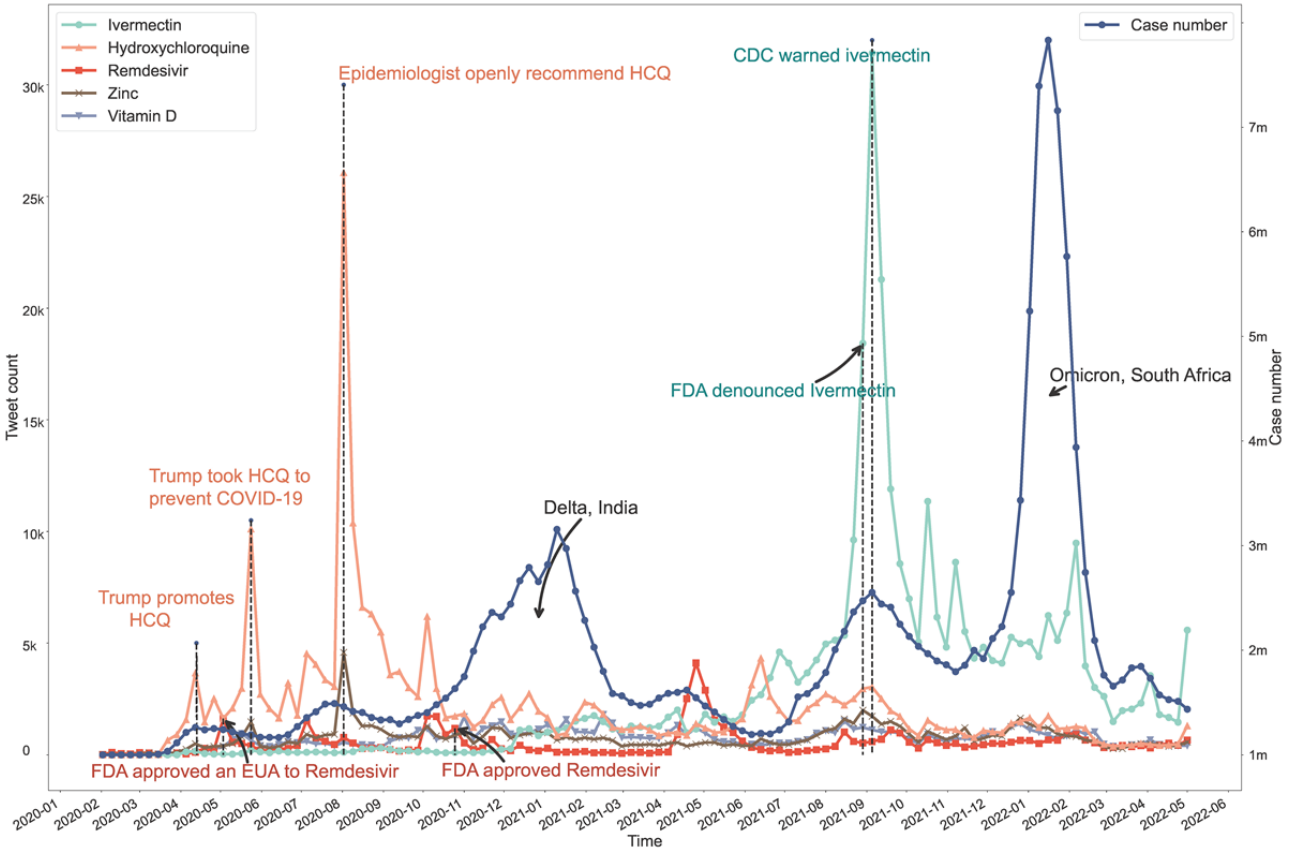
The chi-square test was used to compare the accuracy differences between NER combined with lexicon and lexicon-based only. We used Python software (version 3.8) to conduct the statistical analyses and chose a P value of .001 as the statistically significant threshold.

Ethical Considerations

Ethical approval for this study was granted by the Institutional Review Board of School of Public Health, Zhejiang University (ZGL202201-2).

Results

Data Summary and Trends of Drug Mention Tweets



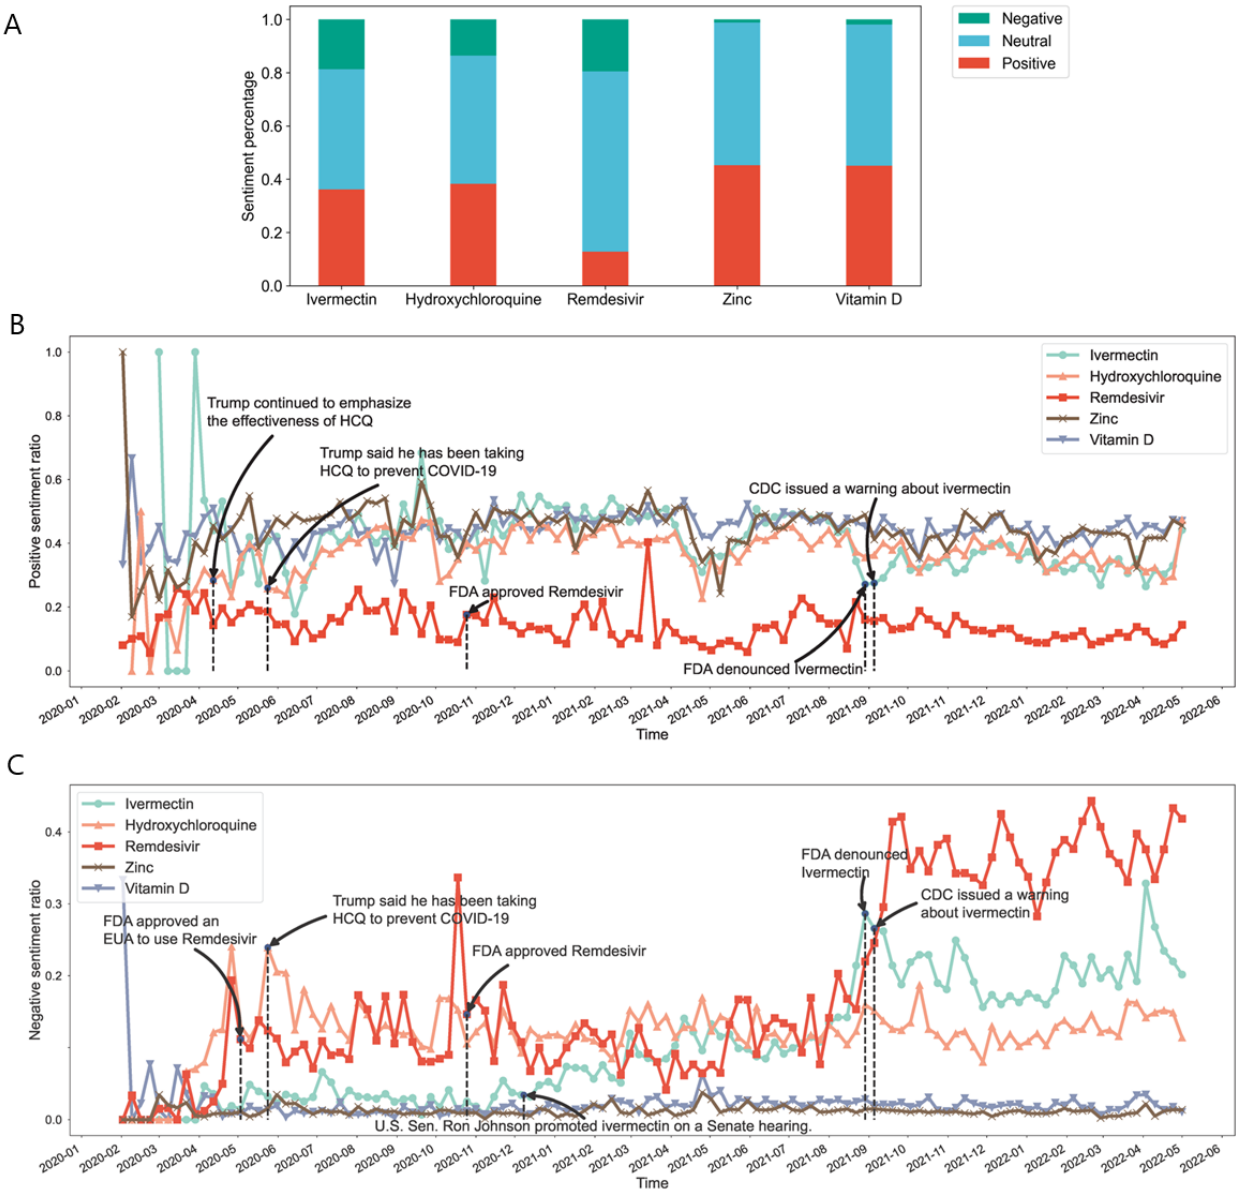
This study used a dataset consisting of 471,371,477 COVID-19–related tweets in English, which were collected between February 1, 2020, and April 30, 2022. After excluding tweets containing URLs, the final dataset used for this study consisted of 169,659,956 (36.0%) tweets from 103,682,686 users. Using CT-BERT-NER, we identified 2,124,757

XSL•FO
RenderX

drug-related tweets from 1,800,372 unique Twitter users, accounting for approximately 1.25% of the raw COVID-19–related tweets dataset. Table S2 in Multimedia Appendix 1 provides more detailed statistical results of the medical entity recognition.

Table S3 in Multimedia Appendix 1 presents the 67 most frequently mentioned drugs, each with an occurrence exceeding 1000 times. The most frequent taxonomies are ATC [41] N (nervous system drugs) and J (anti-infective drug). We ranked the total occurrence of all drugs and identified the top 5 most-mentioned drugs: ivermectin, hydroxychloroquine, remdesivir, zinc, and vitamin D to visualize their weekly time trends. Figure 2 presents these temporal trends. The new case counts were collected from the World Health Organization (WHO) [37] on a weekly basis, beginning on February 1, 2020. Given that the dataset is confined to English-language tweets, the scope of new case counts was likewise restricted to the top 4 English-speaking nations with the highest Twitter activity: the United States, the United Kingdom, the Philippines, and Canada [38].

Figure 2. Weekly popularity trends of the top 5 most-mentioned drugs on Twitter examined with COVID-19–related tweets collected between February 1, 2020 and April 30, 2022. The left Y-axis represents the total number of tweets for each drug in a given week (unit: thousand tweets). The right Y-axis represents the weekly new case count (unit: million cases). CDC: Centers for Disease Control and Prevention; FDA: Food and Drug Administration; HCQ: hydroxychloroquine.



Among the 5 drugs, the public focused mostly on repurposed drugs (ie, hydroxychloroquine and ivermectin), followed by daily supplements (ie, zinc and vitamin D). The only officially approved drug among the 5, remdesivir, received the least attention. The frequency of discussion of hydroxychloroquine and ivermectin fluctuated significantly across time, which seemed to be related to relevant news events or policies (marked in Figure 2). In the early stage of the pandemic, drug-related discussions focused on hydroxychloroquine, with 2 prominent peaks occurring on May 24, 2020, and August 2, 2020. Discussion of ivermectin began to increase in the later stages of the pandemic, with only 1 prominent peak located on September 5, 2021. In contrast, remdesivir received the least public attention, which increased only sporadically throughout the pandemic, with no apparent pattern and a much lower peak on May 3, 2020. As supplements to COVID-19 treatments, vitamin D and zinc elicited much less public interest than ivermectin and hydroxychloroquine, with no significant outbreaks or visible patterns.

Changes in Sentiment for Five Most Frequent Mentioned Drugs

We calculated the sentiment proportion for the 5 drugs and the weekly time trends of positive and negative tweets. Figure 3A shows the visualization of the overall attitude proportions. The public tended to hold positive and neutral attitudes toward the repurposed drugs, ivermectin and hydroxychloroquine. The immune supplements, zinc and vitamin D, were frequently mentioned with positive sentiments. The only COVID-19 drug approved by the Food and Drug Administration (FDA), remdesivir, received the lowest positive attitude, far lower than those of the other drugs.

XSL•FO
RenderX

Figure 3. Sentiment analyses of the 5 top-discussed drugs from February 1, 2020, to April 30, 2022, grouped according to their polarity, including (A) sentiment distribution, (B) weekly ratio of positive tweets, and (C) weekly ratio of negative tweets. The denominator of the percentage was the entities with sentiment. CDC: Centers for Disease Control and Prevention; EUA: emergency use authorization; FDA: Food and Drug Administration; HCQ: hydroxychloroquine.

Figures 3B and 3C present weekly trends of tweets expressing positive and negative attitudes, respectively. The major turning points of the trends tend to coincide with new government policies, major social events, and research findings. The criticism of remdesivir (Figure 3C) and ivermectin increased over time since September 2021, and the turning point for remdesivir came at almost the same time as emerging studies showing that the drug is ineffective [45] and has severe side effects [46-48]. For ivermectin, public sentiment was associated with announcements of health authorities and celebrity effects. For example, the FDA denouncing the use of ivermectin for COVID-19 on August 29^{t}, 2021 had simultaneously increasing negative discussions.

Topic Distributions of Drug-Mentioned Tweets

We applied the LDA topic model to all 2,124,757 drug-related tweets and obtained 15 general topics based on their relatively high topic coherence scores and low confusion levels (further discussed in Figure S3 in Multimedia Appendix 1). We displayed the corresponding top 20 most likely keywords in Table 1 and assigned a theme for each topic from these keywords. The topic "clinical treatment effect of drugs" included 288,967 related tweets and dominated the discussions, accounting for 13.6% of all related tweets. In addition, 251,571 (11.84%) were related to "physical symptoms," whereas 220,125 (10.36%), 197,177 (9.28%), 174,868 (8.23%), 172,955 (8.14%), and 154,470 (7.27%) were related to "COVID-19 control," "causes of death," "general treatment," "immune response," and "daily supplement intake." In addition to the overall topic

XSL•FO
RenderX

summary, we explored the distribution of the 15 topics for the 5 drugs. Figure 4 shows a visualization of the distribution. For ivermectin, the prominent theme was “immune response.” In contrast, discussions of remdesivir centered on “hospital care.” Hydroxychloroquine received relatively even attention among the 3 topics “causes of death,” “drug scare,” and “COVID-19 control.” Vitamin D was frequently mentioned in tweets about “daily life,” and the main topics about zinc focused on “hospital care” and “COVID-19 control.”

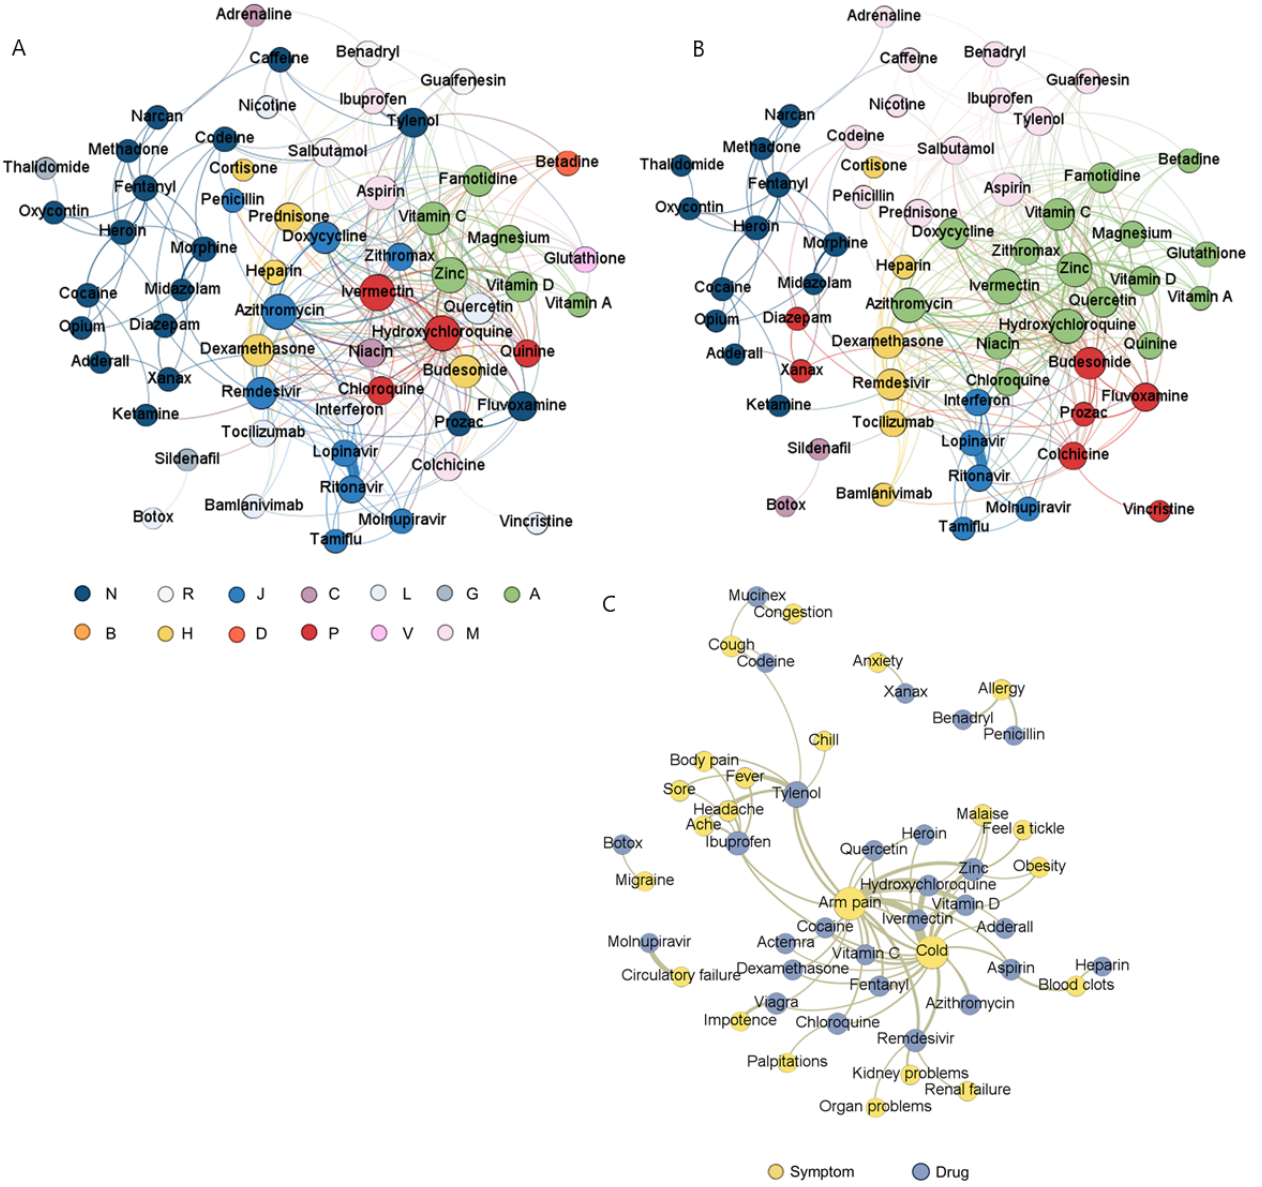
Public health care	report, support, health, public, supplement, question, kid, child, datum, stage, issue, american, answer, term, prophylactic, mental, phase, safety, concern, inflammation	"@USER[a] Then, even hcq, zinc, and zithromax had a estimated 50% success and the CDC and WHO said it didnt, so it shouldnt be used. Imagine half of the death tolls because of at least TRYING something instead of shitcanning it just because you are an "authority" that hates Trump."	48,232 (2.27%)

[a]Username and other sensitive information were masked off using @USER. Public figures such as @realdonaldtrump are shown in their usernames.

Figure 4. Topic distribution of 5 top-discussed drugs.



Co-Occurrence Networks

We visualized the co-occurrence network for drug-drug and drug-symptom relations in Figure 5. The nodes represented either drugs (as shown in Table S3 in Multimedia Appendix 1) or symptoms (as shown in Table S4 in Multimedia Appendix 1). The size of each node corresponded to its degree, which referred to the number of connections it has. The weights of the edges indicated the cosine similarity score between two connected nodes.

XSL•FO
RenderX

Figure 5. Visualization of drug-related co-occurrence networks by Gephi, including (A) drug-drug associations based on Gephi clustering (τ=0.005), (B) drug-drug associations based on ATC (τ=0.005), and (C) drug-symptom associations (τ=0.05). The color dots on the lower right of the figure represent the ATC categories for (B). ATC: Anatomical Therapeutic Chemical classification system.

Drug-Drug Network

The origin drug-drug network contained 67 drugs (nodes) with more than 1000 mentions and 1103 relations (edges) among them. A predefined similarity threshold (τ) was established to only visualize relationships with substantial co-occurrence, as measured by cosine similarities exceeding τ. After filtering it with a τ of 0.005, 62 drugs and 317 relations remained in the network. By using the Fast Unfolding (Louvain) algorithm built in Gephi for modularity classification [49], the drugs were clustered into 5 categories and were colored in Figure 5A. The same network with drugs colored by ATC classification (12 types) was shown in Figure 5B for comparison. Drugs in the same group are denoted with the same color. Both figures share similar clustering characteristics, especially in psychotropic drugs ATC-N (Anatomical Therapeutic Chemical classification system, psychotropic drugs; eg, fentanyl, opium, and morphine) and anti-infectious agent ATC-J (Anatomical Therapeutic Chemical classification system, anti-infectious agents; eg, lopinavir, ritonavir, and azithromycin). However, drugs in the ATC-P (Anatomical Therapeutic Chemical classification system, antiparasitic drugs) group (ie, ivermectin, hydroxychloroquine, quinine, and chloroquine) are clustered with the ATC A group in Figure 5A. The reason may partially lie in the fact that most parasites are intestinal [50], so most people who need to take antiparasitic drugs (ie, ATC-P drugs) often present concomitant digestive manifestations [51], thus necessitating the use of digestive medications (ie, ATC A drugs), therefore the 2 drug groups are closely related. Association between some of the significant drug-drug pairs like 2 HIV protease inhibitors ritonavir and lopinavir has been widely studied [52]. In addition, through the co-occurrence network, we observed several unusual drug pairings, such as midazolam and morphine, salbutamol and prednisone, and zinc and quinine. These strong

XSL•FO
RenderX

co-occurrences suggest potential unexplored synergistic effects, adverse reactions, or other public health concerns that warrant further investigation. For instance, we noted a distinct correlation between morphine and midazolam, drugs not typically combined in direct COVID-19 treatment. An analysis of all 376 tweets mentioning both drugs revealed that most discussions focused on end-of-life management for patients with COVID-19 and on conspiracy theories about the intentional misuse of these drugs, leading to deaths attributed to causes other than COVID-19 infection.

Drug-Symptom Network

The original drug-symptom network had 136 nodes (ie, 69 drugs and 67 symptoms) and 3099 edges. After filtering by τ of 0.05, 50 nodes and 71 edges remained and are shown in Figure 5C. We observed that the edges often represented symptoms and corresponding treatments, such as Tylenol for fever medication, suggesting the reliability of our association network. We also observed some side effect relations, such as remdesivir to acute kidney failure [46] and some novel associations receiving no clinical investigation like molnupiravir to circulatory failure, cocaine to chest cold, and vitamin D to malaise. We visualized the top 10 closest drugs and symptoms with co-occurrence relationships to the 5 drugs under investigation (Figure S4 in Multimedia Appendix 1). These networks revealed the great relevance between hydroxychloroquine, ivermectin, and azithromycin from each other. Furthermore, remdesivir was also significantly associated with dexamethasone and tocilizumab.

Discussion

Principal Results

Leveraging new advances in NLP, we constructed a pretrained language model driven by the drug entity recognition model and a new targeted sentiment analysis model for the polarity prediction of target drugs. Based on over 2 years of relevant data, our comprehensive NLP pipeline demonstrates advanced accuracy and completeness in collecting and analyzing data for social media-based drug studies. Our NER model identified the top 5 most-discussed drugs and sentiment and topic analysis revealed that public perception concerning these drugs was predominantly shaped by celebrity endorsements, media hot spots, and governmental directives rather than empirical evidence of drug efficacy. Furthermore, network analysis identified emerging patterns of DDI and ADR (ie, molnupiravir to circulatory failure) that could be critical for public health surveillance like better safeguarding public safety in medicines use. Our pipeline is open-sourced and it can serve as a comprehensive tool to enhance drug safety control, provide crucial guidance for formulating drug usage policies, and support public health decision-making after the outbreak of infectious diseases.

Compared with traditional pharmacovigilance research, the study of drug-related information on social media exhibits distinctive characteristics and advantages. Social media platforms offer real-time and immediate data, enabling the rapid reflection of drug usage patterns and patient feedback, facilitating the prompt identification of potential risks and benefits [53-55]. Furthermore, social media captures the viewpoints and experiences of patients, thus furnishing critical insights for the formulation of patient-centered care [56,57]. For example, understanding patient's preference for drugs and disease burden can improve drug development strategies, enabling pharmaceutical companies to better focus on specific drugs that meet patient needs and preferences [58]. In contrast to previous COVID-19 social media studies [59-62], this work extracted more rigorous data covering a more extended study period and identified the five most discussed drugs to be investigated through a fully data-driven method. The substantial volume of social media data allows for large-scale real-time dynamic analysis, and it also covers a broader population than electronic health records, which are confined to hospitalized individuals and have restricted access [63]. Social media datasets could also provide large-scale samples for the detection of rare events and the examination of specific population responses, which are challenges in electronic health records–based analysis.

Sentiment analysis on drugs can highlight patient misconceptions and disagreements about a specific medication, enabling pharmaceutical companies and public health agencies to address public anxiety and reduce misinformation about drugs. Our results confirmed findings from Hua et al [59] that the public concern and polarity for ivermectin and hydroxychloroquine, which received the most social media attention, are highly correlated with emotional and political factors, such as personal political orientation, presidential elections, and conspiracy theories. For instance, there was a surge of approximately 200% in acquisitions of medication alternatives such as hydroxychloroquine within 2 days after the press briefing conducted by Donald Trump on March 19, 2020 [3]. The topic distribution indicated possible effects or side effects of ivermectin on the immune system and the wide in-hospital treatment use of remdesivir, but the sentiment analysis showed most opposing stances toward remdesivir which climbed significantly as the crisis unfolded. It was due to shortages, emergency needs, inefficiency [64], and potential side effects of remdesivir like bradycardia [65], and increased risk of hepatic, renal, and cardiovascular reactions [66,67]. Some people even hyped up on Twitter that remdesivir was approved solely for the purposes of reaping big profits for Anthony Fauci and the democidal cabal that he fronts, bilking the taxpayers of billions, and all while quietly euthanizing an unwitting public. Furthermore, we also found that daily supplements like zinc and vitamin D did not attract much public attention, but their immune-enhancing properties make them significantly more commended by the public than the other three drugs, especially remdesivir.

Analyzing social media data helps identify patterns of drug abuse, adverse reactions, and epidemics, thereby improving health policy planning and resource allocation to address emerging challenges [68,69]. For example, social media plays a pivotal role in addressing drug-related outbreaks and trends, enabling policy makers to respond swiftly and enhance public safety. Its interactive nature fosters direct engagement with the public, allowing policy makers to better understand community needs and concerns. Since public trust in policy makers is critical, for instance, the successful promotion of drugs and

XSL•FO
RenderX

vaccines relies heavily on public confidence [70,71], tracking public sentiment through social media in real time enables policy makers to align policies with public attitudes, so as to increase their acceptance and effectiveness. In addition, this approach helps in combating misinformation about drugs and vaccines [72]. For public health agencies, timely monitoring of drug-related concerns on social media is especially crucial when managing new drug candidates during pandemics. Specifically, our pipeline allows for real-time monitoring of public opinion on social media, which can be an important tool for public health agencies and organizations to implement clear communication plans, physical and mental health interventions, and a coordinated emergency response [73,74]. It could also help conduct rapid and dynamic screening of special populations [60] during public health emergencies, enable targeted communication [75], and combat public health misinformation [72,76].

Our work found that Twitter discussion topics of drugs during the COVID-19 pandemic were consistent with relevant studies focusing on non-drug COVID-19–related topics [25,77,78]. Similar to them, this study uncovered public concerns about "public health measures" and "treatment and recovery." In addition, by focusing on drugs, we discovered new drug-specific concerns, such as "drug panic" and "immune response." The focus on "drug panic" may reflect societal uncertainty and anxiety about drug use during the epidemic. Understanding these anxieties can be instrumental in enabling mental health professionals and policy makers to take measures to support mental health and implement interventions to alleviate anxiety. Care about the "immune response" may be indicative of public concerns about the immune system, including vaccines and immunotherapies. This can help health agencies better communicate information about vaccinations and immunization support to increase public awareness of immunization.

Many previous studies aimed to detect potential DDI and ADR from social media [79-81] or online literature [82] but largely depended on external vocabulary for keyword-matching and little visualization was performed. This study used advanced pretrained language models to identify drug mentions and classify the corresponding sentiments from social media text, ensuring the accuracy of information extraction and sentiment prediction. As the pretrained language model is the main NLP structure in our pipeline, it can be easily extended by integrating better large language models (LLMs) [83-85] that have a similar deep learning network structure but with larger parameters, given enough computational resources. The visualization module could illustrate associations between drugs, drug-symptoms pairs, and possible clusters or patterns intuitively and clearly, making it easier for researchers to understand and interpret the findings for DDI and ADR [86]. In addition, our co-occurrence network analysis found many widely studied drug-drug and drug-symptom pairs which could verify the reliability of network analysis. The clustering results are consistent with the classification of the general clinic (ie, ATC) to a certain extent, such as the similar clustering characteristics in psychotropic drugs (ie, ATC N) and anti-infectious agent (ie, ATC J), suggesting its potential to capture similarities and associations between drugs. Notably, we also found many drug pairs with not widely examined associations, such as zinc and quercetin. Their complex (Q/Zn) is considered a potential new drug therapy for improving glycemic control and pulmonary dysfunction in diabetes mellitus [87], which needs to be further investigated. We found new drug-related associations, such as rheumatoid drugs (hydroxychloroquine, dexamethasone, etc.) may affect COVID-19 treatment due to drug repositioning. For these novel drug-drug and drug-symptom pairs, researchers interested in further exploration may undertake additional studies, such as cross-study analyses using multiple data sources or more detailed quantitative studies. We expect studies could examine the novel associations and provide more robust evidence in future work. Furthermore, networks of the top 5 drugs revealed the significant associations between them such as the co-medication of ivermectin, hydroxychloroquine, and azithromycin for COVID-19 infection. Our network analysis also indicated the combination of remdesivir and tocilizumab or dexamethasone, and a randomized controlled trial showed their efficacy for the treatment of severe COVID-19 infection [88-90].

In essence, the use of NLP techniques and network analysis in our pipeline to analyze vast amounts of social media data is an emerging research approach in pharmacovigilance [91,92]. It holds immense potential in various areas such as the monitoring of ADR, the analysis of drug usage trends, the prediction of epidemics, and the evaluation of drug treatment effects. This novel method could serve pharmaceutical firms, regulatory agencies, and the health care fields with more precise and timely information to enhance their efforts in safeguarding public health.

Limitations

Certain limitations apply to this study. First, social media users can't represent the general population. For example, Twitter users in the United States are younger, more democratic in their political affiliations, and the most prolific 10% of users create 80% of tweets [93] and older people with lower socioeconomic status may have limited access to social media [94], which may result in bias of our observations. The specific events, geographical contexts, and the dynamic nature of social media usage may also influence the observations. Second, although we tried to automate the information extraction with deep learning, we still relied on an empirical lexicon to cluster different concept representations. This allowed us to effectively reduce false positives but not to avoid false negatives. Third, manual checks for symptom recognition suggested that approximately 2%-3% of the tweets may still be false positive (eg, lexical ambiguity like an American fever dream), which would lead to fake associations, despite the combination of rigorous rules and advanced NLP models based on deep learning. Data accuracy, as well as the reliability of the network analysis, are also limited by the authenticity of social media data and the influence of noisy information and misinformation. However, the primary advantage of social media information is its vast scale and timeliness, which offers opportunities for advancing valuable research directions, such as identifying novel drug interactions. Finally, due to the relatively low accuracy of the TSA module (ie, 75.07%), future work should

XSL•FO
RenderX

develop more effective NLP solutions to facilitate opinion mining.

Comparison With Previous Works

Hua et al [59] used BERT models to examine public perceptions of approved and off-label medications for COVID-19 infection and found these perceptions to be heavily skewed by misinformation and biases. However, the study suffered from methodological limitations, including a narrow and subjectively chosen selection of drugs, manual lexicon-based extraction, and a small time span. Similarly, Wu et al [38] made the very first attempt to construct co-occurrence networks to study symptoms during COVID-19 infection, but their technique was solely based on lexicon matching. Both of them relied solely on lexicons for extraction and, as a result, suffered from insufficient accuracy and a lack of generalizability. In contrast, this study combined advanced deep learning models with lexicon-match to improve the accuracy of entity recognition and sentiment analysis, creating a comprehensive and generalized pipeline to streamline information tracking in public health emergencies.

Conclusion

Our study proposed a pipeline of using social media data and NLP techniques to mine potential drug information, timely track drug-related hot events, facilitate public health stakeholders to conduct reasonable policy enactment, monitor drug public opinion, and avoid malignant events during a public health emergency period. In addition, it can supplement the existing ADR and DDI databases by constructing multiple medical entity co-occurrence networks to provide real-world clues for future research. Our framework applies not only to the COVID-19 pandemic but also to other periods of epidemics or major social events. It can also target other public health care foci such as vaccination.

Data Availability

Due to the privacy restrictions of Twitter, only tweet IDs can be released. Tweet IDs can be obtained from https://github.com/echen102/COVID-19-TweetIDs. The source code and pipeline tutorial of this paper are available at https://github.com/zju-liwanxin/covid-twitter-drug. Datasets and models for NER and TSA models are publicly available at https://github.com/YLab-Open/METS-CoV. All codes are based on Python software (version 3.8) and the NER, and TSA models are developed by PyTorch (version 1.0).

Authors' Contributions

JY, WL, and XX designed the study. WL and JY drafted the manuscript. JY is the senior author. YH collected the data and drafted and revised the manuscript. WL performed data and statistical analysis. PZ built the NER and TSA models. LZ provided critical reviews. All authors reviewed the manuscript. WL takes responsibility for the integrity of the work.

Conflicts of Interest

Abstract

Background: The COVID-19 pandemic necessitated the rapid development and implementation of health ITs to support health care delivery. Health IT implementation is difficult at the best of times, due to complex sociotechnical challenges that vary across contexts and settings; however, it is currently unclear how the pandemic impacted health IT implementation processes. The aim of this study was to explore the impact of the pandemic on health IT implementation processes, including pre- and postimplementation phases, and identify the sociotechnical factors that shaped health IT implementation during an unprecedented circumstance.

Objective: This study aimed to explore the impact of the pandemic on HIT implementation processes, including pre- and postimplementation phases, and identify the socio-technical factors that shaped health IT implementation during an unprecedented circumstance.

Methods: Participants were from one of two teams: (1) health care staff members (doctors, nurses, nurse unit managers, and support staff members) from a virtual hospital in Australia; and (2) IT professionals within the broader health care organization assigned to the hospital. Participants took part in an interview or focus group from July to November 2022. Participants were asked to describe the process used for rapid health IT design and implementation during the COVID-19 pandemic. Qualitative data were analyzed thematically.

Results: A total of 15 participants took part in the study. Both internal and external team structures, and the communication pathways that underpinned these, were reported to influence the health IT lifecycle, which in turn impacted outcomes, particularly when perceived normal ways of working were challenged during the pandemic. Across the pre-post lifecycle, preimplementation processes were viewed to be most impacted by the COVID-19 pandemic. Participants reported that their roles and responsibilities changed during health IT implementations in the pandemic, impacting co-design processes and highlighting the need for health IT implementation processes to cater for new work and the redistribution of existing work.

Conclusions: Our study uncovered the negative impact of the COVID-19 pandemic on team structures, communication pathways, and health IT preimplementation processes (project management and co-design). While health care organizations are keen to transition beyond the ways of working during the pandemic, it is imperative to learn from the health IT implementation successes and failures that occurred in the pandemic via process evaluations. Our evaluation offers learnings for research (an adapted interdisciplinary team communication framework), practice (the need for health care organizations to review their communication

XSL•FO
RenderX

structures, IT staff skills, and proposed processes), and education (the need for better education and training of IT professionals working in clinical settings on health concepts) on health IT implementations as the world transitions to the "new norm."

Introduction

The implementation of health IT to improve safety, quality, and efficiency in health systems is increasing globally, more so during the COVID-19 pandemic [1-3]. However, health IT implementations are notoriously difficult due to complex sociotechnical challenges, which vary across contexts and are often hard to navigate and envisage for those managing change [4]. Despite significant efforts to identify and apply the sociotechnical factors that enable successful health IT implementations, this remains an ongoing challenge [5]. One reason for this may be that the commonly used approach to evaluate existing health ITs tends to focus on assessing each aspect of the health IT implementation, rather than using a "whole of system" approach [6]. As new health IT implementations can learn from the evaluation of existing health ITs, there is a strong need for comprehensive evaluations that transcend a disease focus or preliminary adoption, to provide in-depth insights into the various sociotechnical factors that enable successful health IT implementations.

The Technology, People, Organizations, and Macro-environmental factors (TPOM) framework [5] is one model that provides a comprehensive understanding of the socio-technical factors impacting health IT implementations using a "whole of system" approach. TPOM has been used to evaluate a large-scale health IT implementation for the National Health Service [7] before the COVID-19 pandemic, and other health IT implementations in Europe and United States during the pandemic [8]. Unlike other health IT implementation frameworks [9], the TPOM framework is neither illness-specific, nor focused on the likelihood of adoption or spread, but considers both the microcontext of use and macroenvironmental dimensions that impact all stages of implementation [5]. Therefore, we use the TPOM framework as a lens to consider the gaps in evidence regarding the impact of the pandemic on key sociotechnical factors, across the four TPOM domains, that shape the outcomes of health IT implementations.

From a technology use perspective (TPOM domain 1), diverse health systems have leveraged health ITs in response to the COVID-19 pandemic. This has included the development of new devices and applications for remote consultations to minimize transmission of infection, and mobile apps to monitor vital signs data [1]. These health IT implementations experienced mixed success and highlighted that many technology-driven challenges (eg, data sharing across systems) present in the prepandemic times were perpetuated, and potentially magnified, during the pandemic and postpandemic "new-normal" times [10]. Furthermore, these challenges may impact the pre-post-implementation lifecycle, including perpetuating interoperability challenges [10]. However, little is currently known about the impact of the pandemic on these technology-driven challenges across the pre-post implementation lifecycle.

With people at the core of health IT implementations (TPOM domain 2), effective stakeholder engagement including collaboration between clinicians and IT staff is key [11,12]. However, the divide that exists between these 2 groups, such as communication challenges and different viewpoints on system performance and usability, has been well-documented [13-16]. The health system's response to the pandemic was not limited to clinical care delivery, and virtual stakeholder engagement sessions in the context of health IT implementation became increasingly common to support rapid policy changes and social distancing guidelines [17]. As such, the use of flexible locations enabled more efficient use of clinician time in supporting the design and implementation of health ITs [10,18]. While it may be likely that greater use of virtual sessions, rather than face-to-face sessions can exacerbate the clinician IT divide, the impact of virtual engagement on health IT implementations since the pandemic has not been evaluated.

Health service organizations (TPOM domain 3), in response to the COVID-19 pandemic, increasingly aimed to become "learning health systems" intent on learning from what worked and what did not work during pandemic-driven health IT implementations, in an effort to transition to the "new-normal" [19,20]. Despite this intention, there have been limited process evaluations of health IT implementations in real-world health service organizations that span across the pre-post implementation phases, particularly in virtual hospitals. Virtual hospitals substitute in-person consultations with telephone or video consultations and often include asynchronous data collection from the patient via survey tools with or without real-time remote monitoring [21].

The macroenvironmental context (TPOM domain 4) during the COVID-19 pandemic placed unprecedented time pressure on health IT implementations, and other pressures on health care services [1,22]. Yet, the impact of the COVID-19 pandemic on the technology, people, and organizations involved in health IT implementation has not been evaluated.

This study set out to address the identified gaps in literature and knowledge across the 4 TPOM domains highlighted above by interviewing stakeholders involved in rapid implementations of health IT during the pandemic. In particular, we aimed to explore the impact of the pandemic on health IT implementation processes, including pre- and postimplementation phases, and identify the sociotechnical factors that shaped health IT implementation, to guide future successful implementations of health IT.

Methods

Study Design

This was a cross-sectional qualitative study. As a qualitative study design is appropriate for providing insights into people's experiences of a complex phenomenon or activity [23], we conducted semistructured interviews to explore participants' experiences. The COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist was used to report the study (Multimedia Appendix 1).

Setting and Recruitment

This study was conducted at a virtual hospital in Australia from July to November 2022. The virtual hospital was equipped with care pods (workspaces) with videoconferencing, telephone facilities, an electronic medical record, and used remote monitoring tools such as wearables, mobile apps, and dashboards. The majority of the videoconferencing and remote monitoring tools were simultaneously implemented during the COVID-19 pandemic. Although multiple teams were involved in health IT implementation at the study site, this study focused on the interdisciplinary relationship and communication processes between clinicians and IT teams. Both teams are part of the same health service but not colocated within the same building.

Using purposive sampling, all clinical (ie, doctors, nurses, and nurse unit managers) and nonclinical staff members from the virtual hospital were invited by email to participate in interviews based on their involvement in health IT implementations, as identified by a clinician-researcher team member who works at the virtual hospital. Participants were eligible for purposive sampling if they were (1) either doctors, nurses, nurse unit managers, or nonclinical support staff members, and (2) took part in any pre or postimplementation activity in health IT implementations at the virtual hospital since the hospital's establishment in March 2020. We conducted semistructured interviews and a focus group discussion to collect qualitative data. Due to scheduling constraints and the limited time availability of participants, we conducted a focus group discussion when individual interviews were not possible.

Data Collection Procedure

The interview questions were broadly guided by the TPOM framework (Multimedia Appendix 2). Participants were asked to describe the process used for rapid health IT design and implementation during the COVID-19 pandemic and to reflect on aspects that worked well and those that did not. Except for one face-to-face interview, other interviews and the focus group were conducted online. For the focus group discussion, participants were fully informed about the data confidentiality responsibilities of both the researchers and the participants and the necessary housekeeping rules. The moderator (AB-A) asked open-ended questions throughout the session to allow participants to share information they were comfortable with and prompted those who spoke less frequently to contribute to the discussion to ensure inclusivity and diversity of voices using probing techniques, tracking of questions for completion, in line with existing research [24]. Data collection ended when no new information emerged, and saturation was achieved. All sessions were recorded and transcribed verbatim. The sessions were conducted by AB-A, a postdoctoral researcher experienced in qualitative research and health IT implementations, and she had no previous relationship with the participants.

Data Analysis and Interpretation

Deidentified transcripts were thematically analyzed independently by 2 researchers (ABA and MB), who first identified and coded the transcribed data through inductive thematic analysis, using a data-driven approach to understand participants' experiences and perceptions [25,26]. Following this, the researchers mapped the identified codes to the interdisciplinary team communication framework of Kuziemsky et al [27] for assessing interdisciplinary teams through the exploration of sociotechnical and other factors that drive teamwork. The framework by Kuziemsky et al [27] is based on Donabedian's [28] meta-concepts of structures, processes, and outcomes, which posits that structures lead to processes, which lead to outcomes [28]. The framework by Kuziemsky et al [27] was selected to provide an understanding of the complex and nonlinear structures, processes, and outcomes involved in pandemic-driven health IT implementation as experienced by the 2 interdisciplinary teams (clinicians and IT staff).

Our analytical approach included data familiarization, coding, generating initial themes, reviewing potential themes, defining and naming themes, and producing the report [29]. Specifically, the 2 researchers (ABA and MB) familiarized themselves with the transcribed data by reading it multiple times before coding independently. After initial code generation, the researchers developed themes by merging codes with a shared meaning. Following this, the researchers reviewed the candidate themes to ensure coherent patterns were formed which contributed to the overall narrative and interpretation of the dataset. Finally, to ensure consistency and improve study rigor, the researchers discussed and reported the themes in relation to the dataset and the research aim. The 2 researchers met frequently throughout data collection and analysis to compare themes. Disagreement in themes was discussed until a consensus was reached. Emerging themes were presented to some participants and key stakeholders, and feedback received informed the final refinement of the themes.

Ethical Considerations

Ethics approval was obtained from the hospital's Human Research Ethics Committee (X21-0362 & 2021/ETH11708). Written informed consent was obtained from all participants, who were informed of their right to withdraw from the study at any time. The data presented in this article have been deidentified.

Results

A total of 15 participants took part in this study, one more person was invited but was too busy to participate. Out of 8 staff at the virtual hospital, including representation from clinical and nonclinical roles, and 7 staff from the IT department (refer to Table 1 for demographic details). The mean duration of the

XSL•FO
RenderX

interviews (n=11) was 58 (range 32-93) minutes and the focus group (n=4 participants) lasted 62 minutes.

Our findings are organized according to the meta-concepts of structures, processes, and outcomes. The concepts and subconcepts that emerged for each of these 3 meta-concepts are described using quotes from the data to illustrate examples of the concepts and subconcepts.

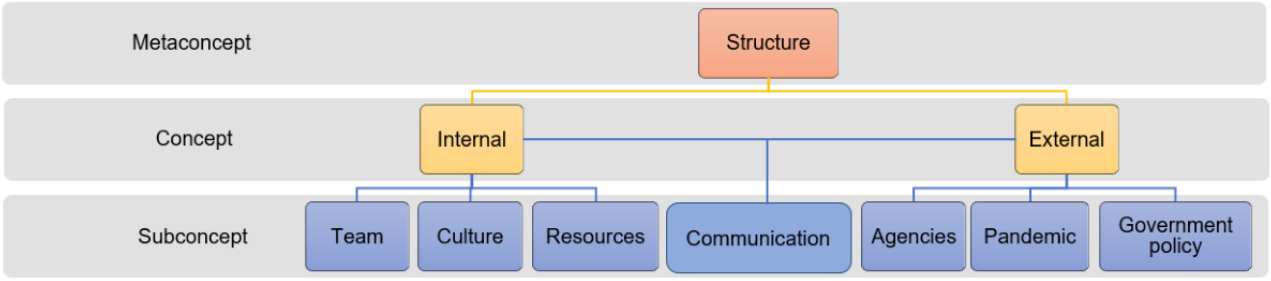

Table 1. Demographic characteristics.

Demographic characteristic	Values
Role, n (%)	
Nurse	2 (13)
Nurse unit manager	3 (20)
Doctor	2 (13)
Nonclinical	1 (7)
IT professionals	7 (47)
Team, n (%)	
Virtual hospital staff	8 (53)
IT staff	7 (47)
Years of experience, n (%)	
0-5	2 (13)
6-10	4 (27)
11-20	6 (40)
>20	3 (20)
Sex or sex assigned at birth, n (%)	
Male	4 (27)
Female	11 (73)
Age (years), mean (range)	41 (28-62)

Structure

Structure represents a meta-concept that describes how the virtual hospital organized their team, culture, and resources internally, and how it interacted with external entities via various communication pathways. Structure was therefore conceptualized as internal and external concepts with communication as a subconcept that enabled the relationship between the internal teams and external teams and agencies (Figure 1).

Figure 1. Ontology of concepts and sub-concepts for the structures of a health care organization during the COVID-19 pandemic.

Internal Structure

Internal structure describes how the team functions from within. Out of 3 main subconcepts describing the internal structure emerged from the data. These were team, culture, and resources. Culture and resources were described in relation to dynamics within each of the teams (clinician and IT).

Culture Within Clinician Team

The clinician team comprised doctors, nurses, and nurse unit managers. Within the clinician team, participants reported a culture that fostered the ability of staff members to adapt to rapid changes that frequently occurred during the pandemic.

> *So everyone is working very collaboratively for things to be implemented efficiently, but also quickly …And I think it's purely based on the fact that we got so used to it with the rapid changes with COVID. And*

XSL•FO
RenderX

> *we knew we had to adapt to the change very quickly.* [P005, clinician team]

Also, participants described strong leadership support for health IT implementations, particularly leadership willingness to receive and respond to staff members feedback.

> *I had a lot of experience working on the wards before this. And not much changed, really ever. You know, things really were kind of, this is the way it's done [but here] I think, they [executives] really listen to the feedback of staff and take that on board.* [P004, clinician team]

Culture Within IT Team

Within the IT team, participants reported a learning culture, with IT members reflecting on, and constantly, improving health IT implementation processes.

> *now we've stepped back and gone, hang on, let's just take some time to stop the crisis. Think about what our role is, educate [the clinician team], and give them a process that they can follow, and a process that can follow quite easily…Yes, we have that process now.* [P010, IT team]

Resources Within IT Team

Regarding operational resources, the IT team perceived that the clinician team appeared to have insufficient time to participate in the co-design of health ITs, although it was acknowledged that pandemic patient care is, and should be, their priority. For example, a participant said:

> *…the problem is time, they [clinician team] never have enough time.* [P010, IT team]

High staff turnover within the IT team was identified by participants as another resource concern impacting health IT implementations.

> *And we had people coming and going, so we had business analysts, stop starting. And then we had a six week period where we didn't have a business analyst and we were trying to develop workflow and testing and all of those things… it was a new project team from our side.* [Focus group, P013, IT team]

External Structure

External structure describes the influence of external agencies and factors on health IT implementation. Out of 3 influences were identified including the COVID-19 pandemic, vendors, and government policies.

COVID-19

The onset of the COVID-19 pandemic necessitated the rapid development of virtual health care services to help manage the large numbers of patients affected by the disease and mitigate the risk of shortage of hospital resources. Participants explained that this led to rapid COVID-19 management policy changes, but also unrealistic delivery timelines. The impact was seen to be rapid design without time for adequate reflection.

> *remember policy were changed and we have to roll it out within the week. So we were given one week to do [it]…which caused a lot of problems, because you didn't have time to think about downstream implications. And you really didn't have time to think about, you know what, there's good design required for this. It was just, 'here is what you need to meet, go on ahead and meet that'. So the design was very, very rapid. And it allowed no time to really review.* [P010, IT team]

Vendors

In the context of a virtual hospital where a variety of remote monitoring tools were rapidly and simultaneously implemented during the COVID-19 pandemic, internal teams said that they engaged with multiple vendors to deliver the required technologies. However, participants from the IT team reported that they were unable to themselves configure certain vendor products, which meant that simple configuration tasks were delayed. For example, a participant said:

> *Everything has to go back to the vendor. But that's also one of the features that we wanted to ask them that we could have is to for us to basically be able to configure it ourselves.* [P009, IT team]

Government Policy

Furthermore, it was perceived that the sustainability of the virtual hospital depended on the availability of supportive legislative policies. Participants reported that there was a need for policies to change to recognize virtual hospitals as a viable hospital system.

> *…a lot of systems are built around legislation. And the change in those legislations then mean, we're able to do what we want to do. Because at the moment, the definition of a hospital is not what we are in terms of what we want to do.* [P003, clinician team]

Communication

This is a subconcept that enables the relationship within internal teams and between internal and external teams or agencies for example, state government agencies, vendors so on. Themes emerged surrounding the communication medium and communication approach.

Navigating the Virtual

In terms of the communication medium, virtual co-design sessions became increasingly common during the COVID-19 pandemic to support the rapid design and development of health ITs under time pressure. However, participants explained that virtual co-design sessions often removed the "human" from "human-centered design." Face-to-face co-design sessions were preferred over remote sessions because it was easier to understand each person's role in the project, have informal conversations, and build a social connection.

> *…meetings are online, everything is via [online meeting platform], and that physical element is missing. And it's sort of, you know, watered down the prototyping and the UX [user experience] bit…. Yeah, you don't hear that hallway conversation. … And without these hallway conversations, it seems like*

XSL•FO
RenderX

> *yeah, there's no collaboration that happens.* [P009, IT team]

Some participants described the virtual sessions as transactional and rapid, impacting the interpersonal relationships between project team members as well as the project.

> *A lot of the other projects that we do, we have team forming activities, we get to know each other…We missed all that because there was no time to do it.* [P010, IT team]

Varied Lexicon

Regarding the communication approach within internal teams, participants from both parties reported that clinicians had limited IT literacy and IT teams had limited health literacy, which resulted in miscommunication and key messages being lost in translation. For example:

> *So technically they use English words, and I use English words, but we have different interpretations of what those words mean.* [P002, clinician team]

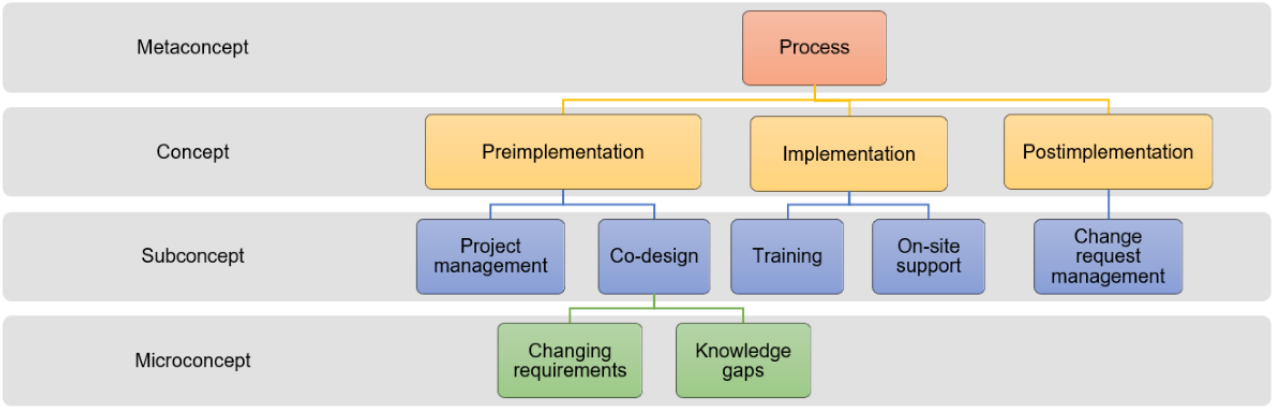
Another participant said that:

> *we just tell ICT [information and communications technology] and ICT will consult with [the vendor] … and sometimes our request gets lost in translation.* [P005, clinician team]

In addition, participants from the IT team acknowledged that it was important for their team members to simplify complex language and tailor communication to individuals when communicating with clinicians.

> *…like, [staff name]'s great, but [they] use very, very complex language. And sometimes we get lost in that. And so I think that just makes [clinician team] just turn off. And so having to rephrase things all the time, just so they understand is a problem. I think we need to make it simpler, like the development process.* [P010, IT team]

Bridging the Transparency Gap



When reflecting on the communication approach between the internal and external teams, participants from the IT team reported limited transparency and responsiveness from external teams, regarding timelines, strategy, and the continuous improvement of the technology. For example:

> *…there were a lot of problems with [external party] committing to things, also being transparent, showing what they're up to, showing what their intentions were in terms of timeframes in terms of strategy, where the product will be going.* [P011, IT team]

Processes

In this study, Process refers to the health IT development lifecycle and was conceptualized as preimplementation, implementation, and postimplementation phases, as shown in Figure 2.

Figure 2. Ontology of concepts and sub-concepts for health IT implementation processes during the COVID-19 pandemic.

Preimplementation Processes

Preimplementation processes were reported to involve activities undertaken when planning and co-designing HITs. During preimplementation, participants discussed issues related to both project management and co-design.

Optimizing Project Management

In terms of project management, participants raised concerns about how project meetings were planned, managed and documented. For example, regarding time management 1 participant said:

> *Project status meetings with clinicians, we schedule 30 minutes just to say these are the quick updates, but then it goes on for like an hour... I feel like sometimes we don't respect their [clinician team] times in terms of a project team perspective.* [P009, IT team]

Another participant explained that meetings were not well documented because they were conducted virtually, and the minutes were generated electronically:

> *…there were no minutes for almost all the meetings. And then the same questions would come up three months later. And we'd say, well, we discussed this in February. Can we go back to that meeting? No. They're all recorded on [videoconferencing platform], I hate. I hate meetings recorded on teams. That is not minutes. That does not give people an opportunity to reflect on what was said and see if it is what they said.* [P002, clinician team]

Adapting Co-Design to Shifting Realities

Regarding the co-design process, participants described challenges associated with changing requirements over time, and knowledge gaps within both the clinician and IT team.

Adapting to Changing Requirements

Participants reported that fluctuations in COVID-19 patient numbers in different waves of the pandemic led to changes in the system requirements gathered over time:

> *So it was started 12 months prior, and then stopped, and then came into fruition or asked to be activated, once the real COVID number started coming through in that sort of mid-year … So the requirements that were gathered 12 months prior were somewhat different to the requirements that were needed for the COVID dashboard proper, because it had changed.* [P012, IT team, Focus group]

Furthermore, participants stated that the pandemic had placed unprecedented pressure on IT teams resulting in a change in their roles and responsibilities. For example:

> *…the pandemic has put a lot of pressure or more pressure on ICT services staff because you now need to learn a lot more and really quickly to be able to deliver digital solutions not just for clinicians, now it has moved on to patients and now you have to learn AI, clinical decision support systems and all of that. And at a fast pace.* [P009, IT team]

Participants explained that rapid upskilling was needed with user experience (UX) design one of the core skills necessary in the new health IT implementation landscape:

> *…we're not in that UX [user experience] business … we usually just configure things based on what our suppliers have…we don't have that core capability.* [P009, IT team]

Bridging the Knowledge Divide

In addition, some participants reported that the clinician team had knowledge gaps regarding the system development processes, which influenced their expectations around the levels of complexity of some technology requirements and delivery timelines. For example, a participant said:

> *I think their expectations around time to deliver were very short…they don't actually quite understand… that, you've got to do a build, you've got to put it into a non-production environment, you've got to validate it, it's got to go into a staging environment, it's got to be tested, and then it's'got to go into production'environment. And if it's a major change there might be security implications, so there's this whole group of people that are involved, there's an integration activity.* [P010, IT team]

Participants within the clinician team also mentioned that they were unclear about their level of involvement in the co-design process and the level of technical literacy that was required:

> *if I'd known how much work this would be, and how technical it became … I never would have put my hand up to build something. I thought I was just providing some clinical advice about how we use it.* [P002, clinician team]

Conversely, some participants reported that the IT team had knowledge gaps regarding clinical staff roles and levels of seniority, which made it challenging to know when the IT team could engage clinicians; which clinicians should be engaged; and at what stage in the co-design process the clinicians should be engaged. For example, a participant said:

> *So I got asked the other day by the project lead what the difference between a consultant and a registrar is... And for us. That's a really important distinction. And we've worked together for 12 months. And [they] didn't know that difference.* [P002, clinician team]

In addition, participants within the IT team stated that their approach to co-design was not tailored to user needs and rarely included a visual of the user design preferences, noting this to be a knowledge gap within the team.

> *So I think there's a really low level of prototyping or co-design that's happening. ... because people are not comfortable with that level of creating visuals for people… And I guess UX people don't only do visual design, but they try to understand the problems more. So I think we lack a lot in that first part of first understanding people and understanding what they need.* [P009 IT team]

Implementation Processes

Implementation processes involved activities undertaken to facilitate the successful rollout and uptake of health IT. Two main subconcepts describing implementation processes emerged from the data: Training and on-site support.

Tailored Training Strategies

Participants generally viewed training positively and explained that training provided by educators within the clinician team had been tailored for each model of care and was excellent. For example, a participant stated that:

> *Every time there's a new or something goes live, then the staff, the nursing and the medical staff will get training in what are you supposed to do, how are you supposed to assess patients, And they get access to … instructions on what do you do with this patient as part of this trial? …So it's a bit different with each different ones.* [P001, clinician team]

However, some participants identified a need to simplify training to accommodate those who are not technology-savvy and incorporate a more inclusive training approach for older staff.

> *Like, it'll be this huge mass of information. And then there'll be this really essential thing. And I'll think I didn't know that. And then I look at my notes. And I think, why didn't I know that? And I look at my notes, and I didn't know it, because nobody told it to me… I want something I can write on, like, I want something I can look at, because I'm getting older now, and even looking at a screen, I can't see everything, you know, with these presentations. So*

XSL•FO
RenderX

for me to like strain, look and write, it's just messy. [P007, clinician team]

Defining Limits to On-Site Support

During the go-live period, participants from the clinician team reported that the length of time that on-site support was received from the IT team was insufficient. Participants explained that support was available for a predefined length of time, regardless of how many patients were seen, which was problematic when patient numbers were low:

> *So once we went live, we had a small group ICT team that was for support ... That support was supposed to run for 2 weeks. We haven't got [any] patient [for the diverticulitis model of care] for around 3 weeks. So at the end of the 2 weeks. They were like hey guys, so our [diverticulitis model of care] support team is going to finish now. I'm like, we haven't even had our 1st patient. So we don't even know what type of support we will need.* [P005, clinician team]

Postimplementation Processes: Improving Vendor Communication

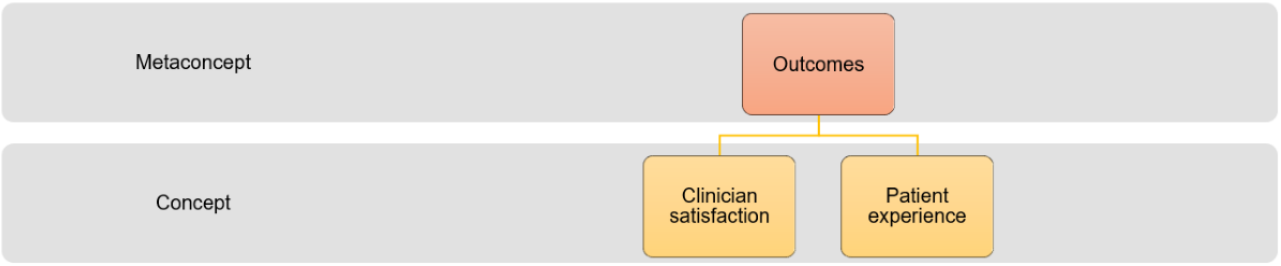
Postimplementation processes involved activities undertaken to maintain the health IT.

During postimplementation, participants identified one key process that had been challenging, that of issuing requests to the vendor to make technology changes. The change request process, where the IT team requested changes from the vendor, was viewed as ambiguous as it was unclear what tasks required formal requests for change and the associated cost implications. For example, a participant said:

> *So you have to raise change request for that, or you have to raise change requests, everything you want to do, we have to raise change requests for and then they don't tell you if you actually have to pay for the change requested or not. …So they may be doing it for free but they don't tell you that upfront, you only find out afterwards, it makes it really difficult to negotiate anything with them.* [P011, IT team]

Participants also emphasized that it was imperative to involve the IT team in the vendor product release cycle, to allow IT staff to plan and communicate in a timely manner with the stakeholders involved (eg, the clinician team). For example, a participant mentioned that:

> *…if you know there's a bug fix for something coming up, then you can actually communicate that and say, yep, we're on it, rather than keep asking, can we get the colour changed … knowing that in the third quarter release that the colours are all changing.* [P013, IT team]



Focus group Another participant said:

> *And then you can manage your stakeholders better ... And then have a co-design with the [vendor] team on what that product release cycle would look like as well. You know, having input in that.* [P012, IT team, Focus group]

Outcomes

When asked about the performance of the health IT that resulted from the rapid implementation process, participants described impacts on clinician satisfaction and patient experience (Figure 3).

Figure 3. Ontology of concepts for the outcomes of health IT implementation during the COVID-19 pandemic.

Clinician Satisfaction

Following health IT implementation at the virtual hospital, clinicians reported mixed levels of satisfaction with the technology, but they explained that this improved over time as teething issues with the technology were addressed. Participants raised concerns about negative UX, poor reporting capabilities of the technology, and limited system integration, with the majority of these problems being identified in the first few months following implementation. For example, a participant described a usability problem with one of the dashboards in use:

> *Another issue surrounding alerts is the fact that the dashboard is so big. You need to press… to see more on the dashboard… For us, it's not a scroll. It's a press, it says right here, you have to press it to go all the way to right now… if you don't press all the way towards the right, you can only see half the heart rate.* [P005, clinician team]

Another participant stated that the initial reporting capability did not meet the needs of medical staff members:

> *I actually refused to move the medical workflow to it [dashboard] for two months, because there was no reporting. So, you know, they moved the nursing workflow, and we had medical workflow running on our teams, spreadsheets, and I was like… there's no way of me telling which doctor was asked to see which patient at what time.* [P002, clinician team]

XSL•FO
RenderX

Perceived Patient Experience

As the IT team received direct reports of patient experiences with the remote monitoring mobile phone applications, participants described challenges related to the interface and customizability of the technology. For example, 1 participant said that:

> *Patient facing app…I don't think it's good. I think it doesn't meet the need of the patient…It's interface is terrible. The workflow is not very good. The customization is very, very difficult. And the timeframe for development is way too long for what we want to do.* [P010, IT team]

Also, another participant commented on the ability of the app to present personalized self-management information to patients:

> *Or even just have a link to the website that gives them information about like, heart health or something. They can't do that. So it's like, that's not performing well in terms of the patient's experience, because there's an expectation for you. If you've downloaded an app, you expect more also the things to be contained in that app or will link you to things. Very simple feature set. I don't think the patients are getting that.* [P009, IT team]

Discussion

Principal Findings

In this study, we found that both internal and external team structures and the communication pathways that underpinned these influenced the health IT lifecycle, and pre-to-post implementation, which in turn impacted outcomes, particularly when the normal ways of working were challenged during the pandemic. Preimplementation processes, particularly project management and co-design, were viewed to be most impacted by the COVID-19 pandemic. Specifically, as meetings were held virtually due to social distancing guidelines, and health IT implementations in the pandemic were rapid, participants reported that meeting documentation was automated as it was faster but the outcome of this approach was deemed suboptimal. Also, fluctuations in COVID-19 patient numbers in different waves of the pandemic led to changes in the system requirements gathered over time which led to the need to adapt to shifting realities during co-design. Taken together, our study brings to the fore, the knotty relationship between technology, people, organizational and macroenviromental factors across different health IT implementation phases, aligning with previous research [4].

Comparison With Previous Studies

Effective interdisciplinary communication across the implementation lifecycle was key for successful health IT implementation during the pandemic. Our findings align with existing research demonstrating communication challenges between clinicians and IT teams prepandemic [13,14,30], but showed communication difficulties were exacerbated by time pressures and social distancing guidelines that arose during the pandemic. Our study revealed that the social fabric (ie, web of interactions and connections) that existed within interdisciplinary teams were disrupted due to the urgent need for responsiveness between the internal and external teams, changing system requirements, the communication medium and the varied lexicon between the 2 internal teams. This led to miscommunication, information being lost in translation, and poor interpersonal relationships. While our study adds to the growing body of knowledge on the clinician IT divide, it also highlights effective communication as a necessity for bridging the divide between clinicians and IT experts in time pressured contexts [30]. As the new norm is established, with longer health IT delivery timelines, more stable system requirements, and time for manual meeting documentation and review; factors contributing to miscommunication are minimized but not eliminated as issues such as the varied lexicon between the clinician and IT teams appear enduring.

Regarding the communication medium between teams during health IT implementations, our findings suggest the need to minimize virtual co-design sessions when possible. Virtual co-design sessions became increasingly common during the COVID-19 pandemic to support rapid policy changes and needs, which often occurred with limited experience, preparation or preference of the participants in those sessions. However, it allowed flexibility in the location of co-design and more efficient use of clinician time [18]. Despite these benefits, our interviews revealed that there was limited social connection within co-design teams which contributed to poor interpersonal relationships. This result aligns with that of a simulation study that experimentally manipulated an interdisciplinary co-design process and found that physical separation during co-design led to less social connectedness and misalignment in design outcomes between the subgroups [31]. Another study on virtual co-design with children during the pandemic found that sustaining online sessions over an extended period of time was difficult due to the lack of social connectedness between co-design participants [32]. Also, the clinicians, in our study, reported the limited efficacy of virtual communication, which perhaps reflects the widely experienced videoconferencing fatigue experienced by professionals in health care and other similar service domains [33,34]. Together, these results indicate the need to: identify the types of co-design discussions that suit virtual or face-to-face settings; improve the design and processes around videoconferencing to make it a more acceptable medium for co-design discussions; and reintroduce face-to-face co-design sessions as we transition back to the "new-norm."

The challenges we identified with the preimplementation processes appeared to have a lasting impact on health IT outcomes as they contributed to poor clinician satisfaction and a negative patient experience. For example, in the co-design process, participants from the IT team reported that new work requiring UX expertise was added to their key tasks during the design and implementation of health ITs during the pandemic, thus changing their roles and responsibilities. As their work was previously focused on configuring health ITs from vendors rather than co-designing health ITs with users, the implemented health ITs were sometimes seen to be unsatisfactory to the users. This draws attention to the need for health care organizations to review their IT staff skills and capabilities and align them to the capability needs of a proposed health IT project so that

XSL•FO
RenderX

existing staff members are not required to learn and apply new skills to health IT projects simultaneously. Furthermore, it is imperative for organizations to analyze existing and proposed processes (eg, co-design process) systematically at the organizational level as health IT implementations inevitably lead to new work and redistribution of existing work [35,36]. Consequently, it is imperative for health care organizations to ensure health IT implementation processes cater for work changes within and across clinicians and IT teams rather than the mere purchase of health ITs [37].

In addition to communication and process improvements highlighted in this study, our findings revealed digital health workforce development needs for both clinical and IT students and professionals, to address knowledge gaps and communication challenges. For clinicians, digital competence is typically viewed as knowledge, skills and motivation to use and interact with technologies [38-41]. However, we contend that the perception of *clinicians as users* [42] of digital health technologies must evolve to that of a continuum where clinicians can be at any point of the spectrum that *clinicians as users* to *clinicians as co-designers*. We propose that digital health curriculum should offer clinicians an opportunity to learn the principles of HIT co-design, and the health IT design, development, and implementation lifecycle, to ensure clinicians are equipped with the capabilities and skills to both practice in digital environments and drive digital health innovations. In addition, the suboptimal patient experience reported in our study highlights the need to ensure that patients are also involved as users and co-designers of patient-facing health ITs.

Whilst significant attention has been placed on the development of digital competencies for clinical students, the development of health competencies for IT professionals designing, developing, and implementing health ITs in clinical settings is not as advanced [43-45]. Although clinical informatics programs attempt to bridge this gap, it is not a requirement for IT professionals working in clinical settings, and these skills are sometimes learned on the job [46]. Our findings suggest that IT professionals working in clinical settings may need additional training in the "health sciences" domain, which could encompass knowledge in areas like health concepts, and health sector structures and roles [47].

Strengths, Limitations, and Future Directions

The results from this study have made contributions to the research, practice, and educational requirements for health IT implementations. From a research perspective, we have adapted the interdisciplinary team communication framework (Figures 1-3), incorporating the macro-environmental factor (COVID-19 pandemic) that has significantly impacted health IT implementations since 2020. We tailored the framework to unpack complex structures, processes, and outcomes involved in pandemic-driven health IT implementations between teams. The adapted framework will be useful for researchers undertaking process evaluations for health IT implementations that have occurred since the pandemic.

From a practice perspective, we identified communication structures, including the medium and approach, as key factors that impact health IT implementation processes and outcomes. In our setting, this study resulted in a review of the communication structures available to facilitate better development of interactions and connections that exist within and across internal and external teams. It also led to concrete steps being taken to ensure face-to-face meetings occurred, the creation of office space for IT staff to co-locate in the virtual hospital, and the sustainability of the clinical informatics expertise to work with both the clinician and IT teams.

From the education perspective, we have brought to light the importance of ensuring that digital health education accommodates clinicians as they transition from users to co-designers of health ITs. We further identified the need to better incorporate "health science" knowledge domains in IT curriculum [45] for IT professionals who deliver HITs in clinical settings.

Limitations of our study include that it was an exploratory study that focused on 2 teams within a health service, which may limit the generalizability of the results. The adapted interdisciplinary framework for HIT implementations during the pandemic needs to be validated and studied in the context of other team-based settings. Also, as patients were unable to be recruited for this process evaluation study, our findings may not adequately capture patient perceptions of health ITs during the pandemic. Future work will involve determining the extent to which findings from this study transfer to brick-and-mortar hospital settings and in other interdisciplinary team settings.

Conclusion

The primary purpose of health IT is to facilitate the delivery of quality health care and improve health outcomes [48], but these can only be realized if health IT implementations are successful and health IT is used. Various technological, people, organizational, and macroenvironmental factors have impacted health IT implementation success, more so since the COVID-19 pandemic. Specifically, we found that team structures, communication pathways, and health IT preimplementation processes (project management and co-design) were negatively impacted by the pandemic. While health service organizations are keen to transition to the "new norm," it is imperative to learn from the health IT implementation successes and failures that occurred during the pandemic via process evaluations. Our process evaluation offers learnings for the research (an adapted interdisciplinary team communication framework), practice (the need for health care organizations to review their communication structures, IT staff skills, and proposed processes), and educational requirements (need for better education and training of IT professionals working in clinical settings on health concepts) of health IT implementations as the world transitions to the "new norm."

Abstract

Background: Virtual reality (VR) training uses computer-generated simulations that enable users to engage with immersive virtual environments, simulating real-world activities or therapeutic exercises. This technology is increasingly recognized as a promising intervention to address the physical and psychological challenges faced by dialysis patients, who frequently experience diminished physical function, social isolation, and emotional distress associated with prolonged treatment regimens. Given the increasing prevalence of dialysis patients and the limitations of conventional rehabilitation approaches, VR presents a novel, interactive method that has the potential to enhance patient well-being and improve quality of life.

Objective: This meta-analysis aimed to evaluate the effectiveness of VR training interventions for dialysis patients, with a focus on assessing their impact on motor abilities, psychological symptoms (specifically anxiety and depression), social functioning, and self-efficacy. This analysis also explores whether VR can offer comprehensive benefits to support both the physical and mental health of dialysis patients.

Methods: The meta-analysis was conducted following Cochrane guidelines. Comprehensive searches were performed across major databases, including China National Knowledge Infrastructure, Wanfang database, China Science and Technology Journal Database, China Biomedical Literature database, Cochrane library, Web of Science, PubMed, and Embase, encompassing all studies up to December 2023. Inclusion criteria targeted studies assessing VR's impact on motor performance, psychological well-being, social functioning, and self-efficacy in dialysis patients. Two reviewers independently extracted data and assessed methodological quality using Cochrane's risk of bias criteria, ensuring data synthesis reliability.

Results: A total of 12 studies, involving 625 dialysis patients in total, met the inclusion criteria. The meta-analysis demonstrated that VR training led to significant improvements across multiple domains. VR interventions were associated with improved physical capacity, evidenced by higher scores in the 6-minute walk test (standardized mean difference [SD]=29.36, 95% CI 14.32-44.4, P<.001, I^2=46%). VR training was associated with significant reductions in depression (SD=–6.30, 95% CI –7.14 to –5.47, P<.001, I^2=96%) and anxiety (SD=–8.91, 95% CI –9.69 to –8.14, P<.001, I^2=95%). In addition, VR interventions enhanced social functioning (SD=16.20, 95% CI 14.49-17.9, P<.001, I^2=72%), and improved self-efficacy (SD=20.47, 95% CI 18.55-22.39, P<.001, I^2=99%). However, VR training did not yield significant differences in gait speed, balance, or functional tests (Ten Sit-to-Stand Test, Five Sit-to-Stand Test, Sixty Sit-to-Stand Test, Timed Up and Go Test, and fatigue) compared with control groups.

Conclusions: The findings suggest that VR training is a promising intervention for dialysis patients, providing benefits in physical endurance, social engagement, and psychological well-being. Despite these advantages, VR remains underused among peritoneal dialysis patients compared with hemodialysis patients. Further studies with larger sample sizes and more refined

XSL•FO
RenderX

experimental designs are recommended to validate these results and support VR as a complementary tool in the holistic care of dialysis patients.

KEYWORDS

virtual reality; VR; training; dialysis; hemodialysis; peritoneal dialysis; chronic kidney disease; rehabilitation; quality of life; meta-analysis

Introduction

End-stage renal disease (ESRD) signifies a severe impairment in kidney function, rendering the body incapable of meeting normal metabolic demands. This condition is chronic and progressive, with a global prevalence reaching 442.13 per million [1]. Dialysis, encompassing both hemodialysis (HD) and peritoneal dialysis (PD), serves as a common therapeutic approach for ESRD, substituting renal filtration function albeit necessitating frequent hospital visits, significantly impacting patients' lives. Prolonged dialysis treatment often precipitates complications such as anemia, muscle wasting, skeletal disorders, and cardiovascular ailments. Exercise therapy plays a pivotal role in managing patients with ESRD by yielding multifaceted benefits, including enhancements in cardiovascular function [2], alleviation of fatigue and sleep disturbances, bolstering mental health by mitigating anxiety and depression [3], regulating blood pressure, managing anemia [4], and optimizing dialysis adequacy [5]. Furthermore, regular exercise effectively retards the deterioration of muscle strength [6] and maintains superior physical function. Despite extensive research corroborating the merits of exercise in augmenting hemodialysis patients' quality of life, there remains a notable deficiency in exercise awareness, knowledge application, and adherence among patients with ESRD [7] predominantly attributable to inadequate comprehension, deficient self-management skills, and low compliance levels.

Virtual reality (VR) technology represents a computer-generated simulation environment enabling user interaction within virtual realms, engendering an immersive experience that transports individuals into diverse environments [8]. Within the medical sphere, VR has gained traction and is increasingly adopted. VR facilitates immersive encounters that divert patients' attention from the discomfort and anxiety associated with medical procedures, such as dialysis treatment [9]. By creating immersive and interactive virtual environments, VR offers a unique platform to improve operational skills, health knowledge, and psychological resilience among these patients.

The application of VR in dialysis begins with its role in enhancing operational skills and ensuring treatment safety. Patients can engage in simulated environments that replicate dialysis machine operations and scenarios. This allows them to practice procedures and familiarize themselves with equipment without the inherent risks associated with real-world settings. Such training not only reduces procedural errors but also boosts confidence and competence in managing treatments, ultimately contributing to better treatment adherence and patient safety.

In addition, VR serves as a powerful educational platform in dialysis care. It facilitates the delivery of comprehensive health education, covering critical aspects such as medication management, dietary guidelines, and health monitoring techniques [10]. By engaging patients in interactive simulations, VR enables them to acquire a deeper understanding of their treatment regimen and develop essential self-management skills. This educational empowerment is pivotal in encouraging patients to take an active role in their health management, thereby improving treatment outcomes and enhancing overall quality of life.

Furthermore, VR addresses the significant psychological challenges faced by dialysis patients. Long-term treatment often leads to emotional stress and psychological burdens, including conditions such as anxiety and depression. VR environments provide a therapeutic avenue for relaxation and emotional support. Patients can participate in virtual mindfulness exercises, guided relaxation sessions, or social interactions within a controlled setting. These activities help alleviate stress, improve mood, and foster emotional resilience among patients, thereby enhancing their psychological well-being.

VR training offers significant advantages over traditional physical therapy for treating dialysis patients. First, VR technology provides highly immersive experiences that enhance patient engagement and motivation. Dialysis patients often face long-term treatments and physical limitations, and VR environments immerse them in compelling experiences that encourage greater participation in rehabilitation training. Second, VR allows for personalized treatment plans tailored to individual patient needs, including adjusting training difficulty and environment to accommodate varying abilities and therapeutic requirements. This personalized approach enhances treatment efficacy and specificity.

Furthermore, VR training provides a safer therapeutic environment with better control mechanisms. Conducting exercises and rehabilitation in virtual environments reduces real-world safety risks for patients, while health care teams can monitor progress and responses in real time to adjust treatment plans promptly. In addition, VR systems can collect detailed data such as movement skills and physiological responses, offering crucial insights for health care professionals to optimize treatment plans and deliver personalized care.

Conducting a meta-analysis on the application of VR in dialysis patients holds significant clinical implications. Systematically synthesizing data from multiple studies allow for a comprehensive evaluation of VR therapy's actual impact on improving quality of life and enhancing rehabilitation outcomes in dialysis patients. Such meta-analysis not only compares VR

XSL•FO
RenderX

training with traditional physical therapy but also identifies potential biases and inconsistencies in research, providing scientific grounds for designing future clinical trials and refining treatment strategies. Therefore, exploring the effectiveness of VR through meta-analysis in dialysis patients not only deepens understanding of its clinical role but also informs future clinical decisions and rehabilitation strategies based on robust scientific evidence.

Methods

Overview

This meta-analysis was conducted in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. The PRISMA checklist is provided in Multimedia Appendix 1.

Search Strategy

We conducted a comprehensive literature search across 8 databases, namely China National Knowledge Infrastructure (CNKI), Wanfang database, China Science and Technology Journal Database, China Biomedical Literature database (SinoMed), Cochrane library, Web of Science, PubMed, and Embase. We used a combination of subject terms and free terms tailored to each database. The search was performed for studies published from inception up to December 2023. Two researchers independently executed the searches and managed the retrieved literature using EndNote software. Detailed search strategies for each database are provided in Multimedia Appendix 2.

Inclusion and Exclusion Criteria

Textbox 1 shows the inclusion and exclusion criteria.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Study design: randomized controlled trials following the Population, Intervention, Comparison, Outcome framework.
- Population: adults aged ≥18 years undergoing dialysis (hemodialysis or peritoneal dialysis).
- Intervention: exercise training incorporating virtual reality.
- Comparison: conventional hemodialysis care interventions (including health education and routine exercise) or exercise not based on virtual reality.
- Outcome measures: motor ability, psychological symptoms, social functioning, and self-efficacy.
- Language: studies published in Chinese or English.

Exclusion criteria

- Duplicate publications.
- Non-Chinese or non-English literature.
- Studies with incomplete data (eg, missing outcome indicators).
- Conference abstracts and review articles.

Data Extraction

Two researchers independently extracted data from the included studies, including details such as author, publication year, country, sample size, intervention specifics, and outcome measures. Studies were initially screened based on titles and abstracts, followed by a full-text review to ensure they met the inclusion criteria. Discrepancies between the 2 researchers were resolved through discussion, and if consensus could not be reached, a third researcher was consulted for final arbitration.

To ensure comprehensive data extraction, we contacted study authors by email to request missing or unclear data. Studies with unresolved data issues were excluded from the meta-analysis.

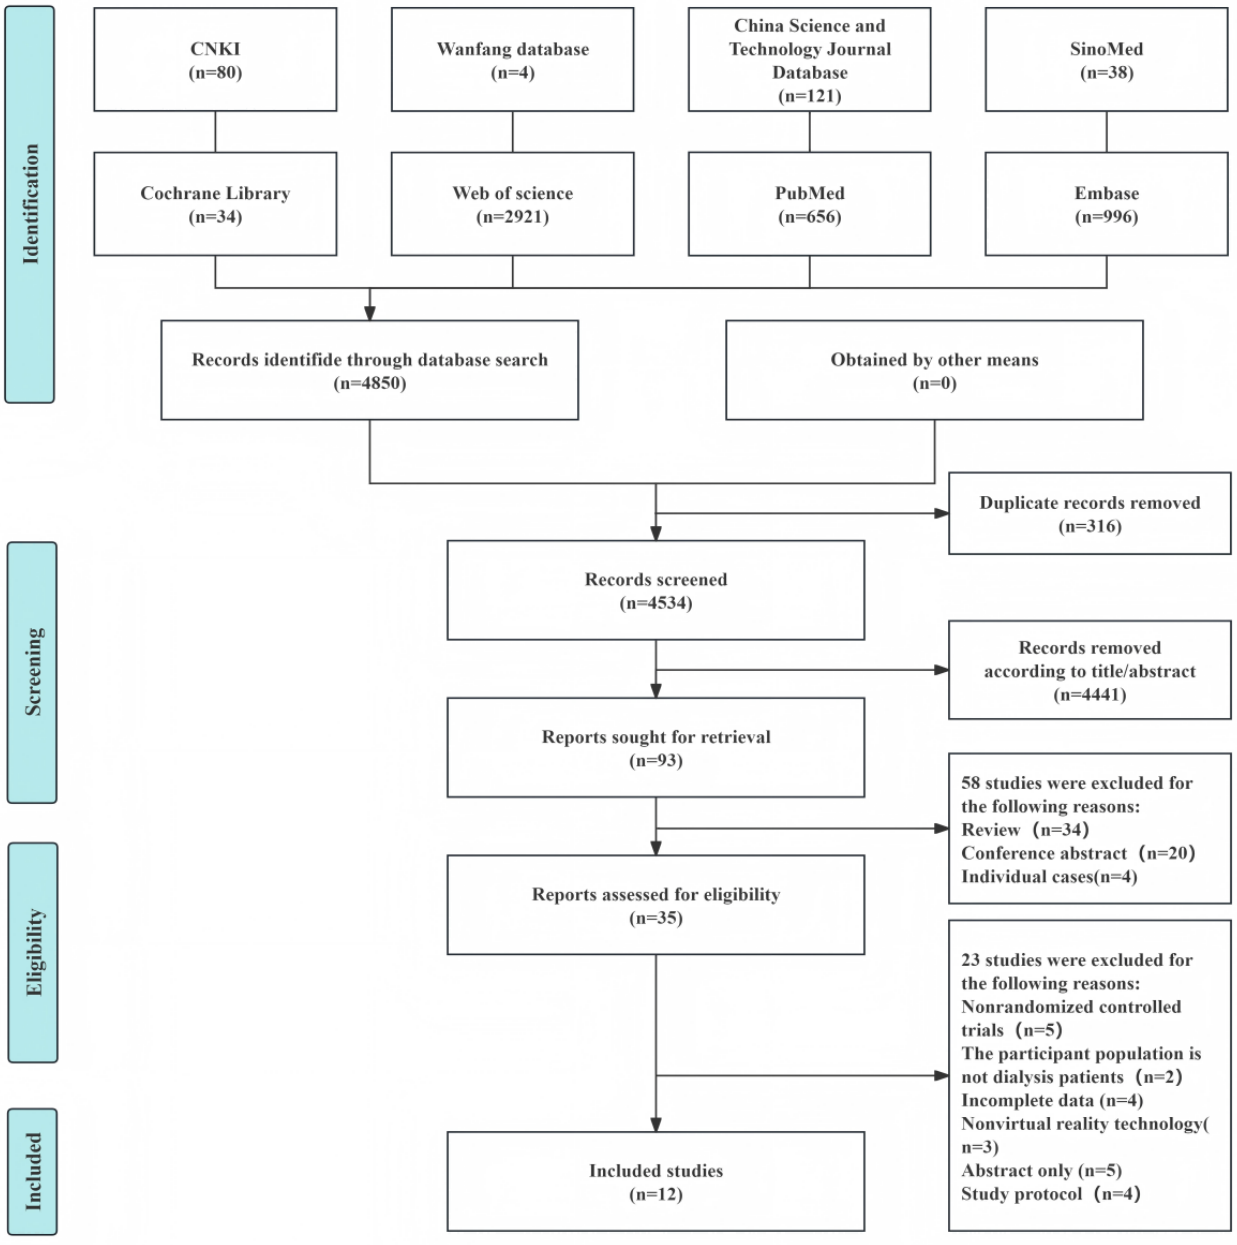
Quality Assessment of Literature

The quality of included studies was assessed using the Cochrane Collaboration's risk of bias tool. We evaluated studies on several criteria, such as random sequence generation, allocation concealment, blinding of participants and personnel, blinding of outcome assessment, incomplete outcome data, selective reporting, and other potential biases. Each criterion was classified as low risk, unclear risk, or high risk of bias [11].

Statistical Methods

Statistical analyses were performed using RevMan (version 5.4) software and State (version 17) provided by the Cochrane Collaboration. We analyzed both continuous and dichotomous variables, reporting relative risk with 95% CIs. A fixed-effects model was used for the meta-analysis of outcome indicators. We assessed heterogeneity among studies using the chi-square test and *I*-squared (I^2) statistic, with I^2 values of 25%, 50%, and 75% indicating low, moderate, and high levels of heterogeneity, respectively. Publication bias was evaluated through funnel plots and Egger regression test [12]. A 2-tailed *P* value of ≤.05 was considered statistically significant [13]. Due to the limited number of studies, further subgroup and sensitivity analyses were not performed.

In cases where data were incomplete or unclear, we sought additional information from the authors. Studies for which relevant data could not be obtained were excluded from the systematic review and meta-analysis.



XSL•FO
RenderX

Results

Results of Literature Search

A total of 4850 articles were initially retrieved from the literature search, comprising 80 from CNKI, 4 from Wanfang database, 121 from China Science and Technology Journal Database, 38 from SinoMed, 34 from the Cochrane library, 2921 from Web of Science, 656 from PubMed, and 996 from Embase. After a systematic screening process, 12 articles were ultimately included. The detailed screening process and the reasons for exclusion are illustrated in Figure 1.

Figure 1. Flowchart of the study selection process.

Basic Characteristics of Included Studies

The included studies were conducted across 7 countries: namely, Poland [14], Spain [15,16], China [17-21], Qatar [22], South Korea [23], Germany [24], and Brazil [25]. One study used a 3-arm design [24], while the remaining 11 studies used a 2-arm design. Of the 12 trials, 2 focused on patients undergoing PD, while the remaining 10 involved patients undergoing HD [17,21]. Five trials compared VR training with conventional care [18-21,23], 2 trials included specified interventions in the control group [14,16], and the remaining trials compared VR training with other types of interventions, such as printed materials [17], exercise programs based on daily habits [15,18], and nurse-led exercise programs [16,22]. Summary of included studies are provided in Multimedia Appendix 3. Details regarding the number of participants, interventions, and outcomes are presented in Table 1. Further information on the interventions under experimental and control conditions is detailed in Multimedia Appendix 2.

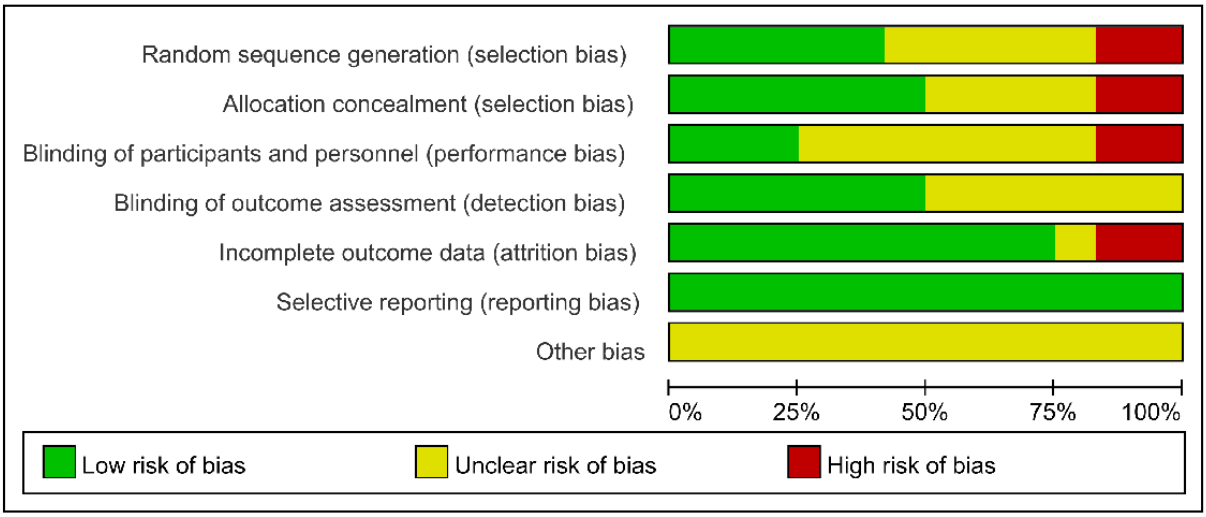
Risk of Bias Assessment

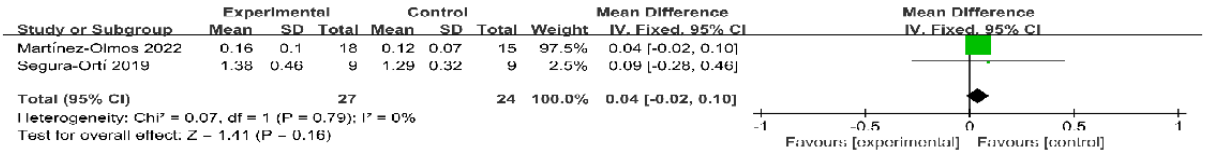


According to Cochrane criteria, the risk of bias assessment is illustrated in Figures 2 [14-25] and 3. Of the 12 studies, 7/12 (58.3%) studies [14,15,17,18,21,22,24] were rated as having "some concerns" of bias, and 5/12 (41.7%) studies [16,19,20,23,25] were rated as high risk of bias. In the domain of "random sequence generation," 5/12 (41.7%) studies [16,17,22,24,25] had low bias, 5/12 (41.7%) studies [14,15,18,20,21] had unclear risk of bias, and 2/12 (16.7%) studies [19,23] had high risk of bias. In the domain of "allocation concealment," 6/12 (50%) studies [16-18,22,24,25] had low bias, 4/12 (33.3%) studies [14,15,20,21] had unclear risk of bias, and 2/12 (16.7%) studies [19,23] had high risk of bias. In the domain of "blinding of participants and personnel," 3/12 (25%) studies [21,23,24] had low bias, 7/12 (58.3%) studies [14-19,22] had unclear risk of bias, and 2/12 (16.7%) studies [20,25] had high risk of bias. Blinding participants was not feasible due to the nature of the intervention methods used in all trials. In the domain of "blinding of outcome assessment," 6/12 (50%) studies [16,19-21,23,24] had low bias and 6/12 (50%) studies [14,15,18,20,22,25] had unclear risk of bias. The absence of blinding outcome assessors or data analysts was observed in studies with some bias. In the domain of "incomplete outcome data," 9/12 (75%) studies [14,15,17-23] had low bias, 1/12 (8.3%) studies [24] had unclear risk of bias, and 2/12 (16.7%) studies [16,25] had high risk of bias. In the domain of "selective reporting," 12/12 (100%) studies [14-25] had a low bias.

Figure 2. Risk of bias analysis of each included study [14-25].

XSL•FO
RenderX

Figure 3. Overall risk of bias analysis of included studies.



Meta-Analysis Results

Motor Ability

Gait Speed

Two trials used gait speed as a measurement outcome [15,16]. The results indicate no significant difference in gait speed improvement between VR training and other training methods (standardized mean difference [SD]=0.04, 95% CI –0.02 to 0.1, *P*=.16) with low heterogeneity (I^2=0%, *P*=.79; Figure 4 [15,16]). Since there were fewer than 3 studies, publication bias was not assessed.

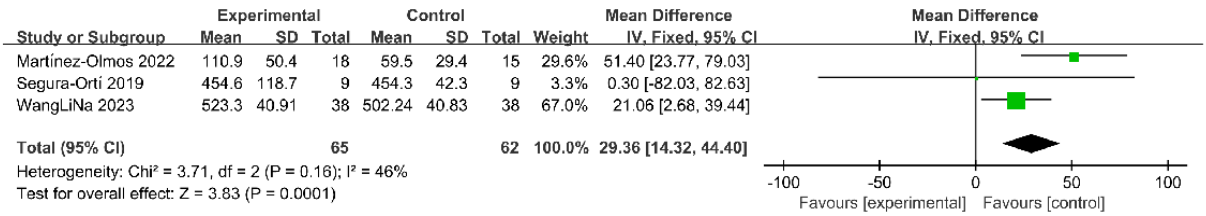


Figure 4. Forest plot of virtual reality on exercise capacity of gait speed [15,16].

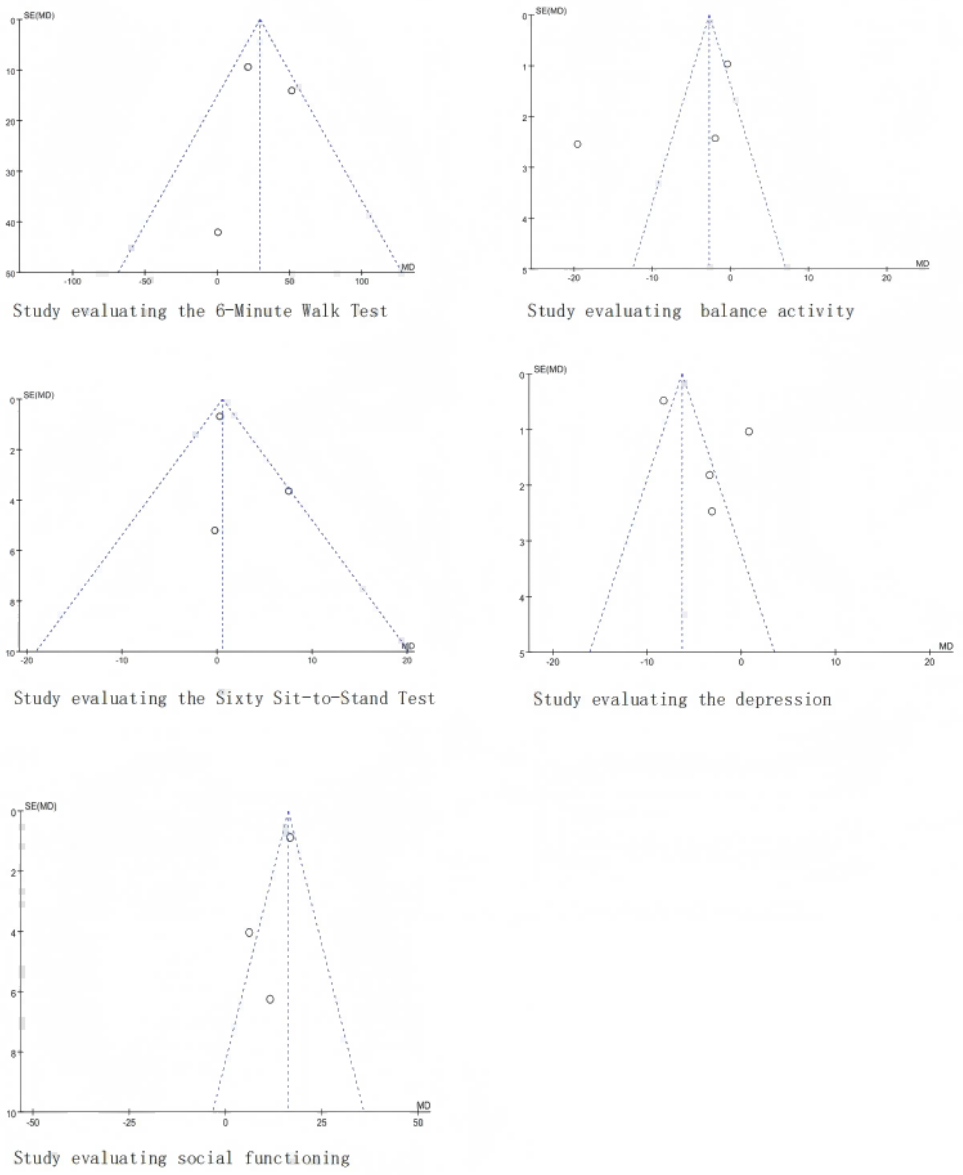
6-Minute Walk Test



Three trials measured walking ability using the 6-minute walk test (6MWT) [15,16,21]. Results showed that VR training improved walking ability significantly more than the control group (SD=29.36, 95% CI 14.32-44.4, *P*<.001) with middle heterogeneity (I^2=46%, *P*=.16; Figure 5 [15,16,21]). Egger regression test and funnel plot showed that there was no significant publication bias between the included studies (*P*=.99; Figure 6).

Figure 5. Forest plot of virtual reality on exercise capacity of 6-minute walk test [15,16,21].

XSL•FO
RenderX

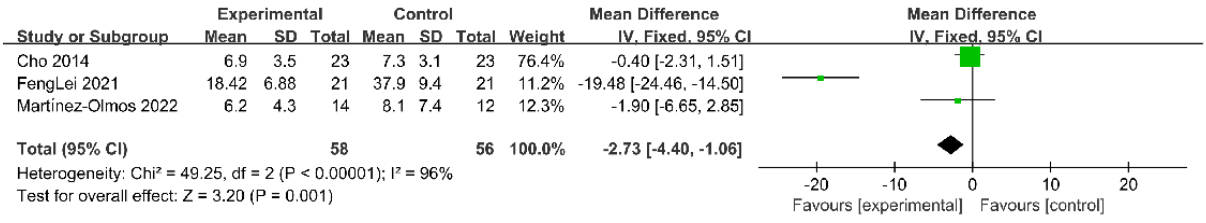


Figure 6. The funnel plot of the effect of virtual reality on dialysis patient.

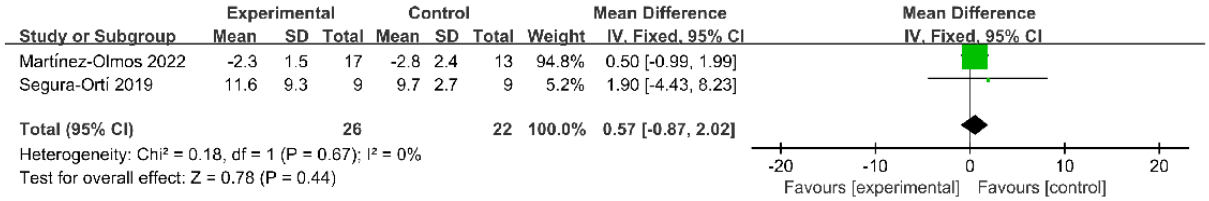
Balance Ability

Three trials included the measurement of balance ability as an outcome [16,18,23]. The findings suggest that VR training did not lead to an improvement in the balance ability of the subjects when compared with the control group (SD=–2.73, 95% CI –4.40 to –1.06, *P*<.001), and considerable heterogeneity was found (I^2=96%, *P*<.001; Figure 7 [16,18,23]). Egger regression test and funnel plot showed that there was no significant publication bias between the included studies (*P*=.48; Figure 6).

Figure 7. Forest plot of virtual reality on exercise capacity of balance [16,18,23].



Five Sit-to-Stand Test

Two studies were conducted using the Sit-to-Stand Test 5 (STS-5) as a measurement outcome [15,16]. The results indicate that there was no significant difference in Sit-to-Stand Test performance between VR training and the control group (SD=0.57, 95% CI –0.87 to 2.02, *P*=.44) with low heterogeneity

XSL•FO
RenderX

(I^2=0%, *P*=.67; Figure 8 [15,16]). However, since there were fewer than three studies, publication bias was not assessed.

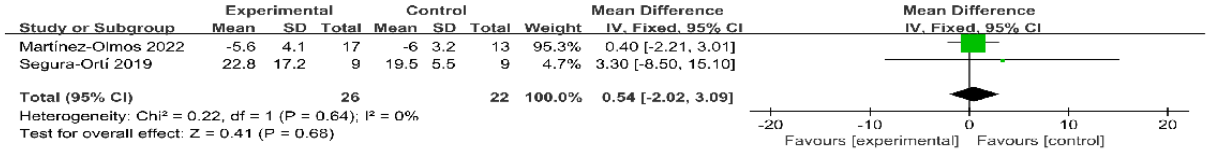


Figure 8. Forest plot of virtual reality on exercise capacity of Five Sit-to-Stand Test [15,16].

Ten Sit-to-Stand Test

In 2 trials [15,16], Sit-to-Stand Test 10 (STS-10) was used as a measurement outcome to compare the Sit-to-Stand Test performance between the VR training group and the control group. The results did not show any significant difference (SD=0.54, 95% CI –2.02 to 3.09, *P*=.68) with low heterogeneity (I^2=0%, *P*=.64; Figure 9 [15,16]). As there were fewer than 3 studies, publication bias was not assessed.

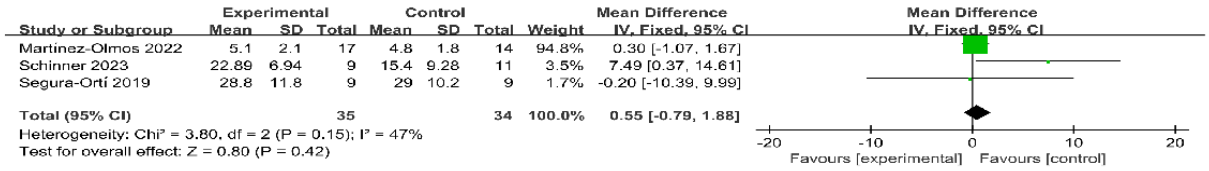

Figure 9. Forest plot of virtual reality on exercise capacity of Ten Sit-to-Stand Test [15,16].

Sixty Sit-to-Stand Test

Three trials were conducted with the Sit-to-Stand Test 60 (STS-60) as the measurement outcome [15,16,24]. The results suggest that there was no significant difference in the STS-60 test performance between VR training and other training methods for dialysis patients (SD=0.55, 95% CI –0.79 to 1.88, *P*=.42) with middle heterogeneity (I^2=47%, *P*=.15; Figure 10 [16,18,24]). Egger regression test and funnel plot showed that there was no significant publication bias between the included studies (*P*=.57; Figure 6).

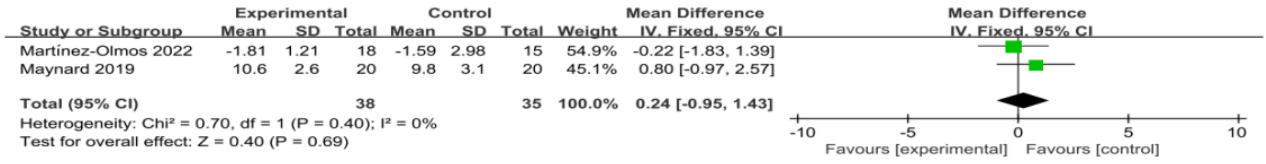

Figure 10. Forest plot of virtual reality on exercise capacity of Sixty Sit-to-Stand Test [16,18,24].

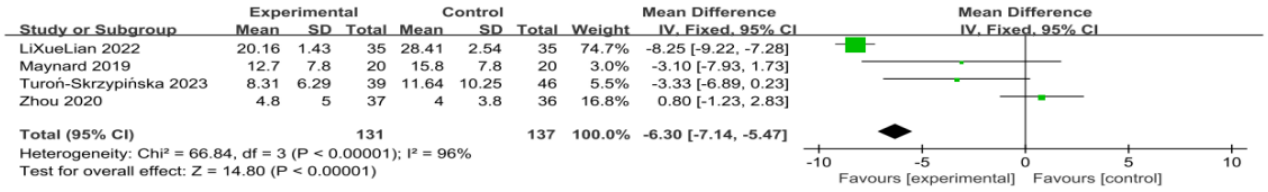
Timed Up and Go Test

Two trials included the Timed Up and Go Test (TUG) test as a measurement outcome [16,25]. The results showed that there was no significant difference between the VR training and control groups (SD=0.24, 95% CI –0.95 to 1.43, *P*=.69) with low heterogeneity (I^2=0%, *P*=.40; Figure 11 [16,25]). However, since there were fewer than 3 studies, publication bias was not assessed.

Figure 11. Forest plot of virtual reality on exercise capacity of Timed Up and Go Test [16,25].

Psychological Outcomes



Depression

Four trials used depression scores as outcome measures [14,20,22,25]. The results show that patients undergoing VR training had lower depression symptoms compared with the control group, indicating that VR was more effective in improving the participants' depressive condition (SD=–6.30, 95% CI –7.14 to –5.47, *P*<.001) and considerable heterogeneity was found (I^2=96%, *P*<.001; Figure 12 [14,20,22,25]). Egger regression test and funnel plot showed that there was no

XSL•FO
RenderX

significant publication bias between the included studies (*P*=.34; Figure 6).

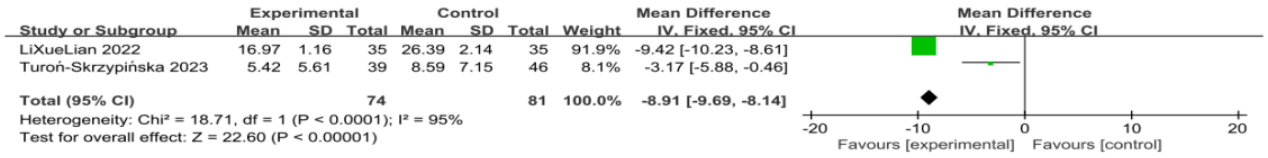


Figure 12. Forest plot of virtual reality on psychological outcome of depression [14,20,22,25].

Anxiety

Two trials used anxiety scores as outcome measures [14,20]. The results show that patients undergoing VR training had lower anxiety levels compared with the control group, indicating that VR was more effective in improving the participants' anxiety condition (SD=–8.91, 95% CI –9.69 to –8.17, *P*<.001) with high heterogeneity (I^2=95%, *P*<.001; Figure 13 [14,20]). Since there were fewer than 3 studies, publication bias was not assessed.

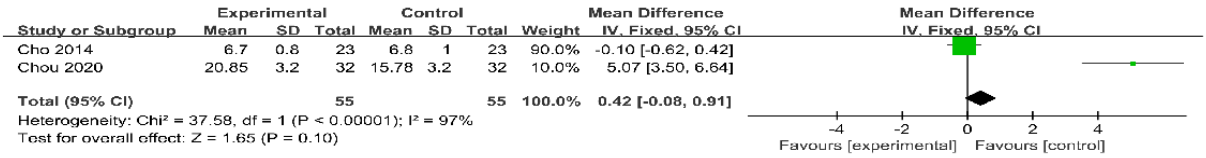

Figure 13. Forest plot of virtual reality on psychological outcome of anxiety [14,20].

Fatigue

Two trials used fatigue scores as outcome measures [19,23]. The results indicate no significant difference in improving fatigue among dialysis patients between VR training and other training methods (SD=0.42, 95% CI –0.08 to 0.91, *P*=.01) with high heterogeneity (I^2=97%, *P*<.001; Figure 14 [19,23]). Since there were fewer than 3 studies, publication bias was not assessed.

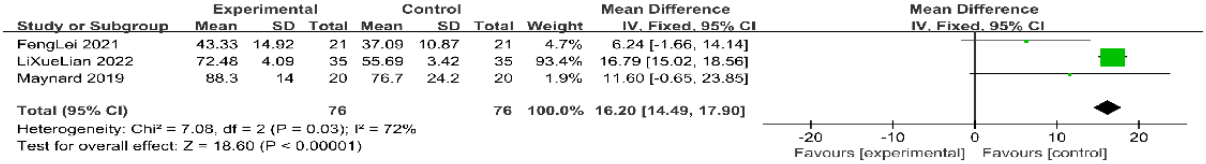

Figure 14. Forest plot of virtual reality on psychological outcome of fatigue [19,23].

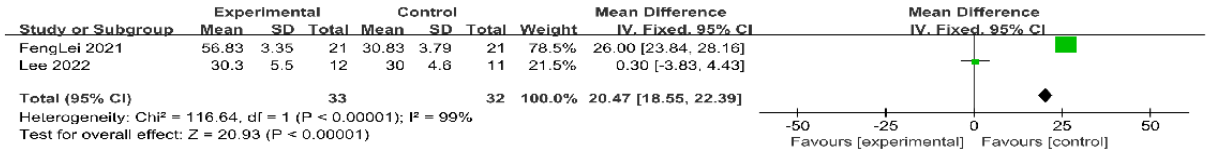
Social Functioning

Three trials used social functioning scores as outcome measures [18,20,25]. The results demonstrate that VR training was more effective than the control group interventions in improving patients' social functioning (SD=16.20, 95% CI 14.49-17.90, *P*<.001) with middle heterogeneity (I^2=72%, *P*=.03; Figure 15 [18,20,25]). Egger regression test and funnel plot showed that there was no significant publication bias between the included studies (*P*=.35; Figure 6).

Figure 15. Forest plot of virtual reality on social function [18,20,25].



Self-Efficacy

Two trials used self-efficacy scores as outcome measures [17,18]. The results indicate that VR training was more effective than the control group interventions in improving patients' self-efficacy (SD=20.47, 95% CI 18.55-22.39, *P*<.001) with high heterogeneity (I^2=99%, *P*<.001; Figure 16 [17,18]). Since

XSL•FO
RenderX

there were fewer than 3 studies, publication bias was not assessed.

Figure 16. Forest plot of virtual reality on self-efficacy [17,18].

Discussion

Summary of Main Findings

This meta-analysis encompassed 12 trials involving 625 participants, of whom (99/625; 15.8%) were PD patients. All studies used VR training as the intervention, while control groups received conventional methods such as health education, routine care, and exercise adapted to patients' daily routines. Of these 12 studies, 5 reported the use of random sequence generation.

This meta-analysis offers a thorough evaluation of the effectiveness of VR training in comparison with traditional methods across various outcome measures, including motor abilities, balance, and psychological well-being. The findings indicate that VR training significantly enhances walking ability, as measured by the 6MWT, with an SD of 29.36. This effect is notably more pronounced compared with gait speed and other motor ability measures, where VR training did not produce significant improvements. Furthermore, VR training was linked to significant reductions in symptoms of depression and anxiety, along with enhancements in social functioning and self-efficacy. However, VR training did not show significant benefits for balance, Sit-to-Stand tests, or the TUG.

Physical Mobility

The substantial improvement observed in the 6MWT with VR training stands in stark contrast to the absence of significant results in gait speed. The 6MWT evaluates endurance and walking capability over a period, which may be well-suited to the interactive and engaging nature of VR environments. The immersive qualities of VR training may enhance patients' motivation and engagement during prolonged walking tasks, thereby contributing to better performance on the 6MWT. Silva et al [26] demonstrated that visual and auditory stimuli in virtual environments encourage active participation in training, leading to increased exercise, walking distance, and time, which enhances the effectiveness of the 6MWT and improves patients' walking ability. Research indicates that gait rehabilitation programs using VR can aid dialysis patients with muscle weakness and joint pain in improving walking speed and quality by simulating diverse walking environments and obstacles, thereby enhancing their independence in daily life [27]. The inclusion of dynamic, goal-oriented tasks in VR may better simulate real-world walking scenarios, motivating participants to exert greater effort and maintain activity for extended periods. In contrast, gait speed, a measure of immediate walking performance, may not benefit as substantially from the immersive features of VR training. The effectiveness of VR in enhancing gait speed may be influenced by the intensity and duration of training sessions, which varied across studies. Consequently, the lack of significant differences in gait speed improvement may suggest a need for more specific training protocols or supplementary interventions to optimize gait speed outcomes.

Psychological Symptoms

The observed significant improvement in walking ability among dialysis patients underscores the potential of VR training to address key aspects of patient care. Improving walking capability can significantly impact daily functioning and overall quality of life, particularly in individuals with mobility impairments [28]. The capacity to enhance physical function while concurrently addressing psychological factors, such as depression and anxiety, highlights the comprehensive benefits of VR training. Research by Schröder et al [29] further demonstrates that VR training can alleviate patients' negative emotions, including anxiety and depression. By offering a multifaceted therapeutic approach, VR has the potential to enhance both physical performance and mental well-being, essential components of holistic patient care. Furthermore, the effectiveness of VR in reducing depression and anxiety suggests that VR training may serve as a valuable tool for mitigating the broader psychosocial impacts of chronic illness [30]. The immersive and interactive features of VR provide an engaging and motivating environment that fosters positive changes in mood and self-perception, thereby contributing to improved overall patient outcomes [31].

Social Functioning

The findings of this meta-analysis demonstrate that VR training significantly improves social functioning in patients, as evidenced by a SD of 16.2. This result suggests that VR training can substantially enhance social interaction and integration, which are crucial aspects of overall well-being. The positive effect of VR on social functioning may be attributed to various factors inherent to the VR experience. VR environments frequently offer engaging and interactive scenarios that promote social engagement and collaboration, even among individuals with limited mobility or social anxiety. VR training usually includes interactive tasks and group-based activities that encourage active participation, thereby enhancing patients' social skills and interactions. The immersive nature of VR provides opportunities for patients to practice social scenarios in a controlled environment, thereby enhancing their confidence and comfort in real-world social interactions. Furthermore, participation in VR-based social activities may foster a sense of community and support, further enhancing social functioning. Despite these promising results, it is crucial to consider the variability in social functioning outcomes reported across

XSL•FO
RenderX

studies. The observed heterogeneity (I^2=72%) indicates that factors such as the design of VR interventions, the nature of social interactions, and the duration of training may affect the effectiveness of VR in enhancing social functioning. Future research should focus on exploring these variables in detail and identifying the specific components of VR training that most effectively improve social interaction and integration [32].

Self-Efficacy

Virtual reality training demonstrated a significant improvement in self-efficacy, with an SD of 20.47, indicating that VR interventions substantially enhance patients' confidence in their ability to manage various tasks and challenges. Self-efficacy, defined as the belief in one's ability to achieve goals, is a crucial determinant of both physical and psychological health. The observed improvement in self-efficacy with VR training can be attributed to the interactive and engaging nature of VR environments, which frequently include goal-setting, feedback, and achievement [33]. VR training typically integrates elements such as progress tracking, rewards, and virtual challenges, which can enhance patients' confidence in their abilities. By offering immediate feedback and a sense of accomplishment, VR can reinforce positive behaviors and attitudes, thereby contributing to improved self-efficacy. Furthermore, the immersive and supportive features of VR environments may help patients overcome fears and build confidence in a controlled setting, potentially translating into improved self-efficacy in real-world situations [34]. However, the high heterogeneity (I^2=99%) in the self-efficacy outcomes suggests that the effectiveness of VR in enhancing self-efficacy may be influenced by several factors, including the design of the VR interventions and individual patient characteristics. Future research should focus on identifying the most effective VR components for enhancing self-efficacy and investigating how different patient characteristics may influence the outcomes of VR training.

Challenges and Limited Use of VR in PD Patients

The use of VR training among PD patients has been relatively limited compared with other patient populations. Several factors are likely to contribute to this limited use. PD patients face distinct challenges, such as the requirement for specialized equipment and potential complications related to fluid management, which may complicate the integration of VR training. In addition, this patient population may have unique physical and psychological conditions that necessitate tailored interventions. Current research on VR training for this population is still emerging, and the application of VR may need adaptation to address these specific needs effectively.

Furthermore, PD patients may experience varying levels of physical capability and psychological stress compared with other patient groups, which may influence the outcomes of VR interventions. Future research should focus on developing and testing VR programs specifically tailored for this population, considering their unique requirements and limitations to ensure that the interventions are both safe and effective.

Advantages and Limitations

This meta-analysis highlights the potential of VR training as an adjunctive therapy for enhancing walking ability and psychological well-being in dialysis patients. The substantial improvements in walking endurance and psychological outcomes observed in this analysis suggest that VR training may be a valuable addition to existing therapeutic strategies. Nevertheless, the observed variability in results and heterogeneity in certain outcomes underscores the need for further research.

The strengths of this study include (1) it is the first meta-analysis to assess the impact of VR training on dialysis patients and (2) we assessed the effectiveness of VR training using 12 outcome measures: gait speed, balance, 6-minute walk test score, STS-5, STS-10, STS-60, TUG, depression, anxiety, fatigue, social functioning, and self-efficacy, providing a comprehensive reference for future research.

This study also has limitations: (1) it included only published articles in Chinese and English, which may impact the meta-analysis results, (2) some studies did not provide details on sequence generation, allocation concealment, and blinding, and (3) the 12 studies included in the analysis used different control interventions and the intervention durations across the studies varied significantly, which may have contributed to significant heterogeneity among the studies.

Future research should focus on refining VR interventions, exploring their optimal implementation, and addressing the specific needs of diverse patient populations. Larger and more diverse sample sizes, coupled with standardized training protocols, will be crucial for comprehensively evaluating the benefits and limitations of VR.

In this study, we used multiple databases for literature retrieval to ensure comprehensive coverage of relevant research in the field. Our selected databases included CNKI, Wanfang, China Science and Technology Journal Database, SinoMed, Cochrane Library, Web of Science, PubMed, and Embase. These databases offer a wealth of research outputs, particularly the Chinese databases, which aggregate a substantial amount of high-quality studies conducted by Chinese scholars, reflecting the region's active contribution to this field. However, we recognize that our current search strategy may not fully represent the entire research landscape, particularly the lack of studies from North America.

Although our initial search did not yield relevant North American research, this may be attributed to the limitations of our search strategy and keyword selection. We acknowledge that this omission could impact the representativeness of our results and potentially influence the conclusions drawn from the study. Therefore, we emphasize this limitation within the article and recommend that future research consider broader literature retrieval strategies to ensure a more holistic understanding of the field.

This reflection provides important guidance for subsequent studies, ensuring that future efforts can better integrate research findings from diverse regions, thereby enhancing the breadth and depth of analysis.

Conclusions

This meta-analysis offers a thorough evaluation of the use of VR training in dialysis patients. The findings indicate that VR training effectively enhances patients' physical fitness, alleviates anxiety and depression, and improves adherence, thereby facilitating better self-management. However, research focusing on VR training in peritoneal patients is relatively limited compared with that on hemodialysis patients. Future research should involve PD patients and use rigorous, large-scale studies to validate the findings of this review for both hemodialysis and PD populations.

Acknowledgments

The authors would like to acknowledge that all research and manuscript preparation were conducted by the authors themselves, with no external assistance.

Data Availability

All data generated or analyzed during this study are included in this published article and Multimedia Appendices 1-3.

Authors' Contributions

XK contributed to writing the original draft, data curation, validation, software, formal analysis, and investigation. YZ managed writing the original draft, data curation, visualization, software, formal analysis, and investigation. CS handled validation, investigation, and data curation. ZC and JZ contributed to investigation and data curation. RZ managed conceptualization, data curation, writing—review and editing, supervision, project administration, and visualization.

Abstract

Background: Extended reality (XR) technologies are increasingly being used to reduce health and procedural anxieties. The global effectiveness of these interventions is uncertain, and there is a lack of understanding of how patient outcomes might vary between different contexts and modalities.

Objective: This research used panoramic meta-analysis to synthesize evidence across the diverse clinical contexts in which XR is used to address common outcomes of health and procedural anxiety.

Methods: Review-level evidence was obtained from 4 databases (MEDLINE, Embase, APA PsycINFO, and Epistemonikos) from the beginning of 2013 until May 30, 2023. Reviews that performed meta-analysis of randomized controlled trials relating to patient-directed XR interventions for health and procedural anxiety were included. Studies that analyzed physiological measures, or focused on technologies that did not include meaningful immersive components, were excluded. Furthermore, data were only included from studies that compared intervention outcomes against no-treatment or treatment-as-usual controls. Analyses followed a preregistered, publicly available protocol. Trial effect sizes were extracted from reviews and expressed as standardized mean differences, which were entered into a 3-level generalized linear model. Here, outcomes were estimated for patients (level 1), studies (level 2), and anxiety indications (level 3), while meta-regressions explored possible influences of age, immersion, and different mechanisms of action. Where relevant, the quality of reviews was appraised using the AMSTAR-2 (A Measurement Tool to Assess Systematic Reviews, Revised Instrument) tool.

Results: Data from 83 individual trials were extracted from 18 eligible meta-analyses. Most studies involved pediatric patient groups and focused on procedural, as opposed to general, health anxieties (eg, relating to needle insertion, dental operations, and acute surgery contexts). Interventions targeted distraction-, education-, and exposure-based mechanisms, and were provided via a range of immersive and nonimmersive systems. These interventions proved broadly effective in reducing patient anxiety, with models revealing significant but heterogeneous effects for both procedural (d=–0.75, 95% CI –0.95 to –0.54) and general health (d=–0.82, 95% CI –1.20 to –0.45) indications (when compared with nontreatment or usual-care control conditions). For procedural anxieties, effects may be influenced by publication bias and appear more pronounced for children (vs adults) and nonimmersive (vs immersive) technology interventions, but they were not different by indication.

Conclusions: Results demonstrate that XR interventions have successfully reduced patient anxiety across diverse clinical contexts. However, significant uncertainty remains about the generalizability of effects within various unexplored indications, and existing evidence is limited in methodological quality. Although current research is broadly positive in this area, it is premature to assert that XR interventions are effective for any given health or procedural anxiety indication.

Introduction

Health and procedural anxiety can lead to delayed engagement with treatment, reduced treatment adherence, worsening symptoms, and compromised quality of life. Two primary approaches to alleviate health and procedural anxiety are exposure and distraction therapies. Distraction-based approaches seek to reduce anxiety by diverting attention away from distressing thoughts, situations, or physical sensations. While controversial as a long-term technique [1], these are effective for short-term anxiety reduction [2]. However, distraction methods may not always be readily available or accessible, particularly in moments of acute anxiety/stress. Exposure therapy has been traditionally delivered in vivo. By directly facing the fearful stimuli without resorting to escape, avoidance, or rituals, the patient's connection between the stimulus and memory structures is modified, leading to a potential reduction in the elicited anxiety response [3]. While effective, in vivo exposure has several limitations; it can be difficult to instigate when the anxiety-inducing environment or stimulus is inaccessible and can be time-consuming and expensive to simulate. There is, therefore, a drive toward the use of technologies that can deliver these therapies in a more cost-effective and accessible manner.

Extended reality (XR) technologies—including virtual reality, augmented reality, and mixed reality—are well suited to deliver these therapies [4]. XR immerses users in a digital environment, providing a heightened sense of presence and interaction with synthetic sensory stimuli. These simulations can feel realistic, enabling users to practice skills or experience environments in a controlled and immersive setting that can ultimately aid the therapeutic process. For example, XR can gradually expose patients to anxiety-inducing cues, to elicit realistic emotional responses that can become habituated over time, and they can also supply experiential patient education material about a procedure or condition. Similarly, the highly immersive and interactive nature of XR makes it an ideal distraction tool, which can divert attention toward more pleasurable or relaxing sensory environments. From a practical perspective, XR interventions can be used to address wide-ranging anxiety indications, given the breadth of stimuli that can now be simulated effectively and the capability to be delivered remotely (eg, headsets could be posted to patient's homes before attending appointments). They are also considered highly engaging forms of therapy [5] that can provide personalized patient experiences (eg, by tailoring exposure- and distraction-based cues to individual user data), so they may promote better treatment adherence [6]. XR is therefore a scalable tool that has the potential to enhance the accessibility of therapeutic interventions for patients who may be unwilling or unable to participate in more conventional forms of psychological treatment [7].

Panoramic meta-analyses are a tool to integrate evidence from trials covering the same intervention and the same outcomes over a range of indications. Originally designed for use in the context of overviews of reviews (ie, systematic reviews of systematic reviews), early panoramic meta-analyses addressed topics such as sutures versus staples for wound healing in a range of surgical sites [8]. More recently, panoramic meta-analyses have also addressed mental health outcomes, such as cognitive behavioral therapy for health-related quality of life [9]. When used to evaluate evidence for a given intervention method, panoramic meta-analyses offer a statistical advantage for random effects modeling, in that they generate more stable estimates of between-study variance. But more importantly, they generate "global" estimates of effectiveness that allow for (1) assessment of likely future effects via prediction intervals; (2) assessment of the relative importance of indication in explaining effect heterogeneity via variance partitioning; and (3) tests of effect modification (ie, via meta-regression) that may be better powered by drawing on evidence from multiple indications. Thus, in this research, panoramic meta-analyses can indicate the broad impact that XR interventions have on patient anxiety across diverse clinical contexts, while also offering unique insight into the exchangeability of effects between different intervention types, technologies, populations, and indications. From an applied perspective, one can use this insight to inform future clinical programs (eg, by deciding whether to adopt XR based on pooled data that reflects efficacy or inefficacy over general/specific contexts, or by using findings that indicate whether certain indications/methods are associated with greater efficacy or uncertainty).

Consequently, a panoramic meta-analysis was undertaken to synthesize evidence across the diverse health-related contexts in which XR is used to address common outcomes of health and procedural anxiety. The aim of this analysis was to consider the global effectiveness of XR, to assess the likelihood of effectiveness for other clinical indications, and to explore whether key intervention characteristics are associated with varying levels of effectiveness.

Methods

Overview

A protocol for this review was registered on the Open Science Framework [10], a widely used, publicly available platform that permits the open sharing of research data and material. This analysis is part of a larger evidence-synthesis project focusing on XR interventions for health and procedural anxiety.

Included Studies

A set of systematic reviews was identified, which included meta-analyses of randomized controlled trials relating to patient-directed XR interventions for health and procedural anxiety outcomes published from 2013 onward. In line with the panoramic meta-analysis approach, these reviews informed the sample of trials and effect sizes that were subsequently examined in generalized linear models (see the Statistical Methods section

XSL•FO
RenderX

below). Specific inclusion and exclusion criteria are detailed in Table 1. Procedural anxiety was defined as anxiety both related and proximal to specific medical procedures, generally as a measure of state anxiety [11]. Health anxiety was defined as anxiety relating to broader health conditions, generally as a measure of trait anxiety [12]. Studies that based their analyses on physiological measures of anxiety were excluded (eg, blood pressure and heart rate), and data were only extracted that compared intervention outcomes against no-treatment or treatment-as-usual controls. Eligibility criteria did not impose any further stipulations for the trial-level data, and the extraction of effect sizes was not restricted to studies from any given language, date, or region.

Table 1. Eligibility criteria.

Characteristics	Inclusion criteria	Exclusion criteria
Study design	• Systematic reviews[a] of randomized controlled trials that included meta-analyses or forest plots with reported effect sizes • Reviews published as full-text articles in peer-reviewed journals from 2013 onward[b] • Randomized controlled trials that feature in these systematic reviews	• Reviews that did not perform adequate searches of an electronic database, using the structured search query, with inclusion/exclusion criteria specified • Conference abstracts, dissertations, and theses • Nonrandomized trials
Interventions	• Focus on patient-directed XR[c] interventions[d] in any primary or discrete subgroup analyses	• Focus on technologies that do not include meaningful immersive components (eg, mobile apps)
Comparators	• Data comparisons against no-treatment or treatment-as-usual controls	• None
Outcome	• Patient health or procedural anxiety measures	• Trial data relating to pain outcomes or physiological indicators of anxiety

[a]Definitions of systematic reviews were based on criteria developed for the Database of Abstracts of Reviews of Effects.

[b]Trial eligibility was not restricted to studies from any given date.

[c]XR: extended reality.

[d]XR interventions included virtual reality, mixed reality, or augmented reality systems.

Search and Selection

Searches were carried out on May 30, 2023, in MEDLINE and Embase (on the Ovid platform), APA PsycINFO (in Ovid), and Epistemonikos. This variety of databases was selected to cover general medical literature, specialist psychology sources, and a collection of systematic reviews. Searches used appropriate subject headings and keywords for the intervention (virtual reality), outcome (health anxiety), and study design (systematic reviews), with full terms and methods specified in Multimedia Appendix 1. Records were screened independently and in duplicate, both at the title and abstract stage and at full-text stage, recording reasons for exclusion at full-text and involving a third reviewer in case of disagreement.

Data Extraction, Risk of Bias, and Classification

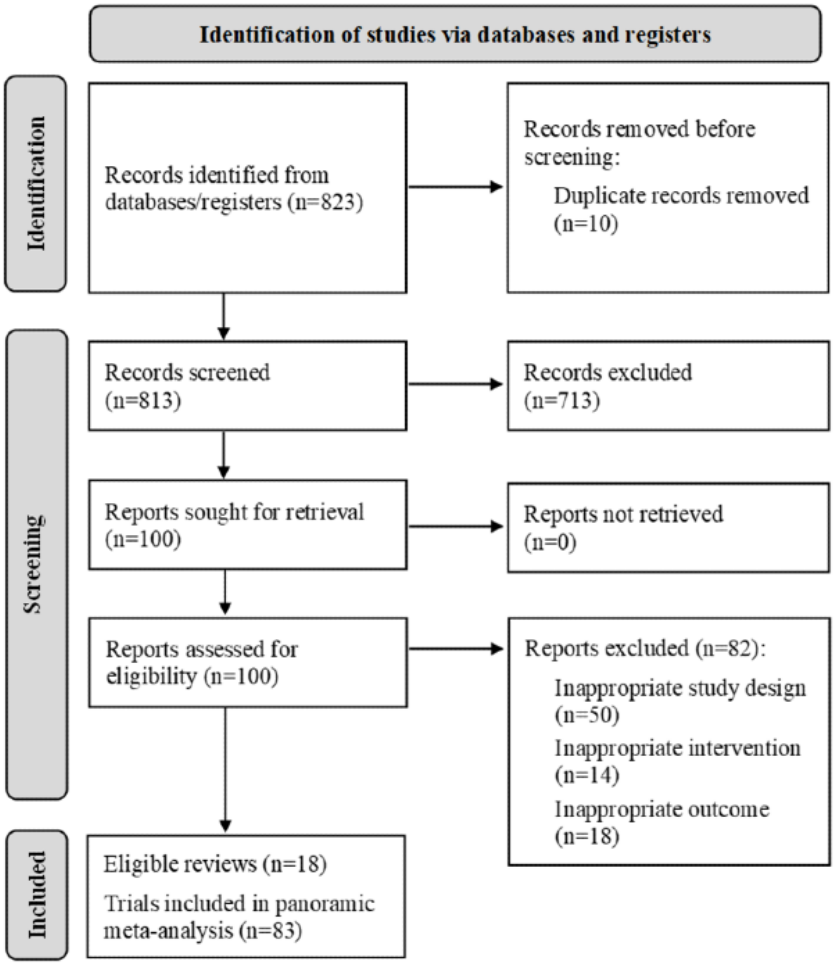
Informed by included reviews and relevant trials within them, a set of high-level indications were inductively generated as distinct “use cases” of XR. Different classifications were developed for procedural anxiety and general health anxiety. Within each indication and outcome, the highest quality, the most recent review was prioritized for effect size extraction from included forest plots, defining quality using the results of appraisal with the AMSTAR-2 (A Measurement Tool to Assess Systematic Reviews, Revised Instrument) [13]. The analysis then proceeded through the remaining reviews sequentially, organizing reviews by publication year and, within year, by quality, until no additional trials were identified, extracting evidence from randomized controlled trials only and preferring effect estimates for the same trial and outcome from higher-priority reviews. Where available, trial-level risk of bias (RoB) assessments were extracted, from included reviews providing sufficient evidence. Extraction items are provided in the protocol. The original trial was consulted when (1) extracted effect sizes were inappropriate or possibly inaccurate (eg, a standardized mean difference greater than 2) or (2) effect sizes were not presented as standardized mean differences and relevant standard deviations were not presented in included plots. One reviewer led extraction with auditing by a second.

Statistical Methods

All effect estimates were expressed as standardized mean differences, where negative values are positive (ie, greater reduction in anxiety). For each outcome, a 1-step meta-analysis model was estimated using a 3-level generalized linear model, where level 1 (patients within trials) is implied, level 2 is the study-level effect estimate, and level 3 is the indication. All models were estimated using restricted maximum likelihood and random effects at level 2 and level 3, with a common level 2 variance component across all indications to stabilize estimation. Heterogeneity was quantified using a standard variance partitioning method, generating a between-study, within-indication I^2, and a between-indication I^2 based on the Higgins and Thompson method. Statistical analyses were undertaken on Stata (version 18; StataCorp).

XSL•FO
RenderX

Sensitivity and Exploratory Analyses



The registered protocol stated that for any instances containing too few indications in an outcome (fewer than 10), sensitivity analysis would be undertaken with a 2-level model, using fixed effects for indication at level 2. This model was compared with an unconditional meta-analysis model using a likelihood ratio test as an additional assessment of the value of indication as a grouping variable. Additionally, protocol-specified meta-regressions by age group (adult vs children), system immersion (immersive vs nonimmersive), and mechanism of action (relaxation or distraction vs exposure or education) were undertaken, where sufficient variation was present. Finally, funnel plots were drawn as an exploratory analysis, and an Egger test was estimated to examine small-study bias where the number of trials for any one indication and outcome was greater than 10.

Results

Search Results

A total of 18 meta-analyses informed the sample of trials, of which 10 provided procedural anxiety outcomes and 8 provided general health anxiety outcomes. Across these meta-analyses, 53 trial effects for procedural health anxiety outcomes and 30 trial effects for general health anxiety outcomes were examined. Two studies [14,15] reported data from multiple XR interventions, which were examined separately. Analyses excluded 15 trials that other meta-analyses included: 14 did not meet the specified definitions of XR, and one used physiological measures only. Study selection processes are outlined in Figure 1, via a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart (see full list of included reviews in Multimedia Appendix 2 [16-33]).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart of retrieved, screened, and included studies.

Trial Characteristics

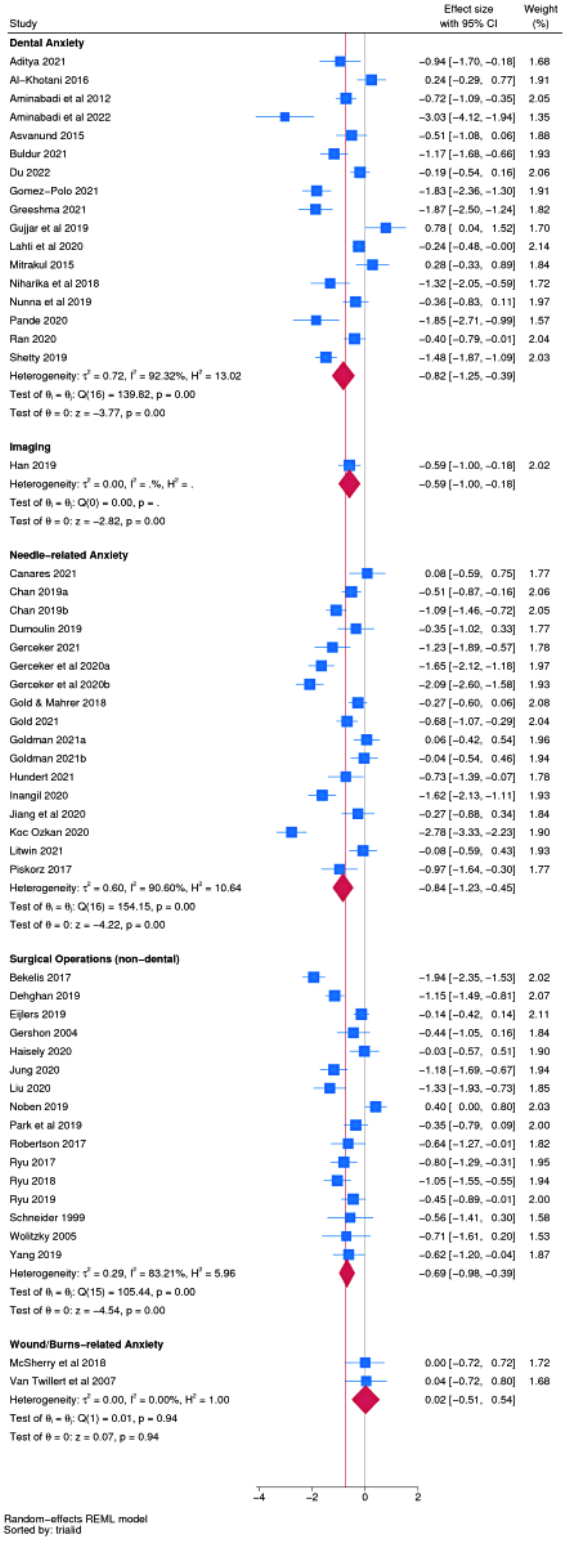
Details of study-level extraction, measures used, and interventions are provided in Multimedia Appendix 3. Reviews examined anxiety indications relating to either a specific medical procedure (n=8) or those additionally relating to general health conditions and prolonged treatment pathways (n=10). The average number of trials examined within each review was 6.67 (SD 3.38), although 18 overlapping trials were detected in multiple meta-analyses. Trial-specific RoB assessments or quality appraisals were reported in all but 3 of the included studies and are presented in Multimedia Appendix 4. These methodological evaluations followed inconsistent assessment criteria (eg, the Cochrane RoB, ROBINS-I, and Delphi List tools); however, only 8 trials were considered to have low RoB overall and 49 were deemed to have a high risk or some concerns. Methods for assessing anxiety notably varied between trials and were dependent on clinical indications. The most common measures were the Modified Dental Anxiety Scale (for

XSL•FO
RenderX

dental studies), the State-Trait Anxiety Inventory (for cancer treatment, cardiac rehabilitation), the Modified Yale Preoperative Anxiety Scale (for nondental surgical operations), the Self-rating Anxiety Scale (for maternity), the Observational Scale of Behavioral Distress for radiographic procedures (for imaging), the Pain Anxiety Symptoms Scale (for chronic pain conditions), and simple visual analog scales (for wound care, needle-related anxieties).

Most of the included trial analyses (44/83, 53%) evaluated anxiety in pediatric patients only, while 36 trials focused on adults only, and 3 trials involved mixed-age samples (ie, children and adults). From an intervention perspective, the vast majority of procedural anxiety interventions (46/53, 55%) included just a single XR-based therapy session, the duration of which varied from 1 minute [34] to 90 minutes [35] (based on the context and population). Interventions for general health anxieties were more heterogeneous in design, ranging from single sessions to repeated activities over a period of months (Multimedia Appendix 3). Immersive forms of XR were adopted in 37 study interventions, whereas 46 interventions used nonimmersive methods. Interventions incorporated a range of XR technologies, including standalone virtual reality systems, portable glasses, mobile phone head-mounted displays, and monitor-based simulation devices.

In total, 66 interventions were classed as distraction-based or relaxation-based. These included natural scenery experiences (28 trial interventions), adventure or rollercoaster games (22 trial interventions), cartoons (12 trial interventions), mindfulness applications (1 trial intervention), and 3D images/videos (2 trial interventions). Conversely, 16 interventions were classified as education- or exposure-based. Separations between education- and exposure-based methods were not made, as numerous interventions incorporated elements of both components, and studies rarely provided sufficient details or rationale about XR procedures. This was also the case for distraction- and relaxation-based approaches (although it is also worth noting that all distraction experiences could be considered somewhat relaxing relative to anxiety-inducing medical stimuli).



Procedural Anxiety

Overview of Trials

Classification of trials measuring procedural anxiety outcomes identified 5 indications: dental anxiety (n=17), imaging (n=1), needle-related anxiety (n=17), nondental surgical operations (n=16), and anxiety related to wounds and burn care (n=2). Indication-specific meta-analyses are presented in Figure 2. In brief, all interventions generated significant effects within indication, except for interventions for wounds and burn care.

XSL•FO
RenderX

Figure 2. Forest plot for procedural anxiety outcomes.

Panoramic Meta-Analysis

A panoramic meta-analysis model nesting trials within indication generated an overall pooled effect (*d*) of –0.75 (95% CI –0.95 to –0.54) (Table 2). The between-indication (level 3) variance parameter for this model was equal to 0, whereas the within-indication, between-trial (level 2) variance parameter was equal to 0.48. Thus, the I^2 attributable to indication was 0%, and the I^2 attributable to between-trial differences was 89.0%. However, a prediction interval for the pooled effect spanned –2.11 to 0.62, indicating that effectiveness in a future trial would be highly uncertain.

XSL•FO
RenderX

Table 2. Panoramic meta-analysis models.

Model	SMD[a] (95% CI)	Between-indication τ^2	Between-trial τ^2
Procedural anxiety			
Overall	–0.75 (–0.95 to –0.55)	0.00	0.48
Age		0.00	0.45
Adults	–0.27 (–0.73 to 0.18)		
Children	–0.86 (–1.07 to –0.64)		
Difference	–0.58 (–1.08 to –0.08)		
Immersive		0.00	0.44
Nonimmersive	–0.97 (–1.22 to –0.71)		
Immersive	–0.46 (–0.75 to –0.16)		
Difference	0.51 (0.12 to 0.90)		
Mechanism		0.00	0.48
Relaxation/distraction	–0.82 (–1.05 to –0.58)		
Education/exposure	–0.53 (–0.95 to –0.11)		
Difference	0.28 (–0.19 to 0.76)		
General health anxiety			
Overall	–0.82 (–1.29 to –0.45)	0.09	0.33
Immersive		0.09	0.35
Nonimmersive	–0.86 (–1.30 to –0.41)		
Immersive	–0.78 (–1.25 to –0.30)		
Difference	0.08 (–0.44 to 0.60)		

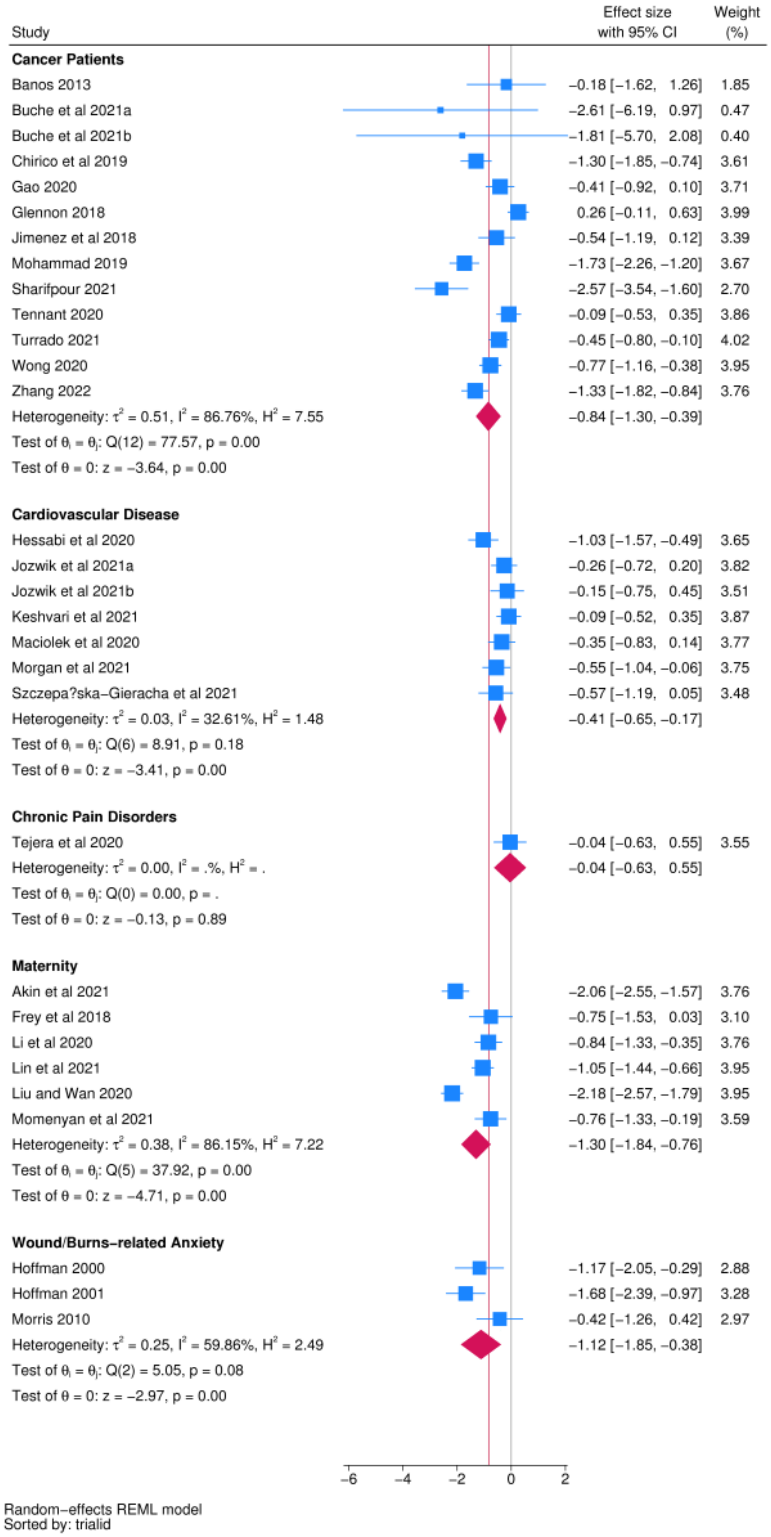
[a]SMD: standardized mean difference.

Sensitivity Analyses

Because the number of indications was fewer than 10, a protocol-specified sensitivity analysis was undertaken, treating indication as a fixed effect. A likelihood ratio test comparing this model against a simple 2-level model suggested that including an indication as a fixed effect did not improve model fit (χ^2_4=2.47, *P*=.65).

Three protocol-specified meta-regressions were then undertaken. Because of the size of each indication category, these should be regarded as indicative only. Across indications, interventions were significantly more effective in children versus adults (difference: *d*=–0.58, 95% CI –1.08 to –0.08), and immersive interventions appeared less effective than nonimmersive interventions (difference: *d*=0.51, 95% CI 0.12-0.90). There was no significant difference in the size of effect between interventions using relaxation or distraction and interventions using education or exposure.

An Egger test for the dental anxiety indication implied some evidence of small-study bias (*P*=.048), with a funnel plot reflecting this possibility (Multimedia Appendix 5). While an Egger test for needle-related anxiety did not generate a significant result (*P*=.97), a funnel plot indicated significant unexplained heterogeneity. An Egger test for surgical operations was not significant (*P*=.86), and a funnel plot did not suggest evidence of small-study bias.



General Health Anxiety

Overview of Trials

Classification of trials measuring general health anxiety outcomes identified 5 indications: cancer (n=13), cardiovascular disease (n=7), chronic pain disorders (n=1), maternity (n=6), and anxiety related to wounds and burn care (n=3). Indication-specific meta-analyses are presented in Figure 3. All interventions generated significant effects within the indication, except for interventions for chronic pain disorders.

XSL•FO
RenderX

Figure 3. Forest plot for general health anxiety outcomes.

Panoramic Meta-Analysis

A panoramic meta-analysis model nesting trials within indication generated an overall pooled effect (*d*) of –0.82 (95% CI –1.20 to –0.45; Table 2). The between-indication (level 3) variance parameter for this model was equal to 0.09, whereas the within-indication, between-trial (level 2) variance parameter was equal to 0.33. Thus, the I^2 attributable to indication was 17.7%, and the I^2 attributable to between-trial differences was 67.3%. The conditional I^2 using only trial-level and between-trial variance was 81.8%. The prediction interval for the pooled effect spanned –2.09 to 0.45, indicating, as for procedural anxiety, the highly uncertain effectiveness of XR interventions in any future trial.

Sensitivity Analyses

Since the number of indications was fewer than 10, a protocol-specified sensitivity analysis was undertaken, which

XSL•FO
RenderX

treated indication as a fixed effect. A likelihood ratio test comparing this model against a simple 2-level model suggested that including indication as a fixed effect did not improve model fit (χ^2_4=8.57, *P*=.07), albeit with a marginal significance test.

Of the 3 protocol-specified meta-regression analyses, tests for age and mechanism were not undertaken, as only 2 indications had a variation on these meta-regressors. The difference between immersive and nonimmersive interventions was small and not significant (difference: *d*=0.08; 95% CI –0.44 to 0.60). Finally, an Egger test for trials in the cancer indication generated a nonsignificant result (*P*=.19), and a funnel plot did not suggest conclusive evidence of small-study bias (Multimedia Appendix 5).

Discussion

Principal Findings

Using an innovative statistical method, this analysis demonstrated that the effectiveness of XR interventions for both procedural and health anxiety is heterogeneous but conclusive; however, the evidence base for procedural anxiety is limited by publication bias, and effectiveness for procedural anxiety is moderated by age of participant and mechanism of effect. As a distinctive feature of panoramic meta-analysis, it was demonstrated that effects in procedural anxiety generalize across currently tested indications, while indication explains a relatively low amount of variance in general health anxiety outcomes; but that generalizability in a future trial is highly uncertain. Put otherwise, the evidence for the effectiveness of XR interventions in currently assessed indications cannot be used to assert that XR interventions would likely be effective for *any* given indication.

Implications for Research and Practice

Although positive effects emerged across a range of general and procedural health anxieties, various indications remain poorly established. Indeed, most meta-analyses are based on context-dependent intervention data, which relates to specific medical procedures (eg, needle insertions and dental surgery) or long-term conditions (eg, cancer and cardiovascular disease). Panoramic meta-analysis methodologies were specifically undertaken to synthesize evidence from diverse clinical contexts and to establish the exchangeability of effects between different intervention types, technologies, populations, and indications. However, key questions remain about the effectiveness of XR within broader domains. For instance, studies are notably lacking in relation to imaging and diagnostic screening procedures (eg, endoscopies and mammography), where anxiety can have well-documented impacts on the quality of care [36-38]. Moreover, most current trials concern pediatric patient groups, despite health-related anxieties showing significant (and potentially growing) prevalence among adults [39,40]. Given the uncertain generalizability of study data that was highlighted in the present analyses, research needs to ascertain the best-suited clinical contexts for future XR interventions.

For the management of procedural anxieties, meta-regressions showed XR to be more effective in children (vs adults), and when using nonimmersive (as opposed to immersive) technologies. These findings imply that age and technology-related variables could influence the success of future XR programs. However, these findings did not replicate general health anxieties, indicating a role for broader, psychopathological factors in shaping effectiveness. For instance, positive outcomes may be more easily achieved when targeting relatively minor forms of anxiety (eg, a child's worries about needles), compared with more complex and longstanding dispositions (eg, anxieties relating to major surgery or lifelong phobias). Relatedly, nonimmersive XR may be used for implementing simple, distraction-based interventions, whereas immersive devices may be required when attempting to administer more sophisticated or wide-ranging therapeutic solutions that are challenging to deliver successfully. When developing future applications, practitioners must consider the role of these interrelated components, since the value of key technological features (eg, fidelity and face validity) will depend on an intervention's wider situational context.

Future research is needed to advance our mechanistic understanding of the empirical data. Here, studies should not just explore population- and technology-specific variables (eg, the age of patients, system immersion, and types of hardware), but also broader methodological components relating to how the intervention is delivered and how it actually "works". Notably, the present results found no significant differences in the management of procedural anxiety between interventions using relaxation or distraction and interventions using education or exposure. However, there were a limited number of trials that examined exposure- and education-based XR methods in the evaluated review evidence, and there were insufficient data for analyzing general health anxiety outcomes. In addition, the included studies rarely provided sufficient details or rationale about their XR procedures and any cointerventions that were present, which limited capabilities for comparing different mechanisms of action. It is important that the contrasting psychophysiological processes implicated by different XR methods are considered during prospective assessments, as they are likely to impact on system requirements. For instance, a high degree of affective fidelity may be important for exposure therapies aiming to provoke "lifelike" stressors and psychophysiological responses; whereas aspects of user presence and task engagement may be more pertinent in simple distraction-based applications (see [41] for related framework). Nonetheless, without further empirical attention in this area, the relationships between different intervention types, psychophysiological mechanisms, and system features remain somewhat unclear. Overall, it is therefore vital that future work aims to address these "gaps" in theoretical understanding, so that the prospective design of XR programs can be sufficiently optimized for clinical implementation.

Strengths and Limitations

The use of panoramic meta-analysis meant that it was not possible to examine questions not generally addressed in single-indication meta-analyses. While the use of an overview of reviews was efficient in this analysis (and in keeping with the original implementation of this method), it is possible that very recently published trials not captured in existing systematic reviews were missed. In addition, this analysis was reliant on

XSL•FO
RenderX

the quality of underpinning systematic reviews including search, extraction, and appraisal. None of the available reviews were rated as high-quality on AMSTAR-2, and many reviews were rated as critically low. Most trials were not rated as being at low RoB in their "parent" reviews. Relatedly, both the trials and reviews contained inconsistencies and inaccuracies in the reporting of study interventions (eg, in terms of describing levels of system immersion, or conceptualizing procedural and general health anxieties). Though included reviews were able to be traced to "saturation", ensuring the identification of all relevant trials identified across reviews, it is possible that relevant trials were still missed.

Conclusions

While XR interventions are promising for both procedural and health anxiety, a number of unanswered questions remain. Future research should broaden the indications in which XR interventions are used, and should continue to develop emerging approaches, such as immersive technology interventions, to optimize their effectiveness while continuing to refine approaches for which effectiveness is well established.

Abstract

Background: During infectious disease outbreaks such as the COVID-19 pandemic, nurses are crucial in patient care and public health safety; however, they face challenges such as inadequate training and high stress in isolation wards. Virtual reality (VR) technology offers innovative training solutions to enhance nurses' clinical skills and preparedness. However, extensive studies on its effectiveness in isolation ward environments are still limited.

Objective: This study aims to develop a nonimmersive VR (NIVR) simulation training program for isolation wards and further validate its feasibility and training effectiveness in aiding nurses in adapting to isolation ward settings.

Methods: This study was a prospective, parallel, open-label, randomized controlled trial. A total of 90 nurses from 3 hospitals in China were randomly assigned to either the control or intervention group, with 45 (50%) individuals in each group. Both groups received training on isolation ward layout and nursing procedures. The control group underwent a 4-hour conventional training session consisting of 2 hours of face-to-face lectures and 2 hours of ward visits. The intervention group received a 4-hour NIVR simulation training session. Subsequently, both groups completed approximately 4 hours of emergency drills and assessments.

Results: After the intervention, there were no significant differences in theoretical test or performance assessment scores between the 2 groups (t_{88}=–0.30, P=.75; Cohen d=–0.06; z score=0.00, P>.99), using a 2-tailed t test. However, the intervention group completed 6 tasks faster than the control group (t_{88}=5.10, P<.001; Cohen d=1.08), with an average reduction of about 3 minutes (control group: mean 43.91, SD 2.99 min; intervention group: mean 40.77, SD 2.85 min). Notably, they completed task 3 (patient reception inward) and task 6 (exiting the isolation area) significantly quicker (t_{88}=3.22, P=.002; Cohen d=0.68; t_{88}=3.03, P=.003; Cohen d=0.64, respectively), with no significant differences for the other tasks.

Conclusions: This study highlights the potential of NIVR simulation training for nurses working in isolation wards. Although NIVR simulation training does not significantly surpass traditional methods in imparting theoretical knowledge, it does reduce task completion time for specific activities. Its capacity for safe, repetitive practice and realistic scenario simulation makes NIVR a valuable tool in medical education. Further research and optimization of VR simulation training programs are recommended to enhance nurses' practical skills and pandemic preparedness.

Introduction

Background

The world faced the challenge of outbreaks of new infectious diseases. During the COVID-19 pandemic, nurses played a vital role in ensuring that patients received personalized, high-quality care while also being essential in patient management, infection prevention, and public health safety [1]. However, there were shortcomings in nurses' abilities to respond to the COVID-19 pandemic [2-6]. Therefore, it was necessary for nurses to receive adequate guidance and training to ensure a safe work environment, protect themselves, and effectively manage the pandemic [1]. To address this issue, the *National Nursing Career Development Plan (2021-2025)* released by the National Health Commission of China explicitly proposed targeted training in scarce nursing specialties, such as infectious diseases [7]. With national policy support, training programs for infectious disease specialist nurses are gradually developing. However, existing programs still face challenges, such as insufficient training, incomplete content, unitary training patterns, limited scenario simulations or emergency drills, and insufficient knowledge of ethics and law, particularly in professional training programs for nurses in the COVID-19 pandemic response [2-6,8-12].

When an pandemic breaks out, isolation wards protect health care workers and patients from infection. Studies have shown that the mental stress and occupational safety of frontline health care workers were linked to unfamiliarity with isolation wards [13,14]. Therefore, it is crucial to train nurses to familiarize them with isolation wards before they enter the quarantine area. Building on the COVID-19 pandemic response experience, health care institutions have intensified emergency training programs for professionals [15]. Nurses need to understand the spatial layout and division of the functional regions in isolation wards and critical aspects, such as standard procedures, personnel management, and infection prevention and control. The training and support aimed to help nurses acclimate to the work environment before entering the isolation area, thus reducing stress and anxiety stemming from unfamiliar surroundings, enhancing preparedness and teamwork abilities, and contributing to a more efficient response. However, studies on related topics remain relatively scarce.

Virtual reality (VR) technology uses digital techniques to create 3D VR environments, allowing users to interact with these environments through head-mounted displays, body sensors, and direct input devices [16]. On the basis of the level of immersion, VR is categorized into immersive VR, semi-immersive VR, and nonimmersive VR (NIVR) [17]. NIVR presents a virtual environment via a computer screen or mobile device, allowing users to interact using a keyboard, mouse, or touch devices [18]. Although NIVR offers a relatively diminished sense of immersion, its low cost, ease of deployment, and lack of a requirement for special equipment confer significant application potential across various scenarios, particularly in training [19-21]. Users can easily access these scenarios on PCs or mobile devices, overcoming temporal and spatial limitations.

Studies indicate that in nursing education and clinical practice, the effectiveness of NIVR can be comparable to, or even surpass, traditional simulation training [22-24]. This technology can effectively simulate complex medical procedures and nursing scenarios, allowing trainees to practice repeatedly in a safe, controlled environment, thus enhancing clinical skills, decision-making ability, and critical thinking [22,25-33]. In addition, a study indicates that the design characteristics of VR simulations encompass patient management content, the implementation of various scenarios and NIVR experiences lasting >30 minutes, and the provision of feedback following the conclusion of the scenarios. These strategies can significantly enhance the effectiveness of VR simulations [34]. During the COVID-19 pandemic, VR proved helpful in addressing the training needs of medical students; however, the lack of hands-on practice might impact the development of clinical skills [35,36]. Therefore, it is necessary to explore integrated training that combines VR with hands-on practice. Yang et al [37] demonstrated that combining NIVR and face-to-face simulation training effectively enhances nursing clinical judgment and encourages student progress in comprehensive simulations. Thus, when integrating VR with traditional training methods, it is crucial to understand the strengths and limitations of each technology and adopt the best practices [29,30,38]. Studies should explore how to integrate these technologies more effectively into the training process, driving innovation and progress in medical education.

The COVID-19 pandemic has underscored the necessity of advancing VR-based remote education [33]. NIVR has advantages in remote virtual training and is increasingly being adopted in nursing degree programs and preservice education [13,33,39]. During outbreaks, practical clinical applications of NIVR simulation training cover multiple aspects, such as infection prevention and control, the use of personal protective equipment [40-42]. It also includes training for managing patients in critical condition, such as basic life support, advanced cardiac life support, and extracorporeal membrane oxygenation [43-47]. NIVR training related to simulating clinical scenarios and integrating clinical cases continues to evolve, with management programs for patients with COVID-19 and Ebola virus diseases among the initiatives [42,48-50]. Currently, research on using VR simulations for nurses to familiarize themselves with and adapt to isolation ward environments remains very limited.

Objectives

The primary objective of this study was to develop an NIVR simulation training program specifically designed for isolation wards and to validate its feasibility and effectiveness in assisting nurses in adapting to this unique environment.

Methods

Participants

This study recruited qualified nurses from 3 comprehensive hospitals in Hengyang City, Hunan Province, from April 1 to April 20, 2024. This study included registered nurses aged 18 to 40 years, with ≥1 year of clinical experience, no previous work experience in isolation wards, good physical health, and a willingness to fully participate in the training. Nonvoluntary participants and those who withdrew midway were excluded. Before commencing the training, each participating nurse was provided with an informed consent form outlining the project training process and duration. The study was initiated after the nurses signed the consent form voluntarily.

A total of 90 eligible nurses participated in this study and were randomly divided into control and intervention groups, with 45 (50%) nurses in each group.

Study Design

This prospective, parallel, randomized controlled trial was registered in April 2024 with the Chinese Clinical Trial Registry (registration number: ChiCTR240083155).

Ethical Considerations

This study was approved by the ethics committee of Affiliated Nanhua Hospital, University of South China (2024-ky-044). This study complies with the Declaration of Helsinki. All participants provided written informed consent and were made aware of their right to opt out of the study at any time. All collected data are anonymous and confidential, and only the authors can access them. Upon completing the training and assessment for this study, participants will be awarded a gift worth approximately US $30 as compensation.

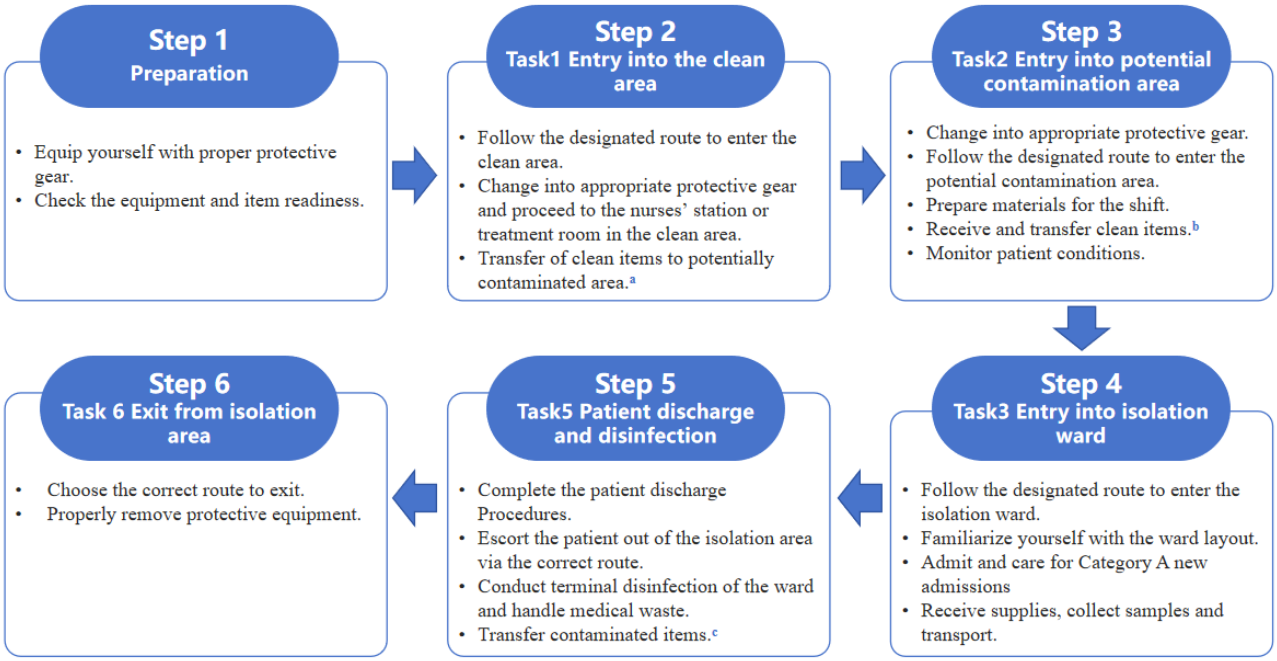
Randomization and Blinding

Participant randomization into intervention and control groups was conducted using SPSS software (version 25.0; IBM Corp) to generate random numbers for a 1:1 allocation. To ensure the integrity of the allocation sequence, it was concealed using sequentially numbered, opaque, and sealed envelopes, which were only opened at the time of intervention assignment after all participants had completed their baseline assessments.

Due to the open-label nature of the study, it was not possible to blind participants or research assistants involved in the intervention. However, we implemented several measures to minimize subjective biases and ensure objective data collection. First, we scheduled intervention sessions for the 2 groups at different times to prevent cross-group communication. Second, distinct teams managed different stages of the study, ensuring that data collectors were not aware of participants' group allocations. Moreover, outcome adjudicators remained blinded to group assignments throughout the process.

Interventions

The control group completed the training on May 25, 2024, while the intervention group finished the training on May 26, 2024. Both groups underwent a 4-hour training session on isolation ward layout and nursing workflow in the morning. The intervention group received NIVR simulation training, while the control group received training in the form of conventional lectures and on-site ward visits. After the training, emergency drills and assessments were completed in the afternoon. The specific details of the training program are outlined subsequently.



The control group received conventional training. Participants in the control group initially received 2 hours of theoretical training. An experienced senior nurse who has worked in isolation wards for >5 years and has responded to pandemics multiple times was the lead instructor and used PowerPoint (Microsoft Corporation) presentations, images, videos, and other tools for face-to-face lectures. The topics covered in the training included an overall layout diagram of the isolation ward; the unique environment of the ward; specific distributions of clean areas, semicontaminated areas, contaminated areas, buffer zones, health care provider passages, and patient pathways; the correct personal protective measures; and disinfection. It also covered the work responsibilities and routes to the wards for the nursing shift, including procedures for entering and exiting the ward, patient admission and discharge management, methods for transferring items through pass windows, and transporting collected specimens.

Subsequently, the participants spent 2 hours familiarizing themselves with the isolation ward environment. The infectious disease building at the training site comprises 3 floors of negative pressure isolation wards. Each floor features an identical ward layout and is supervised by 2 senior isolation ward nurses as mentors. The group of 45 participants was further divided into 3 groups, each of 15 participants, with 1 group assigned to tour the first-floor ward. In the first hour, participants toured the layout of the ward under the guidance of a mentor. The following hour was dedicated to individuals or teams independently familiarizing themselves with and exploring the ward's layout. Mentors were available on-site to address any inquiries from the participants.

Next, 4-hour simulation drills and assessments were conducted using a team-based approach in the isolation ward to replicate the management of cases involving class A respiratory infectious diseases. The procedure for the simulation drills is provided in Figure 1. The participants were divided into 3 groups, each consisting of 15 individuals. The group leader assumed the role of the head nurse, while the members performed duties as ward nurses. The team leader scheduled shifts for 15 staff in the unit, assigning each person different shift responsibilities to simulate the management of patients in the isolation ward. The first hour was dedicated to practicing to familiarize oneself with various tasks, followed by a 3-hour Objective Structured Clinical Examination (OSCE) assessment.

a,b,c Task 4 Use the transfer window to deliver items.

The intervention group received VR simulation training. First, from February to April 2024, our study team of medical experts collaborated closely with a virtual technology team to design and develop a VR project titled "Isolation Ward Layout and Nursing Procedures." The medical experts provided expertise on the layout and procedures of isolation wards, while the technology team used advanced VR technology to transform this guidance into a highly interactive and realistic simulation environment.

In terms of hardware, the project used a NIVR solution that presented a virtual environment via standard PCs or mobile devices, eliminating the necessity for specialized headsets. Participants could engage with the virtual environment on any compatible device using a keyboard, mouse, or touch screen. This approach enhanced accessibility and convenience, rendering NIVR training suitable for large-scale training applications, particularly in contexts where logistical simplicity and widespread access were essential.

For software development, Unreal Engine 5 (Epic Games) was used as the platform. With its powerful graphics rendering capabilities and realistic physics engine, Unreal Engine 5 enabled high-fidelity simulation of the isolation ward environment and layout. Its flexibility and scalability supported complex interactive mechanisms, providing users with an immersive learning and training experience.

This project used a combination of 2D map navigation and interactive 3D dynamic scenes of the isolation ward (Figure 2) to demonstrate specific aspects of high-security (negative pressure) isolation wards. The scenarios presented detailed descriptions of the unique working environments and layouts within these isolation areas, setting out specific tasks for nursing personnel in different shifts. The scenes covered procedures for entering isolation areas, receiving patients with class A infectious disease upon admission, monitoring patient conditions, providing treatment and care, discharging patients, and exiting the isolation ward. Key details included protection and disinfection practices in various areas, the preparation and transfer of supplies, specimen collection, and transportation. This approach aimed to familiarize trainees with distinct area layouts, working environments, and standard procedures. Following practice sessions, assessments were administered to reinforce the learned knowledge and evaluate training effectiveness. The ability to repeat the experiments addressed the challenge of limited opportunities for trainees to engage in on-site field training within infectious disease outbreak isolation areas.

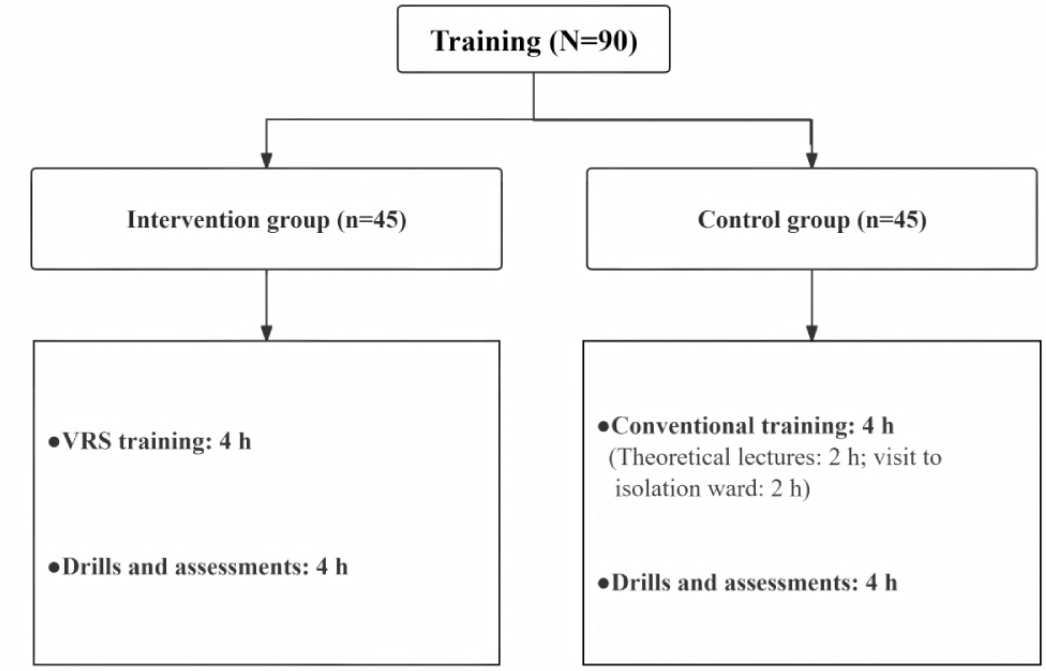

Figure 2. Example of 2D map navigation and 3D layout of isolation ward. The nurse's position is indicated in real-time by a yellow arrow on a 2D navigation map, while a 3D real-life simulation of the current location is provided to help participants become familiar with the ward.

Participants underwent a 4-hour VR simulation training in a computer-simulated laboratory. An instructor provided a 30-minute demonstration and explanation of the VR simulation operations before the participants practiced various simulated tasks. Participants completed virtual simulation tasks, including approximately 3 hours of practice and postpractice evaluation. During the practice, the instructor solved the participants' problems on-site. Subsequently, the instructor led an approximately 30-minute discussion and reporting session to address practice-related queries and share experiences.

For the intervention group, the content of the simulation drills and assessments lasting 4 hours was the same as that of the control group. Figure 3 illustrates the training protocols for the 2 groups.

Measurement Indicators

Primary Outcome Measures

Theoretical Test Scores Before and After the Training

Both groups underwent web-based theoretical quizzes simultaneously before and after completing the training. The quizzes consisted of multiple-choice and fill-in-the-blank questions, with a total score of 100 points.

Evaluation of Drill

The assessments were conducted in the afternoon following the completion of training by the 2 groups. The 3 isolation wards were each arranged as assessment venues. Participants were randomly assigned by drawing lots, forming teams of 15 nurses each, who then entered the assessment area of a specific isolation ward. OSCE was used for the evaluation of the test, comprising 6 stations: nurse's entry into the ward to reach the clean nurses' station (10 points), entry into the potentially contaminated area and preparation of therapeutic and caring materials (20 points), entering the patient's room and completing the reception of incoming patients (20 points), using the transfer window to pass items (clean item transfer window, ward transfer window, and contaminated item transfer window; 15 points), handling patient discharge and completing terminal disinfection after discharge (20 points), and nurse's departure from the contaminated area to leave the ward (15 points), with the total score adding up to 100 points. The key scoring aspects included assessing whether the route selection aligned with the optimal path, ensuring the correct implementation of personal protective measures, appropriate use of materials, and adherence to standardized operational procedures. Each participant adhered to the team leader's schedule, arriving at the assigned task stations, sequentially completing tasks at each station, and recording their performance at every station.

Secondary Outcome: Duration of Drill Task Completion

The time each group of participants spent at each station during the OSCE test was simultaneously recorded (excluding the time for wearing and removing protective equipment and performing treatment procedures).

Statistical Analysis

Two researchers entered and verified the data and analyzed it using SPSS software (version 25.0). Continuous data were summarized with mean and SD, while categorical data were summarized using percentages. Student *t* tests (**2-tailed**) were applied to the intergroup comparisons of normally distributed continuous data. In cases of nonnormal distribution, the data were described as median (IQR), and the Mann-Whitney *U* test was used. Group comparisons for count data were conducted using χ^2 tests or the Fisher exact probability method. Statistical significance was denoted by 2-sided *P* values <.05.

Results

Demographic Data

The demographic characteristics of the 2 groups of participants are presented in Table 1. A total of 90 participants were included, with 45 (50%) individuals allocated to the intervention and control groups each (Figure 4). This study primarily included female nurses, with 96% (43/45) of them in the control group and 93% (42/45) in the intervention group. The average age was 27.53 (SD 4.0) years in the intervention group and 28.78 (SD 4.8) years in the control group. The demographic characteristics, including sex, age, highest degree, professional title, and work experience, were comparable between the 2 groups. All participants completed both baseline and postintervention assessments.

Figure 4. CONSORT (Consolidated Standards of Reporting Trials) flowchart of the study.

Primary Outcome 1: Comparison of the Theoretical Test Scores Between Groups Before and After Intervention

Before the intervention, no significant difference was found in the score of theoretical tests between the 2 groups (t_{88}=1.15, *P*=.25, Cohen *d*=0.24; Table 2), using a 2-tailed *t* test. However, after the intervention, the total scores of the theoretical tests in both groups significantly improved compared to the scores before the intervention. However, the 2 groups had no statistically significant difference in scores (t_{88}=–0.30, *P*=.75, Cohen *d*=–0.06; Table 2).

Table 2. The theoretical test scores between groups before and after intervention (N=90).

	Control group (n=45), mean (SD)	Intervention group (n=45), mean (SD)	*t* test (*df*)	*P* value	Cohen *d*
Preintervention score	49.49 (11.46)	46.47 (13.35)	1.15 (88)	.25	0.24[a]
Postintervention score	85.80 (6.49)	86.24 (7.49)	–0.30 (88)	.75	–0.06[b]

[a]According to Cohen conventions, a small effect size of 0.24 indicates a minor difference between the control and intervention groups before the intervention.

[b]Postintervention score Cohen *d* of –0.06: this effect size is negligible, indicating very little or no practical difference between the groups after the intervention.

Primary Outcome 2 and Secondary Outcomes: Comparison of the Drill Scores and Completion Times Between Groups After Intervention

After the intervention, no statistically significant differences were observed in the drill scores between the 2 groups (all *z* scores=0.00, *P*>.99; Table 3). However, the intervention group demonstrated a notably shorter total duration in completing the 6 target tasks than the control group (t_{88}=5.10,*P*<.001, Cohen *d*=1.08; Table 3). Among the 6 work tasks, the intervention group completed task 3 (patient reception inwards) and task 6 (leaving the isolation area) significantly faster than the control group (t_{88}=3.22, *P*=.002, Cohen *d*=0.68; t_{88}=3.03, *P*=.003, Cohen *d*=0.64; Table 3). In comparison, there were no differences in completion times for the remaining 4 tasks between both groups (*P*>.05; Table 3). The *t* test was 2-tailed.

XSL•FO
RenderX

Table 3. The drill scores and completion times between groups after intervention (N=90).

Variable	Control group (n=45)	Intervention group (n=45)	*t* test (df)	*z* score	*P* value	Cohen *d*
Task 1: the nurse enters the isolation ward and reaches the clean area in the nurses'station						
Scores, median (IQR)[a]	10 (10-10)	10 (10-10)	—[b]	0.00	>.99	—
Time taken (min), mean (SD)	3.88 (0.92)	3.62 (0.94)	1.36 (88)	—	.18	0.28[c]
Task 2: the nurse enters the potentially contaminated area and prepares the necessary supplies						
Scores, median (IQR)[a]	20 (18-20)	20 (18-20)	—	0.00	>.99	—
Time taken (min), mean (SD)	3.79 (0.79)	3.59 (0.80)	1.19 (88)	—	.24	0.25[c]
Task 3: the nurse enters the patient's room and completes the reception of the newly admitted patient						
Scores, median (IQR)[a]	20 (17.5-20)	20 (18-20)	—	0.00	>.99	—
Time taken (min), mean (SD)	11.71 (1.71)	10.76 (1.00)	3.22 (88)	—	.002	0.68[d]
Task 4: the nurse uses the transfer window to deliver items						
Scores, median (IQR)[a]	15 (13.5-15)	15 (13.5-15)	—	0.00	>.99	—
Time taken (min), mean (SD)	2.59 (0.82)	2.48 (0.60)	0.76 (88)	—	.50	0.15[e]
Task 5: the nurse completes the patient discharge procedures and performs terminal disinfection of the ward after the discharge						
Scores, median (IQR)[a]	20 (17-20)	20 (18-20)	—	0.00	>.99	—
Time taken (min), mean (SD)	9.41 (1.13)	9.24 (1.58)	0.60 (88)	—	.55	0.12[e]
Task 6: the nurse exits the isolation ward from the contaminated area						
Scores, median (IQR)[a]	15 (15-15)	15 (10-15)	—	0.00	>.99	—
Time taken (min), mean (SD)	7.00 (2.32)	5.59 (2.09)	3.03 (88)	—	.003	0.64[d]
Total						
Scores, median (IQR)[a]	93 (85-98)	92 (88-97)	—	0.00	>.99	—
Time taken (min), mean (SD)	43.91 (2.99)	40.77 (2.85)	5.10 (88)	—	<.001	1.08[f]

[a]Nonnormally distributed data are presented as median (IQR), using *z* score (Mann-Whitney *U* test).

[b]Not applicable.

[c]Task 1 and task 2: the effect sizes are small (Cohen *d*=0.28 and Cohen *d*=0.25, respectively), indicating minimal to small practical differences in time taken between the 2 groups for these tasks.

[d]Task 3 and task 6: the effect sizes are moderate (Cohen *d*=0.68 and Cohen *d*=0.64, respectively), suggesting that these tasks saw a noticeable improvement in efficiency for the intervention group compared to the control group.

[e]Task 4 and task 5: the effect sizes are very small (Cohen *d*=0.15 and Cohen *d*=0.12, respectively), suggesting very little difference in performance between the groups.

[f]The effect size for the total time taken is large (Cohen *d*=1.08), indicating a significant reduction in overall time taken for completing all tasks by the intervention group, reflecting a substantial practical significance.

Discussion

Principal Findings

In this study, we developed an NIVR simulation training program for isolated ward settings aimed at training nurses and assessing the program's effectiveness through a randomized controlled trial. A total of 90 nurses participated in the training program and underwent pre- and posttraining assessments. The results showed no significant differences between the 2 groups regarding scores of theoretical knowledge and drills after the training (t_{88}=–0.30, *P*=.75, Cohen *d*=–0.06; Table 2 and *z* score=0.00, *P*>.99; Table 3). However, the intervention group that received NIVR simulation training significantly reduced their total task completion time compared to the control group (t_{88}=5.10, *P*<.001, Cohen *d*=1.08; Table 3). It should be noted that this advantage was only evident in task 3 (receiving patients in the ward: t_{88}=3.22, *P*=.002, Cohen *d*=0.68) and task 6 (leaving the isolation ward: t_{88}=3.03, *P*=.003, Cohen *d*=0.64; Table 3), with no significant differences in the remaining 4 tasks (all *P*>.05), and the average total time difference was approximately 3 minutes (control group: mean 43.91, SD 2.99 min; intervention group: mean 40.77, SD 2.85 min). These findings suggest that NIVR training is comparable to traditional training in enhancing knowledge and skills and can reduce the time nurses take to complete tasks to some extent. Although the study did not conclusively demonstrate a significant advantage of NIVR training, the findings indicate that VR training can facilitate the

XSL•FO
RenderX

effective application of knowledge and skills in real-world settings [34,42]. Moreover, it allows nurses to familiarize themselves with ward environments before pandemics, thus improving their response capabilities. However, further studies are required to confirm other potential benefits. Therefore, it is essential to explore the implementation of VR training to better prepare nurses for future pandemics.

VR training has introduced a highly efficient new method for training nurses in isolation wards. Although traditional training methods, such as using simulated laboratories or observing natural ward settings, are effective, they face challenges including labor intensiveness, financial constraints, resource limitations, time constraints, and risks of cross-infection [13]. Several studies [43,49,51-53] have indicated that VR simulations demonstrate significant potential in pandemic management, covering areas such as infection prevention and control, simulated transmission behaviors, clinical skill training, mental health improvement, and emergency response. These studies have highlighted the vital role of VR technology in managing infectious disease outbreaks such as COVID-19 and Ebola virus disease, leading to enhanced health care professionals' skills, reduced stress, and improved patient experiences. Our isolation ward VR simulation training program focuses on training nurses to enhance their adaptation to isolation ward settings within a simulated environment, improving their preparedness and capabilities in managing infectious diseases. The training integrates a 2D ward map with dynamic interactions in 3D simulated ward environments through NIVR technology, reconstructing realistic isolation ward scenarios. This innovative training method allows nurses to operate in a safe, noncontact virtual environment, significantly reducing the risk of cross infection [13,25]. This approach aids nurses in comprehensively understanding the unique layout and standardized protocols of isolation wards, significantly enhancing training safety and effectiveness [49,51]. Customized course design helps nurses familiarize themselves with different working environments before entering the wards, alleviating their stress and anxiety [32]. Meanwhile, this highly interactive training allows nurses to realistically simulate various emergencies, strengthening their ability and resilience in handling unexpected events [29]. Importantly, NIVR simulation training supports repetitive practice to improve proficiency in critical skills [26]. Therefore, there is a need to focus on and promote VR technology to comprehensively improve health care workers' emergency response capabilities and infection control skills.

During outbreaks of infectious diseases, VR training effectively mitigates the challenges posed by contact restrictions encountered in traditional on-site instruction.

In the early stages of the COVID-19 pandemic, restrictions on clinical internships resulted in the widespread adoption of remote virtual simulation technology, particularly in programs where securing face-to-face clinical internships is difficult [39,54-56]. Research by Zhang et al [13] indicates that web-based VR not only meets the training requirements of isolation wards but also effectively enhances nurses' learning motivation and professional safety [13]. NIVR training, due to its low cost and minimal resource requirements, facilitates remote VR and emerges as an ideal choice for postpandemic nursing education [39]. Our isolation ward virtual simulation training provides an effective learning experience by simulating real environments for learners. The study results show that VR training can replace emergency on-site training, assisting nurses in quickly adapting to their work environment [36,42,57]. Particularly under the circumstances of restricted contact time, remote VR training offers nurses a learning platform unrestricted by time, location, and resources [58,59], improving learning efficiency while enhancing confidence and competence in high-risk areas [42]. Looking ahead, with continuous technological advancements and expanded application scenarios, VR training is poised to play a more significant role in nursing education and medical training. It has the potential to enhance health care professionals' skills and provide more practice opportunities while simultaneously ensuring greater safety for both medical personnel and patients.

Studies indicate that interactive VR training can enhance health care professionals' clinical decision-making skills and critical thinking, thereby improving efficiency and quality of care [27,29,30,60]. In high-risk, high-workload isolation wards, effective time management and operational efficiency are particularly crucial for nurses. Our study shows that nurses who underwent VR training required less time to complete specific tasks, such as entering the wards to receive patients and exiting isolation zones (t_{88}=3.22, P=.002, Cohen d=0.68; t_{88}=3.03, P=.003, Cohen d=0.64, respectively; Table 3). This suggests that VR training may offer advantages in managing complex tasks. However, there are still debates regarding the effectiveness of VR. While some studies highlight VR's ability to effectively enhance nursing students' knowledge levels, it has not yet significantly outperformed traditional methods in skills, satisfaction, confidence, and performance time [38,42,61]. Therefore, policy makers should proceed cautiously when promoting VR training and consider integrating various training methods to ensure comprehensive skill improvement for nurses. Future research can further validate the effectiveness of VR training through large-scale, multicenter, randomized controlled trials and explore its application advantages and limitations in specific medical contexts. In addition, establishing task efficiency assessment mechanisms and delving into the long-term effects and cross-disciplinary applications of VR training can further elevate training outcomes.

Cost-Benefit Considerations

In this study, although both groups had the same training duration, the cost of developing VR training programs is an important factor that needs to be considered. While NIVR training significantly enhanced caregivers' coping skills, its initial development costs were relatively higher compared to traditional training methods. However, as the number of trainees increases, these initial investments are progressively amortized, reducing the average cost per trainee. Farra et al [62] noted that despite the average cost per person for VR training being US $327.78 in the first year, which was US $97.99 higher than the US $229.79 for live drills, the cost gradually decreased in the subsequent years. After 3 years, the average cost of VR training had dropped to US $115.43 per person, while live drills remained at US $229.79, resulting in savings of approximately US $114.36 per person for VR training. Due to its reusability,

XSL•FO
RenderX

VR demonstrated greater cost-effectiveness over a three-year period, proving to be more economically advantageous in the long run compared to traditional on-site practice [62,63]. Halfer and Rosenheck [64] further supported this view by discovering that although the development cost of a VR program was higher than that of paper floor plans, it significantly enhanced nurses' efficiency in navigating a new hospital building and reduced the required practice time. Specifically, the total cost for traditional methods was US $570,000, whereas it was US $421,000 for the virtual methods. Therefore, researchers and decision makers need to carefully weigh the cost and impact of VR training, considering its long-term feasibility and effectiveness in medical training. Future cost-benefit analyses will provide crucial support for these evaluations. A comprehensive assessment of VR education's economic efficiency and academic value is essential for determining its long-term viability when considering implementation costs and training outcomes.

Limitations

This study has several limitations. First, the small sample size limits the generalizability of the results, indicating a need for future research with larger samples. Second, the training content and methods are preliminary and require further refinement to address diverse nursing scenarios. Third, the absence of a baseline speed measure before training leaves open the possibility that observed group differences may partly arise from factors unrelated to the training method. This should be considered when assessing our findings. Moreover, the lack of blinding for assessors introduces potential bias in performance evaluations. Future studies should use blinded assessments to enhance reliability. Although VR simulation training appears promising, further research with improved measures of work efficiency and controlled conditions is essential to validate and expand these initial findings.

Conclusions

This study developed an NIVR simulation training program for isolation wards and evaluated its effectiveness through a randomized controlled trial. While the NIVR simulation training demonstrates faster performance in certain tasks, it shows no significant differences in theoretical and drill scores compared to traditional training. Nevertheless, its safety, repeatability, and realistic simulated environment suggest potential for pandemic response training. Despite not significantly outperforming traditional training methods, NIVR simulation training can still facilitate the practical application of knowledge and skills. It helps nurses familiarize themselves with the ward environment in advance, thus improving their response capabilities. Future research should focus on optimizing training programs and validating and enhancing VR training through large-scale, multicenter randomized controlled trials. In addition, establishing mechanisms for task efficiency evaluation and exploring its long-term effects and interdisciplinary applications will enhance pandemic preparedness.

Acknowledgments

The authors would like to thank all participants in this study and the staff from the Affiliated Nanhua Hospital, University of South China; The First Affiliated Hospital, Hengyang Medical School, University of South China; and Xi'an Jiaotong University Health Science Center. They are also deeply grateful to Kun Feng and the virtual technology team at Xi'an Technological University for their technical support on this study. This study was partially supported by grants from the Fund of Hunan Social Science Achievement Appraisal Committee (grant XSP21YBC228 to DZ) and the fund of the innovative program on COVID-19 prevention and treatment from Hengyang Science and Technology Bureau (grant 202010031581 to DZ), Shaanxi Province (grant SGH140537 to YPZ), and the Xi'an Jiaotong University Fund (grant 202107164 to YPZ).

Data Availability

The datasets generated during and analyzed during this study are not publicly available due to participant privacy concerns but are available from the corresponding author upon reasonable request.

Authors' Contributions

DZ, ZZ, MF, and YPZ contributed to the conception and design of the study. DZ, ZZ, YJC, and MF contributed to the design and development of this virtual reality project. DZ generated a random allocation sequence, while YJC and ZZ participated in recruiting and screening participants. JZ, YJC, LC, MF, and YL contributed to the study delivery, data collection, and data interpretation. DZ, ZZ, and YPZ wrote the manuscript, and all authors read the final manuscript and approved its submission.

Abstract

Background: Immersive virtual reality (iVR) has emerged as a training method to prepare medical first responders (MFRs) for mass casualty incidents (MCIs) and disasters in a resource-efficient, flexible, and safe manner. However, systematic evaluations and validations of potential performance indicators for virtual MCI training are still lacking.

Objective: This study aimed to investigate whether different performance indicators based on visual attention, triage performance, and information transmission can be effectively extended to MCI training in iVR by testing if they can discriminate between different levels of expertise. Furthermore, the study examined the extent to which such objective indicators correlate with subjective performance assessments.

Methods: A total of 76 participants (mean age 25.54, SD 6.01 y; 45/76, 59% male) with different medical expertise (MFRs: paramedics and emergency physicians; non-MFRs: medical students, in-hospital nurses, and other physicians) participated in 5 virtual MCI scenarios of varying complexity in a randomized order. Tasks involved assessing the situation, triaging virtual patients, and transmitting relevant information to a control center. Performance indicators included eye-tracking–based visual attention, triage accuracy, triage speed, information transmission efficiency, and self-assessment of performance. Expertise was determined based on the occupational group (39/76, 51% MFRs vs 37/76, 49% non-MFRs) and a knowledge test with patient vignettes.

Results: Triage accuracy (d=0.48), triage speed (d=0.42), and information transmission efficiency (d=1.13) differentiated significantly between MFRs and non-MFRs. In addition, higher triage accuracy was significantly associated with higher triage

XSL•FO
RenderX

knowledge test scores (Spearman ρ=0.40). Visual attention was not significantly associated with expertise. Furthermore, subjective performance was not correlated with any other performance indicator.

Conclusions: iVR-based MCI scenarios proved to be a valuable tool for assessing the performance of MFRs. The results suggest that iVR could be integrated into current MCI training curricula to provide frequent, objective, and potentially (partly) automated performance assessments in a controlled environment. In particular, performance indicators, such as triage accuracy, triage speed, and information transmission efficiency, capture multiple aspects of performance and are recommended for integration. While the examined visual attention indicators did not function as valid performance indicators in this study, future research could further explore visual attention in MCI training and examine other indicators, such as holistic gaze patterns. Overall, the results underscore the importance of integrating objective indicators to enhance trainers' feedback and provide trainees with guidance on evaluating and reflecting on their own performance.

Introduction

Overview

Medical first responders (MFRs) are confronted with extreme demands at mass casualty incidents (MCIs), during which they must attend to more patients than their resources allow [1]. Whether those situations are due to natural disasters, accidents, or terrorist attacks, peak performance of MFRs under such demanding circumstances is crucial. However, current MCI training is insufficient to prepare MFRs adequately for MCIs due to low immersion and realism of classroom learning and scarce real-life exercises that are typically used [2-4].

An increasingly popular tool for MCI training is immersive virtual reality (iVR; [3,5]). iVR is typically experienced through a head-mounted display (HMD) that elicits the user's impression of being completely surrounded by a 3D, virtual world [6-8]. In addition, users are often able to move around, explore, and interact with their environment (eg, by walking and using controllers). Especially in the context of MCI training, iVR offers the possibility to train numerous scenarios in a safe, flexible, and resource-efficient way [5]. iVR training applications also allow for high-quality assessments of performance, which are crucial for enabling systematic and structured training [9] and for assessing the degree to which MFRs are prepared for MCIs. Moreover, high-quality performance assessments allow for the evaluation of training effectiveness and the comparison of training methods, contributing to an ongoing improvement of MCI preparedness [10]. However, a systematic evaluation of performance indicators for iVR MCI training is still missing. This study aims to fill this gap by evaluating the usefulness of different performance indicators in virtual MCI scenarios. Specifically, we first provide an overview of the potential of iVR for MCI simulation training. Next, we discuss various performance indicators that cover different aspects of the performance of MFRs who arrive first at an MCI scene (ie, visual attention, triage accuracy, triage speed, and information transmission). Finally, we introduce self-rated performance as a potential tool for a holistic assessment.

MCI Training and iVR

The gold standard for MCI training is to take part in real-life scenarios with patient actors and manikins [11]. However, such exercises are particularly resource-intensive in terms of preparation time and costs. Therefore, technological training solutions have been developed to increase the level of preparedness, such as training in iVR [5].

iVR provides near-realistic training sessions that require fewer personnel and financial resources compared to real-life MCI exercises with patient actors [4]. iVR also allows the creation of an infinite number of scenarios that can be quickly and flexibly adapted to training objectives [8]. By providing a safe training environment where mistakes can be made and scenarios can be repeated until they are handled correctly [12,13], iVR can be used in training for otherwise dangerous scenarios, such as fire or terrorist attacks. The training and its challenges can also be adapted to individual needs and expertise levels, thus providing an opportunity to maintain a balance by being complex enough to trigger learning without leading to overload [8,14]. On the basis of their current skills, MFRs may be placed in virtual scenarios with few patients and distractions or may train in large-scale MCIs with more patients under complex conditions (eg, nighttime and difficult terrain). Another advantage of iVR-based training is the ability to implement automated monitoring of objective performance indicators, which can help improve both the trainees' learning process and their preparedness [15]. Furthermore, iVR facilitates the inclusion of novel performance indicators, such as visual attention assessed with eye-tracking, which integrates seamlessly with the technology [16].

Performance Indicators

Overview

Performance indicators can be validated with the known-groups validation approach [17,18] which tests the expectation that distinct groups (eg, age groups, experts, and novices) differ on a certain measure [19]. Effective indicators should distinguish between experts and novices, as experts, by definition, possess the knowledge and skills to consistently perform at high levels [20]. Previous studies have classified experts and novices based on various measures, including having or not having a specific

XSL•FO
RenderX

profession or certificate, often intertwined with (years of) job experience (eg, medical students vs physicians) [21]. In addition, experts generally possess more knowledge than novices [22].

Because performance assessments should capture multiple dimensions of performance [9], we evaluate three areas for a broad performance assessment of the first MFRs who arrive at an MCI: (1) the process of gaining an overview of the situation when arriving on scene, which could be assessed based on visual attention, (2) the triage process, and (3) the efficiency of information transmission to the control center. Furthermore, to obtain a holistic assessment of performance, self-reports are also included.

Visual Attention During Orientation at the MCI Scene

Visual attention has been suggested as a potential factor contributing to medical performance [17]. Consistent with the eye-mind hypothesis, gaze fixations are usually the focus of thought [23], which is why the interest in gaze behavior is increasing in research on medical decision-making and medical training [24,25]. Previous research demonstrated that perception and recognition skills improve with increasing medical experience [24]. Furthermore, visual attention differs with expertise in several medical tasks, such as surgical simulations and diagnostic decision-making [24,26]. Among other aspects, experts fixate on task-relevant cues more often and fixate less on task-irrelevant areas than novices [27].

Only a few studies have tested visual attention in prehospital settings thus far. Eye tracking while viewing photos of accident scenes revealed that MFRs fixated significantly longer on task-relevant cues, such as injured people or safety hazards, than non-MFRs [28]. However, the association between visual attention and expertise was less clear when tracking the eye movements of physicians and nurses watching a 2D video of an MCI [29]. Regardless of the number of years working in emergency medical services, all participants spent more time observing the patients who were severely injured. In addition, participants navigated through the scenes with less predetermined or structured patterns than initially expected. Another study assessed the visual attention of college students viewing a computer screen with photos of injuries and information boxes about airway, breathing, and circulation [30]. One group was trained in the *simple triage and rapid treatment* (START) triage algorithm, while the active control group was instructed in patient transport. After training, the START triage group fixated on relevant information boxes significantly faster. However, all of these studies relied on 2D stimuli presented on computer screens, and none tested visual attention of MFRs in 3D iVR MCI scenarios, although differences between 2D input and iVR have been documented for many cognitive and behavioral processes [7].

Accuracy and Speed of the Triage Process

Typical objective performance assessments in MCI training address accuracy and speed of the triage process [5,10]. Effective allocation of available resources and a well-decided sequence of patient care and transport are essential for managing MCI situations [4] and require the ability to triage patients correctly even under high stress. Triage accuracy refers to the correct choice of triage levels based on a specific triage algorithm. The START triage algorithm is an internationally known algorithm developed in the United States and used in several emergency medical services organizations [31]. According to START, patients are classified based on their injuries as green (minor priority), yellow (delayed priority), red (immediate priority), and black (dead or fatally injured). In addition to accuracy, triage speed is also considered crucial in the management of MCI situations so that patients with immediate priority receive medical treatment as quickly as possible [32]. In particular, triage accuracy, but also triage speed, have been used as effectiveness indicators for evaluating MCI training in previous studies [5]. Regarding iVR studies, only a few have included objective performance assessments within the virtual environment. These studies suggest that triage accuracy in iVR improves with more iVR training [33]. Furthermore, when comparing iVR to real-life exercises, MFRs had similar triage accuracy scores [4,34], but completed the triage process faster in iVR [4]. However, emergency physicians with more experience did not have higher triage accuracy scores in iVR than those with less experience [35]. This may be because the study did not aim to compare experts and novices, and those with less experience were already practicing residents. Therefore, the difference in practical experience was probably not large enough to be considered a typical expert-novice comparison.

Transmission of Information to the Control Center

One of the main problems commonly found during major incidents is poor communication with the control center [10,36]. For instance, communication problems, such as excessive radio traffic, can lead to several negative consequences, including increased mortality rates and reduced safety for MFRs at the scene [37]. Although information transmission to the control center is crucial to ensure proper coordination of all rescue services, studies measuring the quality [10] and efficiency (ie, accurate information in few words) of such radio messages are still missing. In Germany, the widely used *scene, safety, situation, and support* (SSSS) scheme serves as a standard for the assessment of onsite emergency situations [38]. This scheme provides a structured approach to assessing critical aspects of an incident. Sometimes referred to as the 3S scheme, with *support* not specifically named, the scheme assists MFRs in identifying and communicating all relevant information, especially potential hazards and environmental risks [39]. *Scene* refers to the assessment of the emergency site. In terms of safety, MFRs assess the risk to themselves and others. *Situation* refers to an estimation of the number of patients and evaluation of injury mechanisms. *Support* refers to the possible need for reinforcements and other emergency services, such as police and fire brigades [38]. On the basis of interviews and workshops with European MFRs, communication and the correct use of the scheme were identified to be key performance indicators in training for high-stress situations like MCIs [39]. While no studies seem to have evaluated the efficiency of information transmission, it was found that trained physicians reported more accurately than untrained physicians in a real-life MCI exercise [40].

XSL•FO
RenderX

Subjective Performance Ratings

A large part of MCI training studies evaluates the training effectiveness with self-rated indicators, such as self-ratings in knowledge and skills. For example, emergency medical technicians with more work experience rate their triage skills more favorably than those with less work experience [41]. However, general skill assessment does not necessarily relate to performance in a specific situation, and studies assessing self-rated MCI performance directly related to a previously completed simulation are still missing [5]. Not specific to MCI training but to medical education in general, previous research suggests that self-assessed performance has at least a low to moderate validity [42,43]. Self-rated indicators have the advantage of being easily implemented in all possible training modalities without any technical effort. Although objective performance assessment can be implemented in iVR, such assessment may be more complex in other training modalities, impairing potential comparison studies. If a global subjective performance indicator is accurate, it may be a low-threshold indicator for such studies. Including self-assessment alongside objective performance evaluation could also enhance the debriefing process by encouraging trainees to reflect on their performance and improve self-awareness [44]. However, comparisons between (global) subjective performance and objectively measured behavior in iVR MCI training are still lacking.

Research Aims and Hypotheses

This study aimed to investigate whether different performance indicators that were used in previous MCI training studies can be effectively extended to MCI training in iVR. As a method of validation [17], indicators were tested with a focus on their ability to differentiate between different levels of expertise. For comprehensive testing, 2 indicators of expertise were used, including occupational group as a dichotomous indicator (MFR or non-MFR) and triage knowledge test scores as a continuous indicator. For a broad assessment, we investigated visual attention after arriving on scene, triage accuracy, triage speed, information transmission efficiency, and subjective performance. Overall, this study intends to provide insights into which indicators are suitable for incorporation into the design of effective iVR MCI training programs and MFR performance assessments. The following hypotheses were formulated: hypothesis 1a: with greater expertise, medical staff pays more attention to task-relevant information during MCIs; hypothesis 1b: with greater expertise, medical staff show greater triage accuracy during MCIs; hypothesis 1c: with greater expertise, medical staff complete the triage process faster during MCIs; hypothesis 1d: with greater expertise, medical staff transmit information more efficiently; hypothesis 2: attentional indicators demonstrate incremental value in the discrimination of different levels of expertise beyond performance indicators, such as speed, accuracy, and information transmission during triage; and hypothesis 3: subjective evaluation of one's own performance is better with greater attention to task-relevant information, greater triage accuracy, faster triage time, and more efficient transmission of information.

The wording of 2 hypotheses has changed from the preregistration. Previously, they were "Hypothesis 1d: with greater expertise, medical staff transmits information more quickly and completely" and "Hypothesis 3: subjective evaluation of own performance is better with greater attention to task-relevant information, greater triage accuracy, faster triage time, and faster transmission of information."

Methods

Study Design

In this quasi-experimental, multimethod study, participants (MFRs and non-MFRs) completed virtual MCI scenarios while their performance was assessed.

Procedure

Overview

Interested people visited a website following the link or QR code provided on the recruitment materials. On the website, they received information on the study aims and procedure, provided informed consent, and answered a web-based preliminary questionnaire covering demographics, personal characteristics, and a triage knowledge test. The web-based questionnaire was answered before participants came to their appointment to shorten the time in the laboratory. At the end of the questionnaire, participants scheduled a 2-hour appointment in the VR laboratory. In the laboratory, participants filled out additional questionnaires, were shown the START triage algorithm, and engaged in an iVR familiarization scenario with people who were uninjured and at no accident site. During the familiarization, participants practiced information gathering and navigation within the virtual environment. The familiarization ended when participants announced that they feel sufficiently prepared. The main phase of the study involved 5 virtual MCI scenarios to cover the different performance levels of our sample, thus avoiding floor and ceiling effects and increasing the reliability of the measurements. The scenario order was randomized for each participant using a random number generator.

MCI Scenarios in iVR

The scenarios were built with the XVR software (XVR Simulation BV) and consisted of traffic accidents that varied in scenario complexity (Table 1; Multimedia Appendix 1 gives a detailed description). Tasks included gaining an overview of the situation, performing triage, and transferring all relevant information to the control center via radio messages.

XSL•FO
RenderX

Table 1. Scenario descriptions. After the familiarization scenario, the scenario order was randomized for each participant.

Scenario	Scene description	Number and triage levels of patients	Duration in minutes, mean (SD)
Familiarization	Quiet residential area, no accident, clear vision, middle of the day; 6 healthy people present, 3 of them sitting in cars	0 patients but healthy people to practice the iVR[a] handling	5.78 (1.71)
1 (very low difficulty)	Accident with 2 cars on a countryside road, clear vision, middle of the day	3 green patients and 1 yellow patient	3.32 (1.03)
2 (low difficulty)	Accident with a car, a van, and a motorcyclist on a motorway, clear vision, cloudy day	1 green patient, 3 yellow patients, and 1 red patient	5.33 (1.37)
3 (medium difficulty)	Accident with a car and an SUV[b] in a busy inner-city area with a crowd of bystanders around, clear vision, cloudy day	1 green patient, 3 yellow patients, and 2 red patients	5.06 (1.59)
4 (greater difficulty)	Expressway accident with 3 cars and a van; several bystanders, twilight, end of the day	1 green patient, 3 yellow patients, 3 red patients, and 1 black patient	7.28 (1.97)
5 (highest difficulty)	Expressway accident involving a bus and a truck, nighttime and fog	4 green patients, 6 yellow patients, 4 red patients, and 4 black patients	10.66 (3.08)

[a]iVR: immersive virtual reality.

[b]SUV: sports utility vehicle.

Participants were asked to remain in the starting position for the first 30 seconds during each scenario and were allowed to turn and look around. This time frame was used to assess initial attention processes measured via eye tracking. During the scenario, participants could use visual cues like wounds to select triage levels. Further information about the patients could be acquired verbally and was provided with the help of standardized audio tracks. For example, if participants inquired about the respiration rate, they would hear a prerecorded answer. Obtainable information included whether the patient could walk, whether the airways were clear, respiration rate, recapillarization time, presence of a radial pulse, existence of heavy bleeding, the patient's responsiveness to simple instructions, and localization of injuries (eg, head injury and leg injury). The participants could announce their intention to perform actions, including clearing the airway, stopping heavy bleeding, and conducting triage. After each scenario, they filled out questionnaires and had the option to reread the START algorithm.

Hardware Description

The Varjo Aero HMD had a display resolution of 2880×2720 pixels per eye at 90 Hz. Its field of view was 115° horizontally and 134° diagonally (at 12 mm eye relief), and the gaze data output frequency was 200 Hz. The HMD was connected to a laptop (ROG Strix G with Windows 10, Intel Core i7-9750H central processing unit at 2.60 Hz 2.59 GHz, NVIDIA GeForce TTX 2070 graphical processing unit, 32 GB of RAM) through the standard HMD cable and Varjo laptop adapter. Participants used the Varjo Aero HMD from Varjo Technologies Oy and could freely move within a 3×4-m size area. For greater distances, participants used controllers to teleport (Figure 1).

Figure 1. Immersive virtual reality (iVR) lab (left) and use of teleportation in iVR (right).

Participants

Emergency services personnel, hospital personnel (physicians and nurses), and medical students (all semesters) were recruited to participate in this study. Inclusion criteria were a minimum age of 18 years, proficiency in German, and the absence of a hearing aid. Participants were recruited through social media,

XSL•FO
RenderX

email distribution lists, flyers, and short presentations at local hospitals, emergency medical services, and university courses. Data collection lasted from February to October 2023. Of the 150 participants who filled out the web-based, preliminary questionnaire, 76 (50.7%) scheduled an appointment with our iVR laboratory and participated in the study. Participants were aged between 18 and 49 (mean 25.54, SD 6.01) years, and 59% (n=45) of participants were male. Among the 76 participants, 51% (n=39) were categorized as MFRs (n=36, 92% paramedics and n=3, 8% emergency physicians). The remaining 49% (37/76) non-MFR participants were mainly medical students (n=30, 81%), other medical staff not working in prehospital emergency settings (n=4, 11%), or both at the same time (n=3, 8%).

Measures

Study Data

The data presented in this paper were derived from a larger project, which focused on investigating the stress dynamics and performance of MFRs in virtual MCI training. For detailed information of all measures and instruments used during the study, refer to the construct overview on the web [45].

Web-Based Preliminary Questionnaire

Demographic information included age, gender, profession, years of job experience in the medical sector, and prior MCI training in hours. In the case of profession, participants could choose multiple options from the following: emergency physicians, other physicians, paramedics, emergency medical technicians, medical students, or specify another option through an open text field. Prior MCI training was assessed with the following answering options: none, 1 to 5 hours, 5 to 10 hours, 10 to 20 hours, 20 to 30 hours, 30 to 40 hours, 40 to 50 hours, or >50 hours.

In terms of expertise, participants were classified as MFRs if they were emergency physicians or paramedics; otherwise, they were classified as non-MFRs. The second expertise measure was a triage knowledge test based on Cuttance et al [46] and adapted to the START algorithm. Participants had 10 minutes to assign triage levels to 20 case descriptions, after which the test ended, and the next page opened. One point was awarded for each correctly assigned color, resulting in a score range of 0 to 20.

Triage algorithm or algorithms. Participants were asked which triage algorithm they typically used in the field or in training sessions, including the option to select “none.”

Prior experience with iVR was assessed with the item “How much prior experience do you have with VR?” and a dropdown menu with 9 answering options from “no experience” to “daily use of VR.”

Visual Attention During Orientation in Each iVR MCI Scenario (Onsite)

Attention to task-relevant information was assessed using eye tracking in the first 30 seconds of each scenario. Eye-tracking data were collected using Varjo Base and analyzed with the software iMotions [47]. The gaze behavior was analyzed in terms of average fixation durations and number of fixations of the areas of interest (AOIs; [48,49]). AOIs included patients, vehicle impact zones, safety aspects, and a distractor (Multimedia Appendix 1 gives scenario descriptions). Within the iMotions software, AOIs were defined graphically, and the software automatically computed the fixation parameter [50].

Objective Triage Accuracy and Speed in Each iVR MCI Scenario (Onsite)

Triage accuracy was measured by the number of correctly assigned triage colors per scenario. The accuracy score for each scenario was divided by the number of patients in that scenario. The accuracy scores of all 5 scenarios were then averaged, leading to possible values between 0 and 1 (standardized Cronbach α=0.76).

Speed of triage was measured as the time from the start of the scenario to the completion of triaging the last patient (standardized Cronbach α=0.82). Note, however, that due to the different lengths of the scenarios, averaging with nonstandardized times would lead to a stronger weighting of the more complex scenarios with longer duration and a larger temporal variance. To avoid this, a standardization was performed: values were divided by the average triage speed of the specific scenario before being averaged. Consequently, values <1 signified a triage process faster than the average, while values >1 denoted a slower-than-average triage pace.

Information Transmission to Control Center in Each iVR MCI Scenario (Onsite)

To assess how quickly and completely medical staff transmit information, an efficiency measure was formed as a combination of completeness and speed. Participants’ radio messages during the scenarios were recorded and transcribed according to the content-semantic transcription by Dresing and Pehl [51]. A coding system based on the qualitative content analysis by Mayring [52] was then applied, with categories derived from the SSSS scheme [38] and added to a coding template. Next, 2 independent raters (university students specifically trained for this) analyzed the transcripts with the software MAXQDA (VERBI GmbH), without access to any information on the participants (interrater agreement: 97% for categorization and 93% for assessment of correctness). Discrepancies were resolved through discussion and, if necessary, together with a third rater (ASB). Statements were categorized, with a maximum of 1 point awarded for each of the 4 categories. Half a point was awarded for the category *scene* if participants only mentioned that it was a traffic accident, and a full point if more information was given (eg, the type of street or number of vehicles involved). Furthermore, a penalty for mistakes was implemented: 0.3 points were deducted for each error in the respective category. Regarding the category *situation*, an error was given if the number of patients was not stated correctly. In the 2 most complex scenarios, no penalty was applied if an estimate close to the correct number was reported (+2 or –2; eg, for scenario 4 with 8 patients, “almost 10” or “between 7 and 9”; n=4 cases). No penalty was given for incorrectly stated triage colors, as these are already covered by the triage accuracy variable. The scores of the 4 categories were added up (range: 0-4 points) and standardized based on the number of words in the radio message

XSL•FO
RenderX

(ie, divided by the word count). This standardization accounted for unclear, redundant, and superfluous communication (possibly even in the same time by simply speaking faster), which poses a risk to the management of MCIs [53]. Finally, the average score across all 5 scenarios was calculated (standardized Cronbach α=0.83; range 0.03-0.15).

Subjective Performance of Each iVR MCI Scenario (Onsite)

Subjective performance was assessed with 2 items after each scenario: "How do you rate your performance in the last scenario?" (1=very bad and 10=very good) and "What school grade does your performance correspond to?" (scale: 1-6, with 1 being the best grade). We used 2 items to increase the reliability in capturing the construct. Before the items were averaged, the second item was inverted and transformed to match the 1 to 10 scale of the first item (Cronbach α=0.86):

(1)

Analyses

Analyses were conducted with R (version 4.3.2; R Core Team). Hypotheses 1a to 1d were tested with both expertise measures separately, distinguishing between MFRs and non-MFRs as well as using the triage knowledge test. For hypothesis 1a specifically, a multivariate ANOVA was used because of the multiple AOI categories. According to the Mardia test, the assumption of multivariate normal distribution was violated, but multivariate ANOVAs are robust to this specific violation, particularly in cases of homogeneous covariance matrices, which was given [54]. For hypotheses 1b, 1c, and 1d, independent *t* tests were performed to test for differences between MFRs and non-MFRs. For hypothesis 1b, the Welch *t* test was used because the Levene test indicated a violation of the assumption of homogeneity of variance. Hypotheses 1c and 1d were tested with the student *t* test. According to the Shapiro-Wilk test, the assumption of normality was violated testing hypotheses 1b and 1d. However, *t* tests are largely robust against this violation, especially because both group sample sizes were relatively similar and >30 [55,56]. The Bonferroni-Holm method was used to control for multiple testing in the *t* tests (hypotheses 1b-1d). Spearman rank-order correlations were used to examine the relationship between the knowledge test score and the outcome variables in hypotheses 1a to 1d, as they are robust to distributional violations and outliers. In addition, when correlations were significant, regression analyses were conducted to test the relationship while controlling for age and gender. We selected these 2 control variables because they are potential influencing factors in iVR performance situations [57,58]. For the regression analyses, independent variables and covariates were centered (for gender: –1=female and 1=male). Hypothesis 3 was tested with Spearman correlation analyses.

Outliers were defined as values that were 3 SDs above or below the mean. These values were winsorized (ie, set to mean +3 or –3 SDs, respectively) to reduce the influence of outliers on the results [59]. Analyses were conducted with adjusted outliers and with original variables to examine the robustness of results. When technical problems occurred during the assessment (eg, technical failure of the eye tracking or the microphone for radio message recording), the respective measure was excluded instead of excluding the entire dataset of the participant. Therefore, hypothesis 1a, which addressed eye-tracking data, was tested with a sample of n=71 for the AOIs *patients*, *safety*, and *vehicle impact zone*, and n=57 for the *distractor*. Hypothesis 1b and c, which examined triage behavior, were tested with n=74 and hypothesis 1d, which focused on information transmission, was tested with n=70 participants. There were no missing values for subjective performance (hypothesis 3).

Ethical Considerations

This study was preregistered [60], approved by the ethics committee of the Faculty of Behavioral and Empirical Cultural Sciences at Heidelberg University (AZ Bae 2023 1/1), and carried out in accordance with the Helsinki Declaration on Ethical Principles of Research Involving Humans. To ensure transparency in the analysis process, the R Markdown file, containing the R code and all results, is available on the web [45]. Data was collected in a pseudonymized manner and subsequently anonymized for analysis. As an incentive, the participants received €25 (US $27.48 on Feb 1, 2023).

Results

Analyses

To capture 2 different measures of expertise, analyses were conducted with occupational group as a dichotomous measure (MFRs vs non-MFRs) and the triage knowledge test scores as a continuous measure. Means and SDs of performance indicators per scenario can be found in Table S1 in Multimedia Appendix 1.

Demographics

The classification of expertise based on the profession was supported by the results of the knowledge test. MFRs had a significantly higher knowledge score than non-MFRs, $t_{Welch66.17}$=–3.43, *P*=.001, *d*=0.79. More information on the groups can be found in Table 2. Most participants were not familiar with any triage system before this study (43/76, 57%; 34/43, 79% of those being non-MFRs). Some (27/76, 36%) participants knew the mSTART (modified START) algorithm, 12% (9/76) knew PRIOR (Primäres Ranking zur Initialen Orientierung im Rettungsdienst), and 1% (1/76) the START algorithm. Of the non-MFR group, 65% (24/37) had no prior MCI training, and 30% (11/37) non-MFRs had <5 hours. 3% (1/37) had up to 20 hours, and 3% (1/37) had up to 30 hours of MCI training. Regarding the MFRs' prior MCI training experience, 8% (3/39) reported none, 31% (12/39) had up to 5 hours, 18% (7/39) had up to 10 hours, 18% (7/39) had up to 20 hours, 5% (2/39) had up to 30 hours, 8% (3/39) had up to 40 hours, 5% (2/39) had up to 50 hours, and 8% (3/39) had >50 hours.

Table 2. Description of expertise groups: medical first responders (MFRs) and medical students and other medical staff (non-MFRs).

Characteristics	MFRs (n=39)	Non-MFRs (n=37)
Age (y), mean (SD)	27 (7.15)	24 (4.07)
Gender: female, n (%)	11 (28)	20 (54)
Job experience (y), mean (SD)	6.53 (7.01)	1.62 (1.94)
Experience with iVR[a], none or only 1-2 times, n (%)	33 (85)	34 (92)
Knowledge test score, mean (SD)[b]	13.46 (2.73)	10.89 (3.70)

[a]iVR: immersive virtual reality.

[b]The knowledge test score could range from 0 to 20.

Visual Attention During Orientation and Expertise (Hypothesis 1a)

MFRs and non-MFRs did not differ significantly in their mean durations of average fixation in the 4 AOI categories of patients, vehicle impact zones, safety aspects and distractor, Pillai trace=0.03, $F_{4,52}$=0.40, P=.81. Furthermore, there were no significant correlations between the knowledge test score and the average fixation duration in any of the 4 AOI categories (Table 3).

Regarding the fixation count, MFRs and non-MFRs did not differ across the 4 AOI categories (Pillai trace=0.15; $F_{4, 52}$=2.37; P=.06). Again, the triage knowledge test was not significantly associated with the fixation count in any of the AOI categories (Table 4).

Table 3. Duration of average fixation (DOAF) of specific area of interest (AOI) categories across the 5 scenarios. Time in milliseconds: fixation duration was first averaged per scenario and then averaged across the 5 scenarios.

DOAF AOIs	Patients	Safety	VI[a] zone	Distractor
Examples of AOI cues	All patients and no bystanders	Scenario 1: spilled oil; scenario 2: ongoing traffic; and scenario 5: ongoing traffic, spilled oil, broken glass	VI zones in all scenarios; in scenario 3 and scenario 4 mean value of 2 VI zones	Only in scenario 3: filming bystander
Value per group, mean (SD)				
MFRs[b]	397.41 (105.55)	319.09 (105.69)	314.50 (80.39)	215.13 (92.28)

Triage Accuracy and Expertise (Hypothesis 1b)

MFRs had a significantly higher triage accuracy than non-MFRs ($t_{Welch61.62}$=–2.04; *P*=.02 [Bonferroni-Holm corrected *P*=.045]; *d*=0.48). On average, MFRs triaged 84% (SD 12%) of the patients correctly while non-MFRs triaged 77% (SD 18%) correctly (Figure 2A depicts the distributions).

Furthermore, a higher knowledge test score was associated with significantly higher triage accuracy (Spearman ρ=0.40; *P*<.001). A multiple regression analysis was used to test this relationship while controlling for age and gender. More prior triage knowledge significantly predicted higher triage accuracy during the scenarios (*b*=0.02; SE 0.005; *P*=.002), while age (*b*=–0.001; *P*=.67) and gender (*b*=0.005; *P*=.89) were not significant predictors. The model explained 9% of the variance (adjusted R^2) (R^2=.13; $F_{3,70}$=3.45; *P*=.02). However, according to the Shapiro-Wilk test, the assumption of normal distribution of the residuals (*P*<.001) was violated. Therefore, bootstrapping with 5000 draws was used to test the stability of the results. Again, prior triage knowledge significantly predicted triage accuracy during the scenarios (*b*=0.02, SE 0.00, 95% CI 0.01-0.03).

Figure 2. (A) density plots per group for triage accuracy, (B) triage speed, and (C) information transmission efficiency. The dashed lines mark the average per group. MFR: medical first responder.

Triage Speed and Expertise (Hypothesis 1c)

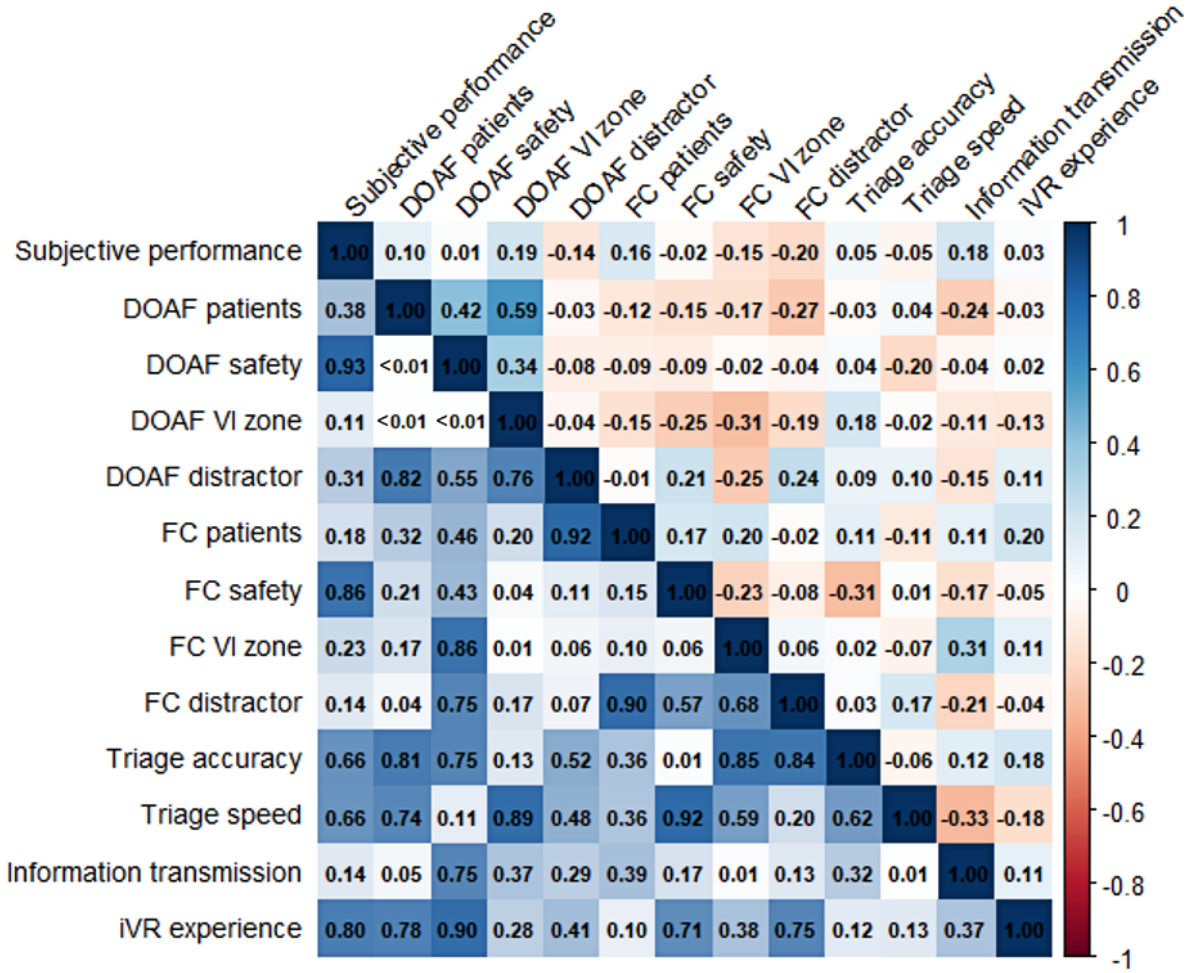
MFRs completed the triage process significantly faster than non-MFRs (t_{72}=1.79; *P*=.04 [Bonferroni-Holm corrected *P*=.045]; *d*=0.42). On average, MFRs required 95% of the average triage speed, whereas non-MFRs needed 5% more than the average (MFRs: mean 0.95, SD 0.23; non-MFRs: mean 1.05, SD 0.23; Figure 2B depicts the distributions). The knowledge test score was not significantly associated with triage speed (Spearman ρ=–.04; *P*=.72).

Information Transmission and Expertise (Hypothesis 1d)

MFRs transmitted information significantly more efficiently than non-MFRs (MFRs: mean 0.09, SD 0.03, and non-MFRs: mean 0.06, SD 0.03; t_{68}=–4.74; *P*<.001 [Bonferroni-Holm corrected *P* <0.001]; *d*=1.13) (Figure 2C depicts the distributions). However, there was no significant correlation between the knowledge test score and efficiency of information transmission (Spearman ρ=0.19; *P*=.11).

XSL•FO
RenderX

Explorative analyses were conducted with information transmission scores and word counts separately. Averaged across the scenarios, MFRs did not transmit significantly more correct information (MFRs: mean 2.15, SD 0.80, and non-MFRs: mean 2.07, SD 0.72; maximum score=4; t_{68}=–0.44; P=.33; d=0.11). However, MFRs transmitted information in fewer words (MFRs: mean 32.34, SD 20.99, and non-MFRs: mean 46.09, SD 23.68; t_{68}=2.57; P=.006; d=0.62). Knowledge test scores were not significantly correlated with the number of correct information transmissions (Spearman ρ=–0.05; P=.67) or information transmission length (Spearman ρ=–0.13; P=.29).



Testing the Incremental Value of Attention (Hypothesis 2)

As reported for hypothesis 1a, the attentional indicators assessed with eye tracking did not discriminate between different levels of expertise. Accordingly, testing the incremental value of visual attention indicators beyond the other performance indicators for distinguishing levels of expertise (hypothesis 2) was inapplicable.

Subjective Performance and Objective Performance Indicators (Hypothesis 3)

There were no significant correlations between subjective performance (mean 6.77, SD 1.13) and any of the objective performance indicators (all P>.05; Figure 3). Conversely, significant associations were observed between some objective performance indicators, including between greater triage speed and less efficient information transmission (ρ=–0.33; P=.01), and between less visual attention to safety cues (as measured by fixation count) and greater triage accuracy (ρ=–0.31; P=.01).

Figure 3. Spearman correlation analysis of the performance indicators and immersive virtual reality (iVR) experience (above diagonal: ρ values, below diagonal: P values). iVR experience refers to prior iVR experience as assessed in the preliminary questionnaire; prior iVR experience was not winsorized because of the ordinal data structure. DOAF: duration of average fixation; FC: fixation count; VI: vehicle impact.

Explorative Analyses

Exploratively, we tested whether prior iVR experience was associated with any of the examined performance indicators. For both MFRs and non-MFRs, the overall median value was 2 (ie, tried iVR 1-2 times). Prior iVR experience did not correlate with any performance indicator (all P>.05; Figure 3).

Discussion

Principal Findings

The prehospital triage process is a central aspect of managing MCIs, and if done correctly, leads to an efficient allocation of treatment and transport. As MCI real-life exercises are resource-intensive and therefore infrequently conducted, iVR

XSL•FO
RenderX

has emerged as a new triage training method [5]. Due to the novelty of such training, systematic evaluations of potential indicators that can be used to assess performance are still needed. This study aimed to provide such an evaluation. The objective performance indicators of triage accuracy and speed, as well as information transmission efficiency, significantly differentiated between MFRs and non-MFRs. In addition, higher triage accuracy was significantly associated with more prior triage knowledge, even when controlling for age and gender. Interestingly, however, visual attention did not differ with the level of expertise. Furthermore, in contrast to the third hypothesis, subjective performance was not correlated with any other performance indicator. Next, we discuss possible explanations as well as future directions for deriving meaningful performance indicators in iVR MCI training.

Visual Attention During Orientation

Visual attention represents a relatively novel potential performance indicator that has received limited attention from research in prehospital contexts. In other medical fields, studies using eye tracking have already identified differences in visual attention between experts and novices [17,24,26]. In this study, we found no significant associations between visual attention and expertise, which aligns with findings based on 2D videos of an MCI [29]. However, the results stand in contrast to 2 studies using 2D, prehospital images as stimuli [28,30]. Loth et al.[30] showed that after START triage training, participants directed their attention more swiftly to triage information boxes. The transferability of such findings to a 3D virtual scenario without information boxes remains uncertain [30]. In the second study, MFRs and novices differed significantly in their visual attention when looking at MCI photos without information boxes [28]. Several factors could explain the discrepancies. First, the former study used a purely 2D examination, which may not translate seamlessly into 3D. In contrast, iVR offers greater ecological validity for natural gaze behavior by providing a larger field of view and the ability to visually explore the environment by moving the head [49]. Moreover, the stereoscopic visualization in iVR enhances depth perception through binocular cues [61]. Previous research has demonstrated that 3D input can significantly alter attentional processes compared to 2D input [62], although it has not yet been directly compared in the context of MCI scenarios. The additional visual cues in the iVR scenarios of this study may have enabled non-MFRs to more quickly identify relevant AOIs, thereby reducing differences between MFRs and non-MFRs. Second, it is also possible that MFRs had to exert more effort in filtering out irrelevant visual stimuli than they would with 2D input, which could diminish potential differences between MFRs and non-MFRs. Furthermore, the former study [28] included true novices, whereas this study included non-MFRs with medical knowledge (primarily medical students), suggesting a possible power issue due to minimal effects between these groups, necessitating a larger sample size. Alternatively, it is plausible that both groups in this study possessed a minimum level of medical expertise necessary for effective visual attention, and effective visual attention remains relatively stable with additional triage knowledge.

Furthermore, for MFRs, visual attention, especially toward nonpatient information, such as safety threats and distractors, may be less critical than in professions such as law enforcement or military, where constant threat awareness is an integral part of training. For instance, police officers with specialized training have exhibited superior visual search behavior for threats and overall performance in real-life exercises compared to their counterparts without such training [63]. Another possibility is that differences in visual attention may only manifest when observing individual patients and their injuries, whereas our study primarily involved participants viewing a broad overview of an accident scene during eye-tracking measurements. Finally, it is worth considering that alternative visual attention indicators may offer more nuanced insights. The selection of appropriate eye-tracking measures is crucial, as certain fixation and saccade metrics or scan paths may be more applicable for specific purposes than others, depending on the task and study population [64]. This study used 2 eye-tracking measures often used in studies on visual attention in medical contexts [21,24], the number and length of fixations in predefined areas of interest (ie, patients, safety aspects, vehicle impact zone, and distractor AOIs). While fixation-derived metrics can be used as a measure for visual attention and processing, saccade-derived metrics could provide further insights into visual search strategies [24]. Furthermore, experts may exhibit distinct eye movement patterns and rapidly develop a holistic view of the scene, as observed in other medical domains [24].

Triage Accuracy and Speed

During real-life MCI exercises, triage accuracy and speed have proved to be useful as performance indicators, although usually not comparing different levels of expertise but prepost improvements after training [65-67]. Other studies used the indicators to compare different training methods [4,68-70]. Triage accuracy and speed have also been used in iVR settings [4,33,35], with evidence suggesting that with more iVR training, participants become better and faster at triaging in virtual MCI situations [33].

The results of this study suggest that accuracy is a suitable performance indicator to differentiate between different levels of expertise, with a medium effect size in terms of profession (MFRs vs non-MFRs) and a medium to large effect size in terms of triage knowledge [71]. These results are consistent with a previous study that found paramedic students to be as good at triage accuracy in a real-world exercise as in an iVR scenario [4]. Conversely, a previous iVR study based on 360° video recordings found a less clear relationship between triage accuracy and expertise, as there were no significant differences in triage scores between residents and attendings or between those with and without prior MCI experience [35]. The medium rather than large effect size in the comparison between MFRs and non-MFRs may be because the non-MFR group were not true novices but also had some medical knowledge. In addition, participants were able to reread the START triage algorithms before starting the scenarios, possibly reducing the difference in triage accuracy performance.

In addition, this study suggests that speed can serve as an indicator to discriminate between MFRs and non-MFRs, as

XSL•FO
RenderX

MFRs completed triage faster with a medium effect size [71]. However, caution should be exercised when comparing this marker to real-life exercises, as previous studies suggest that triage in virtual MCI scenarios may occur faster than in real-life scenarios [4]. This difference is likely due to differences in locomotion and information retrieval. In this study, participants were able to teleport with their controllers, allowing them to quickly cover large distances. Walking, as a method of locomotion, would be closer to real life but would require significantly larger training areas. Future studies could compare MFRs and non-MFRs in iVR systems with natural locomotion and more realistic patient information retrieval to test whether the differences between the groups are similar or greater than in this study.

Information Transmission

The transmission of information to the control center is crucial for the effective coordination of rescue services and thus for the management of large-scale operations. As depicted in the SSSS scheme, the rapid and clear transmission of information regarding the MCI scene, safety hazards, patient information, and the need for additional support is essential for mobilizing necessary reinforcements [38]. To our knowledge, this study was the first to record radio messages and assess information transmission efficiency as a performance indicator differentiating between different levels of expertise in iVR MCI training. MFRs transmitted information more efficiently than non-MFRs (large effect size [71]), yet no correlation with the triage knowledge test score was observed. Furthermore, exploratory tests revealed that MFRs did not transmit significantly more accurate information but managed to do so using fewer words. These results suggest that a certain level of theoretical triage knowledge, that both groups seem to have had, is sufficient to facilitate MFR communication. However, the ability to quickly convey relevant information may improve with practical field experience.

The finding that MFRs transmit information more efficiently is consistent with a previous non-iVR study, which found that trained physicians were better at following a reporting scheme in a real-world simulation than their untrained counterparts [40]. However, the radio messages in the former study were rated by observers only in 3 categories: not performed, incomplete, and complete. In this study, the radio messages were analyzed in more detail. With the proposed method, trainees could receive more specific feedback in addition to their efficiency score, including which SSSS categories they missed or inaccurately reported. Furthermore, information transmission as a performance indicator holds promise for seamless integration into iVR, given the prevalent incorporation of microphones in iVR headsets and the increasing feasibility of automated evaluations through real-time transcription and artificial-intelligence applications. Future research may want to compare radio transmissions from iVR exercises with real-life exercises and actual MCI radio communications, providing further insight into differences in communication effectiveness and situational awareness, including the recognition and prioritization of hazards. In an Austrian study with 7 firefighters and 6 paramedics, participants underwent a 1-minute reporting phase following either an MCI scenario in iVR or nonimmersive VR on a computer screen [72]. In the former study, the information given during the reporting phase was analyzed regarding situational awareness, the anticipation of consequences, and the communication of actions. There was no significant difference between the 2 training modalities. This highlights the utility of verbal information reporting as a performance indicator not only within iVR contexts but also across various training modalities.

Nevertheless, future training should consider the locally used reporting schemes. In the United Kingdom, for instance, the METHANE (a mnemonic for “major incident declared; exact location; type of incident; hazards; access; number and type of casualties; emergency services present and required”) framework is commonly used as a guideline for reporting information [36]. While the SSSS scheme greatly overlaps with METHANE, certain aspects were not particularly explored in this study, such as the exact location and access possibilities. In this study, participants started at the accident site instead of arriving there using a virtual ambulance vehicle and also received no detailed information about the site beforehand. Such aspects must be considered in studies using the METHANE scheme.

Subjective Performance

Self-reported performance did not correlate with the applied objective performance indicators, which contradicts previous research suggesting that self-assessed performance validity is at least low to moderate in medical education [42,43]. This discrepancy may stem from the fact that individuals often base their perception of abilities on comparisons [73]. In terms of self-evaluation, people commonly compare themselves to others (social comparisons) or to their own past performance (temporal comparisons) [73]. However, in this study, the participants did not witness other trainees’ performances, limiting social comparison options. In addition, comparing one’s own progress in performance may have been complicated by the scarcity of MCI training, particularly because the non-MFR group lacked prior MCI training experience. It is also possible that asking about a specific behavior, such as self-rated information transmission performance, might have resulted in an estimate closer to the specific objective indicators. While we assessed global self-rated performance, future studies could test whether specific self-rated performance assessments correlate with objective indicators.

Overall, the findings underscore the significance of integrating objective indicators, providing trainees with benchmarks to assess their performance. Still, self-evaluations remain important because they help trainees reflect on their performance and enhance their self-awareness [44]. Furthermore, comparing objective and subjective performance could potentially mitigate biases, such as the tendency for women to underestimate themselves compared to men [43].

Limitations and Future Research

This study included a German sample of participants that were, on average, relatively young. Consequently, the generalizability of these findings to older populations and those from other countries should be tested in future research. For instance, previous iVR research found that cohorts over the age of 40

XSL•FO
RenderX

years had lower triage accuracy than younger cohorts [35]. This could potentially be attributed to greater familiarity with learning technologies.

This study was based on the START triage algorithm because it is well known internationally, and several triage algorithms are based on it [74]. However, in Germany, the learned triage algorithm varies depending on the rescue organization and region; thus, most of our sample was unfamiliar with START beforehand. Nevertheless, it is quite similar to the mSTART algorithm [74], which was the most frequently known algorithm in our sample. Future studies could program scenarios to initially allow selection of the learned algorithm, through which the scenario would then proceed, as in a previous study [75].

Furthermore, research on visual attention in prehospital settings is still in its infancy. Larger studies considering various attention and eye-tracking indicators, such as gaze movement patterns, would be beneficial in this regard. In this study, we investigated visual attention after arriving on scene and therefore only used the first 30 seconds. For standardization purposes, participants stayed at the starting position during this time. However, visual attention during the exploration of the scene or even during the whole scenario could also be an interesting indicator and more representative of behavior at real MCIs.

In this study, the ability to interact with patients was limited due to technical constraints of the software. In contrast to 360° videos, a major strength of this study was that participants were free to move around, which required them to decide how to navigate the environment, gain a full overview, and ensure that all patients were located. However, other than moving freely and using the controllers to open car doors, other actions, such as obtaining patient information, relied solely on visual and auditory cues as well as verbal information acquisition. Recent advances in iVR MCI software have introduced additional interaction features, including the use of a virtual toolkit with controllers, haptic feedback through vibrating controllers when taking a pulse, and patients responding to simple commands through automated speech recognition [15]. As the need for verbal requests to obtain patient information may have reduced immersion, future training may benefit from the use of iVR MCI tools with more interactive features than those available in this study.

In addition, the assessment of expertise should be examined in a more nuanced manner. We used the participants' professions as well as a triage knowledge test as expertise indicators to cover the expertise construct in a broad manner, including theoretical knowledge and practical experience. In contrast, previous studies often only used one indicator, such as years of experience [29] or profession [28]. Still, measuring expertise is challenging and likely depends on numerous factors, such as years of experience (full or part-time), exposure to MCIs, and the amount of MCI training. Future studies could delve deeper into identifying measures suitable for assessing expertise and perhaps propose a composite measure encompassing multiple factors.

Practical Implications

This study's results highlight the suitability of iVR scenarios for MCI training and performance assessment. With its resource-efficient implementation, iVR training offers a valuable opportunity to supplement current MCI training. Although nonimmersive VR on a computer monitor may be an even more affordable option, immersive training is associated with learning gains, increased enjoyment, and improved concentration [76,77]. While initial costs for hardware, software, and personnel occur, iVR becomes less expensive with repeated use compared to real-life exercises, which require ongoing organizational and financial resources [4]. In addition, iVR software can reduce costs associated with observers by automating performance assessments, facilitating self-directed training, and allowing trainers to focus on higher-level observations. Because previous research has shown that MCI performance declines over time, MCI training should be conducted more frequently than once a year to ensure high-quality triage [67]. In this context, iVR training and performance assessment could provide a valuable supplement to enable regular MCI training for large numbers of first responders. The integration of iVR into standard training curricula could begin with theoretical instruction [67], followed by regular iVR training, which could also be used to prepare MFRs for large-scale, real-life exercises.

In particular, triage accuracy, speed, and information transmission seem to be effective performance indicators for possible incorporation into iVR MCI training, complementing each other by providing insights into various aspects of overall performance. These indicators could be seamlessly integrated into future iVR learning programs to automate performance evaluation, thereby reducing the workload on trainers and allowing them to focus on higher-order evaluations, such as general procedures. The tested indicators are all suitable for individual MCI training but may also be applied in team training and could even be enhanced with novel team performance indicators, such as position and movement tracking [78]. Furthermore, the integration of real-time performance measurement into a (smart) scenario control could be valuable. On the basis of live data, the scenario difficulty could be dynamically adjusted by either the trainer or artificial intelligence to meet the individual needs of trainees.

Conclusions

Overall, iVR proved to be a valuable tool for assessing the performance of MFRs in MCIs scenarios. The performance indicators triage accuracy, triage speed, and information transmission can be extended to MCI training in iVR and capture multiple aspects of MCI performance. While visual attention did not function as a valid performance indicator in this study, future research might further explore visual attention as a potential indicator by examining other aspects, such as gaze patterns. Overall, iVR could be integrated into current MCI training curricula to provide objective and potentially automated performance assessments and allow for more frequent practice.

Acknowledgments

This project was part of the European Union's Horizon 2020 project Medical First Responder Training using a Mixed Reality Approach featuring haptic feedback for enhanced realism (MED1stMR; grant agreement 101021775). Special thanks to Samantha Ullrich for her support with the web-based questionnaires and for reviewing the R code file. The authors would also like to thank Guy Pires Cabrita for his support with the eye-tracking data and Paula Bleier and Julia Adam for their support with the radio messages.

Authors' Contributions

ASB, YH, MOF, and CW designed the study. ASB, YH, CW, BR, and MK planned the scenarios, which were constructed by BR, MK, and ASB. The scenarios and patient information were reviewed by GS, TB, and SM. SG supported the technological setup and developed software for standardized behavioral data collection and audio recordings with triage information. ASB and MB were responsible for data collection. ASB analyzed the data and wrote the manuscript. All authors reviewed and approved the manuscript.

Conflicts of Interest

None declared.

Multimedia Appendix 1
Descriptions of immersive virtual reality scenarios and performance per scenario.

Abstract

Background: Laparoscopic surgery training is a demanding process requiring technical and nontechnical skills. Surgical training has evolved from traditional approaches to the use of immersive digital technologies such as virtual, augmented, and mixed reality. These technologies are now integral to laparoscopic surgery training.

Objective: This scoping literature review aimed to analyze the current augmented reality (AR) solutions used in laparoscopic surgery training.

Methods: Following the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines, we conducted a scoping review using 4 databases: Scopus, IEEE Xplore, PubMed, and ACM. Inclusion and exclusion criteria were applied to select relevant articles. Exclusion criteria were studies not using AR, not focused on laparoscopic surgery, not focused on training, written in a language other than English, or not providing relevant information on the topics studied. After selecting the articles, research questions (RQs) were formulated to guide the review. In total, 2 independent reviewers then extracted relevant data, and a descriptive analysis of the results was conducted.

Results: Of 246 initial records, 172 (69.9%) remained after removing duplicates. After applying the exclusion criteria, 76 articles were selected, with 25 (33%) later excluded for not meeting quality standards, leaving 51 (67%) in the final review. Among the devices analyzed (RQ 1), AR video–based devices were the most prevalent (43/51, 84%). The most common information provided by AR devices (RQ 1) focused on task execution and patient-related data, both appearing in 20% (10/51) of studies. Regarding sensorization (RQ 2), most studies (46/51, 90%) incorporated some form of sensorized environment, with computer vision being the most used technology (21/46, 46%) and the trainee the most frequently sensorized element (41/51, 80%). Regarding training setups (RQ 3), 39% (20/51) of the studies used commercial simulators, and 51% (26/51) made use of artificial models. Concerning the evaluation methods (RQ 4), objective evaluation was the most used, featured in 71% (36/51) of the studies. Regarding tasks (RQ 5), 43% (22/51) of studies focused on full surgical procedures, whereas 57% (29/51) focused on simple training tasks, with suturing being the most common among the latter (11/29, 38%).

Conclusions: This scoping review highlights the evolving role of AR technologies in laparoscopic surgery training, although the impact of optical see-through devices remains unclear due to their limited use. It underscores the potential of emerging technologies such as haptic feedback, computer vision, and eye tracking to further enhance laparoscopic skill acquisition. While most relevant articles from other databases were included, some studies may have been missed due to the specific databases and

XSL•FO
RenderX

search strategies used. Moreover, the need for standardized evaluation metrics is emphasized, paving the way for future research into AR's full potential in laparoscopic skill acquisition.

(J Med Internet Res 2025;27:e58108) doi:10.2196/58108

KEYWORDS

laparoscopic surgery; surgical training; surgical simulator; augmented reality–based laparoscopic simulator; AR-based laparoscopic simulator; augmented reality; mobile phone

Introduction

Background

Training in laparoscopic surgery is a long and demanding process that requires extensive theoretical knowledge, along with technical and nontechnical skills. Learning models in surgical training have rapidly evolved from traditional approaches based on the educational philosophy of "*see one, do one, teach one*" to more sophisticated surgical simulators that aim to increase the number of training sessions, thus dramatically enhancing the skills of medical professionals and the safety of patients [1]. Among the formative strategies, there are some based on animal models [2] and cadavers [3]. However, due to the economic and ethical issues involved in some of these solutions, surgical training has rapidly shifted toward the use of simulation-based systems, mainly for the early formative stages [4].

The emergence of immersive digital technologies such as virtual reality, augmented reality (AR), and mixed reality (MR) has led to a paradigm shift in the field of surgical training. Virtual reality allows users to be immersed in a fully digital environment replacing the physical world, whereas AR superimposes virtual elements onto the real world, enhancing or augmenting the user's environment. The latest evolution of these immersive technologies is MR, which merges virtual and real objects, enabling realistic interactions and coexistence. The use of these technologies is becoming an important part of the training process in laparoscopic surgery, enhancing the training experience and content without putting the patient at risk [5,6]. This technique can generate customized 3D models of each patient on which to train. Similarly, during the training process, this technology allows for the inclusion of enriched information, such as holographic images or 3D objects to guide the user during the training process and facilitating a more precise alignment between virtual information and physical objects in a simulator, an experimental model, or a patient. The use of AR technologies is constantly evolving and being integrated into the field of minimally invasive surgery. However, the current level of development of this technology as a tool to assist in the training process in laparoscopic surgery, as well as the available solutions (both commercial and prototypes) and the training functionalities they offer, is not precisely known.

Objectives

This scoping review intended to analyze the current AR and MR solutions used to assist in laparoscopic surgery training. Similarly, we reviewed the types of surgical simulators that make use of this technology, the training assistance information offered, and the main training tasks and procedures in which they have been used. This gave us a more detailed view of the current state of AR in the field of laparoscopic surgery training.

Methods

Search Strategy

A structured bibliographical search was conducted in the Scopus, IEEE Xplore, PubMed, and ACM databases. The same search query adapted to each database query syntax was used. We used a set of keywords related to the topic of this scoping review to identify relevant studies published up to January 1, 2024 (Multimedia Appendix 1). In general terms, the initial search encompassed all articles that included the following terms in the title or abstract or as keywords: "laparoscopic"; AND "augmented reality" OR "mixed reality" OR "extended reality"; AND "training" OR "practice."

Eligibility Criteria

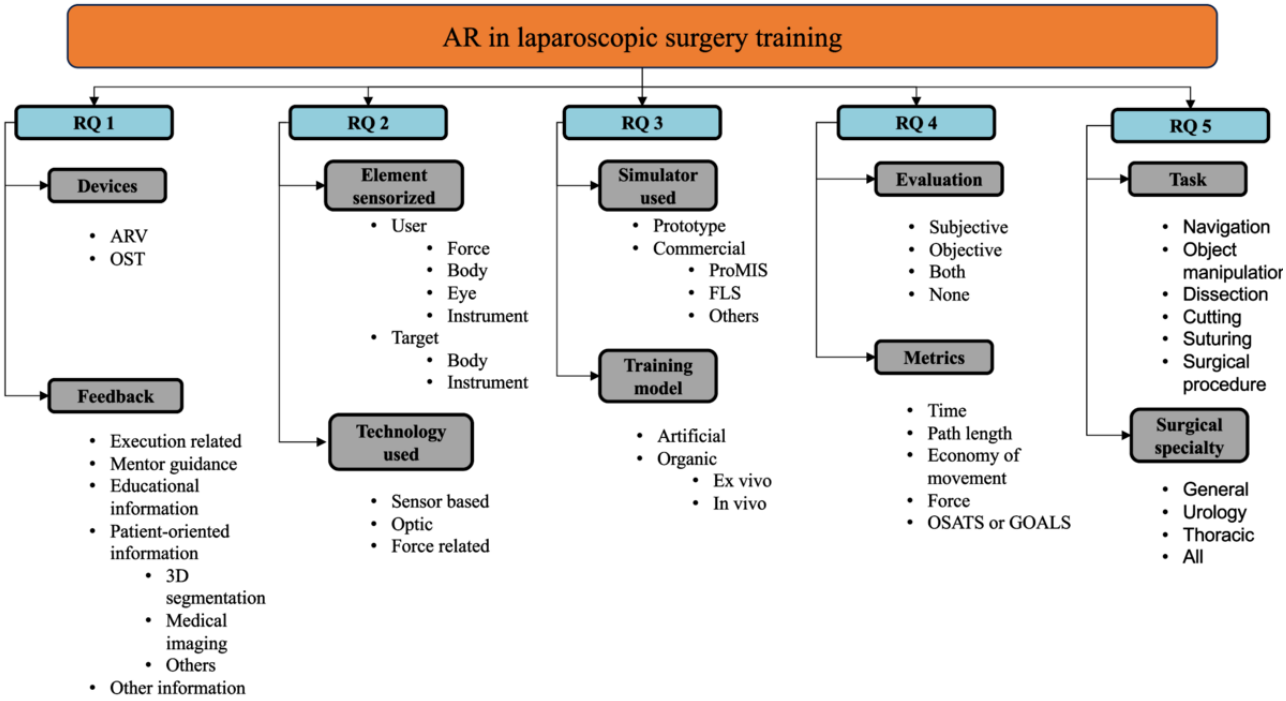
A series of inclusion and exclusion criteria were considered to select the articles that best applied for our objectives. In general, articles on studies that did not make use of AR technologies or did not provide information on the inclusion of such technologies in laparoscopic surgery training, articles that did not focus on laparoscopy or its skill training, articles that were written in a language other than English, reviews, or articles that were not accessible were discarded. In addition, regarding the quality of the articles, those studies that did not provide relevant information on the topics studied were excluded.

Selection of Articles

Results were screened by 2 independent reviewers. In case of discrepancies between reviewers regarding the inclusion or noninclusion of an article, a third reviewer was consulted. The PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines were followed to carry out this scoping review [7], including the completion of the corresponding checklist (Multimedia Appendix 2).

Research Questions

The aim of this work was to analyze the studies published in scientific literature in relation to the use of AR in laparoscopic surgery training and analyze the relevant aspects that facilitate the development of new investigations in this field. Therefore, with this scoping review, we intended to answer the following research questions (RQs):



1. What type of devices and feedback are used for AR-based laparoscopic surgery training? (RQ 1)
2. What type of sensorization is used for AR-based laparoscopic surgery training? (RQ 2)

XSL•FO
RenderX

3. What type of simulator and setup is used for AR-based laparoscopic surgery training? (RQ 3)
4. What type of evaluation is used to assess skill acquisition in AR-based laparoscopic surgery training? (RQ 4)
5. What type of surgical tasks or procedures are used in AR-based laparoscopic surgery training? (RQ 5)

To do so, we classified every article based on different dimensions, each one related to one of the RQs (Figure 1).

Figure 1. Taxonomy of articles regarding each research question (RQ). AR: augmented reality; ARV: augmented reality video; FLS: Fundamentals of Laparoscopic Surgery; GOALS: Global Operative Assessment of Laparoscopic Skills; OSATS: Objective Structured Assessment of Technical Skills; OST: optical see-through.

Data Collection and Processing

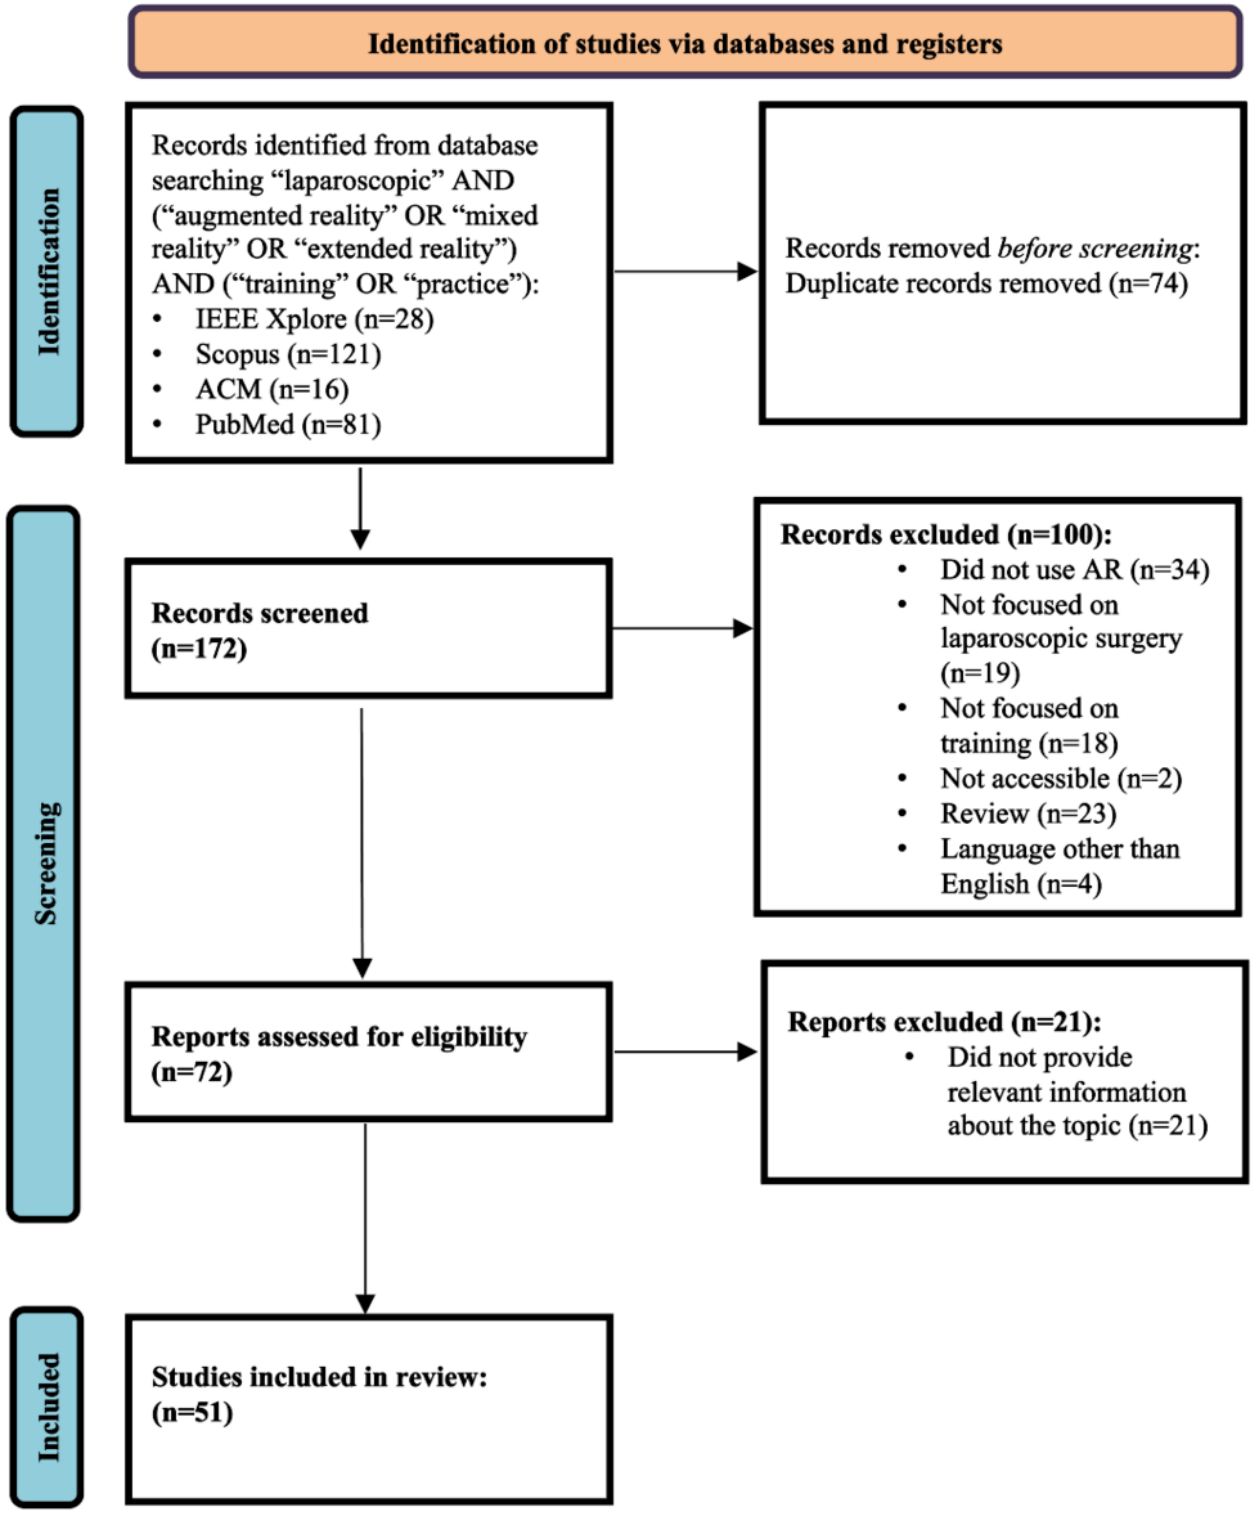
For each selected study, information on the following aspects was recorded: (1) year of publication, (2) summary of the complete study, (3) modality of teaching (tele-mentoring or conventional), (4) type of device used for AR, (5) type of information provided to the learner, (6) type of sensorization, (7) type of AR simulator (commercial or prototype, and which one if commercial), (8) type of evaluation (objective or subjective), (9) training tasks or procedures performed, and (10) specialty of laparoscopic surgery.

As with the selection of articles, the data collected for each article were screened by 2 independent reviewers. In case of discrepancies between reviewers regarding the data collected for each article, a third reviewer was consulted.

Results

Overview

A total of 246 records were obtained (n=28, 11.4% in IEEE Explore; n=121, 49.2% in Scopus; n=16, 6.5% in ACM; and n=81, 32.9% in PubMed). After removing duplicate records, 69.9% (172/246) remained. Once the exclusion criteria were applied, 44.2% (76/172) of the articles were left. Of these 76 articles, 25 (33%) that did not meet the quality criteria were eliminated so that 51 (67%) articles were finally included in this review Figure 2 illustrates the complete workflow.



The papers included were published between 2002 and 2023, most of them (37/51, 73%) were scientific journal articles [6,8-43], and the rest (14/51, 27%) were papers presented in scientific conferences [44-57].

The evolution of the papers included in this scoping review was heterogeneous (Table 1), although it seems to be related to the launch of new AR devices on the market. Among them, the appearance of the first AR applications in games and smartphones in 2009, the launch of the Google Glass device in 2015, or the launch of the second version of Microsoft's HoloLens in 2019 are highlighted.

In the following sections, we will analyze each of the RQs defined to provide a comprehensive analysis of the current application of AR technology in laparoscopic surgery training.

RQ 1: What Types of Devices and Feedback Are Used for AR-Based Laparoscopic Surgery Training?

Our first RQ was about the AR devices used and the information provided. This analysis allowed us to see the evolution of the technology used and how these systems provide relevant information to enhance laparoscopic surgery training.

Regarding the devices, we classified them into 2 main types: optical see-through (OST) and AR video (ARV)–based devices (Table 2). OST refers to those devices that are capable of rendering information on a medium while allowing the real world to be seen through it. Devices such as HoloLens fall into this category as they allow information to be rendered on the screen while superimposing this information on our visual perception of the real world. ARV refers to the use of conventional video devices such as monitors, tablets, or other types of screens in which reality information is displayed (such as a real-time video) and overlaid with expanded information, creating an AR system. OST systems usually include voice commands, eye tracking, and interaction with real-world objects, whereas ARV systems reduce interaction and rely mainly on the display of additional information on the screen. Some articles (2/51, 4%) did not specify the device used, and so they were classified as unspecified devices.

The feedback provided by the system is closely related to the devices being used as it conditions the user-system interaction. We divided the articles by the information given to the user, differentiating among (1) *execution-related* information, which refers to any type of information related to the actions being performed by the trainee, such as the force exerted or time expended; (2) *mentor guidance*, which refers to those systems in which the AR technology allows the mentor to enhance the way in which they provide guidance to the trainee, for instance, using virtual pointers or annotations; (3) *educational information*, which could be general information about the training activity being performed, such as images of the organs and structures involved in the surgical activity or other general information; and, finally, (4) *patient-oriented* information, which corresponds to personalized information about the patient to be operated on. In this case, information was divided into *medical imaging* (as preoperative imaging), *3D segmentation* created from preoperative imaging, or *other* personalized information. *Other information* comprised information that did not fit into any other classification. *Unspecified information* comprised articles that did not indicate the type of information provided to the user of the AR device (Table 2).

[c]Combinations of devices and information types under which no articles were categorized, indicating nonapplicability in the reviewed studies.

Most of the studies analyzed (43/51, 84%) used ARV devices, and only 12% (6/51) used OST devices. A total of 4% (2/51) of the articles did not specify which kind of device was used.

Regarding the ARV studies, although most of them (11/43, 26%) did not specify what information they provided to the user, among those that specified this information, execution-related information was highly common (9/43, 21%), such as in the study by Zahiri et al [14], which showed the time remaining for the trainee to complete the current task in the form of either a numerical timer or a progress bar. Regarding mentor guidance (6/43, 14%), Andersen et al [16] developed a tool for tele-mentoring, allowing the mentor to use different-colored dots for annotation. A common type of information was patient-oriented information (8/43, 19%). Pessaux et al [20] conducted a 3D segmentation from preoperative images to generate a 3D model of the patient's body, which was later superimposed over the real patient's body during a duodenopancreatectomy. Regarding medical imaging, Koehl et al [50] developed a system that allowed trainees to visualize and manipulate preoperative images. Arts et al [12] provided trainees with educational videos with instructions for the ongoing task. Regarding other information, Shao et al [43] used prerecorded ultrasound videos that were played depending on the position of the laparoscopic tools so that their system could be used for training purposes on ultrasound-guided laparoscopic interventions.

Of the 6 studies using OST devices, 3 (50%) used HoloLens version 1 [10,11,56], and 3 (50%) used HoloLens version 2 [6,9,55]. In addition, the year of publication of those articles was 2020, so it could be considered a technology of recent application in laparoscopic training. Although far fewer studies that used OST devices were found, they mainly provided patient-oriented information (4/6, 67%). For instance, Zorzal et al [11] gave users the possibility to obtain access to the preoperative magnetic resonance image of the patient. Others (2/6, 33%) provided educational information, such as the study by Simone et al [10], which used annotations on the patient's body and a mentor's voice instructions.

RQ 2: What Type of Sensorization Is Used for AR-Based Laparoscopic Surgery Training?

To assist in the training activity, it is essential to know in real time the location of the different elements involved in the training environment, such as the training scenario, surgical

XSL•FO
RenderX

instruments, patient, and posture of the surgeon. By monitoring these elements, it is possible to adapt the training process to the trainee's educational needs. In addition, as this task is manipulative, it is relevant to consider the haptic stimuli. Therefore, in this section, we analyze which aspects related to the use of sensors (sensorization) were used in scientific literature. In this regard, we classified systems according to 2 aspects: the element being measured or sensorized (Table 3) and the technology used (Table 4).

Table 3. Classification by type of element being measured and technology.

Element being measured or sensorized	Studies
User tracking	
Force feedback	[26,39,46,52]
Body	[6,8,29,42]
Eye	[11,41]
Instrument	[9,12,15,18,19,21-25,27-40,43,45,46,49,51-54]
Target tracking	
Body	[13,14,16,17,20,22,33,38,48,49,51,53]
Instrument	[13,44,56]
Unspecified	[10,47,50,55,57]

Table 4. Classification of articles by sensorization technology.

Technology	Studies
Sensor based	[6,11,13,18,21,25,27,33,51]
Optic	[8,9,12-20,22-24,28-33,35-38,40-45,48,49,53,54,56]
Force	[26,34,39,46,52]
Unspecified	[10,47,50,55,57]

As we have pointed out, there are different elements in the training environment that can be tracked to know their location, motion, or behavior. We distinguished *user tracking* (ie, monitoring the surgeon and elements related to the surgeon). In this case, we organized the tracked elements into 3 categories: *body*, which were systems that recorded the surgeon's body motion for kinematic analysis; *eye*, to refer to the analysis of the surgeon's gaze and where they focus their attention; and *instrument*, which referred to the tracking of the surgical instruments. In addition to the user, the target can be tracked (*target tracking*), that is, the patient or the simulated model of the patient. This type of analysis was usually conducted using computer vision techniques. In this case, when we talk about *body*, we refer to the patient's body and organs, whereas *instrument* refers to other objects or markers that can be placed inside the patient and can be tracked or recognized, such as the needle used in suturing tasks [44].

Not only the object being tracked is important but also how they were tracked, that is, the technology and techniques used to achieve this tracking. For this reason, we divided the technology into 3 categories: *sensor based*, *optic*, and *force*. *Sensor-based* technology refers to those systems that used a set of sensors specifically located to track and measure certain interactions in those locations. An example could be the use of electromagnetic trackers for recording laparoscopic tool motion [25]. *Optic* technologies refer to the identification and tracking of objects using artificial vision techniques. Felinska et al [41] used iSurgeon, an AR tool that allowed instructors to project their hand gestures in real time onto the laparoscopic screen, enhancing mentoring guidance during laparoscopic training sessions. *Force* refers to those systems that used devices capable of measuring the interaction force of the laparoscopic instrument [26].

Most of the studies (46/51, 90%) used some type of sensorization of the training environment in which the surgical simulation was performed.

In most AR systems, the user saw a real world augmented only with visual information and had no means to interact with virtual objects. If we want to manipulate virtual objects, we need another kind of information—*haptic* [58]. Therefore, together with the display of visual information recorded by tracking devices, the availability of augmented haptic information seems relevant in laparoscopic surgery training, where manipulative tasks are fundamental. In this sense, 8% (4/51) of the studies included some type of haptic feedback in the laparoscopic surgery training environment. For example, Ivanova et al [52] used a virtual 3D model of an organ and a sensorized physical simulator, providing force feedback on the hardness of the tissue being touched and the force exerted.

Regarding the element being measured or sensorized (tracked), the most common was tracking of the surgeon (user tracking). In this case, the most relevant elements tracked were the instruments used by the surgeon (32/51, 63%). Pagador et al [27] used electromagnetic trackers to record the instrument's position during the training activity, whereas Lahanas et al [45]

XSL•FO
RenderX

used fiducial markers attached to the tip of the instrument for tracking instrument position and rotation. There were only a few studies (4/51, 8%) that made use of surgeon posture tracking. For example, Cizmic et al [42] tracked hand position to project the hand movements of the trainer onto the laparoscopic image to enhance communication between trainer and trainee. The use of eye tracking was present in only 4% (2/51) of the studies analyzed. This technique was used by some authors to interact with sets of images and other elements of a user interface by means of gaze [11] or to assess performance and quality of communication [41].

Target tracking was the next most used sensorization in laparoscopic surgery training solutions. In this case, body tracking (tracking objects in the training environment or patient organs) was the category that comprised most of the reviewed articles. For this purpose, most of the studies (35/51, 69%) used artificial vision techniques to identify and track body structures. Viglialoro et al [13] used AR as a training aid in simulator-based laparoscopic cholecystectomy training, mainly during the isolation of the cystic duct and artery (Calot triangle). AR technology allowed trainees to visualize these hidden structures during the training activity [13]. Pessaux et al [20] proposed an AR-based assistance system to superimpose information from preoperative images onto the patient's skin using a beamer, generating body transparency with visualization of deep structures. Finally, only few studies (2/48, 4%) tracked information about artificial markers or objects (instruments) within the surgical workspace inside the patient's body. Preetha et al [44] tracked the surgical needle during a laparoscopic suturing task.

RQ 3: What Type of Simulator and Setup Is Used for AR-Based Laparoscopic Surgery Training?

Regarding the simulator and setup used for laparoscopic training, 2 main characteristics were considered. The first was the origin of the training system, which may be a widely used commercial simulator (eg, ProMIS) or a prototype developed specifically for the research being carried out or pending to be released into the market. The second was the physical characteristics of the simulator and the models used in the training activity (training model). It could be an artificial model created solely for the purpose of training or an organic model (in vivo or ex vivo) obtained from organic tissue (Table 5).

Table 5. Classification of the different training models (artificial training model, ex vivo, and in vivo) according to the type of simulator (commercial or prototype).

	Training model: artificial	Organic		Unspecified
		Ex vivo	In vivo	
Prototype	• Viglialoro et al [13] • Andersen et al [16] • Horeman et al [21,26] • Kim et al [39] • Shao et al [43] • Shabir et al [47] • Condino et al [48] • Viglialoro et al [51] • Wagner and Rozenblit [53]	• Baumhauer et al [38]	—[a]	• Zorzal et al [11] • Loukas et al [22] • Rozenblit et al [46]
Commercial

[b]FLS: Fundamentals of Laparoscopic Surgery.

XSL•FO
RenderX

The use of commercial simulators was more widespread (20/51, 39%) than the use of prototypes (14/51, 27%). Commercial simulators mostly used artificial models (10/20, 50%), such as beads for the eye-hand coordination tasks [15]. There were also some studies (6/20, 30%) that used organic models. In this case, some authors compared skill acquisition after training with human cadavers versus using AR-enhanced artificial models [31]. Strickland et al [28] used a lamb liver to which a piece of marshmallow was introduced to simulate a tumor to be removed, and Pagador et al [25] used a porcine stomach for suturing tasks. There were some studies (4/20, 20%) that did not specify the model used by the commercial simulator or that could not be included in any of the defined categories.

Regarding the simulator prototypes, most (8/12, 67%) used artificial models. Lahanas et al [18] used markers inside a box trainer to superimpose images of different interactive objects, such as rings or beads that needed to be manipulated. Regarding the use of organic models, only Baumhauer et al [38] used an ex vivo porcine kidney to test the image overlay capability of the AR-based training system presented. The rest of the papers did not specify the model used or did not fit into any of the categories.

Artificial models were the most used training models (26/51, 51%), especially in simulator prototypes (10/17, 59%), followed by ex vivo training models (8/51, 16%). The latter stand out as 62% (5/8) of the studies that used ex vivo models used commercial simulators. The studies that used in vivo models did not refer to the simulator used as these were real operations (either on humans or animals).

There were studies that did not specify whether they used a commercial simulator or developed a prototype (17/51, 33%). Of these studies, 41% (7/17) used artificial training models, such as the system presented by Doughty et al [55], which did not use a specific laparoscopic simulator as it was intended to be used in any type of surgery. Meanwhile, 6 of the studies that did not specify whether they used a commercial simulator or a prototype used organic models, with 4 (67%) of them being in vivo models. Simone et al [10] used MR smart glasses to enable tele-mentoring in real surgical procedures during the COVID-19 pandemic.

There were a few articles (4/51, 8%) that did not specify either the type of simulator or training model used. Gupta et al [57] mentioned the need for a development framework for this type of simulators in laparoscopic surgery training and which aspects should be considered. However, they did not make use of any training system as it was a theoretical study [57]. Another study tested the impact of AR elements on inattentional blindness during a laparoscopic operation using a prerecorded video [17]. The study by Koehl et al [50] focused on the generation of modular models that could be used for other applications as a 3D visual model or as a force feedback generation system. Pagador et al [27] designed and evaluated a laparoscopic tool tracking system for further assessment purposes.

RQ 4: What Type of Evaluation Is Used to Assess Skill Acquisition in AR-Based Laparoscopic Surgery Training?

In total, 2 main ways of addressing the assessment of laparoscopic skill acquisition in AR-based laparoscopic surgery training solutions were reported. One way of evaluation was through objective evaluation metrics [15-18,22-26,28-30,32-34,38,40-42,44,49,52,54-56] usually calculated by the training system. Another way was subjective evaluation carried out by experts or by means of interviews or self-assessment questionnaires [6,10,11,36,43,47]. Some studies used both ways [8,9,12-14,19,21,31,35,37,48], while others used none [20,27,39,45,46,50,51,53,57].

Objective evaluation was the most used method for the assessment of skill acquisition in laparoscopic surgery. In terms of the metric used, most of the studies (25/51, 49%) evaluated the performance of surgeons to assess whether the system enhanced laparoscopic skill acquisition. A variety of metrics were used, such as execution time, path length, or motion smoothness (Table 6). Time, whether related to task completion or training duration, was a commonly used metric [41] that assessed the time spent on each task as a performance indicator. There were other studies (2/31, 6%) that, instead of measuring the time needed to complete the task, measured the time that the laparoscopic instruments spent in a specific area, for instance, during a suturing task [35].

Table 6. Type of metric used for objective evaluation in each study analyzed.

Metric	Studies
Training time or task time	[8,12,19,23,28,34,35,40,41]
Time in correct area	[34,35]
Path length	[15,18,19,21,24,25,29,30]
Objective Structured Assessment of Technical Skills	[8,31,32,41,42]
Global Operative Assessment of Laparoscopic Skills	[8,42]
Economy of movement	[15,24]
Force	[21,26,34,35]

Path length was another prevalent objective metric (8/31, 26%). This metric records the path followed by the laparoscopic instruments during the performance of the training task. There were another 6% (2/31) of the studies that, apart from measuring path length, also computed the economy of movements of the surgical instruments [15,24]. Force metrics were also commonly used (4/31, 13%). Botden et al [34] evaluated the performance of a suturing task by assessing the strength of the knot. The

XSL•FO
RenderX

Objective Structured Assessment of Technical Skills (OSATS) and the Global Operative Assessment of Laparoscopic Skills (GOALS) formularies are 2 recognized standards for assessing laparoscopic skills that were also used in some of the studies, with the OSATS being used in 14% (5/36) of the studies and the GOALS being used only twice (2/36, 6%).

Subjective evaluation was mostly used for evaluating the usability of the AR tools (6/51, 12%). For example, Arts et al [12] made use of a questionnaire to assess the validity of the ProMIS as an AR laparoscopic surgery simulator. The combination of both types of evaluation (objective and subjective) was used in 22% (11/51) of the studies. Cau et al [9] combined an expert's subjective assessment of a suturing task with metrics obtained by the system itself.

RQ 5: What Types of Surgical Tasks or Procedures Are Used in AR-Based Laparoscopic Surgery Training?

Regarding the laparoscopic training activities (tasks or procedures), in most of the studies (26/51, 51%), trainees performed basic tasks commonly used in the early stages of laparoscopic surgery training programs. These tasks were divided into 5 main categories: navigation tasks focused on the skill needed to explore the surgical workspace using the camera and laparoscopic instruments; object manipulation tasks aimed to train the user to move, rotate, or manipulate objects or organs using the laparoscopic instruments; dissection tasks focused on the ability to separate tissue and anatomical structures without causing any damage to them; cutting tasks focused on training users to make precise cuts in organs and tissues; and suturing tasks focused on training for suturing tissues, including knotting skills. Finally, there were studies that used surgical procedures such as partial nephrectomy on ex vivo models [38] or sigmoid colectomy on cadavers [31].

Similarly, considering its main clinical features, such as the surgical procedure performed or the training model used, the category of surgical specialty into which each study fell or could fall was defined. For those studies in which a training surgical intervention was performed, the surgical specialty was the one which that procedure corresponded to. There were also some studies that included simple tasks. In this case, the surgical specialty was selected based on the training model used. For those cases in which surgical skills did not focus on a particular surgical specialty, the studies were classified as "All" specialties (Table 7).

XSL•FO

[a]Combinations of training task or procedure and clinical specialty under which no articles were categorized, indicating nonapplicability in the reviewed studies.

A large proportion of the studies analyzed (20/51, 39%) used surgical procedures rather than simple tasks to train and assess surgical skills. General surgery was the surgical specialty of most of the studies (14/20, 70%). In the study by Viglialoro et al [13], they presented an AR solution that assisted in the identification of the artery and cystic duct in a training simulator for cholecystectomy. Other studies (4/20, 20%) were included under the specialty of urology, such as the study by Teber et al [33], who presented a system for formative assistance during laparoscopic partial nephrectomy. Other studies (3/20, 15%) performed procedures that were not classified into any specific surgical specialty but could be used in any specialty, such as the study by Doughty et al [55], who developed a context-aware system capable of assisting the surgeon depending on the training task being performed.

Regarding basic laparoscopic surgery training tasks, the most common task used was suturing (11/25, 44%). Botden et al [34], for example, used suturing to analyze the evolution of the trainees' technical skills, assessing how fast trainees performed tasks and the strength of the knotting. Object manipulation tasks was also common in the studies analyzed (9/25, 36%). Lahanas et al [18] presented 3 different object manipulation tasks to assess trainees' laparoscopic skills using their AR-based simulator. The use of navigation tasks was less common in the training settings (5/25, 20%). Fusaglia et al [49] presented an

XSL•FO
RenderX

overlay system to show hidden anatomical structures during the performance of laparoscopic navigation tasks. The first task was to press a set of buttons in a specific order using the laparoscopic instruments, the second task was to transfer an object using the laparoscopic tools, and the last task was to cut a virtual object (using AR technology). Another type of task were dissection tasks, but they were less common that the rest (3/25, 12%). One study proposed the use of 2 balloons (one inside the other) that the trainee had to separate keeping the inner balloon inflated (ie, without being damaged) [12]. Only 16% (4/25) of the studies focused on cutting tasks. In the study by Brinkman et al [24], a full week of laparoscopic surgery training was proposed, having training sessions once a day in which some laparoscopic cutting tasks were included. Finally, there were 12% (6/51) of the articles that did not specify the task performed.

Discussion

Principal Findings

Overview

AR is an emerging technology that is being applied to various fields, including health care. In this sense, applications have been developed mainly oriented toward surgical planning, medical and surgical training, and surgical assistance [59,60]. In this study, a review of scientific literature oriented toward solutions for assistance in laparoscopic surgery training was carried out. We analyzed aspects that we considered critical to innovate and advance in this field, such as the devices used to provide AR to the user, the training environments, the types of training tasks or procedures, and the evaluation metrics used to analyze the evolution of students during the training activities and provide them with educational feedback. For this purpose, we analyzed all the RQs raised in this work with the aim to provide some observations that may help researchers guide their new proposals and innovative solutions to achieve an improvement in the field of laparoscopic surgery training.

The evolution of the number of publications included in this scoping review was heterogeneous and may be associated with the evolution of AR technology and the introduction of new applications and devices. Although there were some studies in the first years of this century associated with the appearance of the first AR applications in games and smartphones, it was in 2009 when a relevant increase in interest in the use of AR was observed, coinciding with the success of applications such as the AR toolkit, an open-source library for the creation of AR applications based on the identification of visual markers. This relevant interest continued until 2015, which could be related to the launch of Google Glass. This device was the first proposal that took AR out of the screen and into the real world using a wearable device. However, it was not until the launch of the second version of Microsoft's HoloLens (2019) when the potential of this type of technological proposals increasingly distanced from solutions linked to screens began to be glimpsed. This fact may be related to the recent increase in interest in the use of this type of AR-linked technologies in laparoscopic surgery training.

In the following sections, we will analyze the results to identify relevant insights that address each of the RQs.

Devices and Feedback (RQ 1)

While video devices such as monitors, laptops, smartphones, and tablets have traditionally been used in the early stages of AR technologies to enhance laparoscopic surgery training, the use of OST devices is a relatively new development due to the recent emergence of devices that facilitate these functions (the first device appeared in 2020). Therefore, only 12% (6/51) of studies were found that explored the application of OST technology in this context [6,9-11,55,56].

OST devices offer greater versatility than traditional video devices (monitors, smartphones, and tablets) for laparoscopic surgery training. As several studies (6/51, 12%) demonstrated, OST devices provide novel interaction methods and functionalities such as eye or gaze tracking, voice commands, and gestural interactions to manipulate virtual objects or add annotations. For instance, the head gaze was used to point at the laparoscopic virtual screen to enhance communication between trainer and trainee [11]. Felinska et al [41] used eye-tracking technology to create a heat map and analyze differences between the visual focus areas of trainees and instructors. In another study using OST technology, the Vuforia library was used to recognize artificial visual markers in the training environment to insert virtual elements to enhance the experience of laparoscopic surgery training [56]. However, this solution was limited to simulated environments, making it difficult to use in real clinical settings as it relied on 5 cameras for marker recognition. Sánchez-Margallo et al [6] and Simone et al [10] focused on the creation of 3D models from real preoperative images to implement AR-based training applications. In addition, this functionality was extended by allowing tutors to add annotations and information to the models [10].

One of the advantages of OST devices is that they can be used in any training environment used in laparoscopic surgery. The trainee always visualizes the real training environment, and it is the augmented information (holograms) that is superimposed onto the real image through the glasses. For instance, in the study by Sánchez-Margallo et al [6], it was not necessary to connect the OST device to the laparoscopic simulator as it did not require the laparoscopic video feed.

However, Zorzal et al [11] accessed the video source from the laparoscopic tower and explored the ergonomic improvements that OST devices could provide by displaying the endoscopic video in any place of the operating room and even following the surgeon's head.

Regarding ARV devices, the analyzed studies highlighted their potential to enhance the experience during laparoscopic surgery training. In the study by Preetha et al [44], a convolutional neural network was used to predict depth from laparoscopic imaging and recognize the manipulation of laparoscopic instruments for use in surgical skill assessment. Another study also used depth prediction to generate and display optimal trajectories for surgical instruments [53]. Solutions for depth perception support were also presented to improve the training process of novice

XSL•FO
RenderX

trainees in laparoscopic surgery [45,49]. The presence of assistive information in the surgeon's field of view is not a major disadvantage as it has been shown that the use of information-enhanced holograms does not have a negative impact on the surgical working field [17]. In another case, ARV technology was used to generate 3D models from preoperative imaging and superimpose them onto laparoscopic images as a support during the performance of the surgical task or formative procedure [20].

Another important aspect to consider during laparoscopic surgery training is to analyze force feedback during the performance of different laparoscopic tasks and procedures. This factor was explored in an ARV training environment, showing that feedback of force exerted improves the acquisition of tissue-handling skills [21,26]. Other studies (6/51, 12%) investigated the overlay of assistive content in the performance of training tasks and procedures by means of ARV applications and concluded that it helps the trainees reduce path length and deviation along the depth axis and improve their orientation skills [18,48,49,52-54].

All in all, we can see that both OST and ARV devices show significant potential as training aids in laparoscopic surgery. Although OST devices are a more recent and less explored development, they offer enhanced versatility compared to traditional video devices used in early AR technologies. The reviewed studies highlight the various applications of OST and ARV, including novel interaction methods, access to preoperative imaging, ergonomic improvements, depth analysis, and instrument motion analysis. This suggests that both OST and ARV have the potential to enhance laparoscopic surgery training, with OST devices offering greater versatility and opportunities for innovation in this field.

Sensorization (RQ 2)

The studies analyzed in this review mainly presented 2 types of sensing technologies: haptics and tracking. The use of haptic technology in laparoscopic surgery training has been a topic of considerable interest, as evidenced by the number of studies found on this topic (9/51, 18% of the studies in total). These studies explored the potential benefits of haptic feedback in enhancing the acquisition of laparoscopic skills and improving surgical performance. The use of haptic feedback in laparoscopic surgery simulation was examined in several studies (4/51, 8%), demonstrating its efficacy in improving surgeons' dexterity [24,26,39,52] The incorporation of haptic feedback in AR-based laparoscopic surgery training applications has been shown to lead to improved performance among novice surgeons [61] and improve surgeons' skills in laparoscopic suturing [23]. The efficacy of haptic feedback in laparoscopic skill acquisition was also studied by other authors (4/51, 8%) [34,36,37,62], who showed that it significantly enhanced surgeons' precision and instrument manipulation skills. These studies highlighted the potential of haptic feedback as a valuable adjunct to laparoscopic surgery training. It seems evident that haptic technology promises further advances in laparoscopic surgery training and proficiency.

Regarding tracking technologies, there were 2 main approaches: a sensor-based approach and an optical technology–based approach. The sensor-based approach uses sensors placed at specific locations to track the object in the training environment. Meanwhile, the optical technology–based approach uses image analysis to perform tracking of the objects of interest. The studies included in this review used artificial vision techniques and optical sensorization, mainly by using the laparoscopic camera feed. For instance, Loukas et al [22] used 2 different algorithms to estimate the tooltip position, one of them using an adaptive model of a color strip attached to the tool and the other one tracking directly the shaft of the tool. Optical technology plays a crucial role in accurate tracking in clinical settings. Zahiri et al [14] used this technology to evaluate the performance of an object transfer task in basic training environments by tracking colored rings. Another study focused on tracking anatomical structures such as the Calot triangle and user interaction during the training procedure [13]. Vision-matching techniques enhance trainees' visualization of hidden anatomical structures by superimposing 3D models onto the laparoscopic camera source, improving trainees' understanding of spatial relationships [33]. Vision-matching techniques were also used for pairing of real and augmented vision, some of them automatically and others semiautomatically. Thus, in the study by Hughes-Hallet et al [17], a semiautomated real-time overlay of preoperative models onto the anatomical field structures was performed, improving accuracy and efficiency in the AR-guided training process, whereas Pessaux et al [20] and Condino et al [48] used manual assistance to align the virtual objects with the patient's anatomy. Overall, the integration of artificial vision techniques and optical technology plays a crucial role in the identification and tracking of the anatomical structures of the patient. These solutions improve the understanding of the steps to be carried out during training activities, as well as the identification of manipulated objects by trainees in laparoscopic surgery training.

The eye-tracking technology present in many of the OST devices has shown great potential in various fields, including human-computer interaction and cognitive sciences. However, in the context of laparoscopic surgery training, the use of this technology remains relatively unexplored. In this scoping review, only 4% (2/51) of the studies investigated the incorporation of eye-tracking technology for assistance in laparoscopic surgery training. In one of the studies, gaze tracking (using head tracking) was performed to focus the laparoscopic camera on the area where the surgeon's gaze was centered [11]. This study made it possible to optimize the way of visualizing the information on the surgical working environment and the surgeon's ergonomics. Another study aimed to use eye-tracking technology to detect convergence between the trainee's and the trainer's gaze, as well as between the trainee and the target area [41]. By monitoring eye movements and fixation points, the system could provide objective feedback on the trainee's visual attention and alignment with the desired gaze targets. This approach has the potential to enhance trainee-trainer communication and improve the trainee's spatial awareness within the surgical field. Considering these aspects, there is a clear need for further investigation on the use of this technology to improve the training process in laparoscopic surgery. Eye tracking offers unique advantages, such as providing the trainee's visual focus, gaze patterns, and cognitive workload in

XSL•FO
RenderX

real time. The integration of eye-tracking technology into laparoscopic simulators and training platforms can enhance the visual perception, spatial orientation, and overall surgical performance of the trainee.

In addition, tracking of laparoscopic instruments and deformations in bodies or organs was also performed using artificial visual markers. In some cases, these were colored markers that were placed around the distal area of the instrument shaft [22,37,40]. Reflective markers were also used, although in this case, it was necessary to use infrared light and camera filters for identification [9]. The use of these techniques helps improve the identification and tracking of the laparoscopic instruments, which is essential to evaluate the surgical performance of trainees and assist them during the training activities. In addition, various studies (3/33, 9%) explored the calculation and modeling of deformations in bodies or organs to be used in advanced AR applications for laparoscopic surgery training. In one study, visual markers were inserted directly on the liver so that they could be identified by the laparoscopic image and allow for the localization and superimposition of preoperative 3D models of the liver and other relevant information on the endoscopic image [33,38]. Another study used retroreflective markers on the laparoscopic instruments and within the formative surgical field to facilitate the superimposition on the laparoscopic image of a preoperative 3D model [49].

Another type of technology used for tracking surgical instruments and organs involved in the formative activity was the use of electromagnetic sensors. Viglialoro et al [51] incorporated these sensors into the laparoscope and bile ducts or arterial tree of an artificial training model for real-time monitoring during the performance of simulator tasks. Electromagnetic sensors inserted into nitinol tubes representing the ducts and arterial trees helped infer possible deformations of the sensed tubular structures. Consequently, the virtual scene was updated in real time, augmenting the laparoscopic images with information on the real-time position of these anatomical structures.

By using the aforementioned techniques for the calculation of organ deformations and the inclusion of 3D models, these studies significantly contributed to the integration of virtual models into the laparoscopic surgery environments, enhancing surgical training scenarios in real time.

Training Simulator and Setup (RQ 3)

Regarding the type of simulator used for AR-based laparoscopic surgery training, most of them were box trainers to which an AR assistance system was added. Of note is the ProMIS simulator (Haptica, Inc), which was one of the first commercial simulators for laparoscopic surgery training with AR functionalities. This simulator included basic training tasks such as dissection and suturing but also more complex procedures such as liver resection and sigmoid colectomy. This is the AR-based simulator with the largest number of scientific publications. Apart from this simulator, we highlight other commercial options to which AR-based laparoscopic surgery training assistance systems were added, such as the Fundamentals of Laparoscopic Surgery simulator (Limbs & Things Ltd) [14,19], the Szabo Pelvic Trainer simulator (ID Trust Medical) together with the iSurgeon system [8,42], the eoSim simulator (eoSurgical) [12], the SIMULAP-IC05 simulator (Jesús Usón Minimally Invasive Surgery Centre) [25], or the Body Torso laparoscopic trainer simulator (Pharmabotics Ltd) [49].

Regarding the training model, the use of artificial models was most common because they are generally more accessible than organic models, although with less realism. However, more and more realistic artificial models have been achieved by simulating the anatomy and behavior of real tissues, as in the case of the study by Viglialoro et al [51], in which they presented a 3D replica of the patient's own liver and gallbladder. Other options presented were the enhancement of the physical model using AR imaging [18].

Evaluation (RQ 4)

In the different studies analyzed, various types of metrics were used to evaluate the quality of surgical performance and the surgical skills of trainees. These metrics, according to their nature, were divided into objective and subjective metrics.

Obtaining objective metrics is one of the main advantages of using AR techniques in laparoscopic surgery training. Some of the training simulators, as is the case of ProMIS, allow for recording the actions executed by the trainee to obtain metrics such as path length or motion smoothness of the laparoscopic instruments, which can help evaluate the trainee's performance and learning curve without the need for constant supervision by an expert evaluator.

Although there are some metrics that were recurrently used in the analyzed studies, so far there is no standardized set of objective metrics used to evaluate performance or technical skills in laparoscopic surgery. The most common metrics used were execution time, path length, economy of movement, and motion smoothness of laparoscopic instruments [15,18,24,25,28-30,40]. Other metrics were also used for specific tasks, such as knotting strength, time spent in the correct suturing and knotting area [34,35], or force exerted by laparoscopic instruments on the target organ or tissue [21,26].

Other types of surgical performance quality assessments based on questionnaires administered by external evaluators were also used, such as the OSATS, a highly standardized surgical assessment tool [8,31,32,41,42]. Horeman et al [21] and Leblanc et al [31] also used similar questionnaires based on peer reviews to determine surgeons' experience in laparoscopic surgery.

Subjective evaluation was commonly used for assessing the validity of the proposed solution. None of the studies used a standard questionnaire for assessing system validity, but many similarities were found in terms of the aspects of the systems they evaluated. For example, usability, realism, and didactic value were included in several studies (7/18, 39%) [12,13,19,35-37,48]. Questionnaires with Likert scales were the most commonly used format in the studies.

Regarding assessment, the size and type of the samples included in the studies were also important. There was a wide variation in sample size, with samples ranging from 10 individuals [13]

XSL•FO
RenderX

to 270 participants [15]. Some studies (2/25, 8%) included >100 participants [12,15], but most of them (23/25, 92%) presented sample sizes of <100 participants [8,17,23,24,29,31,32,37,41,42] or <30 individuals [9,13,14,16,19,28,30,34,35,40,43,47,48].

Finally, the included studies encompassed participants with different levels of laparoscopic surgery experience: novices, intermediates, and experts. Novices, referring to individuals with limited or no previous laparoscopic surgery experience, were frequently included in the studies. Intermediate-level participants, characterized by a moderate level of experience, were present in a few studies (4/25, 16%) [12,28,36,43]. This may be because their inclusion makes it difficult to differentiate results between study groups as there is sometimes no clear difference between the intermediate group and the novice or expert groups. Experts, representing individuals with advanced laparoscopic skills, were also included in several studies (8/25, 32%). This stratification of participants allows for a comprehensive validation of the system's effectiveness across different proficiency levels and helps detect the different needs that these groups may have.

Tasks and Procedures (RQ 5)

Regarding the tasks and procedures used as training activities in the studies analyzed, the most widespread ones were those focused on eye-hand coordination tasks, such as peg transfer, instrument movement, and instrument navigation tasks [14-16,18,21-24,36,45,46,53,54,56]. The next most used type of task was the simulator suturing task [9,19,25,26,34-37,40,44,47]. Although less frequent, some studies (17/51, 33%) also presented more complex models for procedures such as cholecystectomy [8,13,15,42,51]. In this case, models of the liver and biliary anatomy were used to facilitate the training of novice surgeons in gallbladder extraction using laparoscopic techniques. These types of procedures, although still basic, are highly appropriate for learning basic tasks such as the localization of critical anatomical structures (cystic duct and cystic artery) and the performance of dissection and cutting tasks for dissection and cutting of the cystic duct, cystic artery, and gallbladder removal. In a closer-to-reality environment, AR-based assistive tools were used for procedures such as cholecystectomy [41] in ex vivo (porcine) experimental models and sigmoid colectomy in human cadavers [31,32].

Considering that the main objective of AR-based training assistance applications in laparoscopic surgery is to provide the students with support tools during their training activities, the type of task or procedure to be chosen has a great influence on the usefulness of these tools. It seems evident that, in considerably basic tasks, the training assistance systems would not provide significant value to the student, mainly due to the low level of complexity of the activity. However, it is in the more challenging tasks and procedures where training assistance systems may provide remarkable training value. For instance, a task that can present a high level of difficulty for novice laparoscopic surgeons is the performance of suturing. Support tools can enhance reality for the student with visual information to assist in the performance of the suture, such as the proper grip of the needle, the passage of the needle through the tissue, or the process of double and single knotting. In more complex procedures such as laparoscopic cholecystectomy or lymphadenectomy, these training assistance systems could support the students in locating complex or hidden anatomical structures, as well as remotely transmitting instructions from tutors who are reviewing the students' training process, among other possibilities.

Limitations

Although the PRISMA-ScR guidelines were followed to carry out this scoping review to reduce possible biases, we must highlight some limitations encountered in our work. Although most relevant articles found in other databases such as Springer or Google Scholar also appeared in the databases consulted, it is possible that some papers were not included because these databases were not used directly. In addition, the specific search strategies and keywords used in the various databases may have led to the exclusion of articles that used different terminology to refer to the same topics. Although the number of articles affected was small, restricting the selection to English-language publications and excluding articles that we could not access may have led to the omission of studies that could have provided relevant information.

Regarding the devices used, OST devices are relatively new, so there is still much to explore in terms of what they can contribute to the field of laparoscopic surgery training, which we will address in future studies. It should also be noted that there may be interesting technical proposals for the support of laparoscopic surgery training that, as they have not yet been used for such training, were not included in the studies analyzed in our scoping review. Furthermore, the lack of standardized metrics for evaluating the different support systems did not allow for a comprehensive comparison between systems and a comparative analysis of their results.

Conclusions

In conclusion, this scoping review sheds light on the dynamic landscape of AR technologies within laparoscopic surgery training. Although OST devices have recently emerged and their advantages over traditional AR methods are still being explored, it is relevant to indicate that the results obtained are promising and open up new opportunities for the use of AR in this type of training activities. In turn, haptic feedback emerges as a valuable asset for the acquisition of laparoscopic skills. Eye-tracking technology provides relevant information during learning, although its application is in an incipient phase that requires further exploration. The prevalence of commercial simulators and artificial models underscores the delicate balance between safety and realism. Regarding assessments, this review highlights the importance of extending the use of expert assessments, such as OSATS or GOALS, and underlines the need for standardized objective assessment. These assessments are based on the study of participants' behavior in simple tasks such as navigation and object manipulation and in other tasks with a higher level of difficulty, such as suturing. In any case, it seems clear that AR would be more useful for more complex tasks related to complex surgical procedures. These findings beckon future research to analyze the complete potential of AR in enhancing laparoscopic skill acquisition.

Abstract

Background: Virtual reality (VR) interventions have demonstrated efficacy for more than a decade for mood and anxiety disorders and emerging evidence suggests they can reduce pain symptoms in both acute and chronic pain. More recently, these interventions have abounded within the commercial and academic sectors, immersing participants within a virtual environment to confer health benefits to users. VR immersion can facilitate the delivery of health interventions by isolating participants from distractors and stressors in a therapeutic environment. While recent studies of VR interventions have exploded, they are not uniform in approach or device type, limiting generalizability. Recent scoping reviews on VR and chronic pain have focused on specific diseases or limited inquiries to specific interventions or study types.

Objective: We conducted a scoping review to generate new knowledge about the sum total of VR studies on chronic pain with specific emphasis on the methods and results of each study, including (1) the type of interventions, (2) outcomes chosen, (3) samples studied, and (4) data generated.

Methods: A scoping review was performed on the literature on VR and chronic pain to describe themes associated with the literature to date and identify important gaps and unanswered questions to guide future research. CINAHL [EBSCO] (Cumulative Index to Nursing and Allied Health Literature) and PubMed were queried for the terms “virtual reality” and “pain,” providing studies of chronic pain adult participants using VR delivered through headset displays. We included English-language manuscripts that had at least one VR intervention arm with adults with chronic pain. For this analysis, we only included VR interventions that were immersive (ie, using headsets). Non–study reports, studies with no specific chronic pain component, those not involving adults, and those using VR as part of a comprehensive rehabilitation program were excluded. A descriptive analytical method was used to extract data, compare studies, and contextualize the presented outcomes. Articles were categorized into several themes including the type of intervention, outcomes chosen, participant characteristics, degree to which immersion was achieved, and adverse effect monitoring and reporting.

Results: A total of 36 articles were included in our analysis. We summarize the literature using 5 themes: (1) heterogeneity of chronic pain types, (2) highly variable intervention types, (3) highly variable secondary and exploratory outcomes, (4) immersion was highly variable between studies and not systemically explored in many articles, and (5) side effect monitoring was limited.

Conclusions: The literature on VR in chronic pain is highly variable and lacks theoretical rigor. While there is emerging evidence that supports VR use in a wide variety of health conditions including chronic pain, future research should focus on producing theoretically rigorous work that focuses on mechanisms and that systematically assesses side effects to generate robust generalizable knowledge.

Introduction

Chronic pain affects 50 million US adults [1], and treatments have limited long-term efficacy, significant side effects, or limited accessibility [2-5]. As a result of the continuing opioid overdose crisis, numerous clinical and research guidelines have recommended further study of nonpharmacological options [6-8].

Virtual reality (VR) treatments have the potential to immerse participants within a virtual environment to confer health benefits to users. VR typically uses a headset to display a 3D image or video that participants can watch or interact with. Immersion produced through VR can facilitate the delivery of health interventions by isolating participants from distractors and stressors in a therapeutic environment [9]. VR interventions have demonstrated efficacy for more than a decade for mood and anxiety disorders [10,11], and emerging evidence suggests they can reduce pain symptoms in both acute and chronic pain [12-15].

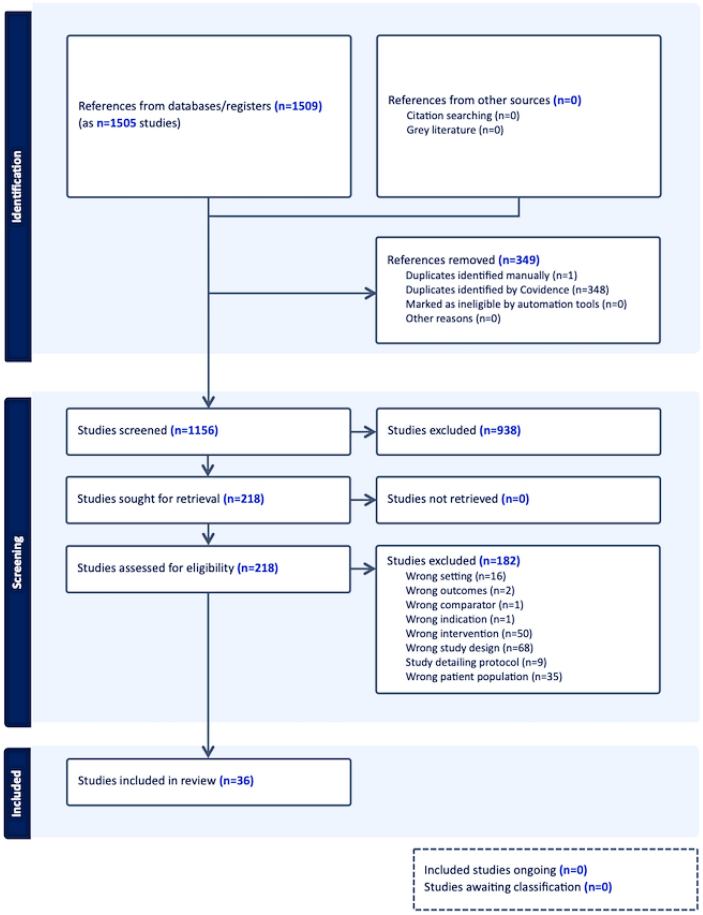
Studies of VR interventions have exploded in recent years, due to advances in technology and the widespread availability of consumer-facing VR devices. Unfortunately, studies to date of VR in chronic pain have not been uniform in approach or device type, limiting generalizability. Recent scoping reviews on VR and chronic pain have focused on specific diseases or limited inquiries to specific interventions or study types [13,15]. We conducted a scoping review specifically to generate new knowledge about the sum total of VR studies on chronic pain with specific emphasis on the methods and results of each study, including (1) the type of interventions, (2) outcomes chosen, (3) samples studied, and (4) data generated. We expect the results of this scoping review will assist in generating new hypotheses and provide new areas of research inquiry for chronic pain VR researchers.

Methods

We conducted a scoping review of the literature on VR and chronic pain to describe themes associated with the literature to date and identify important gaps and unanswered questions to guide future research.

Eligibility Criteria

To develop the eligibility criteria, we conducted an initial search of the literature on PubMed and CINAHL and reviewed the first 100 articles that had initially resulted from general search terms of “virtual reality” and “pain.” As a first step, reviewers (HP, MD, and HT), independently screened these articles using Covidence software, followed by a meeting to discuss workflow and conflicts. Consensus was made regarding inclusion and exclusion criteria, which will be discussed below.



We decided to include English-language manuscripts and abstracts if at least one intervention arm included patients with chronic pain (even if compared with patients without chronic pain). We included patients with chronic pain of any type, even rare chronic diseases (eg, phantom limb syndrome). Because we noted some manuscripts defined VR as interchangeable with “interactive game” and because we only wished to explore studies about immersive VR, we only included studies of adult participants that used VR delivered through headset displays, not through other modalities (such as projection, computer screens, or television screens). We excluded nonstudy reports (letters, commentaries, and reviews), studies with patients with no specific chronic pain component (eg, acute burns), studies not involving adult patients, and studies using VR as part of a comprehensive rehabilitation program (eg, VR gait training). We did not focus on a particular set of outcomes of interest, and instead aimed to describe relevant outcomes in this research. We included research studies, case studies, and qualitative studies that met our inclusion criteria.

Information Sources

We performed a literature search of 2 electronic databases, CINAHL and PubMed between April 1, 2006, and March 21, 2022. These 2 comprehensive databases reference the nursing, allied health, and medical literature. Search terms included “Virtual reality” and “pain” to be broad and included all publications from the inception of both databases. We elected not to use MeSH (Medical Subject Headings) terms in searches to be sufficiently broad in our initial search. Results were prescreened using Covidence software (Melbourne, Victoria, Australia), with duplicate articles removed. The databases and platforms are outlined in the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) diagram (Figure 1).

XSL•FO
RenderX

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) flowchart.

Selection of Sources of Evidence

After an initial prescreen, all citations and abstracts were screened by at least 2 independent reviewers (HP, MD, and HT). Abstracts that passed initial screening were included in a full-text eligibility review conducted by the same reviewers as above, with disagreements resolved by the senior author (HP).

Data Coding and Synthesis of Results

We used a data abstraction form our team designed to extract data using Covidence software. The major categories on the data abstraction form included are (1) study characteristics (year of publication, authors, and country of origin), (2) research setting (population, study design, and research problem), (3) intervention (detailed description of intervention type and immersion quality), and (4) results and conclusions. Two reviewers (MD and HT) and 1 senior reviewer (HP) extracted data; HP resolved discrepancies. Subsequently, we used a descriptive-analytical method to synthesize data, compare studies, and contextualize the presented outcomes [16]. In our review, we categorized articles into several themes to illustrate the diversity of the literature. We focused on some specific elements a priori and allowed for additional themes to emerge upon our reading of the literature. Specific elements categorized included are (1) the type of intervention, (2) outcomes chosen, (3) participant characteristics, (4) the degree to which immersion was achieved, and (5) adverse event monitoring and reporting.

Results

Overview

After removing duplicate citations, we screened 1156 studies using titles and abstracts, and retrieved 218 articles for full-text screens for eligibility. We included 36 articles in the final sample [17-52]. About two-thirds (n=23, 63.9%) were completed in the United States [17,20-24,28,29,32-35,37-41,43,48-52]. About one-fifth (n=7, 19.4%) were randomized controlled trials [22-24,27,30,45,46], 6 (16.7%) were randomized cross-over studies [18,19,31,36,40,41], 16 (44.4%) were single-arm case studies, case series, or cohort studies [17,20,21,26,28,29,32-35,37-39,43,49,52], 6 (16.7%) were qualitative, mixed methods, or included some interview component [19,25,26,33,37,44], 4 (11.1%) were nonrandomized cross-over studies [42,47,50,51], and 1 (2.8%) was a nonrandomized controlled study [48]. We present summaries of all articles in Multimedia Appendix 1.

In our review, we categorized articles into several themes to illustrate the diversity of the literature. We focus here on 5 themes for which we present narrative reviews of pertinent articles. First, while individual articles tended to focus on a particular pain type, conclusions from the literature are limited by the heterogeneity of chronic pain types. Second, intervention types were highly variable. Third, while most articles focused on pain outcomes, secondary and exploratory outcomes were highly variable. Fourth, the degree to which immersion was achieved was highly variable and not systematically explored

XSL•FO
RenderX

in many articles. Fifth, side effect monitoring was limited in most research.

Pain Types

While we expected to see variability in pain diagnoses because of our broad search terms, we found that the heterogeneity of pain types in the research to date limited external generalizability. In our literature search, 10 out of 36 (27.8%) articles focused on chronic pain, not otherwise specified [17,20,26,31,32,34,37,47,50,51]; 9 out of 36 (25%) focused on chronic back pain [22-24,28,29,35,44,45,49]; and 6 out of 36 (16.7%) focused on chronic regional pain syndrome [21,30,36,41,42,52]. Neuropathic pain was the focus of an additional 5 out of 36 (13.9%) articles, [18,36,38,40,48] but 3 were in the context of spinal cord injury [18,40,48]. Two out of 36 (5.6%) articles recruited patients with fibromyalgia [22,27]. Common pain types such as lower extremity osteoarthritis, diabetic neuropathy, abdominal pain, or noncardiac chest pain are absent from the primary literature, though it is possible many participants included in studies had multiple chronic pain types. There were no articles focusing on chronic overlapping chronic pain conditions, such as endometriosis, painful bladder syndrome, chronic fatigue syndrome, and irritable bowel syndrome.

Intervention Types

To understand the breadth of literature, we included articles that ran the spectrum of VR intervention design. We found VR interventions were highly heterogeneous. The plurality (11, 30.6% studies) were on VR behavioral therapy interventions [17,22-26,34,35,38,43,45]. Among these 11 studies, behavioral therapies included related but disparate modalities, including mindfulness techniques (8 out of 11) [17,22-26,34,35] pain education (6 out of 11) [17,22-24,35,45], and hypnosis (2 out of 11) [38,43]. Another 10 (27.8%) studies immersed participants in noninteractive passive environments, such as landscapes or walks [18,19,26,32,33,40,46,47,50,51]. An additional 6 (16.7%) used interactive, and sometimes strenuous, games in VR to attempt to reduce chronic pain [27-29,31,44,45]. VR body swapping or body observation was common in studies of complex regional pain syndrome or neuropathic pain, and constituted an additional 7 (19.4%) studies [21,30,36,41,42,49,52]. VR neurofeedback and "commercially available" VR applications constituted categories with 1 (2.8%) study apiece [20,39].

Outcomes

Almost all non-qualitative studies used pain scales, either numerical rating scales or visual analog scales, as outcome measures (30/32, 96.9% studies). Pain outcomes were not primary outcome measures in 4 studies, all of which were either primarily feasibility or usability studies [28,33,37,47]. Other outcomes varied widely. Changes in mood were assessed in 9 articles [17,18,22-24,33,39,43,52], and changes in sleep were assessed in 5 articles [22-24,39,52]. Changes in kinesophobia or changes in fear avoidance were assessed in 5 articles [27-29,45,46]. Physiological changes, such as heart rate variability or skin temperature, were assessed in a further 3 articles [42,50,51]. Physical activity, quality of life, and opioid use were assessed as outcomes in 2 [27,52], 1 [27], and 1 article, respectively [17].

Immersion

Immersion, or the tendency for a participant to feel the illusion of reality within a VR simulation, was uncommonly assessed. Only 3 studies systematically assessed immersion in the VR world [17,40,45]. Presence, or the tendency to feel one is within a virtual environment, is often used interchangeably with immersion and was assessed in 3 articles [18,19,40]. An additional 2 studies assessed engagement in VR, a related concept, but 1 which relates more to adherence and satisfaction than immersion [20,32].

Side Effect Monitoring

Despite common reports of side effects in commercial VR devices, side effects were variably assessed in studies. There was no reported assessment of side effects in 21 (58.3%) studies [17,18,21,27-31,34-36,38-46,48]. Among studies that systematically reported side effects, most were low frequency, low intensity, or not durable. Most side effects did not adversely affect participation, but 2 studies reported participants dropping out due to side effects (Figure 1) [26,31].

Discussion

Principal Findings

In this scoping review, we describe patterns in the current literature on VR interventions in chronic pain. We identified 36 articles that tested VR interventions through a variety of study designs. We reported 5 themes that encapsulate research to date: (1) pain types are highly heterogenous in the literature to date, (2) VR design was highly variable, (3) secondary and exploratory outcome choice was highly variable, (4) VR immersion was infrequently assessed, and (5) side effect monitoring was limited. These themes are somewhat related and have implications for conclusions to be generated from the research published to date. We provide some recommendations for future research studies.

Heterogeneity Between Studies and Comparison to Previous Work

Studies were heterogeneous in many aspects, including type of VR intervention, patient population, and study design. In the literature we reviewed, even the term VR was used inconsistently and was even used to refer to nonimmersive modalities and platforms such as computers and projector screens. In developing our search strategy, we found that "virtual reality" was not a universal term and had to exclude non immersive devices from our sample of articles; this heterogeneity of study design was also encountered by one other scoping review [53]. The patient population was additionally highly variable between studies. Another scoping review of seven studies on VR-based mindfulness programs for chronic pain noted differences in populations and VR interventions between studies [15]. Such differences pose challenges in making generalizable VR recommendations for patients with chronic pain, as different VR treatments may only ameliorate certain pain types. This in turn, if left unchecked, may negatively

XSL•FO
RenderX

affect the future generalizability and use of VR as a treatment for chronic pain.

There was significant heterogeneity in pain type among those receiving VR interventions. The existing literature on VR for the most common pain types is lacking. For example, it is difficult to find studies on previously mentioned common types such as lower extremity osteoarthritis, diabetic neuropathy, and abdominal pain. Instead, there have been many more studies on VR modalities focusing specifically on rarer types such as phantom limb pain and complex regional pain syndrome. This is likely because there already exist therapeutic elements backed by an evidence base (eg mirror therapy) in treating these painful conditions that can be directly incorporated into VR. Of note, VR behavioral management and VR therapies directly targeting kinesiophobia seem to have an emerging evidence base, stemming from their evidence toward treating relevant pain types in non-VR trials. For example, Lin and colleagues analyzed evidence for pain neuroscience education, a theoretical framework for educating and empowering the patient on his or her pain condition and management options [54]. They found evidence for pain neuroscience education in reducing pain and kinesiophobia in patients with chronic neck pain. Likewise, a recent review on cognitive behavioral therapy (CBT) and chronic pelvic pain has noted the efficacy of CBT in treating many conservative treatment-refractory pain types such as nociplastic pain disorders [55]. Research on employing CBT or CBT elements in VR interventions, and how best to do this without a live, skilled therapist, is a focus of current research, including our own ongoing clinical trials.

Ultimately, which VR interventions to offer which patients and when and how are important and significant questions for which current data is still insufficient. The insufficiency of current data to date was echoed in other recent scoping reviews of VR interventions [12,13,15,18,53,56]. A recent scoping review of 44 studies in chronic pain also concluded that while VR showed promise, the exploratory nature and heterogeneous design of most research limits generalized conclusions [13]. Further, another scoping review of 13 studies in back pain also found that research was highly variable and concluded the field was still nascent [12]. Future research should build on exploratory research conducted to date and should also include comparative effectiveness studies between VR intervention types to move the field forward. In addition, consistent, regular assessment of participant side effects is imperative to producing clear risk and benefit data for clinicians and patients in the future.

Relatedly, we found a lack of theoretical rigor in most studies of VR. Basing study design on theory can help elucidate mechanisms for how interventions work and can help researchers build more robust clinical trials. In particular, such a framework would include identifying and testing the various elements of the VR experience, isolating the aspects of VR that can lead to pain relief, and understanding whether there are mediation or moderation effects that influence the efficacy of VR interventions in chronic pain. For example, immersion is theorized to be a key target for how VR works on chronic pain [57-60]. Nonetheless, as we have shown, it was rarely systematically assessed. Different VR interventions can have markedly different effectiveness in generating immersion, owing to many factors: hardware weight and comfort, graphical fidelity, and the level of involvement and stimulation. Other important mediators, such as mood or fear of physical activity, are also infrequently assessed. Moderators, such as a participant's comfort with technology and video games are also rarely assessed formally. No strong theoretical model yet exists to explain how VR interventions might work in chronic pain [61]; it is important that future research aims to develop and empirically test theoretical models to ensure generalizable knowledge is produced. In addition, and specifically, future studies should measure and compare levels of immersion between various VR types.

Limitations

There were a few limitations to this scoping review. First, we searched 2 large databases, PubMed and CINAHL, for relevant articles because they constitute a significant portion of the clinical literature in chronic pain and we used a broad searching strategy with broad search terms, but it is possible we may have missed some manuscripts due to our search strategy. Future reviews can determine the utility of searching other comprehensive databases. Second, we included only English language articles in our initial search. This may have excluded data from other countries which may alter the conclusions drawn by our study. Future reviews can determine how non-English literature might differ from the English language articles included in this review. Third, we note that this article is unable to make a detailed examination of particular methodologies of VR interventions, partly because of a lack of data but also partly because of lack of comprehensive detail on VR methods in many of the articles reviewed. This is a limitation of the literature at large at this point, and it is very important for the reproducibility of research that there is transparency in research methods. Future VR interventional studies should include more descriptive details about the methodologies of the VR interventions used.

Conclusions

In summary, we found the literature on VR in chronic pain to be highly variable and lacking theoretical rigor. While there is emerging evidence that supports VR use in a wide variety of health conditions including chronic pain, future research should focus on producing theoretically rigorous work that focuses on mechanisms, and transparency in research methods and that systematically assesses side effects in order to generate robust generalizable knowledge.

Abstract

Background: The concept of immersive reality (IR), an umbrella term that encompasses virtual reality, augmented reality, and mixed reality, has been established within the health care realm as a potentially valuable tool with numerous applications in both medical education and patient care.

Objective: This review aimed to introduce anesthesiologists to the emerging and rapidly evolving literature on IR, its use in anesthesia education, and its transferability into the clinical context.

Methods: A review of the relevant literature was conducted using the PubMed database from inception to July 5, 2023. Additional references were identified from the reference lists of selected papers.

Results: A total of 51 papers related to the use of IR in anesthesia medical education (including both technical and nontechnical skills) and 63 papers related to applications in clinical practice (eg, preprocedure planning, patient education, and pain management) were included. We present evidence supporting the use of IR in the training and clinical practice of modern anesthesiologists.

Conclusions: IR is useful for a variety of applications in anesthesia medical education and has potential advantages over existing simulation approaches. Similarly, IR has demonstrated potential improvements in patient care across several clinical contexts relevant to practicing anesthesiologists. However, many applications remain in the early stages of development, and robust trials are urgently needed to confirm clinical or educational effectiveness and to assess mechanisms, educational validity, and cost-effectiveness.

Introduction

Nomenclature and Definitions

The nomenclature surrounding immersive reality (IR) has evolved, and in this review, we provide some definitions to assist the reader. We use IR as an overarching term encompassing virtual reality (VR), augmented reality (AR), and mixed reality (MR), although other umbrella terms, such as extended reality, can also be found in the literature [1,2]. VR is any type of computer-generated immersive environment that users can interact with, including both 2D and 3D experiences. AR involves overlaying computer-generated elements on a real-world environment, and MR blends aspects of VR and AR [3,4], capturing both real-world and virtual elements in 3D and allowing for interaction across these realms [5].

IR experiences are often facilitated using a head-mounted display (HMD or headset), a piece of hardware worn on the face of the user, surrounding their field of view, with 1 or 2 small displays showing stereoscopic computer-generated imagery [6]. In this form of VR, users wearing an HMD can only perceive images of the virtually generated world displayed on the screens. This allows a user to experience a fully immersive, computer-generated 3D environment and interact with objects using handheld controllers or a set of virtual hands that mimic their own. More recently, with advances in consumer-level hardware, many IR headsets allow users to physically walk around within a defined interactive VR environment. In contrast to VR headsets, AR and MR headsets allow the user to see the real world while immersed in an overlaid computer-generated environment within the field of view of the headset.

Consumer-level HMDs most commonly used for clinical and medical education purposes incorporate variable levels of functionality (Table 1). For example, different devices are capable of tracking various types of motion. Simple systems with 3 degrees of freedom can only detect rotation around a fixed point. Newer, more complex systems, with 6 degrees of freedom can detect rotation and position in 3D space.

Regarding HMDs, 3 degrees of freedom devices can only detect where you are looking (the rotation and tilt of your head) but not your position in space (ie, whether you move forward or backward, left or right, or crouch down). Devices with 6 degrees of freedom can detect all the abovementioned types of motion using either sensors built into the device itself or external sensors, such as tripod or wall-mounted hardware.

Similar to headsets, VR controllers with 3 degrees of freedom have limited tracking ability, while newer controllers with 6 degrees of freedom allow a more naturalistic, full range of motion (eg, extending your controller in real life will be replicated in VR). Eye tracking refers to an extra set of lenses within the HMD, which tracks the movement of each eye. This allows the device to track where the user is looking and, in some cases, it allows interaction with the virtual environment through changes in gaze alone [31-33]. Hand tracking uses a front-facing camera on the HMD to track a user's hands and project them into the virtual environment, allowing users to interact with the virtual environment without the need for controllers.

Handheld devices (eg, cell phones and tablets) can also be used for AR, by observing digital images overlaid on the real world using the camera viewer. However, these devices offer limited functionality as they have only a small field of view and are not ergonomic, as they must be held up by the user.

The Spectrum of Immersion

Immersion is the ability of a system to create the sensation of "presence," the subjective feeling of existing in a computer-generated world [34]. This is created in computer-based simulations by providing sensory input, including visual, auditory, and tactile (ie, haptic feedback) stimuli. Placing an individual in an IR system with these stimuli creates the sensation of being physically present in a virtual environment. Advancements in computational processing power and associated decreases in the size of electronic components have led to lower costs and rising availability of consumer-level IR technologies. This increase in availability has been accompanied by a parallel increase in the adoption of virtual-based simulation in medicine and beyond [35].

Historically, 2D worlds, which lack the increased sense of presence provided by newer 3D immersion technology, have also been labeled immersive experiences. In the context of medicine, this has mainly been limited to medical education, where learners view a 2D screen with a virtual image of a simulated task to be practiced. Many examples of simple 2D simulation exist in surgical training [36,37] and anesthesia [38-42], where students view virtual anatomical images on a screen and use partial task trainers or practical tools (eg, endoscopes, bronchoscopes, and surgical instruments), which provide haptic feedback to practice their technical skills.

Affordable HMDs and 360° cameras developed in recent years have allowed educators to increase immersion in IR educational experiences. Instead of watching on a 2D screen, learners can now be immersed in 360° experiences using headsets to experience real or animated clinical environments. As reduced work hours for medical trainees has resulted in fewer clinical learning opportunities, IR has emerged as an alternative method to supplement traditional clinical curricula. In addition, during the global COVID-19 pandemic, where social distancing and remote learning presented challenges for clinical learning, IR enabled students and residents to continue participating in interactive training. However, the literature is just beginning to examine how IR modalities can most effectively be incorporated into clinical teaching curricula.

Another relevant component of teaching curricula is simulation-based training. Simulation is an educational technique that allows interactive, immersive activity by recreating all or part of a clinical experience without exposing patients to associated risks [43]. Historically, full-body manikin simulation has been proposed as an adjunct to clinical learning, complementing clinical experience. Simulation in medical education is a well-established pedagogical practice [44], providing a viable alternative to practice with actual patients, whereby medical trainees are afforded the opportunity to train until they reach a specific competency level. Simulation ranges from decontextualized bench models and VR-based environments to high-fidelity recreations of actual operating rooms [45]. Simulation can engage the trainee in the progressive accumulation of knowledge through deliberate practice, allowing for careful matching of the complexity of the learning environment to the trainees' current level of advancement [46]. Although simulation is widely used in medical education, it is often resource intensive, cost prohibitive [47] and requires learners to physically attend simulation centers. A survey of 154 anesthesiologists found that insufficient time and training opportunities were major barriers to taking part in simulation-based education, with 48% of respondents saying that they would be more likely to attend simulation-based courses if they were hosted at their own hospital [48].

Current advances in IR technology are addressing these limitations through the development of innovative, immersive experiences using cost-effective, consumer-level hardware capable of engaging trainees. A major advantage of IR over manikin-based simulation is increased accessibility, as learners can use the equipment on-site or access IR educational applications remotely. IR equipment can be set up in small spaces (eg, call rooms and conference rooms) with minimal time requirements so that the curricula can be delivered instantaneously in perioperative settings. In addition, although there are costs associated with developing IR applications, the end products can be made modular with the potential for both learning and assessment embedded within. IR curriculum delivery is highly cost-effective and can be easily scaled for additional learners with minimal expense, unlike manikin-based programs. These advantages may result in increased feasibility and reduced costs for IR-based simulation training, although this must still be verified using appropriate cost-benefit studies.

In addition to the use of IR simulation for education and training purposes, IR technologies are increasingly being used directly in patient care, both in patient-centric interventions (eg, as a distraction during painful procedures) and by health care providers (eg, real-time AR-image guidance). In this review, we discuss the theory underlying the use of IR technology in both medical education and clinical care as well as the evidence supporting specific examples relevant to practicing anesthesiologists.

Methods

Overview

This narrative review aimed to identify uses of IR relevant to practicing anesthesiologists. As such, we focused on

XSL•FO
RenderX

perioperative applications and applications related to techniques in which anesthesiologists commonly take part (eg, fiber-optic intubation). Applications of IR focused on addressing pain or anxiety in instances where an anesthesiologist is not normally present (eg, burn wound dressing changes [49]) were excluded. Similarly, while a large amount of research has been done in the area of pediatric anesthesia, we chose to focus on IR applications relevant to those practicing in adult populations. IR applications in pediatric populations have been described elsewhere [50-52]. Finally, we focused on describing existing applications of IR in anesthesia, including up-to-date clinical protocols, while a review focused on theoretical and future applications has been recently published elsewhere [53].

Search Strategy

Relevant publications were identified using PubMed and search terms including "Virtual Reality" AND ("anesthesia" OR "Anaesthesia" OR "Anesthesiology" OR "Anaesthesiology"); "Augmented Reality" AND ("anesthesia" OR "Anaesthesia" OR "Anesthesiology" OR "Anaesthesiology"); vital AND signs AND monitoring AND anesthesia AND display; ("anesth*" OR "anaesthe*") AND (virtual reality OR immersive reality OR augmented reality OR mixed reality OR 360 video) AND (simulation) AND (education) AND (technology) AND (pedagogy OR teaching); ("anesth*" OR "anaesthe*") AND (virtual reality OR immersive reality OR augmented reality OR mixed reality OR 360 video) AND (simulation) AND (education) AND (pedagogy OR Teaching) AND (clinical medicine); ("anesth*" OR "anaesthe*") AND (virtual reality OR immersive reality OR augmented reality OR mixed reality OR 360 video). The literature search included articles published from inception to the date of the search, July 5, 2023. Additional references were identified from the reference lists of the selected papers.

Results

Education Through Immersion: Current and Potential Uses in Medical Education

Overview

Virtual simulation can lead to better learning outcomes for various procedures. Improved health outcomes (eg, patient safety, reduction in costs, and morbidity) have also been reported after the use of computer-enhanced training [54]. Moreover, there are many cases where both technical [55-57] and nontechnical [11] skills acquired during virtual simulation–based training have proven transferrable to subsequent performance in clinical settings.

However, studies aiming to address IR-based educational tools have been heterogeneous in their design and validation, leading to mixed results. This is compounded by the fact that many IR frameworks are designed without using educational theory as a foundation [54,58]. Literature discussing the theory behind the use of immersive technology is limited. However, by taking a broader perspective and viewing the educational literature as a whole, one can begin to form a narrative supporting its use. For example, the learning theory of constructivism outlines that learning occurs by amalgamating previous knowledge and new information to create meaning from an educational activity [59-61]. Both accuracy and real-life relevance of a problem increase learner engagement, and meaningful learning occurs when learners actively interact with the environment through decision-making. IR content is well suited to these tasks as realistic, deeply immersive clinical scenarios can be created, allowing learners to interact with their environment and to have a safe space to make mistakes, free of consequences.

Similarly, medical education has evolved toward self-directed learning and case-based practice [62-64], including the involvement of learning theories, such as self-regulated learning (SRL). SRL is a process by which learners autonomously set goals, monitor their own performance, reflect on outcomes, and then repeat the process to attain desired goals, without an emphasis on instructor-led learning and feedback [65-70]. The versatility of IR learning environments lends itself well to incorporating important components of SRL. For instance, immersive environments based on SRL concepts could provide the learner with educational objectives, allowing them to practice clinical scenarios at their own pace with mechanisms incorporated into the software to assist with progressive difficulty, automatic evaluation, and improved learning.

Many applications in health care, especially those related to nontechnical skills, are still in prototype stages that lack an explicit pedagogical basis [5]. However, this does not imply that IR applications related to clinical decision-making should not be developed. Rather, we are at a critical stage where medical learning theory must inform future IR-based learning applications. Thus, robust research studies examining the effectiveness of these applications, beyond subjective assessments, are urgently needed [71].

IR solutions have the potential to be, and in some cases already are [72,73], effective teaching tools when based on a foundation of learning theory–based design. While this foundation is not always present in current IR-based medical education solutions, we attempted to highlight examples of how IR has been used in anesthesia-based medical education for both technical and procedural teaching and nontechnical skills.

Technical Skills

Traditionally, the most common use of IR in medical education has been to train technical and procedural skills. Training programs in laparoscopic, neurological, endovascular, and orthopedic surgery have led the development of IR with positive learning outcomes [74-77]. This could be considered counterintuitive, as a principal criticism of IR in medical education has been the lack of life-like haptic (the means whereby information is conveyed through touch) technology [78], which is thought to be needed to teach technical skills.

However, educators in heavily procedural medical specialties are faced with a conundrum. On the one hand, trainees require greater autonomy as exposure to clinical settings is reduced. On the other hand, learning technical skills from text alone or by merely watching the corresponding procedure being performed has shown mixed results [79]. IR allows learners to not only visualize procedural skills in the first person but also practice the steps needed for completion in an active manner,

XSL•FO
RenderX

with or without haptic capabilities. The sense of touch has been simulated using joysticks, haptic gloves, and by attaching sensors to common medical tools (eg, syringes).

Existing IR simulators with relevance to anesthesia include simulators for teaching regional anesthesia techniques [39,80-82], bronchoscopy or intubation [40,41,57,83,84], and central vein insertion [85,86] (Table 2; Table S1 in Multimedia Appendix 1) [28,38-42,56,57,80-103]. Often these applications take the form of nonimmersive VR simulators where the trainee uses a clinical tool such as a fiber-optic bronchoscope on a physical model while receiving appropriate clinical feedback (eg, ultrasound or endoscopy images) through a 2D screen. Furthermore, several MR and AR simulators have been developed that combine physical anatomical models with live tracking of handheld tools (eg, ultrasound probes and syringes) translated onto a virtual 3D computer model mimicking real anatomy [80,101,104]. Thus, the user can see, in real time, how their actions performed on the model map onto the 3D virtual anatomy model. By combining physical anatomical models and tools with IR-simulated environments, these models can effectively simulate complex procedures such as vascular access [101,104] and regional anesthesia blocks [80]. In other instances, immersive 360° VR environments have been combined with existing manikin-based simulations to increase immersion and learner engagement [91].

RenderX

Table 2. Immersive reality (IR) interventions for both technical and nontechnical skills in anesthesia education.

Educational application	Clinical skill
Technical skills	
IR intervention	
AR[a] or MR[b] simulator (nonimmersive)	• Nasogastric tube placement [96] • Central line insertion [85,86,101] • Intravenous insertion [90] • Epidural injection [80] • Transthoracic and transesophageal echocardiography [28] • Lumbar puncture [87] • CPR[c] [92]
VR[d] simulator (nonimmersive)	• Fiber-optic bronchoscopy and intubation [40,41,57,83,84,97,99,102] • Lung isolation [100] • Regional anesthesia [38,39] • Cystoscopy [94] • Ultrasonography [98] • Intravenous insertion [103] • Spinal cord stimulation [42]
VR simulator (immersive)	• Regional and spinal anesthesia [56,81] • CPR and ACLS[e] [17,88,89,91] • Ultrasound guided regional anesthesia [82] • Central line insertion [93]
Nontechnical skills (eg, clinical reasoning and communication)	
IR intervention	
Virtual simulator (nonimmersive)	• Recognition of clinical intraoperative events [105] • Stress response: clinical deterioration [106]
AR simulator	• Communication skills: ACLS scenario [29]
VR simulator (immersive)	• Airway crisis management [26] • Anesthesia crisis management and local anesthetic systemic toxicity [107] • Emergency medicine [108] • Operating room fire safety [10,24,30,109] • Operating room infection prevention [12] • Persuasion training (influenza vaccine hesitancy) [11] • Preparation for an epidural procedure [110] • ACLS team leadership [111] • Surgical unit virtual tour [112] • Therapeutic communication skills [113]
Multiuser VR simulator (immersive)	• Operating room communication [25]
MR simulator (virtual humans)	• Operating room communication [114] • Operating room conflict resolution [115]

[a]AR: augmented reality.

[b]MR: mixed reality.

[c]CPR: cardiopulmonary resuscitation.

[d]VR: virtual reality.

[e]ACLS: advanced cardiac life support.

Nontechnical Skills

IR simulations have also been adapted to teach important nontechnical skills, such as clinical reasoning, communication, and teamwork. These nontechnical skills are crucial to successful clinical encounters, and efficacious uptake of these skills is vital for reducing medical errors and enhancing patient safety. IR simulations can be used to strengthen these skills.

Immersive instructional 360° videos have been developed to teach clinical reasoning skills, allowing for more active learning by incorporating problem-solving elements into the immersive experience. For example, Masson et al [12] developed a 360°

XSL•FO
RenderX

simulation that teaches perioperative infection prevention techniques and allows the learner to make choices during key decision-making points, creating a more "active" observational learning process.

Active learning can also be achieved through computer-generated immersive simulations (Table 2; Table S2 in Multimedia Appendix 1) [10-12,17,24-26,29,30,105-109,111-115]. This is especially useful for teaching comparatively rare or complex clinical events with steep learning curves (eg, airway crisis scenarios). Using commercially available HMDs (Table 1) and tracking sensors, our group [116] (NCT04451590 and NCT04591041) and others [24,26,106,111,117] created simulated crisis scenarios that allowed learners to create objectives and manage patients who are critically ill in virtual operating rooms or trauma bays. Crucially, these IR simulations respond to learners' decisions and provide feedback upon completion. These serve as self-contained simulation scenarios learners can use for deliberate practice to supplement their clinical experiences. Specific clinical scenarios relevant to anesthesiology that have been developed include response to an operating room fire [24,118], airway crisis scenarios (NCT04451590) [26,117], advanced cardiac life support [29,111], and operating room procedures for preventing surgical site infection [12] (Table 2; Table S2 in Multimedia Appendix 1). In addition to specific clinical scenarios, IR can be used to teach and practice "soft skills," such as teamwork and patient communication. Real et al [11] developed a simulator that uses virtual standardized patients to teach health care providers persuasion techniques for supporting patients who are hesitant about vaccines. VR training translated directly to improved clinical communication, as demonstrated by reduced vaccine refusal rates in the 3 months following VR training relative to controls [11].

In another study by Cordar et al [115], virtual humans were used as an operating room team to model conflict resolution skills during critical operating room scenarios. They found that participants were positively influenced by the virtual humans demonstrating ideal conflict resolution techniques and, conversely, were negatively influenced when they modeled negative conflict resolution behavior. These findings demonstrate that IR can be an effective method to teach nontechnical skills, such as team training and communication [115].

We have discussed the theoretical foundation for the use of IR in medical education and specific applications related to anesthesia education for both technical and nontechnical skills. IR allows learners to actively experience the complex anatomy of patients and how they interact with medical tools in a safe, accessible environment. Similarly, IR using HMDs and 360° recordings, facilitated by advances in technology, offers the ability to develop important nontechnical skills. Further information regarding the key outcomes of studies supporting the use of IR in anesthesia medical education is provided in Tables S1 and S2 in Multimedia Appendix 1. Moving forward, it is important to conduct robust trials to assess the educational efficacy of IR, determine its simulator validity, and confirm its cost-effectiveness.

Clinical Uses of IR in Anesthesia

Overview

In addition to the educational applications described in the Education Through Immersion: Current and Potential Uses in Medical Education section, IR technologies are increasingly being used directly in patient care. These include patient-centered interventions, where patients are exposed to IR as an educational tool or as a distraction during painful procedures (Table 3; Table S3 in Multimedia Appendix 1) [7-9,13-16,18-23,27,32,119-144] as well as applications focused on health care providers, where IR technology and 3D visualizations are used to plan or guide clinical care (Table 4; Table S4 in Multimedia Appendix 1) [145-166]. In this Clinical Uses of IR in Anesthesia section, we discuss existing clinical uses of IR technology relevant to practicing anesthesiologists.

XSL•FO
RenderX

Table 3. Patient-based clinical applications of immersive reality (IR) in anesthesia.

Clinical application	Clinical scenario
Intraprocedure distraction	
IR intervention	
Immersive video	• Awake hand surgery [13,19,139] • Orthopedic surgery with regional anesthesia [7,8,138] • Ambulatory surgery [144] • Pregnancy termination [18] • Episiotomy repair [143] • Outpatient hysteroscopy [128] • Lipoma excision [133] • Cystoscopy [129] • Bone marrow aspiration [132] • Transcatheter aortic valve implantation [122] • Gastrointestinal endoscopy [126] • Endovascular aneurysm repair [130] • Breast biopsy [134]
Interactive environment	• Adductor canal catheter insertion [32] • Upper gastrointestinal endoscopy [141,142] • Cystoscopy [135] • Outpatient hysteroscopy [124] • Bone marrow biopsy [121] • Awake hand surgery [127]
Interactive game	• Lumbar puncture [27]
Guided breathing, hypnosis, or relaxation	• Hip or knee arthroplasty [23,125,136] • Upper limb surgery [14,15,123] • Atrial fibrillation ablation [137] • Epidural placement for labor [20] • Endoscopic urological surgery [21]
Preprocedure preparation

Table 4. Applications of immersive reality (IR) focused on health care providers in clinical anesthesia practice.

Clinical application	Clinical scenario
Clinical data visualization and vital signs monitoring	
IR intervention	
AR[a]- or MR[b]-based HMD[c] or smart glasses	• Simulated operating room scenarios [163,165] • General surgery [166] • Nurse anesthetists anesthesia care [155] • Supervising anesthesiologist (simulated) [156,164]
VR[d] HMD	• Arterial blood gas monitoring [145]
Real-time procedure guidance	
IR intervention	
AR HMD overlay or projection	• Epidural and spinal anesthesia [153,157,161] • Simulated epidural and spinal anesthesia [147-149] • Simulated peripheral nerve block [160,162] • Simulated central venous catheterization [159] • Fine-needle aspiration [158] • Triage decision-making and mass casualty event [154] • Percutaneous rhizotomy [146]
Preprocedure planning	
IR intervention	
Immersive VR HMD	• Difficult airway intubation [150]
Nonimmersive VR simulation	• Regional anesthesia administration [152]
AR or MR HMD	• Awake craniotomy [151]

[a]AR: augmented reality.

[b]MR: mixed reality.

[c]HMD: head-mounted display.

[d]VR: virtual reality.

Clinical Data Visualization

AR-based HMDs allow users to see virtual data overlaid on the real world. For example, an anesthesiologist can view patient vital signs overlaid on the surgical field of view. Since 1995, researchers have been investigating the utility of AR-based HMDs in clinical anesthesia [166]. Several studies of anesthesiologists have reported advantages of using IR, including easier and faster recognition of clinical events [156,163,167] and the ability to spend more time focusing on the patient and the surgical field compared to vital sign monitors [168,169].

Liu et al [163] studied whether 12 anesthesiologists in a simulated environment would notice different events that occurred either on the patient monitor or in the operating room. The HMD did not interfere with participants' ability to detect clinical events and may have allowed participants to detect some events more quickly when they were physically constrained by the need to perform a concurrent clinical procedure [163]. Conversely, Sanderson et al [164] reported that IR displays did not improve the ability to detect clinical events relative to advanced auditory displays [170], and others reported that HMDs might make individuals less likely to detect unexpected clinical events [171]. Thus, further research is needed to confirm how to optimally use HMDs, best ergonomic visualization practices, and whether increased attention leads to improved patient outcomes.

Preanesthesia Planning and Real-Time Guidance

Anesthesiologists often use x-rays, computerized tomography (CT), magnetic resonance imaging (MRI), and ultrasound sonography data to evaluate and plan for complex cases [172]. This provides a foundation for planning the safe management of patients with difficult airways, complex comorbidities, or complex neuraxial anatomy for regional blocks.

The use of AR-based HMDs allows for images obtained via CT, MRI, or ultrasound sonography to be mapped directly onto a patient, offering a window into the patient's anatomy. In a surgical context, systems that generate 3D models of solid organs from CT data and overlay them onto the patient using AR enable precise planning of the optimal approach for abdominal procedures [173,174]. Similarly, our group used IR to augment real-life regional anesthesia procedures using AR holographic projections [175]. Here, live ultrasound scans are converted into holographic projections overlaid on a patient's anatomy to serve as a pathway for an operator's needle to follow. Holographic pathways create reliable needle trajectory guidance that has the potential to facilitate neuraxial block

XSL•FO
RenderX

procedures, reducing unsuccessful attempts, needle repositioning, patient discomfort, hematomas, and failure. These studies, along with findings from simulation or phantom models [147-149], reflect the potential for IR systems in preanesthesia planning and procedure guidance, although further research is needed to confirm clinical findings [153].

Pain Management

IR applications have been widely studied with regard to their use as an adjunct to traditional anesthesia, analgesia, and anxiolytic techniques during painful or uncomfortable procedures [176-178]. These interventions come in many forms (eg, passive 360° videos, interactive games, guided breathing exercises, and hypnosis) and have been studied in diverse patient populations. IR applications of most relevance to anesthesiologists include distraction during minor surgery using local or regional anesthesia [7,14,15,19,125,136] as well as during epidural placement [20,123] and adductor canal catheter insertion [32] (Table 3; Table S3 in Multimedia Appendix 1).

IR is generally well received by patients and health care providers. However, studies have shown conflicting results regarding effectiveness. These contradictory findings can likely be explained by the considerable heterogeneity in study design (eg, the nature of control groups and outcome measures) and in the specific nature of the intervention (eg, passive 360° video vs interactive game) that impede useful comparisons between studies [179]. Thus, while the use of IR as a distraction technique during painful or stressful procedures is well reported [176,177], full-scale, adequately powered studies with appropriate controls are needed to confirm the effectiveness in specific patient populations.

Recent studies have shown that reductions in pain or anxiety can reduce or eliminate sedative requirements, for example, during an orthopedic surgery with spinal anesthesia [125,136] or adductor canal catheter insertion [32]. In a study of endoscopic urological surgery comparing VR distraction without sedation to sedation using intravenous midazolam, participants in the VR group required no rescue sedation and reported higher satisfaction and fewer respiratory adverse events. Despite these promising results, other recent studies have shown no difference in sedation use between IR and control groups [7,137]. Therefore, additional research is needed to clarify the observed effects and determine which populations are most likely to benefit.

Similarly, to optimize the utility of these interventions and better understand how and where they will be useful, further robust studies are needed to determine how IR is able to influence pain and anxiety. For example, are reductions in pain or anxiety the result of distraction via immersion in the virtual environment, due to the content of the intervention (eg, videos and guided relaxation), or due to the novelty of the experience itself? While distraction likely contributes to the analgesic effects of VR, some studies suggest that IR may reduce pain directly through inhibition of ascending pain pathways [180]. These findings have been verified using functional MRI studies, where reductions in brain activity secondary to pain stimuli have been demonstrated with the use of IR. Notably, improved immersion and image quality have been associated with higher levels of pain reduction [181].

Patient Preparation and Education

A significant proportion of patients experience anxiety before anesthesia and surgery, often triggered by fear of the unknown [182-184]. Importantly, preoperative anxiety is associated with negative patient outcomes, including increased intraoperative anesthetic requirements, increased postoperative pain, and longer recovery times [185-187]. IR offers the ability to reduce preoperative anxiety, either through immersive, guided relaxation exercises before the procedure [22] or by providing information that alleviates anxiety through exposure therapy [188,189]. In the latter case, immersive operating room tours can allow patients to witness the steps and processes leading up to the induction of anesthesia and continuing to the recovery room firsthand. While much of the research in this area focuses on pediatric populations [51,190-192], 2 randomized controlled trials have demonstrated reduced preoperative anxiety and higher patient satisfaction using VR relative to standard preoperative procedures in an adult population [9,140].

Overall, IR preprocedure preparation is well received by patients, and the creation of similar 360° content is relatively easy. This, therefore, makes for an accessible entry into IR for anesthesiologists looking to create content at low cost [193].

Further information regarding the key outcomes of studies supporting the use of IR in anesthesia-related patient care is provided in Tables S3 and S4 in Multimedia Appendix 1. However, further research is needed to assess whether these findings are reproducible and generalizable to additional patient populations.

Discussion

Future Applications: Practicality of the Technology and Culture Change

The continued development of low-cost, consumer-level IR technology is facilitating a shift in pedagogy from traditional 2D images and videos to learning through interactive IR environments. This is particularly important in medical education, where knowledge acquisition usually includes greater experiential, self-directed, and hands-on learning than in many other disciplines [4]. As described in this paper, IR technologies have already been used to educate trainees, prepare health care providers, and help patients. Over time, emerging technologies, such as multitouch displays, telepresence (an immersive meeting experience that offers high video and audio quality), 3D environments, natural language processing, and artificial intelligence (AI) software [194], have the potential to transform not only medical education and practice but also teaching and learning in general [195].

Expanding Current Use

The advances in technology discussed above in the Introduction section allow for higher fidelity, increased presence, and creation of new applications in the field of IR, but it is also important to consider how existing IR technologies can extend the impact and reach of experts in the field of anesthesia. For instance, IR

XSL•FO
RenderX

can be used in conjunction with traditional or virtual simulations to facilitate feedback and decrease demands on facilitator time. For example, IR can assist with the initial prebriefing [196,197], wherein participants are oriented to objectives and frameworks for their upcoming experience by facilitating a "flipped classroom" experience [198]. In this case, learners are virtually oriented to the simulation center from home, reducing the time required of facilitators and the overall time spent at the simulation center, allowing more time for participation in the simulated scenarios upon their arrival.

Similarly, telesimulation and telementoring, whereby a skilled practitioner can remotely guide a less experienced colleague through a complex procedure, either for educational purposes [199-201] or in an emergency situation [202], have been successfully used in surgical contexts [199-202]. The most complex versions of these apparatuses allow for annotations and even the movements of surgical tools, manipulated by an instructor, to be projected onto the surgical field of view of a colleague using AR technology [200,203]. This provides a proof of concept for using this technology to extend anesthesia services and aid in training anesthesiologists in underserved and rural communities, where they often work in challenging, underresourced environments to serve populations with high needs. In Ontario, Canada, the government is paying attention to the needs of such populations, especially Indigenous populations [204], as they have higher mortality rates and poorer health outcomes compared to urban populations [205]. IR applications, including telementoring and IR simulation training delivered via remote technology, are tools that can be used to advance health care in these regions and bring it in line with urban centers.

One noteworthy strength of IR over other simulation strategies is the ability to readily reimmerse in a simulation. For example, during feedback stages, IR allows both the facilitator and learner to be reimmersed in the simulation scenario. This can trigger the same emotional cues as when the learner was managing the simulated crisis, heightening recall and potentially leading to more fruitful discussions. This would similarly apply to self-debriefing, where learners are able to visualize the scenario from their own perspective but without the cognitive and emotional burden of managing the case, facilitating focus on the decision-making cues. Finally, during interprofessional training, immersive 360° cameras can be oriented to provide the point of view of each participant (eg, a surgeon could use an HMD to be immersed in the anesthesiologist's point of view), potentially leading to a greater appreciation of one another's roles.

The importance of well-being in health care providers has gained greater attention in recent years and presents another area where IR may have utility. Emerging evidence suggests that IR interventions, such as guided relaxation, could also help reduce stress and burnout among health care practitioners both during training [206] and in high-stress situations, such as a pandemic [207,208]. Intriguingly, a recently published small study of 20 nurses has also provided preliminary evidence that the increased usability of VR patient education compared to traditional approaches may lead to improved health care provider satisfaction and reduced burnout scores [209]. While further studies are needed, this early evidence suggests potential indirect benefits of IR, which have not been fully characterized.

Incorporating Technological Advances

As technology advances, the ways we interact with it also evolve. Instead of interacting through touchscreens or hand controllers, we will be able to interact directly through hand motions and eye movement tracking. This may accelerate as promising design breakthroughs, such as transparent interfaces, are integrated into IR systems. AI is another emerging technology that can be incorporated into medical training and presents a potentially paradigm-shifting advancement. For instance, an early study using AI-based feedback has shown evidence for effectiveness in achieving learning goals [118]. In a simulated operating room fire scenario, this study showed a significant performance improvement when an AI-guided virtual trainer provided timely feedback to users in the virtual operating room.

Further technological advances will occur in the field of haptics. Basic haptic (touch simulation) feedback is already widely available at the consumer level through devices that provide vibration feedback (eg, video game controller "rumble packs" or mobile phone vibrations). Furthermore, pseudohaptics [210,211], where illusory haptic sensations are created using combinations of audio, visual, and kinesthetic cues, has also been used to convey various touch-based properties [212-214]. However, currently available consumer-level haptic devices cannot provide the high level of fidelity and range of motion required to simulate many tasks realistically [215], and high-fidelity haptic solutions are cumbersome, complex, and often cost prohibitive [216,217]. As consumer interest in haptics grows, haptic devices capable of providing force feedback beyond simple vibrations will become more widespread. Notably, integrating haptic feedback into IR enhances immersion by simulating sensations and has been used in medical simulations, including training and simulation of medical procedures, allowing trainees to practice realistic interactions in a safe environment.

Adopting new technological advances in IR systems benefits from the increasing availability of so-called maker spaces. These are collaborative workspaces that contain equipment such as laser cutters, computer numerical control machines, soldering irons, and 3D printers that can easily create innovative, customizable, and cost-effective learning tools. 3D printing, in particular, which is becoming widespread in part due to decreased cost, allows digitally designed objects to be replicated in the real world, facilitating the merger between IR and real physical form, albeit with some limitations [4]. In the context of anesthesia, this creates the potential for faithful recreations of anatomical features (eg, airway or spinal column) to be generated using imaging data for use in training or preprocedure planning [218,219].

Limitations

While the potential benefits of IR simulation are considerable, the potential downsides of IR technology must also be considered. This includes the presence of cybersickness (negative symptoms associated with immersion in a digital

XSL•FO
RenderX

world, including feelings of nausea, dizziness, or headache), which can limit usefulness in both educational and clinical contexts [220,221]. The incidence of cybersickness resulting from the use of IR systems depends on many different factors (eg, frame rate, field of view, sex, and previous game playing experience) and ranges from common to very rare [222]. The heterogeneity of both IR technology and interventions studied likely contributes to this variability [220]. However, both practical factors, such as limiting exposure duration, and technological factors, such as improved latency and higher levels of immersion, are known to reduce cybersickness [177,220,223], with 1 recent review concluding that benefits outweigh risks, at least in some patient populations [221]. Further research is needed to identify factors that can reduce unwanted side effects, such as cybersickness, while preserving the many advantages of IR technology.

Furthermore, it must be acknowledged that potential costs associated with the initial implementation of IR technologies, especially in low-resource settings, could be a barrier and potentially exacerbate existing inequality in health care outcomes. Until recently, IR technology was expensive, cumbersome, and restricted to several large institutions and research centers. However, recent increases in computational processing power and the accompanying decrease in the size of electronic components have led to decreasing costs and rising availability of consumer-level technologies (Table 1). The introduction of freely available game engines and mobile devices (eg, tablets and smartphones) capable of reproducing education-worthy environments with adequate fidelity has made IR technology an exciting and emerging field [4]. Widely available low-cost options, such as Google Cardboard [224] and other smartphone-based IR headsets, are suitable for many of the most common clinical uses of IR, such as patient education and pain distraction [134,225,226]. This suggests that the implementation of IR technology does not need to be limited to high-resource settings.

However, further research is needed to identify potential barriers and secondary costs related to the implementation of IR programs in different settings. Similarly, if supported by evidence from continued research, wide adoption of IR technology facilitated by funding support in low-resource settings could have an important impact on reducing inequality and generating long-term cost savings.

From Virtual to Concrete: Are We There Yet?

Despite the great technological advancements made, particularly with respect to computational processing, it is important to consider the limitations of computer hardware with IR applications, particularly when using VR devices. More specifically, designers and developers of IR applications should consider the fidelity of their virtual environments, that is, the level to which a virtual environment resembles the real world it is meant to represent. It is not currently feasible to create a high-fidelity virtual simulation that includes all the senses (ie, input related to sight, sound, and touch). Furthermore, higher-fidelity environments require greater computer processing requirements, which may not be readily available to the average computer users.

Moreover, we must consider the high variability of users who may be susceptible to motion sickness and address accessibility issues, including those related to visual impairment and other disabilities. Finally, as IR technologies in health care are relatively new, it is essential to address ethical concerns. These include the potential short- and long-term effects of virtual environment exposure and HMD use on both patients and health care providers, as well as whether VR headsets should be classified as medical devices?

Conclusions

In this review, we have presented the theoretical basis and evidence supporting the use of IR in the training and clinical practice of modern anesthesiologists. For those interested in implementing IR technology into their own practice, many ready-made technologies exist (Table 1). The processes and techniques required to create and implement low-cost 360° videos and virtual environments using commercially available cameras and software have been described elsewhere [116,193].

Despite recent advancements and increasing interest in IR as a research field, many applications remain in the early stages of development. Robust trials are urgently needed to confirm its clinical and educational effectiveness and to assess its mechanism, educational validity, and cost-effectiveness. While the use of IR technologies may have practical applications in medical education and for a variety of clinical patient populations, it is important to ensure that enthusiasm for this new technology does not overtake available evidence and that all applications are guided by pedagogical theory and evidence-based practice. Thus, there is a unique opportunity to innovate in a promising area of research to show the validity of IR within the anesthesia specialty and demonstrate its ability to optimize learning and clinical delivery of care. Our group founded the University of Toronto's Collaborative Human Immersive Interaction Laboratory to develop IR solutions for clinical research, medical training, and patient education. The Collaborative Human Immersive Interaction Laboratory also aims to scientifically validate IR as a tool to enhance patient care now and in the future.

Acknowledgments

The authors would like to thank the team at the he authors would like to thank the team at the Sunnybrook Canadian Simulation Centre and Dr. Jordan Tarshis, Dr. Stephen Choi, Dr. Connor Brenna, Dr. Sanch Gupta, Shelly Au, and Monica Caldeira for their help with our research programs, and Kyle Wilcocks for his contributions and discussions during the early stages of this project. The authors would also like to acknowledge funding provided to FA and PG from Physicians' Services Incorporated Foundation

XSL•FO
RenderX

(20-14) and additional funding to support FA and PG's research program via a private donation from the Pasare family to the Sunnybrook Foundation. Funders played no role in the conception, design, or writing of this manuscript.

Authors' Contributions

AF and LK completed the literature search, constructed summary tables, and addressed reviewer comments. AF, LK, BK, CM, and FA were involved in drafting the initial version of the manuscript. EBRB, PG, and JW provided contributions during the editing and revision of the manuscript. All authors provided final approval of the initial and revised manuscript and agreed to be accountable for the published work.

Conflicts of Interest

None of the authors have any financial disclosures that would serve as a conflict in writing this paper. However, some of the immersive reality examples mentioned in this paper were developed in our research laboratory (FA).

Abstract

Background: Enhancing the effectiveness of current pain relief strategies is a persistent clinical challenge. Although transcutaneous electrical nerve stimulation (TENS) is used in various painful conditions, its effectiveness may decline over time, requiring additional pain management strategies. Immersive virtual reality (VR) with personalized visuo-tactile stimulation has demonstrated analgesic properties. Nevertheless, whether visuo-tactile stimulation can enhance the pain-relieving outcomes of TENS and its underlying neurophysiological mechanisms remains largely unknown.

Objective: The study aims to investigate whether the integration of visuo-tactile stimulation with TENS can enhance the pain-relieving outcomes of TENS alone, and we also aim to explore the brain mechanisms underlying the analgesic effect of this integrated intervention.

Methods: In this study, 75 healthy participants were enrolled and randomly assigned to 1 of 3 groups: congruent TENS-VR (TENS-ConVR) and 2 control groups (incongruent TENS-VR [TENS-InVR] and TENS alone). In the context of TENS-ConVR, we combined TENS and VR by connecting TENS-induced paresthesia with personalized visual bodily feedback. The visual feedback was designed to align with the spatiotemporal patterns of the paresthesia induced by TENS. A pain rating task and a 32-channel electroencephalography were applied.

Results: Two-way ANOVAs showed that TENS-ConVR exhibited a statistically greater reduction in pain rating ($F_{1,48}$=6.84; P=.01) and N2 amplitude ($F_{1,48}$=5.69; P=.02) to high-intensity pain stimuli before and after stimulation than TENS alone. The reduction of brain activity was stronger in participants who reported stronger pain-relieving outcomes. TENS-ConVR reduced the brain oscillation in the gamma band, whereas this result was not found in TENS alone.

Conclusions: This study observed that combining TENS and visual stimulation in a single solution could enhance the pain-relieving effect of TENS, which has the potential to improve the effectiveness of current pain management treatments.

Introduction

How to improve the efficacy of existing analgesic strategies has always been a clinical concern. The application of transcutaneous electrical nerve stimulation (TENS) has been widely used for pain management, such as postoperative pain, labor pain, and chronic neck pain [1-3]. Low-intensity and high-frequency (50-100 Hz) electrical pulses, a form of TENS, can activate large-diameter A fibers and inhibit the nociceptive volley transmitted via small-diameter A and C fibers that innervate spatially adjacent skin areas [4]. However, the stand-alone applications of TENS may produce limited analgesic effects [5], necessitating the incorporation of additional pain management strategies.

Virtual reality (VR) is a more recent technology that immerses users in a 3D computer simulation environment [6]. Research indicated that VR could reduce pain through various mechanisms, including offering an effective distraction for users to divert their attention away from pain or regulate their emotions [7,8]. One recent study established a connection between spinal cord stimulation and visual feedback in an immersive VR platform, and they found that the combination of stimulation-induced paresthesia and personalized visual bodily feedback resulted in more potent analgesic effects compared to participants who only had VR [9]. This finding suggested that visuo-tactile stimulation in immersive VR might present an opportunity to optimize analgesic efficacy and enhance the analgesic effects of nerve stimulation, such as the TENS. However, the extent to which visuo-tactile stimulation might improve the analgesic effects of TENS and its underlying neurophysiological mechanisms are still poorly explored.

Electroencephalography (EEG) is a reliable bioassay for evaluating how people experience pain and understanding the underlying neurological processes involved in TENS-induced pain relief [10-12]. For example, Peng et al [11] observed that low-frequency TENS had a long-lasting effect on the brain state, as it increased the alpha oscillations in the primary sensorimotor cortex and enhanced the functional connectivity between S1/M1 and the medial prefrontal cortex. Expanding on the research by Peng et al [11], if the incorporation of immersive VR with TENS (TENS-VR) results in enhanced pain relief, it is expected that the reduction of brain activity evoked by painful stimuli will be more pronounced compared to the use of TENS alone.

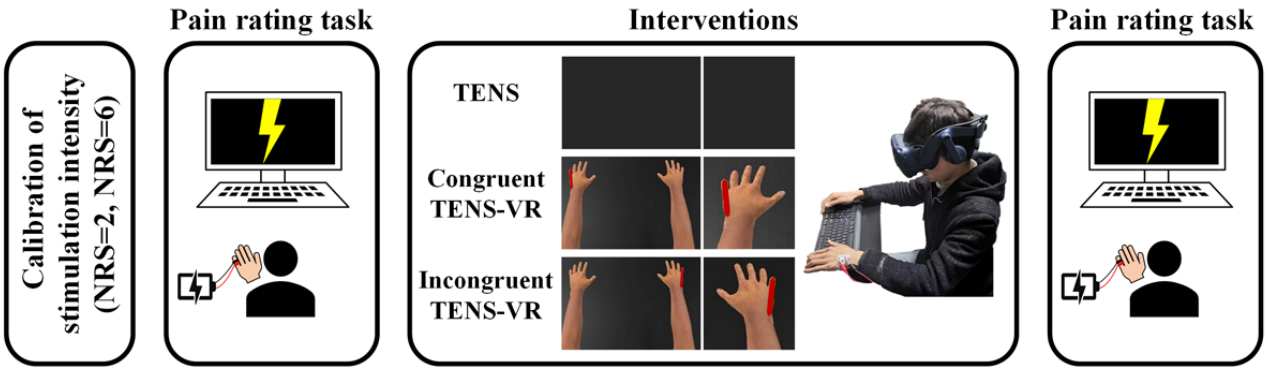
In this study, we hypothesized that visuo-tactile stimulation that integrated immersive VR with TENS could enhance the analgesic effects of TENS alone in a model of experimentally induced pain, and we also aimed to explore the brain mechanisms underlying the analgesic effect of this integrated intervention. To achieve our aim, we developed a digital therapeutic platform that integrated TENS and immersive VR into a single solution. This immersive VR platform could be able to record and immerse participants in any 360-degree stereoscopic environment and provide additional visual feedback by manipulating digital scenes in a controlled and realistic manner. Three distinct forms of stimulation were applied to produce analgesia, namely TENS alone, congruent TENS-VR (TENS-ConVR), and incongruent TENS-VR (TENS-InVR). The participants in the TENS-ConVR group experienced spatiotemporal congruency between the visual illumination and the tactile sensations elicited by TENS. However, the participants in the TENS-InVR group had spatiotemporal incongruency.

Methods

Participants

Healthy participants were recruited from the local community (Multimedia Appendix 1 [11,13-15]). Participants were told that the aim of the study was “to investigate the neurophysiological and perceptual effects of some electrical stimulation delivered to the skin.”

Ethical Considerations



The experimental procedures were approved by the institutional review board of the Ethics Committee at the First Affiliated Hospital of Xi'an Jiaotong University (XJTU1AF2025 LSYY-384). For privacy and confidentiality, all data were anonymized before analyzing. All participants signed consent forms including a detailed declaration of study-related benefits and risks before participating in the study. All participants received a compensation of CN ¥200 (~US $27.46) upon completion of the study.

Experimental Design

The experiment consisted of 4 stages conducted on a single day: stimulus intensity correction, a pain rating task, an intervention, and a reperformed pain rating task (Figure 1). Two researchers participated in the experiment: one served as the assessor, while the other administered the intervention. To mitigate bias, the outcome assessor was blinded to the intervention conditions.

Figure 1. Schematic illustration of the experimental procedure. The experimental procedure included stimulus intensity correction, a pain rating task, an intervention, and a reperformed pain rating task. NRS: numerical rating scale; TENS: transcutaneous electrical nerve stimulation; TENS-ConVR: congruent virtual reality with transcutaneous electrical nerve stimulation; TENS-InVR: incongruent virtual reality with transcutaneous electrical nerve stimulation.

Using a constant-current electrical stimulator to deliver nociceptive stimuli via electrodes on the participant's left little finger (Multimedia Appendix 1), the stimulus intensity is calibrated using an ascending method until the participant rates the intensity of pain as 2 and 6 on a numerical rating scale (NRS; from 0=no pain to 10=unbearable pain). Low-intensity (NRS=2) and high-intensity (NRS=6) electrical stimuli were used in the pain rating task. The determination of the thresholds for low-intensity and high-intensity electrical stimuli is grounded in research conducted by Peng et al [11].

The pain rating task was used to assess the subjective perception of pain in response to pain-inducing stimuli. Participants experienced 2 distinct levels of physical stimulation: low-intensity (NRS=2) and high-intensity (NRS=6). The experiment comprised 4 sessions. Each session consisted of 15 trials, with 10 high-intensity trials and 5 low-intensity trials. These trials were presented in a pseudorandomized order. Each trial began with an 800-1200 ms fixation cross, and participants received either a low-intensity or high-intensity stimulus to the left little finger through a pair of ring electrodes (duration=50 ms). Participants then rated the intensity of the perceived pain on the 0-10 NRS for 2000 ms. The intertrial interval was 8000 ms.

All participants were randomly assigned to receive 1 of 3 interventions: TENS alone, TENS-ConVR, or TENS-InVR. After the pain rating task, participants received a 30-minute intervention according to the randomized stimulation protocols. TENS was generated by a constant current electrical stimulator (Sanxia Technique Inc) and delivered through a pair of surface round electrodes (diameter: 16 mm; interelectrode distance: 3 cm) placed over the ulnar nerve on the dorsum of the left hand. The frequency of stimulation was 85 Hz [3], and the pulse width was 200 µs. The duration of the TENS session was 30 minutes and was divided into 5 blocks. Each block was stimulated for 5 minutes and rested for 1 minute. The stimulus intensity was individually adjusted to elicit a strong but nonpainful tingling sensation (Multimedia Appendix 1).

In order to test whether visuo-tactile stimulation from TENS-ConVR could enhance the analgesic effects of TENS alone, we developed an immersive digital environment referred to as the "VR pain relief experiment platform." A neutral physiotherapy environment was established, comprising a small room with no additional things that could interfere with the experiment. Participants entered the scene using an HTC Vive Pro headset (2880×1600 display resolution; 110 field of view; 90 Hz refreshing rate; and head orientation tracking gravity sensor, gyroscope, magnetometer, and constellation tracking camera), while also being connected to electrical stimulation devices.

The digital arm positions were aligned with respect to the participant's real physical arms. Initially, participants were instructed to identify the area of the hand where they experienced tactile sensations from the TENS. Then, the defined region was illuminated by adjusting visual parameters until it was closely aligned with the subjective experience reported by the participants. In the TENS group, participants observed a dark screen in the immersive digital environment (Figure 1). In the TENS-ConVR group, the immersive TENS-VR platform illuminated the area according to the sensations the individual experienced as induced by TENS (Figure 1). In the TENS-InVR group, VR illuminated the area of the hand contralaterally to the TENS side in real time (Figure 1). The regions of the digital arm matching the electrical stimulation were highlighted during the 5-minute periods of TENS and not highlighted during the 1-minute breaks, aligning with the changes in the electrical stimulation. Following the completion of the intervention, participants were asked to perform the pain rating task again.

EEG Data Collection and Processing

During the pain rating task, a 32-channel EEG system was used to record EEG data synchronously (TMSi SAGA; pass band: 1-100 Hz; sampling rate: 1000 Hz). EEG data were preprocessed in the MATLAB environment using EEGLAB, developed by the Swartz Center for Computational Neuroscience at the University of California, San Diego [13]. The details of the data collection and processing can be found in Multimedia Appendix 1.

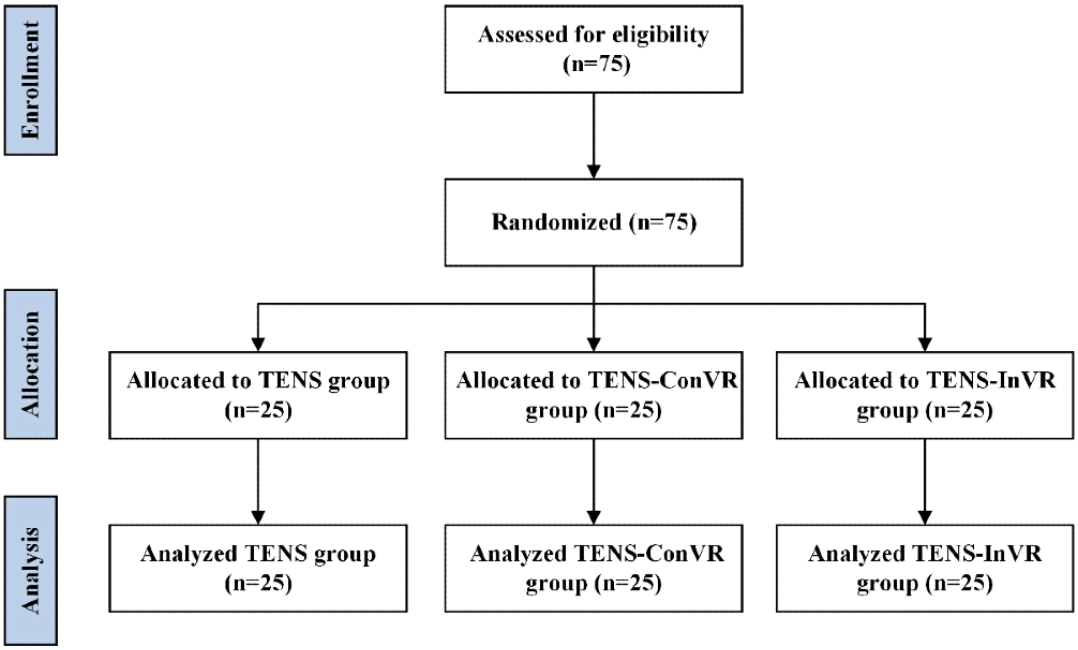
RenderX

Time- and Frequency-Domain Analyses

The event-related potential (ERP) was calculated by averaging the single-trial waveforms in the time domain. The peak latency and amplitude of the N2 and P2 waves were measured from each single-subject average waveform at Cz [11]. Time-frequency distributions of EEG the trials were estimated using a windowed Fourier transform with a fixed 250-ms Hanning window. A frequency-domain analysis was also conducted to evaluate the effect of interventions on spontaneous brain oscillations. Prestimulus EEG signals were extracted from a time window ranging from –1000 ms to 0 ms relative to the stimulus onset (Multimedia Appendix 1).

Statistical Analysis



Two separate 2-way ANOVAs were conducted to evaluate the effects of different interventions on pain ratings and electrophysiological responses. The first ANOVA compared the TENS-ConVR group with the TENS group, and the second ANOVA compared the TENS-ConVR group with the TENS-InVR group. Each ANOVA involved 2 factors: a between-group factor and a within-participants time factor (before and after intervention). Post hoc comparisons were conducted using 2-tailed paired *t* tests with Bonferroni correction when significant main effects or interactions were observed.

Results

Demographics and Questionnaires

A priori power analysis using G*Power software (University of Kiel) [16] indicated that 66 participants were required to achieve a statistical power of 0.95 with an α value of .05 for repeated measures ANOVA designs. To account for potential dropouts or errors, a total of 75 healthy, right-handed participants (mean age 21.52, SD 0.26 years) who never had TENS before were recruited (Figure 2). No significant between-group differences (TENS, TENS-ConVR, and TENS-InVR groups) in demographics were found (Table 1; all $P>.05$). No participants reported any adverse effects related to the experiment.

Effect of TENS, TENS-ConVR, and TENS-InVR on Pain Rating

For high-intensity trials, significant interactions were observed between the "group" and "time" variables in relation to pain rating in ANOVA analysis (TENS-ConVR group vs TENS group and TENS-ConVR group vs TENS-InVR group; Figure 3A). Specifically, participants in the TENS-ConVR groups had a greater pain reduction compared to those in the TENS group ($F_{1,48}$=6.84; *P*=.01) and TENS-InVR group ($F_{1,48}$=11.54; *P*<.001). After conducting post hoc 2-tailed paired *t* tests on 3 groups, the results showed a significant reduction in pain rating for both the TENS group t_{24}=2.32; 95% CI 0.04-0.63; *P*=.03; Cohen *d*=0.46) and the TENS-ConVR group (t_{24}=5.84; 95% CI 0.57-1.19; *P*<.001; Cohen *d*=1.17). However, the TENS-InVR group did not exhibit a statistically significant difference in pain intensity before and after intervention (t_{24}=0.55; 95% CI –0.27 to 0.46; *P*=.59; Cohen *d*=0.11). For low-intensity trials, no significant interactions were observed between the "group" and "time" when comparing the TENS-ConVR group with the TENS group ($F_{1,48}$=1.72; *P*=.20) or the TENS-ConVR group with the TENS-InVR group ($F_{1,48}$=2.08; *P*=.16; Figure 3B). In the TENS alone group, no significant difference was observed between high-intensity and low-intensity trials ($F_{1,48}$=0.33; *P*=.57; Figure S1A in Multimedia Appendix 2). However, TENS-ConVR–induced pain relieving for high-intensity trials was greater than that for low-intensity trials ($F_{1,48}$=8.78; *P*=.005; Figure S1B in Multimedia Appendix 2).

Figure 3. Effect of TENS, TENS-ConVR, and TENS-InVR on subjective pain rating. (A) Subjective pain rating before and after interventions in high-intensity trials. (B) Subjective pain rating before and after interventions in low-intensity trials. Effect of Different Interventions on ERP

Figure 4 depicts the time-domain scalp morphologies of the ERP waveforms and the N2 pain waves before and after different interventions in high-intensity trials (Figure 4A-C). Significant interactions were observed between the "group" and "time" variables in relation to N2 amplitude in ANOVA analysis (TENS-ConVR group vs TENS group and TENS-ConVR group vs TENS-InVR group; Figure 4D). Specifically, participants in the TENS-ConVR group decreased N2 amplitude more when compared to those in the TENS group ($F_{1,48}$=5.69; *P*=.02) and the TENS-InVR group ($F_{1,48}$=5.41; *P*=.02). After conducting post hoc 2-tailed paired *t* tests on 3 groups, the results showed a significant reduction in N2 amplitude for both the TENS group (t_{24}=3.53; 95% CI –2.93 to –0.77: *P*=.002; Cohen *d*=0.71) and the TENS-ConVR group (t_{24}=8.37, 95% CI –4.29 to –2.59; *P*<.001; Cohen *d*=1.67). However, the TENS-InVR group did not exhibit a statistically significant difference in N2 amplitude before and after intervention (t_{24}=1.19, 95% CI –3 to 0.8; *P*=.25; Cohen *d*=0.24). For P2 amplitude, no significant interactions were observed between the "group" and "time" when comparing the TENS-ConVR group with the TENS group ($F_{1,48}$=0.04; *P*=.85) or the TENS-ConVR group with the TENS-InVR group ($F_{1,48}$=0.11; *P*=.74; Figure S2 in Multimedia Appendix 2). A significant negative correlation was found between the changes in N2 amplitude and pain ratings (*r*=–0.34; *P*=.02; Figure 4E). The time-domain scalp morphologies of the ERP waveforms and the N2 pain waves, both before and after different interventions in low-intensity trials, are detailed in Figure S3A-C in Multimedia Appendix 2. Our analysis found no significant interactions between the "group" and "time" variables in N2 amplitude (TENS-ConVR group vs TENS group: $F_{1,48}$=0.002; *P*=.97 and TENS-ConVR group vs TENS-InVR group: $F_{1,48}$=1.25; *P*=.27; Figure S3D in Multimedia Appendix 2) or P2 amplitude (TENS-ConVR group vs TENS-group: $F_{1,48}$=0.24; *P*=.63 and TENS-ConVR group vs TENS-InVR group: $F_{1,48}$=0.002; *P*=.96; Figure S3E in Multimedia Appendix 2).

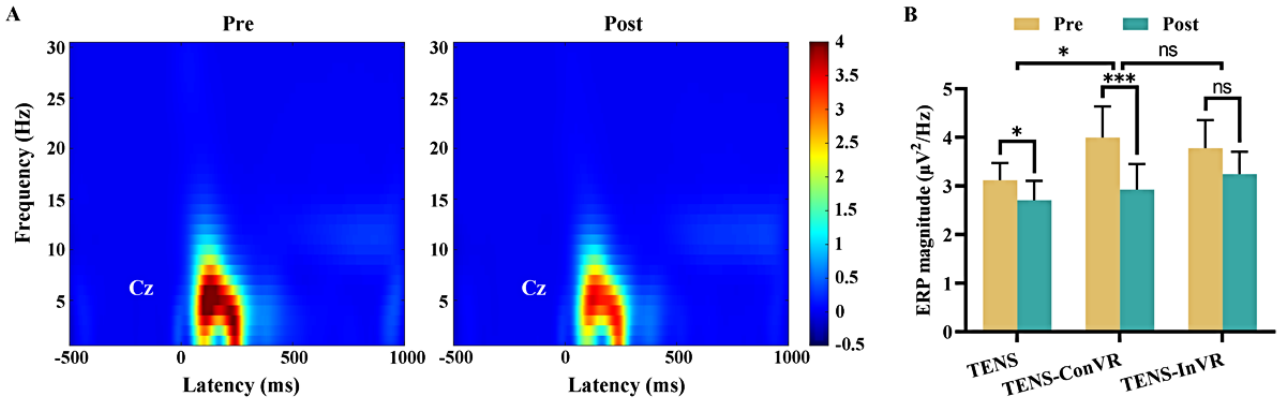

Figure 5A illustrates group-level, time-frequency distributions in high-intensity trials, with electrical stimuli eliciting a substantial phase-locked response (ERP:100-500 ms, 1-10 Hz). Significant interactions were observed between the "group" (TENS-ConVR and TENS groups) and "time" variables in relation to ERP magnitude in ANOVA analysis (Figure 5B). Specifically, participants in the TENS-ConVR group had a greater reduction in ERP magnitude compared to those in the TENS group ($F_{1,48}$=4.85; *P*=.03). Post hoc paired *t* tests showed a significant reduction in ERP magnitude for both the TENS group (t_{24}=2.22; 95% CI –0.03 to –0.79; *P*=.04, Cohen *d*=0.44) and the TENS-ConVR group (t_{24}=4.54; 95% CI 0.59-1.56; *P*<.001; Cohen *d*=0.91). This result was not observed in the TENS-InVR group (t_{24}=1.92; 95% CI –0.04 to 1.11; *P*=.07; Cohen *d*=0.38). The group-level, time-frequency distributions in low-intensity trials have been provided in Figure S4A in Multimedia Appendix 2. Our analysis found no significant interactions between the "group" and "time" variables in relation to ERP magnitude for low-intensity trials (TENS-ConVR group vs TENS group: $F_{1,48}$=0.002; *P*=.96 and TENS-ConVR group vs TENS-InVR group: $F_{1,48}$=1.25; *P*=.27; Figure S4B in Multimedia Appendix 2).

Effect of Different Interventions on Spontaneous Oscillations

Figure S5A-C in Multimedia Appendix 2 depicts the EEG spectra of spontaneous oscillations and scalp topographies before and after different interventions. Participants in the TENS-ConVR and TENS-InVR groups showed a statistically significant reduction in gamma amplitude after stimulation (P=.02 and P=.001, respectively; Figure S5D in Multimedia Appendix 2). No significant pre- and postintervention differences were observed in the remaining frequency bands for all intervention groups (P>.05). A significantly negative correlation was observed between the changes in N2 amplitude and gamma amplitude (r=–0.33; P=.02; Figure S5E in Multimedia Appendix 2).

Discussion

Principal Findings

This study presented a digital therapeutic platform that synergistically combines TENS and VR. Our results demonstrated that the combined TENS and VR intervention, referred to as TENS-ConVR, enhanced the pain-relieving effect of TENS. This integrated approach led to a more pronounced decrease in N2 amplitude compared to TENS alone. Interestingly, participants who reported stronger pain relief also showed a greater decrease in brain activity. Additionally, TENS-ConVR was found to reduce gamma amplitude, which was correlated with the decreased N2 amplitude. These findings suggested that the integration of TENS and visual stimulation in a single solution had the potential to improve the effectiveness of current pain management treatments.

Multiple studies have provided evidence that immersive VR could alleviate pain through distraction or mindfulness-based emotional regulation [7,8,17]. This is achieved by immersing individuals in a computer-generated environment with serene landscapes, soothing music, and other elements [8,18]. However, our findings indicated that the enhanced pain-relieving effect of TENS-ConVR cannot be simply attributed to the distracting effects of VR. This is evidenced by the lack of a statistically significant difference in pain intensity reduction in the TENS-InVR condition, where visual stimuli and tactile stimuli were not spatially congruent. Notably, the analgesic effect of TENS-ConVR was found to be more than double the effect observed in the TENS-InVR condition. Therefore, simply exposing participants to VR or incorporating a visual representation of a participant's body in TENS does not suffice to replicate the pain-relieving effect observed in the TENS-ConVR condition. Notably, we observed an enhanced pain-relieving effect of TENS-ConVR only in high-intensity trials, not in low-intensity trials. Consistent with this, previous studies indicated that VR-based distraction might be more effective at higher levels of pain intensity [19,20]. Therefore, we speculated that the increased pain relief observed with TENS-ConVR may be associated with pain stimuli intensity. Additionally, using a 2-point NRS may lack the sensitivity required to detect minor changes for TENS-ConVR, potentially explaining the absence of an enhanced pain-relieving effect in low-intensity trials.

Studies have demonstrated that pain perception is susceptible to the influence of multisensory inputs and the integration of various body signals [21-23]. This perception is closely tied to any abnormalities in the central representation of painful body parts [24]. The use of congruent multisensory stimulation has the potential to modify this central body representation, thereby providing potential pain relief [9,25]. In a study conducted by Solcà et al [25], participants were shown their digital hands flashing in synchrony or asynchrony with their detected heartbeat. The study found that when the flashing was congruent, it led to reduced pain and increased hand strength in patients with complex regional pain syndrome. This effect was not observed when the flashing was incongruent. Our findings are consistent with the above results. We speculated that the congruent combination of visual and tactile stimulation in the TENS-ConVR condition may foster a sense of ownership over the digital body. This could potentially influence the central representation of the body and consequently enhance the pain-relieving effects of TENS.

Notably, the enhanced pain-relieving effect of TENS-ConVR was further supported through the ERP findings. It showed a

XSL•FO
RenderX

significantly reduced N2 amplitude in the TENS-ConVR condition compared to both TENS alone and TENS-InVR conditions. The N2 component, triggered by painful stimuli and indicating neuronal activation in both the operculo-insular cortices and the contralateral primary somatosensory cortex, is believed to be associated with the processing of pain [26]. According to the gate control theory of pain, applying low-intensity, non-noxious TENS could activate Aβ fibers, thereby inhibiting the transmission of nociceptive signals [27]. Recent studies have used nociceptive stimulation to investigate the analgesic effect of TENS. Researchers measured perceptual and cerebral responses and observed a reduction in N2 amplitude in the active TENS group compared to the sham TENS group [11]. We speculated that the reduced N2 amplitude in the TENS-ConVR condition may be attributed to the congruent visuo-tactile stimulation, which could drive a coherent body representation and potentially enhance somatosensory inhibitory interactions. The discovery of a statistically significant positive connection between the reduction in pain ratings and the decrease in N2 amplitude may provide validity to our inference.

Spontaneous EEG gamma oscillations have been extensively investigated in cognitive processes involved in perception and attention [28]. A study by Hauck et al [29] examined the impact of directed attention on pain-related oscillations and synchronization processes. They found a pronounced increase in induced oscillatory activity within the gamma frequency band when participants focused their attention on painful stimuli. In our results, we found that TENS-ConVR reduced spontaneous gamma oscillations. Additionally, a negative correlation between changes in N2 amplitude and gamma amplitude was observed. We speculated that the reduced spontaneous gamma oscillations may be attributable to decreased attention to pain, facilitated by the multisensory information presented in the immersive VR condition.

TENS is a cost-effective, nonpharmacological intervention that has been widely used for pain management [30]. However, repeated application of TENS has been shown to result in analgesic tolerance within several days in both animal and human studies [31,32]. Unlike other additional therapies for TENS [33-35], such as the combining TENS with local heat and cold applications [35], TENS-VR minimizes the risk of allodynia, a condition where movement or even gentle touch can increase or induce pain, reported by many patients with chronic pain [36]. Furthermore, our digital immersive VR platform enables automatized integration with existing pain treatments, minimizing the active involvement of both patient and therapist. It could enable the implementation of prolonged and repeated stimulation in future TENS-VR investigations, potentially improving its effects.

Limitations

This study has several limitations that should be acknowledged. First, the simplicity of the VR scenario may not adequately induce the desired levels of immersive experience and ownership illusions within the VR environment. Further studies could refine and customize the VR scenario to enhance immersion. Second, the pain relief effect of the TENS-VR was only assessed in healthy participants experiencing experimental pain. Further work is necessary to determine the effectiveness of pain relief in both acute and chronic conditions. Third, there is a weak but statistically significant association between the change in N2 amplitude and the change in NRS score, potentially affected by individual variability and a small sample size. Further studies require validation with a larger sample. Furthermore, the absence of applying a stimulus to the pain threshold and tolerance to assess the effectiveness of TENS, TENS-VR on pain relief represents a limitation in our study. Future studies should include these factors to provide a more comprehensive evaluation of treatment efficacy.

Conclusions

This study observed that combining TENS and visual stimulation in a single solution could enhance the pain-relieving effect of TENS, which has the potential to improve the effectiveness of current pain management treatments.

Abstract

Background: Measurement-based care improves patient outcomes by using standardized scales, but its widespread adoption is hindered by the lack of accessible and structured knowledge, particularly in unstructured Chinese medical literature. Extracting scale-related knowledge entities from these texts is challenging due to limited annotated data. While large language models (LLMs) show promise in named entity recognition (NER), specialized prompting strategies are needed to accurately recognize medical scale-related entities, especially in low-resource settings.

Objective: This study aims to develop and evaluate MedScaleNER, a task-oriented prompt framework designed to optimize LLM performance in recognizing medical scale-related entities from Chinese medical literature.

Methods: MedScaleNER incorporates demonstration retrieval within in-context learning, chain-of-thought prompting, and self-verification strategies to improve performance. The framework dynamically retrieves optimal examples using a k-nearest neighbors approach and decomposes the NER task into two subtasks: entity type identification and entity labeling. Self-verification ensures the reliability of the final output. A dataset of manually annotated Chinese medical journal papers was constructed, focusing on three key entity types: scale names, measurement concepts, and measurement items. Experiments were conducted by varying the number of examples and the proportion of training data to evaluate performance in low-resource settings. Additionally, MedScaleNER's performance was compared with locally fine-tuned models.

Results: The CMedS-NER (Chinese Medical Scale Corpus for Named Entity Recognition) dataset, containing 720 papers with 27,499 manually annotated scale-related knowledge entities, was used for evaluation. Initial experiments identified GLM-4-0520 as the best-performing LLM among six tested models. When applied with GLM-4-0520, MedScaleNER significantly improved NER performance for scale-related entities, achieving a macro F_1-score of 59.64% in an exact string match with the full training dataset. The highest performance was achieved with 20-shot demonstrations. Under low-resource scenarios (eg, 1% of the training data), MedScaleNER outperformed all tested locally fine-tuned models. Ablation studies highlighted the importance of demonstration retrieval and self-verification in improving model reliability. Error analysis revealed four main types of mistakes: identification errors, type errors, boundary errors, and missing entities, indicating areas for further improvement.

XSL•FO
RenderX

Conclusions: MedScaleNER advances the application of LLMs and prompts engineering for specialized NER tasks in Chinese medical literature. By addressing the challenges of unstructured texts and limited annotated data, MedScaleNER's adaptability to various biomedical contexts supports more efficient and reliable knowledge extraction, contributing to broader measurement-based care implementation and improved clinical and research outcomes.

Introduction

Measurement-based care (MBC), which involves the systematic use of standardized scales to assess patient conditions, track progress, and inform clinical decisions, has been shown to enhance patient outcomes and optimize health care processes [1]. Despite its significant benefits, MBC remains underused worldwide, with less than 20% of health practitioners incorporating it into their routine practice [2]. A primary barrier is the lack of accessible and comprehensive knowledge about these scales [3,4]. Clinicians are often unaware of which scales are suitable for specific conditions and lack a clear understanding of the concepts and items within those scales [5]. Acquiring this knowledge requires considerable time and effort in searching and reviewing various unstructured documents, such as technical reports, academic papers, and manuals. This not only adds to the workload of already busy medical professionals [6] but also hinders the widespread adoption of MBC [7]. Transforming unstructured scale-related documents into computable and accessible knowledge systems, such as knowledge graphs, could help alleviate the burden on practitioners and promote MBC adoption [8].

The key to this transformation lies in accurately extracting scale-related knowledge entities from unstructured medical texts. However, several challenges complicate this task. The complexity of medical language, coupled with the variety of scale-related entities, including scale names, measurement concepts, and measurement items, makes accurate extraction difficult [1]. For instance, the entity "scale name" may refer solely to the scale itself or include additional details such as its developer, language, version, or population-specific characteristics. Furthermore, extracting knowledge entities from Chinese medical texts introduces additional difficulties due to linguistic variations and the limited availability of annotated data specific to medical scales in Chinese [9]. Traditional information extraction methods often depend on extensive data annotation and model fine-tuning, which are resource-intensive and struggle to adapt to new tasks or domains.

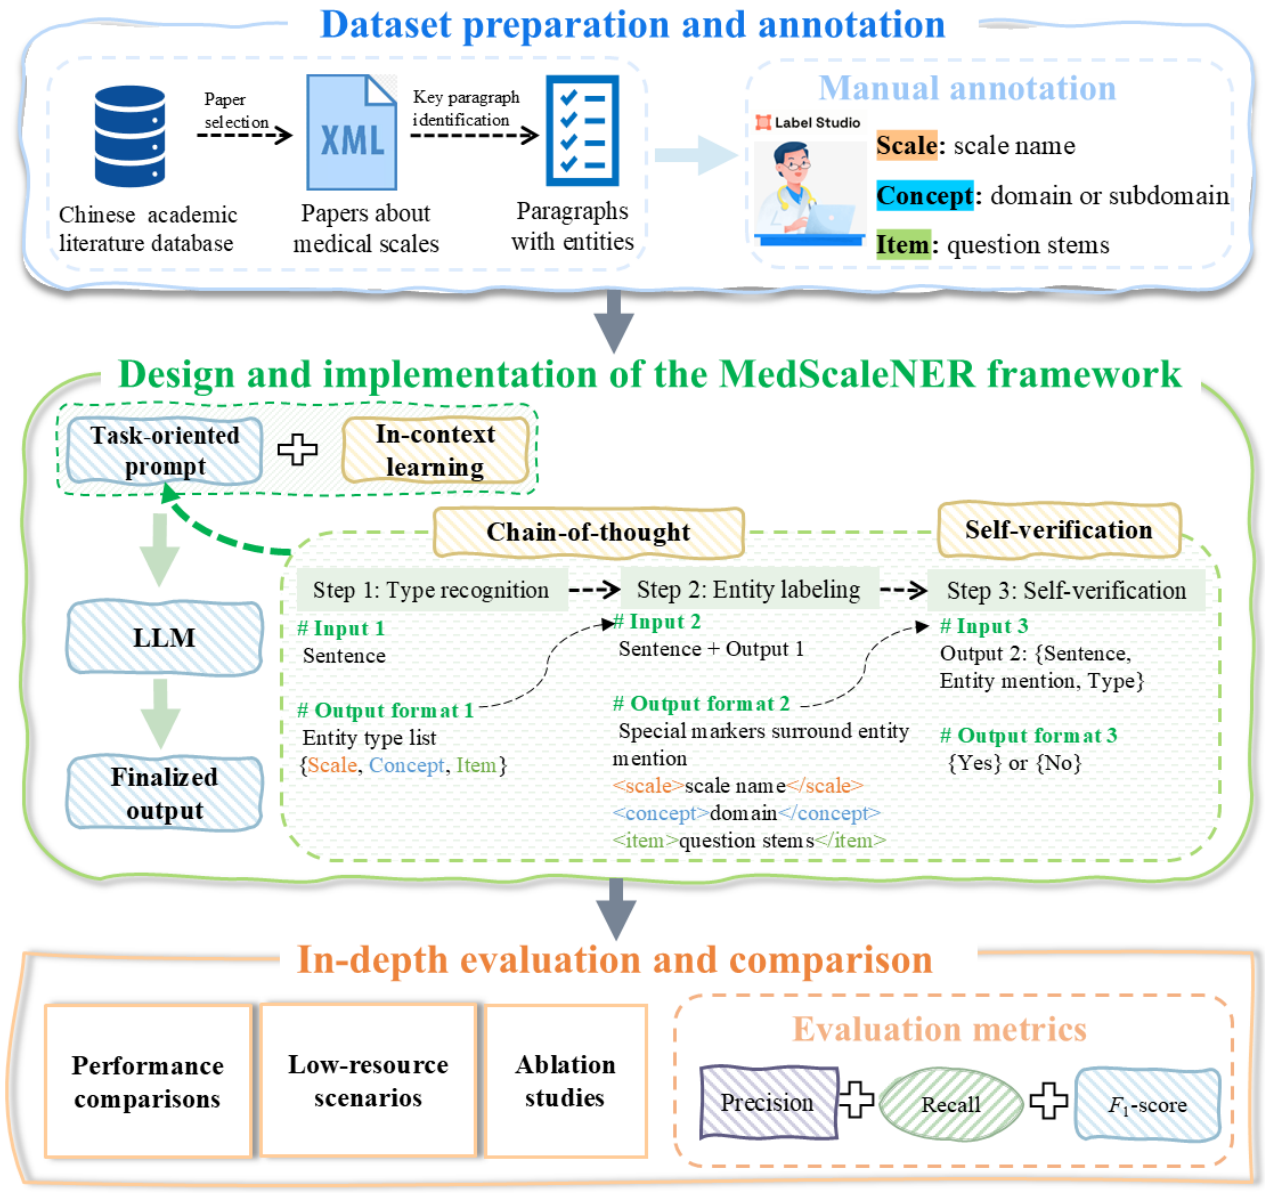
Addressing these challenges requires innovative solutions that can handle the complexity and variability of medical scale information, particularly in Chinese, with limited resources. Large language models (LLMs) such as GPT [10], GLM [11], LLaMA [12], and Qwen [13] have recently demonstrated impressive capabilities in natural language understanding and in-context learning (ICL) [14], enabling them to perform complex language tasks with minimal fine-tuning and limited annotated data [15,16]. By leveraging prompt engineering, these models can generate targeted outputs from well-crafted inputs, reducing the need for extensive datasets and making them particularly valuable in low-resource scenarios [17-19]. Moreover, LLMs have shown the ability to perform tasks in zero-shot and few-shot settings [20,21], allowing them to generalize from minimal demonstrations (examples) [22]. However, their effectiveness in information extraction tasks is highly dependent on the quality of the prompt design, including the task instructions, example selection, and output formats [23]. In few-shot settings, selecting the most appropriate examples is crucial for guiding the LLM toward accurate information extraction [24]. This selection process is particularly challenging in specialized domains, where the examples should not only be relevant but also representative of the task's complexity.

To improve the performance of LLMs in information extraction tasks, researchers have explored techniques such as demonstration retrieval within the ICL paradigm [25]. In this approach, relevant examples are dynamically selected from a pool of annotated data based on their similarity to the input text, addressing the issue of sample representativeness [26]. Moreover, techniques such as chain-of-thought (CoT) prompting [27] and self-verification [25] have been used to enhance the accuracy and robustness of domain-specific tasks. CoT prompting involves breaking down complex tasks into subtasks, and guiding the LLM step-by-step through multiturn dialogue [27], while self-verification allows the model to review and refine its outputs [28]. Despite these promising strategies, most existing research focuses on extracting common medical entities such as diseases, symptoms, drugs, and procedures [29], with limited attention to the extraction of scale-related entities.

Given the importance of task-oriented prompt design and the linguistic complexities of Chinese medical literature, there is an urgent need to develop a specialized framework for medical scale–related knowledge extraction. In this study, we propose MedScaleNER, a task-oriented prompt framework tailored for named entity recognition (NER) of medical scales in Chinese medical literature. MedScaleNER incorporates demonstration retrieval, CoT prompting, and self-verification strategies to tackle the specific challenges associated with extracting scale-related knowledge entities in Chinese. By dynamically selecting representative examples, the framework enhances the generalization capabilities of LLMs and improves extraction performance in few-shot scenarios. CoT prompting decomposes the scale-related NER task into manageable subtasks, easing

XSL•FO
RenderX

the cognitive load on LLMs, while self-verification ensures output reliability.



This study emphasizes the significance of prompt design in LLM-based information extraction, particularly in specialized domains with limited annotated data. By combining demonstration retrieval with advanced prompt strategies, we aim to overcome the challenges posed by data scarcity and the linguistic variations of Chinese medical literature. To facilitate evaluation, we constructed a manually annotated corpus of Chinese medical scales, covering three key entity types of scale names, measurement concepts, and measurement items. We conducted an in-depth assessment of MedScaleNER's effectiveness on this self-built dataset, examining the impact of the number of demonstrations, the contributions of CoT and self-verification, and the annotated data size required for optimal performance. Our approach contributes to building comprehensive scale knowledge systems, supporting clinicians and researchers in clinical and research efforts, promoting MBC adoption, and ultimately improving patient care.

Methods

Overview

The workflow of the proposed MedScaleNER prompt framework is illustrated in Figure 1 and consists of three main stages: dataset preparation and annotation, design and implementation of the MedScaleNER framework, and in-depth evaluation and comparison. The process begins with the collection of high-quality Chinese journal papers focused on medical scales. These papers are preprocessed and manually annotated to extract three key types of scale-related entities: scale names, measurement concepts, and measurement items. This manually annotated corpus fills the gap caused by the limited availability of annotated data in this area, while also reflecting the complexities unique to Chinese medical literature.

Figure 1. Workflow of the MedScaleNER prompt framework. LLM: large language model.

XSL•FO
RenderX

To address the task of medical scale–related NER, we introduce the MedScaleNER framework, which incorporates demonstration retrieval within the ICL paradigm, CoT prompting, and self-verification techniques. The framework selects relevant examples dynamically, breaks down complex NER tasks into manageable subtasks, and improves the reliability of outputs through self-verification. We evaluate MedScaleNER comprehensively, including comparisons of performance with varying numbers of retrieved demonstrations, ablation studies to determine the impact of CoT and self-verification, and assessments of its effectiveness in low-resource scenarios with different training data sizes. Additionally, we benchmark its performance against traditional fine-tuned LLMs in local.

Formally, the task is defined as follows. Given a collection of Chinese academic documents related to medical scales, denoted as D, where each document D_i consists of a sequence of sentences $S = \{s_1, s_2, ..., s_n\}$, and a set of entity types $T = \{\text{scale, concept, item}\}$, the goal of MedScaleNER is to identify all entities e_i within D and assign the appropriate type $t_i \in T$ to each identified entity.

Ethical Considerations

This study used only publicly available published papers from the China National Knowledge Infrastructure, which consist of academic literature and do not contain real patient information. Since the data is publicly accessible and does not involve human participants or private data, ethical approval was not required.

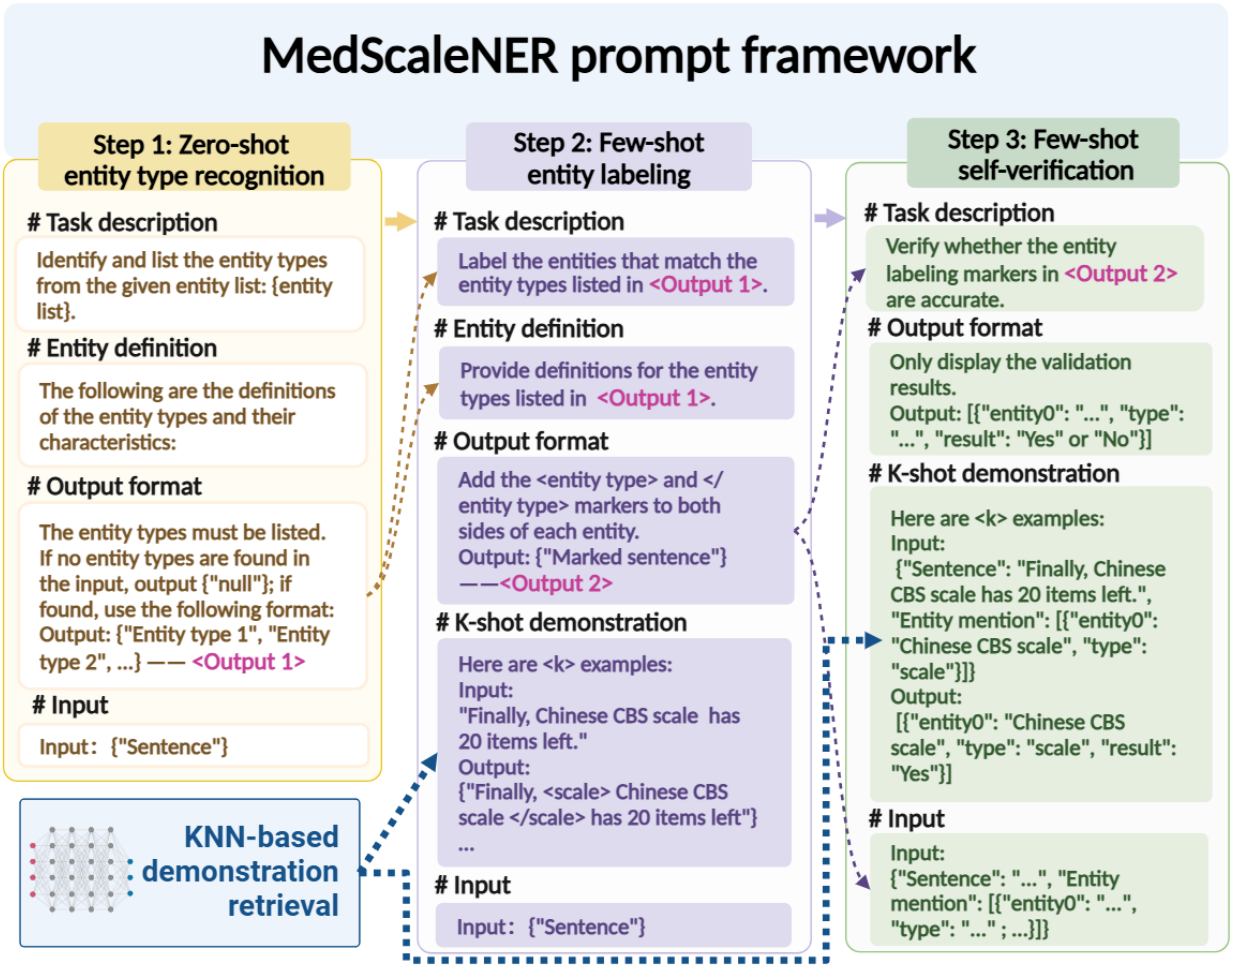
Dataset Preparation and Annotation

Due to the lack of annotated datasets for knowledge entity recognition in Chinese medical scales, we constructed a manually annotated corpus from full-text medical journal papers. The annotation focused on three key types of knowledge entities within medical scales: scale name, measurement concept, and measurement item. The scale name refers to the official or widely recognized title of the medical scale used in MBC, such as “The M. D. Anderson Symptom Inventory.” The measurement concept is defined as the broader theoretical or clinical construct that the scale is designed to assess, such as anxiety or cognitive function. The measurement item, on the other hand, refers to the individual questions within the scale that evaluate specific aspects of the measurement concept.

We began by retrieving abstracts of Chinese core medical journal papers from the China National Knowledge Infrastructure [30], which is a Chinese academic journal full-text database, targeting scale development research. The search was conducted using the “Abstract” and “Chinese Library Classification” criteria. From the retrieved papers, we selected the top three subfields within the Chinese Library Classification R code (Medicine and Health) based on literature frequency. Each abstract was manually reviewed to ensure the inclusion of original research papers, and the corresponding full texts were obtained in XML format. A detailed analysis of these full texts revealed that the Methods, Results, and Discussion sections contained a higher density of mentions related to scale names, measurement concepts, and items. Compared to scale names, mentions of concepts and items were less frequent, with items being particularly sparse.

To improve the balance and density of these entities, we extracted paragraphs specifically from the Methods, Results, and Discussion sections based on their XML structure. We then used key clue words such as “dimension,” “domain,” “variable,” “concept,” “factor,” “item,” and “entry” to identify paragraphs likely to contain the targeted entities. Paragraphs containing these terms were retained for annotation, while others were excluded.

For data annotation, we used the Label Studio tool [31]. Prior to formal annotation, a preannotation phase was conducted to train annotators. During this phase, annotators were introduced to the annotation scheme, guidelines (summarized in Multimedia Appendix 1), and tools. Feedback from this stage was used to refine both the scheme and guidelines through discussions. In the formal annotation phase, each paper was independently annotated by two annotators. A third annotator then checked for consistency, corrected discrepancies based on either annotator’s results, addressed missed annotations, and documented uncertain cases, which were later resolved through group discussions. Cohen κ coefficient was calculated to assess annotation consistency, yielding an overall score of 0.95, indicating a high level of reliability for the constructed dataset [32]. Specifically, the type-specific Cohen κ values were 0.961 for scale entities, 0.950 for concepts, and 0.970 for items.



Design and Implementation of the MedScaleNER Framework

Overview

We developed the MedScaleNER prompt framework to identify scale-related entities in medical texts using LLMs. The framework is designed to optimize entity recognition by incorporating three key stages: zero-shot entity type recognition, few-shot entity labeling, and self-verification. To enhance LLM performance, MedScaleNER integrates CoT prompting, which helps guide the model step by step through complex tasks, reducing the cognitive load. This is achieved by first identifying entity types in a zero-shot setting and then labeling the entities with a few examples. To further improve contextual understanding, the framework dynamically retrieves relevant examples using k-nearest neighbors (KNN) and uses self-verification to minimize hallucinations and overprediction, which are common issues in NER tasks [33]. Figure 2 outlines the MedScaleNER prompt framework, which consists of four main components: demonstration retrieval, entity type recognition, entity labeling, and self-verification.

XSL•FO
RenderX

Figure 2. Design of the MedScaleNER prompt framework. KNN: k-nearest neighbors.

Step 1: Zero-Shot Entity Type Recognition

In the first step, we design a prompt that includes four essential components: task description, entity definitions, output format, and input text [25]. Previous research in medical entity recognition using LLMs emphasizes the critical importance of prompt design, especially in specialized tasks [34]. Therefore, in this step, the model is framed as a "sophisticated linguist and named entity annotation expert" and tasked with identifying and listing entity types present in the input text without examples. This is the zero-shot stage, where the LLM uses only the provided definitions to perform entity-type recognition without any prior labeled examples.

To improve the model's understanding of domain-specific terminology, we provide clear definitions and possible forms for each entity type. This enables the LLM to comprehend and distinguish between different medical scale–related entities. The output is structured as a list of identified entity types, with explicit instructions to avoid unnecessary information, limit responses to the provided entity list, and return "{null}" if no entities are found. The output is structured as a list of identified entity types present in the input text, without repeating types for multiple occurrences. For instance, if the entity type "scale" appears multiple times in the input, it is represented only once in the output to indicate its presence. Step 1 is instructed to limit responses to the provided entity type list and return "{null}" if no entities are found. By guiding the model through these structured prompts, we leverage CoT prompting to break down the task into manageable steps for better performance (detailed in Multimedia Appendix 2).

Step 2: Few-Shot Entity Labeling

The second step builds upon the output of step 1 by introducing few-shot entity labeling. The prompt in this stage includes the task description, entity definitions, examples (demonstrations), output format, and the input sentence. The role of the LLM remains that of a named entity annotation expert. Now, the task is to label the entities that match the entity types identified in step 1 within the input text.

Here, we use few-shot prompting because providing a small number of high-quality examples typically boosts performance, especially in specialized tasks like medical NER [35]. Few-shot prompting often achieves results comparable to those of fine-tuned models trained on hundreds of samples. However, it is sensitive to the representativeness of the examples, as well as the length of the input. To mitigate these challenges, we use KNN retrieval to dynamically select the most relevant examples from the training corpus. These examples, which are semantically similar to the input text, serve as demonstrations for the LLM to follow, guiding it in accurately labeling entities

XSL•FO
RenderX

within the text. Moreover, we incorporate CoT prompting by breaking the task into incremental steps: first identifying entity types (step 1), followed by entity labeling (step 2). Step 1 involves identifying the entity types present in the input text, which informs the candidate pool for KNN retrieval in step 2. For instance, if step 1 determines that the entity types are {scale, concept}, step 2 specifically retrieves examples containing both scale and concept entities. The LLM surrounds the identified entities with appropriate markers in the text [36], as illustrated in Figure 3, with detailed prompts provided in Multimedia Appendix 3.

Figure 3. Output format of entity labeling.

Output format

 # Example 1

Chinese:

<scale> 痴呆态度量表 **</scale>**共有20个条目，**<concept>** 痴呆知识 **</concept>**(dementia knowledge)和**<concept>** 社会舒适度 **</concept>**(social comfort)两个维度。

Translation:

<scale> Dementia Attitude Scale **</scale>** consists of 20 items, covering two dimensions: **<concept>** Dementia Knowledge **</concept>** and **<concept>** Social Comfort **</concept>**.

 # Example 2

Chinese:

公因子4 (**<concept>** 母乳喂养健康和喂养量 **</concept>**)包括2个条目,如**<item>** 母乳喂养的孩子比奶粉喂养的孩子更健康 **</item>**，**<item>** 比奶粉喂养令婴儿吃得更多 **</item>**。

Translation:

Common Factor 4 (**<concept>** Breastfeeding Health and Quantity of Feeding **</concept>**) includes two items, such as **<item>** breastfed children are healthier than formula-fed children **</item>**, and **<item>** infants eat more than formula-fed infants **</item>**.

KNN Demonstration Retrieval

For demonstration retrieval, we use KNN, a widely used method in ICL [37]. The KNN algorithm retrieves semantically similar examples from the annotated dataset to provide the LLM with contextually relevant demonstrations. We begin by generating sentence-level embeddings for both the input texts and candidate examples using the SimCSE [38] method implemented in the acge_text_embedding model [39]. The cosine similarity between the input text and each candidate example is then computed, and the top k examples with the highest similarity scores are selected.

To enable efficient retrieval from large-scale, high-dimensional embedding spaces, we use the FAISS library [40]. FAISS provides specialized data structures and algorithms for fast indexing and searching of embeddings. After indexing the training embeddings, retrieving demonstrations for a given test sentence simply involves extracting its embedding and performing a semantic similarity search against the indexed embeddings. This approach significantly reduces computational overhead by eliminating exhaustive pairwise comparisons.

To determine the optimal value of *k*, we conducted experiments with a range of different *k* values. We selected the value that maximized model performance by balancing the need for enough examples to help the LLM generalize while avoiding performance degradation caused by irrelevant or excessive examples. These examples are fed to the LLM to improve generalization and entity labeling.

Step 3: Few-Shot Self-Verification

The final step incorporates a self-verification mechanism to improve the accuracy and reliability of the labeled entities. After completing the entity labeling, the LLM undergoes a self-verification process through few-shot prompting, where it reviews its own output for correctness. In this step, the model's task in this step is to verify whether the labeled entities are accurate by responding with either "Yes" or "No" for each entity. If the answer is "No," the entity is removed from the output.

The input for this step includes both the labeled entities and their surrounding context, allowing the LLM to validate its previous output holistically. This self-verification step improves the reliability of the final results, ensuring that the identified and labeled entities meet the expected standards of accuracy (detailed prompts are provided in Multimedia Appendix 4).

In-Depth Evaluation and Comparison

To comprehensively assess the performance of MedScaleNER, we conducted an in-depth analysis. Before the formal experiments, we first identified the best-performing LLM for use in MedScaleNER by comparing various LLMs accessed via the application programming interface (API). Following this, we compared MedScaleNER's performance with that of

XSL•FO
RenderX

locally fine-tuned LLMs on the NER task. Additionally, we carried out ablation studies focusing on the two key components of MedScaleNER: CoT prompting in step 1 (zero-shot entity type recognition) and self-verification in step 3. By isolating these components, we examined their individual contributions to the overall framework, specifically their impact on entity recognition accuracy and output robustness. These studies provided valuable insights into the importance of each step in enhancing model reliability and precision.

Furthermore, we evaluated MedScaleNER in low-resource settings by varying the amount of training data and the number of demonstrations in the few-shot setting (steps 2 and 3). This analysis was essential for understanding how the framework performs under limited data conditions and testing its scalability and effectiveness when annotation resources are scarce. By experimenting with different proportions of available data and examples, we gained insights into the adaptability of MedScaleNER in resource-constrained scenarios.

For evaluation, we used precision, recall, and macro F_1-score. Precision represents the proportion of correctly predicted entities out of all entities predicted by the model. Recall is the proportion of correctly predicted entities out of all actual entities present in the dataset. Macro F_1-score is the harmonic mean of precision and recall, averaged across all entity classes to account for imbalanced class distributions. We determined the correctness of entity recognition using exact string matching, meaning only perfect matches between the model's predictions and the ground truth were considered correct. This strict evaluation method ensured a high standard for assessing model performance across all comparisons, providing a clear and objective measure of MedScaleNER's effectiveness.

Results

Summary Statistics of CMedS-NER

We constructed the CMedS-NER (Chinese Medical Scale Corpus for Named Entity Recognition) dataset specifically for the NER task in the context of Chinese medical scales. The dataset consists of 720 full-text Chinese academic papers focused on medical scales, which include 5582 paragraphs and 22,743 sentences. After conducting a concordance test and making necessary emendations, CMedS-NER contained a total of 27,499 entity mentions. These consisted of 12,340 mentions of scales, 11,968 mentions of concepts, and 3191 mentions of items. For evaluation purposes, the dataset was randomly split at the document level into 90% for training and 10% for testing. Detailed characteristic statistics of the training and test data are presented in Table 1.

Table 1. Statistics of training and test data.

Data type	Training set, n (%)	Test set, n (%)	Total, n (%)
Papers	648 (90)	72 (10)	720 (100)
Paragraphs	5055 (90.56)	527 (9.44)	5582 (100)
Sentences	20,454 (89.94)	2289 (10.06)	22,743 (100)
Entities			
Scale	11,106 (90)	1234 (10)	12,340 (100)
Concept	10,836 (90.54)	1132 (9.46)	11,968 (100)
Item	2947 (92.35)	244 (7.65)	3191 (100)
All	24,889 (90.51)	2610 (9.49)	27,499 (100)

LLM Selection and Experimental Setup

To determine the best-performing LLM for the MedScaleNER framework, we conducted preliminary experiments with six generative LLMs: GPT-3.5-turbo, GLM-4-0520, ERNIE-Bot-turbo, Moonshot-v1-8k, AGI Sky-Chat-3.0, and Qwen-turbo-0624. These models were accessed via APIs and evaluated on randomly selected sentences from the CMedS-NER test set, which included ten scale entities. Among the tested models, GLM-4-0520 performed the best, accurately recognizing nine out of ten scale entities, Qwen-turbo-0624 followed, identifying eight entities (complete results are provided in Multimedia Appendix 5). Based on this superior performance, GLM-4-0520 was selected for subsequent experiments. For the GLM-4-0520 setup, we used temperature sampling, setting the temperature parameter to 0.02 and the max_tokens parameter to 2048, while leaving all other hyperparameters at their default values.

In addition to evaluating the API-accessed LLM, we implemented local fine-tuning for four models: GLM-4-9B-Chat [41], Qwen2-7B [42], BiLSTM-CRF [43] (Chinese-BERT-wwm), and W2NER [44] (MacBERT). Fine-tuning was performed using Pytorch 1.12.1+cu11.6 on NVIDIA RTX A6000 graphics processing units. For these locally fine-tuned models, hyperparameters were optimized using empirical tuning methods to achieve the best performance on the CMedS-NER dataset. Detailed hyperparameter settings for each model are provided in Multimedia Appendix 6.

Performance Comparisons

Optimal k-Shot Demonstration Selection

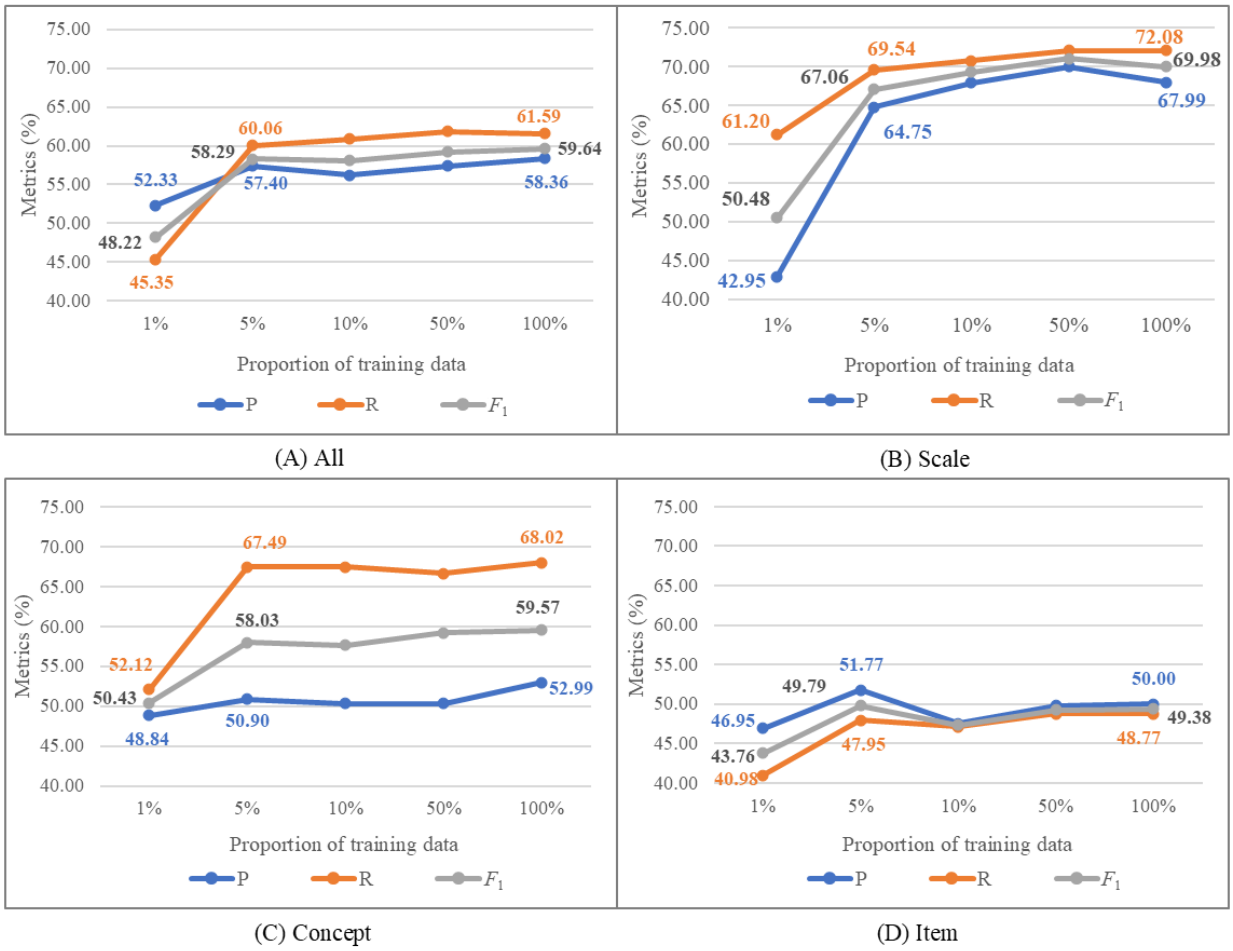
To determine the optimal number of demonstrations (k) for few-shot learning, we tested various k-shot settings (0, 5, 10, 15, 20, and 25) on a randomly selected set of 100 sentences from the test set. As shown in Table 2, overall performance improved as the number of demonstrations increased, with the

XSL•FO
RenderX

highest F_1-score of 81.23% achieved at 20-shot. However, different entity types peaked at different k values. For instance, the F_1-score for concepts peaked at 10-shot (85.07%), while the F_1-score for scales and items reached their highest performance at 20-shot, with scores of 77.27% and 84.21%, respectively.

Table 2. Entity extraction performance with different k-shot values.

k-shot	All, F_1-score (%)	Scale, F_1-score (%)	Concept, F_1-score (%)	Item, F_1-score (%)
0	17.11	23.26	28.07	0
5	68.74	61.87	74.34	70
10	67.59	67.69	*85.07* [a]	50
15	78.55	71.88	83.78	80
20	*81.23*	*77.27*	82.19	*84.21*
25	71.06	75.19	78.73	59.26



[a]The best performance is italicized.

Low-Resource Comparison

To evaluate MedScaleNER's performance in low-resource scenarios, we trained the model using different proportions of the training data (1%, 5%, 10%, 50%, and 100%) and assessed its performance on the test set. As presented in Figure 4A, the overall F_1-score increased as more training data was used. Notably, significant performance gains were observed when increasing the training data from 1% (205 sentences) to 5% (1023 sentences), with the overall F_1-score rising from 48.22% to 58.29%, precision improving from 52.33% to 57.40%, and recall jumping from 45.35% to 60.06%. Beyond this point, improvements plateaued, with only a 1.35% increase in the F_1-score between 5% and 100% of the training data (from 58.29% to 59.64%). A similar trend was observed for precision and recall, although precision dropped slightly at 10% of the training data. When examining scale and concept entities (Figure 4B and C), the same pattern emerged: a significant improvement from 1% to 5% of the training data, followed by minimal gains from 5% to 100%. However, for item entities (Figure 4D), precision, recall, and F_1-scores slightly declined as the training data increased from 5% to 100%.

XSL•FO
RenderX

Figure 4. Low-resource performance of MedScaleNER: precision (P), recall (R), and macro F_1-scores (F_1) across different proportions of training data for (A) all entities, (B) scales, (C) concepts, and (D) items.

Ablation Studies

To evaluate the contributions of different components within the MedScaleNER framework, we conducted ablation studies to examine the impact of CoT prompting and self-verification under various low-resource settings. We tested the GLM-4-0520's performance with and without these components using different proportions of the training data (1%, 5%, 10%, 50%, and 100%). The baseline model involved directly prompting the task description and labeling entities in the input using 20 examples.

As shown in Table 3, incorporating self-verification consistently improved F_1-scores across all training data sizes. With 100% of the training data, self-verification led to a 0.89% increase in the F_1-score, while breaking down the task into subtasks using CoT resulted in a 2.11% increase. However, in extremely low-resource scenarios (eg, 1% of the training data), adding CoT without self-verification did not enhance performance and slightly decreased the F_1-score. The combination of both CoT and self-verification yielded the best performance across all training data sizes. In low-resource settings, self-verification had a significant impact. It increased the F_1-score of MedScaleNER by 7.92% with 1% of the training data and by 3.27% with 5% of the training data, compared to configurations without it (ie, baseline + CoT).

XSL•FO
RenderX

Table 3. Ablation study results: P[a], R[b], and F_1[c] scores for different components of MedScaleNER across different proportions of training data.

Proportion of training data (n of sentences)	Baseline			Baseline + self-verification			Baseline+ CoT[d]			MedScaleNER		
	P (%)	R (%)	F_1 (%)	P (%)	R (%)	F_1 (%)	P (%)	R (%)	F_1 (%)	P (%)	R (%)	F_1 (%)
1% (205)	48.21	45.70	46.63	51.42	45.59	48.14	36.52	45.46	40.30	52.33	45.35	48.22
5% (1023)	44.21	66.41	52.35	47.61	66.71	55.07	51.10	60.20	55.02	57.40	60.06	58.29
10% (2045)	45.88	66.11	54.37	47.99	65.54	55.03	50.84	60.95	55.13	56.22	60.84	58.11

Comparison With Local Fine-Tuned Models

We compared MedScaleNER with several locally fine-tuned models on the CMedS-NER dataset, including GLM-4-9B-Chat, Qwen2-7B, BiLSTM-CRF (Chinese-BERT-wwm), and W2NER (MacBERT). Both GLM-4-9B-Chat and Qwen2-7B were fine-tuned using the low-rank adaptation method with a parameter-efficient fine-tuning strategy with identical fine-tuning parameters, ensuring a fair comparison. After fine-tuning, we prompted the fine-tuned GLM-4-9B-Chat and Qwen2-7B for the NER task using a similar prompt structure as our Baseline, but without KNN retrieval.

As shown in Figure 5, MedScaleNER achieved an overall F_1-score of 59.64%, which is lower than the fine-tuned Qwen2-7B (79.91%), GLM-4-9B-Chat (80.34%), BiLSTM-CRF (80.99%), and W2NER (81.38%). Notably, under low-resource scenarios (eg, using only 1% of the training data), MedScaleNER significantly outperformed the other fine-tuned models. At 5% of the training data, while MedScaleNER's F_1-score was lower than W2NER and BiLSTM-CRF, it remained substantially higher than Qwen2-7B and stayed competitive with GLM-4-9B-Chat.

XSL•FO
RenderX

Figure 5. F_1-score comparison of MedScaleNER and locally fine-tuned models across different proportions of training data.

Error Analysis

We conducted an error analysis by manually reviewing 300 randomly selected sentences from the model outputs to identify common types of mistakes and areas for improvement. The errors were classified into four main types: (1) identification errors, where nonentity terms were incorrectly identified as entities; (2) type errors, where entities were correctly identified but assigned the wrong entity type; (3) boundary errors, which involved incorrect determination of the start and end positions of entities; and (4) missing entities, where entities present in the text were not identified by the model.

Figure 6 provides examples of each error type, illustrating the nature of these mistakes. Identification errors were the most common and often resulted from ambiguous entity definitions. For example, generic terms like “item” or “scale” were sometimes misinterpreted as specific entities due to their inclusion in prompt definitions. Type errors occurred when entities were recognized but misclassified. For instance, “overall evaluation of the quality of nursing services” was mistakenly labeled as a concept rather than an item. Boundary errors included incorrect inclusion or exclusion of surrounding text or punctuation, such as parentheses or modifiers that should not be part of the entity span. Finally, missing entities were frequently associated with English names or abbreviations of scales and items, especially in cases involving long or complex strings.

Discussion

Principal Findings

This study is among the first to explore the use of LLMs and prompt engineering for NER tasks related to Chinese medical scales. We proposed a novel prompt framework, MedScaleNER, which enhances the adaptive learning capabilities of LLMs by dynamically retrieving optimal examples through KNN retrieval. By using a CoT strategy, the framework decomposes the complex task of entity recognition into two sequential steps: first, identifying entity types and then labeling entities. This approach strengthens the logical reasoning ability of LLMs. Additionally, incorporating self-verification mechanisms ensures the accuracy of the final recognition results, improving the reliability of the model's outputs.

Our evaluation of the self-constructed CMedS-NER dataset demonstrated that MedScaleNER effectively recognizes medical scale–related entities. The dataset, comprising 720 full-text Chinese academic papers with 27,499 annotated entities, is a high-quality resource for training and evaluating NER models in this specialized domain. Notably, in low-resource settings with as few as 205 sentences, MedScaleNER outperformed locally fine-tuned models such as BiLSTM-CRF (Chinese-BERT-wwm), W2NER (MacBERT), GLM-4-9B-Chat, and Qwen2-7B. When more annotated data became available (eg, 1023 sentences), MedScaleNER remained competitive. This low-resource performance is particularly significant in biomedical and clinical contexts, where domain-specific annotations are often expensive and time-consuming to produce.

Ablation studies further highlighted that KNN retrieval significantly improved performance in low-resource settings, aligning with previous findings [37] on the benefits of such strategies in ICL. Integrating CoT prompting and self-verification with KNN retrieval boosted the F_1-score by approximately 6% when using 5% of the training data. This suggests that while retrieving representative examples is crucial, the structured CoT and self-verification steps are also important, contributing to more accurate and robust entity annotation than retrieval-based demonstration alone.

Although using high-quality demonstrations improved the LLM's ability to recognize scale-related entities [25,45], performance declined when the number of examples exceeded an optimal threshold. Context length limitations, example ordering [46], and entity-type specific sensitivities influenced this trade-off. For instance, concept entities benefited from fewer examples compared to scale and item entities. It suggests that tailoring demonstration strategies by entity type could maximize performance.

Compared to traditional and fine-tuned NER methods designed for similar biomedical contexts, MedScaleNER offers several advantages. Conventional approaches often require extensive domain adaptation, large annotated corpora, or multiple rounds of fine-tuning to achieve competitive results [47,48]. In contrast,

XSL•FO
RenderX

MedScaleNER excels under low-resource settings by leveraging KNN retrieval, CoT, and self-verification. Its flexible, task-oriented design allows simple modification of entity definitions to adapt to new domains, other languages, or even other LLM backbones. This adaptability supports broader generalizability, enabling MedScaleNER to scale beyond Chinese medical scales to other medical domains and even entirely different biomedical NER tasks.

Moreover, moving toward a human-centered medical scale NER workflow is crucial [23,49]. Allowing domain experts to provide feedback, customize prompt components, control retrieval parameters, and determine when to use self-verification can improve transparency, trust, and overall user satisfaction [50,51]. Such a human-in-the-loop approach ensures that MedScaleNER remains aligned with real-world clinical and research priorities, particularly important in dynamic health care environments.

Limitations

Despite these strengths, there are limitations to this study. First, we primarily focused on the GLM-4 model, and future work should evaluate additional LLMs [52] such as LLaMA, Mistral, GPT, and PaLM, to validate generalizability. Second, our example retrieval strategy relied on KNN based on sentence similarity. Alternative retrieval strategies [53] and more advanced similarity models may further enhance performance. While we focused on three main scale-related entity types: scale names, measurement concepts, and measurement items, future research could extend this framework to other entities, such as functions, targets, and validity measures. Finally, integrating LLMs with traditional NER models could leverage the complementary strengths of both approaches, potentially resulting in more robust and accurate entity recognition systems.

Conclusions

In this study, we introduced MedScaleNER, a task-oriented prompt framework that integrates demonstration retrieval, CoT prompting, and self-verification strategies to enhance the recognition of medical scale-related entities in Chinese medical literature. Evaluated on our self-constructed CMedS-NER dataset, MedScaleNER demonstrates robust performance even with limited annotated data. By allowing simple adjustments to prompt definitions, MedScaleNER readily adapts to diverse biomedical domains, languages, and entity types, making it a resource-efficient solution for broader information extraction challenges. This adaptability supports more efficient and reliable knowledge extraction, ultimately contributing to better clinical and research outcomes in MBC. By continuing to refine and expand MedScaleNER, we aim to advance automated knowledge extraction systems and promote the widespread adoption of MBC in health care.

Abstract

Background: Named entity recognition (NER) plays a vital role in extracting critical medical entities from health care records, facilitating applications such as clinical decision support and data mining. Developing robust NER models for low-resource languages, such as Estonian, remains a challenge due to the scarcity of annotated data and domain-specific pretrained models. Large language models (LLMs) have proven to be promising in understanding text from any language or domain.

Objective: This study addresses the development of medical NER models for low-resource languages, specifically Estonian. We propose a novel approach by generating synthetic health care data and using LLMs to annotate them. These synthetic data are then used to train a high-performing NER model, which is applied to real-world medical texts, preserving patient data privacy.

Methods: Our approach to overcoming the shortage of annotated Estonian health care texts involves a three-step pipeline: (1) synthetic health care data are generated using a locally trained GPT-2 model on Estonian medical records, (2) the synthetic data are annotated with LLMs, specifically GPT-3.5-Turbo and GPT-4, and (3) the annotated synthetic data are then used to fine-tune an NER model, which is later tested on real-world medical data. This paper compares the performance of different prompts; assesses the impact of GPT-3.5-Turbo, GPT-4, and a local LLM; and explores the relationship between the amount of annotated synthetic data and model performance.

Results: The proposed methodology demonstrates significant potential in extracting named entities from real-world medical texts. Our top-performing setup achieved an F_1-score of 0.69 for drug extraction and 0.38 for procedure extraction. These results indicate a strong performance in recognizing certain entity types while highlighting the complexity of extracting procedures.

Conclusions: This paper demonstrates a successful approach to leveraging LLMs for training NER models using synthetic data, effectively preserving patient privacy. By avoiding reliance on human-annotated data, our method shows promise in developing models for low-resource languages, such as Estonian. Future work will focus on refining the synthetic data generation and expanding the method's applicability to other domains and languages.

Introduction

In the era of data-driven health care, the effective extraction of valuable information from electronic health records (EHRs) has become increasingly vital for informed decision-making, medical research, and public health initiatives. Named entity recognition (NER) stands as a cornerstone in the realm of natural language processing, playing a pivotal role in the automated extraction of named entities, such as diseases, medications, symptoms, and medical procedures, from unstructured text [1]. NER facilitates the transformation of text data into structured information, enabling health care professionals and researchers to carry out statistical analyses on the data.

While NER has achieved remarkable success in several languages and domains, the journey to attain proficient NER models for low-resource languages presents intricate challenges [1-3]. Estonian, a Finno-Ugric language spoken by approximately 1.1 million people, is one such language that grapples with limited linguistic resources, especially in specialized domains such as health care, largely because health records are sensitive, personalized data, which makes sharing them for labeling very difficult [4] in addition to the task being already time-consuming and expensive. The same challenges are faced with storing and sharing the annotated data. To tackle this, attempts have been made at removing or masking personally identifiable information [5,6]; however, this can still leave the data vulnerable to reconstruction attacks [6]. Despite its importance, the scarcity of annotated Estonian health care text data has hindered the development of robust NER models tailored to the unique linguistic features and domain-specific nuances of the language. At the same time, large language models (LLMs) such as GPT-4 have been shown to provide impressive results in tasks related to understanding different languages [7].

Many approaches using transformer-based models have been applied to EHRs to extract medical named entities [8-10]; however, these approaches primarily rely on human-annotated data for the training data, which we do not use for training. Most transformer-based approaches rely on using a model pretrained on a large corpus of text and fine-tuning it with the annotated data.

To tackle the problem of low-resource languages lacking annotation data, attempts have been made to improve the model using data from other languages via transfer learning [11,12], which has been shown to improve the model's performance by adding resources from languages with more data.

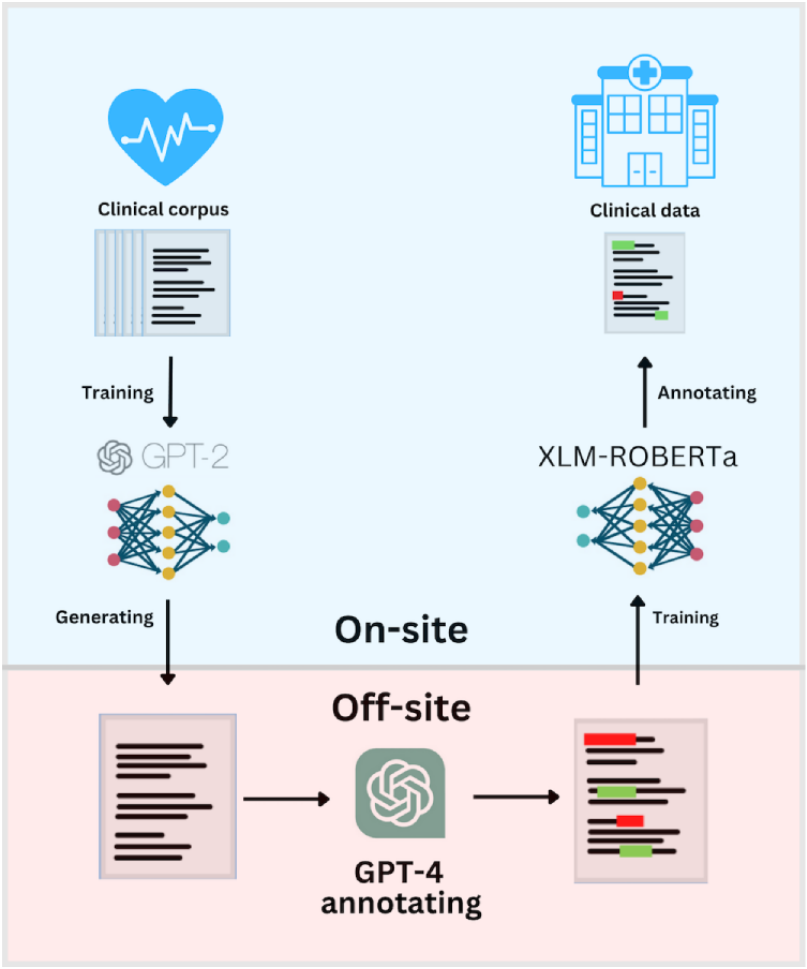
With the rapid increase in the performance of LLMs, attempts have also been made to leverage these models to extract named entities from texts. It has been shown that using GPT-3 for annotating the texts can be much cheaper and faster than using humans; however, there is room for improvements in the quality of the annotations made by the model [13].

Tang et al [14] used ChatGPT (OpenAI) [15] to generate synthetic medical texts with annotations to train a downstream model for different applications including NER. The performance of the resulting models was promising, considering the approach of using synthetic data. Their approach uses ChatGPT directly to generate the synthetic texts, meaning there is no potential for possible data leakage from the synthetic texts. However, because the GPT models were trained on data that are publicly available, they are not trained to understand the nuances of a specific medical domain in a low-resource language, and the synthetic data can be very different from real EHRs, possibly causing poor performance for the downstream model.

This study introduces a comprehensive pipeline using LLMs to train an NER model, enabling the annotation of targeted entities within health care texts. First, synthetic Estonian EHRs are generated by GPT-2 [16] trained locally on real data. We generate the synthetic data to avoid sharing sensitive information with third-party applications. These are passed to GPT-3.5-Turbo and GPT-4 as payload in a prompt, instructing the model to annotate the text with entities specified by the user. The responses are parsed and converted into training data for token classification with XLM-RoBERTa [17], which can be used on the downstream task of annotating real data. This approach ensures that sensitive data do not get passed to third-party LLM hosts via their application programming interface (API) calls and enables all the training to be carried out on-site.

We showcase the differences in performance between the selected prompts. We then compare the performance of GPT-3.5-Turbo, GPT-4, and a local Llama-based model for the best prompt. We continue with using the best prompt with GPT-4 to annotate generated synthetic data in batches, showcasing the improvement of the model based on the amount of training data. Finally, we discuss the performance of this method and possible room for improvements and conclude the results of this paper.

With this paper, we aim to show how we take advantage of powerful LLMs for training locally usable NER models without risking the privacy of patient records by using synthetically generated data.



Methods

Study Design

Our work follows the pipeline depicted in Figure 1. OpenAI models were selected for annotating the synthetic data due to their availability and their existing wide use in research. The clinical corpus was used for training the GPT-2 model, which we used to generate synthetic data. We then passed the synthetic data to GPT-4 through an API, asking it to annotate the data. The results were parsed and converted into training data for a downstream model, which we used to annotate real-world data.

Figure 1. Illustration of pipeline.

Generating Synthetic Data With GPT-2

As health care data are very sensitive, sharing them with third-party LLM hosts such as OpenAI or Azure (Microsoft Corp) is not possible. For this reason, we used synthetic data for the annotating process, generated by a GPT-2 small model. The dataset we used for training the model consists of around 10 million texts from 200,000 Estonians collected between 2010 and 2020 [18]. The texts are from a national registry of discharge reports covering both primary and secondary care contacts. The documents include anamnesis, summary, test results, objective findings, and procedures. During training, each medical document was prefaced with the document type, patient's age group, patient's gender, and diagnosis code, a similar idea to that used by Keskar et al [19], to generate synthetic health care records based on our specifications.

As the model can generate exact copies of the text it was trained on, it is important to ensure that no generated texts are identical to the training data. One way to verify this is by comparing the generated text directly against all training data. However, this method is unreliable because it fails to detect copies when even a single token differs. Some works [20,21] check if n-grams with a length of 13 in the generated texts are present in the training data, and if there is a match, then the generated texts are considered unoriginal. The problem with such an approach is that it can consider the training text with a length of 13 originals if we switch 1 word in it with a synonym. To address this, we considered using the longest common subsequence (LCS). For each generated text, we calculated the LCS with each training text, selected the longest, and divided by the generated text length, producing a score between 0 (unique) and 1 (identical).

The advantage of LCS is its ability to classify a generated text as a copy of the training data, even if some words have been replaced, deleted, or added. While calculating the LCS for every training instance is computationally expensive, with a training dataset of 10 million texts, we felt it was feasible and critical to ensure that no training text (real medical texts) copies were present in subsequent steps. However, with longer texts, the LCS elements were scattered across hundreds of tokens in the training text not representing continuous expressions. To mitigate this issue, we explored using a penalized LCS, which factors in the distances between matched tokens within the sequence. Given a penalty length k, we subtracted a penalty term *distance/k* for each consecutive LCS element, where the distance between LCS elements is the maximum of distances in x and y_i. If the distance is larger than k, we would subtract 1. If k is 1, then this is the same as finding the longest n-gram. For larger k values, the penalty would be smaller and we would match more texts. We experimented with various penalties and

XSL•FO
RenderX

found 20 to be effective in removing scattered matches without being overly restrictive.

Using LLMs for Annotations

The synthetic texts generated by our custom GPT-2 were passed as payloads into a prompt for Azure Cognitive Services GPT models via their API, which were instructed to annotate the data. We opted out of human review of data in Azure to further ensure the privacy of even the synthetic EHRs. For all experiments, we use the default parameters for the models. Our goal was to find the corresponding text spans for each annotation class; however, LLMs have been shown to make errors when prompted to return indexes for text spans [22], and our experiments showed that both the GPT-3.5-Turbo and GPT-4 models gave us incorrect spans when asked. Therefore, we only asked it to give us the text and the annotation class and map it to the text, finding the spans manually. To make the results as easy to parse as possible, we asked it to return the results in a *JSON* format, with each annotation class as an element and each text as a value of the corresponding element.

Prompt engineering has been shown to largely influence the quality of the output of the models [23]. This led us to select 4 different prompts to test how well they performed so we could choose the best one to annotate the data with. The prompts are listed in Table 1.

First, we used a zero-shot prompt because it is the most simplistic way to ask a model to complete a task. Our zero-shot prompt includes a description of the task, the wanted output format, and the input text.

The second prompt consists of instructions in Estonian to test if the accuracy of the annotations improves if the language of the prompt matches the language of the data. It is the zero-shot prompt translated into Estonian.

As human annotators have annotation guidelines as their instructions, we decided to explore whether adding definitions of entities in the prompts would increase the accuracy of the annotations. By providing definitions, we can specify what counts as an entity in our domain rather than relying on the model's understanding of the terms. The definitions for the classes were written by the same medical expert who annotated the synthetic data against which we tested the accuracy of the GPT model's annotations. Our prompt with definitions was inspired by Li et al [24] because they had promising results using prompts with additional annotation guidelines for NER with a BERT model.

As GPT models have been shown to perform better when provided with examples of task completion [20], we also tried a few-shot prompt. It consists of 5 pairs of example inputs and the expected *JSON* outputs. Few-shot prompts are particularly effective in low-resource settings, as they provide semantically relevant context that helps bridge the language gap between the target language and the high-resource language the model is proficient in [23].

The resulting responses were parsed in Python (Python Software Foundation) to convert them into *.tsv* format for training the downstream model. It was carried out by searching for the annotation entities from the original text, mapping them to spans, and finally aligning the spans into tokens.

RenderX

Evaluating the Performance of the GPT Models' Annotations

To evaluate which prompt to use for annotating the data, we generated 500 synthetic texts with 5 of the most frequent *International Classification of Diseases, Tenth Revision* (*ICD-10*) codes in our dataset. For each code, we generated 67 patient summaries and 33 procedures ranging from all age groups and both genders. This dataset was then annotated by a medical expert for drugs, procedures, diseases, and smoking entities to compare the LLM annotations with human annotations. The numbers of entities for each class are depicted in Table 2.

We compared the annotations made by the LLM word level by taking the human annotations as the ground truth and measuring precision, recall, and F_1-score (harmonic mean of precision and recall) of the annotations. We do this using the *seqeval* [25] library to obtain the classification reports with the default options from the annotations.

After determining the most effective prompt for all the annotation classes, we used the prompt with 3 different models—GPT-3.5-Turbo; GPT-4; and Llammas [26], a Llama-2-7B–based [27], instruction-tuned model adapted to Estonian.

This gave us an estimation of how well the different models annotate the data and which prompt to use for annotating the data that are used for training the downstream model.

Table 2. Entity counts.

Annotation class	Entity count, n
Drug	219
Procedure	643
Smoking	58
Disease	322

Training Downstream XLM-RoBERTa Model

Once the responses from the GPT models were parsed into training data format, we used this as data for fine-tuning a BERT-based model. We chose the XLM-RoBERTa base with 125M parameters as its pretraining data includes Estonian and other languages similar to Estonian. Additionally, because it is multilingual, we could later add annotations from other languages to further improve its performance. For each model we trained, we used 15% of the training data for the validation set.

The parameters for fine-tuning the model were the following:

- batch_size=16
- evaluation_strategy="epoch"
- learning_rate="2e-5"
- per_device_train_batch_size=16
- per_device_eval_batch_size=16
- num_train_epochs=8

All the trained models were evaluated at the token level with *seqeval* default settings using 300 documents from real-world data as the test set. We chose 150 texts from patient medical histories and 150 texts from patient procedure texts to make sure we had enough test data for all the annotation classes. We had 2 medical experts annotate these texts for drugs and procedures. The instructions given to the annotators were only the names of the entity classes to ensure that the instructions were similar to the ones given to the models annotating the data. We used one set of annotations as ground truth for our experiments and the second set to calculate the pairwise interannotator agreement [28], which was an F_1-score of 0.73 for drugs and 0.48 for procedures. Once the models were trained on the synthetic data annotated by the GPT models, we could use the models on the test data in a secure local environment and retrieve the results.

Ethical Considerations

The medical texts were accessed according to the Estonian Committee on Bioethics and Human Research approval (1.1-12/3797) that waived the requirement of informed consent for the use of the data. The methodology presented in this study prioritizes patient privacy by exclusively using synthetic health care data for model training instead of augmenting original data. This means there is no direct link between the patients and the generated texts. We furthermore ensured privacy by removing verbatim and close-to-verbatim copies of synthetic texts. All sensitive medical records remain protected, and synthetic data were generated using local models. This ensures that no actual patient data are shared with external platforms, in compliance with privacy laws and ethical standards governing medical data use.

Results

Overview

To test the performance of the pipeline as a whole, we chose 4 annotation classes that we wanted to extract from the texts—drugs, procedures, smoking, and disease. Extracting drugs and smoking is a simple task with relatively fixed vocabularies that we hypothesized would be easy to learn for the model. Procedures and diseases are slightly trickier, as they are often written in shorthand and their representation may vary, making context very important.

Generating the Data

Based on the annotation classes for the experiment, we chose procedures and patient medical history for the types of EHRs we wished to generate. We also added specifications for 13 age

XSL•FO
RenderX

groups, ranging from 15 to 80 years, to generate data for more diverse patients. We chose C50 as the *ICD-10* diagnosis code, generating the texts for patients with malignant neoplasms of the breast. We started with 10,000 generated texts and used our LCS algorithm to filter out texts that were too close to the original data. We ended up with around 4100 documents we could use for annotating with LLMs, out of which 2700 were of medical history and 1400 of procedures.

Prompt Selection

We used all the selected prompts for annotating the 500 synthetically generated texts with GPT-3.5-Turbo to compare their performance. For each prompt, we compared the annotations made by the GPT-3.5-Turbo model with the human annotations. The results for each prompt are depicted in Table 3. For precision and recall, 95% CIs were calculated using the Wilson score method [29]. The parsed responses column displays how many of the responses contained a valid *JSON* element containing the annotation classes.

For drugs, procedures, and smoking, the highest F_1-score was reached by using the few-shot prompt on GPT-3.5-Turbo. In the case of diseases, using the definitions prompt resulted in the highest F_1-score of 0.44, although the Estonian prompt had a higher recall of 0.52 versus 0.43. For smoking, the definitions prompt gave the highest precision of 1 versus 0.92 for the few-shot prompt; however, its recall and F_1-score were lower than those of the few-shot prompt.

We selected the prompt with the highest combined F_1-score for all the classes, which was the few-shot prompt, to continue annotating the rest of the synthetic data. We first used the same training data that GPT-3.5-Turbo annotated and redid it both with GPT-4 and a locally hosted Llammas model to compare the differences in performance. The results are depicted in Table 4.

In all instances, GPT-4 had a higher F_1-score than the GPT-3.5-Turbo and Llammas models; however, for procedure and smoking, GPT-3.5-Turbo had the highest precision.

Table 3. GPT-3.5-Turbo annotation performance compared to human expert annotations.

Annotation class and prompt	Precision (95% CI)	Recall (95% CI)	F_1-score	Parsed responses, n
Drug				
Prompt 1: zero-shot	0.61 (0.55-0.67)	0.75 (0.69-0.80)	0.67	495
Prompt 2: Estonian	0.3 (0.26-0.34)	0.63 (0.56-0.69)	0.41	487
Prompt 3: definitions	0.6 (0.54-0.65)	0.82 (0.76-0.87)	0.7	500
Prompt 4: few-shot	0.63 (0.57-0.68)	0.88 (0.83-0.92)	0.74	495
Procedure				
Prompt 1: zero-shot	0.25 (0.21-0.3)	0.15 (0.12-0.18)	0.19	495
Prompt 2: Estonian	0.24 (0.21-0.28)	0.22 (0.19-0.25)	0.23	487
Prompt 3: definitions	0.25 (0.22-0.28)	0.26 (0.23-0.3)	0.26	500
Prompt 4: few-shot	0.34 (0.3-0.38)	0.26 (0.23-0.3)	0.3	495
Smoking				
Prompt 1: zero-shot	1 (0.65-1)	0.12 (0.06-0.23)	0.22	495
Prompt 2: Estonian	0.21 (0.14-0.31)	0.29 (0.19-0.42)	0.24	487
Prompt 3: definitions	1 (0.85-1)	0.36 (0.25-0.49)	0.53	500
Prompt 4: few-shot	0.92 (0.75-0.98)	0.41 (0.29-0.54)	0.57	495
Disease				
Prompt 1: zero-shot	0.24 (0.21-0.27)	0.5 (0.45-0.55)	0.32	495

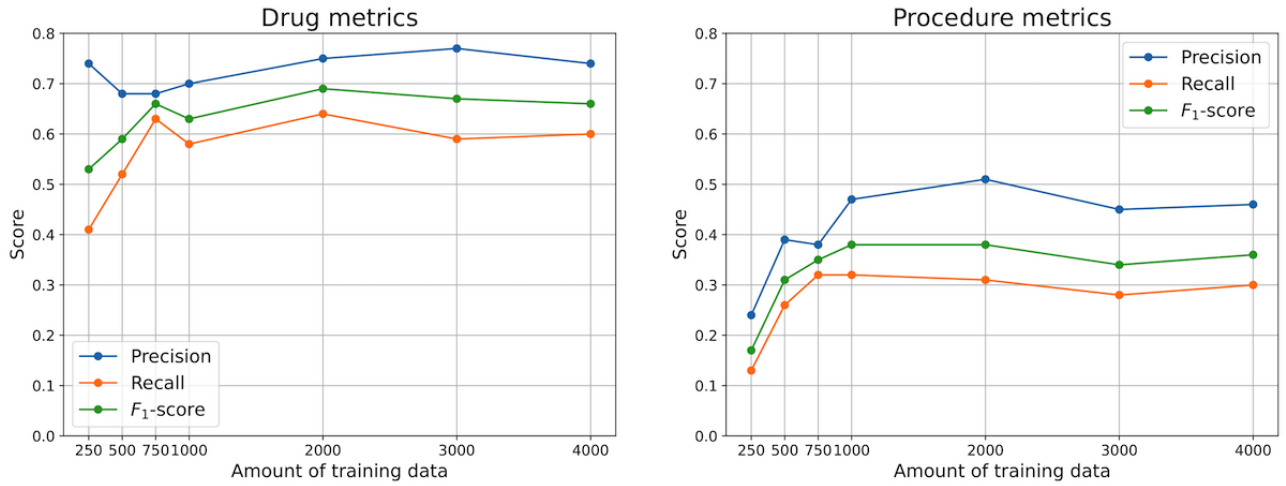
Table 4. Few-shot annotation performance of different models compared to human annotations.

Annotation class and model	Precision (95% CI)	Recall (95% CI)	F_1-score
Drug			
GPT-3.5-Turbo	0.63 (0.57-0.68)	0.88 (0.83-0.92)	0.74
GPT-4	0.66 (0.6-0.71)	0.88 (0.83-0.92)	0.75
Llammas	0.63 (0.57-0.69)	0.67 (0.61-0.73)	0.65
Procedure			
GPT-3.5-Turbo	0.34 (0.3-0.38)	0.26 (0.23-0.3)	0.3
GPT-4	0.33 (0.3-0.36)	0.42 (0.38-0.46)	0.37
Llammas	0.28 (0.24-0.32)	0.22 (0.19-0.25)	0.25
Smoking			
GPT-3.5-Turbo	0.92 (0.75-0.98)	0.41 (0.29-0.54)	0.57
GPT-4	0.69 (0.55-0.8)	0.55 (0.42-0.67)	0.61
Llammas	0.75 (0.47-0.91)	0.16 (0.09-0.27)	0.26
Disease			
GPT-3.5-Turbo	0.4 (0.35-0.45)	0.5 (0.45-0.55)	0.44
GPT-4	0.4 (0.36-0.44)	0.7 (0.65-0.75)	0.51
Llammas	0.21 (0.18-0.25)	0.35 (0.3-0.4)	0.26

Training the Downstream Model



We used the 2700 medical history texts and 1400 procedure texts resulting from LCS filtering to create batches of training data to see how well the model performs with additional training data. For each batch, we selected two-thirds of the texts from medical history and one-third from procedures, to fully use all the training data. Each model was then validated on 300 real-world documents annotated by a medical expert for drugs and procedures.

Figure 2 shows the performance of the model on the drug and procedure annotation classes. For every amount of data depicted on the x-axis, a downstream model was trained and evaluated on the test data.

For drugs, the performance of the model increased until 750 texts, lowered slightly for 1000 texts, and reached the peak at 2000 texts, achieving a precision of 0.75, a recall of 0.64, and an F_1-score of 0.69. In the case of procedures, the model peaked at 1000 synthetic annotated texts, achieving a precision of 0.47, a recall of 0.32, and an F_1-score of 0.38. For 2000 texts, the F_1-score remained the same; however, the precision increased by 0.04 whereas the recall dropped by 0.01.

We have used the annotations made by the second medical expert as validation data to show how the metrics vary with annotation variability. The results showed similar dynamics to the scores shown in Figure 2, although the absolute F_1-scores were slightly lower for procedures (Multimedia Appendix 1).

Discussion

Principal Findings

For the final model trained on different batches of data with annotations made by GPT-4, we found that the best-performing model achieved an F_1-score of 0.69 for the drug and an F_1-score of 0.38 for procedures. The result was achieved with 2000 annotated synthetic texts for drugs and 1000 for procedures. Training the models on more texts did not improve the results. Based on these results, it seems there is a cap on how much one can gain from synthetic data using this method. The downstream model seems to learn the task after 2000 texts, and afterward, adding more data just creates more noise and possibly makes the model overfit on similar synthetic texts.

It is important to note that the interannotator agreement showed an F_1-score of 0.73 for drugs and 0.48 for procedures, which means there is inherently a lot of room for disagreement and subjectivity between the entities. In many instances, the disagreement stemmed from how many prefixes to include for the entity (eg, location of the procedure). This result tells us that achieving a perfect F_1-score is not realistic, as ground truth itself can be subjective and depend on the annotators, further strengthening the achieved result of this paper. The disagreement between the medical experts and the LLM can be somewhat mitigated by providing more clear annotation guidelines for both the medical experts and the LLMs annotating the data.

We found that the most effective prompt for generating accurate annotations for our downstream model was the few-shot approach. Notably, while the texts themselves were in Estonian, prompts provided in English consistently produced more precise annotations compared to prompts written in Estonian. Openly available, multilingual LLMs are known to be heavily trained on English text, as English is vastly overrepresented in publicly available datasets. As a result, the model's understanding of English instructions and its ability to follow them are significantly more robust than for low-resource languages such as Estonian [30,31]. The local Llammas model did not perform as well as the GPT-3.5-Turbo, likely because it is a much smaller model, and parsed only 454 of the responses, meaning in some instances it did not return coherent outputs.

We then found that when comparing the performance of the annotations between GPT-3.5-Turbo, GPT-4, and Llammas, GPT-4 performed better per F_1-score for all cases, which was to be expected, because it is a larger and more powerful model. For procedures and smoking, the GPT-3.5-Turbo model achieved a higher precision; however, in the case of procedure, it was only by 0.01, and in the case of smoking, even though the difference was 0.23, there were only 58 entities in the texts, meaning the difference in results is not very reliable.

Comparison to Prior Work

While our model's results do not surpass standard transformer-based models trained on human-annotated data, which achieve F_1-scores of 0.9 for drugs [8,9] and 0.7 for procedures [8], it is crucial to contextualize this comparison. These prior results are derived from English, a high-resource language with abundant training data. In contrast, our approach demonstrates the efficacy of using synthetically generated data for low-resource languages such as Estonian, without relying on human annotations. Considering that our approach does not use any human-annotated data and the models are all trained on synthetically generated data, a good starting point is to use synthetic data for an initial model that can be used to enrich a model trained on real data or help annotators with their tasks on real-world data.

Future Directions

The pipeline of the method described in this paper consists of many pieces, each with room for improvement. First, both the generation and annotation of synthetic data could be enhanced by leveraging more advanced models. The synthetic texts were generated by GPT-2, but newer model architectures with more parameters could outperform this and generate better data, while more specialized models for clinical texts, such as Me-LLaMA [32] and GatorTron [33], could improve annotation accuracy. Second, we saw a noticeable change in performance depending on the prompt used, suggesting that further prompt engineering could lead to more improvements. Third, human annotators in health care settings typically rely on lengthy annotation guidelines, while in contrast, our method provided only 5 examples. A more detailed description of annotation classes could improve the accuracy of model-generated annotations.

Conclusion

In this paper, we took advantage of powerful LLMs GPT-3.5-Turbo and GPT-4 without risking the privacy of the data by using synthetically generated data. We used these models to annotate the synthetic texts, on which we locally trained a BERT-based NER model for use on real-world data. We obtained an F_1-score of 0.69 for drugs and an F_1-score of 0.38 for procedures, which are impressive, given that the data used were synthetic and without human annotations. We then showcased the difference in performance using GPT-3.5-Turbo and GPT-4 for the task, finding that GPT-4 is substantially better for the task. We also showed how the performance of the model is influenced by the amount of synthetic training data used for training it. Altogether, the proposed method allows for developing NER models while removing the bottleneck of using medical experts for data annotation, automating the process of extracting facts from unstructured data while preserving patient privacy.

Acknowledgments

This research was carried out with the support of the Estonian Research Council grants PRG1844 and PRG1604 and the Optimal Treatment for Patients With Solid Tumours in Europe Through Artificial Intelligence (OPTIMA), which is funded through the IMI2 (Innovative Medicines Initiative 2) Joint Undertaking and is listed under grant agreement 101034347. from the European Union's Horizon 2020 research and innovation program and the European Federation of Pharmaceutical Industries and Associations (EFPIA). This work was also supported by the Estonian Centre of Excellence in AI, funded by the Estonian Ministry of Education and Research, by the European Union and Ministry of Education and Research via project TEM-TA72 and by Nordic Innovation (grant 407-7003-P22026).

Data Availability

The medical texts from the Estonian Biobank were used according to the Estonian Committee on Bioethics and Human Research approval (1.1-12/3797). These data cannot be shared publicly because they may contain identifiable information about the participants. To access these data, official procedures outlined in reference [34] have to be followed. The synthetic data used for annotations can be accessed on a case-by-case basis upon contacting author RK. The code for the pipeline is publicly available in GitHub [35].

Authors' Contributions

HŠ conceived and designed this paper, focusing on the primary idea, concept, experiments, and analysis. ML designed and implemented GPT-2 synthetic data generation and longest common subsequence filtering pipelines. VK did the research on prompt selection, MM and NI provided medical annotations, HAK managed the local Llammas model, and RK supervised the project. All authors—HŠ, ML, VK, MM, NI, HAK, and RK—reviewed and approved the final paper.

Conflicts of Interest

Abstract

Background: Avoiding technological innovation does not simplify life. In fact, using internet-based medical services can enhance the quality of life for older adults. In the context of an aging population and the growing integration of information technology, the demand for internet-based medical services among older adults is gaining increased attention. While scholars have highlighted the important role of intergenerational support in promoting digital inclusion for older adults, research on the relationship between intergenerational support and older adults' intentions to seek online care remains limited.

Objective: This study aims (1) to explore the association between intergenerational support, online medical information, and older adults' intention to seek medical care online, and (2) to examine the mediating role of technology perception and trust, as well as the moderating role of eHealth literacy.

Methods: A cross-sectional survey was conducted in China, collecting 958 valid responses from older adults aged 60 years and above. A vast majority of participants were between the ages of 60 and 75 years (771/958, 80.5%). Of the 958 participants, 559 (58.4%) resided in rural areas, while 399 (41.6%) lived in urban areas. The survey included questions on intergenerational support, perceived usefulness, perceived ease of use, trust, online medical information, eHealth literacy, and the intention to seek medical care online. Structural equation modeling and linear regression analysis were applied to explore the relationship between intergenerational support and the intention to seek medical care on the internet.

Results: Intergenerational support was positively associated with perceived ease of use (β=.292, *P*<.001), perceived usefulness (β=.437, *P*<.001), trust (β=.322, *P*<.001), and the intention to seek medical care online (β=.354, *P*<.001). Online medical information also positively affected the intention to seek medical care online among older adults (β=.109, *P*<.001). Perceived ease of use (β=.029, 95% CI 0.009-0.054), perceived usefulness (β=.089, 95% CI 0.050-0.130), and trust (β=.063, 95% CI 0.036-0.099) partially mediated the association between intergenerational support and the intention to seek medical care online. Further analysis found that perceived ease of use, perceived usefulness, and trust played a chain mediating role between intergenerational support and the intention to seek medical care online (β=.015, 95% CI 0.008-0.027; β=.022, 95% CI 0.012-0.036). Additionally, eHealth literacy played a moderating role in the relationship between intergenerational support and perceived ease of use (β=.177, *P*<.001), perceived usefulness (β=.073, *P*<.05), trust (β=.090, *P*<.01), and the intention to seek medical care online (β=.124, *P*<.001).

Conclusions: An integrated model of health communication effects was constructed and validated, providing empirical support for the intention to seek medical care online and for the impact of health communication. This model also helps promote the role of technology in empowering the lives of seniors.

KEYWORDS

intergenerational support; older adults; internet medical intentions; perceived technology; trust

Introduction

Background

The internet has become an important medium for providing various eHealth services and a source of medical information [1]. Smartphones bring the convenience of telemedicine to users' fingertips [2]. According to the 52nd China Internet Network Information Center report [3], China has 364 million internet medical care users, accounting for 33.8% of all internet users. The number of online hospitals continues to grow, and the development of large-scale online medical care platforms shows strong momentum.

The World Health Organization has encouraged member states to actively use digital technologies to improve medical, health, and social services, thereby promoting active aging [4]. Given that older adults are the primary users of health care services [5], there is significant potential for internet-based medical services to enhance geriatric health. Currently, China's population is aging rapidly [6]. As of the end of 2023, the population of older adults in China (aged ≥60 years) has reached 297 million, accounting for 21.1% of the total population. For older adults, proficient use of technology is key to accessing internet-based medical services [7]. However, digital disparities—such as difficulties in acquiring, operating, and using basic equipment, as well as insufficient knowledge—limit their ability to equally benefit from technological advancements. Given the trend of population aging, the challenge of successfully integrating older adults into the digital health ecosystem has become a pressing issue.

Some prior studies have explored this question, noting that older adults are particularly concerned about the quality and risks of internet-based medical services [8]. Additionally, older adults' habits play an important role in explaining their use of such services [9]. However, further discussion is needed to clarify the complexities and mechanisms that influence older adults' intention to seek medical care online.

Seeking Medical Care Online

Intention to adopt internet-based medical services refers to individuals' subjective beliefs and willingness to seek care through such services when facing health problems [10]. It reflects the importance individuals place on their health, as well as their trust in and reliance on internet-based medical services. This intention is influenced by multiple factors, including disease severity, individual perceptions and attitudes toward the illness, and the quality and availability of health care services.

Examinations of the intention to adopt internet-based medical services currently follow 3 approaches. The first approach is based on the Technology Acceptance Model or the Unified Theory of Acceptance and Use of Technology [11], which assesses user acceptance of online health platforms and the willingness of different population groups to use internet-based medical services [12]. The second approach constructs an analytical model centered on trust within the doctor-patient relationship, focusing on factors such as personal trust preferences and website trustworthiness [13]. The third approach is based on Social Exchange Theory, which examines the physicians' perspectives on the potential impact of interactive tools on their careers [14], as well as how regulatory systems, reputation systems, and communication exchanges shape their motivation to use these services [15].

Examining older adults' access to online health care in greater detail, Mansson et al [16] argued that the use of mobile health (mHealth) apps may reduce treatment costs. However, Askari et al [17] identified several factors influencing older adults' willingness to use mHealth apps, including perceived usefulness (PU), ease of use, social connections, social norms, and anxiety.

Intergenerational Support

Intergenerational Support Theory asserts that the flow of resources among family members is bidirectional [18], encompassing economic, technological, and emotional exchanges [19]. In the context of internet-based medical services, intergenerational support focuses on the technical assistance provided by the children to their parents in using these services.

Perceived ease of use (PEOU) measures older adults' ratings of technology's friendliness versus their beliefs about ease of mastery [20]. However, many older adults are unfamiliar with smartphone operation, are often excluded from various internet services, and are unable to benefit equally from digital technologies [21]. Additionally, they perceive apps as complex [22], resulting in low overall levels of PEOU. The lack of digital literacy and the challenges of aging are significant barriers to older adults' intention to use mHealth technology [23]. In the context of online-based medical services, children can assist older adults by guiding them through the process of using online platforms—such as downloading, registering, finding, and consulting internet-based medical services. They can also help resolve technical issues, thereby reducing frustration [24]. This support will make it easier for older adults to use these services, leading to an increase in their assessment of PEOU. Based on this, the following hypotheses are proposed.

- Hypothesis 1a: Intergenerational support is positively associated with perceived ease of use of internet-based medical services among older adults.

PU reflects older people's views that a particular technology can improve their health care experience. It encompasses their belief that internet-based medical services can meet their health management needs, such as online appointment booking, teleconsultation, and e-prescription flow. Studies have shown that older adults are more likely to adopt technology when they gain insight into its usefulness and potential benefits. Through direct operation or demonstration by children, older adults can independently or semi-independently use the internet-based medical service platform to experience its advantages in simplifying clinical services, saving time and energy for medical

XSL•FO
RenderX

treatment, and enhancing their knowledge and acceptance of the platform. Once older adults experience the tangible benefits of internet-based medical services, it may stimulate positive feedback mechanisms that gradually ease the psychological barriers to adopting new technologies. This, in turn, can enhance psychological adaptation and cognitive health [25], thereby deepening the PU of the internet-based medical service platform.

- Hypothesis 1b: Intergenerational support is positively associated with the perceived usefulness of internet-based medical services for older adults.

Trust typically builds up gradually through continuous and intimate interactions, which can enhance patients' positive expectations [26]. However, many older adults have conservative and negative attitudes toward new technologies and are hesitant to use online services. As a result, it can be challenging for services such as internet-based medical services to gain the trust of older adults [27]. According to Ma et al [28], trust serves as a critical criterion for older adults in identifying individuals who can help them enhance their digital skills. Consequently, the younger generation plays a significant role in building trust and security for older adults. This support also involves a sense of being recognized and respected [29]. We hypothesize that greater intergenerational support is more likely to reduce older adults' unfamiliarity and thus increase their trust in these services.

- Hypothesis 1c: Intergenerational support is positively associated with older adults' trust in internet-based medical service.

According to Li and Kostka [30], social support plays a significant role in affecting older adults' digital engagement. Many older adults who maintain close contact with their families tend to receive more effective support for digital learning and engagement [30]. Additionally, given the importance of filial piety in Chinese culture, adult children are expected to assist disadvantaged family members [31]. This includes providing help and counseling regarding digital access, use, and literacy, as well as facilitating bottom-up technology transfer [32] to help their parents accomplish reverse socialization [33]. As a result, support and feedback can effectively enhance the digital competence of older adults [34] and promote the adoption of new technologies.

- Hypothesis 1d: Intergenerational support is positively associated with older adults' intention to seek medical care on the internet.

Perceived Usefulness and Perceived Ease of Use

As the key elements determining users' behavioral intentions, PU indicates the extent to which using a particular system or operation can improve task performance or achieve a specific goal. PEOU reflects the user's subjective evaluation of the convenience and ease provided by using something [35].

Some studies have shown that the PU of social media affects people's trust in the platform as well as the channel [36]. Acharya et al [37] further found that the PU of recommender systems can directly impact consumers' trust. It has also been confirmed that PEOU is positively correlated with consumer trust [38]. This study suggests, therefore, that older adults may trust internet-based medical services if they perceive them as useful or easy to use.

- Hypothesis 2a: Perceived ease of use is positively associated with older adults' trust in internet-based medical service.
- Hypothesis 2b: Perceived usefulness is positively associated with older adults' trust in internet-based medical service.

Currently, technology perception has been studied in various contexts, such as the adoption of smart home technologies [39] and the willingness to use internet applications [40]. Naidoo and Leonard [41] found that the continued willingness to use e-services is entirely dependent on high levels of PU. Further research indicates that the PU of the internet is an important predictor of an individual's use of eHealth solutions and plays a significant role in patients' sustained use of online health care communities [42]. For older adults, the functions of internet-based medical services are far more complex than simple services such as browsing short videos. Older patients tend to consider using these services only if the transition to new medical treatments is easy [43]. This study therefore argues that older adults are more likely to use internet-based medical services if they perceive them to be useful or easy to use.

- Hypothesis 3a: Perceived ease of use is positively associated with older adults' intention to seek medical care on the internet.
- Hypothesis 3b: Perceived usefulness is positively associated with older adults' intention to seek medical care on the internet.

Trust

Schoorman et al [44] suggested that trust in internet-based medical services is the tendency for people to believe that these services can fulfill their health needs and to be willing to use them, reflecting the level of acceptance for such services [45]. Trust is a crucial factor for assessing users' willingness to use internet-based medical services [46], and establishing trust improves the likelihood of older adults using these services [47]. This study therefore suggests that older adults who trust internet-based medical services are more likely to be willing to access such services. We therefore propose the following hypothesis:

- Hypothesis 4: Trust is positively associated with older adults' intention to seek medical care on the internet.

Online Medical Information

Online medical information—encompassing all types of medical-related content delivered and shared through internet platforms such as search engines, medical websites, and online forums—is highly sought after. The causes and treatments of diseases are among the most popular topics for medical information searches [48]. Notably, 60% of individuals view online medical information as equally good or better than information provided by physicians [49]. Online medical information enhances the efficiency of medical knowledge dissemination and is rapidly replacing traditional approaches for seeking advice and information [50]. It helps to improve individuals' knowledge, promote disease prevention, and

XSL•FO
RenderX

facilitate access to appropriate medical services. To pursue more informed health decisions [51], older adults often seek health-related medical information online, which influences their health behaviors [52]. Consequently, older adults may be motivated to seek guidance from physicians practicing online [53]. The following research hypothesis is therefore proposed:

- Hypothesis 5: Online medical information is positively associated with older adults' intention to seek internet-based medical services.

eHealth Literacy

eHealth literacy refers to the ability needed to access, understand, and evaluate health information from digital resources and make informed health decisions [54]. It encompasses active information-seeking, 2-way interactive communication, and information utilization/sharing [55]. Although older adults are increasingly relying on the internet to access health-related services, they often struggle to meet the necessary eHealth literacy requirements [56]. Families play an important role in promoting eHealth literacy among older adults [57]. By strengthening intergenerational support, they can help older adults better learn and apply new technologies. When confronted with a complex internet health care delivery system, families can assist in quickly getting up to speed and becoming proficient in its operation. At this level, internet health care services are easy to use. At the same time, families can help older adults obtain rich health information from the platform [58] and manage their daily health needs, which can enhance their perception of the usefulness of these services. Therefore, we propose the following:

- Hypothesis 6a: eHealth literacy positively moderates the relationship between intergenerational support and perceived ease of use.
- Hypothesis 6b: eHealth literacy positively moderates the relationship between intergenerational support and perceived usefulness.

A study found that social interaction, access to technology, and digital literacy are positively correlated. With the assistance of their children, older adults can significantly improve their ability to access, understand, and apply digital health information [59]. High levels of eHealth literacy can increase older adults' confidence and ability to assess the reliability and validity of internet-based health care services, thereby enhancing their trust in such services.

- Hypothesis 6c: eHealth literacy positively moderates the relationship between intergenerational support and trust.

According to Health Empowerment Theory, eHealth literacy and social support can promote self-care behaviors among older adults [60]. The findings of Hsu et al [61] further indicate that individuals with higher levels of eHealth literacy have a greater potential to make informed health choices, improved health care competence, and ultimately higher quality of life. Therefore, we propose the following:

- Hypothesis 6d: eHealth literacy positively moderates the relationship between intergenerational support and intention to seek medical care on the internet.

Methods

Data Collection and Participants

In this study, a questionnaire (Multimedia Appendix 1) was used to validate the research model. To ensure reliability and validity, all items were borrowed from well-established domestic and international scales and adjusted according to the theme of internet medical care. The questionnaire comprises a total of 7 latent variables, involving 24 items, all measured on a 7-point Likert scale. Before the official survey, a presurvey was conducted with 50 older adults to ensure a high degree of internal consistency. Based on their feedback, questions with ambiguities or semantic problems were adjusted.

Between March 20, 2024, and March 31, 2024, we officially launched the distribution of the questionnaire using a combination of online and offline methods. This approach ensures that the data (Multimedia Appendix 2) collected are broad and representative, providing a more comprehensive understanding of the attitudes and needs of older adults regarding the use of the internet for health care services. The study was conducted among individuals aged 60 years and older who had autonomous behavioral skills and some experience with internet use, encompassing both rural and urban areas. Those who lacked basic knowledge of the internet or were unable to participate due to daily activities or cognitive limitations were excluded.

Online questionnaires offer the advantages of low cost, autonomy, and comprehensive documentation, as well as the ability to effectively expand the range of respondents. In this study, an online self-report questionnaire was designed using Questionnaire Star (Changsha Ranxing Information Technology Co., Ltd.). The questionnaire was distributed through a convenience sample with a snowball approach. An online survey link was shared across various social media platforms and WeChat (Tencent Holdings Limited) app groups, where participation was voluntary. This approach covered older adult groups from regions such as Chongqing, Hunan, Guizhou, and Zhejiang, among others. To address the unfamiliarity of some older adults with the operation of the Questionnaire Star and the limitation of their text reading comprehension ability, this study required them to complete the questionnaire in the presence and under the guidance of their middle-aged or young relatives or friends. This approach ensured the accuracy and reliability of the data by providing assistance with understanding and navigating the questions.

Although many older people already have smart devices, they may be wary of clicking on a link to participate in an online questionnaire. Therefore, face-to-face interviews are particularly necessary. In the offline questionnaire survey, we adopted a dual strategy: on the one hand, the research team personally visited communities and villages in Chongqing and Hunan, directly communicating with older adult groups through on-site visits to ask them in detail about their willingness to use internet health care services. On the other hand, with the support of governmental agencies where the researchers are domiciled, we commissioned local staff to assist in distributing some of the questionnaires. For the older adults interviewed who had the

XSL•FO
RenderX

ability to write, we asked them to fill in the questionnaire themselves; for patients who were unable to fill in the questionnaire by themselves, their primary caregiver or interviewer filled in the questionnaire on their behalf. The questionnaires were collected on-site after completion.

During the data collection phase, a total of 1200 questionnaires were collected. After eliminating invalid questionnaires (including online questionnaires that took less <90 seconds to complete, failed the honesty test, had missing values, or provided the same answer to all questions, as well as offline questionnaires that were obviously invalid, such as choosing "strongly agree" for all of them), a total of 958 valid questionnaires were ultimately obtained for an effective response rate of 79.8%.

Measurements

Intergenerational Support

The measurement items for this dimension were derived from Lang and Schütze's study [62] and consisted of 3 items. It was measured with good reliability (α=.887) [63]. This factor collectively explained 81.6% of the variance (Kaiser-Meier-Olkin [KMO]=0.748). Specific items included "My children encourage me to seek medical care on the internet, and I am willing to try it," "My children guide I would be willing to try," and "When I have problems with internet health care, my children help me solve the problem, so I would be willing to try it."

Online Medical Information

Based on a study by de Boer et al [64], 4 items were used to measure the medical information that older adults sought online. The measurement items included "I would search for medical information on the internet" and "Online medical information has taught me something about health." The results of factor analysis for the 4 items showed a KMO value of 0.843, with the factor explaining a total of 76.2% of the variance; these items also had good reliability (α=.895).

Trust

This dimension is based on the studies by Fogel and Nehmad [65] and Deng et al [66] and consists of 3 items. Specific items included "Most of the doctors on the online medical service platforms are health experts in their fields, and I have no doubt about their professionalism" and "Generally, I trust the health advice or tips from doctors on the internet." The overall performance of these items indicated good reliability (α=.868); this factor collectively explained 79.2% of the variance (KMO=0.735).

Perceived Ease of Use

The 5 items were based on the study by Deng et al [66]. Typical items include "I don't think it is difficult to use the internet for health counseling" or "In general, I think internet health care is easy to use." The results of factor analysis for the 3 items showed a KMO value of 0.885, explaining a total of 72.7% of the variance. The 5 items showed good reliability (α=.906).

Perceived Usefulness

The items for this factor were based on those in the study by Deng et al [66]. The items included "I believe that using the internet for medical care can improve the efficiency of health care" and "Overall, I think online medical care is useful for health management." The results of the analysis showed a KMO value of 0.746, explaining a total of 81.7% of the variance, and good reliability (α=.888).

Intention to Seek Medical Care on the Internet

These 3 items referred to the study by Deng et al [66]., including "When I face health problems, I think I will solve them through internet health care" and "I am willing to use internet health care services for health counseling, such as disease control." These analyses showed a KMO value of 0.751, explaining a total of 82.8% of the variance; all 3 items also had good reliability (α=.895).

eHealth Literacy

This dimension combines health and media literacy and references the study by Norman and Skinner [67]. The 3 items included "I know how to find useful health resources and messages online" or "I know how to use the health care-type information I find on the internet to help myself," with 82.6% variance explained, a KMO value of 0.751, and good reliability (α=.894).

All 24 items were rated on a 7-point Likert scale (1=strongly disagree, and 7=strongly agree). All measurement items can be found in Table S1 in Multimedia Appendix 3.

Data Analysis

Cronbach α was used to determine the reliability of the scales. Construct validity and reliability were examined using exploratory factor analysis with varimax rotation, Bartlett test, and KMO statistics, as well as confirmatory factor analysis (CFA).

For the analysis of structural equation modeling, Amos 26.0 (IBM Corp.) was used to analyze the data and the effect of the model was measured by the fit indices, which included chi-square/degree of freedom (χ^2/df), the goodness of fit index (GFI), the adjusted goodness of fit index (AGFI), the incremental fit index (IFI), the comparative fit index (CFI), the nonnormed fit index (NNFI), and root mean square error of approximation (RMSEA). Additionally, the bootstrap method was used to test the mediation model with 5000 iterations of repeated sampling. Results were also obtained using SPSS 26.0 (IBM Corp.) to test for interaction effects.

Ethical Considerations

Ethical approval for this study was obtained from the academic committee (acting as the ethics committee) of the School of Journalism and Communication at Chongqing University (approval number 20240320). Informed consent was obtained from all participants before their participation in the survey. Participants were provided with a detailed informed consent form outlining the purpose of the study, the duration of the investigation, the procedures, and the potential risks and benefits. They were informed that their participation was

XSL•FO
RenderX

voluntary and that they had the right to withdraw at any time without facing any negative consequences. Participants were assured of the confidentiality and anonymity of their responses.

Results

Participant Characteristics

The sample demographics are as follows: of the 958 participants, 771 (80.5%) were between the ages of 60 and 75 years, 511 (53.3%) were females, and 447 (46.7%) were males. In terms of residential area, 559 (58.4%) participants resided in a rural area and 399 (41.6%) in an urban area. Most participants (812/958, 84.8%) had between 1 and 3 children, about one-quarter (214/958, 22.3%) of the participants reported an education level of high school and above, nearly half (440/958, 45.9%) rated their self-assessed health status as fair, and 186 (19.4%) rated it as poor or very poor. Detailed demographic information is presented in Table 1.

Structural Model

The CFA model was fit to the data (Table S2 in Multimedia Appendix 3): χ^2_{231}=525.021, GFI=0.958, AGFI=0.945, IFI=0.980, CFI=0.980, NNFI=0.976, and RMSEA=0.036. The model fit appeared to be good, and all items met the criteria proposed by Hu and Bentler [68] and Kline [69].

According to Bagozzi and Youjae [70] and Hair [71], composite reliability (ρ)≥0.60 and average variance extracted ≥0.50 indicate good internal consistency and convergent validity. We therefore used composite reliability to measure the reliability of the constructs, with the following results: intergenerational support=0.887, online medical information=0.896, trust=0.869, PU=0.888, PEOU=0.906, eHealth literacy=0.894, and intention to seek medical care on the internet=0.896. As shown in Table S3 in Multimedia Appendix 3, the factor loadings for all question items were greater than 0.60. Convergent validity was assessed using the average variance extracted, which yielded the following values: 0.723 for intergenerational support, 0.684 for online medical information, 0.690 for trust, 0.726 for PU, 0.659 for PEOU, 0.739 for eHealth literacy, and 0.742 for intention to seek medical care on the internet. These results indicate good convergent validity. As shown in Table S4 in Multimedia Appendix 3, the square root of the average variance extracted for each construct is greater than the correlation coefficients between the variables, indicating good discriminant validity [72].

Based on the final CFA model, a full structural equation modeling was conducted to test the hypotheses. The model fit indices (Table S5 in Multimedia Appendix 3) were as follows: χ^2_{179}=498.30, GFI=0.954, AGFI=0.940, IFI=0.975, CFI=0.975, Tucker-Lewis Index=0.971, and RMSEA=0.043. These indices indicate a good model fit, and the structural equation modeling approach allowed the constructed and hypothesized model to be tested in a more satisfactory manner.

Association of Intergenerational Support and Other Variables and Intention to Seek Medical Care on the Internet

Table 2 shows the results of the path analysis. Intergenerational support was positively associated with PEOU, PU, trust, and older adults' intention to seek medical care on the internet (β=.292, *P*<.001; β=.437, *P*<.001; β=.322, *P*<.001; and β=.354, *P*<.001, respectively); therefore, hypotheses H1a, H1b, H1c, and H1d were supported. PEOU and PU were positively associated with older adults' trust in internet-based medical services (β=.263, *P*<.001 and β=.261, *P*<.001, respectively), supporting H2a and H2b. PEOU and PU were also positively correlated with older adults' intention to seek medical care on the internet (β=.099, *P*=.002 and β=.204, *P*<.001, respectively), supporting H3a and H3b. Trust was positively correlated with older adults' intention to seek medical care on the internet (β=.197, *P*<.001), supporting H4. Online medical information was also positively correlated with older adults' intention to seek medical care on the internet (β=.109, *P*<.001), supporting H5.

SMCI ← OMI[f]	0.109	0.034	3.781	<.001

[a]IS: intergenerational support.

[b]PEOU: perceived ease of use.

[c]PU: perceived usefulness.

[d]SMCI: intention to seek medical care on the internet

[e]T: Trust

[f]OMI: online medical information.

Table 3 shows the mediating relationship between PU, PEOU, and trust. The total effect value of the relationship between intergenerational support and willingness to use internet-based medical services was 0.573, while the direct effect value was 0.354. Both had a positive 95% CI and a *P* value of less than 0.05, indicating that the total and direct effects were significant. The indirect effect of trust was 0.063 (95% CI 0.036-0.099). More specifically, trust partially mediated the association between intergenerational support and older adults' willingness to use internet-based medical services. PEOU, PU, and trust also played a chain mediating role between intergenerational support and willingness to use internet-based medical services, with specific mediation effect sizes of 0.015 and 0.022, respectively. The 95% CI for the PEOU path was 0.008-0.027, and for the PU path, it was 0.012-0.036. The *P* values for both chain mediation paths were less than 0.05, suggesting that intergenerational support can enhance PEOU and PU among older adults. This, in turn, enhances trust, which subsequently increases the willingness to use internet-based medical services.

RenderX

Table 3. Total, direct, and indirect effects.[a]

Mediation effect and path	Estimate	95% CI	*P* value
Total effect			
IS[b] → SMCI[c]	0.573	0.509-0.632	<.001
Direct effect			
IS → SMCI	0.354	0.278-0.428	<.001
Indirect effect			
IS → T[d] → SMCI	0.063	0.036-0.099	<.001
IS → PEOU[e] → SMCI	0.029	0.009-0.054	0.005
IS → PU[f] → SMCI	0.089	0.050-0.130	<.001
IS → PEOU → T → SMCI	0.015	0.008-0.027	<.001
IS → PU → T → SMCI	0.022	0.012-0.036	<.001

[a]Standardized estimation of 5000 bootstrap samples.

[b]IS: intergenerational support.

[c]SMCI: intention to seek medical care on the internet.

[d]T: trust.

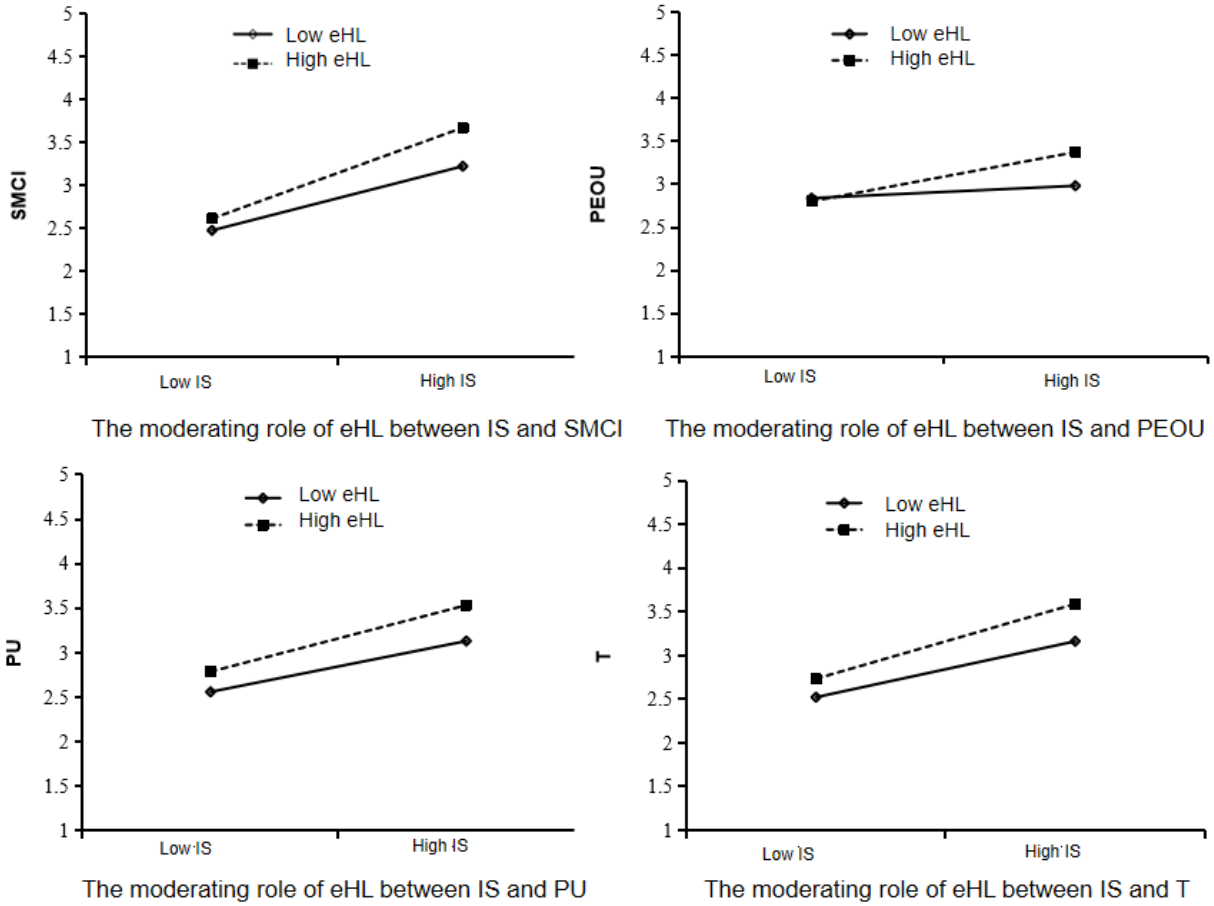
[e]PEOU: perceived ease of use.

[f]PU: perceived usefulness.

Table 4 shows the moderating relationships of eHealth literacy. The interaction term between intergenerational support and eHealth literacy was a significant positive predictor of PEOU (β=.177, *P*<.001) and PU (β=.073, *P*=.018). This suggests that eHealth literacy moderates the effect of intergenerational support on PEOU and PU, thereby supporting H6a and H6b. The interaction term between intergenerational support and eHealth literacy was a significant positive predictor of trust (β=.09, *P*<.01), suggesting that eHealth literacy moderates the effect of intergenerational support on trust, thus supporting H6c. The interaction term between intergenerational support and eHealth literacy had a significant positive predictive effect on the intention to seek medical care on the internet (β=.124, *P*<.001). This indicates that eHealth literacy moderates the influence of intergenerational support on the intention to seek medical care on the internet, thereby supporting H6d. A further simple slope analysis was then conducted (Figure 1). The slope was shallower when eHealth literacy was low (solid line) and steeper when eHealth literacy was high (dashed line). This suggests that intergenerational support was a more significant positive predictor of the intention to seek medical care on the internet, PEOU, PU, and trust at high levels of eHealth literacy.

Table 4. Moderated effect.

Path	Intention to seek medical care on the internet, β (*P* value)	Perceived ease of use, β (*P* value)	Perceived usefulness, β (*P* value)	Trust, β (*P* value)
Intergenerational support	.447 (<.001)	.183 (<.001)	.337 (<.001)	.389 (<.001)
Electronic health literacy[a]	.15 (<.001)	.094 (.002)	.167 (<.001)	.173 (<.001)
IS[b] × eHL[c]	.124 (<.001)	.177 (<.001)	.073 (.018)	.09 (.003)



[a]Electronic health literacy was used as a moderating variable in the model after controlling for the variables age, gender, education, residential status, occupation now or before retirement, monthly income, urban /rural, number of children, self-assessed health status.

[b]IS: intergenerational support.

[c]eHL: eHealth literacy.

Figure 1. Simple slope plot. eHL: eHealth literacy; IS: intergenerational support; PEOU: perceived ease of use; PU: perceived usefulness; SMCI: intention to seek medical care on the internet; T: trust.

Discussion

Principal Findings

Older people are often referred to as digital refugees [73]. A lack of digital skills may contribute to the risk of widening health disparities and unequal access to services [74]. Studies have shown that many older individuals face numerous barriers to using smartphones, often due to a lack of knowledge about apps and their features [75] and technology anxiety [76]. Most older adult patients are also accustomed to face-to-face outpatient services, making the adoption of internet-based health care not easily achievable for this population. Although the digital divide hinders active aging by reducing the social participation, as well as the physical and mental health, of older adults [77], the active bridging provided by intergenerational support helps older adults overcome their fears, improve their digital skills, and enhance their sense of well-being and accessibility. This, in turn, facilitates their integration into the digital age by fostering a positive and optimistic mindset that promotes effective active aging [78].

Intergenerational support to address the technical aspect occurs when children explain to older adults how to operate the online medical platform, help them understand error messages, and provide tips on various operations such as registration, logging in, booking appointments, and online counseling [79]. This support involves not only technical guidance but also spiritual care and comfort. This kind of benign emotional exchange can promote older people's perception of satisfaction, enhancing their acceptance of new technologies. Therefore, online medical care with intergenerational support is not only a reflection of filial piety but also an endorsement of positive intergenerational relationships. Children's counseling and assistance can improve the cognitive abilities [80] and overall health awareness of older adults, alleviate their fear of technology, reduce digital loneliness, and strengthen their confidence in using internet-based medical services.

The results of this study show that the higher the level of intergenerational support, the greater the PEOU and usefulness of internet health care platforms among older adults, which in turn enhances their willingness to access these services. Through the help and guidance of family members, older adults are able to master internet technologies more quickly and effectively utilize these tools for health management. This support not only increased older adults' PEOU of internet-based health care services but also boosted their confidence and security, leading to a greater willingness to try and use these services. In addition, this support implies encouragement and companionship on an emotional and psychological level [81]. When older adults feel the concern and attention from their family members or later generations regarding their health problems, and the possibility of obtaining a convenient and professional health care experience through internet health care services, they are more likely to develop positive psychological expectations that these services are valuable and can practically solve their health issues [82]. This positive cognitive shift directly enhances older adults'

XSL•FO
RenderX

acceptance of and reliance on internet health care services, thereby strengthening their willingness to seek medical care.

There is also a transformational path between social support factors that generate the intention to adopt internet-based medical services; trust mediates between intergenerational support and the intention to adopt internet-based medical services. Trust, in this context, refers to the extent to which an individual relies on an internet-based medical service to meet health management needs [83], encompassing aspects such as the professionalism of the health care service, platform security, and a positive user experience. Cao et al [84] suggested that mistrust is a common reason for digital disengagement and that trust is crucial for an individual's ongoing behavior when using information technology. This is also true in the internet-based medical service environment [85]. Studies have shown that the realization of internet-based medical services is divided into 2 phases: first, patients develop perceptions about the technical aspects of the health care platform, including its functionality, usefulness, and convenience [86]; second, patients evaluate the trustworthiness of the care provided and the service process [87]. Strong behavioral intentions only occur if older adults have a positive perception of the trustworthiness of the care.

Based on previous studies, this study further clarifies the influence of intergenerational support on older adults' intention to adopt internet-based medical services. It constructs and validates an integrated model of the effect of health communication: intergenerational support → PEOU → PU → trust → intention to adopt internet-based medical services. As a new approach to medical care, internet-based medical services improve convenience and efficiency. With intergenerational support, older adults perceive the technical aspects (PEOU and PU) of these services more positively. This, in turn, enhances their trust and intention to use internet-based medical services, facilitating the integration of online care into health care.

Intergenerational support had a greater effect on the willingness of older adults to use internet-based medical services among those with high eHealth literacy. According to Jung et al [55], eHealth literacy enhances older adults' ability to manage health-related issues effectively. Health literacy has also been positively associated with help-seeking intentions [88], older adults' choice of physician, and their understanding of the physician's recommendations [89]. Older adults with high eHealth literacy are thus more likely to have a higher intention to seek medical care on the internet when they receive support from their children and are more likely to participate in internet-based medical services actively for a better health care experience [90].

Previous studies have shown that PU and trust in online medical information [91] can improve eHealth literacy. However, this study demonstrated that the degree of intergenerational support for perceived technology, as well as trust in internet-based medical services, is deeper when older adults have higher eHealth literacy. According to Nie et al [92], people with higher eHealth literacy better assess the usefulness of searching for health information online. However, it may be that eHealth literacy increases older adults' interest in health, their knowledge, and their expectations of health care [93] while inducing confidence and a sense of the efficacy of internet-based medical services.

Much of the health and medical information provided by internet-based medical service platforms originates from authoritative health care institutions and professionals, ensuring a high degree of accuracy. These platforms can support long-term disease management and health monitoring [94], allowing older people to access the health information they need. Bundorf et al [95] argued that this shift to searching for medical information online has obvious impacts on health behaviors as well as on treatment choices [96], improving older adults' health beliefs and motivating them to engage in healthy activities [97]. There is also evidence that online medical information not only encourages self-initiated participation in health care [98] but also increases the likelihood that older adults will take an active role in disease management. It is thus reasonable to believe, based on the present results, that online medical information can play an active role in disease management and increase the willingness of older adults to use internet-based medical services.

Limitations

Although this study initially verified the proposed theoretical model, certain limitations remain. First, the study focused exclusively on the PEOU and PU of internet-based medical services, leaving other related perceptions (eg, risks and benefits) unexplored. Moreover, it considered only the factors influencing older adults' willingness to use internet-based medical services, without addressing motivation, sustained willingness to use, or actual usage. Finally, this study examined only the influence of the core variable of intergenerational support. Other factors, such as peer influence, social influence (eg, doctors' recommendations), and subjective norms, could be explored in greater depth and incorporated into models in future research.

Implications

Examining technology use among older adults is also a valuable starting point for addressing the range of social issues associated with aging [99]. This study's focus on the needs of older adults regarding internet-based medical services, as well as their intentions to use such services, offers constructive insights for improving health equity and enhancing the inclusiveness and equity of internet-based medical services in particular [100]. Perceptions of and trust in technology are crucial factors in facilitating older adults' adoption of internet-based medical services. Efforts to encourage older adults to use these services may first need to ensure that they recognize such services as not only useful and easy to use but also trustworthy.

Medical institutions and internet-based medical platforms can take the following measures: in platform design, they should fully consider the characteristics and needs of older adults, implement age-adapted designs, lower the barriers to use, and create an age-friendly online environment. Additionally, medical institutions and platforms must establish a highly credible environment by ensuring transparency in the treatment process and maintaining honesty and openness with patients. Protecting the personal information of older adults and preventing data

XSL•FO
RenderX

breaches are essential to enhancing their confidence in using internet-based health care services.

Furthermore, the role of intergenerational support in enhancing older adults' intention to seek medical care online must be emphasized. This highlights the importance of understanding the barriers older adults may face when using internet-based medical services, as well as the critical role children/young adults can play in facilitating the adoption of new technologies by older generations.

Within families, the younger generation should take the initiative to help older adults adapt to digital technology by offering emotional support and technical guidance while leveraging the advantages of the internet for health management.

The use of internet-based medical services by older adults holds significant value for management. First, it improves management efficiency. Internet-based medical services simplify traditional medical processes, enhancing hospital management efficiency. These platforms can allocate medical resources more effectively based on the health status and needs of older adults, optimizing resource utilization. Second, it fosters an innovative service model. Internet-based medical platforms can leverage technologies such as big data and artificial intelligence to deliver more precise medical services. Additionally, they can collaborate with other industries, such as care services for older adults, to innovate and expand service models. Third, it facilitates policy implementation. As a platform for policy dissemination, internet-based medical services can help raise awareness among older adults about national health and pension policies, thereby supporting the effective implementation of these policies. Fourth, it reflects social value. Internet-based medical services address the health needs of older adults, demonstrating social care and respect for older adults. This contributes to the transformation and upgrading of the national health care industry, ultimately improving the overall quality of medical services.

Conclusions

Population aging is a long-term national issue in China, and the availability of medical services is directly linked to the quality of life for older adults. This study provides evidence that intergenerational support is a key factor in promoting the adoption of internet health care services by older adults. Encouraging children to offer guidance and assistance to their parents is essential. To increase older adults' willingness to use internet health care, future efforts should focus not only on intergenerational support but also on improving the PEOU and usefulness of the technology, building trust, and fostering eHealth literacy among older adults.

Abstract

Background: The idea of making science more accessible to nonscientists has prompted health researchers to involve patients and the public more actively in their research. This sometimes involves writing a plain language summary (PLS), a short summary intended to make research findings accessible to nonspecialists. However, whether PLSs satisfy the basic requirements of accessible language is unclear.

Objective: We aimed to assess the readability and level of jargon in the PLSs of research funded by the largest national clinical research funder in Europe, the United Kingdom's National Institute for Health and Care Research (NIHR). We also aimed to assess whether readability and jargon were influenced by internal and external characteristics of research projects.

Methods: We downloaded the PLSs of all NIHR National Journals Library reports from mid-2014 to mid-2022 (N=1241) and analyzed them using the Flesch Reading Ease (FRE) formula and a jargon calculator (the De-Jargonizer). In our analysis, we included the following study characteristics of each PLS: research topic, funding program, project size, length, publication year, and readability and jargon scores of the original funding proposal.

Results: Readability scores ranged from 1.1 to 70.8, with an average FRE score of 39.0 (95% CI 38.4-39.7). Moreover, 2.8% (35/1241) of the PLSs had an FRE score classified as "plain English" or better; none had readability scores in line with the average reading age of the UK population. Jargon scores ranged from 76.4 to 99.3, with an average score of 91.7 (95% CI 91.5-91.9) and 21.7% (269/1241) of the PLSs had a jargon score suitable for general comprehension. Variables such as research topic, funding program, and project size significantly influenced readability and jargon scores. The biggest differences related to the original proposals: proposals with a PLS in their application that were in the 20% most readable were almost 3 times more likely to have a more readable final PLS (incidence rate ratio 2.88, 95% CI 1.86-4.45). Those with the 20% least jargon in the original application were more than 10 times as likely to have low levels of jargon in the final PLS (incidence rate ratio 13.87, 95% CI 5.17-37.2). There was no observable trend over time.

Conclusions: Most of the PLSs published in the NIHR's National Journals Library have poor readability due to their complexity and use of jargon. None were readable at a level in keeping with the average reading age of the UK population. There were significant variations in readability and jargon scores depending on the research topic, funding program, and other factors. Notably, the readability of the original funding proposal seemed to significantly impact the final report's readability. Ways of improving the accessibility of PLSs are needed, as is greater clarity over who and what they are for.

Introduction

In recent years, the idea that science should involve and be accessible to nonscientists has grown. Activities such as patient and public involvement, citizen science, open science, and research coproduction represent different facets of this development and are grounded in both practical and normative motives [1-7]. In health research, one aspect of this involves writing a plain language summary (PLS), sometimes also called a "plain English summary" or lay summary. PLSs are short summaries of a study or project intended to increase its accessibility to nonspecialists. Many regulatory agencies and research funders now require them. For example, the European Union requires a PLS as part of the reporting of all clinical trials [8], and PLSs must be included in all systematic reviews published in the Cochrane Library [9] and all proposals submitted to funders such as the Medical Research Council and the National Institute for Health and Care Research (NIHR), the 2 major state-backed funders of health research in the United Kingdom.

There is evidence to suggest that PLSs do not improve accessibility to the extent we might hope. For example, patients enrolled in clinical trials often have a partial or incorrect understanding of the trial in which they are participating, such as its risks and benefits, despite requirements that they be informed about these issues [10-12]. Pharmaceutical and other industry groups have proposed standards for the preparation of PLS [13-15]. Existing guidelines on how to write a PLS vary and are sometimes contradictory [16] but often highlight issues around readability and avoidance of jargon [17]. Studies of how research findings are disseminated to nonspecialists usually focus on potential users of research and what they need to do to understand research better rather than on examining how characteristics of researchers and research settings influence dissemination to nonacademic audiences [18,19]. Like those who develop public health guidelines, researchers may emphasize internal validity (confidence in the reliability of the results) over external validity (whether and how the results can be applied in other places) [20]. Studies of public health researchers [21] and dissemination and implementation researchers [22,23] found that the context in which research is funded and conducted influences efforts to communicate it to nonspecialists, but we are aware of no studies comparing across fields or subfields. More knowledge about how different characteristics of research influence attempts to communicate the research could help improve communication in the future.

Our aim was to assess the readability and level of jargon in the PLSs of research funded by the United Kingdom's NIHR. The NIHR is the largest single funding body in the United Kingdom and the largest national clinical research funder in Europe [24]. Full reports of all projects funded in its major research programs are published on the web. Since 2014, it has been obligatory for these to include a PLS that sets out a clear, simple summary of research in a way that is accessible to nonspecialists and members of the public. NIHR guidance for researchers on PLSs [25] is that they should follow "a few simple rules" that include "avoid, wherever possible, jargon, abbreviations, and technical terms," "avoid complicated language or uncommon words," and "keep sentences short." In this study, we addressed 3 questions about these PLSs: How readable are they? How much jargon do they contain? Are readability and use of jargon influenced by study characteristics such as topic and size?

Methods

Overview

Our data came from all NIHR Journals Library reports published from mid-2014, when the requirement for inclusion of a PLS was introduced, to mid-2022 (May 30). We downloaded the full text of each report from the NIHR website, where they are publicly available [26]. We then used a purpose-written computer program (written in the computing language called Python) to go through each text and find the PLSs. In a few instances, we could not process the reports in this way, in which case we looked up the PLS manually. We had complete data on 1241 PLSs that were part of reports published in the NIHR Journals Library. Apart from 5 reports that did not have a PLS, we included all the reports published during this period.

Ethical Considerations

Our study was based on open-access data related to academic publications and we did not engage directly with the individuals or groups making or receiving these publications. As such, our study was exempt from ethical review as per the terms of the authors' institutional ethics policy and framework (University of Exeter Research Ethics Policy and Framework, Paragraph 4.3.1).

Outcome Variables

We measured readability using the Flesch Reading Ease (FRE) formula. The FRE is often used in analyzing written health information [27] as well as other scientific texts [28,29] and is based on the idea that longer words and longer sentences make a text less readable. Each text is given a score that gets lower in proportion to the number of longer words and sentences used, so a higher score indicates a text that is easier to read. The formula is as follows:

FRE scores can be categorized as "extremely easy," "very easy," "fairly easy," and so on, down to "very difficult," as well as by approximate reading age (Table 1). We used a short prewritten computer program [30] to calculate readability scores for each PLS. In the rest of this document, when we refer to readability scores, we mean FRE scores calculated in this way.

XSL•FO
RenderX

Table 1. Distribution of summaries by Flesch Reading Ease score classification.

	Approximate reading age (years)	Difficulty	Values, n (%)
Readability score			
≥100	Up to 10	Extremely easy	0
90-100	11	Very easy	0
80-90	12	Easy	0
70-80	13	Fairly easy	3 (0.2)
60-70	14-15	Plain English	32 (2.6)
50-60	16-18	Fairly difficult	169 (13.6)
30-50	Undergraduate: 18-21	Difficult	768 (61.9)
0-30	Postgraduate: ≥21	Very difficult	269 (21.7)

We measured jargon using a calculator called the "De-Jargonizer." It was created to help scientists engage with the public, and it identifies jargon based on the frequency with which words appear in everyday English usage. The developers of the calculator analyzed more than 90 million words used in around 250,000 papers on the British Broadcasting Corporation websites (including news, sports, and science pages) [31] during the years 2012-2015. Based on existing work about how commonly words are used and understood in everyday communication, they categorized the words into high frequency (belonging to the 2000 most common word families, which each appeared more than 1000 times), mid-frequency (appearing between 50 and 1000 times), and jargon (fewer than 50 appearances). Acronyms, which can often be part of jargon, are treated the same way as words, which means that common acronyms such as NHS (National Health Service) or USA (United States of America) fall into the "high frequency" category. Full details of how the calculator was put together, including testing and validation, have been published [32], and a web-based version of the calculator contains a description and additional details [33].

The developers of the calculator also created a score to indicate how suitable a text was for a general audience. If a text uses only common words, the score is 100; lower scores indicate more use of mid-frequency and jargon words. The score is calculated using this formula:

We downloaded the source code [34] for the calculator and used it to work out a jargon score for each PLS. A higher score means that less jargon was used.

We created additional outcome variables to identify PLSs that were better in terms of readability and jargon. For readability scores, we focused on summaries with scores of >50: those classed as "fairly difficult to read" or better. A total of 204 summaries (16.4%, 204/1241) fell into this category. The starting point of this study related to the average reading age in the United Kingdom (see the "Patient and Public Involvement" section). We created an outcome variable showing whether a readability score was suitable for a reading age of 9 years—that is, a readability score of 100 or above (Table 1). However, no summaries fell into this category. Rakedzon and colleagues [32] refer to 2 levels of jargon (2% or 5%) as "recommended for general comprehension." We used the more generous 5% score and categorized scores of more than 95 as having low levels of jargon. A total of 269 (21.7%, 269/1241) summaries fell into this category. Multimedia Appendix 1 shows examples of PLSs with high and low readability and jargon.

Study Characteristics

We used the following information relating to each PLS in our analyses:

1. Research topic: NIHR classifies all research projects using the UK Clinical Research Collaboration Health Research Classification System. This is a system for categorizing health research funding and is used to allow funders and others to assess funding schemes [35]. We used the Health Categories dimension of the Health Research Classification System, which groups each project into 1 or more of 21 categories. In our analysis, we included categories if they had at least 50 projects associated with them, which left us with 12 categories: cancer and neoplasms, cardiovascular, infection, mental health, metabolic and endocrine, musculoskeletal, neurological, oral and gastrointestinal, reproductive health and childbirth, respiratory, stroke, and "generic health relevance."
2. Funding program: Reports published in the National Journals Library relate to 5 NIHR funding programs: Efficacy and Mechanism Evaluation, Health Technology Assessment, Health and Social Care Delivery Research, Programme Grants for Applied Research, and Public Health Research. Of these, the Efficacy and Mechanism Evaluation program is generally considered most "upstream" (closer to basic than applied science), and the Health and Social Care Delivery and Public Health Research programs are most "downstream" (most applied). Details of all NIHR programs are available on the web [36].
3. Project size: We wanted to know whether the size of a project made a difference to the PLS, and we used the amount of funding as an approximate measure for this. Smaller projects tend to be more focused and contained; larger projects may have more resources to move around and support activities such as public engagement (which does not necessarily mean that a "better" PLS will be produced). We categorized projects by size by ranking them

XSL•FO
RenderX

in terms of the amount of funding received and then sorting them into 5 equal groups: top 20%, next 20%, and so on.

4. Length in words: When preparing their report for the National Journals Library, authors are asked to write a PLS of up to 300 words, but some write shorter summaries, and some write longer ones. Studies of patient-information leaflets in trials have found that long [37,38] and short [39] texts each have problems associated with them regarding readability and clarity, and we wanted to see whether the length of the PLS made a difference.
5. Readability and jargon scores of the original funding proposal: Information about all projects funded by the NIHR is publicly available on the web, including a copy of the PLS submitted as part of the original funding proposal. The difference between this and the final National Journals Library PLS is that the original one sets out what the researchers proposed to do; the PLS in the National Journals Library summarizes what they ultimately did and found. NIHR instructs writers of summaries to "follow the same principles and procedures as in writing the plain language summary that accompanied your funding submission" [40], and we wanted to find out whether original and final report summaries were written in similar ways. Just as we did for the National Journals Library PLSs, we calculated readability and jargon scores for each of the funding proposal PLSs. We categorized these scores by ranking them and then sorting them into 5 equal groups.
6. Publication year: PLSs became a requirement in mid-2014, and we downloaded our data in mid-2022 (July 22). We wanted to see whether the readability and use of jargon in PLSs had changed over time and did this by categorizing each one according to the year it was published.

Analysis

We analyzed our data using Stata/SE (version 17.0; StataCorp LLC) and Microsoft Excel (version 2409; Microsoft Corporation). For each of the study characteristics described in the preceding section (research topic, funding program, project size, length in words, readability or jargon used in the original proposal, and publication year), we calculated descriptive statistics on the number of PLSs in each category or, where categories were of equal size, the range covered by the category. For each category, we estimated the average readability and jargon score, the percentage of summaries with readability scores higher than 50, the percentage of summaries with jargon scores higher than 95, and the 95% CIs for these estimates. We looked at the relationship between readability and jargon scores by calculating their pairwise (Pearson) correlation. We estimated incidence rate ratios and 95% CIs of PLSs in the hardest-to-read categories (readability scores of >50 and jargon scores of >95) using a generalized linear model with a modified Poisson approach and robust error variances [41]. We report the results of a model in which all study characteristics were entered simultaneously.

Patient and Public Involvement

This study was prompted by the assertion made at a patient and public involvement meeting, attended by AK (who is a patient and member of the public but not a researcher) and hosted by a leading UK research-funding charity, that the average reading age of the UK population is 9 years. This assertion (along with a few variations) can be found on numerous websites by searching on the web for the term "UK average reading age" (we subsequently found that these figures come from the UK Government's Skills for Life Survey [42]). This raised the question: if this is the case, how accessible to the general population are the PLSs routinely produced in health research funding applications and reports? AK and IAL's discussions about how to address this question led to the writing of this paper. AK has been involved throughout and is a coauthor.

Results

Readability scores in our sample ranged from 1.1 to 70.8. The mean (average) FRE score was 39.0 (95% CI 38.4-39.7), and the median (middle) score was 39.8. The distribution of scores across readability categories is shown in Table 1. Around one-fifth of summaries had a score below 30, "very difficult to read."

Jargon scores in our sample ranged from 76.4 to 99.3. The mean (average) jargon score was 91.7 (95% CI 91.5-91.9), and the median (middle) score was 92.4. The distribution of scores across jargon categories is shown in Table 2. Around one-fifth of summaries had a score of 95 or above, suggesting that they would be suitable for a general audience.

Table 2. Distribution of summaries by jargon score.

Jargon score	Values, n (%)
95-100 (least jargon)	269 (21.7)
90-95	592 (47.7)
85-90	300 (24.2)
85 or lower (most jargon)	80 (5.4)

The pairwise correlation between readability scores and jargon scores was 0.249 (P<.001), which suggests that when one score is higher, the other is also likely to be higher but that the relationship is moderate. Sixty-six summaries (5.3%, 66/1241) were in both the "easier to read" and "least jargon" categories.

Table 3 shows, for each of the study characteristics, the number of summaries in each category (where relevant) and the mean readability and jargon scores for that category. We found statistically significant variations in estimated readability and jargon scores between categories for each study characteristic.

XSL•FO

Scores in original proposal[c]			
Lowest 20% of original scores		35.3 (33.8-36.8)	88.0 (87.5-88.4)
2		36.8 (35.3-38.4)	90.5 (90.1-91.0)
3		39.4 (38.0-40.7)	92.2 (91.8-92.6)
4		39.7 (38.4-40.9)	93.3 (92.9-93.6)
Highest 20% of original scores		43.9 (42.5-45.3)	94.7 (94.4-94.9)

[a]Some summaries were associated with more than 1 area of research, so the total percentage does not add up to 100.

[b]Percentages may not add up to 100 because of rounding.

[c]Readability scores are categorized by the readability score of the original funding proposal; jargon scores are categorized by the jargon score of the original funding proposal.

For the research topic, the highest estimated readability score (most readable) was in the "Metabolic and endocrine" category, and the lowest score (least readable) was for "Generic health relevance." However, the "Generic health relevance" category was associated with the highest estimated jargon score (least jargon), and the lowest score (most jargon) was for "Infection."

For the funding program, the highest estimated readability score was associated with the Public Health Research program, and the lowest was in Health and Social Care Delivery Research. In contrast, the Health and Social Care Delivery Research had the highest estimated jargon score (least jargon). The lowest jargon score (most jargon) was associated with the Efficacy and Mechanism Evaluation program.

For project size, mean readability scores but not jargon scores rose as projects got larger. The highest estimated readability score was associated with the largest projects (top 20% of funding), and the lowest readability was associated with the smallest (bottom 20%). There was no clear pattern of variation in jargon scores.

For length of summary, longer summaries were associated with better readability and less jargon, but only up to a point. Scores appeared to rise across the first 80% of summaries when ranked by length but then dipped so that the lowest scores were in the longest 20% of summaries.

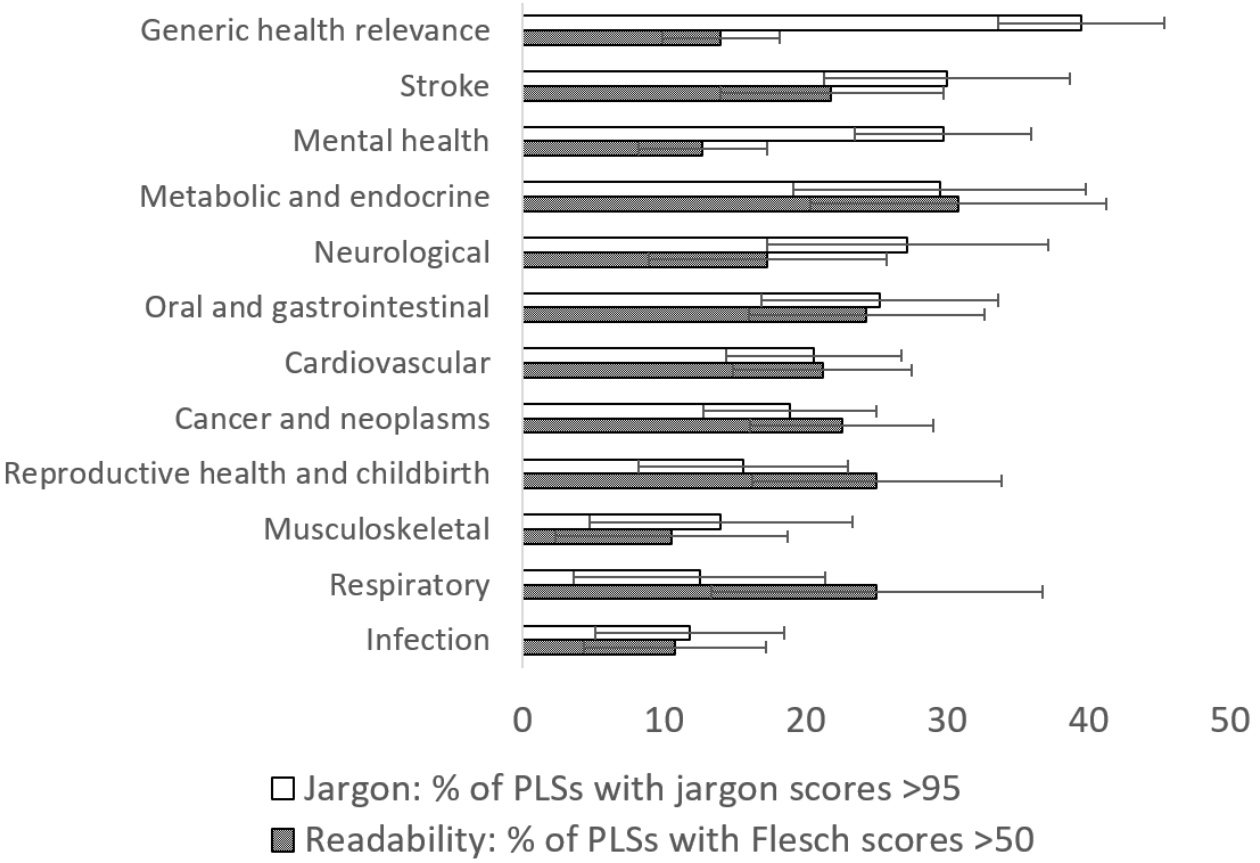
For publication year, the lowest readability score was for 2022, but data for that year were incomplete at the time we collected our data. Readability and jargon scores varied by year, but there did not appear to be any trend in either score over time.

Our estimates of scores in summaries in relation to scores in original proposals rose steadily across the categories from lowest to highest proposal scores for both readability and jargon. For both readability and jargon, the highest estimated scores were for PLSs that had the highest scores in the proposals, and the lowest estimated scores were for PLSs that had the lowest scores in the proposals.

The proportion of summaries that have readability scores over 50 ("fairly difficult to read" or better) and jargon scores >95 (low level of jargon) are shown in Figure 1 (by research topic), Figure 2 (by funding program), Figure 3 (by project size), and Figure 4 (by scores in original proposals).

XSL•FO
RenderX

Figure 1. Percentage of summaries with readability scores >50 ("fairly difficult to read" or better) and with jargon scores >95 (low level of jargon), by research topic, with 95% CIs. PLSs: plain language summaries.



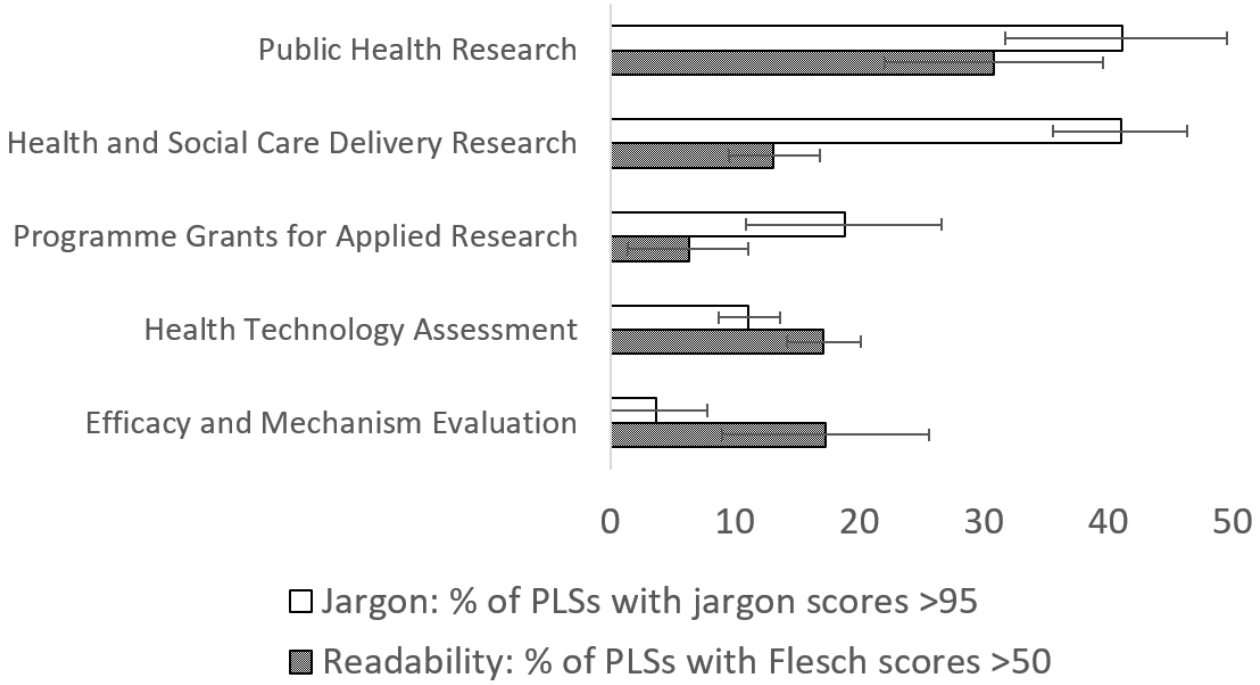


Figure 2. Percentage of summaries with readability scores >50 ("fairly difficult to read" or better) and with jargon scores >95 (low level of jargon), by National Institute for Health and Care Research funding program, with 95% CIs. PLSs: plain language summaries.

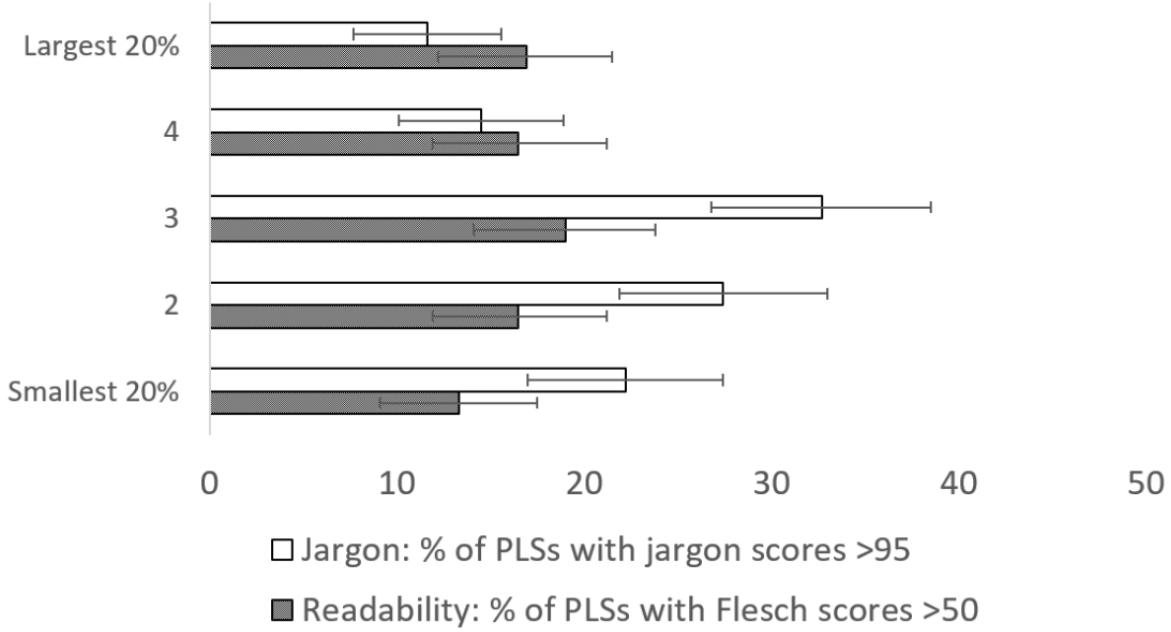
XSL•FO
RenderX

Figure 3. Percentage of summaries with readability scores >50 ("fairly difficult to read" or better) and with jargon scores >95 (low level of jargon), by project size, with 95% CIs. PLSs: plain language summaries.



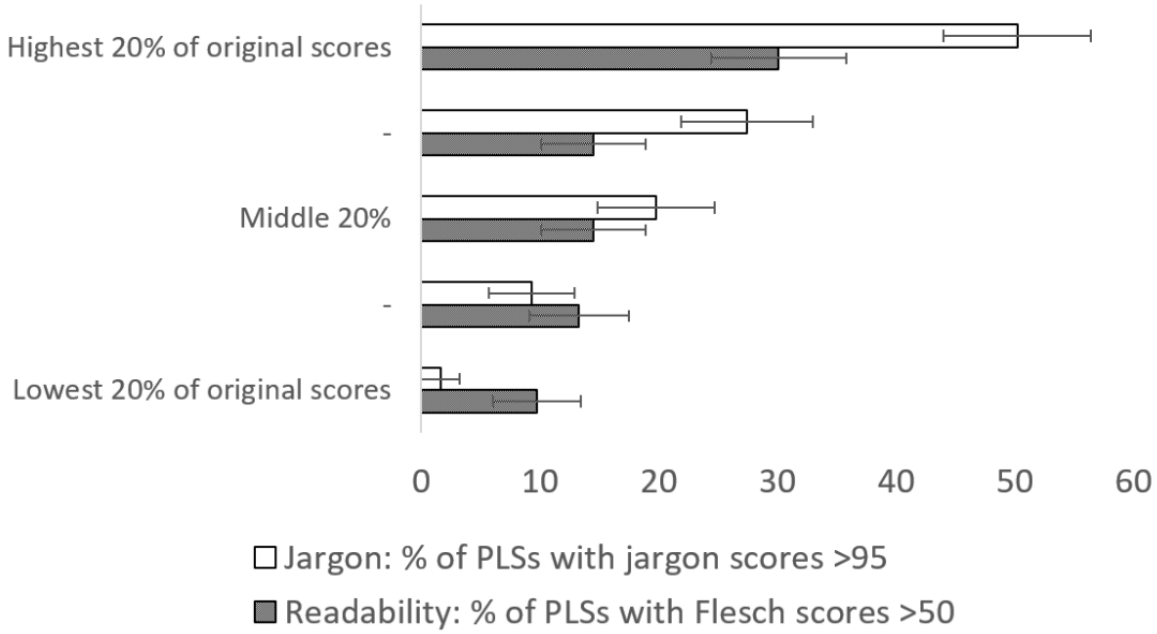


Figure 4. Percentage of summaries with readability scores >50 ("fairly difficult to read" or better) and with jargon scores >95 (low level of jargon), by readability scores or jargon scores (as appropriate: readability scores are categorized in relation to the readability score of the original funding proposal, and jargon scores are categorized in relation to the corresponding original jargon score) in original proposals, with 95% CIs. PLSs: plain language summaries.

Finally, Table 4 shows the incidence rate ratios of having each of these "better" scores when all study characteristics are included in the same model. This is useful because it allows us to assess whether the differences we have observed are still there when the other differences between summaries are accounted for. It could be, for example, that summaries in the Public Health Research program were more likely to be in the easier-to-read category, compared with Programme Grants for Applied Research, because of differences in project size or research topic. The results of the regression suggest, however, that even when other differences (eg, size, topic, year) are controlled for, Public Health Research summaries are approximately 5 times as likely as Programme Grant summaries to be more readable. Similarly, we can say that projects for which the original proposal had little jargon are markedly more than 10 times as likely to have little jargon in their final reports when compared with those with lots of jargon in the original proposal, even when differences in size, topic, and so on are accounted for.

Highest 20% of original scores	2.88 (1.86-4.45)	13.87 (5.17-37.2)

[a]We analyzed readability score outcomes in relation to the readability score of the original funding proposal and jargon score outcomes in relation to the jargon score of the original funding proposal.

Discussion

Main Findings

Our findings suggest that the PLSs published in the NIHR's Journals Library are often difficult to read and likely inaccessible to a general audience. Despite the NIHR's advice to avoid jargon and complicated words and to keep sentences short, many published summaries had lots of jargon and poor readability. We analyzed more than 1200 summaries and found none with readability scores suggesting that they would be accessible to people with the average UK reading age of 9 years.

Readability and jargon scores varied significantly in relation to research topic (where "Metabolic and endocrine" projects did best), funding program (where projects in the Public Health Research Programme did best), and, most noticeably, in relation to how readable the original funding proposal was. The relationship between original funding proposal summaries and final report summaries is notable because it suggests that some authors are consistently better (or worse) at writing accessible summaries.

Readability scores and jargon scores were correlated but did not always coincide. For instance, summaries in the "Generic health relevance" category used relatively few jargon words but were not very readable. The opposite was true of larger projects, which, compared with small projects, had more readable summaries and less jargon. The Efficacy and Mechanism Evaluation funding program was also associated with summaries that were moderately readable yet had high levels of jargon. These differences suggest that summaries may be accessible or easy to read in some ways but not in others and that relying on a single measure to assess a text may miss important aspects of readability. We found no pattern over time: looked at year-on-year, there are differences but no upward or downward trend in either readability or jargon scores.

Comparisons With Other Studies

The mean FRE score we found was higher than the mean score of 23.6 reported for PLSs in 2 psychology journals [43] and the mean of 21 found in a sample taken from the Physiotherapy Evidence Database [44]. A study of research on cystic fibrosis found that the FRE score of PLSs in journals was 43.3 and in Cochrane reviews was 46.3 [45]. An analysis of medicine information sheets produced by the professional associations of rheumatologists in 3 countries found that the average FRE score for those from Australia was 50.8, from the United Kingdom was 48.5, and from Canada was 66.1 [46]; in patient information leaflets produced by the British Association of Dermatologists, the mean score was 52.2 [47]. An analysis of Cochrane PLSs, which used a different readability formula, concluded that most would be difficult to read for someone with no medical education [48] and is in line with a previous analysis of Cochrane PLSs that found that they were very heterogeneous and often failed to adhere to standards [49]. Comparing scores across different samples of texts is not straightforward because of differences in the intended audiences for each. What is clear is that the level of readability we found is markedly worse than that recommended for texts in plain language and suitable for a general audience, which is a score of 60 or above (Table 1).

We are aware of only 1 previous use of a jargon calculator to assess PLSs by the developers of the calculator we used [32]. They compared levels of jargon in academic abstracts and lay summaries in 2 journals, *PLOS Computational Biology* and *PLOS Genetics*. Although they found that the PLSs contained less jargon than the abstracts, they—like us—found that jargon use in the summaries was significantly higher than the recommended levels. We used a cutoff of 5% to identify summaries with low levels of jargon and identified that only 21.7% (269/1241) of papers met this criterion; of the summaries in our sample, only 1.0% (13/1241) met the more stringent 2% cutoff proposed by Rakedzon and colleagues [32].

Strengths and Weaknesses of This Study

Previous studies of PLSs have focused on specific research areas (such as physiotherapy) or methods (such as reviews). Our broader approach has enabled us to address a part of what Uphold and colleagues [18] described as a critical gap in the dissemination and implementation literature, the analysis of how researcher characteristics and environmental determinants influence attempts to disseminate research findings. We also looked at both readability and jargon, whereas previous studies have focused on one or the other.

FRE scores are widely used [27], are recommended by NIHR and other funders as a way of assessing the readability of PLSs [25], and—as we have used them here—provide a way of looking at large numbers of texts and identifying trends and tendencies in readability. We recognize, all the same, that readability indices are an imperfect way of assessing texts. They can be misleading and have little to do with how easy a text is to understand [50-52], and scores may be inconsistent when

XSL•FO
RenderX

tested across different pieces of software because of formatting or other differences [27]. Readability indices also capture only 1 aspect of how science is communicated to the public. There are more sophisticated ways of understanding [53,54], conducting [55,56], and assessing [57-59] science communication. Our approach focused on summaries written by research teams and could be extended by looking at the perceptions and responses of readers and evaluating the impact of summaries [60-62]. We had no information on the extent to which teams responded to NIHR's "strong encouragement" to involve a nonacademic member of the public in writing the PLS [25], so we cannot comment on whether this alters their content and presentation.

The way we have assessed jargon focuses on single words and ignores the use of phrases that might otherwise count as jargon. Multimedia Appendix 1 contains some examples of this. For example, "confidence" and "interval" are both classed as mid-frequency words in our jargon calculator, but the phrase "confidence interval," often used in reporting statistical estimates in health studies (as in this paper), would probably be considered jargon. The same applies to longer jargon terms such as "incremental cost-effectiveness ratio," which has a specific technical meaning but which the jargon calculator does not pick up on. We have not accounted for other aspects of summaries that can affect how readable they are, such as the use of numbers and statistics.

The summaries we looked at were all funded by a single large funder (NIHR) and relate to research done in a single country (the United Kingdom). Over the past 3 decades, the United Kingdom has more swiftly embedded public involvement and engagement in health research than most other countries [63,64]. While we may appear critical of NIHR, this study has been possible only because NIHR requires researchers to write summaries and then makes these publicly accessible. NIHR sponsors the UK Standards for Public Involvement, intended as a "description of what good public involvement looks like," and 1 of the 6 standards is "Communication—use plain language for well-timed and relevant communications, as part of involvement plans and activities" [65]. The NIHR also says that it is "the world's first health research funder to publish comprehensive accounts of its funded research within its own publicly and permanently available journals" [26].

The PLSs included in National Journals Library publications are central to these 2 commitments—to make publicly available details of the work it funds and to communicate in plain language—and are "in keeping with the NIHR Journals Library's commitment to accessibility" [26]. They also relate to a substantial investment: the cost of the research represented in the reports at which we looked is not easy to calculate, but NIHR expenditure on these funding streams in financial year 2021/22 was £206.3 million (approximately €241 million/US $268 million), so it seems reasonable to assume that the cost over the years covered here exceeded £1 billion (approximately €1.17 billion/US $1.30 billion). We might expect to see in the work of the NIHR a well-developed set of processes and mechanisms by which to communicate the results of research to the public, and for this reason, we consider the NIHR's flagship publication stream, the Journals Library, to be an apt focus for our enquiry here.

The extent to which the assessment of readability can be regarded as an indication of comprehension is not included in this study, as there is no existing measure that captures this relationship. Assessing comprehensibility usually involves asking people to read 1 or more texts and then measuring their understanding (eg, as Koops et al [66] did), which would be challenging to do with a large sample of texts such as those in the NIHR Journals Library. In the absence of measurable comprehensibility, assumptions on the accessibility of PLSs deserve scrutiny and a willingness to reconsider the methods of their production.

Unanswered Questions and Future Research

We would like this study to contribute to a debate on 2 connected questions: What and who are PLSs for?

From a funder's perspective, PLSs are a relatively cheap and easy way of disseminating research findings. The teams doing the research are responsible for producing a PLS, and this has strengths (the information "straight from the horse's (or scientist's) mouth" [67] is presumably less likely to be incorrect or imprecise) as well as weaknesses (researchers often lack training in science communication). Scientific writing can be exclusive: "The language of science, though forward-looking in its origins, has become increasingly anti-democratic… [it] sets apart those who understand it and shields them from those [who] do not" [68] but fluency in this language is necessary for scientists to do their work and have it accepted by other scientists [69]. PLSs could be an important aspect of a more "engaged" university sector [64], but the intended role and audience for PLSs are unclear, and this limits their potential value.

Communicating in a certain way means communicating to a group of people who can understand that type of communication. Attempts to communicate to "the general public" [25] must address multiple audiences [70], but the members of the public being addressed include people who differ widely in their interest, knowledge, and trust in science [71]. Ahmed [72] argues, drawing on the work of Warner [73], that addressing a public generates a public that can be addressed. Saying something in Swahili implies that you are speaking to people who can understand Swahili, and writing something using lots of scientific jargon and complicated sentences implies that you intend it for an audience who can understand such language. The dissemination of research findings has been challenged as a 1-way form of communication that falls short of the principles and expectations of public engagement [74], can be seen as representing public relations rather than science communication [75,76], and contributes to the exclusion of people from low-income, minority ethnic groups [77]. If we regard the production of PLSs as an aspect of Open Science, with its commitments to social engagement in the conduct and outcomes of research [5], we also need to be aware of what is being made visible and invisible in the process [78] and of who is being included and excluded.

XSL•FO
RenderX

Evidence on what is most effective in PLSs of scientific research, in terms of both form and content, is emerging [16,67,79], but there is still much for us to learn about what works, for whom, and why. The value of training to improve science communication is unclear [80], and attempts to improve PLSs have met with mixed results. For example, Kirkpatrick and colleagues [81] tested 2 approaches: having authors rewrite PLSs using new guidance and having an independent medical writer edit the PLS. In each case, a group of nonspecialists rated the revised versions as easier to read but not easier to understand. A service designed to improve recruitment to studies by having trained patients and carers review research documents was successful in reducing the amount of jargon but not in improving readability [82].

Creative approaches to communicating research findings have the potential to enable 2-way communication and flatten hierarchies between scientists and nonscientists [83]. Again, when putting this to the test, results have been mixed: one recent study found that PLSs of published research were more effective than scientific abstracts or graphical abstracts in terms of comprehension and understanding [84], whereas another study concluded that graphical summaries were one of the most preferred formats [85]. A recent review of instructions for authors on writing PLSs found a lot of inconsistency across journals and suggested that consistent instructions could be developed with members of the public [17]. The creation of common standards for summaries has also been proposed as part of the OpenPharma project [13,14]. Expert consensus conference methods have been used to produce recommendations on maximizing the accessibility of study patient-information leaflets and informed-consent forms [86], and a similar approach could potentially be applied to the preparation of PLSs.

Another approach from which we might learn is citizen science. Communication of all aspects of research is fundamental to citizen science, which has been described as one of the most dramatic developments in science communication in decades [87] It emphasizes multidirectional and ongoing communication [88] and recognizes storytelling and visualization as central to this [89]. At least in aspiration, citizen science has the potential to improve and transform science communication at the same time as it empowers and informs citizen scientists [90]. Other approaches to dissemination have emphasized coproduction [91] and community engagement [92]. As Knowles and colleagues noted, “finding mutually acceptable and valuable ways to express findings is yet another area requiring open discussion and negotiation” [93].

Conclusions

We found that the sample of PLSs that we examined had low readability and contained lots of jargon. Although these things differed in relation to study characteristics, such as topic and size, none of the PLSs had readability scores in line with the average reading age of the UK public. The aims of, and audiences for, these PLSs are unclear, and their place in science communication and public engagement requires further consideration. It is uncertain whether these summaries improve public access to research.

Acknowledgments

This report is independent research supported by the UK National Institute for Health and Care Research Applied Research Collaboration South West Peninsula (grant reference number: NIHR200167). The views expressed in this publication are those of the author(s) and not necessarily those of the National Institute for Health and Care Research or the UK Department of Health and Social Care. We did not use generative artificial intelligence in any portion of the writing of this manuscript.

Data Availability

The data we used came from the texts and metadata of reports published in the NIHR’s Journals Library. This is an open-access resource, and all the data we used are publicly available on the web via the Journals Library website: https://www.journalslibrary.nihr.ac.uk/journals/

Authors' Contributions

IAL and AK contributed to conceptualization and methodology. IAL contributed to statistical analysis and writing the original draft. IAL, AK, KB, KS, LA, JD, and KL contributed to the interpretation of the data, critical revision of the manuscript for important intellectual content, and writing—review and editing, and all authors agree to be accountable for all aspects of the work.

Conflicts of Interest

None declared.

Abstract

Background: Depression is a widespread mental health issue affecting older adults globally, with substantial implications for their well-being. Although digital interventions have proven effective in high-income countries, research on the potential of internet usage to alleviate depression among older adults in high-income countries remains limited.

Objective: This study aimed to examine the impact of internet usage on depression among older adults in high-income countries by developing a comprehensive theoretical framework and testing key hypotheses.

Methods: Using data from the China Health and Retirement Longitudinal Study (CHARLS), a 2-stage instrumental variable approach was applied to address endogeneity and estimate causal relationships between internet usage and depression.

Results: The findings indicate that internet usage results in a 1.41% reduction in depression levels among older adults. This effect is mediated by four primary mechanisms: (1) enhanced social interaction, (2) increased physical activity, (3) improved intergenerational contact, and (4) expanded access to educational opportunities. A heterogeneity analysis revealed that these effects are more pronounced in urban areas, eastern regions, and regions with superior internet infrastructure.

Conclusions: Internet usage plays a crucial role in alleviating depression among older adults in high-income countries, with regional variations. The findings highlight the need for targeted policy interventions to improve internet access and digital literacy, which can mitigate depression and enhance the mental health of older adults.

internet usage; depression; older people; mechanism; heterogeneity; mobile phone

Introduction

Background

Depression is a prevalent psychological and mental health condition. Globally, the prevalence of depression among the older population aged 60 years and above is 5.7%. This issue is even more pronounced in low- and middle-income countries [1]. Data from the United Nations Economic and Social Commission for Asia and the Pacific indicate that the older population in Southeast Asia is growing rapidly. By 2030, individuals aged 65 years and older are projected to make up over 11% of the total population in the region. Mental health issues among this demographic, particularly depression, are becoming a growing concern. A study by the Asian Mental Health Association shows that depression is particularly prevalent among older adults in Southeast Asia. This is especially true for older adults affected by loneliness, physical health issues, and lifestyle changes, which can contribute to higher rates of depression. Common symptoms of depression in older adults include feelings of isolation, sleep disturbances, and low mood [2].

XSL•FO
RenderX

In China, the prevalence of depression among older adults is estimated to be as high as 25.55% [3]. From 2020 to 2050, China's older population aged 60 years and older is projected to increase from 263 million to 522 million, with its proportion of the total population rising from 18.7% to 39.5% [4]. Depression significantly affects the quality of life, daily activities, incidence of geriatric diseases, and suicide rates among older adults [5,6]. It not only causes severe harm to the physical and mental health of older adults but also imposes a significant burden on society. Estimates suggest that health care expenditures for individuals with depression are 50% to 100% higher than for those without depression [7]. Thus, effectively alleviating depression among older adults has become an urgent global health issue.

In recent years, information and communication technology has been recognized as a potential factor for alleviating depression in older adults [8]. Studies in early-aging countries such as the United Kingdom, the United States, Japan, and South Korea have confirmed that digital interventions can effectively alleviate depression among older adults [9-11]. Internet usage in Southeast Asia has experienced a significant upward trend in recent years. Statista reports that the internet penetration rate in the region was about 67.1% in 2024, with most countries exceeding a 70% penetration rate. However, smaller countries like Laos, Myanmar, and Timor-Leste have lower internet access rates, although improvements are ongoing. Digital technologies are increasingly applied in health management and social connectivity, with the widespread use of smartphones and wearable devices offering older adults comprehensive platforms for health monitoring and social interaction [12].

As the world's largest high-income country, China had 119 million older internet users by the end of 2021, with an internet penetration rate of 43.2% among older adults. This raises a critical question: can internet usage effectively alleviate depression among older adults in China, and what are the potential mechanisms at play? Unfortunately, the academic community has paid insufficient attention to this issue, with few studies providing rigorous theoretical analysis and empirical evidence. To fill this gap, this paper investigates the causal relationship between internet usage and depression among older adults from both theoretical and empirical perspectives. The study aims to elucidate the underlying mechanisms and assess the impact of internet usage, thereby providing evidence from high-income countries to improve the mental health of older adults.

The primary challenge of this study is the inherent issue of reverse causality between internet usage and depression among older adults. Internet usage may influence depression among older adults, and conversely, depression may affect internet usage among older adults. This potential endogeneity problem significantly disrupts causal inference, greatly reducing the reliability of the regression coefficients. Existing studies have inadequately addressed this issue. The 2-stage instrumental variable (IV) method is widely regarded as one of the most effective approaches to overcome potential endogeneity issues [13]. By using an exogenous instrument, this method aims to eliminate the endogeneity of the primary variable, thereby enabling precise estimation of the regression coefficients. This approach requires the IV to be correlated with the primary variable while being exogenous to the error term.

This paper innovatively uses the National Big Data Comprehensive Pilot Zone policy as an IV for internet usage, using the 2-stage IV method to achieve more accurate causal identification. The National Big Data Comprehensive Pilot Zone policy, through the development of age-friendly applications and digital literacy training, significantly increases internet usage among older adults, meeting the relevant criterion. Simultaneously, depression among older adults does not influence the National Big Data Comprehensive Pilot Zone policy, satisfying the exogeneity criterion. In addition, to further eliminate endogeneity caused by omitted variables, this paper controls both time-fixed effects and individual-fixed effects in the 2-stage IV approach.

Compared with existing studies, this paper offers several potential contributions: First, this study provides a rigorous analysis of the causal relationship between internet usage and depression among older adults, both theoretically and empirically, thereby contributing to the literature on the mental health of older adults. Second, it is the first to use the 2-stage IV approach for a stringent empirical examination, effectively mitigating endogeneity issues in regression analysis, and thereby enriching existing empirical methodologies. Third, this paper conducts a heterogeneity analysis across different regions, expanding on current research that mostly focuses on heterogeneity based on demographic characteristics, thus broadening the scope of existing studies. Finally, we offer several specific and actionable policy recommendations, providing a basis for decision-making to improve the mental health of older adults in other high-income countries.

The remainder of this paper is organized as follows: (1) section 2 proposes testable theoretical hypotheses; (2) section 3 discusses empirical design, including data sources, econometric models, and variable definitions; (3) section 4 presents a series of empirical tests and provides an in-depth discussion of the results; and (4) section 5 concludes with the findings, policy recommendations, and limitations.

Theoretical Hypotheses

Social Interaction Effect

Social networks refer to stable relationships formed through mutual connections among individuals and social members, encompassing both online and offline networks. Among these, family and friend networks constitute the most crucial offline social networks for older adults. However, due to physical decline, generation gaps, and children moving away or being busy with work, older adults find it challenging to maintain offline social networks. With the proliferation of the digital society, the internet provides a new social platform for older adults, helping them engage in social interactions, learning, and shopping, thereby enhancing their connection with the outside world. As of June 2023, China had approximately 140 million internet users aged 60 years and older, and this proportion continues to expand with increasing internet penetration. Internet usage not only alleviates loneliness among older adults but also

XSL•FO
RenderX

expands their social relationships, prevents social isolation, and increases interaction frequency with family and friends [14].

Enhanced social networks have a significantly positive impact on the psychological well-being of older adults. Social interactions through the internet reduce feelings of loneliness and depression among older adults [15]. Social engagement enhances their sense of achievement, happiness, and security, serving as a crucial pillar for their integration into society and promotion of psychological health. The activity theory suggests that older adults can achieve self-awareness, bridge the gap with society, lessen loneliness, and attain higher life satisfaction through new social engagements. Increasing participation in both conventional and novel social activities is a valuable objective for improving the mental health of the increasingly aging population. The Social Convoy Theory also highlights the protective role of social relationship networks on psychological health. Therefore, by strengthening family and friend networks, the internet alleviates loneliness among older adults, promotes psychological health, and effectively reduces depression, a phenomenon termed here as the social interaction effect. Based on this, hypothesis 1 is proposed.

Hypothesis 1—Internet Usage Mitigates Depression Among Older Adults Through the Social Interaction Effect

Physical Exercise Effect

A series of studies have shown that internet usage among older adults transcends temporal and geographical constraints, enhances interaction with sports service providers, and offers high-quality, convenient, and diverse sports services [16,17]. In the era of big data, the internet also accurately delivers nearby sports information and suitable sports equipment, thus lowering barriers to the participation of older adults in physical activities. Older adults who frequently use the internet engage in physical exercise and moderate- to high-intensity activities more frequently each week. This suggests that the internet significantly boosts older adults' enthusiasm for physical activity by providing convenience, scientific guidance, interactivity, and entertainment.

Increasing physical exercise has a significant positive impact on the psychological health of older adults. Physical exercise can enhance the cardiovascular function and physical fitness of older adults, promote health, delay aging, reduce the incidence of age-related diseases, and improve sleep quality. Research indicates that physical activity enhances subjective well-being [18], effectively treats depression, and reduces anxiety [19]. Based on the active aging theory and health demand model, studies have found that regular physical exercise significantly increases the likelihood of social participation among older adults [20]. Therefore, through increasing physical exercise, older adults not only improve their physical health but also significantly alleviate depression and enhance overall quality of life. We refer to this mechanism as the "physical exercise effect." Based on this, hypothesis 2 is proposed.

Hypothesis 2—Internet Usage Alleviates Depression Among Older Adults Through the Physical Exercise Effect

Intergenerational Contact Effect

The current high population mobility in China often leaves adult children unable to care for their older parents due to work or study commitments, resulting in a shift in social roles and interpersonal relationships for older adults upon retirement. This situation limits their access to information and deepens their sense of social isolation, impacting their psychological and mental health [21]. The development of internet technology has provided convenient means for older individuals to stay in touch with their children, overcoming temporal and spatial barriers. This has significantly increased the frequency and quality of interactions between older parents and their children, thereby enhancing intergenerational support and subsequently improving the older adults' subjective well-being [22].

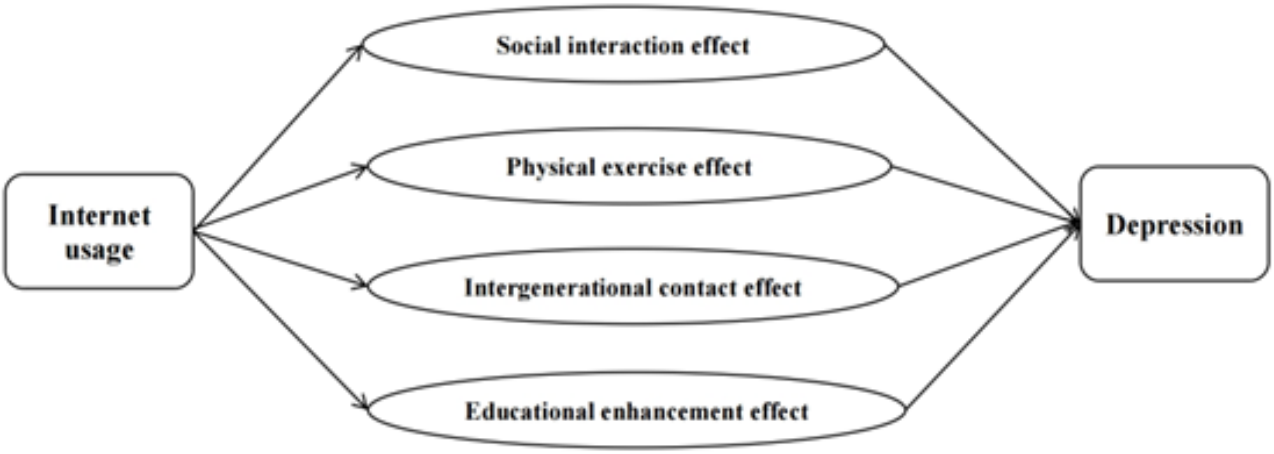
According to the social support buffering model and main effects model, intergenerational support plays a crucial role in alleviating depression among older adults. On the one hand, intergenerational support helps mitigate the impact of resource loss and buffers the effects of stress on the depression of older adults. On the other hand, intergenerational support provides older adults with positive social evaluations for effective parenting, directly reducing their depression [23]. The cognitive behavioral theory of depression emphasizes that cognitive assessments are crucial variables influencing depression [24]. Intergenerational support meets the primary social goal of emotional management for older adults and fosters a more positive attitude in cognitive assessments, effectively reducing depression among older adults. We refer to this mechanism as the "intergenerational contact effect" and propose hypothesis 3 based on this premise.

Hypothesis 3—Internet Usage Mitigates Depression Among Older Adults Through the Intergenerational Contact Effect

Educational Enhancement Effect

With the widespread adoption of the internet, an increasing number of older individuals are engaging in online education, learning new knowledge and skills through virtual courses. This allows them to find new joys and values in the learning process [25,26]. The internet enables older individuals to access a broader range of information and knowledge, enhancing cognitive abilities and better adapting to social changes, thereby reducing feelings of loneliness caused by information isolation. In summary, the internet provides new learning opportunities for older individuals, expands their knowledge boundaries, and profoundly impacts their education.

Education can effectively mitigate the negative impact of age, gender, and family structure on the psychological health of older individuals [27-29]. As individuals age, their physical fitness gradually declines, but higher levels of education can help older individuals enhance their objective awareness of their health status, thereby influencing their psychological well-being. Studies indicate a positive correlation between cognitive



XSL•FO
RenderX

function and life satisfaction among older individuals [30]. Education enhances the self-awareness and self-care abilities of older individuals, reducing psychological issues, and providing social and recreational opportunities, thereby improving mental health and enhancing overall quality of life. We refer to this mechanism as the educational enhancement effect. Based on this, hypothesis 4 is proposed.

Hypothesis 4—Internet Usage Alleviates Depression Among Older Individuals Through the Educational Enhancement Effect

Figure 1 below presents the conceptual framework of this study.

Figure 1. Conceptual framework.

Internet usage serves as the primary exposure variable in this study, while depression is the main outcome variable. In addition, 4 potential mechanisms are explored: the social interaction effect, the physical exercise effect, the intergenerational contact effect, and the educational enhancement effect. These mechanisms are examined to better understand how internet usage might influence depression through various indirect pathways.

Methods

Data Sources

The data for this study primarily originate from the China Health and Retirement Longitudinal Study (CHARLS). CHARLS is a comprehensive, large-scale interdisciplinary survey led by the National School of Development at Peking University, conducted in partnership with the China Social Science Survey Center and the Youth League Committee of Peking University. The survey's objective is to gather household and individual-level data on Chinese adults aged 45 years and older. CHARLS uses a probability proportional to size sampling method, systematically selecting samples from counties, villages, residential areas, households, and individuals. The national baseline survey was conducted in 2011, encompassing 150 counties (districts), 450 villages (residential areas), 10,257 households, and 17,708 individuals, offering a comprehensive representation of China's middle-aged and older population. The CHARLS questionnaire collects data on demographics, family structure, employment and retirement, health status, and health-related behaviors. This study uses longitudinal panel data from 5 waves of CHARLS, spanning 2011 to 2020. The longitudinal data structure facilitates the analysis of individual-level changes over time, offering a more robust framework for examining causal relationships than cross-sectional data. In contrast to cross-sectional data, which captures a snapshot of individuals at a single point in time, longitudinal data enable the observation of changes within the same individuals across multiple time periods. This approach enhances our capacity to control unobserved individual heterogeneity and to more effectively assess temporal dynamics and causal mechanisms. Currently, CHARLS is recognized as the most authoritative and largest representative database for studying the health of older adults in China.

The data cleaning process proceeded as follows: (1) the data from the 5 survey rounds were matched and merged, resulting in a total of 96,616 observations; (2) missing values for the key explanatory and dependent variables were removed, totaling 15,735 (ie, 96,616–80,881); (3) further removal of missing values for control variables amounted to 1179 (ie, 80,881–79,702); and (4) subsequently, 2826 (ie, 79,702–76,876) singleton group values were removed. This resulted in a final sample of 76,876 observations for use in regression analysis.

Econometric Equation

This study uses the IV regression method to address potential endogeneity issues in the data. Endogeneity occurs when an explanatory variable is correlated with the error term, often due to omitted variables, measurement errors, or reverse causality. This endogeneity can result in biased and inconsistent estimates of causal relationships. IV regression addresses this issue by using IVs that are correlated with the endogenous regressor but uncorrelated with the error term, providing a source of exogenous variation to identify causal effects. This method is particularly valuable in panel data analysis, where variable relationships are dynamic and prone to simultaneity bias. Using IVs allows for more reliable and unbiased estimates of causal effects, making this method well-suited for the study design. Thus, the IV approach offers a robust statistical framework to address endogeneity concerns and ensure the validity of causal inferences. The specific econometric model is as follows:

XSL•FO
RenderX

Equation (1) represents the first-stage regression, where  denotes the fitted values of internet usage, $NBDCPZ_{it}$ represents the dummy variable for National Big Data Comprehensive Pilot Zones (NBDCPZ), $X`\theta$ denotes a series of control variables, σ_i represents individual fixed effects to control for individual differences, and γ_t represents time fixed effects to control for unobserved shocks across different years. Controlling for both time- and individual fixed effects aims to further eliminate endogeneity issues caused by omitted variables. The essence of the first-stage regression lies in regressing the endogenous variable $Internet_{it}$ on exogenous variables to obtain the fitted values . Equation (2) represents the second-stage regression, where denotes depression among the older adults, ε_{it} represents the error term, with other variables as in Equation (1). The essence of the second-stage regression lies in regressing $Lndepress_{it}$ on the instrumented  to obtain accurate estimates of the coefficient α_1.

Variable Definition

Depression (LnDepress)

The level of depression among older adults was assessed using the widely recognized 10-item Center for Epidemiologic Studies Depression Scale (CESD-10). This scale consists of 10 items, each rated on a 4-point Likert scale ranging from 1 to 4, with items 5 and 8 reverse scored. The total score, derived by summing the individual item scores, reflects the level of depression, with higher scores indicating a greater risk of depression. To mitigate the impact of extreme values and facilitate the interpretation of results, the total depression score was logarithmically transformed.

Internet Usage (Internet)

Internet usage was assessed by asking respondents in the CHARLS survey, “Have you used the internet in the past month?” Responses were coded as 1 for “yes” and 0 for “no.” This core explanatory variable exhibits significant potential endogeneity issues with depression; higher levels of depression among older adults may inversely affect their internet usage behavior, potentially compromising the credibility of regression results.

Instrumental Variable (National Big Data Comprehensive Pilot Zone)

On March 1, 2016, China’s first NBDCPZ (Guizhou) received official approval from the National Development and Reform Commission, the Ministry of Industry and Information Technology, and the Cyberspace Administration of China. This pilot zone aims to conduct systematic trials in areas such as data resource management and sharing, data center integration, and data resource application. The plan is to develop a series of advanced big data products and cultivate key big data enterprises over 3 to 5 years, thereby promoting economic transformation and upgrading.

On October 8, 2016, these authorities issued another notice approving the establishment of additional NBDCPZ in 7 regions, including Beijing-Tianjin-Hebei. These newly approved national-level pilot zones comprise 2 interregional comprehensive pilot zones (Beijing-Tianjin-Hebei and the Pearl River Delta), 4 regional demonstration pilot zones (Shanghai, Henan, Chongqing, and Shenyang), and 1 pilot zone focused on the coordinated development of big data infrastructure (Inner Mongolia). The construction of these zones will facilitate trials and exploration in areas such as big data policy innovation, public data openness and sharing, big data innovation applications, big data industry clustering, big data element circulation, data center integration and use, and international cooperation in big data, thereby driving the innovative development of big data in China.

In this study, we creatively use the NBDCPZ as an IV for internet usage for older adults. This approach effectively addresses potential endogeneity issues, thereby enhancing the credibility of the regression results.

Control Variables

The selected control variables include gender, age, household registration, marital status, education, self-rated health, medical insurance, personal income, and alcohol consumption.

Mechanism Variables

In line with the theoretical hypotheses, the mechanism variables encompass the social interaction effect, physical exercise effect, intergenerational contact effect, and educational enhancement effect. Detailed measurement methodologies for these variables are provided in the section “Mechanism Explorations.”

Descriptive Statistics

Table 1 presents the main variables and their descriptive statistics are as follows: (1) the mean score for depression (LnDepress) is 2.847 (SD 0.322); (2) the mean for internet usage (internet) is 0.149 (SD 0.356), indicating that 14.9% of the sample has used the internet; and (3) and the mean for NBDCPZ is 0.1 (SD 0.3), suggesting that 10% of observations are from the NBDCPZ. Details for other variables are omitted for brevity. It should be noted that in Table 1, the number of observations for variables is higher than in the regression tables. This discrepancy is due to the removalx of some singleton groups during the regression process. This deletion was automatic and did not substantively affect the conclusions of this study.

XSL•FO
RenderX

Table 1. Definition and description of main variables.

Variables	Observations, n	Mean (SD)	Definition
LnDepress	79,702	2.847 (0.332)	Using the CESD-10[a] scale, scores were summed and logged
Internet	79,702	0.149 (0.356)	Respondents were asked whether they used the internet in the past month, with responses coded as 1 for "yes" and 0 for "no"
National Big Data Comprehensive Pilot Zone	79,702	0.1 (0.3)	If located in a pilot area, assign a value of 1 to years after the pilot period; otherwise, assign a value of 0
Gender	79,702	1.521 (0.5)	Male=1, female=2
Age	79,702	60.296 (9.731)	Current year: year of birth. Due to the presence of outliers, perform a 1% truncation of the upper and lower ends
Household registration	79,702	0.45 (0.497)	Rural household registration=1, others=0
Marital status	79,702	0.88 (0.325)	Married=1, others=0
Education	79,702	2.398 (4.116)	Not completed primary school=0, primary school=6, junior high school=9, senior high school or technical school=12, junior college=15, bachelor's degree=16, master's degree=19, doctorate=22
Self-rated health	79,702	2.78 (0.933)	Very poor=1, poor=2, fair=3, good=4, very good=5, excellent=6
Medical insurance	79,702	0.95 (0.219)	With medical insurance=1, other=0
Personal income	79,702	0.231 (0.421)	Received wages or bonuses in the past year=1, other=0
Alcohol consumption	79,702	2.375 (0.88)	In the past month, drank alcohol more than once=1, less than once=2, did not drink= 3
Social interaction effect	41,934	0.357 (0.455)	The frequency of social interaction activities was used as a measure, as detailed in the section "Mechanism Explorations"
Physical exercise effect	47,768	2.277 (0.552)	The frequency of physical exercise activities was measured as detailed in the section "Mechanism Explorations"
Intergenerational contact effect	34,020	1.871 (0.909)	The frequency of contact with children was used as a measure, as detailed in the section "Mechanism Explorations"
Educational enhancement effect	32,108	0.013 (0.115)	Measured by participation in school training courses over the past month, as detailed in the section "Mechanism Explorations"

Ethical Considerations

The original data used in this study are derived from the CHARLS, which has been reviewed and approved by the Biomedical Ethics Review Committee of Peking University (approval IRB 00001052–11015). The current analysis is a secondary analysis of deidentified and publicly accessible data. This study does not involve any direct interaction with human participants or observation of individuals. In addition, this study does not involve any procedures or activities that may raise ethical concerns and complies with all applicable laws and regulations regarding research conduct. Therefore, no ethical approval is required.

Results

Benchmark Regression

To present comparative results, columns 1 and 2 in Table 2 show the results of ordinary least squares (OLS) regressions: column 1 indicates that the coefficient of internet usage (internet) on depression (LnDepress) is –0.05, significant at the 1% level. Column 2 presents the regression results further controlling for both individual fixed effects (FE) and year FE; the coefficient of internet usage "Internet" is –0.02, still significant at the 1% level. In Table 2, columns 3 and 4 present the results of the 2-Stage IV method: column 3 shows that the coefficient of internet usage "Internet" on depression (LnDepress) is –0.00, significant at the 1% level, with Kleibergen-Paap rk LM statistic and Cragg-Donald Wald F statistic tests confirming the validity of the instruments. Column 4 presents the regression results further controlling for individual FE and year FE; the coefficient of internet usage "Internet" is –0.01, and the instruments remain valid.

[h]KP-LM: Kleibergen-Paap rk LM statistic, testing the relevance of IV.

[i]CD-Wald: Cragg-Donald Wald F statistic, testing the weak relevance of IV.

[j]Year FE: time fixed effects, controlling for unobserved shocks across different years.

[k]Individual FE: individual fixed effects, controlling for heterogeneity across individuals.

[l]Robust: the use of robust SEs, addressing heteroskedasticity effects.

The baseline regression results indicate the following: first, the coefficient significantly decreases after using IV regression, suggesting that the OLS regression overestimated the impact of internet usage on depression. Second, column 4, which simultaneously controls both individual FEs and year FEs, further mitigates endogeneity issues due to omitted variables. Therefore, column 4 is used as the baseline regression in this study, showing that internet usage significantly reduces depression scores by 1.41%. This finding indicates a significant alleviation of depression among older adults, consistent with the theoretical hypothesis.

Column 4 also reports the impacts of other control variables: education significantly reduces LnDepress, indicating that higher education levels ease depression. Self-rated health significantly reduces LnDepress, suggesting that better self-rated health decreases the likelihood of depression. Medical insurance significantly promotes LnDepress, implying that medical insurance does not alleviate depression. Alcohol consumption significantly reduces LnDepress, indicating that alcohol consumption is beneficial in alleviating depression. The other variables gender, age, household registration, marital status, and personal income do not show significant effects in the baseline regression. It is important to note that the reported R^2 in the IV regression process has no practical significance; hence, it is not reported in this study [31].

XSL•FO
RenderX

Robustness Checks

To examine the robustness of the baseline regression results, this section conducts a series of robustness tests, as detailed in Table 3: column 1 transforms the depression variable into a binary outcome, following the approach of Li and Luo (2024) [32], where depression scores exceeding 10 are assigned a value of 1, and 0 otherwise. Using the IV method based on a Probit model, the results indicate a significant reduction in depression due to internet usage (the coefficient is –2.116 and statistically significant at the 1% level), confirming robustness. Column 2 re-estimates the regression by internet usage frequency instead of binary internet usage. Frequency categories (almost daily=3, almost every week=2, not regularly=1) are derived directly from the CHARLS questionnaire. The results show a significant decrease in depression by 2.01%, reaffirming robustness. Column 3 replaces the IV method with propensity score matching to address potential selection bias in internet usage, where the choice of using the internet may be influenced by other factors, leading to biased regression coefficients. Using a 1:1 nearest-neighbor matching, the results indicate a significant reduction in depression by 0.0761%, demonstrating robust results. Column 4 uses a smart city pilot virtual variable as a new IV for the re-estimation. The results show a significant reduction in depression by 1.35%, confirming robustness. In addition, we conducted other robustness tests, such as re-estimating using the total depression score and applying a negative binomial regression model. The results remained robust across these specifications, and further details are omitted for brevity. In addition, we conducted weighted regressions at the individual, gender, household registration, household, community, and city levels. The results remained robust and are detailed in Multimedia Appendix 1.

Mechanism Explorations

The empirical results above clearly demonstrate that internet usage significantly reduces depression levels among older adults. Moreover, the theoretical hypotheses proposed above have anticipated potential mechanisms. This section will therefore conduct mechanism tests to validate these theoretical hypotheses. Detailed results are provided in Table 4 below.

XSL•FO
RenderX

Table 4. Mechanism test. Robust standard errors are in parentheses.

Variables	Social interaction effect (1)	Physical exercise effect (2)	Intergenerational contact effect (3)	Educational enhancement effect (4)
Internet	0.492[a] (0.244)	0.680[a] (0.291)	0.374[a] (0.151)	2.183[b] (0.260)

[f]Robust: the use of robust standard errors, addressing heteroskedasticity effects.

Social Interaction Effect

Regarding social interactions, the following activities were quantified: visiting friends in the past week; playing mahjong, chess, cards, or visiting community activity rooms; providing assistance to non-cohabitating relatives, friends, or neighbors; engaging in activities such as dancing, fitness, or qigong with clubs or organizations; volunteering or participating in charitable activities; and caring for non-cohabitating patients or disabled individuals. The total frequency of these activities was aggregated and log-transformed in this study. Column 1 indicates that internet usage increases the frequency of older social interactions by 49.2%, confirming the social interaction effect.

Physical Exercise Effect

Regarding physical exercise, the following activities were quantified: the number of days per week engaging in vigorous, moderate, or light physical activities for more than 10 minutes. The total frequency of these activities was aggregated and log-transformed in this study. Column 2 indicates that internet usage increases the frequency of older adults' physical exercise by 68%, confirming the physical exercise effect.

Intergenerational Contact Effect

Regarding intergenerational contact, activities include contacting all children through phone, message, WeChat, mail, or email, and assigning reverse scores based on the frequency of these contacts as follows: almost every day=10, 2-3 times a week=9, once a week=8, every 2 weeks=7, once a month=6, once every 3 months=5, once every 6 months=4, once a year=3, almost never=2, other=1. The total scores of these frequencies were aggregated and log-transformed in this study. Column 3 indicates that internet usage increases the intergenerational contact scores of older adults by 37.4%, confirming the intergenerational contact effect.

Educational Enhancement Effect

Regarding educational enhancement, the following activity was quantified: whether the individual attended school or training courses in the past month. Clearly, this is a binary variable and should be regressed using the 2-stage IV method based on the Probit model. Column 4 demonstrates that internet usage significantly increases the likelihood of older adults receiving education, confirming the educational enhancement effect.

Heterogeneity Analyses

To further enrich the understanding of the relationship between internet usage and depression, this study conducted a series of heterogeneity analyses, as shown in Table 5.

XSL•FO
RenderX

Comparison of Urban and Rural Areas

Urbanization exacerbates the hollowing-out problem in rural areas, leading to higher levels of loneliness and more severe depression among rural older adults [33]. The cumulative disadvantage hypothesis suggests that this urban-rural depression disparity stems from the urban-rural divide, where rural residents accumulate disadvantages that peak in old age. The diffusion of the internet has varying effects on alleviating depression among older adults in urban and rural areas. Due to better infrastructure, urban older adults benefit more from internet access, facilitating easier social participation, information access, and entertainment, thereby effectively reducing feelings of loneliness and depression [34]. Moreover, proximity to children's residences and stable family support systems in urban areas, coupled with internet usage, further alleviates their depression. In contrast, rural older adults face limited internet access due to inadequate infrastructure, resulting in fewer opportunities to use internet benefits for social interaction and support. Combined with a lack of effective family support systems and communication channels, the internet's impact in alleviating depression among rural older adults is less pronounced compared with their urban counterparts. Therefore, it is expected that the alleviating effect of internet usage on depression would be more significant in urban areas. The grouped regressions in columns 1 and 2 confirm this hypothesis, indicating that the alleviating effect of internet usage is higher in urban areas (–1.74%) compared with rural areas (–0.774%).

Comparison of Eastern and Noneastern Regions

In eastern China, older adults have more opportunities to engage in social activities, access health information, and participate in online entertainment through the internet, resulting in a more pronounced alleviation of depression [35]. Furthermore, the higher economic development in eastern regions generally correlates with higher levels of education and economic capability among older adults, facilitating easier access to and utilization of the internet for psychological well-being [36,37]. In contrast, the older adults in noneastern regions experience lower internet usage rates and breadth due to limited internet resources, technological barriers, and economic constraints, leading to less significant alleviation of depression compared with their counterparts in eastern regions [38]. Therefore, it is anticipated that the therapeutic effect of internet usage on depression in older adults is more pronounced in eastern China and remains limited in noneastern regions. According to the classification standards of the National Bureau of Statistics, eastern China includes the provinces (and cities) of Beijing, Tianjin, Hebei, Shanghai, Jiangsu, Zhejiang, Fujian, Shandong, Guangdong, and Hainan. The grouped regressions in columns 3 and 4 confirm this hypothesis, indicating that the alleviating effect of internet usage is higher in eastern regions (–1.85%) compared with noneastern regions (0.00196, which is statistically insignificant).

Comparison of Broadband China Pilot and Nonpilot Areas

Since its implementation in 2013, the "Broadband China" strategy has significantly enhanced broadband network coverage and accessibility through advanced network technologies and infrastructure development. In pilot areas, older adults have more frequently used the internet for social interactions and access to health information, resulting in a notable reduction in depression. In contrast, nonpilot areas, constrained by limited internet resources and technical support, offer fewer

XSL•FO
RenderX

opportunities for internet usage by older adults, leading to less significant alleviation of depression compared with pilot areas [39]. Moreover, the widespread availability of broadband networks has facilitated increased older adults' participation in social activities and access to more health services, further mitigating depression [40]. Therefore, this study anticipates that the therapeutic effect of internet usage is greater in the pilot areas of Broadband China and smaller in the nonpilot areas. The grouped regressions in columns 5 and 6 confirm this hypothesis, indicating that the alleviating effect of internet usage is higher in pilot areas (–1.9%) compared with nonpilot areas (–0.000707, which is statistically insignificant).

Discussion

This study's core finding is that internet usage significantly alleviates depression symptoms among older adults, with a reduction of 1.41%. This result suggests that internet usage alleviates depression through four main mechanisms: the social interaction effect, physical exercise effect, intergenerational contact effect, and educational enhancement effect. Specifically, internet usage facilitates social activities among older adults, helping to reduce loneliness and, in turn, alleviating depressive symptoms. In addition, the internet enables older individuals to more easily participate in physical activities, which improves both their physical and mental health. Furthermore, internet usage strengthens communication with children, enhancing intergenerational support and reducing depressive feelings. Finally, internet usage provides older individuals with access to more educational resources, which improves self-awareness and self-management, thereby reducing depression symptoms. In summary, this study provides empirical evidence on how internet usage alleviates depression in older adults through multiple pathways, highlighting the potential of the internet to improve mental health in older adults.

The findings of this study align with existing literature emphasizing the positive impact of internet usage on mental health in older adults. Internet usage reduces depression by alleviating social isolation [41] and enhancing intergenerational relationships [11]. In addition, it reduces loneliness through increased social contact [9,42] and improves psychosocial functions, including physical activity and education [43,44]. Our study expands on this by incorporating the mediating effects of physical activity and education in depression reduction. While excessive internet usage may lead to social media fatigue and worsen mental health [45], our findings suggest that appropriate internet usage fosters mental well-being, as indicated by Lam et al [8]. Furthermore, mobile health apps have been shown to reduce depression in other populations, supporting the efficacy of digital interventions [46]. Despite concerns about internet addiction [47], our results suggest that regulated internet usage can improve both mental and functional health, particularly in older adults [48]. By using a 2-stage IV approach, this study mitigates endogeneity issues, providing robust causal inferences consistent with previous research [49].

The study's findings suggest several policy measures to enhance the mental health of older adults via internet usage, based on the identified mechanisms and observed heterogeneity in the effects of digital engagement: (1) strengthen internet infrastructure in rural and underserved regions: while internet usage enhances mental health through social interaction, physical activity, and educational access, its impact is greater in urban areas. Policy makers should prioritize the expansion of internet infrastructure in rural and noneastern regions to ensure that older adults can fully benefit from digital engagement. (2) Initiate targeted digital literacy programs: considering the influence of digital literacy on the effectiveness of internet usage, targeted training programs for older adults, particularly in rural areas, should be prioritized. These initiatives should emphasize teaching older users to engage in online social activities, access health resources, and participate in educational content, which have proven effective in reducing depression. (3) Create age-appropriate digital mental health platforms: mental health platforms should be customized for different subgroups. In urban areas, platforms should prioritize enhancing social interaction and intergenerational communication, whereas, in rural areas, the emphasis should be on bridging the digital divide by providing simple and accessible health and social resources. (4) Promote the development of age-friendly digital applications: policymakers should facilitate the creation of digital tools that encourage physical activity and cognitive stimulation among older adults. These applications can address mechanisms identified in the study, such as exercise and education, and contribute to reducing depression among older users.

While this study provides valuable insights into the relationship between internet usage and depression among older adults, several limitations must be considered. First, the reliance on self-reported data for depression and internet usage may introduce biases, such as social desirability or recall bias. Future studies could incorporate objective measures, such as log data from internet providers or wearable devices, to improve accuracy. Second, although the 2-stage IV approach addresses endogeneity, the exogeneity of the chosen instrument, the NBDCPZ, may still be questioned, and alternative instruments or experimental designs, like randomized controlled trials, could strengthen causal inference. In addition, the heterogeneity of internet usage effects across subgroups (eg, by age, education, or income) was not fully explored and warrants further investigation. Finally, while this study focused on short-term effects, future research should examine the long-term impacts of internet usage on the mental health of older adults, including potential risks such as internet addiction or over-reliance on digital platforms.

Abstract

Background: New health care services such as smart health care and digital therapeutics have greatly expanded. To effectively use these services, digital health literacy skills, involving the use of digital devices to explore and understand health information, are important. Older adults, requiring consistent health management highlight the need for enhanced digital health literacy skills. To address this issue, it is imperative to develop methods to assess older adults' digital health literacy levels.

Objective: This study aimed to develop a tool to measure digital health literacy. To this end, it reviewed existing literature to identify the components of digital health literacy, drafted preliminary items, and developed a scale using a representative sample.

Methods: We conducted a primary survey targeting 600 adults aged 55-75 years and performed an exploratory factor analysis on 74 preliminary items. Items with low factor loadings were removed, and their contents were modified to enhance their validity. Then, we conducted a secondary survey with 400 participants to perform exploratory and confirmatory factor analyses.

Results: A digital health literacy scale consisting of 25 items was developed, comprising 4 subfactors: use of digital devices, understanding health information, use and decision regarding health information, and use intention. The model fit indices indicated excellent structural validity (Tucker-Lewis Index=0.924, comparative fit index=0.916, root-mean-square error of approximation=0.088, standardized root-mean-square residual=0.044). High convergent validity (average variance extracted>0.5) and reliability (composite reliability>0.7) were observed within each factor. Discriminant validity was also confirmed as the square root of the average variance extracted was greater than the correlation coefficients between the factors. This scale demonstrates high reliability and excellent structural validity.

Conclusions: This study is a significant first step toward enhancing digital health literacy among older adults by developing an appropriate tool for measuring digital health literacy. We expect this study to contribute to the future provision of tailored education and treatment based on individual literacy levels.

Introduction

Background

The proliferation of digital technology and the widespread use of smart devices have facilitated convenient and ubiquitous access to current information and services. The worldwide adoption rate of smartphones is approximately 76%, with South Korea having the highest rate at 95% [1]. The diverse services in the digital realm can immensely benefit individuals using them [2]. Cutting-edge medical services, such as digital therapeutic gadgets, intelligent monitoring, and telemedicine are intricately connected to the digital revolution in health care [3]. The medical device sector, in an attempt to actively identify and meet patient needs, develops digital health care services at medical treatment sites. These digital health care services improve the accessibility of medical care and individualized therapy [4]. For instance, the use of smartphone applications for medication reminders and the implementation of disease monitoring systems that rely on patient-generated health data prove highly beneficial for patients with chronic illnesses [5]. To effectively use digital health care services, patients and those without underlying medical conditions must possess the necessary skills to retrieve and use the desired health information in the digital domain [6,7].

Digital health literacy is a newly developed term that combines 2 distinct concepts: health and digital literacy [8]. Beyond comprehending health information, it includes the ability to efficiently use digital tools and resources for health care. However, the adoption of new technologies varies with the social environment and individual abilities. These disparities contribute to a digital divide and information gap. In South Korea, digitally marginalized groups, including older adults, rural areas residents, individuals with disabilities, and low-income individuals, are unable to keep up with advancements in digital technology [9], with studies recognizing the digital divide as a noteworthy societal problem among these populations [10-12]. The most vulnerable group is the older adult population, who have limited exposure to smart devices and limited opportunities for education in information and communication technology [13]. The COVID-19 pandemic has exacerbated this phenomenon [14].

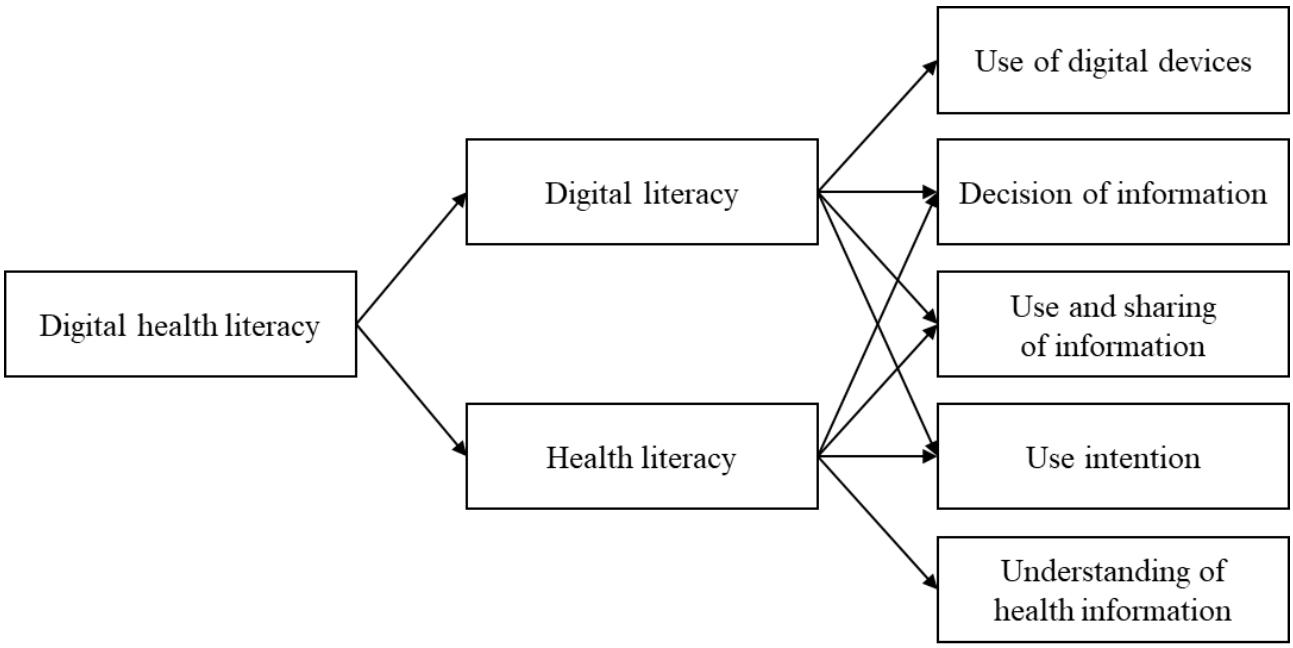
By 2025, South Korea's population aged 65 years and older is projected to surpass 20% of the total population [15]. Over the next decade, population aging is expected to worsen, with the proportion of older adults steadily increasing [16]. Consequently, South Korea and other countries with aging populations have recognized digital exclusion among older adults as a new social issue. Older adults experience difficulties using everyday technologies such as kiosks and self-checkout counters and medical services such as digital therapeutic devices and telemedicine [17]. Although social support can motivate older adults to use digital technologies [18], those living alone may have limited access to digital health care services owing to a lack of assistance from family members. Therefore, it is crucial to develop a strategy that enhances the digital health literacy level among those lacking access to digital services. Enhancing digital health literacy can offer significant health benefits for individuals [19]. Individuals using digital health services understand which information is most appropriate for their needs, while service providers can deliver optimum services to them [20]. For instance, wearable devices such as smartwatches can transmit real-time vital health signs data including temperature, heart rate, blood pressure, and stress levels, to health care providers, thereby enabling continuous monitoring of patients' conditions [21]. To improve digital health literacy, it is essential to assess the current level of digital health literacy among users.

Despite efforts to assess digital health literacy, there has been a deficiency of thorough, comprehensive research that specifically examines and quantifies its various dimensions [22]. According to the previous systematic review investigating the measurement properties of eHealth literacy instruments, the most widely used scale is the eHealth Literacy Scale [23]. This scale estimated the ability to locate, comprehend, evaluate, and use electronic health information to address health concerns [24]. However, this assessment was insufficient in evaluating digital health literacy comprehensively [25], as it was developed before the emergence of social media and mobile-based health care technologies and was reported to not reflect recent advancements in digital health technologies [23]. van der Vaart and Drossaert [26] developed the Digital Health Literacy Instrument to measure various competencies, emphasizing the ability to use internet information. However, their study's reliance on a highly educated sample might have overestimated digital skills, and the limited platforms used could affect generalizability. Karnoe et al [27] categorized digital health literacy into 7 components, 4 related to health literacy and 3 to digital literacy, and developed a corresponding measurement scale. However, this scale only evaluates the comprehension of health information and the use of digital technologies without considering social literacy elements such as information sharing. Also, the transactional eHealth literacy instrument was evaluated as the best instrument for comprehensive assessments of eHealth literacy; however, its applicability was limited to healthy individuals or patients younger than 40 years [23].

Furthermore, previous studies limited that could not represent certain populations such as older adults or low-income individuals. Age is often cited as a sociodemographic factor that can influence digital health literacy, with evidence generally showing that digital health literacy tends to decline with increasing age [28]. Particularly, the previous study on digital literacy assessment tools for older persons found that further research on the appropriateness of these instruments for this demographic is necessary [29]. This suggests that there may be differences in digital habits and learning potential between older and younger individuals dependent on needs and experiences with digital technology, highlighting the need for specialized measurement tools tailored to the older.

Objective

This study aimed to identify the fundamental components of digital health literacy among older adults and develop a systematic self-report scale that can be used to effectively assess their level of digital health literacy.



XSL•FO
RenderX

Methods

Overview

This study investigated the subjective experiences of digital health literacy among older adults, focusing on their ability to use digital technologies and skills in searching for, understanding, and using health information (Figure 1). We used 2 approaches to create an item pool: a literature review to identify digital health literacy components and focus interviews with health care experts to validate these items. Subsequently, we used a 2-step survey and analysis using exploratory and confirmatory factor analyses.

Figure 1. Factor structure of digital health literacy.

Development of the Digital Health Literacy Scale

We examined previous studies to develop an initial item pool based on pertinent hypotheses regarding motives, functionality, and experiences related to health care technology use among older adults. To achieve this, we searched multiple sources, including the National Library of Medicine PubMed database and Web of Science, using predefined keywords such as “Digital Health Literacy scale,” “Mobile health device,” “eHealth,” “Health Literacy,” and “Digital Literacy.” The inclusion criteria for selecting studies were as follows: (1) studies focusing on digital health literacy or related concepts, (2) studies providing quantitative evaluations of digital health literacy tools, and (3) studies where measurement scales were openly available in the publication or could be obtained upon request. Exclusion criteria included: (1) studies that did not explicitly assess digital health literacy, (2) studies without quantitative data on digital health literacy tools, and (3) studies where measurement scales were unavailable or inaccessible upon request. Two reviewers (SMK and JWC) independently extracted appropriate instruments, considering study design, target population, measured variables, and psychometric properties of the scales, and discrepancies were resolved through consensus. The final selection of items was determined through discussions among the research team, which included medical doctors, medical informatics experts, and psychologists.

The final item pool was informed by a detailed review of five key instruments: (1) the Mobile Device Proficiency Questionnaire (covering basics, communication, data storage, and internet use), (2) European Health Literacy Survey Questionnaire (assessing the ability to understand and process health information), (3) Unified Theory of Acceptance and Use of Technology (evaluating perceived usefulness, ease of use, and attitudes), (4) digital health literacy instrument (focusing on the reliability of health care information), and (5) Transactional eHealth Literacy Instrument (related to health information communication) [27,30-33]. In addition, by reviewing the literature on digital health literacy and older adults [23,29], we categorized validated and available scales, identifying the characteristics of each scale item as well as their limitations. Therefore, the scales used in this study were selected based on two key criteria. First, each scale has been validated for reliability and validity in previous research, ensuring their credibility as assessment tools. Second, the scales were chosen for their ability to comprehensively evaluate various aspects of digital health literacy, such as mobile device proficiency, health information processing, and attitudes toward technology acceptance, allowing for a well-rounded measurement.

Our second approach involved a focus group interview with 10 experts from nursing, social work, public health, education, and medicine. These experts regularly engage with older individuals in digitized medical environments, offering several forms of assistance, which understand the issues and demands typically encountered by seniors. Focus group interviews were conducted with participants in 2 groups of 5, each lasting 2 hours. The interview was audio-recorded, and transcribed immediately after the interview. The data was categorized into 3 overarching themes by the researchers, who independently extracted meaningful units from the transcripts. The initial theme, “Accessibility of Digital Health care Services,” addressed

XSL•FO
RenderX

concerns such as the ability to pay medical expenses through hospital applications and the necessity of locating hospital information during emergencies. The second theme, "Understanding and Utilizing Medical Information," encompassed the capacity to effectively interpret and use health check-up results, medication instructions, and nutritional information. The third theme, "Autonomy through Digital Health Technologies," underscored the ability to use health-related applications independently to access medical services or evaluate personal health without external assistance. Items derived from these themes were developed and refined through expert feedback to ensure their relevance and were subsequently included in the preliminary scale. The guidelines for focus group interviews are included in Multimedia Appendix 1. The initial item pool included 74 items: 59 from the literature review and 15 from focus group interviews (Multimedia Appendix 2).

Participants and Data Collection

The target population comprised Korean adults aged 55 years to 75 years. The target population comprised Korean adults aged 55 years to 75 years. Participants were recruited using a closed survey approach in the platform of the survey agency via emails and website visits. Quota sampling was used to ensure balanced representation by gender and age groups. Data collection was conducted in two phases: the first survey included 600 participants from August to September 2023, and the second survey included 400 participants from October to November 2023. Individuals who participated in the first survey were not eligible to participate in the second survey. To prevent duplicate responses, each participant accessed the survey through a unique URL. IP address checks and cookie-based mechanisms were implemented to ensure data quality and prevent multiple submissions from the same individual.

Data Analysis

Exploratory Factor Analysis

To conduct exploratory factor analysis (EFA), an absolute minimum of 100 participants is required, with 200 participants considered fair and 300 participants deemed good [34,35]. With 600 participants, we performed the first EFA to explore the scale's factor structure and selected items using IBM SPSS Statistics for Windows (version 25.0). Moreover, we conducted frequency analysis to verify demographic information and reliability analysis. Descriptive statistics are summarized as frequencies, percentages, or means (SD). The factor extraction method used was the maximum likelihood method with direct oblimin rotation to calculate factor loadings [36]. We present the number of factors to 5 based on the literature review, which was verified using parallel analysis [37]. To ensure the item structure's validity, we followed factor analysis guidelines, removing items with factor loadings below 0.4 and items with cross-loadings above 0.3 on 2 or more factors [38]. The adequacy of the factor analysis was assessed using the Kaiser-Meyer-Olkin (KMO) measure and Bartlett's test of sphericity.

In addition, we conducted a second EFA with a sample of 200 randomly selected individuals from the entire pool of 400 participants in the second survey to validate the final 33 items in the first survey. A determining factor is the ratio of tested items to participants, with a ratio of 5 participants per item considered appropriate [35]. The EFA was conducted using the same method as in the first survey. As before, items with factor loadings below 0.4 and items with cross-loadings above 0.3 on 2 or more factors were removed to select the final items for the confirmatory factor analysis (CFA).

CFA to Validate the Scale's Structure

To validate the scale structure, which consisted of 25 items, we conducted a CFA with 200 participants after the second EFA using IBM SPSS Amos for Windows (version 25.0), and structural equation modeling. It is known that the minimum sample size for CFA is to have at least 200 participants [39] and a ratio of sample size to the number of model parameters is more than 5 in factor analysis [35]. Model fit was evaluated using the chi-square statistic, comparative fit index (CFI), Tucker-Lewis Index (TLI), standardized root-mean-square residual (SRMR), and root-mean-square error of approximation (RMSEA). A model with the ratio of the chi-square statistic to the respective df less than 3, CFI and TLI values greater than 0.90, and SRMR and RMSEA less than 0.08 was considered an acceptable fit. In addition, convergent validity was assessed using average variance extracted (AVE) values, ensuring that they were above 0.5, and construct reliability (CR) with values above 0.7. Discriminant validity was evaluated by comparing the square root of the AVE for each construct with the correlations between the constructs [40].

Ethical Considerations

This study received approval from the institutional review board of the Catholic University of Korea, Songeui Campus (approval number: MIRB 20230825-007). The study adhered to institutional and national ethical guidelines for research involving human participants. Before participation, all participants received detailed information about the study's purpose, procedures, anonymous, data usage, and their rights. Participation was voluntary, and participants could withdraw at any point. Data protection measures were implemented, including the anonymization of all collected data to prevent unauthorized access. No personal identifiers such as names or contact information were collected. Only completed surveys were included in the final analysis. The survey was web-based and conducted through the online platform of the survey agency (Macromill Embrain Co. Ltd.). Participants who completed the survey received a reward of 500 points (approximately US $0.35) redeemable within the online platform.

Results

Participants

The mean age of the sample was 63.63 (SD 5.26) years, and 50% (500/1000) were women. Further, 90.8% (908/1,000) were married, and 4.0% (40/1,000) were single. Regarding the presence of chronic diseases, 48.2% (428/1,000) had been diagnosed with at least one of hypertension, diabetes, or hyperlipidemia, while 51.8% (518/1,000) had not been diagnosed with any chronic disease. Regarding subjective economic status, 51.5% (515/1,000) and 48.5% (485/1,000)

XSL•FO
RenderX

indicated that their economic position was above average and below average, respectively. Regarding subjective health status, 87.5% (875/1,000) and 12.5% (125/1,000) reported their health to be above average and below average, respectively. Participants provided demographic data encompassing gender, age, marital status, chronic disease, subjective economic situation, and subjective health status, along with digital health literacy items (Table 1).

Table 1. The demographic characteristics (N=1000).

Characteristics	First survey (n=600), n (%)	Second survey (n=400), n (%)	Participants, n (%)
Sex			
Male	300 (50)	200 (50)	500 (50)
Female	300 (50)	200 (50)	500 (50)
Age (years)			
55-65	300 (50)	200 (50)	500 (50)
66-74	300 (50)	200 (50)	500 (50)
Marital status			
Married	557 (92.8)	351 (87.8)	908 (90.8)
Not married	17 (2.8)	23 (5.9)	40 (4)
Divorced	26 (4.4)	26 (6.5)	52 (5.2)
Chronic disease (hypertension, diabetes, or hyperlipidemia)			
Yes	276 (46)	206 (51.5)	482 (48.2)
No	324 (54)	194 (48.5)	518 (51.8)
Subjective economic level			
High	3 (0.5)	3 (0.8)	6 (0.6)
Upper middle	50 (8.3)	37 (9.3)	87 (8.7)
Middle	261 (43.5)	161 (40.3)	422 (42.2)
Low middle	233 (38.8)	166 (41.5)	399 (39.9)

Subjective health status			
Very good	21 (3.5)	12 (1)	33 (3.3)
Good	233 (38.8)	127 (11.8)	360 (36)
Average	272 (45.3)	210 (52.5)	482 (48.2)
Not good	72 (12)	47 (31.8)	119 (11.9)
Not very good	2 (0.3)	4 (3)	6 (0.6)

First Validation Survey: EFA

Based on the literature review and focus group interviews (Multimedia Appendix 3), we assembled a pool of 74 items reflecting the 5 factors of older adults' digital health literacy and extracted the underlying structure of items using EFA. In the first survey sample (n=600), all participants were aged 55-75 years, and 50% (n=300) were women. The number of factors was determined using parallel analysis. The eigenvalues of the real data were more significant than those of the random data up to the fourth eigenvalue (real data eigenvalue=0.461; random data eigenvalue=0.334). However, from the fifth eigenvalue onwards, the eigenvalues of the real data were smaller than those of the random data (real data eigenvalue=0.160; random data eigenvalue=0.299). Following the examination of item discrimination and determination of factor loadings, 29 items were retained. The domains of health information decision and use and sharing were consolidated, while other aspects remained. The KMO value, representing the suitability of factor analysis, was 0.981, and Bartlett's test of sphericity yielded a significant result (χ^2_{406}=19365.0, P<.001), confirming the appropriateness of the model. The results also demonstrated a satisfactory level of internal consistency for each factor (Cronbach α values: 0.925-0.944). Table 2 lists the selected components' commonalities and factor loadings.

Factors and Items	Communality	Standard Factor Loading
Understanding of Health Information		
Q42. I can understand the instructions for medication provided by the hospital app.	0.861	0.902
Q41. I can understand the emergency manual provided by health-related apps.	0.824	0.770
Q39. I can understand the health check-up results provided by the hospital app.	0.794	0.752
Q48. I can understand the terms of the privacy consent form when registering on the hospital app.	0.781	0.703
Q40. I can understand the nutritional information of food provided by health-related apps.	0.803	0.700
Q49. I am aware of the precautions for online payment when paying medical bills.	0.772	0.636
Q46. I can understand the information about health check-ups (such as target, date, price, fasting requirements, etc.) provided by the hospital app.	0.811	0.566
Use of Digital Devices		
Q7. I can save photos and texts about healthy activities found on the Internet.	0.765	0.856
Q9. I can use the desired services (payment, location search, etc.) through the hospital kiosk.	0.709	0.851
Q13. I can delete health-related apps that I have used.	0.737	0.839
Q8. I can book and confirm medical services through the hospital app.	0.745	0.801
Q6. I can find a suitable hospital for my symptoms using my smartphone.	0.723	0.792
Q3. I can find information about disease symptoms and treatments using my smartphone.	0.661	0.770
Q12. I can use the online “store” (e.g., Apple App Store or Google Play Store) on my device to find health-related apps.	0.711	0.764
Q15. I can use appropriate words or search terms to find the health service information I want on the Internet.	0.788	0.716
Q14. I can access hospital websites through an Internet search.	0.793	0.714
Q17. In an emergency, I can find information about nearby hospitals using my smartphone.	0.751	0.678
Use Intention		
Q32. I believe it is necessary to exchange health information online.	0.692	0.885
Q33. I am willing to use health-related apps to collect health information.	0.753	0827
Q30. I have a lot of interest in health-related apps.	0.678	0.790
Q35. I am interested in learning health knowledge or skills from the Internet.	0.758	0.739
Q29. I find the necessity and convenience of health management through health-related apps.	0.682	0.507
Q25. Using health-related apps improves my ability to manage my health.	0.580	0.431
Use and Decision of Health Information		
Q57. I can judge whether the health information found on my smartphone is trustworthy.	0.784	0.886
Q58. I can evaluate the pros and cons of various treatment methods provided by the hospital app.	0.771	0.785
Q61. I can determine the medical services I need.	0.734	0.707
Q59. I can judge how to use the health information provided by health-related apps.	0.753	0.705
Q51. I can determine if the health information found on the Internet is written for commercial purposes (advertisements).	0.706	0.516
Q64. I can use the health information provided by health-related apps for disease management.	0.774	0.449

In addition, we made minor adjustments to the working scale to align it with the conceptual framework of digital health literacy. First, the health information decision and use and sharing were combined to create a new factor called the use and decision of health information. Second, hospital apps were renamed health-related apps to encompass a broader range of applications. Finally, 4 new items related to digital health services were added. As a result, we created 33 items divided into 4 domains and their associated subscales (Multimedia Appendix 4).

Second Validation Survey: EFA

We randomly selected 200 responses (women 53.0%) from the 400 valid and unique responses in the second survey. Majority

XSL•FO
RenderX

of the respondents were aged 55-65 years (51.5%). Of the 200 participants, 86.5% (173/200) were married, 4% (8/200) unmarried, and 9.5% (19/200) divorced. The subjective economic level was categorized as high (2/200, 1%), upper middle (21/200, 10.5%), low middle (85/200, 42.5%), or low (16/200, 8.0%). Subjective health status was categorized into four groups: (1) high (4/200, 2.0%), (2) upper middle (62/200, 31.0%), (3) low middle (21/200, 10.5%), and (4) low (1/200, 0.5%).

The results of the secondary EFA also supported the feasibility of performing factor analysis (KMO 0.945; Bartlett test of sphericity: χ^2_{300}=4664.2, P<.001). Parallel analysis indicated that the 4 factors were consistent with the primary study. The fifth eigenvalue for the real data was 0.207, while that for the random data was 0.320. The internal reliability of each component and subscale was satisfactory, as indicated by the Cronbach α values for the 4 subscales falling between 0.91 and 0.96, which is above the minimum threshold of 0.7. The first factor (use of digital devices) comprised 10 items and had a Cronbach α value of 0.96. The second factor (understanding health information) had 5 items and exhibited a reliability coefficient of .92. The third (use and decision of health information) and fourth factors (use intention) consisted of 5 items and demonstrated high reliability, with coefficients of 0.91 and 0.93, respectively. The 25-item scale demonstrated a high level of dependability with a value of 0.96. Almost all items had factor loadings above 0.6 (Table 3). Overall, these results suggest that the 4 factors extracted through EFA were appropriate.

CFA

We performed CFA on a sample of 200 responses (women 47.0%) that were not included in the previous EFA from the 400 valid and unique responses in the second survey. Majority of respondents were aged 66-74 years, comprising 103 of 200 (51.5%) respondents. Of the 200 participants, 89% (178/200) were married, 7.5% (15/200) unmarried, and 3.5% (7/200) divorced. Subjective economic level was classified into four categories: (1) high (1/200, 0.5%), (2) upper middle (16/200, 8.0%), (3) low middle (81/200, 40.5%), and (4) low (17/200, 8.5%). Subjective health condition was classified into four categories: (1) high (8/200, 4.0%), (2) upper middle (65/200, 32.5%), (3) low middle (26/200, 13.0%), and (4) low (3/200, 1.5%). Following the outcomes of the previous EFA, 4 distinct factors were identified, and all 25 items were associated with each component. The model demonstrated strong fit across key indices. The CFI was 0.924, and the TLI was 0.916, both surpassing the commonly accepted threshold of 0.90, indicating a good fit. The SRMR was 0.044, reinforcing the adequacy of the model. The RMSEA was 0.088, with a 90% CI between 0.080 and 0.096, falling within acceptable limits. These results

XSL•FO
RenderX

confirm the robustness of the 4-factor structure and its alignment with the theoretical framework.

The factor loadings per item in Table 4 were all greater than 0.7, indicating a strong relationship between the items and their respective factors. The AVE values were higher than 0.7 and CR values ranged from 0.93 to 0.96. The high AVE and CR values of this scale indicate that it adequately explains the latent construct it aims to measure and demonstrates high internal consistency. Therefore, the results support the convergent validity. Discriminant validity was also confirmed, as the square roots of the AVE values for each factor were greater than the correlations between the factors. Figure 2 displays the factor structure and standardized factor loadings obtained from the CFA, which demonstrated the validity of the scale developed in this study. The final scale comprised 4 factors and 25 items (Multimedia Appendix 5). Participants assign 4 points for strong agreement and 0 points for severe disagreement to each item. The digital device use component consists of 10 items, contributing up to 40 points. The remaining three components which are (1) understanding health information, (2) use and decision-making of health information, and (3) use intention, each consist of 5 items, contributing up to 20 points per component.

Discussion

Principal Results

This study aimed to develop and validate a scale for measuring digital health literacy. The only validated digital health literacy scale previously translated and validated in Korea was the eHealth Literacy Scale adapted by Chang et al [41]. Despite its extensive translation and use in many countries [42], this scale does not keep pace with current technological development. We developed a Korean version of the Digital Health Literacy Scale designed specifically for older adults who are vulnerable to the digital information divide. This scale has the distinctive feature of being specifically designed for older adults, who are an important but often overlooked population in digital health literacy research. This scale comprises 25 items across 4 main factors: use of digital devices, processing of health information, use and reliability assessment of health information, and evaluation of usage intentions. While other scales primarily focus on the general population or specific health conditions, our scale addresses the unique challenges faced by older adults, such as lower familiarity with technology and specific health information needs. The Korean version of the digital health literacy scale considers various factors, making it a valuable tool for comprehensively assessing the digital health literacy level of older adults. Furthermore, it can serve as an essential foundational resource for developing digital health literacy education programs and applying patient-tailored digital therapeutic devices for older adults.

Use of Digital Devices evaluates the ability to search for and use health information using digital devices such as smartphones, tablets, and computers. Efficient digital device usage is essential for searching and using health information, making it a fundamental element of digital health literacy. Studies have shown that older adults have lower skill levels in using the internet to search for health information compared to younger people [43], with a lack of digital device proficiency cited as a primary cause. Therefore, assessing the use of digital devices on this scale can help develop tailored strategies for enhancing older adults' digital health literacy capabilities.

Understanding of Health Information measures the ability to understand and practically apply health information. Although many applications are available to assist individuals in health management, if users fail to comprehend basic health information, they will struggle to use these tools effectively, resulting in poor health management. Accurately measuring the ability to understand and apply health information based on this factor can serve as a starting point for improving digital health literacy.

Use and Decision of Health Information measures the ability to evaluate the reliability of health information obtained through digital devices and apply it in practice. This is a crucial aspect of digital health literacy, as it includes the ability to use reliable information to engage with personal health information. For instance, it includes the ability to determine whether health information found on the Internet is for commercial purposes. Initially, we hypothesized that "Decision of Health Information" and "Utilization and sharing of Health Information" would form separate factors. However, it revealed that combining these items into a single factor was a more suitable structure that improves the internal consistency of the factor and strengthens its interpretability. Consequently, the results indicated that older persons viewed behaviors associated with decision-making, using, and sharing health information as a cohesive behavioral pattern rather than as separate processes. Compared to younger people, older adults might find it more challenging to discern false information [44], which increases the risk of accepting incorrect health information. Given the vast amount of information available online, it is essential to identify the relevant information and that which contains evidence. Particularly, it is necessary to include items such as digital content creation and digital safety [29]. The questions measuring digital content creation and digital safety were included in the initial items (Multimedia Appendix 2). These items were excluded to enhance the reliability and validity of the scale, but

XSL•FO
RenderX

future studies should focus on developing and validating questions that can assess these aspects.

Finally, Use Intention measures an individual's intention to use digital health applications, that is the motivation and willingness to adopt and use new technologies, which are critical elements for enhancing an individual's digital health literacy level. One of the reasons older adults do not use digital devices is a negative attitude toward new technologies, such as a sense of resistance [45]. Consequently, older adults are slower to adopt new technologies, and even when educational programs are necessary, they may exhibit low learning motivation. For individuals with low intention to use digital health devices, it is critical to first raise awareness of the importance of digital health literacy and present convenient health services. This, in turn, will strengthen digital health literacy.

Digital health literacy significantly improves older adults' ability to manage their health and the effectiveness of digital health care services. This study highlights the importance of digital health literacy in South Korea's medical domain and provides fundamental data for addressing digital exclusion among older adults. Moreover, this study used a distinct approach to assess the digital health literacy of older adults using the 4 key factors, distinguishing it from previous studies. This approach contributes to a more systematic understanding of digital health literacy and a more precise assessment of older adults' actual literacy levels. By measuring overall digital device proficiency as well as the ability to understand and use health information, this scale can be effectively used in countries where smartphones are widely available. In the future, research is needed not only to validate this scale across diverse cultural contexts to enhance its generalizability but also to evaluate its predictive validity, thereby ensuring its utility in identifying individuals' properties with low digital health literacy.

Limitations

First, because data were collected through an online survey, it is possible that participation from older adults unfamiliar with digital devices was limited and resulted in an underestimation of the actual digital health literacy levels in groups with low literacy. Therefore, future studies should consider parallel offline surveys for more accurate data. Second, this study focused on older adults, who are the most vulnerable to digital exclusion [13], which may limit the findings' generalization to other age groups or populations with diverse backgrounds. To achieve broader generalizability, future research should aim to collect samples that include a wider range of ages and backgrounds. Third, we prioritized expert feedback during the item development stage to ensure content validity but did not directly include focus group interviews with older participants to gather insights into their digital device usage for health management. Future studies should consider conducting focus group interviews with older adults to further refine the scale and enhance its relevance to this population. Finally, due to the disparity in total scores among the subscales, caution should be observed while using the overall score.

Conclusions

In conclusion, this study developed and validated a novel scale to assess digital health literacy among older adults, addressing the unique challenges posed by the digital information divide in this population. The Digital Health Literacy Scale, comprising 25 items across four factors, provides a comprehensive framework for evaluating older adults' digital device proficiency, understanding of health information, decision-making, and usage intentions. By highlighting these dimensions, the scale facilitates tailored interventions to enhance digital health literacy, ultimately improving health management outcomes and the adoption of digital healthcare services. This study underscores the necessity of targeted approaches in promoting digital inclusion for older adults, especially in rapidly digitizing societies. Future research should extend this work by validating the scale across diverse cultural and demographic contexts and exploring its utility in predicting health-related behaviors and outcomes.

Acknowledgments

This research was supported by the Ministry of Science and ICT (Information and Communication Technology) of Korea and Korea Medical Device Development Fund (RS-2023-00255145), and the Basic Medical Science Facilitation Program through the Catholic Medical Center of the Catholic University of Korea funded by the Catholic Education Foundation.

Authors' Contributions

JWC and JHK contributed to the conception and design of the study. SMK and JWC wrote the manuscript text and prepared the figures and tables. SMK and CHP performed data analysis. CHP and SHP contributed to the data acquisition and extraction. YSB and JHK contributed to the deliberation of the topic and provided expertise and guidance for the study. DJK assisted with the interpretation of the data and critically revised the manuscript for important intellectual content. JWC was responsible for composing and coordinating the review process, incorporating the comments provided by coauthors. All the authors contributed to the manuscript and approved its final version.

Abstract

Background: The digital divide is apparent not only between older and younger generations but also within the older adult population itself. Identifying digital literacy profiles among older adults is crucial for developing targeted strategies to narrow this divide.

Objective: This study aimed to identify profiles of digital literacy among community-dwelling older adults and to examine factors associated with these profiles.

Methods: Data were collected from community-dwelling older adults in South Korea through a nationwide cross-sectional survey that assessed digital literacy and related factors. Digital literacy was evaluated across 3 domains: information and communication (9 items), content creation and management (4 items), and safety and security (9 items). Latent profile analysis was used to identify profiles of digital literacy among community-dwelling older adults, and multinomial logistic regression was used to identify predictors of profile membership.

Results: A total of 1016 older adults completed structured questionnaires (average age 68, SD 6.5 years; 486/1016, 47.8% men). Three digital literacy profiles were identified (P<.001): “low level” (346/1016, 34.1%), “middle level” (374/1016, 36.8%), and “high level” (296/1016, 29.1%). With the “middle-level” digital literacy group as the reference group, older adult participants (odds ratio [OR] 1.11, 95% CI 1.07-1.15) with less than a middle school education (vs with a college degree or higher; OR 7.22, 95% CI 2.31-22.54), who needed help with one of the 10 instrumental daily activities (vs ≥2 activities; OR 3.06, 95% CI 1.11-8.40) and who did not engage in in-person social activities (OR 1.81, 95% CI 1.07-3.07), were more likely to be in the “low-level” group. Women were less likely to be in the “high-level” digital literacy group than men (OR 0.45, 95% CI 0.25-0.80). Participants with less than a college education were also less likely to be in the “high-level” group, with those having less than a middle school education showing the lowest OR (OR 0.17, 95% CI 0.07-0.41). Those who had never worked (OR 0.23, 95% CI 0.06-0.90) and those not engaging in regular physical exercise (OR 0.58, 95% CI 0.40-0.84) were also less likely to be in the “high-level” digital literacy group. Participants with greater social support were more likely to be in the “high-level” digital literacy group (OR 1.70, 95% CI 1.22-2.37).

Conclusions: These findings underscore the characteristics linked to lower digital literacy and suggest a tailored approach to meet the needs of diverse groups of older adults in a digitalizing society. To promote digital literacy among older adults, potential strategies include improving access to and guidance for using digital devices, specifically designed for this demographic, as well as promoting social support and encouraging participation in social activities.

Introduction

Background

In a digitalizing world, new technology-supported lifestyles hold the potential to foster healthy and independent aging among older adults. These individuals can manage their health and medical conditions through mobile devices [1] or benefit from telecare and access to online health information [2]. In addition, smart homes powered by the Internet of Things can support the daily activities of older adults [3]. Digital devices also enable older adults to maintain social connections and participate in social activities, even when traditional face-to-face interactions are not possible [4]. Therefore, it is crucial to encourage older adults to embrace digital technology to enhance self-care, functionality, and social connection [5].

Nevertheless, the digital divide remains a substantial challenge in our increasingly digital world [6]. Research consistently shows a gap in digital engagement between older adults and younger generations [7,8]. Furthermore, there is a considerable variation in digital proficiency among older adults themselves. For instance, individuals aged ≥75 years generally demonstrated lower levels of digital use and literacy compared to those aged <75 years [9]. In addition, factors such as race and ethnicity and socioeconomic status significantly influence internet use among older adults [10]. To effectively support older adults in adapting to and participating in the digital society, it is essential to recognize and understand the diversity within this demographic.

To address this knowledge gap, it is necessary to understand the varied characteristics of digital literacy within the population and to identify the factors associated with it. Previous research on digital literacy in older adults has primarily focused on their abilities to search for information and communicate online [11-13]. However, the definition of digital literacy is evolving [14]. It is now described as “the ability to access, manage, understand, integrate, communicate, evaluate, and create information safely and appropriately through digital technologies” [15]. In response, the European Commission has introduced a detailed self-assessment grid within the Digital Competence (DigComp) framework. This framework covers a broader range of skills, including content creation and management as well as safety and security, in addition to information search and online communication [11,16]. Therefore, conducting a comprehensive assessment of digital literacy among older adults is both relevant and timely.

Previous studies have primarily focused on identifying factors associated with digital literacy levels among older adults, treating this population as uniform. These studies revealed that not only sociodemographic factors—such as gender [17], age [18,19], living arrangement [8], education level [18], and region [8,19]—but also health-related factors, including cognitive functioning [20], physical limitations [21], and depressive symptoms [22], as well as social factors, such as social support [23] and social participation [24], are linked to digital literacy. However, this method may overlook the varied expressions of digital literacy within the older adult population. A person-centered approach that recognizes this diversity is essential for developing comprehensive education and training programs aimed at enhancing digital literacy among older adults [25].

Objective

Therefore, this study, grounded in the most recent definition of digital literacy, aims to achieve three objectives: (1) identify the profiles of digital literacy among community-dwelling older adults in South Korea, (2) understand the characteristics of digital literacy profiles, and (3) determine the predictive factors that distinguish these profiles.

Methods

Study Design and Setting

This cross-sectional study aimed to assess the digital literacy levels and associated factors among community-dwelling older adults in South Korea. Data were collected through a nationwide survey conducted from October to November 2022 [26]. The survey used proportional stratified sampling on the basis of region, sex, and age groups, reflecting the population distribution documented in South Korea as of June 2022. The inclusion criteria were (1) being aged ≥60 years, (2) achieving a minimum score of 22 on the Korean version of the Mini-Mental State Examination (second edition), and (3) being proficient in the Korean language. In total, 58 trained interviewers visited the homes of potential participants identified through the sampling process. They provided comprehensive information about the study and obtained informed consent from those who were eligible and willing to participate. A total of 1016 older adults completed structured questionnaires designed by the research team to collect data on digital literacy, sociodemographic characteristics, health status, health behaviors, social activities, and social support. The survey was conducted via one-on-one interviews using tablet PCs, with an average completion time of 26.8 minutes per participant. Interviews were conducted in person by trained interviewers with extensive experience in interviewing older adults. Errors or inaccurate responses identified during the review or verification process of completed surveys were corrected or supplemented by interviewers through follow-up phone inquiries.

Ethical Considerations

In compliance with the Helsinki Declaration, this study received approval from the Institutional Review Board of Yonsei University (4-2022-0396). All participants provided written informed consent before their involvement in the study and received gift vouchers worth 10,000 Korean won (US $6.90) upon completing the survey. The collected data were made accessible only to the research team, and the respondents’ personal information was deidentified before analysis.

Measures

Digital Literacy

In this study, we evaluated the components of digital literacy in older adults using the Everyday Digital Literacy Questionnaire (EDLQ), which consists of 22 items developed from our earlier research based on the European Commission's DigComp framework [26]. The EDLQ has shown satisfactory validity and reliability, and it is organized into 3 domains: information and communication (9 items), content creation and management (4 items), and safety and security (9 items) [26]. Responses to each item were recorded on a Likert scale from 1 (strongly disagree) to 5 (strongly agree), with higher aggregate scores indicating greater digital literacy. In our sample, the Cronbach α value was 0.98, confirming high internal consistency [26].

Predictor Variables of Digital Literacy

Sociodemographic Factors

On the basis of previous studies [8,17-19], several sociodemographic factors were identified as influencing the digital literacy of older adults. These factors included age, sex, educational level, living arrangements, region, and economic activities. Age was treated as a continuous variable, measured in years. Sex was categorized as a binary variable, with male coded as 1 and female coded as 0. Educational levels were divided into 4 categories: below middle school graduation (coded as 0), below high school graduation (coded as 1), below college graduation (coded as 2), and college graduation or higher (coded as 3). Living arrangements were classified into 3 categories: living alone (coded as 0), living with a spouse (coded as 1), and residing in a multigenerational household (coded as 2). Region was split into 2 categories: metropolitan areas (coded as 1), which included Seoul, Incheon, and Gyeonggi province, and nonmetropolitan areas (coded as 0), encompassing cities and provinces outside the metropolitan area. Economic activities were categorized into 3 groups: currently engaged in income-generating activities (coded as 2), previously employed but not currently (coded as 1), and never having worked (coded as 0).

Health Factors

On the basis of previous studies [20-22], variables related to health status and behavior were selected as factors influencing the digital literacy of older adults.

For health status, participants provided information on their cognitive, physical, and psychological health. The cognitive health of the participants was assessed using the Korean version of the Mini-Mental State Examination (second edition) [27]. Following the most widely used cutoff point for screening the extent of cognitive impairment [28], we recoded the scores into a binary variable: 24 or higher (coded as 1) and below 24 (coded as 0).

The physical health of the participants was assessed, covering disabilities, chronic diseases, and physical function. Disability status was determined as a binary variable, indicating whether participants had received an official medical diagnosis from specialty physicians: yes (coded as 1) or no (coded as 0). In South Korea, the Act on Welfare of Persons with Disabilities defines a "person with a disability" as someone whose daily life or social activity is significantly impaired by a physical or mental disability over a long period. This act recognizes 15 medical disability categories, including disabilities of the extremities; vision disability; hearing disability; speech and language disability; disability due to facial deformity; intellectual disability; and disabilities resulting from brain injury, renal failure, heart problems, liver disease, respiratory issues, ostomy, epilepsy, autism, and mental disorders [29]. Chronic diseases were categorized into 3 groups based on the number of chronic conditions that lasted over 3 months as diagnosed by a physician: none (coded as 0); 1 (coded as 1); and ≥2 (coded as 2). Physical function was evaluated from 2 perspectives using the Korean-Activities of Daily Living (K-ADL) and the Korean-Instrumental Activities of Daily Living (K-IADL). The K-ADL assesses the level of assistance needed in 7 basic activities of daily living: dressing, washing face and hands, bathing, eating, transferring, toileting, and continence. The Cronbach α value for K-ADL at the time of its development was 0.94 [30], and in this study, it was 0.75. The K-IADL measures the level of assistance needed in 10 instrumental activities of daily living, including decorating, housework, meal preparation, laundry, short-distance travel, using transportation, shopping, handling money, using the telephone, and managing medication. The Cronbach α value for K-IADL at the time of its development was 0.94 [31], and in this study, it was 0.78. We recoded the number of items requiring assistance in K-ADL and K-IADL into 3 categories for each: none (coded as 0); 1 (coded as 1), and ≥2 (coded as 2).

The psychological health of the participants was assessed through health-related quality of life and depressive symptoms. Health-related quality of life was evaluated using the Short-Form Health Survey, which examines 8 domains: physical functioning, role-physical, bodily pain, general health, vitality, social functioning, role-emotional, and mental health. For our study, we used version 2 of the 12-item Short-Form Health Survey, an abbreviated version of the 36-item Short-Form Health Survey [32]. Scores were derived using published algorithms that set the mean score of the US general population at 50 and the SD at 10, which were used to calculate the physical component summary and mental component summary scores [32,33]. Scores ranged from 0 to 100, with higher scores indicating a better quality of life. Depressive symptoms were assessed using the integrated Korean version of the Center for Epidemiological Studies-Depression (CES-D) [34]. Participants rated the frequency of their feelings and behaviors over the past week for a total of 20 items, ranging from "rarely or never (<1 day)" (coded as 0) to "most or all of the time (5-7 days)" (coded as 3). After reverse coding the 4 positively worded items, we calculated the total score from the 20 responses. Using the widely accepted threshold for identifying individuals at risk of clinical depression (ie, ≥16) [35], we categorized participants into 2 groups: those at risk for clinical depression and those not at risk. The Cronbach α values for the original CES-D scale and its Korean version were 0.85 and 0.91, respectively [34,36]. In our study sample, the Cronbach α was determined to be 0.89.

XSL•FO
RenderX

For health behaviors, participants provided information on smoking, alcohol consumption, and physical activity. Participants were categorized into 3 groups based on their smoking habits: nonsmokers (coded as 0), ex-smokers (coded as 1), and current smokers (coded as 2). Regarding alcohol consumption, participants indicated whether they had consumed alcohol at least once in the past year (coded as 1) or not (coded as 0). Physical activity was assessed by determining whether participants engaged in daily physical exercise for 10 minutes or more on a regular basis (coded as 1) or not (coded as 0).

Social Factors

On the basis of prior studies [23,24], variables, such as participation in in-person and digital social activities, along with social support, were included as social factors influencing digital literacy among older adults.

To understand participants' in-person social activities, we inquired about their participation over the past year in various activities, including religious or social gatherings; leisure, culture, or sports activities; alumni meetings; volunteer work; political, civic, interest group activities; or other activities [37]. Participants indicated the annual frequency of their involvement in each category of social activities using a scale ranging from "several times a week" (coded as 1) to "not at all" (coded as 7). For our analysis, we grouped these responses into 2 categories: nonparticipation (coded as 0), which includes only the responses indicating "not at all" for all social activity categories, and participation (coded as 1), which includes all other responses. We also evaluated participants' digital social activities by examining their use of digital devices such as desktops and laptops, mobile phones, tablets, e-books, and wearable devices. Participants were asked whether they had used each of the 5 types of digital devices and to specify the duration of use in months. The longest duration reported by each participant was recorded as a continuous variable to represent their overall digital device use. Responses from 10.5% (107/1016) of participants who had no experience using any digital device were recorded as 0 months.

We used the Multidimensional Scale of Perceived Social Support (MSPSS) to assess perceived social support from family, friends, and significant others. The original scale featured a 7-point Likert scale for its 12 items, ranging from "very strongly disagree" (coded as 1) to "very strongly agree" (coded as 7) [38]. For our study, we used the Korean translated version of the MSPSS, which modified the scale to range from "strongly disagree" (coded as 1) to "strongly agree" (coded as 5) [39]. Higher average scores indicate stronger perceived social support. The Cronbach α values were 0.88 for the original version, 0.89 for the Korean translated version, and 0.94 for our sample.

Data Analysis

We chose latent profile analysis (LPA) as the analytical method to identify profiles of digital literacy among older adults living in the community. LPA is a person-centered clustering approach that classifies individuals into unobserved latent subgroups on the basis of similar profiles of observed continuous variables [40]. Our sample size met the minimum recommended criterion (n≥500) for accurate identification using LPA [40,41]. We used 22 items measuring digital literacy across 3 domains as indicator variables for this analysis.

In the initial step of LPA, we selected the model by using information criteria, classification quality indexes, and relative fit indexes. We calculated the Bayesian information criterion, Akaike information criterion, and sample size–adjusted Bayesian information criterion as our information criteria, with lower values indicating a better-fitting model [42]. To assess the quality of model classification, we analyzed the entropy value, targeting a criterion of ≥0.8 [43]. To determine if significant differences in model fit existed between models with K-1 and K profiles, we evaluated the *P* values ($P<.05$) using the Lo-Mendell-Rubin likelihood ratio test, adjusted Lo-Mendell-Rubin likelihood ratio test, and bootstrapped likelihood ratio test [44]. Subsequently, we chose the most suitable number of profiles on the basis of the goodness-of-fit results and their interpretability. Finally, we incorporated predictor variables that affect digital literacy as auxiliary variables to reduce classification errors among profiles [45]. The LPA process was carried out using Mplus (version 8.8; Muthén & Muthén).

To compare the characteristics of the profiles identified through LPA and determine if there were statistically significant differences, we conducted Kruskal-Wallis *H* tests and chi-square tests. In addition, to identify predictor variables that differentiate each profile, we estimated the odds ratio (OR) and their corresponding 95% CIs for the probability of belonging to a specific profile membership using a multinomial logistic regression model. The analysis for intergroup comparisons was performed using SPSS Statistics (version 26; IBM Corp).

Results

We analyzed data from 1016 community-dwelling older adults in South Korea who completed the survey. The participants' average age was 68.0 (SD 6.5) years, and 47.83% (486/1016) of participants were men.

Identification of Digital Literacy Profiles

Model Selection: 3-Class Model

Table 1 presents the available model selection scenario for our sample. The Bayesian information criterion, Akaike information criterion, and sample size–adjusted Bayesian information criterion values decreased as the number of profiles increased, with the rate of decrease diminishing after the 3-profile point. The entropy values exceeded 0.8 in all simulations, indicating satisfactory classification quality. Relative fit indexes demonstrated significant fit only in the 2-profile, 3-profile, and 4-profile scenarios across all 3 indexes (all $P=.002$ or $<.001$). Overall, the model evaluation results suggested that both the 3-profile and 4-profile models were statistically appropriate. However, given the theoretical interpretability of the profile characteristics, the 3-profile model was deemed the most suitable for our sample.

Describing Digital Literacy Profiles

As shown in Table 2, the indicators of digital literacy revealed statistically significant differences across the 3 profiles (all *P* values <.001). Profile 1, which comprises the second-largest group (346/1016, 34.1%), demonstrated the lowest digital literacy levels, with mean scores <2 (out of 5) for each item. Within profile 1, the items “social networking” (mean 1.78), “find information on the Internet” (mean 1.77), and “evaluate internet information” (mean 1.71) in the information and communication domain showed relatively higher self-reported proficiency. Conversely, “convert document formats” (mean 1.12), “edit and share content” (mean 1.13), and “troubleshoot device issues” (mean 1.13) in the content creation and management domain, along with “block spam/phishing” (mean 1.13) in the security and safety domain, scored relatively lower.

Profile 2, the largest group, comprising 36.8% (374/1016) of the sample, exhibited median scores across all items when compared to the other 2 profiles. The mean scores for each item varied significantly, ranging from 1.86 to 3.56. Notably, within the information and communication domain, the items “find information on the Internet” (mean 3.56) and “social networking” (mean 3.54) achieved higher mean scores, both exceeding a mean of 3.5. Conversely, in the content creation and management domain, items such as “edit and share content” (mean 1.86), “convert document formats” (mean 1.89), “troubleshoot device issues” (mean 1.99), and “create documents” (mean 2.10) recorded lower mean scores.

The smallest group, profile 3 (296/1016, 29.1%), comprised participants with the highest relative level of digital literacy. Although the difference was not substantial compared to profile 2, there was a notable variation in the mean scores among the items within this group. All items in the domains of information and communication and safety and security scored a high mean, around 4 (ranging from 3.83 to 4.33), with the exception of “seeking technical help,” which scored a mean of 3.63. However, similar to the other 2 profiles, items in the content creation and management domain exhibited the lowest relative scores, ranging from 3.10 to 3.56.

Figure 1 illustrates the distribution of mean scores for digital literacy indicators across 3 latent profiles. The x-axis represents the measurement items from the 3 domains, while the y-axis shows response scores ranging from 1 to 5 points. On the basis of the distribution characteristics of the 22-item EDLQ scores that measure digital literacy, the profiles were labeled as follows: profile 1 as “low level” (346/1016, 34.1%), profile 2 as “middle level” (374/1016, 36.8%), and profile 3 as “high level” (296/1016, 29.1%).

Figure 1. The distribution of digital literacy mean scores among 3 latent profiles.

Comparison of Participant Characteristics Among Digital Literacy Profiles

Table 3 provides an overview of the participant characteristics and the differences between the groups in the adopted 3-profile model. The average age of the participants was 68 (SD 6.5) years. Among the total number of participants (N=1016), the majority were female (n=530, 52.2%), had completed at least high school (n=551, 54.2%), lived with a spouse (n=524, 51.6%), resided in nonmetropolitan areas (n=547, 53.8%), and were engaged in income-generating activities (n=622, 61.2%). Most participants had no cognitive impairment (n=969, 95.4%), had been diagnosed with one or more chronic diseases (n=704, 69.3%), and had no diagnosed disabilities (n=967, 95.2%). They were capable of performing independent activities of daily living (n=952, 93.7%) and instrumental activities of daily living (n=839, 82.6%). Regarding health-related quality of life, the mean score for the physical aspect was 50.1 (SD 7.3; out of 100), and for the mental aspect, it was 49.4 (SD 8.4; out of 100). Most participants were not at risk of clinical depression (n=750, 73.8%), engaged in regular physical exercise for more than 10 minutes a day (n=594, 58.5%), had not consumed alcohol in the past year (n=516, 50.8%), and were nonsmokers (n=628, 61.8%). Most participants reported having participated in in-person social activities over the past year (n=853, 84%), and the average perceived social support score was 3.9 (SD 0.7; out of 5). Participants reported an average digital device use history of 82.9 (SD 64.9) months.

When comparing participant characteristics across the 3 profiles, statistically significant differences were observed in sociodemographic, health, and social factors on the basis of digital literacy levels, with the exceptions of region and ADL (both *P* values>.05). In the group with “high-level” digital literacy, the average age was the lowest at 64.7 (SD 4.6) years, and the majority (260/296, 87.8%) had attained at least a high school education. In addition, this group had a higher proportion of male individuals (190/296, 64.2%) and a greater participation in current income-generating activities (217/296, 73.3%) than the other 2 groups. Conversely, in the group with “low-level” digital literacy, a higher percentage of participants had education levels below high school (277/346, 80.1%) and a larger proportion lived alone (117/346, 33.8%), relative to the other 2 groups.

Distinct health patterns were observed among the profiles analyzed. In the “high-level” digital literacy group, a higher proportion of participants exhibited no cognitive impairment (294/296, 99.3%), no diagnosed chronic conditions (120/296, 40.5%), no disabilities (286/296, 96.3%), and no depressive symptoms (244/296, 82.4%) compared to the other 2 groups. This group also scored highest in health-related quality of life, both physically and mentally (physical component summary: mean 53.2, SD 5.0; mental component summary: mean 51.4, SD 7.9), indicating a quality of life that surpasses the average of the reference group. In contrast, the “low-level” digital literacy group displayed poorer outcomes across these health indicators. Although there was no significant difference in ADL among the 3 groups, IADL differed significantly. Notably, the “low-level” digital literacy group had a higher proportion of participants reporting dependency in one or more IADL items (96/346, 27.8%) compared to the other groups. In terms of health behaviors, the “high-level” digital literacy group had a relatively higher proportion of participants who engaged in regular exercise for more than 10 minutes (211/296, 71.3%), consumed alcohol (183/296, 61.8%), and were current smokers (48/296, 16.2%) than the other groups.

Regarding social factors, the “high-level” digital literacy group had the highest proportion of participants engaging in in-person social activities than the other 2 groups, at 92.2% (273/296). In addition, this group reported the longest history of using digital devices, averaging 128.0 (SD 74.8) months, and the highest mean score for perceived social support, at a mean of 4.1 (SD 0.7; out of 5).

Predictor Variables for Identifying Digital Literacy Profiles

Table 4 represents the results of multinomial logistic regression for predictor variables of digital literacy profiles. The statistically significant predictors that differentiate each group are age, sex, educational level, income-generating activities, dependence on IADL, physical health-related quality of life, physical exercise, in-person social activities, history of digital device usage, and perceived social support.

Among these variables, participants with an educational level below middle school were over 7 times more likely to be categorized in the “low-level” digital literacy group than the “middle-level” group compared to those holding a college degree or higher (OR 7.223, 95% CI 2.314-22.541). In addition, participants who required assistance with 1 of 10 instrumental activities of daily living, such as housework, meal preparation, or laundry, were over 3 times more likely to fall into the “low-level” digital literacy group than those requiring assistance with 2 or more such activities (OR 3.055, 95% CI 1.111-8.399). Furthermore, participants who did not engage in in-person social activities were nearly twice as likely to be in the “low-level” digital literacy group compared to those who did participate (OR 1.810, 95% CI 1.068-3.065). Each 1-month increment in the history of digital device use was associated with a lower likelihood of being in the “low-level” than “middle-level” digital literacy group (OR 0.986, 95% CI 0.981-0.991).

Meanwhile, women were 55.1% less likely to be in the "high-level" digital literacy group than the "middle-level" group than men (OR 0.449, 95% CI 0.253-0.795). Regarding educational attainment, participants with less than a college education were 66.8% less likely to be categorized as "high-level" in digital literacy compared to those with below a college degree (OR 0.332, 95% CI 0.179-0.614). Those with less than a high school education were about 89.4% less likely (OR 0.106, 95% CI 0.050-0.223), and individuals with less than a middle school education were nearly 83.4% less likely (OR 0.166, 95% CI 0.068-0.405). Participants who had never worked were 76.6% less likely to be in the "high-level" digital literacy group compared to those currently engaged in income-generating activities (OR 0.234, 95% CI 0.061-0.902). Participants who did not regularly engage in physical exercise for more than 10 minutes were 42.2% less likely to be in the "high-level" digital literacy group than those who did (OR 0.578, 95% CI 0.397-0.843). Each one-month increment in the history of digital device use was associated with a higher likelihood of being in the "high-level" than "middle-level" digital literacy group (OR 1.009, 95% CI 1.006-1.013). In addition, each 1-point increase in perceived social support nearly doubled the likelihood of being in the "high-level" digital literacy group (OR 1.700, 95% CI 1.219-2.369).

Discussion

Principal Findings

This study identified distinct profiles of digital literacy among community-dwelling older adults using the EDLQ [26], an instrument developed for this demographic in accordance with the European Commission's DigComp framework [11]. We categorized digital literacy into 3 distinct profiles: low level, middle level, and high level. Across all profiles, we observed a common pattern where digital literacy related to online information searching and social networking activities was relatively high. In contrast, skills in content creation and management, such as creating and editing documents, converting document formats, sharing content, and troubleshooting device issues, were notably lower. The low-level group exhibited particularly low skills in the security and safety domain, especially in their ability to block spam or delete search history. Meanwhile, the middle-level group displayed deficiencies in managing device security settings and seeking assistance for resolving technical issues within the security and safety domain.

Comparison to Prior Work

Our results highlight 2 critical areas essential for supporting the digital literacy of older adults. The first relates to the ability to customize digital content according to individual needs. The second underscores the importance of literacy in digital security and safety. Concerns about security and safety, as noted in previous studies [46,47], can present a significant challenge for older adults when adopting new technology. These findings provide valuable insights that have not been adequately addressed in earlier research, which primarily concentrated on information search and online communication as benchmarks for evaluating digital literacy [13,48].

Notably, our findings highlight the presence of a digital divide among community-dwelling older adults in South Korea, emphasizing the need for tailored strategies to address this issue. Consistent with prior research [9,17,49,50], older adults who were female, of greater age, and had lower educational levels were more likely to exhibit low digital literacy. This suggests that despite high smartphone usage among older adults in countries like South Korea [51], a significant digital divide can still exist within this demographic. It further highlights the importance of considering sociodemographic factors when supporting digitally vulnerable populations [17-19]. For instance, in Singapore, a successful initiative known as "Project Wire Up" was implemented to ensure that older adults with lower socioeconomic status are not left behind in the digital

XSL•FO
RenderX

society [52]. Skilled volunteers visited the homes of older adults to deliver a progressively challenging, tiered curriculum designed specifically for their needs. Consequently, the digital literacy scores of the participants in the intervention group improved significantly compared to those in the control group [52].

One approach to mitigating the digital divide among older adults is to increase the accessibility and use of digital devices. In our study, older adults with a longer history of using digital devices were more likely to achieve a middle-level of digital literacy rather than a low-level, and a high-level rather than a middle-level. Project Wire Up in Singapore [52] exemplifies this approach; a major component of the program was assisting older adults in acquiring smartphones and accessing the internet. In addition, the project focused on shifting traditional face-to-face social networking activities to digital platforms [52]. The recreational use of digital devices has been acknowledged as crucial for improving the digital literacy of older adults [23]. Furthermore, both the frequency and duration of internet use have shown a positive correlation with digital health literacy [53].

From a social connectedness perspective, the significance of social support and active participation in social activities is crucial for increasing the digital literacy of older adults. In our study, older adults who perceived greater social support were more likely to belong to the high-level digital literacy group rather than the middle level. Similarly, those engaged in in-person social activities tended to fall into the middle-level digital literacy group rather than the low-level group. A qualitative study investigating how older adults acquire digital literacy found that support from family, professionals, and peers significantly influenced not only the initiation but also the depth and frequency of digital device use [23]. Furthermore, a systematic review of the adoption of digital health technologies indicated that high social connectedness acts as a promoting factor across various cultural groups [54]. Although the exact mechanism of this association requires further exploration, social connectedness may impact digital literacy in older adults in 2 primary ways: first, by aiding them in learning and acquiring the skills to use digital devices [55], and second, by establishing a norm for digital device use [56].

In a similar context, our study showed that older adults currently engaged in economic activities were more likely to belong to the high-level digital literacy group compared to those who had never done so. Since economic activities often fall within the broader spectrum of social activities [57], it is plausible that the mechanism related to social connectedness also played a role here. In addition, previous research has shown that digital literacy in middle-aged and older adults positively affected their participation in managing personal finances [58]. Typically, most older adults may have primarily earned income through their careers until retirement. It is also conceivable that those more proficient in using digital devices and systems had better opportunities to engage in digital-based economic activities, such as using a mobile app for stock investments. However, since engagement in economic activities was measured with a single item, and the involvement of older adults in digital-based economic activities has not been extensively studied, our findings should be interpreted with caution and further research is needed.

Our findings also indicate that health-related factors are closely associated with digital literacy. Interestingly, our analysis revealed that older adults who are more dependent on IADL tend to fall into the middle-level digital literacy group rather than the low-level group. This contrasts with previous studies that focused on older adults with diabetes in South Korea [50,59]. This discrepancy suggests a potential new perspective on technology use among community-dwelling older adults. Since the early 2000s, there has been an increase in the use of smart home technology to assist individuals with diminished capabilities due to aging or disabilities [60-63]. These technologies, which incorporate sensors and robotics, can aid in supporting the IADL of older adults, such as meal preparation and bathing [60,61]. When introducing technology to older adults, the most critical factors to consider are the perceived benefits and ease of use [64,65]. Physical and cognitive aging can significantly hinder the adoption of new technologies by older adults [66]. As aging often requires more time to manage daily tasks like taking medication and undergoing physical therapy [67], older adults may view the adoption of new technologies as an additional burden that necessitates the reallocation of their time and energy [65].

In addition, in our sample, older adults who engaged in regular physical exercise were more likely to be categorized within the high-level digital literacy group. Similarly, a pilot study that used a smartphone app and activity-tracking device for physical training reported that participants with high technological proficiency were more receptive to modern technologies such as fitness trackers or smartphones compared to their less technologically adept counterparts [68]. Further research is required to explore the relationship between the health status or health behaviors of older adults and their use of digital technology.

Limitations

This study has several limitations. First, it relies on cross-sectional data, which precludes making causal inferences about the relationships between variables. Further longitudinal research is necessary to determine the temporality of the variables identified. Second, although the study assessed a wide range of sociodemographic, health-related, and social variables, it is possible that some potential correlates of digital literacy were overlooked. In addition, significant variables measured by a single item, such as economic activity, may not allow for robust interpretation. Third, our assessment of digital literacy covered a broad spectrum of domains using a measurement that reflects the most recent definition of the concept. However, as digital literacy is an evolving field, future studies might find our assessment to be incomplete. Despite these limitations, this study effectively provides a current understanding and characterization of digital literacy among community-dwelling older adults in South Korea.

Conclusions

Our findings reveal a significant disparity in digital literacy among older adults in a rapidly digitalizing country. Specifically,

XSL•FO
RenderX

factors such as social connectedness and health status were closely associated with the levels of digital literacy observed within this population. Older adults with higher digital literacy may have more opportunities in the digital society. To prevent older adults, particularly those who are digitally vulnerable, from being marginalized in the digital society, we propose a tailored approach. This approach focuses on understanding the characteristics of these older adult groups and addressing modifiable factors. Strategies to enhance digital literacy among older adults could include improving access to digital devices and providing step-by-step instructions tailored to the needs and education levels of digitally vulnerable older adults. In addition, efforts are needed to promote social support and encourage participation in social activities.

Abstract

Background: The integration of digital technology into older adult health and care has enhanced the intelligence of health and older adult care products and services while also transforming how seniors acquire and share health information. Assessing older adults' digital health literacy (DHL) is crucial for developing targeted interventions.

Objective: This study aims to develop and validate a DHL assessment questionnaire for older adults. It also seeks to evaluate the questionnaire's scientific validity and feasibility among community-dwelling older adults in China, providing a reliable tool for assessing their level of DHL.

Methods: A literature review, focus group discussions, and the Delphi method were used to construct the questionnaire item pool and perform item screening. Item analysis was conducted for comprehensive evaluation, and questionnaire validity was assessed through construct validity (exploratory factor analysis, confirmatory factor analysis, convergent validity, and discriminant validity), content validity, and criterion-related validity. Reliability was analyzed using Cronbach alpha coefficient, split-half reliability, and test-retest reliability.

Results: The study included 710 participants. Item analysis indicated that the questionnaire had strong discriminant validity. Correlation coefficient analysis showed that the item-total correlation coefficients ranged from 0.497 to 0.920 (P<.01). After multiple exploratory factor analyses, 6 common factors were extracted, with a cumulative variance contribution rate of 73.745%. Confirmatory factor analysis demonstrated a good model fit (χ^2/df=2.803, root-mean-square error of approximation=0.071, comparative fit index=0.907, goodness-of-fit index=0.773, incremental fit index=0.908, Tucker-Lewis index=0.901, normed fit index=0.863). The questionnaire demonstrated favorable convergent validity, content validity, and criterion-related validity. The total Cronbach α coefficient was 0.976, with dimension-specific Cronbach α coefficients ranging from 0.819 to 0.952, indicating satisfactory internal consistency. Additionally, the test-retest reliability coefficient for the total questionnaire was 0.925, demonstrating good stability over time.

Conclusions: This study developed a questionnaire specifically designed to assess DHL in older adults through a scientifically rigorous and systematic process. The questionnaire demonstrates strong psychometric properties and can serve as an empirical tool for health professionals to design personalized intervention policies and enhance health service delivery.

Introduction

Health literacy (HL) is the ability of an individual to access, understand, evaluate, and apply health information to make appropriate health decisions. It can help people make rational judgments about health care, disease prevention, and health promotion in their daily lives, thereby maintaining or enhancing an individual's quality of life throughout the life span [1]. Digital health literacy (DHL) is an expansion of HL in the digital era, which refers to an individual's ability to access, process, communicate, and understand health information and services in the context of the use of digital technology and information to promote and improve individual and collective health through effective health decision-making [2]. Different from HL, DHL emphasizes the technical skills required in the digital environment, such as using digital devices and the internet to search for health information, operating health-related apps, identifying and assessing the reliability of online health information, safeguarding the privacy and security of personal health information, and communicating effectively on digital platforms. In addition, DHL involves using critical thinking in digital environments, using digital tools for self-management and health monitoring, and adapting learning to the development of digital technology and health information, which are not included in the concept of HL [2,3]. Studies have shown significant associations between DHL and anxiety [4,5], health-promoting behaviors [6], self-efficacy [6,7], and self-care competence [7] in the older adult population. After controlling for sociodemographic variables, DHL in older adults was found to be able to directly and positively influence health-related quality of life in the study by Liu et al [8]. Kim et al [9] stated that there is a positive association between DHL and health-related behaviors. DHL in older adults significantly promotes health behaviors, health support behaviors, and disease management behaviors. Arcury et al [10] found a positive correlation between DHL in older adults and individual health knowledge, attitude, and computer use.

In recent years, digital technology has developed rapidly and has been increasingly applied to the field of older adults' health and aging. This advancement has enhanced the intelligence of health and aging products while also requiring a higher level of DHL for older adults to adapt to society and promote health [11]. To date, 5 DHL evaluation tools have been used for older adults [3]. Among them, the eHealth Literacy Scale (eHEALS) [12] is the most widely used DHL assessment tool, primarily measuring an individual's self-perceived ability to use information technology to process health information. However, it has a relatively limited scope of skills for assessment. By contrast, the electronic Health Literacy Scale [13] and the Digital Health Literacy Instrument [14] focus on evaluating individuals' operational skills in gathering online health information. However, these 2 tools may only partially cover the dimensions of DHL, particularly the practical skills required for operating digital devices and interactive communication. While the eHealth Literacy Questionnaire [15] was designed to keep pace with the growing prevalence of digital technology, it does not sufficiently address the security of personal information, content creation, and information exchange. The Digital Health Literacy Assessment [16] scale primarily focuses on using computers, smartphones, and other devices to access and assess health information. However, it falls short of accommodating the rapidly evolving demands of digital health capabilities. The emergence of new digital technologies may extend beyond the scope of assessment in existing DHL assessment tools. If assessment tools fail to accurately measure older adults' DHL levels, they may struggle to effectively use digital health information resources and fully engage with digital tools for health management. This could lead to deficiencies in understanding health issues, difficulties in making informed health decisions, and an increased risk of health inequalities among older adults.

The Digital Competence Framework (DIGCOMP) was developed by the European Commission's Joint Research Centre in 2013 to identify and define digital competencies relevant to all citizens living and working in Europe. The framework outlines 5 key competence areas: information, communication, content creation, safety, and problem-solving [17]. The framework provides a comprehensive and systematic approach to assessing digital competence, enabling comparisons across regions and groups. It also categorizes different levels of digital competence and encourages individuals to engage in lifelong learning to continuously refine and enhance their digital skills. Developed through extensive research and practice, DIGCOMP encompasses a range of digital competencies at different levels, from basic to advanced, allowing assessment tools to align with older adults' varying skill levels. Additionally, the DIGCOMP framework covers various aspects of digital competence and can be adapted to meet the specific needs and real-life situations of older adults, ensuring better alignment with their characteristics. Studies have been conducted to develop and validate assessment questionnaires for the everyday digital literacy of older adults based on the DIGCOMP framework, demonstrating good psychometric properties. These questionnaires have been successfully used to assess the digital literacy of older adults in Korea [18].

Because of declining cognitive function and changes in health status, older adults have an increasing need for health information and services. As the digital health domain continues to evolve, health management processes and efficiencies are being optimized. However, this also presents the challenge of a digital divide for older adults. Differences in educational background and technology acceptance lead to significant variations in their digital health capabilities [19]. Therefore, accurately assessing the digital health competence of older adults and implementing targeted interventions are crucial for improving their DHL. Currently, no digital health assessment tools specifically designed for older adults have been developed. In this context, our study constructed a questionnaire to assess DHL in older adults, using DIGCOMP as a theoretical framework while considering their cognitive and physiological characteristics. This questionnaire aims to identify the current level of DHL among older adults, providing a scientific basis for health care professionals to develop personalized interventions and health management policies, as well as to optimize health service processes.

Methods

Building DHL Questionnaire Entries for Older Adults

The research group conducted a scoping review to comprehensively gather relevant research findings on DHL evaluation questionnaires for older adults [3]. The initial literature search was performed in January 2022, followed by a supplementary search in June 2022. After the screening process, 16 published articles were identified that included evaluations of DHL in older adults, encompassing 5 assessment tools. Our analysis revealed that previous studies on DHL among older adults have primarily focused on assessing their ability to access, evaluate, and apply health information, while lacking assessments of their ability to communicate, integrate health information, and protect their privacy. Furthermore, no assessment tools specifically designed to address the unique characteristics of the older population have yet emerged. Based on these findings, we developed a new questionnaire with particular emphasis on the above dimensions, considering the cognitive and operational characteristics of the older population. Semistructured interviews were conducted before expert consultation (Multimedia Appendix 1). The corresponding author (WL) recruited experts through her personal network and applied a snowball sampling method to further expand the participant pool. The criteria for selecting experts for the semistructured interviews are listed in Textbox 1.

Textbox 1. Criteria for selecting experts for the semistructured interviews.

1. Health management of older adults
   - Experts were required to have over 10 years of experience in the field, hold at least an intermediate professional title, possess a postgraduate degree or higher, voluntarily participate, and be able to complete consultations in a timely manner.
2. Electronic health and digital health
   - Experts were required to have more than 5 years of experience, hold at least an intermediate professional title, have a bachelor's degree or higher, voluntarily participate, and be able to complete consultations in a timely manner.

A total of 6 experts participated in interviews and group discussions. These included a PhD supervisor specializing in health management, a chief physician in community general medicine, a chief physician in geriatric medicine, a master's supervisor specializing in public health, a master's supervisor in geriatric nursing, and a chief nurse. The interview outline included the following questions:

- What do you think should be included in the evaluation index of DHL for older adults?
- What fields of expertise do you think should be consulted via correspondence, and for what reasons?

The original DHL questionnaire was developed based on expert interviews. Five rounds of group discussions were conducted to refine the questionnaire, ensuring its alignment with China's national context and cultural background. Subsequently, the first version of the DHL Questionnaire was formulated, using DIGCOMP as its theoretical framework.

Validation of Questionnaire Contents

This study used expert consultation to validate the questionnaire's content. Sixteen experts from Shanghai's tertiary hospitals, colleges, universities, and technology companies—who have long been engaged in geriatric care, geriatrics, internet and health care, health policy, and computing—were selected for this study. The criteria for selecting experts were the same as those used for the semistructured interviews; however, the experts themselves were different. The experts' questionnaire consisted of 3 parts (Textbox 2).

Textbox 2. Parts of the experts' questionnaire.

1. Introduction
   - Outlining the purpose of the study, instructions for completing the questionnaire, details on how and when to submit it, contact information, and acknowledgments.
2. Digital health literacy evaluation questionnaire correspondence form for older adults
   - Experts rated the importance and relevance of each dimension and item on a scale of 1 to 5 (ranging from "very unimportant" to "very important") and 1 to 4 (ranging from "very irrelevant" to "very relevant"), with 2 additional columns—"Opinions and Reasons for Indicator Modification or Deletion" and "Items to be Added"—for experts to provide modification suggestions.
3. General information and expert authority questionnaire
   - Collecting basic information about the experts, along with their self-assessments of their authority and familiarity with the questionnaire content.

Three rounds of expert correspondence were conducted, with questionnaires distributed and returned via WeChat (Tencent Holdings Limited) or email. Upon receipt, the research team checked for completeness and verified any ambiguities or omissions with the experts to ensure the validity of the responses. The inclusion criteria for the entries were as follows:

XSL•FO
RenderX

a mean importance score >3.5, a total score rate >20%, and a coefficient of variation <0.25 [20]. Entries were adjusted based on discussions within the research team, incorporating expert modifications. After each round, responses were compiled, and items with significant opinion divergences were identified. In the subsequent round, these contentious items, along with summaries of expert opinions (median and standard deviation), were presented to encourage reflection and adjustment, gradually moving toward consensus. The study used Kendall *W* to measure the consistency of evaluations among experts, with the consultation stopping when Kendall *W* ranged between 0.4 and 0.5, indicating a satisfactory level of consensus [21]. The final DHL questionnaire for older adults included 6 dimensions and 46 items.

Evaluation of the Reliability and Validity of the Questionnaire

Participants and Data Collection

Given the high acceptance and response rate among older adults following advocacy by community health workers, and the fact that those able to attend the physical examination in person generally met the study's inclusion criteria, convenience sampling was used. The inclusion criteria were as follows: (1) signed informed consent and willingness to participate in the research; (2) aged 60 years or older and residing in the community for over 6 months; (3) possession of full communicative language abilities, including listening comprehension, oral expression, reading comprehension, and written expression. The exclusion criteria were (1) diagnosed mental disorders (eg, schizophrenia, delusions) or cognitive disorders (eg, Alzheimer disease, vascular cognitive impairment) and (2) diagnosis of a major or advanced terminal illness, such as a malignant tumor or end-stage renal disease.

Our study utilized an online survey method, with uniformly trained investigators rigorously selecting participants based on the inclusion and exclusion criteria. After eligible older adults completed their physical examination, the investigator explained the purpose and significance of the study. Participants were guided on how to navigate the questionnaire interface, key considerations for completing the questionnaire, and the rules for successful submission. Older adults completed the questionnaire independently on the spot. To prevent duplicate participation, the questionnaire was configured to allow only 1 submission per WeChat user. After the survey concluded, researchers conducted a quality check on all questionnaires. A preexperiment revealed that it was nearly impossible for older adults to complete the questionnaire within 2 minutes while carefully reading each question. Therefore, to ensure data quality, questionnaires completed in under 2 minutes were excluded.

The sample size was determined based on the principle that factor analysis requires at least 5-10 times the number of questionnaire items [22]. Given that the questionnaire contains 46 items and considering a 20% increase for potential invalid responses, the sample size was calculated as $46 \times 5 \times (1 + 20\%) = 276$. As both exploratory and confirmatory factor analyses require 2 independent samples, the minimum required sample size for the study was 552. Study participants were selected from August to November 2023 among 710 older adults undergoing their annual physical examination in Shanghai. The obtained samples were randomly divided into 2 groups for pretesting (n=355) and formal testing (n=355).

Ethics Approval

The study was approved by the Ethics Committee of Renji Hospital, affiliated with Shanghai Jiao Tong University School of Medicine (approval number RA-2021-465). Participants understood the purpose, process, risks, and benefits of the study and voluntarily agreed to participate. The survey adhered to the principles of anonymity and confidentiality, and responses were collected anonymously. Health science popularization books were provided to participants as compensation.

Instruments

In our study, the questionnaire was in Chinese and consisted of 4 parts (Multimedia Appendix 2): (1) informed consent form; (2) general information questionnaire (designed by the researcher), which included information on gender, age, education level, marital status, residential situation, household monthly income, the primary source of income, and medical payment methods; (3) the eHEALS (developed by Norman et al [12]), which consists 8 questions assessing the ability to apply online health information and services, judgment ability, and decision-making ability. It is scored on a 5-point Likert scale, with a total score ranging from 8 to 40, where higher scores indicate better eHealth literacy (eHL). The scale demonstrated high internal consistency (α=.967); (4) Digital Health Literacy Questionnaire for Older Adults (designed by researchers WL and XW), which includes 6 dimensions: Information (14 items), Interaction (11 items), Content (3 items), Safety (7 items), Attitude (4 items), and Behavior (7 items). A 5-point Likert scale was used, with each item scored from 1 to 5, ranging from "very inconsistent" to "very consistent," where higher scores indicate better DHL.

Statistical Analysis

Excel 2019 (Microsoft Corporation) was used for raw data entry, and SPSS 25.0 (IBM Corp.) and AMOS 26.0 (IBM Corp.) statistical software were used for statistical analysis. Sociodemographic information was expressed as the number of cases and percentages. Given that all variables in our study were bivariate normally distributed and exhibited a linear relationship, we used Pearson correlation analysis.

The first pretest sample (N=355) was subjected to item analysis, exploratory factor analysis (EFA), and further screening of entries to develop the formal questionnaire. The questionnaire items were comprehensively evaluated based on the item analysis screening criteria listed in Textbox 3.

XSL•FO
RenderX

Textbox 3. Item analysis screening criteria.

1. Critical ratio method
   - The total questionnaire score was divided into high and low groups, comprising the top 27% and bottom 27%, respectively. The critical value (*t* value) for each item between these groups was compared, with a requirement of $t \geq 3$ and a statistically significant difference.
2. Correlation coefficient method
   - The correlation coefficient between each item and the total score, as well as the corrected item-total correlation coefficient, should be ≥0.4.
3. Homogeneity test
   - The Cronbach α coefficient of the total questionnaire should not increase after deleting any item. The factor loading of each item on the common factors of the questionnaire should be ≥0.4, and the communality should be ≥0.2. An item was deleted if it failed to meet at least three of these 6 indicators [23].

The Kaiser-Meyer-Olkin (KMO) test and Bartlett test of sphericity were used to assess the adequacy of the data. A KMO value close to 1 and $P<.05$ after the Bartlett test indicate that the original variables are suitable for factor analysis. Principal component analysis was used to extract common factors with eigenvalues greater than 1, combined with the scree plot for judgment. The varimax method of orthogonal rotation was applied to enhance factor loadings, with strong associations considered to exist when factor loadings were ≥0.4. If an item had factor loadings ≥0.4 across multiple dimensions, it was assigned to the dimension with the highest factor loading [24]. The deletion criteria were as follows: (1) items with loadings <0.4 on their respective factors; (2) items with communalities <0.2; (3) items with multiple loadings of similar values across dimensions; (4) items with factor loadings inconsistent with the original conceptual framework and inexplicable; and (5) dimensions with fewer than 3 items [25].

Validation factor analysis, convergent and discriminant validity tests, content validity tests, validity scale assessments, and internal consistency reliability tests were conducted on the second round of formal questionnaire test samples (N=355) to verify the reliability and validity of the questionnaire.

To further verify the structural validity of the questionnaire, confirmatory factor analysis was conducted using the maximum likelihood method to estimate model parameters. The chi-square to degrees of freedom ratio (χ^2/df), root-mean-square error of approximation, goodness-of-fit index, adjusted goodness-of-fit index, comparative fit index, incremental fit index, Tucker-Lewis index, and normed fit index were used to evaluate the model [26]. When the average variance extracted (AVE) is greater than 0.5 and the composite reliability exceeds 0.7, the questionnaire demonstrates ideal convergent validity. Additionally, when the correlation between questionnaire dimensions is significant but remains lower than the square root of the corresponding AVE, the questionnaire exhibits desirable discriminant validity [27].

In this study, experts from relevant fields (N=16) were invited to evaluate the content validity of the questionnaire. The item-level content validity index (I-CVI) represents the proportion of experts who rated each item as 3 or 4. The scale-level content validity index (S-CVI/Ave) is the average of all I-CVIs. When the number of experts exceeds 6, an I-CVI>0.78 and an S-CVI/Ave>0.90 are generally considered to indicate good relevance of the items and questionnaire to the conceptual content being measured [28].

The eHEALS was used as the criterion tool in this study. A positive and statistically significant correlation between the criterion tool and the DHL questionnaire for older adults, both in total score and across dimensions, indicates that the criterion-related validity is satisfied [29].

Cronbach α coefficient and Spearman-Brown split-half reliability are the most commonly used methods for testing the internal consistency reliability of questionnaires. Generally, a Cronbach α coefficient greater than 0.500 for each dimension and a total Cronbach α coefficient and Spearman-Brown split-half reliability greater than 0.700 indicate acceptable reliability. Retest reliability analyses were conducted with a retest sample (N=20) [29]. For all tests, the significance level was set at $\alpha=.05$.

Results

Characteristics of Participants

The study included 710 participants, consisting of 354 males (49.9%) and 356 females (50.1%). Participants ranged in age from 65 to 100 years, with a mean age of 70.7 (SD 6.3) years. The results are presented in Table 1.

Item Analysis

The results of the item analysis are summarized in Multimedia Appendix 3. In the extreme group comparisons, all items showed statistically significant differences between the high- and low-score groups (P<.001). Correlation coefficient analysis indicated that item-total correlation coefficients ranged from 0.468 to 0.744, while corrected item-total correlation coefficients ranged from 0.442 to 0.725 (P<.001). The Cronbach α coefficient for the total questionnaire was 0.981, and no increase was observed after deleting any item. Factor analysis revealed that item factor loadings ranged from 0.365 to 0.697, with communalities ranging from 0.446 to 0.677. Ultimately, 3 items failed to meet 1 criterion; however, they did not meet the deletion threshold. Therefore, all 46 items were retained for further analysis.

Validity Analysis

Construct Validity

Exploratory Factor Analysis

EFA was conducted on the 46 items, yielding a KMO value of 0.955 and a significant Bartlett test of sphericity (χ^2_{1035}=8299.714, P<.001), indicating that the data were suitable for factor analysis. Six common factors with eigenvalues >1 were extracted, accounting for 53.810% of the cumulative variance. The scree plot also confirmed that retaining 6 factors was appropriate. EFA was performed multiple times, setting the number of factors to 6, and noncompliant items were gradually removed. Ultimately, 39 items remained, forming 6 factors with a cumulative variance contribution rate of 73.745%. The factor loadings for the items in each dimension ranged from 0.452 to 0.815, as detailed in Multimedia Appendix 4.

Confirmatory Factor Analysis

The results indicated that the model was identifiable and successfully converged but initially exhibited poor goodness of fit. The modification indices revealed high correlations between 5 pairs of error terms, each with values greater than 10, suggesting potential local dependence issues in the model [26]. Upon further analysis, we found that while these item pairs were designed to measure distinct concepts, they exhibited some conceptual overlap. This finding was consistent with the high modification indices, indicating that the error terms might not be entirely independent as initially assumed. To address this, and after confirming that the model's complexity was not artificially inflated, we sequentially added 5 error covariances to account for these observed relationships. Following these adjustments, the standardized regression coefficients of the revised model ranged from 0.538 to 0.931, indicating a good model fit. The model fit indices are presented in Table 2, and the confirmatory factor analysis model diagram is shown in Figure 1.

XSL•FO
RenderX

Figure 1. The confirmatory factor analysis model diagram.

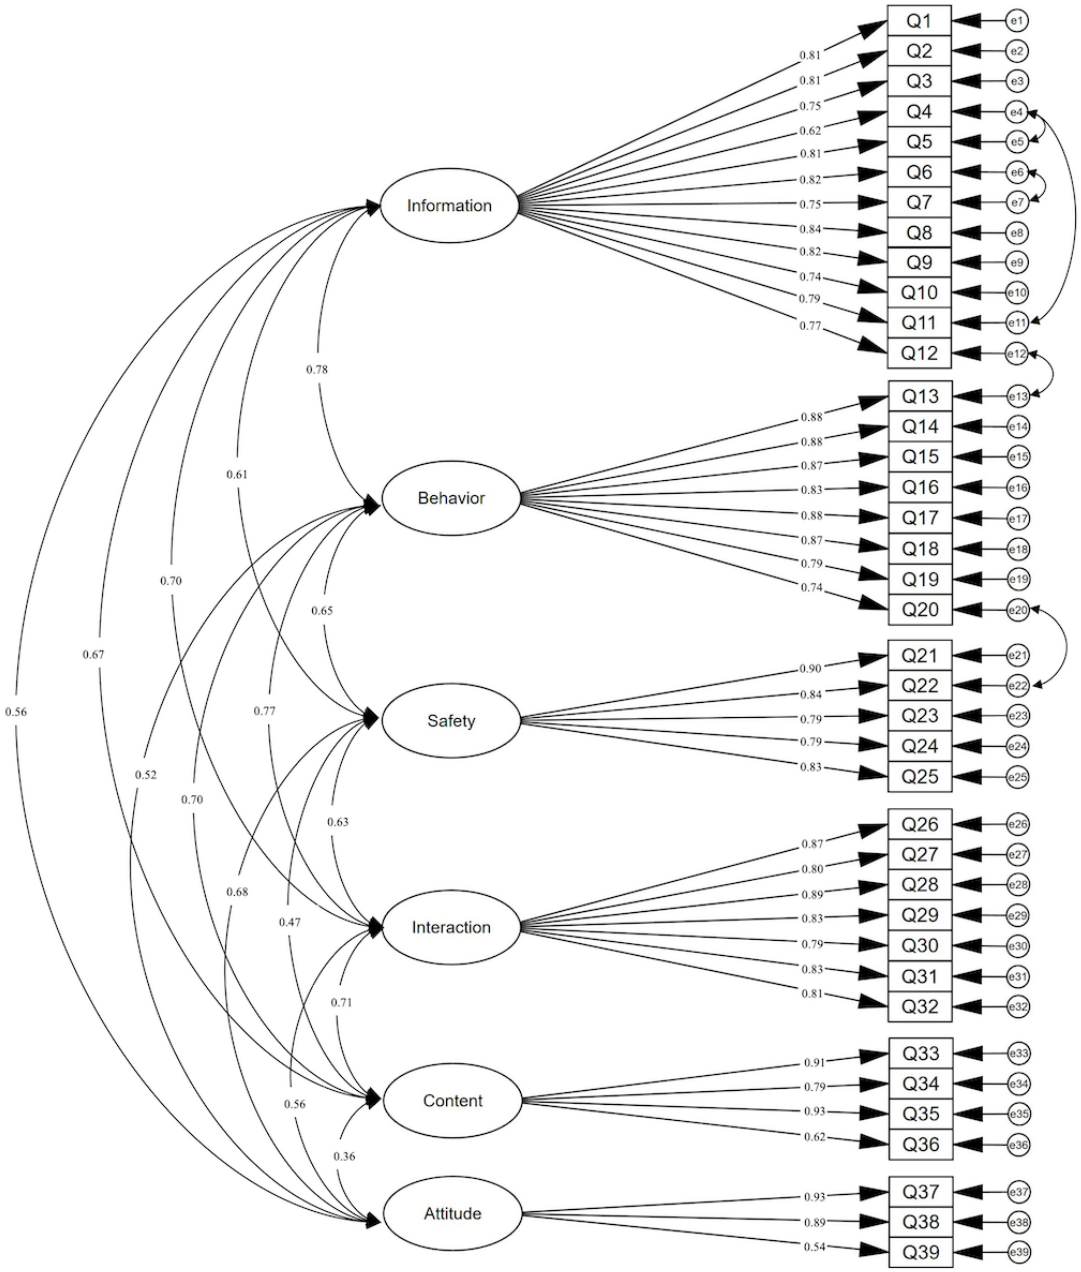

Table 2. Goodness-of-fit indices for confirmatory factor analysis of the digital health literacy questionnaire in older adults.

Item	Chi-square/*df*	Root-mean-square error of approximation	Comparative fit index	Goodness-of-fit index	Incremental fit index	Tucker-Lewis index	Normed fit index
Reference standard	<5	<0.08	>0.9	>0.9	>0.9	>0.9	>0.9
Initial model	3.404	0.082	0.875	0.733	0.876	0.855	0.833
Revised model	2.803	0.071	0.907	0.773	0.908	0.901	0.863

Convergent and Discriminant Validity

Convergent Validity

Based on the well-fitted model, the convergent validity of the questionnaire was tested, with results presented in Table 3. The factor loadings for the items across the 6 dimensions ranged from 0.538 to 0.931, all exceeding 0.500, indicating strong representativeness of the items within their respective dimensions. Additionally, the AVE for each dimension ranged from 0.608 to 0.768, all above the 0.500 threshold, while the composite reliability values ranged from 0.841 to 0.952, all exceeding 0.700, confirming the excellent convergent validity of the questionnaire.

XSL•FO
RenderX

Table 3. Convergent validity of the digital health literacy questionnaire in older adults.

Factors and items	Factor loadings	Average variance extracted	Composite reliability
Information		0.608	0.949
1. I pay attention to whether health information is released and disseminated by official or authoritative institutions	0.814		
2. I compare similar health information	0.809		
3. I verify the correctness of health information from other sources	0.752		
4. I remain vigilant about the health information I obtain and do not easily believe it	0.618		
5. I understand digital health technologies (eg, wearable devices, smart health electronic products)	0.810		
6. I understand that digital technologies can be used for health management or health promotion (such as health and medical mobile apps)	0.817		
7. I do not immediately share health information with others after receiving it but first check the content	0.751		
8. I can browse, search, and obtain health information through digital devices or software	0.844		
9. I pay attention to updates on health information	0.818		
10. I can judge whether health information is related to commercial interests (eg, contains product advertisements)	0.742		
11. I understand that digital health devices or software can be used to store personal health information	0.788		
12. I have used digital health devices or software to record personal health information	0.768		
Behavior		0.714	0.952
13. I know how to use digital health tools to track my health behavior	0.880		
14. I can judge whether digital health tools are trustworthy	0.879		
15. During the use of digital health tools, I can adjust my frequency, intensity, and methods based on the actual situation	0.872		
16. I am used to using digital services to handle health information	0.832		
17. I can use digital devices or electronic health products or software	0.878		
18. I know when, how, and what health information to use	0.874		
19. If necessary, I think I can persist in using digital health tools	0.790		
20. I believe the use of digital technologies is beneficial for my health management	0.743		
Safety		0.688	0.917
21. I believe I have the right to pursue legal responsibility for unauthorized data acquisition or improper data storage that leads to data breaches	0.895		
22. I believe I have ownership of personal data, and others can only obtain my personal health data with my authorization	0.840		
23. I do not click on unsafe web links; I do not visit websites that are flagged as risky	0.787		
24. I can avoid health risks related to the use of digital technologies that threaten physical and mental health	0.792		
25. I know the potential security risks in the online environment	0.829		
Interaction		0.693	0.940

XSL•FO
RenderX

Factors and items	Factor loadings	Average variance extracted	Composite reliability
26. I can share information with others on the internet	0.869		
27. I can share the information I obtained online with others offline	0.803		
28. I can use digital devices or software to communicate health information with others	0.894		
29. I am familiar with the user interface of digital devices or software	0.829		
30. I use information dissemination platforms (eg, Weibo, WeChat Moments) to share information	0.792		
31. I can use digital devices or software to communicate health information with artificial intelligence	0.825		
32. I imitate the health-promoting behaviors or health management methods mentioned in health information	0.811		
Content		0.768	0.908
33. I can edit and improve health content created by myself or others	0.907		
34. I can protect the integrity of original works and cite sources when referencing	0.787		
35. I can integrate health information from multiple sources and rephrase it	0.929		
36. In the past 12 months, I have participated in online health lectures and health care experience sharing activities	0.621		
Attitude		0.650	0.841
37. I adhere to the correct political direction in online behavior	0.931		
38. I do not fabricate or spread false, unverified health information	0.891		
39. I care about health information related to myself	0.538		

Discriminant Validity

Further examination of discriminant validity showed that all questionnaire dimensions were significantly correlated, with correlation coefficients ranging from 0.363 to 0.779 (P<.001). These values were all lower than the square roots of the corresponding AVEs, indicating that while the dimensions are interrelated, they maintain sufficient discriminant validity. This confirms that the questionnaire structure demonstrates ideal discriminant validity. See Table 4 for details.

Table 4. Discriminant validity of the digital health literacy questionnaire in older adults.

Dimensions	Information	Behavior	Safety	Interaction	Content	Attitude
Information	1	—[a]	—	—	—	—
Behavior	0.779[b]	1	—	—	—	—
Safety	0.614[b]	0.650[b]	1	—	—	—
Interaction	0.704[b]	0.773[b]	0.629[b]	1	—	—
Content	0.660[b]	0.704[b]	0.465[b]	0.708[b]	1	—
Attitude	0.555[b]	0.518[b]	0.676[b]	0.560[b]	0.363[b]	1
Square root of average variance extracted	0.779	0.845	0.829	0.832	0.876	0.806

[a]Not applicable.

[b]P<.01.

Content Validity

Based on expert ratings, the I-CVI of the questionnaire ranged from 0.81 to 1.000 and S-CVI/Ave was 0.92, both meeting the required standards, indicating good content validity.

Criterion-Related Validity

The criterion validity analysis showed that the total and dimension scores of the Digital Health Literacy Questionnaire for Older Adults were positively correlated with the total and dimension scores of the eHEALS, with correlation coefficients ranging from 0.363 to 0.980, all statistically significant (P<.01).

XSL•FO
RenderX

This demonstrates good criterion-related validity of the questionnaire, as shown in Multimedia Appendix 5.

Reliability Analysis

Cronbach α Coefficient

The results showed that the total questionnaire's Cronbach α coefficient was 0.976, and each dimension's Cronbach α coefficient ranged from 0.819 to 0.952, demonstrating high internal consistency of the questionnaire.

Split-Half Reliability

The results showed that the total questionnaire's Spearman-Brown split-half reliability coefficient was 0.925, and the Spearman-Brown split-half reliability coefficients for each dimension ranged from 0.739 to 0.956, indicating good internal consistency of the questionnaire.

Test-Retest Reliability

In this study, test-retest reliability was assessed by readministering the questionnaire to 20 individuals 2 weeks after the initial administration. The results showed that the total questionnaire's test-retest reliability coefficient was 0.925, while the coefficients for each dimension ranged from 0.875 to 0.933, all exceeding 0.700. These findings indicate that the questionnaire exhibits good stability over time. See Table 5 for detailed results.

Table 5. Reliability analysis of the digital health literacy questionnaire in older adults.

Dimensions	Item numbers	Cronbach α coefficient	Split-half reliability	Test-retest reliability
Information	12	0.950	0.946	0.903
Behavior	8	0.952	0.956	0.933
Safety	5	0.916	0.837	0.897
Interaction	7	0.939	0.888	0.880
Content	4	0.880	0.888	0.891
Attitude	3	0.819	0.739	0.875
Digital health literacy	39	0.976	0.925	0.925

Discussion

DIGCOMP-Based Framework for Assessing Digital Health Literacy

The study utilized the DIGCOMP framework as a conceptual foundation, integrating expert opinions and empirical research to refine the structure and content of the questionnaire. The final instrument assesses 6 dimensions of DHL and demonstrates strong psychometric properties. This provides a solid empirical basis to support health professionals in developing individualized intervention strategies and optimizing health service delivery.

Questionnaire Formation Is Meaningful

As the global population ages, older adults are becoming a priority in the health care sector [30]. With the rapid advancement of digital technology, they face multiple challenges in managing their health. Cognitive decline and limited digital training can make it difficult for them to use digital tools for health management. This can hinder their access to essential health information and resources, as well as services such as online appointments, telemedicine consultations, and electronic health records. As a result, these barriers may increase the risk of medication errors and exacerbate health inequalities.

From the perspective of enhancing older adults' engagement in health management, improving DHL is a top priority in developing a digital service system for older adults [11]. The concept of DHL is continuously evolving and requires distinct competencies compared with eHL. Although both are related, they differ significantly in their practical application for older adults. eHL primarily focuses on their ability to process and apply health information online, such as searching for disease-related information, comparing data from multiple authoritative sources, and identifying false medical advertisements. It emphasizes critical thinking and the ability to assess the authenticity of health information [14,31]. By contrast, DHL emphasizes older adults' ability to effectively use digital health devices, such as smart blood pressure monitors or health tracking bracelets, to manage their health data. It involves applying digital tools to adjust exercise routines, modify daily diets based on professional advice, and engage in self-care. This requires a certain level of technical competence. Additionally, DHL highlights the importance of exchanging and evaluating health information, as well as ensuring privacy protection in digital interactions [3]. Therefore, if an assessment tool is not designed based on the latest DHL concepts, it may fail to align with the essential skills older adults need to develop and demonstrate. There will be no direct comparison between the results of different studies, which may limit their reproducibility and generalizability. However, most existing assessment tools for older adults have been developed based on eHL, without considering the unique characteristics of this population [12-16]. Currently, there is no specific DHL assessment tool designed for older adults. The questionnaire developed in this study addresses this gap by evaluating the current status of DHL in older adults and identifying areas where digital health competencies need improvement. This provides a foundation for developing appropriate intervention strategies and targeted health education, making it highly relevant in the current digital health landscape.

XSL•FO
RenderX

Questionnaire Construction Process Is Reasonable

This study conducted a comprehensive review of relevant literature and government policy documents. Using the widely accepted DHL concept, the DIGCOMP framework was adopted as the theoretical foundation to ensure the questionnaire's scientific rigor. The initial framework was developed through face-to-face semistructured interviews with 6 experts and 5 rounds of research group discussions. To ensure content validity, 3 rounds of expert consultations were conducted with 16 specialists from hospitals, academic institutions, and technology companies. These experts, with extensive experience in geriatric care, provided valuable insights into the characteristics and needs of older adults. The recommendations provided by these experts were comprehensive and highly instructive. The questionnaire development process emphasized aspects that had been overlooked in previous assessment tools, including interaction (both with others and with devices), content editing (such as information integration and copyright awareness), and security (covering privacy protection, device security, and health-related safety). The questionnaire items were designed to align with the realities of older adults' daily lives and health care experiences, focusing on potential challenges they may face when using digital technologies to access, process, communicate, and understand health information and services. To ensure its relevance and usability, a presurvey was conducted with 10 older adults from diverse backgrounds. Through individual interviews, participants' experiences with completing the questionnaire were observed and recorded. Based on these insights, the questionnaire was simplified in terms of language and optimized in layout to enhance its applicability and improve data collection efficiency. Additionally, complex terminology was replaced with more accessible wording to make it easier for older adults to respond. For essential terms that needed to be retained but might be difficult to understand, clear explanations were added to ensure clarity.

The Contents of the Questionnaire Are Scientific

The study refined the questionnaire entries through empirical research. The research team conducted multiple discussions on the professional significance of each entry, making modifications and deletions based on predefined criteria and expert knowledge.

The "Information" dimension evaluates older adults' ability to access, assess, and utilize health information through digital devices, as well as their understanding of digital health. This dimension is a core component of DHL measurement. In our study, 12 of the original 14 items in this dimension were retained in the final questionnaire. The item "I will check if the health information is of value to me" was removed after discussions with the research team, as it was semantically similar to other items in the same dimension and had a factor loading below 0.4. Additionally, the item "I care about health information related to myself" was reassigned to the "Attitude" dimension.

The "Behavior" dimension assesses older adults' ability to manage their health using digital devices and their understanding of how digital technology can support their well-being [32]. During the revision process, the item "I think digital health information is trustworthy," originally part of the "Attitude" dimension, was removed, while the remaining items were reassigned to the "Behavior" dimension. Additionally, through expert consultations and group discussions, the "Problem-Solving" dimension from the DIGCOMP framework was subdivided into the "Attitude" and "Behavior" dimensions. As a result, the empirical study justified the reclassification of certain items between these 2 dimensions.

The "Safety" dimension assesses older adults' ability to protect their personal information and physical and mental well-being while managing their health through digital devices. This competency, which has not been explicitly addressed in the concept of eHL [3], is crucial for ensuring the safe and effective participation of older adults in digital health activities [17,19]. During the questionnaire evaluation, most items remained within this dimension. However, the item "I believe that personal health data can be accessed by medical staff directly involved in the treatment" was removed due to insufficient factor loading. Additionally, the item "I know how to protect personal digital devices from cyber attacks" exhibited double loading with similar values. Apart from these adjustments, no attributional changes were made to the remaining items.

The "Interaction" dimension in evaluating older adults' DHL emphasizes their ability to communicate health information with individuals, health care platforms, artificial intelligence, and other digital systems. Previous research has primarily focused on older adults' ability to communicate with people in the context of DHL [33], likely due to the traditional perspective that health information exchange occurs mainly between individuals. However, with advancements in technology, the ability of older adults to effectively interact with digital devices is not only crucial for accessing timely and accurate health information but also directly influences the quality of their health management and self-care. During the evaluation of questionnaire entries, 1 item exhibited multiple loadings, and 3 items were reassigned to other dimensions after discussion. No items from other dimensions were added to this category.

The "Content" dimension emphasizes older adults' ability to integrate and enhance digital health information. While it is related to other dimensions, it is distinct in its focus on evaluating overall competencies [17]. In this dimension, we incorporated the item, "I have participated in online health knowledge seminars, health care experience-sharing activities, and similar events in the past 12 months," which was originally part of the "Interaction" dimension. Although each dimension of the DIGCOMP framework has unique characteristics, there are inherent overlaps and interconnections between them [17]. The "Content creation" competency in the DIGCOMP framework includes "Sharing information and content," which aligns with the competencies assessed in the "Content" dimension. As interaction serves as a prerequisite for content creation and addressing health concerns [17], this reallocation is justified.

Additionally, we identified 2 entries from the original "Interaction" dimension—"I can adhere to the correct political direction in my online behavior" and "I can refrain from fabricating or spreading false and unverified health information"—as well as 1 entry from the former "Information"

XSL•FO
RenderX

dimension—"I care about health information related to myself." These 3 entries differ significantly in connotation from the other items in their respective dimensions. After an in-depth group discussion, we consolidated them into a newly established "Attitude" dimension. This dimension was created to assess older adults' sense of responsibility, political sensitivity, and concern for personal health information when managing digital health information.

The Implications of This Study for Future Research

The DHL questionnaire for older adults developed in our study provides future researchers with a standardized measurement tool, facilitating comparative studies across different regions and populations. Our findings also underscore the importance of enhancing DHL in older adults. Future research can build on our study to further refine the questionnaire's structure and content. Additionally, researchers can explore targeted educational interventions in greater detail, such as developing digital skills training programs tailored for older adults and designing user-friendly digital health education resources. Additionally, researchers can use these findings to develop more targeted policies, such as promoting digital inclusion initiatives for older adults and establishing a comprehensive community support system. This could include community health education programs, volunteer service networks, and mutual aid groups. Such measures will effectively enhance the DHL of older adults, ultimately improving their overall health and quality of life and supporting the goal of healthy aging.

Limitations

There are some limitations to our study. The questionnaire developed was a self-assessment tool, which may lack objectivity. Older adults completing self-assessment questionnaires might select responses they believe are more socially acceptable or aligned with the investigators' expectations rather than their true thoughts, feelings, or behaviors regarding digital health. This tendency could introduce social desirability and response biases, potentially reducing data accuracy. Additionally, self-assessments may be affected by recall bias, as older adults might struggle with memory inaccuracies or overestimate their DHL, leading to discrepancies between their reported and actual abilities. Methods such as scenario modeling could be considered for objective evaluation in the future. Additionally, our study used a web-based survey, requiring older adults to complete the questionnaire independently, which may have excluded those with poorer numerical ability and health. These individuals may prefer obtaining health information through traditional channels (such as television, newspapers, and face-to-face communication), have lower familiarity with and less frequent use of the internet and digital technologies, and may face difficulties in accessing and interpreting health information. However, excluding them may result in health needs and issues specific to certain groups of older adults being inadequately explored, potentially affecting the ubiquity and applicability of the findings. Future research could incorporate both online and traditional face-to-face surveys. Additionally, a more concise and comprehensible questionnaire should be designed, and older adults should be provided with the necessary digital skills training to facilitate their participation in research. Furthermore, this questionnaire has only undergone psychometric testing among Chinese older adults. Therefore, cross-linguistic validation is needed to confirm its cultural invariance.

Conclusions

As scientific and technological advancements intertwine with theoretical research developments, the concept of DHL must be continuously explored and updated. Our study developed a DHL questionnaire for older adults based on the latest DHL concepts, assessing 6 dimensions: Information, Behavior, Security, Interaction, Content, and Attitude. The questionnaire closely reflects the real-life experiences of older adults and demonstrates strong differentiation, reliability, and practicality. It provides health-related practitioners with a scientifically sound and feasible tool for accurately and comprehensively assessing the current status of DHL in older adults. Future research should conduct an in-depth assessment of the questionnaire's applicability across different linguistic and cultural contexts and evaluate its validity among older adults with varying health statuses, educational backgrounds, and socioeconomic conditions. Additionally, the effectiveness of the questionnaire in specific intervention programs should be assessed to validate its practical guiding role. Furthermore, it is essential to explore ways to integrate assessment results into targeted health promotion strategies and incorporate theories and methods from multiple disciplines, such as psychology, sociology, and education. Through interdisciplinary collaboration, DHL enhancement initiatives for older adults can be more effectively implemented, providing comprehensive support for their health management.

Abstract

Background: Mobile health care is rapidly expanding in China, making the enhancement of eHealth literacy a crucial strategy for improving public health. However, the persistent urban-rural divide may contribute to disparities in eHealth literacy between urban and rural university students, potentially affecting their health-related behaviors and outcomes.

Objective: This study aims to examine disparities in eHealth literacy between university students in urban and rural China, identifying key influencing factors and their contributions. The findings will help bridge these gaps, promote social equity, enhance overall health and well-being, and inform future advancements in the digital health era.

Methods: The eHealth Literacy Scale (eHEALS) was used to assess eHealth literacy levels among 7230 university students from diverse schools and majors across 10 regions, including Guangdong Province, Shanghai Municipality, and Jiangsu Province. Descriptive statistics summarized demographic, sociological, and lifestyle characteristics. Chi-square tests examined the distribution of eHealth literacy between urban and rural students. A binary logistic regression model identified key influencing factors, while a Fairlie decomposition model quantified their contributions to the observed disparities.

Results: The average eHealth literacy score among Chinese university students was 29.22 (SD 6.68), with 4135 out of 7230 (57.19%) scoring below the passing mark. Rural students had a significantly higher proportion of inadequate eHealth literacy (2837/4510, 62.90%) compared with urban students (1298/2720, 47.72%; P<.001). The Fairlie decomposition analysis showed that 71.4% of the disparity in eHealth literacy was attributable to urban-rural factors and unobserved variables, while 28.6% resulted from observed factors. The primary contributors were monthly per capita household income (13.4%), exercise habits (11.7%), and 9-item Patient Health Questionnaire (PHQ-9) scores (2.1%).

Conclusions: Rural university students exhibit lower eHealth literacy levels than their urban counterparts, a disparity influenced by differences in socioeconomic status, individual lifestyles, and personal health status. These findings highlight the need for targeted intervention strategies, including (1) improving access to eHealth resources in rural and underserved areas; (2) fostering an environment that encourages physical activity to promote healthy behaviors; (3) expanding school-based mental health services to enhance health information processing capacity; and (4) implementing systematic eHealth literacy training with ongoing evaluation. These strategies will support equitable access to and utilization of eHealth resources for all students, regardless of their geographic location.

university students; eHealth literacy; urban-rural disparities; Fairlie decomposition model; health equity

Introduction

Health literacy is a midstream determinant of health that can improve outcomes, reduce inequalities, and promote health-related behaviors [1]. Today, the internet is widely used due to its accessibility, broad information coverage, ease of use, affordability, and anonymity [2]. It has become a key platform for disseminating health information, particularly in middle- and high-income countries such as China, where health care resources and face-to-face medical appointments are limited [3]. However, the widespread availability of the internet has also exposed shortcomings in online health information, especially concerning its quality [4]. Individuals frequently encounter false or dubious health information online, a challenge that is not new [5]. eHealth literacy extends the concept of health literacy into the digital domain. It was first introduced by Norman and Skinner [6]. Gilstad [7] later expanded its definition to encompass the ability to address health problems by communicating, locating, understanding, evaluating, and applying health information and digital technologies within specific cultural and social contexts [8]. It should be emphasized that eHealth literacy requires not only the ability to access necessary information but also the ability to assess the quality of eHealth information and distinguish between reliable and unreliable sources [6]. eHealth literacy is essential for maintaining good health and preventing disease. Improving eHealth literacy enables individuals to access health information for disease prevention, treatment, and health promotion [9]. People with strong eHealth literacy can make informed decisions, select appropriate health services, and manage their health effectively. This includes monitoring their health status, following medical advice, and taking preventive measures against disease. Furthermore, eHealth literacy can enhance communication between patients and physicians, improving the effectiveness and overall satisfaction of medical services [10].

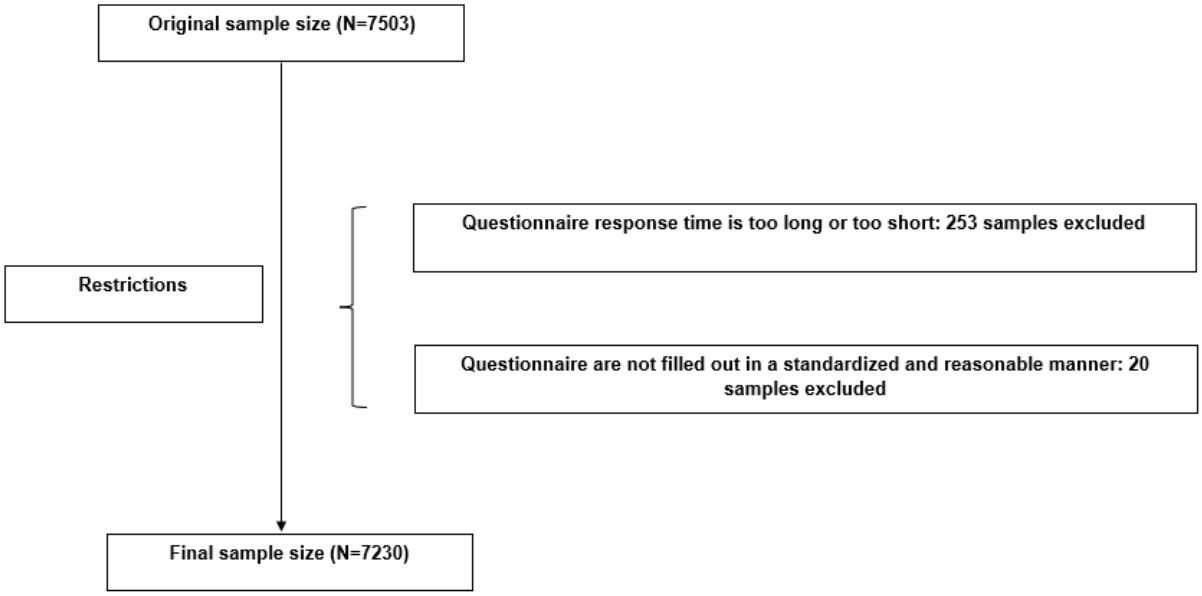
As the future builders and pillars of development in their home countries, the health status of young people and their ability to maintain it deserve attention. Their knowledge, attitudes, and behaviors not only impact their own lives but also influence society as a whole [11,12]. For university students transitioning to adulthood, the development of health behaviors during this stage is crucial for maintaining a healthy lifestyle throughout adulthood [13,14]. However, they are exposed to various health risks [15-17]. At the same time, even students in good health often engage in risky health behaviors [18]. This highlights an increased need for reliable health information. Conducting an internet search may align with young people's desire for autonomy and self-sufficiency [19]. Currently, it is estimated that most university students (99%) rely on the internet as their primary source of health-related information [20]. The eHealth Literacy Scale (eHEALS) has emerged as a valid measurement and intervention tool for promoting healthy behaviors among adolescents [21]. Improving eHealth literacy can encourage students to adopt healthier behaviors [22], better manage their health, and maintain both their physical and mental well-being [23,24]. However, despite frequently using digital media to access health information, a significant proportion of university students lack adequate eHealth literacy [25,26], which severely hinders disease prevention and the effectiveness of health services [27]. Stellefson et al [9] demonstrated that while students are confident in their ability to use the internet, their practical eHealth literacy is often insufficient. Moreover, another study found that a considerable proportion of students struggle to critically evaluate the health information they encounter online [26].

According to the latest data from the Chinese Ministry of Education, the total number of students enrolled in various forms of higher education in China in 2023 was 47.63 million [28]. Research on university students' eHealth literacy is both important and urgent, particularly given the lack of a strict verification mechanism for health information on most websites in China [29]. While research on health literacy in China began relatively late, the widespread use of internet technology in health care has gradually brought eHealth literacy into public focus. As university students are a key demographic of internet users, they have become a focal point of eHealth literacy research due to their frequent use of digital tools and ability to access information. One major area of research is the localized adaptation of eHealth literacy measurement tools. In 2013, Guo et al [30] pioneered the translation and adaptation of eHEALS in China, focusing on adolescents, with a reported Cronbach alpha coefficient of 0.913. Subsequent applications of this version among university students have consistently demonstrated high reliability and validity [31,32]. Another important research direction is examining the current state of students' eHealth literacy and analyzing the factors that influence it. Overall, the eHealth literacy of Chinese university students appears to be at a relatively optimistic level. In recent years, studies have shown that the average eHealth literacy scores of university students typically range between 27 and 29 points [33-35], with variations influenced by the time and region of the research. The key factors affecting university students' eHealth literacy primarily include individual characteristics such as gender, major, academic performance, and place of origin (urban or rural). Family-related factors, such as income and number of siblings, as well as the students' own health status, also play a significant role [36]. With the promotion of initiatives such as the "Healthy China Strategy" and the "14th Five-Year Plan for National Health Informatization," the eHealth literacy of university students has become a key issue, highlighting the urgent need for intervention research. However, existing studies are largely limited to single-region samples, lacking large-scale cross-sectional surveys that cover multiple regions. Additionally, research on the determinants of eHealth literacy remains insufficient, with limited detailed data analysis and stratified comparisons among students with different characteristics. Furthermore, there is a lack of systematic

XSL•FO
RenderX

comparisons on how variations in eHealth literacy impact health outcomes, making it difficult to establish a concrete and reliable empirical foundation for intervention research and policy development.

Existing academic research on the role of the internet in health communication and promotion often emphasizes macro-level social inequalities, commonly referred to as the digital divide [37,38]. eHealth literacy plays a crucial role in promoting health equity, improving health outcomes, and reducing health care costs [5], offering significant potential to bridge this divide. This study highlights the widening digital gap between urban and rural students in China, with a particular focus on the challenges faced by rural students as a digitally disadvantaged group. Specifically, it explores the following: (1) Are there differences in eHealth literacy between urban and rural students? (2) What similarities or differences exist in the factors influencing their eHealth literacy? (3) How do these factors contribute to the observed differences? The study's results will serve as a reference for developing intervention methods and improvement strategies for eHealth literacy among students. Additionally, it seeks to recognize and address these social inequalities, ensuring that eHealth can truly benefit people worldwide, including those in marginalized and underserved areas.



Methods

Data Source

This study is a cross-sectional survey. From January to February 2023, the researcher distributed an anonymous electronic questionnaire via the Questionnaire Star platform [39] using a convenience sampling method. The questionnaire was distributed to university students across 10 regions, including Guangdong Province, Shanghai Municipality, and Jiangsu Province, covering majors such as economics, medicine, management, and literature.

To ensure data accuracy and reliability, the questionnaire included 2 verification questions: a repetitive question and a general knowledge question ("What is the capital of China?"). If a respondent answered either question incorrectly, the questionnaire was deemed invalid and excluded from further analysis. A total of 7503 questionnaires were collected. After screening, 253 questionnaires with anomalous response times and 20 with irregular completion patterns were excluded, resulting in 7230 valid questionnaires and an effective response rate of 96.36%. Participants in this study were required to meet the following inclusion criteria: (1) undergraduate students and (2) normal cognitive function with the ability to complete the questionnaire independently. The exclusion criterion was an incorrect response to the verification questions. The exclusion process is illustrated in Figure 1.

Figure 1. Participant screening flowchart.

eHealth Literacy

This study used the Chinese version of the eHEALS to assess university students' eHealth literacy levels. The eHEALS was developed by Norman et al [6] in 2006, based on the concept of eHealth literacy and Lily's model for evaluating an individual's ability to search for, screen, understand, assess, and utilize health information [6]. Since its inception, eHEALS has become the most widely used scale for measuring eHealth literacy across different populations in contemporary studies [40]. The Cronbach alpha coefficient for eHEALS is high across numerous studies involving diverse populations, typically ranging from 0.84 to 0.94. This indicates that the scale demonstrates strong internal consistency and reliability. The scale consists of 8 items, categorized into 3 competency areas related to the use of online health information and services: application competencies (items 1-5), judgmental competencies (items 6 and 7), and decision-making competencies (item 8). The scale uses a 5-point Likert scale, with scores ranging from 1 (very poorly met) to 5 (very well met). The total score for the

XSL•FO
RenderX

8 items ranges from 8 to 40, with higher scores indicating a higher level of eHealth literacy. In this study, the widely recognized cut-off score of 32 was used to classify the eHealth literacy of urban and rural university students into 2 categories: "qualified" (≥32 points) and "unqualified" (<32 points) [33,41]. The overall Cronbach α coefficient for this study was 0.974, with 0.973 for the rural university student group and 0.974 for the urban university student group.

Ethics Approval

The study was approved by the Biomedical Ethics Committee of Southern Medical University (Ethics Review Board [2023] No. 46). All participants signed an informed consent form before the survey began. The distribution, collection, and storage of questionnaires were managed via the Questionnaire Star platform. Data access was restricted to the researcher, and the information was tamper-proof to ensure security and integrity. This study strictly adhered to relevant laws and regulations. To protect participant privacy, all public reports will exclude personal identifiers. The final data set was exported in EpiData format for subsequent statistical analysis.

Grouping Variables

Respondents were classified as rural or urban based on the household type they reported in the survey.

Covariates

To obtain more reliable results, a range of potential confounding variables were controlled for, including demographic and sociological characteristics, personal lifestyles, and mental health status—factors previously considered in studies on eHealth literacy levels.

Demographic Characteristics

Participants were classified based on 2 variables: gender (male or female) and personal religious belief (yes or no).

Sociological Characteristics

Respondents were classified into 4 groups based on their academic performance, determined by class ranking: below 25%, 25%-50%, 50%-75%, and above 75%. Additionally, monthly per capita household income was categorized into 4 groups: less than 2500 RMB (1 RMB=US $0.14), 2500-<5000 RMB, 5000-10,000 RMB, and above 10,000 RMB.

Personal Lifestyle

The variables of exercise, smoking, and alcohol use were dichotomized into a binary format, with responses categorized as "yes" or "no." "Exercise" was defined as engaging in physical activity at least three times in the past month, with each session lasting a minimum of 30 minutes. Additionally, the use of tobacco products and alcoholic beverages (including distilled spirits, beer, wine, and rice wine) in the past month was recorded as a dichotomous variable (yes or no).

Mental Health Status

The 7-item Generalized Anxiety Disorder (GAD-7) tool was used to assess the prevalence and severity of anxiety symptoms among study participants. This tool consists of 7 items, each rated on a 4-point scale ranging from 0 to 3: 0="not at all," 1="a few days," 2="more than half the time," and 3="almost every day." A score below 5 indicates the absence of anxiety symptoms, while a score of 5 or higher suggests the presence of anxiety symptoms [42]. In this study, the GAD-7 demonstrated a Cronbach α coefficient of 0.944.

The 9-item Patient Health Questionnaire (PHQ-9) was used to assess depressive symptoms among participants. This tool consists of 9 items and follows the same scoring method as the GAD-7. A score below 5 indicates the absence of depressive symptoms, whereas a score of 5 or higher suggests their presence [43]. In this study, the PHQ-9 demonstrated a Cronbach α coefficient of 0.931.

Statistical Analysis

The demographic characteristics and lifestyles of the study population were analyzed descriptively. Continuous variables were presented as mean (SD), while categorical variables were expressed as percentages. A chi-square test was used to examine the distribution of eHealth literacy levels among urban and rural university students. Subsequently, a binary logistic regression model was constructed to identify key determinants of eHealth literacy levels in these groups. The outcome variable was defined as a binary classification of eHealth literacy (qualified/unqualified), while independent variables were selected from 4 domains: demographic characteristics, sociological characteristics, personal lifestyle, and mental health status. Initially, variables were screened using univariate analysis (retention criterion: $P<.05$) and subsequently included in the multivariate model. Statistically significant predictors ($P<.05$) were retained in the final model. All statistical analyses were performed using SPSS Statistics 23 (IBM Corp.). To examine the factors contributing to discrepancies in eHealth literacy levels between urban and rural university students, the Fairley model was applied using Stata MP 18.0 (StataCorp). The significance level was set at .05.

Fairlie Decomposition Model

In this study, we applied a multivariate Fairlie decomposition analysis (FDA) based on a binary regression model. FDA is a decomposition technique used in multivariate models to quantify the contribution of predicted differences between 2 groups to an outcome variable. It extends the Blinder-Oaxaca decomposition, which has been widely criticized for its inefficiency in handling logit and probit models. FDA was specifically developed for nonlinear regression models, including logit and probit models [44]. The FDA quantifies the contribution of independent variables to differences between groups by calculating the change in the mean predicted probability when substituting 1 independent variable at a time in 1 group (eg, rural university students) while holding other variables constant in the other group (eg, urban university students). The Fairlie decomposition technique ensures that the predicted probability remains within the range of 0-1. Studies have shown that the FDA provides a more precise quantification of variable contributions and significance levels in nonlinear regression models [45-47]. Given that the dependent variable was dichotomous, we applied Fairlie nonlinear decomposition to attribute differences in university students' eHealth literacy to various contributing factors. As outlined by Fairlie [48], the

XSL•FO
RenderX

decomposition of the nonlinear equation can be expressed as follows:

The symbols  represent the mean probabilities of the 2 binary outcomes. The F is used to indicate the cumulative distribution function of the logistic distribution. Y_e-Y_w represents the total difference in the differences between the 2 groups; N^e and N^w represent the sample sizes of the 2 samples. In equation 1, the first term in parentheses represents the portion of the gap attributable to differences in observed characteristics, while the second term denotes the portion of the gap explained by differences in estimated coefficients.

Results

Basic Characteristics of the Study Participants

The study included a total of 7230 participants. The mean eHealth literacy score among university students was 29.22 (SD 6.68; Table 1). Prior research on eHealth literacy among Chinese university students has established a passing threshold of 32 points [33], with scores below this cutoff indicating insufficient eHealth literacy. As shown in Table 2, 4135 out of 7230 (57.19%) students did not meet the eHealth literacy standard, while 3095 out of 7230 (42.81%) students qualified. Notably, a higher proportion of rural university students (2837/4510, 62.90%) failed to meet the standard compared with their urban counterparts (1298/2720, 47.72%; P<.001).

The chi-square test results in Table 2 indicate significant differences in the distribution of 8 covariates between urban and rural university students. These covariates include gender (P<.001), religion (P<.001), class ranking (P=.02), monthly per capita household income (P<.001), exercise (P<.001), drinking (P<.001), GAD-7 scores (P=.002), and PHQ-9 scores (P=.04). However, no significant difference was observed in the distribution of smoking (P=.93).

Table 1. eHealth literacy score for university students.

Item	Overall, mean (SD)	Rural, mean (SD)	Urban, mean (SD)
Q1: I know how to find helpful health resources on the internet	3.69 (0.93)	3.59 (0.91)	3.86 (0.94)
Q2: I know how to use the internet to answer my health questions	3.67 (0.92)	3.57 (0.90)	3.85 (0.93)
Q3: I know what health resources are available on the internet	3.64 (0.91)	3.53 (0.89)	3.82 (0.91)
Q4: I know where to find helpful health resources on the internet	3.65 (0.90)	3.54 (0.88)	3.83 (0.91)
Q5: I know how to use the health information I find on the internet to help me	3.69 (0.89)	3.58 (0.87)	3.86 (0.91)
Q6: I have the skills I need to evaluate the health resources I find on the internet	3.63 (0.90)	3.52 (0.87)	3.81 (0.92)
Q7: I can tell high-quality from low-quality health resources on the internet	3.67 (0.90)	3.55 (0.88)	3.86 (0.90)
Q8: I feel confident in using information from the internet to make health decisions	3.59 (0.90)	3.48 (0.88)	3.76 (0.92)
Total score	29.22 (6.68)	28.36 (6.48)	30.65 (6.75)

Comparison of Variables' Distribution

Table 3 presents the relationship between covariate distribution and eHealth literacy qualification status among urban and rural university students. The data indicate that certain covariate distributions share similar characteristics among students who passed or failed the eHealth literacy assessment. Gender, religious belief, monthly per capita household income, and drinking were identified as factors associated with eHealth literacy among university students.

Logistic Model Results

Table 4 presents the results of logistic modeling for eHealth literacy qualification among urban and rural university students. Among rural university students, the following were identified as risk factors for failing to meet the eHealth literacy standard: female gender (odds ratio [OR] 0.847), class ranking in the 25.0%-49.9% and 50.0%-74.9% ranges (both OR 0.788), a PHQ-9 score of ≤5 (OR 0.648), and lack of exercise (OR 0.260). Conversely, higher monthly per capita household income was identified as a protective factor (5000-10,000 RMB: OR 1.607; ≥10,000 RMB: OR 1.944). Among urban university students, risk factors included class ranking in the top 25% (OR 0.708), a PHQ-9 score of <5 (OR 0.603), and lack of exercise (OR 0.267).

XSL•FO
RenderX

In conclusion, the discrepancies in eHealth literacy between urban and rural university students were primarily reflected in 2 key areas. First, gender was a significant factor only in rural settings, where being female was associated with a lower likelihood of meeting the eHealth literacy standard (OR 0.847). Second, higher monthly per capita household income (5000-10,000 RMB: OR 1.607; ≥10,000 RMB: OR 1.944) served as a protective factor in rural contexts but was not significant in urban ones.

Decomposition Analysis Results

To ensure the stability of the results, the decomposition model was repeated 100 times using the Stata MP 18.0 (StataCorp). Multimedia Appendix 1 presents the decomposition model results for differences in eHealth literacy levels between urban and rural university students. The findings indicate that observed factors accounted for 28.6% of the disparity, while 71.4% was attributed to urban-rural differences and unobserved factors. Significant contributors to the eHealth literacy gap (P<.001) included monthly per capita household income (13.4%; P=.007), exercise habits (11.7%; P<.001), and PHQ-9 scores (2.1%; P<.001).

Discussion

Principal Findings

This study explores the relationship between eHealth literacy among urban and rural university students in China and factors such as sociodemographic characteristics, personal lifestyle, and psychological health. It quantifies the extent to which these factors contribute to disparities in eHealth literacy between the 2 groups. Our findings confirm significant differences in eHealth literacy levels between urban and rural students, influenced by multiple factors.

The study found that 57.2% of university students had eHealth literacy below the passing threshold, with an average score of 29.22 (6.68). These scores were comparable to those reported for Chinese university students (mean 30.16, SD 6.31) [34], higher than those of students from other Asian countries [49,50], and similar to those of their European and American peers [51,52]. However, all average scores remained below the qualifying standard, highlighting a concerning issue: overall eHealth literacy levels among university students are insufficient. Previous research by Bailey et al [53], Chesser et al [54], Gustafson et al [55], Mengestie et al [56], and others have documented disparities in eHealth literacy between urban and rural populations. Our study found that a significantly higher proportion of rural university students (2837/4510, 62.90%) did not meet eHealth literacy standards compared with their urban counterparts (1298/2720, 47.72%; P<.001). These findings highlight substantial urban-rural disparities in eHealth literacy among Chinese university students, aligning with previous research by Chinese scholars [57]. The study identified a 15.2% point gap between urban and rural students failing to meet eHealth literacy standards, emphasizing the critical role of the upbringing environment in shaping eHealth literacy. Enhancing eHealth literacy among rural students should be a priority to address and potentially mitigate these disparities. Notably, the study by Giger et al [58] found that eHEALS scores were not influenced by rural status or gender. This outcome may stem from uncertainties in the theoretical framework of eHealth literacy, potentially leading to misinterpretations of data measured by the eHEALS scale. Additionally, the lack of variation in scores could be due to a somewhat biased study population.

The logistic regression analysis revealed both similarities and differences in the covariates influencing eHealth literacy among Chinese urban and rural university students. Class ranking, exercise, and PHQ-9 scores were significant factors in both groups. Notably, better academic performance emerged as a protective factor for higher eHealth literacy. To some extent, higher grades indicate better information access and comprehension skills, aligning with findings from previous studies [12,23]. Exercise is a common protective factor, consistent with findings from Tsukahara et al [49], Mitsutake et al [21], and others. Exercise habits reflect an individual's greater health awareness and willingness to seek information. Additionally, many physical activities facilitate social interaction and information sharing. Individuals with high eHealth literacy are also more likely to engage in regular exercise [59], which collectively contributes to the accumulation and enhancement of health literacy. Conversely, PHQ-9 scores were identified as a risk factor for eHealth literacy among both urban and rural students, a finding supported by previous studies [59-61]. Extensive research has confirmed that depressive symptoms negatively impact cognitive function [62], information processing, and health decision-making. Furthermore, depression directly undermines self-efficacy [63], which in turn influences health literacy both directly and indirectly [64], ultimately hindering its development and maintenance.

The covariates influencing eHealth literacy levels differ between urban and rural students. This study found that gender significantly affects rural students, with rural female students exhibiting lower eHealth literacy levels. The existing literature presents mixed findings on this issue. In countries with prevalent gender inequalities, women tend to have lower health literacy, whereas in some Western nations, women demonstrate higher health literacy levels [65,66]. In the context of this study, these results may partially reflect the persistent gender gap in education in rural China, as well as traditional societal views on gender roles. This disparity objectively limits rural female students' access to and use of health information, while also indirectly influencing their health awareness, needs, and confidence in using eHealth resources. Additionally, potential gender differences in health needs, attitudes, and communication patterns underscore the importance of tailored interventions and support. By contrast, urban students do not exhibit significant gender differences, likely due to relatively greater resource availability and a more equitable social environment, where information dissemination is more diverse and access to electronic tools and health information is more convenient. In addition, monthly per capita household income serves as a protective factor for eHealth literacy among rural students but not among urban students. This may be because high-income rural families can better support students in accessing and utilizing eHealth information resources, whereas in urban settings, the impact of income differences is mitigated by greater environmental support and resource availability. The study [67] highlights the importance of tailoring eHealth literacy interventions to specific populations.

The results of the Fairlie decomposition model indicate that 28.6% of the difference in eHealth literacy between urban and rural students can be attributed to observed factors, primarily monthly per capita family income (13.4%), exercise habits (11.7%), and PHQ-9 scores (2.1%). These factors not only demonstrate statistical significance in the empirical data but

XSL•FO
RenderX

also have clear, real-life implications, which is common in logistic regression analyses. Several studies have shown that family income is a key determinant of health literacy, both in the general population and among students [68], as it directly influences their ability to access health information. Students from higher-income families are more likely to afford smart devices and internet services, facilitating easier access to online medical resources [69]. Exercise, by contrast, reflects students' healthy habits, which are not only positively correlated with health literacy but also subconsciously motivate them to seek more health knowledge [70]. Additionally, the PHQ-9 score, as a self-report measure of depressive states, suggests that students with higher scores may be less likely to engage with and comprehend health information due to low mood, a relationship that has been confirmed in studies on mental health and health literacy [71].

In this study, 71.4% of the difference in eHealth literacy between urban and rural students was attributed to unobserved factors, which may be linked to structural disparities between urban and rural areas. Health inequalities between urban and rural populations remain a global issue, with developing countries experiencing more pronounced disparities than developed countries [72]. Strengthening health services in rural communities is widely recognized as a priority. Multiple factors contribute to the observed disparities in health outcomes between rural and urban areas [73]. The pervasive socioeconomic disadvantages endemic to rural areas often result in reduced access to health care services, perpetuating a cycle of disadvantage. Geographic isolation and a shortage of health care providers further exacerbate this issue. Additionally, rural populations face higher risks of injury, encounter significant barriers related to transportation and communication, and are affected by diseconomies of scale due to their sparse distribution. Collectively, these factors negatively impact the health outcomes of individuals living in nonmetropolitan areas. Nevertheless, evidence suggests that even after geographic barriers are removed, health service utilization remains low in some rural communities [74]. Additionally, studies indicate that barriers to self-management—such as limited formal education and poverty—may be further exacerbated in areas with fewer health care professionals and weaker health infrastructure [75]. Patterson et al [76] found that adjusting for socioeconomic status did not fully account for the observed differences in health risk factors between rural and urban populations. Moreover, other factors that differ between these regions may further contribute to disparities in health outcomes. Given the critical role of eHealth literacy in health outcomes, it is plausible that it represents one of these contributing factors.

Existing research has confirmed the crucial role of mobile technology in enhancing eHealth literacy and improving health outcomes, particularly in rural areas and among disadvantaged groups [77]. As health services continue to transition to digital platforms, the need to promote eHealth literacy becomes increasingly urgent. Our findings offer valuable insights for policy makers. First, efforts should be made to improve access to eHealth resources in rural and underserved areas. Additionally, the government should implement measures to enhance residents' incomes and living conditions, thereby addressing structural barriers to eHealth engagement. Given the urban-rural divide, collaboration between the government and educational institutions is essential to developing a multichannel eHealth education platform. This platform should provide tailored eHealth knowledge and telemedicine services, such as live-streamed health lectures and regular dissemination of health information, specifically targeting rural and resource-limited areas to bridge the urban-rural information access gap. Importantly, interventions should be designed with consideration for less educated and lower-income populations, who have the greatest need for such support [78]. Second, fostering a positive environment for physical activity can help encourage the adoption of healthy behaviors, as health literacy and healthy behaviors are mutually reinforcing [79]. To encourage students to develop healthy exercise habits, universities should collaborate with local communities to establish well-equipped sports facilities and organize regular sports events and health-related activities. Additionally, implementing a reward system—where students earn points for participating in sports and health lectures, redeemable for incentives—could further motivate engagement. Third, expanding on-campus mental health services is crucial for enhancing students' ability to process health information. Given the significant impact of mental health on eHealth literacy observed in this study, universities should establish a comprehensive mental health support system. This could include online psychological counseling, crisis intervention services, and routine psychological assessments to ensure early detection and support. Universities should provide high-quality online mental health resources through their health and counseling center websites [80] and establish an integrated framework linking mental health support with eHealth literacy training. This approach would enhance students' understanding and application of health knowledge while effectively reducing barriers to accessing health information. Finally, eHealth literacy training should be systematic, with a structured approach to evaluating its effectiveness. The influence of education on health is well established [81], and numerous studies have shown that elective courses can significantly impact students' health literacy levels [82,83]. Universities can implement targeted eHealth literacy training programs that comprehensively cover all aspects of eHealth literacy. Regular monitoring through surveys and evaluations can help identify educational gaps and optimize the curriculum accordingly. Additionally, fostering supportive environments at home and school can enhance students' self-efficacy and confidence, ultimately contributing to improved health outcomes.

Strengths and Limitations

This study is the first to investigate disparities in eHealth literacy between urban and rural university students in China. Using Fairlie's model for quantitative decomposition, we identified key influencing factors and their specific contributions. However, certain limitations must be acknowledged. First, as this study is based on a cross-sectional questionnaire survey, it does not capture dynamic changes in participants' eHealth literacy over time, limiting our ability to establish causal relationships between eHealth literacy and urban-rural factors. Second, although the eHEALS has been widely validated and

XSL•FO
RenderX

is considered reliable across various cultural contexts and countries, it remains a self-assessment tool and is therefore susceptible to individual subjective biases. Notably, large-scale epidemiological studies worldwide, such as the UK Biobank and China Health and Retirement Longitudinal Study (CHARLS) databases, often rely on self-reported data. These subjective assessments can be supplemented with objective indicators to provide a more comprehensive evaluation of actual eHealth skill levels. Third, our sample size is relatively limited compared with the overall population of university students. Therefore, caution should be exercised when generalizing the findings to a broader or global scale. To enhance the universality of these results, future studies could refine the sampling method and expand the survey scope. Comparative studies in other countries could also provide insights into the similarities and differences between China and other contexts. Finally, while this study considered a broad range of demographic, sociological, and personal lifestyle factors, eHealth literacy is influenced by numerous variables. Future research should explore additional influencing factors. Moreover, if disparities in eHealth literacy between urban and rural students continue to be observed, it will be crucial to develop scientifically sound, context-specific interventions. Researchers should also focus on validating, refining, and addressing potential shortcomings in the implementation of these interventions.

Conclusions

The regression and decomposition analyses in this study revealed that urban university students had higher eHealth literacy levels than their rural counterparts. Key factors contributing to this disparity included monthly per capita household income, exercise habits, and PHQ-9 scores. The Fairlie decomposition model indicated that 28.6% of the difference in eHealth literacy between urban and rural students could be attributed to observed factors, with monthly per capita household income accounting for 13.4%, exercise for 11.7%, and PHQ-9 scores for 2.1%. These findings provide novel insights into urban-rural disparities in eHealth literacy among Chinese university students, offering valuable guidance for developing or refining policies to enhance eHealth literacy.

The policy strategies specifically include the following: (1) improving access to eHealth resources in rural and underserved areas; (2) fostering an environment that encourages physical activity to promote healthy behaviors; (3) expanding school-based mental health services to enhance health information processing capacity; and (4) implementing systematic eHealth literacy training with ongoing evaluation. These strategies and policies will help promote equitable access to and utilization of eHealth resources for all students, regardless of their location.

Acknowledgments

The research is supported by the National Social Science Foundation project of China (project number 21BGL301), entitled “A Multidimensional Evaluation of University Students’ Health and the Development of an Evidence-Based Intervention Model in the Context of the Healthy China Strategy.” We thank the participants and researchers of this survey for making this study possible. Because of ethical constraints and privacy commitments approved by the Institutional Review Board, the storage of raw data sets containing personally identifiable information about undergraduate students in public repositories is not permitted. In accordance with the stipulated data use agreement, applicants are obligated to sign a data use agreement and specify the intended use of the study. Following the acquisition of approval from the Southern Medical University Bioethics Committee, applicants can formally request deidentified data and analysis scripts from the corresponding author (YQ).

Authors' Contributions

YQ, YY, and ZL designed the study. YY, ZL, and QZ checked the data quality and performed the statistical analysis. QZ, YT, CW, and SL managed and checked all the data. YQ, YY, ZL, QZ, YX, XW, and ZW participated in the drafting, editing, reviewing, and revising of the manuscript. All authors read, revised, and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Primary intracranial germ cell tumors (iGCTs) are highly malignant brain tumors that predominantly occur in children and adolescents, with an incidence rate ranking third among primary brain tumors in East Asia (8%-15%). Due to their insidious onset and impact on critical functional areas of the brain, these tumors often result in irreversible abnormalities in growth and development, as well as cognitive and motor impairments in affected children. Therefore, early diagnosis through advanced screening techniques is vital for improving patient outcomes and quality of life.

Objective: This study aimed to investigate the application of facial recognition technology in the early detection of iGCTs in children and adolescents. Early diagnosis through advanced screening techniques is vital for improving patient outcomes and quality of life.

Methods: A multicenter, phased approach was adopted for the development and validation of a deep learning model, GVisageNet, dedicated to the screening of midline brain tumors from normal controls (NCs) and iGCTs from other midline brain tumors. The study comprised the collection and division of datasets into training (n=847, iGCTs=358, NCs=300, other midline brain tumors=189) and testing (n=212, iGCTs=79, NCs=70, other midline brain tumors=63), with an additional independent validation dataset (n=336, iGCTs=130, NCs=100, other midline brain tumors=106) sourced from 4 medical institutions. A regression model using clinically relevant, statistically significant data was developed and combined with GVisageNet outputs to create a hybrid model. This integration sought to assess the incremental value of clinical data. The model's predictive mechanisms were explored through correlation analyses with endocrine indicators and stratified evaluations based on the degree of hypothalamic-pituitary-target axis damage. Performance metrics included area under the curve (AUC), accuracy, sensitivity, and specificity.

Results: On the independent validation dataset, GVisageNet achieved an AUC of 0.938 (P<.01) in distinguishing midline brain tumors from NCs. Further, GVisageNet demonstrated significant diagnostic capability in distinguishing iGCTs from the other midline brain tumors, achieving an AUC of 0.739, which is superior to the regression model alone (AUC=0.632, P<.001) but less than the hybrid model (AUC=0.789, P=.04). Significant correlations were found between the GVisageNet's outputs and 7

XSL•FO
RenderX

endocrine indicators. Performance varied with hypothalamic-pituitary-target axis damage, indicating a further understanding of the working mechanism of GVisageNet.

Conclusions: GVisageNet, capable of high accuracy both independently and with clinical data, shows substantial potential for early iGCTs detection, highlighting the importance of combining deep learning with clinical insights for personalized health care.

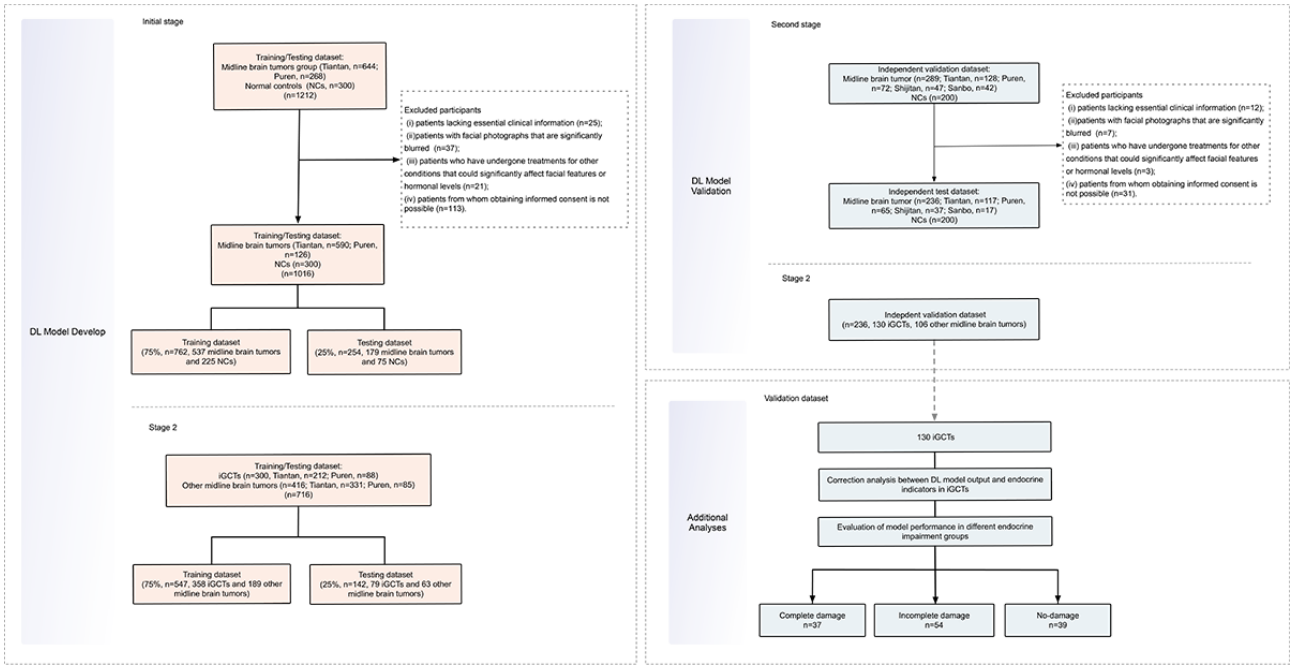
Introduction

Intracranial germ cell tumors (iGCTs) are primary malignant brain tumors of the central nervous system, predominantly affecting children and adolescents [1]. In East Asian countries, iGCTs account for 15% of all pediatric and adolescent brain tumors, making them the third most common primary brain tumor [2]. In other regions, the incidence of iGCTs is only 2%-3%, classifying them as rare tumors [1]. IGCTs typically occur in the midline structures of the brain, with approximately 90% located in the pituitary and pineal regions, and a minority in the fourth ventricle and brain parenchyma [3]. IGCTs can be treated with radiotherapy and chemotherapy, with only about 20% of patients requiring surgical resection [4,5]. The symptoms of iGCTs vary depending on the tumor's location, size, and cerebrospinal fluid dissemination. Common symptoms include headaches, nausea, vomiting, visual changes, endocrine disorders, ataxia, seizures, behavioral and cognitive changes, and cranial nerve dysfunction [6]. The manifestation and severity of these symptoms differ among individuals and according to the specific tumor characteristics. Patients often present with various symptoms and are diagnosed with an intracranial tumor through computed tomography or magnetic resonance imaging scans. However, due to the rarity of iGCTs in most regions, patients are frequently misdiagnosed with craniopharyngiomas, pituitary tumors, gliomas, or pinealocytomas and undergo unnecessary surgical resection [7]. Postoperative pathology often reveals iGCTs, necessitating subsequent radiotherapy and chemotherapy, thus indirectly leading to overtreatment [8].

According to the clinical consensus, iGCTs can be clinically diagnosed when tumor markers (eg, human chorionic gonadotropin [HCG] and alpha-fetoprotein) are elevated [7]. However, due to a lack of diagnostic experience, these tumor markers are often overlooked at initial diagnosis, leading to unwarranted surgical treatment. Therefore, developing a noninvasive, efficient, and universally applicable screening tool is crucial to provide clinicians with indicative information at the first patient visit, guiding targeted examinations. Since iGCTs patients exhibit facial feature changes compared with normal children, we hypothesize that facial recognition algorithms can be developed to alert clinicians at the initial consultation, providing personalized diagnostic approaches [9,10].

The application of facial recognition algorithms is extensive, especially those based on machine learning algorithms, which have been profoundly studied in the medical field. For instance, Bottinelli et al [11] used a binocular rivalry task to assess emotional processing in patients with panic disorder (PD), finding that with PD had a greater initial threat bias toward fearful faces compared with controls, indicating that threat-evoking stimuli more rapidly captured their attention. Yeung et al [12] analyzed 148 studies on facial emotion recognition in autism spectrum disorder, revealing significant impairments in recognizing all basic facial emotions in individuals with autism spectrum disorder compared with typically developing controls. Nigam et al [13] examined facial emotion recognition deficits in remitted patients with bipolar disorder and their first-degree relatives compared with healthy controls, finding significant deficits in recognizing emotions such as fear, anger, surprise, and happiness in patients with bipolar disorder compared with first-degree relatives and healthy controls. iGCTs are a type of intracranial tumor often accompanied by significant endocrine abnormalities, and facial recognition technology holds the potential for uncovering diagnostic information. Nevertheless, current research on this aspect remains unclear

Therefore, this study aims to design a deep learning-driven binary facial recognition model using frontal facial photographs of patients to first distinguish between midline brain tumors and normal controls and then differentiate iGCTs from other midline brain tumors. We will initially screen for the optimal model among commonly used deep learning (DL) models in facial recognition, using development and independent external validation datasets composed of open-source databases (Wild Young Labeled Faces) and multicenter clinical patient facial photographs. Finally, we will develop visualization software to demonstrate the practical clinical application of our model.



Methods

Study Design

The objective of this multicenter retrospective diagnostic study was to develop and validate a 2 stage DL facial recognition classification model, GVisageNet, using frontal facial photographs to distinguish patients with midline brain tumors and normal controls (NCs), and further distinguish iGCTs from other patients with midline brain tumors, thereby facilitating early detection. Data collection occurred across 4 Chinese medical institutes from January 2010 to May 2023. The study design and participant flow are illustrated in Figure 1.

XSL•FO
RenderX

Figure 1. The study design and participant flow. DL: deep learning; iGCT: intracranial germ cell tumor; NC: normal control.

Participants

Inclusion criteria were (1) patients diagnosed pathologically with midline brain tumors (specify tumors originating in the sellar region, pineal region, or the fourth ventricle); (2) availability of frontal facial photographs taken within 2 weeks before the date of diagnosis; (3) gender- and age-matched NCs from the “Wild Young Labeled Faces” dataset with age and gender matching from the GitHub repository managed by the Institute of Systems and Robotics at the University of Coimbra. Exclusion criteria were (1) patients lacking essential clinical information, including but not limited to demographics (eg, age and gender), symptoms, and hormonal levels; (2) patients with facial photographs that are significantly blurred, to the extent that key facial landmarks or features are indistinguishable; (3) patients who have undergone treatments for other conditions that could significantly affect facial features or hormonal levels; and (4) patients from whom obtaining informed consent is not possible. Finally, patients were categorized into the midline brain tumors group and NCs, and further divided into iGCTs and the other midline brain tumor groups.

Study Setting

This investigation was systematically conducted in 3 phases, using a multicenter approach for patient recruitment and data collection. During the initial phase, NCs and patients diagnosed with midline brain tumors (including iGCTs and other midline brain tumors) were recruited from the wild young labeled faces dataset, as well as from Tiantan, Puren Hospital, Capital Medical University. This can be deleted from the text. In this phase, our goal was to construct a binary tandem DL model (GVisageNet). We randomly divided the NCs and patients with midline brain tumors (n=1016) into 2 groups, 75% for training the GvisageNet and 25% for testing its performance (762:254). Furthermore, an independent external dataset was compiled from 4 distinct medical institutions (Tiantan, Puren, Shijitan, and Sanbo Hospital, Capital Medical University) between January 2020 and May 2023, aiming to establish an independent validation dataset (n=436) for validating the DL model. Subsequently, the patients with midline brain tumors (n=716) from the first phase were randomly divided into a training dataset and a testing dataset in a 75:25 ratio to differentiate iGCTs from other midline brain tumor patients (574:142). Finally, the facial photographs of patients with midline brain tumors (n=236) from the independent external validation dataset were used as a separate validation dataset in the second phase.

Since both iGCTs and other midline brain tumors affect the brain's midline functional areas in clinical diagnosis, leading to similar facial characteristics caused by impacts on the patient’s endocrine function, differential diagnosis becomes even more challenging. However, incorrect predictions could result in misdiagnosis, misinterpretation, and inefficient use of resources. To further enhance predictive accuracy, the subsequent phase of the study aimed to develop a regression model using clinical variables marked by statistical disparities between the 2 groups (iGCTs vs other midline brain tumors). This included demographic characteristics, clinical manifestations, and hormonal profiles, where significant differences were observed. This model was then integrated with the outputs generated by GVisageNet (from the second stage), enabling the construction of an integrated hybrid model. The primary goal of this integration was to clarify the contribution of clinical data in improving the model’s predictive performance.

In the final phase of the study, the correlation analysis between the outputs of GVisageNet and 15 endocrine indicators in the independent validation dataset was conducted to explore the potential mechanism of GVisageNet. Finally, stratified studies were carried out in the independent validation dataset based on the degree of hypothalamic-pituitary-target (HPT) axis damage (complete damage, incomplete damage, and no damage), further verifying that endocrine changes are the potential mechanism behind the effectiveness of GVisageNet.

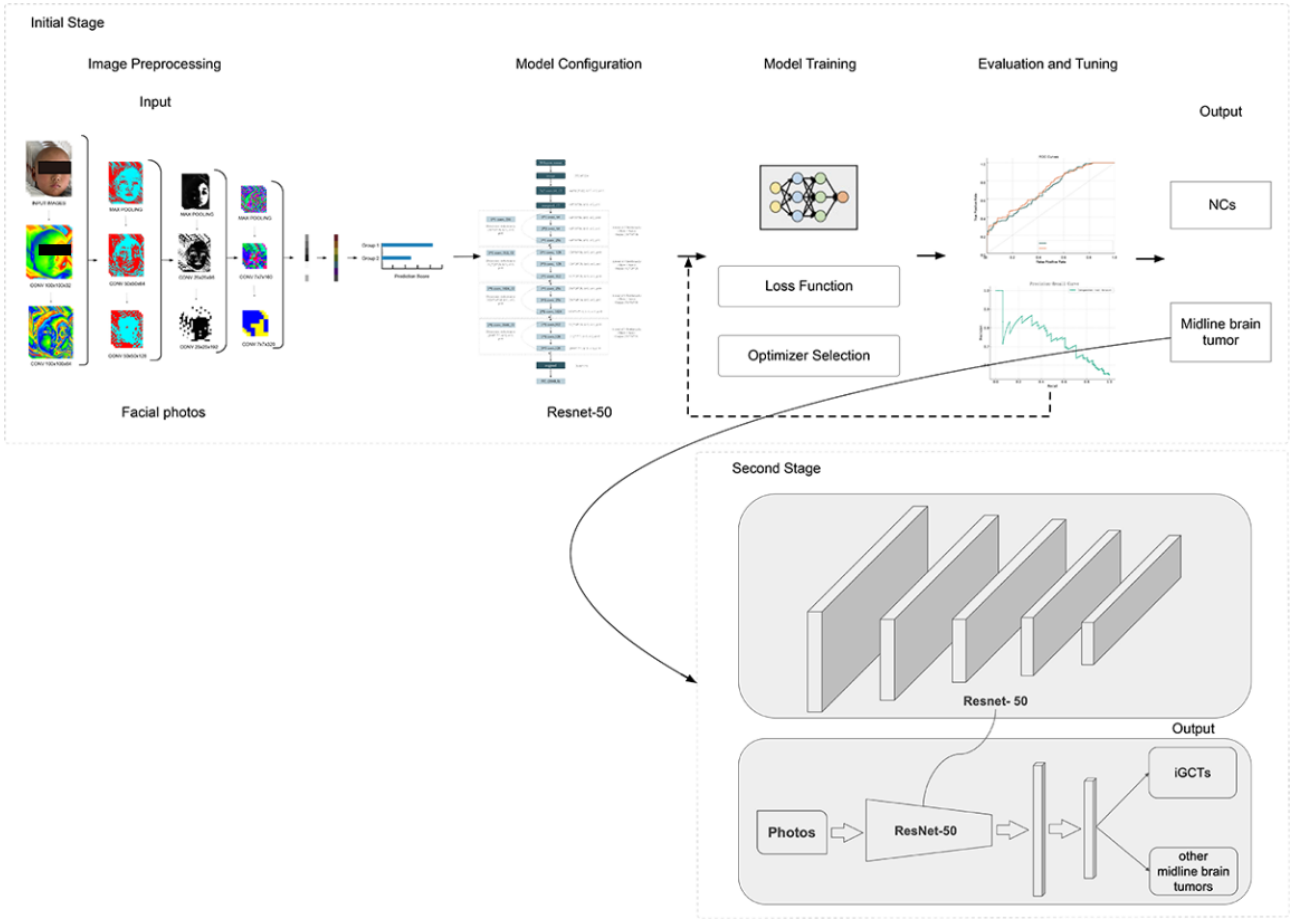
RenderX

Data Collection

Frontal views of each patient were routinely captured at the initial hospital visit using a standardized protocol. This involved a digital camera with a resolution exceeding 10 million pixels (the criteria and details of photograph taking are presented in Method S1 in Multimedia Appendix 1).

In studying the correlation between facial recognition features and endocrine functions, the selection of specific clinical indicators is designed to comprehensively assess patients' endocrine conditions and their potential impacts on facial characteristics. This includes baseline data such as gender, age, BMI, initial symptoms, disease duration, and the primary site of the tumor, which provide an initial understanding of the patient's overall health and endocrine function. Key endocrine indicators include the adrenal axis (Adrenocorticotropic hormone), thyroid axis (thyroid stimulating hormone [TSH], triiodothyronine, free triiodothyronine [FT3], thyroxine, and free thyroxine [FT4]), growth hormone-insulin-like growth factor-I axis (growth hormone [GH], insulin-like growth factor 1, insulin-like growth factor binding protein 3 [IGFBP-3]), and gonadal axis (follicle-stimulating hormone [FSH], luteinizing hormone [LH], testosterone, estradiol, progesterone, and prolactin). Variations in these hormone levels can lead to significant changes in facial features, such as puffiness, growth retardation, or precocious puberty. In addition, routine monitoring of 24-hour urine volume, specific gravity, and osmolality indirectly reflects the patient's endocrine health status, thereby supporting the potential application of facial recognition technology in clinical diagnostics. This comprehensive data collection is crucial for exploring the link between facial characteristics and endocrine functions, holding significant academic value.

Pathological Diagnosis



The criterion for correct GVisageNet prediction is consistency with pathological results. All patients enrolled in the study were classified according to the 2021 WHO (World Health Organization) pathological classification [14]. Two experienced neuropathologists, XL and YJH, each with 10 years of experience in neuropathology, independently reviewed the histological diagnoses for both the development and independent test datasets. Their reviews were aligned with the 2021 WHO classification of tumors of the central nervous system [15]. Any specimens that did not conform to the 2021 WHO classification underwent a secondary review by other neuropathologists (JD with 30 years of experience). The criteria for immunohistochemical and diagnostic assessments in the independent validation dataset were consistent with those used for the development dataset.

Facial Photo Preprocessing

The quality of facial photographs was evaluated by 2 investigators who were blinded to the study design, as outlined in the protocol (Method S2 in Multimedia Appendix 1.). Those that were deemed qualified were processed by cropping to isolate only the facial area, thus removing any excess background and clothing, and were resized to the dimensions of 256×256 pixels. Figure 2 depicts the ResNet-50 model workflow for facial photo analysis, including preprocessing, configuration, training with loss function and optimizer selection, and evaluation using receiver operating characteristic (ROC) and precision-recall curves on an independent external test dataset.

Facial Recognition Deep Learning Model Development

DL Model Architecture

Our facial recognition DL model (GVisageNet) was primarily based on a Convolutional Neural Network (CNN; Figure S1 in Multimedia Appendix 1). We evaluated 3 of the most commonly used candidate models in the field of facial recognition—AlexNet, ResNet-50, and Inception—with ResNet-50 emerging as the most effective through comparative analysis. The development dataset was randomly divided into training and testing datasets in a 75:25 ratio. We used the area under the curve (AUC) to evaluate the classification performance on the testing dataset. To address sample imbalance, resampling techniques were applied to the training dataset, as detailed in Method S3 in Multimedia Appendix 1.

Development and Validation of the Facial Recognition DL Model

We selected ResNet [16], specifically ResNet-50 [17], as our model due to its training efficiency. ResNet-50 is composed of 4 blocks, each containing CNN layers of various depths, culminating in a total of 50 CNN layers (Figure S2 in Multimedia Appendix 1). A fully connected layer was added following ResNet-50 for classification purposes. During training, images were resized to 256×256 pixels. Each patient's facial photos were combined into a 12-channel image stack, ensuring a comprehensive representation of facial features. The supervised model underwent 10 training epochs, using Adam as the optimizer. The initial learning rate was set at $1e^{-4}$ and adjusted through cosine learning rate decay. The loss function used was cross-entropy. Training was conducted on the training dataset and testing was performed on the testing dataset. Upon completion, the DL model produced probabilities for each image belonging to one of 2 categories, with the highest probability determining the category label. The DL framework was based on PyTorch and operated on an Ubuntu 18.04 system equipped with an NVIDIA V100 Tensor Core GPU. Method S4 in Multimedia Appendix 1 shows the details of the development and validation ResNet-50 based DL model.

Evaluating the DL Model

We developed 2 additional models to detect iGCTs, aiming to compare their performance with our primary model. First, we constructed a multivariable logistic regression model using 7 clinical variables, which showed statistical significance in the training dataset as detailed in Table 1. Second, we built a hybrid model that integrates the output of GVisageNet with the results from the logistic regression model, Figure S3 in Multimedia Appendix 1. Both differential diagnostic models underwent training on the training dataset, testing on the testing dataset, and validation on the independent validation dataset.

[a]Not applicable.

[b]Indicate statistical difference.

The *P* values were determined by the one-way analysis of variance test for age and tumor volume, and the chi-square test for gender, T1WI performance, T2WI performance, enhancement appearances, degree of enhancement, hemorrhage, and necrosis.

The Working Mechanism of Interpretation Model Potential

To explore the hypothesis that endocrine changes contribute to alterations in facial characteristics, we conducted a correlation analysis between prediction scores and endocrine indicators. This analysis focused on the independent validation dataset, aimed to uncover the underlying mechanisms. In addition, we segmented the independent validation dataset into 3 subgroups based on the extent of HPT axis damage: complete damage, incomplete damage, and no damage, Method S5 in Multimedia Appendix 1 defines the “complete damage,” “incomplete damage,” and “no-damage” of the HPT axis damage. The performance of GVisageNet was then compared across these subgroups to determine if the degree of endocrine damage influenced the model’s effectiveness.

Statistical Analysis

For our statistical analysis, we used SPSS (version 25.0) software (IBM Corp). Continuous variables were presented as mean (SD), and discrete variables as percentages. We assessed the normality of continuous variables using the Shapiro-Wilk test. Depending on the results, either the independent samples *t* test, Friedman test, or the Mann-Whitney *U* test was used for comparison. Categorical variables, such as gender and endocrine abnormalities in patients with NCs and midline brain tumors (including iGCTs and other midline brain tumors), were analyzed using the chi-square test. We calculated the 95% exact CIs for both proportions and mean differences.

To evaluate the performance of the DL model, we computed its diagnostic accuracy, sensitivity, specificity, and the area under the ROC curve, using pathological diagnosis as the benchmark. The model’s performance was evaluated at 2 specific points on the receiver operating characteristic ROC curve, chosen for their maximum sensitivity and specificity. We used the Delong test [18] to compare the AUCs of the different models. Multinomial logistic regression was used to examine the correlation between the prediction scores and the endocrine indicators. All comparisons were conducted as 2-sided tests, with a *P* value of less than .05 considered statistically significant.

Ethical Considerations

Ethical approval was granted by the institutional review board of Beijing Tiantan Hospital, Capital Medical University (KY2021-142-02). Informed consent was secured from all patients or their guardians. Privacy and Confidentiality: In this study, all participant data, including images, are processed with strict measures to ensure privacy and confidentiality. Each participant’s data, including facial photographs, is anonymized and deidentified before analysis to prevent any direct or indirect identification. For cases where anonymization is not feasible, such as if the integrity of facial features is required for model training or analysis, robust data protection protocols are implemented. These include secure storage solutions, restricted access, and ethical review board oversight, ensuring compliance with data privacy standards.

Compensation details are that the participants involved in the study were compensated fairly for their contributions. All individuals provided informed consent, detailing the nature and amount of compensation received, proportional to the time and effort required for their participation, in accordance with ethical guidelines.

Results

Patient Characteristics

Initially, we obtained frontal facial photographs of 989 subjects (including 300 NCs, 437 patients with iGCTs, and 252 patients with other midline brain tumors). These photos were collected for the training and testing of the DL model with facial recognition, GVisageNet, from January 2010 to December 2020 at 2 medical institutes. In addition, an independent validation dataset, comprising 200 NCs, 130 patients with iGCTs, and 106 patients with other midline brain tumors, was collected from four medical institutes between January 2021 and May 2023 for validation of the DL model. The demographic data, symptoms, and endocrine hormone levels of all patients across all datasets (training, testing, and independent validation) are summarized in Table 1. The training, testing and independent validation datasets included 500 NCs (250 males and 250 females, with mean age of 13.00, SD 5.15 years), 567 patients with iGCTs (256 males and 290 females, with a mean age of 12.81, SD 5.79 years) and 358 patients with other midline brain tumors 155 males and 203 females, with a mean age of 13.61, SD 4.93 years), respectively. We filtered 7 clinical variables (limb movement disorder, diabetes insipidus, sexual abnormality, affective disturbance, convulsive seizure, TSH, and GH) that were statistically different between the iGCTs group and other midline brain tumors group in the training/testing dataset. Figures 3A and 3B illustrate the distribution of iGCT tumor sites across various hospitals in different datasets, as well as the distribution of tumor types within all datasets among other midline brain tumor groups.

Figure 3. (A) Tumor site distribution of iGCTs in different hospitals of different datasets. (B) Distribution of tumor types in all datasets in the other midline brain tumors group. (C) Comparison of performance of different algorithms (accuracy, sensitivity, specificity, and area under the curve). AUC: area under the curve; iGCTs: intracranial germ cell tumors.

Evaluation of Three Candidate Algorithmic Models

In this investigation, we conducted a comparative analysis of 3 distinct candidate algorithms by training each on the training dataset and then evaluating their respective performances on the testing dataset. The algorithms tested were AlexNet, ResNet-50, and Inception. In the testing dataset, GVisageNet and the other models (AlexNet and Inception) yielded similar results in the first stage (distinguishing patients with midline brain tumors and NCs) with AUCs of 0.972 (95% CI 0.951-0.992), 0.963 (95% CI 0.943-0.984), and 0.983 (95% CI 0.937-1.000), respectively, and $P>.05$. Therefore, we proceeded to compare the results from the second stage. In the second stage, based on the AUC values with 95% CIs, the following results were observed: AlexNet achieved an AUC of 0.667 (95% CI 0.582-0.777), ResNet-50 reached an AUC of 0.705 (95% CI 0.590-0.760), and Inception yielded an AUC of 0.657 (95% CI: 0.583-0.776; Figure 3C and Table 2). Given these outcomes, ResNet-50 emerged as the most proficient model in terms of classification performance and was subsequently chosen as the final model for our classification tasks. Table S1 in Multimedia Appendix 1 and Figure S2 in Multimedia Appendix 1 presented additional details.

Table 2. The AUC, accuracy, sensitivity, and specificity of the different model of testing and independent external validation datasets.

Model	Dataset	AUC[a] (95% CI)	Accuracy (95% CI)	Sensitivity (95% CI)	Specificity (95% CI)
GVisageNet	Testing	0.705 (0.590-0.760)	71.71% (57.42%-77.11%)	75.24% (70.89%-77.57%)	73.40% (69.04%-76.80%)

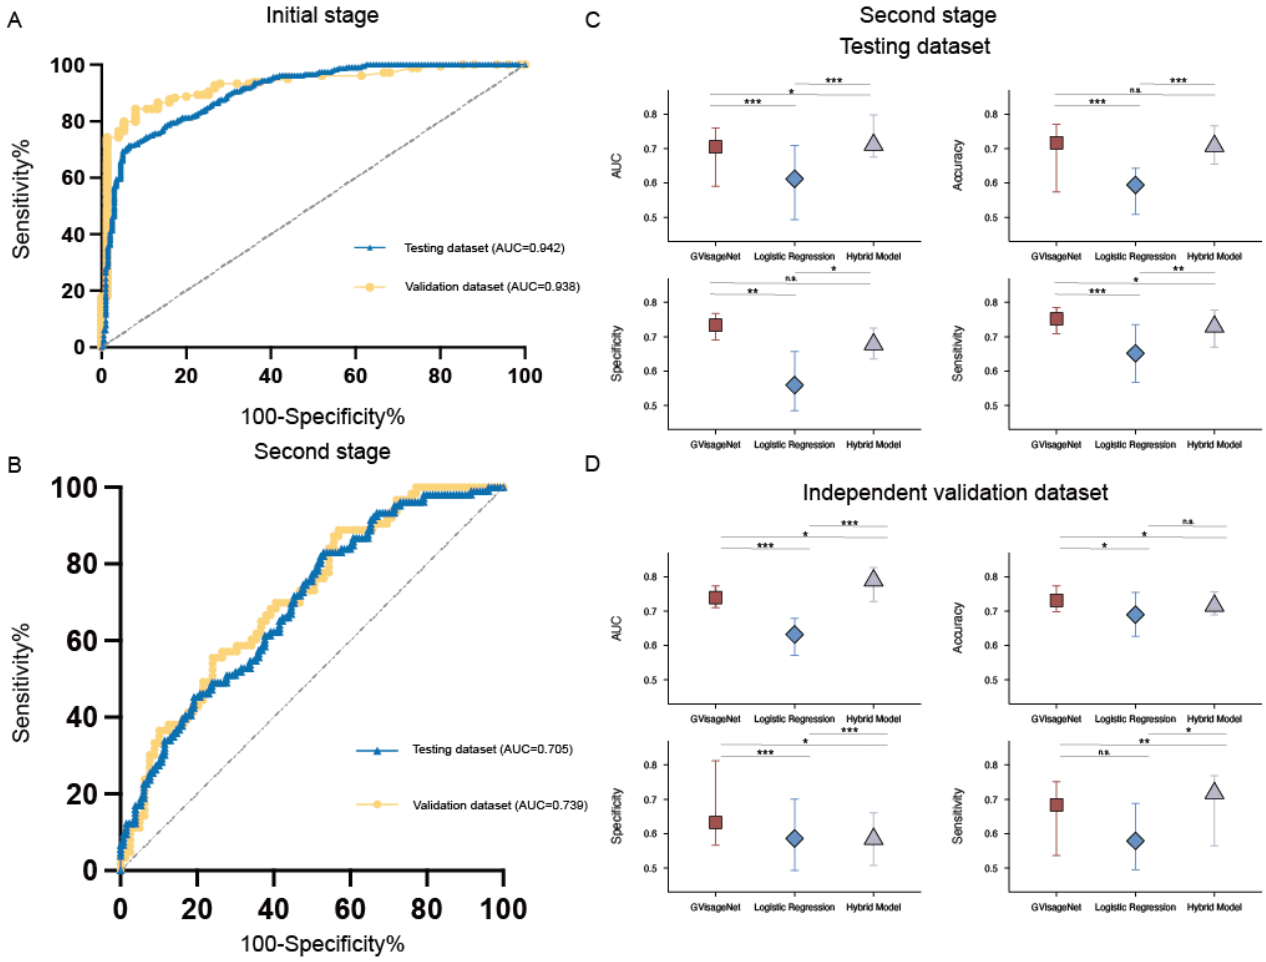
Logistic regression	Independent validation	0.632 (0.571-0.679)	68.97% (62.68%-75.44%)	57.88% (49.45%-68.74%)	58.59% (49.24%-70.04%)
Hybrid model	Testing	0.711 (0.676-0.798)	70.77% (65.48%-76.65%)	72.94% (66.99%-76.84%)	67.78% (66.31%-72.53%)
Hybrid model	Independent validation	0.789 (0.728-0.793)	71.56% (68.90%-73.84%)	71.77% (56.48%-76.88%)	58.45% (50.73%-66.05%)

[a]AUC: area under the curve.



Performance of GVisageNet

In the testing dataset, GVisageNet achieved an AUC of 0.942 (95% CI 0.921-0.972), an accuracy of 94.33% (95% CI: 91.00%-95.96%), a sensitivity of 93.51% (95% CI: 90.00%-96.50%), and a specificity of 93.39% (95% CI 89.48%-97.00%) in distinguishing NCs from midline brain tumors. In second stage, GVisageNet achieved an AUC of 0.705 (95% CI 0.590-0.760), an accuracy of 71.71% (95% CI 57.42%-77.11%), a sensitivity of 75.24% (95% CI 70.89%-77.57%), and a specificity of 73.40% (95% CI 69.04%-76.80%) in distinguishing iGCTs from other midline brain tumors.

In the independent external validation dataset, GVisageNet demonstrated effectiveness in distinguishing NCs and midline brain tumors. It achieved an AUC of 0.938 (95% CI 0.913-0.967), an accuracy of 83.77% (95% CI: 71.45%-92.33%), a sensitivity of 91.67% (95% CI 87.42%-100.00%), and a specificity of 77.55% (95% CI 66.43%-80.46%; Figure 4A). In distinguishing iGCTs from other midline brain tumors, as shown in Figure 4B, it achieved an AUC of 0.739 (95% CI 0.728-0.773), an accuracy of 73.10% (95% CI 69.85%-77.34%), a sensitivity of 68.33% (95% CI 53.65%-75.14%), and a specificity of 63.24% (95% CI 56.59%-81.20%). The AUC, accuracy, sensitivity, and specificity of GVisageNet in the testing and validation datasets of the second stage are depicted in Figures 4C and 4D.

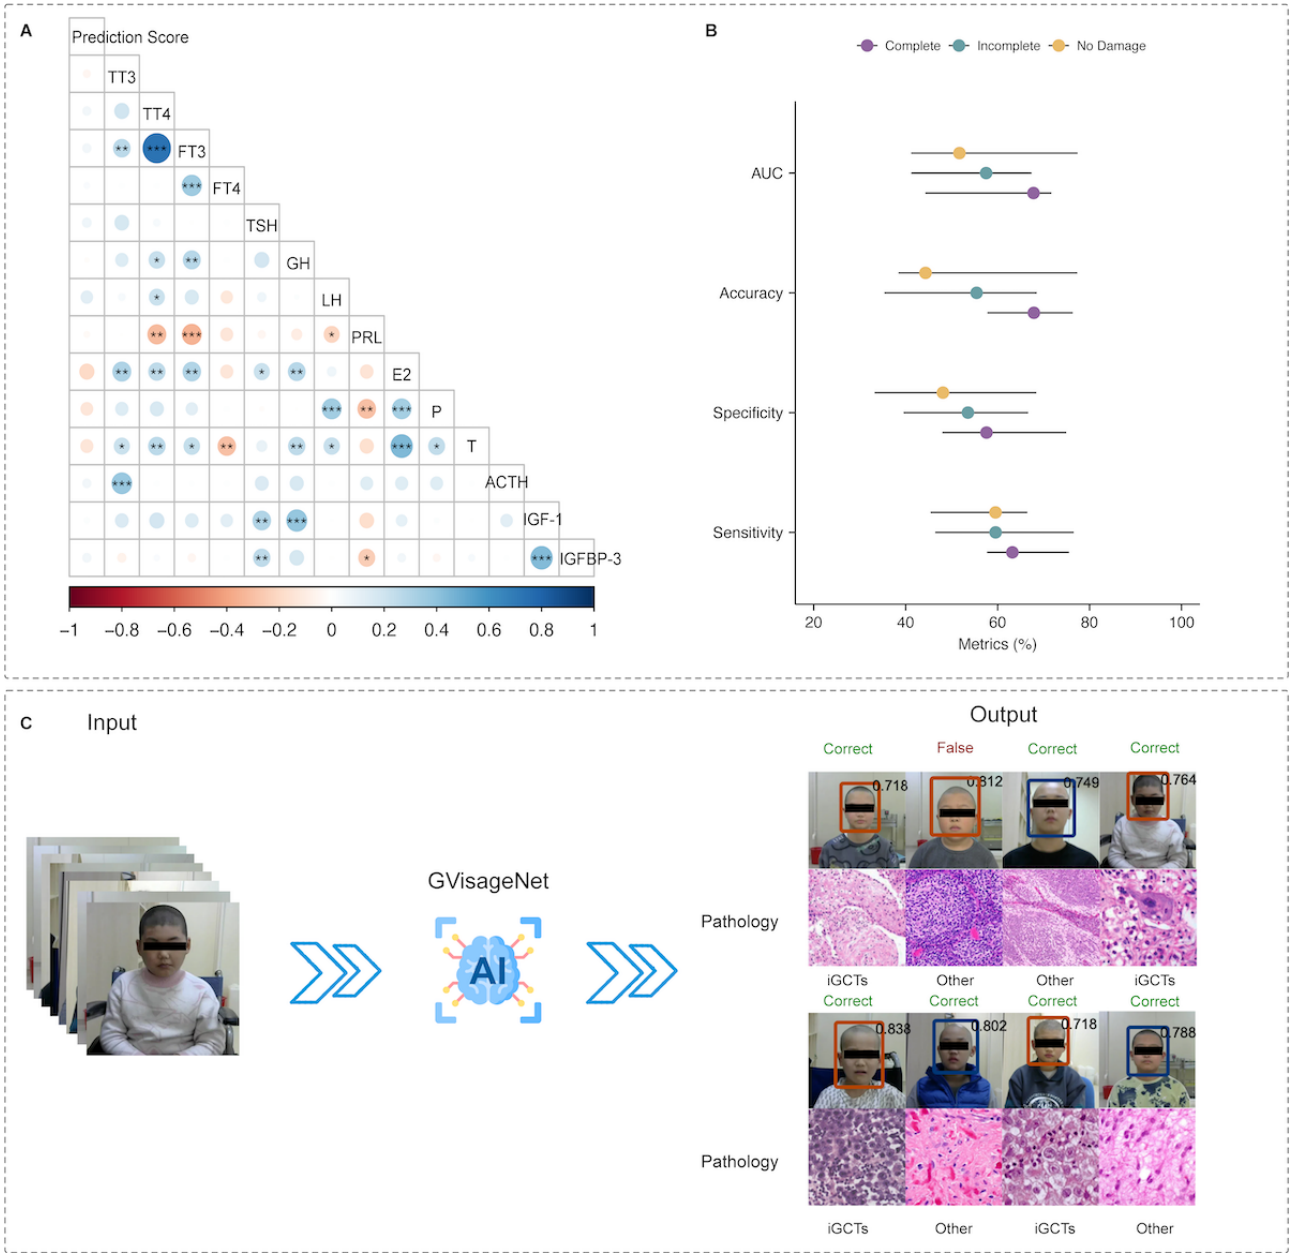
Clinical Variables and Hybrid Model Performance in Differentiating iGCTs From Other Midline Brain Tumors

To enhance GvisageNet's ability to distinguish iGCTs from other midline brain tumors, we compared the performance of a logistic regression model using clinical variables with a hybrid model. In the testing dataset, the logistic regression model, which used clinical variables, achieved an AUC of 0.612 (95% CI 0.493-0.709), an accuracy of 59.41% (95% CI 50.85%-64.28%), a sensitivity of 65.18% (95% CI 56.78%-73.54%), and a specificity of 55.93% (95% CI 48.48%-65.74%). In the independent external validation dataset, this model attained an AUC of 0.632 (95% CI 0.571-0.679), an accuracy of 68.97% (95% CI 62.68%-75.44%), a sensitivity of 57.88% (95% CI 49.45%-68.74%), and a specificity of 58.59% (95% CI: 49.24%-70.04%), as depicted in Figures 4C and 4D, and Table S2 in Multimedia Appendix 1.

The hybrid model in the testing dataset achieved an AUC of 0.711 (95% CI 0.676-0.798), an accuracy of 70.77% (95% CI 65.48%-76.65%), a sensitivity of 72.94% (95% CI 66.99%-76.84%), and a specificity of 67.78% (95% CI 66.31%-72.53%). In the independent external validation dataset, the hybrid prediction model reached an AUC of 0.789 (95% CI 0.728-0.793), an accuracy of 71.56% (95% CI 68.90%-73.84%), a sensitivity of 71.77% (95% CI 56.48%-76.88%), and a specificity of 58.45% (95% CI 50.73%-66.05%), as shown in Figures 4C and 4D.



In a comparative analysis conducted on the independent external validation dataset, GVisageNet was found to significantly outperform the logistic regression model, demonstrating higher accuracy (AUC 0.739 vs 0.632; P<.001). However, its performance was slightly inferior to that of the hybrid model (AUC 0.739 vs 0.789; P=.04).

Correlation Analysis Between Prediction Output and Endocrine Indicators

Correlation analysis revealed a significant positive correlation between the prediction scores and the levels of TSH and IGFBP-3 (P<.05). Conversely, there was a significant negative correlation between the prediction scores and the levels of total thyroxine (TT4), FT3, FT4, GH, prolactin, and estradiol (P<.05). Detailed pairwise concordances of endocrine indicators are presented in Figure 5A.

XSL•FO
RenderX

Figure 5. (A) Correlation analysis between the output results of GVisageNet and endocrine indicators in the independent external validation dataset. (B) The area under the curve, accuracy, sensitivity, and specificity of the GVisageNet for the stratified analysis of the HPT axis damage degree in the independent external validation dataset. (C) The visual integration of GVisageNet into the facial photo collection system (independent validation dataset). ACTH: adrenocorticotrophic hormone; E2: estradiol; FT3: free triiodothyronine; FT4: free thyroxine; GH: growth hormone; iGCTs: intracranial germ cell tumors; IGF-1: insulin-like growth factor 1; IGFBP-3: insulin-like growth factor binding protein 3; LH: luteinizing hormone; P: progesterone; PRL: prolactin; T: testosterone; TSH: thyroid-stimulating hormone; TT3: total tri-iodothyronine; TT4: total thyroxine.

Moreover, the independent validation dataset was divided into 3 groups based on the degree of HPT axis damage: complete damage (n=37), incomplete damage (n=54), and no damage (n=39). In the task of differentiating iGCTs from other midline brain tumors, GVisageNet achieved varying levels of performance across these groups. In the complete damage group, GVisageNet achieved an AUC of 0.678 (95% CI 0.443-0.717), an accuracy of 67.89% (95% CI 57.79%-76.33%), a sensitivity of 63.21% (95% CI 57.67%-75.54%), and a specificity of 57.58% (95% CI 47.99%-74.91%). For the incomplete damage group, the model reached an AUC of 0.575 (95% CI 0.412-0.674), an accuracy of 55.43% (95% CI 35.37%-68.54%), a sensitivity of 59.56% (95% CI 46.43%-76.54%), and a specificity of 53.54% (95% CI 39.54%-66.64%). In the no-damage group, GVisageNet achieved an AUC of 0.517 (95% CI 0.412-0.774), an accuracy of 44.32% (95% CI 38.43%-77.33%), a sensitivity of 59.54% (95% CI 45.43%-66.47%), and a specificity of 48.11% (95% CI 33.23%-68.42%; Table 3). The AUC, accuracy, sensitivity, and specificity for each group are detailed in Figure 5B. An analysis of variance (Friedman test) revealed a significant difference in AUC among the 3 groups (P=.03). The visual integration of GVisageNet into the facial photo collection system is shown in Figure 5C.

Discussion

Principal Findings

This study successfully developed and validated an automated binary DL model, GVisageNet, to differentiate midline brain tumors from NCs and further distinguish iGCTs from other midline brain tumors using facial images. We also constructed a logistic regression model and a hybrid model using clinical data to explore whether clinical variables could enhance the diagnostic performance of the model. The results showed that in differentiating iGCTs from other midline brain tumors, the hybrid model slightly outperformed GVisageNet (0.739 vs 0.789; P=.04). Finally, we attempted to explain the mechanism of GVisageNet by analyzing endocrine changes in patients and found that the model's predicted probability values were strongly correlated with seven endocrine indicators (P<.05). In addition, GVisageNet performed best in the group with complete endocrine axis damage, suggesting that endocrine axis impairment may be a reason for the facial texture changes observed in patients. GVisageNet can be integrated into outpatient facial photo collection systems, enabling the routine collection of facial images during a patient's initial visit. This allows for real-time preliminary screening diagnoses, guiding clinicians to conduct targeted examinations, thereby saving medical resources and reducing patient costs.

The enhanced ResNet-50 model demonstrated significant advancements in this field, outperforming both its original version and other conventional CNN models in terms of training and testing accuracy. This improvement was achieved through structural modifications and an optimized training process, including an adaptive learning rate that effectively adjusts weights within the network layers. Moreover, the model effectively addressed the common issue of overfitting in DL, thereby enhancing its reliability and consistency in screening applications. A crucial aspect of this improvement was the model's reduced loss values and fluctuations, contributing to its increased stability. Importantly, visualization tools were used for feature extraction from specific layers of ResNet-50 [19], enabling precise identification of potential tumor indicators from facial photographs [20], which is essential for early screening and intervention. In addition, the introduction of a standard operating procedure for preprocessing facial photos significantly improved the quality of input data, aiding in more accurate tumor screening.

In addition to the analyses conducted, it is essential to consider the potential issue of collinearity among features. Collinearity, or high intercorrelation among predictor variables, can adversely affect the performance and interpretability of regression models and other machine learning techniques. Detecting and addressing collinearity is crucial to ensure the robustness of our models. Methods such as correlation matrices, variance inflation factors, and condition indices can be used to detect collinearity [21]. Mitigation strategies include removing or combining highly correlated features and using regularization techniques like Ridge regression or Lasso [22]. Future work should include a thorough investigation of collinearity and its impact on model performance. By addressing collinearity, we can enhance the stability and interpretability of our models, leading to more reliable diagnostic predictions. Therefore, it is recommended that future studies incorporate collinearity diagnostics and report any steps taken to mitigate its effects. This approach will provide a more comprehensive understanding of the model development process and ensure the robustness of the predictive models.

Furthermore, DL models, especially those designed for facial recognition, are adept at extracting and analyzing complex image patterns that may reflect physiological changes due to endocrine imbalances. Several mechanisms underlie the potential correlations between DL model outputs and endocrine indicators. First, models like CNNs can identify subtle changes in facial features associated with hormonal imbalances, such as those caused by conditions like acromegaly or Cushing's syndrome, which alter fat distribution, skin texture, or facial bone structure. Second, these models use extensive training datasets to recognize patterns associated with specific conditions, such as the protruding eyes or facial puffiness seen in hyperthyroidism, and can correlate these visual cues with hormone levels (eg, TSH, triiodothyronine, and thyroxine) to predict endocrine states from the facial analysis. In addition, hormones significantly affect physical characteristics, where elevated cortisol levels may cause a "moon face" appearance or a buffalo hump, and excess growth hormone can change the jawline and brow prominence, all detectable through DL analysis. Finally, integrating DL outputs with clinical data, such as hormone levels, enhances predictive accuracy. A hybrid model that merges image-based phenotypic features with biochemical markers provides a comprehensive understanding of a patient's endocrine state, enabling nuanced predictions and personalized health assessments. This integrated approach leverages facial recognition technology to noninvasively assess endocrine conditions, thereby enhancing diagnostic precision and patient care.

In addition, exploring the potential broader applications of our DL model in diagnosing other diseases with distinct phenotypic manifestations is imperative. For instance, conditions such as Parkinson disease, characterized by specific facial expressions and muscle rigidity, or genetic disorders like Down syndrome,

XSL•FO
RenderX

which presents with unique facial features, could benefit from analogous DL-based diagnostic approaches [23,24]. By training models to recognize these specific phenotypic patterns, we can expand the use of our DL model to provide early and accurate diagnoses across a variety of medical conditions. This broader application not only enhances the model's relevance in the medical field but also contributes to more comprehensive patient care through the early detection of diseases that manifest through observable physical changes.

Significant correlations were observed between DL model outputs and endocrine markers, including TSH, IGFBP-3, TT4, FT3, FT4, GH, prolactin, and estradiol, suggesting that endocrine variations may play a crucial role in the development of facial features in patents with iGCT. Notably, approximately 40% of iGCTs secrete β-HCG [1,5,25], which also induces endocrine changes at sufficiently high levels. The cross-immunoreactivity of β-HCG with LH triggers peripheral precocious puberty or gonadotropin-releasing hormone–independent precocious puberty, distinct from central precocious puberty and nonprogressive pubertal variants. In males, elevated β-HCG levels activate LH receptors on Leydig cells, enhancing testosterone production [26]. Conversely, in females, β-HCG does not induce precocious puberty, as activation of both FSH and LH receptors is requisite. Consequently, precocious puberty in iGCTs is predominantly observed in male toddlers and school-aged boys, characterized by facial features such as acne, beard growth, increased oil secretion, and skeletal maturity. Excess GH production leads to acromegaly [27], resulting in enlarged facial bones, while hypothyroidism causes facial puffiness [28-32], especially around the eyes [33-35]. When DL model results were integrated with clinical indicators, the detection efficacy was significantly enhanced. It is imperative to clarify that β-HCG was excluded from our study since only 40% of patients exhibit β-HCG secretion, and the DL model serves as a prediagnostic screening tool, hinting at further examination. Premature inclusion of tumor markers could compromise model accuracy. This observation was further underscored in the stratified analysis. Our findings indicate that the predictive efficacy of GVisageNet was least effective in cases without HPT axis impairment, and most effective in instances of complete HPT axis disruption. This underscores a direct correlation between the model's predictive capacity and endocrine function. Notably, when the HPT axis was fully compromised, the resultant endocrine-driven alterations in facial characteristics were most pronounced.

This study had several limitations that should be considered when interpreting the findings. First, the relatively small sample size of each iGCT subtype (germ cell tumors [germinomas] and nongerminomatous germ cell tumors) limited the ability to conduct a more detailed analysis and might have impacted the statistical power of the study. Future research should aim to include larger cohorts to enhance the robustness and generalizability of the findings. Second, the study only collected baseline facial photos of the patients. The lack of longitudinal follow-up data limits the ability to observe changes in facial features and endocrine parameters over time. Longitudinal studies are needed to evaluate the progression and potential predictive value of facial recognition technology in monitoring patients with iGCTs. Third, the study was conducted across multiple centers, which introduced variability in data collection and image quality. Although efforts were made to standardize procedures, some degree of inconsistency is inevitable. Future studies should implement stricter protocols and quality control measures to minimize such variability. Finally, while the study focused on differentiating iGCTs from other midline brain tumors, it did not explore the potential of this technology in distinguishing iGCTs from other types of intracranial tumors or nontumorous conditions. Expanding the scope of future research could provide a more comprehensive understanding of the clinical applications of deep learning-based facial recognition in neuro-oncology.

In addition, "no identifiable personal information" (such as unique facial characteristics) is presented in any figures or supplementary materials of the manuscript. In cases where participant consent is necessary for image inclusion, signed consent forms have been obtained and can be uploaded in the "Other files" field upon resubmission. This ensures transparency and adheres to the highest standards of ethical research practices.

Conclusion

In summary, this study demonstrates the potential application of facial recognition technology in the diagnosis of iGCTs. Facial recognition could not only aid in early detection and screening of iGCTs but also might become a valuable tool in advancing future clinical decision-making.

Acknowledgments

We thank all the patients for their efforts.

Abstract

Background: Poor health outcomes are well documented among patients with a non-English language preference (NELP). The use of interpreters can improve the quality of care for patients with NELP. Despite a growing and unmet need for interpretation services in the US health care system, rates of interpreter use in the care setting are consistently low. Standardized collection and exchange of patient interpretation needs can improve access to appropriate language assistance services.

Objective: This study aims to examine current practices for collecting, documenting, and exchanging information on a patient's self-reported preference for an interpreter in the electronic health record (EHR) and the implementation maturity and adoption level of available data standards. The paper identifies standards implementation; data collection workflows; use cases for collecting, documenting, and exchanging information on a patient's self-reported preference for an interpreter; challenges to data collection and use; and opportunities to advance standardization of the interpreter needed data element to facilitate patient-centered care.

Methods: We conducted a narrative review to describe the availability of terminology standards to facilitate health care organization documentation of a patient's self-reported preference for an interpreter in the EHR. Key informant discussions with EHR developers, health systems, clinicians, a practice-based research organization, a national standards collaborative, a professional health care association, and Federal agency representatives filled in gaps from the narrative review.

Results: The findings indicate that health care organizations value standardized collection and exchange of patient language assistance service needs and preferences. Informants identified three use cases for collecting, documenting, and exchanging information on a patient's self-reported preference for an interpreter, which are (1) person-centered care, (2) transitions of care, and (3) health care administration. The discussions revealed that EHR developers provide a data field for documenting interpreter needed data, which are routinely collected across health care organizations through commonly used data collection workflows. However, this data element is not mapped to standard terminologies, such as Logical Observation Identifiers Names and Codes (LOINC) or Systematized Medical Nomenclature for Medicine–Clinical Terminology (SNOMED-CT), consequently limiting the opportunities to electronically share these data between health systems and community-based organizations. The narrative review and key informant discussions identified three potential challenges to using information on a patient's self-reported preference for an interpreter for person-centered care and quality improvement, which are (1) lack of adoption of available data standards, (2) limited electronic exchange, and (3) patient mistrust.

Conclusions: Collecting and documenting patient's self-reported interpreter preferences can improve the quality of services provided, patient care experiences, and equitable health care delivery without invoking a significant burden on the health care

XSL•FO
RenderX

system. Although there is routine collection and documentation of patient interpretation needs, the lack of standardization limits the exchange of this information among health care and community-based organizations.

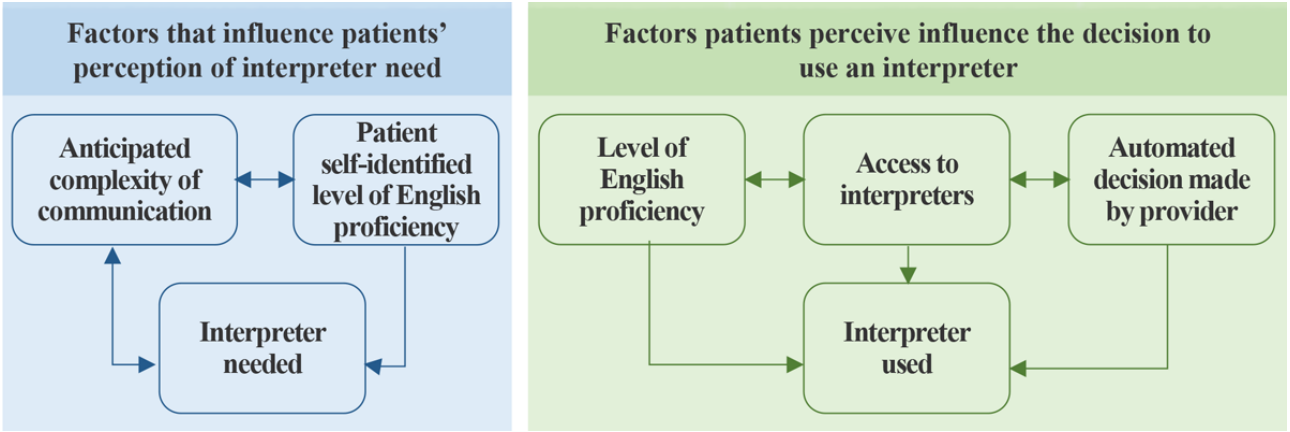
KEYWORDS

health information exchange; interoperability; electronic health records; interpreter; limited English proficiency; communication barriers

Introduction



Background

Health disparities are a prevalent issue in health care delivery in the United States today. Among the contributors to care inequities are barriers to language assistance services. Barriers to language assistance services are associated with misdiagnosis and inappropriate treatment by providers [1] and contribute to poor health outcomes that are well documented among patients with a non-English language preference (NELP) [2]. Compared with English-speaking patients, patients with NELP experience worse health outcomes, such as undiagnosed or uncontrolled hypertension, prolonged hospital stays, and poor asthma control [3]. Among Hispanic communities, which represent the fastest growing non-English language population in the United States, stroke is a leading cause of death and has been attributed to factors such as barriers to language assistance services [4]. Studies have also found that patients who experience barriers to language assistance services have a reduced likelihood of physician and mental health provider visits and are more likely to have an unplanned emergency department visit compared with patients who are proficient in English. Furthermore, patients with NELP are at an increased risk for unplanned repeat emergency department visits within 72 hours of discharge [5,6].

Interpretation services represent both a growing and unmet need in the United States health care system [7]. The National Council on Interpreting in Health Care defines a medical interpreter as an individual who “interprets in health care settings of any sort, including doctor’s offices, clinics, hospitals, home health visits, mental health clinics, and public health presentations” [8]. In 2021, the Migration Policy Institute estimated that approximately 26 million individuals in the United States reported a NELP [9,10].

The use of interpreters has been found to improve the quality of care for patients with NELP, with patients reporting overall high satisfaction with care and communication with their care team [11]. However, despite the benefits, rates of interpreter use are consistently low, and additional research is needed to better understand how patients assess the need for and use an interpreter [12]. The findings from Schwei et al [12] inform our current understanding of a patient’s decision-making processes (Figure 1) and could be beneficial to inform how health care organizations engage with patients to gather and use data on a patient’s self-reported preference for an interpreter.

Figure 1. Factors that patients say influence whether an interpreter is needed or used (adapted from Schwei et al [12]).

In the absence of medical interpreters, patients with NELP are left to rely on ad hoc interpreters such as family members, hospital staff members, or their own language fluency to obtain needed medical information. This leaves room for a variety of common interpretation errors to occur such as omissions, embellishments, false fluency, paraphrasing, and family members or ad hoc interpreters providing their own opinions [13]. Interpreter use can also be impacted by concerns from health providers or patients regarding the privacy and confidentiality of the communications between the patient and interpreter [5,14,15]. Patients may be reluctant to use an interpreter if they are uncertain of the privacy and confidentiality protections. These issues highlight the importance of both identifying patient language access needs and providing linguistically appropriate interpretation and translation services.

The standardized collection and exchange of patient interpretation needs can help improve access to appropriate language assistance services. Once collected from patients, this data can be stored in the electronic health record (EHR) and accessed by the patient’s care team to support person-centered care or exchanged electronically with other providers (eg, specialists and long-term care facilities) to support transitions of care.

Objectives

This paper examines current practices for collecting, documenting, and exchanging information on a patient's self-reported preference for an interpreter in the EHR. The paper identifies data standards implementation, data collection workflows, use cases for information on a patient's self-reported preference for an interpreter, challenges to data collection and use, and opportunities to advance the standardized collection and use of the interpreter needed data element to facilitate patient-centered care.

Methods

We used 2 methods to assess the collection, documentation, and use of information on a patient's self-reported preference for an interpreter, which are (1) a narrative review and (2) key informant discussions.

Literature Scan

We conducted a narrative review [16] to describe the availability of terminology standards to facilitate health care organization documentation of a patient's self-reported preference for an interpreter in the EHR, and the implementation maturity and adoption level of available data standards.

We searched both the peer-reviewed and gray literature using PubMed and Google (Textbox 1). We also searched the websites of standards development organizations including the Health Level Seven (HL7) website and Confluence pages, the Assistant Secretary for Technology Policy/Office of the National Coordinator for Health Information Technology (ASTP/ONC) website, the Logical Observation Identifiers Names and Codes (LOINC) website, the Gravity Project website, PCORnet (the National Patient Centered Clinical Research Network), and the Centers for Medicare & Medicaid Services (CMS) website. We conducted supplemental searches on barriers to language assistance services and available standards (eg, Systematized Medical Nomenclature for Medicine-Clinical Terminology [SNOMED-CT] and Clinical Document Architecture) based on discussions with key informants. In total, we included a total of 31 sources.

Textbox 1. Example search terms.

PubMed search terms

- "interpreter needed" AND "data element", "interpreter" AND "data element", "interpreter" AND "data" AND "EHR", language translator needed data element, interpretation, communication barriers, limited English proficiency, and "translating*"

Gray literature keywords

- "interpreter*", "interpreter needed", "interpreter service", "interpreter required", "translating*", "language translator", "communication facilitator*", United States Core Data for Interoperability (USCDI), "data element", electronic health record (EHR), language translator needed data element, inclusion of language preference in EHR, inclusion of language preference in EHR, Centers for Medicaid & Medicaid Services (CMS) Data Element Library (DEL) Health Information Technology Workgroup, Health Level 7 (HL7) Workgroup, Office of the National Coordinator (ONC), Gravity Project, and PCORnet Common Data Model.

Key Informant Discussions

We conducted key informant discussions to complement findings from the literature scan and contextual information gaps by identifying emergent topics not yet reflected in the literature. We identified a purposive sample of informants across 3 stakeholder categories to gather diverse perspectives on the collection and use of data on a patient's self-reported preference for an interpreter in the EHR, which are (1) EHR developers (n=3), (2) health systems and clinicians (n=8), and (3) policy-making and advocacy organizations (n=5). The EHR developers included in the study represented over 70% of the market share by bed count in the inpatient setting [17] and nearly half of the ambulatory market share among clinicians that report using a 2015 edition certified EHR product [18]. Health system and clinician informants included representatives from academic medical centers, a Federally Qualified Health Center, a primary care clinic, an integrated health care system, and acute care hospitals. Finally, policy-making and advocacy organization informants were comprised of Federal agency staff, language service professionals, members of a national consensus–based standards collaborative, and a community health center association. The key informants provided perspectives on the experience of a wide variety of health care organizations' processes for collecting, documenting, and using information on a patient's self-reported preference for an interpreter.

We generated transcripts for each key informant discussion. We used qualitative content analysis to identify key themes using the existing United States Core Data for Interoperability (USCDI) ONC New Data Element and Class Submission System, focusing on new data element submission requirements and emergent themes from gaps in the literature. The USCDI ONC New Data Element and Class submission requirements include (1) similar or related data elements in USCDI, (2) why the new data element should be considered separately, (3) main use cases to support the adoption of the data element into the USCDI, (4) estimates of the breadth of applicability of the use cases for the new data element, (5) data element maturity (eg, existing vocabulary, terminology, or content standards), (6) availability of additional technical specifications, (7) level determination representing the use of the new data element, (8) level of electronic exchange with external organizations, and (9) challenges to implementation (eg, restrictions on standardization or use, privacy and security concerns, and implementation burden) [19].

XSL•FO
RenderX

Analytic Approach

The findings from the literature scan were summarized and grouped into two primary categories, which are (1) standards for certified EHR and health information technology systems and (2) health care quality improvement. We used a data abstraction matrix to identify themes from the key informant discussions. We abstracted data from the discussions into five domains: (1) current practices for collecting information on a patient's self-reported preference for an interpreter, (2) use cases for this information, (3) EHR product support for an interpreter needed data element, (4) interoperability standards, and (5) challenges to collecting, documenting, and using information on a patient's self-reported preference for an interpreter. The authors also identified common themes from across the 5 domains to identify key considerations and opportunities to improve data interoperability and expand upon the use of the interpreter needed data element.

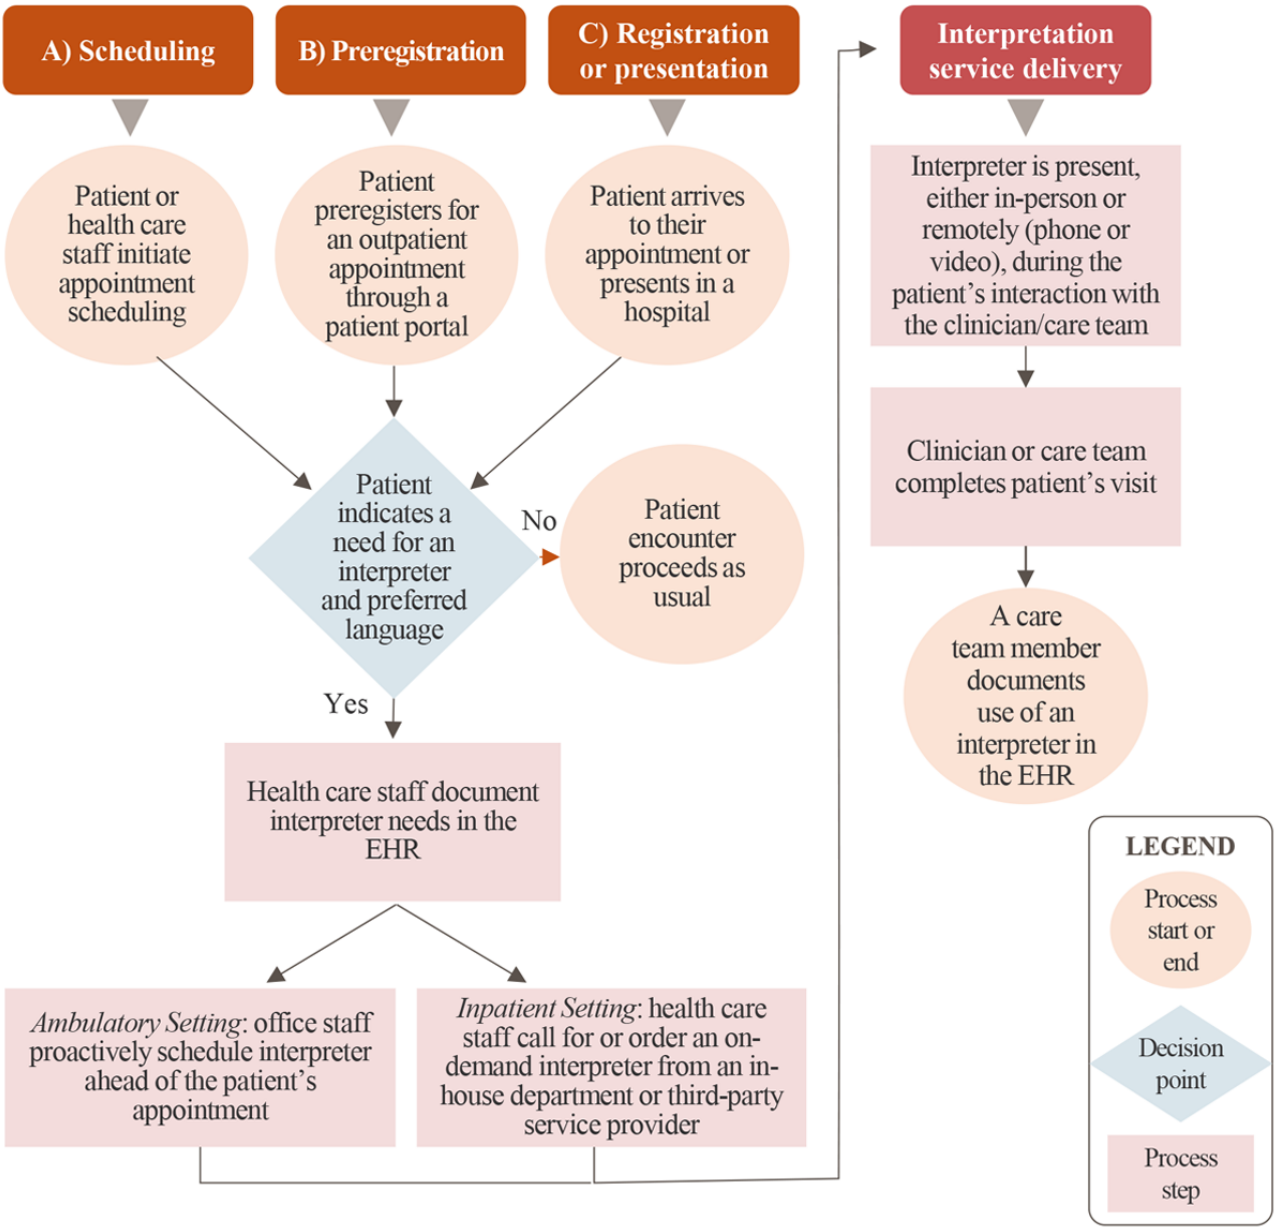
Ethical Considerations

This study was reviewed by the NORC at the University of Chicago Institutional Review Board and did not meet the definition of research with human subjects set forth in Federal Regulations at 45 CFR 46.102.

Results

Overview

Health care organizations routinely collect information on a patient's self-reported preference for an interpreter and preferred language data to facilitate interpretation service delivery. Health care organizations recognize the limitation of using either preferred language or English proficiency alone to identify a patient's preference or need for an interpreter and, therefore, collect a patient's self-reported preference for interpretation services in tandem with preferred language to accurately reflect language service access needs.



Current Health Care Organization Data Collection Practices

We did not find evidence of health care organizations using available standard terminologies (eg, LOINC and SNOMED-CT) in the literature. Key informant interviews with health systems, clinicians, and EHR developers affirmed this finding, stating that health care organizations use structured fields to document a patient's self-reported preference for an interpreter in the EHR but do not map this data to available clinical terminologies.

Through the key informant discussions, we identified common practices for the collection, documentation, and use of information on a patient's self-reported preference for an interpreter in both the ambulatory and inpatient settings. We present a workflow diagram for the common data collection and documentation processes in Figure 2 and describe each step below.

XSL•FO
RenderX

Figure 2. Interpretation service requests and delivery workflow. EHR: electronic health record.

In Figure 2, three events (A-C) begin the process of gathering information from the patient on their self-reported preference for an interpreter and the subsequent provision of interpretation services. However, nuances exist depending on the EHR, organizational practices, care delivery setting, the availability of interpretation services, and interpretation service delivery method. Event A indicates scheduling a patient encounter. When a patient or health care staff initiates appointment scheduling, office staff members document the need for interpretation services in the EHR through an interpreter needed data field. Office staff members may proactively schedule interpretation services for the patient. Event B begins with patient preregistration. During preregistration, the patient may self-report their preference for an interpreter and their preferred language within the patient portal. Office staff members document this information in the patient's record and may proactively schedule interpretation services for the patient. Event C occurs with patient registration or when a patient presents in a hospital. When a patient self-reports their preference for an interpreter at arrival for an outpatient appointment or presents at a hospital, staff members document this information in the EHR and contact an interpreter for on-demand service.

Interpretation services can be delivered in-person or remotely through phone or video connection. Providers may use an interpreter from an internal interpretation services department, or a third-party vendor, or rely upon a clinician or staff member who is medically proficient in the patient's preferred language. Outpatient clinics often proactively schedule in-person or remote interpreters from third-party services because they may have collected a patient's self-reported preference for an interpreter before the patient encounter. If the clinic serves a significant number of patients with NELP, they may have in-house interpreters available or staff members who are medically proficient (ie, someone whose non-English language skills include communicating medical terminology and information) in the patient's preferred language. In the inpatient setting, interpretation services are provided either on-demand from an

XSL•FO
RenderX

in-house interpretation service department or remotely (eg, through a video connection). Upon completion of the patient visit, a member of the care team may document the use of the interpreter within the patient notes section of the EHR.

Use Cases for Data on a Patient's Self-Reported Preference for an Interpreter

Overview

Using the information on a patient's self-reported preference for an interpreter can assist health care organizations in providing more appropriate patient-centered care and eliminate guesswork or assumptions made by health care teams regarding which patients need an interpreter, ultimately improving the patient experience. Key informants described three primary use cases for the collection, documentation, and use of information on a patient's self-reported preference for an interpreter, which are (1) person-centered care, (2) transitions of care, and (3) health care administration (Table 1).

Table 1. Use cases and illustrative quotes for using data on a patient's self-reported preference for an interpreter.

Use case	Illustrative key informant quotes
Person-centered care	• The biggest benefit of collecting interpreters needed is improving the patient care experience for patients with limited English proficiency. [Health system representative] • Accuracy of language is especially important because you need to understand what specific problems the patient is experiencing and ask follow-up questions to make a solid differential diagnosis. [FQHC[a] representative] • It helps drastically with patient satisfaction when we think about being able to communicate with your provider, understand what they're saying, and feeling comfortable that you are understanding medical jargon in your native tongue. [Health system representative]
Transition of care	• If that information is exchanged, then it can be good, because other providers have that information in advance, and can arrange for interpretation services. This could be really good in situations where it's a referral. [Health system representative] • I think one place where exchanging this field would be helpful is when we bring in contracted specialists...So, if a patient was going for a first-time visit with an external provider, that would be valuable for the specialist to know, and to meet with patient needs. [Health system representative] • I could see exchanging Interpreter Needed being useful for patients that are being transferred to long-term acute care hospitals (LTACH). That facility should have the ability to see what language the patient needs to be served in. [FQHC representative]
Health care administration	• Requiring the [interpreter needed] data element might help normalize requesting interpreter services, and/or create a downstream effect of improving the interpreter services payment structure. [Health system representative]

[a]FQHC: Federally Qualified Health Center.

Use Case 1: Person-Centered Care

Improving communication with patients and ensuring person-centered care is the central purpose behind collecting information on a patient's self-reported preference for an interpreter and their preferred language. Key informants and available literature both indicate that interpretation services improve patient comprehension of clinician discussions, patient care quality, and care processes [11,20].

Patients with NELP who receive professional interpretation services are less likely to be readmitted to the hospital and more likely to experience a shorter length of stay than patients with NELP who do not receive interpretation services [11]. Key informants echoed that interpretation services can enhance the delivery of safer patient care and patient decision-making by facilitating better communication between providers and patients regarding patient preferences, medical and nonmedical care needs, clinical information, and care instructions [21].

Finally, collecting information on a patient's self-reported preference for an interpreter also facilitates services for patients with communication needs beyond spoken language, such as indications for an American Sign Language interpreter.

Use Case 2: Transitions of Care

Multiple key informants stated that exchanging data on a patient's interpretation needs facilitates care transitions and referrals to specialty care, social care organizations, and postacute care (PAC) facilities. Exchanging information on a patient's self-reported preference for an interpreter allows specialists to arrange interpretation services in advance of the patient's appointment and may decrease the likelihood that patients are lost to follow-up due to interpretation service scheduling issues. Sharing patient language assistance needs through social care coordination platforms such as Unite Us facilitates patient access to interpreters at community partner organizations.

PAC facilities are required to collect data on whether a patient needs or wants an interpreter using standardized patient assessments under the CMS Quality Reporting Program. The data are collected using the Interpreter Needed LOINC terminology [22], allowing for interoperable data exchange among postacute providers and timely coordination of interpretation services.

Use Case 3: Health Care Administration

A few key informants noted that collecting data on the number of patients requiring interpretation services assists health care

XSL•FO
RenderX

administrators in tailoring such services to adequately serve their patient population. For example, administrators can provide in-person interpretation services for the most requested languages and offer telephonic or remote interpretation services for less commonly requested languages.

Administrators also use information on a patient's self-reported preference for an interpreter to fulfill reporting requirements and support quality improvement efforts. For example, Federally Qualified Health Centers are required to report the number of patients "best served in another language" as part of the Health Resources and Services Administration Uniform Data System. In addition, one of the 2023 quality improvement activities for the CMS Quality Payment Programs is to "Create and Implement a Language Access Plan" that adheres to the National Standards for Culturally and Linguistically Appropriate Services in Health and Health Care [23,24].

EHR Products Support Documentation of Data on a Patient's Self-Reported Preference for an Interpreter

Key informants from the 3 EHR developers stated that functionality to document information on a patient's self-reported preference for an interpreter is available to health care organizations through a structured field in the EHR.

Interpreter Needed Data Element Interoperability Standards

There are well-specified standard terminologies for the interpreter needed data element. The literature and key informants identified both LOINC and SNOMED-CT codes for identifying a patient's self-reported preference for an interpreter: LOINC code 54588-9, "patient/resident's need or want an interpreter to communicate with a doctor or health care staff" and the SNOMED-CT code 315593009, "need for interpreter (finding)" [25,26]. The ASTP/ONC 2024 Interoperability Standards Advisory identifies LOINC code 54588-9 as an available value set to use when communicating information in a patient's preferred language [27].

Mapping information on a patient's self-reported preference for an interpreter to one or both standards can facilitate the exchange of these data between providers, community-based organizations, and others to support patient needs. The HL7 Fast Healthcare Interoperability Resources (FHIR) and Clinical Document Architecture standards define how health care data can be exchanged between health care organizations with different health IT systems [28,29]. In addition, informants identified a FHIR standard (the FHIR Patient Resource-Interpreter Required) for exchanging information on whether a patient "requires an interpreter to communicate health care information to the practitioner" along with patient demographic and administrative data. This FHIR standard offers a practical solution to exchanging these data [30,31]. While our key informants reported that health care organizations do not routinely map information on a patient's self-reported preference for an interpreter to standard terminology, representatives from the 3 EHR developers we spoke to indicate that mapping can be implemented with minimal burden.

Challenges

Our key informants revealed the following 3 potential challenges to using information on a patient's self-reported preference for an interpreter for person-centered care and quality improvement, which are (1) lack of adoption of available data standards, (2) limited electronic exchange, and (3) patient mistrust (Table 2).

XSL•FO
RenderX

Table 2. Challenges to using information on a patient's self-reported preference for an interpreter and illustrative key informant quotes.

Challenge	Illustrative key informant quotes
Lack of adoption of available data standards	• I don't think Interpreter Needed is exchanged right now in a structured field...When I do see data coming through from other systems, I see interpreter information coming through in a free text field. [Health system representative] • If it's a continuation of care document (CCD) that we're sending, it's not a required field. I did check with our [EHR[a] developer lead], and we aren't sharing that Interpreter Needed field. It's currently not technically possible...I imagine if it was something required by regulators, that might spur development. [Health system representative]
Limited electronic exchange of interpreter needed data	• When we refer patients to specialists, the need for an interpreter is often included in free text notes and tends to get lost. I know anecdotally of instances where the specialist's office misses that note, so they don't know to provide an interpreter for the patient. Because it's so challenging for patients to make those appointments in the first place, if the interpreter is not available at the specialist's office the first time, it is common for them to never reschedule. [FQHC[b] representative] • I would guess that Interpreter Needed is a bit difficult to exchange between healthcare systems because it is not consistently labeled with one code" [FQHC representative]
Patient mistrust	• This [interpreter needed] standardized data could also be used in a discriminatory way. On one hand, I want to advocate for patients to have better access to interpreters, but I also don't want it to be used by providers to avoid patients that do need an interpreter. We need to be careful about how we use that information. [Health system representative] • Another issue is that it can feel like there will be an added charge or cost to you if you request a translator, even if it is a free service. Patients don't always feel like they're entitled to ask for those services. Even with Public Charges, when they're told they're entitled to interpretation services, they may not feel like they can access those resources. [Language services professional representative]

[a]EHR: electronic health record.

[b]FQHC: Federally Qualified Health Center.

Lack of Adoption of Available Data Standards

Key informants noted that while most health care organizations currently collect interpreter needed data, most do not map this data to an existing terminology standard. Limited mapping impedes data interoperability and efficient monitoring, tracking, and reporting on the need for interpretation services.

Limited Electronic Exchange of Interpreter Needed Data

Due to the lack of data standardization, there is limited electronic exchange of interpreter needed data among most health care organizations. Key informants stated that a patient's self-reported preference for an interpreter is often exchanged as free text in an administrative or clinical note, or it is shared through phone or fax when notifying a provider that a patient has requested an interpreter. Without standardized electronic exchange, communication of patient needs and preferences is inefficient, creating additional burden on the patient and room for care coordination errors. For instance, key informants shared examples of clinical notes indicating a patient's self-reported preference for an interpreter not being reviewed, causing delayed or missed care if an interpreter is not available at the specialist's office when the patient arrives for the appointment.

Patient Mistrust

The findings from the literature revealed that collecting a patient's self-reported preference for an interpreter from all patients may pose implications for patient trust. For example, a patient with NELP who would benefit from interpretation services may decline due to concerns about privacy and stigmatization [32]. Similarly, negative past experiences with interpreters (eg, misinterpretations or extended wait times for interpretation services) may lead to a patient declining interpretation service [33]. A few key informants also suggested that patients with NELP may decline an interpreter because they believe they will be billed for using those services, even when the patient is informed that they will not be charged. Although these findings transcend standardized collection and use of interpreter needed data, they are important challenges for health care organizations to consider when asking patients for this information.

Discussion

Principal Findings

Overall, while EHR developers and health systems indicated that interpreter needed data are routinely collected and used by most health care organizations, these data are not often mapped to available standards within the EHR. All the health care organizations and EHR developers we spoke with described well-defined administrative and clinical workflows to facilitate data collection of patients' self-reported preference for an interpreter.

Collection of Interpreter Needed Data Can Improve Quality of Care

Despite limited standardization, our findings suggest the collection, documentation, and use of interpreter needed data can improve the quality of care for patients with NELP. The provision of language and communication services for individuals with a NELP or other communication needs (eg, those who are deaf or hard of hearing) can facilitate the accurate

XSL•FO
RenderX

exchange of information regarding prevention, symptoms, diagnosis, treatment, care coordination, discharge planning, and shared decision-making between patients and their care team [34,35]. In short, addressing communication needs may assist in improving patient satisfaction, patient safety, and health outcomes of historically underserved populations.

Use of Interpreter Needed Data Has the Potential to Enhance Health Equity Research

Much of the research on English proficiency–related disparities in health care uses preferred language data abstracted from the EHR, patient experiences of care surveys (eg, Consumer Assessment of Healthcare Providers and Systems), and standardized PAC patient assessments to identify care gaps. Access to more accurate data on interpretation needs could assist researchers in more granularly identifying important health disparities among patients with NELP, understanding experiences of care among NELP individuals, and longitudinally tracking disparities. In addition, the use of standardized interpreter needed data alongside preferred language can support the development of more accurate estimates of language assistance needs that can be used to define quality measures for language service access for patients with NELP and help providers understand ways to better serve patients with NELP.

Greater Adoption of Standardized Interpreter Needed Data Is Necessary

The National Standards for Culturally and Linguistically Appropriate Services in Health and Health Care provide implementation guidance for offering communication and language assistance, which includes developing processes for identifying the languages an individual communicates in and documenting this information in the patient's medical record [34]. Our findings support using available LOINC and SNOMED-CT codes for documenting a patient's self-reported preference for an interpreter. Adoption of these standards will further efforts to use interpreter needed data for quality improvement initiatives aimed at achieving the Quintuple Aim.

Exchange of Interpreter Needed Data Has the Potential to Improve Disease Surveillance

EHR developers and health system key informants noted the potential benefits of exchanging interpreter needed data between health care organizations and public health authorities for the purpose of certain mandated public reporting, such as disease surveillance. For example, contact tracing could be more effective if information on individuals with language service access needs was shared in advance with public health authorities, thus improving communication regarding disease risk and transmission control.

Limitations

The primary objective of this study was to identify health care organization practices for documenting a patient's self-reported preference for an interpreter in the EHR, and the adoption level of available standards. We acknowledge that quantifying the impact of standardized interpreter needed data on health outcomes and patient experiences is important; however, this was out of the scope of our project. Future research on the adoption of the interpreter needed data element will help elucidate the impact of standardized data collection practices to address health disparities and improve patient outcomes.

Conclusion

Improving the quality of services provided to patients with NELP requires health care organizations to systematically collect information from patients regarding their language preferences and to use these data to plan for and offer communication and language assistance services. Despite the presence of common practices for the collection, documentation, and use of data on patient interpretation needs, the lack of standardization limits the exchange of this information among health systems. The use of standard terminologies for interpreter needed data offers one mechanism to facilitate the consistent use of the data within and across health care organizations, resulting in quality improvement [36]. As the US demographics change, there is the potential for unmet patient needs to become more glaring. Standardized data collection and EHR documentation can streamline the use of these data and may help to reduce health disparities.

Abstract

Background: Myocardial infarction (MI) is a medical emergency resulting from coronary artery occlusion. Patients with acute MI often experience disturbed sleep and circadian rhythm. Most previous studies assessed the premorbid sleep and circadian rhythm of patients with MI and their correlations with cardiovascular disease. However, little is known about post-MI sleep and circadian rhythm and their impacts on prognosis. The use of actigraphy with different algorithms to evaluate sleep and circadian rhythm after acute MI has the potential for predicting outcomes and preventing future disease progression.

Objective: We aimed to evaluate how sleep patterns and disrupted circadian rhythm affect the prognosis of MI, using actigraphy and heart rate variability (HRV). Nonparametric analysis of actigraphy data was performed to examine the circadian rhythm of patients.

Methods: Patients with MI in the intensive care unit (ICU) were enrolled alongside age- and gender-matched healthy controls. Actigraphy was used to evaluate sleep and circadian rhythm, while HRV was monitored for 24 hours to assess autonomic nerve function. Nonparametric indicators were calculated to quantify the active-rest patterns, including interdaily stability, intradaily variability, the most active 10 consecutive hours (M10), the least active 5 consecutive hours (L5), the relative amplitude, and the actigraphic dichotomy index. Follow-ups were conducted at 3 and 6 months after discharge to evaluate prognosis, including the duration of current admission, the number and duration of readmission and ICU admission, and catheterization. Independent sample *t* tests and analysis of covariance were used to compare group differences. Pearson correlation tests were used to explore the correlations of the parameters of actigraphy and HRV with prognosis.

Results: The study included 34 patients with MI (mean age 57.65, SD 9.03 years) and 17 age- and gender-matched controls. MI patients had significantly more wake after sleep onset, an increased number of awakenings, and a lower sleep efficiency than controls. Circadian rhythm analysis revealed significantly lower daytime activity in MI patients. Moreover, these patients had a lower relative amplitude and dichotomy index and a higher intradaily variability and midpoint of M10, suggesting less sleep and wake activity changes, more fragmentation of the rest-activity patterns, and a more delayed circadian rhythm. Furthermore, significant correlations were found between the parameters of circadian rhythm analysis, including nighttime activity, time of M10 and L5, and daytime and nighttime activity$_{SD}$, and patient prognosis.

Conclusions: Patients with acute MI experienced significantly worse sleep and disturbed circadian rhythm compared with healthy controls. Our actigraphy-based analysis revealed a disturbed circadian rhythm, including reduced daytime activities,

XSL•FO
RenderX

greater fluctuation in hourly activities, and a weak rest-activity rhythm, which were correlated with prognosis. The evaluation of sleep and circadian rhythm in patients with acute MI can serve as a valuable indicator for prognosis and should be further studied.

myocardial infarction; circadian rhythm; actigraphy; nonparametric analysis; prognosis; sleep; heart rate variability; activity

Introduction

Myocardial infarction (MI) is a medical emergency resulting from the occlusion of coronary arteries, which causes impaired perfusion and myocardial damage. It continues to be a leading cause of mortality globally despite progress in clinical management and revascularization techniques, especially in developed countries [1,2]. Annually, more than 2.4 million deaths occur due to MI in the United States, and over 4 million deaths occur across Europe and northern Asia. Furthermore, the burden of cardiovascular disease and MI has increased in middle- and low-income countries, where more than 80% of cardiovascular deaths now occur [3], highlighting its significant socioeconomic impact.

Accumulating evidence shows that the incidence and prognosis of MI, including mortality, cardiovascular events such as reinfarction, admission duration, and readmission, are influenced by numerous factors. Risk factors identified in the INTERHEART study include smoking status, lipid profile, blood pressure, diabetes, obesity, diet, physical activity, alcohol consumption, and psychosocial factors [4,5]. These risk factors account for over 90% of the risk of acute MI and are similar in all geographic regions, races, and genders. According to a previous study [6], when all modifiable risk factors are optimal, the lifetime risk of coronary artery disease or MI for the middle age group is estimated to be less than 5%, and with more than two major risk factors, it rises to 50% for men and 31% for women. These findings highlight the importance of identifying modifiable risk factors. The correlations among sleep, circadian rhythm, and risk of cardiovascular disease have been studied [7,8]. Insomnia has been found to be associated with cardiovascular and metabolic disease risk and mortality [9]. Both short sleep (less than 5 hours) and long sleep (more than 9 hours) can increase the incidence of cardiovascular events [10,11]. Disturbed circadian rhythm due to shift work can also increase cardiovascular risk [12]. Additionally, the frequency and mortality of MI have been found to increase in the morning [13], and patients with onset during the dark-to-light transition period can have a larger infarct size [14]. This is known as the circadian variation of MI, which is related to variations in clock genes [15].

Nowadays, many studies have shown the efficacy of the use of wearable technology in clinical practice and its potential in predicting outcomes. Actigraphy objectively measures patients' activities and can represent their sleep-wake patterns and sleep quality. Studies have found that monitoring sleep patterns and activity intensity can help in the diagnosis, monitoring, and treatment of depression, anxiety, and narcolepsy [16-18]. Different mathematical algorithm analyses of actigraphy recordings can predict the recurrence of panic attacks in patients with panic disorder and hypersomnia attacks in those with Kleine-Levin syndrome [19,20]. While abundant evidence supports the correlation of heart rate variability (HRV) with the prognosis of MI [21], actigraphy may also provide valuable insights. A study has identified its correlation with the outcomes of patients with heart failure [22], while the study by Peter-Marske et al [23] discovered associations of actigraphy-measured physical activity and sedentary behavior with the incidence of cardiovascular disease, MI, and ischemic stroke. The application of different mathematical algorithms of actigraphy to evaluate sleep and circadian rhythm and their correlations with the prognosis of MI can thus be worthy of investigation.

Currently, most studies have evaluated the premorbid sleep and circadian rhythm of patients with MI and analyzed their correlations. Little is known about sleep and circadian rhythm following the onset of acute MI. Although studies have reported the predictive role of HRV for the prognosis of MI, no study has explored the correlations among sleep, circadian rhythm, and prognosis. Therefore, we conducted a case-control prospective follow-up study to investigate the sleep and circadian rhythm of patients with acute MI, using actigraphy, along with HRV assessment. We followed these patients for 6 months after discharge to evaluate their prognosis. Considering the crucial role of circadian rhythm in cardiovascular function [8], actigraphy data were further analyzed with different mathematical algorithms to assess the circadian rhythm of patients.

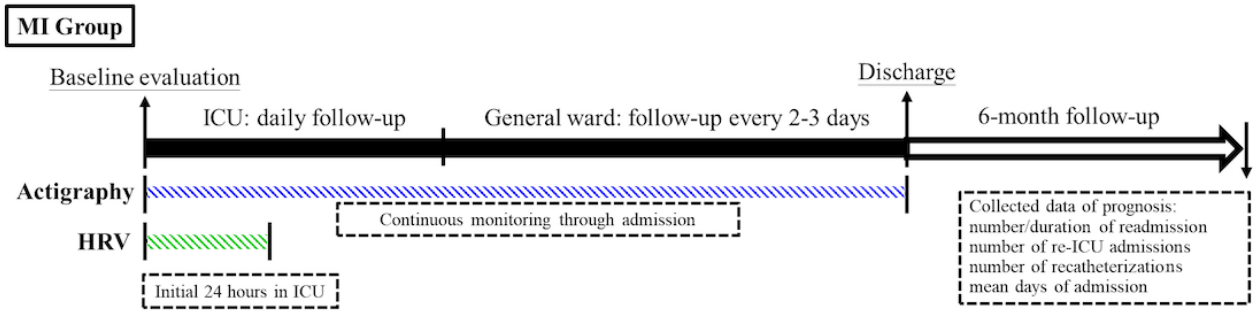
Methods

Participants

This case-control prospective follow-up study aimed to evaluate sleep and circadian rhythm in patients with acute MI and their correlations with prognosis. Patients who met the inclusion criteria without the exclusion criteria were recruited from the intensive care unit (ICU) following admission. They received standard MI treatments and light therapy during their ICU stay, alongside assessments by a team of cardiologists and psychiatrists experienced in sleep medicine during hospitalization.

The inclusion criteria were as follows: (1) age between 35 and 85 years, (2) diagnosis of acute MI (Killip I-III), and (3) agreement to participate in this study and provide informed consent. The exclusion criteria were as follows: (1) unclear consciousness, (2) use of sedative or hypnotic drugs, (3) blindness or severe cataracts, (4) severe neurological diseases (eg, seizure, brain injury, or severe organic brain diseases), (5) severe psychiatric disorders (eg, schizophrenia, bipolar disorder,

XSL•FO
RenderX



mental retardation, or substance use disorder), (6) unwillingness to participate, and (7) high mortality risk.

An age- and gender-matched healthy control group was also recruited for comparison.

Study Design

Upon admission to the ICU, patients were screened and invited if they met the inclusion criteria and were not excluded based on the criteria. Physical evaluation and the diagnosis and treatments of acute MI were conducted by experienced cardiologists, while mental status evaluation was performed by psychiatrists to rule out severe psychiatric disorders. One-hour light therapy was administered each morning during ICU stay to prevent delirium. Baseline evaluation included age, gender, BMI, and blood pressure. Participants also underwent blood sampling for tests, including blood routine tests (white blood cell count, red blood cell count, hemoglobin, hematocrit, mean corpuscular volume, mean corpuscular hemoglobin, mean corpuscular hemoglobin concentration, platelet, platelet distribution width, and mean platelet volume), renal and liver function tests (blood urea nitrogen, creatinine, alanine aminotransferase, and aspartate aminotransferase), electrolyte tests (sodium and potassium), thyroid function tests (thyroid-stimulating hormone and free T4), and vitamin D tests. Actigraphy was used to evaluate sleep and circadian rhythm, while HRV was assessed within 24 hours of ICU admission to evaluate autonomic nerve function (Figure 1). Participants' conditions were monitored throughout their ICU stay and subsequent general ward stay. Two delirium screening scales (the Confusion Assessment Method for the ICU and the Intensive Care Delirium Screening Checklist) were administered by psychiatrists daily to screen delirium during ICU stay and every 2 days in the general ward [24,25], and only 1 participant had delirium during the study period. Prognosis was evaluated with follow-ups at 3 and 6 months after discharge, and data on prognosis, including the duration of current admission, the number and duration of readmission and ICU admission, and catheterization during the 6-month follow-up period, were collected and confirmed via phone contact and by medical records (Figure 1).

Figure 1. Timeline of the study. Patients with myocardial infarction (MI) underwent actigraphy after admission to the intensive care unit (ICU) and kept wearing the device until discharge. They also underwent heart rate variability (HRV) evaluation for the initial 24 hours in the ICU. After discharge, they were followed for 6 months to evaluate the prognosis.

Actigraphy

Actigraphy, a nonintrusive approach involving a wristwatch-like device, can monitor participants' motions and light exposures over extended periods [26]. Data analysis by the widely used parametric method provided sleep parameters, including sleep onset latency, total sleep time, sleep efficiency, wake after sleep onset, and times of awakening, and all 34 participants were included in the analysis. The estimation of these parameters is based on the observation that there is less motion during sleep than during wakefulness [27]. Participants wore the device from enrollment until discharge or withdrawal from the study, which could occur if they met exclusion criteria such as hypnotic use or delirium. Healthy controls wore the device for 2 weeks. To analyze circadian rhythm, participants with actigraphy recording of less than 3 days were excluded. Consequently, 28 of the 34 patients with acute MI and 17 healthy controls were included in the circadian rhythm analysis (Figure 2). Representative actograms for the MI and control groups are shown in Figures 3A and 3B, respectively.

Circadian Rhythm Analysis and Algorithm of Actigraphy

Since the circadian rhythms of patients with MI can be disrupted and are not easily modeled by a 24-hour sinusoidal wave, we calculated several nonparametric indicators based on the hourly averaged activity from minute-by-minute actigraphy epochs. These indicators are designed to quantify the active-rest patterns and include interdaily stability, intradaily variability, the most active 10 consecutive hours (M10), the least active 5 consecutive hours (L5), the relative amplitude, and the actigraphic dichotomy index (I<O). Detailed mathematical formulas can be found elsewhere [20,28-30]. The interdaily stability and intradaily variability values quantify the stability and fragmentation of the rest-active patterns, respectively, and lower interdaily stability and higher intradaily variability indicate a disrupted circadian rhythm. While M10 and L5 identify the peak and trough of daily activity intensities, relative amplitude quantifies the daily circadian activity amplitude by calculating the difference between M10 and L5, normalized to their means. The midpoints of M10 and L5 represent the central times of these periods. The average daily values of M10, L5, and relative amplitude, and the midpoints of M10 and L5 were used to represent the circadian activity profiles of each participant (Multimedia Appendix 1). The actigraphic dichotomy index (I<O) measures the percentage of in-bed activity counts that fall below the median of out-of-bed activity counts. A lower index suggests a weaker circadian rest-activity rhythm [31].

HRV Assessment

HRV, reflecting autonomic nervous system tone, was monitored for 24 hours in patients with acute MI after enrollment. Healthy controls underwent HRV assessment for 15 minutes. It has a well-established role as a marker of cardiovascular risk [32]. Previous studies have found that HRV can predict the mortality rate of patients with acute MI [33-35]. Six patients with a history of arrhythmia were excluded, and 22 patients with acute MI and 16 healthy controls were included in the HRV analysis (Figure 4).

Figure 4. Protocol for heart rate variability (HRV) monitoring within the initial 24 hours of intensive care unit (ICU) admission for patients with acute myocardial infarction (MI). The chart delineates the steps from HRV recording to data analysis.

XSL•FO
RenderX

Statistical Analysis

Data were analyzed using SPSS version 20.0 (IBM Corp). Variables were presented by mean and percentage. Independent sample *t* tests and analysis of covariance (ANCOVA) were used to compare differences between the MI group and healthy control group, and age, gender, and BMI were controlled. Pearson correlation tests measured correlations between the parameters of actigraphy and HRV and the prognosis of patients with MI, and partial correlation coefficient (*r*) analysis was used to adjust age and gender. A *P* value of <.05 was considered statistically significant, while a *P* value of <.01 was considered highly statistically significant.

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki and was approved by the Institutional Review Board of Chang Gung Memorial Hospital (201902108A3). Before enrollment, participants were fully informed about the purpose, voluntary participation, and confidentiality of the study, and all signed an informed consent form. Data were anonymized and deidentified. Participants were not offered any form of compensation for their involvement.

Results

A total of 34 patients with acute MI (mean age 57.65, SD 9.03 years; range 41-73 years; 29 males and 5 females) were enrolled, and all completed the 6-month follow-up. The healthy control group consisted of 17 age- and gender-matched controls (mean age 57.71, SD 12.56 years; 11 males and 6 females). Table 1 shows the comparison of baseline characteristics between the MI group and the healthy control group. BMI was significantly higher in the MI group than in the control group (mean 26.79, SD 4.11 vs mean 23.09, SD 2.15; *P*=.001). After controlling for BMI, laboratory findings showed that many variables were significantly lower in the MI group than in the control group, including vitamin D (mean 17.43, SD 5.00 vs mean 26.53, SD 5.72 ng/mL; *P*<.001), sodium (mean 137.39, SD 2.75 vs mean 139.47, SD 7.25 mEq/L; *P*=.049), potassium (mean 3.83, SD 0.45 vs mean 4.15, SD 0.27 mEq/L; *P*=.04), and thyroid-stimulating hormone levels (mean 0.91, SD 0.46 vs mean 1.66, SD 0.62 µIU/mL; *P*=.02). On the other hand, some variables were significantly higher in the MI group than in the control group, including white blood cell count (mean 9.87, SD 2.56 vs mean 6.47, SD 1.87 ×1000/µL; *P*<.001), aspartate aminotransferase (mean 37.06, SD 23.77 vs mean 19.53, SD 3.47 U/L; *P*=.02), and alanine aminotransferase (mean 31.88, SD 17.62 vs mean 19.71, SD 5.72 U/L; *P*=.04). Of the 34 participants, 5 (18%) experienced initial symptoms of MI within an hour after awakening, and the onset time for 6 participants could not be confirmed due to atypical clinical presentations.

Table 2 shows the comparison of the general parametric sleep parameters of actigraphy between the MI group and the healthy control group after controlling for age, gender, and BMI. In the MI group, the average duration of actigraphy monitoring was 5.75 (SD 2.01) days. The parametric analysis of actigraphy showed that patients with MI had significantly more wake after sleep onset (mean 97.70, SD 59.95 vs mean 50.2, SD 18.17 min; *P*=.01), increased number of awakenings (mean 33.29, SD 12.61 vs mean 22.25, SD 6.14 times; *P*=.007), and lower sleep efficiency (mean 77.96, SD 7.73% vs mean 84.65, SD 4.03%; *P*=.01) than controls (Table 2). Circadian rhythm analysis of actigraphy is shown in Table 3 after controlling for age, gender, and BMI. Compared with the control group, the circadian patterns in the MI group showed less diurnal change and more individual differences (Figures 5 and 6; Multimedia Appendix 2 and 3). Moreover, patients with MI had significantly lower daytime activity (mean 70.65, SD 32.74 vs mean 188.46, SD 84.53; *P*<.001) and averaged M10 (mean 91.00, SD 42.79 vs mean 233.66, SD 106.05; *P*<.001) than controls, suggesting lower activity when awake. Both nighttime activity and averaged L5 were not significantly different between the groups, but the MI group had significantly lower daytime (mean 130.27, SD 39.55 vs mean 283.69, SD 100.78; *P*<.001) and nighttime activity$_{SD}$ (mean 87.13, SD 42.12 vs mean 122.58, SD 43.71; *P*=.03), suggesting less daytime and nighttime activity daily changes. The MI group had a significantly lower relative amplitude (mean 0.69, SD 0.13 vs mean 0.87, SD 0.10; *P*<.001) and dichotomy index (mean 0.85, SD 0.05 vs mean 0.93, SD 0.04; *P*<.001) than the control group, indicating that patients with MI had less sleep and wake activity changes and a weak active-rest rhythm. Moreover, the significantly higher intradaily variability in the MI group than in the control group (mean 1.13, SD 0.27 vs mean 0.94, SD 0.21; *P*=.02) suggested that the MI group had more fragmentations and disturbances during the wake and sleep states. The time of M10 (mean 14.86, SD 1.76 vs mean 13.52, SD 1.07; *P*=.02) was significantly higher in the MI group than in the control group, which supported a more delayed circadian rhythm.

Table 2. Comparison of the results of actigraphy between the myocardial infarction and healthy control groups after controlling for age, gender, and BMI.

Variable	Myocardial infarction group (n=28)	Healthy control group (n=17)	*P* value[a]

[a]*P* values were calculated using analysis of covariance (ANCOVA) controlling for age, gender, and BMI.

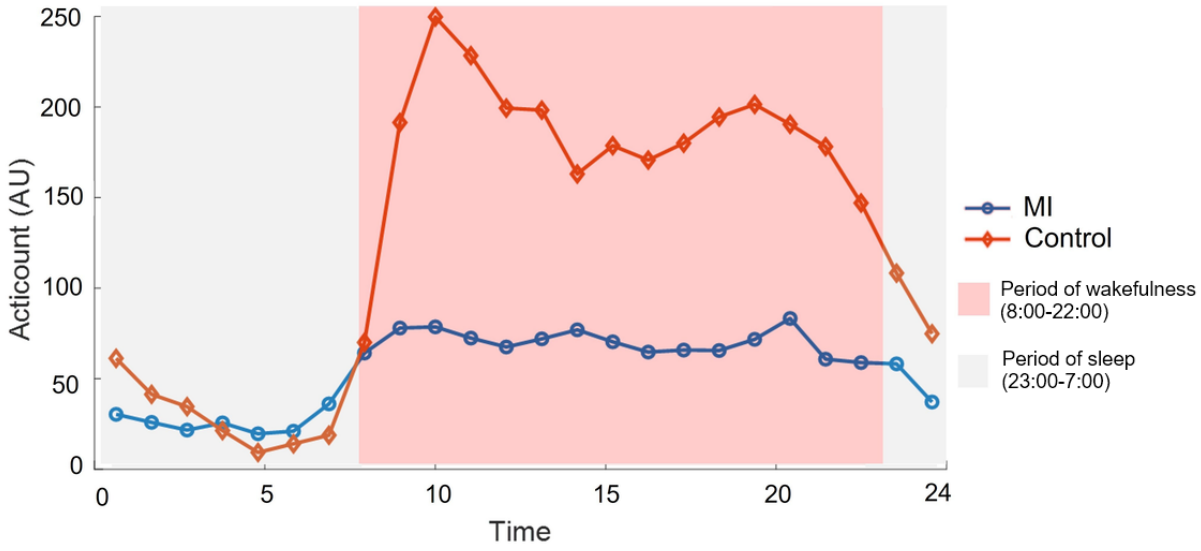
[b]M10: most active 10 consecutive hours.



[c]L5: least active 5 consecutive hours.

[d]RA: relative amplitude.

[e]IV: intradaily variability.

[f]IS: interdaily stability.

Figure 5. The average circadian activity template of the myocardial infarction (MI) patient cohort, synthesized from actigraphy data. It depicts the group's collective rest-activity cycles over a standard 24-hour period, highlighting the marked decreased amplitude of daytime and nighttime activity changes observed after acute MI.

XSL•FO
RenderX

Figure 6. Acrophase map showing the timings of the midpoint of M10 of myocardial infarction (MI) patients and healthy controls. Patients with MI had higher individual variability in the timing of the midpoint of M10 compared to healthy controls. M10: most active 10 consecutive hours.

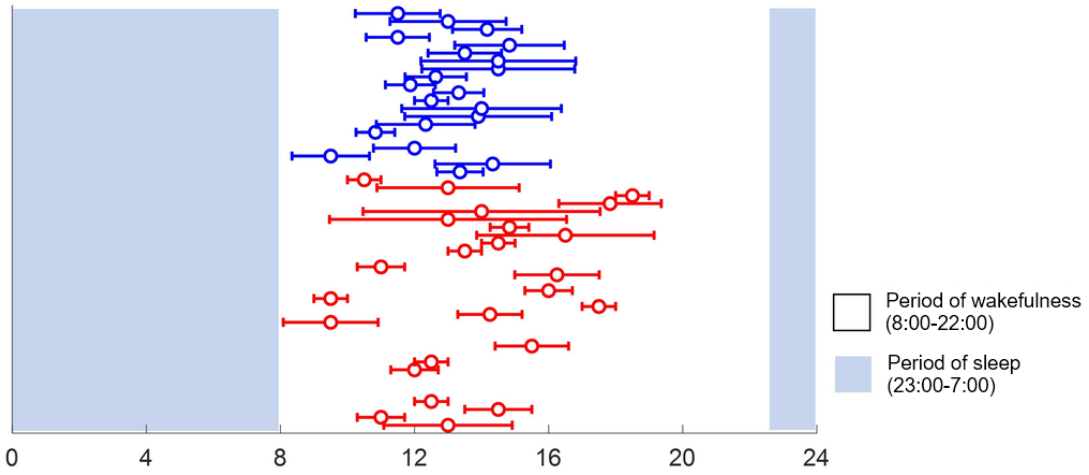


Table 4 shows the comparison of the parameters of HRV between the MI group and the healthy control group after controlling for age, gender, and BMI. The MI group showed a significantly lower root mean square of successive differences (mean 17.27, SD 9.49 vs mean 28.94, SD 17.22; *P*=.04), percentage of successive RR intervals that differ by more than 50 ms (mean 3.19, SD 4.63 vs mean 12.33, SD 16.60; *P*=.04), Poincaré plot SD perpendicular to the line of identity (SD1) (mean 12.20, SD 6.70 vs mean 20.43, SD 12.16; *P*=.04), and SD ratio (mean 0.27, SD 0.09 vs mean 0.44, SD 0.23; *P*=.01) than the control group, suggesting lower parasympathetic nerve function in the MI group.

Table 4. Comparison of the results of heart rate variability between the myocardial infarction and healthy control groups after controlling for age, gender, and BMI.

Variable	Myocardial infarction group (n=22)	Healthy control group (n=16)	*P* value[a]
Overall, mean (SD)	836.35 (129.88)	878.91 (130.74)	.40
HR[b], mean (SD)	73.53 (10.12)	69.65 (9.96)	.32
SDRR[c], mean (SD)	37.89 (19.59)	37.38 (15.39)	.90
RMSSD[d], mean (SD)	17.27 (9.49)	28.94 (17.22)	.04
pNN50[e], mean (SD)	3.19 (4.63)	12.33 (16.60)	.04

After adjusting for age and gender, there were still significant correlations between several parameters of actigraphy and the prognosis of patients with MI (Multimedia Appendix 4). Significantly positive correlations were found between nighttime activity and total days of current admission (r=0.56; P=.003); and between time of M10 and any ICU readmission (r=0.457; P=.02), times of readmission (r=0.527; P=.006), total days of readmission (r=0.579; P=.002), and mean days of readmission (r=0.466; P=.02). Significantly negative correlations were found between IS and recatheterization (r=–0.423; P=.03) and mean days of readmission (r=–0.413; P=.04).

Table 6 shows the correlations between the parameters of HRV and the prognosis of patients with MI during the 6-month

XSL•FO
RenderX

follow-up. Significantly positive correlations were found between the SD ratio and days of readmission (r=0.425; P=.049), recatheterization (r=0.426; P=.048), and mean days of readmission (r=0.425; P=.049). Significantly negative correlations were found between the SD of the RR interval and any readmission (r=–0.447; P=.04) and times of readmission (r=–0.447; P=.04); between Poincaré plot SD along the line of identity (SD2) and any readmission (r=–0.448; P=.04), times of readmission (r=–0.448; P=.04), days of readmission (r=–0.424; P=.049), and mean days of readmission (r=–0.424; P=.049); and between the deceleration capacity of heart rate (DC value) and any readmission (r=–0.457; P=.03) and times of readmission (r=–0.457; P=.03).

Table 6. Correlations (r) of the parameters of heart rate variability and the prognosis of patients with myocardial infarction (n=22).

After adjusting for age and gender, there were fewer significant correlations between the parameters of HRV and the prognosis of patients with MI (Multimedia Appendix 5). Significantly positive correlations were found only between the SD ratio and days of readmission (r=0.455; P=.04), recatheterization (r=0.456; P=.04), and mean days of readmission (r=0.455; P=.04).

Discussion

Principal Findings

Previous studies have used actigraphy to evaluate activities and sleep in patients with MI [23,36,37]. However, to our knowledge, no study has examined the circadian rhythm of patients after the onset of acute MI using actigraphy and analyzed its correlations with prognosis. Therefore, our findings are significant as they not only reveal sleep and circadian rhythm disturbances after acute MI but also support the application of actigraphy and HRV in evaluating the prognosis.

Unsurprisingly, baseline laboratory work-up assessments showed significant differences between patients with MI and healthy controls. Patients with MI exhibited more obesity and more abnormalities, including a lower vitamin D level, which is known to be negatively associated with the incidence of cardiovascular diseases [38,39]. This study further revealed significant differences in sleep patterns between the 2 groups. After acute MI, patients had significantly worse sleep, characterized by more wake after sleep onset and number of awakenings, and lower sleep efficiency. These findings align with a previous study, which has reported sleep disturbances in patients after acute MI, including more wakefulness and awakening, more stage shifts, less rapid eye movement, decreased sleep efficiency, and increased daytime sleep [40]. These changes can be attributed to MI itself rather than differences in a hospital setting [40] and can be normalized with an improved physical condition. Sleep has been proposed as a vital sign and a marker for disease and recovery [41], and thus,

XSL•FO
RenderX

routine monitoring and evaluation of sleep are recommended in patients with MI.

The circadian rhythm analysis using actigraphy data supports that both sleep quality and circadian rhythm can be disturbed in patients with MI. Compared with controls, the activities of patients with MI were significantly less during the daytime, while nighttime activities remained unchanged. Moreover, there was less variability (SD) in both daytime and nighttime activities, indicating less change in activity levels throughout the day. Although these findings may be linked to the bed rest and activity restrictions commonly advised for patients with acute MI, the higher intradaily variability contradicts this hypothesis and instead suggests greater fluctuations in hourly activities during both the daytime and nighttime. Furthermore, a lower relative amplitude and actigraphic dichotomy index suggested less distinct activity changes between sleep and wakefulness and a weak circadian rest-activity rhythm. Patients with MI also exhibited a significant delay in their circadian rhythm, as indicated by a higher time of M10.

Most studies on circadian rhythm and MI have focused on the circadian variances of MI [42-44], which can be explained by the fact that circadian rhythm–related coronary vasoconstriction and increased sympathetic tone may disrupt atherosclerotic plaque [45]. In this study, 5 out of 34 participants (18%) experienced initial symptoms within 1 hour after awakening, but we did not find any correlation between their onset time and prognosis. The nonsignificant result can be influenced by several factors. We only enrolled patients with Killip I to III and excluded those with severe comorbidities and a high mortality risk. Some participants could have recall bias due to their atypical clinical presentations. Circadian variances of MI and their correlations with prognosis necessitate further investigation.

Delayed and disturbed circadian rhythm has been found to be associated with cardiovascular diseases [46,47]. Consistent with our findings, a cross-sectional study also found a lower 24-hour rest-activity rhythm amplitude and overall rhythmicity in patients with coronary artery disease, using actigraphy [48]. Although little is known about circadian rhythm after the onset of MI, our findings indicate that several parameters derived from the circadian rhythm analysis have significant correlations with prognosis, including the total days of current admission, ICU readmission, and the number and duration of readmissions during the 6-month follow-up period. Patients with a more delayed circadian rhythm (higher times of L5 and M10) were more likely to have a longer duration of current admission, more frequent readmissions, and a longer duration of readmission. Since gender and age can have impacts on both sleep and the prognosis of MI [49-51], we adjusted age and gender in the correlation analysis. Most of the significant correlations could still be found (Multimedia Appendix 4). Although a causal relationship cannot be confirmed, these findings are consistent with those of previous studies that suggest abnormal circadian rhythm as a core vulnerability factor for MI [15,52]. Interventions targeting the circadian rhythm of patients with MI, especially those with a disturbed and delayed sleep phase, may be beneficial. Exercise programs and rehabilitations have already been demonstrated to improve prognosis and reduce mortality in patients with MI [53], and they can also help improve sleep. During the acute phase, light therapy and environmental modifications may aid in the regulation of circadian rhythm and are worthy of further investigation.

We found that patients with MI had lower parasympathetic activities compared to healthy controls, and there were correlations between several HRV parameters and prognosis. HRV is an indirect measure of autonomic nervous activity [29] and has been investigated for its ability to predict prognosis in patients with acute MI. Previous studies have reported associations between HRV and mortality or cardiovascular events [54-57]. In this study, better parasympathetic nerve activity after acute MI could be correlated with a better prognosis. However, we also found positive correlations between the ratio of SD1 to SD2 (SD ratio) and prognosis, including recatheterization and the duration of readmission, contradicting other findings. A previous study found a correlation between a high SD ratio and arrhythmia such as ventricular tachycardia [58]. Thus, although a higher parasympathetic nerve activity can correlate with a better prognosis, the SD ratio may not always be “the higher, the better.”

Comparing correlations with the prognosis of MI, the circadian rhythm analysis using actigraphy showed more significant findings than the HRV analysis, especially in nighttime activity and the time of M10. Moreover, fewer significant correlations between HRV parameters and prognosis were found after adjusting for age and gender (Multimedia Appendix 5). These findings suggest that the evaluation of sleep and circadian rhythm after the onset of MI is a valuable prognosis indicator. Previous studies have demonstrated the potential of actigraphy to predict the outcomes of various diseases [19,20]. The application of actigraphy in the evaluation and treatment of patients with MI is promising, as it has already been suggested to play a role in the prognostication of heart failure [59]. Another study showed that the evaluation of subjective sleep complaints through questionnaires may serve as a prognostic marker in patients after acute MI [60], emphasizing the importance of sleep in the risk stratification of MI. Although our study found fewer HRV correlations with prognostic factors, it differed from past research as there was no morality after excluding patients with Killip IV. Furthermore, instead of analyzing mortality, our study focused on correlations with prognostic factors such as admission duration, readmission, and recatheterization. Given that only 22 cases were included in the HRV analysis, factors, including age, gender, and medications such as beta-blockers [61], might have affected the findings. Further research is required to compare the 2 evaluation tools in terms of their correlations with the prognosis of MI.

Limitations

The study has some limitations. First, the study had a small sample size, which limits detailed subgroup analysis by age or gender. Second, we only evaluated participants after the onset of MI during their admission, and therefore, the observed delayed and disturbed circadian rhythm may not represent their premorbid sleep and circadian rhythm. They did not undergo actigraphy monitoring during follow-up, and thus, subsequent changes in sleep and circadian rhythm were not known. Further

XSL•FO
RenderX

studies following MI patients with actigraphy after discharge can increase the understanding of the long-term changes in sleep and circadian rhythm after MI and their impacts on prognosis. Third, patients in our study received light therapy during their stay in the ICU to prevent delirium. However, the duration of light therapy was short (1 hour per day for only 1-2 days), limiting its potential impacts. Fourth, some patients with MI were excluded, such as those classified as Killip IV. Therefore, caution is required when generalizing our findings, especially to severe cases with high mortality rates. Lastly, comorbidities that can contribute to sleep disturbance were not controlled. Sleep disorders, such as obstructive sleep apnea, cannot be ruled out, as polysomnography is challenging to perform in patients with acute MI in the ICU setting. Nevertheless, our findings not only support but also extend the use of actigraphy beyond its conventional role in sleep medicine to include applications within cardiology.

Conclusions

Patients with acute MI experienced significantly worse sleep and disturbed circadian rhythm compared with healthy controls. Actigraphy-based analysis revealed a disturbed circadian rhythm, including reduced daytime activities, a greater fluctuation in hourly activities, and a weak rest-activity rhythm, which were correlated with prognosis. The evaluation of sleep and circadian rhythm in patients with acute MI can serve as a valuable indicator for prognosis and warrants further investigation.

Abstract

Background: Patients with antimelanoma differentiation–associated gene 5 antibody–positive dermatomyositis–associated interstitial lung disease (anti-MDA5+DM-ILD) are susceptible to rapidly progressive interstitial lung disease (RP-ILD) and have a high risk of mortality. There is an urgent need for a reliable prediction model, accessible via an easy-to-use web-based tool, to evaluate the risk of death.

Objective: This study aimed to develop and validate a risk prediction model of 3-month mortality using machine learning (ML) in a large multicenter cohort of patients with anti-MDA5+DM-ILD in China.

Methods: In total, 609 consecutive patients with anti-MDA5+DM-ILD were retrospectively enrolled from 6 hospitals across China. Patient demographics and laboratory and clinical parameters were collected on admission. The primary endpoint was 3-month mortality due to all causes. Six ML algorithms (Extreme Gradient Boosting [XGBoost], logistic regression (LR), Light Gradient Boosting Machine [LightGBM], random forest [RF], support vector machine [SVM], and k-nearest neighbor [KNN]) were applied to construct and evaluate the model.

Results: After applying inclusion and exclusion criteria, 509 (83.6%) of the 609 patients were included in our study, divided into a training cohort (n=203, 39.9%), an internal validation cohort (n=51, 10%), and 2 external validation cohorts (n=92, 18.1%, and n=163, 32%). ML identified 8 important variables as critical for model construction: RP-ILD, erythrocyte sedimentation rate (ESR), serum albumin (ALB) level, age, C-reactive protein (CRP) level, aspartate aminotransferase (AST) level, lactate dehydrogenase (LDH) level, and the neutrophil-to-lymphocyte ratio (NLR). LR was chosen as the best algorithm for model construction, and the model demonstrated excellent performance, with an area under the receiver operating characteristic (ROC) curve (AUC) of 0.866, a sensitivity of 84.8%, and a specificity of 84.4% on the validation data set and an AUC of 0.90, a sensitivity

XSL•FO
RenderX

of 85.0%, and a specificity of 83.9% on the training data set. Calibration curves and decision curve analysis (DCA) confirmed the model's accuracy and clinical applicability. Moreover, the model showed strong predictive performance in the external validation cohorts (cohort 1: AUC=0.836, 95% CI 0.754-0.916; cohort 2: AUC=0.915, 95% CI 0.871-0.959), indicating good generalizability. This model was integrated into a web-based tool to predict the 3-month mortality for patients with anti-MDA5+DM-ILD.

Conclusions: We successfully developed a robust clinical prediction model and an accompanying web tool to estimate the 3-month mortality risk for patients with anti-MDA5+DM-ILD.

Introduction

Idiopathic inflammatory myopathies (IIMs) encompass a heterogenous group of autoimmune diseases characterized by muscle weakness and inflammation. Dermatomyositis (DM), which predominantly affects the skin and muscles, is a prevalent subtype within the IIM spectrum. Interstitial lung disease (ILD) is a common comorbidity in DM, with an incidence varying widely from 5% to 65% [1]. The clinical presentations, treatment responses, and outcomes of IIMs are highly variable and correlate with the presence of specific myositis-specific antibodies (MSAs). One such antibody, the antimelanoma differentiation–associated gene 5 (MDA5) antibody, targets the MDA5 protein, a member of the retinoic acid inducible gene I (RIG-I) receptor family, which is crucial for the detection of viral RNA and the activation of the interferon pathway in response to viral infections [2]. Approximately 1%-30% of patients with DM test positive for anti-MDA5 antibodies [3]. A recent surge in MDA5+DM cases has been observed in England in the wake of the COVID-19 pandemic, with an associated mortality rate of 32% for antimelanoma differentiation–associated gene 5 antibody–positive dermatomyositis–associated interstitial lung disease (anti-MDA5+DM-ILD) [4]. Patients with anti-MDA5 autoantibody often exhibit minimal muscle involvement. Initially, anti-MDA5 autoantibody was identified in a cohort of East Asian patients with clinically amyopathic myositis (81%) and rapidly progressive ILD (74%) [5], with >90% of rapidly progressive interstitial lung disease (RP-ILD) cases and 84% mortality occurring within the first 6 months of disease onset [6]. Notably, the first 3 months following diagnosis are particularly critical, with 46% of the deaths occurring in this period [6]. However, recent studies have revealed that early and aggressive intervention can significantly improve the 6-month survival rate of patients with anti-MDA5+DM-ILD from 33% to 89% [7-9]. Thus, there is an urgent need to accurately identify these high-risk patients at an early stage of the disease.

In recent years, various mortality risk models incorporating independent predictors have been explored to predict outcomes in patients with anti-MDA5+DM-ILD. Lian et al [10] developed the FLAIR score, which includes 5 key indicators: ferritin levels, lactate dehydrogenase (LDH) levels, the anti-MDA5 antibody grade, the high-resolution computed tomography (HRCT) imaging score, and RP-ILD [10]. However, the FLAIR score was designed to predict mortality in patients with amyopathic DM. Some independent prognostic factors, such as Krebs von den Lungen-6 (KL-6), interleukin (IL)-6, IL-18, and soluble CD206, are challenging to access in clinical practice [11], and HRCT imaging scores are subject to considerable interobserver variability [10]. Most existing prediction models rely on logistic or Cox regression analysis, with limited external validation and only fair overall performance. Recent evidence suggests that machine learning (ML) algorithms, which can handle numerous multidimensional variables with nonlinear relationships, may offer superior predictive accuracy for clinical outcomes [12]. To date, ML approaches for predicting mortality risk and prognosis in patients with anti-MDA5+DM-ILD have been infrequent, and there remains a lack of a concise, practical tool for directly calculating mortality risk in these patients.

Considering the limited sample sizes and inadequate establishment and validation of practical quantitative methods in previous studies, we identified the 3-month mortality risk, established a prediction model, and validated the model using real-world data from multicenter studies in China involving patients with anti-MDA5+DM-ILD. The aim was to create a reliable and easily implemented tool for clinical use.

Methods

Ethical Considerations

The Medical Ethics Committee of the Drum Tower Hospital Affiliated to Nanjing University Medical School approved the study (2020-050-01). The patients included in this study were derived from a secondary analysis of the previously confirmed study. The ethics committee determined that a second round of approval was not required.

Patients and Study Design

From January 2017 to December 2022, our study screened patients with anti-MDA5+DM-ILD across participating institutions. Inclusion criteria were patients with a newly observed ILD, detectable serum anti-MDA5, and DM. The diagnostic criteria for DM included Bohan and Peter criteria and were retrospectively reconfirmed according to the 2017 European League Against Rheumatism (EULAR)/American College of Rheumatology IIM classification criteria or the 2018

XSL•FO
RenderX

European Neuromuscular Centre (ENMC) DM criteria by experienced rheumatologists and pulmonary clinicians [13-15]. Exclusion criteria were as follows: (1) DM-ILD with other positive MSAs; (2) other connective tissue diseases (CTDs); (3) evidence of pulmonary infections at initial admission, as diagnosed clinically and by identifying pathogens; and (4) incomplete data or lost to follow-up.

Following application of these criteria, 509 (83.6%) eligible cases from an initial 609 patients were identified. Patients from the Nanjing Drum Tower Hospital (NJDTH; n=254, 49.9%) were randomly allocated to a training data set (n=203, 79.9%) for model development and internal validation using k-fold cross-validation and a testing set (n=51, 20.1%) for further model validation. External validation was conducted using cohorts from 4 additional institutes, referred to as external cohort 1 (n=92, 18.1%) and external cohort 2 (n=163, 32%).

Clinical Data Collection and Reference Standards

All clinical and laboratory data were extracted from electronic medical records (EMRs) at the beginning of the patients' admission. Demographic characteristics, including age and gender, and clinical signs, such as muscle weakness, the Raynaud phenomenon, mechanic's hands, Gottron sign/papules, heliotrope rash, fever, and arthralgia/arthritis, were documented and compared. Serum levels of muscle enzymes, such as creatine kinase (CK), alanine aminotransferase (ALT), aspartate aminotransferase (AST), and lactate dehydrogenase (LDH), were recorded. Serum antibody abnormalities, including Ro/SSA-52kDa antibody (Ro52) and MDA5 (autoimmune inflammatory myopathies 16 Ag-(IgG); EUROLINE), were analyzed. Disease severity evaluations and inflammatory mediators, such as C-reactive protein (CRP), the erythrocyte sedimentation rate (ESR), the white blood cell (WBC) count, the lymphocyte count, the neutrophil-to-lymphocyte ratio (NLR), and ferritin levels, were recorded and compared. In this study, all these variables were meticulously recorded during hospitalization, with a low incidence of missing data of less than 2%. Missing data were processed with the k-nearest neighbor (KNN) algorithm.

ILD has been defined by the American Thoracic Society/European Respiratory Society [16]. RP-ILD is characterized by the acute and progressive deterioration of ILD, manifesting as worsening dyspnea and interstitial changes on chest HRCT, necessitating hospitalization due to disease-related acute respiratory failure within 3 months of the onset of respiratory symptoms, after exclusion of other potential etiologies (eg, pulmonary infection, heart failure, embolism) [17,18]. The duration of the disease is marked from the initial occurrence of pulmonary, muscle, joint, or skin symptoms/signs.

The primary outcome was the risk of mortality at 3 months. Secondary outcomes included the 1-month mortality risk and the 6-month mortality risk.

Screening of Important Features for Model Construction

We used the BorutaShap algorithm for feature selection, which integrates Boruta and Shapley Additive Explanations (SHAP) algorithms to pinpoint the most influential features within a data set [19]. Consequently, the BorutaShap algorithm was used to sift through 25 parameters, including demographics, clinical features, and laboratory parameters, from the EMR system and identify the most pertinent features for model construction. In this study, only features categorized as "accepted" by the BorutaShap algorithm were incorporated into model development. Features labeled "tentative" or "rejected" were omitted.

Establishment and Validation of Prediction Models

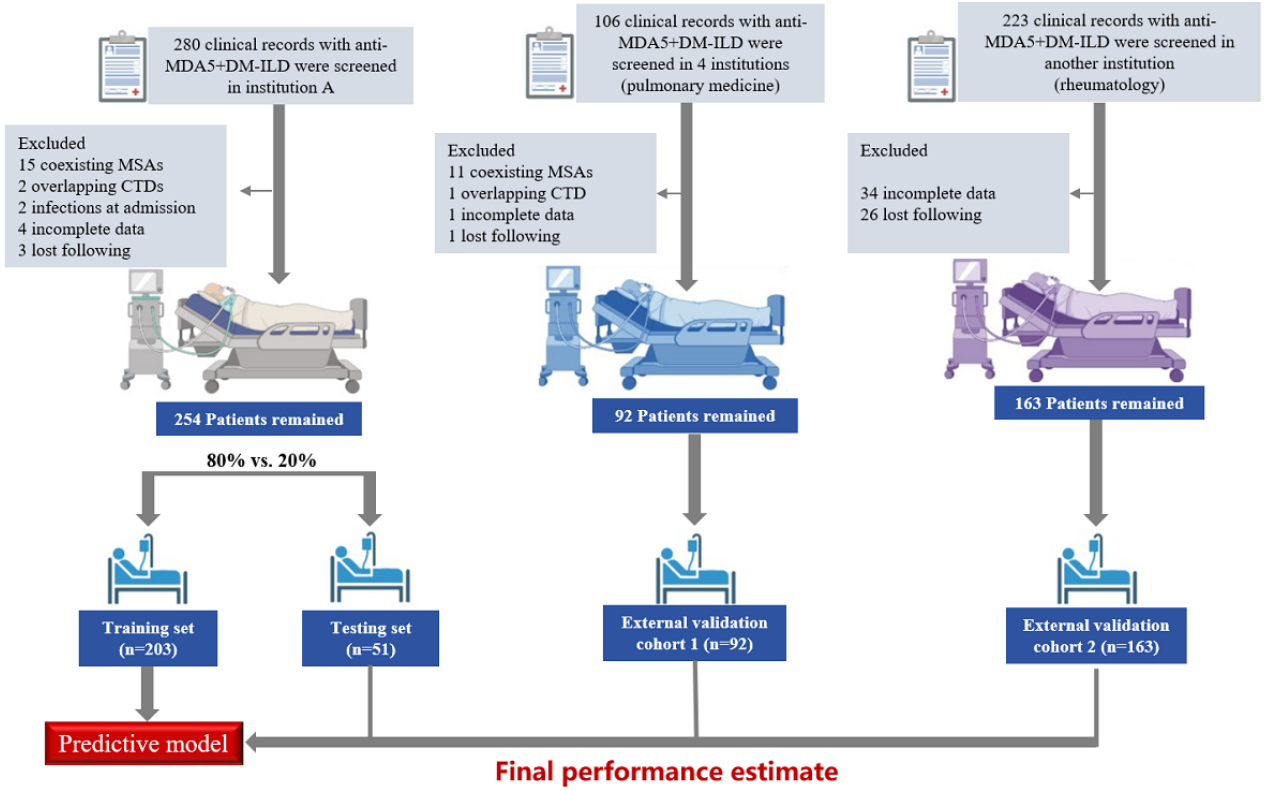
Six ML algorithms were deployed to build prediction models: Extreme Gradient Boosting (XGBoost), logistic regression (LR), Light Gradient Boosting Machine (LightGBM), random forest (RF), support vector machine (SVM), and KNN. To guarantee robustness and reproducibility, all models were provided with identical input features. A thorough search of the hyperparameter space was conducted using both grid and random searches to optimize each model's performance. The reliability of these models was appraised using various evaluation metrics, including the area under the receiver operating characteristic (ROC) curve (AUC), sensitivity, specificity, the positive predictive value (PPV), the negative predictive value (NPV), accuracy, and the F_1-score. Moreover, 10-fold cross-validations were implemented in the derivation cohort to validate the models.

The optimal model was elucidated using the SHAP methodology, which delineates the importance and contribution of each feature to the model. The model results were interpreted by qualifying the impact of each feature on the predictions. Ultimately, the optimal prediction model was integrated into a user-friendly web-based tool.

Statistical Analysis

Descriptive statistics were applied to summarize continuous variables as mean (SD) values and categorical variables as frequencies and percentage. The Fisher exact test was performed for categorical variables, while the Mann-Whitney *U* test was used for continuous variables to assess differences between the survival and mortality groups within 3 months. Statistical significance was set at $P<.05$. All statistical analyses were performed using SPSS Statistics version 26.0 (IBM Corporation), R Studio version 3.6.3 (R Foundation for Statistical Computing) and Python version 3.7.

Results



Patients' Basic Clinical Characteristics

The study flowchart is shown in Figure 1. The NJDTH cohort had 280 (55%) patients with anti-MDA5+DM-ILD, and after exclusion, the final count was 254 (49.9%) patients. These patients were followed for a median of 6 months, divided into a training cohort of 203 (79.9%) patients and an internal testing cohort of 51 (20.1%) patients. The external validation cohort was further refined to 92 (18.1%) patients in cohort 1 and 163 (32%) patients in external cohort 2 (Figure 1). The entire patient group was analyzed for all-cause mortality. A comparative baseline analysis of 31 clinical variables, encompassing demographics, clinical severity, inflammatory indicators, serum antibody levels, is presented in Table 1. The study evaluated

XSL•FO
RenderX

statistically significant differences in these variables among the groups. Of 254 valid samples, 159 (62.6%) were in the 3-month survival group and 95 (37.4%) in the 3-month death group in the NJDTH cohort. In terms of mortality, 108 (42.5%) patients died during the investigation period, with 71 (27.9%) within 30 days, 95 (37.4%) within 90 days, and 101 (39.78%) within 180 days. The 3-month mortality was up to 37.4%, suggesting the majority of deaths occurred within the first 3 months. Patients who died within 3 months showed more severe injury, as indicated by higher levels of inflammatory markers, such as CRP, ESR, LDH, WBC, ferritin, and NLR, and lower levels of lymphocytes compared to patients who survived beyond 3 months. RP-ILD characteristics were observed in 78 (82.1%) of 95 patients who died within 3 months in contrast to only 30 (18.9%) of 159 survivors. The mean age of patients who died within 3 months was 56.68 (SD 9.97) years, which was higher than that of patients who survived for 3 months (mean 51.50, SD 10.68 years). There were no statistically significant differences in patients' characteristics between the training and testing sets. Other severity indices were comparable between the training and testing sets (Table 2).

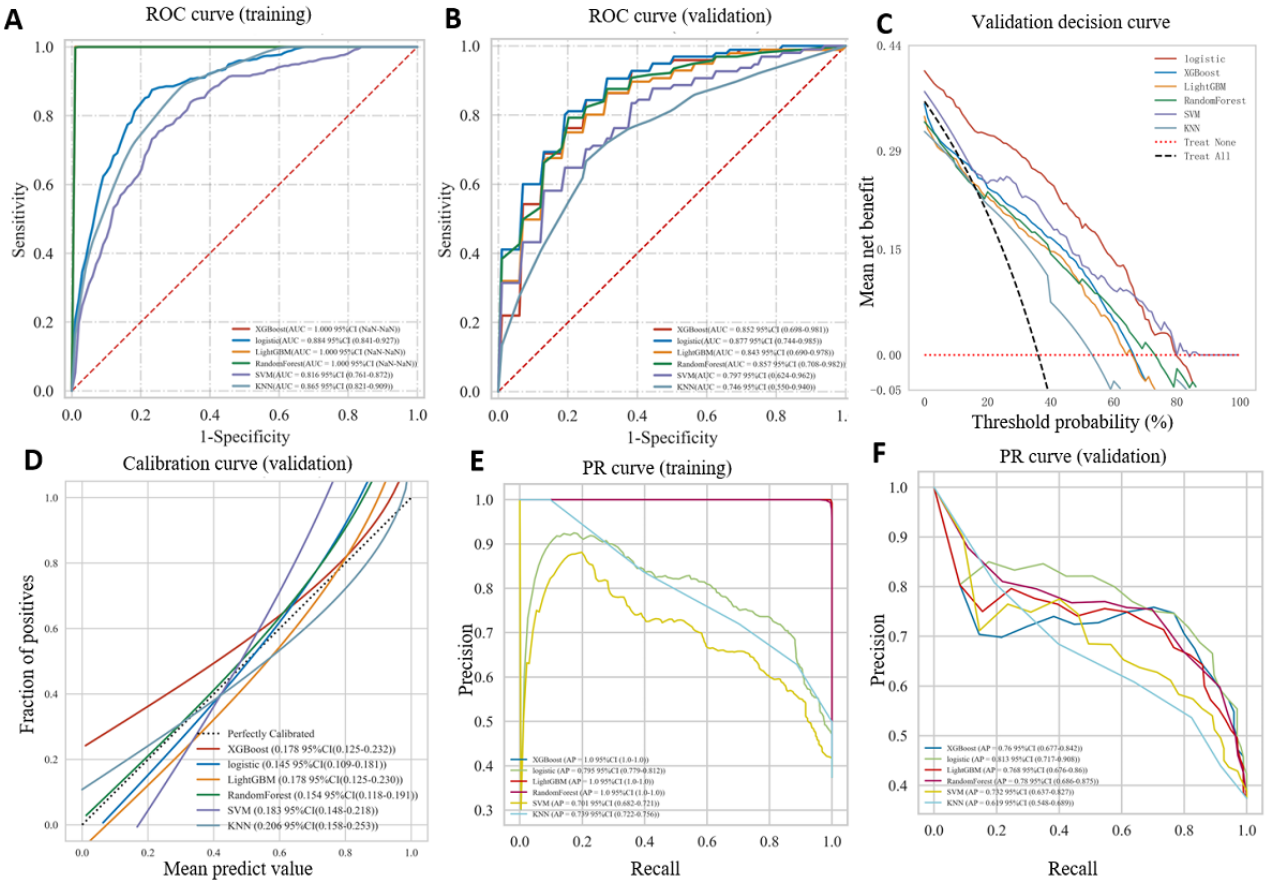
To account for varying severities of with anti-MDA5+DM-ILD patients, we recruited external cohort 1 mainly from the pulmonary medicine department and external cohort 2 from the rheumatology department. Patients in external cohort 1 tended to have severe illness than those in external cohort 2, as patients with respiratory failure were more likely to be admitted to the pulmonary medicine department. Analysis on a diverse range of severities of patients enhanced our model's practicality and robustness.

Screening of Characteristic Factors for Risk of 3-Month Mortality

In total, 9 parameters (ie, RP-ILD, age, LDH, albumin [ALB], CRP, ESR, AST, NLR, and duration of disease) were selected for analysis using the BorutaShap algorithm (Figure 2). However, due to the overlap between disease duration and RP-ILD, RP-ILD was left for model development to balance model complexity and generalizability. Hence, 8 parameters were selected for further analysis.

XSL•FO
RenderX

Figure 2. By using the BorutaShap algorithm, selected parameters or patients' characteristics were calculated for the importance of evaluation. Parameters with green color were categorized as "accepted" for the next step of analysis ALB: albumin; ALT: alanine aminotransferase; ANA: antinuclear antibody; AST: aspartate aminotransferase; CK: creatine kinase; CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; LDH: lactate dehydrogenase; MDA5: melanoma differentiation–associated gene 5; NLR: neutrophil-to-lymphocyte ratio; RF: rheumatoid factor; RP-ILD: rapidly progressive interstitial lung disease; SHAP: Shapley Additive Explanations; WBC: white blood cell.



Comprehensive Analysis of the Prediction Model and Selection of the Optimal Model

To identify the best prediction model for the 3-month mortality risk in patients with anti-MDA5+DM-ILD, all models were evaluated using identical input features and assessed via AUC values, decision curve analysis (DCA), calibration curves, and precision-recall (PR) curves. XGBoost, LightGBM, and RF algorithms showed the highest AUCs in the training data set, but LR demonstrated the highest AUC of 0.877 (95% CI 0.744-0.985) in the validation data set (Figure 3A,B). Tables S1 and S2 in Multimedia Appendix 1 provide more details, indicating potential overfitting in the XGBoost, LightGBM, and RF algorithms. Furthermore, the LR model achieved a significantly lower Brier score of 0.145 compared to other models. The DCA curves in Figure 3C and the calibration plots in Figure 3D demonstrate that all 6 models provided a net clinical benefit over the full treat-all or treat-none strategies, with the LR model outperforming the other 5 models in the validation data set. Additionally, the LR model obtained the highest average precision (AP) value of 0.813 on the validation data set (Figure 3E,F). Based on these findings, the LR model was selected as the final model due to its superior performance.

XSL•FO
RenderX

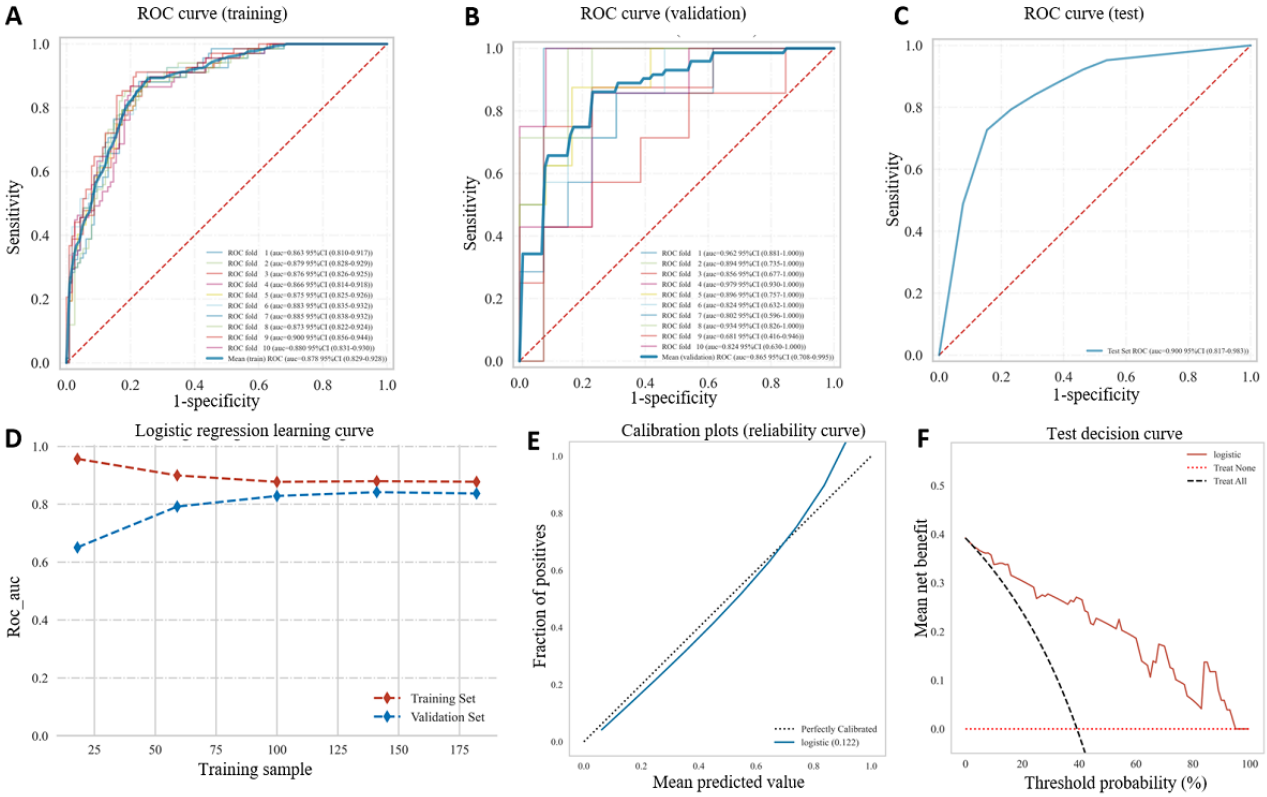


Figure 3. Comparison of prediction models for performance using 6 ML algorithms. ROC results for predicting 3-month mortality obtained by using different models for the (A) training cohort and (B) validation cohort. (C) DCA, (D), calibration curves, and (E, F) PR curves were used to verify which model was preferable. DCA: decision curve analysis; KNN: k-nearest neighbor; LightGBM: Light Gradient Boosting Machine; LR: logistic regression; ML: machine learning; PR: precision-recall; RF: rheumatoid factor; ROC: receiver operating characteristic; SVM: support vector machine; XGBoost: Extreme Gradient Boosting.

Ultimately, we selected RP-ILD, age, LDH, AST, ALB, NLR, CRP, and ESR as input features for the LR model. As shown in Figure 4 and Table S3 in Multimedia Appendix 1, the LR model demonstrated optimal performance with an AUC, sensitivity, specificity, and accuracy of 0.86, 84.8%, 84.4%, and 79.3%, respectively, on the validation data set and 0.90, 85.0%, 83.9%, and 84.3%, respectively, on the training data set (Figure 4A-D). The calibration of the LR model indicated strong concordance between the predicted probabilities and the actual observed 3-month deaths using Brier scores (Figure 4E). DCA revealed that the model provided greater net benefits over both treat-all and treat-none strategies (Figure 4F).

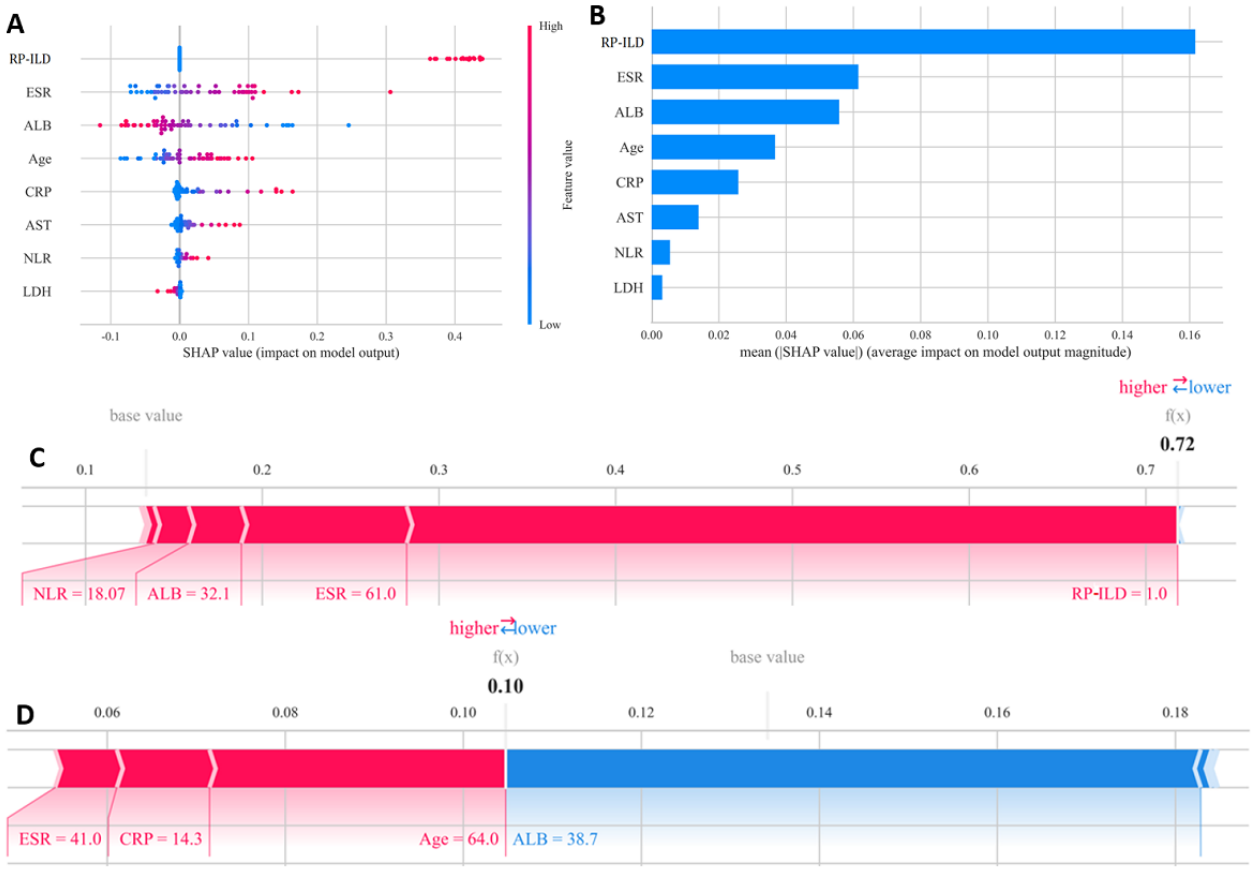
AUC: area under the receiver operating characteristic curve; DCA: decision curve analysis; LR: logistic regression; ROC: receiver operating characteristic.

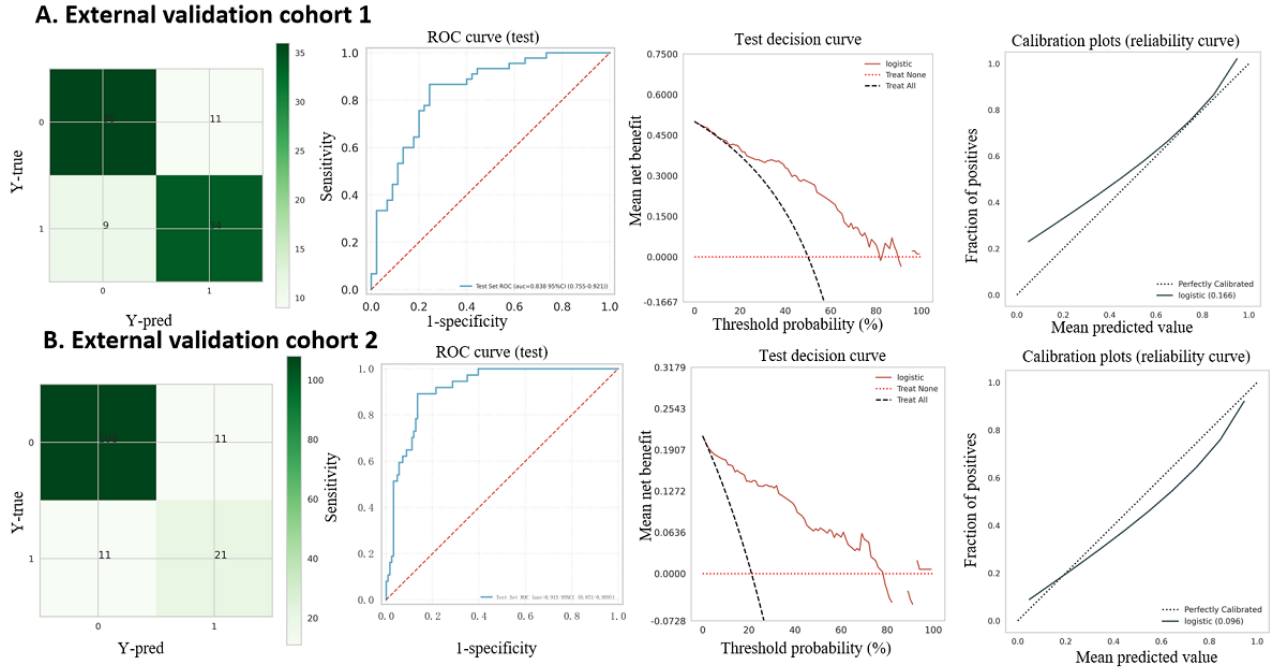


SHAP Model Interpretation and Individual Analysis

To provide a clear explanation of the selected variables, we used SHAP to illustrate how these variables predict the 3-month mortality within the model. Figure 5A displays the 8 most influential features (RP-ILD, ESR, ALB, age, CRP, AST, NLR, and LDH) in our model. Each feature's importance line is represented by colored dots, where red dots indicate high-risk values and blue dots signify low-risk values. Figure 5B ranks these 8 risk factors based on their average absolute SHAP values, with the x axis representing SHAP values that denote the prediction model's importance. Additionally, in this model, the probability threshold for the 3-month mortality risk was established at 0.40473. We then provided 2 exemplary cases to illustrate the model's interpretability. In one instance, a patient presenting with RP-ILD exhibited a notably elevated SHAP-predicted mortality risk of 0.718 (Figure 5C), and unfortunately, this individual succumbed to the disease within a 3-month period postonset. In contrast, a 64-year-old participant demonstrated a substantially lower SHAP-predicted mortality risk of 0.105 (Figure 5D) and remained alive, underscoring the potential utility of the web-based prognostic tool in clinical practice.

XSL•FO
RenderX

Figure 5. SHAP interpretation of the model. (A) Attributes of characteristics in the SHAP chart, (B) mean SHAP value of 8 important variables, (C, D) 2 clinical cases illustrating the usage of a weighing model. ALB: albumin; AST: aspartate aminotransferase; CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; LDH: lactate dehydrogenase; NLR: neutrophil-to-lymphocyte ratio; RP-ILD: rapidly progressive interstitial lung disease; SHAP: Shapley Additive Explanations.



Model External Validation and Establishment of a Web-Based Calculator

The AUC of our proposed model on external cohort 1 from 4 hospitals in China was 0.836 (Figure 6). The sensitivity, specificity, and accuracy for this cohort were 0.87, 0.739, and 0.783, respectively. For external cohort 2, the AUC, sensitivity, specificity, and accuracy were 0.915, 0.892, 0.865, and 0.847, respectively, indicating the model's robust extrapolation capabilities. In addition, secondary outcomes (1-month and 6-month mortality risks) were evaluated in the 2 external validation cohorts. The model's superior discrimination performance, using the AUC, sensitivity, specificity, precision, accuracy, and the F_1-score, is detailed in Tables S4 and S5 in Multimedia Appendix 1, Figure S1 in Multimedia Appendix 2, and Figure S2 in Multimedia Appendix 3.

XSL•FO
RenderX

To enhance generalizability and facilitate clinical application, the optimal ML model was adapted to create a web-based calculator [20]. The calculator serves as a practical clinical tool for physicians specializing in respiratory medicine, rheumatology, and critical care medicine. It is particularly useful in the assessment of patients presenting with RP-ILD attributed to anti-MDA5+DM-ILD. A score exceeding 40.47% indicates a heightened risk of mortality, warranting consideration for aggressive management strategies.

Discussion

Principal Findings

To the best of our knowledge, this is the largest retrospective multicenter study to investigate the risk factors for 3-month mortality and to explore 6 ML models for comprehensive predictive analyses on anti-MDA5+DM-ILD cohorts in China. We identified a set of predictive risk factors and constructed a prediction model for patients with anti-MDA5+DM-ILD using ML algorithms in conjunction with clinical and laboratory data easily extracted from the EMR system. In this study, LR, using routinely collected data from real-world clinical practice, demonstrated superior performance across 8 predictive measures. The optimal model exhibited favorable discrimination and calibration, while also emphasizing explainability to enhance trust and transparency. Furthermore, variable importance was investigated at both individual and population levels. Additionally, external validation confirmed the superior predictive performance of this optimal model. To facilitate clinical application, a web-based tool was developed for health care professionals to use the proposed prediction model.

Previous studies have consistently reported high mortality rates exceeding 60% among patients with anti-MDA5+DM-ILD, particularly in East Asian populations, such as China [21]. The majority of deaths occurred within the first 3 months [22]. It is widely recognized that an excessive inflammatory response is associated with a heightened risk of RP-ILD and all-cause mortality [23]. Hyperinflammation plays a crucial role in the development and progression of anti-MDA5+DM-ILD. Uncontrolled hyperinflammation and persistent immune activation contribute to severe lung injury and RP-ILD, which may resemble the phenomenon known as “cytokine storm” observed in COVID-19 [24]. Previous studies have indicated that poor outcomes in patients with DM are correlated with certain factors, including advanced age and elevated levels of serum ferritin, LDH, NLR, and CRP [21]. Consistent with these findings, we established a prediction model incorporating 8 key variables of significant predictive importance: RP-ILD, ESR, ALB, age, CRP, AST, NLR, and LDH. Most of these variables are inflammatory markers that can reflect the hyperinflammatory state and were easy to obtain and observe in previous studies on patients with DM in a clinical setting. Moreover, classical statistical analysis has identified risk factors in these patient populations, including RP-ILD and age [21,25,26]. In line with previous findings, RP-ILD was found to be the most important feature according to the SHAP value and contributed to this prediction model. Age was ranked fourth in terms of its significance as a parameter associated with worsened outcomes. Therefore, this prediction model demonstrated superior performance, yielding AUCs of 0.90 in the internal cohorts and 0.832-0.919 in external cohorts.

There are currently no existing ML-based prediction models for 3-month mortality in individuals with anti-MDA5+DM-ILD, making it impossible to make a direct comparison with prior work. Previous studies have used logistic or Cox proportional hazard models as alternatives [10,27-29]. For instance, a nomogram model incorporating the duration of first-time symptoms, the presence of fever, pleural effusion (PE), total CT scores, and AST has been recommended as a prognostic predictor for anti-MDA5+DM-ILD outcomes [29]. Another

XSL•FO
RenderX

model known as the "FLAIR score," which combines ferritin, LDH, the semiquantitative anti-MDA5 grade, the HRCT imaging score, and RP-ILD/non-RP-ILD classification, was proposed to predict mortality in amyopathic DM-related ILD based on a large-scale Chinese single-center cohort study [10]. In contrast to our study, which specifically targeted patients with anti-MDA5+DM-ILD, Lian et al's [10] investigation encompassed a more expansive patient population, not restricting their analysis solely to anti-MDA5+DM-ILD cases. Furthermore, although their investigation incorporated HRCT findings for scoring purposes, our study deliberately excluded HRCT as a discriminating factor in the evaluation process, attributable to the recognized interobserver and intraobserver variability inherent in HRCT interpretation.

Ouyang et al [30] reported a novel matrix prediction model that includes baseline characteristics, such as fever, ferritin≥1250 μg/L, and positive carcinoma embryonic antigen, which can predict 6-month all-cause mortality in patients with anti-MDA5+DM-ILD. However, these prediction models lack thorough external validation due to their reliance on small and nonrepresentative populations (eg, individuals from a single hospital), primarily due to the rarity of the disease. Moreover, the HRCT imaging score and the radiomics-based prediction model [31,32] are overly complex and impractical for routine clinical use. In contrast, this study leveraged routinely collected data from real-world clinical practices in China to develop an optimal prediction model, which is now accessible as a web-based tool. This tool enables clinicians to calculate individualized risks of 3-month mortality based on easily obtainable clinical data, including RP-ILD, age, AST, CRP, NLR, LDH, ALB, and NLR. It is important to emphasize that in real-world clinical practice, such models should be used holistically, considering all key features, rather than relying on a single feature for risk prediction. Therefore, the models require the input of a comprehensive set of features to accurately assess the risk in patients with anti-MDA5+DM-ILD.

Strengths and Limitations

Our study has several notable strengths. First, we conducted external validation in independent cohorts from 4 hospitals in China, encompassing various regions and settings. This inclusion of external cohorts 1 and 2 in China allows our findings to be representative of real-life clinical practice in our country. Second, we extracted, analyzed, and used data from routine clinical practice and finally established a practicable web-based algorithm for predicting 3-month mortality for patients with anti-MDA5+DM-ILD. Additionally, our study included a substantial number of patients with anti-MDA5+DM-ILD, further enhancing the robustness of our results.

However, it is important to acknowledge some limitations of our study. First, it was a retrospective study, which inherently introduces certain biases. Our patient population was sourced from large tertiary referral hospitals and consisted only of hospitalized patients, potentially leading to the inclusion of individuals with more severe disease. Second, although the predicted forced vital capacity (FVC<50%) was shown to independently predict 6-month all-cause mortality in patients with anti-MDA5-positive DM [29], we were unable to incorporate pulmonary function parameters into our prediction model due to missing data, particularly in patients with severe disease who had no opportunity to finish the pulmonary function test. Lastly, although the model demonstrated good discrimination and calibration in our study, the external validation cohort was limited to a Chinese population. It is necessary to develop a multiregion and multirace worldwide analysis and generate a more comprehensive and classical system to predict 3-month mortality for patients with anti-MDA5+DM-ILD.

Conclusion

In summary, our use of ML techniques and routinely collected clinical features helped us successfully develop an LR model that reliably predicts the risk of 3-month mortality in patients with anti-MDA5+DM-ILD. To facilitate the translation of our findings into clinical practice, we created a web-based tool that allows clinicians to calculate individualized risks of 3-month mortality. This tool can guide risk-stratified approaches to patient care and treatment.

Acknowledgments

We thank Xtreme Smart Analysis for technical support and analytical and visualization support provided for our research. This study was supported by Jiangsu Provincial Key Research and Development (no BE2016611) and the National Natural Science Foundation of China (grant 81970063).

Data Availability

Due to patient privacy, the data related to patients is not available for public access. However, it can be obtained from the corresponding author upon reasonable request, subject to approval by the institutional review board of the enrolled centers.

Authors' Contributions

HL wrote the draft and interpreted the data regarding the anti-melanoma differentiation–associated gene 5–positive dermatomyositis complicated with interstitial lung disease; RYZ, HXX, PH, and BX collected crude data; YQT, QZ, XY, XHQ, YJG, YL, MC, and HYJ managed patients in the capital institution; BC, QH, JC, GCW, and HRC conceived the study; and HRC analyzed the data and strictly revised the manuscript.

Abstract

Background: Medication errors constitute a major contributor to patient harm, driving up health care costs and representing a preventable cause of medical incidents. Over the past decade, many hospitals have integrated various medication-related technologies into their pharmacy operations. However, real-world evidence of the impact of these advanced systems on clinical prescription dispensing error rates remains limited.

Objective: This study aims to prospectively detect and record the categories and rates of dispensing errors to illustrate how medication-related technologies, such as automated dispensing cabinet (ADC), barcode medication administration (BCMA), and smart dispensing counter (SDC), can be used to minimize dispensing errors.

Methods: This study used a before-and-after design at a 2202-bed academic medical center in Taiwan to assess the impact of implementing medication-related technologies (ADC, BCMA, and SDC) on patient medication safety. Dispensing error rates were analyzed from January 1, 2017, to December 31, 2023, using data from the China Medical University Hospital Patient Safety Database. The study periods were defined as stage 0 (preintervention, January to November 2017), stage 1 (post-ADC intervention, December 2017 to June 2018), stage 2 (post-BCMA intervention, July 2018 to October 2020), and stage 3 (post-SDC intervention, November 2020 to December 2023). Medication errors were defined according to the National Coordinating Council for Medication Error Reporting and Prevention (NCC MERP). Chi-square or Fisher exact tests were used to analyze differences between intervention periods, with Bonferroni correction for multiple comparisons. Statistical significance was set at $P<.05$.

Results: Following the introduction of medication-related technologies, the average dispensing error incidence rate significantly decreased by 39.68%, 44.44%, and 77.78%, from 0.0063% in stage 0 to 0.0038%, 0.0035%, and 0.0014% in stages 1, 2, and 3, respectively ($P<.001$). The frequency of “wrong drug” errors, the most common error type in stage 0, significantly decreased by 51.15%, 56.85%, and 81.26% in stages 1, 2, and 3, respectively. All error types, except for “wrong dosage form,” “wrong strength,” “wrong time,” and “others,” demonstrated statistically significant differences ($P<.001$). The majority of harm severities were categorized as “A” (no error; 97%-98.8%) and “B-D” (error, no harm; 1.2%-3%) according to the NCC MERP classification. The severity of “no error” (category A) significantly decreased at each stage ($P<.001$). Statistically significant differences in dispensing error rates were observed between all stages ($P<.001$), except between stages 2 and 1 ($P>.99$).

Conclusions: This study provides significant evidence that the implementation of medication-related technologies, including ADC, BCMA, and SDC, effectively reduces dispensing errors in a hospital pharmacy setting. Specifically, we observed a substantial decrease in the average dispensing error rate across 3 stages of technology implementation. Importantly, this study appears to be the first to investigate the combined impact of these 3 specific technologies on dispensing error rates within a hospital pharmacy.

KEYWORDS

medication error; dispensing error; medication-related technology; pharmacy; smart dispensing counter

Introduction

Medication errors pose a significant risk to patient safety and incur substantial economic losses. Recognizing this, medication safety has been identified as a critical area for improvement in all health care settings globally [1]. In March 2017, the World Health Organization (WHO) launched the third Global Patient Safety Challenge, focusing specifically on medication safety. This initiative aims to address systemic weaknesses within health care systems that contribute to medication errors and their potentially severe consequences. The WHO has set an ambitious goal to globally reduce the level of severe, avoidable medication-related harm by 50% within 5 years. This challenge emphasizes improvements across all stages of the medication process, including prescribing, dispensing, administering, monitoring, and patient use [2,3]. In the United States, the Joint Commission on Accreditation of Healthcare Organizations also prioritizes medication safety by including it among its annual patient safety goals [4]. Previous research indicates that approximately 22%-25% of medication errors occur during the dispensing phase [5]. Dispensing errors often precede administration errors, highlighting the critical role of the pharmacy in preventing medication errors. Estimates of medication errors vary significantly across different regions within the prescription (10%-39%), dispensing (11%-40%), and administration (10.5%-38%) stages of medication management. These variations can be attributed to multiple factors [6-14].

Medication errors can arise when weak medication safety systems and human factors, such as fatigue, poor environmental conditions, or staff shortages, compromise any stage of the medication management process [15]. Dispensing errors can lead to preventable patient harm, including adverse drug events, hospitalization, or even death. A systematic review examining the global prevalence of dispensing errors across various pharmacy settings revealed rates ranging from 0% to 33.3%. The worldwide prevalence of dispensing errors was determined to be 1.6% across community, hospital, and other pharmacy settings [16]. Factors influencing dispensing errors include pharmacists' machine usage, workload, and the length of their monthly vacations. Adequate staffing and the use of automated medication preparation systems may be necessary to minimize dispensing errors. Pharmacists returning to dispensing duties after an absence exceeding 72 hours should gradually reintegrate to regain their proficiency [17]. Near-misses, incidents with the potential for medication errors, often share the same root causes as actual errors [18]. Proactively identifying and addressing near-misses is crucial for preventing future medication errors.

Health information technology is believed to be transformative in addressing inefficiencies, preventing medication errors, and improving overall care quality [19]. The integration of health information technology throughout the medication use process is expected to enhance health care safety and efficiency. Past research demonstrates that automated equipment and systems are generally more effective than manual methods, providing a more standardized and reliable execution of medication use processes and thereby reducing errors [20-22].

The use of medication-related technologies, such as automated dispensing cabinets (ADCs), barcode medication administration (BCMA), and smart dispensing counters (SDCs), is increasingly prevalent in hospitals. These technologies aim to reduce medication errors, safeguard medications from improper use, and improve the efficiency of medication processes. This study aims to evaluate the impact of medication-related technologies on both workflow efficiency and prescription dispensing accuracy following their implementation in a Taiwan academic medical center.

Methods

Definitions of Medication Error

The definition of medication error mainly refers to the definition provided by the US National Coordinating Council for Medication Error Reporting and Prevention (NCC MERP). A medication error is defined as "any preventable event that may cause or lead to inappropriate medication use or patient harm while the medication is in the control of the health care professional, patient, or consumer" [3]. Medication errors occur at each stage of the medication process, including prescribing, dispensing, administering, monitoring, and use.

Dispensing medication is the core function of pharmaceutical care and involves a complex combination of processes, technologies, and human interactions. Dispensing errors include, but are not limited to, dispensing the medicine for the wrong patient, incorrect medicine name, incorrect strength, and incorrect dosage [7].

Study Design

Our hospital experiences 190,000 outpatient visits; 12,000 emergency visits; 7600 inpatient admissions; and 5100 surgeries monthly. To evaluate the impact of implementing medication-related technologies (ADCs, BCMAs, and SDCs) on patient medication safety, we conducted a before-and-after study at our 2202-bed academic medical center in Taiwan.

We analyzed medication error rates within the medication use process from January 1, 2017, to December 31, 2023, using data from the China Medical University Hospital Patient Safety Database (Multimedia Appendices 1 and 2). Our analysis specifically focused on medication errors that occurred during pharmacist medication dispensing. Power business intelligence was used for visual data analytics to conduct a frequency and cause analysis of these errors.

Intervention-Medication–Related Technologies

To address common errors in pharmacist medication dispensing, we used ADC, BCMA, and SDC as interventions. The study periods were defined as follows: stage 0 (preintervention, January to November 2017), stage 1 (post-ADC intervention, December 2017 to June 2018), stage 2 (post-BCMA

XSL•FO
RenderX

intervention, July 2018 to October 2020), and stage 3 (post-SDC intervention, November 2020 to December 2023).

ADC Intervention

An ADC, also called a unit-based cabinet, automated dispensing device, or automated dispensing machine, is a computerized medicine cabinet for hospitals and health care settings. ADCs allow medications to be stored and dispensed near the point of care while controlling and tracking drug distribution [20].

BCMA Intervention

BCMA is a barcode system designed to prevent medication errors in health care settings and improve the quality and safety of medication administration. The overall goals of BCMA are to improve accuracy, prevent errors, and generate digital records of medication administration [20,22,23].

SDC Intervention

The SDC is also known as the LED-guided picking plus lockable drawer (LED-LD) system. The LED-LD system is linked to the medicine management information system, allowing the extraction of data on the location of the medication. The LED-LD system has adopted LED technology to aid in locating the correct medication bin. When scanning the quick response code on a medication label, the LED corresponding to the medication location lights up, directing the pharmacy staff to the correct medication bin. The LED-LD system uses a remote lockable drawer system integrated with LED technology. Upon scanning the quick response code, only the drawer containing the corresponding medication is unlocked, enabling its retrieval. The drawer locks automatically when it is shut [24] (Multimedia Appendix 3).

Outcome

All medication orders, including those written or cosigned by physicians during the study period, were included in the analysis. The pharmacy, providing continuous services for both outpatients and inpatients, adheres to standardized protocols for medication preparation and dispensing. The primary outcome measure was the monthly rate of prescription dispensing errors before and after the implementation of medication-related technologies (ADC, BCMA, and SDC). This rate was calculated by dividing the number of reported prescription dispensing errors by the total number of prescriptions filled each month. Secondary outcome measures included the types of dispensing errors and their severity. The severity of medication errors was assessed by two pharmacists using the NCC MERP method. In case of disagreement, consensus was reached through discussion with a third senior pharmacist.

Statistical Analysis

Descriptive statistics were used to summarize the dispensing error rates at each stage of the medication use process. The dispensing error rate was calculated by dividing the total number of dispensing errors by the total number of medications dispensed. We compared the incidence of dispensing errors before and after the implementation of medication-related technologies (ADCs, BCMAs, and SDCs). Furthermore, we stratified the analyses by the type and severity of dispensing errors.

Differences among the intervention periods were analyzed using chi-square or Fisher exact tests. The Bonferroni method was applied to adjust for multiple comparisons. All statistical analyses were conducted using R software (version 4.1.0, R Foundation for Statistical Computing). Statistical significance was defined as $P<.05$.

Ethical Considerations

This study was conducted in accordance with the Declaration of Helsinki and approved by the Institutional Review Board of the Research Ethics Committee at China Medical University Hospital, Taichung, Taiwan (approval CMUH114-REC2-041). Following the 'Patient Safety Incident Reporting and Reward Operation Guidelines' of China Medical University Hospital, reporter information is automatically identified and transferred upon acceptance and establishment of a patient safety incident report, facilitating subsequent review and collaborative processes. This study utilized secondary use data, derived from a descriptive qualitative analysis of the patient safety notification database, to quantify error type categories related to healthcare information technologies. Notably, this study did not involve any patient or staff identification, and therefore, participant compensation disclosure is not applicable.

Results

Characteristics of Prescription Dispensing Errors of Prevalence, Type, and Potential Severity

Table 1 presents the proportions of prescription dispensing errors by prevalence, type, and potential severity before and after the implementation of medication-related technologies. A total of 15,410,968 medication orders were dispensed in stage 0 (preintervention), followed by 10,721,238 in stage 1; 44,193,666 in stage 2; and 56,260,136 in stage 3. The total number of dispensing errors observed were 968, 406, 1556, and 773 in stages 0, 1, 2, and 3, respectively. The average number of dispensing errors per month decreased from 88 in stage 0 to 58 in stage 1, 56 in stage 2, and 20 in stage 3. Correspondingly, the dispensing error rates declined from 0.0063% in stage 0 to 0.0038% in stage 1, 0.0035% in stage 2, and 0.0014% in stage 3.

In stage 0 (preintervention), the 3 most frequent types of dispensing errors were wrong drug (459/968, 47.4%), wrong dose (335/968, 34.6%), and wrong technique (55/968, 5.7%). While the specific ranks varied slightly across stages, wrong drug, wrong dose, and wrong patient consistently ranked among the top 3 types of dispensing errors. According to the NCC MERP classification, the severity of harm (97%-98.8%) was categorized as “A” (no error) in all stages. The remaining severity of harm primarily fell into categories “B-D” (error, no harm). In stage 2, two cases were categorized as “C” (dose omission and wrong dose), and one case was categorized as “D” (wrong drug), all with no harm. In stage 3, only one case of “C” (wrong dose) was observed, again with no harm.

Effect of Medication-Related Technology on Reducing Dispensing Errors

Figure 1 shows a significant decrease in the rate of reported prescription dispensing errors across the observation periods. Compared with the preintervention stage 0 (traditional manual medication picking), where the average dispensing error rate was 0.0063%, a notable reduction was observed in subsequent stages: stage 1 (post-ADC intervention) at 0.0038% (39.68% decrease), stage 2 (post-BCMA intervention) at 0.0035% (44.44% decrease), and stage 3 (post-SDC intervention) at 0.0014% (77.78% decrease).

Figure 1. The trend curve of the dispensing error rate before and after the implementation of medication-related technology in each stage from 2017 to 2023. ***P<.001. ADC: automated dispensing cabinet; BCMA: barcode medication administration; SDC: smart dispensing counter.

Effect of Introducing ADC on Reducing Dispensing Errors

Table S1 in Multimedia Appendix 4 shows the incidence of dispensing errors by type before and after the introduction of an ADC. Compared with the preintervention stage (stage 0), the post-ADC intervention stage (stage 1) demonstrated significant reductions in the incidence of the wrong drug (0.0030%-0.0015%; P<.001), wrong dose (0.0022%-0.0012%; P<.001), and total dispensing error rates (0.0063%-0.0038%; P<.001). Other error types, including wrong dosage form, wrong strength, wrong patient, wrong time, dose omission, monitoring error, wrong technique, and other errors, showed either minimal changes or slight decreases.

Regarding the severity of harm, a significant reduction was observed in category A (no error) from 0.0061% in stage 0 to 0.0037% in stage 1 (P<.001). Furthermore, the prevalence of category B (error, no harm) decreased from 0.00019% in stage 0 to 0.00005% in stage 1 (P=.02).

Effect of Introducing BCMA on Reducing Dispensing Errors

Table S1 in Multimedia Appendix 4 shows the incidence of dispensing errors by type before and after the introduction of BCMA. Compared with the preintervention stage (stage 0), the post-BCMA intervention stage (stage 2) demonstrated significant reductions in the incidence of wrong drug (0.0030%-0.0013%; P<.001), wrong dose (0.0022%-0.0012%; P<.001), dose omission (0.00015%-0.00005%; P=.001), monitoring errors (0.00006%-0.00001%; P<.001), wrong technique (0.0004%-0.0001%; P<.001), and the total dispensing error rate (0.0063%-0.0035%, P<.001). Compared with the post-ADC intervention stage (stage 1), only the wrong technique showed a significant reduction in stage 2 (P=.005).

Regarding the severity of harm, a significant reduction was observed in category A (no error) from 0.0061% in stage 0 to 0.0035% in stage 2 (P<.001). Similarly, category B (error, no harm) also demonstrated a significant reduction from 0.00019% in stage 0 to 0.00005% in stage 2 (P<.001). No significant differences in the severity of harm were observed between stage 1 and stage 2.

Effect of Introducing SDC on Reducing Dispensing Errors

Table S1 in Multimedia Appendix 4 shows the incidence of dispensing errors by type before and after the introduction of SDC. Compared with the preintervention stage (stage 0), the post-SDC intervention stage (stage 3) demonstrated significant reductions in the incidence of wrong drug (0.0030%-0.0006%; P<.001), wrong dose (0.0022%-0.0004%; P<.001), wrong patient (0.0003%-0.0001%; P<.001), dose omission (0.00015%-0.00004%; P<.001), monitoring errors (0.00006%-0%; P<.001), wrong technique (0.0004%-0.0001%; P<.001), and the total dispensing error rate (0.0063%-0.0014%; P<.001). Significant reductions were also observed between stage 1 and stage 2, as well as between stage 2 and stage 3 for multiple error types, including wrong drug, wrong dose, wrong dosage form, wrong patient, others, and the total dispensing error rate.

Regarding the severity of harm, a significant reduction was observed in category A (no error) from 0.0061% in stage 0 to 0.0014% in stage 3 (P<.001). Similarly, category B (error, no harm) also demonstrated a significant reduction from 0.00019% in stage 0 to 0.00002% in stage 3 (P<.001). Significant reductions in category A were also observed between stage 1 and stage 3 (P<.001), as well as between stage 2 and stage 3 (P<.001).

As given in Table 2, statistically significant reductions in prescription dispensing error rates were observed between each stage (P<.001), except when comparing stage 1 to stage 2.

Discussion

Main Findings of Medication-Related Technology in Reducing Dispensing Errors

The study revealed that prescription dispensing error rates significantly decreased after the introduction of medication-related technologies, including ADC, BCMA, and SDC. Specifically, error rates reduced by 39.68%, 44.44%, and 77.78% from stage 0 (preintervention) to stage 1 (post-ADC intervention), stage 2 (post-BCMA intervention), and stage 3 (post-SDC intervention), respectively. The average number of dispensing errors per month also significantly decreased from 88 in stage 0 to 58 in stage 1, to 56 in stage 2, and to 20 in stage 3. The most frequent error type in stage 0, wrong drug, was significantly reduced by 51.15%, 56.85%, and 81.26% in stages 1 to 3, respectively. Similarly, the wrong dose, the second most frequent error type, was significantly reduced by 42.93%, 42.85%, and 82.34% across the stages. Compared with stage 0, the severity of harm, as categorized by category A (no error) and category B (error, no harm), was significantly decreased in all subsequent stages. These findings demonstrate the effectiveness of medication-related technologies in reducing dispensing errors in a hospital pharmacy and improving medication safety.

The Actual Effectiveness of Introducing ADC in Reducing Dispensing Errors

In stage 1 (post-ADC intervention), the dispensing error rate decreased significantly from 0.0063% in stage 0 (preintervention) to 0.0038% (a reduction rate of 39.71%). This reduction was observed across all error types, including wrong drug, wrong dose, and the total number of dispensing errors. Notably, the reduction rate of wrong drug was substantial, decreasing from 0.0030% to 0.0015% (a 51.15% reduction), and the reduction rate of wrong dose also decreased significantly from 0.0022% to 0.0012% (a 42.93% reduction). These findings are consistent with previous studies that have demonstrated the effectiveness of ADCs in reducing dispensing errors [22,25-27]. The primary impact of ADC implementation was observed in a significant reduction of wrong drug and wrong dose. Previous research by Shah et al [26] highlighted that while ADCs can eliminate certain error types, they may also introduce new error types from a pharmacist's perspective [26]. Therefore, pharmacists play a crucial role in ensuring the safe and effective use of ADCs by implementing appropriate policies, procedures, and quality assurance programs to address safety, accuracy, security, and patient confidentiality [28].

The Actual Effectiveness of Introducing BCMA in Reducing Dispensing Errors

In stage 2 (post-BCMA intervention), the dispensing error rate decreased significantly by 43.95% compared with stage 0 (0.0063% vs 0.0035%). These findings were consistent across all error types, including wrong drug, wrong dose, monitoring error, wrong technique, dose omission, and the total number of dispensing errors. Notably, the reduction rate of the wrong drug was substantial, decreasing from 0.0030% to 0.0013% (56.85% reduction). The reduction rates of wrong dose, dose omission, and monitoring errors were also significant, decreasing from 0.0022% to 0.0012% (42.85% reduction), from 0.00015% to 0.00005% (66.67% reduction), and from 0.000058% to 0.000005% (92.25% reduction), respectively. The wrong technique error rate also decreased significantly from 0.0004% to 0.0001% (67.03% reduction). Compared with stage 1, only the wrong technique error rate showed a statistically significant difference. These findings are consistent with previous studies [29-31] and demonstrate the effectiveness of BCMA in reducing dispensing errors, particularly in preventing wrong drug, wrong dose, dose omission, monitoring error, and wrong technique.

Consistent with other studies, our analysis showed that BCMA implementation was associated with a reduction in dispensing errors, especially for medications with high error rates or those prone to confusion. However, the effectiveness of BCMA relies heavily on proper implementation, including comprehensive education and training on standard operating procedures. For example, simultaneous scanning of multiple medications can lead to errors, and issues with barcode quality or accuracy can also hinder the system's effectiveness. In addition, damaged and unreadable drug barcodes, as well as medications labeled with incorrect barcodes, can also cause problems.

XSL•FO
RenderX

The Actual Effectiveness of Introducing SDC in Reducing Dispensing Errors

In stage 3 (post-SDC intervention), the dispensing error rate decreased significantly by 78.13% compared with stage 0 (0.0063% vs 0.0014%). These findings were consistent across all error types, including wrong drug, wrong dose, wrong patient, dose omission, monitoring error, wrong technique, and the total number of errors. Notably, the reduction rate of wrong drug errors was substantial, decreasing from 0.0030% to 0.0006% (81.26% reduction). The reduction rates of wrong dose and wrong patient errors were also significant, decreasing from 0.0022% to 0.0004% (82.34% reduction) and from 0.0003% to 0.0001% (59.56% reduction), respectively. Monitoring errors were completely eliminated in stage 3. The wrong technique and dose omission error rates also decreased significantly. Compared with stage 1 and stage 2, significant reductions were observed in multiple error types in stage 3, including wrong drug, wrong dose, wrong patient, and others. The implementation of SDC demonstrated significant reductions in wrong drug, wrong dose, wrong patient, dose omission, monitoring error, and wrong technique. These findings are consistent with a previous study by Teo et al [24], which observed that technology-assisted medication picking systems, such as an LED-guided system with a lockable drawer, significantly reduced near-miss medication errors in a tertiary referral hospital in Singapore.

Our observations highlight the potential of the SDC system, designed to address the unique dispensing needs of Taiwan, to significantly reduce medication errors. By incorporating visual, auditory, and perceptual cues, the SDC system can guide pharmacists through the dispensing process, minimizing errors that may occur due to factors such as infrequent medication use, similar packaging, or distractions. This is particularly important for new pharmacists who are still familiarizing themselves with medication locations and workflow.

Limitations

This study has several limitations. First, variations in medication error definitions across the literature make comparisons challenging. We attempted to standardize error classification according to the NCC MERP guidelines and calculated error rates based on the total number of dispensing errors and medication orders per prescription. Second, the staggered implementation of ADC, BCMA, and SDC (December 2017, July 2018, and November 2020, respectively) may have introduced a time-related bias. To mitigate this, we implemented standardized staff training on system operation and troubleshooting and provided on-site technical support. Furthermore, direct observation of drug dispensing was not conducted, making it difficult to confirm the absence of management errors despite random checks of standard dispensing procedures.

Automated systems may face challenges with irregularly shaped or infrequently used medications, requiring backup systems during downtime and maintenance [32]. Concurrent manual workflows during automation can also introduce potential sources of error. Based on our findings, optimizing the benefits of dispensing and management technologies requires adequate resource allocation for postimplementation support, including education, training, and technical assistance. The occurrence of system-related errors highlights the need for continuous monitoring and proactive problem-solving. For example, the system should track the movement of drugs after delivery, including any necessary withdrawals by pharmacists and nursing staff. Clear procedures for responding to system failures must be communicated to all employees. To maximize the benefits of these technologies, continuous evaluation, system refinement, and process optimization are crucial.

Conclusions

This study demonstrated that the implementation of 3 medication-related technologies (ADC, BCMA, and SDC) significantly reduced dispensing errors compared with traditional manual medication picking. Overall, the study observed a significant reduction in dispensing errors across all stages. Except for wrong dosage form, wrong strength, wrong time, and other minor error types, all major error categories (including wrong drug, wrong dose, and wrong patient) showed statistically significant reductions (P<.001). The severity of harm also decreased significantly at each stage (P<.001). Significant differences in dispensing error rates were observed between all stages (P<.001). These findings underscore the potential of medication-related technologies to enhance medication safety and improve the efficiency of medication dispensing processes in hospital settings. Notably, the study observed significant reductions in critical error types such as wrong drug and wrong dose, which can have serious consequences for patient safety. This study shows that medication-related technology reduces dispensing errors and improves medication safety in hospitals. As hospitals work to enhance efficiency and safety, more targeted research is needed to assess the benefits and risks of these technologies. The findings highlight that technology can reduce errors and enhance medication management by improving dispensing and prescribing, optimizing clinical pharmacist resources, and allowing staff to focus more on patient care.

Acknowledgments

We are grateful to China Medical University Hospital for providing administrative and technical support. We also thank Ying-Shu You (Institute of Epidemiology and Preventive Medicine, College of Public Health, National Taiwan University, Taipei, Taiwan) for her statistical analysis and consultation.

Abstract

Background: Accurate classification of patient complaints is crucial for enhancing patient satisfaction management in health care settings. Traditional manual methods for categorizing complaints often lack efficiency and precision. Thus, there is a growing demand for advanced and automated approaches to streamline the classification process.

Objective: This study aimed to develop and validate an intelligent system for automatically classifying patient complaints using machine learning (ML) and natural language processing (NLP) techniques.

Methods: An ML-based NLP technology was proposed to extract frequently occurring dissatisfactory words related to departments, staff, and key treatment procedures. A dataset containing 1465 complaint records from 2019 to 2023 was used for training and validation, with an additional 376 complaints from Hangzhou Cancer Hospital serving as an external test set. Complaints were categorized into 4 types—communication problems, diagnosis and treatment issues, management problems, and sense of responsibility concerns. The imbalanced data were balanced using the Synthetic Minority Oversampling Technique (SMOTE) algorithm to ensure equal representation across all categories. A total of 3 ML algorithms (Multifactor Logistic Regression, Multinomial Naive Bayes, and Support Vector Machines [SVM]) were used for model training and validation. The best-performing model was tested using a 5-fold cross-validation on external data.

Results: The original dataset consisted of 719, 376, 260, and 86 records for communication problems, diagnosis and treatment issues, management problems, and sense of responsibility concerns, respectively. The Multifactor Logistic Regression and SVM models achieved weighted average accuracies of 0.89 and 0.93 in the training set, and 0.83 and 0.87 in the internal test set, respectively. Ngram-level term frequency–inverse document frequency did not significantly improve classification performance, with only a marginal 1% increase in precision, recall, and F_1-score when implementing Ngram-level term frequency–inverse document frequency (n=2) from 0.91 to 0.92. The SVM algorithm performed best in prediction, achieving an average accuracy of 0.91 on the external test set with a 95% CI of 0.87-0.97.

Conclusions: The NLP-driven SVM algorithm demonstrates effective classification performance in automatically categorizing patient complaint texts. It showed superior performance in both internal and external test sets for communication and management problems. However, caution is advised when using it for classifying sense of responsibility complaints. This approach holds

promises for implementation in medical institutions with high complaint volumes and limited resources for addressing patient feedback.

(J Med Internet Res 2025;27:e55721) doi:10.2196/55721

KEYWORDS

complaint analysis; text classification; natural language processing; NLP; machine learning; ML; patient complaints

Introduction

Background

Patient complaints refer to patients feeling dissatisfied or having opinions regarding medical services, treatment processes, medical staff attitudes, or health care institution management during their participation in medical care [1]. These complaints are expressed through written or verbal feedback or grievances to relevant organizations or individuals. Complaints can involve various aspects, including medical errors, poor treatment outcomes, unfriendly service attitudes, and excessive waiting times among other issues.

Handling patient complaints is an essential part of health care institution management, as it can help improve the quality of medical services and enhance patient satisfaction. Patient complaints also serve as valuable sources for gaining insights into safety-related issues within health care institutions. Patients are often more sensitive to a range of issues within medical services compared with health care professionals within the institution. Some of these issues may not be identified by traditional medical surveillance systems [2], such as adverse event reporting systems or mortality case reviews. Therefore, patient complaints can provide crucial information for health care institutions on how to improve patient safety.

Currently, patient satisfaction surveys are conducted through SMS text messages or online methods (such as through a WeChat [Tencent] official account) in our hospital. If a patient responds negatively, a staff member from the outpatient office follows up with a phone call. Under traditional management methods, satisfaction survey personnel meticulously document specific complaints from patients regarding dissatisfaction with the hospital's medical management. These complaints are then summarized and regularly sent to the hospital's Patient Advocacy Center (PAC). They are manually categorized and reported every 2 weeks during hospital meetings and also distributed to the email addresses of relevant clinical and medical technology department heads for corrective action and improvement. Only if the patient receives feedback from the relevant department, it will be considered as closing the loop on the complaint-handling process.

On average, about 25 new complaints are submitted through various channels each day, while the PAC can only analyze and process approximately 10 complaints loops per day. At this rate, it can be estimated that the hospital's PAC will still have over 5400 patient complaints waiting to be analyzed and addressed within a year. Clearly, without significant changes to the screening and categorization process, the hospital's PAC will be unable to analyze all submitted complaints within a reasonable timeframe to provide adequate feedback and resolution. The crux of the issue lies in the inability to classify patient complaints in a timely manner, which consequently hampers targeted communication between subsequent departments and patients. This delay leads to patients lodging secondary or even multiple complaints due to prolonged waiting times. In addition, departments with the capability to address specific issues remain idle as they do not receive timely patient complaints. Experience with several hundred such interventions at community and academic medical centers shows fewer subsequent complaints associated with most of those receiving timely and effective feedback [3]. Therefore, tardily and ineffectively addressing patient complaints has become a significant bottleneck restricting the enhancement of hospital management quality and medical safety.

Automatic classification tools play a crucial role in streamlining the triage process, enabling health care providers to efficiently prioritize and address patient concerns based on the severity and nature of their complaints. By automating this classification process, clinicians can allocate resources more effectively, leading to improved patient outcomes and satisfaction. In addition, such tools facilitate the organization and analysis of large volumes of patient data, ultimately contributing to evidence-based decision-making and enhanced health care delivery. The problem is that there are hardly any studies, articles, or systems focusing on the automatic classification of patient complaints. The need for automatic classification of patient complaints is crucial, as manual identification of complaints is inefficient, time-consuming, and highly prone to errors.

The main contributions of this study are by automating the patient complaint triage process, PAC can allocate resources more efficiently, thereby improving patient care experience and satisfaction. In addition, such tools help organize and analyze large amounts of patient complaint data, ultimately contributing to evidence-based medical decisions and improved medical services to ensure patient treatment safety.

The structure of the article is as follows. "Existing Approaches to Text Classification" introduces previous studies on existing approaches to text classification and the patients complain auto-classification methodology. "Methods" and "Results" introduce machine learning (ML) models and experimental results. "Discussion" presents an analysis and discussion of selected results and offers some suggestions for future research. Finally, "Conclusion" summarizes our research.

Existing Approaches to Text Classification

The classification of patient complaint texts falls within the realm of text auto-classification. Therefore, many previous studies in text classification provide valuable insights for us (Multimedia Appendix 1) [4-9]. Especially, auto-classification

XSL•FO
RenderX

of texts based on patients' chief complaints (CC) during the diagnostic process is the most relevant to our research on auto-classifying patient complaint texts.

CC text classification refers to the task of automatically categorizing or classifying text data based on the main concerns or symptoms expressed by patients when they seek medical attention [10]. In principle, each patient complaint should be classified into 1 category, but typically 1 patient complaint may be classified into a single or multiple categories because it contains more than 1 category of disease. A recorded free-text CC is assigned to a category either manually by emergency medicine physicians or other emergency department (ED) professionals, or by using an automated mapping algorithm [11-14]. Automated CC categorization, on the other hand, are more suitable for a wide range of (ED) applications. Traditional automated CC classification algorithms typically use a linear mapping algorithm (keyword search and category matching algorithm [15]), or a semantic model based on Bayesian network [12].

The study by Arnaud et al [16] leveraged natural language processing (NLP) solutions to predict medical specialties at hospital admission by integrating structured data with unstructured textual notes. An MLP model and a convolutional neural network (CNN) were independently used to achieve promising accuracy in the analysis of over 260,000 ED records. Although the classifier model could only achieve about 68% accuracy of prediction, this research contributes to the growing use of NLP methods in health care analytics. NLP models achieved high accuracy in predicting the need for admission, triage score, critical illness, and mapping free-text CC to structured fields. Incorporating both structured data and free-text data improved results when compared with models that used only structured data. However, the majority of studies (16/20, 80%) were assessed to have a high risk of bias, and only 1 study reported the deployment of an NLP model into clinical practice [17].

These traditional linear classification methods are all based on the bag-of-words (BOW) representation, which treats text as an unordered collection of words, ignoring the position and grammatical structure of words, and only focusing on the frequency of word occurrences. In the BOW model, text is represented as a vector, where each dimension corresponds to a word, and each element of the vector represents the frequency or occurrence of the corresponding word in the text. However, it is known that BOW technique suffers from issues such as loss of word order information, curse of dimensionality, sparsity, and semantic loss. These limitations restrict the performance of the BOW model in NLP tasks [18,19]. Therefore, researchers have proposed various improvement methods to overcome these issues, such as using word embedding techniques and models that consider contextual information [20]. A representative work was proposed by Alhazzani et al [21], who used pretrained static word embeddings and pretrained vector word embeddings to train deep learning (DL)–based BiLSTM (Bidirectional Long Short-Term Memory) and BiGRU (Bidirectional Gated Recurrent Unit) classifiers. Lee et al [13] developed a recurrent neural network (RNN)–based long short-term memory (LSTM) and gated recurrent unit (GRU) cells for text classification [13], and they reported that in all instances, the RNN models outperformed the BOW classifiers suggesting DL models could substantially improve the automatic classification of unstructured text for syndromic surveillance.

Currently, 1 significant innovation using the transformer architecture [22] and using bidirectional encoding to effectively capture dependency relationships from both directions of context simultaneously, has significantly propelled technological advancements across various CC text classification tasks [23,24]. The performance of those models (BERT [Bidirectional Encoder Representations from Transformers; Google], Bio_BERT, Clinical BERT, KP_BERT, CC_BERT) was compared with that of the term frequency–inverse document frequency (TF-IDF) [25] model serving as the baseline. However, the results revealed that the TF-IDF model outperforms a robust BERT-based model on the test dataset and exhibits statistical comparability in terms of misspelling sets.

Despite the application of DL methods, including CNNs, RNNs, and BERT, in text categorization—particularly in handling large-scale, high-dimensional data and significantly enhancing text classification performance for complex tasks [26,27]—traditional ML approaches continue to offer advantages in terms of computational resource requirements and the interpretability of results compared with DL, CNNs, and RNNs. Modern RNNs can have millions of free parameters and thus require huge datasets [28]. Training models of this size require significant computing resources. In the task of patient complaints classifying, besides pursuing classification accuracy, the interpretability of ML models should be prioritized. This is because our goal was to identify the root causes of patient complaints through a correct interpretation of classification results, and the interpretability of models such as DL, CNNs, and RNNs is notably low. This significantly undermines the credibility of clinical interpretations of the aforementioned analysis results and their subsequent applicability. Therefore, 3 interpretable common ML classification models (Multifactor Logistic Regression [MLR], Multinomial Naive Bayes [MNB], and Support Vector Machines [SVMs]) are used in our research work.

By training ML models on large datasets of labeled complaint data, these models can learn to accurately categorize complaints based on their content and context. This automated classification approach can significantly improve the efficiency and accuracy of complaint management systems, reducing reliance on subjective human intervention and enabling faster processing and resolution of patient complaints. In addition, it can help to identify patterns and trends in complaints so that PAC can proactively address common issues and improve overall patient satisfaction.

In this study, we explore the automatic text classification of patient complaints using 2 types of TF-IDF techniques and trained an ML tool for automatic classification of patient complaint texts written in Chinese based on the existing mature English text automatic classification models.

We posit that an automated classification architecture for the categorization of patient complaints can be created, which consists of 2 modules.

XSL•FO
RenderX

First, the NLP module is based on the TF-IDF technique. The function of this module is to perform word frequency and extract features from the patient complaint texts. By using the TF-IDF technique (Word-level TF-IDF and Ngram-level TF-IDF), the importance of each word and semantics in the text can be calculated and keywords representing the core meaning of the complaint can be extracted. This helps the model to better understand and classify the complaint texts.

Second, the ML module is to classify complaint texts. ML algorithms have been widely adopted for text classification [29-33]. However, existing research in the literature has primarily focused on the English language. Therefore, patient comments written in Chinese are currently difficult to automatically analyze using traditional ML or statistical approaches. While several classification models based on Chinese text have emerged, their efficacy, algorithmic intricacy, and substantial hardware requirements have impeded the broad implementation of this approach in scholarly discourse [34,35]. The challenge of dealing with Chinese text lies in its complex linguistic features, including character-based writing, tonal variations, and the absence of explicit word boundaries. In addition, Chinese exhibits rich contextual meanings and cultural nuances, which can pose difficulties for NLP tasks such as machine translation, sentiment analysis, and text summarization. By using translation tools (such as ChatGPT 3.5 [OpenAI] or other professional translation tools) to translate Chinese text into English, and then having English professionals review and correct the translated results, these reviewed English texts were used as input data for ML models for classification training. This approach can overcome the challenges of directly processing Chinese text and provides an effective way to use Chinese text data in the test classification process.

Methods

Data Acquisition and Preprocessing Flow

A retrospective study of patient complaints was conducted at Hangzhou Red Cross Hospital and Hangzhou Cancer Hospital from 2015 to 2019. A comprehensive compilation of 1817 documented complaints were carefully collated. Complaints involving the same patient and the same incident were grouped into 1 independent complaint case. This study was approved by the ethics committee, which granted a waiver of review and exempted it from the informed consent requirement. The data from Hangzhou Red Cross Hospital were used for model training and internal validation, while the data from Hangzhou Cancer Hospital were used for external testing of the model with the best performance in the ML model. All data collection and analysis methods in this study strictly adhere to the "Guidelines for Developing and Reporting Machine Learning Predictive Models in Biomedical Research" [36].

Due to the current difficulty of directly applying ML and classification training to Chinese text, coupled with the availability of mature software and tools for translating Chinese into English, along with the review of translation results by English-proficient graduate students, converting the Chinese written text into English for training purposes is a feasible and efficient approach for automatic text classification. All the texts recorded in Chinese were translated into English by ChatGPT 3.5. Furthermore, 2 postgraduates with English language skills were responsible for reviewing the machine-translated texts; if there were obvious translation errors, the texts were corrected after the 2 individuals proposed unanimous modification suggestions.

If 2 individuals had a disagreement regarding the translation of the same Chinese word, we would escalate the matter to native English-speaking professors in the International Education Department of the hospital. They would make the final decision to ensure that each identical Chinese word in all Chinese complaint texts was translated into English with complete consistency. To ensure the efficiency of the expert correction mechanism, we have established a reward system. For every flaw or error found in the machine-translated text, a certain amount of funds would be allocated from our project budget for rewards.

Once sufficient data have been collected, preprocessing is divided into the 3 steps.

In the first step, the complaint texts are tokenized. After comparing jieba (Multimedia Appendices 2 and 3), THULAC [37], and HanLP [38], the more mature tool jieba is used in this study. To achieve the best balance between speed and accuracy in tokenization, the Hidden Markov Model Bigram (HMM-Bigram) [39] algorithm is used. Part-of-speech tagging is performed at the same time as tokenization. This involves assigning labels to words based on their respective parts of speech, such as adjectives, verbs, nouns, and so on. Part-of-speech tagging is based on maximum entropy and maximum likelihood approaches.

The second step is to eliminate duplicate parts in the tokenized results and ensure that each word appears only once. In this way, a total vocabulary is generated.

In the third step, all complaint texts are searched. If a word from the total vocabulary occurs in a particular complaint text, the corresponding position is marked with 1. If it does not appear, it is marked with 0. This creates a matrix with words and tokens as horizontal and vertical axes. Each complaint text can be regarded as a vector of 1s and 0s.

Feature Extraction

After preprocessing, feature extraction was adopted before model training. The features are presented in text form, whereby words and phrases with a strong semantic meaning are included as a feature set. The feature set contains most of the information from the entire text, which is beneficial for document classification. Content that is not included in the feature set may result in the loss of some semantic information but has minimal impact on the classification task. Complaint texts usually have a length of 10-100 words and are therefore relatively short. To achieve a relatively accurate classification, the TF-IDF technique was used for the extraction of text features.

After the preprocessing step, there are still many semantically meaningless particles or signs in the text. For example, "doctor" appears frequently in the text, but its contribution to text classification is relatively small. In addition to the common 841

XSL•FO
RenderX

Chinese stop words, we included an additional 17 frequently occurring but semantically insignificant words from the medical complaint domain into our stop words list based on unanimous recommendations from the staff of our collaborating hospital's PAC. This decision was made based on our previous experience, as detailed in Multimedia Appendix 4. By including them as stop words, we can focus on more specific and meaningful keywords and thus improve the accuracy and relevance of extracting high-frequency words.

Semantic Analysis

Due to the singularity of the environment in which patients complain, the content of the text has a high similarity in terms of scenes and semantics. Therefore, in addition to using Word-level TF-IDF, we also used Ngram-level TF-IDF to examine the impact of consecutive words on the importance of text. Given our dataset's modest size of approximately 2600 cases and the need for higher granularity in data analysis, the decision was made to use n=2 for Ngram-level TF-IDF.

After TF-IDF analysis and extension of existing stop words, the problem of particles such as "doctor" can be alleviated, and the feature text is more suitable for the following ML text classification training. For example, the complaint text "Doctor issued unnecessary examination orders for financial reasons" was changed to "unnecessary examination orders financial reasons." The top 10 high-probability words and word clouds for each type of complaint are calculated and displayed. This step not only allows for an understanding of the basic structure of existing complaint text data but also enables the examination of the correctness of manually labeled complaint texts, preparing necessary groundwork for subsequent model training and verification.

Unbalanced Data Handling

The degree of imbalance of dataset is based on the proportion of a minority class in the whole dataset and could range from mild (20%-40%), moderate (1%-20%) to vigorous (<1%) imbalances [40]. Previous studies showed that the resampling approach is a useful preprocessing step to handle the imbalanced dataset [41]. This method modifies the imbalanced distribution of the majority and minority classes at the data level before training with classifiers. Before training the datasets, we used the Synthetic Minority Oversampling Technique (SMOTE) as an imbalanced adjustment strategy [42]. The decision was made due to a moderate dataset imbalance (sense of responsibility/communication problem=11.9%). The datasets of the minority class, including diagnosis and treatment, management problem, and sense of responsibility, were all up sampled to 719. Unlike regular SMOTE, we matched the data volume of minority classes to the majority class through up sampling, while keeping the actual amount of data in the majority class unchanged. This maneuvering minimized the impact on the raw data distribution. One important point to emphasize is that SMOTE only oversamples the internal data used for training and validation, while the independent external data used for testing remains untouched.

Classification Model Training and Validation

In order to ensure the consistency of the labeling by the 2 experts, the complaint data were independently labeled by the 2 experts. Secondary annotations for the data of different categories were made by PAC staff from our cooperative hospital, comprising 3 people in total. Finally, the classification results were counted from 5 people for this annotation, and the category that received the most votes was determined as the final complaint classification annotation. We implemented a comparison of several well-known ML classifiers to determine if a supervised ML algorithm can achieve a reasonable classification accuracy compared to the expert rules. The complaint types are "communication problem," "diagnosis and treatment," "management problem," and "sense of responsibility." The sample counts for each type are shown in Table 1.

In total, 3 ML methods (MLR, MNB, and SVMs) were used to train and validate the model. In the training process, 75% (539/719) of the data in each category were used for training, the rest of 25% (180/719) was used for verification. Another 376 patient complaint records from Hangzhou Cancer Hospital were used for external testing of the trained model with the best performance in the training and verification section. The composition of the 376 patient complaint records is communication problem (n=122), diagnosis and treatment (n=89), management problem (n=85), and sense of responsibility (n=80). The performance of ML algorithms in the training and verification sets is shown in Table 2. To assess the generalization ability of the trained model in a more objective manner, a 5-fold cross-validation (CV) was applied to evaluate the model performance during external testing. Figure 1 summarizes the entire process of preprocessing and ML method for patient complaint classification.

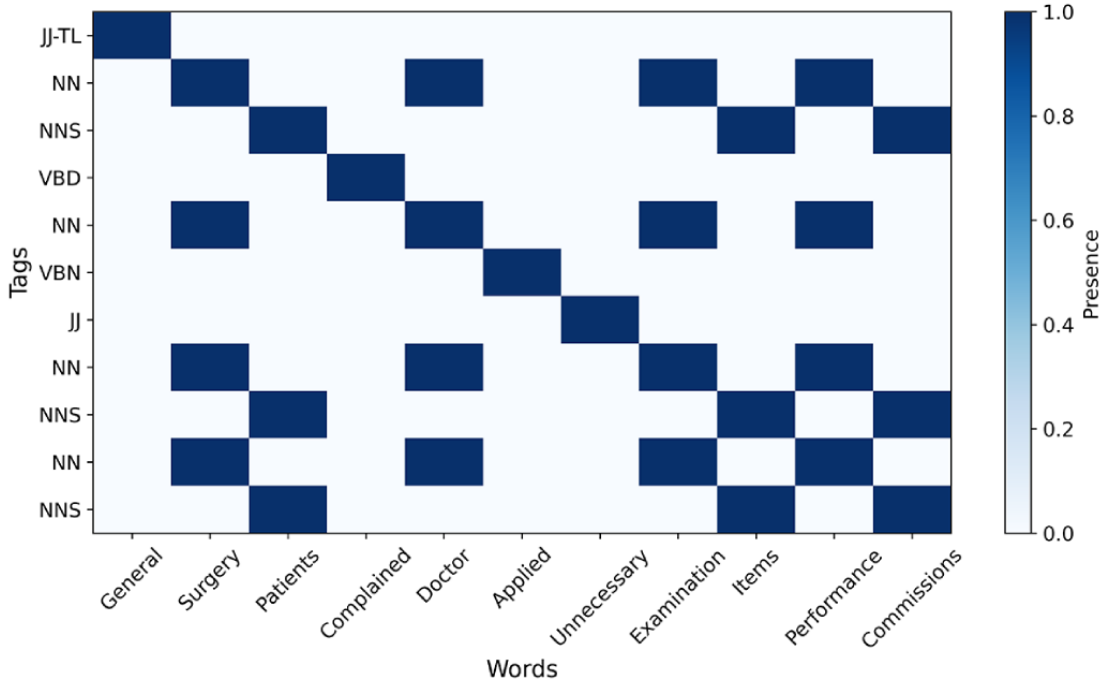
Ethical Considerations

From an ethical standpoint, the present study focused on the examination of public behavior in human subjects. The information collection methods used by the researchers were designed to ensure that subjects could not be directly identified, nor could they be indirectly identified through associated identifiers. To facilitate the effective handling of patient complaints, informed consent was obtained for telephone recordings or written complaints, with access to this information restricted to designated hospital departments. In the context of this research, only the specific content of patient complaints was analyzed, without any extraction or linkage to personal identifiable information. Furthermore, the identities of hospital staff members who were the subjects of complaints were anonymized, with only their departmental affiliation being retained. This approach served to mitigate potential conflicts between complainants and the staff involved. In addition, the potential for harm or discomfort anticipated in the study did not surpass that which individuals might have experienced in daily life or during standard physical and psychological examinations. Consequently, the hospital's ethics review committee granted a waiver of review for this research.

The study was carried out in compliance with the Declaration of Helsinki and received ethical approval as a waiver of review from the Ethics Committee of Hangzhou Red Cross Hospital.

Results

Overview



In our investigation, we discovered that out of 1817 patient complaints, approximately 23 cases, accounting for 1.3% of the total, required modification post translation by ChatGPT 3.5 to avoid potential ambiguity. Among these cases, communication problem accounted for 7 instances, diagnosis and treatment only had 1, management problem had 4, while sense of responsibility constituted 11 cases. Most ambiguities were concentrated within communication problem and sense of responsibility categories, with relatively fewer occurrences in the more objective diagnosis and treatment and Management Problem categories. This observation may be attributed to the inherent difficulty patients encounter in articulating issues related to communication problem and sense of responsibility, compared with the relatively straightforward nature of diagnosis and treatment and management problem categories.

The HMM-Bigram algorithm was used for part-of-speech tagging. For the input text: "General surgery patients complained that unnecessary examination items were applied by the doctor," the tagging results are as follows: [('General', 'JJ-TL'), ('surgery', 'NN'), ('patients', 'NNS'), ('complained', 'VBD'), ('that', 'DT'), ('doctor', 'NN'), ('applied', 'VBN'), ('unnecessary', 'JJ'), ('examination', 'NN'), ('items', 'NNS'), ('performance', 'NN'), ('commissions', 'NNS')]. Each tag consists of 2 parts, the first being the word itself, and the second being the part-of-speech tag for that word. For example, in the first tag of the results ('General', 'JJ-TL'), "General" is the word, and "JJ-TL" is its part-of-speech tag. In this tag, "JJ" indicates an adjective, while "TL" represents the word's tag in the Brown Corpus. Similarly, ('surgery', 'NN') indicates that "surgery" is a noun.

The following image (Figure 2) illustrates a matrix with words and tokens as horizontal and vertical axes with the HMM-Bigram algorithm.

In the methodology section, 2 methods, Word-level TF-IDF and Ngram-level TF-IDF (with n=2), were used for feature extraction from the text. The TF-IDF values and their performance on the training and verification sets are shown in Figure 3 and Table 3, respectively.

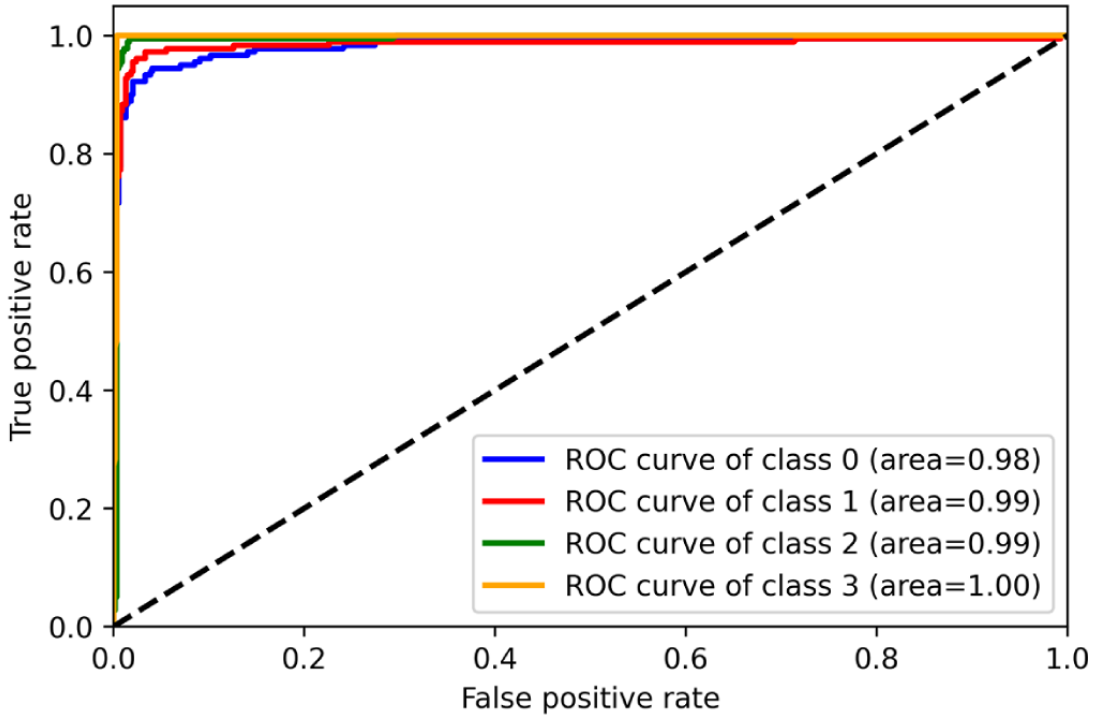
Semantic Analysis

A total of 4 complaint categories underwent preprocessing after incorporating expended stop words to enhance the specificity of medical complaints. This process generated high-frequency word histograms, and the word frequency analysis results for the 4 types of complaints will be uploaded as supplementary files (Multimedia Appendices). The top 3 vocabulary words in the category of "communication problem" are "explanation," "enough," and "believes." In the category of "diagnosis and treatment" complaints, apart from "diagnosis and treatment" itself, the main concerns were "effect," "pediatric," and "emergency." In the category of "management problem" complaints, the primary content revolves around "clinic," "waiting," and "time." As for the category of "sense of responsibility," the prominent content includes "medicine," "back," and "went."

Performance of Patient Complaint Classification Models

The performance of 3 ML models in the training and validation sets was demonstrated in Table 2 (for more detailed data including the 95% CIs for each metric, please refer to Multimedia Appendix 5). It was found that MLR achieved the best performance in classifying the communication problem, as assessed by F_1-score. However, in the classification tasks of



XSL•FO
RenderX

the remaining 3 categories, SVM outperformed MLR and MNB, comprehensively. Furthermore, from the training and validation iteration process, it can be observed that the model began to converge well by the eighth epoch (Figures 4 and 5). In addition, the best model achieved very high receiver operating characteristic (ROC) values (ROC>0.97) in classifying the 4 types on the test set. Hence, the SVM algorithm was adopted for the subsequent external data validation section with a 5-fold CV method applied. A more detailed comparison of the point estimate and 95% CIs for each model's performance metrics has been included in Multimedia Appendix 6.

Figure 4. Demonstration of training and validation performance in machine learning iteration process. Training and validation performance of Support Vector Machine. acc: accuracy.

Figure 5. Training and validation performance of Support Vector Machine (receiver operating characteristic curve). ROC: receiver operating characteristic.

Stability of Model Iteration Process

To monitor the stability of the model's training effects during the machine-learning process, we set a maximum iteration number of 30. It was found that all ML algorithms perfectly converged in the first 20 iterations, and the MLR had the most stable output and the best generalization performance during the training and validation iterations (Figures 6-8). However, due to the use of the SGD (Stochastic Gradient Descent) algorithm, the SVM algorithm tended to output significantly fluctuating results during the training process (Figures 4 and 5). Although the MNB algorithm performed well on the training set, it exhibited overfitting and mediocre generalization ability on the test set (Figures 9 and 10).

Performance of the 5-Fold SVMs Algorithm on the External Test Dataset

It was inspiring to see that the SVM classification algorithm achieved a commendable result in accurately categorizing 3 distinct types of patient complaints (communication problem, diagnosis, treatment, and management problem) on the external test dataset. The average area under the curve (AUC) for these 3 types was 0.94, 0.86, and 0.81, respectively, with an average SD below 0.1 in all 3 types of patient complaints (Figures 11-13). However, the average AUC for the sense of responsibility category was only 0.7 (in the 5-fold testing, the minimum AUC is 0.48, and the maximum AUC is only 0.82; Figure 14).

Discussion

Principal Findings

Ambiguities arise more frequently in areas where patients may struggle to clearly articulate their concerns, particularly in subjective categories like communication and responsibility. Word-level TF-IDF proved sufficient for our needs. The result also revealed that Ngram-level methods did not significantly enhance model performance, even after optimal tuning of N. The NLP-driven SVM algorithm effectively classifies patient complaint texts, demonstrating superior performance in both internal and external test sets for communication and management problems.

XSL•FO
RenderX

Related Systems for Patient Complaints Text Classification

Traditional text classification relies on hand-coded keyword-based methods suffer from low efficiency and accuracy. The manual creation of these classifiers (often in the form of expert rules) is a difficult and expensive process [43] that requires the coordinated work of medical experts and knowledge engineers. To the best of our knowledge, there are currently 3 manual approaches to classifying patient complaint texts: The first one is Patient Advocacy Reporting System (PARS), the second mainly focused on Healthcare Complaint Analysis Tool (HCAT [44]), developed by UK researchers Alex Gillespie and Tom Reader, and the last one is based on the use of the qualitative analysis software NVivo [45,46], launched by the Australian company QSR (now Lumivero). However, both HCAT and NVivo require human classification at various stages of the classification process. Therefore, these methods are at best semiautomatic means for text classification. They have not yet fully solved the problem of manual intervention in the classification process [47].

Ngram-Level TF-IDF Failed to Enhance Classification Performance

As gleaned from Table 3, the increment in precision, recall, and F_1-score with Ngram-level TF-IDF (n=2) merely amounted to 1%, rising from 0.91 to 0.92. The reason analysis for why Ngram-level TF-IDF (n=2) did not improve the classification performance of Word-level TF-IDF could be as described further. First, the primary reason might be Ngram-level TF-IDF with n=2 considers pairs of words, capturing some contextual information. However, this may not always lead to significant improvements, especially when text prone to ambiguity undergoes review by language experts, the additional information obtainable from conjunctions becomes relatively limited. The second possible reason was Ngram-level TF-IDF, particularly with smaller datasets (only 2157 cases for training), which could be prone to overfitting. It might capture too much noise or specific patterns from the training data that did not generalize well to unseen data, resulting in worse performance on the test set. For tuning the parameter of Ngram-level TF-IDF, we used the MNB method and set N to values ranging from 1 to 5. The results were depicted in Multimedia Appendix 7. It can be observed that when N=1, the model achieved its maximum values for precision, recall, and F_1-score. Consequently, N=1 for Ngram-level TF-IDF corresponds to using Word-level TF-IDF.

The Feasibility of Using ChatGPT as a Bulk Translation Tool

The process of translating patient complaints into English through ChatGPT could potentially introduce several issues into the classification, especially concerning the accuracy of translation. Common knowledge holds by European and American litterateurs that translating ancient Chinese poetry into English is extremely challenging. However, in a study reported by Gao et al [48], they compared the performances of ChatGPT with Google Translate and DeepL Translator in translating Chinese classical poetry in terms of fidelity, fluency, language style, and machine translation style. The results revealed that ChatGPT outperformed Google Translate and DeepL Translator in all evaluation criteria. Therefore, in our research, the difficulty level of the Chinese text of patient complaints was significantly lower compared with classical poetry. The texts were generally very clear and complete, containing specific elements and structures such as precise time, location, individuals involved, and events. As the complainants were patients and their family members, the language was relatively common, devoid of esoteric medical terminology. Consequently, for ChatGPT 3.5, the translation results were very close to the outcomes of human translations. In addition, 2 postgraduates with English language skills were responsible for reviewing the machine-translated texts. If there were obvious translation errors, the texts were corrected after the 2 individuals proposed unanimous modification suggestions. Therefore, we believe that at least using ChatGPT 3.5 for translating bulk of simple complaint texts into English was acceptable and efficient, as we did not have to struggle with balancing the accuracy and efficiency of the translation.

Appropriate Number and Types of Categories

Reader et al [49] developed a coding taxonomy for analyzing patient complaints. The subcategories were thematically grouped into 7 categories and then 3 conceptually distinct domains. Their "3-domain" classification system is similar to our "4-category" one. For instance, "the safety and quality of clinical care" corresponds to our "diagnosis and treatment," "management of health care organizations" corresponds to our "management problem," and "healthcare staff-patient relationships" corresponds to our "communication problem" and "sense of responsibility."

We subdivided "healthcare staff-patient relationships" into 2 categories because it was considered that communication issues were skill-related problems that can be addressed through targeted training. At the same time, the sense of responsibility is a matter of the staff's character that requires long-term education and may even necessitate stricter rewards and penalties to improve. They also reported that the most common issues complained about were "treatment" (113,738/88,069, 15.6%) and "communication" (12,065/88,069, 13.7%). However, our research shows that complaints mainly stem from "communication" (719/1465, 49.9%) and "diagnosis and treatment" (376/1465, 26.1%), respectively. However, when focusing on categorizing complaints, we must analyze the data sources, as there can be significant differences between patient complaint data from specialized hospitals and data from comprehensive hospitals. Even within the same hospital, there can be significant variations in complaint data between different departments.

Another similar research carried out by HaCohen-Kerner et al [50], showed that their study attempted to reduce the number of categories for automatic text classification from 7 to 4 across 2073 samples. The predictive model's performance reached its peak accuracy (93.8%) on the test set when the number of categories was reduced to 4. Therefore, it was reasonable in our research to limit the predicted categories to 4 in similar sample sizes.

XSL•FO
RenderX

Optimal Number of Folds to Use in a K-Fold Cross-Validation in External Dataset

It is well-accepted that larger k means less bias toward overestimating the true expected error but higher variance and higher running time. In both of these cases, selecting k depends on the same thing. We must ensure that the training set and testing set are drawn from the same distribution and that both sets contain sufficient variation such that the underlining distribution is represented. The problem we encountered involved using training and verification data sourced from a general hospital and external test data from a specialized cancer hospital. Discrepancies in patient treatment expectations and compliance between the 2 hospitals may introduce biases in the distribution of complaint data. Consequently, we opted to use CV testing during external testing to mitigate the potential impact of these factors on data representation.

Selecting k is not an exact science because it is challenging to find a balance in a fold of data that effectively represents the overall dataset while also minimizing data bias. We try to use a 5-fold cross validation, in this case, with approximately 75 (376×0.2) instances per fold, conducting 10-folds CV would result in only about 37 instances per fold. As a result, all 4 types of complaints may not be encompassed within a single fold. However, if our dataset size increases dramatically, like if we have over 10,000 instances, a 10-fold cross validation would lead in folds of 1000 instances. In a related work carried by Oyedele [51], a bigger independent testing set of size 10,000 (independently sampled from the same distribution and using the same parameters with 5000 samples per class) was created in order to estimate the performance (ie, error probability) of the network. Therefore, for a task with 2 classifications and 10,000 samples, they adopt a 10-fold CV, which poses much less risk of bias in the results compared with our 5-fold CV approach.

Advantages of Using TF-IDF and SVM for Patient Complaint Text Classification

Elmessiry et al [52] compared a text classification method using 6 ML classifiers and suggested that the TF-IDF–based random forest classification algorithm has advantages in text classification both in accuracy and F_1-score. However, based on their results, the achieved accuracy, F_1-score, sensitivity, and specificity in correctly classifying patient complaints were relatively low, with values of 82%, 81%, 0.76, and 0.87 respectively.

Previous studies have used ML algorithms such as SVMs [53], Logistic Regression [54], and Naive Bayes classifiers [55] for classification purposes [56]. Compared with other ML algorithms, the SVM algorithm has demonstrated superior performance in text classification, which aligns closely with our research findings. The strong generalization capability of SVM in high-dimensional feature spaces can be credited for their effectiveness in text classification tasks. SVMs eliminate the need for feature selection, simplifying the classification process. Their regularization parameters help prevent overfitting, making them robust in handling noisy data and datasets with many features. In addition, SVMs are efficient in processing small to medium-sized datasets, producing reliable performance even with limited training data. Our research also confirmed that, even with very limited sample sizes, such as in the cases of “management problem” and “sense of responsibility” with raw data sizes of only 260 and 86, the SVM algorithm achieved average AUC scores of 0.81 and 0.7, respectively, in external test sets.

In the text preprocessing and ML section, we used the pipeline training architecture, which can be seen as a tool to connect multiple data processing and model training steps. It allows users to combine multiple operations in a specific order to form a complete flow and ensures data flows between each operation. Through pipeline, data preprocessing, feature engineering, model training, model evaluation, and other steps can be organically combined into a complete ML process. The advantage of doing this is improving code maintainability and reusability, making it easier to perform the same workflow on different datasets and better managing dependencies between each step.

We initialized SVM parameters as listed in Multimedia Appendix 8 and adopted a fine-tuning with genetic algorithm–SVM as proposed by Ali et al [57] and Nair et al [58], which has the best model performance while keeping a reasonable optimization time. The detailed tuning process and prediction results before and after tuning have been illustrated in Multimedia Appendices 9 and 10).

ML Model Selection Strategy

A critical consideration is the balance between model accuracy and model simplicity or interpretability. High accuracy is essential for a model’s effectiveness, especially in scenarios that rely on making correct predictions. While complex models (such as DL or ensemble methods) can achieve higher accuracy due to their ability to capture intricate patterns in the data, they often require large amounts of data and substantial computational resources. Models with high interpretability foster trust and accountability, as stakeholders can see and understand how decisions are made. However, there is a trade-off here; complex models may exhibit lower bias but higher variance, meaning they might fit the training data very well but perform poorly on unseen data due to overfitting. Conversely, simpler models tend to have higher bias, potentially missing significant patterns in the data, but they perform more consistently across different datasets.

In this study, a hybrid strategy was adopted in ML model selection. In the first stage, 3 ML algorithms (MLR, MNB, and SVM) were used for model training and validation. In the second stage, the best-performing model was tested using 5-fold CV on external data. Ultimately, the choice of model should be guided by the specific context of the problem, including the importance of accuracy versus interpretability, the stakes involved, and the audience for the model outputs. In the specific task of patient complaint classification, we prioritize the generalization ability of the model, which means achieving the best prediction accuracy on unseen data. This preference is crucial because if the model’s generalization is insufficient, misclassified complaint cases will require more human effort to resolve, and the resulting delay in complaint resolution might exacerbate patient-doctor conflicts and disputes.

XSL•FO
RenderX

Limitations and Further Research Directions

In this study, the original data were initially in Microsoft Excel format, and each row of complaint content was separately saved as a text file before subsequent data cleaning and analysis were performed. Consequently, similar processing was required during application to ensure compatibility with the model. Failure to align the actual input data format with that of the model could lead to the inability of the model to predict outcomes correctly. Therefore, in subsequent work, a complaint text organization code will be developed to support both individual complaint text prediction through copy-and-paste operations and batch text processing.

It is noteworthy that despite ultimately selecting the SVM algorithm for validating external data, it displayed consistent fluctuations in learning accuracy and verification loss throughout in training iteration. We attempted to improve the situation by reducing the learning rate from 0.5 to 0.1, but this did not yield positive results. After ruling out factors such as randomness and model complexity, we speculate that it is likely due to the SVM algorithm using SGD optimization, which can cause the model to converge to local minimum or exhibit more significant fluctuations in results. Another possibility may be the imbalance in our raw data distribution, with the third class, “management problem,” and the fourth class, “sense of responsibility,” having too few data samples.

The primary challenge addressed in this study pertains to the imbalanced distribution of raw data and the limited dataset size. Although we used SMOTE to adjust for imbalanced data, the synthetic samples generated by SMOTE may introduce noise or distortions into the dataset, potentially leading to information loss and affecting the classifier’s performance on the minority class. To address this issue, our future work will involve collaborative efforts with multiple hospitals to enhance data volume. Furthermore, as is well-known, more advanced NLP models (eg, BERT) provide contextual understanding, enabling them to grasp complex relationships within text and improve analysis accuracy and depth. As a future direction for our work, we plan to develop a user-friendly graphical user software interface powered by BERT to facilitate the classification and management of complaints by PAC personnel.

Another issue that must be stated is that the semantic features extracted using NLP technology are quite different from the common scenarios based on explicit independent and dependent variables. In ML problems with clear relationships between independent and dependent variables, it is possible to rank the importance of independent variables, as these features have stable meanings themselves. However, semantic features are influenced by the linguistic context, meaning that the same word can have different meanings in different language environments and contexts. Therefore, our results cannot pinpoint which specific words significantly influence the classification of complaint text types.

Conclusion

The NLP combined SVM algorithm performs well in automatically categorizing patient complaint texts. Furthermore, it has the best performance in both internal and external test sets for communication and management problems. However, caution is necessary when used for the classification of sense of responsibility. It has excellent prospects for application in medical institutions with many complaints and a shortage of medical-patient processing specialists.

Abstract

Background: Accurately measuring the health care needs of patients with different diseases remains a public health challenge for health care management worldwide. There is a need for new computational methods to be able to assess the health care resources required by patients with different diseases to avoid wasting resources.

Objective: This study aimed to assessing dissatisfaction with allocation of health care resources from the perspective of patients with different diseases that can help optimize resource allocation and better achieve several of the Sustainable Development Goals (SDGs), such as SDG 3 (“Good Health and Well-being”). Our goal was to show the effectiveness and practicality of large language models (LLMs) in assessing the distribution of health care resources.

Methods: We used aspect-based sentiment analysis (ABSA), which can divide textual data into several aspects for sentiment analysis. In this study, we used Chat Generative Pretrained Transformer (ChatGPT) to perform ABSA of patient reviews based on 3 aspects (patient experience, physician skills and efficiency, and infrastructure and administration)00 in which we embedded chain-of-thought (CoT) prompting and compared the performance of Chinese and English LLMs on a Chinese dataset. Additionally, we used the *International Classification of Diseases 11th Revision* (ICD-11) application programming interface (API) to classify the sentiment analysis results into different disease categories.

Results: We evaluated the performance of the models by comparing predicted sentiments (either positive or negative) with the labels judged by human evaluators in terms of the aforementioned 3 aspects. The results showed that ChatGPT 3.5 is superior in a combination of stability, expense, and runtime considerations compared to ChatGPT-4o and Qwen-7b. The weighted total precision of our method based on the ABSA of patient reviews was 0.907, while the average accuracy of all 3 sampling methods was 0.893. Both values suggested that the model was able to achieve our objective. Using our approach, we identified that dissatisfaction is highest for sex-related diseases and lowest for circulatory diseases and that the need for better infrastructure and administration is much higher for blood-related diseases than for other diseases in China.

Conclusions: The results prove that our method with LLMs can use patient reviews and the ICD-11 classification to assess the health care needs of patients with different diseases, which can assist with resource allocation rationally.

Introduction

With the imbalance in regional economic development, there are 2 extreme problems in the accurate assessment of medical resources. On the one hand, health care management cannot accurately measure patients' health care needs [1]. On the other hand, the assessment of medical resources cannot be accurate for each clinical department in hospitals, which leads to wastage of health care resources [2]. Research has shown that the improvement of health care resources enhances patient satisfaction [3]. To promote the sustainable development of the world, the United Nations has been advocating 17 Sustainable Development Goals (SDGs) since 2015. SDG 3 ("Good Health and Well-being") and SDG 10 ("Reducing Inequalities") suggest that the realization of universal health care coverage and avoiding lack or wastage of health care resources are urgent tasks [4-6]. SDG 9 ("Industry, Innovation and Infrastructure") is about maintaining scientific research and innovation with the sustainable development of health care infrastructure and resources [7]. Overall, it is crucial to guarantee equitable access to health care services for all [8]. In this context, it is particularly important to assess health care resources based on patient needs within specific clinical departments [9]. For this reason, in this study, we planned to analyze patient dissatisfaction through their reviews after consultations to understand a macro view of their health care needs.

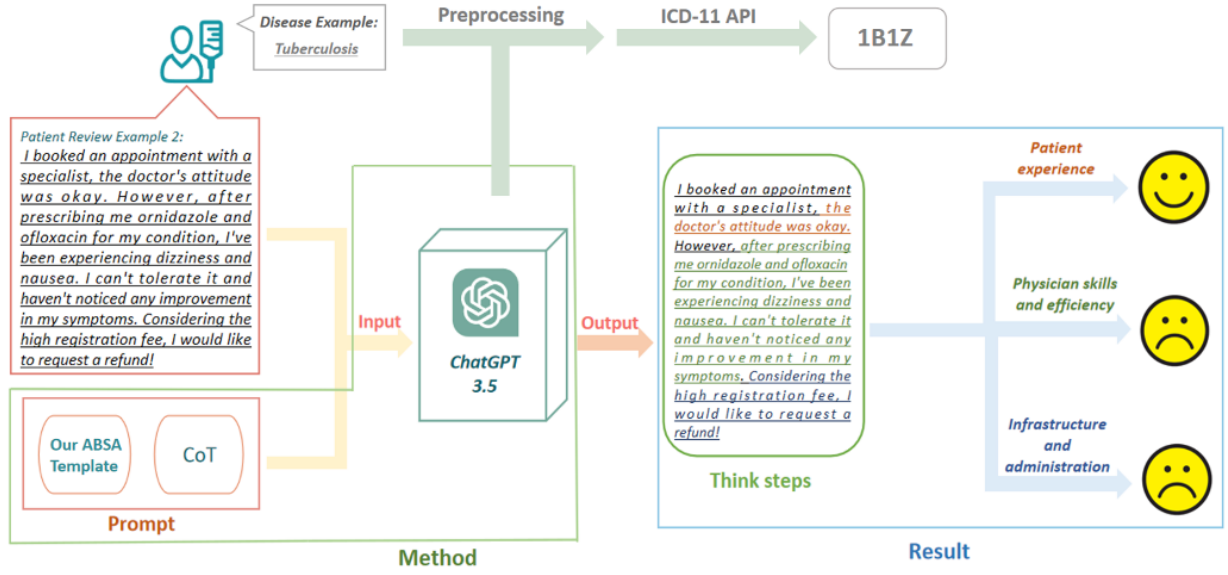
Chat Generative Pretrained Transformer (ChatGPT), a representative model of large language models (LLMs), was introduced in November 2022 [10], and its responsiveness as well as performance make it a possibility for further scientific research [11]. Several studies have pointed out that LLMs show strong performance in medical [12], financial [13], and education [14] fields, especially in the medical field, where ChatGPT shows reliable accuracy in questioning dialogues [15], diagnosing illnesses [16], suggesting treatments [17], and predicting prognosis [18]. Therefore, we wanted introduce LLMs into this health care needs study because with the powerful capability of LLMs, we can accomplish an in-depth assessment of health care resources.

Traditional sentiment analysis can determine whether the sentiment of a text is negative or positive, but it cannot determine sentiment from multiple perspectives [19]. However, some studies have shown that using aspect-based sentiment analysis (ABSA) can determine the affective state of a text from multiple perspectives, which is more suitable for us to determine the different perspectives of a patient's health care needs [20-22], and therefore, we adopted ABSA for this study [20]. In this work, we proposed ABSA prompts that include "patient experience," "physician skills and efficiency," and "infrastructure and administration." ABSA can more accurately indicate which of the patients' health care needs are not being met by refining the direction of patient dissatisfaction with health care services, coupled with modern macro analysis of big data, in order to assess overall health care resources. However, in specific clinical application scenarios, different diseases have different disease characteristics, as well as their own different functional managers [23,24], so it is clinically important to analyze data from patient reviews of different disease types.

The *International Classification of Diseases 11th Revision* (ICD-11) coding data have been widely used in many fields [25], such as health statistics, public health monitoring, health care performance evaluation, and reimbursement [26]. ICD-11 is the latest international health information standard, adopted at the 72nd World Health Assembly in 2019, and was implemented in 2022. ICD-11 is a modern, integrated classification and nomenclature system with a modern digital medical model with application programming interfaces (APIs). One of the critical reasons why the World Health Organization (WHO) wants countries to move to ICD-11 is that a standardized classification based on the latest medical and scientific knowledge provides the best access to valuable data for prevention, resource allocation, or evaluation [2]. Several studies have shown that ICD-11 can be integrated with electronic medical records, and WHO's multiple tools and guidelines can reduce training and implementation costs. Therefore, it is critical to expand ICD-11 research and program implementation worldwide [27].

As such, using ICD-11 to classify patients with different diseases, together with our ABSA prompts, it is possible to find differences in the satisfaction and dissatisfaction related to health care resource allocation among patients with different diseases. However, since the classification and statistical standards of medical diseases vary from one health care institution to another, normalization using ICD-11 as the standard will allow comparison of the same disease types to assess the balance of medical resources, as well as a comparison of different disease types to evaluate the differences in health care needs. By standardizing the classification of diseases, it will be possible to not only collect as much valid data as possible under the same standard but also conduct comparative studies of health care resources more effectively. Some researchers have indicated that they tested the coding accuracy of ICD-11 in a large-scale pilot study in 59 public hospitals in China. The results indicated that ICD-11 is well in line with Chinese disease classification habits, with the accuracy of the total coding domains and the accuracy of the word stem codes reaching 82.9% and 92.2%, respectively [28].

In this study, we analyzed patient comments using a LLM and determined the health care medical needs of patients with different diseases using ICD-11. We also discussed the reasons for these results in the context of our findings and the potential applications in clinical settings.



XSL•FO
RenderX

Methods

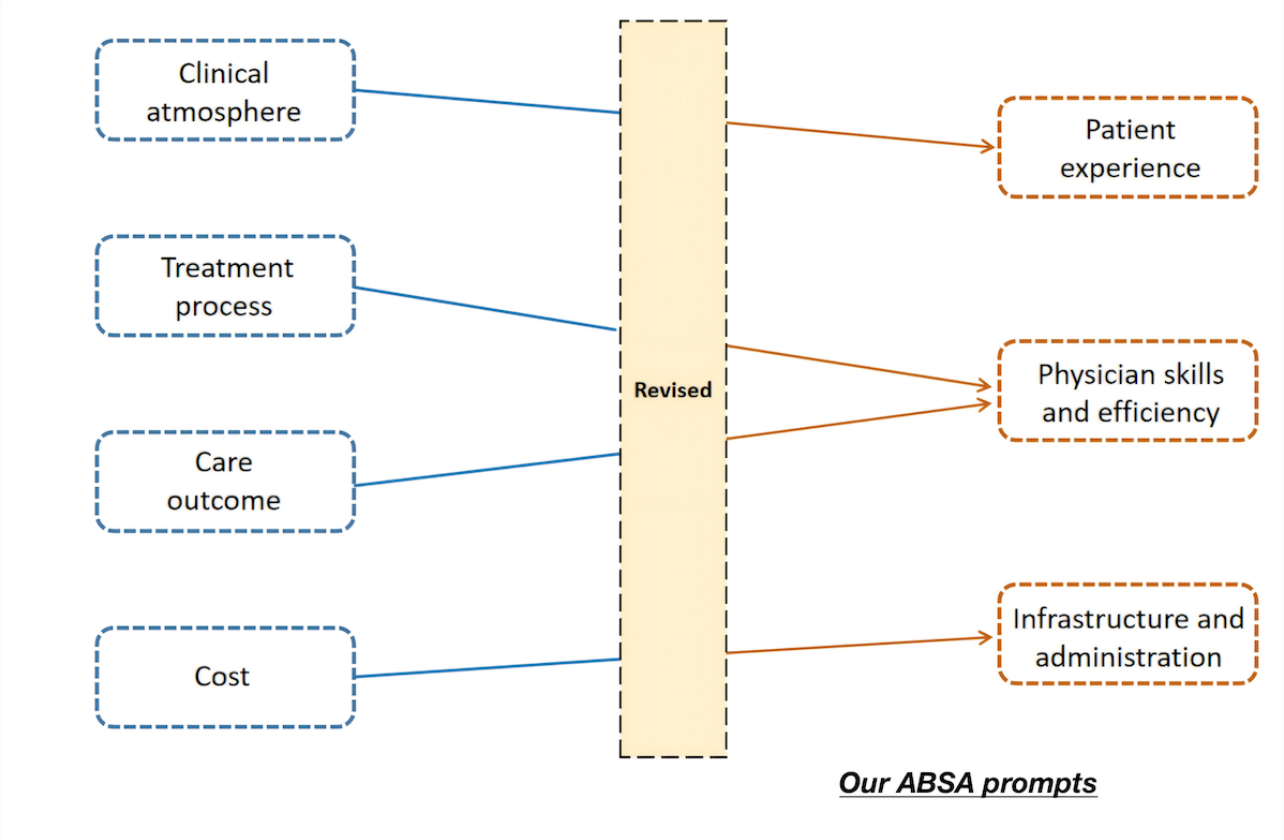
Architecture of the Experiment

Figure 1 illustrates the proposed architecture for identifying medical needs from patient comments. In this architecture, we used our ABSA prompts in conjunction with chain-of-thought (CoT) prompting to generate questions fed into an LLM to analyze the content of patient comments. Considering the practicality and cost, we chose ChatGPT 3.5 Turbo as the LLM for our experiments as it is the most cost-effective choice. In the output, the model should be able to provide 3 categories of sentiment results. For example, the sample review presented in Figure 1 shows a positive sentiment for the category "patient experience" but a negative sentiment for the categories "physician skills and efficiency" and "infrastructure and administration." Finally, we preprocessed the patients' disease names through ChatGPT and typed the disease codes through the ICD-11 API. For example, the disease code 1B1Z returned from the API suggested that the disease belongs to Chapter 01 (the first digits of the code) of ICD-11.

Figure 1. Proposed architecture for ABSA for analyzing patient data across different diseases using ChatGPT and the ICD-11 API. ABSA: aspect-based sentiment analysis; API: application programming interface; ChatGPT: Chat Generative Pretrained Transformer; CoT: chain of thought; ICD-11: *International Classification of Diseases 11th Revision*.

Data

The data used in this study came from Haodf Online [29], which is the most well-known online health care website in mainland China, with more than 6.1 million patients having uploaded their visit experiences [30]. Other studies have pointed out the data from online health care websites as important and valuable for research [31,32]. In addition, a study has shown that ChatGPT can directly process Chinese data without additional translation [33]. The comments contain the name of the disease, the type of treatment, the treatment outcome, the date of the visit, the location, the hospital name, the physician's name, and patient comments. The datasets are in Chinese. The platform validates the comments to ensure that actual patients publish them.



We analyzed 552,764 comments on Haodf Online from November 2022 to June 2023. The data were not manually screened or deleted and spanned from October 2003 to June 2023. A total of 504,198 comments (91.2%) were retained after initial cleaning, including removing incomplete and duplicate data.

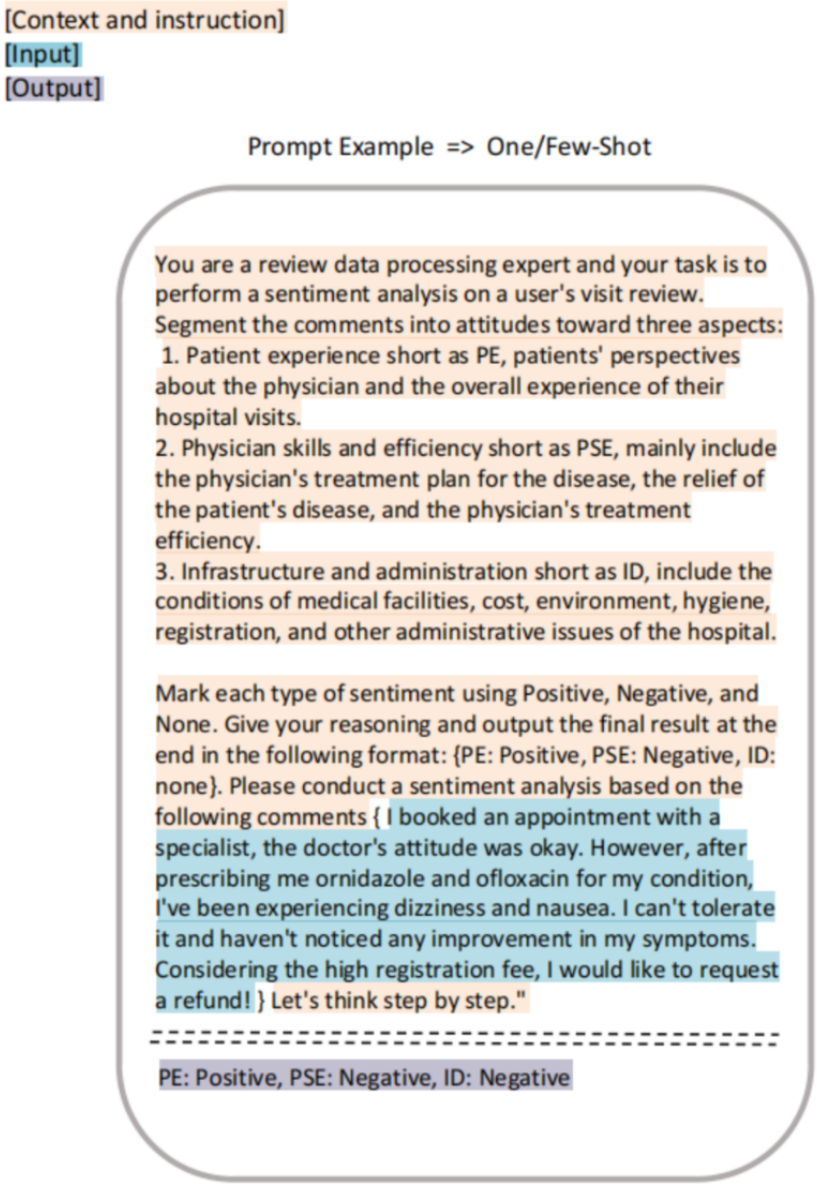
Aspect-Based Sentiment Analysis Prompts

Traditional sentiment analysis can only categorize sentiments for overall reviews and can only be performed with the entire content. However, positive and negative emotions may exist in long comments addressing different aspects of the medical process. Based on the existing literature and data, we designed prompts to address this issue [29,34]. Afrashtehfar et al [34] constructed an instrument that successfully assessed patient satisfaction in several ways. We optimized the latest version of their tool. Specifically, as shown in Figure 2, author QZ summarized 3 categories based on Afrashtehfar et al's [34] findings and his own clinical experience and observations.

XSL•FO
RenderX

Figure 2. Illustration of formulating ABSA prompts from the dimensions of patient satisfaction. ABSA: aspect-based sentiment analysis.

Specifically, "patient experience" includes perceptions of physicians, such as attitudes toward attending the hospital and the overall experience of attending the hospital. Second, "physician skill and efficiency" includes the physician's treatment plan for the patient's disease, the remission of the disease, and the physician's treatment efficiency. Third, "infrastructure and administration" includes medical facility conditions, costs, the environment, hygiene, registration, and other administrative issues of the hospital. In summary, our ABSA prompts consisted of 3 categories (patient experience, physician skills and efficiency, and infrastructure and administration), all of which are clinically relevant and clinically meaningful.



Chain of Thought

Some studies have shown that the use of CoT can alleviate problems such as hallucinations in an LLM to improve its accuracy [35-38]. We used the CoT technique to differentiate between the emotions related to the various topics in the comments. This process required logical reasoning to guide the LLM step by step through the thinking process, ensuring that steps were not skipped or omitted. With CoT, the LLM was guided to analyze the comments, confirm that each topic was been evaluated, and complete all the necessary steps in generating the final answer. Compared to outputs that do not use CoT, our approach can improve accuracy and facilitate checking the reasoning logic of the model.

In addition, as shown in Figure 3, we used a zero-shot technique and added an example to the prompt to allow the model to learn to control its output. Once the LLM received our task, the CoT forced it to complete it step by step. Specifically, when ChatGPT received a patient's comment, the model first extracted all the sentences related to "patient experience" from the comment and then analyzed the sentiment. After completing the sentiment analysis for the first category, the model extracted all sentences about "physician skills and efficiency" and performed sentiment analysis. Finally, the model extracted sentences about "infrastructure and administration" for sentiment analysis and output the results of all sentiment analyses. Our prompts were written in English, which aligns with the recommendations of other studies that suggest that using English in interactions with ChatGPT results in better performance. Other studies have noted that CoT performs better in English.

Figure 3. Prompt and CoT examples used in our work. CoT: chain of thought.

ICD-11 API

It has been pointed out that the study of individual diseases is of little significance but that quantifying the distribution and determinants of different kinds of diseases is of significant importance [39,40]. Because diseases of the same kind tend to be highly interdependent, and similar diseases often share similar pathogenesis, risk factors, etc, it is much more important to perform clustered disease analyses than individual disease analyses [39,40]. Therefore, we intended to explore more meaningful information about patients' health care needs by categorizing dispersed information about individual diseases through the ICD-11 API. It is also for this reason that some countries are piloting the possibility of health care system access to the ICD-11 API [28,41-44].

The ICD API is an HTTP-based REST API that allows programmatic access to the ICD [45]. Before the advent of the ICD-11 API, the only way to obtain a disease code was to search for it one at a time. In the 4-digit disease code, the first digit is the disease chapter code. There are 24 chapters in total. In version 2024, the International Classification of Functioning, Disability, and Health (ICF) was added as the second linearization of the API [46]. All linearization endpoints can access the ICF [46]. WHO provides a set of open source ICD-11 classification tools called API [47], we used Python's Requests library to call the linearlization search method provided by the API remotely.

Although in this version (2023-01), the ICD-11 API claims to have the capability of workin with the Chinese language, in our actual test, we found that the accuracy rate is lower than that for English when the input language is Chinese. One of the reasons for this is that when inputting Chinese, there are more requirements for the text to match. For example, we found that the ICD-11 API cannot recognize the Chinese characters for "disease" or "symptom" if they are missing (similar to issues reported in other work [28,48]). However, when we translated the terms into English and entered them into the ICD-11 API, it accurately recognized them and provided a disease code regardless of whether the Chinese character was or was not missing. In summary, we used ChatGPT 3.5 to translate Chinese

XSL•FO
RenderX

disease names to solve the problem of the Chinese version of the ICD-11 API being too stringent in its search scope. In this way, the ICD-11 API generated correct results (as shown in the validation before).

Evaluation Method

To more fully assess accuracy of our method, we used 2 approaches. First, we tested the performance of our method using manually labeled test sets and calculated precision, recall, and F_1-scores. Evaluating the results using manual random sampling enhances their interpretability and makes them more comprehensive and credible. Therefore, we used a dual criterion to evaluate the output fully. Finally, we evaluated the cost and run time to assess the pertinence of our method in practical applications.

Model Performance

We manually annotated patient comment data using the 3 categories defined in our ABSA prompts. We labeled each category as "positive" or "negative" within the same comment. If the comment did not refer to a particular category, it was labeled "none." Multiple authors with medical backgrounds performed the labeling. Two annotators worked independently (and one of them is a PhD candidate in the artificial intelligence [AI] field, while the other is a specialized physician at West China Hospital of Sichuan University). If the annotation results of the two annotators were inconsistent, we invited a professional doctor from a third-party hospital to resolve the conflict. We selected a test set of 2000 comments to assess precision, recall, and F_1-scores. The F_1-score combines precision and recall and is a widely used assessment metric in multicategory and uneven classification situations. Therefore, we use the F_1-score to evaluate sentiment categorization methods. Its calculation is as follows:

TP (true positive) stands for actual cases, indicating the number of samples that the model correctly predicted as positive cases; FN stands for false-negative cases, indicating the number of samples that the model failed to predict as positive cases correctly; and FP stands for false-positive cases, indicating the number of samples that the model incorrectly predicted as positive cases. To avoid sample imbalance affecting the accuracy of the conclusions, we chose to use the modified weighted F_1-scores to calculate the model's scores using Equation 4, where i is the index of the category, which is used to indicate the category of indicators currently being calculated, and w^i is the weight of category i, defined as the proportion of the sample size of that category to the total sample size.

Reliability and Stability Evaluation

Although we used a manually labeled test set to assess the model's accuracy, several studies have pointed to the instability and unreliability of LLMs. Therefore, we used a mixture of 3 sampling methods, whose merits have been pointed out by multiple studies, to assess the reliability and stability of the LLM model in our study. Specifically, mode 1 was simple random sampling, where 2000 pieces of data were drawn at a time within the total sample; mode 2 was incremental random sampling, where a total of 4 samples were taken, with 200, 400, 600, and 800 pieces of data, from the total sample; and mode 3 was isometric sampling, with a total of 4 draws each with 500 pieces of data taken from the total sample.

Hyperparameterization

There are several adjustable hyperparameters in the GPT model we used, such as temperature, top_p, frequency_penalty, and presence_penalty. We did not change these hyperparameters but followed the default settings to ensure our experiments were broadly applicable. Thus, temperature was set to 1.0, top_p was set to 1.0, and frequency_penalty and presence_penalty were set to 0.

Ethical Considerations

The dataset in this study was anonymized, and ethical clearance was obtained from the Macao Polytechnic University (approval no: HEA005-FCA-2024).

Results

Model Comparisons

Results showed that the accuracy of GPT-4o is slightly higher than that of ChatGPT 3.5, while its running time and costs are substantially higher than those of ChatGPT 3.5, which is not consistent with the research goal of sustainable development. GPT-4o took 104 minutes to process 1000 patient reviews, while ChatGPT 3.5 took only 71 minutes. In addition, GPT-4o cost US $1.7 to run 1000 patient reviews, while ChatGPT 3.5 cost only US $0.8 per 1000 reviews. The open source model Qwen-7B cost US $0 in comparison. In addition, the accuracy of GPT-4o was only 0.004 times higher than that of ChatGPT 3.5, while the accuracy of Qwen-7B was too low at 0.682 to meet the research criteria of this study. Therefore, we selected ChatGPT 3.5 as the experimental base model.

Table 1. Accuracy, run time, and cost of the 3 candidate models.

Model	Accuracy	Run time[a] (minutes)	Cost[a] (US $)
ChatGPT[b] 3.5	0.907	71	0.8
GPT-4o	0.911	104	1.7
Qwen-7B	0.682	73	0

[a]Per 1000 reviews.

RenderX

Model Performance

We tested the model on a test set of 2000 patient reviews with labels. To demonstrate the variability of the study, we introduced 95% CIs. As shown in Table 2, the model's weighted total results indicated a precision of 0.907 (95% CI 0.865-0.949), an F_1-score of 0.793 (95% CI 0.784-0.802), and a recall of 0.748 (95% CI 0.737-0.759). Thus, the model fulfilled the quality requirements of our experiments.

Table 2. Results for model precision, F_1-score, and recall by category.

Category	F_1-score	Precision	Recall
Patient experience	0.965	0.971	0.970
Physician skills and efficiency	0.899	0.948	0.879
Infrastructure and administration	0.405	0.860	0.394
Weighted total	0.793	0.907	0.748

Model Reliability and Stability

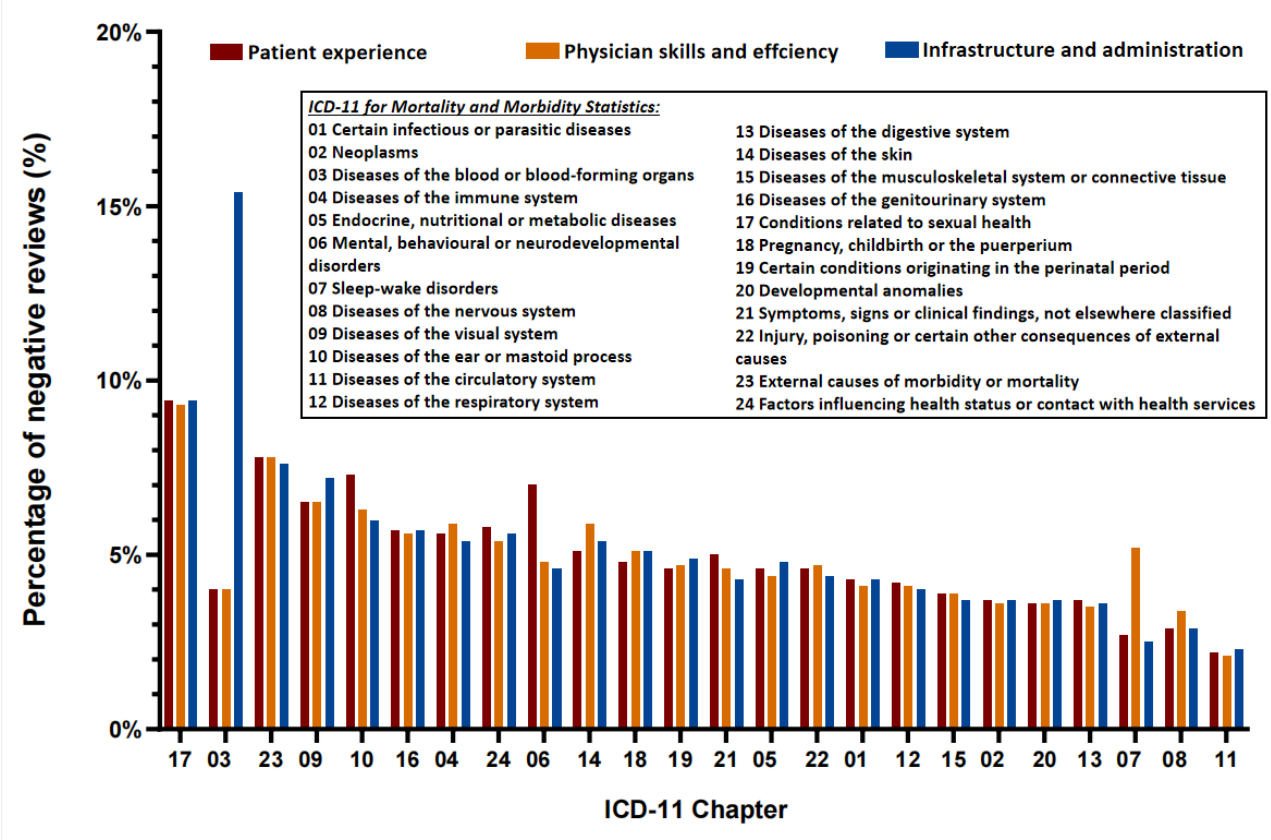
We used 3 different manual test sampling methods in this work. As shown in Table 3, the average accuracies of the 3 different sampling methods were 90.1%, 88.5%, and 89.4%, respectively. This was close to our accuracy of 0.907 described before, again confirming the reliability of both evaluation methodologies in the experiment.

Table 3. Model accuracy results for 3 manual random sampling methods.

Mode and characteristics	Sampling			
	First	Second	Third	Fourth
Mode 1 (entire sample accuracy: 90.1%)				
Sample size, n (%)	2000 (100)	—[a]	—	—
Patient experience accuracy (%)	92.2	—	—	—
Physician skills and efficiency accuracy (%)	89.4	—	—	—
Infrastructure and administration accuracy (%)	88.6	—	—	—
Mode 2 (entire sample accuracy: 88.5%)				
Sample size, n (%)	200 (10)	400 (20)	600 (30)	800 (40)
Patient experience accuracy (%)	94.0	90.3	92.5	91.3
Physician skills and efficiency accuracy (%)	90.5	88.8	89.8	88.6
Infrastructure and administration accuracy (%)	83.0	82.8	86.2	84.3
Mode 3 (entire sample accuracy: 89.4%)				
Sample size, n (%)	500 (25)	500 (25)	500 (25)	500 (25)
Patient experience accuracy (%)	93.8	95.8	89.6	90.8
Physician skills and efficiency accuracy (%)	88.8	92.4	95.4	90.4
Infrastructure and administration accuracy (%)	83.2	84.4	81.8	86.0

[a]Not applicable.

ICD-11 API Accuracy



We used Python to randomly extract 1000 disease names with ICD-11 codes from the datasets with ICD-11 chapter labels. Under the guidance of one of the authors of this paper, from the West China Hospital of Sichuan University, these data were reviewed for accuracy, and the results showed that 954 (95.4%) were correct, while 46 (4.6%) were incorrect; this accuracy of 95.4% met our experimental requirements.

Chapters of ICD-11

We calculated the distribution of the different types of diseases in ICD-11 across the 3 different categories of health care needs in our ABSA prompts. As shown in Figure 4, the diseases in ICD-11 Chapter 3 ("Diseases of the Blood or Blood-Forming Organs") showed a high degree of variability, with the percentage of negative comments on the "infrastructure and administration" category exceeding 15%, which is significantly higher than in all other chapters. However, the percentage of negative comments on "patient experience" and "physician skills and efficiency" was only about 4%, which was only higher than for diseases of the nervous system, sleep-wake disorders, and diseases of the circulatory system (ICD-11 Chapters 8, 7, and 11, respectively).

XSL•FO
RenderX

Figure 4. Percentage of negative comments by chapter in ICD-11. The x-axis was sorted by the average percentage of negative reviews on all aspects. ICD-11: *International Classification of Diseases 11th Revision*.

Next, to explore the overall patient demand by disease, we calculated the average percentage of negative ABSA comments and ranked them in descending order. As shown in Table 4, most of the chapters had similar rates of poor ratings for all 3 categories of health care needs in our ABSA prompts. In chapters on diseases of the blood or blood-forming organs; mental, behavioural, or neurodevelopmental disorders; and sleep-wake disorders (Chapters 3, 6, and 7, respectively), there was a significant difference in a single category. In the chapter on mental, behavioural, or neurodevelopmental disorders (Chapter 6), the “patient experience” category had a negative review percentage of about 7%, while the remaining 2 categories were below 5%. In the chapter on sleep-wake disorders (Chapter 7), the percentage of negative comments for “physician skills and efficiency” exceeded 5%, while the remaining 2 categories were below 3%.

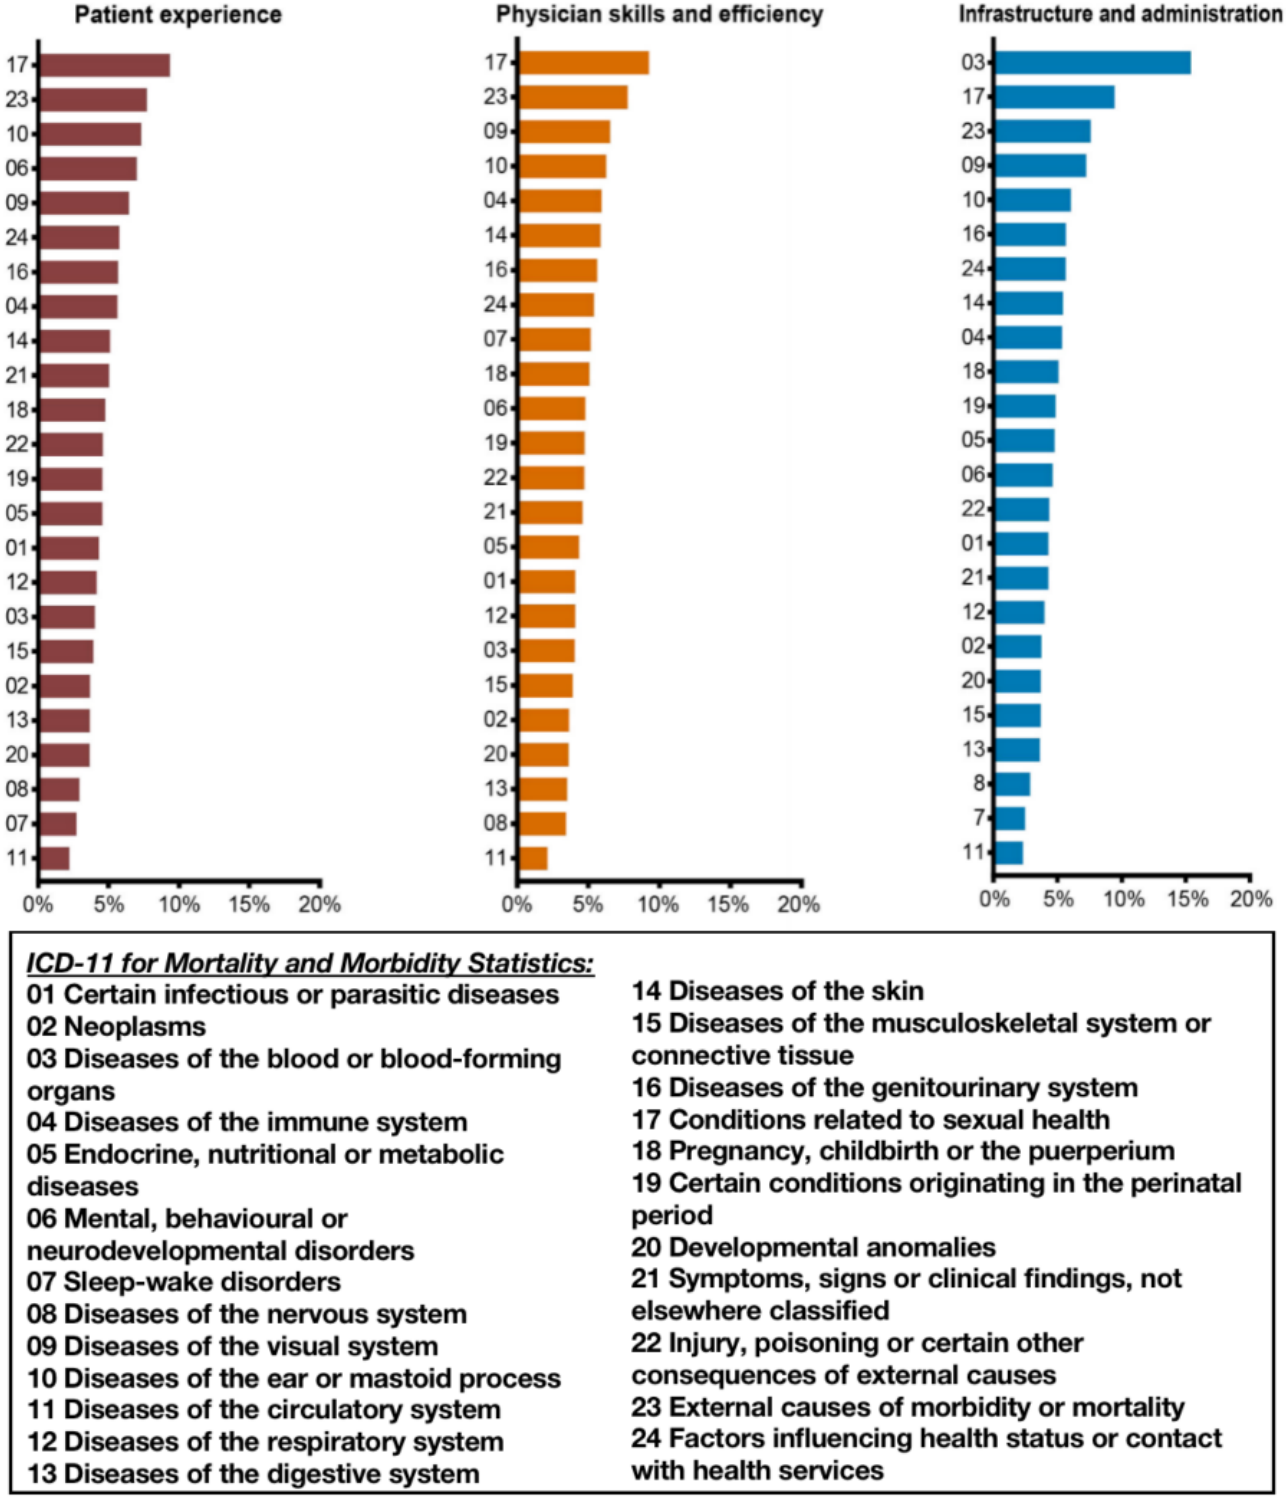
1	4.30	4.10	4.30	4.23
12	4.20	4.10	4.00	4.10
15	3.90	3.90	3.70	3.83
2	3.70	3.60	3.70	3.67
20	3.60	3.60	3.70	3.63
13	3.70	3.50	3.60	3.60
7	2.70	5.20	2.50	3.47
8	2.90	3.40	2.90	3.07
11	2.20	2.10	2.30	2.20



[a]ICD-11: *International Classification of Diseases 11th Revision*.

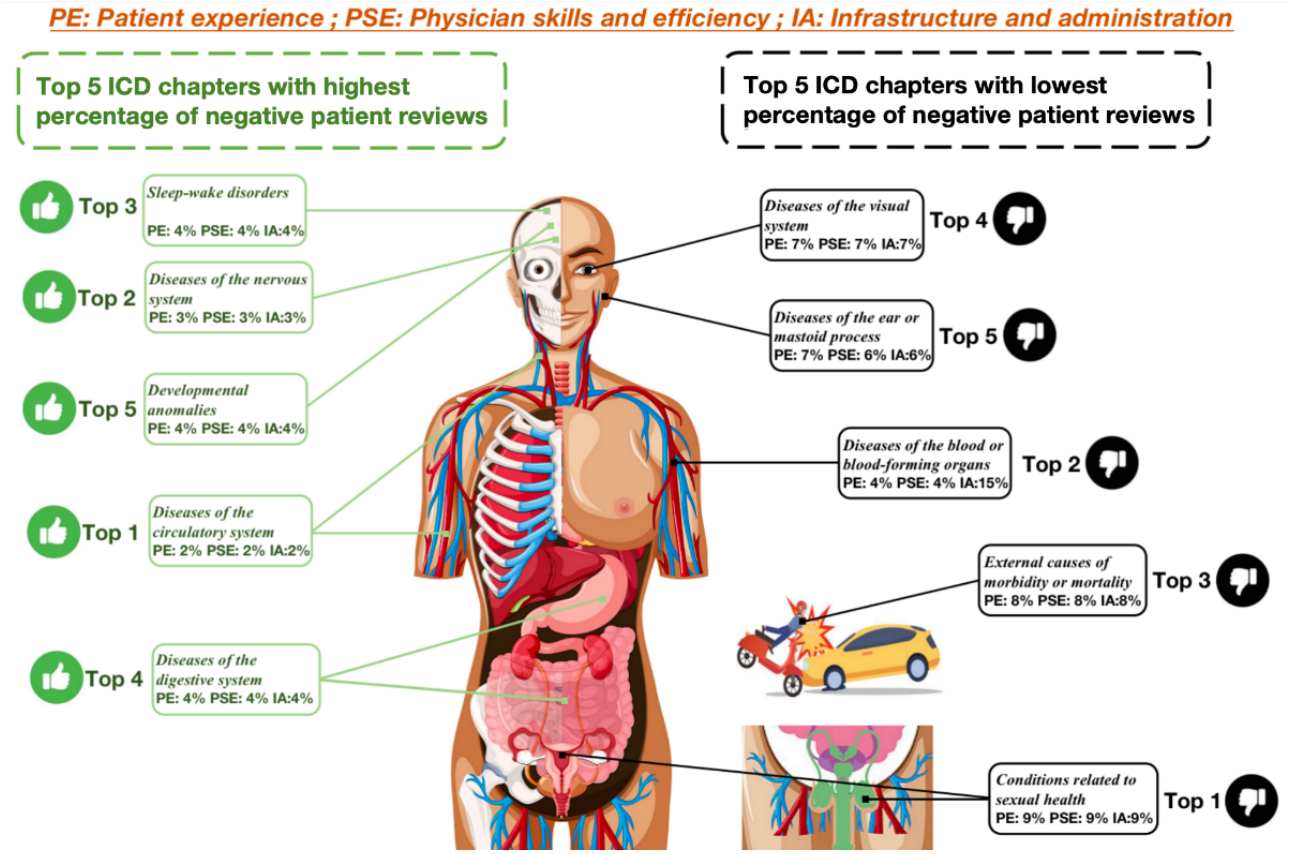
As also listed in Table 4, chapters on diseases of the blood or blood-forming organs (Chapter 3), conditions related to sexual health (Chapter 17), external causes of morbidity or mortality (Chapter 23), and diseases of the visual system (Chapter 9) had the top 4 highest percentages of negative comments, exceeding 9.8%, 7.8%, 7.7%, and 6.7%, respectively. The direction of "infrastructure and administration" in diseases of the visual system (Chapter 9) and "patient experience" in diseases of the ear or mastoid process (Chapter 10) reached 7.2% and 7.3%, respectively, significantly higher than the other 2 categories. In addition, chapters on diseases of the digestive system, diseases of the nervous system, sleep-wake disorders, and diseases of the circulatory system (Chapters 13, 8, 7, and 11, respectively) had the lowest poor ratings, which were below 4%, 3.5%, 3%, and 2.5%, respectively, except for the classification of "physician skills and efficiency" in sleep-wake disorders (Chapter 7).

Figure 5 shows a better visualization of the percentage of negative reviews in each category in the ABSA prompts and the differences between the different chapters. In the "patient experience" category, the 3 chapters on conditions related to sexual health, external causes of morbidity or mortality, and diseases of the ear or mastoid process (Chapters 17, 23, and 10, respectively) had the highest percentage of negative comments, which exceeded 9%, 7.5%, and 7%, respectively. In addition, chapters on mental, behavioural, or neurodevelopmental disorders; diseases of the visual system; factors influencing the health status or contact with health services; diseases of the genitourinary system; diseases of the immune system; and diseases of the skin and symptoms not elsewhere classified (Chapters 6, 9, 24, 16, 4, 14, and 21, respectively) had negative comments exceeding 5 %, for a total of 9 chapters. Except for these 9 chapters, the rest were below 5%, and the 3 chapters with the lowest percentage of negative comments were on diseases of the nervous system, sleep-wake disorders, and diseases of the circulatory system (Chapters 8, 7, and 11, respectively), at less than 3%, 3%, and 2.5%, respectively.

XSL•FO
RenderX

Figure 5. Percentage of negative reviews by ICD-11 chapter. ICD-11: *International Classification of Diseases 11th Revision*.

In the “physician skills and efficiency” category, chapters on conditions related to sexual health, external causes of morbidity or mortality, and diseases of the visual system (Chapters 17, 23, and 9, respectively) had the highest percentage of negative comments at 9%, 7.5%, and 6.5%, respectively. In addition, chapters on diseases of the ear or mastoid process , diseases of the immune system, diseases of the skin, diseases of the genitourinary system, factors influencing the health status or contact with health services, sleep-wake disorders, and diseases of the nervous system (Chapters 10, 4, 14, 16, 24, 7, and 8, respectively) had more than 5% of negative comments, for a total of 10 chapters. In addition, the 3 chapters with the lowest negative comment percentage were on diseases of the digestive system, diseases of the nervous system and diseases of the circulatory system (Chapters 13, 8, and 11, respectively) at about 3.5%, 3.5%, and 2%, respectively. The rest of the chapters had a negative comment percentage between 5 and 3.5%.



Finally, in the “infrastructure and administration” category, the 3 chapters with the highest percentage of negative comments were on diseases of the blood or blood-forming organs,

XSL•FO
RenderX

conditions related to sexual health, and external causes of morbidity or mortality (Chapters 3, 17, and 23, respectively), at 15%, 9%, and 7.5%, respectively. Additionally, 15% was the highest percentage of negative comments among all 3 categoriess. The next highest percentage of negative comments was found for chapters on diseases of the visual system, diseases of the ear or mastoid process, diseases of the genitourinary system, factors influencing the health status or contact with health services, diseases of the skin, diseases of the immune system and pregnancy, childbirth or the puerperium (Chapters 9, 10, 16, 24, 14, 4, and 18, respectively), with the following highest percentage of negative comments being found for chapters on diseases of the circulatory system, sleep-wake disorders, and diseases of the nervous system (Chapters 11, 7, and 8, respectively), at less than 3%.

To visually observe the relationship of ABSA results among diseases, we visualized the top 5 ICD-11 chapters with the highest and the lowest percentage of negative patient reviews using a body map. Based on the visualization, we obtained a clearer image of different body parts with the highest and lowest percentages of negative reviews. As shown in Figure 6, most of the top 5 chapters with the lowest percentages focus on diseases near the brain, including neurological disorders, sleep disorders, and developmental disorders.

Figure 6. Visualization of parts of the body systems with the highest and lowest percentages of negative patient reviews by ICD-11 chapter. ICD-11: *International Classification of Diseases 11th Revision*.

Discussion

Principal Findings

Model Accuracy and Feasibility

The results showed that our model achieves an F_1-score, precision, and recall of 0.793, 0.907, and 0.748, respectively, proving the effectiveness of our combination of ABSA prompts and CoT architecture. In addition, the model achieved 90.1%, 88.5%, and 89.4% accuracy in the stability and reliability tests conducted in random sampling modes 1, 2, and 3, respectively. We used an earlier version of LLMs (ChatGPT-3.5-turbo-0613), which was released in 2023. This proved that the initial version of GPT was already sufficient for our task, and it was expected that newer versions of the model can also be used for this type of task.

Differences in Patients' Health Care Needs Across ICD-11 Chapters

Overall, across all classifications, patients with sexual health–related illnesses had high health care needs and showed high levels of dissatisfaction with all aspects. Based on the clinical setting and research in China [49-51], we hypothesize that this may be related to the extremely private nature of the disease, which leads to shame and low self-esteem, which, in turn, leads to a sensitive and vulnerable mindset and, therefore, extreme concern for the physician's attitude, skills, and the environment in which the consultation takes place. In contrast, patients with circulatory disorders expressed satisfaction with current medical resources, suggesting that China has an advantage in researching and treating this type of disease.

Second, although the overall medical needs of patients with sleep-wake disorders are not high, patients with these disorders

XSL•FO
RenderX

show a higher demand for physician skills and efficiency, probably because it is difficult to see immediate results in the treatment of these patients and because insomnia can lead to neurasthenia, etc, which can have a significant impact on work and life. Therefore, there is a strong demand for efficacy for such types of conditions.

In addition to the aforementioned diseases, patients with ear or mastoid disorders also have a relatively high demand for patient experience. This may be because ear diseases make patients wary and uncomfortable with all the sounds in their environment and, therefore, extremely sensitive to the attitude and tone of the physician's dialogue. Furthermore, immune system disorders have a higher need for physician skill and efficiency, which may be related to the degree of difficulty in treating the diseases, as immune system disorders are generally more difficult to cure. Therefore, there is generally a robust and heartfelt expectation from patients regarding the physician's skill.

Lastly, neurological or hematopoietic organ diseases lead the way regarding the "infrastructure and administration" category. This may be because these diseases depend highly on advanced hospital infrastructure, such as specific hemodialysis equipment. In short, each disease has different medical needs. Therefore, medical management can allocate or solve problems according to the medical needs of various diseases. If one needs to continue to explore the specific causes of a problem, as proposed in a previous work [52], one can do so downstream of the task, such as word frequency analysis and word cloud construction. In this way, we can uncover specific negative reasons in patient comments.

Implications for Sustainable Development Goals

Our work on analyzing patient comments using ICD-11 and LLMs to identify health care needs for different diseases has important implications for the SDGs. First, in SDG 3 ("Good Health and Well-being"), the precise analysis of patient comments can provide a more accurate understanding of the specific needs of different diseases, promote accurate consultation and treatment in health care units, and improve the quality of their health care services. In SDG 9 ("Industry, Innovation and Infrastructure"), our research demonstrates the use of LLMs and ICD-11 for health care innovation to improve diagnosis and treatment efficiency, promote smart health care infrastructure, and enhance the accessibility and efficiency of health care services in various ICD-11 chapters. In addition, for SDG 10 ("Reducing Inequalities"), by revealing the health needs and health care disparities among different groups, we can help develop more targeted health policies to reduce health care inequalities and ensure that all people have access to appropriate health care, as well as emphasizing the importance of the patient's voice and promoting inclusive health care.

Finally, for SDG 17 ("Partnerships for Goal Achievement"), this research highlights the importance of interdisciplinary collaboration, combining medicine, data science, and AI technologies to encourage multiple parties, including public health organizations, academic institutions, and technology companies, to work together to address health challenges worldwide.

In conclusion, our research not only has important application value in the medical field but also provides valuable insights into the achievement of the SDGs and promotes the innovation and development of health care services through the full use of modern scientific and technological tools to enhance health worldwide and promote the sustainable development of society.

Potential Applications of the Assessment of Health Care Services

Several studies have shown that physicians or hospitals in the United States are incentivized by patient scores or ratings [53-55], which helps them provide efficient, high-quality care [56,57]. At the same time, these scores or ratings are made public on medical websites, and people can choose their preferred departments or hospitals through the ratings. In China, there is a need for ratings for hospitals [58], and although some medical websites have ratings for physicians or hospitals, the ratings on websites could be more sketchy and include only a small number of physicians or hospitals [59]. Therefore, governments and health authorities can use our approach to obtain fine-grained ratings of each health care unit to enhance monitoring and management, which would benefit both patients and the administration.

From the patients' perspective, aggregating satisfaction and dissatisfaction scores based on ICD-11 codes can help them select health care providers based on their preferences. For example, if a patient is more concerned about the facilities and customer experience of a hospital, they can choose a hospital with a lower ratio of negative reviews in the "infrastructure and administration" category. In addition, as shown in Multimedia Appendix 1, the health care administration can obtain ABSA results with ICD-11 codes using our method and use it for continuous improvements. The result with ICD-11 codes can be shown as a dashboard, and management can identify areas with high satisfaction and dissatisfaction. Patient reviews in such areas can be further analyzed using natural language processing techniques (eg, word frequency analysis or topic modeling) to identify the root causes.

Taking our datasets as an example, assuming that the they originate from the same hospital, management can prioritize the verification and optimization of health care resources for equipment and environments in different departments with a high percentage of negative comments in the "infrastructure and administration"category (eg, ICD-11 Chapters 1, 17, and 23 in this case). Second, management can organize quality education and psychoeducation for doctors to optimize departments with a high percentage of negative comments in the "patient experience" category (eg, ICD-11 Chapters 10, 17, and 23). Finally, management can provide systematic training to doctors and organize professional meetings to address departments with a high percentage of negative comments in the "physician skills and efficiency" category (eg, ICD-11 Chapters 9, 17, and 23). These evaluation cycles can be iterated over time for checking whether there is any improvement.

Limitations

This study has several limitations. Since this study proposed a new ABSA template, there are no other datasets with annotations

XSL•FO
RenderX

to be compared and cross-validated with this study for now; therefore, it is not possible to validate whether this method can be applied to datasets in other languages. In addition, it is not possible to verify whether it is meaningful to apply the ABSA in this study to regions with different health care environments. In terms of application, we might be able to make in-depth analyses by comparing data from multiple regions in the future. Finally, to prove that the problem of SDGs has been solved requires a comprehensive evaluation framework and evaluation method [32,60]. In the future, we anticipate collaboration with multiple hospitals to conduct a more comprehensive evaluation and practice in a specific clinical setting to determine the positive impact of this study on health care resource allocation and SDGs.

Conclusion

We analyzed the distribution of health care resources by disease through an LLM of patient reviews. In addition, we combined the results with the ICD-11 classification and found that conditions related to sexual health have the lowest overall patient satisfaction. In contrast, patient satisfaction is highest among patients with diseases of the circulatory system. Our approach demonstrates the possibility of using an LLM to understand patients' needs and extract aspect-based information from reviews written by them and health consumers.

Acknowledgments

We thank Rong Chen and the First Affiliated Hospital, Sun Yat-Sen University, for their contributions and guidance in this research. This research was supported by Macao Polytechnic University (submission code: fca.1c2e.6826.4) and the Macao Science and Technology Development Fund (funding ID: 0088/2023/ITP2).

Data Availability

The datasets analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

JL contributed to conceptualization, methodology, formal analysis, writing—original draft, project administration, and data curation. YY contributed to methodology, project administration, and software. CM contributed to project administration, investigation, and methodology. PCIP contributed to supervision, funding acquisition, and writing—review and editing. QZ and DX contributed to visualization, validation, and resources. YW contributed to supervision and writing—review and editing.

Conflicts of Interest

None declared.

Multimedia Appendix 1
Two potential directions of the application of our method. ABSA: aspect-based sentiment analysis; ICD-11: *International Classification of Diseases 11th Revision*.

Abstract

Background: Patients inevitably incur some cost for accessing health care, even in universal systems such as Canada. The COVID-19 pandemic dramatically shifted health care delivery from in-person to telehealth services, also shifting the proportion of costs offset by patients and their families by reducing the need to travel to in-person appointments.

Objective: This study aimed to develop a method for estimating the costs patients and their families incur and CO_2 emissions attributed to travel needed for emergency department (ED) visits, hospitalizations, and physician appointments.

Methods: We present a method to evaluate the costs associated with in-person and telehealth care appointments from the perspective of patients, their families, and the environment. We used ED locations, road distances, and duration of appointment to account for costs paid by patients (ie, lost productivity, informal caregiving, and out-of-pocket expenses) attributed to travel to receive medical care. Costs to the environment were evaluated by calculating the amount of CO_2 emitted per medical visit. Using our costs calculated per visit, we apply our method to calculate total patient costs for a simulated population over 1 year.

Results: Our method estimates that patients in British Columbia pay up to $300 (2023 CAD, CAD $1=US $0.86) on average to attend an in-person ED visit, depending on where they live; $166 may be attributed to lost productivity, $83 to informal caregiving, and $50 to out-of-pocket expenses. These estimates are higher than most observed cost estimates. In addition, avoiding in-person care diverts up to 13 kg of CO_2 per medical visit, depending on the distance and frequency of travel to appointments. This translates to up to $0.70 in carbon costs per visit, or cumulatively $44,120 per year in British Columbia, conventionally not included in patient cost estimates.

Conclusions: We present a novel method for estimating patient-incurred costs and CO_2 emissions from accessing health care and apply it to estimate that every year, patients in British Columbia pay upwards of 30 million dollars to access health care services, primarily for medical travel. Our method adds to the economic evaluation literature by providing a more comprehensive and context-modifiable calculation of patient costs that will allow for more informed decision-making regarding health care services.

Introduction

Patients and their families incur costs when accessing health care services, even in universal, publicly funded systems such as Canada. However, patient-paid costs are often overlooked or underestimated in evaluations of health services because they are difficult to quantify and often considered out-of-scope for health policy decisions [1,2]. All patients pay to access health services either directly through co-pay cost-sharing arrangements or in other ways, such as needing to take time off work, travel to health care facilities, or attend an appointment as a caregiver. Methods to calculate and analyze patient costs are therefore of interest to account for the degree of cost-sharing that is passed off to patients and to protect them against financial hardship associated with receiving basic medical care. There are concerns about equity in cost-sharing because certain components contributing to patient-paid costs (ie, travel time or visit duration) may vary according to geographic location or service type, resulting in patient-paid costs that depend on where patients live and what type of service they access. Intergenerational inequities may arise from environmental costs to be paid in years to come, including greenhouse gas (GHG) emissions, such as CO_2, associated with the need to travel to receive in-person service visits.

Over the past decade, studies on the patient-paid portion of health care costs have focused primarily on out-of-pocket expenses, such as travel costs [3-7]. Occasionally, some studies also consider time costs by accounting for lost productivity (ie, foregone paid or unpaid work) [8-13] and GHG emissions [13-19]. Studies on time costs and lost productivity have found that the majority of these costs are attributable to the amount of time patients spend attending appointments, estimating that patients pay between $80-$125 (2023 CAD, CAD $1=US $0.86) for their time to attend in-person medical appointments in developed countries [9,10,13]. Of the studies that accounted for GHG emissions and environmental costs, a systematic review found that 0.70-372 kg of CO_2-equivalent emissions were avoided by telemedicine appointments [16]. Many of these studies are based on assumed values for key parameters, such as cost per unit of travel distance, wage, fuel efficiency, and CO_2 emissions, for different patient groups defined by age, sex, or type of service accessed. Costs are typically presented either by determining per-visit costs or analyzing costs over a longer time horizon.

Based on costing methods currently available, we see a significant gap in estimating patient-paid costs. Current methods calculate costs for a specific population subgroup, often including patient data that prevents cost results from being generalizable to other cases. Furthermore, more general studies of patient costs do not include all aspects of costs; instead, they focus on a specific type of cost, resulting in an incomplete picture of the full burden of costs to patients. We propose to construct a multidimensional method for a cost analysis to calculate patient costs and do so in a way that is able to be objectively and consistently applied to different service models, be they in-person or telehealth. In doing so, we present an open-source analytical tool that can be used to calculate these costs generally, using easy-to-obtain or public datasets, and without the need for specific patient-level administration data or costly patient-reported data. Incorporating a geospatial component allows our method to function for both rural and urban areas and can be applied by other health systems to capture patient costs specific to their region. The advantage of this approach is that it provides a standardized way to calculate these costs that will allow for increased opportunities for economic evaluations and comparisons across different service approaches, such as in-person, telehealth, or hybrid care. The aim of this paper, thus, is to present a transferrable method to comprehensively account for patient costs to access health care, inclusive of lost productivity, informal caregiving, out-of-pocket costs, and GHG emissions.

Methods

Overview

The geospatial method was developed to calculate the per-visit costs for health service use from the perspective of patients, their family caregivers, and future generations. The method is inclusive of costs attributed to the receipt of care that are paid at the time of health service use but are not covered by the health care system, in alignment with methods used by the World Health Organization to measure progress on universal health systems' objective to provide financial protection from the high costs of illness [20]. We calculate costs attributed to attending emergency departments (EDs), being admitted to the hospital, and receiving in-person or telehealth physician services. We use publicly available data on distances, appointment durations, and average wage statistics to determine productivity losses for paid or unpaid work with the human capital method of valuation. All data and code used in the method are available in a companion repository on GitHub [21]. Costs to receive care are expressed as service-specific unit costs, comprised of the subunits of lost productivity, informal caregiving, and out-of-pocket expenses, disaggregated by age and region. GHG emissions are expressed as the volume of CO_2-equivalent emissions. All costs are reported in 2023 CAD, approximately equal to US $0.86. Results were simulated for individuals in British Columbia based on the age, region, and service use patterns observed from the real British Columbia population.

Geospatial Evaluation

The geospatial method accounts for geography specific to British Columbia, a province in Canada with approximately 16% rural and 84% urban population (population density ranging between 0.01/km^2 to 18804.48/km^2) [22]. The geographic regions are defined as community health service areas (CHSA) and 5 broader health authority (HA) geographies. At the time of analysis, there were 218 CHSAs defined in British Columbia [23]. Our geospatial method operates primarily at the CHSA level, with results aggregated and presented at the HA level. Travel distances were calculated for hospitalizations, physician visits, and ED visits by determining the geographic center of each CHSA and then calculating the real street distance from each CHSA center to the nearest emergency department, assumed to be a proxy for the nearest location to access care, using road network data obtained through the *OpenStreetMap* package (version 4.0) and calculating with R (version 4.2; R Core Team). Travel duration was also calculated with this method, using speed limits of the specific roads traveled on each trip. The calculated travel distance and duration for each CHSA were aggregated to the HA level using the population-weighted mean of all CHSAs within each HA.

In addition, we also analyzed unit costs for CHSAs using an urban and rural stratification. In the Government of British Columbia record of all health regions, each CHSA is given a classification, numbering 1 through 7, of which 4 and below are considered urban and 5 and above are considered rural [22]. We then aggregated data for all CHSAs considered urban or rural and computed a unit cost for each. This involved calculating travel distance and duration, using our geospatial method, for both urban and rural CHSAs.

Patient and Family Costs

Overview

British Columbia has a publicly funded, single-payer health system, where the provincial government pays for core health services. In our model, costs not paid by the health care system were defined as patient and family costs and were attributed to the following health service types: ED visits, hospital admissions, and telehealth or in-person physician encounters. Costs were calculated for each service type by age group and health authority. For ED visits, costs were calculated separately for Canadian Triage Acuity Scale (CTAS) levels I-III and IV-V [24]. The CTAS is a method for grouping patients according to the severity of their condition upon presentation to an ED, with level I being the most severe and level V being the least severe, resulting in differentials in the amount of time patients spend at ED. We used age groupings of 0-14, 15-64, and ≥65 years, which were chosen to distinguish the working-age population to account for lost productivity and align with Statistics Canada's definitions of working and retirement ages [25,26]. Average hourly wage rate data taken from Statistics Canada begins at age 15, which is consistent with the Employment Standards Act of British Columbia, which allows light work for persons aged 15 without a permit [27,28]. Each calculated cost for each service type and category is comprised of the following subunits: lost productivity, informal caregiving costs, and out-of-pocket expenses. A goal of the method is to create a unit cost database containing all costs, organized by age group, service type, and region.

Lost Productivity

Lost productivity was calculated from the time costs attributed to any foregone paid or unpaid work required to attend appointments or clinic visits. Time costs include time spent on travel, which was obtained by our travel distance calculations, time spent waiting to receive health services, and appointment time (see Multimedia Appendix 1 for details). For physician appointments, ED visits, hospitalizations, and telehealth visits, the total time was multiplied by the average hourly wage rate for British Columbia for 2022. Lost productivity costs were calculated for all working-age patients (15-64 years), and productivity costs were zero for individuals aged 0-14 and ≥65 years. For hospitalizations, due to the increased length of stay, we capped time costs for lost productivity at 8 hours per 24-hour period.

Informal Caregiving

Informal caregiving was evaluated from the time required for caregivers to accompany patients for physician appointments, ED visits, or admissions. For physician, ED, and telehealth visits, we assumed that 50% of all patients aged 15 years and older attend appointments with a caregiver, and 100% of patients in the 0-14 age group attend with a caregiver. We assumed that the caregiver would have the same time commitment for travel time, wait time, and appointment duration as the patient. For hospitalizations for admitted patients, we assumed that 25% of all patients in the 15-64 and ≥65 years age groups and 75% of patients in the 0-14 years age group have a caregiver present for the duration of their visit. For hospital admissions, the caregiver costs were prorated to 8 hours per day to account for lost wages only within a regular workday. Given the lack of clear estimates available in the published literature to draw from, we derived estimates from several Canadian sources and updated them with input from clinical study team members who see patients in clinical practice in order to estimate caregiver attendance percentages [29,30].

Out-of-Pocket Costs

The out-of-pocket subunit includes costs incurred by patients that are a direct result of the appointment but not for the appointment itself. This includes costs such as, but not limited to, vehicle costs, gas, parking, or accommodation. For physician visits, ED visits, and hospital admissions, direct travel costs were calculated based on standard Canadian rates for a compact car (eg, Toyota Corolla) with 80% highway and 20% urban road driving, gas prices of approximately $2 per liter, and average annual mileage of 20,000 km [31]. For physician and ED visits, accommodation costs were assumed to be $0 for all visits as none of the travel distances would require an overnight stay. For hospitalizations, we assumed accommodation would be needed for the caregiver for 2 days if the total travel distance was greater than 50 km to account for extra travel and time necessary on the patient's admission and discharge days. As a result, accommodation costs were only included for hospitalizations in Northern Health Authority and equaled $0 for all other unit costs. When applicable, the accommodation

XSL•FO
RenderX

cost was determined by averaging hotel costs in the area using Google Travel [32]. This accommodation cost was then multiplied by the appropriate caregiver attendance percentage, depending on the age group (75% for age <15 years, 25% for age ≥15 years) to estimate the final caregiver accommodation cost. For ED visits, one meal, at a $15 value, was assumed to be needed for patients in CTAS I-V. For hospitalizations, 3 meals per day for 2 days (admission and discharge days), at $15 value, was assumed to be needed for caregivers. Meal costs were then also multiplied by the appropriate attendance coefficient (75% for age <15 years, 25% for age ≥15 years) to estimate the final caregiver meal costs. Parking costs were determined using rates from a city within the relevant health authority. Average parking rates from the chosen city's core were used for physician visits, and hospital rates were used for ED visits and hospitalizations. Furthermore, for hospitalizations, parking was assumed to be required for the caregiver for 2 days to align with the assumption made for accommodation costs.

Telehealth Visit Costs

Telehealth visit costs were similarly comprised of lost productivity, informal caregiving, and out-of-pocket subunits. However, as many expenses for in-person visits, such as travel-related costs, are not applicable to telehealth visits, the content of the subunits differ. The lost productivity and informal caregiving costs included only appointment wait time and duration, given that travel time is zero. For out-of-pocket expenses, instead of meals, parking, or direct travel costs, the telehealth visit cost included data usage costs. Data usage costs were obtained using estimates of data used for an average telehealth encounter length and using per-unit data costs from the least expensive plans available in British Columbia. Telephone and internet were both considered, based on the current modality of using telehealth care, with 80% weight given to telephone data costs and 20% weight to internet data costs to determine the final data usage rate. Multimedia Appendix 1 shows the details of the full data usage cost calculation. We assumed as a baseline that everyone has access to a phone, so the cost of a device was considered to be zero, and electricity costs were negligible.

Greenhouse Gas Emissions

In-person visits also carry an environmental cost in the form of carbon costs from travel. We included this in our calculations by inputting total travel distance into an emissions calculator [33], using a fuel efficiency rate of 7.06 L/100 km for a 2022 Toyota Corolla. We obtained CO_2-equivalent emissions, in kilograms, per visit for each health authority, based on the distance traveled for a visit in that region.

Sensitivity Analysis

As our method requires assumptions to be made for certain parameter values, we have conducted a sensitivity analysis to explore how the cost output changes based on changes to specific parameters. We conducted the sensitivity analysis on 4 different parameters: wage, travel distance, travel duration, and caregiver attendance percentage. We tested the wage assumption using British Columbia minimum wage ($16.75) [34], $20, $25, $30.54 (base case), and each $5 increment from $35 to $50 (all CAD). The caregiver attendance percentage was tested for 0%, 25%, 50% (base case), 75%, and 100% of appointments attended. Travel distance and duration were varied in 10% increments from 50%-150% of the base case average value. The overall street distance calculation method was also compared with the haversine (straight-line) distance from the center of each CHSA to the nearest in-person visit location. When varying one parameter value, we kept all other parameters constant and applied the method to compare the resulting unit cost output to our base case.

Simulated Population

To illustrate a potential application of this method, we simulated costs and CO_2 footprint for 100,000 individuals distributed across age groups and regions (health authority). We used a Canadian Institute for Health Information (CIHI) report on ED visits to estimate the total number of ED visits per person in British Columbia in one year [35]. We then used NACRS data from British Columbia in 2022 to determine what proportion of ED visits were assigned CTAS I-III and CTAS IV-V in order to apply the appropriate unit cost [35]. For physician visits, we used an international report that found an average of 2.7 provider visits per year in Canada [36]. For telehealth visits, we used a cross-sectional study of telehealth care usage in Ontario, which found an average rate of 48 visits per 1000 people per week, which we then converted to 2.5 visits per person per year [14]. We then distributed these visits between age groups and regions, according to the population distribution in British Columbia, and simulated the impact across British Columbia. Costs were applied to determine the estimated total patient cost by service type for a 1-year period. In addition, we calculated GHG emissions for the simulated population over the 1-year period using the total distance traveled across all ED and physician visits.

Ethical Considerations

All datasets analyzed in this study are publicly available, and their secondary use does not require human consent; therefore, ethics approval was not needed for this study as per the University of British Columbia's Behavioral Research Ethics Board guidelines [37].

Results

Geospatial Evaluation

Travel distances and durations were calculated using our method for each CHSA in British Columbia. The longest distance calculated was 302.37 km for the Mackenzie CHSA, and the longest duration calculated was 429.58 minutes for the Mackenzie CHSA. The shortest distance was 0.59 km for the Fort Nelson Population Centre CHSA, and the shortest duration calculated was 1.21 minutes for the Fort Nelson Population Centre CHSA. Figure 1 shows the resulting map of all CHSA with their calculated route. The street distance calculation method uses a route beginning at the center of each CHSA. In cases where a street is not present, the method may deviate to find the nearest street. Distances and durations calculated from each CHSA were then aggregated to the HA level using a

XSL•FO
RenderX

weighted mean based on the population of each CHSA, the results of which are presented in Table 1.

Figure 1. Map of calculated routes.

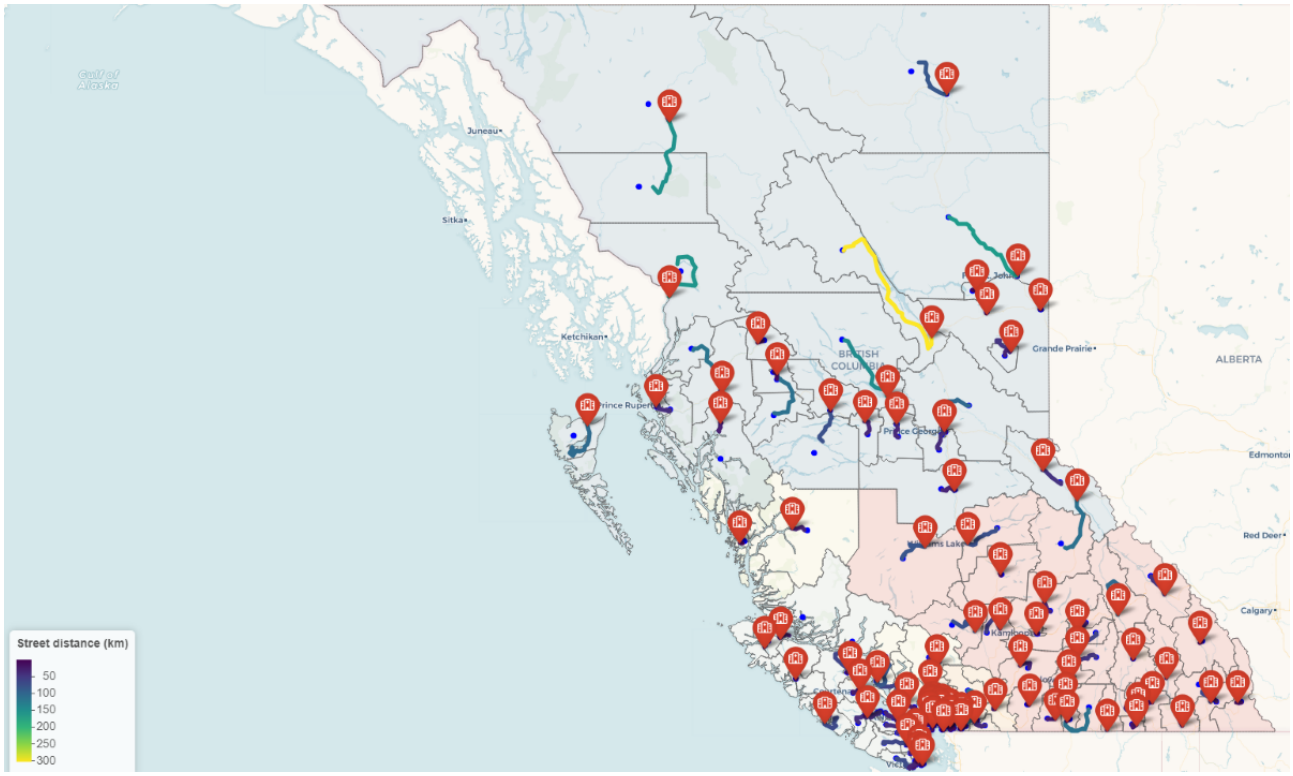

Table 1. Distance and duration by health authority.

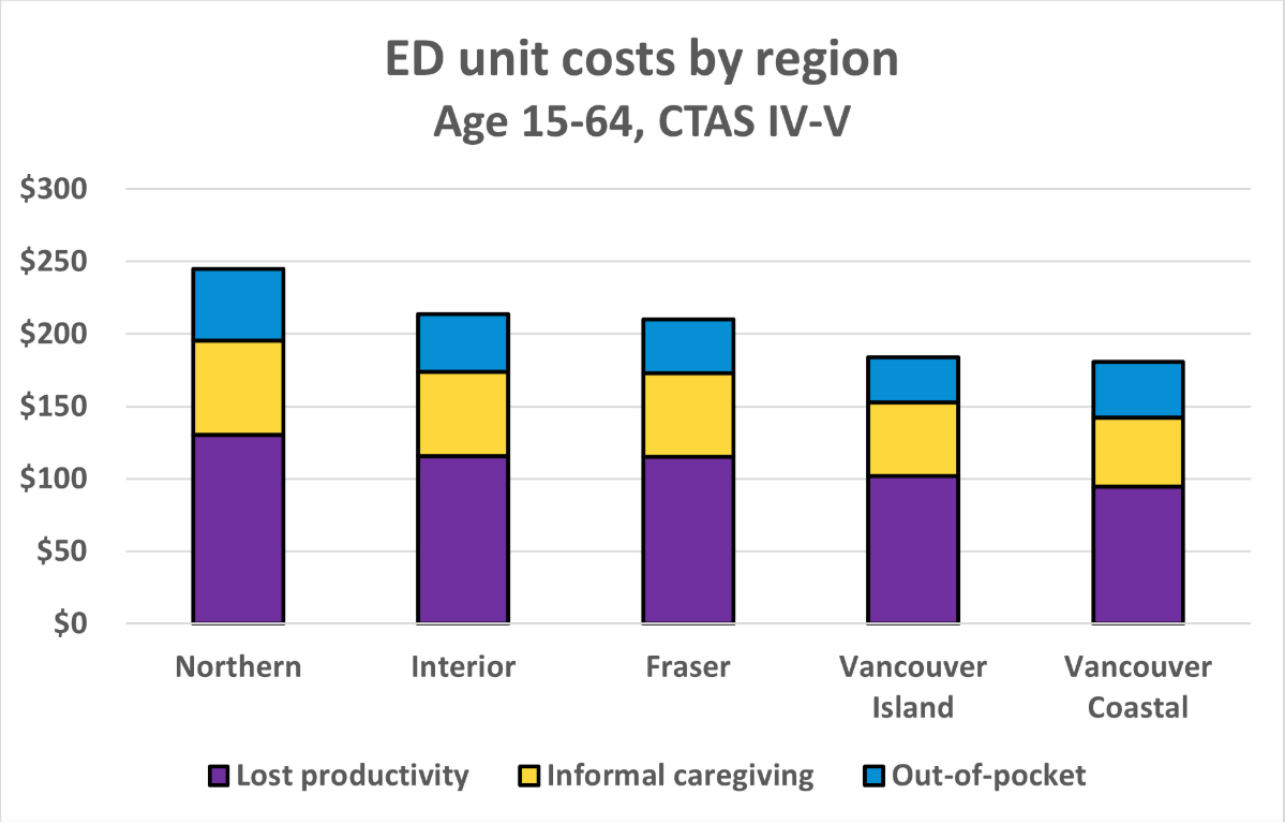
Health authority	Weighted mean distance (km)	Weighted mean duration (min)	CO_2-equivalent emissions per visit (kg)
Fraser	30.6	64	4.67
Interior	42.8	65.2	6.53
Northern	69.4	93.8	10.59
Vancouver Coastal	12.06	24.2	1.84
Vancouver Island	24.4	37.8	3.72



Patient and Family Costs

Our method produced individual costs associated with each category (ie, each combination of age group, health authority, and service type), which we have defined as unit costs. Each unit cost, therefore, represents the total cost for one visit of that type. The cost database also includes the cost for each subunit: lost productivity, informal caregiving, and out-of-pocket costs (see Multimedia Appendix 2 for full database). The creation of the cost database allows for the comparison of unit costs across different categories. Costs can be compared between service types, regions, or age groups. From the cost database, we determined the range of costs across the different categories, from a minimum cost of $31 for a physician consult in Vancouver Coastal Health to a maximum cost of $300 for an ED visit in Northern Health.

Visits to EDs with the highest urgency (CTAS IV-V) in the Northern Health region among patients in the 15-64 years age group had the highest costs per visit ($245), considerably higher than the amount for patients accessing the ED in regions covered by Vancouver Coastal Health ($181; Figure 2).
